The technological divisions between the northern and southern countries of the EC is clearly visible. Penetration rates of the basic telephone line in countries such as Spain, Portugal, and Greece do not match those of France, Germany, the UK or the Netherlands. The UK is the most liberalised with free competition in both the telecommunications equipment market and in services and public network operations.

In order to aid these countries, the European Commission has for a number of years put into place such programmes as STAR, whereby funds are made available to a Member State on the basis that the money will be used to improve, extend and update the telecommunications architecture within a specific period of time. The role of ETSI is to produce 'European' telecom standards (ETS) and promote their use within the member countries and to coordinate a European view on global standards.

OUTLOOK

The future for EC equipment manufacturers rests on their abilities to effectively combat increased competition in the market following full liberalisation. The comfortable relation-

ship which existed in the early 1980s between indigenous equipment manufacturers and operators is rapidly disappearing. European based suppliers are increasingly under threat from new suppliers who have the benefit of experiencing similar but earlier upheavals in their national markets.

Equipment manufacturers will experience the same fight for survival not only in European but global markets. Gradually, markets will become oriented towards the survival of the fittest as new entrants from other fields such as consumer electronics begin to take advantage of the proximity of technologies to enter the telecommunications markets. By the year 2000 (if not earlier), those manufacturers experiencing continued success will need to become global players to survive as the traditional barriers expand beyond geographic limits.

Ultimately the balance of power between consumers and suppliers will begin to change. Market deregulation, new players, the changing business environment and the globalisation of trade will be the key factors affecting this change.

Significant opportunities are offered by developing technologies such as ISDN and broadband communications, personal and satellite communications. East European country markets for basic network equipment are being addressed by establishing local production. Low cost terminal equipment markets in these countries will be dominated by far-eastern companies, possibly in joint ventures with local suppliers. For EC suppliers, more sophisticated network infrastructure or terminals represent a potentially large opportunity in these countries.

Consumer electronics
NACE 345.1, 345.2

The consumer electronics industry has been subject to harsh trading conditions with recession leading to both a decline in sales and production and declining prices and profits. This has in turn resulted in the closure of plants and in some cases severe rationalisation of company structures and ownership. Mergers, acquisitions and alliances have been commonplace and joint ventures are now seen as the way forward to develop effective new global products for a more sophisticated user base.
Competition still comes mainly from Japan (which is particularly dominant where new technologies are concerned), while European manufacturers still rely heavily on mature products. Increased legislation is a feature of the Single Market, particularly in the areas of high-definition television (HDTV), recorded music, environmental issues, fair competition and encouraging the future success of the European consumer electronics industry.

INDUSTRY PROFILE

Description of the sector

In the past, the main products of this industry have centred on audio-visual products for domestic use including video equipment such as television sets, VCRs, video cameras and camcorders, audio equipment, (from hi-fi to compact disc players used in the home and car), and accessories for this equipment (NACE 345.1). The consumer electronics indsutry also encompasses "brown goods" such cable terminals and pay TV decoders. Although discs, cassettes and CDs, whether blank or recorded are part of NACE 345 (NACE 345.2), these products are not included in the data provided by the industry association EACEM. A separate chapter on music recording appears elsewhere in this book.

Recent years have seen the gradual merging of consumer electronic equipment with equipment from other sectors. Because of major technological advances, equipment that was once only for business use is now approaching the price range of the consumer. Consumer equipment manufacturers realise the extent to which their future success relies on advances made in the computing and telecommunications industries. For this reason, joint ventures between companies previously associated with consumer equipment only and other sectors are beginning to emerge. Many leading European companies currently involved in consumer electronics also have divisions dedicated to telecommunications, components, computing or office equipment.

Main indicators

European consumption and production of consumer electronics goods grew steadily over the period from 1982 to 1991 at a compound annual growth rate of 8.4% and 6.5% respectively, with only a minor drop in consumption from 1990 to 1991 (refer to Table 1). Extra-EC exports also grew (with a compound annual growth rate of 13.1%). Over 75% of extra-EC exports by value are of CTVs (colour televisions). In 1991, production was valued at 38.5 billion ECU, consumption at 51.7 billion ECU and extra-EC exports at 8.4 billion ECU. Employment declined at a compound annual growth rate of -0.6%.

Recent trends

In constant terms, apparent consumption nearly doubled in the period 1982 to 1991. Overall productivity has increased, with production increasing 160% while employment declined to 95% of its 1982 value. Despite these developments, extra-EC imports were still necessary to meet demand and grew by over 250% in real terms. A significant proportion of imports are audio products and newer items, such as camcorders which are traditionally dominated by Japanese brands and European manufacturers have been less successful.

International comparison

Companies located in Japan were the main producers of consumer electronics goods for the world market, with an estimated 43% of total production. Japan controls over 99% of its domestic production and accounts for 20% of production in the USA and 27% of production in Europe. The EC manufactures 15% of all consumer electronics goods while the USA produces 13% of the total. Europe is now the second largest market for consumer electronics in the world, after the USA. Growth in Japanese consumption slowed in recent years as the market for audio and video products saturates, forcing manufacturers to place more emphasis on the US and Europe for sales. Both the US and EC are net importers of consumer goods. Japan exports over 50% of its consumer electronics production. This is likely to fall as the trend towards overseas production bases continues and exports to China decrease.

Foreign trade

Intra-EC trade increased approximately 17% per year over the period 1982 to 1991 (refer to Table 7). Imports from outside the EC have grown more than exports, leaving an increasingly negative trade balance, which in 1991 was valued at -13.2 billion ECU.

EC production of consumer goods has not kept pace with consumption and the increasing gap between the two has lead to larger imports. Japan remains the prime country of origin for EC imports, occupying approximately 36% of the total imports by value (refer to Figure 7). However, very few EC products are destined for Japan (refer to Figure 6). The EFTA countries and the USA were the main destinations for exports, accounting for 26% and 15% of the total exports, respectively.

MARKET FORCES

Demand

The definition of this NACE sector rests purely on its end user - the consumer. In many ways, the redefinition of the product range has occurred because of more sophisticated buying preferences and demand for new types of equipment. Products are moving away from purely technical commodities to lifestyle products. There is growing demand to offer intelligent products which can help with repetitive tasks. On the other hand, market saturation and advances in technology are also forcing manufacturers towards redefinition of the sector. In the past, the consumer electronics industry relied on advances made in other sectors, but this situation is beginning to change. Suppliers are investing in R&D to create new technologies for the consumer and to create demand for new business opportunities, for example, with CD-I (compact disc-interactive) and advanced television.

Traditionally the consumer electronics sector has been concerned with hardware. New products and increased sophistication means that software now plays a major role in the future success of the sector. Companies are therefore trying to increase capabilities in this area through joint ventures and buy-outs.

Europe represents approximately one-third of total world demand. Demand for consumer electronics in the EC fell by 0.7% in 1991. This occurred despite hopes that Eastern Europe would contribute to continued growth. The four largest markets (Germany, France, Italy and UK) contribute 75% of total ex-

Figure 4: Consumer electronics

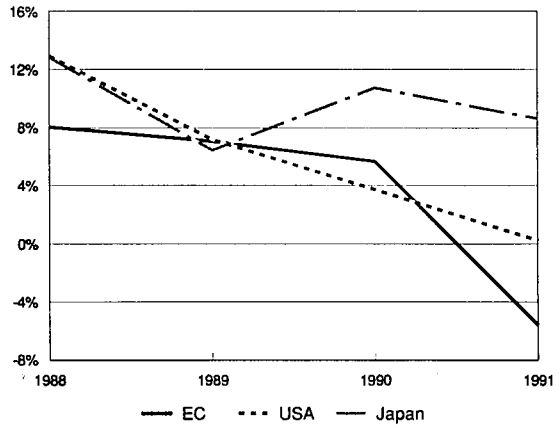
Figure 5: Consumer electronics
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

penditure. Because of low labour rates, Spain has been an important production base and has increased opportunities for component suppliers which presently import most parts.

Southern European markets are most likely to grow in traditional product ranges in the future simply because penetration is generally lower than in northern European countries.

Demand for consumer goods is heavily dependent on general income levels. Depressed market conditions and reduced disposable incomes have resulted in decreased consumption. The only exception to this has been the boost from former East Germany, where low quality imports have been readily purchased. The main export destination of EC production is the EFTA countries. Eastern Europe has played a major part in consumption growth. However, this growth has been dominated by low quality imports.

Western European players are believed to have an advantage in supplying to Eastern Europe because of geography, trade relationships and transport costs. Japanese players are seeking to address this market through West European bases. Asian manufacturers are concentrating on Eastern Europe while building higher quality models for the EC market. The Japanese economy has suffered, with slow growth in consumer electronics demand, and this area remains of low priority for EC exports. Furthermore, the Japanese consumer electronics market remains very restrictive, allowing only marginal access to European as well as South Korean manufacturers.

Supply and competition

Intra-EC competition is most readily seen in the CTV market where European suppliers are strong. European brands are genuine leaders in most European markets. Players in the consumer electronics market face extreme competition. Success in the market will be based on brand strength, new technology developments and manufacturing to suit regional demand. In response to such competition and development of the Single Market, some companies have decided to adopt pan-European branding, rather than individual brands for individual countries. Key European players in the market have always adopted European or world brands, supported by local brands where necessary.

Japanese companies dominate this sector worldwide. The only EC companies which appear in the top twelve consumer electronics companies worldwide are Philips and Thomson at third and sixth places, respectively. Korean manufacturers are the only others to appear on this list. Companies from the USA are scarcely represented in this sector. Despite rising manufacturing costs in Hong Kong, Taiwan, Singapore and Korea,

European labour and manufacturing costs are still much higher. There is also a shortage of skilled labour in the EC. The industry's shift from labour-intensive to capital-intensive operations as a whole may provide increased opportunities for EC players to be successful on a world scale, but this shift relies on sufficient resources and capital.

Japanese manufacturers have the benefits of economies of scale, and may have vertically integrated manufacturing. Many of the world's top consumer electronics companies are also the prominent players in the components and computing markets. The key to the strength of the Japanese is the vertical integration of the consumer electronics industry as a whole, with close cooperation at the technical development stages and component supply. In Europe, mergers and acquisitions have not facilitated improved scale economies and financial returns. The depreciation of the yen and dollar in relation to European currencies and less favourable financing conditions have not been beneficial to European manufacturers.

Reliance on innovation and pursuit of standards involves considerable risk on the part of suppliers. Again, Japanese companies have an advantage because of their substantial R&D and production resources, and a high degree of technical expertise.

Competitiveness also varies with the product considered. The main EC players have strengths in mature technologies, for example CTV. Newer products, such as camcorders, are particular strengths of the Japanese and Korean suppliers. European manufacturers are attempting to redress this balance by concentrating on future technologies in new areas and aiming to develop innovative new products.

The EC Commission is attempting to improve the situation for its consumer electronics manufacturers with industrial support policies and the improvement of competitive operational conditions and infrastructures. This encompasses stimulating demand, research and training. Reliance on the component industry, and the increasing need for manufacturers to source supplies from East Asia means that parts availability in Europe must also be addressed.

Japanese companies face tougher conditions in their domestic territory with slowed growth. It is likely that this will mean increased emphasis on other regions. Declining exports from Japan suggests that this may be achieved through offshore sites. Japanese consumer electronics companies have proved themselves to be dedicated to expansion and investment (including local investment) throughout Europe.

The market has been characterised by pressure on prices and this downward trend is expected to continue. For example, videocassette prices decreased 15% in 1990 but have now stabilised in certain EC countries where margins have been reduced greatly. Profits have declined substantially because of reduced margins and the heavy investment needed for future success.

Production process

As existing products reach maturity in the market, the consumer electronics industry is constantly seeking to expand and redefine its product portfolio. New products, such as virtual reality and multimedia systems, will soon be offered in Europe. Costs associated with the production of new products, such as CD-I, HDTV (High Definition Television) and LCD TV are still relatively high because of the cost of R&D and the development of adequate standards. These are expected to reduce with time.

Software development is now emphasised to improve technology and systems, such as audio and image signal processing, speech interfaces and fuzzy logic. Digital technology is also of increasing importance. The development of Mini-disc and Digital Compact Cassette, like CDs, is likely to revolutionise the recording media market. DCC has potential for near perfect digital sound while allowing existing analogue cassettes to be played on the equipment.

The design process has been improved in recent years. Manufacturers are using CAD and ASICS to develop new products and designs. More efficient manufacture of the components and the products themselves has facilitated product miniaturisation, which has become common as products have developed.

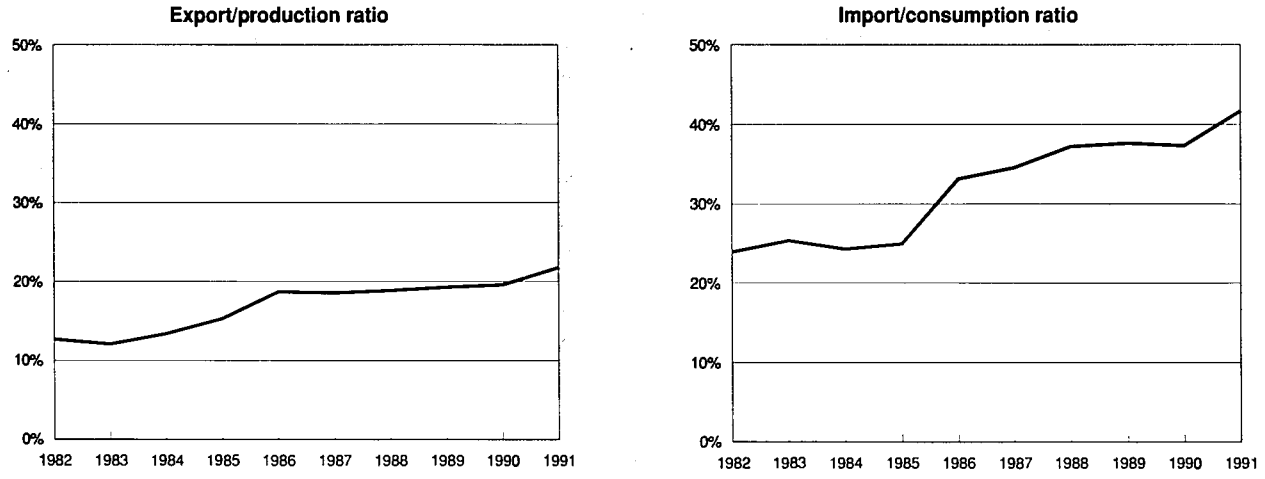
INDUSTRY STRUCTURE

Companies

The number of enterprises in the consumer electronics industry has been declining on average by 20% per annum. There are presently almost half the number of companies as in 1987. This has partly been due to mergers and acquisitions. There are now approximately 170 production plants throughout Europe.

As stated previously, the main players in this market often have divisions dedicated to consumer electronics, telecommunication activities and computing. Public and private sector organisations are active in this sector, with increasing emphasis on private organisations. The main EC players in hardware are Philips, Thomson, Grundig, Nokia and Blaupunkt, respectively.

Figure 8: Consumer electronics
Trade intensities



Source: Eurostat

The top EC consumer electronics industries vary with product line. CTV sales in the EC are dominated by EC manufacturers. Philips, Thomson and Nokia respectively hold the top positions and together account for around 45% of sales. Local manufacturers, such as Finlux in Finland and Seleco in Italy, hold a significant proportion of sales in their own country. In VCRs, Philips and Thomson hold approximately 20% of the market with the remainder of the market being held by Japanese companies. Major players in the camcorder market are all Japanese, with Sony, JVC and Panasonic as prime suppliers. Regarding videocassettes, 3M, BASF, TDK, Sony and Maxell are the main players.

Strategies

Consumer electronics suppliers face challenges of increased competition, saturation of the market for existing product ranges and expansion into new product areas, new legislation and customer pressure. Responses to these challenges are varied.

Most of the major companies (for example, Philips and Thomson) have stated their intention to pursue new product areas such as home office and telecommunications equipment. Distribution has also been particularly emphasised. While the consumer has identified a need for high quality products, manufacturers have identified a need for increased commitment to customer service and see the distribution chain as a means of achieving this.

Most of the major EC companies have undergone radical restructuring in an effort to counteract declining profits. There has been considerable lay-offs and factory closures in the process. Many CTV production plants have closed in recent years. Mergers, acquisitions and alliances all characterised the industry in 1991.

The main strategy for European manufacturers has been co-operation and joint ventures. European manufacturers are trying to gain the support of broadcasters and stimulate the availability of D2MAC and widescreen programming. The EC and some individual governments also recognise the importance of this to the European consumer electronics industry and are providing investment funds.

Investment by consumer electronics companies is relatively high. EC companies spend a similar percentage of turnover as their Japanese counterparts. However, in actual terms this is only half as much expenditure as the Japanese. Investment has centred on new product development, R&D and related technologies, such as LCD for HDTV and laptops.

The main players have the resources to commit to such large scale and sometimes long term investments although there has been a trend for European R&D funding by a number of manufacturers and governments. The Japanese have invested heavily in EC production facilities to ensure a secure base for the Single Market. This base has traditionally been in the UK (40% of all Japanese investment in the EC is in the UK) but companies are now beginning to invest in Spain as a new base for manufacturing facilities.

REGIONAL DISTRIBUTION

Production is highly concentrated in the main markets of the EC: France (35% of total production and 31% of total consumption), Germany (20.5% of total production and 23.3% of total consumption), Italy (15.6% of total production and 17.8% of total consumption) and the UK (15.1% of total production and 14.4% of total consumption).

ENVIRONMENT

Manufacturers in this industry sector have started to consider the environmental impact of both production and disposal of products. In Germany, legal constraints have instigated working groups on the discarding of electronic equipment and several manufacturers have ensured environmental safety of raw materials and components. For example, CFCs are no longer used to manufacture printed circuit boards nor are cadmium and mercury used in batteries. EC laws and recycling targets will force suppliers to produce easily recyclable and biodegradable products. This may in turn lead to increased prices of between 1% and 10% which are likely to be passed on to the consumer.

REGULATIONS

Regulations will be introduced by 1994 to limit interference when equipment is attached to the mains supply. This is obligatory for all suppliers of consumer equipment and may necessitate redesign of the power supply stage. A higher production cost will be associated with this. Laws concerning waste disposal have already been introduced in Germany and in France.

The advent of the Single Market has lead to the need to review recorded music laws and blank recording media laws. Several countries (such as France, Germany, Portugal, Spain and Italy) have introduced home taping royalties for hardware and tape sales. This is likely to cover all EC member states by 1993. Reproduction rights are also being addressed by the EC Commission to ensure similar durations of protection (50 years) and thus foster uniform competition between EC countries. The right of a producer to control rental is another issue. France, Portugal, Spain and the UK currently have legislation to control rental. Performance royalties are not given in certain EC countries (Belgium, Greece, Luxembourg, the Netherlands and Portugal). With the increase in public access to recorded music products, it is likely that this will also be addressed by EC legislation.

EC directives on HDTV have been issued in an attempt to encourage broadcasters to adopt D2MAC, with proposed funding, and to encourage adoption of a pan-European HDTV standard. Technological advances are likely to cause further review of existing legislation, particularly with Digital Audio Broadcasting and DCC. Industry leaders announced in 1989 the "Serial Copy Management System". This system recommends that first generation digital recordings of CDs, pre-recorded Digital Audio Tapes and digital broadcasts would be allowed but not second generation copies. A EC Commission proposal on the use of SCMS is being prepared.

OUTLOOK

The consumer electronics industry's future hinges on its development and successful marketing of new technologies. Without these the industry will become more dependent on replacement sales of mature technologies in a saturated marketplace. HDTV provides the long-term opportunity.

Table 9: Consumer electronics
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	5.0	4.3
Production	5.6	4.8
Extra-EC exports	7.0	7.0

Source: BIS Strategic Decisions

Significant opportunities are offered by Digital Audio Broadcasting and DCC. However, the EC must work to define legislation to protect revenues and discourage piracy. EC manufacturers have many obstacles to overcome in order to

remain successful on their home territory and increase penetration of world markets. This necessitates significant investment in new technologies, development of appropriate standards and ensuring that other raw material supplies, particularly components, are freely available in Europe.

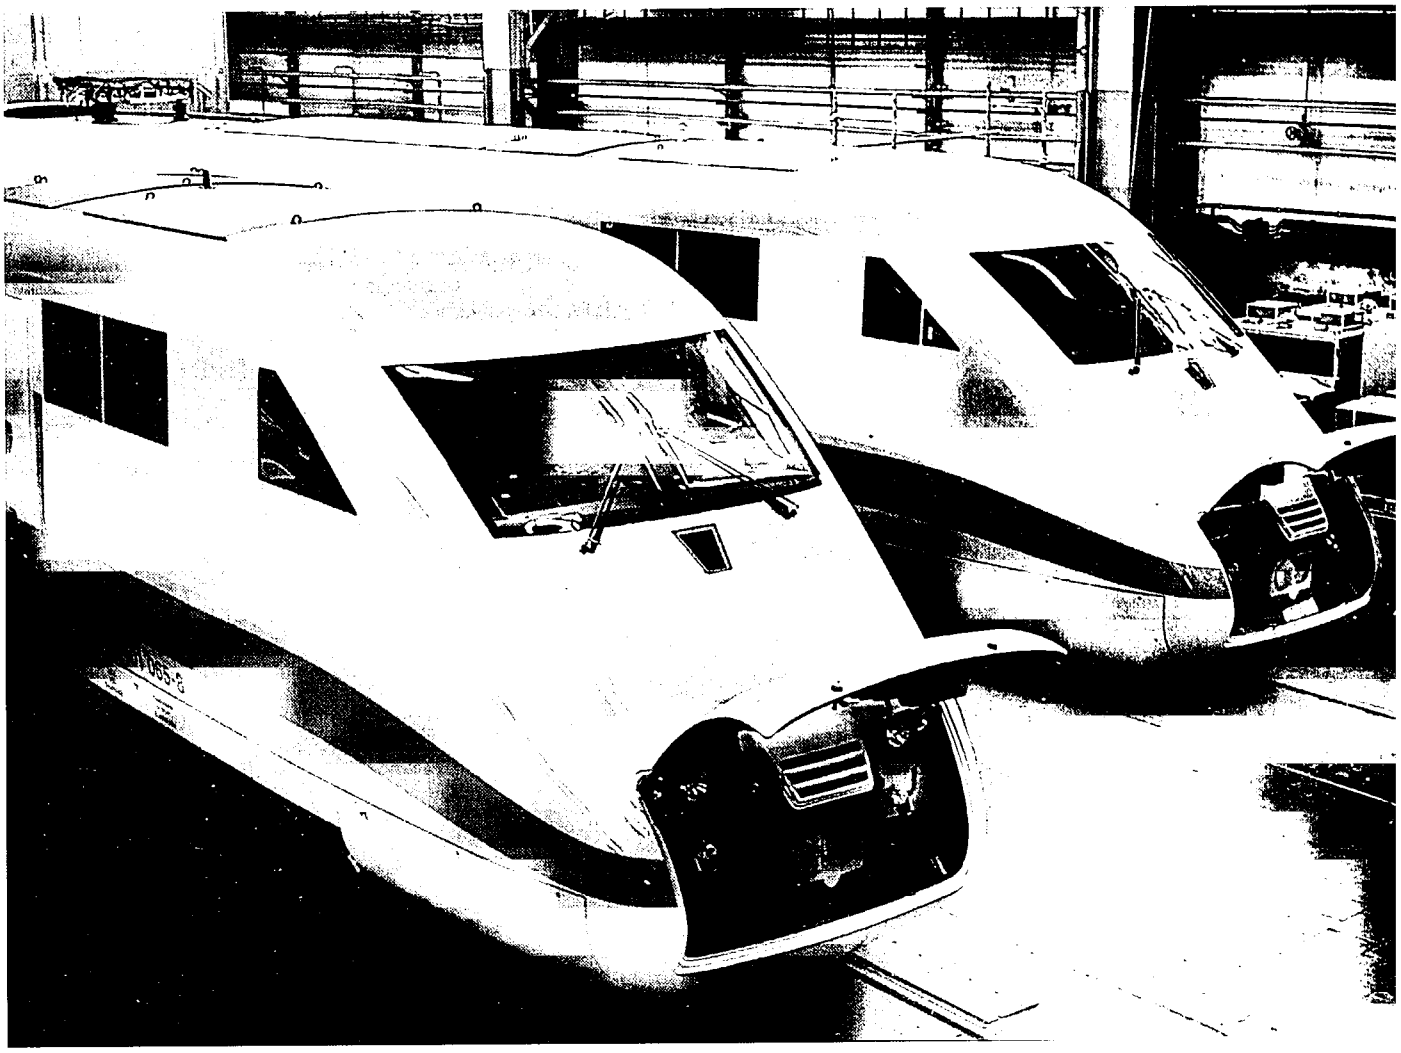
The industry is represented at the EC level by: European Association of Consumer Electronics Manufacturers (EACEM). Address: Rue d'Arlon 69-71, B-1040 Brussels; tel: (32 2) 230 50 10; fax: (32 2) 230 96 08.



Transport equipment
NACE 35, 36

The transport equipment sector is one of the largest industries in the EC and has significant influence over other sectors such as ferrous metals and rubber and plastics. After experiencing a downturn in 1990 and 1991 amidst a worldwide recession, the transport industry is poising itself not only for economic improvement but also for changes brought about in the movement toward the Single Market.
Given that the motor vehicle industry is unquestionably the largest subsector of transport equipment, increasing import penetration (particularly from Japan) will play a very important role in the health of the industry as a whole.

INDUSTRY PROFILE

Description of the sector

According to the NACE classification, the transport equipment sector covers the following subsectors:

- motor vehicles (NACE 351 and 352);
- motor vehicle parts and accessories (NACE 353);
- shipbuilding (NACE 361);
- railway rolling stock (NACE 362);
- mopeds and motorcycles (NACE 363);
- aerospace equipment (NACE 364).

In terms of production, the most important sector by far is the motor vehicle industry (including parts and accessories), which accounted for nearly three-quarters of the output of the transport equipment sector overall in 1991.

Note that there is no clear consensus as to the composition of the parts and accessories sector for motor vehicles. NACE 353 which corresponds to motor vehicle parts and accessories underestimates the size of an industry which presently manufactures components included under sectors such as electrical and electronic equipment.

Main indicators

After maintaining production growth rates (at constant prices) above 5% between 1987 and 1989, the transport equipment industry grew only 1.3% in 1990 and contracted 1.0% in 1991. A worldwide slump in demand for transport equipment had an even greater negative impact on extra-EC exports. The downturn was particularly strong in the motor vehicle industry, the largest subsector of transport equipment. Exports of luxury cars in particular to the United States were hampered by a number of factors. The most obvious include a recession in the United States, a declining US dollar, and a new 10% luxury tax placed on automobiles with an invoice price above 30 000 US dollars. Such a downturn in overseas demand caused a near halving of the sector's trade surplus as extra-EC imports increased by 20.5% in 1991; such import growth occurred mainly in the aerospace and motor vehicle sectors.

With an output (in terms of value added) of nearly 41% of the EC total, Germany is by far the largest producer within the EC. The three largest producers behind Germany are France, the UK, and Italy, in descending order of value added contribution.

Recent trends

Given that the motor vehicle industry is the largest component of the transport sector, it is not surprising to find that similarities in production and employment data for motor vehicles and the transport sector exist; the 3.2% average annual growth rate in production of the transport equipment sector is just slightly below the annual 3.6% rate of growth of the motor vehicles industry over the period 1982 and 1991. This contrasts with the declines in production registered by the shipbuilding and railway rolling stock industries. Motor vehicle parts and accessories was the fastest growing industry over the ten period with average annual increases in production in real terms of 4.6%.

In 1991, however, both the motor vehicles and the motor vehicle parts and accessories industries suffered production declines of more than 2.5% compared to 1990. Weak demand at home and from export markets produced this sharp downturn. Moderate growth in the aerospace industry, the second largest subsector of the transport equipment sector, helped to counter the situation in the motor vehicle industry, allowing

production growth of transport equipment sector overall in real terms to continue its expansion.

International comparison

The EC remains the world's largest producer of motor vehicles and railway rolling stock. The EC's aerospace industry has made great improvements over the last decade. Production and exports have attained significant gains in comparison to the USA, the world's largest aerospace producer.

In 1991, EC production (in current prices) of transport equipment was almost double that of 1982. By contrast, US production in 1991 was only 40% greater than 1982 production. Japanese production more than doubled over the same period, reflecting Japan's ability to penetrate markets worldwide, particularly in the motor vehicles subsector.

Foreign trade

The near tripling of extra-EC imports (in value) over the past decade significantly reduced the EC trade surplus, which peaked in 1985. Swings in currency values (mainly between European currencies and the US dollar) since 1985 have made imported goods relatively cheaper compared to their domestic counterparts.

Since 1986, the transport equipment sector experienced a number of major shifts in both the destination of extra-EC exports and the origin of extra-EC imports. Japan accounted for an increasing share of EC exports in 1991 compared to 1986 while export shares to the EFTA and OPEC countries remained stable. A notable decline in the export share to the USA can be mainly attributed to a substantial devaluation of the dollar during this period. By the same token, the USA increased its share of extra-EC imports from 23% in 1986 to 35% in 1991, mainly to the detriment of import shares for the EFTA countries and Japan.

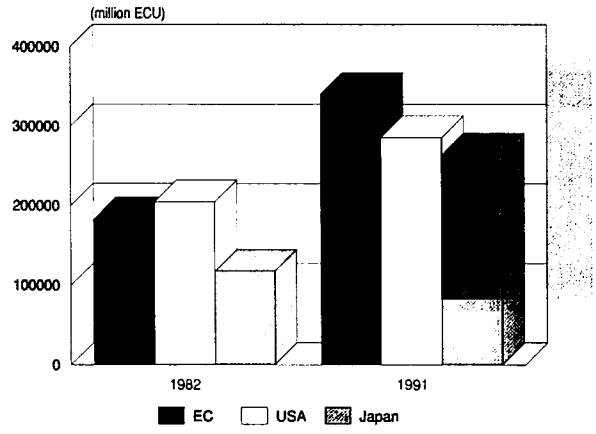
After experiencing a near halving of the trade surplus in 1991, a slowdown in import growth for 1992 should maintain the transport sector's trade surplus, albeit a smaller surplus than in 1991.

MARKET FORCES

Demand

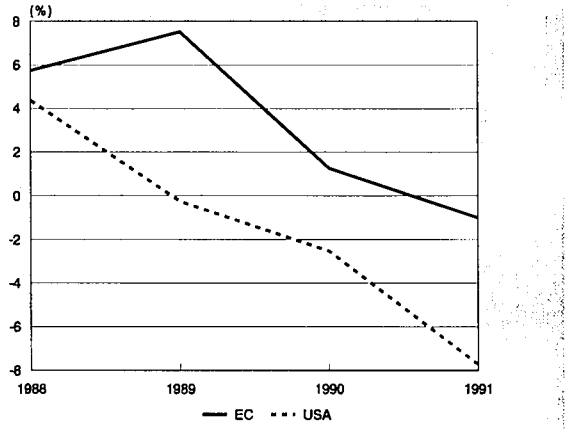
Demand in the different subsectors can be attributed to a wide variety of factors as certain forms of transportation are close substitutes for each other (travelling by car versus rail

Figure 4: Transport equipment
International comparison of production at current prices



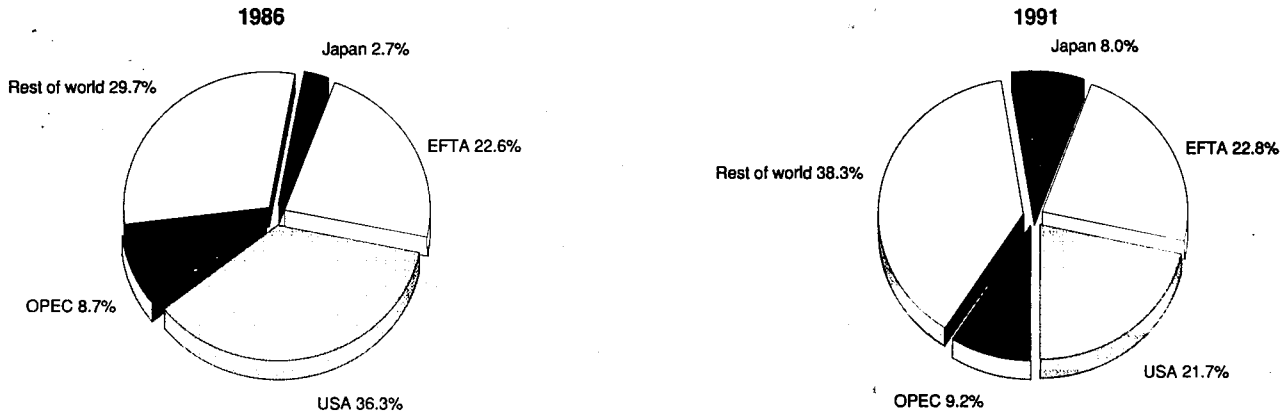
Source: Eurostat, Census of Manufacturers

Figure 5: Transport equipment
International comparison of production growth at constant prices



Source: Eurostat

Figure 6: Transport equipment
Destination of EC exports



Source: Eurostat

or air travel, for example). Furthermore, an increased awareness of transportation's impact on the environment on the part of the general population may also affect demand as increased use of public transportation reduces emissions and traffic congestion.

Supply and competition

As a whole, the EC transport sector is fully capable of meeting the demand for transport among its Member States. In fact, the EC maintains a trade surplus (albeit declining) in transport equipment on an annual basis. Declines in the EC trade balance are most noticeable in the motor vehicle and aerospace subsectors.

In the motor vehicle industry, Japanese competition clearly constitutes the main challenge faced by European producers over the next two decades. In response to such competition, EC car manufacturers need to further implement so-called lean production techniques in order to at least maintain market shares.

The profits to turnover ratio shows the European transport industry improved its profitability between 1982 and 1991. The effects of the worldwide recession, however, have diminished a previously positive trend which peaked in 1989. The most notable rise and subsequent fall in this trend occurred in the aerospace subsector, which experienced a considerable drop in orders for both civil and military aircraft.

Production process

As rationalisation and innovations in automated production techniques continue to be applied to the production process, employment in the sector continues to dwindle, with only slight upturns occurring in 1989 and 1990. The chronic downward trend continued in 1991 is not expected to change in the near future.

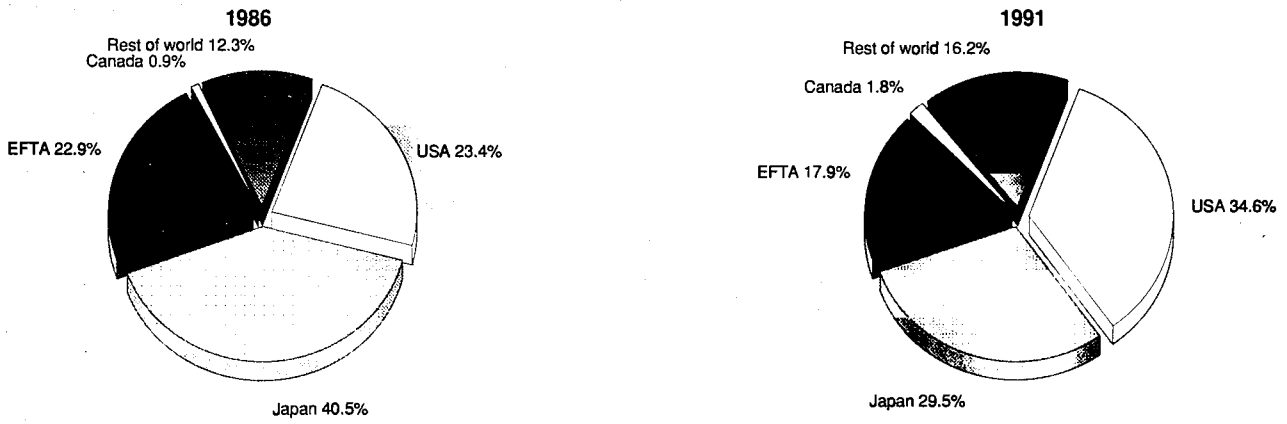
Innovations in the production process are particularly noticeable in the motor vehicle industry, where new techniques such as just-in-time production and increased emphasis on quality control are reducing production times and allowing for greater cost-effectiveness.

INDUSTRY STRUCTURE

Companies

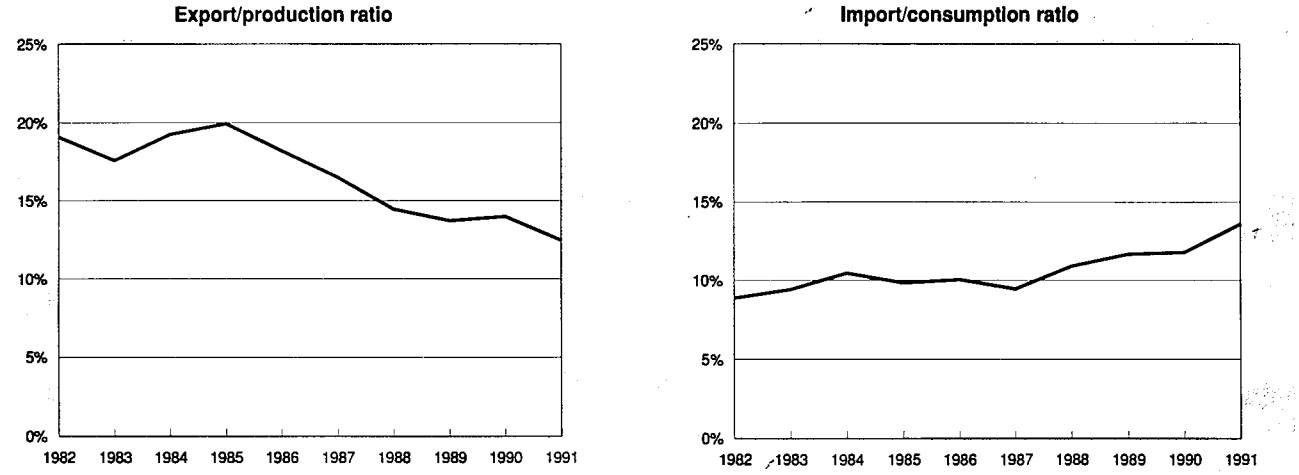
The transport equipment sector is well represented among the leading European companies. Daimler-Benz, which is the leader in terms of turnover, is the third largest industrial com-

Figure 7: Transport equipment
Origin of EC imports



Source: Eurostat

Figure 8: Transport equipment
Trade intensities



Source: Eurostat

pany in Europe. The sector is considerably concentrated as the top 6% of the companies (i.e. companies with more than 99 employees in 1988; see Table 5) accounted for 94% of the transport equipment industry's turnover.

Some of the leading corporations in this sector have interests in various industries. Many of the large volume car manufacturers, such as Renault, Fiat and Daimler-Benz, also have interests in the truck industry. Peugeot SA produces mopeds, motorcycles and bicycles, whereas both Fiat and Daimler-Benz are involved in both the motor and aerospace sectors. In addition, British Aerospace now holds a majority stake in Rover Group. At the time of the Rover Group takeover by British Aerospace, much was made of the opportunity for the two companies to enjoy industrial synergy. Although there does not seem much evidence of this synergy in general, companies with dual interests are at least able to allocate risks across their diversified branches.

Strategies

Although the EC can still lay claim to some of the largest transportation companies in the world, a strong movement towards international cooperation between EC manufacturers and American and Japanese companies is quite prevalent.

In the motor vehicles industry, a number of mergers have occurred, in particular between the large mass-producers and smaller luxury car makers. Some examples include Fiat's takeover of Alfa Romeo, Ford's purchase of Jaguar and General Motors' 50 % stake in Saab's car division. Apart from outright mergers, a cooperative agreement between Volvo and Renault through complex cross-shareholdings has made Volvo/Renault the world's largest truck producer.

Collaboration has not taken place solely between EC producers, however. In recent years, there have been a number of collaborative ventures or cooperative agreements between EC companies and Japanese or American organisations. The Japanese motor industry's superior standing in certain areas of the production process has led to a steady stream of joint manufacturing agreements, for example, General Motors' arrangement with Isuzu to jointly produce vans in the UK, and the much-publicised Rover-Honda tie-up which has now been existence for over ten years.

In terms of cooperation between US and EC companies, the aerospace sector is the unquestionable leader. This cooperation is essentially taking place between aerospace engine manufacturers (MTU and Pratt & Whitney or General Electric and Snecma, for example). It is also worth mentioning the contribution of out-sourcing, particularly between US companies to the Airbus programme as well as of European companies to some of the Boeing and McDonnell-Douglas programmes.

Although cooperation among companies has occurred, outright mergers and acquisitions activity are still somewhat limited in industries such as aerospace where governments of respective Member States still have a controlling interest (particularly in the production of military equipment). Given the advantages of scale economies and large R&D expenses, however, some very important mergers and acquisitions have occurred in the aerospace industry. Such a development is quite pronounced in Germany, where much of the aerospace industry is performed by divisions under Daimler-Benz which were acquired through mergers and acquisitions.

REGIONAL DISTRIBUTION

In 1991, as in previous years, more than 85% of EC production was concentrated in four Member States: Germany, France, the UK and Italy. For motor vehicles, these four countries accounted for 91% of all value added within the EC.

In the aerospace sector, Germany, France, Italy and the United Kingdom produced about 94% of value added in Europe.

The opening of frontiers with Eastern Europe promises to have a significant impact on the distribution of European production facilities, particularly for the motor vehicle industry. For example, many major West European manufacturers have already entered into agreements with East European producers, in anticipation of future rewards. Opel (a subsidiary of General Motors), Volkswagen, and Mercedes-Benz have all set up production units in former East Germany. In addition, Volkswagen has also acquired a large stake (to become a majority stake by 1995) in Skoda (the largest Czech car manufacturer) and has signed a joint venture agreement with BAZ (the second largest Czech auto company).

ENVIRONMENT

Transport has been one of the main targets of environmental regulations for several years. Transport services account for one-quarter of total carbon dioxide emissions (carbon dioxide is the main gas responsible for the so-called "greenhouse effect").

Given the strong "technological" link between carbon dioxide emissions and energy consumption, heavy energy users such as the aerospace and motor vehicle industries are likely to be under attack over the course of this decade. This could be to the benefit of some of the smaller transport subsectors like rail.

In the area of personal transport, increasing congestion in most towns and cities, coupled with growing environmental awareness should benefit the moped and motorcycle industry, as well as the public transport equipment sector.

In the long term, the kind of solution adopted to solve the global warming problem is of major importance, given that it could lead to a significant shift in production between certain branches of the sector.

REGULATIONS

Increasing penetration of Japanese motor vehicles will have a substantial effect on the sector as a whole. An agreement made in 1991 between the EC and Japan called for a complete opening of the European market to Japanese vehicles by the year 2000. During the agreement's interim period through 1999, the share of Japanese car makers will be progressively raised. Japanese producers have promised to refrain from a rapid adjustment of their penetration rates in what are presently the most protected markets, France and Italy.

OUTLOOK

The European auto industry has experienced rather difficult conditions during the past two years, conditions which are not expected to change in the near future. Following a 1% fall in 1990, car sales increased by 3% in 1991, a result entirely accounted for by the short-term explosive demand in the former East Germany. During the 1990's, European producers will face a series of important challenges ranging from Japanese competition to environmental pressures and the development of the East European market. The restructuring of the industry will continue and important lay-offs are expected.

Despite a recent downturn in the aerospace subsector, growth is expected to be encouraged by both a rapid growth in air

Table 7: Transport equipment
Expected real annual growth rates

(%)	1992-93	1992-96

traffic and the need for airlines to replace their ageing fleets. Such a forecast also assumes that airlines will be in a favourable position to make such investments.

Prospects for the railway rolling stock industry are somewhat different, with problems stemming more from the demand than from the supply side as world demand remains sluggish. Sales in Europe will be somewhat spurred by investments in a European high speed rail network, the upgrading of the Italian and East German networks, and increased environmental concern which puts more emphasis on the development and expansion of efficient transport networks. In addition, an expected hike in oil prices will likely raise the cost of travelling (by car or by air, in particular), making rail travel a more affordable form of transportation.

Overall, production growth in the transport equipment sector is expected to average 2.6% per year to 1996, weaker than the more than 4% annual rate of growth over 1985 to 1991.

Written by: DRI Europe

Motor vehicles
NACE 351

The motor vehicle industry is the largest European industry with a value added of more than 7 billion ECU. Following remarkable growth during the latter half of the 1980's, which was extended by a burst of demand in the former East Germany following reunification, the EC motor vehicle markets are now experiencing a downturn. Establishment of the Single Market will have particularly strong effects on the truck industry as restrictions on the road haulage industry are reduced between Member States.

INDUSTRY PROFILE

Description of the sector

NACE 351 covers the manufacture and assembly of motor vehicles and the manufacture of motor vehicle engines. Motor vehicles include passenger cars and commercial vehicles. All the volume motor vehicle manufacturers also operate on the commercial vehicle market. Several vehicle manufacturers such as Rover, Mercedes-Benz, Rolls-Royce, and (to a lesser extent) Fiat are part of large diversified groups with activities in the aerospace, electronic, defense or financial services industries. All the vehicle manufacturers also operate upstream in the part and accessories sector.

Main indicators

In 1991, the turnover of the EC motor vehicle industry for the first time exceeded 200 billion ECU. Due to restructuring, employment steadily decreased over most of the 1980s, but was still close to 1.2 million in 1991.

Extra-EC exports account for more than 12% of the sector's turnover. The industry is a net exporter and an important contributor to the EC's current account surplus; however, this contribution fell significantly during the second half of the 1980s and particularly in 1991.

As is evinced in Table 5, the trade position of the EC varies according to the different segments of the industry. The EC is a net exporter of cars but a slight net importer of both light and heavy commercial vehicles.

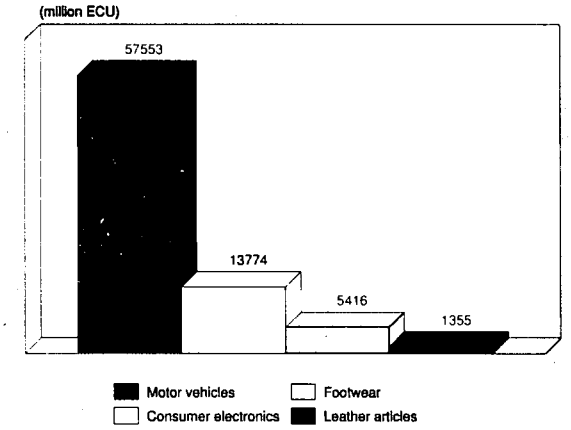
Germany is by far the largest European producer (it is important to keep in mind that "German production" refers to production taking place in Germany, including that of subsidiaries of foreign companies but excluding the output of foreign subsidiaries of German companies). It accounts for about half of the value added generated in the EC, a share which is more than three times larger than that of France, the second EC producing country. Other important producers are the United Kingdom, Italy and Spain. Thanks to heavy foreign investments, Spain is actually producing more vehicles than the UK or Italy, but a large share of its industry still consists of assembly operations.

Recent trends

After five successive years of growth, the industry entered a downturn in 1990. With the exception of Germany, all the largest European markets confronted stagnation or serious drops in new vehicle registrations. In 1991, the slide continued and even accelerated, but was compensated in part by a burst of sales in former East Germany following unification. Owing to its cyclical nature, the industry grows faster than the manufacturing average during expansion phases but is hit more severely during recessions.

The level of direct employment in the EC motor vehicle industry reflects the restructuring which has been taking place since the early 1980s. Overall, approximately 390 000 (18%) jobs were lost in the industry between 1980 and 1987. In contrast to France and the UK, which were the hardest hit, the Federal Republic of Germany managed to increase employment by 68 000 jobs. Productivity improvements have continued since 1987, though lay-offs have been somewhat cushioned by a rapid growth in production.

Figure 1: Motor vehicles
Value added in comparison with other industries, 1991



Source: Eurostat

International comparison

With sales of about 12.6 million units in 1991, the EC market for passenger cars represents 37% of world sales. The EC is the largest car market in the world, well ahead of North America and Japan. With an output exceeding 12.9 million units, the EC is also the world's largest producer, ahead of Japan and North America. Fuelled by the strength of its domestic market, the European lead on North America has been expanding over the past years. On the other hand, Japanese production has been progressively catching up over the same period.

Between 1987 and 1991 period, total vehicle production (i.e. including commercial vehicles) rose in volume by 8% overall in the EC, 20% in Japan and dropped by 11% in the US.

Foreign trade

Exports of motor vehicles are relatively diversified compared to imports. Three regions, the EFTA countries, North America and developing countries, account for more than three-fourths of extra-EC exports. In the mid-1980s, North America was the most important export market for the EC and the major outlet for the European luxury car output. Following the decline of the dollar and the American recession, demand for luxury cars plummeted and imports from the EC plunged. With a share of 20% in 1991, North America is now a less important market than the EFTA with 32% or developing countries with 24%. Japan remains a relatively minor destination for European production, but its share of extra-EC exports has increased rapidly in recent years, reaching 12.5% in 1991.

Imports of motor vehicles into the EC originate mainly from Japan, a country with whom the EC is running a 7 billion ECU trade deficit. Though the share has decreased somewhat over the past years, Japan still accounts for 56% of all extra-EC imports. The share of imports from Japan highlights the importance of the present under valuation of the Yen with respect to European currencies. With 24% of imports of motor vehicles into the EC, EFTA countries remain well behind Japan. Though its share increased recently to 5.5%, North America is a rather minor source of imports to the EC. However, to a large extent this reflects the high level of local production achieved by the European subsidiaries of US vehicle manufacturers.

MARKET FORCES

Demand

The demand for passenger cars is characterised by a combination of short term cyclical fluctuations and long term growth. From just over 3 million units in 1960, the demand for passenger cars in the EC has enjoyed considerable growth, to pass the 12 million unit mark in 1989. Growth has been almost uninterrupted between 1960 and 1974, when the impact of the first oil shock caused registrations to decline by 14.3%. The growth pattern then resumed until the second oil crisis at the end of the 1970s signalled a two year decline for car demand. During the early 1980s, the EC motor vehicle industry suffered a period of relative stagnation, followed by a recovery in the latter half of the decade to push total sales over 12

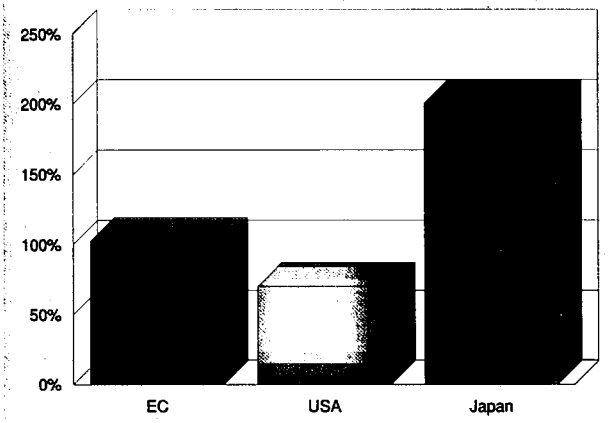
Ratio of production to domestic sales, 1991



Source: DRI Europe

million units. After five successive years of growth between 1984 and 1990, the industry again experienced lower sales in 1990 and 1991. Apart from Germany, all of the volume markets posted stagnating or diminishing sales in 1990 and total Community demand dropped by 1%. The UK and Spain were the hardest hit with a drop in registrations of nearly 13% each. In 1991, the decline accelerated and UK sales plummeted by 20%, while Spanish and French registrations each plunged by more than 10%. Sales in Germany following unification compensated for losses in other countries as total EC sales actually increased by 3%. German registrations surged by 37%, aided by demand in former East Germany estimated at 700,000 units. Such demand, however, will be much weaker during the coming years with the demand overhang created by supply shortages in the former German Democratic Republic reduced.

In the short run, consumer demand for cars depends mainly on personal income and wealth not to mention business and consumer confidence. These factors account for the cyclical nature of sales over the past two decades. Economic downturns are generally triggering important slumps in new car registrations. In the medium and long term however, demand for cars will continue to rise and car penetration (i.e. car parc per capita) will continue to increase especially in the Member States where it is presently low. Average car ownership figures vary widely across countries, exceeding 450 units per 1000 inhabitants in Germany (in the western Länder) and in Italy but falling short of 320 units per 1000 inhabitants in Spain and short of 160 units in Greece.

Sales of commercial vehicles exhibit an even greater fluctuation than sales of cars. The truck market underwent dramatic slumps in the mid-1970s and early 1980s. The second half of the 1980s were marked by a sustained growth which was first fostered by the need to replace the fleet built up in the late 1970s and later spurred by an increase in fleet capacity. In 1990 and 1991, the industry experienced a slump with a 6.2% and 15.4% drop in new registrations (Germany excluded). As in the case of cars, the downturn was compensated in 1991 by a jump of German sales following unification. East German demand, however, will soften considerably in the coming years as the initial replacement of East German vehicles is completed.

Table 5: Motor vehicles
Breakdown by product line, 1991

(1000 units)	Production	New registration
Cars	12 886	12 580
Light trucks 6 tonnes	1 252	1 257
Trucks 6 tonnes	252	257

Source: DRI Europe

Long term truck demand depends essentially on the health of the road haulage industry which in turn is related to two main factors:

- the growth of the most important end markets for transport services such as the food, drink, tobacco, construction, metal, and wholesale distribution industries;
- the competitive edge of road haulage with respect to other transport modes. Over the past two decades, the road haulage sector has consistently gained market shares to rail or inland waterways; the trend is expected to continue over the 1990s.

Several upcoming structural changes in the EC's economy may have an important effects on the demand for trucks. The Single Market has already and will continue to foster intra-EC trade. The Single Market also entails a further restructuring of European industry into larger commercial units. These two elements imply additional demand for transport services, including road haulage. On the other hand, the planned deregulation of the road haulage industry is expected to step up the efficiency of the existing fleet as a result of the introduction of cabotage and the eradication of supply restrictions. A more efficient fleet implies that less trucks will be required to ship a given quantity of goods.

Supply and competition

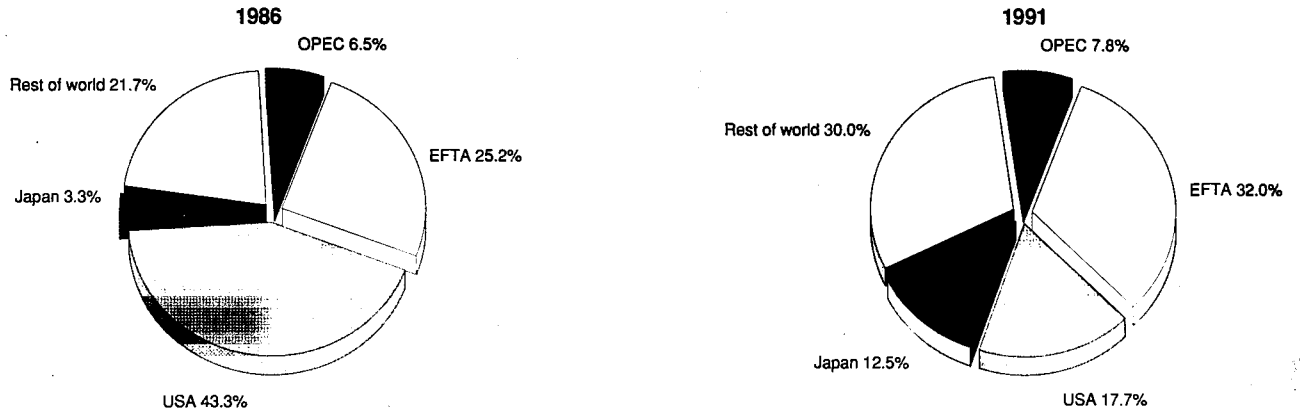
The late 1970s and early 1980s were marked by some uncertainty in the wake of the second oil crisis, and fears concerning overcapacity. Most companies experienced a period of consolidation and restructuring. Intensifying competition, (from Japanese companies and rapidly evolving Pacific Basin companies) caused EC manufacturers to make substantial changes to their production processes and cut costs. Revolutionary cost-effective Japanese techniques, known as lean production techniques, were paramount in causing producers to re-evaluate their systems.

The main objectives of reducing unit production costs, improving productivity, allowing greater flexibility and increasing research and development expenditures were achieved by various means. The rationalisation of operations, with substantial lay-offs, and the increasing use of common platforms for several models helped minimise costs. Simultaneously, the introduction of flexible manufacturing systems and "just-in-time" management were directly adopted from the Japanese, leading to a substantial reduction in the number of component suppliers. This development is in turn contributing to the restructuring and the increased consolidation taking place in the automotive supply sectors.

Following the rapid expansion of demand during the second half of the 1980s, most of the European producers have found themselves short of capacity by the end of the decade. Plummeting sales on most of the volume markets in 1990 and 1991, however, have taken some pressure off production capacities. Germany is a major exception and local manufacturers had difficulties keeping up the pace with surging domestic sales. As a result, German car imports increased by 20% in 1990 and nearly 50% in 1991.

Whereas Japanese motor vehicle manufacturers concentrated most of their marketing efforts in North America during the 1980s, their priority will shift to the European market during the 1990s. Japanese competition certainly constitutes the main challenge faced by European producers over the next two decades. To meet Japanese production standards, EC car manu-

Figure 7: Motor vehicles
Destination of EC exports



Source: Eurostat

facturers will have to undertake another set of restructuring in order to continue to implement the so-called lean production techniques. European producers have made important efforts over the past years to step up productivity, improve quality, reduce stocks. Nevertheless, large differences still exist between European and Japanese efficiency as is evidenced in table 7 (data provided in table 7 are from 1989, and though no update is available yet, European companies are estimated to have partly closed the gap since that year).

Another set of redundancies seems inevitable during the coming years. Mercedes-Benz and Volkswagen have already announced important cuts in their labour force for the coming years. Meanwhile, other manufacturers estimate that they will have to reduce their workforce substantially if they are to meet Japanese productivity standards by the end of the century.

It is worth noting that the European Commission put forward several proposals in May 1992 in order to increase the competitiveness of the EC auto industry. These mainly include higher R&D spending and special funds for professional training and reconversion.

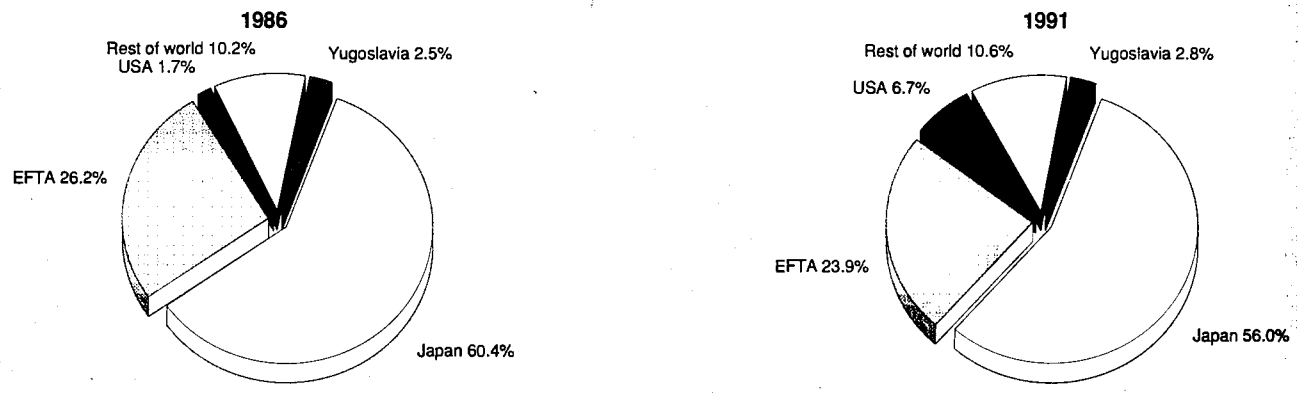
The financial performance of the EC vehicle manufacturers improved markedly during the second half of the 1980s. After combined losses of 2.2 billion ECU for the period 1981-84, the period 1985-87 saw motor vehicle companies realising a net profit of 10.6 billion ECU, and from 1987 onwards, almost all companies have been operating profitably. This turnaround was principally the result of a succession of good years for the EC passenger car and truck markets, but was also assisted by the long period of restructuring in the late 1970s and early 1980s.

As a result of the downturn, results deteriorated considerably in 1990 and 1991 as all major motor vehicle manufacturers reported drops in profits. Given manufacturers' much improved financial health, however, the situation is much less dramatic than it was during the beginning of the 1980's. However, necessary restructuring might put a strain on the financing capacity of the industry once again.

Production process

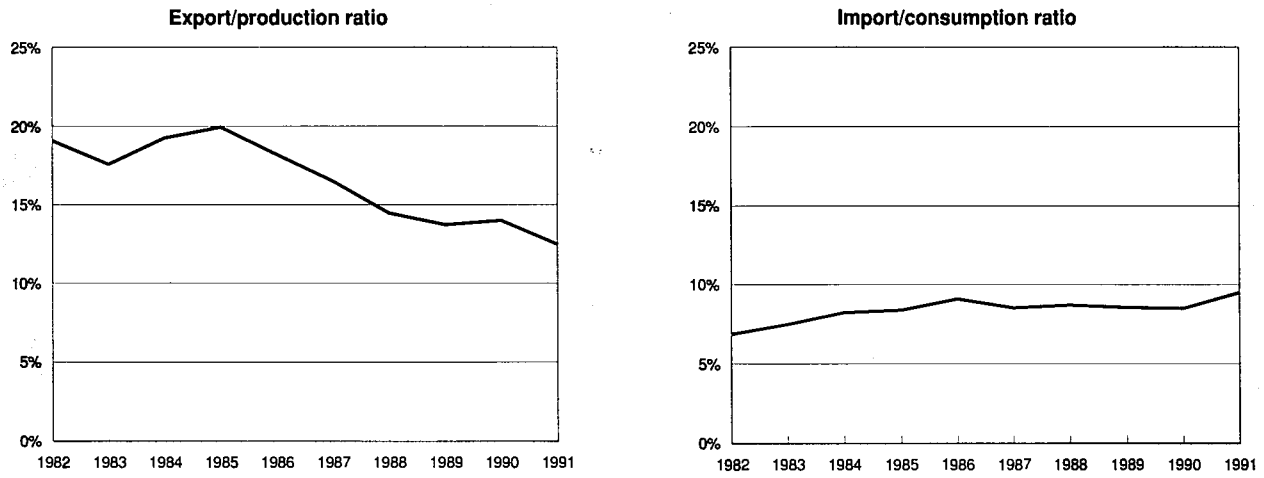
In terms of the production process, the implementation of lean production constitutes the most thorough structural

Figure 8: Motor vehicles
Origin of EC imports



Source: Eurostat

Figure 9: Motor vehicles
Trade intensities



Source: Eurostat

change faced by European manufacturer during the coming decade. Lean production is seen by many analysts as a revolutionary method with consequences as important as the shift from craft to mass production initiated by Henry Ford in the early 20th century.

Lean production was implemented by Toyota during the 1950s and the 1960s and has been now progressively adopted, (though to various degrees) by all Japanese manufacturers. It is based on a set of techniques aimed at higher quality with a lower per unit requirement of all inputs, namely labour, capital, inventories and time. Furthermore, increased flexibility should allow the profitable production of smaller series. As a result, the output is improved both in terms of quality and diversity. Lean production applies both to the production process and to the product development phase. In the mid-1980s, development time for a new car averaged 46 months for Japanese manufacturers against about 60 months for American and European producers. Product cycles average about 4 years for Japanese models against 6 to 10 years for European models. For several years, European car manufacturers have started to implement some elements of lean production such as just in time, quality management, quality circles or closer links with upstream suppliers. It is important to keep in mind that lean production demands more than the mere implementation of a few new management techniques. It is a continuous improvement process which mainly runs bottom up, requiring total commitment from the shop floor and completely new forms of labour management with a combination of more skilled labour and increased responsibilities at the shop floor level.

INDUSTRY STRUCTURE

Companies

In the car industry, the 6 largest companies account for 75% of total sales in Western Europe. Nevertheless, the industry's market power is hindered by the presence of several players with very similar strengths and sizes. The market shares of the volume car-makers range between 10% and 16%, with most of them clustering at about 12%. Given its size, the industry exercises substantial market power on its upstream suppliers.

The truck industry posts a concentration rate similar to that of the car industry though the market leader of both the light and heavy segments enjoy higher shares than in the case of the car industry. In the light trucks segments, 6 firms account for more than 70% of the production in Western Europe. That share rises to over 85% in the case of heavy trucks. In addition, the market position of the heavy truck leader, Mercedes-Benz, is particularly strong as the company accounts for one-third of European sales.

In 1991, as during the two previous years, the Volkswagen Group turned out to be the leader of the European market. The German manufacturer stepped up its lead on its usual challenger, the Fiat group which was handicapped by its dependence on a weak domestic market. Volkswagen posted a share of the West European market close to 16% (against 12.5% for Fiat). One of 1991's surprises was the strong performances of two American subsidiaries, Ford Europe and General Motors Europe, which both increased their share of the European market. With a 12.04% share of European sales, General Motors Europe is now very close to PSA, the third largest group with 12.07%.

In the light commercial vehicle (LCVs up to 6t GVW) market, Renault held onto market leadership in 1991. The French group was followed by PSA, Ford, and Volkswagen (in that order). Thanks to the new market in former East Germany and to the launch of a new model, Volkswagen achieved a considerably higher production level than in previous years. Mean-

Table 7: Motor vehicles
Productivity of car assembly plants, 1989 (1)

	Japanese in Japan	Japanese in North America	American in North America	Europe
Productivity (hours/vehicle)	16.8	21.2	25.1	36.2
Quality (assembly defects/100 vehicles)	60.0	65.0	82.3	97.0

(1) Automotive activities only
Source: IMVP World Assembly Plant Survey

while, PSA experienced a downturn in market share of approximately 14%.

Mercedes-Benz dominates the heavy end of the truck market. In 1991 it accounted for more than 30% of EC truck production (over 6t GVW). It was followed by Fiat/IVECO with 15%.

Strategies

During the second half of the 1980s, concentration increased which was marked by the nearly completed disappearance of luxury auto manufacturers as independent producers. Fiat took over Alfa Romeo, Ford acquired Jaguar and General Motors took a 50% stake in Saab Automobile. Trucks makers have not been much less active in terms of take-overs as is evidenced by the merger of British Leyland and DAF or the control of Spain's Enasa by Fiat/Iveco.

Acquisition is not the only form of alliances. Several companies have resorted cooperation of one form or another, especially for the production of commercial vehicles and vehicles components. Ford and Iveco have joined forces in the UK, while Peugeot and Fiat manufacture vans together. In addition, several links have been or are being established with Japanese manufacturers. Honda has an equity stake in Rover of the UK, and several joint-ventures have been set up between Volvo and Mitsubishi in the Netherlands, between Volkswagen and Suzuki and between Ford and Nissan in Spain. The most ambitious cooperation experience set up so far is that between Renault of France and Volvo of Sweden. The agreement (which was signed in 1990) concerns both the truck and the car divisions of the two companies and involves substantial cross-share holding.

ENVIRONMENT

Since the early 1970s, EC legislation has controlled the emission of both unburned hydrocarbons and carbon monoxide. In 1978, oxides of nitrogen also became subject to control. In 1987, the "Luxembourg Compromise" of 1985 finally became law as a result of the Single European Act. It provided for the implementation of very tight emission standards for passenger cars within the period 1988-1993. While the limit values for models equipped with engines above 1400 cc. displacement were an integral part of it, the Luxembourg Compromise left the limit values for a second step in emission requirements for small cars to be the subject of further discussions between the Member States. Particulate emissions of diesel engines were also not of part of the compromise.

For the manufacturers, the technical changes required to meet these regulations were substantial, with the consequence of higher costs for both producers and consumers. For the most part, catalytic converters were required, creating a need for unleaded gasoline. In fact, a separate EC directive, requiring Member States to make sure that unleaded petrol was widely available by the end of 1989 (lead itself being regarded as a pollutant), was issued in 1985.

In 1988, particulate limit values for diesels were adopted. In 1989, the second step in emission requirements for small cars was defined in such a way that three-way catalyst technology would become necessary also for this category of vehicles. At that time the Council made the application of the new directive mandatory in each Member State. Previously, Member States retained the option of delaying the implementation of emission directives. In June 1991, the new European driving cycle was introduced and a single set of limit values for all passenger car categories was adopted. By December 1992, the European Commission is also due to propose new emission limits for 1996.

As far as trucks are concerned, more stringent standards were adopted in 1991 which will apply two steps in 1992 and 1996. The norms regulate emissions of unburned hydrocarbons, carbon monoxide, nitrogen oxides and particulates and correspond, as far as their severity is concerned, to the current US standards.

The issue of carbon dioxide emissions (which add to global warming) is still under consideration, and different regulatory options to control these emissions are being examined at present. At the moment, there are no specific technological methods to reduce carbon dioxide emissions from cars, other than improving the fuel efficiency of their engines and reducing their weight. Road transport is estimated to account for around 20% of total European emissions.

A further consequence of growing public consciousness of the problems caused by motor vehicles to the environment has been the negative press reports given to the diesel engine. Attention to the effect of diesel engines is founded on their high particulate emission levels. In fact, because of their greater economy, diesel engines do have a positive part to play in the environment debate. The diesel issue is particularly relevant to the truck industry which is completely reliant on this form of fuel.

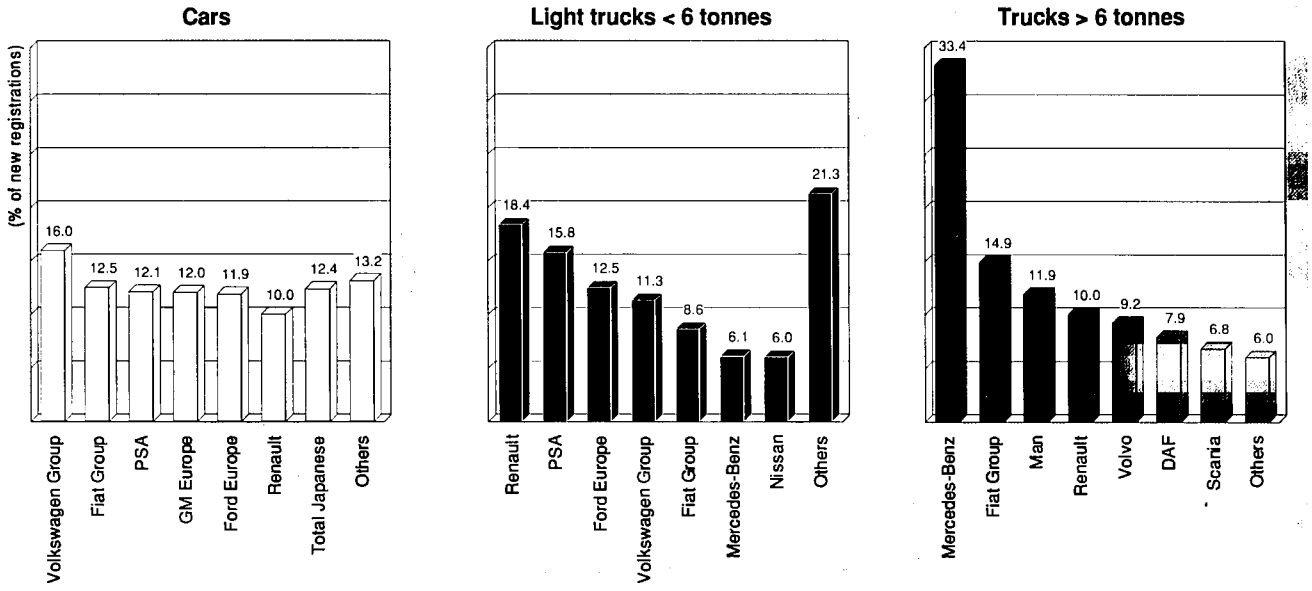
In addition to the measures against air pollution, the noise level of motor vehicles including motorcycles and mopeds, which constitute another major environmental hazard, has been covered by EC regulations since the 1970s.

More recently, waste is increasingly seen as a major environmental nuisance resulting from the use of motor vehicles. Given the large number of cars scrapped each year, manufacturers are seriously working on the problem of their disposal and some of them have already set up recycling plants.

EC TRADE POLICY

Until the end of 1992, various EC countries have imposed their own individual quota systems. Broadly speaking, Japanese imports account for 3% of the French market, 11% of the UK market, and below 1% of the Spanish and 2% of the Italian markets. In 1991, Japanese car sales amounted to approximately 10% of the EC market. In July 1991, the EC and Japan reached an arrangement on the access of Japanese vehicle manufacturers to the EC market. Under this arrangement, the EC market will be fully opened to Japanese producers after the year 1999. During the 1990's, Japanese manufacturers will exercise moderation in exporting vehicles to the EC market. EC and Japanese officials will meet twice a year to monitor

Figure 10: Motor vehicles
Market shares in Western Europe, 1991



Source: Eurostat

the arrangement. Based on existing assumptions, the EC has provided some indicative numbers of Japanese penetration in 1999. Assuming a 15.1 million unit market in 1999 (including cars and light commercial vehicles up to 5 tonnes), Japanese exports to the EC could reach 1.23 million units with transplant production at 1.2 million units, resulting in a global market share of about 16%. In addition, specific targets will be set for the exports of Japanese vehicles to the presently protected markets: France, the UK, Italy, Spain and Portugal.

EASTERN EUROPE

Much of the development of the East European motor industry got under way during the 1960s when most of the current production capacity and product designs and technology were developed and licensed. Much of this development occurred with the assistance of West European companies, notably Fiat in the Soviet Union and Poland, and Renault in Romania. Although there was a marked increase in activity and output during the 1970s, political and economic reasons led to a slowdown in the pace of expansion during the 1980s.

The opening up of Eastern Europe has led to a strong revival of interest from the Western automotive manufacturers, both in terms of a potentially huge markets, and also as a low-cost production base. Eastern Europe and the former Soviet Union constitute a market of 370 million consumers with low levels of per capita car ownership. In addition, production levels have failed to satisfy consumer demand, with 5 to 10 year waiting lists not uncommon. It will, however, take some time before Eastern demand translates into additional sales for Western producers. So far, Eastern demand for Western cars has been constrained by the poor shape of local economies, by current account imbalances and high import tariffs aimed at protecting local industries. Second-hand cars have constituted most of the recent imports from the West.

Many major West European manufacturers have already entered into agreements with Eastern Bloc producers, in anticipation of future rewards. Opel, Volkswagen, and Mercedes-Benz have all set up production units in former East Germany. In addition, Volkswagen has also acquired a large stake (to become a majority stake by 1995) in Skoda (the largest Czech car manufacturer) and has signed a joint venture agreement with BAZ (the second largest Czech auto company). Meanwhile, Mercedes-Benz was establishing links with Liaz and Avia (two Czech truck manufacturers) and General Motors was investing in Hungary and Poland for the assembly of cars and the production of engines. Fiat has acquired a 30% stake into VAZ (a Russian auto company). The Italian group has also acquired a majority stake into FSM (a Polish auto company) and is negotiating with Tatra (a Czech car manufacturer).

The major impact on production is not likely to be realised until the beginning of 1994. By 1995, total production in Eastern Europe (excluding the former Soviet Union) is forecast to be slightly more than 960 000 units. In comparison, production for 1990 was 800 500 units and in 1991 was estimated to have dropped to 636 000 units.

OUTLOOK

The European car industry has experienced rather difficult conditions during the past two years which is not expected to change in the near future. Following a 1% fall in 1990, car sales increased by 3% in 1991, a result entirely accounted for by the short-term explosive demand in former East Germany. East German sales excluded, the EC car market would have dropped by 3% that year. Several volume market such as France, the United Kingdom or Spain will pick up again in the near future. Nevertheless, this increase will be more than compensated for by a drop in German demand. Overall EC registrations are likely to fall by about 1% in 1992 before picking up again in 1993. A strong rebound of the market will however not take place before 1994, when German sales head up again and the EC market crosses the 13 million unit barrier.

During the 1990s, European companies will continue to face a series of important challenges ranging from Japanese competition to environmental pressures as well as to distribution as a result of potential modifications in the EC legislation concerning exclusive distribution practices. The restructuring of the industry will continue implying, most certainly, a further reduction in employment levels.

Table 8: Motor vehicles
Annual growth rates in number of vehicles

	1992	1993	1992-96

Commercial vehicles:			
New registrations	0.7	3.1	3.1
Production	1.7	4.1	4.3

Source: DRI Europe

The van and light truck market also suffered from lower sales in 1990 and 1991. The market will resume as of 1992 and is set for steady progress during the coming years. In particular, sales will benefit from increasing demand for new image-conscious products such as off-road vehicles, minivans and pick-ups. Most of the major EC manufacturers have now embarked on plans to produce one or more of this type of product, and although volumes are not initially projected to be very high, the outlook for growth is promising.

With regard to the heavy truck market, the sharp surge in demand in the late 1980s was partly a result of investments made by the road transport industry in anticipation of the Single Market. Markets such as Belgium and the Netherlands, which are major players in the haulage industry, have enjoyed exceptionally strong growth. There have been numerous new entrants to the business, causing competition to intensify and margins to tighten. This buoyant period was followed by a sharp contraction in 1990 and 1991 when the market shrunk by nearly 9%. The outlook, however, is less upbeat than for light trucks. Sales will continue to drop in 1992 and stagnate in 1993 and 1994 before increasing slightly in 1995.

Motor vehicle parts and accessories

NACE 353

The motor vehicle parts and accessories industry employs about the same number of people (approximately 1 million) as the motor vehicle industry it supplies. Unlike the motor vehicle industry, the parts and accessories sector presently includes a sizeable number of small firms; however, greater industry concentration is expected as trends in vehicle production techniques increasingly demand a tighter integration with the parts and accessories industry.
The business climate for parts and accessories is strongly tied to the cyclical performance of the motor vehicle sector. Hence, the foremost competitive threat to the EC motor vehicle industry, Japan, also poses similar challenges to the parts and accessories sector.

INDUSTRY PROFILE

Description of the sector

The parts and accessories market is traditionally broken down into two main segments. The first is the market for original equipment manufacturers (OEM), that is the parts that car manufacturers buy from specialised producers for assembly into their vehicles. The second is the replacement market which comprises parts destined for repairs and automotive accessories.

The precise coverage of the component industry in terms of products is difficult to assess. Data which corresponds to NACE 353 (parts and accessories for motor vehicles) is too narrow in its coverage as its excludes for instance most of the electrical and electronic components that are so important in vehicle manufacturing today. Furthermore, existing statistics which are based on the production of companies of more than 20 employees understate the value of production of the fragmented parts and accessories industry.

A study carried out for DGIII, also sourced in this monograph, covers a wider range of products than the strict NACE definition.

Main indicators

With a turnover estimated at almost 100 billion ECU, the EC parts industry represents about half of the size of the auto industry. In terms of employment, however, the parts and auto industries are much closer in size with each exceeding 1 million workers.

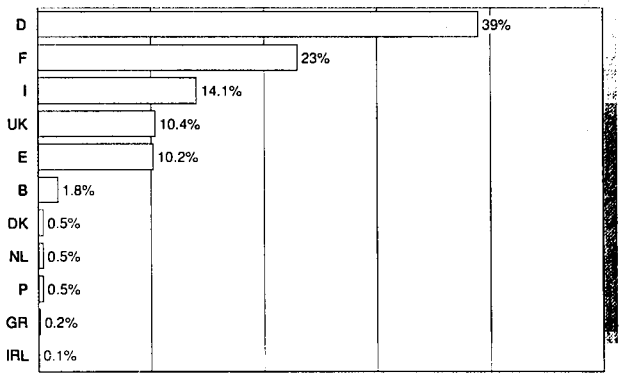
Within the parts and accessories sector, independent manufacturers account for nearly 90% of both production and employment, the remaining 10% stemming from subsidiaries of vehicle manufacturers.

Turning to the breakdown of production by Member States, leading vehicle producing countries are also leading parts producers. Germany accounts for nearly 40% of EC turnover. It is followed by France, Italy, the UK and Spain. Similar rankings can be observed in the auto and parts industries. This is explained by a frequent geographical clustering of parts manufacturers in proximity to vehicle production sites.

Recent trends

Over the 1980s, the industry has been expanding somewhat faster than its main industrial end-market, the auto industry. It has grown consistently between 1982 and 1990 before dipping in 1991, following a downturn in the car market.

Figure 1: Motor vehicle parts and accessories Distribution of production by Member State, 1991



Source: PRS, BCG, Commission Services

Productivity improvements have been marginally faster than improvements for the manufacturing industry on average. They have been achieved thanks to rapidly expanding production rather than lay-offs, and as a result, employment was still higher in 1991 than in 1982. The industry has not recently suffered from the type of painful restructuring endured by car manufacturers during the first half of the 1980s.

International comparison

Once relatively sheltered from foreign competitors, EC component suppliers are now facing increased domestic, European and worldwide competition. This trend, which is tracing a new international division of component production, is fostered by several factors:

- The creation of the Single Market is forcing European suppliers to intensify cross-penetration of each others' markets.
- The increased internationalisation of EC car producers implies geographically enlarged supply bases, with a tougher competition prompting a constant search for lower cost purchasing alternatives.

Source: Eurostat

- Japanese investments for car assembly plants within the EC are also drawing the attention of Japanese component makers on the European market.

The latter development in particular has been seen as a major threat to the EC component industry. Use of just-in-time and close links with suppliers (typical of the Japanese car industry) require the proximity of component plants and auto assembly plants. The risk exists that Japanese component makers will follow the Japanese car manufacturers move to the EC, first supplying the Japanese transplants and later competing with EC component makers as their potential transplant supply base remains too limited to allow profitable operations. This is what occurred in the US where Japanese component makers established more than 300 plants during the 1980s. The European situation is, however, different for several reasons:

- The European independent component industry is larger than the American one (which suffers from the high degree of vertical integration with vehicle manufacturers).

- The European industry is considered to be more competitive than its American counterpart.

There is presently little Japanese parts investment in Europe (about 50 companies) and the pace of future Japanese expansion within the EC will be slower than that which took place in the US during the past decade. The Japanese component industry, however, has several serious competitive advantages over its European counterpart. Although smaller than the EC industry (0.5 million people compared with 1 million people), the Japanese component industry is much less fragmented and already benefits from the tiered structural shape which the EC industry is presently constructing. Aside from the 40000 sub-contractors who form the second and third tiers of the pyramidal structure of the Japanese industry, there are 310 first tier component suppliers, compared to 3200 companies in Europe. The average size of enterprises is 900 people compared with the European average of 270. 45% of the Japanese firms employ more than 500 people, compared with only 10% in Europe.

Japanese companies have close organisational and financial links with vehicle manufacturers, and most of them are attached to groups around a major manufacturer. For instance, Nippondenso (the largest Japanese component producer) is partly owned by Toyota. Many component producers are owned by more than one vehicle producer. This system has resulted in an industry which is more specialised and concentrated than the European industry.

According to a study undertaken for the EC Commission, the EC industry remains competitive with Japan in terms of technology, but suffers from several disadvantages such as:

- lower labour productivity

- lower product quality

- lower stock turns

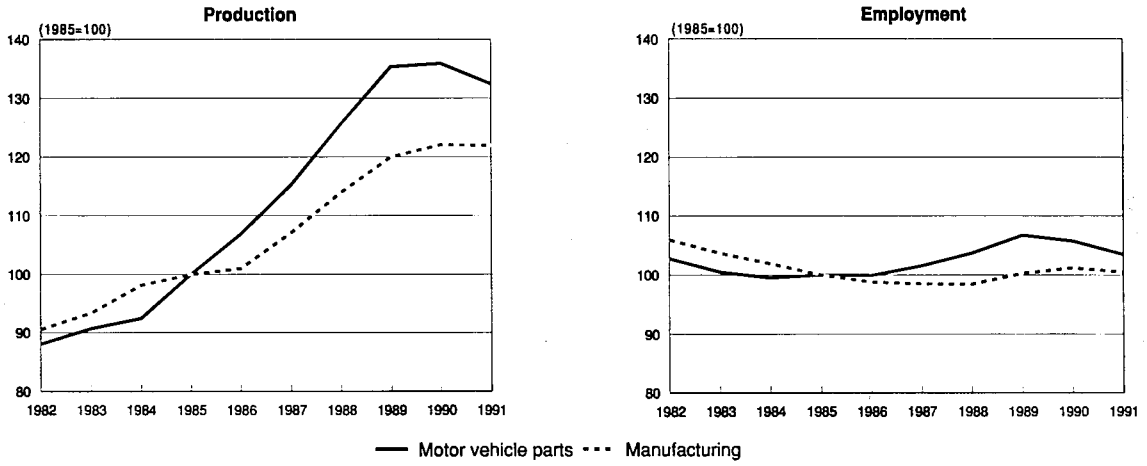
- slower design and development cycles.

Several European component producers, however, have interests in the Japanese industry, such as Bosch (which has a minority stake in Nippondenso).

Foreign trade

The internationalisation of the industry has been a determining factor in the substantial increase in foreign trade experienced since 1980. The expansion of intra-EC trade has been particularly rapid in recent years as intra-EC trade reached the 14 billion ECU level in 1991, a threefold increase compared to 1980. The industry remains essentially intra-EC oriented and intra-EC imports are more than 4.4 times higher than extra-EC imports, a ratio which is usually in the 2 to 2.5 region for most of the engineering and transport industries. Given the difficult nature of defining the industry, a word of caution regarding trade figures is in order. Statistics on trade are not necessarily related to the independent component industry's products but frequently include the movements of the OEM's own in-house products to and from assembly plants across national borders, thus causing significant distortions in the data.

Figure 2: Motor vehicle parts and accessories
Production and employment indices compared to EC manufacturing



1992 are DRI Europe estimates
Source: Eurostat

The industry is a traditional balance of payment earner. After a peak in 1985 when it reached 6.5 billion ECU, the EC trade surplus decreased to almost 2.5 billion ECU in 1991. The second half of the 1980s were marked by a rapid increase in extra-EC imports and a relative stagnation in extra-EC exports. This situation is partly attributable to a change in the classification of trade statistics and, more importantly, to the rapid growth of car demand experienced in Europe between 1986 and 1990. During that period, European parts producers were predominantly busy trying to meet increased demand from the EC car manufacturers. As a result, their export effort remained limited, while imports were boosted by the buoyancy of the EC car market. Nevertheless, the trend was not really reversed in 1990 and 1991 when the European vehicle demand was somewhat weaker. The dwindling European trade surplus certainly signals some of the structural problems presently encountered by the European industry.

Extra-EC exports are relatively diversified in terms of destinations with the EFTA countries and North America respectively accounting for about 27% and 15% of total shipments as developing countries also remain an important end market with a share of more than 35%. In terms of extra-EC imports, flows are more concentrated with 50% of total non-EC supply originating from the EFTA countries, Sweden in particular. With a share of 20%, Japan is the second largest supplier to the EC. The share of trade with North America has dwindled considerably in recent years both in terms of imports and exports. With regard to the EC trade surplus, Germany continues to be the major contributor.

MARKET FORCES

Demand

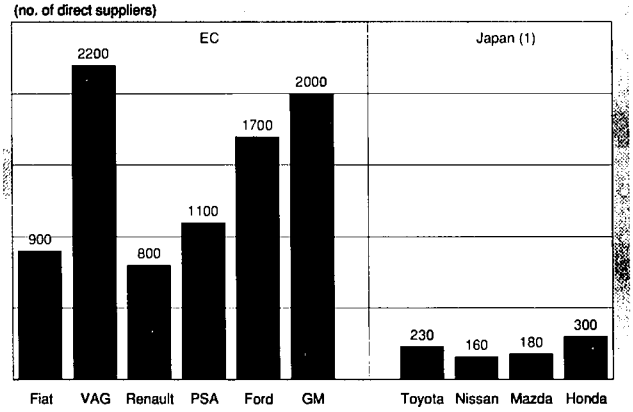
Demand for OEM is, by definition, linked to the level of activity in the automotive production. Some segments of OEM, however, benefit from a faster growth than the auto market in general. This situation corresponds to components whose rate of penetration in vehicles is still on the rise. Such is the case, for instance, of equipment which a few years ago was optional (primarily in the upper car segment) and are now increasingly fitted as standard equipment on most models. Some examples include: electronic fuel injection, anti-lock brakes and air conditioning systems. In addition, original equipment manufacturers have largely benefited from a trend towards increasing outsourcing by vehicle makers.

On the other hand, demand for replacement parts depends on the usage of automobiles and other motor vehicles, as opposed to new sales. Demand is likely to be more stable in this market than in the original equipment market. The replacement parts market differs greatly from country to country. Market features in the various EC countries depend largely on the annual mileage per vehicle, the age of the car parc and the existence of specific legislation with regard to obligatory inspection of vehicles when they reach a certain age.

Supply and competition

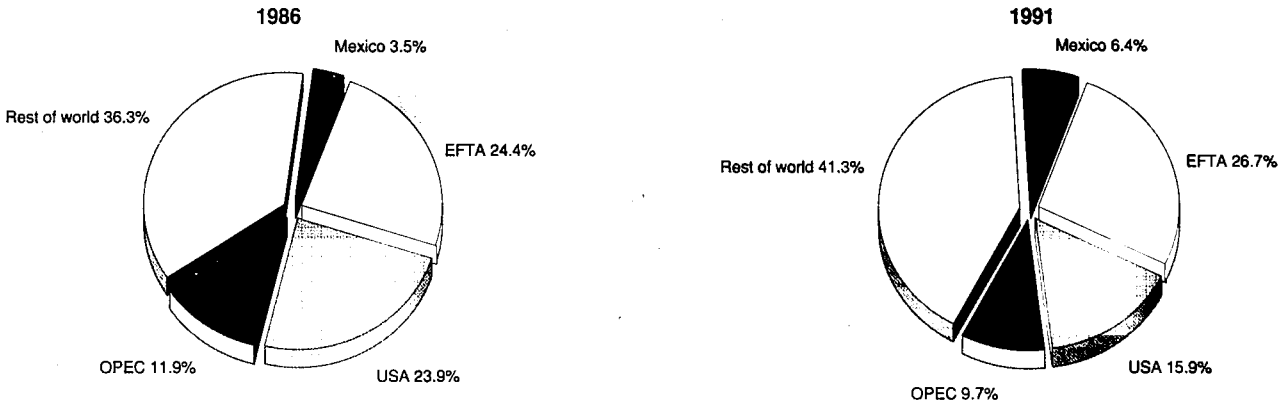
The supply of original equipment is undergoing fundamental structural change. Increasing internationalisation of vehicle manufacturers calls for the emergence of large international (sometimes worldwide) component manufacturers. In addition, the pattern of relationships between manufacturers and suppliers is being substantially modified and a rising share of the value added generated in the auto industry is transferred from vehicle to component manufacturers. To some extent, the balance of power is now shifting from the former to the latter.

Figure 3: Motor vehicle parts and accessories
Direct suppliers to original equipment manufacturers, EC and Japan



(1) Kyoryokukai members, except Honda
Source: PRS, BCG

Figure 4: Motor vehicle parts and accessories
Destination of EC exports



Source: Eurostat

A major reason behind such a change arises from the necessity for car manufacturers to limit investment and resources to essential activities which represent the core of their industry. One method is to increase outsourcing and to pass on the responsibility for product development, manufacturing and quality assurance functions to their suppliers (systems suppliers and/or specialised affiliated companies). Component producers contribute to the competitiveness of the industry, and the two sectors become increasingly interdependent.

Although conceiving, designing and producing in accordance with manufacturers' specifications, the component producer is increasingly technically autonomous. This is typically the case of systems suppliers who possess proprietary technology and product know-how. As a result of these transfers of value added, car manufacturers reduce the number of their suppliers to a smaller number of large producers which will in turn outsource part of their output to smaller companies, the whole supply chain thus posting a tiered structure.

The current pattern with regard to outsourcing practices within the EC automotive industry differs greatly from manufacturer to manufacturer. It is generally accepted, however, that the overall level of outside purchasing carried out by the European car manufacturers (60% to 70% of total component requirements) is more important than in the US industry (40% to 50%) but less than in Japan (around 80%).

Turning to the replacement equipment, it is generally estimated that about 70% of the market supplied by independent parts manufacturers, with the remaining 30% is controlled by the car manufacturers via their distribution and service networks. With regard to the industrial origin of such parts, however, car manufacturers comprise only a 10% share of the market.

Production process

The nature of the automotive products, together with shorter product life cycles, puts increased emphasis on the technological content of automotive parts. Increased use of electronics and new materials leads to increased collaboration with other leading high-tech industries and a sizeable investment in R&D organisations and equipment at all levels of the pyramidal structure of the sector. Once almost exclusively oriented towards applied engineering, the existing R&D resources of the sector are now taking greater initiative in terms of new technologies offering improved performance, fuel economy, emission control, safety and comfort. Black-box engineering is becoming an increasingly standard practice within the industry requiring enlarged R&D functions utilising up-to-date CAD (Computer-aided design) equipment and involve-

ment at an early stage of the development process of new vehicles.

The competitive pressure on costs, prices, quality and delivery standards has led the industry to restructure in a parallel manner to the car manufacturers. Automotive parts suppliers compete on the basis of price as well as delivery and quality. The excellence of the Japanese industry in such fields (considered as a major reason for their competitive edge) has generated a trend towards adapting Japanese-type production techniques in order to achieve better control of all factors having a significant bearing on production costs. Just-in-time, zero-defect, CAM (Computer-aided manufacturing), automation, and faster communication systems, are some of the features which have allowed substantial productivity gains while improving flexibility and allowing self quality assurance schemes to be put in place. This process (requiring sizeable investment and a recourse to skilled manpower) is far from being complete, especially among small to medium-sized producers.

INDUSTRY STRUCTURE

Companies

The industry is basically composed of three types of producers:

- the large diversified producer, whose output consists of many products in addition to auto parts (Bosch and Siemens in Germany)
- the larger producers specialising in auto parts (Valeo in France, Magneti-Marelli in Italy)
- hundreds of SMEs producing auto parts on a smaller scale.

The trend towards more component outsourcing by car manufacturers combined with fundamental changes in the nature of the industry are having a dramatic result on the overall numbers of independent operators present in the industry. Vehicle manufacturers are cutting back on the number of suppliers and committing larger shares of their purchasing requirements to preferred systems suppliers. These systems suppliers outsource part of their work to second or third tier suppliers. Overall, during the past five years, it is estimated that the number of independent companies (previously direct suppliers to the EC car manufacturers) has been reduced by approximately 50%. A large part of this reduction has been achieved via mergers, takeovers and consolidations among previous competitors or companies having industrial synergies, such as Valeo/Neiman and Magneti-Marelli/Solex/Jaeger/Weber.

In spite of the increased presence of large international companies, the original equipment sector continues to be very fragmented. The average size for firms is about 270 people, but 64% of these enterprises employ less than 100 persons. Only 4% of the companies account for 50% of total employment (firms with more than 1 000 employees). This is essentially due to the nationally based nature of parts procurement. Although intra-EC trade has grown to extremely high levels during the past decade, most vehicle manufacturers continue to source largely from their domestic suppliers. For instance, Daimler-Benz procures approximately 90% of its needs from Germany, Renault, about 70% from France, and Fiat, about 85% from Italy.

The independent German industry dominates the European market with about 39% of the total European production (estimated at 79 billion ECU in 1988). This strength comes from the sheer size of the German motor vehicle industry, the importance of the upper market segment, and from strict legislation on car maintenance. The large German firms have played a major role in developing new products as illustrated by Bosch (the world's largest unaffiliated auto parts producer) which is a pioneer in the fields of fuel injection and anti-locking brake systems. Bosch alone is estimated to account for nearly a quarter of German production. The leader's vitality aided many smaller firms and contributed (together with other large firms such as ZF, Fichtel and Sachs, Teves, and VDO) to the unchallenged leadership of Germany within the European ASI.

The French industry is the second largest in Europe, with about 23% of the European total. Its structure is still char-

acterised by a large number of nationally oriented small to medium-sized producers. Major restructuring has taken place in recent years, led by the three international scale emerging groups: Valeo, Epeda-B-Faure and ECIA (PSA group).

The Italian industry (which accounts for about 14% of the European production) is dominated by the Fiat group. The leading producer is Magneti-Marelli (a subsidiary of Fiat) which now has an increased presence in all major European markets. Widely dispersed in the early 1970s, the sector is being tightly restructured under the influence of Fiat.

The UK components industry (10% of the total sector) has been badly hit by the decline of British vehicle production and its excessive dependence on domestic manufacturers. The existence of an important replacement market, however, together with the increased rate of Japanese investment in automotive production activities in the UK, has allowed the large British component producers (Lucas-Girling, T&N and GKN) to restructure and regain vitality in a market with considerable potential.

The Spanish industry has emerged since the late 1970s as another important producer of automotive components, having now reached a size comparable with the UK. Originally developed to comply with local content requirements, the industry has grown considerably since the early 1980s, thanks to the increased importance of Spain as a car manufacturing country. However, most of the components producers present in Spain are subsidiaries of foreign companies.

Strategies

As the Japanese car industry has shown, the necessity for the car manufacturer to rely increasingly on a smaller supply base implies fundamental changes in the structure of the sector. This means an increase in the sharing of high-value added products, faster growing R&D expenditure, and a need for organisations to adapt to new constraints (excellence in quality, delivery and price, not to mention production flexibility). Finally, there is a need to share productivity gains on a continuous basis with car manufacturers and to finance a growing share of productive investments (tooling and specific equipment) necessary for tailor-made products.

In return, car manufacturers are offering longer term purchasing commitments and closer cooperation, both of which contribute to improved stability in mutual relationships.

As a result of this process, the component industry will increasingly be reshaped into a pyramidal structure. First tier suppliers with a worldwide presence, proprietary technology and scale economies will design and supply full systems rather than single components. They will outsource part of their work from smaller second or third tier suppliers. The observed past trend toward increased concentration will continue during the decade but a further radical reduction in the number of independent producers is unlikely since many will survive as second or third tier suppliers.

OUTLOOK

Production and consumption of original equipment will grow at about 4% to 5% per year in real terms over the next 5 years, outpacing vehicle production (less than 3%). The outlook for replacement components is less up-beat with a possible decline of the market in real terms over the next years.

With regard to the original equipment market, most of the growth will result from:

- vehicles increasingly fitted with such standard equipment as automotive electronics, anti-pollution devices and more efficient safety restraint systems;
- the general "up-market" move in car demand with customers demanding more equipment, comfort and power;
- the increase in component outsourcing by car manufacturers with high added value.

With regard to the replacement market, it should be remembered that this segment is governed by the number and the state of vehicles on the road, as well as changes in consumer behaviour. These changes can either come about spontaneously, or be spurred by legislation on vehicle testing or compulsory maintenance. The constitution of the Single Market makes it likely that such measures will spread to countries where they have been absent until now. This, combined with the consumer's desire for safer and more comfortable driving, and the expected growth of the total car park in Europe, implies that there will be promising demand growth in the replacement parts market. On the other hand, technological advances should result in more durable parts and slow replacement cycles. Increased opportunities in East European markets will also have a positive influence on demand for automotive components.

The overall outlook for growth in motor vehicle parts and accessories is good, but major adaptation and competitive efforts from the industry are still required.

Mopeds and motorcycles
NACE 363

The decline in EC production of cycles, mopeds and motorcycles in the 1980s stemmed both from shrinking market demand and strong import competition from Japanese products. After much restructuring, it was a leaner and more competitive industry that was able to take advantage of the pick-up in demand in the mid-eighties. Since 1988, EC production of cycles, mopeds and motorcycles has followed a steady upward course.

INDUSTRY PROFILE

Description of the sector

NACE 363 comprises the manufacture and assembly of cycles, mopeds, motorcycles, scooters, and their parts and accessories. In Italy, the manufacture and assembly of cycles, mopeds and motorcycles accounts for about three-quarters of total production, with parts and accessories making up the balance. In France, the share is slightly more than 60% for cycles, mopeds and motorcycles with just under 40% of industry output accounted for by parts and accessories.

The largest component of the industry is the production of mopeds and motorcycles where mopeds are defined as motor driven vehicles of two to three wheels with an engine displacement not exceeding 50cc and a maximum design speed of 50 km/h. Motorcycles are motor driven vehicles with two to three wheels with an engine displacement exceeding that of mopeds.

Main indicators

Production of mopeds and motorcycles stagnated during the first half of the eighties, such that by 1987, EC output had not progressed beyond its level in 1982. In line with the weakness in demand and production growth, employment fell drastically. In the last several years, however, there has been a strong recovery in consumption and production. This increase in demand has benefited imports more than domestic production such that the EC's trade deficit on mopeds and motorcycles has widened considerably since the beginning of the eighties. At close to 49 000 in 1990, employment in the mopeds and motorcycles industry remains at about half its 1980 level.

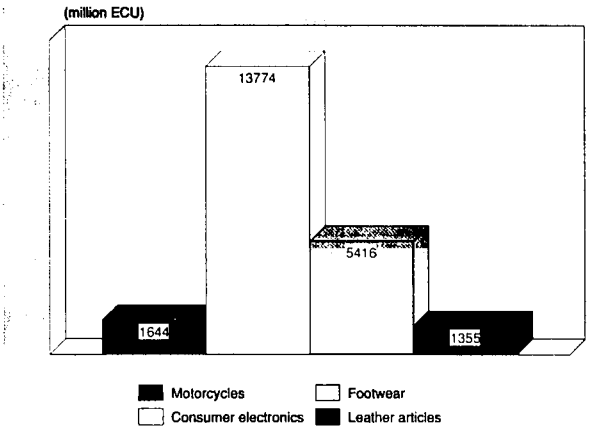
Despite the fact that production volumes for the overall industry as defined by NACE 363 have recovered in the last several years, the actual number of mopeds and motorcycles produced in the EC is still below the levels achieved in 1980.

Italy is the largest producer of mopeds and motorcycles in the EC, twice the size of the next largest producer, Germany. Spain's moped and motorcycle industry, the third largest and the fastest growing in the EC, will soon overtake the number two spot from Germany.

Recent trends

Although very weak in the first half of the 1980s, consumption improved as of 1985, expanding hesitantly at first, before growing by upwards of 10% per year (in real terms) in both 1989 and 1990. Production did not recover as quickly from the downturn in economic activity in the early eighties. After six successive years of declining volumes, it was not until 1989 that production expanded once again. Much of this improvement in output growth was due to the pick-up in home demand as export sales continued to be weak. The stronger

Figure 1: Mopeds and motorcycles
Value added in comparison with other industries, 1991



Source: Eurostat

home demand instead benefited imports. Employment, which by 1988 was but half of the 92 975 employed in the industry in 1980, has remained stable in recent years.

International comparison

World production of mopeds and motorcycles is dominated by the East Asian NIC's, which held 41% of total world production in 1988, followed by Japan, with 26.2%, Eastern Europe, with 16%, and the EC, with 12.9%.

In fact, the strength of Japan and the EC is understated by these figures. First, a large part of East Asian production is carried out under European and Japanese licenses. Second, while production in Eastern Europe may edge out the EC in terms of number of units produced, the technology of these vehicles is looked upon as outdated. The popularity of mopeds and motorcycles in Eastern Europe has been supported by fact that the alternative, passenger cars, has been prohibitively expensive. Taking these factors into consideration, Japan and the EC are raised to the top of the world ranking.

Foreign trade

In terms of units, about one quarter of all mopeds and motorcycles produced in the EC are sold outside of the EC, with the export/production ratio slightly higher for mopeds

Source: Eurostat

than for motorcycles. Italy, as the largest producer, is also responsible for more than two-thirds of extra-EC exports, a share which has increased slightly throughout the 1980s.

Although the EC recorded a trade deficit in 1991, Germany is by the far the largest importer of mopeds and motorcycles in value terms and the largest contributor to the trade deficit for mopeds and motorcycles.

The largest export market for EC producers of cycles, mopeds and motorcycles is the EFTA countries, which account for 40% of extra-EC exports, a share which is slightly up from 1986. The North American market, although the second most important, has declined in importance since 1986, both as a share of total extra-EC exports and in absolute terms. Japan, the OPEC countries, and the EC overseas departments (départments outre-mers) are the fastest growing export markets.

While extra-EC exports were up by only 10% in 1991 over 1986, imports more than tripled in the same five years. Although Japan is the largest supplier of mopeds, motorcycles and parts and accessories, its share of total extra-EC imports has in fact declined since 1986 while imports from the ASEAN countries (Thailand, Singapore, Malaysia, and the Philippines) more than doubled each year between 1986 and 1991.

MARKET FORCES

Demand

Consumers are the single most important component of demand for the mopeds and motorcycle industry. Thus overall economic activity, personal disposable income and trends in demographics are the overriding factors in the demand for cycles, mopeds and motorcycles.

Production weakened in the early to mid-1980s amid faltering demand and the weak economic climate in Europe. Changing demographics reinforced this trend as demand for mopeds and motorcycles by teenagers and young adults in the 1970s gave way to demand for passenger cars in the 1980s. The increased volume of traffic in the cities, and laws aimed at increasing safety requirements for drivers of motorcycles and mopeds also served to reduce the attractiveness of buying a moped or motorcycle. The falling levels of production led to lower direct employment as a result of plant closures and

Figure 4: Mopeds and motorcycles
International comparison of production at current prices

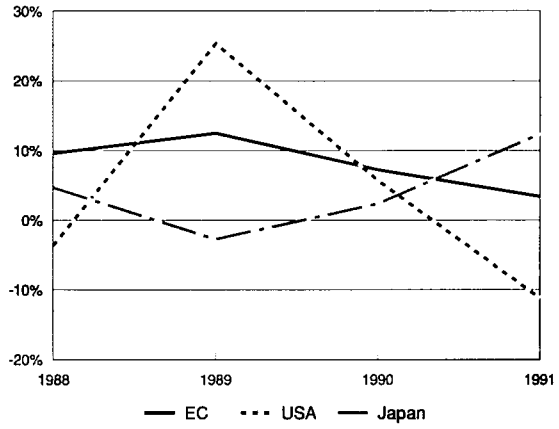
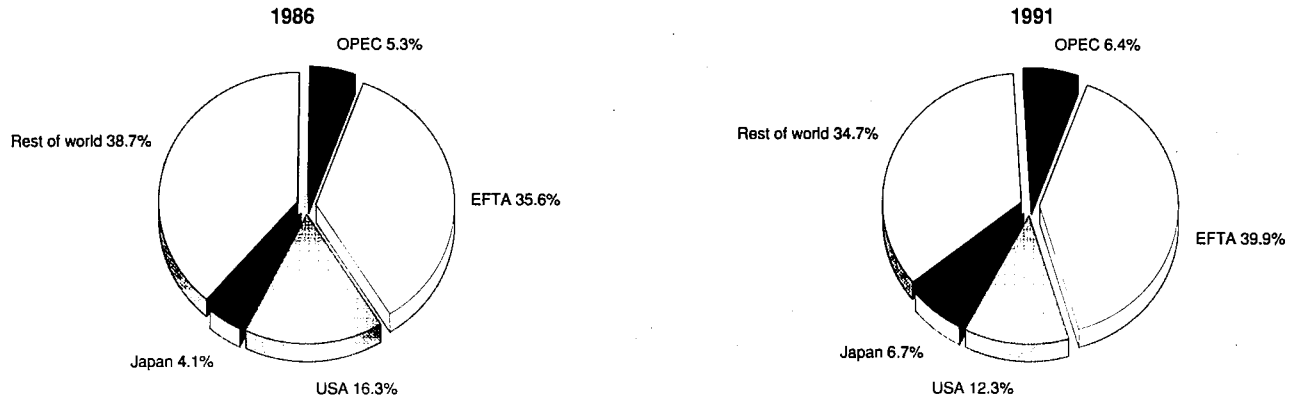
Figure 5: Mopeds and motorcycles
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Figure 6: Mopeds and motorcycles
Destination of EC exports



Source: Eurostat

restructuring activity, especially in the countries of northern Europe.

In the late 1980s, a stronger economic climate led to a re-surgence in demand for both moped and motorcycles, although production and sales (measured in terms of the number of mopeds and motorcycles) have yet to reach the popularity that they held at the beginning of the decade.

Domestic (i.e. EC) demand is the most important outlet for sales, as less than one-third of production is exported. In fact, since the early 1980s, exports have become a less important component of demand for the EC.

Supply and competition

Within the EC, Italy has maintained (if not consolidated) its dominance as the most important producer of mopeds and motorcycles over the eighties. About half of Italy's production of mopeds and motorcycles (excluding parts and accessories) is destined for export markets beyond the EC. France has a slightly more outward looking orientation with one-quarter of its production of mopeds and motorcycles being exported. Output sales of cycles, mopeds, motorcycles and parts and accessories is destined for foreign markets. Whereas extra-EC exports of motorcycles has declined on average across the EC over the eighties, foreign sales of mopeds have become a more important component of demand for Italy, the dominant producer and exporter of mopeds in the EC.

In terms of international competitors, Japan has the largest share of the EC market. Japanese penetration of the EC market has risen despite import restrictions on Japanese goods in Italy, France, Spain and Portugal. The EC's trade deficit with Japan has more than doubled between 1986 and 1991.

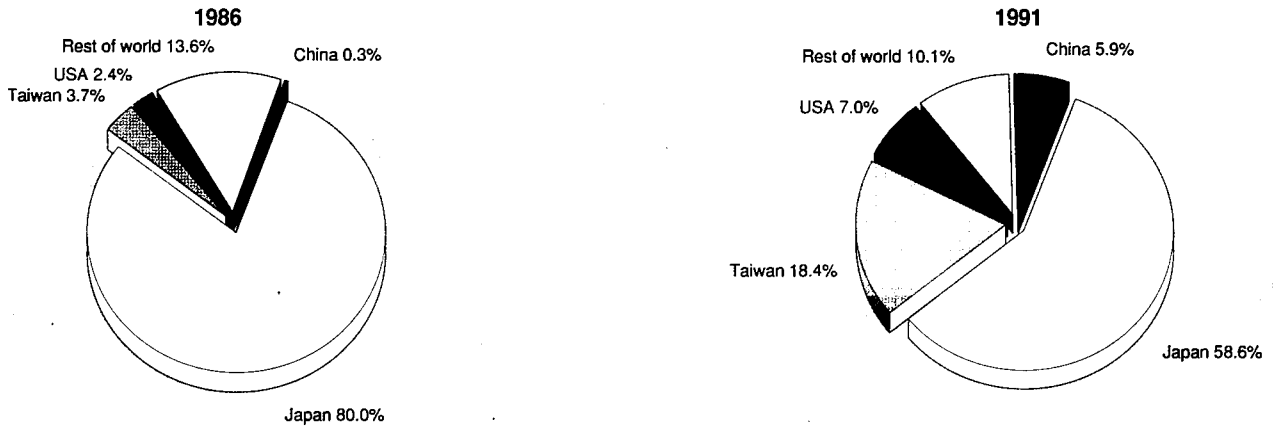
The rise in the share of imports in comes not only from Japan. EC manufacturers have licensed companies in South East Asia, India, the People's Republic of China, Taiwan and the Middle East to produce or assemble European models. This has had the effect of increasing imports to the EC from these countries, and reducing extra-EC exports from the EC.

Production process

Falling levels of production as the eighties progressed have led to lower employment levels in the industry as a result of plant closures and restructuring activity, mostly in the northern European countries. The associated improvements in productivity, however, have increased the industry's competitiveness.

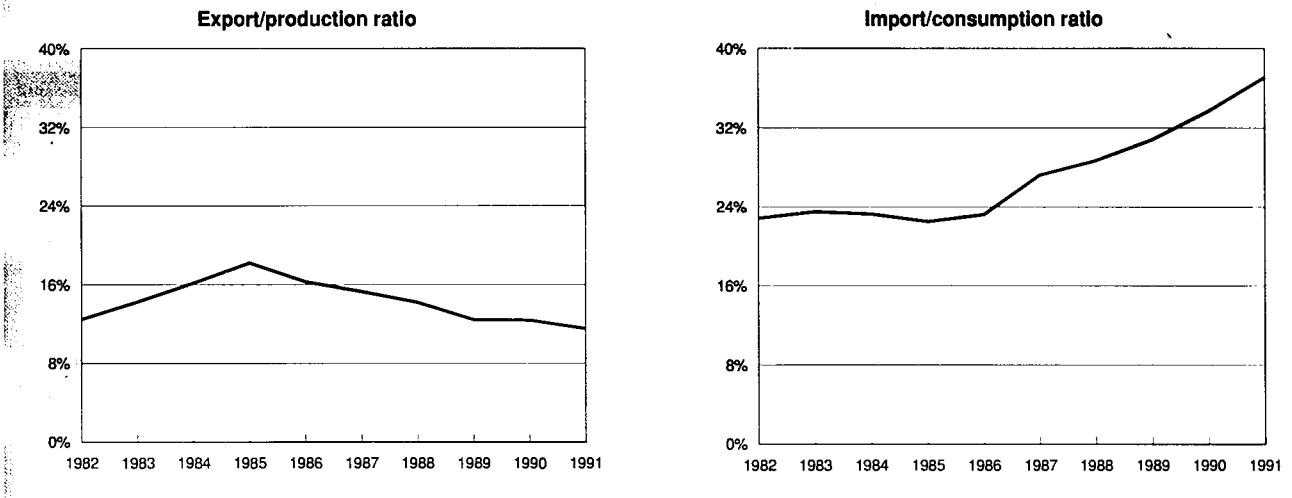
Part of the impetus to improve competitiveness has come from the Single Market as all major EC manufacturers are

Figure 7: Mopeds and motorcycles
Origin of EC imports



Source: Eurostat

Figure 8: Mopeds and motorcycles
Trade intensities



Source: Eurostat

actively pursuing strategies to help them capitalise upon opportunities offered by the new competitive environment resulting from the Single Market. The common standards (licences, legislation, etc.) adopted by the Member States will lead to further rationalisation and automation of the EC manufacturing process. Standards presently differ widely across the EC as illustrated by the number of gears on mopeds, motorcycles of 50cc and less. In Belgium, France and Portugal, automotive gears are required; in Denmark, the maximum number of gears is 2 and in Spain, 4. The opportunities arising from the Single Market will also depend on a common transport policy and the result of trade talks with Japan, especially on the opening of its market and easier access to its distribution network.

The industry is developing new technology both in terms of the design of the vehicle and its construction. The use of CAD/CAM has introduced the use of robotics, laser cutting machines, improved painting systems and more sophisticated quality control systems.

Labour productivity varies, depending on the type of model that is produced by each company. Thus labour productivity ranges from 18 units per employee per year at BMW in 1989, to 102 at Honda, and 122 at Moto Vespa. On average, labour productivity averages around 100 units per employee per year for the biggest companies.

INDUSTRY STRUCTURE

Companies

Fifty-one manufacturers of mopeds and motorcycles in the EC account for about 85% of total EC production, with the remainder being accounted for by Japanese producers. Of the EC producers, more than half are located in Italy. Spain and Portugal are the next most important countries in terms of number of manufacturers, with seven and six respectively.

The moped and motorcycle industry (excluding parts and accessories) is fairly concentrated with the ten largest producers accounting for about 68% of EC production. The size of the enterprises is larger than average in France, Spain, Italy and the Benelux.

In terms of output, Italy again dominates, accounting for 42% of EC moped production, and 78% of EC motorcycle production. Spanish manufacturers hold 20% of EC moped and motorcycle production (excluding parts and accessories), and France, 18%. Japanese manufacturers control 15% of EC mopeds and motorcycle production through licensing agreements and financial holdings in local plants.

The number of domestically owned manufacturers in the EC has remained fairly stable over the last several years. The number of Japanese manufacturers have increased their financial holdings of existing European companies, gradually assuming control.

Based on sales, the Italian Piaggio Group is the largest supplier of mopeds and motorcycles on the EC market followed by Peugeot MTC (France), Moto Vespa (Spain) and Derbi (Spain). Piaggio is ranked third at the world level, behind Honda and Yamaha of Japan.

The Piaggio Group includes Piaggio, Gilera, Puch (Austria) and Moto Vespa (the largest producer in Spain). Other important Italian manufacturers are the Cagiva Group (Cagiva, Ducati, Husqvarna and Moto Morini), Aprilia and the Moto Guzzi-Benelli Group, plus a large number of smaller producers.

France's largest producer, Peugeot MTC, is primarily engaged in the manufacture of mopeds and scooters (50cc-80cc). Some Peugeot scooters and 50cc engines are produced under licence by Honda which has a 25% stake in Honda. The second largest French manufacturer, MBK Industrie, a company which is under full control by Yamaha. MBK assembles Yamaha scooters and light motorcycles and manufactures mopeds under Motobécane design.

In Spain, Moto Vespa and Derbi are the main manufacturers accounting for 59% of Spain's production of mopeds and motorcycles. The assembly operations of Honda, Yamaha and Suzuki account for one-third of local production in Spain. Germany's largest producer is BMW, which is focused on the manufacture of motorcycles with large engines. In Portugal, SIS Vehiculos Motorizados LTDA is the largest manufacturer, producing moped equipped with engines either from Fichtel & Sachs (Germany) or Franco Morini (Italy). SIS also assembles Yamaha trail bikes. The second largest manufacturer in Portugal is Famel.

Honda Belgium is the largest producer in Belgium. The company uses parts with a European origin rate of 75%. In the Netherlands, the most important manufacturer, SPARTA BV, produces light mofas. The assembly of mopeds and mofas is carried out by Tomos.

The three largest Japanese producers in the EC are Yamaha, Suzuki and Honda. These companies are targeting the market for motorcycles with engines exceeding 251cc, of which they hold an 82% share of the EC market.

Strategies

Since the early eighties, many European manufacturers have carried out major investment projects to improve their competitiveness, yielding advances in the area of moped, scooter and low capacity motorcycle production. To capitalise on the improved demand outlook at the end of the eighties, companies were undertaking further investment to improve production facilities and devoting resources to developing new models. Investment in R&D to develop new, more advanced and cleaner models is becoming increasingly important in the face of heightened competition. According to a sample of nine moped and sixteen motorcycle manufacturers, R&D spending was equivalent to 3.4% of turnover in 1989, while investment in new capacity reached almost 5% of turnover. BMW spent 8.1% of turnover on R&D in 1989.

In response to the poor economic situation of the early 1980s, a number of companies began to engage in merger and acquisition activity to buy market share and to take advantage of economies of scale in production. For example, the Italian Piaggio acquired the Austrian company Puch, and Cagiva-Ducati merged with Moto Morini and Husqvarna.

In general, however, merger and acquisition activity has been dominated by Japanese companies interested in acquiring a base in Europe. In Spain, for example, Suzuki bought Avello-Puch of Spain in 1986, while the following year, Yamaha bought Babesto. The investments are beginning to show positive returns. Although the Japanese have acquired about 15% of the enterprises in the EC, they accounted for 36% of sales in 1989. Although the top 12 EC producers of mopeds and motorcycles accounted for 94% of total EC output in 1989, they accounted for only 64% of sales in the EC, reflecting the high degree of import penetration. Most of these Japanese producers, however, do perform assembly in Europe.

REGIONAL DISTRIBUTION

Italy is the largest producer of cycles, mopeds and motorcycles in the EC, accounting for about one-third of EC production and employment in the industry. Germany, Spain and France follow in terms of importance. If only the number of motorcycles produced is considered, Spain and France are both larger producers than Germany.

Again in terms of the production of motorcycles alone, the downturn in the industry in the eighties was borne primarily by the industry's largest producers, that is, Italy, France and Germany. Germany suffered such a dramatic decline in output that by 1986, Spain, Portugal and Belgium were all larger producers. Spain, now the third largest producer of motorcycles in the EC, has more than doubled its share of total output since 1980.

Most of these declines in production correspond to shrinking home demand for motorcycles at home as the industry is not particularly export intensive. The steepest declines in sales were registered in the markets of Germany, the United Kingdom, France and Italy.

The fast growing demand for Spanish production of motorcycles comes primarily from the home market. In 1987, sales in Spain exceeded home production for the first time. Along with Spain, the Netherlands is the only other Member State where sales of motorcycles in the early 1990's clearly exceeds that of 1980.

Although extra-EC exports declined considerably since the mid-eighties, France remains the largest EC exporter of motorcycles, measured both in terms of overall units and as a share of its production. Whereas extra-EC exports of motorcycles account for slightly more than a quarter of total production in France, extra-EC exports account for just over 10% of total production of motorcycles in Italy.

ENVIRONMENT

The main environmental considerations which may have an effect on the cycles, mopeds and motorcycles industry are the problems of urban traffic congestion and exhaust emissions. Should more governments introduce restrictions on traffic circulation in the larger cities (Italy has already introduced restrictions in Rome and Milan, for example), demand for cycles, mopeds and motorcycles may be stimulated.

REGULATIONS

Regulations concerning the harmonisation of standards in the industry would allow manufacturers to standardise the manufacture of parts. This could give rise to gains in scale economies and instigate further rationalisation in the industry.

As cycle, moped and motorcycle use increases, however, safety requirements will follow. There are suggestions that the Italian requirement to wear crash helmets in 1986, the introduction of speed limits, and the German requirement to have a licence for mopeds in have all dampened demand for mopeds and motorcycles. Such changes in the regulations, however, are viewed as temporary and will diminish as consumers become more accustomed to the new regulations.

OUTLOOK

The most difficult period for the EC moped and motorcycle industry appears to be over. The rationalisation of the industry which has taken place over the last several years and

Table 6: Cycles, motorcycles and parts and accessories

Source: DRI Europe

a stronger economic outlook (compared to 1990 and 1991 results in particular) should combine to improve the prospects for the cycles, mopeds and motorcycle industry. Future success, however, will depend on the sector's ability to achieve a higher degree of concentration in order to benefit from economies of scale in production and research and development. The development of vehicles that could use standard parts and further concentration on the "two-wheel parts and accessories" segment of the market would continue to bring costs down.

A harmonisation of the EC legislation will play a positive role in the development of more standard products and encourage further restructuring in the sector.

On the demand side, environmental concerns could lead governments to encourage the use of mopeds and motorcycles in urban centres to reduce traffic congestion. Growing health consciousness and the penetration of "mountain" and "city" bikes that have already been popularised in North America, will improve the prospects for demand for bicycles.

While growth in real consumption may pause in 1992, as demand increases in line with an improvement in consumer spending, the outlook for growth in real consumption will strengthen to above 5% to 1996. Imports will take an ever increasing share of this demand, however, thus the forecast for production is not quite as buoyant while employment is expected to stabilise at close to its present level. If government initiatives are introduced to encourage the use of two-wheel vehicles are implemented, the production and sales forecast would be revised upwards.

Written by: DRI Europe
The industry is represented at the EC level by: Comité de Liaison de l'Industrie du Motocycles (COLIMO). Address: Boulevard de la Woluwé 46, Bte. 6, B-1200 Brussels; tel: (32 2) 771 0085; fax: (32 2) 762 8171.

Shipbuilding
NACE 361

Contrary to the widely-held belief that Japanese and South Korean shipbuilders are dominant in almost all sectors of the industry, the fact remains that the EC continues as the world leader in the high value added segments of fully cellular container ships and non-cargo vessels.
In sum, however, the EC shipbuilding industry confronts considerable challenges for the near future. Minimal growth in sea-borne trade and a lingering overcapacity in the shipping industry in 1991 worked against the prospect for an immediate upturn in production (at constant prices) or employment. On top of that, the revaluation of the ECU against the US dollar and the yen, and the devaluation of the Korean won have reduced the competitiveness of the EC shipbuilders.
The inclusion of shipyards in former East Germany is prompting debate within the EC with respect to the conformity of subsidy ceilings among Member States.

INDUSTRY PROFILE

Description of the sector

NACE 361 comprises the building and repair of seagoing vessels (NACE 361.1); building and repair of vessels for inland navigation (NACE 361.2); building and repair of boats and yachts (NACE 361.3); painting of ships (NACE 361.4); and ship breaking (NACE 361.5).

Most of the industry is accounted for by the building of seagoing merchant vessels (i.e. NACE 361.1). Given the smaller economic significance of the other subsectors and the limited availability of data, this article refers predominately to trends in the manufacture and repair of seagoing merchant vessels.

Main indicators

In 1991 OECD GNP increased by 1.1%, compared to 2.6% in 1990. Sea-borne trade (measured in tonnes.miles) followed the same pattern with growth of only 1.6% in 1991 after an increase of 4.4% in 1990. Shipbuilding in the EC recorded strong growth in 1990 to exceed 2.7 million compensated gross tonnes (cgt), a 38% increase over 1989, that gave the EC a world production share of just over 23%. However, production declined slightly in 1991 to 2.65 million cgt with a concurrent small drop in world production share to 23%.

The principal product lines, and their corresponding share of EC production (including fishing and non cargo vessels), are as follows: fully container (18.3%); general cargo (18.0%); ferries and passenger ships (7.5%); fishing vessels (8.4%); oil and chemicals carriers (11.1%); and dedicated dry bulk vessels (6.4%).

The production of shipping yards in eastern Germany is concentrated on fishing boats (45%) and cargo ships (35%).

Recent trends

After many years of decline, world ship production began to recover in 1989 and accelerated sharply in 1990. In the EC, production declined steadily from 1983 to 1988. For the first several years, EC production declined more rapidly than world production, so the EC share of total production that was 23.1% in 1980 had fallen to 19.7% in 1986 (former East Germany is included for both years). The EC's share started to improve in 1987 and had reached a comparable 1980 value in both 1990 and 1991.

International freight rate performance varied according to ship-type in 1991, although total employment of the world fleet was very similar to 1990. The Gulf War in early 1991 partially prompted a surge in tanker oil movements and storage. Hence, rates during the first half of 1991 for various tanker sizes, notably VLCC's, Suezmax and Aframax tankers, were the best seen since the early 1970s. However, a significant amount of additional tanker tonnage came onto the market in 1991 approximately 11.5 million deadweight tons (dwt.) was added. This addition of the largest increase in supply since 1977, coupled with high stocks, a reduction in tanker storage, minimal scrapping and a slowing of demand pushed rates down significantly in the second half of 1991. Tanker rates in the first six months of 1992 continued to remain depressed, such that a significant number of tankers were withdrawn from the market (although not fully mothballed) while the number of tankers scrapped witnessed a dramatic rise.

Rates for product tankers followed a similar pattern as that for the crude carriers in 1991, albeit with a slight strengthening of rates at the end of the year. The rates for bulk (and combination) carriers also deteriorated in 1991, but managed to remain more stable than the declines in the tanker rates, despite a fleet increase of 1.7% compared to an increase in demand of 1%.

Developments in other vessel type rates was rather muted. General cargo remained relatively flat, and gas carrier rates declined marginally as the increased supply of new-buildings exceeded demand.

Employment, after falling steadily throughout the eighties appeared to stabilise in 1990, however, the decline continued in 1991 (note that eastern German employment is included for the first time in 1990).

In 1990 the tendency of rising prices for new ships, which started in 1985, has weakened. For certain types of ships, however, in particular the super tankers and gas carriers, prices have continued to be strong. At the beginning of 1991, prices in nominal US dollars rose but stabilised throughout the year for most types of ships. However, in the first half of 1992, tankers prices in European currencies are significantly lower than in 1991.

The weakening tendency for prices of leisure ships, financing difficulties, the widening gap between freight rates obtainable and the price of new ships and the Gulf War have considerably dampened the threat of rising prices in the short term.

Foreign trade

Within the EC, the most important exporting countries by value and cgt in 1991 were Germany, Spain and France in order of rank. All of the EC Member States continued to post a trade surplus with the exception of Greece, which imports more than it exports due to the concentration of shipping companies in that country.

EC exports in new shipbuildings reached 3 038 million ECU in 1991 compared to 2 988 million ECU in 1990.

MARKET FORCES

Demand

In the last several years, demand for EC manufactured vessels has accelerated from the early to mid-1980's decline, which reached a trough in 1986. However, the volume of new orders, which rose by close to 30% in 1989 in terms of cgt, stagnated in 1990 and data for 1991 indicates that new orders fell to 2.17 million cgt (18.2% of the world total) from over 3.1 million cgt in 1990 and 1989.

In 1991, the largest amount of new orders (measured in thousand cgt) among Member States went to Germany (559), followed by Italy (381), France (328), the Netherlands (297) and Denmark (266).

Germany also dominates the EC shipbuilding industry for order books, especially with the addition of the eastern German yards. In 1991, German order books were close to 1.6 million cgt, well ahead of Italy (1.2 million cgt), Denmark (0.9 million cgt), and Spain (0.7 million cgt).

Supply and competition

Contrary to widespread opinion that an increasing proportion of ships are built in developing countries, the figures reveal that three-quarters of world shipbuilding is carried out by industrialised countries. Japan controls the largest share of world production of shipbuilding, with more than 38% of world production in 1991. The EC is in second place with 23%, followed by Korea with 15%. The share of these three regions has in fact increased since 1976, when Japan, the EC, and South Korea accounted for 66% of total world shipbuilding.

The EC dominates the high added value market of fully cellular container ships and non-cargo vessels with increasing competition from South Korea and Japan, both of whom would like to dominate this segment. South Korea and Japan already dominate dry bulk and tanker shipbuilding.

Scrapping

The scrapping of ships at the end of their usable life is decided not only by the age of the ship but by a combination several factors such as the vessel's operating profit margin, changes

in environmental legislation and quality considerations and the existing market psychology (i.e. the expected return on a vessel. Given the aforementioned criteria, it is not surprising that many shipping firms are deciding to scrap their vessels during the recent downturn in the shipping industry. The average age for vessels is presently a few years higher than it was during the last period of intense scrapping activity during the mid-1980s, a further indication that a considerable number of ships were retained during the favourable economic climate in the late 1980s and have served their useful service life. Four countries (India, Pakistan, Bangladesh and China) dominate the vessel scrapping market.

Labour

Employment in the EC shipping industry has experienced a prolonged period of downsizing due to a number of factors. To begin, the worldwide shipbuilding industry experienced an unprecedented period of expansion during the 1970s in which shipping tonnage was doubled within a ten-year period. The sudden influx of new tonnage resulted in an overcapacity of shipping tonnage which the shipping industry has yet to recover from, despite the fact that a number of ships were prematurely scrapped in the mid-1980s (some after less than 10 years of service). A secondary development was the shift in production centres away from Europe and the USA towards new shipyards in Japan and South Korea. For example, South Korea launched only 0.1% of new ships in 1972, by 1988 that share had blossomed to 17.5%.

The reduction in the EC shipbuilding workforce has only recently been augmented by the inclusion of employment figures for the shipbuilding industry in former East Germany. Apart from this statistical increase, employment within the EC continues to decline and in 1991 stood at slightly more than only one-third of a 1975 total of employment for the present Member States.

INDUSTRY STRUCTURE

Strategies

The number of shipbuilding firms in the EC has been reduced by yards either going out of business or by mergers and acquisitions activity, and many of the remaining shipyards have been forced to find niches in the shipbuilding market in order to survive. The EC shipbuilding industry in general seeks to differentiate itself from its main competitors in Asia by specialising in the construction of ships with relatively high value added rather than relatively simpler dry-bulk vessels or oil tankers. Examples of such ships include dedicated refrigerator vessels ("reefers"), gas tankers, liquid pressurised gas (LPG) and liquid natural gas (LNG) carriers.

The major centre for mergers and acquisitions activity has been the privatisation of shipyards in former East Germany by the Treuhandanstalt, the German agency responsible for privatising former East German industries following reunification. Most of the largest acquisitions have been made Germany's largest shipbuilding group, Bremer Vulkan, however, other firms such as Norway's Kvaerner have also acquired facilities in the new Länder.

ENVIRONMENT

Although oil spills are often considered as the greatest environmental threat posed by the shipping industry as a whole, prevention of oil spills is by no means the only major environmental issue confronting the shipbuilding industry. The shipbuilding industry is presently focused on the painting of ships (NACE 361.4) where paint and coating substances and abrasive blasting done to prepare a painting surface are of particular concern.

A number of paint and coating substances have recently been brought under scrutiny. Paint components Red Lead (Pb3O4) and Zinc Chromate (ZnCrO4) are expected to be banned along with previously discontinued substances such as Cadmium and other heavy metals. Meanwhile, other substances used in such as carbonates, silicates, coal tar, organic chloride compounds and polyurethanes are all suspected to cause specific health hazards. Abrasive blasting is another source of concern because of the vast amounts of hazardous dust which results from the preparation of metal or concrete surfaces before painting.

REGULATIONS

The EC shipbuilding industry is presently witnessing a significant restructuring of government subsidisation as Member States converge toward the Single Market. The acquisition of shipyards in former East Germany has stirred controversy within the EC as other shipbuilders fear being undercut by subsidised shipyards in the new Länder. Proposals from EC industry ministers have requested that eastern Germany cut its capacity by 40 percent. In exchange for this capacity reduction, east German shipyards would be subsidised by up to 36% of orders in 1992, far above the EC subsidy ceiling of 9%. Although such regulations are designed to put the

former East German shipbuilding industry on a par with yards in western Germany, a downturn in demand combined with a weak dollar have already raised competition among shipbuilders in western Germany. In addition, yards in eastern Germany must now compete for similar contracts as their previous source of demand, the former Soviet Union has drastically cut orders.

In regard to environmental regulations, the EC and the USA are leading the industry with the preparation of legislation designed to reduce solvent emissions resulting from particular paint substances. Such legislation is expected to be similar to the German TA Luft legislation. Member States such as Denmark and the Netherlands have already initiated programmes designed to reduce solvent emissions.

OUTLOOK

For the immediate future, the outlook for EC shipbuilding industry does not appear to offer any change from the persistent contraction of production and employment. The existing overcapacity in the shipping industry combined with a lingering global recession prevents the likelihood of any immediate boom in demand for new shipbuilding.

On a more encouraging note, in the long-term over half of the current fleet will be over 25 years old by the year 2000 and one-third may need to be replaced during the interim period.

From a long-term perspective, the EC shipbuilding industry will be keenly focused on the development of the next gen-

eration of shipping vessels which are predominantly being developed in Japan by Mitsubishi Heavy Industries. Although Mitsubishi is the primary developer of the superconductive electromagnetic propulsion (SEMP) vessels, certain EC firms are performing crucial roles in the development of the SEMP project. The most significant contributor is Germany's Motoren und Turbinen Union division of Daimler-Benz, which won a prestigious contract to develop two high-speed engines used to power the SEMP's innovative magnetohydrodynamic (MHD) propulsion system.

Another crucial project for the EC industry is the clean E3 tanker which teams up 5 European yards in an attempt to step up the European share of the very large crude carriers markets.

Written by: DRI Europe
The industry is represented at the EC level by: Committee of EC Shipbuilders Associations (CESA). Address: Juan Hurtado de Mendoza, 13-7-9, E-28036 Madrid; tel: (34 1) 345 7078; fax: (34 1) 359 9336.

Railway rolling stock
NACE 362

1991 proved to be a good year for the railway rolling stock industry. Production continued the recovery started in 1989. Due to the reunification of Germany, large contracts with the former USSR brought exports to their highest level since 1982, although this cannot be considered a trend. High speed rail projects accounted for much of the demand, but urban and suburban transit projects also played a large part.
The industry has few clients, mostly railroad and public transportation companies, and is completely dependent upon these clients. Products are tailored to these clients, and continuous innovation is necessary to satisfy them and to ensure that the market does not become saturated and EC firms stay competitive internationally. The industry is becoming more concentrated in an effort to be competitive after the implementation of the Single European Market.
Environmental concerns will increase interest in rail as an alternative method of transportation, as it is a relatively low polluting option compared to both air and road travel, particularly if future anti-pollution measures become a hindrance for road transport. In addition, European integration will lead to a more competitive EC market as national governments open bidding procedures to all EC manufacturers to compete.

INDUSTRY PROFILE

Description of the sector

The railroad rolling stock industry (NACE 362) includes the manufacture of standard large and narrow gauge railway and urban transport railway equipment. This includes:

- diesel and electric locomotives;
- mainline passenger coaches, metro cars and tramways;
- goods wagons;
- rolling stock equipment;
- fixed track equipment;
- electric signalling, safety and control devices for railways.

The performance of the industry is dependent on the transportation needs and on public policies regarding the development of the railroad lines and purchase of rolling stock.

Main indicators

Apparent consumption decreased in 1991, although production increased due to a sizeable increase in extra-EC exports. However, because of the nature of the large, infrequent contracts the increase in exports cannot be seen as a trend. Imports grew less than exports, resulting in an increase in the trade balance. Employment growth rates were well below those of manufacturing, and also those of other transportation equipment sectors such as aerospace equipment.

No one country dominates production. Germany has the largest proportion of value added, with 25% of the total, but is followed closely by Italy with 24%, the United Kingdom with 21%, and Spain with 20%. These four countries make up almost 90% of value added in the EC.

Recent trends

Production fell continuously from 1982 to 1989, after which it began to recover. Apparent consumption did not follow the trend of production, and was more variable throughout the 1980s due to variability in extra-EC imports and exports. Employment fell steadily from 1982, in line with production.

Employment continued to fall in 1991 despite an increase in production, reflecting increasing productivity.

From 1982 to 1991, overall average real annual growth rates were negative. However, the decline of both apparent consumption and production was much more pronounced in the first half of the 1980s than in the latter half. Exports and imports also had stronger showings in the second half of the 1980s. Imports, after falling sharply between 1982 and 1985, recovered to a growth rate high above that of exports from 1985 to 1991, producing a deterioration in the trade balance.

Foreign trade

In general, both extra-EC exports and imports exhibit large variations from year to year, due to the high value nature and irregular delivery of the long-term contracts. In 1991, large exports to the former USSR from Germany, and to some extent from France, caused extra-EC exports to increase by 300%. Such large, extra-EC contracts are very infrequent. These contracts are linked to the integration of Germany. Such a development cannot be seen as an indicator of future exports Rolling stock has a very long life, and may last up to 30 or even 50 years. Intra-EC sales, however, does show a steady increase since 1987, although its share of total sales remained between 60% and 70% throughout the eighties.

Destination of EC exports changed significantly from 1986 to 1991, although the figures are distorted as a result of the integration of the East German sales to the former USSR. Exports to EFTA also increased, while the proportion of trade with the OPEC countries (excluding Iran) dropped.

EC suppliers tend to change significantly. Although EFTA is still the largest exporting country to the EC, the opening of Eastern Europe could provide the EC with important new sources of imports such as Czechoslovakia, the USSR, etc.

MARKET FORCES

Demand

The industry has a relatively small number of customers, in national and regional railroad companies, urban transport companies, private transport companies, private rental and lease companies, and industries with their own railway rolling stock. The industry is less affected by general income developments than by transportation and infrastructure policies. Planning of new networks and increases in infrastructure tend to be long-term plans. Short-term variations arise, however, from budgetary bottle-necks. Railway rolling stock has a long economic life Product innovation does, however, involve the purchase or replacement of certain parts of rolling stock.

Product innovation has a significant effect on demand. Increased demand for fast transportation led to the development of high-speed rail technology and resulted in plans by many countries for new high-speed networks. France is increasing the network of its TGV, and it is expected that by the end of the century, all Western European countries will have high-speed rail connections. In addition to France, Germany, Italy, and Spain in particular are well started on their high-speed networks.

Supply and competition

In 1989, the EC (56% of total orders), Japan, South Korea, the USA and Canada (tied) were the world market leaders, in that order. Eastern European countries could become competitors for the EC eventually, due to lower labour costs. At the moment, however, the level of technology and industrial know-how, as well as the new political situation in Germany, makes them net importers. Japanese manufacturers are looking for new international markets to boost flagging exports, including Europe and the USA. Competition is mainly on the technological side, since high wages and the strong yen currently make Japanese firms less competitive on a price level. However, the Japanese might be concentrating mostly on the USA, which has a comparatively less competitive industry and a growing need for alternative forms of transportation due to overcrowded motor ways.

The Single European Market will have a significant effect on intra-EC trade, especially due to European standardisation efforts, and the enforced opening of public procurement competition to all qualified EC companies regardless of nationality.

Production process

Employment in the railway rolling stock industry has been falling since 1981, while total production has been increasing. The result is growing productivity which should help the EC to maintain its competitiveness compared to producers with lower labour costs, provided its technology remains at the highest level.

Since the industry has only a few clients, who for the most part have very specific needs, and as contracts are generally large, the industry works very closely with its customers. Producers can only develop new equipment in close collaboration with their clients. The Single European Market should make cooperation easier, as requirements will be harmonised.

Innovations have been numerous in the industry. For example, in addition to the several different high-speed and tilting technologies available, multi-microprocessor control equipment and three phase drives have become standard in various countries. The use of aluminium has decreased vehicle weight significantly, increasing power efficiency. Also, on-board computerised networks on trains, and the use of telecommunications equipment and microprocessors in signalling equipment have increased the efficiency and safety of the rail transport sector. Extra-EC innovations include Japan's magnetic levitation system, and satellite-operated train operation control systems. These innovations show certain directions in which the railway rolling stock industry can advance, to ensure increased interest in rail transport.

INDUSTRY STRUCTURE

Companies

The industry contains about 100 locomotive, coach, and wagon builders, and about the same number of railway equipment manufacturers. Locomotives are mainly produced by divisions within large firms engaged above all in other industrial sectors, while passenger coaches and goods wagons are usually the primary product of the producing firm. The size of companies varies widely, from less than 100 employees to several thousand workers. The largest companies include GEC-Alsthom (UK-France), Asea Brown Boveri (Sweden-Switzerland), Siemens and AEG (Germany). All these companies produce in many fields other than transportation. Several of them are the results of mergers. There is a need for a concentrated

industry structure to deal with the continuous expense of R&D and innovation, and with foreign competition.

Strategies

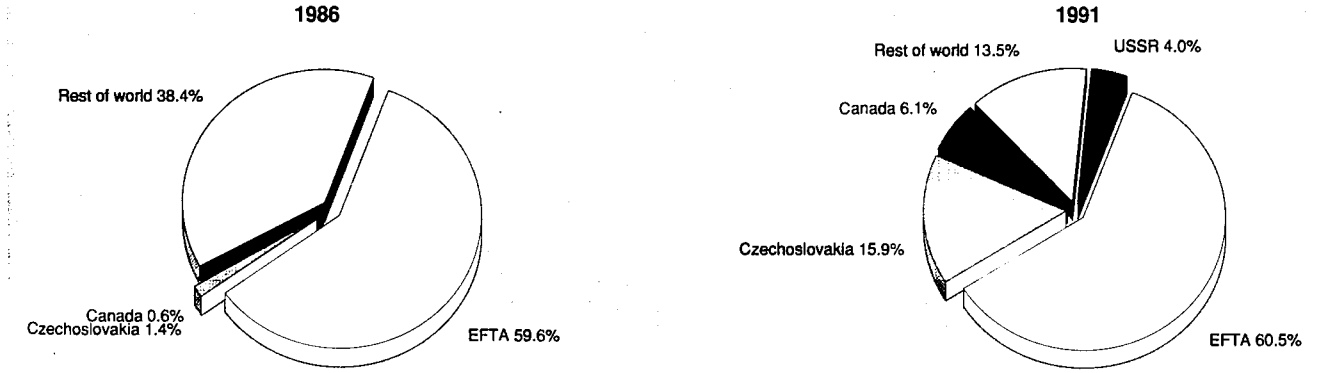
The primary strategies for the leading firms of the industry are increased innovation and technology and increased concentration. Some competitors and possible competitors have lower labour costs than prevailing in EC countries, such as South Korea and Eastern Europe. European firms must therefore stay competitive on the basis of quality and modernisation. Companies must also be large enough to withstand foreign firms. The specialised nature of products does not allow a large amount of economies of scale, but knowledge of different standards and requirements by different EC customers does give European firms an advantage over non-European firms on the world market. This advantage might well disappear after the introduction of European norms. Firms must therefore be prepared to face more direct foreign competition, as well as more intra-EC competition.

The railroad industry is looking in three primary directions. Much of current investment is going into the high-speed railways, which are seen as one of the most important of near-future developments. These high-speed systems will require some transformation of existing networks and infrastructure, as well as new infrastructure, and therefore provide the railway industry with new opportunities.

High-speed systems are limited in scope. However, another area which is receiving a lot of attention is the urban transit sector. Expanding cities and suburbs are making efforts for fast and easy public transportation, especially into the heart of cities. As urban transit systems cut down on both pollution and traffic, this is of primary importance to city planners. With the growth of cities, the transit systems will continue to grow to accommodate the increasing number of people and increased area. This sector is therefore considered by the industry to be of equal importance to the high-speed rail development, because of the almost unlimited room for expansion and demand.

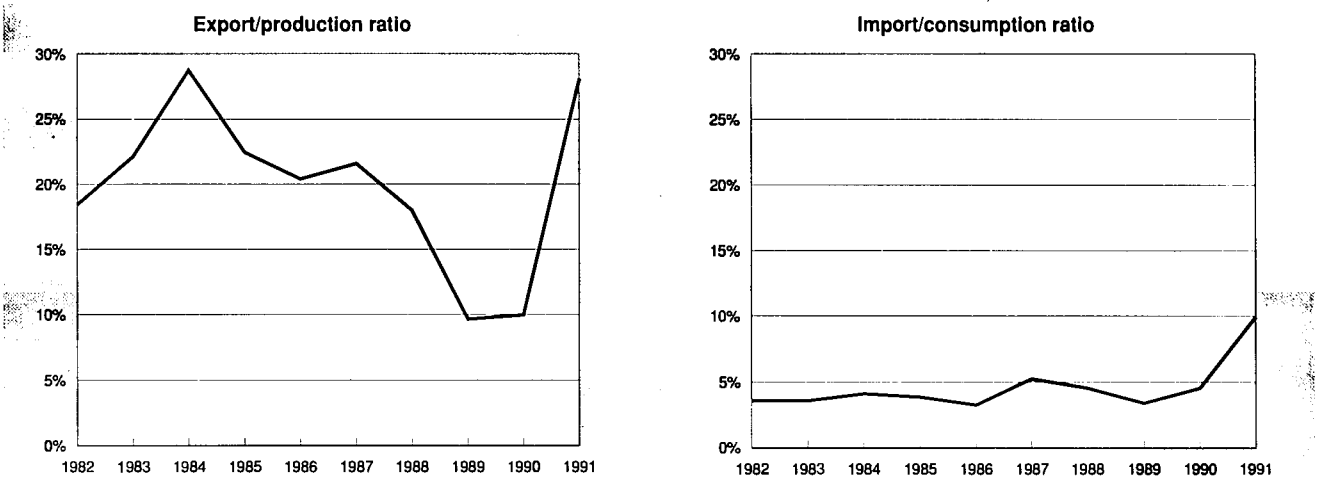
Combined transport is another important field for future activity of the industry. As it is not possible for railways to deliver goods to every location trucks can reach, the combined rail/road haulage offers a good solution, especially as it offers environmental, energy saving, security and anticongestion advantages. Goods can be transported by rail for long distances

Figure 7: Railway rolling stock
Origin of EC imports



Source: Eurostat

Figure 8: Railway rolling stock
Trade intensities



Source: Eurostat

and dispatched to their final destinations by trucks. Quick loading and unloading systems are essential for the success of combined rail/road traffic.

REGIONAL DISTRIBUTION

Production of different subsectors varies slightly from country to country. In 1989, Germany produced the most passenger coaches and goods wagons, while France produced the most locomotives (measured in value). Italy produced more passenger coaches and goods wagons, but fewer locomotives than France. These figures can change quickly, however, depending on incoming orders. In 1989, Spain was a much smaller producer than France. In 1991, Spain's value added was twice as high as that of France. The workforce is concentrated in France, Germany, Italy, the United Kingdom, and Spain.

ENVIRONMENT

Rail transport is a less polluting mode of transportation than air or road. This is one of the most important arguments in favour of railroads, and is becoming even more important as concerns regarding air quality grow. Much of the raw materials used in the industry, especially the large amount of iron, can be reused when the stock's economic life is over.

REGULATIONS

One of the most important regulations affecting the railway industry is the 1990 "excluded sectors" directive which addresses public procurement in the transport, water, energy, and telecommunications sectors. This directive will liberalise bidding for public contracts, which are extremely important contracts for the railway industry. This directive will significantly increase competition between firms, but price is not the only consideration for buyers, who are also very sensitive to quality, delivery time, payment factors, etc. Given that established relationships between clients and firms are also very important in this sector, the effects of the liberalisation will probably not be felt immediately.

OUTLOOK

It is not possible to forecast economic indicators for the railway industry, because the industry is extremely dependent on factors beyond its control, and which are not always foreseeable.

Source:Annual reports, DRI Europe

Changes in the political climate or budgetary situation of a country can lead it to cancel long-standing contracts, for instance. However, by examining medium and long-term trends, general forecasts can be made by the industry.

Despite negative growth trends for railroad rolling stock in the 1980's, the outlook for the early to mid 1990s looks promising if not stellar. Increased interest in high-speed lines as alternatives to air travel and road travel look good in the face of continuing worries about pollution from cars and overcrowded roadways, as well as the proximity of railroad stations to town centres, compared to airports. Large investments in suburban and urban mass transit rail stock can also be expected, for similar reasons. Positive effects of European integration include increased freight and passenger traffic among member states. The former USSR countries can also offer EC manufacturers large new markets, as the need for technology in those countries creates business opportunities for Western firms, provided that financing is available. The USA is another possible market; increased environmental awareness and very overcrowded motor ways have caused increased awareness of need for alternative transportation. However, certain requirements of US policy, such as final assembly work being done in the US, make it more difficult for foreign firms to compete, without involving long-term investments.

Although the Single European Market will offer the railroad industry some advantages, there are risks involved for firms as well. The primary risk is that deregulation of airlines and road haulage firms will make them even more competitive with rail. There is thus no guarantee that the Single Market will increase the demand for railway equipment.

While in the short term, Eastern Europe will increase demand for EC technology; in the medium term, Eastern Europe could become a competitor, especially on a price basis. The EC industry must continue to maintain its competitiveness mainly by staying ahead of the competition in technology.

Aerospace
NACE 364

Following a period of sustained expansion, the aerospace industry is currently facing problems of structural adjustment. Despite considerable efforts at both national and European levels, the aerospace industry in Europe continues to suffer from the consequences of having maintained a fragmented industry structure. The industry now has to reorganise in view of the creation of the Single Market and the increasing globalisation of the economy.
Recent developments have brought to light the extremely weak financial situation of airline companies in the present state of the business cycle, and this weakness is having repercussions on the civil aircraft manufacturers. The drop in air traffic as a result of the Gulf war has led to a decrease in orders of two-thirds.
The end of the period of expansion was brought about by the dramatic reduction in military orders and the drop in civil airline orders. The opening of Central and Eastern Europe and the CIS will have a decisive influence on the future of the European aerospace industry.

INDUSTRY PROFILE

Description of the sector

The aerospace industry is engaged in research, development and the production of aerospace systems (aircraft, missiles, space launchers and satellites, their engines and equipment). These products have both civil and military applications. The industry includes manufacturers of fuselages and missiles, engines, space craft and their equipment.

Main indicators

In 1992 the European aerospace industry produced goods valued at over 40 billion ECU, directly employing more than 450 000 people and indirectly more than a million.

In 1991, the production of aircraft and missiles accounted for nearly half of European aerospace activity, the other half being divided between the production of engines (19%), equipment (27%) and the space sector (6%).

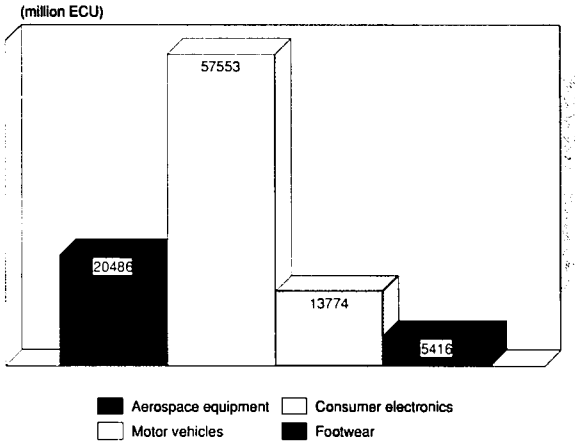
Aerospace production in Europe has always been mainly military: despite the growing share of the civil sector during the 1980s, even in 1990 the share of production for military purposes still amounted to 54% of total turnover.

Structurally, the aerospace industry has a high proportion of qualified engineers and managers on its payroll - nearly 20% in 1990. This proportion is even higher in the space manufacturing and equipment sector. This unusual percentage of highly skilled personnel reflects the crucial importance of R&D activity in production as a whole. In 1990, 24% of all employees were assigned to research and development activity.

Recent trends

Between 1982 and 1991 the value of production (in real terms) of the European aerospace industry increased by more than 5% per year. During this period there was lower than average growth of production of aircraft and missiles and of their engines, because of the cutback in the production of military aircraft. On the other hand, there was above average growth in the production of equipment, the second largest segment of the aerospace industry. Space craft, the smallest sector of the European aerospace industry, expanded considerably during the 1980s, owing to the growth in the European market (its main outlet) and the international market.

Figure 1: Aerospace
Value added in comparison with other Industries, 1991



Source: Eurostat

As a result of political détente, which led to a reduction in military sales, and of the explosion of orders for civil aircraft at the end of the 1980s, the relative share of production for military purposes declined from 70% in 1982 to 54% in 1990.

Generally this growth in turnover was the result of increased productivity, since the volume of employment remained unchanged at around 480 000 persons. However, there was an above average increase in employment in the space and equipment sectors. Employment in the production of aircraft and missiles remained unchanged, while fewer were employed in manufacturing engines. The skill level of employees also increased significantly: there was a 2% annual increase in the numbers of engineers and managers between 1982 and 1990.

International comparison

First it should be noted that the very large fluctuation in the value of the American dollar in relation to European currencies during the 1980s distorts comparisons between countries.

With a production of more than 40 billion ECU in 1992, the European aerospace industry is number two in the world, after the USA. Despite the success of the Airbus consortium, the USA is still the unchallenged leader in the world aerospace market: the whole of the European aerospace industry produces

less than the four leading American manufacturers. However, this domination became somewhat attenuated during the 1980s: the value of American production fell from 326% of European production in 1982 to 238% in 1991, owing to the slowdown in American sales of military equipment coupled with the growth in European civil production. At the present time Japan produces only about 20% as much as the European industry by value. Adequate statistical information about the aerospace industry in the former USSR and other countries of Central and Eastern Europe is not yet available, but they are thought to have a very high potential.

Aerospace production in the world is still dominated by military requirements, notwithstanding the growing importance of civil activities. In 1990, 61% of production in the USA was destined for military use, 54% in Europe and 55% in Japan (1989).

Foreign trade

Aerospace products are traded on an open world market. The importance of trade as a proportion of total turnover confirms this; more than half of production is exported.

For civil products, both exports from and imports into the EC increased considerably during the 1980s. Imported components (motors, equipment) correspond on average to 20/25% of the value of large European and American commercial aircraft. In terms of volume, imports and exports more or less balance. Indeed, in the middle of the 1980s the balance of trade was definitely in Europe's favour. Imports have been rising again since 1990, the result of orders for American civil aircraft by European airlines. Also, the chronic weakness of the American dollar since 1986 has proved a handicap for European exports.

Trade between Europe and the USA dominates international trade in aerospace products, since each country is the other's largest trading partner for these products. The USA absorbs more than 40% of aerospace exports from Europe, whilst nearly 80% of imports of aerospace products into Europe come from the USA. Although the American aerospace industry holds first place in the Japanese market, Europe has a decidedly favourable balance of trade with Japan in the aerospace sector.

Figure 4: Aerospace

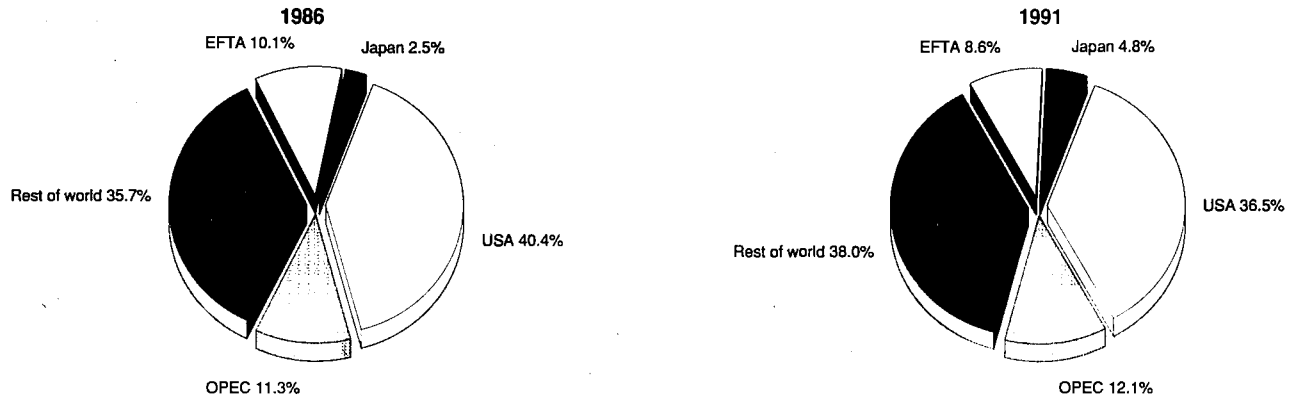
Figure 6: Aerospace
Destination of EC exports



Source: Eurostat

As a result of the development of programmes for European cooperation, intra-European trade in civil products is growing at a very rapid pace.

MARKET FORCES

Demand

Large commercial aircraft

There has been rapid growth in the large commercial transport aircraft sector during the last 25 years, as airlines have enlarged their fleets to cope with a regular yearly growth of 6% in world air traffic since the 1970s. Air traffic grew at the same pace as economic activity in general. Since 1985, the growth in orders for new aircraft has surpassed all expectations, and at the end of the 1980s the backlog of orders for large commercial aircraft was in excess of 3 000 units.

However, owing to the weak economic growth in Europe and the USA since 1989, coupled with the effects of the Gulf war and the high price of fuel, the air transport industry went into recession and sharply reduced its orders for new aircraft. In 1991 - for the first time since 1983 - the order books of the aircraft industry fell, i.e. deliveries of aircraft exceeded new orders. So the aerospace industry, still producing at a record rate, is out of step with the airline companies, who are facing the most serious financial crisis of their history. As a result, after reaching a figure of more than 600 aircraft a year between 1991 and 1993, deliveries are expected to fall to around 400 a year. Total deliveries during the period 1991-2010 are expected to amount to some 5 000 units.

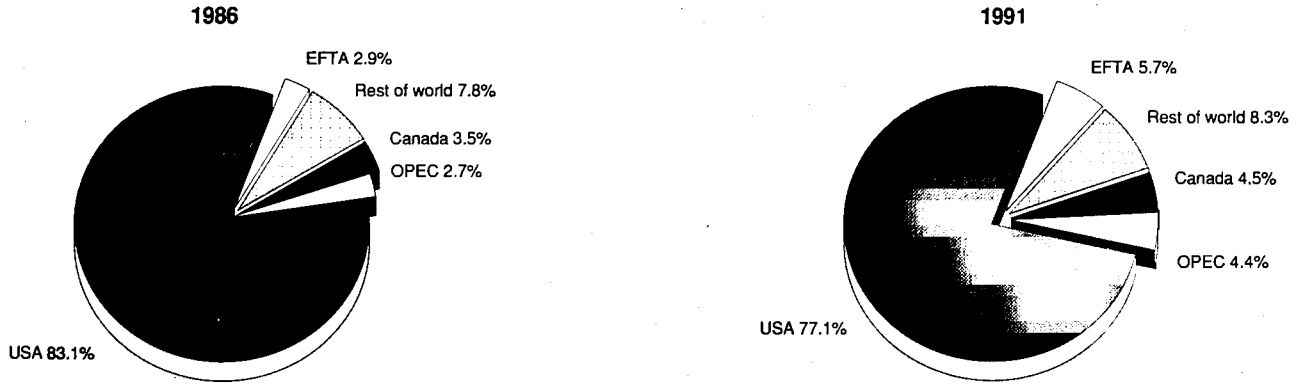
Regional transport aircraft

The growth in the numbers of large commercial aircraft is reflected in the regional transport aircraft sector, in which annual deliveries have increased from about 200 in 1984 to more than 400 in 1991. It is expected that growth at this rate will continue and that new sales will reach between 5 000 and 7 000 units during the period 1991-2010.

Helicopters

All helicopter manufacturers depend to a large extent upon military orders; nearly all the civil helicopters are derived from military ones or have a military equivalent which adds to the production volume. In value terms military sales represent 20 times as much as those to the civil sector. As the demand for military helicopters is shrinking, this has brought lean times to the whole of the helicopter industry. At present some 450 units a year are being delivered to the civil market, though this market is expected to pick up again, leading to a take-up of 5 000 units in the world for the period 1991-2000.

Figure 7: Aerospace
Origin of EC imports



Source: Eurostat

General aviation

The rise in the price of aircraft and the problem of civil liability has caused the market for civil aircraft, comprising business and light aircraft, to collapse. It is expected that during the period 1991-2010 the world market will absorb about 5 000 business aircraft and 60 000 light aircraft.

Military aircraft

The market for military aircraft comprises mainly combat aircraft and helicopters. Political détente has led to a fundamental reappraisal of defence policies, leading to a shrinkage of both domestic and export markets for military aircraft.

However, political détente has served only to catalyse a process that began in the early 1980s. The current crisis in the military aerospace industry is in fact largely due to the explosion of development costs in most recent military programmes, which have exceeded their initial budgetary estimates by large margins. These increases have led to a reduction in the number of aircraft ordered. The relative size of the military market is expected to continue to decrease over the next few years.

Space

The strong growth of space activity during the 1980s was principally linked to the military programmes of the USA and the former Soviet Union and, to a smaller extent, to the burgeoning of the civil and commercial markets. Space agencies play a decisive role in the development of space activities. Telecommunications satellites constitute the largest and most profitable market for space hardware.

In Europe, military space applications, which are concentrated in France and the United Kingdom, still take second place to civil projects. WEU has recently been giving thought to the development of disarmament control satellites.

Missiles

The market for missiles is one of the most volatile. Conventional force reductions consequent upon détente between East and West have caused the demand for missiles to contract, and there is also uncertainty as to the outlook for equipping the new combat aircraft (EFA, RAFALE and GRIPEN).

Supply and competition

Large commercial aircraft

Mergers among the European makers of large commercial aircraft have led to the emergence of a single European producer - Airbus - which is an association between four companies, Aérospatiale, British Aerospace, DASA and CASA. Each of these companies is itself the result of a series of mergers and acquisitions. Airbus has to meet the competition of the two largest American commercial transport manufacturers, Boeing and McDonnell Douglas.

In 1991 Airbus delivered 25 A-300, 19 A-310 and 119 A-320, thus securing about 1/5 of the world market for large commercial transport aircraft by numbers delivered. In terms of orders, Airbus had nearly 25% of the market (in numbers of aircraft). Sales of Fokker 100 and BAe 146 bring the European share to about one-third of the market (in numbers of aircraft). By mid-1992, the Airbus order book amounted to 873 aircraft, made up of 88 A300, 48 A310, 335 A320, 144 A321, 143 A330 and 115 A340.

Notwithstanding the success of Airbus, Boeing is clearly the market leader in terms of volume of production, the range of models and the rate of production. On average Boeing wins 2/3 of deliveries, partly because of the high value of its 747. Boeing is also the only manufacturer with a full range of 100- to 500-seat aircraft. Even though Airbus and McDonnell Douglas both have plans for very large aircraft, Boeing is likely to retain its monopoly in the class of aircraft with over 350 seats for some time-and that means its monopoly of more than 20% of the world market. Subcontracting in the industry for both Airbus projects and its main competitors' (Boeing and McDonnell Douglas) projects represent nearly 10% of Europe's civil aeronautic business.

This situation, combined with the threat of new entrants with new engines from Eastern Europe and the cost escalation of new aircraft, especially for the new 450+ seat aircraft, and potentially for the supersonic aircraft in the longer term, is placing increasing pressure on manufacturers to increase aircraft size and efficiency.

Regional transport aircraft

Several makers are competing in the market for regional transport aircraft. They include ATR, British Aerospace, CASA, DASA (Dornier) and Fokker in the EC, and de Havilland (Canada), Embraer (Brazil), Saab (Sweden) in the rest of the world. European industry accounts for two thirds of world deliveries (by value) in the regional transport aircraft market.

However, rough estimates of the market share needed to secure satisfactory profitability seem to indicate that there may be only half a dozen competitors who can succeed in this market. Consequently, there may be still more rationalisation to come.

Helicopters

There are seven main makers of turbine-driven helicopters, three in Europe (Agusta, Eurocopter and Westland) and four in the USA (Bell, McDonnell Douglas, Sikorsky and Boeing). European makers have a slightly larger share of deliveries than the American ones.

In terms of economies of scale deriving from close links between the design, development and manufacture of military and civil helicopters, the European helicopter industry suffers from an overall handicap compared with the USA, which produces twice as many military helicopters. Notwithstanding the recent concentration of Aérospatiale and MBB in Eurocopter, further rationalisation might be necessary to enable the European manufacturers to remain competitive against the strong competition from America.

General aviation

The market for general aviation, which is largely dominated by American manufacturers, underwent a radical restructuring during the 1980s. In the market for business aircraft, the main competitors of the two European makers (British Aerospace and Dassault) are Beech, Cessna and Gulfstream.

Military aviation

The world market for military aircraft is dominated by American industry, with a turnover twice as high as that of Europe. The main European producers (British Aerospace, DASA, Aérospatiale, Alenia and Dassault) each have a sales value of over 1 billion ECU in military aircraft. They account for two thirds of European military production. Hence military aircraft production exhibits a high degree of concentration, with some main contractors having a near-monopoly in their domestic markets. Nevertheless, the exponential cost of new programmes and the shrinking markets make cooperation the rule, and individual projects are becoming the exception.

The contraction of defence budgets will lead to a diversification by these firms from military production to civil production, in so far as the latter grows sufficiently to enable these new resources to be absorbed.

The outlook for the main European makers of military aircraft (DASA, Dassault, British Aerospace, Alenia, and also Fokker and CASA) is linked to the fate of the new combat aircraft EFA and RAFALE, and hence to the decisions that will be taken for the renewal of combat aircraft fleets. Cost overruns and the new political situation are leading to reductions in the numbers of aircraft required and even to the cancellation of some programmes.

Table 5: Aerospace
Destination of output, 1990

(%)

Exports	31.8
Public procurement	30.9
Civil final consumers	8.1
Intermediate sales	29.2

Source: Industry associations

Engines

The market for engines is dominated by four manufacturers: General Electric, Pratt and Whitney, Rolls-Royce and SNECMA. In order to share the very considerable costs of development, the aircraft engine manufacturers practise a policy of very far-reaching international cooperation. Transatlantic cooperation relates mainly to the civil market, military cooperation being confined to Europe. The consortia CFM International (General Electric and SNECMA) and IAE (Pratt and Whitney, Rolls-Royce, MTU, FIAT and JAE) are typical of cooperative civil engine programmes. Most of the engine makers are also associated in the new programmes for large civil aircraft engines: Trent (Rolls-Royce), GE 90 (General Electric + SNECMA + FIAT) and PW 4000 (Pratt and Whitney + MTU).

In Europe, the outlook for makers of military engines will be largely determined by the future of the proposed EFA and RAFALE combat aircraft. Rolls-Royce and MTU are cooperating on the EJ200 engine for the EFA, while SNECMA is developing the M88 engine for the RAFALE.

Space

The USA dominates the space sector in terms of production, followed by the former USSR. Europe's space effort, which comes third, is grouped around the European Space Agency. The space industry in Europe is considerably less integrated than that in the USA, but is now beginning to concentrate by forming groups, especially in the satellite sector.

Missiles

A lot of restructuring has been occurring with the object of consolidating an industry that is very fragmented, both geographically and in terms of products.

The main European manufacturers are British Aerospace, Thomson-CSF, Aérospatiale, Matra and MBB. Their competitors in America include Raytheon and Hughes.

Most recent missile programmes in Europe have been developed in multinational consortia, but the collapse of the market for missiles could put a stop to this process, or even lead to the dissolution of already existing cooperative arrangements.

Production process

Because an enormous initial investment is required for developing a new aerospace programme (up to 10 billion USD for a large commercial transport aircraft), economies of scale are critically important in the industry. Economies of scale can be achieved both on the supply side by enabling development and production costs to be reduced, and on the demand side in enabling the costs of maintenance, training and so forth to be held in check. Large production runs enable the fixed costs of start-up to be spread over many aircraft, as well as yielding the benefits of the learning curve. Then again, if families of products generating economies of scale are developed, this can engender customer loyalty.

INDUSTRY STRUCTURE

Companies

The aerospace industry is dominated by American firms, which enjoy the advantage of a large domestic market, mainly consisting of military procurement, though some companies have been affected by the reduction in American military expenditure.

In America the industry leaders in terms of turnover are Boeing, McDonnell Douglas, General Electric and United Technologies. The main European firms in the aerospace industry are smaller than their American competitors. Of the ten leading companies in the sector in 1990, four were European: British Aerospace, DASA, Rolls-Royce and Aérospatiale. Their production represents less than a third of that of the ten main producers in the world.

Strategies

Government-industry relationship

Whether for military reasons or considerations of technological independence, the aerospace industry has always been regarded as a strategic industry. Though the precise relationship between the state and the industry may vary from country to country, the state has a massive involvement everywhere. Control is not necessarily entirely direct; it can also be exercised via assistance to R&D and to exports, by regulations, and so on. The state exerts even greater influence in the space sector, where product development is still largely linked to government procurement.

An aerospace company has to make a huge initial investment to enter the market, and then bear several years of cash drain, after which it will take a decade or more to recover its costs. Furthermore, to remain in the market and still be financially solvent, a company has to develop a family of aircraft, the development costs of which are beyond the means of the manufacturer unless he is operating in a number of different market segments with several models that have complementary life cycles. Hence it is difficult for a firm to enter the aerospace market without government support during the interval be-

Source: Eurostat

tween the decision to launch the initial programme and the achievement of sufficient cash flow.

The systems of government funding of R&D in the USA and in Europe are not based on the same approach, but the aerospace industries in the two areas are at different stages of development.

The civil aerospace industry in the USA built up its power in the immediate post-war period and grew until the early 1980s in a situation of virtual monopoly. Because of its strategic importance, the American aerospace industry grew up in symbiosis with the state, which supported it (and still does) through three main finance streams: the DOD (Department of Defence), NASA (National Aeronautics and Space Administration) and the taxation system.

The European aerospace industry, on the other hand, and in particular that of the large civil transport aircraft, did not really emerge until the Airbus programme was started - in other words several decades later than the American aerospace industry. The initial investment, and especially the risk attaching to the start-up of new programmes, was covered by a grant of repayable advances.

Alliances

Firms are having increasing difficulty in assembling the industrial, technical and financial resources needed for launching new aerospace products; indeed, the costs are often far greater than the firm's own equity capital. Furthermore, the associated risks are increasingly heavy to bear - the more so as the economic cycle for aerospace programmes is often longer than 10 years. This has led to the forging of numerous inter-firm alliances in the aerospace sector.

Up to the present, European firms have usually solved the problem of critical size by cooperation within Europe. This was an alternative to industrial integration; and since Member States are mindful of their independence, it has occurred only within national frontiers. No multinational aerospace company exists.

Airbus Industrie, ATR, Tornado, EFA and Arianespace are examples of the strategy of cooperation, whereas Aérospatiale, British Acrospace and Deutsche Aerospace are examples of national integration.

Cooperative alliances imply technological specialisation by the participating companies not only in research and development but also in production. In Europe, this increased integration of production coexists with marked national specialisations, particularly in the maintenance of competing programmes. European cooperation programmes do not bring together a major partner and transatlantic cooperation structures that dominate the European programme, especially as regards power plants.

REGIONAL DISTRIBUTION

Most aerospace production in Europe is divided between four countries - the United Kingdom, France, Germany and Italy.

In 1991 these four countries together produced about 94% of the value added in aerospace in Europe. France with 31% and the United Kingdom with 32% are the two main producers, and have traditionally been the two countries in Europe most committed to this production. Nevertheless, the German and Italian aerospace industries have recently been expanding rapidly; they account for 22% and 9% of European production respectively. The remainder is provided by the Netherlands, Belgium and Spain.

ENVIRONMENT

The most significant impact of air transport on the environment has long been perceived as being the noise it creates. More recently attention has been directed to gaseous emissions in the high atmosphere. This is associated with the growing awareness of problems connected with the greenhouse effect and the wish to protect the ozone layer. These two themes will dominate the environmental aspects of air transport for the foreseeable future.

In this context, proposals for supersonic aircraft arouse concerns which aircraft manufacturers will certainly have to address before future supersonic transport becomes acceptable and economically viable.

The aircraft industry will have to meet the challenge to produce increasingly powerful civil engines to match the growing size of aircraft; these engines will also have to be increasingly efficient in view of the foreseeable rise in the price of fuel, while meeting environmental criteria.

The increase in air transport in the medium and long term will necessitate the extension of existing airports and the building of new ones. This will be environmentally acceptable only if tangible progress is made in terms of noise and gas emissions, which in turn will require more research.

The oldest aircraft have already been withdrawn pursuant to a number of international agreements, with considerable financial impact on the airline companies. Yet it is likely that current environmental standards will have to be made more stringent. For one thing, air transport within Europe will soon face competition from high-speed trains, and furthermore current standards are not adequate to meet the new environmental requirements:

- With respect to noise, the actual growth of air traffic, combined with the increased size of the aircraft, threatens substantially to reduce the benefit derived from the regulations that have come into force during the past decade. Unless aircraft noise is reduced still further, current standards are likely to be swamped by restrictions around airports during the next century.
- With respect to gaseous emissions, the current standards also appear inadequate in so far as they do not take into account the whole flight envelope: during a long haul flight more than 90% of the gaseous emissions are not covered by current standards.

REGULATIONS

Owing to the intensification of international competition, all firms are operating under the same competitive conditions. In the context of progressive globalisation of the aerospace market, this principle applies just as much to competition within the EC as with respect to external competitors. All the factors that could affect competition must be taken into account, and in particular both direct and indirect public subsidies.

Competition policy within the EC

When the rules on competition, particularly Articles 85 and 86, are applied to the aerospace industry, the specific conditions of its viability such as the high level of investment needed, the necessary degree of cooperation and the comparatively small number of producers, are taken into account. Some sectors of the industry are affected by:

- the worldwide dimension of the market, compared with which national markets are too restricted to nourish the development of enterprises strong enough to be internationally competitive;

- industrial operations of such a size that no existing European enterprise can master all the technologies and acquire the production equipment needed to manage a complex programme in industrial and economic terms;
- financial requirements that have reached a level beyond the ability of any individual operator to accumulate;
- the high degree of integration of the main competitors of the European aerospace industry.

Mergers are subject to Council Regulation (EEC) No. 4064/89 dated 21 December 1989. Their impact is generally evaluated on the world market. Consequently a merger bringing together most of the supply capacity of the EC in certain sectors of the aerospace industry does not necessarily amount to the creation of a dominant position incompatible with the common market.

Government subsidies for the aerospace industry are subject to articles 92-94 of the EEC Treaty. At the present time there is no sectoral aid framework laying down special directives for Member States in granting assistance to the aerospace industry. The distorting effects of subsidies on other competitors are also taken into account.

There are general regulations governing State assistance for R&D, but the special features of the sector are taken into account - the advanced technology content of the products, the fierce international competition and lastly the cooperative nature of research.

Commercial policy

The sectoral agreement of GATT [General Agreement on Tariffs and Trade] on international trade in civil aircraft, which came into effect on 1 January 1980, lifted most of the tariff and non-tariff barriers to trade in commercial aircraft. In particular, it regulates the various forms of government subsidy to the aerospace industry.

Because the situation of America is fundamentally different from that of Europe and governed by different considerations, the signatories to the agreement do not agree on how it should be interpreted.

On 1 April 1992 the negotiators of the EC and of the USA concluded an agreement resolving their dispute about large commercial transport aircraft. In July 1992, a multilateral negotiation was opened within the GATT framework in order to reach an agreement covering all types of aircraft and all aircraft producer countries so as to arrive at multilateral rulings for this sector.

THE POLITICAL DÉTENTE

Political détente, and in particular the far-reaching changes that have occurred in Europe since 1989, affect the aerospace industry in the world and in Europe from three points of view:

- it has resulted in a reduction of military aerospace activity and, given the considerable interaction between the civil and military spheres, these developments will have a significant effect on the civil aerospace industry;
- furthermore, competition is strengthening both in contracting military markets and in civil markets in which conversion from military industry is bringing about both contraction of some enterprises and the entry of new competitors;
- lastly, although tainted by great political and economic instability, the opening of the countries of Central and Eastern Europe and the independent republics of the ex-USSR will greatly change the outlook and the context of industrial cooperation.

Conversion of the military aerospace industry

The aerospace industry is facing the question of the effect that the considerable reduction in military expenditure will have. There is a reciprocal dependent relationship, even though an unequal one, between the civil and military aerospace sectors: until now their respective business cycles have been complementary, and this has enabled the potential for aerospace production to be maintained intact. Moreover, whereas the military side is helped by economies of scale made possible by a parallel civil activity, the civil side also benefits from the fallout of the technological advances made on the military side. Thus any reduction in R&D activities for military purposes will have long-term repercussions on technological capability and the competitiveness of the aerospace industry as a whole.

Aerospace industries of the former East bloc

The political and economic disintegration of the former USSR, combined with a considerable reduction in military sales and exports, has made a shambles of its aerospace industry. Yet this industry constitutes the high technology industrial sector which offers the West the best opportunities in terms of industrial and technological cooperation. Activity is expected to start up again in 1994, following the organisation of joint ventures, especially in the field of modernisation and re-fitting of Russian-designed aircraft with new Western engines. However, most sales will still be made on the domestic market.

The upsets that followed the fall of the Berlin Wall have had an enormous impact on the aerospace industry of Central and Eastern Europe. In 1991 the production rate, including that of spares and components, slowed down considerably. This industry is suffering from a serious handicap in terms of efficiency, organisation and over-manning. In the short term, despite its very low wage costs, the problems of organising and managing production, shortage of capital and the obsolescence of civil production tooling constitute formidable obstacles to investment by the aerospace industry of the West.

OUTLOOK

On the basis of information available in mid-1992, the following scenario appears likely for the aerospace industry during the period 1991-2000.

The improvement of air traffic in 1992 announces a recovery for airline companies, following the worst two years in their history, during which they lost more than 6 billion USD. The growth of world air traffic - about 5% per annum - will be reflected in the world commercial aviation industry, which will begin to grow at something like the same rate. The industry in Europe will continue to grow faster than its biggest competitor, the USA, and its market share will grow from 25% to 33% of the world market.

Economic recovery in the world and the need to replace aircraft in service will keep activity going in business aircraft and helicopters, while the market for light aircraft will grow more slowly.

The markets for engines and equipment will continue to grow at the same rate as for aircraft. The market for aviation control equipment might indeed grow more rapidly, because of the investment needed to overcome the problem of air traffic control.

Sales of military aircraft will continue to fall as programmes are cancelled and defence budgets slashed, though modernisation of existing aircraft might go some way to check this decline;

The space market will continue to grow. In Europe, growth in the commercial segment of the space market might make up for the probable falloff in government programmes, par-

ticularly the large ones of the European Space Agency, such as the Hermès space aircraft and the Columbus space module.

In general, consolidation of the European aerospace industry will intensify.

Openness towards the countries of Central and Eastern Europe and the Independent States of the former USSR will provide fresh opportunities for industrial cooperation. Because of the strategic nature of the aerospace industry, and above all the enormous potential of the Russian aerospace industry - probably the biggest in the world - there will be no avoiding the question of cooperation. Some cooperation initiatives are in the making, but in view of the complexity of the present situation and the differing interests, the process will be a long and delicate one.

In the short term, the European aviation industry is continuing to expand in anticipation of long-term growth in the market. In addition to versions derived from existing programmes (Airbus A319, Fokker 130, BAe RJ, etc.) plans for an aircraft of very high capacity - 600-800 seats - due to be started in 1995 for entry into service after 2000 - are under study.

The industry is represented at the EC level by: Association Européenne des Constructeurs de Matériel Aerospatial (AECMA). Address: c/o Technopolis, 175 Rue Jean-Jacques Rousseau, F-92138, Issy-les-Moulineaux Cedex; tel: (33 1) 47 36 98 76; fax: (33 1) 47 36 83 04.

Instrument engineering
NACE 37

The instrument engineering industry is an extremely diverse sector with a wide range of products. Demand for the products differs accordingly. Some products are used in private households while others by industry, particularly in the manufacturing sector. The common feature of nearly all subsectors is the use of microtechniques, increasingly associated with data processing.
Increasing competition coming from outside the EC has recently caused the balance of trade to decline, particularly for photographic equipment and clocks and watches.
The outlook is good for those sectors of the industry where EC producers have remained strong and have increased automation efforts in production processes. Environmental concerns and an ageing population will give fresh impetus to a number of sectors within the industry.

INDUSTRY PROFILE

Description of the sector

The industry of instrument engineering (NACE 37) includes the following activities:

- the production of measuring, checking and precision instruments and apparatus (NACE 371);
- the production of medical and surgical equipment and orthopaedic appliances (NACE 372);
- the production of optical instruments and photographic equipment (NACE 373);
- the production of clocks, watches and parts thereof (NACE 374);

Due to its diversity, the instrument engineering industry is an important supplier to the manufacturing sector. The industry's goods are used in nearly all production processes (metal working industries, electrical engineering, mechanical engineering and others) to monitor and regulate production processes.

The industry's most important sub-sector is NACE 371 (measuring, precision and control instruments) producing roughly 40% of total industry's output, followed by medical devices (30%), optical instruments and photographic equipment (23%) and clocks and watches (7%).

Main indicators

In 1991, the industry sold about 35% of production to non-EC countries. Imports however, were well above exports during the last decade, resulting in a negative trade balance of about 15% of production. About 48% of EC demand was from countries outside the EC. While production increased during the last decade, employment remained constant as productivity rose sharply. The largest producer within the EC is Germany (West), with about 49% of value added, followed by the United Kingdom (18%), France (15%), Italy (10%). The remaining EC producers accounted for 7% of total EC output.

Recent trends

Demand increased during the former decade. The beginning of the eighties was characterised by a sharp rise in exports. A downturn occurred in the second half of the decade, however, as production growth slowed while rising demand caused a sharp increase in imports.

International comparison

The industry's most important producer is the United States. The performance of the main producing areas in the Triad (i.e. the EC, Japan, and the United States), however, varied considerably over the last decade. While production in the United States virtually stagnated during this period, production in the EC grew by 3.3% per year in volume and Japan experienced an average annual growth rate of 5.0%. Consequently, the share of US production in the Triad declined from roughly 60% in 1982 to 53% in 1989, and Japan increased its share in the Triads total from about 21% in 1982 to 30% in 1989. This performance was mainly the result of rapid growth in the measuring, precision and control instruments and the clocks and watches sub-sectors where Japanese firms nearly doubled their production during the period, while American production declined considerably. The EC's share declined slightly, from 20% to 18% for the same period.

Foreign trade

Products of the instrument engineering industry are subject to strong competition from extra-EC producers. While exports grew by 7.3% per year on average (in nominal terms from 1982 to 1991), imports increased by 10% per year for the same period. Consequently, the EC's trade deficit ballooned to a level more than seven times as large in 1991 as in 1982. Concerning imports, the most important competitors for EC firms were Japan, the United States and the EFTA countries, representing 80% of total EC imports. Despite the relatively low share of imports from developing countries (including the East Asian NIC's) at present, imports are likely to gain market shares in the EC. Increased NIC presence will be to the detriment of Japan, in particular, which has already lost about 8.5 percentage points of market share over the last five years. The most important recipients of products from the EC are the developing countries, with a total EC export share of nearly 30%. The EFTA countries and the United States each receive about 24% each of extra-EC exports.

MARKET FORCES

Demand

Demand rose 4.6% annually in volume terms from 1982 to 1991, with the latter half of the period growing at 5.6% annually. As the general field of instruments covers a wide field of diverse products, the demand pattern for its goods differs accordingly.

The growing use of electronic components (often in combination with data processing technology) is an important active force behind demand, a common feature for nearly all subsectors of the industry.

Other important factors which contributed to the favourable development of demand were: the upturn in industrial investment in the second half of the eighties, the necessity to become more competitive in preparation for the establishment of the common market in 1993, and the growing importance of environmental concerns which encouraged new applications for the field of instrument engineering.

The subsector of measuring, precision and control instruments credits its recent success to the developments mentioned above.

Figure 4: Instrument engineering

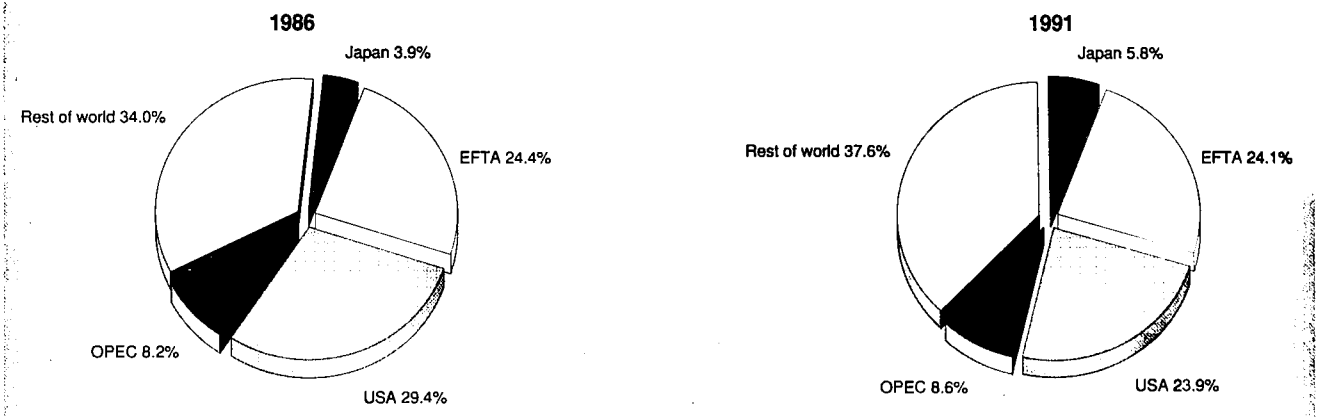
Figure 6: Instrument engineering
Destination of EC exports



Source: Eurostat

The wider use of precision instruments required for automation of production processes in the manufacturing sector also had a positive effect.

Optical precision instruments, a subgroup within optical instruments and photographic equipment was another beneficiary of increased automation in manufacturing processes. One of the best examples is the substitution of mechanical measuring methods with optical measuring methods, a trend which will give new impetus to this sector in the near future.

Demand in the field of spectacles, lenses, frames and mountings stems mainly from private households. Growth is supported by the increasing number of people wearing corrective glasses and by the latest trends in fashion. Demand for photographic and cinematographer equipment has been stimulated by new products development, the introduction of electronic processes, and the simplification of cameras. Such technological innovations are permitting firms to overcome market saturation. Demand for photographic and cinematographic equipment has also benefited from needs to monitor manufacturing processes.

In the field of medical and surgical equipment, increased demand for disposable and sterilised instruments, and new, specially developed bio-compatible materials. In addition, demand is increasing due to an ageing population and a more health consciousness society.

In the sector of clocks and watches and components, demand is linked to consumer expenditure. Demand will benefit more from fashion trends than technological developments (most of which took place more than a decade ago). One characteristic in the evolution of demand during the latter half of the 1980's was the gradual shift from the lower-end of the price range to the higher-end range. This trend is expected to continue in the future.

Supply and competition

The instrument engineering industry is confronted with strong competition from producers outside the EC. While consumption increased by 4.6% in volume, production growth was only 3.6% between 1982 and 1991. In the first half of the eighties, extra-EC exports grew considerably. The second half of the decade, on the other hand, was characterised by a rapid increase of imports from outside the EC, causing the trade deficit to swell to about 3000 million ECU in 1991. Most of the deficit was in the optical instruments and photographic equipment subsector (-1800 million ECU) and clocks

More than 99	641	2.0	55.0	62.7

Source: Eurostat

and watches subsector (-1700 million ECU). The only subsector with a positive trade balance throughout the last decade was measuring, precision and control instruments (600 million ECU). In this section, however, the surplus in extra-EC trade has been declining from a peak of 740 million ECU in 1985 to some 600 million ECU in 1991.

Considering instrument engineering as a whole, the market shares of the United States and the developing countries (especially the East Asian NIC's) in the EC increased in recent years. Although Japan lost market shares in the EC, the EFTA countries share remained fairly stable. A contributing factor to these developments could be the decline of the US dollar against European currencies, causing increased competitiveness of US products. The success of the developing countries in the EC market is mainly the result of the latters strong position in the production of low technology instruments at highly competitive prices.

The situation in the various subsectors, however, varies considerably. In the field of measuring, precision and control instruments, EC companies have a relatively strong position in technologically advanced products. The most serious competitor is the US, with about 40% of total EC imports. The photographic equipment subsector is dominated by Japan and the United States; EC production in this field virtually disappeared during the last decade. The few surviving EC suppliers are at a disadvantage to their competitors, whose large scale production insures lower costs and allows greater expenditures for R&D and marketing. Regarding clocks and watches, the situation is characterised by the strong penetration of Japanese and the South East Asian NIC's products in the lower price range, and of Swiss products in the luxury watch market. Of the EFTA countries, Switzerland is the predominant exporter to the EC, with about 70% of exports from this region. In the field of medical and surgical equipment and orthopaedic appliances, the main source of imports is from the United States, the world's largest supplier for this industry. Medical science in the United States, the most sophisticated in the world, explains the technological lead of their firms. In contrast to other instrument engineering subsectors, Japan plays a minor role in this field. On the other hand, imports from developing countries, including the South East Asian NIC's, seem to be increasing, particularly in less technologically advanced products. Low production cost in these countries seems to be the basic factor in this development.

Production process

Despite the fact that production has increased markedly during the last decade, employment has remained relatively stable. From 1982 to 1984, employment levels actually fell from about 330 000 to about 306 000. Moderate production growth was accompanied by large restructuring efforts in instrument engineering. Since 1984, production increased by nearly 4% per year in volume, while employment increased by roughly 1.3% per year. Productivity increased therefore during the last decade, by some 2.3% per year on average, a consequence of the growing pressures of competition.

A major change within the production process occurred with the introduction of electronic components; as a result, some producers restricted themselves to the assembly and design of their products, as they were not able to produce all components themselves. Given the strength of competition from the South East Asian NIC's, Japan, and the United States, one may expect that the trend toward lower labour inputs will continue, while capital inputs are likely to increase at a fast pace in the next near future.

INDUSTRY STRUCTURE

Companies

The EC instrument engineering industry is generally organised into small to medium sized firms. The largest group of firms, those employing less than 10 workers, represents about 78% of the number of firms operating in the industry. Another 20% of the firms have between 10 and 100 workers. Most of the firms are highly specialised in a particular area of activity; in general, they have few competitors within the European Community. Competition stems mainly from firms outside the EC. Given the low demand for their products, most of the firms are operating at least on the national level, although some are actually operating in the global market.

Apart from the large number of small, narrowly specialised firms, there also exists a small number of larger firms, offering a broad range of products, usually within one single subsector. A few of the large firms are operating in several sectors of instrument manufacturing. The German firm Zeiss, for example, is active in measuring, checking and control machines, and in the field of optical instruments. Other large companies are operating mainly in other branches, such as Siemens, which deals in optics and medical and surgical equipment and even metrology. Only 2% of the 31 760 firms in instrument engineering employ 100 or more workers. Nearly one-third of the workforce is employed by firms of 500 or more workers. These firms, however, account for about 42% of total turnover for the industry.

Strategies

As mentioned above, the EC instrument engineering industry faces strong competition from outside the EC. On the whole, the competition from abroad can in be divided into two categories: competition on technologically advanced products, mainly from the EFTA countries, the United States and Japan; and competition in the field of less technologically advanced standard instruments, produced mainly in the East Asian NIC's, including South Korea, Taiwan and Singapore.

To compete in the field of standard instruments, the efforts of EC firms have to concentrate on cost reduction and increased production efficiency. This could mean a greater rationalisation effort for production processes. Another strategy is the increased use of sub-contracting in order to transfer parts of the production process to lower wage countries. This latter trend is already evident in the clocks and watches subsector.

The position of EC producers in the field of technologically advanced products is stronger, but they will have to increase R&D expenditure in order to remain competitive in the future. The problem is, however, that the present structure of the

industry does not work in favour of EC firms, as they are often too small to finance the necessary R&D efforts. A restructuring of the industry towards larger firms would be advantageous from the perspective of R&D. Cooperation in the field of research and development, as well as in production, could also help this industry meet the challenges of competition from abroad.

REGIONAL DISTRIBUTION

The dominant EC producer in the instrument engineering industry is Germany (West), with about 42% of total EC output. A majority of the large firms are located there. The United Kingdom accounts for about 21% of EC production, followed by France with about 16%, and Italy with about 9%. The share of production for the most important countries in the EC has remained relatively stable during the last decade. Some of the smaller producing countries did increase their share of production, but still contributed only a small part to total EC production. In Ireland, the industrys production nearly doubled from 1985 to 1991, to reach about 5.2% of total EC production.

ENVIRONMENT

The instrument engineering industry does not normally burden the environment to any large extent, as production involves infrequent use of polluting materials. In the field of medical and surgical instruments and orthopaedic appliances, the main burden for the environment stems from the extensive use of packaging materials, in of disposable and sterilised instruments. To restrict environmental damages, an EC Directive requires that all packaging materials are to be recyclable or recovered by the year 2000.

In the field of optical instruments and photographic equipment, the situation regarding production is similar. There is, however, one source of damage to the environment from chemicals used in the production of films and their development, which can possibly contaminate soil and water supplies. Environmental concern for the clocks and watches industry focuses on the use of small batteries containing nickel-cadmium. These substances can also pollute ground water.

More important in this context, however, are the opportunities from which the industry may benefit. The increased attention given to environmental concerns will generate additional demand for several subsectors in the next few years, particularly for the measuring, precision and control instruments industry. Increased requirements for measuring and analysing equipment to investigate harmful effects, and to regulate and reduce environmental damage will provide this industry increased demand for its products. Similar opportunities are offered to the subsector of optical precision instruments, for which the industry of measuring, precision and control instruments is an important client. The use of optical methods to measure and regulate production processes and the output of polluting materials will additionally increase demand for its products.

REGULATIONS

A more general regulation which will affect the instrument engineering industry as a whole is the introduction of technical standardisation of machinery within the EC. The removal of the non-tariff trade barriers within the EC is further supported by the standardisation of metrological regulations, a particularly important element for the measuring, precision and control instruments industry.

In the field of medical equipment, the most important non-tariff trade barrier for European producers is the lengthy and costly process of sanctioning products in the United States. Another important regulation is an EC Directive which requires all medical devices or products sold in the EC to feature an EC stamp of approval, attesting to conformity with EC law.

Regarding environmental legislation, the foremost regulation concerns an EC Directive which requires all packaging materials be recycled or recovered by the year 2000 (for further detail, see Environment section above).

OUTLOOK

The outlook for the instrument engineering industry as a whole appears better in the long-term than in the short-term. The current weakness in investment activities is likely to affect demand for measuring, precision and control instruments, as well as for optical precision instruments, another investment goods supplier. Demand for goods of the subsectors (heavily dependent upon consumer expenditure), is also expected to decline slightly in 1992, as consumers are expected to remain cautious. In the long-term, however, prospects for nearly all subsectors of instrument engineering are quite good. In the field of measuring, precision and control instruments, prospects are favourable, as the increasing automation of industrial processes will increase demand for testing and measuring instruments. Environmental concerns are also likely to boost demand for these products. In the field of optical instruments, the pattern of demand is similar to that described above. Regarding photographic equipment, the outlook is somewhat more pessimistic as competition from the United States and Japan is very strong. Demand for spectacles, lenses and frames is expected to remain high in the coming years; the problem, however, is that health expenditure cutbacks in the industrialised countries are likely to negatively affect demand. The medical equipment sector faces a similar problem. In the field of clocks and watches, the long-term outlook is more encouraging, thanks to the development of new products, and the emergence of new markets. Still, EC firms in this area are confronted with strong competition from abroad.

Measuring, precision and control instruments

NACE 371

The upturn in measuring, precision and control instruments during the last decade was mainly the result of increased investment activities within the EC. In addition, the growing use of electronic components has aided the development for new generations of instruments.
The common market has substantially increased the trade between EC member countries. Competition from outside the EC has also grown, resulting in a decline of the trade balance which remains positive. The medium term outlook is quite favourable due to the improved economic situation and to environmental concerns which will give the industry additional fresh impetus.

Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The manufacture of measuring, precision and control instruments includes the following products:

- gas meters, water meters and other liquid supply meters (including petrol pump meters);
- measuring, checking or automatically controlling instruments and apparatus;
- equipment for navigation, hydrology, geophysics and meteorology;
- drawing and mathematical calculating instruments;
- precision and measuring instruments;
- precision balances, laboratory equipment and teaching equipment;
- other precision equipment and apparatus.

In general, the activities of the industry are organised into small and medium-sized companies, concentrating their activities on one or two products. A few large companies, however, produce a broad range of products in different fields of instrument engineering, a number of them engaged primarily in other fields of manufacturing, such as consumer electronics, computers and motor vehicles.

Main indicators

The sector of measuring, precision and control instruments is the most important branch of instrument engineering, producing about 40% of the output for the entire industry and employing about 40% of its workforce. The largest producer among EC member countries is Germany (West), with more than 50% of value added. About 22% of EC production is exported to non-EC countries. The export orientation of the industry is illustrated by a positive trade balance, however, has been declining during the last decade.

Recent trends

Demand for the products of this industry (as measured by apparent consumption) more than doubled in value during the last decade. In the first half of the eighties, production growth was consistent with demand development. In the second half of the decade, however, production growth declined considerably, a consequence of slower export growth and a rise in imports.

International comparison

The comparison of the production figures between the United States, Japan and the EC, shows, that the United States remain the most important producer of measuring, precision and control instruments. The fastest growth, however, was experienced in Japan which overtook EC production in 1990. The Japanese share of triad production increased from 17% in 1982 to 30% in 1991, to the detriment of US production, which declined from 59% of triad total output in 1982 to 43% in 1991. The EC share of triad production increased from 24% to 27% for the same period.

Foreign trade

In parallel with fast increasing demand over the last decade, EC manufacturers have been confronted with ever stronger competition from abroad. As extra-EC imports increased faster than EC exports, the trade balance deteriorated somewhat, though still remaining positive. Declining import prices, responsible for an increase of the terms of trade in recent years could be one explanation.

The largest share of extra-EC exports is taken by developing countries, including the East Asian NIC's, a potentially dynamic market. The United States and the EFTA countries

are also important markets for EC manufacturers, while Japan remains of secondary importance.

Concerning imports, the largest supplier is the United States with about 40% of the total. Imports from Japan still present only about 12%.

Intra-EC trade more than doubled in value during the last decade. Consequently, intra-EC trade increased slightly compared to imports from abroad.

MARKET FORCES

Demand

The industry covers a wide range of products, with demand across the entire range of the manufacturing and service sectors, not to mention private consumption. Measuring, checking and controlling instruments are used to automate, control and regulate production processes. The most important areas of application are not only in the areas of machine construction, vehicle production, and environmental protection, but also in the chemical, pharmaceutical and food industries. In the field of instruments for navigation, hydrology, geophysics and meteorology, the aircraft and shipbuilding industries are the main clients. The industry of weighing instruments (producing analytical, chemical and precision balances), is involved in industrial uses, as well as in wholesale and retail trade.

As a result of a fast changing environment, demand for measuring, precision and control instruments increased constantly in recent years. The growing use of sensors, the replacement of mechanical devices by electronic components and the requirements of system integration (including hook ups with data processing systems) have stimulated the production of new generations of instruments. In particular, the automation of industrial processes using data processing systems to allow the automatic readjustment of filling, dosing and conditioning processes has given fresh impetus to the industry.

The introduction of new technologies has also led to a shift in demand. For example, the favouring of electronically regulated products to mechanically regulated instruments has caused a decline in the latter's production. For example, the share of electronically controlled products in the weighing industry is now above 90%.

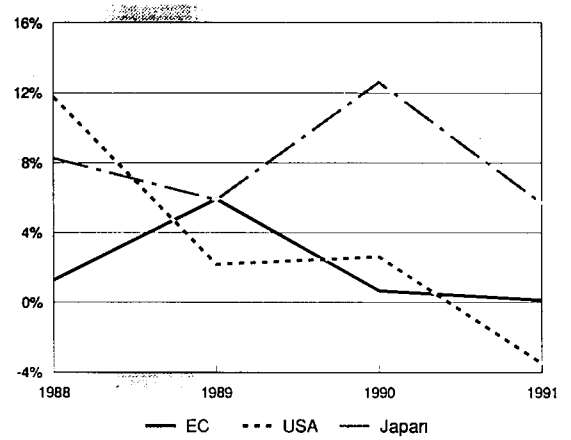
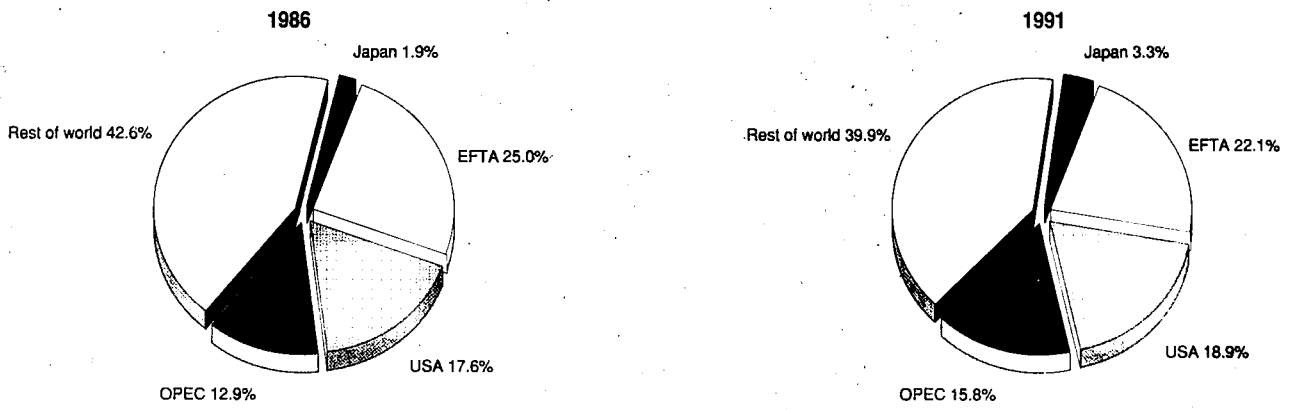
Figure 5: Measuring, precision and control instruments
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Figure 6: Measuring, precision and control instruments
Destination of EC exports



Source: Eurostat

Apart from technological aspects, the recent upturn in demand for measuring, precision and control instruments was the consequence of a considerable increase in investment activities in the manufacturing sector. Reasons for the upturn in investment include the necessity to modernise in order to stay competitive, an increasingly open economy, high levels of capacity utilisation, a healthy economic climate, and positive expectations of the manufacturing sector in context with the EC market in 1993.

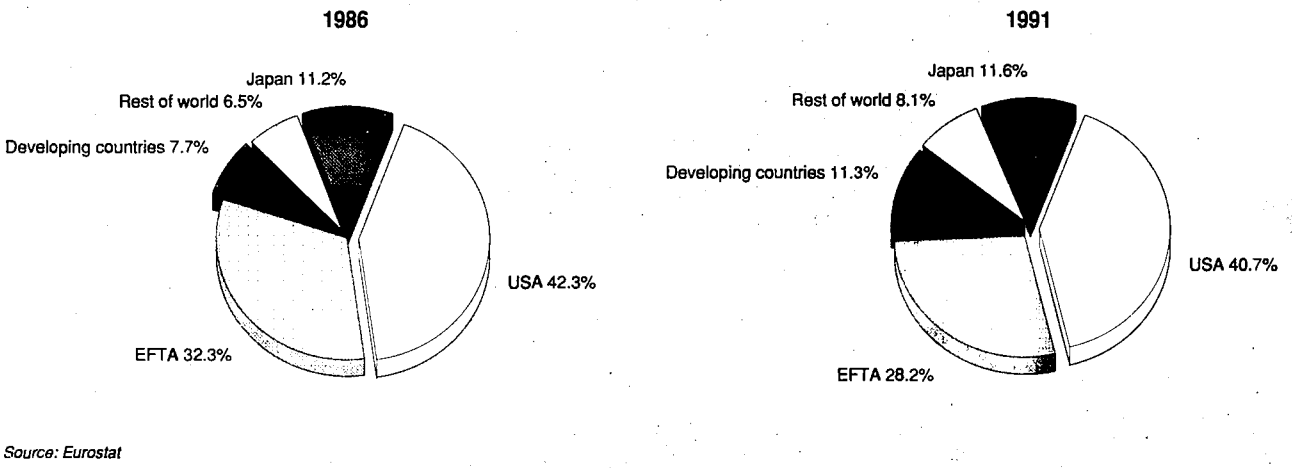
Supply and competition

Over the last decade, the production of measuring, precision and control instruments in the EC grew by an average annual rate of 7.6% in nominal terms. In the United States, in contrast, production recently declined, after a strong performance in the first half of the 1980's. Furthermore, EC manufacturers managed to increase their exports to the USA at a fast pace, thanks mainly to a faster pace of technological innovations compensating for the disadvantage of higher prices due to the decline of the US Dollar in recent years. On the import side, the United States remains the most important competitor to EC manufacturers, but the share of US imports has yielded to imports from Japan and the East Asian NIC's.

From 1982 to 1991, the most remarkable development was experienced by Japanese manufacturers of measuring, precision and control instruments with an average production growth of 13% per year in value. While the share of imports from Japan is still relatively low, it seems likely, that Japanese manufacturers will become more serious competitors in the future. In the weighing industry for example, competitors from Japan are making efforts to penetrate the retail trade market through a policy of price dumping. Such a development could be reinforced by the present decline of the Yen against EC currencies. Another element could be differences in the industrial structure between Japan and the EC. While EC enterprises in this sector are usually small to medium-sized, Japanese enterprises are often larger, which allows them to benefit from an abundance of capital for research and development and, possibly, from synergies and economies of scale. Also, the advent of the common market in 1993 has spurred efforts by the Japanese firms to get a foothold within the EC. In the weighing industry, for example, TEC and ISHIDA already have operations in EC countries, mostly in the United Kingdom. Additional competition for EC manufacturers can also be expected by countries of the East Asian NICs, which are highly competitive producers recognised for lower labour and lower capital costs.

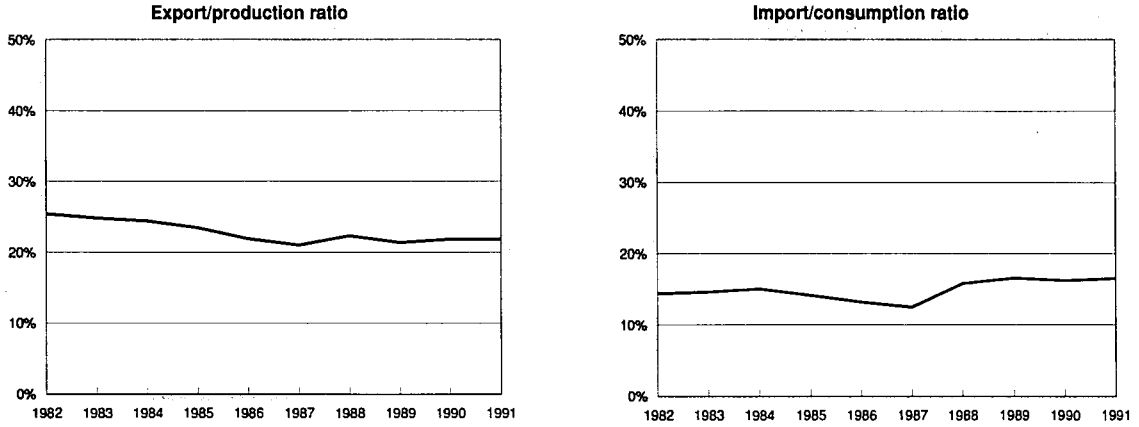
Trade between the EC countries from 1982 to 1991 grew faster than consumption, 8.8% per year on average against consumption growth of 8.3%. The most important exporter

Figure 7: Measuring, precision and control instruments
Origin of EC imports



Source: Eurostat

Figure 8: Measuring, precision and control instruments
Trade intensities



Source: Eurostat

within the EC is Germany (West) with about 32% of intra-EC exports, followed by the United Kingdom with 16%, and France with 15%. The main importer of products of the within the EC is France with about 21%, followed by Germany (West) with 20%, Italy with about 14% and the United Kingdom and the Netherlands with about 11% each. Important driving forces behind the increase of trade between EC members were the technical standardisation of machinery within the EC, and the growing number of cross-border corporate partnerships in expectation of the integrated EC market. This trend is expected to be reinforced during the next few years by an EC directive removing non-tariff trade barriers such as differing metrological regulations in each country.

Production process

The introduction of electronic components has also altered the relation with up-stream industries. Formerly the production of mechanically regulated measuring, precision and control instruments required the input of raw or partially processed materials which were then converted to high-value added products. With the introduction of electronic components, however, manufacturers could no longer produce most parts of their products themselves. The consequence was an increase in subcontracting, particularly with electronic companies. In some cases, producers of instruments have reduced their contribution to the tasks of assembly and design of their products. This development was responsible for a shift of know-how from the manufacturers to their subcontractors. The trend for increased integration with data processing systems is still ongoing. In the sector of precision mechanics, the integration of data processing achievements has opened up new possibilities in drawing and design technology. Similar developments are also taking place in the fields of analysis equipment, process control systems, transducers, measuring devices and other measurement systems and sensors.

Changes also occurred in the production process itself, where modernisation and automatisation were responsible for increased production efficiency. Labour productivity, measured by the value of output (value added) by unit of labour, grew by an average 2.0% per year over the last decade.

INDUSTRY STRUCTURE

Companies

As a result of a high level of specialisation in the industry and the relatively shortness of production runs, most of the industry is concentrated in small to medium-sized companies. Depending on the product line, the structure of the industry varies. In the weighing industry for example, there are about 350 firms, employing some 20 000 people; the size of the enterprises there ranges from firms employing only a few people to firms employing several thousand. Important companies in the weighing industry are Bizerba in Germany, and GEC Avery in the United Kingdom.

The enterprises in this industry are usually active only in the national market, at least as far as small and medium-sized companies are concerned. Other subsectors, such as the counting industry are concentrated mainly in medium to large manufacturing firms. A similar picture is found in a branch of the measuring, checking and controlling machines sector, which is fairly concentrated with about 80 suppliers worldwide. The main EC producers are Zeiss of Germany, Renault Automation and Tri Mesures of France, and Italy's Dea. In measurement and automation technology, about 85% of the firms are small to medium-sized, with up to 200 employees and a few larger firms with more than 1000 employees. Important firms in this sector are Hartmann & Braun and Endress & Hauser in Germany, and Foxborro (taken over by Siebe), in the United Kingdom.

In the last few years a shift in marketing strategy for the industry has evolved. Most companies are now forced to operate at least on a pan-European level, while larger firms will operate on a global level. The tendency to globalise is likely to increase in the near future, as the EC wide market becomes fully operative and overseas markets open up.

Strategies

As already mentioned, international competition will continue to increase in the foreseeable future. In the fields of highly sophisticated products, EC producers will face a fast pace of technological innovation, imposed mainly by Japan, but also by the United States and the EFTA countries. In the field of less technologically advanced products (i.e. the more standard instruments), increased competition can be expected from the East Asian NIC's, who are very competitive in terms of prices. Finally, cross-border competition within the EC is

expected to increase as already mentioned. In the fields of standard instruments, EC firms will need to invest in modernisation and automatisation of the production process, to improve production efficiency and to reduce costs to counteract the effect of higher labour costs (as compared to labour costs in the East Asian NIC's).

In order to remain competitive in the field of highly sophisticated products, EC firms have to increase their R&D expenditures considerably; the problem is, however, that a very high cost strategy cannot be financed by small or medium sized companies. A higher degree of concentration is thus becoming imperative if the industry is to survive and to prosper. Changes in that direction have already been happening. In the weighing industry for example, Toledo has been taken over by Mettler, GEC Avery took over Berkel and Testut has bought Trayvou and Lutrana. In industrial process control, changes have occurred with the takeover of Foxboro by the British firm Siebe, which has thus become the world's second largest producer of these types of instruments, behind Honeywell. At the beginning of 1990, the Italian company Elsag, after selling Bailey Controls to the American Babcock Wilcox Group, bought the Sereg division of Schlumberger. In 1989, CGE-Alsthom took over the industrial control operations of the British GEC.

Another possible strategy, (particularly for specialised niche products) is for the smaller firms to increasingly limit their activities to design and assembly, while upstream activities (i.e. components production) and even marketing and service are subcontracted to other firms.

REGIONAL DISTRIBUTION

The leading producers of the measuring, precision and control instruments are the United States, with about 45% of world production, followed by Japan with about 28% and the EC with about 26%. Within the EC, Germany is the most important producer (about 40% of the EC total), followed by the United Kingdom (34%), Italy (12%) and France (5%).

ENVIRONMENT

The production process for the manufacture of measuring, precision and control instruments has very little impact on the environment. More important in this context are the opportunities that will benefit the industry emanating from the growth of environmental concerns for manufacturing processes and utilities. Developing needs for measuring and analytical equipment for gas, vapour, dust and noxious substances in water and for apparatuses to investigate harmful effects on man, animals, plants, soil and food will provide the industry with growing demand for its products. Beyond this initial source of demand for an identifying and monitoring apparatus, the demand for instruments to regulate and reduce environmental damage (for instance, the provision of gas desulphurisation systems) will also develop. The competitiveness of EC industry in the field of environmental protection systems should be rather good, given that environmental concerns have traditionally been particularly important in most EC countries.

REGULATIONS

As mentioned above, the technical standardisation of machinery within the EC should ease trade between EC member firms. Another EC directive should remove non-tariff trade barriers still caused by different metrological regulations in each country.

In the field of electronic weighing machines, the Commission has issued anti-dumping duties on imports from a number of Japanese firms. Similar measures are being considered regarding electronic weighing machines produced in South Korea and Singapore.

OUTLOOK

Prospects for products of the measuring, precision and control instruments industry are quite good in the medium to long-term. In the short term, however, the outlook is rather pessimistic. Investment activities in the short-term are expected to remain moderate as many firms are still not operating at full capacity following rapid expansion during the 1980's. Given the economic recovery expected in the near future, demand and production will return to a stable growth path. Rapid technological change, the onset of the common market, the development of new markets in South East Asia and the growing weight of environmental requirements in manufacturing and service industries will all invite increased production of the industry's products. EC firms, however, will have to brace themselves for increased competition from abroad. The advent of an era of free movements of goods in the EC market opens a huge market to fierce competition from manufacturers. A major consideration is whether or not extra-EC countries vying for a larger share of the EC market will be compelled to open their own markets to competition. If not, the industry in the EC is likely to lose market share within its own market, without strengthening its presence abroad.

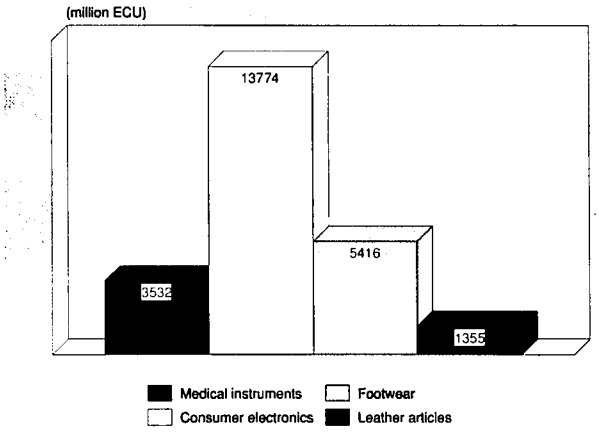
Medical and surgical equipment and orthopaedic appliances
NACE 372

An ageing population and increasing health consciousness of the population in general are the most important driving forces of a strong expansion in health spending. Consequently, the industry of medical and surgical equipment and orthopaedic appliances in the EC experienced a strong period of growth in recent years. The main competitor of EC firms is the United States, which dominates the world market with technologically advanced products. Lately, EC manufacturers have seen their share of world production fall. In order to stay competitive, EC producers will have to increase their R&D efforts.

Figure 1: Medical and surgical equipment and orthopaedic appliances
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The sector of medical and surgical equipment and orthopaedic appliances includes the following activities:

- manufacture of medical apparatus for diagnostic work;
- manufacture of medical, surgical and veterinary equipment and instruments;
- manufacture of dental instruments and apparatus;
- manufacture of orthopaedic appliances, artificial limbs, eyes, teeth, etc.

The sector does not include orthopaedic footwear (refer to NACE 452). X-ray apparatus and electro-medical instruments, including electro-medical diagnostic equipment, electro-medical treatment, electro-dental instruments, electrical hearing aids and pacemakers are also excluded (refer to NACE 344).

The industry in the EC is characterised by a large number of small enterprises, usually specialised in narrowly defined niche markets, often producing a small number of closely related products. The few medium-sized and large firms in the industry produce a broad range of devices, exclusively in the field of medical equipment.

Main indicators

The medical and surgical equipment and orthopaedic appliances industry represents about 30% of total production for the entire sector of instrument engineering. The most important producer in the EC is Germany (West), with more than 50% of the total value added, followed by France (18%), the United Kingdom (15%) and Italy (10%). About 34% of EC production is exported to countries outside the EC. Meanwhile, the industry in the EC faces increasing competition from abroad. After posting surpluses in the mid-eighties (a positive trade balance of about 10% of production), the trade balance turned negative in 1991. Employment in this industry increased between 1982 and 1991 at an average annual rate of 1.8%.

Recent trends

In the development of the industry during the last decade, one may distinguish between two different phases. The first half of the eighties was characterised by the fast growth of extra-EC exports, which also permitted rapid production growth. In the second half of the eighties, the situation changed: while extra-EC exports grew slowly in volume, imports kept growing, capturing an ever increasing share of the EC market.

International comparison

The United States were and have remained the world's largest producer of medical and surgical equipment and orthopaedic appliances. The EC is far behind with a volume of about 30% only of the US production. Japan is a distant third with production about one-third lower than the EC's. Potentially, therefore, US firms are the most serious competitors of EC companies in the industry. But the United States also comprises the largest potential market for EC exports, as consumption is about three and a half times that of the EC. At present, EC imports from the USA are more than twice as large as EC exports to the USA.

Foreign trade

During the last decade, extra-EC trade outgrew production. While exports grew by approximately 11% per year in nominal terms, imports increased by nearly 15% per year for the same period. Consequently, the EC trade balance since 1985 has deteriorated. In 1991, it was negative for the first time during the period considered. Important trade partners for EC companies are the United States, the EFTA countries and, to a

smaller extent, Japan. EC exports to the United States actually stagnated between 1985 to 1990, but exports to Japan more than doubled over the same period; exports to the EFTA countries increased considerably as well. Considering imports, the most important source is the United States, with about 50% of the total. Over the last few years, intra-EC-trade enjoyed growth of about 15% per year in nominal terms.

MARKET FORCES

Demand

During the last decade, the industry enjoyed a rapid growth in demand of around 7% per year in real terms. One reason for this development is the increase in demand facing the health industry due to the ageing of the population as well as to increased health consciousness by the population in general.

Product innovation represents another important factor in the increase of demand over the years. As new findings in medical science and technology find their way more and more rapidly into practical applications, the role of product innovation for developing demand becomes increasingly crucial. In the field of diagnostic apparatus, the implementation of data processing systems for analysing results has widely expanded the product range. In this era, a new method of endoscopic treatment has been developed, minimal invasive surgery. Under endoscopic view, treatments are conducted by high frequencies or lasers, with minimal damage. Further developments are occurring in the field of anaesthetic devices, where the identifying, measuring and monitoring of anaesthetic gas is now supported by data processing systems. Quantitative demand of medical devices for operative and postoperative treatment has greatly increased with the growing tendency to use disposable and pre-sterilised instruments. In the field of prosthetic and orthopaedic devices, bio-compatibility has become a major priority, leading to the development and utilisation of new materials and production processes.

Due to the increasing use of disposable instruments and to the smaller volume and easier use of modern medical equipment, many treatments can now be given in units or at home. This enables substantial savings as hospitalisation can be shortened or avoided all together, reducing staff requirements. The spiralling growth of health costs in all developed countries,

Source: Eurostat

however, is triggering revisions in national health policies. Such measures include putting caps on public costs by transferring an increasing share of costs to the patients, and by encouraging competitive bidding to push down prices. The developments will inevitably have a negative effect on demand for the industry's products.

Supply and competition

As the world's largest producer of medical and surgical equipment and orthopaedic appliances, the United States is also the most important competitor for EC producers. Imports from the United States represent over 50% of total EC imports. This is to be expected if one considers the size of the US domestic market, which consumes 55% to 60% of total world demand. One explanation for the United States' leading position its substantial commitment to medical research and development. The decline in exports of EC countries to the United States in recent years may have been caused by lags in the pace of innovation. An additional hampering factor resides in the lengthy and costly process of sanctioning a product in the USA, often an insurmountable obstacle for small or even medium-sized firms with little financial muscle.

Until now, Japan plays a relatively minor role in the EC trade of the industry's products. EC exports to Japan are about 9% of total EC exports; but about 13% of EC imports come from Japan. This share has declined during the last five years. Imports from the East Asian NIC's are likely to increase (particularly in the field of relatively lower value-added instruments), where these countries have production cost advantages. Examples are standard instruments from East Asian NIC's and Pakistan, as well as blood pressure measuring instruments from Japan.

Intra-EC trade grew from 702 million ECU in 1982 to 2514 million ECU in 1991. This corresponds to an annual average growth rate of 15% in value, well above production growth (10%). One reason for such rapid growth is the technical standardisation within the Community and the more rapid approval of products. This trend can be expected to continue in the future with the adoption of an EC Directive establishing the characteristics required for various products which will enable their free movement in the EC.

Production process

In 1991, about 96 000 employees in the EC were involved in the production of the industry in the EC. Employment has averaged an annual growth rate of 1.8% for the last decade. As value added during the same period increased at an average rate of 4.8% per year, this represents a relatively fast rate of productivity growth of 3% per year, mainly the result of increased efforts by firms to modernise their equipment and

Figure 7: Medical and surgical equipment and orthopaedic appliances
Origin of EC imports

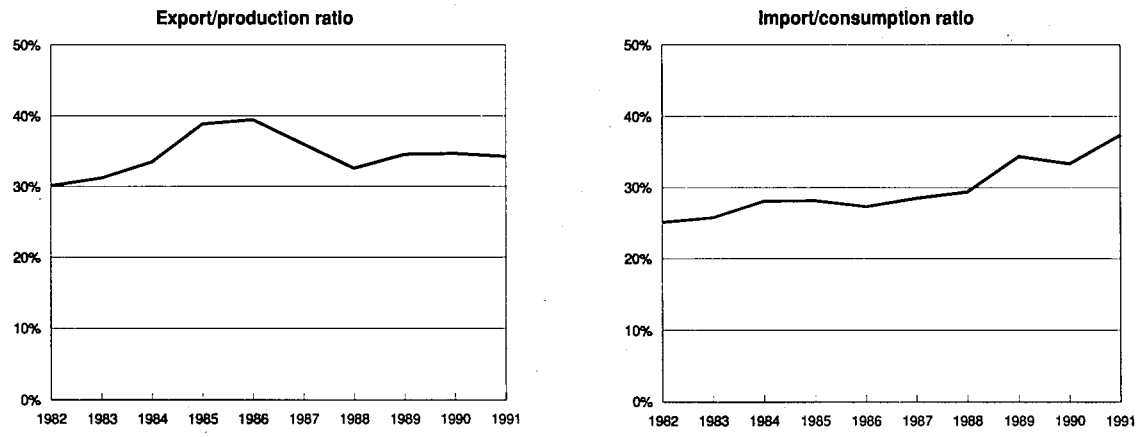
Figure 8: Medical and surgical equipment and orthopaedic appliances
Trade intensities



Source: Eurostat

automate their production process to reduce workforce requirements, a must in the face of rapid increases in unit labour costs.

INDUSTRY STRUCTURE

Companies

The enterprises of the industry in the EC are mostly small to medium sized. There is a large group of small firms, each with less than 250 employees which produce very specialised products to satisfy the heterogeneous demand characteristics of the sector. As a consequence of their narrow specialisation, exports are very important for these firms, as their national market is often too small to ensure survival. The share of exports on total EC production is about two-thirds, one-half of which is intra-EC exports, the other half is extra-EC exports.

In the field of anaesthetic apparatus and equipment, the most important firms are the Draeger Werke in Germany, Air Liquide in France and Ohmeda and British Oxygen in the United Kingdom, all which are not only present in a number of countries in the EC, but also in the United States. In the field of small instrumentation, Germany has a large number of small firms each with about 100 employees, producing approximately 50% of the total world production. Germany's Aesculab is one of the few large companies in this area. Among the other EC producers, the structure of the small instrumentation industry is similar. In the field of operative and postoperative treatment, important firms are Germany's Beiersdorf and Braun. In orthopaedic appliances, there are about 70 firms in the EC employing a combined total of nearly 2500 employees. The most important are Smith & Nephew in the United Kingdom, Dow Corning in France, Otto Bock, Aesculap, Waldemar Link and the Gebr. Martin in Germany. Another important firm is Italy's Sorin, which belongs to Fiat and is specialised in dialysis machines and cardiographs.

The world's largest supplier of health care products, however, is the US firm Baxter, producing in nearly all sectors of medical equipment, (e.g. blood bags, apparatus for diagnostic work, medical dressings, infusion sets, surgical gloves and more). Other important US firms are 3M, Johnson & Johnson and Abbott Laboratories, mainly producing infusion sets and catheters, medical dressings, implants, dental materials and diagnostic devices.

Strategies

EC producers face strong competition from outside the EC, mostly from the United States, as a consequence of technological advantages. The EFTA countries also pose a competitive threat. In the field of standard instrumentation, competition stems mainly from Japan and the East Asian NIC's.

Technical standardisation within the EC is expected to strengthen competition from abroad, since US and Japanese competitors will no longer be forced to adapt their products to the differing requirements of various EC countries. This standardisation, however, will also enhance the capability of EC producers to increase their share of intra-EC trade.

The strategies of EC firms producing standard instruments will continue to be oriented towards cost reduction through the modernisation and automation of production processes. Even so, EC producers may still not be able to lower production costs to the level of their competitors from the East Asian NICs. The result may lead to a loss of market shares not only in the EC, but in other export markets such as Eastern Europe.

In the field of highly sophisticated products, however, the position of EC producers is better, as they have better access to technological innovations. Such innovations however, require increased investments in research and development. For example, R&D investments for most German firms presently represent about 6% to 12% of turnover.

Another problem concerns the weak link between scientific research and industry in the EC. At present, time lags between scientific discoveries and their application to industrial production of a new product may be very long, particularly when compared to the USA.

High levels of R&D expenditure, however, can hardly be expected from small or medium sized firms. The strategy for these firms will have to be the production of very client-specific products designed for small niche markets. Another possibility is a consolidation into larger firms, or at least cooperation in research and development.

REGIONAL DISTRIBUTION

The main producer of medical and orthopaedic equipment in the EC is Germany with about 51% of production. France and the United Kingdom each produce about 16%, followed

by Italy with 11%. The German domestic market offers many opportunities for the industry, as Germany maintains an active policy of promoting modernisation of medical equipment. It is estimated for example, that equipment for dental practises is renewed in Germany twice as often as in France.

ENVIRONMENT

The problems of the industry regarding environmental issues are not usually found on the production side. An important issue is the disposal of waste in the form of packaging materials used in ever increasing quantities for sterilising instruments as well as for single-use disposable devices. An EC directive requires all packaging materials be recycled or recovered by the year 2000.

REGULATIONS

As is the case for all health products, the process for product approval in the United States represents a non-tariff trade barrier. Besides the above mentioned EC directive, another directive planned for July, 1994 will require medical devices and products distributed in the EC to feature an EC stamp of approval attesting to its conformity with EC law. Free movement within the EC is allowed once the product has been shown to be in compliance with the provisions of this Directive. Another EC directive which is coming into force in January, 1993 is related to active implantable devices which will require the EC stamp for free distribution within the EC.

OUTLOOK

The outlook for the industry is quite good, as continuous ageing of the population will sustain demand for all health related instruments. East European countries also offer a huge potential for demand growth as their economies develop. Conversely, EC producers face a number of risks, such as increasing competition from US producers due to their huge domestic market and traditional R&D advantage. The second risk is the EC market in 1993 and the risks emerging from product standardisation. The opening of borders between EC member countries, however, also presents an opportunity for EC producers as the size of their domestic markets increases.

Optical instruments and photographic equipment
NACE 373

World production in the industry of photographic equipment is dominated by the United States and Japan. EC firms are the leaders in optical precision instruments and sight correction products, thanks to their high technological standards.

INDUSTRY PROFILE

Description of the sector

The industry of optical and photographic equipment covers the following sectors:

- spectacles, lenses, frames and mountings, also including equipment for use by opticians;
- optical precision instruments (other than opticians items);
- photographic and cinematographic equipment.

Optical precision instruments in the EC are frequently produced in firms active in the whole sector of instrument engineering, mainly in the field of measurement technology, since the latter plays an increasingly important role in the application of optical technology.

Main indicators

The EC industry of optical instruments and photographic equipment represents about 23% of the larger sector of instrument engineering, with Germany as the most important manufacturer (44% of EC output in terms of value added). About 52% of production is exported to countries outside the EC. The main feature of the industry, however, is the strong market penetration of non-EC producers which is reflected in the large trade deficit of the industry (equivalent to about 33% percent of production in 1991).

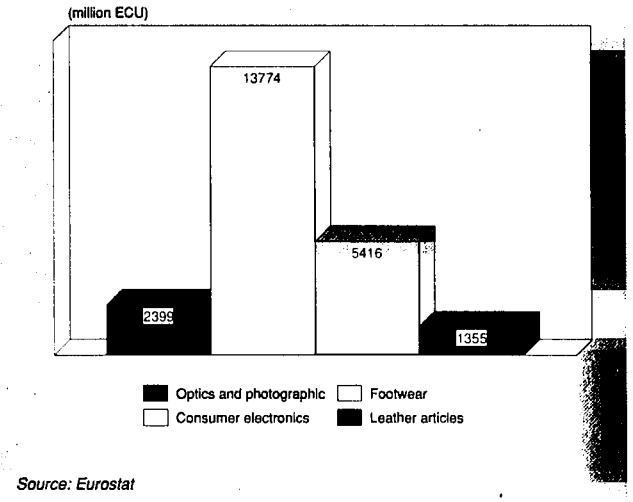
Recent trends

Demand for products of the industry increased considerably from 1982 to 1991, with EC production lagging somewhat behind. But the pattern of development did vary somewhat over time. At the beginning of the eighties, demand in the EC evolved at a relatively moderate pace, and production growth was stimulated by strong demand from outside the EC. During the second half of the eighties, on the other hand, EC consumption increased at a fast pace, while production lagged behind, resulting in increased imports from outside the EC.

International comparison

The United States are the most important manufacturer of optical instruments and photographic equipment; Japan's production represents about 40% of US production, while EC production stands at 25% (in 1991 figures). The development of production over the last decade varied considerably between these three regions. While the United States experienced a production decline of 5.5% per year from 1982 to 1991, in real terms, with a particularly sharp decline after 1985, Japan and the EC managed to increase their production over the same period at an annual rate of 1.7% and 3.1% respectively. Therefore, the share of US production from the total declined from 68% in 1982 to 60% in 1991, to the benefit of Japan (with an increase from 21% to 24%) and the EC (with an increase from 11% to 15%).

Figure 1: Optical instruments and photographic equipment Value added in comparison with other industries, 1991



Source: Eurostat

Foreign trade

Extra-EC exports of EC producers increased by an annual average growth rate of over 6% per year in the last few years. The most important recipients of EC products are the United States and the EFTA countries. Imports from outside the EC, on the other hand, increased by 8.7% per year for the same period, with the consequence that 64% of demand was satisfied by imports in 1991. The consequence was a sharp deterioration in the balance of payment, with the deficit growing 14% per year in nominal terms from 1982 to 1991. The lion's share of imports into the EC was taken by Japan, with more than half of total extra-EC imports. During recent years, however, Japan has lost market share in the EC in favour of the East Asian NICs and the United States (about 20% of EC imports in 1991).

The most dynamic development took place at the level of intra-EC trade, with an average annual growth rate of 11% in the period considered here. As a result, intra-EC imports as a proportion of total imports increased from 47.5% in 1982 to 52% in 1991.

MARKET FORCES

Demand

Demand for products of the optical instruments and photographic equipment industry increased considerably during the last decade. In real terms, EC consumption grew by an average rate of 3.6% per year from 1982 to 1991. As the industry as a whole covers a number of subsectors responding to different demand patterns, the analysis needs to be broken down by product types.

In the field of spectacles, lenses, frames and mountings, increasing demand stems both from the increasing number of people wearing corrective glasses, and from fashion considerations. In line with the ageing of the population, the number of spectacle wearers has been increasing steadily during the last years. In Germany for example, about 50% of the population are now wearing spectacles and lenses.

Furthermore, since the wearing of spectacles has become subject to fashion trends, customers are more and more switching to high quality products, as well as to more than one pair of spectacles (or lenses) for different personal uses. Technological developments of the quality of the glasses, that lead to a rise in prices, also contributed to the positive trend in demand for goods of the ophthalmic industry. Another development over the last years was the substitution of plastic materials for glasses in the production of lenses. From 1989 on, demand for products of the ophthalmic industry in the EC declined, due to changes in refund policies of social security systems.

In the field of optical precision instruments, the main outlet is in industrial processes, to improve testing and measuring methods. Particularly important is the sector of measuring, precision and control instruments, where often optical methods have replaced the mechanical process of measuring. In some cases, advanced optical technology in industrial processes may allow to take precise measurements, without having to make contact with the object. It includes opto-electronic process control and sensor technology, microanalytic equipment, multiple co-ordinate measuring machines and high power telescopes. Laser technology is used for soldering and automatic sheet cutting in the car industry and in the aerospace sector, but also in medical technology to treat materials, as well as to perform endoscopic surgery. Technological innovations and

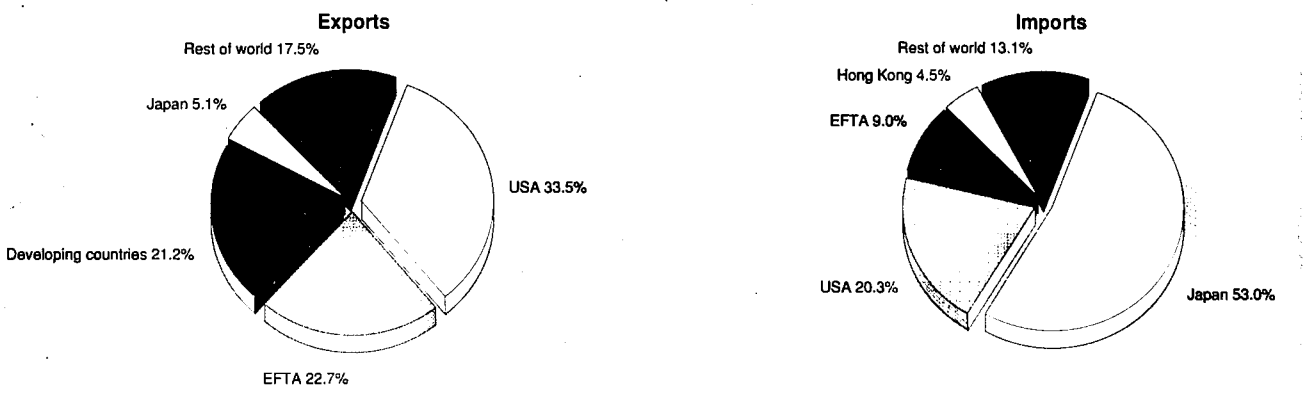
Figure 6: Optical instruments and photographic equipment
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

increased investment activities in manufacturing have been the driving force behind the favourable development of demand in that area of the industry.

In the field of photographic and cinematographic equipment, demand stems mainly from private households, but also from specific industrial branches. In the sector of photographic apparatus, product innovation was the driving force behind the continuously thriving demand of the last years. The introduction of electronics was responsible for a move to electronically regulated cameras, with a decreasing share of mechanical parts. Technological improvements, intended to make sophisticated cameras more user friendly as well as to improve the quality of the pictures, has permitted to offer cameras with features such as autofocus, autorewind and autoflash. These last years however, there appears to be a trend among customers to shy away from highly sophisticated cameras, towards simpler, handier or even throw-away models. At present, demand exhibits a downward trend, as a result of high equipment rates and "innovation fatigue" among customers. The loss of markets in Eastern Europe has also reduced world demand. Another field of demand is the use of state-of-the-art special cameras and lenses in aerial and space photography, traffic and bank hall monitoring, medicine and science, as well as in studio and press photography. Demand for photographic and cinematographic equipment is also supported by the growth in importance of communication systems: transmitted images, videos and communications all require photographic or related equipment.

Supply and competition

Despite the fact that production both in Japan and the United States fell after 1985, due to the gradual maturation of their markets, both producers are trying to supply the still increasing demand for optical instruments and photographic equipment in the EC, inadequately supplied by EC producers. Imports from these two countries and increasingly also from the East Asian NICs more than doubled from 2 203 million ECU in 1982 to 4 663 million ECU in 1991 in current prices.

The few EC survivors in the field of photographic equipment can hardly hope to compete with Japanese and the USA producers, which are highly competitive in prices, as a consequence of their large scale production. In particular, Japanese producers such as Canon, Olympus or Nikon are extremely efficient in both production and marketing and their size allows them to invest heavily in research and development.

In the field of optical precision instruments, the situation is characterised by the strong position in export markets of EC firms producing state-of-the-art technology. The most important export market for these products are the United States, where competition is mainly between EC producers.

In the field of spectacles, EC firms are in a leading position worldwide. In the production of fashion frames, in particular, France and Italy are strong exporters thanks to their excellent image abroad. In the production of spectacles, Germany is very successful on foreign markets. However, competition from Japan and East Asian NICs is on the rise; imports of frames from the East Asian NICs have increased, as a result of their price competitiveness, following the lower production costs. Japan is lately becoming a more serious competitor in the field of spectacles, since the MITI in Japan is encouraging research and development activity in this subsector, to supply rapidly increasing demand from the ageing population.

As a result of enhanced intra-EC trade, competition between EC Member Countries is on the rise. In the field of optical precision instruments, the high degree of specialisation of each firm forces producers to search for additional markets abroad, as national markets for their products are too small to permit them to reach the critical size necessary to render production profitable. France and Italy have become specialists mainly in the field of spectacles, and Germany and the United Kingdom in the field of precision optics. Intra-EC competition is likely to increase even more in the next few years, once impediments to trade, that still exist, are fully eliminated on the internal market.

Production process

Employment in the industry has only changed to a small extent during the period 1982 to 1991; on average, it increased by about 0.5% per year. As production during the same period rose by about 31% during the same period, it follows that productivity increased some 1.6% per year.

The growing use of electronics to enhance the capabilities of optical instruments has given rise to the development of high performance systems. These include opto-electronic process control and sensor technology, microanalytic equipment, multiple co-ordinate measuring machines, high power telescopes and developments in quantitative microscopy. In the sector of photographic equipment, similar developments took place at the photographic laboratory level. The same applies in the field of microfilm technology, which now occupies a strong position in serving high performance systems such as microfiches and EDP retrieval. In ophthalmic optics, innovation occurs mainly through the use of new materials for glasses (plastics) and for frames (carbon fibre).

INDUSTRY STRUCTURE

Companies

In the subsector of spectacles, lenses, frames and mountings, the industry comprises mainly small and medium-sized firms with a maximum of 500 employees. Production of frames is mainly done by even smaller firms, usually employing less than 100 employees. Despite their small size, however, the firms usually operate at the international level, with EFTA countries and the United States as their most important extra-EC outlets. The few large companies in the subsector are Rodenstock in Germany, Essilor in France, Luxottica in Italy, Indo in Spain and Pilkington in the United Kingdom.

In the subsector of optical precision instruments, the German Zeiss, and Philips from the Netherlands, are the most important suppliers of electronically regulated microscopes. Worldwide there are about 12 producers in this area. Leica, the Swiss/United Kingdom company specialised in optical instruments, has become a world leader in the sector, behind the Japanese company Nikon.

In the field of photographic equipment, there are a few large manufacturers in the EC that often are highly specialised, such as Augenieux, a French manufacturer of camera lenses.

Strategies

EC enterprises in the field of photographic equipment face strong competition from outside the EC, especially from the United States and Japan. Intra-EC competition is particularly strong in the field of optical precision instruments, and this type of competition is bound to increase with the onset of the internal market in 1993. Important regrouping has already taken place: the British firm Cambridge instruments, and the Swiss firm Wild Leitz, merged to form the new group, Leica, specialised in optical instruments; in 1988, Wild Leitz had already taken over one of its main competitors, Kern.

The creation of subsidiaries in low wage countries could be another solution for EC firms, to improve price-competitiveness by shifting parts of production to these countries, while restricting themselves mainly to development, design and the assembly of the products.

REGIONAL DISTRIBUTION

The main producers are Germany with a share of production of 37%, followed by France with 25%, Italy with 16% and the United Kingdom with 14%. The largest intra-EC exporter is Germany, with about 37% of the total, followed by France (14%), Italy (13%) and the United Kingdom (12%). The main importer from countries outside the EC is once again Germany with about 34% of the total.

Among EC producers, there is a large degree of specialisation. As already mentioned, Germany produces mainly optical and photographic instruments, while France and Italy are major producers in ocular optics, mainly spectacles frames.

ENVIRONMENT

The production process of optical instruments and photographic equipment has little effect on the environment. On the contrary, the solution to ecological problems may actually offer new opportunities to the industry.

The optical and precision instruments subsector, for example, depends to a considerable extent on demand for measuring and control instruments, as already mentioned. Thus, enhanced monitoring and measuring needs in the context of environmental concerns, will probably boost demand for optical and precision instruments. Similarly, there will be an increase in demand for analysing instruments, such as microscopes, optical instruments for physical and chemical analysis, spectrographs, colorimeters and photometers. Demand for photographic equipment may benefit also from ecological concerns, as highly sophisticated cameras are increasingly used in the field of aerial and space photography to monitor environmental damage.

One area, however, of environmental damage related to photographic equipment concerns the run-off of chemicals used in the production of photographic films and in their development, into the soil and possibly into water supplies.

OUTLOOK

The outlook for the industry of optical instruments and photographic equipment remains somewhat depressed in the short term, but will improve in the medium term. Lower demand for products of optical precision instruments is expected for 1992, as a result of low investment in the manufacturing sector. In the field of the ophthalmic industry, the loss of markets in Eastern Europe will continue to weigh down demand; the German industry of ophthalmic products, however, may still profit from increased demand in former Eastern Germany, though at a lower pace than before. In the medium term, the more optimistic outlook is based on the expected upswing in the West European economy, which will increase demand for optical precision instruments in line with the recovery of investment activities. The ophthalmic industry will continue to benefit from the ageing process of the population and may also find, on a later stage, new markets in Eastern Europe. But producers will need to counter Japanese efforts to gain a foothold in these markets; first steps in this direction have already been taken by German companies looking for business contacts in Hungary. Last but not least, the above mentioned opportunities offered by increased environmental concerns reinforce the prospects for a favourable development of demand in the next few years.

Clocks and watches
NACE 374

Demand in the EC for clocks and watches increased constantly during the last decade, driven essentially by fashion trends rather than by technological developments, which had already taken place in the early sixties. Production, however, declined by 3.2% per year from 1982 to 1991 in value. This development illustrates the strong competition from Japan, the East Asian NICs and Switzerland. This is not expected to change in the next few years. In the medium term, the outlook is somewhat more optimistic thanks to the economic recovery in Western countries and potentially increased demand from China and India.

INDUSTRY PROFILE

Description of the sector

The industry defined as clocks, watches and parts thereof includes watches, instrument panel clocks, clocks, control apparatus and timing devices using clock-work or synchronous motors and time switches, as well as clock and watch movements. The sector encompasses mechanical, electrical and electronic watches.

As a general rule, enterprises in the industry are highly specialised, exclusively producing in their narrowly defined area.

Main indicators

The subsector of clocks and watches is the smallest one among the larger sector of instrument engineering in the EC. In 1991, its output accounted for roughly 6% of total instrument engineering production, and its share of employees was 6.3% of total employment. Germany (former West Germany) and France are the most important manufacturers of clocks and watches in the EC. These two countries' output accounts for nearly 80% of total EC output, measured in terms of value added.

The sector is characterised by increasing competition from outside the EC, giving rise to a fast deterioration of its trade balance during the last decade.

The development of EC production in constant prices underwent different phases during the eighties. In the two years from 1982 to 1984 production decreased by some 39%, following the precipitous fall in prices triggered as a result of the development of electronic watches. From 1984 to 1989, production started increasing again at a rate of 1.9% per year in volume, thanks to a favourable performance of the industry in France (3.1% per year) and in the United Kingdom (3.6% per year). Since 1989, however, EC production has been declining again, to 1 215 million ECU in 1991 in real terms (1985 prices), the lowest production level during the period considered here. EC consumption moved more or less in line with production up to 1989. In 1990 and 1991, however, demand kept increasing, while production decreased resulting in a strong increase of imports.

Extra-EC trade developed rapidly during the eighties. Imports and exports increased at similar rates during that period. But given the fact that imports are more than twice as high as exports, the trade balance further worsened.

International comparison

The largest producer of clocks and watches in the world is Japan, that had a 1991 production value equal to more than eight times that of the EC. Production in the United States is about 81% of that in the EC, with about 1 117 million ECU in 1991. The development of production in the United States during the eighties was similar to that of the EC: production in the United States declined by 3.0% per year in real terms from 1982 to 1991, as compared to 5.8% per year in the EC for the same period. Japanese enterprises in contrast increased their production by 12% per year to reach 11 869 million ECU in 1991. Consequently, EC and US producers saw their shares of world production drop drastically. In 1982, Japan produced about 54% of the output of the Triad, the EC roughly 28% and the United States about 18%. In 1991, the share of EC production dropped to some 9% and that of the USA to 8%, in favour of Japan, now producing 83% of the Triad's output.

Source: Eurostat

Foreign trade

Exports of the EC companies to extra-EC markets increased by 6.4% per year from 1982 to 1991, in nominal terms. The most important markets for the EC are Switzerland, with roughly 31% of total exports, and the developing countries, with a share of 37%. The strong competition faced by EC producers from non-EC producers is underpinned by the fact, that EC imports increased by 8.9% per year during the same period (1982-91). Imports were almost three times as large as exports in 1991, with the result that the deficit of the trade balance as a percentage of consumption more than doubled

over the last decade. Being world leaders in high quality mechanical watches, Swiss producers are the most important extra-EC competitors, with more than 50% of total imports into the EC. Imports from developing countries are the result of strong competition from Hong Kong (about 17% of total imports), an important producer of electronic watches in the low price segment. About 14% of imports are from Japan. All in all, 86% of EC demand is satisfied by products from outside the EC.

MARKET FORCES

Demand

Apparent consumption of clocks, watches and components increased steadily after 1984. Demand, a function mainly of consumer expenditures, was stimulated to a greater extent by fashion trends than by technological developments, given that intensive use of electronic components in this sector's products dates from the early sixties. Innovations, therefore, took place mainly in the form of design changes. Another important feature of demand in the second half of the eighties, was a gradual shift away from the cheap electronic watches produced in Japan and Hong Kong, to top-of-the-range watches. This resulted in increased imports from Switzerland, the main producer of high quality watches.

Supply and competition

The clocks and watches industry in the EC is faced with strong competition from abroad. As mentioned already, about 86% of EC consumption is imported from outside. While consumption in EC countries grew by 1.0% per year in average from 1982 to 1991, production during the same period declined by 5.8% per year (all in real terms). As a result, the EC trade deficit tripled in the same period, to reach 1 683 million ECU in value in 1991.

Extra-EC imports stem mainly from Switzerland, Japan and Hong Kong. The largest exporter towards the EC is Switzerland where clocks and watches manufacturers specialise in top-of-the-range mechanical watches. Competition from Swiss manufacturers is expected to increase further, as Swiss producers try to increase market penetration by supplying their products at very competitive prices. This is made possible mainly by the different industrial structure of the Swiss watch

Figure 4: Clocks and watches

industry. While EC manufacturers are often small and medium sized, Swiss producers are of international size, which enables them to benefit from economies of scale. The result is that SMH, the Société de Microtechnique et d'Horlogerie (the manufacturers chiefly of Rado, Omega, Longines, Tissot and Swatch) have been meeting with mounting success in the EC. Swatch for example sold one million watches alone in France in 1991.

In the field of low-cost electronic watches, Hong Kong and Japan are dominating the world market, with 65% of world production (in volume) in the sector. The share of imports to the EC from these countries, however, declined from 43% of total EC imports in 1986 to 31% in 1991. This result underlines the recent trend for customers to upgrade demand towards high-price watches, as already mentioned.

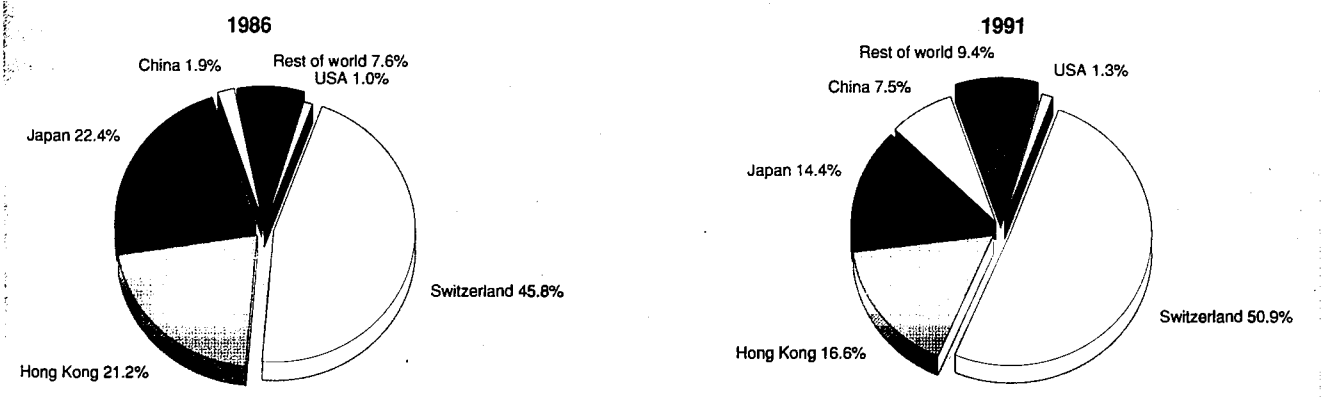
EC manufacturers are operating mainly in the field of mid-range watches. They are not able to compete in prices with electronic watches from the East Asian NICs, as a consequence of lower labour costs in these countries, or of the better availability of components, mainly for the production of electronic movements. Another factor that worked to the detriment of EC producers was a fast fall in prices of electronic watches following the devaluation of the Yen, compounded in 1989 by the efforts of some manufacturers in Japan to clear surplus inventories.

Taking into account that overall demand for watches is likely to decrease in line with the economic slowdown in Europe and the United States, and the loss of markets in Eastern Europe, competition on EC markets can be expected to become even harsher. Prices will drop, the profit situation of EC firms will worsen. Efforts of EC producers to move up to the top-of-the-range segment can also lead to price decreases, as market saturation in that segment is reached also. This has been happening already for French and German watch producers.

Production process

The strong price competition from Japan and Hong Kong caused a difficult profit situation for some of the European manufacturers. Lower labour costs and more efficient production processes in these countries allowed the supply of watches and clocks at very low prices. Watch producers in the EC were compelled to modernise their equipment to reduce costs. Given higher labour costs, a substitution process of capital equipment for labour took place. While EC producers had been employing about 45 000 people at the beginning of the eighties, employment declined during the eighties at an average rate of 8% to reach only 21 000 people only in 1991. The strongest falls in employment could be observed in Germany (-10% per year from 1982 to 1991), Italy (-12%), and the United Kingdom (-13%). Consequently, a restructuring of the production process took place in these producing coun-

Figure 7: Clocks and watches
Origin of EC imports



Source: Eurostat

tries, resulting in increased productivity. In contrast, France's workforce fell first at a much slower rate, but major producers in France were forced to reduce their workforce by 7% in 1991 as the industry there was faced with increasing difficulties. As a whole, productivity of the industry in the EC, as measured by the ratio of value added to employment, rose at an average rate of 2.5% per year from 1982 to 1991.

Another feature of the last years was the tendency of manufacturers to move out of the production of parts, in order to concentrate on the tasks of design, assembly and distribution to jewellers.

INDUSTRY STRUCTURE

Companies

The clocks and watches industry is generally structured into large numbers of small firms, with a few larger companies, seldom employing more than 700 people. The larger companies are mainly in the field of cases and movements production. The most important producers in the European Community are the German firms Junghans (1400 employees), Dufa-Kienzle (800 employees) and Kundo and Staiger. France's Ebauches is one of the most important producers of movements in the world, while Vedette is operating in the field of clocks. Other companies in France are Herbelim and Pequignet, producing in the high price segment,

Most EC companies are active on extra-EC markets, with the United States, the EFTA countries and the East Asian NICs as their main export markets.

Strategies

The clocks and watches industry in the EC faces strong competition from Switzerland in the high-price segment, and from Japan and Hong Kong in electronic low-cost watches. The smaller firms producing in the low-price range were particularly hit by the competition from Japan, since they could not produce on a scale sufficient to permit low-cost production. The mid-range sector, however, is presently dominated by EC manufacturers, but even these are now confronted with increasing efforts on the part of Swiss manufacturers to strengthen their presence in EC markets by supplying some of their products at very competitive prices. In anticipation of the onset of the internal market in 1993, companies from outside the EC, mainly the Swiss and the Japanese, have been increasing their investment activities in the EC. Thus, the Compagnie Générale Horlogère, a subsidiary of the Hattori-Seiko group, has expanded its presence in France by making large investments there, while the Swiss SMH has taken over the rough-hewing manufacturing part of the German Porta.

In order to face up to these challenges on their domestic market, EC companies have intensified their investment activities during the last few years. This has permitted firms in the mid-range sector to retain their place on the market, by frequently renewing their product lines and by improving the quality of their watches.

To better meet the intensification of competition, firms in the mid-range segment are being forced to regroup. In Germany for example, important regrouping took place: the clock producing Dufa-Kienzle, for example, took over the watch firms Haller and Buerk and the clock firms Peter-Uhren, Schmid-Schlenker and Patz. Kundo and Staiger are working together in both research and development and the production of watches. Increased efforts in research and development are very important, as the success of the German Junghans illustrates; the company managed to increase its turnover by 23% in 1991, by introducing first the solar watch and then the radio set watch.

To streamline production costs, some EC firms increasingly subcontract the production of parts to other countries' producers, mainly in South-East Asia; others established subsidiaries there. Thus, the France Ebauches has already subsidiaries in Mauritius, Tunisia, and Hong Kong; even SMH has now subsidiaries in Thailand, Hong Kong and China.

REGIONAL DISTRIBUTION

The production structure in the EC has undergone considerable changes during the eighties. While Germany (former West Germany) was the dominating producer at the beginning of the eighties, with nearly 50% of the EC total, its relative position weakened in the following years in favour of France, whose share of EC production surpassed that of Germany by 1987. In 1989, however, stimulated by the German reunification, Germany (former West Germany) managed to remarkably increase its production. In 1991, the share of Germany in total EC production was 42%, followed by France (37%), the United Kingdom (12%) and Italy (7%).

Intra-EC exports are similarly dominated by these countries, which make up about 80% of the total. The most important intra-EC exporter is Germany (former West Germany) with 45% of the total, followed by France with 20%.

ENVIRONMENT

The only ecological issue related to this industry is the problem of disposal of the small nickel-cadmium batteries used to power electrical and electronic time pieces. As known, the cadmium contained in these batteries may progressively seep into ground water and endanger public health.

REGULATIONS

In the area of trade restrictions, which are in generally almost absent in this sector, the forthcoming directive on gold watches should, nevertheless, facilitate trade in these products, since major restrictions still exist in France, the United Kingdom, the Netherlands, Ireland, and Spain.

OUTLOOK

Prospects for the industry in the EC are not very encouraging, at least in the short term. World demand for watches has decreased lately, due to the recession in Europe and the United States and the loss of markets in Eastern Europe, caused by the dissolution of the communist block and the former Soviet Union.

In the medium term, the general outlook for the industry is somewhat more optimistic, thanks to the expected economic recovery in the United States and in West Europe and to the huge potential for increased demand from China and India. The markets in East Europe are not expected to recover in the next few years. To be able to profit from the global upturn in demand, however, EC producers will have to increase their efforts in product innovation, as well as in the realm of cost reduction, to increase their competitiveness against extra-EC competitors.

Food, drink and tobacco

NACE 41,42

Demand for processed food products rose significantly between 1982 and 1991. Growth of average income positively influenced consumers' preferences toward high-service content, rather than fresh, products.
The food industry is not very concentrated: there are many small companies, but the number of large firms has been steadily growing. In the 1980s, M&A activities increased the level of concentration in all of the main EC markets for this sector.
Changes which recently took place in Eastern Europe offer the food industry further possibilities for expansion.

INDUSTRY PROFILE

Description of the sector

This industry includes all the activities of processing agricultural products, fish, meat, and tobacco, and is coded in the group NACE 411 to 429.

Main indicators

Apparent consumption increased between 1982 and 1991. Production followed the same trend of consumption, at a slightly higher rate. The trade balance was positive, and increased overall during the period, although it was affected by variable export growth after 1985. Employment decreased until 1986, then began a slow recovery; however, employment figures in 1991 were lower than in 1982.

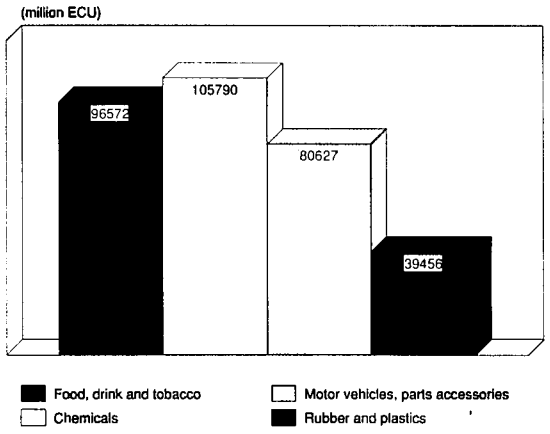
The meat sector has the highest value of production of the various sectors, and is the only sector to experience higher employment in 1991 than in 1982. Employment in the grain milling, dairy and tobacco sectors, on the other hand, decreased overall during that period as a result of the substitution of capital-intensive for labour-intensive production techniques. In the other food sectors, employment decreased through the mid-1980s, then began a slow period recovery. This recovery can be ascribed both to the slowing down of the process of substitution of labour with capital, and to a new expansion phase of activity which increased labour input needs.

Extra-EC exports in value grew substantially more than extra-EC imports, resulting in an 84% increase in the trade balance over the ten year period. Meat processing and processed vegetable and fruit products show the only negative values in the trade balance.

In most sectors, production in current terms increased. The exceptions included oils and fats, sugar, and confectionery which had variable growth, and the alcohol and spirits industry which had an overall decline. In each sector, consumption followed the trend of production for the most part.

Value added for 1991 correlated with the concentration of the food industry in each country. The German industry had the highest value added, followed by the UK and France. In these countries, the food industry has reached a high level of concentration by pursuing conglomerate strategies. American and European multinationals operate in various markets and different sectors in these three Member States. The Spanish and the Italian industry are characterised by the presence of a significant number of small companies, but these markets have been the object of intense M&A activity on the part of both national and foreign companies, which has contributed to an increase in the concentration level in these markets and to a general restructuring of the industrial system. Benelux countries have rather low value added because their national markets have proven insufficient for the establishment of a significant industry. Greece is characterised by a significantly low value added as well, due to an immature and slowly developing industrial system.

Figure 1: Food, drink and tobacco
Value added in comparison to other industrial sectors, 1991



Source: Eurostat

Recent trends

After 1986, there was a slight acceleration in consumption compared to production, and a corresponding decline in exports. In the second half of the decade, imports also slowed down.

Production grew slowly compared to manufacturing. Employment also grew more slowly than in manufacturing until 1991, when employment in manufacturing dropped, while employment in the food drink and tobacco industry continued its slow but steady growth.

Foreign trade

In the second half of the 1980s, growth of both extra-EC imports and exports in volume declined substantially. The export to import ratio increased slightly, due to a slower increase in imports than exports.

The volume of intra-EC trade increased steadily throughout the 1980s, and in 1991 was twice as high as extra-EC exports. During the period from 1986 to 1991, the proportion of exports in value destined for the USA, EFTA and OPEC countries decreased. In the case of the OPEC countries the fall occurred in 1991, and was caused by the Gulf war. The decrease in the importance of the USA as a destination for exports can be linked to protectionist measures taken by the USA and EC countries. Imports from Brazil have also diminished, while those from the rest of the world are increasing.

Extra-EC exports are not significant compared to production, and decreased as a percentage of production from approximately 7% in 1982 to around 6% in 1991. Intra-EC exports are more significant and are an increasing proportion of production (13.6% in 1991), due to the implementation of the Single Market. The ratio of extra-EC imports to apparent consumption has decreased more than exports to production.

MARKET FORCES

Demand

Demand for both fresh and processed food products in Europe grew at a rather modest rate despite nearly 0% growth in population and a decrease in the share of total expenditure for food consumption in most countries. Demand for industrially-made food products is much more dynamic than demand for fresh and artisanal products because of a substitution movement favouring high-service content, easy-to-prepare products which will keep longer than fresh ones.

In addition, the rise of retail chains favours the consumption of industrial products compared to fresh ones due to a number of factors:

- the general decrease in the number of shopping trips the consumer makes per week;
- the logistic optimisation of supplies on the part of the retailers chains with respect to the industry;
- the greater control exerted on the prices of industrial products compared to fresh products, which are periodically subject to over- or underproduction crises which obstruct price controls.

The aggregates are heavily weighted by the high value of fresh and preserved meat, which tends to bias data towards trends in the meat industry.

Supply and competition

Extra-EC trade of processed food products is low since large-size companies find it convenient and cheap to establish and buy production capacity in the main markets. Internationalisation strategies by means of foreign investments toward the main markets have been preferred to exporting because of transport costs and the ability to exercise direct control upon the principal final markets.

Legal obstacles concerning labelling, food content and, with regard to meat, the restraints on breeding techniques also hinder exports in the food sector.

The abolition of some of the factors which limit trade has contributed to the growth of foreign trade in the EC market.

Food companies have shown steady profitability indicators, despite the problems. Such stable profitability, particularly in the early 1990s, was unusual compared to the difficulties experienced by the manufacturing industry.

Production process

Since 1982, the food industry has been characterised by a technological substitution process in favour of increased capital intensity. The decrease in employment which lasted until 1986 can be ascribed to this factor.

Product innovations have also been numerous; while some were designed specifically to fulfil consumers' individual preferences, others had the objective of increasing the quality to price ratio of offered products.

INDUSTRY STRUCTURE

Companies

The number of companies operating in the European food sector is rather large. However, the percentage of turnover in value of the first ten companies (with holding company in the EC) accounted for around 18% of the total market in 1989.

All of the larger-size companies are multinationals, mostly American or from other non-EC countries, which operate as conglomerates, thus favouring business areas such as the food, pharmaceuticals and chemicals sectors.

The largest European food company by sectorial turnover is Nestlé (CH), followed by Unilever (Anglo-Dutch) Unilever is the largest company in the sector in the EC, and turnover in 1989 was only 58% of Nestlé's turnover. Among the first ten companies in the EC there are seven UK companies (including Unilever), two French and one Italian. UK companies account for more than 70% of the turnover of the first ten EC companies.

Only three European companies are positioned among the top ten food, drink and tobacco companies in the world: Nestlé, Unilever and Grand Metropolitan; the others are all American. US companies had the advantage of having first operated inside the large US market: the size and the political structure of the country favoured the first multi-plant strategies by US companies and, therefore, the first multi-market and multi-product strategies.

By contrast, the internationalisation and competitive positioning of European competitors are more recent. For this reason, American companies have a strong position in Europe, while the same cannot be said for European companies in the large American market.

Strategies

M&A activities in the EC food and drink market have been more important than in many other sectors. The largest com-

panies reinforced their positions with respect to medium-size firms by acquiring these firms, and by some important mergers among the major companies.

Northern European markets are more concentrated than those in the southern European countries. The acquisition process has strongly affected markets in the south because of the high growth expectations of brand-name products. The 1980s saw a recomposition in the relative size of competitors due to the acquisition process. This strategy has been pursued by almost all the major companies in the world, and has three objectives.

- to implement a market-product diversification in order to exploit economies of scope;
- to improve or to maintain a relative market position compared to those of the main competitors;
- to inhibit increases in production capacity so as not to induce overproduction crises.

Since 1989, the level and intensity have of M&A activity have tapered off somewhat.

One of the main strategies pursued by the largest companies is rationalising promotional investments for brand strategies.

The acquisition process has been preferred as a strategy of market penetration because the low import-export activity, as well as the different regional preferences and the need for promotional investment for new brands, make introduction of a new product difficult and costly. In addition, the expectation of stability of demand makes investment in industrial capacity unsuitable.

Another aspect which influences the strategies of the food industry is the increasing bargaining power of commercial outlets and the competitive pressures of the large companies. Small and medium-size firms have the most competitive disadvantages because they find themselves squeezed between the two, with a few options including:

- positioning themselves in a high quality segment or niche position;
- becoming the unbranded suppliers of the distribution chains.

A different model of expansion through M&A refers to corporations which are involved in food processing of non-differentiated products such as sugar, starch, Soya, maize, etc.

Firms are expanding vertically, both upstream to production of the raw materials, and downstream to the production of brandable products from these raw materials.

ENVIRONMENT

Cultivation of crops as well as breeding, slaughtering, and dairy production have a negative impact on the environment, especially water, by discharging organic pollutants. The further processing of food, as distinguished from agricultural activities, is not a major environmental hazard. Pollution from processing is directly linked to the degree of energy involved for the necessary heat in the single production processes, which, however, cannot be considered among the pollutant technologies.

The impact on environmental issues is particularly evident with regard to the product itself.

The developments in distribution (selfservice) and demography (small and single households) have had a significant impact on packaging. Packaging plays an important role in the protection, safety, information, shelflife etc. of food and drink products.

Moreover, standardisation in the European legislation also includes common packaging standards, particularly for fresh fruit and vegetables. Packaging materials for all products, food and non food, represent 25% of household waste.

Some countries have introduced special taxes, such as that on plastic bags in Italy or on PVC plastic bottles in Germany. Such measures, however, reintroduce the distortions in competition which the EC is working to harmonise. In some cases, there is a trade off between environmental needs and harmonisation in food legislation, product and packaging standards.

On the other hand, the biodegradability of materials used in packaging processed food might bring a new opportunity, but the higher costs of these materials could damage the competitive position of the companies adopting them. For these reasons, the problem of environmental impact must be considered in the more general context of the harmonisation of laws.

REGULATIONS

EC legislation has certain goals, including:

- the abolition of technical and fiscal obstacles to the free movement of goods;
- the protection of public health and of the final consumer;
- the homogeneity of information;
- economic and technological objectives.

There is legislation concerning general aspects such as labelling, the use of additives, the characteristics of the production process, etc., as well as legislation referring to specific sectors, as in the case of legislation on beer, pasta, etc.

The recent change in policy on the part of CAP must be taken into consideration, since it will influence the supply strategies of the processing industry through changes in availability, quality and prices of the agricultural materials used.

OUTLOOK

EC growth is expected to be higher in the mid-1990s than the late 1980s and early 1990s, both for production and for domestic market, due to increases in income and in consumption propensity for industrial products, especially high-service content products. This kind of propensity is higher in Northern European countries, with more established industrial traditions. However, it is also growing in rapidly developing countries, such as Spain and Greece.

The UK is the exception. Recession has significantly conditioned the sectorial demand expectations and, consequently, production planning. In this case, beverages is the only segment which faces a positive growth expectation.

Population growth will also affect demand, mainly due to immigration rather than increased birth rates. In addition to the immigration flow from Africa, the influx of immigrants from Eastern Europe is expected to reach significant proportions.

Producers face the risk of excessive pressure on prices from the big distribution chains, as well as from possible surpluses.

However, the steady increase in demand for processed products, combined with the possibility of expansion in Eastern European markets provide continuing opportunities for companies. In addition, the industry is not as affected by cyclic economic swings as the manufacturing industry offering a measure of protection to producers.

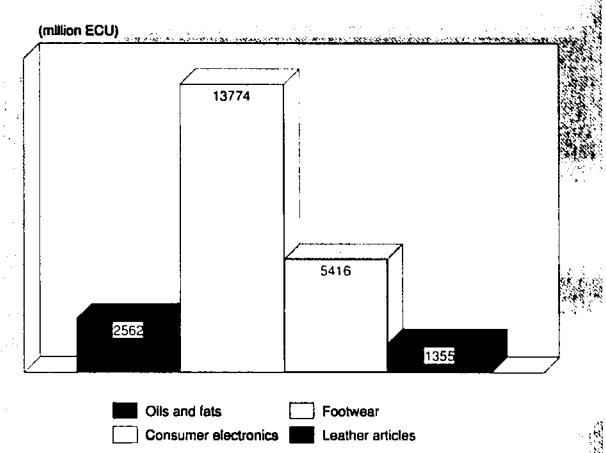
Oils and fats
NACE 411

Consumption of vegetable and animal oils and fats was stable over the 1980s and early 1990s. With respect to products for human consumption, there has been a progressive substitution of animal fats with vegetable fats, and the substitution of traditional products with innovative low-fat content products. The new emphasis on nutrition may encourage a more geographically widespread consumption of olive oil.
Concentration process in the oils and fat industry, which is likely to intensify with the creation of the Single Market, has meant a growing rationalisation of the production process with a consequent improvement in productivity.
From the strategic point of view, advertising outlays and the product range policies are becoming increasingly important.

Figure 1: Oils and fats
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The main products of the oil and fat-producing industry are:

- products of oilseed processing destined for final consumption, which include both seed-oil prepared for human consumption and oil cake and protein meals for animal feed;
- products of oilseed processing which are used as raw materials for the food preservation industry, for cake and biscuit making, confectionery, etc., and for the manufacturing of celluloid, electronic insulation, candles, enamel paints, fuels, glycerine, linoleum, lubricants, paints, soaps, etc.
- products of olive-processing; olive oil, which has different brand names depending on the production technique utilised and the qualitative level of the product;
- margarine, minarine and dairy spreads (a mixture of butter-fat and vegetable fat in varying percentages), which represent the next step in the processing of vegetable and dairy fats.
- fats and oils from land and marine animals.

The increased number of products on the market for human consumption has led to the EC adopting a classification based on the definition of three broad groupings: butter (milk-derived fats only); margarine (vegetable or animal fats not dairy fats); and products with both of these fats, called mixed fats. For each group there are six further categories, based on variations in fat content between 20% and 95%.

Main indicators

The developments in the main indicators in nominal terms have been variable. The result of the harvests , and thus climatic factors, in the major producing areas, can quickly affect trade flows and market prices. Changing relative prices encourage substitution with products endowed with similar functions and uses.

Compared to 1990, 1991 was characterised by a weakness in both consumption and production. The trade balance also worsened slightly. Employment fell by 12 000 between 1982 and 1991. The trends in consumption and production furthermore differed from country to country. In 1991, a drop in output was recorded in Italy, France, Ireland and Belgium, while an increase in production was observed particularly in Portugal, but also in Denmark, Greece and Spain. Consumption rose in Greece, Spain, Holland, Portugal and the United Kingdom, while there was a stationary or downward trend in the other countries.

The dynamics of the aggregate data are, moreover, the outcome of differing trends in the various subsectors, as the end-markets are very heterogeneous. For example, the performance of the oil-seed sector for animal consumption is conditioned by the flexibility of breeders and the compound feed industry in their choice of livestock feed in response to changing prices. With respect to oilseeds destined for human consumption, the effects of the substitution between olive oil and seed oil is an important force affecting demand.

In the olive oil sector, the prices and the quantities consumed are greatly influenced by both the quantity and quality of the harvests in the main producing countries. Furthermore, there is a trend towards an increase in olive oil consumption in countries that are not traditional consumers.

The consumption and production of margarine is conditioned by the degree of success, depending on the country, achieved by the substitute products put onto the market and by the legislative discrimination applied by some countries.

The highest levels of added value are found in Spain, Italy and Germany. German output is mainly oriented towards the

processing of oil-seeds, while in Spain and Italy the production of olive oil plays a significant role.

Recent trends

From 1984 to 1990, production and apparent consumption in real terms grew variably. In 1991, both production and consumption decreased, due to consumption saturation and a significant drop in extra-EC trade. The difficulties encountered on international markets are expected to continue for a considerable time owing to the fact that traditional importing countries are developing their own production and exporting capacity.

Foreign trade

The overall trade balance of the industry is negative: although the EC is a net exporter of olive oil and margarine, it is largely reliant upon imports for its stock-piles of oilseeds, other vegetable oils, cake and meals. In 1990 and 1991, extra-EC imports accounted for approximately 62% of total trade in oils and fats. Two of the main suppliers, Brazil and Argentina, significantly increased their share of total imports between 1986 and 1991, to the detriment of the other largest supplier, the USA. Extra-EC exports make up 8% of the output and are directed mainly towards the EFTA countries and the United States. The terms of trade have undergone a clear-cut deterioration over the last two years.

MARKET FORCES

Demand

Animal feed

The demand for cake and protein meals fluctuates from year to year due to the possibility of varying the composition of the compound with different raw materials according to changes in their relative prices. To a limited extent, cereals, corn gluten feed and green fodder can be used as substitutes for low protein meals produced from softseeds. The basic factor that influences the demand for compound feeds and their composition is represented by the production orientation of EC and world animal breeding, and, ultimately, by the demand for different kinds of meat.

Human consumption

The share of the various kinds of oils and fats within the human diet varies significantly from country to country owing to the diversity of eating habits. For instance, the use of olive oil is found mainly in the major producing countries (Spain, Greece and Italy), while per capita margarine consumption is very high in Holland, Belgium and Denmark. Margarine consumption is negligible in the Mediterranean countries. Per capita consumption of margarine in Denmark, for instance, is 13 times higher than per capita consumption in Italy.

To summarise, the main variables influencing human consumption are:

- price;
- consumer health concerns;
- the entry on the market of innovative products, in particular those with low fat content (i.e. dairy spreads);
- legislative factors, such as the limits imposed by some Member States on the marketing of margarine, minarine and spreads.

Price differentials between olive oil and seed oil and between butter and margarine also bring about significant changes in demand for these products, but health concerns are at the root of the substitution between saturated and polyunsaturated

fats and between animal and vegetable fats. These concerns have had an important effect on the growing popularity of vegetable oil consumption at the expense of both butter and margarine, which has implications for the future growth in sales of dairy spreads throughout Europe. Innovative products such as low-calorie, fat-free oil and fat substitutes also have excellent chances of market success. An important contributing factor to such developments will be the removal of the remaining legislative norms preventing the entry of those products on some national markets.

Supply and competition

The supply capacity of the industry tends to remain above the average annual demand in order to cope with wide fluctuations in consumption. The processing of oilseeds comprises two different production phases that are not always integrated in the same company:

- the processing of oilseeds into crude oil and protein meal;
- the refining, hydrogenation and fractionation of crude oils and fats.

The production capacity of the companies that operate in the first phase is generally greater than that of the companies working in the refining stage. The chance to exploit high technical economies of scale tends to favour a process of concentration of production activities.

The industry structure of olive oil production in Italy and Greece is characterised by the presence of small companies (and a few large ones) working at the local level, whereas in Spain production is carried out in large-capacity plants. This gives Spanish industry a competitive advantage.

The companies of the EC have to face competition from countries such as Argentina, Brazil and Malaysia that are developing and enhancing their production capacities.

Production process

The processing of the oilseeds, largely automated, is capital-intensive. Technological innovations have paved the way for increasing automation of the various phases of the production process. This is reflected (in the data on the industry as a whole) in the higher increase in productivity than in unit labour costs and in total unit costs.

The production of margarine takes place in highly industrialised plants as well, while for the production of olive oil, as has already been stated, there is variability in the market structures across the EC.

INDUSTRY STRUCTURE

Companies

In 1991, following several acquisitions and mergers, the leading European firm in the crushing of oilseeds was the Ferruzzi group, through its subsidiary Cereol, which has a share equal to 18-20%. ADM (US) is also a major crusher in Europe. Unilever is the leader in refining, with Ferruzzi in second place.

In the edible oils sector, the first three groups, Ferruzzi (Italy), Unilever (Anglo-Dutch) and Elosua (Spain), together hold a 45% to 50% share of the market.

In the margarine sector the leading three companies are Unilever, Vandemoortele (Belgium) and Rau (Germany). They account for 60% to 65% of total margarine sales in Europe. In general, the presence of cooperative companies is strong in this sector.

Strategies

The fundamental strategic response to the transformation of the European market consists of the concentration and rationalisation of the production structure, which allows for greater competitiveness based on lower costs.

In oil and fats for human consumption, with the entry of numerous new products onto the market, it is fundamental from the strategic point of view to invest heavily in advertising. The entry and expansion of the multinationals in the sector, which have been very active in the acquisitions of important national companies, is relegating the small- to medium-size companies to geographical niches or to markets for very high quality products.

The competitive strength of the large companies lies in diversification of products. In a market where the product typology grows constantly, a firm which "makes the first move" into new innovative sectors has excellent prospects for growth.

REGIONAL DISTRIBUTION

The European oilseed processing industry is located mainly in Germany, Holland, Spain, Italy, Belgium and France. The production of olive oil is concentrated in Spain, Italy, Greece and Portugal. The production of margarine is located primarily in Germany, the United Kingdom, Holland, Belgium, France and Denmark.

ENVIRONMENT

The main ecological problem affecting the industry regards the disposal and processing of solid urban waste. The volume and the chemical composition of the packaging are subject to regulations. In addition, consumers are becoming increasingly aware of environmental problems and might show a preference for products packaged in the most environmentally friendly way.

REGULATIONS

EC regulations are designed to:

- give producers a guaranteed income (production subsidies);
- support the EC market (intervention price);
- facilitate the marketing of the product within the EC (consumption aid);
- assist exports (export compensation).

Some of the regulations have limited importance or use. Intervention prices have been used to a limited extent. The consumption aid only applies to olive oil. Export compensation is not used for vegetable oilseeds.

OUTLOOK

The process of substitution between animal fats and vegetable fats will continue over the next few years. The innovative products will have an excellent chance of growth at the expense of traditional products.

The creation of the Single Market will mean, firstly, an increase in international competition. As a consequence, the concentration process that is ongoing will probably speed up. The removal of legislative barriers will increase slow the penetration of certain products in several national markets.

On the international markets, the problems already mentioned caused by the competition of some strong raw and semifinished materials producers should be offset by the opportunities that

arise from greater openings in trade with the former USSR and the countries of Eastern Europe.

Future risks to the outlook will come from the development of new substitute products in response to changes in consumption patterns in the EC, the general maturity of the market for human nutrition and animal feed, and greater competition in traditional markets.

Companies, in particular large diversified enterprises at the international level, will be able to take advantage of the trend towards market segmentation, and the prospects of greater trade with the countries of Eastern Europe and the ex-USSR.

Meat
NACE 412

The unification of Germany led to a sudden rise in the production of meat in the EC in the first few years of the 1990s due to a large scale slaughtering program.
As a result of the application of milk quotas, there has been an increase in the slaughtering of milk cows in addition to the shift in cattle breeding from milk to meat cows. Both of these events have contributed to the significant rise in the production of meat and veal.

INDUSTRY PROFILE

Description of the sector

The slaughter and meat processing industry includes five subsectors:

- slaughter-houses (NACE 412.1);
- processing and preserving of meat (NACE 412.2);
- killing, preparing and preserving on poultry (NACE 412.3);
- processing of slaughter by-products (NACE 412.4);
- production of animal guts and meat offal (NACE 412.5).

The degree of diversification of the companies operating in this industry is generally rather low, especially for the numerous medium to small businesses, which tend to specialise. A few large meat processing groups have diversified into other food sectors, such as dairy, to take advantage of economies of scope in marketing and distribution. The leading companies in the poultry sector have diversified into the animal feed sector.

Main indicators

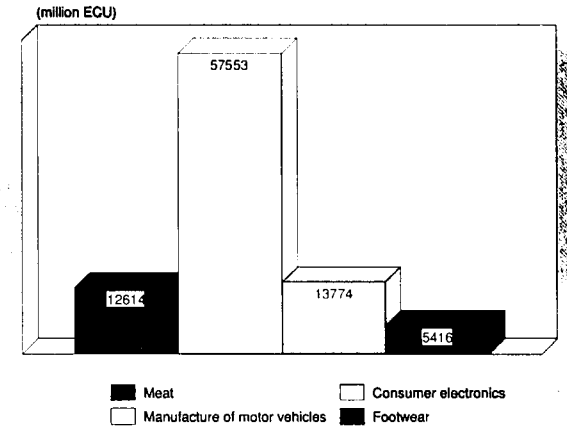
Total production of meat at current prices in 1991 increased by 5.1% compared to 1990, while the rate of apparent consumption growth was slightly lower, at 4.1%. The trade balance was positive for the first time is more than ten years. The increase in production was particularly significant in Ireland and Germany. The unification of Germany has had the most significant contribution to the increase in the production of beef, veal and pork meat, compared to poultry, lamb, mutton and goat meat. East German producers were not competitive compared to EC producers, and chose to slaughter their livestock rather than continue to invest in upkeep. The sizeable increase in meat production attributable to this slaughter activity was therefore a temporary increase

From 1989 to 1991 employment in the EC industry as a whole rose by an average of 2.1% per year. Significant increases were recorded in Germany, France, the UK, Portugal and Ireland. Employment dropped in Italy and Denmark (-2.1% average per year in each country).

The consumption of beef and veal has not been affected very much by the drop in prices, which was not completely passed on to consumers by retail prices. The growth in overall quantitative consumption (7%) was not matched by a parallel increase in per capita consumption, suggesting that increased consumption was caused only by increased population rather than increases in individual consumption.

France has the greatest share of value added in current prices (28.3%), followed by the UK with 16.1%, Germany with 15.1%, Spain with 12.9% and Italy with 11.6%. The top five countries account for 84% of total added value.

Figure 1: Meat
Value added in comparison with other industries, 1991



Source: Eurostat

Recent trends

In the second half of the decade, average yearly growth rates for all the key indicators were lower than over the period 1982 to 1985. Increases in production of meat are expected through to 1994, with less than proportionate increases in consumption, and an increase in exports is also expected due to the opening of trade links with the former USSR and the countries of Eastern Europe.

Foreign trade

The improvement in the trade balance recorded in 1991 is result of the recovery in exports (which increased by 12.6% in nominal terms and 22.4% in real terms), and the reduction in imports (which decreased -7.1% in nominal terms and -2.1% in real terms). Since 1986 there has been a continuing improvement in the terms of trade. Intra-EC trade accounts for approximately 20% of production. The trade flows in beef, veal and pork meat, especially following the entry of Greece, Spain and Portugal in the EC, are mainly from the strong producing countries of northern Europe towards the southern areas. Extra-EC exports comprise 5% of production and are directed primarily towards Japan, the former Soviet Union, EFTA countries and OPEC countries. The significant increase

in the share of meats exported to the former Soviet Union, compared to 1986, is particularly worth noting.

About 80% of EC imports are of EC origin; the main non-EC suppliers are Argentina, New Zealand, Brazil and some Eastern European countries.

MARKET FORCES

Demand

The proportion of fresh meat and meat products in total consumption is around 73% to 75% in quantity and 65% to 70% in value. The main suppliers and consumers of processed meat products are Germany, France and Italy.

In the shopping basket there has been a shift from beef and veal meat to so-called "white", lean meat. This shift, which has been triggered in part by price considerations, is also a response to a new orientation in consumption recorded in the industrialised countries. Consumers are paying a greater attention to dietary factors and, especially in the countries of northern Europe. In addition, there is an increasing preference for specially packaged products, such as individually portioned meats. The convenience of these packaged meats and meat products is resulting in a shift of consumer demand away from frozen meat and meat products, which were previously seen as the most convenient preparations.

Supply and competition

The degree of concentration in the industry varies from country to country. Production of fresh meat is highly fragmented in Italy, Greece, and Portugal, while there is a fair degree of concentration in Germany, the Netherlands. Denmark and France.

The processed meat sector market concentrations tend to mirror those of fresh meat, with the notable exception of Spain, which has a concentrated fresh meat market, but a fragmented processed meat market.

A drastic change in the competitive scenario, from the concentration standpoint, should come about with the enforcement of EC directives regarding quality and hygiene standards. The high financial costs necessary for the modernisation of plant and equipment will lead to the closure of many small-sized

abattoirs. The impact of the enforcement of this measure will differ from country to country; in Denmark, Germany, Holland, France and Belgium more than half of the plants and equipment already comply with EC standards, while in the remaining countries only 10% are up to standard.

The European producers will also have to face an increase in the market power of wide-scale distributors, which is expressed by the progressive reinforcement of distributors' brands. The relative power of the customers is greater in the countries where the supply is not concentrated.

Production process

Productivity in the meat industry in general has increased continuously. Although the nature of the product does not allow for the introduction of technological innovations on such a level as to generate significant economies of scale, the last few years have witnessed an increase in investments aimed at increased efficiency in the production process, with the introduction of automation in those phases requiring less manual skill.

INDUSTRY STRUCTURE

Companies

In 1990 the number of abattoirs was estimated at 6,631. About 40% of these were located in Italy, although they accounted for only 10% of all carcasses. The highest concentration can be found in Germany where 5% of the EC abattoirs account for 22% of all carcasses.

In the fresh beef and veal meat sector, the top three firms, Socopa (France), Inalca-Gruppo Cremonini (Italy) and Sucden (France), together have a 4-6% share of the EC market. In the sector of fresh pork meats, Annuss Fleisch (Germany), West Fleisch (Germany) and Sued-Fleisch (Germany) have a 4-4.5% share of the market. In the lamb and mutton sector, NZ MPB HL Foods (UK) and Socopa (France) account for 15-16% of the market. For the poultry sector, Paribas (France), Sipa (Italy), and AIA-Gruppo Veronesi (Italy) have 15-18% of the total market. In processed meats, Nestlè (Switzerland), Unilever (Anglo-Dutch) and BP Nutrition (UK) cover 9-11% of the market.

Cooperatives hold significant shares of the supply in the main producing countries. In order to cope with the challenges

posed by market globalization, these companies have increasingly taken on an entrepreneurial structure, in some cases setting up joint ventures with private companies.

Public slaughter-houses are also widespread, especially in Italy, Germany and France. However, the share of meat slaughtered in private plants is on the rise throughout Europe.

Strategies

The smaller companies in the industry use a product-oriented approach to strategy, by acting on the price as a competitive variable, or by concentrating on niche policies.

Among the strategies of the large companies in the industry there is a widespread tendency to adopt market-oriented policies, by allocating resources to product innovation and advertising expenditure whose purpose is to establish industrial labels. For the pork and poultry meats, there are attempts at branding and introducing quality trade marks. Although there are a few producer labels on the market for beef and veal, the advertising campaigns are first and foremost aimed at regaining consumer trust and fidelity;

For all the kinds of meat, the strategies of the large companies are also focused on the qualitative improvement of the product; vertical integration upwards fits in with this approach. Integration policies are also adopted downstream in the scope of catering and fast food restaurants. Large companies also engage in mergers and acquisitions to expand company growth in the country of origin, and to facilitate entry into foreign markets where the acquisition of a local company is the most efficient way to overcome the obstacles arising from the diverse consumer traditions and from differing distribution systems. External growth policies are thus relatively frequent. The most significant transactions have taken place in the meat processing sector, in which some large multinationals have entered by way of take-overs. For example, in Italy Kraft-General Foods has taken over Fini, Invernizzi and Negroni; Nestlè (Switzerland) has taken over Vismara, Locatelli and Kings, BSN (France) has taken over Galbani. In addition, Nestlè has taken over Herta, a leading German company in the sector.

Recent acquisitions among slaughterhouses include Guyomarch (France) by Paribas (France); Meadow Irish Meats (Ireland) by Kerry Group (Ireland); Taher Meats (Ireland) by Kepak (Ireland); Studleigh-Royd (UK) by Perkins Food PLC (UK); NVC (Netherlands) by Coveco BV (Netherlands); OMSA (Spain) by Inversiones Ibersuizas SA (Switzerland).

Through consortiums and various state bodies, each Member State is committed to obtaining EC recognition for the protection of its own typical produce.

REGIONAL DISTRIBUTION

The geographical location of slaughtering activity is dependent on the location of breeding activity. About 85% of beef and veal meat is produced in Germany, France, Italy, the UK, the Netherlands and Spain. 83% of the pork meat comes from Germany, France, Spain, Holland, Italy and Denmark. For poultry, France, Italy, the UK, Spain, the Netherlands and Germany together add up to 88% of production. The UK, Spain, France, Greece and Italy produce 86% of the total amount of sheep and goat meat.

ENVIRONMENT

The ecological problems related to the slaughter and meat processing industries can be traced back to the production of the primary material, i.e. livestock rearing. Excessively high territorial concentrations, especially for pig-breeding, create conditions for ground pollution, especially of the underground water-bearing stratum.

There are also difficulties in the disposal of the liquids and the discards of the slaughtering. This fact has stimulated the development of systems for the utilisation of such leftovers in the production of, for example, fertilisers or animal feeds.

REGULATIONS

Beef and veal

The basic regulations for the beef and veal sector go back to Regulation 805/68 EEC, subsequently amended several times.

Regulations 2822/72, 1302/73, 2226/78 and 859/89 are measures intended to sustain the market, including permanent intervention, while Regulation 425/77 acts on import norms. Lastly, Regulation 1208/81 defines a common European classification scale for the carcasses of adult cattle.

The norms for intervention give the producers of each Member State the possibility of selling their product to EC intervention agencies, to reduce the supply on the market when the average EC price falls below 84% of the intervention price (set at the start of the marketing year) and when, at the same time, the average market price within the Member State falls to below 80% of the intervention price. In 1991, after a rapid fall in prices and a corresponding increase in the EC stocks, the latter threshold was lowered to 72%. Subsidies can also be provided for private storage (Regulation 989/68 and 3445/90).

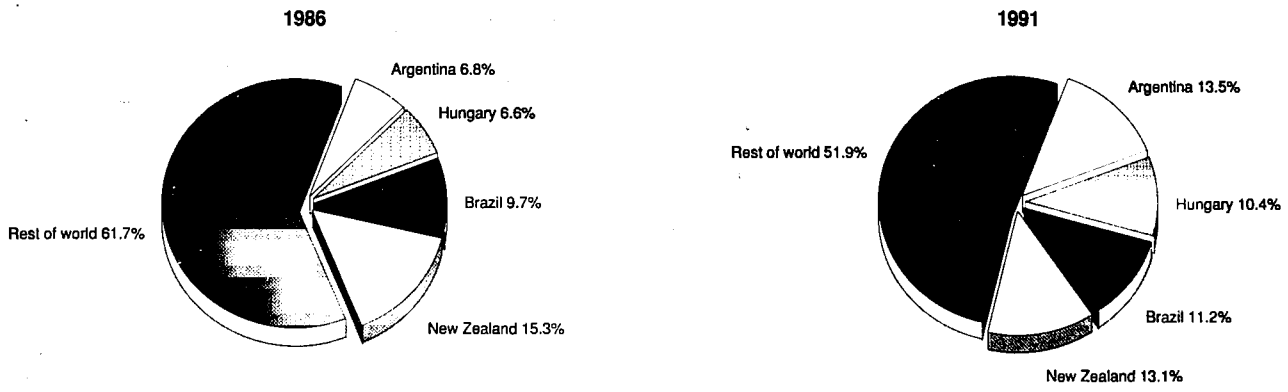
The GATT agreement provides for the partial modification of import levies and export refunds, with six schemes for the importation of meat from non-EC countries, embodied by regulations 3888/89, 3891/89, 2207/90, 2208/90.

There is also a system of premiums made to breeders, aimed at directing production in a particular field (Regulations 1357/80, 468/87, 859/87, 714/89, etc.).

At the end of 1991, under pressure from the high production increases and from the growing resort to intervention, a reform of EC policy in the beef and veal sector was introduced. That reform comprised the following main points:

- beginning from 1/7/93, the intervention price is lowered by 15%;
- premiums to breeders of male bovines and suckler cows will be increased;
- in order to encourage the breeding of higher quality stock, a coefficient of animal-density per farm will be introduced;
- a 100 ECU premium will be introduced for each calf disposed of within ten days of birth;
- the possibility exists of obtaining financing for promotional campaigns for beef and veal meats, from the Feoga-Garanzia.

Figure 7: Meat
Origin of EC imports



Source: Eurostat

Pork meat

The fundamental regulation for pork meat is number 2759/75, which replaces the previous Regulation 121/67. Market support measures are available in this sector as well, similar to those implemented for the beef and veal sector, i.e. import levies and export refunds (Regulation 3602/82). There is a common classification for pig carcasses as well (2967/85).

Poultry

The basic norms that regulate the EC market for poultry are addressed in Regulations 2771/75 and 2777/75, and include amendments of the previous laws. There are no measures of intervention or market support for the poultry sector; market prices within the EC directly reflect the trends in demand and supply. Import levies and sluice gate prices are provided for to prevent the entry of foreign products into the market at prices that are lower than EC production costs.

OUTLOOK

Over the next three years a strong increase in industrial concentration is expected, due to both the enforcement of Directive 497/91, and the intensification of international competition within the EC itself. Both of these factors will lead to many minor companies leaving the market.

It is difficult to evaluate medium-term developments of the main indicators because this is a regulated market, subject to many changeable international agreements; much depends on the evolution of such accords and on EC legislation. Overall internal consumption will continue to increase rather slowly. The European consumer will tend to turn increasingly towards products with high-quality and high added value.

The limits imposed by the EC budget and by outside pressures for a reduction in support to producers might lead to legislative developments whose effect could be the stabilisation of the production of beef and veal and pork meats, and the increase of exports to third-party countries in order to reduce the stockpiles. Exports would benefit from the opportunities offered by the opening of the markets in the former USSR and Eastern Europe.

The latter amount to a source of opportunities as well as risks. The obsolete and inefficient production structure of these countries turns them into potential markets for processed products. Furthermore, there is a chance to reach agreements and joint ventures with local businesses to finance the moderni-

sation of the local productive set-up. Nevertheless, there is a risk linked to the increase in cattle imports coming from these countries with which the EC has already had to deal.

Other sector risks include the difficulty for the beef and veal industry in reversing the new consumer demand for "white" meats, although this is an opportunity for the producers of these products. Consumers will also become more powerful in the market as distribution improves; producers will need to watch consumer demand shifts more closely. Also, many small firms are expected to go out of business as competition increases.

On the other hand, there is a large market now opening in Eastern Europe, and much potential for innovative products exists in the Western European market, as well. There has been little movement in this direction, and untapped consumer demand exists. Quality brands are beginning to appear as well, which will give producers the chance to achieve qualitative differentiation of products.

Dairy products
NACE 413

The period of 1983 to 1989 was characterised by a drop in milk deliveries, a reduction in butter and skimmed milk powder stocks, and rising prices. From the end of 1989 and through to 1991, a recovery in production took place. At the same time, extra-EC exports decreased due to such factors as the Gulf War and the diversification of supply sources away from the traditional countries. As a consequence, prices decreased not only in the EC market but also in the world market. Moreover, the problem of production surpluses once more became acute, with rising stocks of skimmed milk powder and of butter.
The consumption of yoghurt and desserts, fresh cheeses and semi-skimmed milk has increased whereas the consumption of butter has continuously decreased. Technological innovations and an increasing market segmentation on the part of firms favour the spread of higher value added products. M&A activity over the last five years has radically changed the competitive scenario.

Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The main products of the dairy industry are:

- products destined for final consumption: fresh and U.H.T milk, butter, cheese, fresh products (cream, fermented milk, desserts, fresh cheese), powdered milk;
- products which serve as raw materials for further processing and can be regarded as commodities: powdered milk, butter, butteroil, casein, whey powder. These products provide proteins and fats both for human and animal nutrition. Whey protein concentrates have proved to be very good substitutes for egg white in the pastry industry.

Dairy firms are very rarely diversified into non-food sectors. Often dairy fims diversify into related products which provide scope economies. This might include other fresh products areas such as "charcuterie" (marketing economies), and preserved vegetables (production and packaging economies).

Main indicators

In 1991 production and apparent consumption at current prices were stable, while the trade balance improved after a significant drop in 1990. Employment decreased 8.5% from 1987 to 1991.

Particularly worth noting is the increase in Portuguese production, which grew by more than 20% per year on average in 1989 and 1991. Portugal has been subject to production quotas only since 1991.

France has the highest value added share at 24.6%, followed by Germany with 15.9%, Italy with 15.7%, the UK with 15.1% and Spain with 10.4%. The first five countries account for 82% of EC value added.

Recent trends

EC production and apparent consumption in the industry grew approximately 9% between 1985 and 1990, but growth rates are expected to decrease. Growth is varied among different single product lines. Innovative products and fresh cheese show the highest growth rates. Fresh milk products and cheese production and consumption are also growing, while the overall production of milk as an end-product is decreasing. Within this sector, the production of whole milk is decreasing, while semi-skimmed milk production is increasing. In 1989 butter production began to recover from a fall which lasted from 1986 to 1988. The decrease in EC consumption and extra-EC sales caused EC butter stocks to rise from 5,000 to 260,000 tonnes in 1989 and 1990.

Foreign trade

The trade balance, which had improved steadily from 1986 to 1989, worsened in 1990 due to a sudden decrease in exports. In 1991, however, both the trade balance and the terms of trade improved. Extra-EC and intra-EC exports each account for a fairly small share of total production (6% and 15% respectively). High transport costs and the local nature of firms (as opposed to operating on a national or international scale), result in a market better suited for domestic consumption. Those products which are exported from the EC are directed primarily towards OPEC countries and, to a lesser extent, towards the US.

The share of extra-EC imports in total consumption is negligible, at slightly over 1% of consumption in 1990.

MARKET FORCES

Demand

Less than 20% of milk produced in the EC is consumed as an end-product. The remaining milk is used to produce cream and fresh products (8-9%), butter and cheese (50-60%), powders (15-16%), animal feed (4-5%) and other products.

The consumption patterns of dairy products are regional although many consumers throughout the EC are showing a new preference for "healthy" fresh and low fat products. As a consequence, consumption of many kinds of yoghurt, semi-skimmed milk, flavoured milk and fresh cheeses is increasing, whereas that of whole milk is decreasing. Mixed-fat products, such as dairy spreads, are being used increasingly as butter substitutes. Not all countries allow the trade of mixed-fat products in their national market, but liberalisation is expected with the implementation of the Single European Market.

EC butter, powdered milk and cheese surpluses are often exported to international markets but world demand is decreasing due to the consumption saturation of developed countries and an increase in production in some importing countries. Moreover, some of the countries which traditionally imported EC dairy products are diversifying their supply sources. East European countries have higher milk production than the EC, and expanded trade with these countries will alter the world market situation.

Supply and competition

As a consequence of the restrictions represented by the milk "quota system", the dairy industry structure has radically changed, especially in some Northern European countries where mergers among cooperatives have led to significantly increased concentration. The implementation of the Single European Market will increase international competition within the EC, and countries with a more concentrated market will have a competitive advantage.

Production process

In recent years the production process has significantly improved due to technological innovation. The automation of some production steps led to scale economies, especially in the production of powders and of some kinds of cheeses the

development of an ultra-filtration process allows not only more efficient use of raw material components, but also the development of new milk by-products. The production of many regional specialities is still, however, artisanal.

INDUSTRY STRUCTURE

Companies

The total number of EC dairies is estimated at 6,500. Although all EC countries have become significantly more concentrated, there are still remarkable differences in the levels of concentration across countries. Italy shows the lowest ratio (3,200 tonnes of average intake per dairy) and the Netherlands show the highest (334,000 tonnes par dairy).

In the countries where geographical features contribute to a fragmented distribution system, large firms coexist with smaller, more specialised firms which often concentrate on the production of regional specialities. In the liquid milk sector, Parmalat (Italy), Sodiaal (France) and MMB (UK) altogether account for 15% to 20% of the market. In the yoghurt sector, BSN (France), Nestlè (Switzerland) and Sodiaal (France) account for 35% to 40% of the market. In the fresh cheese sector BSN (France), Unilever (Anglo-Dutch) and Philip Morris (Kraft) account for 25% to 30% of the market. In the powdered milk sector Nestlè (Switzerland), France Lait (France) and HL Foods (UK) account for 60% to 65% of the market.

A great number of cooperatives operate in the dairy industry, especially in Ireland, Denmark, Belgium, the Netherlands and Germany. In Italy and Spain there is significant municipal and state involvement in the industry.

Strategies

The restrictions imposed by EC agricultural policies and the saturation of the traditional product markets have forced firms to produce higher value added products. Technological innovations both in the production process and in packaging have favoured product differentiation and market segmentation, primarily by the leading firms. These large firms are also diversifying their product lines to increase their market share in the area of low fat and mixed fat products (like "spreads"). Although cooperative firms are adopting industrial management decision-making processes, they face difficulties in

adopting a market-oriented diversification policy due to their strong relationship with associated farmers.

Remarkable investments both in promotion and in advertisement have allowed the success of producer brands, although in some countries distributor's labels are also present.

Recent structural changes in the industry are due to M&A activity involving both private firms and cooperatives. Companies are acquiring local firms to facilitate the penetration of foreign markets and to strengthen their position in their own countries. Over the last few years, the most important mergers and acquisitions have been the following: the acquisition of Interlait (France) by ULN (France); the acquisition of 51% of Lacteria Espaniola (Spain) by UNL (France); the acquisition of Bridel (France), Jean Jacques (France) and Valmont (France) by Besnier (France); the acquisition of Laiterie D'Auzances (France) by Unilever (Anglo-Dutch); the merger of the Dutch co-ops CC Friesland, Domo Beiland and Noord Nederland in Friesland Frico Domo; the merger of the Dutch co-ops DMV Campina and Melkunie in Campina Melkunie BV; the acquisition of Cloche D'Or (France), La Fromagerie du Velay (France), Fauquet (France), Ludovico (Italy) and Millway Foods (UK) by Bongrain (France); the acquisition of Galbani (I) by BSN (France); the acquisition of Invernizzi (Italy) and Fattorie Osella (Italy) by Kraft; the acquisition of Locatelli (Italy) by Nestlè (Switzerland); the acquisition of many other Italian firms and municipal dairies by Parmalat (Italy) and SME (Italy).

REGIONAL DISTRIBUTION

The milk delivered to French, German, British, Dutch and Italian dairies accounts for 80% of total milk intake. The production of fresh milk products is mainly due to Germany, Spain, United Kingdom, France and the Netherlands, although cheese production is significant also in Italy, the UK and in Denmark.. The largest industrial plants for the production of powdered milk are located in Northern Europe.

ENVIRONMENT

The most important environmental issues related to the dairy industry are soil and water pollution caused by stock-farming. The industry, however, also has to deal with the management of household waste disposal and therefore with packaging regulations.

REGULATIONS

The primary regulations for the dairy industry concern the following:

- market support involving the purchase of butter, of some kinds of cheese and of skimmed milk powder and the adoption of the "Community Preference" principle through import levies and export refunds;

Table 8: Dairy products

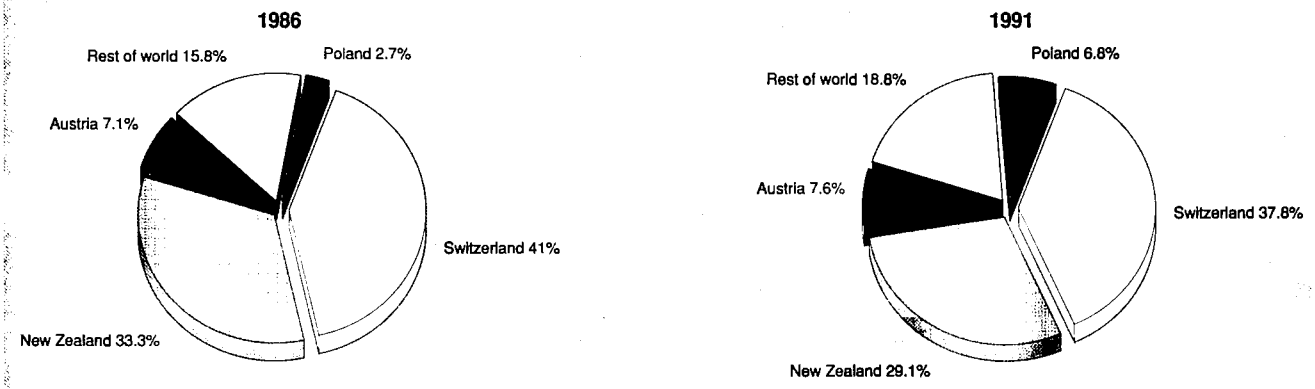
Figure 7: Dairy products
Origin of EC imports



Source: Eurostat

- the disposal of product stocks through special sales on domestic and foreign markets (especially on the USSR market);
- measures for the harmonisation of hygiene and quality standards of milk and milk by-products meant for intra-EC trade;
- the establishment of milk quotas (Regulations 856/84, 857/84, 1447/84, 1527/88) and co-responsibility levies.

OUTLOOK

The development of the dairy industry is strictly related to the future EC agricultural policies and to the many agreements which influence extra-EC trade.

The most important consequences of the establishment of the Single European Market will be the following:

- legislative problems related to the protection of Designation of Controlled Origin products;
- problems related to hygienic and qualitative standardisation of products;
- a further increase in concentration and internationalisation of the industry.

Among the risks the dairy industry faces is a change in consumer demand towards lower-fat products. These include mixed-fat products, which contain both vegetable or grain oils and dairy products and which will be affected by Regulations which will reduce bans on mixed-fat products in certain countries. World demand for certain dairy products is also decreasing as more countries move to produce these products domestically. EC countries which tend towards smaller, more specialised firms will be at particular risk from increased competition at the establishment of the Single European Market.

The current leading firms, however, will be able to advantage of opportunities associated with the implementation of the Single Market, especially in the international sector. Increased concentration will bring gains from the ability to invest in new technological processes and product innovation. Also, although some foreign markets are saturated, there are other niche markets which can be developed.

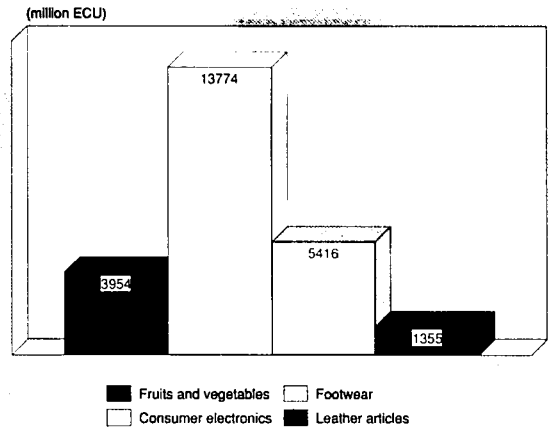
Fruit and vegetable processing and preserving
NACE 414

While the vegetable preserves market in general is going through a phase of slow growth, some sectors (such as fruit juices) are growing more rapidly. Industry is concentrated in the hands of a few multinational enterprises, but a strata of small businesses also exists. These producers are preparing themselves against strong price competition coming from Asian and East European rivals. The promotion and advertising strategies of the companies will take on growing importance in the future, as will the role of large-scale distribution.

Figure 1: Fruit and vegetable processing and preserving Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

This sector includes fruit and vegetable processing activities designed to prolong preservation. The main product categories are tomato preserves, preserves of other vegetables, oil or vinegar preserves, fruit juices, jams, and jellies.

Main indicators

Exports remain small relative to actual production, just under 10% in 1991. Although the real production growth, which was averaging upwards of 4% per year between 1987 and 1990, slowed to gains of closer to 3% in the beginning of the nineties.

The number of people employed in the early 1980's had decreased in parallel with the introduction of more capital intensive technologies. As of 1989, however, this process of labour substitution for capital came to an end, producing renewed growth in the number of employees.

Recent trends

The trend of consumption and production in real terms shows generally steady growth throughout the eighties, apart from a slowdown in 1985. The trend in consumption has been faster than the trend in production, reflecting an increase in import penetration. Exports have remained stable, if not declining.

Although the US market is about the same size as the EC's, growth in the EC has been slightly higher over the last several years.

Foreign trade

While exports were characterised by large fluctuations throughout the 1980's, imports from non-EC countries grew steadily resulting in a worsening of the trade deficit. By 1991, the ratio of exports to imports was close to 40%.

From 1986 to 1991, the make-up of the countries exporting to the EC shifted in favour of the East European countries which export large quantities of semi-finished fruit-based produce and, depending on the area, several kinds of vegetables. Over 50% of imports come from East European and developing countries. In 1991, Turkey alone supplied almost 20% of imported goods, most notably tomato-based semi-finished produce. The trade flow coming from Brazil is also important, consisting largely of concentrated juices of tropical and citrus fruits. Imports from the EFTA countries and the United States account for a small share of total imports, which consist mainly of speciality products.

Regarding exports, the greatest share is destined to the most developed EC and non-EC countries. The share destined to the United States, however, has progressively declined since 1986 because of the proliferation of typical Mediterranean products in the US domestic market. In addition, protectionist measures on fruit and vegetable imports have been introduced in the United States following the implementation of similar European measures on American meat imports. Exports to the Middle East are quite sizeable too, even though EC goods are losing market share as a result of price competition from non-EC competitors. Overall, exports as a share of production increased from 36.3% in 1982 to 41.3% in 1991.

The volume of intra-EC trade is understandably much higher than the value of goods coming from non-EC countries. During the 1980's, intra-EC trade grew at an average rate that was well above overall import growth, increasing its importance in overall EC trade. The slowdown in intra-EC trade in 1986 was most likely affected by the introduction of production quotas for the principal forms of fruit and vegetable processing (tomatoes, peaches, pears etc.), enforced by the EC for the first time in 1985.

MARKET FORCES

Demand

In spite of the well-established product characterisation of vegetable preserves, opportunities still exist for further growth in the market. This is due to the homogenisation of food consumption trends within the EC and to the renewal of products by way of differentiation strategies enacted upon by the companies. Product innovation and advertising made by industry are also giving an impetus to demand. For now, however, product innovation has taken on a supporting role to demand, as large volumes of consumption are still directed towards traditional products.

The products that make up the aggregate reveal different demand dynamics. Fruit juice consumption is experiencing a growth phase throughout Europe both in terms of the overall market and in per capita terms. On the other hand, fruit preserves are going through a slack phase, with consumption declining in some countries. Germany is affected by the greater availability of fresh fruit. Spanish output is turning increasingly to the export market, while domestically there is an increasing substitution away from canned or processed goods to fresh fruit. Growth in the EC market can be credited to higher quality products and product innovation.

The consumption of tomato preserves is increasingly strong in the Anglo-Saxon countries, thanks to the popularity of the Mediterranean diet (particularly pasta). Tomato preserves are fundamental for such dishes.

The market for vegetable preserves is quite stable, although it is affected by competition from frozen and fresh produce. Consumption is still growing strongly in the German and French markets. France is often used by producing companies as a base from which to export produce to other EC countries.

Another factor which influences demand is the expansion of modern and/or large-scale distribution. On the one hand, the distribution network improves communication between industry and consumers. On the other hand, it allows consumers to shop less frequently which tends to encourage the sale of packaged products rather than fresh goods.

Supply and competition

The countries that produce vegetable preserves are located mainly in the Mediterranean basin, i.e. Italy, Spain, Portugal and Greece. Competition between them is complicated by a mechanism of quotas which was introduced in 1985. This institutional factor has indeed limited the redistribution of production among countries on the basis of changes in relative competitiveness. Subsidised domestic production has also contributed to a reduction in import flows.

Exports too have undergone a slowdown owing to the preference of EC industry towards serving customers within the internal market first and foremost. One of the effects of the introduction of production quotas has been a lessening in the degree of external dependency.

Despite the importance of production quotas, other factors do influence relative competition within the EC. Italy, for example, the main producer and exporter within the EC, is characterised by much higher labour costs compared to other Mediterranean countries. This factor works against the Italian producers by limiting their price competitiveness.

Within each country two kinds of industrial organisations can be distinguished. The first group is the principal food multinationals that operate in many sectors; they follow defined advertising and distribution strategies, perform R&D and occupy the upper band of the market. These companies benefit from productive capacity organised in large-sized plants. The second group is a system of small companies that operate in marginal and local markets, organised into territorial systems or zones where there is a large availability of usable primary goods. Some companies occupy niches in the market, while others are destined to become marginal.

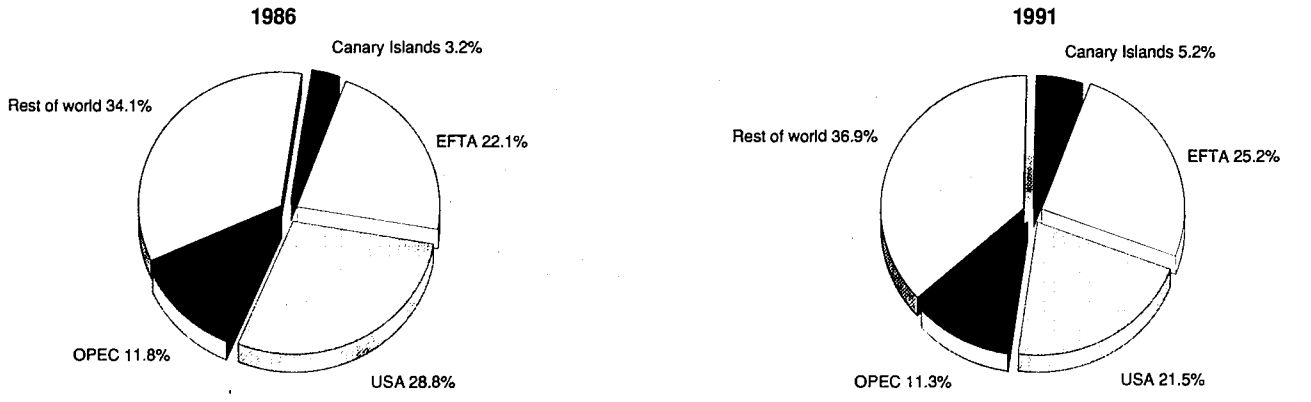
Traditionally, the EC has been affected only marginally by competitive pressure from outside its borders. This development is attributed mainly to the Community's subsidies for agricultural production and quality requirements for vegetable preserves. Trade figures, however, indicate that imports are growing rapidly. Import increases are largely due to low-cost semi-finished produce coming from other Mediterranean countries. One example is Turkey, which provides tomato concentrate and partially processed exotic fruits and vegetables which are unavailable inside the EC. Other imported goods include concentrated and frozen fruit juices, frozen fruit and seedless fruits (for jam-making), raisins, pickled olives and capers etc. Apart from the availability of certain kinds of produce, the competition from non-EC imports is reinforced by lower labour costs in both East European and developing countries.

The recent liberalisation of the East European economies has already made its effects felt with the sudden increase in the availability of partially processed primary agricultural goods. This abundant supply will in future fuel imports into Europe at very advantageous prices.

Production process

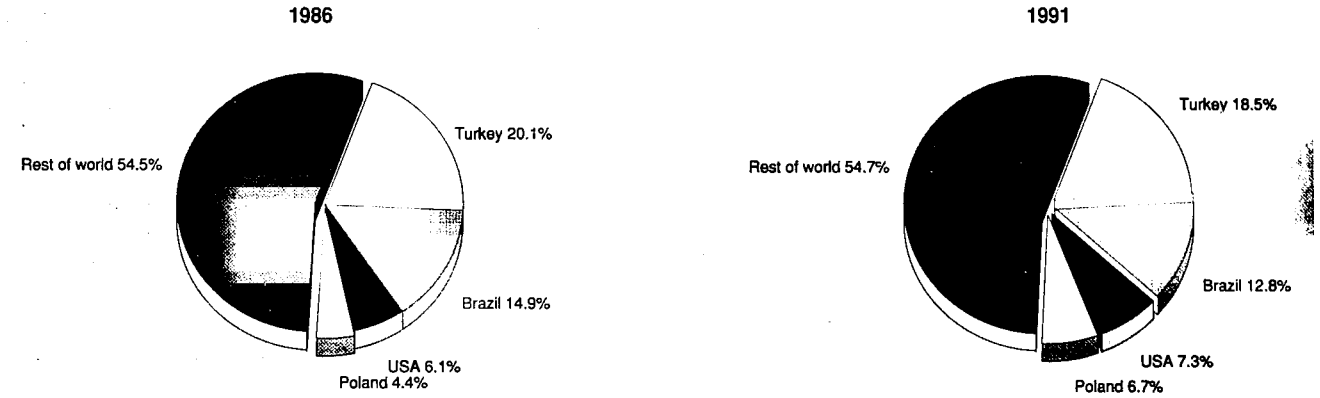
Vegetable and fruit preserves (tomatoes, peas, peaches, pears, etc.) are produced, in most cases, in plants that are located no more than a few hundred kilometres away from the area in which the fresh produce is cultivated. Given this situation, agricultural zones with vegetable and fruit cultures also have

Figure 6: Fruit and vegetable processing and preserving
Destination of EC exports



Source: Eurostat

Figure 7: Fruit and vegetable processing and preserving
Origin of EC imports



Source: Eurostat

a high concentration of processing plants. The technologies for automatic harvesting and processing have indeed helped the creation of hybrids that induce a simultaneous maturation of the produce, which then has to be harvested, transported and processed in a very short period of time. During the 1980's, value added rose consistently as a result of the overall growth in capital intensity. Unit labour costs, however, have risen at a faster rate than labour productivity.

INDUSTRY STRUCTURE

Companies

The number of large companies operating in this sector is small as many producers operate in niche markets. Furthermore, there are very few large companies having multinational features that are present in all major European markets.

In 1989, the foremost enterprises operating in the European market included, for canned vegetables (non-tomato), Bonduelle, CGC, Grand Metropolitan, HL Foods, Suiker Unie, and Heinz, which together had an EC market share of 40% to 50%. For processed tomatoes, SME, Nestlé, BSN, Heinz, Mars and CPC were the dominant producers with a combined EC market share of 50% to 60%. For canned fruit, BSN, Del Monte, Conserves Gard, Odenwald, and Nestlè were the leading EC companies with a combined market share of 50% to 60%. Finally for fruit juices, Eckes, Melitta, Cadbury Schweppes, Hero, Pernod Ricard, and Procter & Gamble were the EC market leaders with a combined share of 30% to 40%.

Strategies

Company response to the demand conditions described above has been varied. Leading or large companies operating in various markets and offering a diversified range of products can increase their own market shares by promoting their own brands with large advertising campaigns. Packaging offers a further element of innovation. These strategies are supported by horizontal product differentiation, where innovations tend to value intrinsic oganoleptic qualities.

Furthermore, important process innovations have been introduced with a view to improving the preserved product from a nutritional standpoint. Such innovations include techniques of irradiation, extrusion and filtration. The preservation industry does not dedicate many resources to research and development but tends to adapt technologies used in other industries, such as the chemical, energy and plastics industries

(1) Estimates
Source: Eurostat

(where R&D has a basic strategic importance) to their own needs. In a secondary group of companies we find the huge cooperative groups that are strongly integrated with the upstream agricultural sector. These firms tend to efficiently exploit the productive capacity of their huge-sized plants. Compared to the first group of large multinationals, they allocate fewer resources to commercial promotions. Such companies are privileged suppliers of brand-name products to large chain distributors.

Small-sized companies tend to develop niche markets by supplying speciality products endowed with a high qualitative content. The distribution sector is concentrated in most of the EC markets. This sector exerts pressure on the design of the commercial strategies of the major companies by means of the promotion of own-brands and compressing the industry's margins by demanding low prices.

The investments made in the 1980's were directed toward the modernisation of production capacity by adopting more capital-intensive technologies associated with higher productivity and investments in advertising campaigns. Acquisitions, mergers and stake-holdings (particularly on the part of large-scale industry) also gained increasing importance in the eighties. The trend towards the acquisition of national brands by big businesses was especially lively in those markets where concentration was rather low, such as in Italy and Spain.

REGIONAL DISTRIBUTION

The distribution of production in the various countries (in addition to reflecting the size of the market) is also marked by sharp differences in the fruit and vegetable processing industry itself. Germany is concentrated in the most significant market segments, fruit juices and preserved vegetables. In France the industry is characterised by the presence of large diversified enterprises in various food segments, with high product differentiation and an emphasis on quality.

In the 1980's, Italy witnessed a process of concentration in its industry which took its level of added value close to that of Germany and France. Spain is proceeding along these lines although it is a couple of years behind. The sector in Greece has numerous small-sized productive units. Furthermore, the level of prices is rather low despite significant production volume. The United Kingdom maintains a well-established and highly concentrated industry. The UK's market is more mature than that of France or Germany and, as a result, prices and margins tend to be narrower.

ENVIRONMENT

The production process, the by-products, and the industry's discharges, do not have a significant environmental impact. The importance of marketing in this mature industry combined with modern self-service distribution needs, however, pave the way for increasingly cumbersome packaging. This means more waste disposal problems in processing the refuse.

OUTLOOK

In the near future, current consumption trends are expected to remain steady. This will take place across Europe as a result of the diffusion of several products that have already

Table 7: Fruit and vegetable processing and preserving Consumption of the main categories of processed and conserved fruits and vegetables 1989 and average yearly growth rate 1985/89

achieved maturity in their markets of origin, such as tomato preserves and fruit juices.

Production will be affected primarily by changes in the CAP (Common Agricultural Policy). Since 1991 a formula to aid agricultural production has been introduced which excludes industry from being subsidised.

Furthermore, the shift from the quotas policy to that of guaranteed minimum thresholds will dissuade unscheduled increases in EC output. This mechanism might affect the containment of the interdependency with the extra-European areas, by having a positive effect on the intra-EC trade flows and by making extra-EC exports merely residual.

A new backdrop is provided by the opening of the East European economies, some of which are especially rich in agricultural produce and which make up one of the few goods they have to trade for technology. Clearly the acquisition of new preservation technologies and the marked price competitiveness of these countries is going to have a significant influence on the competitive scenario of Eastern Europe.

In summary, the risks that the fruit, vegetable, processing and preserving industry faces in the future are:

- high prices and thus the non-competitiveness of European industry;
- the replacement of fresh produce with freezing and chilling;
- the replacement of fresh produce with value-added produce (irradiated or ready-washed vegetables).

Companies which adopt a strategy of product innovation and establish niches based on high quality produce will be the best positioned for growth in the future.

Fish
NACE 415

The strong increase in demand for processed fish over the eighties was not matched by an equal increase in EC production, thus the trade balance decreased sharply.
The markets which show the fastest growth are those of canned and frozen fish. The popularity of these products is due mainly to the product differentiation policies adopted by leading firms through the introduction of "convenience" and high value added products. Fresh fish, however, still constitutes a highly competitive substitute product.

INDUSTRY PROFILE

Description of the sector

The fish and seafood processing industry covers two main subsectors:

- Quick freezing of edible fish and other seafoods (NACE 415.1).
- Processing of fish and other seafoods (not including quick freezing); the subsector includes dried, salted, smoked and canned fish (NACE 415.2).

Main indicators

From 1986 to 1990, production at current prices increased, on average, by 8.5% per year, meanwhile, apparent consumption experienced even stronger growth (10% per year on average). The trade balance deteriorated sharply (the trade deficit has almost doubled in five years) due to a number of factors, most notably a decline in exports. Although in 1991 consumption and production increased by 7% and 8%, respectively, the trade balance continued to worsen despite a 9.8% increase in exports. The fishing sector is witnessing an unsteady trend in employment. In terms of distribution across the EC, Germany's fish industry shows the highest value added, followed by the UK, Spain, France and Italy. These five countries account for 75% of total value added.

Recent trends

The main indicators at constant prices show similar trends to those at current prices. In the second half of the 1980's, a rapid increase in consumption was not matched by a similar development in production. Consequently, extra-EC imports show a significant increase. If we divide the 1985-1991 period into two sub-periods, we can observe a strong slowing down in the growth of production and consumption between 1989 and 1991, which is should improve during the early 1990's.

Foreign trade

The EC is a net importer of processed fish. Between 1982 and 1991 extra-EC imports increased their share of apparent consumption (from 21% in 1982 to 27% in 1991). Among the main suppliers are the EFTA countries (whose share has decreased since 1982) Thailand, the US and Argentina.

By comparison, the share of extra-EC exports on EC production is relatively small, 10% throughout the eighties and slipping to 8% in 1991. Extra-EC exports are directed mainly towards the EFTA countries, the USA, Japan, and the OPEC countries.

MARKET FORCES

Demand

Increased recognition of fish as a healthier alternative to meat has recently attracted more consumers. Due to the improvement of distribution systems and packaging techniques, processed fish still faces strong competition from fresh fish, especially in Greece, Ireland and Portugal. The demand for frozen fish, however, is increasing in almost every country thanks to the development of "convenience" preparations and packaging which increase a product's storage period. The evolution of production technologies and a less than proportional increase in fresh fish services (in certain countries) also has a significant effect on demand. Spain, Belgium and France show the highest per capita consumption of frozen fish. The Italian, Danish and German markets also demonstrate positive demand. Increased dependence on catering will also encourage strong growth in the consumption of frozen fish.

The consumption of canned fish is increasing in Belgium, France, Italy, Spain and in the UK. Tuna is very popular in almost every country. The increase in sales is due mainly to marketing efforts by the leading firms, which adopted product differentiation policies through the introduction of both high quality products and new products such as mixed tuna salads. In Denmark and Holland the market has almost reached saturation, while in Greece canned fish cannot achieve a good market position due to the strong competition of fresh fish.

The increased consumption of smoked salmon in several countries is partially credited to the expansion of salmon farming.

Supply and competition

One of the most important competitive variables for the industry, both within the EC and between the EC and third countries, is raw material availability and price. Regulations aimed at preserving EC fish stocks, together with a growing tendency by coastal nations to defend exclusive fishing zones, may limit the productive capacity of EC fish-processing firms. The expansion of waterculture may be a partial answer to this problem, especially if it creates integrated market-oriented structures involving production, processing, scientific research, and market information.

Production process

The production process of canned fish is characterised by a certain degree of automation and scale economies. Firms operating in the high quality range produce fish in tins and glass containers. The introduction of easy-open aluminium tins is a recent innovation.

The deep-freezing process has been transformed by the innovation of cooling techniques. As shown in Table 4, productivity has increased more slowly than total unit costs throughout the eighties.

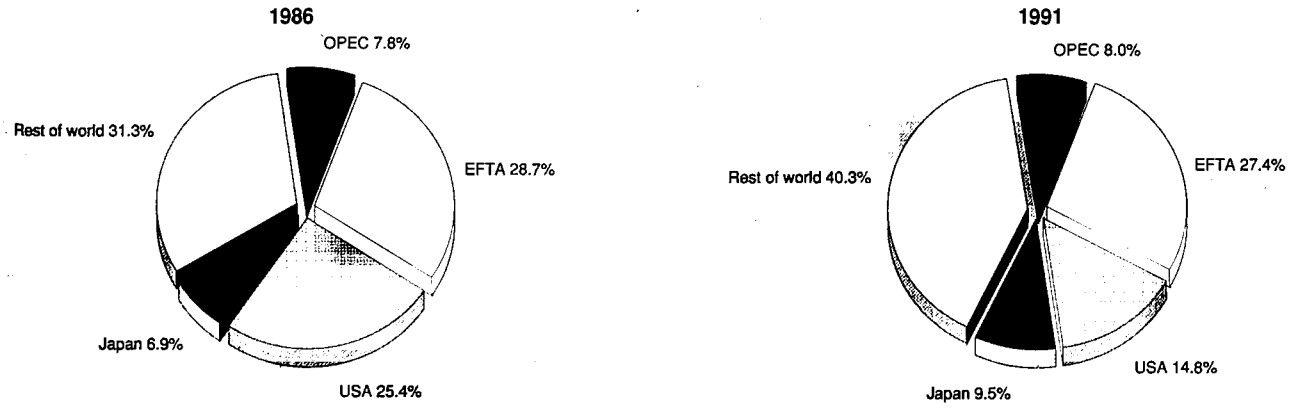
INDUSTRY STRUCTURE

Companies

The fish processing industry is characterised by a medium to high degree of supply concentration in single domestic markets.

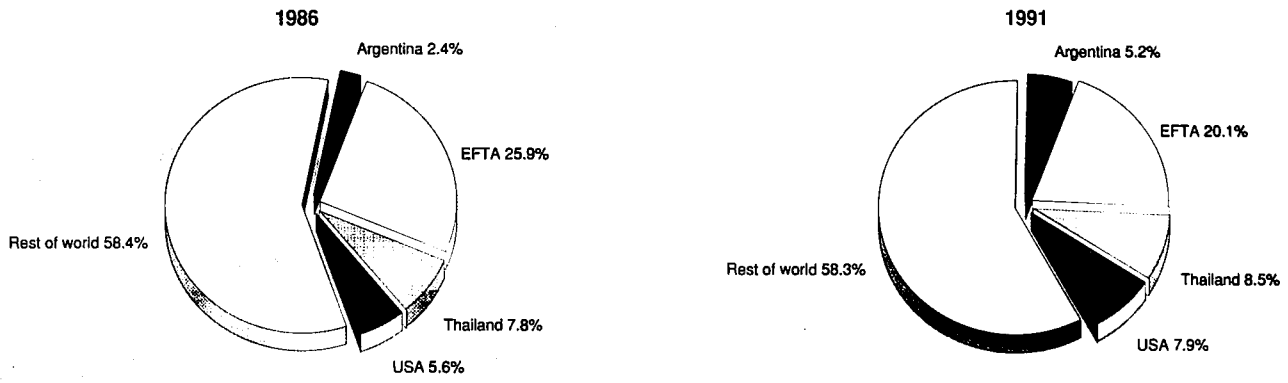
- With respect to canned fish, the three main firms in this sector (Saupiquet, Heinz and Unilever) together comprise 20% to 25% of the total EC market. In the frozen fish market, Unilever is leader, followed by Nestlé and Pescanova. These firms account for 45% to 50% of total EC sales. In the dried, salted and smoked fish sectors, the three main firms (Friedrichs, Unilever and HL Foods) hold 15% to 20% of the total EC market. Unilever and HL Foods also account for a negligible share in the fresh fish sector.

Figure 4: Fish
Destination of EC exports



Source: Eurostat

Figure 5: Fish
Origin of EC imports



Source: Eurostat

Strategies

The most significant competition leading firms in the industry confront comes from fresh fish. Thus the main strategic actions consist of differentiation policies, involving preparation and packaging, which accentuate the "convenience" aspects of the product.

Competition is strong and encourages industrial concentration. Mergers and acquisitions activity performed by multinationals like Unilever and Nestlé, has increased the internationalisation of the industry.

ENVIRONMENT

The environmental issues related to fish processing are mainly connected to raw material supplies. The excessive exploitation of fish stocks caused by global fish consumption is an important ecological issue. This problem can be solved by the proliferation of waterculture. The EC has financed numerous projects in this area. A secondary problem involves the death of thousands of dolphins which are caught in tuna fishing nets. The EC has taken measures to rectify this problem, most notably through the ratification of a Protection of Wildlife Agreement on December 31, 1991, which classifies dolphins as a highly protected species.

REGULATIONS

The EC passed new regulations concerning the preservation of fishing stocks (tenth, eleventh and twelfth modification of Regulation 3094/86/EEC).

Other regulations set the bacteriological standards for shellfish to be marketed in the EC. Moreover, very rigid hygienic measures have been applied to fish processing, unloading operations, freezing plants and regulations for boats equipped for immediate fish processing. Other regulations concern processes for smoking and salting fish.

OUTLOOK

Over the next few years, fish consumption is expected to increase, especially frozen and canned fish. Future market segmentation with the introduction of higher value added products and the expansion of processed fish to markets where fresh fish presently dominates will be the driving forces for this growth. Imports will continue to take an increasing share

Deep-frozen products
NACE 412.21, 414.1, 415.1

The recent demand for deep-frozen products has outpaced that of other food sectors. In countries where per capita consumption is low (Italy and Spain, for example), demand is directed towards other kinds of products, such as pre-cooked foods. Production of deep-frozen products is dominated by two firms but several local producers exist which operate in niche markets. As some markets approach saturation, mergers and acquisitions are concentrating the industry even more.

INDUSTRY PROFILE

Description of the sector

This sector includes a variety of products processed by means of preservation at low temperature. In order for frozen products to be safely preserved, they must be subjected to frigid conditions very rapidly. Goods in this category include: vegetables, potatoes, fish, meat, poultry, fruit, oven products and prepared foods. Deep-frozen products are classified according to different NACE codes. The main NACE groups are: frozen meat (NACE 412.21); frozen vegetables (NACE 414.1); frozen of fish and other sea products (NACE 415.1).

Recent trends

Over the last ten years, the European deep-frozen products industry has consistently grown at a faster rate than other food sectors. Between 1983 and 1989, the increase in consumption was 7.2% per year (the data for 1990 cannot be compared to the previous time-series), even though this increase was different for various countries and product categories.

Meat experienced the swiftest consumption growth (14.8%), followed by potato by-products (9.4%). Consumption forecasts for pre-cooked and oven products are expected to record the highest growth rate. Regarding per capita consumption, the EC can be divided into two groups. The first includes Germany, the UK, Ireland, France and Benelux where per capita consumption is about 20 Kg. The second includes the Mediterranean countries, where frozen-food consumption is very low. Only Spain shows a notable upward consumer trend. Denmark, with a per capita consumption of 36kg, does not fit into either of these two groups. By comparing the EC per capita consumption data (approximately 17 Kg per capita consumption in 1989) with those for the US (about 51 Kg.), we find a strong potential for future growth. It is difficult to predict whether the EC countries will follow US consumption patterns. In countries like the UK and the Netherlands, for example, the consumption growth rate is decreasing. Precise data on foreign trade of deep-frozen products are not available. Significant import flows come from the Scandinavian countries (fish), Eastern Europe, South America (meat) and the US (fruit juices).

MARKET FORCES

Demand

In 1990, about 6 million tonnes of frozen products were consumed in the EC. The products consumed vary from country to country because of different nutritional habits. The most widely consumed deep-frozen products by country were: poultry in Denmark and Germany, potatoes in France, fish in Portugal and Spain, fruit and vegetables in Italy and the UK. Deep-frozen products are found to be more popular in higher-income countries. Apart from different nutritional habits, the demand for frozen products depends on other factors, including: the use of home freezers, dining-out habits (fast food restaurants) and improvements in product distribution. The percentage of European families owning home freezers and microwave ovens varies greatly from country to country. In 1990, home freezers were owned by 94% of families in Denmark, 84% in the UK, 70% in Germany and the Netherlands, 42% in France and even lower percentages in the Mediterranean countries. Microwave-ovens were owned by 84% of families in the US, compared to 51% of UK families, 34% of German families, 20% for other central European countries (data for Mediterranean countries are not available.)

Catering in the US has had a positive impact on the demand for frozen foods. The percentage of sales attributable to catering has been higher than that for retail sales (55.5% versus 44.4%). By contrast, European deep-frozen products are sold mainly through retailing. Catering sales are expected to increase significantly.

The spread of efficient modern distribution systems for deep-frozen products will have a positive impact on demand. In Italy, a majority of deep-frozen products are sold in traditional stores whereas in other countries specific distribution systems are being developed. In France and in the UK, most deep-frozen product distribution takes place via freezer centres; in Germany distribution takes place through discount channels. France and Germany, in particular, are expanding domestic distribution systems for frozen products.

Supply and competition

The deep-frozen products sector is consists of a large number of producers. French production is highly fragmented with more than 400 producers. Germany and Spain each have about 100 producers. Denmark and Italy have about 75 and 60 producers, respectively.

The high fragmentation of the market is due to low entry barriers for deep-frozen product production. Distribution and advertising, on the other hand, are characterised by higher entry barriers, with a small number of multinational firms selling various products while specific products and local markets are often covered by minor producers.

INDUSTRY STRUCTURE

Companies

Using the criteria of market distribution share for both countries and products, only Unilever and Nestlé cover the entire spectrum of products in almost every country (Unilever has a stronger market penetration than Nestlé). The entire market is controlled by these two firms: Unilever has a leading role in the UK, Italy, Germany, Belgium and the Netherlands, while Nestlé dominates in France, Denmark and Portugal. Out of the other firms, only a few are diversified in terms of products or geography (an example is Campbell whose market share is about 1.4%). The others are focused mainly on specific products in particular geographical areas. The foremost product specialised companies are: McCain (accounting for 38% of potato by-products sales in Europe), Grand Metropolitan (oven products), Bonduelle (vegetables) and Coppen&Wise (oven products).

Of the regionally specialised companies, Pescanova has the highest market share in Spain and Portugal. In Italy, SME accounts for 18% of the market; United Biscuits holds 12% of the UK market; Ortiz-Miko in France accounts for 10.8%; and Danish Danisco maintains 11.4% of the domestic market.

Niche oriented firms also exist. An interesting example is provided by Bo*Frost and Eismann, each specialising in channel distribution. Through home-sales they gained a 4.9% and a 3.7% share, respectively, of the German market.

Strategies

Companies which are not focused either on particular areas or products and do not account for a high market share are in a difficult situation. For example, Campbell was forced to sell some of its partner firms operating in the frozen-food sector. Concentration as a result of mergers and acquisitions are particularly frequent between small and medium companies. The limited number of brands a company slates for commercial distribution, is encouraging the acquisition of brands and established distribution networks, even at the local level. Concentration is most prevalent in the UK (Booker, A. Fisher, Perkins), where growth rates are declining. Another important aspect is the marketing of distributors' own labels while utilising the productive capacity of minor companies.

OUTLOOK

The deep-frozen products sector is expected to grow at higher than average rates than the food industry in general. The highest growth rate is expected in pre-cooked products (mirroring a US trend). The proliferation of home microwave ovens and the growing need catering will also have positive effects on this sector. The sector is also expected to grow in those countries where per capita consumption continues to be much lower than average.

In reference to companies operating in this sector, the market remains fragmented and characterised by either large firms with a complete spectrum of products or geographically-isolated small firms focused on specific products. Sector concentration through mergers and acquisitions are increasing, especially for less specialised producers.

Grain milling
NACE 416

The European grain milling industry comprises more than 3 000 mills and produces almost 25 million tonnes of wheat and rye flour. At present, the sector needs first-grade raw material. Although European grain production seems to favour a quantity-oriented over a quality-oriented policy, quality standards for flour in particular have been rising substantially.

Technological progress in the sector has had two major effects: it has improved the quality of the products and has made production process more efficient. However, the industry is still characterised by a low level of plant utilisation, especially in the southern European countries. Further progress is expected in the sector, including the closing down of marginal and technologically outdated plants and their replacement by new updated plants, to meet the quality-oriented demands of the sector.

INDUSTRY PROFILE

Description of the sector

The grain milling industry includes the milling of grain into flour, bran making, seeds and grain milling husking. Produced flour is mainly intended for the baking industry although use varies significantly across the EC Member States.

Main indicators

In 1991, production exceeded ECU 11 billion, a 6% increase (in current prices) compared to the previous year. This represents significant growth when compared to the sometimes negative rates of change in production that prevailed throughout the latter half of the 1980s. Apparent consumption increased in 1991 as well, by 6.4% in current prices compared to the previous year, reaching ECU 10.5 billion.

Extra-EC exports was steady at 7% of total production. The trade balance has also been relatively stable since 1989, with small variations caused by slight movements in exports and a small but steady decrease in imports.

At present, there are more than 35 000 people working in the European grain milling industry, but innovations in processes have significantly affected employment, which has decreased by a total of 16 000 workers since 1982.

In 1991, value added of the industry reached ECU 1.7 billion. France and the UK account for 17.5% of total value added each, while Italy and Spain account for 15% each and Germany for 12%.

Recent trends

Production and consumption growth increased at rates of 1% per year on average in real terms between 1982 and 1991. Growth between 1982 and 1985 was more than double that between 1985 and 1991. The 4% growth in production at constant prices in 1991, however, was the highest growth rate in ten years. Apparent consumption grew 2.7% in real terms in 1991.

Extra-EC exports declined on average in real terms for the period 1982 to 1991, although it was only after 1985 that negative growth rates appeared. The year 1989 marked the beginning of a slight recovery and in 1991 extra-EC exports increased, in real terms, by 17% compared to the previous year.

A one-time significant reduction in extra-EC imports occurred in 1989, when imports decreased from ECU 225 million to ECU 62 million. The decrease has continued since 1989, albeit at a much lower rate.

Foreign trade

The export/import ratio increased dramatically after 1989, from 2 to 1 in 1988 to 15 to 1 in 1991. The trade balance has also improved due to an increase in export value combined with a constant import value.

Intra-EC trade has been variable. The increases which were the first result of increasing integration, have given way to significant decreases. In the latter part of the 1980s, high taxes significantly affected transport costs for the sector, hindering intra-EC trade. Tax reductions forecast for 1993 should result in a recovery of trade. Even with the decreases, intra-EC trade has risen to more than 90% of total imports.

Mediterranean countries represent the primary market for EC exports, particularly Algeria (20% of the total), Libya (8.5%) and Syria (5.2%). Because of the severe food crisis, East European countries are becoming increasingly important markets as well. In the mid-1980's, trade with these countries was practically non-existent; today countries of the former USSR account for 11% of EC exports.

The USA is no longer the most important importer to the EC. Thailand now accounts for almost 30% of EC imports. EFTA countries have significantly increased exports to the European Communities, while OPEC countries have also improved their position. Each group accounts for 8% of total EC imports. As mentioned previously, however, imports are no longer a significant portion of EC consumption.

MARKET FORCES

Demand

Bread making accounts for at least three quarters of the flour produced in the EC. Use varies considerably from country to country, however. In Italy, half of the flour is used for the production of pasta, while 15% is used in the production of pizza dough.

The grain milling industry is particularly influenced by movements of the EC grain market, especially in wheat. The increase in grain production in 1990 (170 million tonnes) was above the guaranteed maximum quantity by 10 million tonnes, and led to a fall in world prices. At the same time, grain consumption is diminishing due to decreasing use of cereal in compound feed.

The amount of land used for grain crops is decreasing in the EC, because of restrictive policies. As a result, there has been a substitution from cultivation of cereals to oilseeds, as well as substitutions between different kinds of grains produced. France and Denmark have expanded their areas cultivated with common wheat. Durum wheat is grown in Italy, France and Spain.

Supply and competition

Competition from foreign firms is not strong; the EC provides 60% of the world trade in flour, followed distantly by the USA, which provides 21% of the flour traded worldwide. High transportation costs are partially responsible for this, as proximity to markets is very important.

The industry's competitiveness, however, is dependant upon the availability of supply of quality raw materials at prices competitive with those of their competitors; this is a perennial concern of producers. The industry is also concerned with discrimination in EC export policies between raw and processed materials.

Technological innovations have helped the EC to maintain its competitive advantage, as well as increase productivity, by increasing the quality control available at the mills themselves.

Production process

Productivity is continuously increasing, and almost doubled at the beginning of the 1980s. Labour productivity reached ECU 48 000 of value added per working unit in 1991 and has remained above the trend of the unit labour costs.

Technological innovation processes, which have greatly increased production capacity, also mean that many plants are now underused, particularly those in France, Italy and Spain, where capacity utilisation is about 50-60%. The increase in final production has therefore not contributed to a change in the utilisation level of the plants.

INDUSTRY STRUCTURE

Companies

Due to inability to compete with the newer mills, many old mills have been shut down in the last twenty years. In 1970, 11 000 mills were operating in the EC countries, in 1991 that number was around 3 000, a decrease of two thirds.

Productivity differs greatly from country to country: France, Italy, Germany and Spain average around 6 000 tonnes of flour per mill per year, while the United Kingdom averages 45 000 tonnes per year per mill, and Denmark and Benelux average around 17 000 tonnes per year per mill. These extraordinary differences can be attributed primarily to the importance in certain countries of small and artisanal mills. France, for example, had 958 operating mills in 1990, while the United Kingdom had 84. France actually produced over a million tonnes more than the United Kingdom in 1990.

Despite its low average production per mill, France has the most concentrated industry in the EC. The two largest companies account for 80% of the national market, which is 12% of the European market share. France Farine, the leading French company, accounts for 60% of the national market. In both Germany and in the UK, the two largest companies account for less than half of the national markets.

No one company in the EC controls more than 10% of the European market share and only six companies account for more than 2% each.

Strategies

Faced with an increasingly demanding market, producers are finding quality control to be one of the most important aspects of production. It involves all aspects of the system, from raw material to preserving, manufacturing and marketing. High quality inputs in particular are becoming necessary. However, by favouring production of high-yield but low-quality wheat, the EC incentive system has resulted in reduced cultivation of high-quality wheat.

Industry has responded with technological innovations designed to increase quality control on-site, to test humidity and protein content for example. Client industries, such as industrial bread making, require high quality inputs, and firms are increasingly concentrating on quality objectives to meet the needs of this, and other, growing client industries.

REGULATIONS

Of particular importance to the grain milling industry are regulations on product labelling and on the amount of residual pesticides which can be used on grain, and which could affect the supply of grain, either by encouraging the cultivation of grains which are less susceptible to pests, or by encouraging the growth of higher value cereals to offset the loss of grain harvested.

Harmonisation of national legislation will also have an effect on the industry. Italian law, for instance, forbids the marketing of frozen bread. If this type of law is repealed by EC legislation, the importance of the industrial baking industry could become more pronounced, and its input requirements could become more significant to the grain milling industry.

Other regulations include Regulation 2176/90, which allows Member States to grant subsidies for non-food employment of grain; such aid aims to avoid the increase in grain production.

OUTLOOK

Change in consumption patterns, and particularly decreased bread consumption in EC countries, is a serious challenge for the grain milling industry, although increased consumption of other products, such as biscuits and rusks could offset some of the decrease in demand. Although bread consumption as a whole is down, demand for industrially produced bread has increased. This could affect the grain milling industry both by altering demand patterns, and by changing distribution systems. Harmonisation of legislation (such as that regarding frozen bread, mentioned above) will offer new challenges for firms in countries where legislation is eased, as competition by substitute products increases.

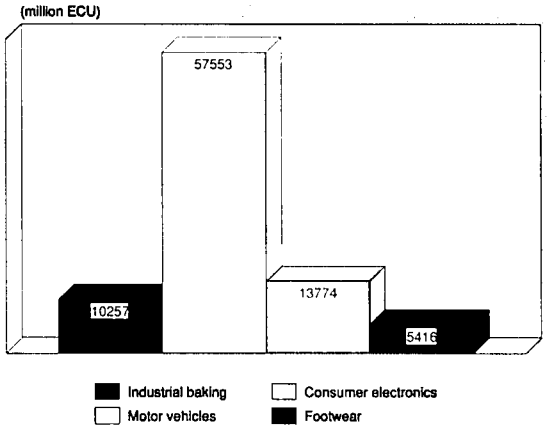
Industrial baking
NACE 419

Consumption of biscuits, rusks and flour-based snacks is expanding. The large number of products available on the market is credited to strong market segmentation policies carried out by leading companies. Supply is subject to a process of rapid concentration and internationalisation. The presence of distributors' own labels is prevalent in many countries.
Mass-produced bread is replacing localised bakery output. In particular, the demand for industrially made bread is increasing with improved distribution and changes in individual dining habits (i.e. fewer meals inside the home). Technological innovations also favour supply concentration in this subsector.

Figure 1: Industrial baking
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

NACE 419 includes the following subsectors:

- 419.1: large scale breadmaking
- 419.2: breadmaking at establishments other than bread factories
- 419.3: cakes and flour confectionery production
- 419.4: rusk making
- 419.5: biscuit production.

Both large companies (which cover the entire production range) and specialised bakeries operate in the industry.

Main indicators

Production and consumption figures are nearly identical while extra-EC trade is minimal. Figures for 1988 to 1991 show an average increase of 7% to 8% per year in production. Between 1990 and 1991, the highest increases were recorded in Germany, Denmark and the United Kingdom. For the period 1986 to 1991, employment rose an average rate of 3.5% per year. The trade balance remains positive and is expected to increase.

Germany and the United Kingdom are the largest markets, followed by Spain, France and Italy. These five countries accounted for more than 87% of total value added in 1991 (Figure 2).

Recent trends

Production and apparent consumption data (at constant prices) exhibited a positive trend throughout the second half of the 1980's. Although decreasing until 1988, figures for extra-EC exports are presently increasing both in terms of volume and value.

Biscuits, rusks, cakes, pastry, flour-based snacks, and frozen products have all recorded increased production and consumption. In many countries, chocolate, whole-wheat, low sugar and fat biscuits have recorded significant gains. Total bread consumption, on the other hand, decreased slightly, especially in the southern European countries. Industrially made bread is particularly popular in areas where retailing patterns have shifted from traditional independent grocery stores (and bakeries) to food discounters and hypermarkets.

Foreign trade

Intra-EC trade accounts for 7% to 8% of apparent consumption and 90% of total imports (intra- and extra-EC). Extra-EC imports account for a small share of consumption. The EC's foremost trading partners in this sector are EFTA countries. Only 3% of production is exported outside the EC. EFTA countries, the US, OPEC and certain East European countries represent the main trading partners. The terms of trade decreased between 1985 and 1990, rebounding in 1991.

MARKET FORCES

Demand

Bread and bakery product consumption is characterised by strong regional preferences. The European market is a huge array of products and items where new products are frequently introduced. Concerning bread consumption, Greece recorded a very small volumes of per capita (30kg). By contrast, Italy (85 kg) and a number of northern European countries (60 to 80 kg) lead the consumption figures. Northern European countries show the highest consumption levels of biscuits and rusks compared to southern European countries. Italy is an exception with a per capita volume consumption similar to that of France and higher than that of Denmark. Changes in dietary habits and distribution channels have a strong influence on present changes in bakery products consumption.

Consumption of industrially made bread in lieu of bread from local bakeries is being aided by the tendency to eat more often in fast-food restaurants and bars. This trend is also responsible for the spread of frozen products (bread, "croissanteries" and cakes). The tendency to substitute meals with snacks also favours growth of flour-based snacks, crispbread, rusks and biscuits. Paradoxically, consumers are seen to prefer healthy eating (i.e. fresh food, whole-wheat, low-fat and low-sugar products) though a rise in indulgence eating (i.e. rich, chocolate-filled biscuits and industrially made cakes) is also prevalent.

Product innovation is rather high and concerns different aspects: recipes, packaging and sizes. Some leading companies have introduced whole wheat product lines for several types of products.

Supply and competition

Bakery products suppliers are mostly fragmented, due to the regional structure of consumption patterns, the high costs of transport and product fragility. Local bakery production is still made up of small artisanal firms which continue to survive in local markets.

Regarding industrially made bread, preservation problems limit both the operating areas and supply capacities of bread factories, forcing them to adopt a multiplant structure for geographical expansion. Companies producing frozen bread can develop higher supply capacity.

Scale economies are not very relevant for biscuits, snacks and crispbread; moreover, economies of scope are limited to raw material supplying and marketing (i.e. using the same labels for different products).

Mergers and acquisitions are still taking place in this sector, redefining the industrial structure. This will lead to a change in competition and in relations between industrial producers and modern distribution operators. Modern distribution, in fact, plays a significant role in the marketing of bakery products. Distributors' market power is evidenced in the success of distributors' own labels. US companies are interested in this industry and, consequently, have entered the European market; a source of concern for European market leaders.

Production process

The production process is subject to continuous technological innovation. Leavening, extrusion, freezing, packaging and transport are all undergoing modernisation. Unfortunately, automation and rationalisation of the production process are not improving productivity significantly.

INDUSTRY STRUCTURE

Companies

The UK shows the highest concentration level for industrially-made bread; here the two largest companies account for 50% to 55% of the national market. In France, the top three companies account for 55% to 60% of the market, while distributors' own labels account for another 25% to 30%.

Crispbread is the most concentrated sector. The share of distributors' own labels in this sector is remarkable in the United Kingdom and Germany.

Strategies

Acquisition of local companies is the best strategic device to enter foreign markets and/or strengthen one's position in domestic markets.

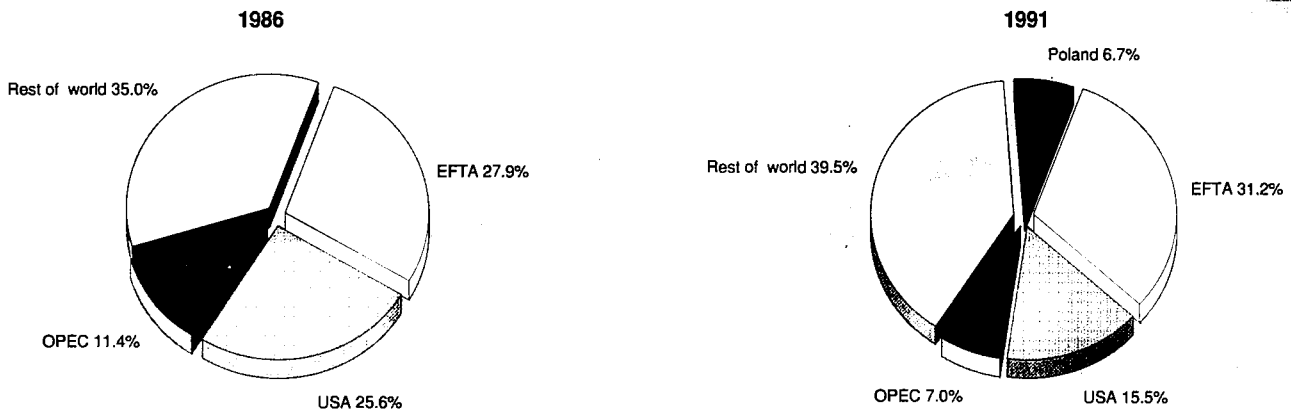
Of the US companies operating in this sector, Borden acquired a number of regional companies, particularly in Germany. Campbell and General Mills are also interested in consolidating their presence in this sector.

Leading companies consider product innovation, market segmentation and an optimal range of products as key strategic factors. Smaller companies (usually less diversified) aim to maintaining leadership (or significant market shares) at regional level.

REGIONAL DISTRIBUTION

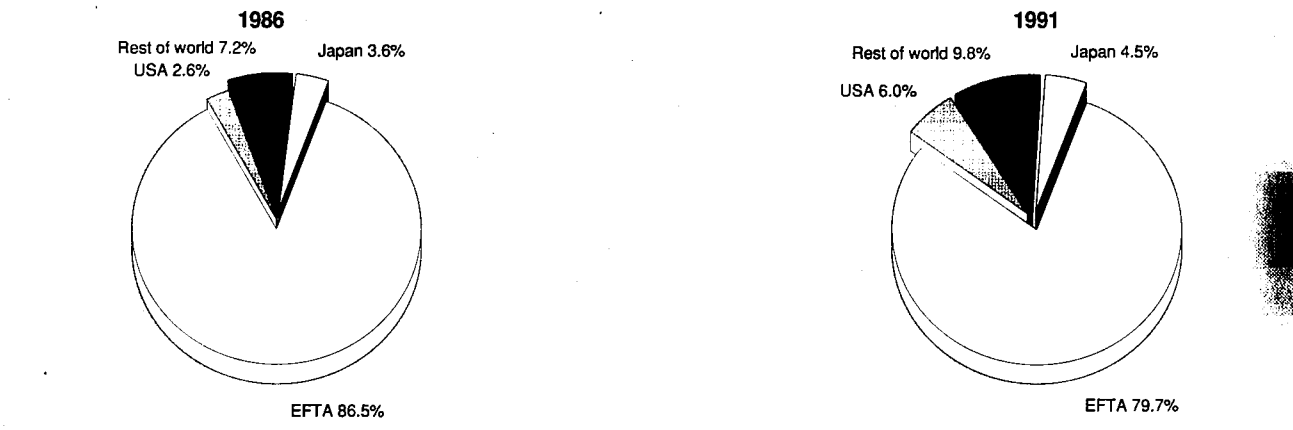
The characteristics of this industry's products favour multi-plant production structures dispersed throughout consumption areas rather than concentration in specific areas. The geographical distribution of companies, therefore, matches consumption patterns.

Figure 4: Industrial baking
Destination of EC exports



Source: Eurostat

Figure 5: Industrial baking
Origin of EC imports



Source: Eurostat

ENVIRONMENT

The environmental issues are limited to the disposal of urban solid waste. In future, companies will encounter increasingly strict regulations regarding volume and chemical composition of packaging material. Given the importance of packaging for preserving such fragile products, it will challenging to create innovative packaging which will meet both environmental, production and marketing requirements.

OUTLOOK

The tendency to substitute locally-produced bread with industrially-made bread is predicted to continue. This trend, however, will be limited by consumer preferences for "natural" and fresh products, which differ between Member States. Such preference will allow a number of artisanal bakeries to survive, especially in countries where modern distribution methods are emerging. The subsectors of snacks and richly filled chocolate biscuits ("indulgence products"). and healthier whole-wheat and dietary products will expand.

Technological innovations, the need to face the growing market power of customers, and the implementation of the Single Market will stimulate the concentration of the industry. A major opportunity for this sector is the emerging internationalisation of consumer patterns.

Sugar
NACE 420

The EC is the world's largest producer of sugar. Production and trade of sugar in the EC are promoted by a system of production quotas, import taxes and export subsidies that are due to be reviewed in 1993. Although this system was originally aimed at achieving self-sufficiency without accumulating surpluses, in recent years EC production has consistently exceeded consumption.
The EC sugar industry is becoming more concentrated as a result of national and cross-borders mergers between sugar companies. Moreover, the industry has recently undergone a process of production rationalisation; the total number of factories involved in beet processing in the EC (excluding former East Germany) has fallen steadily while average plant size has increased.

INDUSTRY PROFILE

Description of the sector

The EC sugar industry is specialised in beet sugar rather than in cane sugar production. Beet is planted during the spring and harvested from September to November. Beets produced in the EC (approximately 102 million tonnes in 1991) are processed by a small number of high capacity factories. The product cycle of beet sugar includes the following phases:

- extraction of the beet plant's sucrose content by treating beet slices with steam and immersing them into tanks of hot water to produce a raw juice;
- purification, evaporation and crystallisation of the juice;
- processing of crystals to obtain sugar in its marketable form.

Molasses is a by-product of sugar production that is used directly as either cattle feed, fertiliser or by the fermentation industry.

Main indicators

All EC countries produce sugar beet. Due to German reunification, the EC area under cultivation increased by 12.7% in 1990/91. This expansion was accompanied by an 11.3% increase in EC production and for the first time in six years EC production exceeded 15 million tonnes.

In 1990/91 more than half of EC production was accounted for by France (27.5%) and Germany (27.1%). Yields (in tonnes of sugar per hectare) vary greatly across countries. In 1990/91, France, Germany, and Italy respectively produced 9.2, 6.9 and 5.5 tonnes of sugar per hectare.

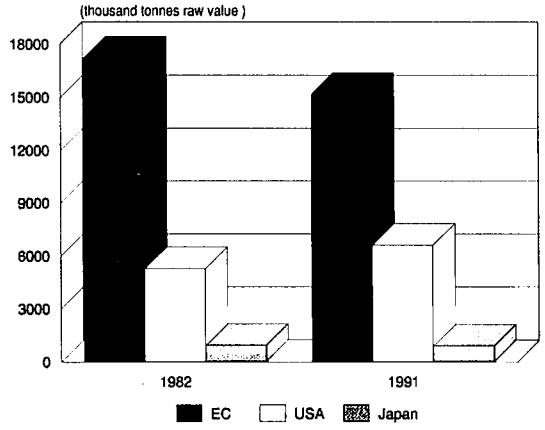
Recent trends

EC sugar consumption has shown only marginal changes during the last ten years (the 90/91 figures are influenced by the inclusion of the former East Germany) while production has been more erratic. Production fell between 1982 and 1984, recovering slightly between 1988 and 1991.

International comparison

The EC remains the major producer of sugar although its output of sugar has decreased since 1982 while the other major producing countries have increased supply. The EC is both the second largest exporter of sugar (after Cuba) and the second largest consumer (after the former Soviet Union).

Figure 1: Sugar
International comparison of production at current prices



EC. including East Germany;
1991 does not include Spain, Portugal, Ireland
Source: FAO, Production Yearbook

Foreign trade

EC exports of refined sugar are mainly to OPEC countries. In the last five years, however, an increasing share of exports has been to the former Soviet Union.

According to the terms of the Lome Convention, the EC is committed to import 1.3 million tonnes of sugar annually from African, Caribbean and Pacific (ACP) countries for an indefinite period (the price paid to producers is based on EC current minimum prices). Since the EC is more than self-sufficient in sugar, these tonnages increase the quantities available for export.

MARKET FORCES

Demand

In 1990/91, sugar for industrial uses accounted for about 67% of total EC demand for sugar. The overall level of consumption in the EC remained roughly constant (at around 11 million tonnes) during the last decade. Consumption is dependent upon various factors including demand saturation and competition from new sweeteners (i.e. isoglucose and synthetic products). Stable levels of overall and per capita consumption are also explained by low values of income elasticity of demand

(which is recognised to be between 0.1 and 0.2). Per-capita consumption of sugar varies considerably (according to national eating habits), being lower in the Mediterranean area than in northern regions.

Supply and competition

EC production levels consistently remain above consumption. This is partly attributable to EC sugar policies (see Regulations section) that guarantee producers secure returns surpluses. Internal competition is limited by EC sugar policies, which set price supports in relatively high cost countries. Moreover, domestic firms are protected from foreign competition by import tariffs.

The industry is presently experiencing a process of rationalisation as evidenced by the steady decline in the number of factories. This has been accompanied by an increase in average plant size. Capacity for the vast majority of establishments is now above 5000 tonnes per day while 15 years ago it was between 2000 and 5000 tonnes per day. This has certainly reduced average costs which are estimated to remain above sugar world market prices in certain European countries

INDUSTRY STRUCTURE

Companies

The European sugar industry is a highly concentrated sector composed of a very small number of companies. At the European level, a 14% share of the market is held by Eridania (also controls Béghin Say). Sudzucker group, after the acquisition of the Belgian RT in 1989, has attained about 13% of the European market. Tate & Lyle (which controls the Portuguese Alcantare) has a market share of 9%.

Given that European firms are not confronted with very fierce internal nor external competition (due to market regulation and protection), strategies are focused mainly on cost reduction and expansion into extra-EC markets. For example, Italy's Ferruzzi group has recently agreed to acquire control of three large Hungarian sugar companies. Tate & Lyle has attempted to acquire control of the Australian company Bundaberg Sugar and has lately acquired a 30% stake of the Hungarian sugar producer Hajdusagi Cukorgyar.

REGULATIONS

Since 1968, the production of sugar has been based essentially on a quota system coupled with a mechanism of guaranteed minimum (or intervention) prices for sugar produced within basic quotas. Each EC country is allocated a national quantity of white sugar distinguished between an A and B quota corresponding to expected internal consumption (plus a safety margin). In turn, each national quota is allocated both among processors and growers.

Both A and B quotas can be bought by national intervention agencies at the minimum guaranteed price. By contrast, C sugar denotes sugar produced above these tonnages and has no price nor disposal guarantees.

The quota system should be reviewed once every five years. Reviews, however, have been rather irregular. The present quota arrangement applies to a period of two years only, 1990/91 - 1991/92. It is an extension of a previous arrangement, amended to increase Germany's quota following German reunification.

The application of the quota system has generally kept European sugar prices above the world market price. In order to sustain domestic prices, a number of import taxes have been levied. Exports of A and B sugar surpluses are subsidised in proportion to the difference between European and foreign world prices. The cost related to financing exports is entirely supported by the sugar sector through production contributions from growers (60%) and manufacturers (40%), as listed below:

- A basic tax of 2% on the intervention price for A and B sugar quotas;
- A tax of 37.5% on the intervention price for B sugar quotas;
- An 'elimination tax' for A and B sugar quotas set at 1.31% of the 1985/86 intervention price. The purpose of the elimination tax is to clear the export account deficit accumulated during the third five-year quota period;
- Finally, to eliminate any further deficit, an extra tax may be collected at a rate which is calculated on the basis of the marketing loss to be covered.

There is no tax on C sugar production as manufacturers are compelled to export non-quota sugar at their own expense.

OUTLOOK

Due to modest population growth and low income elasticity for demand for sugar, EC consumption is expected to show only marginal increases in the short, medium and long term. Expansion in consumption will arise mainly from increased industrial rather than domestic demand.

Sugar production depends heavily on climatic conditions: yields (in tonnes of sugar per hectare) can vary as much as 30% within the same country therefore production forecasts can be highly imprecise. Production of 15.1 million tonnes would be obtained in 1996 if past trends of the period 1985-91 continued. This forecast contrasts with a more optimistic World Bank projection of 16.5 million tonnes by 1995, based on trends for EUR 9 between 1961 and 1982. Long-term production will depend crucially on how sugar policies will

be revised, possibly taking into account the outcome of the GATT Uruguay Round, which will also affect export trends.

In summary, risks for the sugar industry focus largely on the emergence of a handful of influential sugar companies that might affect EC decisions on market regulation by restricting competition in the industry even further. Over-production might also increase the cost of implementing EC sugar policies. The foremost opportunity is the possibility of expansion into East European markets.

Cocoa and sugar confectionery, ice cream

NACE 421

This sector is one of the most highly concentrated in the food and drink industry, although some Member States still have a fragmented industry structure. All major European and North-American food multinationals operate in the competitive arena. Although production and consumption are increasing, changes in consumer demand due to health concerns are affecting the industry significantly. Ageing population has also affected consumer demand. Market trends show a steady growth in most industrialised countries and generally provide above average margins.

INDUSTRY PROFILE

Description of the sector

The industry can be divided into three main subsectors:

- cocoa and chocolate confectionery: chocolate bars, pralines and boxed assortments
- sugar confectionery: chewing gum, pastilles, jellies, boiled sweets, toffees and nougat
- ice cream: figures refer only to industrially made ice cream, although some assessment is made of artisanal production.

Some of the most important and highly diversified multinational groups operate in these segments, next to national specialised companies.

Main indicators

Since 1988, production and apparent consumption have shown a steady increase. In 1991, production at current prices and apparent consumption grew significantly in nominal terms. Trade is a small part of production and consumption, but the trade balance is positive.

Growth rates for production and apparent consumption were much higher in the second half of the 1980s than in the first half. Extra-EC import growth was slightly stronger in the second half of the decade, but growth of extra-EC exports slowed significantly. Exports recovered strongly after the declines of 1986 and 1987, and the export/import ratio is well above the 1982 level.

Since the early 1980s, total production of industrial ice cream has grown steadily. Chocolate and sugar confectionery also show a stable growth rate in production, although the growth rate is lower than that of ice cream. The increase in per capita consumption is significant in all countries, with the exception of the more mature markets, particularly Germany and UK.

Recent trends

Production and apparent consumption trends, in real terms, seem to be highly influenced by the evolution of the economic cycle. Only since 1988, in fact, has this industry had significant growth rates, along with the strong, expansive economic cycle in almost all EC countries. Employment, which in the 1980s had been significantly reduced, has also increased in recent years, although it has not reached the levels of the early 1980s.

Foreign trade

Extra-EC trade is still modest compared to intra-EC trade. Less than 8% of EC production is exported to non-EC markets and imports account for less than 4% of the EC market. After a significant fall both in nominal terms and in volume, extra-EC exports recovered remarkably by the beginning of the 1990s. The terms of trade has been declining steadily since 1986.

Compared to 1986, extra-EC exports in 1991 are destined for increasingly diverse markets. In 1986, the four primary markets for EC exports (EFTA, USA, OPEC, and Canada) accounted for more than 70% of total extra-EC exports, while in 1991 the percentage fell below 60%. Imports, on the other hand, are increasingly coming from EFTA countries. Extra-EC imports, although steadily increasing, account for a small, and decreasing, share of EC consumption.

MARKET FORCES

Demand

Traditionally, ice cream sales are very seasonal. However, growth in freezer and refrigerator ownership have become a determining factor of sales growth. The majority of new ice cream products have focused on premium lines, since major markets are nearing saturation. By introducing high quality, adult-oriented products, manufacturers aim to expand the market; this is particularly necessary in light of ageing population. Ice cream can be further segmented between impulse and

household sectors. The increase in take-home sales derives from the development of individual countlines and multipacks.

Sharp price fluctuations in cocoa and other key raw materials deeply affected the sugar and confectionery market. Falling cocoa prices had a significant influence on new product development, as well. The growth in consumption has been the result of lowering unit prices for chocolate confectionery.

Another factor which has influenced the market is the European consumer's increasing interest in products at the health end of the market. The emergence of niche markets based on sugar-free/low-fat products mirrors this general health trend; at the same time, there has been an contrasting trend towards premium products, which offer the consumer occasional "self-indulgence."

Looking at a broad breakdown of the confectionery market, chocolate products are dominant in the key markets of France, Germany, and the United Kingdom.

Supply and competition

Under financial pressure brought about by a fall in cocoa prices and faced with the growing power of multinational confectioners, the cocoa processing industry is consolidating itself.

Industry globalisation and concentration continue to be the dominating trend in the market. The European market is now concentrated around a handful of major multinationals.

In the ice cream sector, the artisan industry represents a significant part of the market in some Member States, especially Italy, Greece, and Portugal.

Production process

In France, Germany, Luxembourg, and the United Kingdom, ice cream is still considered a pure "dairy product," and national legislation forbids the use of vegetable fat. This explains the variable proportion of butter and vegetable input in different countries.

The European chocolate industry consumes the largest amount of cocoa in the world. However, this industry is also influenced by national regulations regarding the use of vegetable fat is concerned, despite the fact that in 1987, the EC voted on the definition of chocolate, which aimed at liberalising trade in those countries where the use of vegetable fat was banned.

Industry productivity as a whole saw, during the 1980s, the highest increase among all food and drink industries in Europe.

INDUSTRY STRUCTURE

Companies

The ice cream and chocolate confectionery industry is rather concentrated and is controlled by a few industrial groups, in Europe and in the rest of the world. The sugar confectionery subsector is less concentrated.

In the sugar confectionery sector Philip Morris (US), Cadbury (UK), Wrigley (UK), Nestlé (CH), Mars, and Ferrero (Italy) hold all together a 30% to 35% share of the European market.

In the chocolate confectionery sector Nestlé, Mars, Philip Morris, Ferrero and Cadbury combined have a 60% to 65% share.

In the ice cream sector Unilever (UK-ND), Schöller, Ortiz Mico (German), Nestlé and Sme (Italy) (mostly throught the brand Motta) together hold a 50% to 55% share, with artisanal products having a share of about 20%.

Strategies

All the strategies adopted in the 1980s were aimed at increasing the degree of concentration and globalisation. In the confectionery sector, acquisition activity appears to be focusing more on the sugar sector, for instance, with the Cadbury's acquisition of Bassett Foods and Trebor, and United Biscuits' acquisition of Callard & Bowser in the United Kingdom. In mid 1990, Philip Morris bought most of Jacob Suchard's operation and RJR Nabisco sold its candy brands to Nestlé.

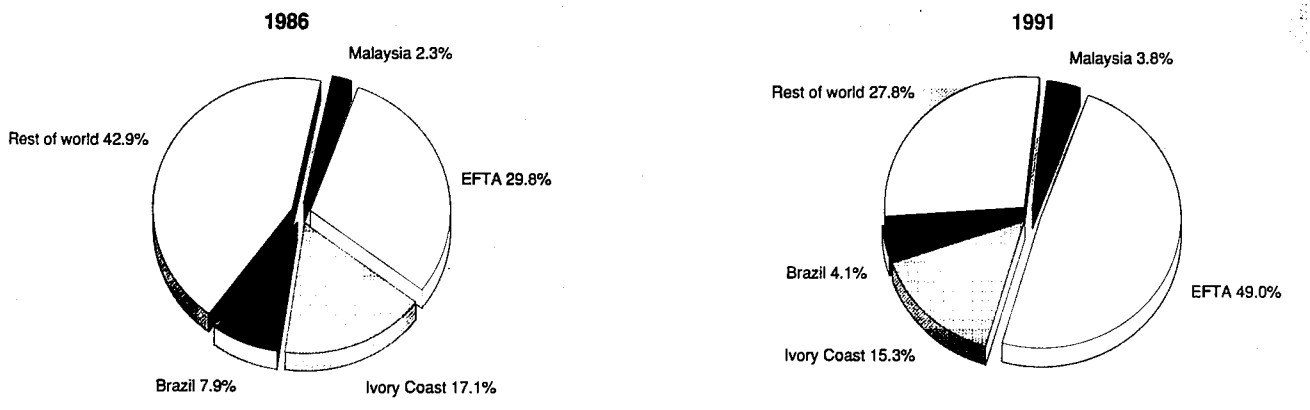
The industrial ice cream multinationals are examining possible acquisitions of dairy producers, especially in Europe, where dairies are placing greater emphasis on value added products. The ice cream industry itself has already attracted some of the largest food conglomerate, including Mars, Coca Cola, Philip Morris (following its acquisition of Kraft) and Grand Metropolitan (following its acquisition of Pillsbury).

Marketing strategies centre on the attempt at a further segmentation of the market by targeting products specifically to adults and children. Effort is being made to seize the opportunities deriving from the "health" and "indulgence" ends of the market.

REGIONAL DISTRIBUTION

Production, is concentrated in Germany, the UK and France, although Italy and Spain are experiencing steadily increasing production. Germany, France and the UK account for about

Figure 5: Cocoa and sugar confectionery, ice cream
Origin of EC imports



Source: Eurostat

70% of the value added produced by the EC industry. The remaining 30% is equally distributed among the other major countries.

In 1991, with a 15% increase in produced volumes, Germany became the primary producing EC country, outperforming the UK.

REGULATIONS

The primary regulations concern the use of vegetable fat, whose use is limited, if not banned, in some countries. EC regulations designed to normalise standards will have a great effect on the industry by opening up those markets to other producers.

OUTLOOK

The growth in the number of adults and the decline in the child population have led to the need to lessen the emphasis on impulse products and to develop more adult-oriented ones. Smaller growth in the market is expected, particularly in those countries with an already high per capita consumption level. "Health" and "indulgence" ends of the market are the areas with the most room for expansion.

Ice cream multinationals foresee considerable market opportunities developing in the Far East and within the Eastern bloc. The industry is already highly internationalised; the realisation of the Single European Market, therefore, should not bring major changes to it.

Compound feed
NACE 422

The two sectors of the compound feed industry for animals, compound feed for animal breeding and pet foods, have for some years been characterised by divergent trends. While the compound feed sector is obliged to operate with a largely under-exploited productive capacity within a saturated market, the pet food sector is going through a phase of full-scale growth, both in the traditional sectors of cat and dog feed, and in the newer market of fish feed.
The drop in demand for animal feed has brought about strong competition among the companies in the sector, which have to develop market strategies while bearing in mind slender profit margins. The need to produce better quality and more diversified kinds of feed has pushed the sector to continually introduce innovations and build new plants, which keeps the industry well below capacity.
The industry's future strategies will be focused on greater price competitiveness the blend of primary materials, along with research into higher quality standards from nutritional, hygienic and environmental standpoints.

Figure 1: Compound feed
Value added in comparison with other industries

INDUSTRY PROFILE

Description of the sector

This sector's activities include production of compound feed for livestock farms such as cattle feed, pig feed and poultry feed, and pet food, such as dog food, cat food and food for other pets, including birds and fish.

Main indicators

The output of the entire EC industry approached 30 billion ECU in 1991, an increase of about 3.5% in current values compared to the previous year. The trade balance in 1991 also recorded a significant improvement, doubling its value compared to 1990. However, many previously net-importing countries are developing their own industries, so the slight increase in exports to those countries in 1991 should not be taken as an indicator of future trends.

The consistent drop in employment over the last decade can be traced to the changing structure of the industry. Since 1982, the EC compound feed industry has shed more than 8,000 workers, as a result of the closure of obsolete labour intensive plants, which were replaced with technologically advanced and capital intensive plants.

The analysis of value added in the compound feed industry in the various EC countries highlights the dominant position held by France, which accounts for a quarter of value added of the EC, followed by the United Kingdom (17.3%), Spain (11.9%), the Netherlands (10.5%) and Italy (9.2%). Altogether, these five countries contribute three quarters of added value in the EC industry. The results in Italy and Spain are particularly interesting because their industry has low concentration of companies, being made up of many small and medium sized firms which still achieve high levels of technology and good economic performances.

Recent trends

EC consumption and production at constant prices have risen constantly since 1986. However, the strong expansion which characterised the second half of the 1980's has come to an end. At that time the positive market trend in compound feed production (a 3.9% average yearly increase) triggered off a recovery in employment figures in this sector and an increase in exports. This phase was accompanied by significant growth in exports to non-EC countries, which increased after 1985 at an average annual rate of 5.2%.

The slowdown in real production growth recorded in the early 1990s should be a factor into the mid 1990s as well, bringing a further drop in employment. The strong growth in extra-EC exports will not be easy to repeat in the future.

Foreign trade

Although the sector has a positive trade balance, it has been decreasing since 1982. The fluctuating trend underscores the difficulties the sector is experiencing in foreign markets, where several traditional importing countries have developed their own domestic output and are reaching self-sufficiency. In 1991, however, the highest trade balance in 6 years was recorded, with export values nearly 40% greater than import values. 1991 terms of trade improved as well when compared to 1990.

The positive effects of EC integration are visible in the trend of intra-EC trade, which has been growing steadily over the last decade, increasing its share of total imports.

Exports to EFTA countries have been increasing over the last five years, while exports to OPEC countries have fallen.

Source: Eurostat

The United States has strengthened its position as net exporter to the EC. From 1986 to 1991, EC exports to the United States remain stationary at a very low level, while EC imports from the United States increased from already high levels. Currently, about 30% of EC compound feed imports come from the United States. Another third of EC imports comes from Chile and Peru, but while Peru has improved its share of EC imports since 1986 , the value of Chile's exports to the EC have been almost halved. Extra-EC imports make up only about 2% of total EC consumption, and are not significant to the industry.

Between 1982 and 1991, the volume of intra-EC exports experienced continual growth, especially after 1987. The growth in intra-EC exports doubled that of production. Extra-EC exports growth, which was subject to considerable fluctuation throughout the 1980's, is consistently below the production volume growth.

MARKET FORCES

Demand

Overall demand for compound feed in the EC has dropped since 1985, as a result of the decrease in the cattle sector, which has not yet been adequately compensated for by increases in the pig and poultry sectors. The drop in demand has also had repercussions in the share of animal feeds bought in relation to intermediate consumption, which stays at around 40% of the overall value of the purchases. Among EC countries, the Netherlands and Italy have the highest expenditure figures on feeds.

The general compound feed price index showed minimal variations over the last decade, a result of increasing prices for simple feeds and decreasing prices for compound feeds since 1985.

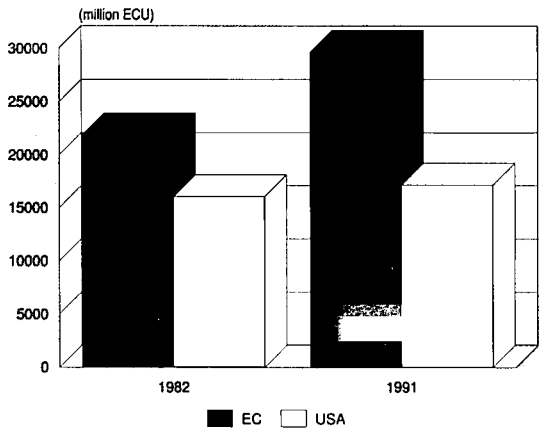
The composition of the compound feeds also takes into account the price variations of primary materials, which have for some years favoured a trend towards the replacement of cereals with soya (oil cakes and meals) and proteins. Livestock consumption of cereals should continue to fall, given the low world price of Soya and the relative price advantage of cereal substitutes, such as manioc (mainly from south-east Asian countries and from China) and sweet potatoes. Currently, 30% of the industrial consumption of primary materials is made up of cereals, about a quarter consists of soya, less than 20% consists of by-products of the food industry, and manioc makes up 5-6%. The different composition of the feeds therefore has an immediate effect on the production costs of livestock breeding, which as a consequence varies significantly within the EC. Dutch big breeders use a compound feed high in manioc and low in cereals, with corresponding low production costs. In Italy, however, pig feed is still typified by heavy use of cereals (60%), making compound feed more expensive for the Italian pig-breeders, and raising production costs. The percentage of cereal in compound feed is about 50% in Italy and Spain, about 30% in France and the United Kingdom, and 15% to 20% in Germany and the Netherlands.

Supply and competition

In 1990 the production of compound feed by the EC industry exceeded 100 million tonnes, while FEFAC estimates for 1991 point to an increase of over 2%. German unification has increased EC production by about 3% in quantitative terms. The production of the former East Germany is a significant share of the EC's stocks of both cattle and pig feed.

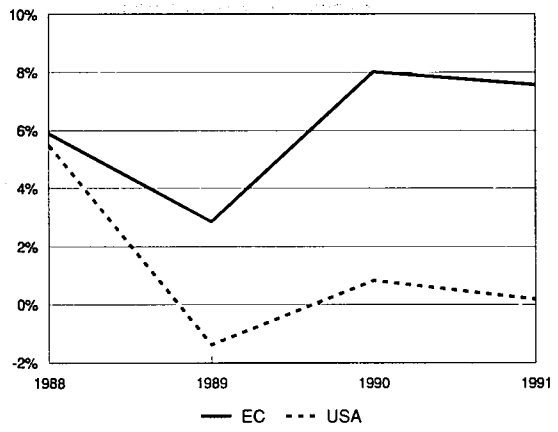
The composition of compound feed per product line is 34.6% for pig feed, 31.2% for cattle feed and 28.1% for poultry feed. Within the EC, France and the united Germany each hold about 20% of the total EC output. In 1991, Germany

Figure 4: Compound feed
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Figure 5: Compound feed
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

strengthened its leadership in the production of cattle feed to about 25% of the EC total, while Dutch production of pig feed has recorded a sharp downturn of 6.5% , suffering more than other countries from the entry of the former East Germany in the EC. In the poultry feed sector France is the leading producer, followed by Italy, reflecting the poultry meat processing industry's strong development in these two countries.

In the pet food sector total production has reached about 4 million tonnes, 54.8% of which is dog food, 36.3% is cat food and 9% other pet foods, mainly for birds and fish. This last segment has recorded strong growth over the last few years, and increased by 288% in 1990 over 1989. All the productive segments show significant increases, although increases in tinned foods are more modest.

Production process

The large animal feed companies usually have several plants spread throughout the home country they belong to. Among the exceptions, it is worth mentioning Purina, a company with its head office in the United States, and which has several plants in the main producing countries of the EC which retain close contact with the parent company in the United States.

The reasons for this national characteristic of the animal feed industry can be found in the different nutritional attitudes of

Table 5: Compound feed

the livestock breeders which, as is stated above, vary from country to country. However, the important changes involving intra-EC mergers and acquisitions that have been taking place of late could change the nature and production specialisation of several companies.

Generally, the sector's productivity is on the rise, fuelled by a general fall in employment which is always concurrent with the introduction of new technologically advanced plants that reduce the need for human intervention. This accounts for the strong increase in the value added/employment ratio over the last decade, which however is lower than the increases recorded in that period by the unit labour costs.

INDUSTRY STRUCTURE

Companies

In 1991, there were approximately 1600 plants operating in the EC, but that number will decrease during the early to mid 1990s as a result of the restructuring processes that are affecting the whole sector. The animal feed production industry is highly decentralised, with plants of varying production capacities. Alongside the large plants which produce the overwhelming majority of compound feed, there are some plants that process very small quantities and which play a marginal role in total production. Plants tend to be located in regions a with high concentration of livestock breeding areas. In particular, small firms need to be close to their primary customers: small family-run livestock farms.

Special importance is attached to the co-operative plants in this sector which, according to FEFAC estimates, account for one third of the EC's compound feed output. The co-operative organisations have only a limited role in the United Kingdom

and Belgium, whereas in the other countries their contributions can range between 40% and 50% of total production.

Within the pet food sector, the European market is dominated by four primary companies with firms spread over the EC. Mars (USA) has over 50% of the market, and its national companies have the leadership in their respective countries (Unisabi in France, Elfem in Germany and in the Netherlands, Doima in Italy, Pedigree P.F. in the United Kingdom). Quaker (USA) controls 15% of the EC market, while Nestlé (CH) and Dalgety (UK) each control less than 10%.

Strategies

EC industry operates under conditions characterised by an underutilisation of production capacities, which often fail to exceed 35-40% of the potential output. The drop in overall demand has forced the companies to cut the overall supply, while trying at the same time to produce better quality feed, an objective that has led to an improvement in the efficiency of the plants. The high technological levels of the plants is a decisive feature of the animal feed industry, and represents the necessity of dealing with new demand characteristics for compound feed, which are no longer merely focused on quantity but also qualitative aspects and the mix of primary materials utilised. The market now demands feed with high nutritional balance and a certain degree of hygiene and healthiness achieved during the productive phase. Processes have

included those to eliminate dust from the end-product which had resulted from the processing of the primary material, to reduce cross-contamination risks.

REGULATIONS

Among the regulations affecting the industry are those concerning the relative price advantage of various raw materials such as manioc and sweet potatoes, which are included in produce of enclosure D of EC Reg. 2727/75. The substitute products are not subject to import duties, while cereals are. The difference in price thus allows firms to substitute these inputs for the higher priced cereals. A change in the import duties will have a significant effect on the industry and on profit margins, which are already slim.

OUTLOOK

A slight increase in demand for compound feeds is expected in the near future, due to expected increases in the pig and poultry sectors that will more than proportionately offset the decrease in the cattle sector. A further decline in use of cereals as primary inputs is expected for cereals, following the trend since 1984. Cereals will be replaced by high energy and protein value components.

Source: Prometeia

The achievement of high technological levels is crucial in order to respond to the new demands being made by a continually evolving market, which calls for medium run strategies. Without such strategies the industry will find itself ill-prepared for the competition which will cross the national borders that still represent an important barrier for the EC.

The EC industry is facing a saturation point in the demand for compound feed, as several importing countries are developing their own production capabilities. The decline of the EC cattle sector has also caused a decline in the demand for cattle feed within Europe. On the other hand, certain subsectors of the industry should see an increase within the EC, especially in poultry and pig feed, in response to the decline of the cattle industry. Firms are also finding low-priced substitutes for the cereals which are increasing in price. These substitutes still benefit from a relative price advantage in the EC, and have been found to contain high protein levels and energy value., thereby increasing the quality of the feed. New technologies are also helping to maintain health and hygiene requirement

Miscellaneous food products
NACE 417, 423

The demand for the primary products of this sector, pasta, coffee and tea, is generally increasing. The consumption of pasta, in particular, is on the rise in Europe thanks to the increased popularity of the Mediterranean diet of which pasta is a basic component. In many EC countries the consumption of coffee and tea is still growing, as is the EC trade balance. The most important multinationals of the food industry operate in almost every subsector of miscellaneous food products.

INDUSTRY PROFILE

Description of the sector

The sector includes the manufacture of pasta, spaghetti, macaroni etc. (NACE 417) as well as the manufacture of other food products: the processing of coffee and tea, the production of roasted chicory and other roasted coffee substitutes, the manufacture of vinegar, mustard and other condiments, the manufacture of ice, the specialised manufacture of infant and dietetic foods, the manufacture of food preparations for making puddings, custards, table creams, and the manufacture of soups, broth and sauces (NACE 423).

Main indicators

Pasta

Consumption and production of pasta nearly doubled in the period between 1982 and 1991. Since 1986, extra-EC exports have increased as well, to a larger extent than have extra-EC imports, resulting in an increase in the EC trade balance between 1986 and 1991. Exports are only 5% of production, while imports are 0.7% of apparent consumption, so trade is a minor portion of the industry. Employment remained stable, after a period of variability at the beginning of the 1980s.

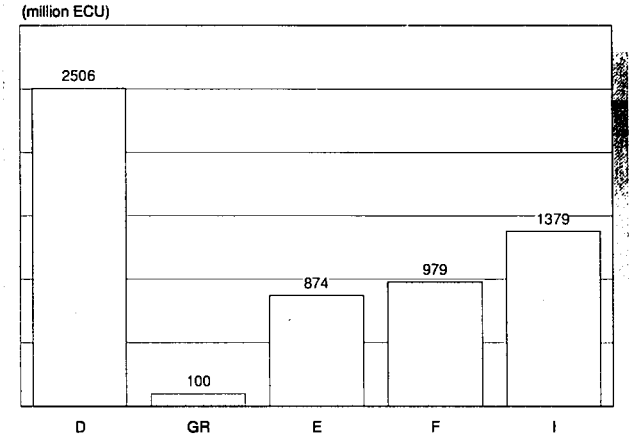
Italy, which has been promoting the consumption of pasta throughout Europe, has the highest value added for the industry, and a 49% share of total EC value added in 1991. France, with a growing domestic market, has experienced an increase in French companies operating in the pasta sector, which account for 17.5% of the EC total of value added. BSN, for example, is present in the sector with the brand Panzani. The German industry operates mainly in domestic and northern European markets; production consists mostly of soft wheat pasta, which is less popular than the durum wheat pasta produced in Italy. Germany's value added was 6% of the EC total in 1991. Greece and Spain each have a small proportion of EC value added.

Other food products

Coffee, tea and infusions are the primary products of the other foods sector. The trade balance, consumption, production and exports all steadily increased after 1987. Employment also increased after 1988. As with pasta, trade in the products of NACE 423 is a small amount of production and consumption, although the proportion of imports to apparent consumption is somewhat higher than that of pasta, at 4%. Intra-EC trade is four times extra-EC imports.

The German industry has the highest value added, and accounted for 26% of EC value added in 1991. France, Italy and Spain have similar value added, although significantly lower than that of Germany, at 8% to 9% each. The coffee sector has become increasingly concentrated through M&A activity in Spain and Italy.

Figure 1: Miscellaneous food products Value added by Member State, 1991



Source: Eurostat

Recent trends

Pasta

During the first half of the 1980s, pasta consumption had a high rate of growth, which tapered off after 1985. Import growth was considerably lower than extra-EC export growth, leading to a nearly 300% increase overall in the trade balance from 1982 to 1991, although trade remained a small portion of industry activity.

Other food products

Consumption and production of other food products increased significantly between 1985 and 1991, after slow growth in the early 1980's. Exports grew slowly between 1985 and 1991, after a period of substantial growth from 1982. Intra-EC trade grew considerably faster than extra-EC trade from 1982 to 1991.

Foreign trade

Pasta

Intra-EC trade is very important to the EC pasta industry; accounting for nearly 80% of total imports in 1991. More than 50% of exports were traded within Europe. There have been some important changes in the import source structure since the early 1980s; in particular imports from developing countries have increased. The weight of exports on production and of imports on apparent consumption is very low, thus indicating a low degree of external dependence.

Other food products

Intra-EC trade has shown the highest increase in other food products as well. Coffee imports from South American countries have increased, although their share of total imports is decreasing. Goods are exported to various countries, in particular to developing countries and to European countries, whereas exports to the USA are decreasing. Also for these products the weight of exports on production and of imports on apparent consumption is quite low even though intra-EC trade volume is rapidly increasing.

MARKET FORCES

Demand

Pasta

The popularity of pasta in northern Europe is due to the spread of the Mediterranean diet from Italy and to increasing concern

for healthy eating habits. Consumption is increasing strongly, especially in the United Kingdom and Germany but in south European countries as well, such as Spain and Greece. On the other hand, in countries where consumption is already very high, such as Italy, consumption is stable or decreasing. Pasta consumption is spreading because it is healthy, easy and fast to prepare.

Other food products

Consumption of primary miscellaneous food products other than pasta is increasing, especially for caffeinated drinks. Instant coffee, for example, has been gaining in popularity in southern Europe, except Italy, which still has the lowest per capita consumption. The consumption of tea is decreasing in those countries, such as the United Kingdom and Ireland, where consumption is extremely high. Per capita consumption of vinegar has remained constant, but the use of distilled alcohol as the basic input has been declining in favour of wine and other materials such as cider. In 1990, EC vinegar production reached 455 million litres, an increase of less than one percent from 1989. This is a decline from the growth rates of the preceding three years.

Supply and competition

Pasta

Due to the success of pasta in the European market in recent years, some multinationals have started to operate in this sector by acquiring production companies and established brands, especially in Italy. Competition from extra-EC producers is almost absent.

Other food products

The other food product industry is characterised by the dominance of a traditional group of firms operating in the various sectors of the industry. No significant changes in the competitive scenario within the EC took place during the 1980s, apart from some redistribution of market shares due to M&A activities. Within the EC, the development of a large distribution system is increasingly important in the development of marketing strategies for the industry's products. Currently, many companies use advertising and brand policies to apply a premium-price on these products; the large distribution system, however, will have a contractionary influence on price policies, resulting in lowered prices and shrinking industry margins.

Production process

During the 1980's, there was little product innovation, although productivity increased due to process innovations. As in other food sectors, these innovations are capital intensive rather than labour intensive. Raw materials are produced for the most part within the EC, while the so-called colonial goods, like tea, coffee and cocoa, are imported primarily from Africa and South America and are affected by price fluctuations on international markets.

INDUSTRY STRUCTURE

Companies

The market structure of the pasta and other food products sectors is very concentrated, and dominated by a few large multinational companies. In the pasta sector Barilla (I) is the market leader, accounting for more than 30% of the EC market. BSN (F) and Nestlè (CH) have attained sizeable shares by acquiring famous Italian brands like Agnesi and Buitoni. These two companies together account for 25% of the EC market. In the coffee sector Philip Morris (USA), Sara Lee, Nestlè, and Lavazza (I) account for 60% of the EC market and have significant shares in the sector of coffee substitutes and tea as well. Unilever (UK-NL) is also a strong presence in the tea sector.

Strategies

The strategies adopted by the primary companies are based on the popularity of product brands and on strong investments in advertising. Product innovation is poor even though production is differentiated on the basis of quality to price, especially in the pasta sector (durum wheat pasta vs. soft wheat pasta), in the coffee sector (raw material quality, Robusta, Arabic) and in the tea sector.

OUTLOOK

Increases in demand for many of the products in NACE 417 and 423 could come from a homogenisation of nutritional habits in the various European countries. Pasta and caffeinated drinks clearly show this trend. Foreign trade, on the other hand, will be limited by transportation and trade costs. In countries with a potentially large market, direct investment in production capacity is generally preferred to importing by producers. Thus, production seems connected to the domestic consumption trend. An increase in intra-EC trade, on the other hand, is expected with the harmonisation of regulations and greater ease of transportation within the EC.

The risks associated with this industry include significant differentiation of products and an excess of supply. The market, however, is expected to increase slightly, as products gain popularity in non-traditional countries, as is occurring in the pasta industry. Negligible competition by extra-EC products can also improve the opportunities of producers.

Alcohol and spirits
NACE 424

The alcohol and spirit sector has been experiencing weakened demand for many years. Due to a change in food habits, consumption is more and more directed to high-income consumers and to specific and Designation of Controlled Origin (DCO) products. During the 1980s, this sector became more concentrated through the acquisition of national trade-marks in order to increase the variety of products offered. Exports to the Far East, where certain aspects of western life style are becoming more prevalent, are increasing.

INDUSTRY PROFILE

Description of the sector

The alcohol and spirits sector as classified under NACE 424 include ethyl alcohol from agricultural origin, and spirits. Most production is consumed directly in the food processing areas (e.g. vinegar) but some semi-manufactured products go to other industries such as pharmaceuticals and cosmetics.

Main indicators and recent trends

EC consumption is consistently less than production of which about 30% is destined for sale in non-EC countries. Although nominal consumption increased throughout the eighties, the data reflect a shift in demand towards more expensive products while physical quantities consumed declined steadily over the past 10 years. The decrease in the number of employees reflects both a decrease in production and a substitution of labour to capital intensive production technologies.

Overall, consumption and production have decreased since the beginning of the 1970s. Extra-EC exports and imports have increased remarkably since the second half of the 1980s.

1991 value added data show the highest values in the UK and France. Among the EC countries, the United Kingdom's industry is the most concentrated. The main products produced in the UK include Scotch whisky, gin and vodka. As for concentration and value added, the French industry holds second place in Europe. A key role is played by Designation of Controlled Origin (DCO) high quality products (mainly meant for export) like cognac, armagnac and calvados, which belong to the high-quality market segment.

Spanish, Italian and German industries show a medium value added. Specific products are sherry and brandy in Spain, "grappa" in Italy and corn brandy in Germany. Many of these products are exported. In contrast, the Greek alcohol and spirits industry shows a very low value added and produces mainly for the domestic market.

International comparison

The EC remains the world's largest producer of alcohol and spirits, with an output more than four times that of the United States in 1991. The steady contraction in demand for alcohol and spirits is shown clearly in Figure 5 for both the EC and the United States.

Foreign trade

In 1991, the EC exported 27% of its production of alcohol and spirits to non-EC markets, up from 20% in 1982. Import penetration, by comparison, is less than 5%, although it has risen considerably since the early eighties. Since 1986, the United States and Trinidad and Tobago (the EC's largest suppliers of alcohol and spirits) have significantly gained market share at the expense of the Bahamas and Martinique. The EC's key export markets are the United States, Japan and Hong Kong. A comparison of export markets shows that East Asia is becoming an increasingly important end market compared to the USA and the EFTA countries. Intra-EC trade is quite high (about 85% of total imports).

MARKET FORCES

Demand

With the exception of Greece, per capita alcohol and spirits consumption has been decreasing for many years in all European markets due to changes in gastronomic habits. A rising standard of living and changing lifestyles have led to a shift in demand to higher quality products for occasional consumption. The consumption of liquor is strongly affected by its substitution with other products such as wine and beer, and non alcoholic beverages, particularly in bars, pubs and restaurants. The market differs depending on the specific products of the various European and extra-European areas.

Supply and competition

Firms operating in this industry face a homogeneous EC market. The most well-known trade-marks operate on a pan-European market. Many firms are diversified, own more than one brand and often import products such as vodka and rum

under license. Although consumption is increasingly oriented towards high quality products, prices remain stable because of a high level of market saturation. Because the market clearly differs depending on typical DCO products and the type of distillate, competition (both intra- and extra-EC) is based more on consumer preferences for certain types of distillate rather than price. Given this situation, products such as rum, vodka and whiskey are mainly imported. Moreover, the main enterprises operate in almost all EC markets with different brands. Each sector of the market is differentiated by a separate quality and/or price policy.

Production process

The production process is very similar for all of the main products which are based on fermentation and filtering of fruits, grapes and cereals. As in a number of the main food sectors, the degree of automation and technological innovation is low. During the 1980s, labour productivity increased less than unit labour cost and total cost.

INDUSTRY STRUCTURE

Companies

The industry is characterised by a few large multinationals. There are, however, many small firms focused on local production of a specific product.

The six largest firms of the sector (Guinness, Pernod Ricard, Grand Metropolitan, Allied Lyons, Martini & Rossi, Seagrams) together have a 35% to 40% share of the EC market.

Strategies

The decrease in demand caused by new consumption patterns has forced firms to invest in both high quality production and advertising. Many enterprises acquire production licences and market imported products in order to differentiate their own range of products. Product innovation is quite low because the success of a marketing strategy lies in the uniqueness of the product. Some local producers try to differentiate their own products by using ingredients typical of their regions.

During the 1980s, the industry witnessed several acquisitions which have expanded the variety of products offered by the main firms operating in Europe. Another strategy has been the diversification into other segments such as beer, wine or non-alcoholic drinks. This kind of diversification capitalises on similar distribution channels for each product.

OUTLOOK

Decreased consumption will continue due to changes in gastronomic habits and consumption patterns. Mergers and acquisitions, however, will continue to increase the degree of concentration for this industry. Firms will tend to gain the highest quality/price ratio of the market by specialising in their own products. Increases in exports will come largely from an emerging market in East Asia.

Wine
NACE 425, 426

The demand for wine in Europe is falling. The decrease in consumption is most pronounced in the table wines sector in which strong price competition has grown. the fear of adulterated wine has also penalised wine exports. quality wines, on the other hand, have been less affected by competition from non-EC countries, and have seen growth in their export markets. In both France and Italy, the cooperative have reinforced their market presence owing to the need for close integration with the vine growers.

INDUSTRY PROFILE

Description of the sector

The sector includes the production of wine and other beverages based on fresh grapes (NACE 425) and the manufacture of cider and of wines (including sparkling wines) and other beverages obtained by fermenting fruit juices other than grape juice (NACE 426).

Main indicators

Production and consumption figures expressed in current values do not show the reduction that is clearly highlighted by the change in physical quantities; the positive trend in the figures is due partly to an inflationary effect and partly to the reorientation of production and consumption towards high quality wines.

The trade balance for 1990 and 1991, though positive, reflects decreasing exports in those years after a sizeable increase in 1989.

Employment levels, which decreased sharply in 1978, through to be mid-eighties stabilised after 1988.

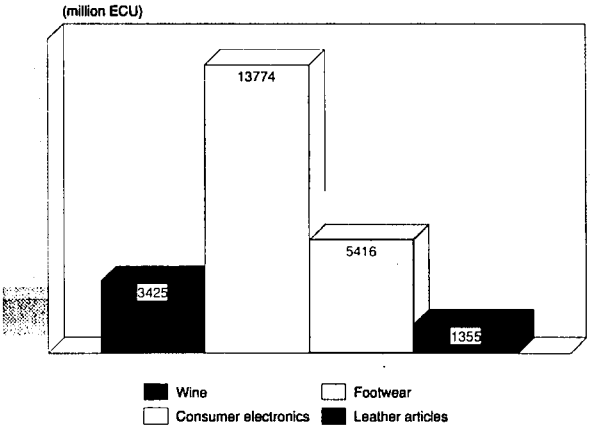
France had the highest of value added in 1991, more than 30% higher than the runner-up, Spain. France also has the highest vine and wine output in terms of amount produced, and is especially oriented towards high-quality, locally produced wines.

Spain's value added is also very high, compared to the other wine producing countries. In terms of actual quantities, between 1983 and 1991 Spanish production decreased. During those years, there was a shift towards higher quality production, which helped Spain retain its high value added in the face of decreases in production in volume terms.

Italy, the top wine-producing country in the EC until 1989, has not only been overtaken by France in terms of actual quantities produced, but also shows a value added level which has been more than halved compared to French levels. In Italy the substantial production of table wine has been penalised on both the domestic and international markets by the reduction in the daily consumption of table wines. In addition, continuing concern about methanol-adulterated wine following the scandal in 1986, has also had an effect on demand for Italian wine.

Germany and the United Kingdom have very similar value addeds. German production, which was generally stable during the 1980's, is targeted to a market that is increasingly oriented towards sparkling wines, which have a higher value added than that of still wines and which have been the object of a more intense brand-name policy. British production, negligible in terms of amount produced, is nevertheless aimed at a high-quality market segment.

Figure 1: Wine
Value added in comparison to other industries, 1991



Source: Eurostat

The low level of value added in Greece reflects both a fragmented supply system and the variable quality of its outputs.

Recent trends

The positive production trend in constant prices, given the downswing shown in the actual quantities in the period between 1982 and 1991, reflects an increase in the average unit value of European production in real terms. The increase in the qualitative level also reflects the decreasing consumption as a whole.

Extra EC exports dropped between 1986 and 1988; this drop was influenced by the protectionist measures adopted by the United States and Japan, which especially affected exports of Italian table wine. Imports have a high growth rate, but are still a negligible portion of consumption

Foreign trade

As a result of the reduction in exports and the increase in imports from outside the EC, the ratio between the two more than halved between 1982 and 1991. Volume of intra-EC trade doubled in that time, and in 1991, growth was more than twice as high as that of extra-EC exports. Volume fluctuated between 97% and 98% of overall imports. The origin of imports has shifted from EFTA countries to the United States.

Exports to the United States have decreased, partly as a result of protectionist measures adopted in response to the normative restrictions imposed by the EC on American meat imports. The latest measures taken in the United Sates have set limits on the import of EC table wines containing procimidone, a fungicide widely used against grey mould. Exports to Japan have grown.

MARKET FORCES

Demand

Since the early 1970s, consumption of alcoholic beverages has experienced a reduction in demand linked to the evolution in patterns of food consumption. The progressive shift of increasingly large segments of the population from manual activities towards more sedentary activities, together with a rise in income levels, has led to increased dietary concern and the need for higher quality food products. Wine was used habitually as a caloric supplement, but the need for wine in this capacity has deteriorated.

Instead, demand for wines has been moving towards higher quality, while overall consumption has decreased. This has occurred in nearly all European markets and especially in countries with high per capita consumption levels: Italy, France, Greece, Spain and Portugal. The reduction in wine consumption has also been affected by the availability of non-alcoholic substitutes.

Supply and competition

Competition inside the EC is conditioned by the trend in favour of the higher quality-price segments. France, which has traditionally produced quality wines, overtook Italy in terms of actual quantity produced in 1990. In spite of the shrinking of the internal market, both intra and extra-EC French exports have made significant steps to catch up with Italian levels. Table wine is the most significant portion of Italian production. Italian wine is greatly affected by the competition from Spanish, Greek or North African wines, whose musts are already imported in quantity in Italy, due to a much lower cost structure.

Although Italy regained the world leadership in volume exports in 1990, which had been lost as a result of the methanol

Source: Eurostat

scandal, yield on Italian exports is rather low. The problem of increasing the quality of Italian vineyard production is all the more complex because of its low-level export market. Small margins leave little room for investments aimed at increasing quality.

European production also has to cope with growing extra-European output. Argentina, ex-USSR countries, the United States, and South Africa have reached high production and quality levels. The United States, Bulgaria and the former Yugoslavia have also established themselves as important exporting countries.

Production process

The productive process has not undergone any recent changes. A strong integration with the primary agricultural sector affects this field. The techniques of vine cultivation, implantation and maintenance are fundamental in determining the quality of the wines. Growing, harvesting, processing, bottling and ageing are thus strongly integrated. Hence, both in Italy and in France the cooperative method of production plays a significant role. During the 1980's the increase in productivity in the EC was lower than the trend in overall unit and labour costs.

INDUSTRY STRUCTURE

Companies

The cooperative companies in France have about 60% of the market share in French table wines, about 40% in quality wines, and about 36% in champagne. The market share of table wines controlled by cooperatives is estimated to be higher in Italy than in France. Cooperatives are significant in the quality wines segment of Italy as well. The quality still and sparkling wine market contains old, established, traditional family concerns such as Gancia and Antinori, although they tend to have low market shares.

There are very few companies that operate in significant levels in more than one EC market. These include Pernod Ricard, Allied Lyons, Seagrams, LVMH, Castel, and Grand Metropolitan. Altogether, these companies control less than 15% of the EC market share.

Strategies

Market structure determines the adoption of different strategies that are often followed simultaneously.

The cooperatives, which are especially strong in the table wines sector, acknowledge that their strength is the close integration with agricultural production. Although there have not been any significant innovations in the production process of the wine itself, research into hybrids, the adoption of mechanised techniques of pruning, ploughing, pesticide sprinkling

and harvesting have strongly increased agricultural output, thus contributing to cost containment.

In the quality wines sector, a good deal of attention is paid not only to the quality of the raw material, but also to fermentation, bottling and ageing, all of which are crucial in the determination of a particular kind of wine-making. A brand-name policy is pursued by way of advertising campaigns.

ENVIRONMENT

The pesticide methods used in grape growing are among the most polluting phases of the process, if the growing of grapes is included as part of wine-making. However, this is a problem which affects all agricultural cultivation. From the point of view of the actual production process, there are no aspects with any particular environmental impact.

Packaging, especially disposable glass, creates a waste disposal problem which Europe has been dealing with for some years by means of differentiated refuse collection and the establishment of recycling consortiums.

OUTLOOK

The well-established trend towards a fall in consumption in the EC is expected to continue through 1995 and probably longer. The incentives adopted by the EC to encourage the uprooting of vines (27,000 hectares in France, 15,000 in Italy and 1,000 hectares in Greece) has not been effective because of the increase in average agricultural yields. For this reason, in 1990 and 1991, output surpluses built up. It is believed that the measures presented by the EC during 1990, aimed at cutting back the surplus, may start being effective between 1992 and 1995.

Exports will continue along a stable path. The table wines will continue to be strongly affected by price competition from East European and North African countries. The quality wines, in a higher price-quality segment, will undergo an increase in export volume.

Producers will thus have an opportunity to expand into the quality wine segment to offset decreased consumption of table wines. However, it is difficult to establish and to maintain a position in the quality wines sector.

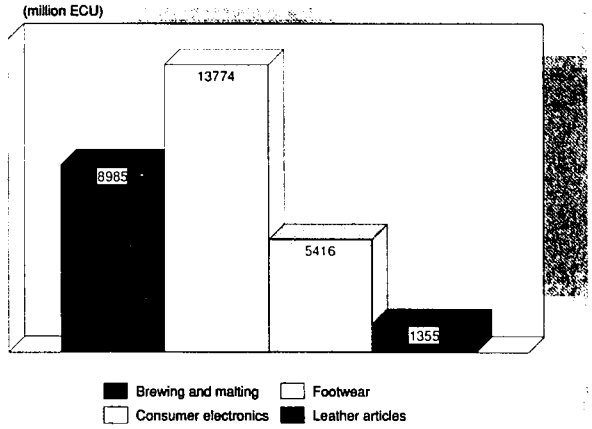
Brewing and malting
NACE 427

The brewing and malting sector is undergoing worldwide consolidation due to mergers, acquisitions and joint venture activity. In northern Europe (where beer consumption is heavy), demand is stable and has almost reached saturation level, while in smaller beer markets, like Italy, Portugal and Spain, demand is increasing. The recently marketed low and non-alcoholic beers are gaining popularity among consumers. Changes in European life styles have partly altered the beer distribution system which has caused a decline in home deliveries in favour of supermarket sales. This sector may be negatively affected by the current decrease in the 18 to 35 year old age population, which is usually characterised by heavier beer consumption.
In Europe, this sector holds a dominant position in comparison to other alcoholic drinks. European production of malt accounts for about 40% of world total production.

Figure 1: Brewing and malting
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

Through a fermentation process, beer is obtained from malt. Its alcoholic degree is variable. According to its production process, beer may be classified into the following three main categories:

- low fermentation beer
- high fermentation beer
- spontaneous fermentation beer (typical of Belgium).

The sector also includes non-alcoholic beers, light beers (recently marketed), normal beers (table and premium DCO), special beers and double malt beers. According to the degree of malt toasting, beers can be divided into light and stout ales.

Main indicators

According to the industry's main indicators, the industry experienced a rise in consumption nominal terms which can be attributed to higher prices. In fact, the deflated index shows no real increase in volume consumed between 1990 and 1991.

In 1990 and 1991, extra-EC exports increased by more than 5% annually in nominal terms, strengthening the trade balance. Employment, after ten years of contraction due to the automation of some steps in the beer production process, experienced a slight increase in 1991 and 1992. Germany (West) shows the highest value added, followed by the UK and Spain, where the Spanish beer market has increased remarkably in the last five years.

Recent trends

After a negative trend between 1982 and 1985, beer consumption has almost reached saturation in countries where per capita consumption is already high. Domestic supply has undergone the same trend as demand, contracting by 1.7% per year between 1982 and 1985 and increasing thereafter.

The increase in imports from extra-EC countries is high but, as imports are but one-tenth the level of exports, the trade balance continues to remain positive.

International comparison

EC production has expanded considerably since 1982. Most of this increase however can be attributed to higher prices rather greater production as increases in volume have been limited. While production in the USA has remained relatively stable (as measured in million ECU), production in volume experienced a downturn of 7% in 1991.

Foreign trade

Intra-EC trade increased remarkably during the beginning of the 1990s. Exports, however, increased less rapidly than total imports, thus causing a decrease in the export to import ratio. In 1986, almost half of the total European beer exports were directed towards the USA. Five years later this share has decreased to only 37%.

Intra-EC trade increased and in 1990 and 1991 outperformed extra-EC exports in value terms, however, both account for a very low share of EC production.

In 1991, Mexico gained a predominant position among EC supplier countries by supplying almost a quarter of the total beer imported by the EC. Mexico appears to have absorbed the decrease in imports coming from the EFTA countries.

As for malt (one of the inputs necessary for the production of beer), about 2.5 million tonnes were exported in 1991, whereas little more than 1 million tonnes were imported. 36% of malt is exported to North and South America (of which 40% goes to Brazil), 33% to Asia (of which 65% goes to

Japan) and the 22% to Africa (of which 37% goes to South Africa).

The main European malt exporting countries are France (where intra-EC and extra-EC exports are high), the UK, and Germany.

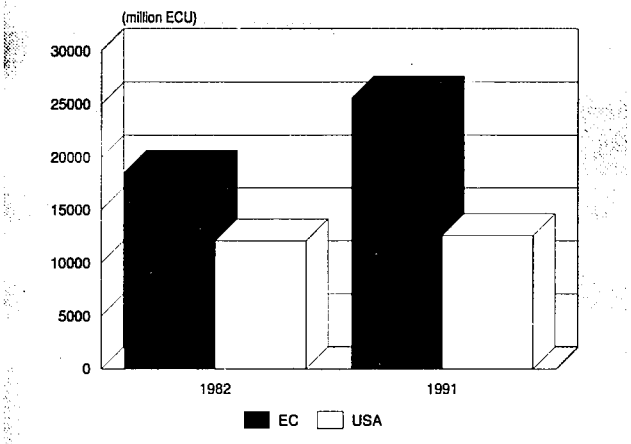
MARKET FORCES

Demand

Beer is traditionally consumed in many European countries. In countries where wine is preferred, such as France and Spain, beer has also become popular. In southern Europe, demand is rather seasonal (in Italy 40% of consumption of beer is between June and September).

In northern European countries, strong and medium beers are preferred (in Sweden their consumption has increased by 50.4% and 20.9% from 1985 to 1989, respectively), despite the fact that distribution is in some cases controlled by public authorities.

Figure 4: Brewing and malting
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Beer is consumed mainly in restaurants, hotels and pubs, but home consumption is rapidly increasing due to changes in purchasing habits following improvement in the distribution system. Young people between 18 and 35 years old are the main beer consumers. In some countries, like Spain, the consumption of beer by young women is increasing.

In Europe the per capita consumption of beer varies between 100 litres (in the UK, Germany, Benelux, Denmark, Austria and Ireland) and little more than 20 litres per year (in Italy). In northern Europe, beer prices are high (Norway, Sweden, and Finland). Prices tend to be more competitive in countries where consumption is relatively low. One exception is Switzerland, where prices are high although consumption is not particularly significant.

Supply and competition

From 1985 to 1989, exports decreased domestic demand increased. In the same period, extra-EC imports increased by 30%. Intra-EC trade has allowed to satisfy the demand in specific kinds of beers. Countries with a negative domestic export/import ratio are Italy, Spain, Portugal and England. Germany, Denmark and Holland, on the other hand, mainly export high quality beers.

The brewing and malting industry is generally run by few companies, but in Germany it is extremely fragmented (1200 beer producers, 70 of which account for 70% of the market). From 1982 to 1984, sales and profit margins decreased. From 1985 onwards the decrease in raw material and energy prices has caused profits to return to 1982 levels.

Industrialisation and mass production have caused the closing of many small local companies and a decrease in the number of employees in the industry. Some steps in the production process have been automated, thus increasing production capacity (Spain excluded).

Production process

The cost of labour is high in Belgium, Germany and France, whereas in Portugal it is lower. In Spain the industry is undergoing a modernisation process which will be completed by 1995.

The malt industry has a structure similar to the beer industry. In 1991, Germany owned about 62% of European malt producing firms; however, global production capacity accounts

for only 29%. France and England, on the other hand, have few malting plants, but production capacity is high.

Although in most of Europe, 70% of malt producing companies are independent, in Germany one-third of malt firms are associated with the beer industry. In Europe, malt production has increased after 1990 and is expected to further increase up to 300 000 tonnes from 1992 to 1993. This increase is also expected in extra-EC countries.

INDUSTRY STRUCTURE

Companies

European beer producers are made up of large multinationals and domestic companies. Heineken NV is the third largest beer producer in the world and the largest in Europe. It accounts for 3% of the world market, and in Holland accounts for 58%, in Italy for 20%, in France it accounts for 25%, and maintains a stable market position in Spain and Greece. BSN, by purchasing 22% of the third largest Spanish firm in the industry, has become the second largest beer producer in Europe.

Among domestic producers, Italian Peroni has a good market position and production has increased by more than one third since 1988 when the firm purchased Wuhrer from BSN. The French company Francaise de Brasserie resulted from the fusion between Union de Brasserie, Brasserie Pelforth and Heineken France.

Strategies

Beer producers try to increase their profits by increasing their market shares and persuading consumers to pay a high price for higher value added products. Moreover, they differentiate their products on the basis of taste and an enhanced marketing strategy.

Main producers are starting to market new "dry" beers whose success is uncertain. One challenge for "dry" beers is establishing whether or not its taste is truly different and not just a marketing gimmick. A second problem is posed by competition from low alcoholic products which are favourably accepted at the moment.

The investments made in the 1980s have allowed the automatisation of certain steps in the production process in order to increase productivity. Large advertising investments have also been made.

In comparison to local companies, beer multinationals are better positioned for increased international sales. In order to establish global brands, consolidation and globalisation are needed, thus multinationals are expanding through mergers, acquisitions and joint ventures. Spain, in particular, is a open market for beer multinationals looking to increase their capacity.

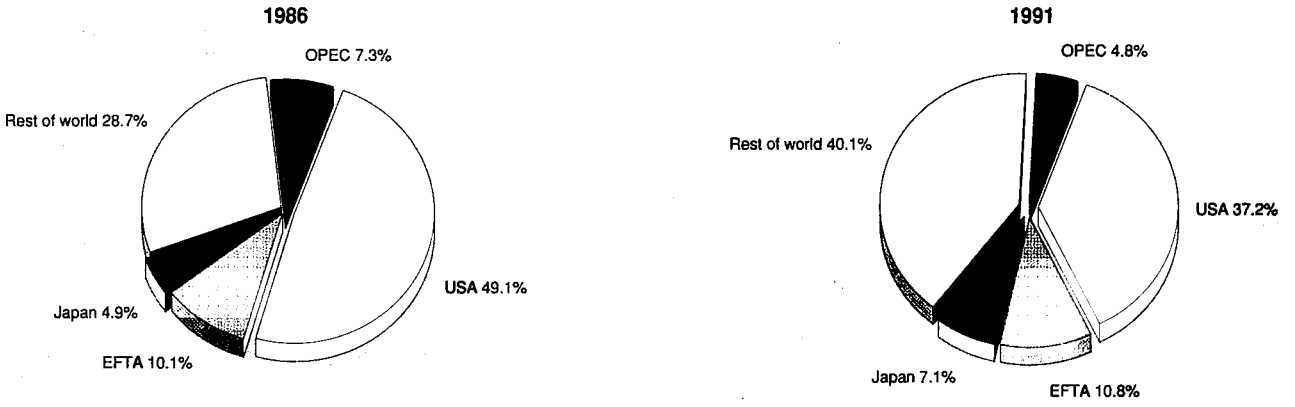
In 1990, the British company Guinness became the fourth largest beer producer in the world in terms of operating profits through the acquisition of the Cruzcampo, the main Spanish beer producing company.

In 1992, BSN acquired 22% of Cervezas San Miguel, the third largest Spanish brewing company. Looking beyond the EC's borders, Heineken is expanding into East European countries (notably Hungary). In addition, the British company Grand Metropolitan has merged with the Australian company, Elders.

ENVIRONMENT

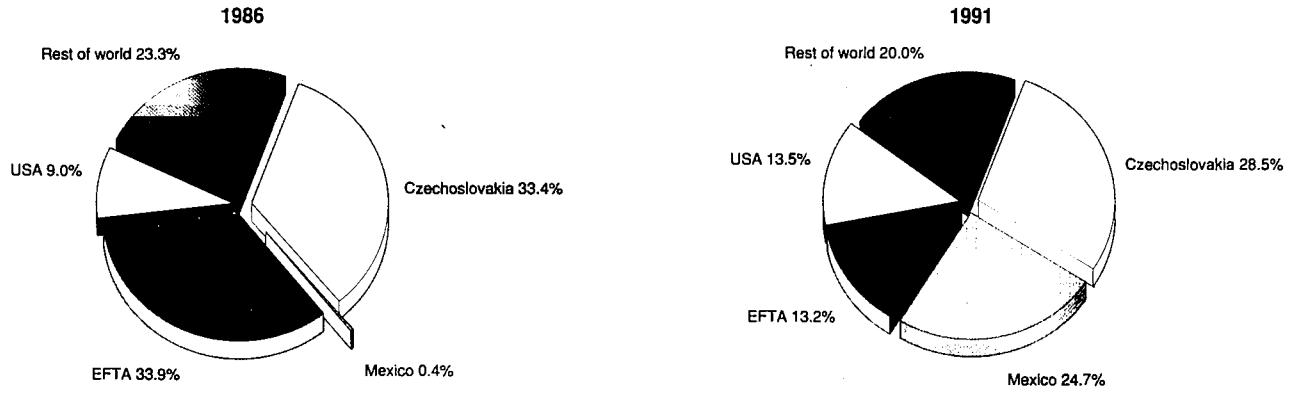
The main environmental issue for the beer industry is recycling. For home consumption, 330ml bottles are mainly used but the expansion of supermarket sales has made returnable empties unpopular. Can packaging restricts recycling efforts

Figure 6: Brewing and malting
Destination of EC exports



Source: Eurostat

Figure 7: Brewing and malting
Origin of EC imports



Source: Eurostat

as no widespread aluminium recycling networks have been established.

REGULATIONS

The revocation of the purity law in Germany ("reinheitsgebot") is expected as this law limits imports. According to this law, beer must be made of only four ingredients: hop, malted barley, yeast and water.

In order to cover the yearly purchasing and processing cycle of the breweries, EC malting plants need licences with a validity of 12 months.

OUTLOOK

In the main beer producing countries, stable demand is expected over the next few years while in small markets like Italy and Spain, demand is expected to increase. In Italy, a 2% to 3% average growth rate per year in volume is expected due particularly to demand from younger segments of the population and increased advertising.

In Germany and in the UK, an increase in demand will be difficult because of anti-alcoholic campaigns in defence of public health and an increase in wine consumption (which is considered to pose lower health hazards). Beer consumption, therefore will probably be stable for the next two or three years as consumers are not expected to change their consumption habits drastically.

Soft drinks, mineral waters

NACE 428

The consumption of soft drinks and mineral waters is increasing in all European countries due to the use of PET plastic containers. The difficult disposal of plastic materials, however, has caused serious environmental issues that have slowed consumption growth in some countries. During the 1980s, the mineral water industry moved towards increased concentration through M&A activity. In the soft drinks sector, isotonic beverages are experiencing significant expansion.

INDUSTRY PROFILE

Description of the sector

The sector includes soft drinks which are ready-to-drink, water-based drinks, optionally sweetened, acidulated, carbonated and which may contain fruit, fruit juices and salts. The flavour may derive from vegetable extracts or flavourings.

The sector also includes natural mineral waters, spring waters or table waters, all of which can either be sparkling or still.

Main indicators and recent trends

During the 1980s, apparent consumption increased significantly, particularly between 1985 and 1990, due to the fact that mineral waters were undergoing a significantly expansive trend in the major European markets. Production data mirrored consumption trends although they tended to be slightly higher. Exports also rapidly increased even though they were low with respect to production (2.4%). The trade balance was positive. Because of a strong increase in consumption and production, employment rebounded in 1987.

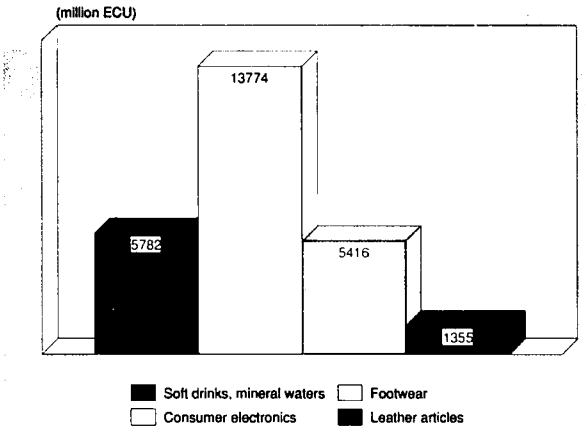
The German non-alcoholic beverage industry has the highest value added in the EC. Germany's production of both mineral waters and soft drinks increased strongly over the last several years. Average prices for soft drinks and mineral waters in Germany are also among the highest in Europe. Spain, the UK, France and Italy show a medium value added. Greece and Belgium show the lowest value added. The Greek market is characterised by a low consumption combined with a strong seasonal component

Consumption of mineral waters and soft drinks in Belgium is rapidly increasing with a substantial share of mineral waters imported from France.

Foreign trade

Intra-EC trade is twice as large as extra-EC exports and accounts for about 90% of total imports. This is due to difficulties in transporting mineral waters and to the ease with which production facilities for soft drinks may be set up near the final markets. As a result, trade volume decreases as the distances to final markets increase. Imports from EFTA countries account for more than 70%. Interestingly, exports are mainly directed towards the United States, with particular emphasis on flavoured sparkling waters, with Perrier as the market leader. Exports to East European countries such as Poland increased and exports to EFTA countries remain high. The extra-EC export to production ratio is increasing but is still very low (2.3% in 1982 and 2.4% in 1991). In 1991, the extra-EC import to apparent consumption ratio was less than 1%.

Figure 1: Soft drinks, mineral waters
Value added in comparison with other industries, 1991



Source: Eurostat

MARKET FORCES

Demand

The increase in demand for this sector in recent years, especially for mineral waters, may be attributed to various factors. The first is the increase in average income in Europe, given the high income elasticity of mineral waters and soft drinks. The second reason for an increase in mineral water consumption is the concern of consumers regarding the quality of tap water.

The third reason is connected to packaging technology, in particular to the adoption of PET. PET is a special plastic material which allows the transportation of sparkling water in plastic bottles, which was not possible with PVC plastic materials. In many markets, the use of PET allows the product to be channelled through the main distribution system, with non-returnable, empty bottles or "empties". In Germany, however, a one DM deposit has been introduced for each PET bottle, which discourages foreign exporters from entering the market as difficulties arise in collecting empty bottles.

The soft drink market is increasing even though its growth rate is lower than that of the mineral waters market. Growth rates are low in areas where per capita consumption is high.

Isotonic drinks, recently introduced in Europe, are remarkably successful source of refreshment which is particularly useful in sports.

Supply and competition

Some factors which affect competition between producers inside the EC countries have already been mentioned in the analysis of demand. In Germany, for instance, the deposit on plastic bottles and the enforcement of a 50 year old law pertaining to "heilwasser" caused a remarkable decrease in exports (particularly from France.) Competition is also limited by transportation costs, which affect both intra-EC and extra-EC trade.

Production process

Changes in the production process are attributed mainly to innovative bottling techniques. The use of PET materials has allowed increases in internal plastic bottle production and sparkling-water bottling. This new process has caused concentration of production due to the existence of scale economies in PET bottle production. During the 1980s, the labour productivity index increased significantly, although total unit costs and labour costs were higher.

INDUSTRY STRUCTURE

Companies

Within the soft drinks industry, a major distinction exists between the firms which market particular brands and the firms which actually bottle and distribute such products. Although certain brands are owned by multinational firms, many bottling plants operating in the soft drinks industry are small and privately owned. During the 1980s, market concentration through acquisitions occurred as larger firms attempted to increase their market share. As most mineral water companies are physically concentrated around a specific source of water, the distinction between the brands and the bottling firms in that sector tends to be much smaller.

The main companies operating in the mineral waters sector are BSN (Evian), Perrier, Nestlé and Brau & Brunner, which accounted for a total market share of approximately 35% to 40%.

In the soft-drinks market, the top companies are Coca-Cola, Cadbury Schweppes and Pepsi-Cola, which combined have a 50% share of the EC market.

Strategies

The firms operating in the mineral water industry have adopted various strategies. Some have increased production to keep prices stable. With respect to PVC materials, the use of PET materials has allowed for more wide-spread transport of bottled products, especially sparkling water. The increase in production, the wider distribution area and non-returnable empties (Germany excluded), have allowed the channelling of products through the main distribution system. Subsequently, the products are advertised on a more national level.

Another strategy consists of differentiating flavoured waters on the basis of their specific source. This strategy allows for the setting of a premium price. Perrier is the leader in this strategy, attaining considerable market shares not only in Europe but also in the United States, where flavoured waters are targeted for the high-quality end of the non-alcoholic beverage market.

Another strategy adopted by firms is to operate in a local market ("niche strategy") which allows firms to manage returnable empties more efficiently.

Firms operating in the soft drink industry are global firms which can take advantage of combining the production of homogeneous products with global advertising campaigns. The predominant firms using this strategy are Coca-Cola and Pepsi.

The mineral water industry has been characterised by strong merger and acquisitions activity which has caused a redistribution of competitors' market share. The most remarkable example is represented by the acquisition of Perrier by Nestlé.

ENVIRONMENT

The environmental impact of production is primarily concerned with the disposal of plastic and glass bottling materials. The use of returnable empties and differentiation in collecting urban solid wastes are the two main solutions to pollution problems. Germany has responded to this problem by passing a deposit law in 1988 which favours the collection of packaging waste. Coca-Cola and Pepsi were the first firms to introduce returnable plastic empties in Germany. For 1992, Italian law 474/88 mandates the recycling of 40% of plastic materials used for containers in that country. The establishment of a

disposal syndicate for plastic containers which would force firms to take part is also being endorsed.

All these measures might hamper free circulation of goods in the Single Market, the Commission has proposed a directive to set up criteria for harmonising those measures. The discharge of Denmark, announced by the Court of Justice on September 20, 1988, from the accuse of having introduced restrictions in the trade of drinks, on the basis of ecological reasons, should be interpreted in this light.

OUTLOOK

In the short run, the increase in consumption and production of non-alcoholic drinks is expected as more consumers decide to substitute such beverages for drinks containing alcohol. The high-income elasticity rate will lead an increasingly large share of the population to reach European consumption rates in richer EC countries. Mineral water consumption will increase as distrust in the quality of tap waters grows. Demand may be hindered, however, as the industry will be required to pay for the disposal and recycling of plastic containers, causing both costs and prices to rise. Mineral water exports will increase with product differentiation in the high-income consumer markets.

Table 7: Soft drinks, mineral waters

Risks for the industry include a possible excess supply of the mineral waters, forcing prices and margins to decrease. Another risk is the damaging of mineral water quality through pollution and noxious residuals at the source. The industry will also encounter higher costs from legal measures connected to the disposal of plastic containers.

A major opportunity can be found in the rapid expansion of the market.

Tobacco
NACE 429

In 1991 the value of production and consumption at constant prices of tobacco products increased in the EC. This expansion is explained mainly by social and demographic changes in Germany, the main consumer and producer of tobacco products in the EC. Before these recent developments, both production and consumption at constant were declining.

INDUSTRY PROFILE

Description of the sector

Within the tobacco sector the following activities can be distinguished:

- growing and initial processing of tobacco;
- manufacturing of tobacco products.

The main products of the industry are cigarettes, cigars and cigarillos. Other tobacco products include smoking tobacco, snuff, chewing tobacco, cut cigarette rag and agglomerated sheet.

Main indicators

In 1991, the real value of EC consumption of tobacco increased quite substantially (5.5%). Germany and the UK, the most important consumers, accounted for a large part (77%) of this increase. In the same year, the real value of production increased by 5.7%. Again, the main part of this expansion was explained by increased production values in Germany and the UK. These two countries are also the main producers of tobacco products; in 1991 they accounted for 65% of the production value and for 47% of the value added for the EC tobacco industry. Employment in the EC tobacco-processing industry fell by 3.6% in 1991. Almost half of this fall in employment is explained by job losses in the UK.

Recent trends

Production and apparent consumption in constant terms displayed similarly descending trends between 1982 and 1986, followed by a period of stagnation and by a significant recovery in 1991 (5.4% for both variables). The 1991 increase in production was almost entirely accounted for by Germany. Employment has steadily fallen since 1983.

The profitability of the industry was enhanced by recent shifts in demand towards the more expensive light cigarettes. This element, together with the drastic reduction in employment experienced by the industry in recent years, contributes to explain the ascending trend of the ratio between value added and employment since 1986.

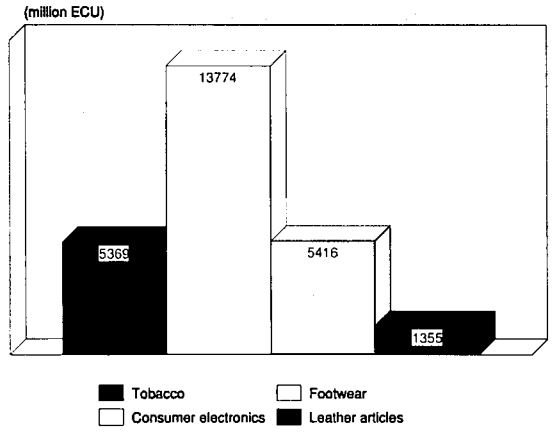
International comparison

Limiting the analysis to cigarettes, the major producers are China (1775 billion pieces in 1988), the USA (694.5) and the EC (625.3). China is also the most important consuming country (1600 billion pieces in 1989), followed by the EC (575.5) and the USA (550).

Foreign trade

EC trade balance of processed tobacco is positive and has improved in recent years. Although extra-EC imports have increased quite substantially (particularly imports from the Canary Islands) extra-EC exports have increased even more (particularly to Hong Kong.) The UK is the major EC exporter to extra-EC countries.

Figure 1: Tobacco
Value added in comparison with other industries, 1991



Source: Eurostat

Intra-EC trade of processed tobacco is not particularly high but becomes quite significant when considered in relation to the value of extra-EC trade. Since 1982, the ratio of intra-EC trade to total imports has never been below 75%. Moreover, intra-EC exports have consistently more than doubled the value of extra-EC exports.

Major net importers from other EC countries are France and Italy while the most important intra-EC exporters are the Netherlands and (to a lesser extent) Germany.

In general, however, exports (both intra and extra-EC) and imports cover a very small proportion of EC production and consumption of processed tobacco.

MARKET FORCES

Demand

EC demand in terms of volume for all tobacco products is declining due to a growing awareness of the health risks of tobacco consumption. Demand of non-cigarette tobacco products in particular shows the most significant contraction as fewer young people are attracted to this market.

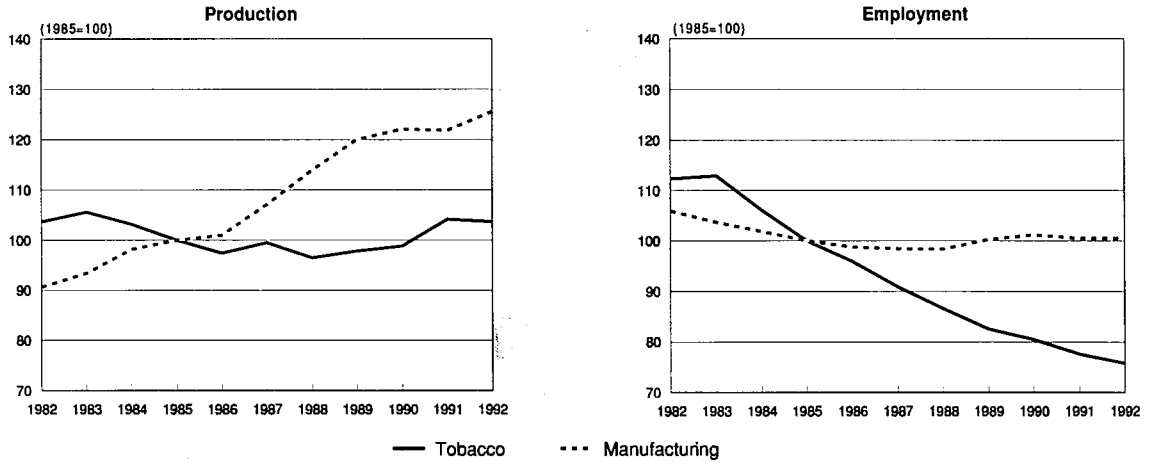
Figure 3: Tobacco
Production and employment indices compared to EC manufacturing



Source: Eurostat

Regarding cigarettes (which account for 90% of tobacco use) consumption trends vary according to a number of factors: anti-smoking campaigns have affected demand of dark tobacco cigarettes (which have lost ground to blonde tobacco cigarettes). Moreover, consumer preferences have shifted toward cigarettes with low tar and low nicotine content. While demand for cigarettes in the EC is declining, consumption is increasing world-wide (+2% in 1990), particularly in LDCs. These countries, together with Eastern Europe and the former Soviet Union, represent potentially lucrative export markets.

Supply and competition

Market segmentation and product differentiation are prominent features of competition between tobacco manufacturers. Cigarettes can be categorised differently, depending on whether they are made from dark or light tobacco and on their nicotine and tar content. The major private companies operate in each of these market segments with one or more brands. Brand loyalty and the oligopolistic nature of the industry contribute to reducing price competition. The latter is further limited in countries with state-controlled tobacco industries and administratively-controlled prices.

INDUSTRY STRUCTURE

Companies

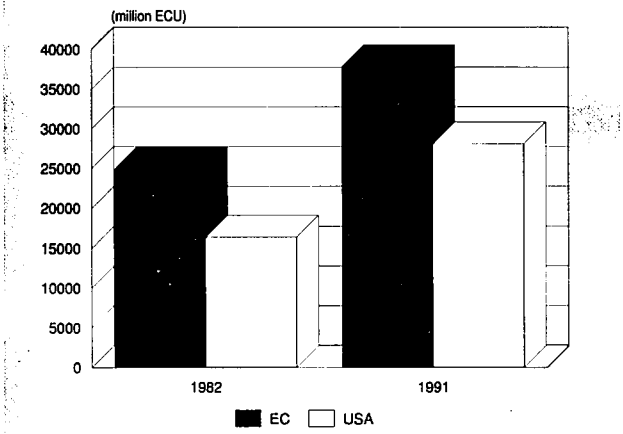
Italy, France, Spain and Portugal have state-owned tobacco monopolies which control both the manufacturing and the retailing of tobacco products. Belgium, Germany, Greece, Ireland, the Netherlands and the UK have private tobacco companies. In particular, some of these countries, like Germany and the UK, host multinational corporations such as American-based Philip Morris and R.J. Reynolds, or the British BAT Industries. Often, these multinational companies are also firmly established in European countries with state-controlled tobacco enterprises where they export or have licensing agreements with the national monopoly. An example of this is provided by France, where in 1988 the Government company SEITA maintained a 53% estimated share of the cigarettes market while a large part of the residual supply was due to Philip Morris (19%), Rothmans (10%) and R.J. Reynolds (6%). In Spain, the public monopoly Tabacalera produces cigars and 'blonde' brand cigarettes under licence for Philip Morris and BAT.

In Germany there are five leading private companies that together control 93.5% of the total cigarette market: Philip Morris (33%), Reemtsma (23.5%), BAT (21.1% in 1990), Brinkmann (9.4%) and R.J. Reynolds (8.1%). Philip Morris, Reemtsma and R.J. Reynolds have all acquired former East German tobacco companies and brands.

REGIONAL DISTRIBUTION

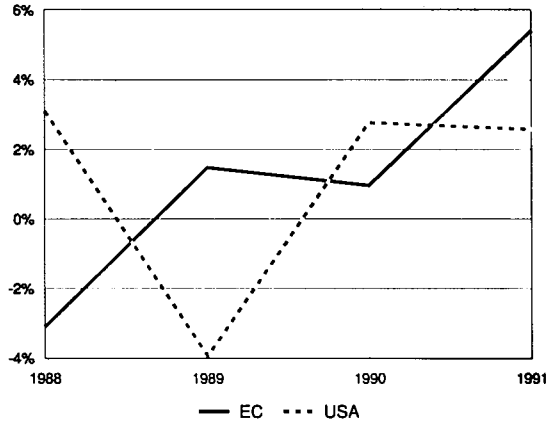
The EC is both a producer of tobacco leaves (424 thousand tonnes in 1991, 6% of world production) as well as a manufacturer of tobacco products. Tobacco leaf is grown in seven of the twelve EC countries. Italy has been the largest producer throughout the 1980s with a 40% share of EC tobacco production; however, Greece has been a close contender and actually exceeded Italy's production in 1986. These two countries grow different varieties of tobacco. Greece is specialised in more labour intensive, oriental varieties while Italy tends to grow less labour intensive, light air-cured and flue-cured varieties. In 1991 Italy and Greece together accounted for 78.8% of EC production. Spain is the third largest producer (11.2% of EC production) followed by France (6.9%), Germany, Belgium, and Portugal which each supply very small quantities of tobacco leaves. It has been estimated that in

Figure 4: Tobacco
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Figure 5: Tobacco
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

1990 tobacco growing required the equivalent of 208 500 full-time jobs.

Each country in the EC has its own tobacco manufacturing sector. Limiting the analysis to cigarette manufacturing, the major producers are Germany, the UK and Spain. In 1990, these countries accounted for 26.2%, 17.9% and 12.7% of EC production of cigarettes in volume terms, respectively.

REGULATIONS

Regulations in the tobacco sector can be distinguished between those concerning growing and first processing of tobacco leaves and those regarding marketing of tobacco products. Since 1970, production of tobacco in the Community has been supported by a system based on:

- guaranteed minimum prices (or intervention prices) at which intervention agencies buy tobacco from producers;
- transformation subsidises transferred to first processors of tobacco;
- import tariffs and export subsidies (reg 727/1970).

In 1992, new regulations should be introduced featuring, among other things, a system of production quotas, according to which each EC country is allocated a national quantity of tobacco to be processed. National quotas are to be distributed among firms involved in the first processing of tobacco on the basis of their production in the last three years.

Regarding the sale of tobacco products, some regulations have been issued and concerning restrictions on direct and indirect advertising, banning of smoking from public places, and tough requirements on health warnings to be carried out by cigarettes packets. Further measures are presently under discussion.

OUTLOOK

Despite the growth in consumption and production in recent years, it must be recognised that this expansion is largely explained by recent demographic and social changes in Germany. A declining trend in consumption is expected to re-emerge once the effects of reunification have subsided. In

particular, overall sales in terms of cigarette volume are expected to decline, with low tar cigarettes increasing their market share at the expenses of full flavour cigarettes. Production may decline to a lower extent than consumption due to expansion of export markets like East Europe and the former Soviet Union.

Major risks for the industry are the national measures concerning health (smoking forbidden or limited in public and working places). Opportunities for tobacco will most likely be caused by increases in cigarette consumption in LDCs.

Textiles, leather, footwear and clothing

NACE 43, 44, 45

The sector can be divided into the upstream industries of textiles and leather and the downstream industries of clothing and footwear. There is significant linkage between the two with the clothing industry absorbing half of the output of the textile industry and the footwear industry absorbing almost half of the leather production.
The industry is an important employer, with a labour force of around 3 million people in 1991. This, however, represents a decline of some 16% over the previous decade. Growth in production in the sector lagged behind growth in consumption between 1982 and 1991, leading to a sizeable balance of trade deficit.
The output of the industry can be either mass-produced items or higher quality goods serving market niches. The former is now subject to intense competition from low cost producers in developing countries and EC companies have yielded market share to these countries in the recent past. The higher quality end of the market is less determined by price, and EC firms possess a competitive advantage in relation to design, market response and distribution.
Much of the industry operates in the context of the Multi-Fibre Arrangement (MFA) and the expected conclusion of this regime is likely to liberalise trade. The EC Commission has set certain conditions for a phasing out of the MFA including the removal of barriers to the expansion of EC exports.
Price and profit levels in the sector are subject to fluctuations due to raw material price changes, and profit levels are generally low, at between 2 and 3% of sales. EC producers also face increased costs due to the relatively high level of environmental regulation imposed.

INDUSTRY PROFILE

Description of the sector

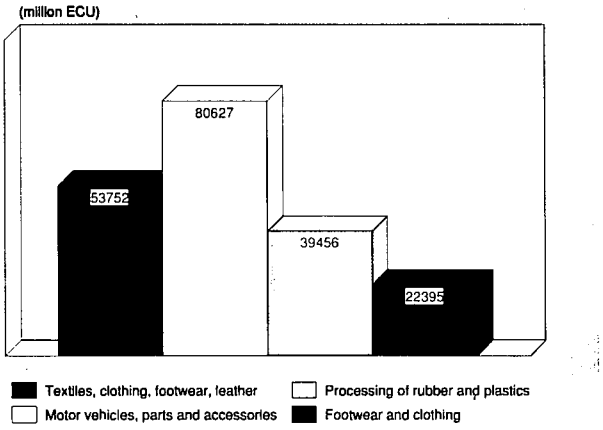
This overview covers the four related industries of textiles, leather, clothing and footwear. NACE 43 covers the textile industry which produces natural and synthetic fibres. NACE 44 covers the tanning and dressing of leather from bovine and ovine raw hides and the dyeing and finishing of leather. NACE 451 and 452 comprise the footwear industry covering mass produced indoor and outdoor footwear, hand-made footwear and other speciality footwear. NACE 453 covers the manufacture of clothing and clothing accessories from various materials.

The two upstream industries, textiles and leather, are partly dependent on demand conditions in the two downstream industries of clothing and footwear. Clothing absorbs about half of the output of the EC textiles industry, although this proportion is declining, while the footwear industry absorbs just under half of leather output in the EC, with the garment industry accounting for over one fifth.

Main indicators

Textiles is the dominant industry of the four subsectors, accounting for 58% of the sector's output, followed by clothing accounting for 28%. Eurostat data suggests that textiles also accounts for half of the total employment in the industry. However, the clothing sector has many small companies of less than 20 employees, and much of the employment in is on an 'out-worker' basis, so employment figures are low. It is likely that employment in the clothing industry is at least as high as in the textile industry.

Figure 1: Textiles, leather, footwear and clothing Value added in comparison with other industrial sectors, 1991



Source: Eurostat

The sector as a whole has a trade balance deficit. The trade balance is negative in the three larger industries, with only the leather industry showing a positive trade balance.

Footwear is the most export oriented of the four industries with over one quarter of its output going to extra-EC markets. The other three sectors have similar export orientation with about one-sixth of production value sold outside the EC.

Italy and Germany together account for almost half of the total value added in the sector in the EC.

Recent trends

Consumption rose significantly faster than production in the period 1982 to 1991, with production in volume actually falling in 1991. Production growth was higher in textiles and clothing than in leather and footwear. Production growth was sluggish in the latter half of the 1980's, partly a result of the poor export performance in that period.

Extra-EC exports grew rapidly in the early 1980s, dipped in the 1986 to 1988 period, then recovered to a 1991 level 40% above the 1982 level in real terms. Extra-EC imports grew at only half the rate of extra-EC exports in the early part of the 1980's, but rose dramatically thereafter. Between 1982 and 1991, the total import growth rate was two and a half times the exports growth rate.

Employment fell in the sector by a total of 12%, from 1988 to 1991. The largest fall in percentage terms was in the leather industry, in which employment fell by 26%.

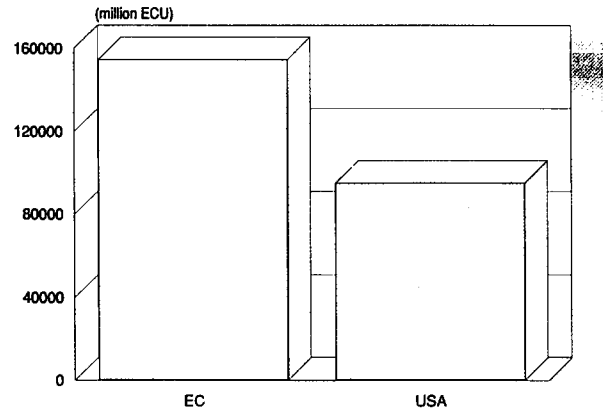
International comparison

The EC is a major force in the clothing industry, accounting for 30% of world exports, and is the origin of 10% of world production and 20% of world exports of footwear. In the leather industry, Europe (primarily the EC) represents nearly half of world trade, with leather production close to double the level of US and Japanese production combined.

Foreign trade

The ratio of exports to imports hovered around parity up to 1986 but subsequently fell to just over two-thirds in 1991. Leather is the only industry to display a ratio in excess of one, while the trade imbalance in the clothing industry now shows imports at two and a half times that of exports. Textiles, which had a ratio of close to one during the 1980s, fell into a significant deficit in 1991. Footwear, which had a ratio of 2:1 in the early to mid 1980s dropped below one in 1991. Consistent with the deterioration in the trade balance, extra-EC imports now account for a greater proportion of total trade than in 1982.

Figure 4: Textiles, leather, footwear and clothing
International comparison of production at current prices, 1991



Source: Cotance, Eurostat, Census of Manufacturers

EFTA countries were the principal destination for EC exports in 1991, ranging from 46% in the clothing sector to 19% in the leather industry. The USA remained the second most important destination, although its significance has decreased in relative terms since 1986. However, the USA is still of particular importance for footwear exports, and accounted for 26% in 1991.

China has doubled its percentage share of EC imports since 1986 and is now the single most important source of imports. In particular it accounts for over one quarter of footwear imports. Other East Asian countries are also important sources of materials and goods: Taiwan, South Korea, Thailand and Indonesia in the leather and footwear industries and Hong Kong in the textiles and clothing sectors. Turkey is also a significant textile and clothing supplier to EC markets.

Total production in the EC rose 18% from 1982 to 1991. In that period, the proportion of production exported to extra-EC markets increased 40%. Intra-EC trade rose over 60%. This suggests a declining dependence on national domestic markets and increased geographical diversification.

Import penetration rose to almost one quarter of total consumption in 1991 from under one sixth in 1982. Penetration is highest in clothing, at almost 32%, and in footwear, at almost 46%. Apart from the leather industry, which experienced an increase of only 2%, import penetration has increased significantly in each of the other sectors.

MARKET FORCES

Demand

The output of the clothing and footwear industries is directed almost completely to final consumer markets and is therefore affected by income developments in the general economy. Some output is sold to manufacturing or service industries, especially medical clothing or protective footwear. On the other hand, textiles and leather are largely used as inputs in the clothing and footwear industries, rather than being sold to end consumers .

Figure 6: Textiles, leather, footwear and clothing

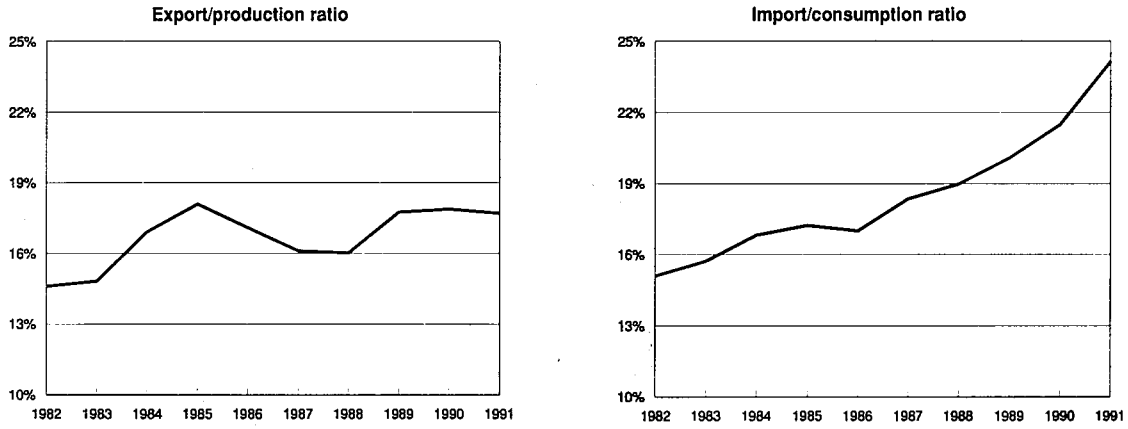
Figure 8: Textiles, leather, footwear and clothing
Trade intensities



Source: Eurostat, Cotance

Although footwear and clothing are both necessities up to a certain income level, they become discretionary beyond that level.

The EC market for these two products can be divided into mass produced items and high quality goods for which price is less of a determinant. The market for mass produced items is being increasingly supplied by low-cost imports from newly industrialised or LDCs. In the mass production market, price remains a key consideration and EC producers have lost market share because of the inability to compete with firms whose labour costs, in particular, are much lower than their own. In the high quality products, price is not as important and price elasticity is lower.

The nature of the products is such that fashions and tastes are key factors in determining demand. Product life cycles can be very short as fashions change quickly. This forces companies to be ready to respond very quickly to shifting demand requirements. A key aspect of this strategy has been the developments of links between manufacturers and retailers especially in the clothing industry and also the integration of some clothing and textile firms.

Many of the primary fashion centres of the world are located in the EC. Paris, Milan and Barcelona, and thus EC producers, have a competitive advantage in relation to speed of response to demand changes.

Product innovation in the downstream industries is driven by changing fashions and the developments of new fabrics in the textile sector. Thus, developments in the textile industry itself allow innovations in the clothing sector, such as the development of thermal fabrics. In the textile sector, new fabrics have been developed by combining natural and existing synthetic fibres in varying quantities.

Supply and competition

Production in the EC lagged behind growth in consumption between 1982 and 1991, as cheaper imports gained increasing market share. Much of this was due to the competitiveness of firms in countries with lower labour costs, especially in East Asia. This fall in production was accompanied by a structural rationalisation in the sector, with larger firms closing plants and some smaller firms closing altogether.

Distribution in the industry has become increasingly concentrated as some of the larger producers have either developed their own retailing networks or entered into alliances with existing retail chains.

Investment in the sector in the recent past has focused on modernisation and automation rather than expansion, and overcapacity is not a problem, particularly in up-market products.

Much of the industry operates in the context of the Multi-Fibre Arrangement (MFA) governing imports into the EC, except the footwear industry which is not covered by the MFA. Countries which have preferential agreements with the EC include Malta, Turkey, Morocco, Tunisia, Egypt, Cyprus, Hong-Kong, China and Malaysia. It is unclear what the impact of the current round of GATT talks will be on this agreement, but it is likely that a freer trade regime world-wide will emerge. The EC has set pre-conditions for the phasing out of the MFA in the clothing and textile sectors. These include:

- the opening up of markets in developing countries;
- action to curb dumping of surplus production on EC markets;
- the removal of certain state subsidies, e.g. export subsidies, in some of the better developed countries with low input costs;
- action to curb counterfeiting of EC brands.

In the context of the completion of the EC internal market, national quotas will disappear and the use of Article 115 of the Treaty of Rome, which allows a country to exclude imports which would cause a serious market disruption, is likely to be greatly reduced.

Export development, seen as a key strategy throughout the sector, is hampered by trade restrictions in some of the potential destinations. Japan, for example, operates a restrictive trade policy vis-à-vis footwear and leather production.

Production within the EC is also hampered by the difficulty and the cost of obtaining raw materials from LDCs. Increasingly, LDCs are attempting to develop downstream industries, and retain their raw materials for domestic value-added production. A case in point is the leather industry, where rawhides previously exported by LDCs are being processed further in the country of origin.

Profitability in the industry is somewhat vulnerable to the volatility of world commodity prices, e.g. wool, cotton and raw hides. Profitability has been squeezed in the EC in recent years as wage cost outstripped productivity gains, and the pressure of cheap imports prevented EC producers from increasing their own prices. Other costs, such as those due to expanding up-market output ranges, and the associated advertising and promotional costs to establish a market foothold, have squeezed margins further. However, the EC industry possesses a significant competitive advantage in the areas of design and quality.

Production process

Employment in the industry has decreased sharply since the MFA was introduced in 1973, falling in textiles alone from 4.5 million to 1.1 million in 1991. Much of this decline can be attributed to technological advances and the inevitable shedding of labour. There is substantial use of outworkers, particularly in clothing, but also in footwear and certain sectors of the textiles and leather goods industries. Labour productivity rose rapidly in the 1980s on foot of the technological developments. However unit labour costs rose more quickly. The textile industry has thus become more capital intensive in the EC, and the capital-labour profile is very different from that in developing countries which still rely much more on labour intensive methods of production. While the introduction of technology in the clothing and footwear sectors was more limited than in textiles and leather, the application of computer aided design (CAD) and computer aided manufacturing (CAM) have become more widespread.

The use of just-in-time (JIT) systems has also become an important feature within the industry particularly in the clothing and footwear sectors. An example of an integrated JIT manufacturing and retailing is the Benetton group which links retailers, production units and warehousing and allows rapid response to market changes or trends.

In addition, the level of labour skills is higher in the EC than elsewhere (including the US), giving EC producers a competitive advantage in the production of higher quality products. The introduction of the EC-sponsored RETEX programme will enhance the quality of labour in the regions where it is being implemented. The FORCE and EUROFORM programmes also assist in the vocational training of workers for the industry.

Product innovation and development is an important strategy for EC industry, particularly in the context of declining competitiveness for mass produced goods. In the textile industry, technological advances have allowed for greater variety in the production of fabrics. The combination of natural and synthetic fibres in varying proportions allows materials possessing different characteristics to be developed, e.g. waterproof, windproof, and thermal fabrics. Technical textiles, the

fastest growing textile sub-sector, have been developed with a wide range of industrial and environmental applications.

Product innovations in the clothing industry are largely based on the development of new fabrics in the textile sector, indicating the degree of interdependence and integration in the sector overall.

INDUSTRY STRUCTURE

Companies

There are around 290 000 firms in the EC industry employing three million people, despite the sharp reduction in the number of employees over the past decade. About 90% of firms are small, employing less than 20 people. These firms account for over one quarter of total employment but less than one quarter of total turnover. In the clothing and textiles sectors, in particular, there has been an increase in the number of smaller firms.

Most of the smaller firms supply domestic or neighbouring markets and the level of extra-EC exports from these firms is low.

Some of the larger firms in the sector span both the clothing and textile sectors e.g. Benetton (Italy), with a turnover of 1.3 billion ECU in 1990, Coats Viyella (UK) which recently merged with the Tootal Group (UK), and Courtalds (UK).

Strategies

Faced with competition from low cost producers abroad, EC producers have reacted by moving up-market into the production of higher quality goods which are less price sensitive and are not amenable to the same degree of mass production as standard items. This strategy is consistent with the spirit of the MFA as originally constituted. Northern European countries in particular have moved towards producing higher quality goods. Countries such as Spain, Greece and Portugal have not moved as quickly towards up-market goods, and remain vulnerable to low cost competition from outside the EC. They will be particularly sensitive to increased competition following the expected liberalisation of trade in the context of the GATT negotiations.

In the downstream industries of clothing and footwear the move away from mass produced items has necessitated increased investment in advertising, branding, adoption of quality management systems of production and distribution, and the implementation of JIT systems. In the leather sector as well, companies have identified smaller more profitable market niches.

The prospect of a move up-market by East Asian producers however, will increase the competitive threat faced by the industry in the EC and further strengthen the need for quality in production and distribution.

Part of the global strategy of EC producers has involved relocating or expanding production to areas within the EC where costs are lower, such as Portugal, or to locations outside the EC.

Other firms, particularly in the footwear sector, now sub-contract parts of the production process to firms located in Taiwan, Hong Kong, China, Thailand, and Brazil. Out processing trade (OPT) has also been an important structural change for EC clothing producers, and has reduced overhead costs, allowing EC producers to retain a certain level of competitiveness.

REGIONAL DISTRIBUTION

The industry is of considerable social and economic importance in certain regions of the EC, which tend to have both the upstream and downstream industries For example, clothing and textiles accounts for over half of manufacturing employment in the Donegal region of Ireland, while they account for a quarter of manufacturing employment in Northern Ireland. In Braga, Portugal these industries accounted for 60% of manufacturing employment. Therefore, structural changes affecting the industry tend to have a disproportionate effect on these regions. Aware of the selective regional impact of the decline in the industry, the Commission has introduced the RETEX programme, which is designed to assist regions in decline which were heavily dependent on the clothing and textile sectors. It will provide support to improve both labour skills and management capabilities, provide assistance for improving production methods and will aid design, research and measures to combat pollution.

At EC level, the four largest countries, Germany, France, the United Kingdom and Italy, account for the bulk of employment and output. Italy is particularly important in the footwear sector, accounting for 37% in volume terms of total EC production and in the leather industry, with three quarters of the EC's tanneries located in Italy.

Table 5: Textiles, clothing, footwear and leather

Source: Eurostat

ENVIRONMENT

The production process in the upstream industries can be damaging to the environment, if not controlled. The major impact is on water courses into which effluent is poured, particularly with the processing of natural fibres and with tanning. There is some concern emerging regarding the danger to employees from the production process in the tanning industry. Some air pollution is also possible in the production of viscose.

In the clothing and footwear sectors the production process itself is not so much an environmental problem as the disposal of worn-out items. Synthetic fabrics are not biodegradable and take up space in landfills.

Compliance with national and EC regulations imposes costs on EC producers which are not felt by producers in other countries where such regulations and controls are much more limited or not implemented vigorously by the authorities.

Environmental awareness can produce opportunities for the industries. Environmentally friendly fabrics have been devel-

oped to meet the requirements of the green consumer movement, including biodegradable or easy to recycle garments.

REGULATIONS

Much of the industry is governed by the MFA. However, it is expected that trade in the sector will be liberalised when the current round of GATT negotiations are complete. The EC also has trade agreements with a host of African, Caribbean and Pacific countries under the Lomé Convention.

In the footwear industry, bilateral trade arrangements existed at the national level to control the import of low cost products from Asian and East European countries. These have been largely phased out and trade policy is increasingly determined at the EC level. Many EC countries also provided assistance to domestic producers but most of these subsidies have been phased out as well, and are being replaced by centralised EC programmes.

The EC has been a leader in environmental damage control in the industry. The most important measure in this regard is the directive on the control of dangerous substances (76/464/129).

OUTLOOK

The expected upswing in world economies will lead to increased demand for the output of the industry although there may be some shifting of the importance of specific products within the sectors. For example, household and technical textiles may grow in importance while textiles for use in the clothing industry may become less important.

Imports are likely to continue to make inroads into EC markets due to greater price competitiveness and the impact of a freer trade regime. Countries with low import penetration at present may be most at risk. Export market development will continue to be a key strategy for EC producers. The success in this regard may depend on gaining access to markets currently protected, such as the Japanese market.

In the longer term the ability of EC producers to develop higher quality products, to find new uses for existing products, and to respond quickly to market changes will determine their performance. The threat of East Asian producers following EC firms up-market cannot be discounted and only serves to emphasise the need for quality and service in the manufacture and distribution of products.

The increased demand from Eastern Europe provides an opportunity for EC producers, but one in which they will face substantial competition from the lower-cost producers. The admission of greater quantities of imports from Eastern Europe will increase competition at the lower end of the EC market.

The completion of the EC internal market can be expected over time to increase merger and acquisition activity in the EC across national boundaries.

Increased use of sourcing in developing countries may make EC firms more competitive but it will involve some job loss within the Community. Likewise, the potential for relocation either within the EC or to Eastern Europe will impact on the structure of the EC industry.

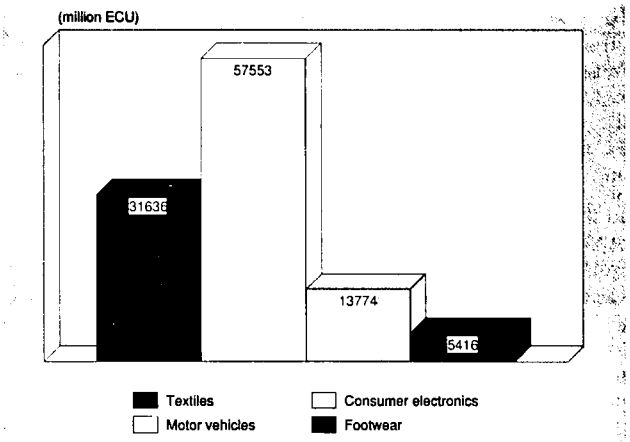
Textiles
NACE 43

The textile industry is very heterogeneous with demand heavily dependent on other industries, particularly clothing and home furnishing but also other industrial sectors such as automobiles. EC textile consumption substantially outstripped production over the last decade with the excess filled by extra-EC imports. International trade in the sector is governed by the Multi-Fibre Arrangement (MFA) and significant trade barriers remain worldwide. Strong price competition from extra-EC textiles has induced many EC firms to move into high quality and less price-sensitive niches and to reduce labour intensity through substantial investment in capital equipment. The main product innovations, and potential for growth, are based on varying the proportion of natural and synthetic fibres to provide a greater variety of fabrics with different features and the development of new markets for technical textiles, mainly used in industrial and environmental applications.

Figure 1: Textiles
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

One of the dominant features of the textile industry (NACE 43) is the heterogeneity of its output which can be differentiated according to fibre used (wool, cotton, synthetic fibre), end use (clothing, household furnishing, technical textiles) or production process (weaving, spinning, knitting). Textiles also differ according to product quality ranging from mass produced cotton for low cost garments to fine wools, linens and silks for designer clothes. NACE 43 also covers textiles which are inputs to other industries such as fabric for car upholstery or technical textiles for filters and linings.

Main indicators

The textile industry employs 1.5 million workers. In terms of production and consumption value, knitwear is the largest sub-sector followed by cotton and wool. Value added figures for Member States in 1991 show that the countries with largest value-added, in order of size were Italy, Germany, France and the United Kingdom. This reflects the size of their economies and the industry is of strong relative importance in other Member States, particularly Belgium and Portugal.

Recent trends

EC production of textiles increased during the early part of the 1980s but increasing pressure on profit margins from low-cost producers, particularly in Asia has resulted in little growth over the 1989-91 period. Since 1985, EC consumption of textiles has increased much more rapidly than production with resultant import growth leading to a sharp deterioration in the EC's balance of trade in textile products. Employment declined steadily throughout the 1980s, with a total fall of 20% between 1982 and 1991, including a fall of nearly 4% in 1991. Output prices for the textile industry vary widely across sub-sectors and across Member States, but on average production price increases have been relatively low over the second half of the 1980s.

International comparison

Production of textiles in the EC measured in value terms was more than twice the level of Japanese production in 1991. This relative size gap has increased over the past decade, EC production being 80% above the Japanese level in 1982.

Production growth has been stronger in the EC than in either Japan or the USA over the past four years with Japan suffering real declines in each of the years 1989, 1990 and 1991. US production fell in both 1990 and 1991.

Foreign trade

The data presented in Table 4 have to be taken carefully, since they include the raw materials (fibres). In fact, the Community has a large trade deficit in the trade of textile fibres, since it imports most of natural fibres used in the production process. On the contrary, the EC has a significant trade surplus in the trade of transformed textiles: Comitextil data show that in 1991 the EC trade surplus for textiles was of about 1.2 billion ECU.

The proportion of trade with the developing countries has increased during the 1986-1991 period, mainly to the detriment of trade with the EFTA countries. This is particularly true as far as imports are concerned.

However, the EC textile industry remains the largest exporter of textiles in the world and Germany is the world's single largest exporter with 11% of total world textile trade, followed by Italy with 8%. France and Belgium/Luxembourg are also among the top 10 exporting countries.

Extra-EC textile exports have grown slowly in recent years principally because the markets with the greatest growth potential, those of the developing countries are effectively closed to EC exports through the imposition of very high tariffs and non-tariffs barriers This explains why the EC stressed the necessity of an opening of those markets in the Uruguay Round negotiations. Another factor was the strong price competition on the EC's traditional export markets from developing and newly industrialised countries. EC exports retained their competitiveness throughout the 1980s in the markets of developed countries through constant improvements in quality.

The EC trade surpluses with the industrialised countries has declined in the past two years. On the EFTA countries' and on the North American markets, textile exports faced a fierce price competition from product originating from developing countries. This decline of competitiveness is also due to the dramatic fall of the value of the US dollar. The Japanese market, because of its size and the purchasing power of its consumers is seen by EC exporters as having great potential for expansion, but is difficult to penetrate because of many subtle barriers to trade.

Exports to Eastern Europe fell between 1985 and 1990. However, increased exports of household textiles through investment in both new and upgraded buildings are expected. Outward processing by EC clothing manufacturers to eastern Europe should also increase demand for EC fabrics from these countries. Despite barriers to trade, EC exports to developing countries have increased considerably in recent years, rising from 23% of total exports in 1985 to 36% in 1990. But imports of textiles from developing countries have risen faster than exports. EC exports to less developed countries can be expected to increase if the existing trade barriers are removed as agreed in the Draft Text of the Uruguay Round negotiations.

MARKET FORCES

Demand

Consumption of textiles in the EC rose slowly in the past decade, although there was a growth spurt during the upturn in the international economy between 1986 and 1990. The output of the textile industry is purchased by clothing and knitwear (45% of EC fibre use), by the home furnishings companies (17%), by the carpets industries (13%) and by a variety of other industries which use technical textiles (25%), among the largest of which is the automobile industry.

Demand for textiles has a low price elasticity and EC producers concentrate to a considerable extent on high quality textiles for which price is a less important factor than quality. Consumption of textiles is income elastic and the higher fibre consumption per capita in the USA than in the EC over the past decade has been attributed to the faster growth in the US economy and the higher disposable incomes in the USA.

Clothing

In 1989 EC households devoted 6% of their expenditure to purchases of clothing and finished textile products for household use. The share of spending on clothing and footwear in total EC spending is declining. Even if clothing is a basic necessity item and the growth in demand is related to population growth, presently quite low in the EC, expenditure on clothing depends largely on income levels and on fashion influences which play a great role in the EC markets.

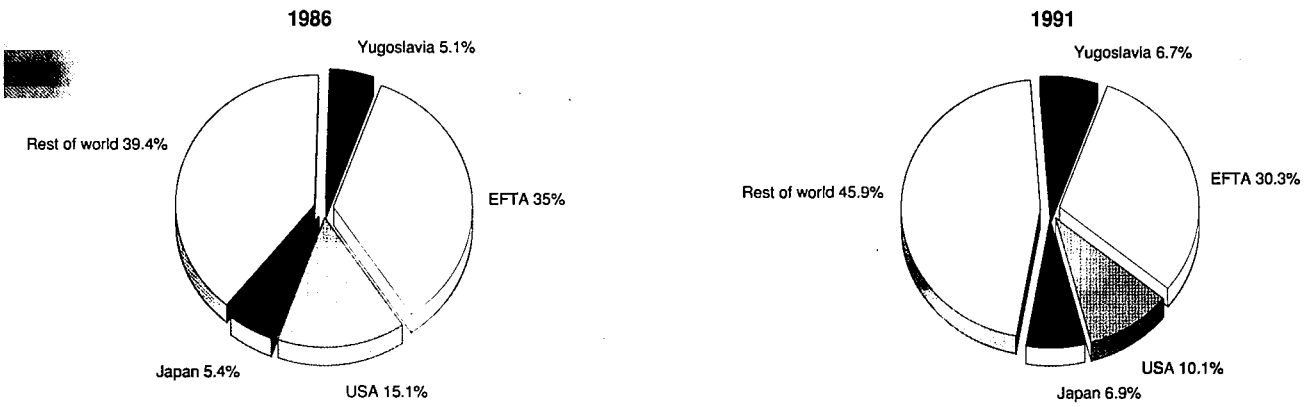
Specific aspects relating to the production of clothing production are important for the EC textile producers. EC clothing manufacturers are increasingly focusing on quality, reliability, technical ability and design capability as well as price for their subcontractors, and also on other factors, particularly delivery time lags and other risks. This evolution will increasingly favour sourcing of many garments in countries near to the EC, through the Outward Processing Traffic which favours EC textile fabrics producers. This is especially true for those who have moved their production in the less price-sensitive markets segments.

Household textiles

Besides fashion trends, sensitivity to income growth is very important in the demand for home furnishings, as well as the increasing number of single persons household are the key element explaining the strong growth in demand for carpets and household textiles (bed linen, table cloth curtains, etc.) during the second half of the 1980s. Other factors with a positive influence on demand are the construction of new dwellings in Germany to accommodate migrants from former Eastern Germany, and the possible faster economic growth in the poorer regions of the Community which would result in an upgrading of the housing stock there.

About 75% of textile floor coverings are purchased by private households while the contract market accounts for 20% and the automobile industry purchases the remaining 5%. Hotels and offices are the largest sectors of the contract market which is extremely important for home furnishing products and which will grew faster if the growth in tourism demand will continue.

Figure 5: Textiles
Destination of EC exports



Source: Eurostat

Technical textiles

Technical textiles has been the fastest growing subsector over the last five years and demand for these textiles is growing rapidly. Technical textiles are the textile product in which the EC's export cover over imports is highest (158% in 1988). The EC exported 2,000 million ECU's worth in 1988. An increasing proportion of the technical textiles used in the USA is supplied by EC firms. New technical textiles and new applications of existing products are constantly emerging. Technical textiles are used for a variety of industrial and environmental purposes such as water and gas filters, stabilisation of soils, protection of crops from weather and pests, etc.

Supply and competition

In general, capacity is not excessive since most recent investment has been in modernisation rather than the expansion. The proportion of turnover reinvested rose from 3% to nearly 8% during the 1980s and the EC textile industry modernised faster than the industries of most of the other countries. Production of fabrics with low design content has been decreasing relative to upmarket fabrics, where EC firms have now built up a strong presence. Price competition among EC producers of high quality textiles is limited because quality, customer service and creativity are more important buyer considerations than price.

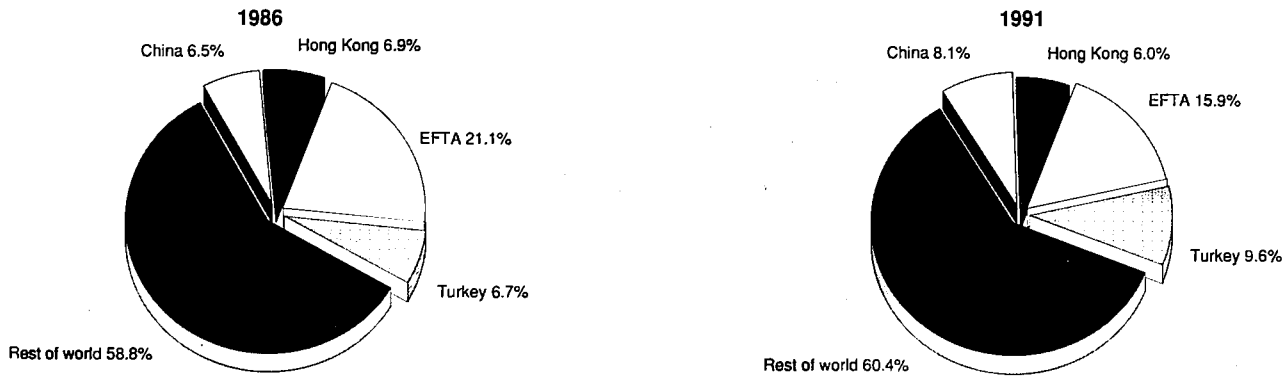
Internal competition after 1993

Intra-EC trade has grown rapidly over the past decade and this trend is likely to accelerate after the completion of the internal market. The Single Market will increase competition between firms in different Member States by reducing or eliminating administrative costs incurred in crossing frontiers. The removal of these barriers may also increase competition from extra-EC imports by facilitating the movement of these imports throughout the EC and by the removal of national quotas established in response to the Multi Fibre Arrangement (MFA). The suppression of national quotas could lead to exporters targeting specific national markets and the textile industries of the smaller Member States would be particularly vulnerable to such targeting.

Competitiveness and profits

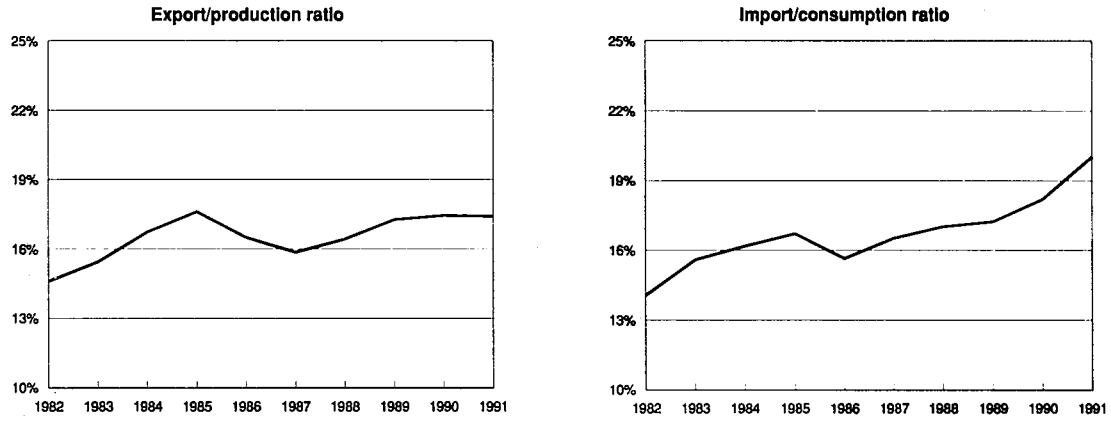
The cost of raw material in finished textiles range from 25% in the case of elaborate lightweight fabrics to 60% in the case of yarns. In the case of cotton fabrics, the textile industry in the USA faces lower raw material costs for cotton, while cotton-producing developing countries often subsidise the price of cotton. The cost of polyester staple is also lower in

Figure 6: Textiles
Origin of EC imports



Source: Eurostat

Figure 7: Textiles
Trade intensities



Source: Eurostat

developing countries, up to 30% lower than that of polyester staple originating in the EC.

At present, the world wool market is oversupplied and wool prices are unlikely to increase significantly in the first half of the 1990s. On the other hand, some increase is expected in cotton prices, about 20% by 1995, as world stocks of cotton are relatively low at present and are not expected to increase much in the medium term.

Output price trends have varied considerably across Member States. Overall, Comitextil estimate production prices increased by 14% between 1985 and 1990, ranging from a decline of 6% in Belgium where investment levels have been particularly high to an increase of 68% in Greece.

In general profit margins in recent years have been relatively low on average but with wide variations across different segments. The IFM (Institut Français de la mode) report suggests that higher margins are achieved on more differentiated fabrics.

The degree of structural adjustment since the MFA was first introduced is evident in the sharp fall in employment in textiles, from 4.5 million in 1973 to 1.5 million in 1991. While much of this reduction was driven by competitive pressures, rapid advances in technology enabling higher labour productivity was the primary driving force. Little of the investment in the EC textile industry in recent years has been aimed at increasing capacity. Labour productivity as measured by value added/employment rose rapidly throughout the 1980s, although unit labour costs rose faster.

All this explains why, in general, increased labour productivity has maintained the competitiveness of some sectors of the industry, textiles can nevertheless be produced in Asian countries at a small fraction of the cost of production in the EC. The average cost per man hour in the EC soft goods (textiles, clothing and footwear) industries is 10 times the average cost in Asian countries. The low wage countries also have minimal regulation of working conditions and minimal environmental restrictions. Some Asian producers, particularly Hong Kong, have invested heavily in new technology and this combined with their advantages of lower labour costs and administrative burden, makes their products very competitive on EC markets.

Two major innovations in textile technology in the past 20 years have been shuttleless looms, although most shuttle looms are regarded as giving better performance at present, and open ended rotors for spinning yarn. Shuttle looms account for 70% of weaving machinery in the EC, about 50% in the USA and Japan and 38% in the rest of Asia. Of the spinning machines used in the EC, 22% are open-ended rotors compared to 20% in the USA, 9% in Japan and 5% in the rest of Asia.

INDUSTRY STRUCTURE

Companies

1988 data from Eurostat indicates that 85.4% of enterprises had less than 20 employees, and only 18% of turnover. Only 3.5% of enterprises had more than 99 employees, yet 57.8% of turnover. There were 76 860 textile firms operating in the EC in 1990 according to Comitextil estimates. Firm size ranges from giant multinational companies like Coats Viyella which employs about 60,000 people to thousands of small firms employing only a few workers. Eurostat estimates, which are

not strictly comparable, indicate that the total number of enterprises in the industry rose by 4% between 1980 and 1988 to 78 500 but the number of firms employing more than 20 people fell by 16% in the same period. The increase in the number of smaller firms occurred mainly in the knitwear industry while the concentration occurred mainly among firms producing higher value-added products.

In 1990 the top EC textile manufacturer, ranked by turnover, was Coats Viyella (Table 6), although expansions and mergers have caused some changes to the listing in the interim. In particular the merger between the UK-based firms Coats Viyella and Tootal will have paced them well ahead of the next four firms who are clustered around the a 1.3 to 1.5 billion ECU range - indeed, more recent estimates quotes by Werner International place Chargeur as the number two firm in terms of turnover, reflecting turnover growth of 19% in the French firm during 1991. Most of the small textile enterprises in the EC operate on a national market or at most, on the markets of one or two other EC countries, while the larger firms sell their products throughout the EC and export outside the EC. Coats Viyella, D.M.C., Courtalds, Benetton and Chargeur in addition to being the top 5 EC firms are also among the top 10 textile firms in the world.

The level of concentration in the EC textile industry increased throughout the 1980s. The governments of the UK and France in particular encouraged mergers in the belief that only large firms could exploit effectively the latest advances in textile technology. The emergence of the giant Coats Viyella group in the 1980s and the restructuring of the Courtalds group represent the most significant UK rationalisations in the 1980s.

Annual investment in the EC textile industry more than doubled in the 1980s. Most of this investment was in modernisation and development of new processes and products. Germany and Italy together accounted for more than half of total new investment during the period in the EC. Benelux has the highest investment per worker followed by Germany and Italy. Investment per worker is lowest in Portugal and Greece.

Slow growth of demand in EC markets and growing competition from imports have caused the EC textile industries to direct a good deal of attention to the promotion of exports.

The industry has been assisted by the EC Commission to survey markets outside the Community and to identify obstacles to trade with a view to their removal. Thus, opening extra-EC markets featured strongly among EC demands in the recent negotiations on phasing out the MFA and bringing the textile industry under GATT rules.

REGIONAL DISTRIBUTION

Reflecting the size of their economies, the four largest textile producing countries are Italy, France, Germany and the UK with Italy having a significantly higher share of total European output and employment. Spain and Portugal's share is significantly higher for employment than for output indicating higher labour intensity in these countries. Within Member States the textile industry is concentrated in certain regions, generally regions which are also strongly dependant on the clothing sector, although in Belgium and the Netherlands textiles are considerably more important than the apparel sector. Regional concentration is not simply a feature of traditional textile industries, the Rhône-Alpes region, for example, accounts for around 75% of French technical textile output, with a particularly strong concentration around Lyon and to a lesser extent at Saint-Etienne.

ENVIRONMENT

The production of textiles requires the use of large volumes of water for certain processes, for example synthetic fibre production, natural fibre cleaning, and general dyeing and finishing. This adds considerably to the costs of textiles if environmental controls are enforced. In addition to EC legislation, the governments of most Member States have legislation which limits various effluents into water and air and these have a considerable impact on the textile industry (see under Regulations).

Different fibre types have different impacts. Pre-treatment will include for wool, a degreasing using strong detergent, the removal of sericin gum coating silk in a similar way. For cotton boiling in a caustic often chlorine based; compound,

Table 7: Textiles

and for removing the mineral spinning oils from manmade fibres adapted detergents are required. All yarn is then "sized" or coated in a flexible protective film which will prevent it breaking during weaving. These sizes have to be removed from the finished fabric by washing, and synthetic (polyvinyl) compounds frequently used today are not biodegradable and waste water from their removal depletes oxygen in water courses.

The coloured effluent from the dyeing process, creating unreactive coloured molecules in sewage systems, is usually thought of as the most polluting aspect of textile production. The mordants used for fixing colour in certain dyestuffs are based on heavy metals such as chrome, tin and titanium whose discharge into water courses is now prohibited in some EC countries. Dye carriers, needed to achieve complete penetration of polyester, are highly toxic carcinogens and are included in the EC Dangerous Substances Directive List 1 substances.

Acrylic is produced from a concentrated solution of polymers in a solvent and this solvent is reclaimed and recycled. To produce polyester and polyamide, polymers are heated until molten before being formed into fibres and there is no effluent from their production though some scientists claim that in the production of nylon, nitrous oxide a chemical which attacks the ozone layer, is released into the atmosphere.

After polyester fabrics are de-sized, they are kept wet until dyeing takes place. During this time, bacteria form on the fabric which would cause uneven dyeing and these are removed with biocides which kill the bacteria needed to break down sewage if released into sewage systems.

The textile industry can respond to the problem of pollution in three ways: it can prevent the problem occurring: it can treat the pollution; and, it can pay a third party to deal with the problem. Prevention of pollution requires the development of technologies which utilise new processes or different, less polluting chemicals. Progress is being made in a number of areas. Vald Hendriksen, a Danish firm has produced a textile dyeing system which greatly reduces the use of water and energy and produces a less polluting effluent.

Progress has also been made in reducing the level of formaldehyde in textile production and research is being undertaken to improve wool scrubbing technology in order to clean up effluent. Treatment of effluent by the firm itself requires the use of filters or scrubbers or chemical processes which break down the harmful emissions. This an expensive option but may be the only one available if the factory cannot discharge its effluent into sewage treatment works.

Although textile recycling dates from the last century, and there is a well developed market for fibre for recycling, only a small part of waste textiles, in the form of clothing and household textiles is recycled. Acrylic, nylon, polypropylene and polyester are not biodegradable except by UV light. While polyester can be produced from recycled plastic and hence make a positive environmental contribution, the problem of disposing of polyester and acrylic remains a major environmental challenge.

EC producers of textiles must incur additional costs in order to reduce the adverse environmental impact of their processing by-products, treatment substances, and to a degree, even the products themselves but this puts them at a disadvantage relative to producers in developing countries who have few environmental measures to contend with. Also, there can often be a conflict between job creation and environmental protection in the textile industry, particularly in the less developed regions of the Community where governments under pressure to expand or maintain employment may resent having to comply with EC Directives aimed at protecting the environment.

OUTLOOK

The general economic climate, combined with the tensions on the currency markets does not provide an incentive to final consumers to increase their consumption of textiles, nor the producers to invest to maintain their competitiveness.

The textile sector currently undergoes a recessionary cycle which looks very much like the one the sector suffered in the early 1980s, which had a profound effect on the industry.

The fall of the US dollar has involved the Asian currencies which are linked to it. This has made imports from these countries more attractive and reduced the number of outlets for EC exports. This situation is aggravated by a stagnating domestic market, except for technical textiles.

Although exports rose in 1991, the increase was very modest compared to the increase in imports. The near stagnation of exports is due to very strong price competition from developing and newly industrialised countries on the EC's traditional markets. These trends, reinforced by the admission to the EC of greater quantities of imports of textiles from Eastern Europe, are likely to continue in the short run and while EC demand is likely to increase by maximum 1.5-2% per annum in the period 1993-1995, it is unlikely that EC production will increase at more than an average annual rate of 2% over the next three years.

The medium term prospects for the EC textile industry will also be dominated by the outcome of the GATT talks. While not finalised it appears that quotas would be phased out over the next decade, while on the positive side for EC producers greater efforts to open extra-EC markets would be made so that, exports to these countries would grow rapidly.

As there are few remaining barriers to intra-EC trade in textiles, the impact of the Single Market may not be very great. With the completion of the Single Market, there are likely to be more joint ventures between textile companies in different Member States and at least some inter-country take-overs. In the late 1980s, the UK group, Coats Viyella, was exploring the possibility of forming an EC "mega company" which could take on low cost competition by exploiting economies of scale made possible by new technology in the textile and clothing industries.

In the long term, the EC textile industry's growth will depend on its ability to develop new products and new uses for existing products. The growth in demand for technical textiles offers tremendous opportunities to the EC industry because of its technical superiority and its capacity for research and development. The development of "green" textiles whose production and disposal do not damage the environment is another opportunity for growth for the industry.

Written by: Fitzpatrick Associates
The industry is represented at the EC level by: Coordination Committee for the Textile Industries in the EC (COMITEXTIL). Address: Rue Montoyer 24, B-1040 Brussels; tel: (32 2) 230 9580; fax: (32 2) 230 6054.

Clothing
NACE 453

One of the top ten industries in the EC in terms of employment, the clothing industry is strongly concentrated in certain regions, and remains highly labour intensive with a share of 2% of EC manufacturing output. Over the past decade the clothing industry has experienced considerable structural change with an increased concentration of its production, a sharp decline in employment, and greater specialisation in high quality garments with low cost clothing now being supplied largely by imports, mainly from Asia. Increasing concentration of retailers contains both threats and opportunities for the industry - while their bargaining power and influence is growing and they often source production in low-cost producer countries, increasing emphasis on time-based competition and back-up services favours EC suppliers. The future success of the EC clothing industry also depends on the extent to which technology can be applied to the labour intensive operations and on the outcome of the current GATT negotiations on international trade in textiles and clothing.

INDUSTRY PROFILE

Description of the sector

The clothing industry comprises the manufacture of clothing and clothing accessories of various materials, i.e. woven, knitted or crocheted fabrics, or fully fashioned parts. Most knitwear products, though sharing much the same demand and supply characteristics as other clothing, are not included in NACE 453. Rather, they are included in NACE 43 as part of the textile sector. Within the clothing sector product categories are generally defined according to functional use, women's outerwear, men's underwear, etc. A report by Institut Français de la Mode (IFM) for ELTAC (European Largest Textile and Apparel Companies) used price sensitivity to distinguish between different segments of the clothing market, a distinction which is generally more useful for analytical purposes than functional characteristics. The report distinguished between totally price sensitive markets (e.g. man-made fibre shirts), medium price sensitive markets (e.g. cotton blouses) and price-insensitive markets (e.g. branded jeans).

The clothing and textile industries are strongly linked - the clothing industry purchases 50%, 70% and 40% respectively of the outputs of the cotton, wool and silk industries. The two industries have common features and trends. They both experienced periods of expansion up to 1973, followed by prolonged stagnation. High and increasing penetration by extra-EC imports characterises both industries.

Main indicators

The clothing industry is one of the top 10 industries in the EC employing about 1.15 million people in 1991. While dominated by large companies, the bulk of the industry's firms are small to medium sized enterprises, many employing less than 20 persons. In addition, the industry has a high proportion of part-time employees and out-workers who are not always captured in official employment statistics. Thus, the employment impact of the clothing industry is likely to be considerably higher than the official estimate.

Germany, Italy, France and the United Kingdom account for about 76% of the EC's clothing employment and 85% of its output, although this dominance reflects the size of their economies rather than the relative importance of the industry. Value added is highest in the more developed EC countries - in Germany, France, Italy and the United Kingdom. In the southern Member States such as Greece and Portugal while the clothing industry is important in terms of employment (see Table 10), it produces mainly low value-added garments.

Recent trends

Apparent consumption of clothing in real (1985) terms increased twice as fast as EC production over the period 19821991, accompanied by a deterioration in the EC's clothing trade balance with non-EC countries. The share of the clothing industry in total EC manufacturing output fell over the past decade, while structural adjustments in response to increased competition from imports has resulted in a decline in employment and in the numbers of clothing firms.

Despite the deteriorating trade balance, extra-EC exports increased substantially in real terms (by over 80%) over the 1982-91 period, although export growth was faster the first half of the 1980s than in the years 19861991. However, with much faster growth in extra-EC imports, the 1991 deficit in the EC's clothing trade in current prices was more than four times its 1982 level. Not all EC countries have clothing extra-EC trade deficits - Greece, Portugal and Italy recorded surpluses between 1982 and 1991.

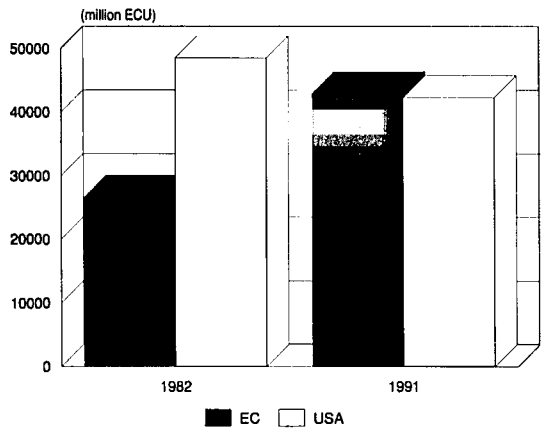
Figure 4: Clothing
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Employment in the EC clothing industry declined by 10% between 1988 and 1991. The decline was greatest in the wealthier Member States, and, contrary to EC trends, employment and output have grown in Spain, Portugal and Greece. Analysis undertaken by Texco/Kurt Salmon Associates for the EC Commission, and recent trends, indicate that countries whose proportionate consumption is out of line can be more easily subject to changes which would bring them closer to the European average.

International comparison

Per capita clothing consumption is slightly higher in the USA than in the EC and is much higher in Japan, although in the latter case this also reflects higher price levels. However, in the latter half of the 1980s, clothing consumption rose more slowly in Japan than in the EC, and fastest in the USA. The value of clothing output in the EC is approximately 75% greater than in Japan or the USA.

The EC is a major force in world clothing trade, accounting for 30% of world clothing exports (of which intra-EC trade accounts for 19% and extra-EC trade 11%). The USA accounts for only 2.2% of world clothing exports and Japan accounts for 0.6%.

Foreign trade

The EC's clothing trade with the rest of the world was in substantial deficit throughout the 1980s and the ratio of exports to imports in current values fell sharply between 1982 and 1991 despite an improvement in the terms of trade for clothing.

The destinations of EC clothing exports changed in order of importance between 1986 and 1991. The proportion of exports going to EFTA countries fell slightly and the share of exports to Japan more than doubled. The USA's share of EC exports fell substantially while the proportion of exports to developing countries and state trading countries fell marginally.

The main sources of EC clothing imports are China and Hong Kong followed by Yugoslavia and Turkey. Hong Kong's share of total imports fell between 1986 and 1991 while China's share tripled in the same period. The proportion of imports from state trading countries and from the USA and developed countries, other than Japan, rose between 1986 and 1991.

Extra-EC import penetration, largely attributable to an increase in imports from developing countries and in particular China, rose very sharply, albeit from a low base in 1982. Import penetration is highest in Belgium, Denmark and the Netherlands and lowest in France, Portugal and Italy.

Intra-EC trade grew faster than extra-EC exports between 1982 and 1991 but intra-EC trade as a proportion of total imports fell over the same period. Extra-EC exports also rose much faster than EC production in the years 1982-91. Intra-EC trade is dominated by France and Germany although the share of the larger countries in intra-EC trade has fallen throughout the 1980s.

MARKET FORCES

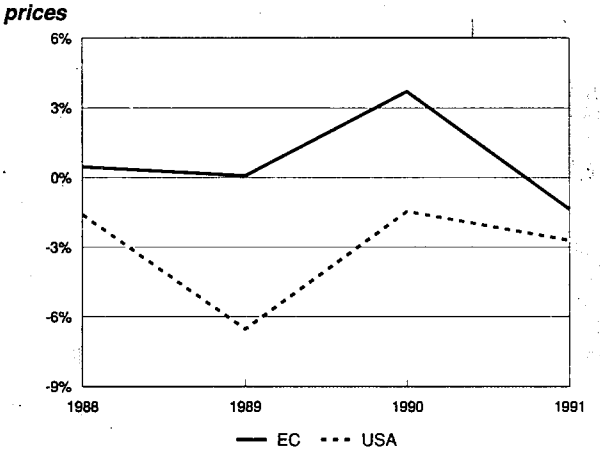
Demand

Clothing is an essential commodity, but once incomes exceed subsistence levels, people demand variety in clothes and most spending on clothes becomes discretionary. In general, spending on clothing does not rise as fast as disposable income although there is some evidence that beyond a certain threshold level of wealth, a greater proportion of household income is devoted to clothing. This is reflected to some extent in that the share of spending on clothing in the wealthier EC Member States is higher than in the other countries. Spending on clothing is highly cyclical: expenditure is reduced or deferred during economic downturns with compensating surges when economies are buoyant.

The EC clothing market comprises two main segments, the market for mass produced low cost clothes and the market for high quality products. Demand for mass produced clothes is relatively price elastic, while demand for high quality clothes is determined to a greater extent by non-price considerations, although the evidence of recent years indicates that price remains an important overall determinant of expenditure levels. Increasing sensitivity to price has been mainly driven from the supply side as the availability of low-cost garments increased and their quality improved.

More than most products, the demand for clothes is determined by fashion and tastes. The demand for fashion elements is growing, appearing in segments traditionally less sensitive to such trends, e.g. underwear. As clothes are non-durable and fashions change frequently, the life cycle for a particular garment may be very short, in some cases as short as a few weeks. The enormous variety of styles, colours and fabrics now available has produced an extremely heterogeneous clothing industry comprising mainly small firms. Manufacturers have considerable scope for specialisation in market niches but this often requires strong links between the manufacturer and final consumer to enable manufacturers quickly to accommodate changes in consumer tastes. This quick response

Figure 5: Clothing
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

system is best exemplified by the large manufacturing and distribution chains such as Benetton, discussed below.

The demand for high quality clothes from the EC remains buoyant in other developed countries which are its main markets. The advantages which the EC enjoys in terms of design and quality of production has ensured a positive trade balance with these developed countries. The EC clothing industry enjoys the considerable advantage of including firms which are the world leaders in production of high fashion clothes. Paris and Milan are the centres of world fashion and the status of firms such as Pierre Cardin, Yves St Laurent and Valentino Cerutti remains largely unchallenged.

Most product innovation is based on changing fashions but is also strongly linked to the development of new textiles. Two such innovations in recent years have been the development of micro fibres and anti-bacterial fibres leading to differentiated high value added products. Materials based on micro fibres such as Ameretta, Sofrina or Belsetta combine the appearance of leather with the texture of velvet and absorb the humidity of the body. The development of new textiles are particularly important in widening the range of leisurewear, sportswear, weather proof garments and protective or specialist clothing.

Supply and competition

Supply capacity

The EC's self sufficiency ratio, i.e. the ratio of production to apparent consumption fell from 94% in 1985 to 81% in 1991, although 1991 data includes the spurt in consumption in post-reunification Germany. In 1991, of the ten countries on which data are available, only Italy and Portugal had self sufficiency ratios of more than 100%. The decline of the EC's self-sufficiency in clothing is reflected in the increase in imports as a percentage of EC consumption shown in Figure 8. Import penetration is high in the Netherlands, Belgium and Denmark while the bigger economies still service large shares of their home markets from domestic production. The lowest levels of import penetration are in Italy and Portugal.

Although down from its 1985 level of 48% the share of intra-EC imports in total imports at 42% in 1991, indicates the importance of intra-EC trade to the EC clothing industry. The countries most dependent on intra-EC trade are the most recent members of the Community, Greece, Spain and Portugal.

Market power of major customers

Over the last decade the distribution and retailing of clothing has become increasingly concentrated, sometimes also internationalised, and the influence and bargaining power of distribution has become much stronger, particularly in areas such as product design. The concentration of distribution remains, however, very different across Member States, being particularly concentrated in the United Kingdom and least concentrated in the southern Member States, indicated by the relatively high share of independent retailers in Spain, Italy and Portugal (see Table 5). The increasing competitive pressure coming from the large retail and distribution groups is also forcing increasing concentration and cooperation among independent retailers.

This trend towards concentration has a number of consequences for the downstream clothing industry. Firstly, as noted, the bargaining power and influence of major customers increases. Secondly, distributors are increasing the share of their purchases sourced in low-cost countries, often designing the products themselves - a lot of the major distributors and retailers now have permanent structures specialising in the sourcing of purchases in the most cost-efficient locations. Thirdly, and related to the last point, certain functions traditionally performed by manufacturers are increasingly being taken over by distributors and retailers and a major feature of the industry

in recent years has been the growing importance of manufacturer-retailers. By 1991, many of Europe's top clothing manufacturers - Benetton, Bidermann, Escada, Burberrys, Laura Ashley, Hugo Boss - were also retailers. In addition to establishing their own retail outlets manufacturer-retailers are also expanding their retail operations, particularly outside their home markets, through franchising, licensing, and joint ventures. The impact of closer integration between EC economies, the opening up of markets in Eastern Europe and closer cooperation with EFTA countries will aid continued expansion and concentration of the major distributors throughout the European clothing market.

Increasing concentration of clothing distribution has another advantage for manufacturers. More professional organisation of distribution has helped to emphasise the importance of time-based, rather than cost-based, competition, thus conferring an advantage to nearby EC producers. Linked to this development the major speciality chains emphasise higher quality clothing offering more individual style. Catering to these requirements generally requires close communication between distributors and manufacturers, for example using Epos (electronic point of sales) systems, which facilitate quick response. Similarly increased emphasis on shorter production runs militates against the labour-intensive mass production runs of many extra-EC manufacturers.

The Institut Français de la mode (IFM) report for ELTAC found that a number of other important factors were also influencing EC distributors which favoured sourcing closer to their main European market base, particularly reliability and quality. Sourcing in faraway markets carries substantially more risk generated by the time lags, distance and other factors - the study reported that to take account of risks involved some distributors compute an additional cost percentage varying from 9% for EC countries up to 20% for NICs and ASEAN countries and as high as 30% for countries such as Pakistan, China, India and Bangladesh. Additional costs such as transportation, clearance, insurance, currency risk, letters of credit, financing and quality control which are negligible when sourcing takes place within the EC, were estimated to account for 7% and 11% of the cost in near non-EC and faraway suppliers respectively. Nevertheless for many clothing products, and in particular for large orders with long lead times, distributors will favour cheaper "faraway" suppliers.

Internal EC competition from 1993

While the barriers to internal trade in clothing are relatively few, the completion of the single market is likely to reduce transport costs directly by about 5% and to allow faster delivery through the removal of administrative barriers. The harmonisation of indirect taxation will also diminish delay and administrative expense.

Liberalisation of public procurement will have little effect on the clothing industry because the public procurement market (mainly for military, police and health worker clothing) is small.

The major external impact of the single market will be the ending of national quota allocations (under the Multi-Fibre Arrangement) on imports, considered to be incompatible with the free circulation of goods within the EC.

Foreign competition

The EC's clothing imports come mainly from low cost countries which have "preferential" agreements with the EC such as Malta, Turkey, Morocco, Tunisia, Egypt and Cyprus or the developing countries covered by the EC's "textile policy". These are mainly South East Asian countries (particularly Hong Kong, Malaysia and China) whose trade is governed by the MFA. Extra-EC exports are mainly to high income countries (Switzerland, USA, EFTA, Japan and Saudi Arabia) and more recently to newly industrialising countries, particularly Hong Kong.

EC imports are mainly low price, mass-produced clothes while exports are mainly high quality products. These trade patterns reflect two dominant characteristics of the EC clothing industry, its relatively high labour costs relative to less developed producers and its superior know-how in areas such as product quality, marketing, industry organisation and design. The long run competitiveness of most EC clothing firms lies in their ability to supply high income markets, where mainly non-price factors determine consumer choice. Technological and organisational innovations may increase labour productivity but it will not make EC firms as competitive as those in Asia in the production of low price garments. The competitive advantages which the EC clothing industry enjoys lie in design and marketing, quality of fabric and finishing of garments. EC know-how also exerts an influence on EC imports with includes products designed in Europe and carrying European brands - a report by Texco\KSA for the EC Commission estimates that a third of EC clothing imports are controlled by EC manufacturers.

In most product areas the EC clothing industry's competitiveness depends less on price than on the ability to deliver high quality, well-designed and branded garments quickly and efficiently. To facilitate fast and flexible response to changing fashions and retailer demands, the larger firms in the industry have rationalised production and distribution. In particular, just in time (JIT) production methods were widely adapted in the clothing industry during the second half of the 1980s. The study by IFM estimated that average lead time for first orders varied from 2-4 weeks for most EC-based manufacturers, 3-6 weeks for nearby countries and 4-5 months for Far East suppliers, although up to seven months in the case of China and Bangladesh.

Partly successful to remain cost competitive against cheaper extra-EC producers, has been the growth of outward processing trade (OPT) in the EC clothing industry. This involves sourcing the most labour intensive stages of production which cannot be effectively automated in countries with cheap labour supplies. This system had its roots in the early 1980s West German practice of exporting ready cut pieces of garments to low wage countries to be sewn up, initially in Eastern Europe but later extended to Turkey, Portugal, Hong Kong, China and other countries in North Africa and Asia. While Germany is still the largest user of outward processing, the system is also used by firms based in other northern Member States. Because of the time lags involved, low to medium priced products are best suited for OPT and in general the method is not compatible with fast response strategies. While OPT will continue to be important in the 1990s, it inevitably has a limited life span, mainly because the EC clothing industry produces a diminishing share of world output of low cost clothes. Increasingly EC firms have turned to importing and distributing low cost garments produced in developing countries or in some cases engaging in joint ventures with native firms in such countries.

While the Uruguay Round of the GATT negotiations is not yet complete, the package for the clothing and textile industry is expected to include a phasing out of the MFA quota arrangements over a transitional period of around ten years. Major pre-conditions specified by the EC as part of such agreement are likely to include the opening of markets in developing countries, action to curb dumping of surplus products on EC markets, the removal of certain state subsidies (particularly export subsidies) to the clothing industries in the more developed low-cost exporting countries and action to curb counterfeiting of EC brands.

Price and profit trends

The price of clothing to consumers in the EC remained generally stable in the 1980s in the three largest producing countries, Germany, France and Italy but prices fell in the United Kingdom as a result of the inflow of cheap imports from developing, mainly Commonwealth, countries. Falls in import prices from 1985 to 1990, partly due to a decline in the value of the dollar, compelled EC producers to reduce their own prices of mass produced clothing in intra-EC and external trade resulting in a profit squeeze. But rising unit prices for EC high quality clothing exports in the late 1980s did not significantly reduce the volume of exports because of demand for high quality products is not very price elastic.

Profitability is low in the EC clothing industry with high contributions to raw material and labour costs. The Texco/KSA report estimates average return on sales in the clothing industry at 3%, with higher profitability evident in larger firms. Profitability in the industry has been declining because of a variety of factors including pressure on prices linked to competition from developing countries, increased labour costs above those justified by productivity gains, the costs of expanding the variety of output, advertising and promotional costs associated with establishing brands or market positions and delays and/or defaults in payments by the trade.

Production process

The major input into a garment is a natural or synthetic artificial fabric. The EC textile industry produces an abundance of both types of fabrics and has been in the forefront of innovation in the design and production of textiles for the clothing industry. Many textile producers co-operate with clothing manufacturers in textile design and innovation and the degree of vertical integration between the two sectors is high. The production of a garment involves four basic operations -product initiation, pre-assembly, assembly and finishing. Product initiation is a purely creative function involving the design of the garment and the selection of fabrics which requires a high level of expertise. EC firms excel at design although there is serious problem with the copying of EC designs by producers, particularly in Asia, who attach copied brand marks and logos to garments.

Throughout the 1980s unit wage costs increased faster than productivity as measured by value added per person employed. The limited introduction of new technology into the clothing industry was sufficient to increase labour productivity. The investment rate in the clothing industry is lower than in most other industries. The countries with the most capital intensive clothing industries are Belgium, Germany and France.

The introduction of technology in the EC clothing industry has helped slightly to reduce the cost gap between Member States but differentials in wage costs remain high. There are wide differentials in labour costs between the wealthier and the less developed Member States. Labour costs in Germany are over 5 times those in Portugal and the share of labour costs in total costs is 40% in Germany compared to 18% in Portugal, although high wage EC countries such as Germany, France, and the Netherlands had higher productivity levels, as measured by turnover per employee in 1989.

INDUSTRY STRUCTURE

Companies

The majority of firms in the clothing industry are small with those employing less than 20 people accounting for 22% of total output in 1990. This polarised structure of a few large firms and a multitude of small to medium, particularly small, firms is common within all Member States. The Texco\KSA analysis indicated that in the seven major clothing producing Member States the industry was most concentrated in Belgium and least concentrated in France. In general, concentration of production is greatest in the smaller EC states.

The top two EC clothing firms in 1990 in terms of turnover were both Italian, Benetton and Gruppo GFT (Table 7). Since then, however, there have been a number of mergers in the industry, the most important of which was that between the UK companies Coats Viyella and Tootal, whose combined turnover would now place them alongside Benetton, while the French company Bidermann's acquisition of Cluett Peabody will have moved it up the rankings. Concentration of production among the largest firms has increased in the past decade, although small firms still pre-dominate. This has been paralleled by concentration of distribution which has increased the influence and bargaining power of distributors over product design, price and conditions of supply.

Strategies

The strategies employed by EC manufacturers are largely geared to distinguishing their products (and associated services) and maintaining their competitive advantage vis-à-vis low-cost producers from outside the EC. Thus, strategies for markets outside the EC have concentrated on capitalising on Europe's competitive advantage in terms of design and product quality and have embraced greater investment in branding, increasing adoption of quality management philosophies, and continued concentration on high value-added markets. Within the EC this has been supplemented by increased reliance on time-based competition embracing quick-response strategies and JIT systems, increased cooperation with retailers and cross-border alliances and mergers aimed at establishing a larger and more uniform presence in the more integrated EC internal market. These strategies to improve quality and service competitiveness have been supplemented by those aimed at reducing cost disadvantages. Thus, the importance of OPT has increased, production and distribution systems have been subject to rationalisation and the use of technology both in terms of automation and through the introduction of flexible management systems has continued to increase.

The importance of these different strategy elements varies across firms. The Economist Intelligence Unit report "The Clothing Industry and the Single European Market" (1991) grouped EC clothing companies into three categories. The first category were dynamic efficient firms, mainly located in France, Italy, Germany and the United Kingdom, the second category were the many firms in the Netherlands and Belgium who are increasingly substituting trade and distribution for production and, thirdly, the industries of the less developed EC Member States which have been sheltered from competition and are more vulnerable to trade liberalisation.

Many of the dynamic firms now consider the EC as their domestic market and are most concerned with expanding sales

in extra-EC markets. The main threat to these firms is the movement upmarket of East Asian producers that may diminish the advantages which these firms enjoy.

Production costs are becoming less and less decisive in determining competitiveness in the EC clothing industry. A study commissioned by the EC Commission shows that the service incorporated in the product is rapidly becoming the key factor in supply strategies, as it reduces the level of services which have to be added subsequently and saves on management costs, storage, quality control and sales strategies. These savings enable retailers to improve co-ordination of supply and demand and avoid unsold stock.

Source: Eurostat

Improving coordination between the stages of production and distribution is a vital element in the EC clothing industry's strategy. This explains the trend for greater integration between manufacturing and distribution which characterises the larger EC firms. Increasing backward linkages to the textile industry has been less important as a strategy element. Many of the larger companies straddle both the clothing and textile sectors and while this feature of the industry has become more pronounced with the increase in mergers and acquisitions in recent years establishing strong backward linkages has not generally been the prime motivation.

Investment in the EC clothing industry has increased throughout the 1980s and most of this investment has been in improving technology rather than in increased capacity. Investment per worker in the clothing industry is lower than in most EC industries and most investment is concentrated in the pre-assembly stage of production. There are wide disparities in investment per employee across Member States with higher levels in more developed northern states.

REGIONAL DISTRIBUTION

The relative importance of the clothing industry varies across Member States and tends to be further concentrated in certain regions within each Member State. In general, the clothing industry also tends to be located in the same regions as the textile industry, so that structural changes impacting on both industries may have a multiplicative impact at a regional level.

Studies undertaken by the EC Commission's DG XVI confirmed the heavy dependence and vulnerability of a number of sub-regions, usually relatively less developed, within some EC Member States. For example, textiles and clothing accounted for over half of manufacturing employment in Ireland's least developed region Donegal, while clothing accounted for 14% (and textiles a further 10%) of manufacturing employment in Northern Ireland, the least developed region in the United Kingdom. Similarly in Portugal, 60% of industrial employment in Braga was in textile and clothing and including neighbouring regions of Porto and Aviero accounted for 72% of Portuguese employment in clothing and textiles in 1990. The relative importance of the industry at a regional level was less important in more developed Member States.

ENVIRONMENT

The production process for clothing does not give rise to any significant threat to the environment but the disposal of waste from clothing manufacture and of used clothing may cause an environmental problem. Waste cut-offs, referred to as rem-

nants, may be sold for the manufacture of clothes if they are sufficiently large. Where the remnants are small they can be sorted into waste suitable for pulling into flock (called "mungo" or "shoddy") that can be used for the manufacture of lesser quality textiles. Small off-cuts can also be used as industrial wipers.

The recycling of clothing is carried on mainly by charitable organisations who run shops to which used clothes are donated and which the charity sells for very low prices to finance their activities. This form of recycling postpones the problem of final disposal of clothing waste. Woollen garments can be recycled by unravelling the wool fibre and reusing it. This is the oldest form of clothing recycling and technology has existed for 150 years to reduce old woollen garments to fibre. Recycled wool is not redyed and does not have to be scoured, resulting in savings on water use and energy. Recycled wool fibre is used primarily for upholstery fabrics in contract work for hotels and offices. A UK company, Evergreen Recycled Fashions, has recently launched a range of clothes using recycled wool.

The disposal of clothing, particularly of synthetic clothing can present an environmental problem. Synthetic fabrics are not biodegradable and take up substantial space in landfill sites. Europe's largest apparel manufacturer, Klaus Steilman, has pioneered the manufacture of a range of "environmentally friendly" garments. These garments are made from textiles produced using few chemicals. They are easier to recycle and will biodegrade when disposed of in landfill sites. The fibre used is a blend of linen and viscose, both of which are biodegradable. Klaus Steilman consider that environmental awareness among consumers will ensure a market for this clothing.

OUTLOOK

The EC clothing industry faces a number of major challenges in the years ahead. Competition from East Asia is likely to increase with the possibility that Hong Kong producers may move into the production of higher quality clothes and acquire distribution outlets in the EC. Low cost imports from Eastern Europe will increase as trade restrictions against these countries are lifted. To maintain competitiveness, the EC industry needs to invest in technology and develop more integrated methods of production and distribution. The clothing industries of the less developed Member States face the greatest challenge as they are more dependent on low cost labour to maintain competitiveness.

Free and fair trade in clothing in the short term is unlikely to emerge from the current GATT talks, it is likely that import quotas to the EC will be progressively increased. With the completion of the Single Market national quotas will be eliminated posing a particular threat to countries which have low import penetration at present.

The completion of the Single Market is compelling EC clothing manufacturers to develop EC-wide, and in some cases, global strategies. Very large firms are emerging which have integrated all stages of production and distribution. These firms are also investing in new technology which increases labour productivity. Recent advances in technology made in Japan suggest that an effective method of automating sewing may soon be developed.

The opening of the economies of Eastern Europe offers the possibility of increasing internationalisation of the EC clothing industry through the opening of subsidiaries in Eastern Europe where labour costs are likely to remain lower than in the EC for the foreseeable future.

The industry is represented at the EC level by: European Clothing Association (ECLA). Address: Rue Montoyer 24, B-1040 Brussels; tel: (32 2) 230 7420; fax: (32 2) 230 7119.

Footwear
NACE 451, 452

The EC is one of the world's largest footwear markets but increasing consumption has been accompanied by a sharp decline in production and rapid growth of extra-EC imports over the last decade. Italy accounts for a third of the value of EC production and over 50% of extra-EC exports, but increased competition from low-labour cost countries has led to relocation of manufacturing facilities within the Community to lower labour cost Mediterranean countries, and to developing countries. The structure of distribution is changing - a number of large manufacturers are developing their own retail chains, while some of Europe's large fashion groups now have manufacturing interests in footwear. Technology developments in the industry, particularly computer-based applications, have shortened production lead times enabling faster response to fashion changes.

Figure 1: Footwear

INDUSTRY PROFILE

Description of the sector

The different types of footwear produced within the Community are classified in NACE 451 and 452 as follows: mass produced outdoor footwear (451.1); mass produced indoor footwear (451.2); special types of footwear (451.3); and handmade footwear (452). It is also common to classify footwear into broad groups by the major material of the upper - leather, synthetic, rubber, textile, and other. Some of Europe's large fashion groups have interests in a number of sectors which include footwear - Benetton, primarily a clothing company, manufactures footwear which it sells through its own outlets.

Main indicators

The main indicators for the EC's footwear industry point to continued contraction. The problems facing the industry are reflected in falling production and employment, despite increasing Community consumption. It is estimated that in 1991 EC production volume decreased of almost 10%. The EC's trade balance deteriorated substantially, recording a deficit, for the first time, in 1991 (485 million ECU). Employment is also falling, with a total workforce of approximately 337 000 in 1991 (including firms with less than 20 employees).

Italy is Europe's major footwear producer accounting for a third of the total value of Community production in 1991. The next largest producer, France, accounted for 19%. Other major producers are Germany (14%), Spain (10%) and the United Kingdom (10%).

The Confédération Européenne de l'Industrie de la Chaussure (CEC) estimates 1991 footwear production at 1.177 billion pairs, with leather footwear accounting for approximately 65% of EC output. The importance of different types of footwear production varies across Member States. The production of leather footwear accounts for over 90% of the quantity of footwear produced in Denmark and Portugal and over 70% in Germany, Italy, the Netherlands and Spain. Nearly 50% of Belgium's production of footwear is slippers. Approximately 30% of footwear produced in the United Kingdom is synthetic or rubber uppered. In France, slippers account for 30% of production while textile uppered and synthetic uppered footwear account for 15% and 11% respectively.

Recent trends

The latter half of the 1980s was a difficult period for the European footwear industry. EC production levels fell although consumption grew, by 36% in the 1985-91 period. Overall trends mask considerable variation between Member States.

The footwear industry within the Community is dominated (in value terms) by five countries: Italy, France, Spain, the United Kingdom and Germany. Their relative importance has, however, declined. They accounted for 86% of the value of EC production in 1991, compared to 95% in 1982 and contractions in traditional producers such as Spain and the United Kingdom, have been partially offset by increases in other Member States, particularly those with the lowest labour costs, Portugal and Greece.

While the volume of all footwear produced fell by 4% between 1987 and 1990, the quantity of non-leather footwear production fell by 8%. The volume of leather footwear production increased in 1990 having fallen in 1988 and again marginally in 1989. Of non-leather footwear, plastic is most important although output volume has fallen since 1987. In contrast, the production of textile uppered footwear in the EC increased over the same time period.

International comparison

The EC is a major producer of footwear, accounting for approximately 10% of world footwear production and nearly 20% of world footwear exports. In contrast the USA accounts for approximately 3% of world production while Japan accounts for about 4%.

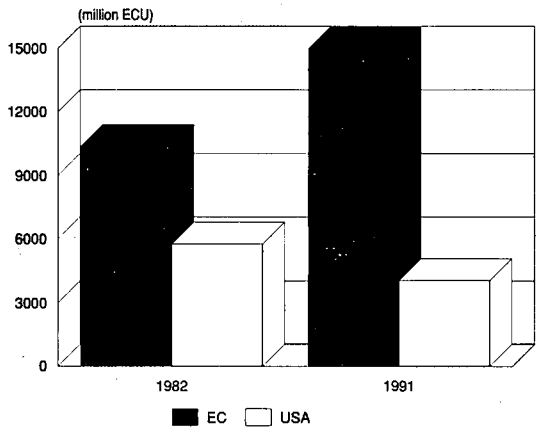
Foreign trade

International trade in footwear is not covered by the Multi Fibre Agreement (MFA) which governs trade in the textile and clothing sectors. The EC footwear sector is heavily dependent on international trade, with approximately 25% of EC production exported in 1991, although, in current prices, extra-EC exports have fallen by 6% since 1985. Between 1982 and 1991 the current value of extra-EC imports rose by 266% and in 1991 accounted for 29% of EC consumption. Traditionally the EC recorded a surplus in footwear trade but, having declined throughout the 1980s, a deficit of 485 million ECU was recorded in 1991.

Textile uppered footwear accounted for 33% of total extra-EC imports in 1990. Leather footwear accounted for only 28% of the volume of extra-EC imports in 1990. In contrast the majority of extra-EC exports were leather (68%) in 1990.

The EC has a trade surplus in footwear with the USA, Japan and the EFTA countries. However, it has a large trade deficit in footwear trade with developing countries and with the former Eastern Bloc. The leading market for extra-EC exports is EFTA countries, the other important market being the USA.

Figure 4: Footwear
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

However the importance of the USA as an export destination has been declining. Italy is the EC's major exporter, accounting for over half of extra-EC exports in value terms. Other major extra-EC exporters include Germany, Spain, France and Portugal. In 1991 Italy, Spain and Portugal maintained a surplus in the value of extra-EC trade.

The majority of extra-EC imports to the Community come from developing countries and their value has been increasing steadily. However, the largest growth in imports to the EC in nominal terms has been from China. The former West Germany is the largest importer of extra-EC footwear, importing nearly 39% of total extra-EC imports. France, the United Kingdom and Italy are also major importers in value terms. The penetration rate of extra-EC imports has increased from 16% in 1985 to 29% in 1991, although some of this increase includes growth in imports of partly finished shoes for further production.

Since 1986 the value of intra-Community trade has increased by 15%. Intra-EC imports account for 60% of total (intra and extra-EC) import trade. The main intra-EC purchasers are: Germany, accounting for 39% of the total value of intra-Community imports, France (19%) and the United Kingdom (13%). Intra-EC exports account for nearly 62% of the value of total (intra and extra-EC) export trade.

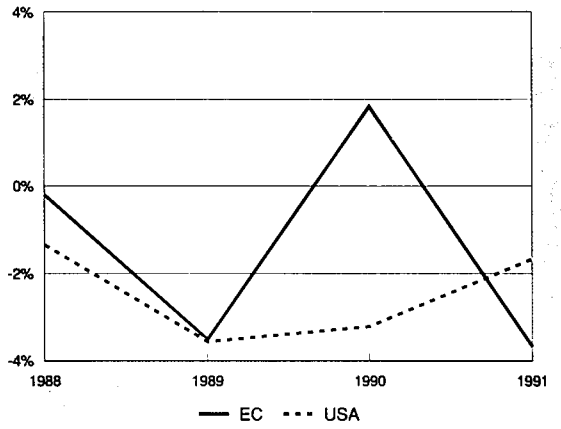
MARKET FORCES

Demand

Most footwear is purchased by individual consumers, while contract sales to major customers such as the military, or industries requiring specific work or safety footwear is an important niche market. According to the Economist Intelligence Unit report "Consumer Spending Patterns in the European Community: Forecasts to 1995", clothing and footwear together account for a declining proportion of total EC consumer spending. Spending on footwear also tends to be cyclical, expenditure being reduced or deferred during a recessionary period with a compensating upturn during a recovery.

While having a fashion content, footwear is seen primarily as a necessity and a smaller proportion of income is spent on footwear as income rises. Some niches within footwear, in particular the market for trainers are strongly influenced by fashion trends. Demand for sports footwear has also been

Figure 5: Footwear
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

boosted by higher levels of sports participation. Increased fashion demand has also resulted in increasing usage of coated fabrics and textiles, rather than leather, for uppers or lining material.

Both volume and value figures show the largest market for footwear in the EC is Germany. In value terms the former West Germany accounted for 36% of EC consumption in 1990 and subsequent reunification has further increased the size of this market. France is the second largest and has the highest per capita consumption of footwear, 6.04 pairs per annum in 1990 compared to an EC average of 4.52 pairs. Comparison between Member States show significant differences in prices paid per pair, reflecting to some extent greater quality and fashion consciousness. The price paid per pair is highest in Italy.

In the sports footwear sector, product innovation allied to substantial promotional expenditure was the key to maintaining competitiveness in the late 1980s. The proliferation of different shoes offering both technical and fashion gimmicks reflect this trend, as does the rapid inroads into European markets by top USA brands such as Nike and Reebok. Innovations have also taken place in manufacturing technology in the industry which has helped maintain the competitiveness of European footwear producers.

Supply and competition

Market power of major customers

Traditionally distribution of footwear was mainly through independent retailers, but distribution has become more concentrated leading to shifts in relative bargaining strengths. The importance of independent retailers has declined to the advantage of larger generalist stores and multiple retail chains. Some large manufacturers such as the Bata Organisation and Bally have also established retail arms with outlets in a number of European countries. Other manufacturers, such as André, Charles Jourdan, Eram, and Salamander AG also operate retail units both within their own domestic markets and in other Member States.

The key competitive advantages of EC footwear manufacturers, under pressure from lower priced imports, is based on time and service quality and successful EC manufacturers offer strong commitments on price, delivery performance and flexibility. In response to the needs of the retail groups, footwear manufacturers are increasingly adopting quick response strategies, although the number of companies using this strategy remains relatively low in comparison to the clothing sector.

Internal EC competition

With a large number of firms, the presence of few restrictions on extra-EC imports, and of few barriers to intra-EC trade, the internal EC market in footwear is relatively competitive. Internal EC competition is expected to increase following the completion of the Single Market and some of the larger retail chains are presently expanding into other EC Member States.

The removal of customs and other physical barriers to intra-EC trade should lead to a reduction in transport cost and time. This will benefit firms who are dependent on markets in other Member States and should also benefit firms seeking to compete on the basis of quick response. One of the principal features of the Single Market for the footwear industry will be VAT harmonisation, to be implemented in 1997. EC countries with a low VAT rate on footwear, i.e. Ireland, Spain, Italy and Luxembourg, will experience tax rises by 1997.

Foreign competition

Imports of footwear into the EC originate mainly from low labour cost countries, traditionally China, Indonesia, South

Korea, Thailand and Taiwan, although imports from other developing countries, such as India and Brazil, are growing.

Extra-EC exports are generally high quality leather footwear to developed countries such as the USA, Canada, Switzerland, Austria and other EFTA countries. The volume of exports to destinations such as the USA and Canada has fallen, partially explained by the depreciation of the dollar during the latter half of the 1980s. The long run competitiveness of the EC footwear industry will depend on its ability to continue to supply high quality products to high income markets. Expansion into extra-EC markets is blocked in a major part of countries by high duty levels and tariff barriers, particularly in Japan. European production is also hampered by restrictions operating in countries which prevent the export of raw materials necessary for higher-value added production.

To help improve the prospects of EC footwear firms, there is a budget for export promotion voted by the European Parliament, whose aim is to improve access to markets of third countries and to reduce high levels of duty imposed on extra-EC exports by many countries. With respect to extra-EC footwear import controls, these will have to be at the single Community level only and will not vary between Member States. This will impact most on producers in Member States where low-cost import penetration is still relatively low.

Price and profit trends

A report by Texco International/Kurt Salmon Associates (1991) for the EC Commission found that profitability in the footwear sector is low, approximately 2.5% return on sales. Furthermore, non-leather footwear performs better in terms of profitability than leather footwear. The fragmented nature of the industry has meant that is difficult for manufacturers to benefit from economies of scale. Footwear prices in the Community have been under pressure from cheap imports from low wage countries. This pressure coupled with increases in the cost of labour has led to a decline in profitability in the sector. European manufactures trying to compete with cheap imports have tried to maintain market share by expanding their existing line of products, while companies responsive to changing fashions have smaller production lots and increased product costs.

Production process

Major inputs and their productivity

Traditionally the production of footwear has been a relatively simple labour intensive manufacturing process, which can be divided into a number of stages. The first stage, called "clicking", involves the cutting out and preparation of components for the upper and the sole. This is followed by "closing", when the components are stitched together to produce an "upper" and then the upper is shaped and an insole and a sole are affixed. Finally, the shoe is finished by cleaning the upper, inspected and boxed.

Footwear production is still mainly based around a stack of foot-shaped formers, the last, over which the upper is draped and constructed and to which the sole is joined. Mechanised footwear production has usually been organised in a track system along which progressively assembled shoes are carried and are lifted from the track by operatives to perform the next stage. The introduction of a "rink" system has increased productivity and has led to a significant reduction in the volume of rejects. The "rink" system involves arranging the various steps in the shoe-making process in sequence, generally in the shape of a horseshoe. Each function is the responsibility of an operator, although each operator should have the flexibility to perform a number of tasks. Work is passed from one operator to the next, one pair at a time. The team is responsible for quality control and inspects its own work.

Production of footwear within the EC is becoming more mechanised and specialised. The introduction of computer-aided design (CAD), which allows a shoe to be designed on computer and the details to be downloaded to production machines, has been one of the most important developments. The use of CAD allows the time span between design and production to be reduced to a few hours enabling manufacturers to respond quickly to changes in styles for fashion footwear. The use of CAD systems has been accompanied by computer aided manufacture (CAM) and computer integrated manufacture (CIM). CAD systems are increasingly being linked with computer aided cutting systems.

Labour unit costs within the Community increased by nearly 36% in current terms between 1982 and 1990. The need to rationalise costs to maintain competitiveness with developing countries has led larger companies in some Member States to transfer production facilities to lower labour cost countries, including Portugal within the EC. Unit labour costs in Portugal are approximately one third the EC average and nearly a quarter of unit labour costs in Germany. While the majority of EC countries are unable to compete with developing countries on price, due to higher labour costs, production within the Community can compete by adopting quick response strategies. However, any real European advantage may be negated if European manufacturers use CAD to transmit new designs on-line to production facilities in the low-cost countries.

INDUSTRY STRUCTURE

Companies

The footwear industry within the Community is highly fragmented, characterised by a large number of small business.

Table 6: Footwear

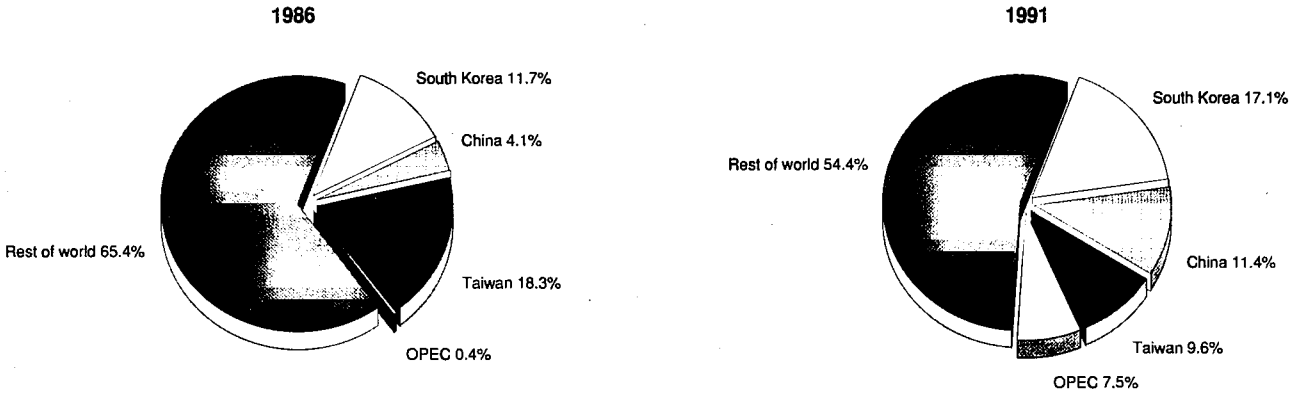
Source: CEC

Figure 7: Footwear
Origin of EC imports



Source: Eurostat

According to the CEC, there were about 15 900 footwear firms in the EC in 1990, employing an average of 21 workers. Major EC footwear manufacturers include Salamander AG (D), Romika & Co. KG (D), Eccolet Sko (DK), Eram (F), André (F), Clarks (UK), Simod SpA (I) and Filanto SpA (I).

Strategies

The value of net investment in the EC in current prices increased marginally, by 4.5%, between 1985 and 1988. However, despite the absence of major investment in plant and machinery, EC footwear employment fell throughout the second half of the 1980s and into the 1990s, reflecting falling production. However, employment in some Member States, Portugal and Spain, increased, reflecting the sourcing strategies of major EC producers, although this has been accompanied by growth of indigenous Spanish and Portuguese manufacturers.

Examples of companies which have transferred production to lower-cost countries within the EC such as Spain and Portugal include the French company Charles Jourdan, that transferred production from the Rhône valley to Spain. Some French manufacturers now sub-contract to Portugal as well as to extra-EC countries such as Tunisia, Morocco and China. Eram, one of France's largest producers and distributors of footwear operates ten plants within France along with one in Portugal and one in Spain. Many German producers have transferred their production to Portugal and many also operate plants in Austria. The Danish footwear manufacturer, Eccolet, operates plants in Portugal and Czechoslovakia as well as in Denmark. Bata, the world's largest footwear organisation is to modernise a manufacturing facility in Czechoslovakia.

Many EC producers have also shifted operations to low labour cost developing countries outside of the EC. The German company Wortmann, has factories which manufacture inputs in Taiwan, Hong Kong, China, Thailand, Brazil as well as in different EC countries. Europe's leading sports footwear manufacturers such as Adidas and Puma also transferred substantial proportions of their production facilities to the Far East in the second half of the 1980s in order to remain competitive with their main competitors who already manufacture

Source: Fitzpatrick

the majority of their footwear in the Far East. South Korea, Taiwan and Thailand are the most popular countries for sourcing as some of the lower cost countries are not yet as well organised or as reliable. The importing of uppers and other labour-intensive parts from low labour cost countries for assembly is also becoming common, although this is less popular in Italy and most popular in Germany, which pioneered such outward processing in Eastern Europe.

Some EC footwear firms, particularly sports footwear firms, are adopting global strategies, acquiring manufacturing and retail outlets or franchises outside the EC, as part of their expansion strategies. However, this process is also working in reverse with Japanese and South Korean companies such as Asics and Kukje establishing strong presence in Europe. This trend is not confined to sports footwear - the acquisition of part of Charles Jourdan, the French shoe maker, by Dickson Concepts, a Hong Kong retailing group in early 1992 indicates a similar trend in the classic footwear market.

REGIONAL DISTRIBUTION

Italy accounts for 25% of EC footwear industry employment. Other major employers include the United Kingdom (16%), France (14%), Germany (10%) and Portugal (10%).

Much of the EC's footwear industry is concentrated in particular countries and within regions in these countries. These regions also tend to be areas with little alternative employment to the footwear industry. Towns and areas such as Herzogenaurach and Pirmasens in Germany, the East Midlands in the United Kingdom, the Pays de Loire in France, Marche and Veneto regions in Italy and northern Portugal are highly dependent on the footwear industry. The impact of any adverse developments for the industry are therefore particularly concentrated within specific areas of the EC.

ENVIRONMENT

Environmental issues are more important in industries supplying the footwear industry than in the industry itself. The leather and tanning industry is a major source of raw materials to European producers. Suppliers in this sector are under pressure to use water and chemicals more carefully to reduce effluent. The need to install water effluent treatment equipment to meet increasing environmental standards will lead to increased tanning costs and an increase in costs of the raw material for the footwear industry, although there is already sourcing of materials outside the Community. Suppliers of raw materials for non-leather footwear production are likely to face increasing constraints from regulations on usage of polyurethane and polyvinylchloride (PVC).

REGULATIONS

Since after World War II most EC countries established quotas against imports from state trading countries. These regulations were summarised under EC directives 3420 - 1766 - 1765. Due to the Single Market, from 1993 onwards the control of national quotas becomes impossible, which calls for an EC-wide quota system. The EC authorities are still working on a global proposal, not restricted to footwear.

Whatever the outcome of Community trade policy developments, protection of national markets will be eliminated with the removal of customs frontiers. Article 115 of the Rome Treaty can preclude extra-EC footwear imports from circumventing Member State level import controls by their goods through another Member State. However, the implementation of the Single Market will phase out this control.

Following concerns about the impact that national legislation on footwear labelling in France and Spain would have on intra-EC trade, a proposal for an EC directive has been forwarded concerning the labelling of the materials used in the main components of footwear for sale to the final consumer. It deals primarily with indicating the composition of footwear by means of "pictograms" is likely to come into force on June 30, 1994.

OUTLOOK

The EC footwear industry faces a difficult future. The outlook for consumption over the next few years is for modest growth. Extra-EC imports are expected to grow while extra-EC exports will continue to decline due to lack of market access. Employment and production by EC firms are also expected to fall. While technology will assist the industry in its struggle to regain competitiveness it will not provide the complete solution. Increased cost effectiveness will also be needed along with greater emphasis on marketing and satisfying the changing demands of the consumer.

While the Community dominates the world quality leather footwear market, the outlook for demand in this niche is depressed in the short term. Poor economic conditions in the USA and Japan has slowed demand for luxury goods. The upturn in this niche will lag overall economic recovery in these countries and growth for high quality footwear can only be expected in the medium term.

Easier access to East Europe will allow European manufacturers to locate production facilities in these countries. Provided political stability is maintained the volume of extra-EC footwear imports from these countries seems likely to increase as does the volume of imports of uppers or part assembled inputs.

Leather tanning and finishing

NACE 441

Tanners in the EC have been faced not only with the erosion of much of their traditional markets but also with rising costs and tougher environmental legislation. Shifting to quality and fashion segments, developing flexibility in production and quicker delivery times will help to consolidate the EC tanning industry's competitive edge. Trade restrictions in developing and developed countries including the non-availability of raw materials, continue to limit the growth of EC industry while distorting prices and competition.

INDUSTRY PROFILE

Description of the sector

The NACE 441 (tanning and dressing of leather) includes

- Tanning and dressing (NACE 441.1);
- Manufacture of imitation leather based on natural leather (NACE 441.2);
- Currying, dyeing and finishing of leather (at independent workshops) (NACE 441.3).

The NACE nomenclature includes (under subsector 441.2) activities which are not considered by the trade as leather production. Products resulting from this activity are not to be classified as leather according to the definition set by the International Council of Tanners (ICT).

Tanning and finishing consists of sequenced industrial processes where raw hides and skins are converted into leather which serves for the production of footwear, clothing, furniture, leather goods and other consumer goods. Leather manufacturing includes, therefore, companies involved in one or more of these processes during which value is progressively added to the raw material. Products can leave the production cycle at the semi-finished phase (wet-blue/crust) where the range of applications is still large, or at the end of the last process, after finishing (leather) where leather for shoes, clothing, upholstery or leather goods, etc., receive their characteristic touch.

Tanning is a traditional sector of industry which combines technical skills and technological know-how with fashion and design.

The tanning industry has not only significant linkages with the footwear, clothing and upholstery sectors, to which it provides raw material input, but also has strong links with the chemicals and agricultural sectors. The standard of animal husbandry has a significant impact on the quality of the raw hides used in the industry, while the chemical industry provides key material inputs for all wet and dry processes such as tanning salts and dyes.

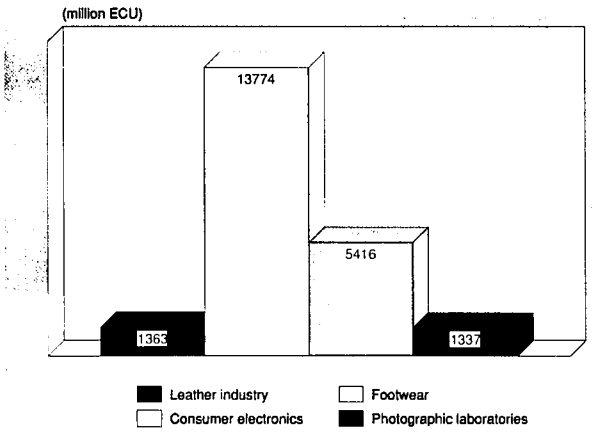
Main indicators

With a value of 7 billion ECU, the EC leather market is one of the world's leading trade areas for this industry.

The value of the EC leather production dropped in 1991 by 13% compared to 1989 where it reached a peak after a period of steady increases.

Since 1982, employment in the leather sector fell by 26% to about 60 000 people. The decline would be slightly higher at about 28% over the same period, if former East Germany were not included following reunification.

Figure 1: Leather tanning and finishing
Value added in comparison with other Industries, 1991



Source: Eurostat

The cattle and calf sector accounts for 70% of production and consumption in the EC, with the sheep and goat sector accounting for most of the remaining production.

Italy accounts for more than 50% of total EC production, well ahead of Spain at 15% and France, Germany and the United Kingdom with 7%, 6% and 5%, respectively. Portugal now accounts for almost 3% of the total production value.

Recent trends

The EC leather industry is undergoing a process of structural adjustment to adapt to the new competitive environment. It is shifting from mass production of standard products (which is being increasingly taken over by developing countries) to smaller volumes of higher quality, higher value-added production. The reduction in output over the past three years partly reflects the shift from mass markets to smaller segments and the increasing penetration of the internal market by cheap imports from East Asian NICs and developing countries, which have developed strong export oriented leather industries.

The opening up of the former COMECON countries will offer consumption possibilities but also present threats to EC producers and will cause further restructuring within the EC, resulting in a further decline in the number of companies and the level of employment over the next decade.

Production trends vary according to different types of leather. The production of cattle and calf leather registered an increase until 1987, levelling off at about 182 million square metres and 70% of total leather output by surface area in 1991. Output of sheep and goat leather fell sharply in the EC to 71 million metres and their share in total EC leather production by surface area declined from 42% in 1985 to 27% in 1991.

International comparison

The European tanning industry represents nearly 50% of total trade in leather. Compared to the USA and Japan, the EC is a much more significant player in finished leather. In 1991, production of EC leather was 7 226 million ECU. Leather production the USA is about 2 500 million ECU and Japanese manufacturers produce approximately 1 500 million ECU.

Among developing countries, East Asian countries account for over one-fifth of world trade while the Latin American region accounts for another 13%.

It is important to note that in the USA (which is the world's largest supplier of cattle hides) large meat packers tends to tan an increasing share of this by-product until the wet-blue stage. This trend, which is also evident in certain EC countries, is likely to revolutionise the global leather trade. The US leather industry could then regain its former position as one of the world's largest tanners.

Japan has become one of the USA's largest clients for wet-blue stage leather, and, protected from competition in the finished leather segment by a penalising tariff-quota system, has invested heavily in its tanning industry.

Foreign trade

Extra-EC exports remained static in 1991 following a significant fall of 12% in 1990. Extra-EC imports dropped by nearly 27% in 1991 from their 1990 peak. Although still representing 58% of total leather trade in the EC, intra-EC trade in leather also suffered from the overall recession in the sector falling by 8% in 1991. The leather trade balance recovered to a strong positive balance in 1991, following the small deficit recorded the previous year.

The EFTA countries, USA and Japan continue to be the main export markets for EC manufactured leather articles with 19%, 15% and 15% respectively in 1991. In finished leather, the EFTA countries now account for about 14% of EC export markets, the USA, 11%, and Japan, due to MITI's protectionism, 2%.

Due to the development of its leather articles manufacturing industry, Yugoslavia had become an important export destination for the EC tanning industry with 18% of total extra-EC exports in 1990. Such exports, however, have declined due to the political difficulties in the region.

South Korea, Hong Kong, and Taiwan in the Far East have maintained their importance as export markets with 10%, 7% and 2%, respectively of all EC leather exports.

China has become the single most important supplier of leather and leather articles with 27% of all EC imports in 1991 compared to just over 7% in 1986. The significance of other East Asian suppliers such as Taiwan and South Korea has decreased in relative terms.

In finished leather, however, India continues to be the EC's most important foreign supplier with about 22% of all imports. Pakistan follows closely with 13%. Bangladesh has progressively developed its share in EC imports to 5%. EFTA and

Figure 4: Leather tanning and finishing
International comparison of production at current prices

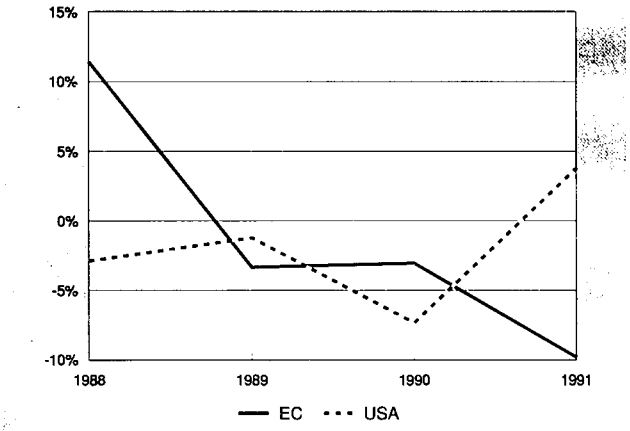
Figure 5: Leather tanning and finishing
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

the USA account for 11% and 6% of all extra-EC imports of leather, respectively.

Intra-EC trade increased consistently over the period 1982-1989, rising by a quarter in real terms. EC production, although less consistent over the period, was 23% higher in 1989 than in 1982. In 1990 and 1991, however, the difficult market situation was reflected in a decline in both indicators. Intra-EC trade dropped by 11% and production by 12.5% over the two year period.

Extra-EC exports followed a similar pattern rising by over 50% between 1982 and 1989 and falling in 1990. However, they recovered in 1991 growing by 5% in real terms. Extra-EC exports represented about 16% of production in 1991, compared to 10% a decade ago. The import penetration rate has increased somewhat since 1982, reaching nearly 15% in 1990 and falling to under 13% in 1991. Extra-EC imports have doubled in value terms during the last decade.

MARKET FORCES

Demand

Leather is an intermediate product sold to industrial customers for the manufacture of a wide range of consumer goods and some technical applications.

The footwear industry remains the EC tanners' largest market, consuming 48% of all leathers. The garment industry follows well behind purchasing 22% of the EC leather industry's production and is likely to fall in importance as the upholstery market grows. It currently absorbs about 16% of leather output. In Germany and the Netherlands the upholstery market has become as important as footwear and in the United Kingdom and Italy the same pattern is likely to occur in the medium term. Leather for leather goods and other uses such as wallets, suitcases, etc., rank as the least important end use with 13%.

The leather industry is very sensitive to changes in economic activity, especially in consumer demand which depends on general income. The reduction of consumer spending in leather articles in the major markets during 1991 has depressed the leather trade globally. The recession in the USA and the impact of reunification of Germany (among other factors) have slowed down general consumption and thus had a negative impact on EC leather production.

Export development has become a key strategic element in the management of EC tanneries. The main target export markets are high income countries, of which the USA and the EFTA countries are the largest, but new markets for leather are emerging in East Asian NICs and Latin America as those regions have developed industries such as footwear, leather clothing, and leather goods.

The demand for "genuine leather" in the general public dominates consumer behaviour and attempts to develop markets in imitation products have been largely unsuccessful.

The proportion of leather-uppered shoes has increased steadily and accounts for about two-thirds of all footwear produced in the EC. In the furniture upholstery industry, alternatives to leather have not penetrated the market significantly but in the clothing industry, textiles fabrics continue to predominate. In the automotive sector, leather now dominates the upholstery in luxury cars and it is expected that this trend will develop into middle-range cars.

Product innovation plays a fundamental role in the leather industry as competition becomes more and more intense. Especially in the fashion industry, product improvement is a crucial element of success. The tanner must attempt to anticipate colour trends and consumer preferences. Product innovation has also brought forward qualitative improvements of leather. There are now waterproof and even washable leathers on the market. The emergence of environmental awareness has also brought new types of leather and there are already some "eco-leathers" appearing at fairs. Although environmental pressure has brought product improvements such as water-borne topcoats which are substituting solvent lacquers and lacquer emulsions in leather finishing, chrome tanning is unlikely to be replaced in the foreseeable future.

The manufacture of leather articles has boomed in East Asia and Latin America. South Korea has become the third largest export market for EC leather with 121 million ECU in 1990. EC tanners have not been able to benefit significantly from the growth in the Japanese leather market because of the maintenance of punitive tariff-quota system which precludes the development of sensible long term trade relations by applying duties at 60% in excess of a very small quota tariffed at 20%.

Latin American markets are still insignificant for EC industry. EC leather cannot compete in countries where leather production is boosted by governmental measures geared towards speeding up the development of their domestic industry. Mexico, however, with the dismantling of the protectionism and the signature of the North American Free Trade agreement has become a potential export market for EC tanners.

The crisis in Yugoslavia has caused a severe downturn in EC leather exports to that country, which was engaged in producing leather garments and other manufactures for major EC and US markets.

Supply and competition

Supply capacity

The EC tanning industry's supply capacity varies according to the different subsectors and the developments in the different user industries.

Between 1980 and 1990 bovine leather consumption and production grew in the EC due to an increased demand in the footwear and upholstery markets. EC production failed to keep pace with the growth in EC consumption in the second half of the decade. In the sheep and goat leather sector, lower priced imports of garment leather and leather clothing from developing countries and NICs have contributed to the increasing overcapacity in EC tanneries.

The EC leather industry has been forced to move towards the supply of smaller market segments where price considerations are less important than quality, fashion, and consistency with specifications and on-time delivery.

Market power of the major customers

Quick response and just-in-time (JIT) techniques are becoming more important as EC producers attempt to maximise the advantage of market proximity. By providing a more competitive service to manufacturers, EC tanners may find themselves in a position either to charge a higher price and/or to attract a more consistent level of orders.

Internal EC competition

The completion of the internal market will not have a significant effect on the EC tanning industry as intra-EC barriers to trade in leather are non-existent.

The progressive erosion of the internal EC market for leather due to the relocation of client industries in low wage countries has a more important impact on competition among EC tanners.

Foreign competition and EC competitiveness

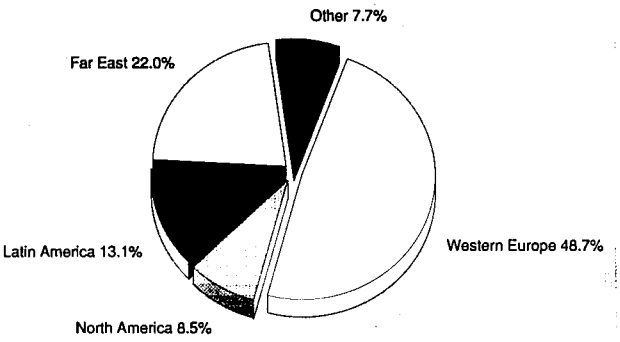
The EC tanning industry is increasingly being put under pressure by lower priced imports, particularly from lower cost producers in South America and Asia with protected access to raw materials.

Export restrictions on raw hides and skins have been implemented by a number of developing countries in order to speed up the growth of their domestic tanning industry. These trade restrictions can give companies located in those countries a considerable price advantage. Leather producers in Argentina, for example, have been able to undersell EC tanners by almost 20%.

Additional threats to the EC tanning industry are caused not only by the relatively high wages but also because of increasingly stringent environmental regulations. A recent study on industrial competitiveness and environmental protection made by SEMA for the EC Commission illustrates the different cost burdens for tanners in the EC and in developing countries. Whereas European tanners have to contend with labour costs of 20% to 25% of total production costs and a competitive disadvantage estimated at 2% to 4% of turnover for environmental protection, their counterparts in developing countries face production costs 5% to 15% lower due to lower wages and practically no environmental costs because of lack of regulations or of their effective implementation.

The competitiveness of the EC leather industry depends on its ability to secure reasonable access to potentially profitable export markets for its high quality output and so achieve economies of scale in production. Among OECD countries,

Figure 6: Leather tanning and finishing
Distribution of production by country, 1988-90



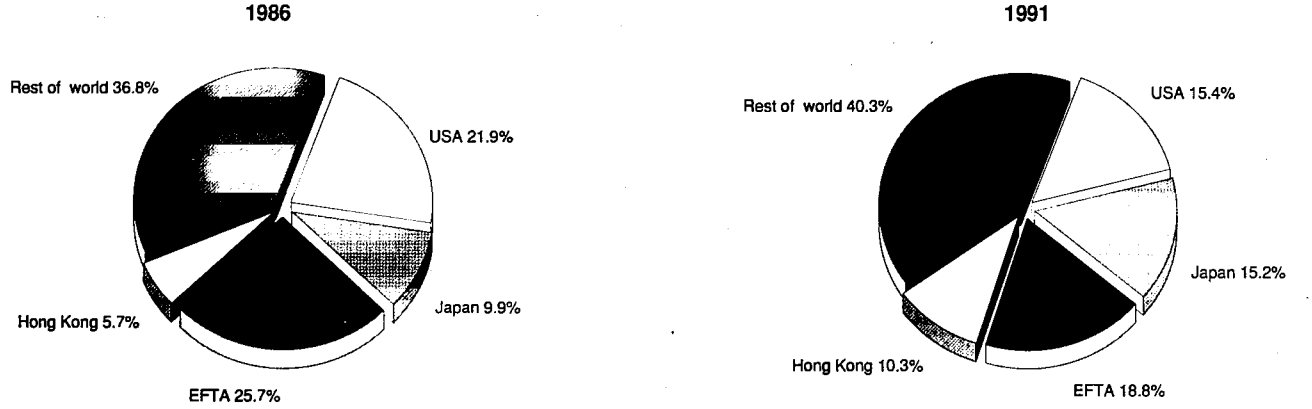
Source: Eurostat

which are target export markets for the leather sector due to their high level of discretionary consumer expenditure, Japan has been the only country that EC tanners have not managed to penetrate significantly. The principal reason for this is restricted access due to a tariff-quota system which effectively limits imports to a mere 1% to 2% of Japanese production. It is estimated by some European producers that exports to Japan could increase sixfold if that market were free. The present round of multilateral trade negotiations in the context of the GATT discussions may ease the level of Japanese protection.

Production process

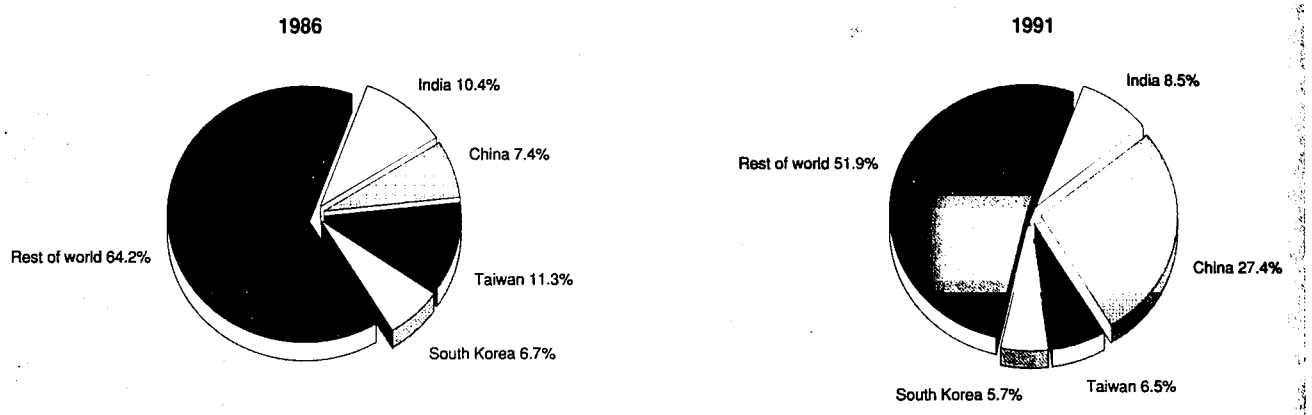
Raw materials for the production of leather are hides and skins, a by-product of stock breeding. Supply is thus independent from tanners' demand. Agricultural and trade related policies do influence the availability of raw materials on world markets. The introduction of milk quotas by the EC, for instance, has led to reductions in the size of dairy herds (and hence the supply of cow hides) in the EC. Export restrictions of raw hides and skins throughout the world have led to a situation where 24% of bovine hides and 22% of sheepskins were under protectionism at the beginning of the decade.

Figure 7: Leather tanning and finishing
Destination of EC exports



Source: FAO

Figure 8: Leather tanning and finishing
Origin of EC imports



Source: Eurostat

Hides and skins typically represent 50% of the costs of the finished leather making it very vulnerable to fluctuations in prices on world markets. The international market for hides and skins is predominantly supplied by the USA, Western Europe and Australasia

The protectionism which developing countries with large live stocks apply on raw materials in order to boost downstream leather production, and the trend of large meat packers and abattoirs in industrialised countries to process fresh hides and skins until the wet-blue stage, has resulted in fewer raw hides and skins coming on the market.

The EC has a large livestock of 196 million heads, including 81 million cattle and 114 million sheep and goats. While self-sufficient in hides and skins in quantity terms, quality requirements impose the use of varieties not available in the EC.

Over the past few years, a progressive deterioration in the quality of raw materials has been observed and this deterioration worries EC tanners. Dung, scratches, parasites and animal diseases are responsible for a number of damages caused to hides and skins which could be avoided through more animal care and better practices. Improper skinning and preserving techniques in the abattoirs cause grain strain and other detrimental quality losses in the raw material.

In spite of large scale initiatives (measures to prevent warble fly proliferation or against poor flaying techniques) or more modest ventures (field experiments on methods designed to improve the whole leather production chain, from the farm to the tannery), some European raw materials are having difficulties meeting the standards required for high quality leather.

A positive spin-off of the tanning industry is that it effectively contributes to a reduction of 5% to 15% in the price of meat by maximising the abattoirs return per animal through the sale of hides and skins.

Tanning is a capital intensive industry. The EC leather industry is well endowed with tanning machinery and chemical producers placing EC tanners at the forefront of leather technology both in terms of processing and anti-pollution treatment. However, the costs of such equipment causes substantial entry barriers to the industry.

EC tanners face a third challenge in relation to staff training and management renewal. The tanning sector is attracting fewer and fewer people. Newly-recruited staff often possess poor technical and professional skills. In order to counteract this negative development, the EC leather industry is participating in a continuing vocational training project in the framework of the EC FORCE programme.

INDUSTRY STRUCTURE

Companies

The number of enterprises operating in the EC tanning industry continued to decline in 1991, falling to 3423 companies. This represents a decline of 5.4% compared to 1990 and 15.4% compared to 1982. Northern European countries experienced the largest decrease in the number of establishments.

Europe's tanning industry is mainly composed of small to medium sized enterprises. With the exception of the Netherlands' average of 28 workers per plant, northern European tanneries tend to be larger than those in the southern Member States. Germany leads with an average of over 90 employees per plant, followed by Belgium and the United Kingdom with about 60 workers per plant. Portugal, Spain and France range from 20 to 50 people per tannery and Italy, the largest European leather producer, employs an average 11 workers per plant. The latter average could be explained by the extent of specialisation in Italian enterprises, which often just finishes leather roughly tanned by other operators. This phenomenon partly explains Italy's success in the sector since the small size of its tanneries makes them more flexible and adaptable to the market.

The leading companies in the different Member States include Gruppo Mastrotto (I), Grupo Colomer (E), Costil Tanneries de France SA (F), Lederfabrik Louis Schweizer GmbH & Co. (D), The British Leather Co Ltd (UK) and Conolly Leather (UK).

Strategies

Tanners in the EC are under threat from several directions:

- import penetration of leather products is eroding many domestic market shares;
- trade restrictions are limiting access to raw materials and allowing foreign competitors a price advantage;
- high wages and frequent difficulties in attracting qualified; and
- increasing environmental costs.

The EC tanning industry has taken up these challenges by orienting its production to smaller but more profitable market

niches in the high quality and top fashion segment, thus exploiting the advantage of its proximity to the consumer markets and the concentration of fashion expertise in Europe. This strategy, combined with the sector's efforts geared towards more flexibility in production and quicker delivery times, allow EC tanners to recover some competitive advantage over their Asian counterparts. It remains almost impossible, however, to compete simply on the basis of price.

Under the EC SPRINT programme, leather research institutes throughout Europe are preparing a model for EC tanneries with a view to assisting them in the implementation of quality assurance systems of the ISO 9000 series. Accreditation to ISO 9000 will allow companies in the leather sector to certify the high quality standard of their product.

As the gap between the stock of raw materials available and the level of global demand for finished leather is expected to widen in the medium term, the EC is seeking, in the framework of GATT, to open up the access to raw materials in countries implementing protectionist measures. Uruguay Round negotiations have, however, not brought yet any meaningful results in this issue, nor in the problem of the access to the Japanese market for leather.

EC tanneries have understood that with a shrinking internal market, export orientation is the only way to survive and grow. Extra-EC exports have been growing over the past decade by an average of 4% per annum in real terms illustrating the success of European tanners in penetrating new markets with open access.

Continuing vocational training in the leather sector and particularly for shop floor workers is perceived as a means to improve EC tanneries competitiveness and the quality of their leather.

Specialisation in the production of a single or limited range of products is progressively gaining ground in the EC leather sector. Again, northern European tanners tend to be more specialised than their southern counterparts. Whereas German tanners have concentrated on footwear and/or upholstery leather, many Portuguese tanners produce all types of leather in the same plant.

Due to the family owned structure of many of the smaller tanneries, mergers and acquisitions are not common features in the leather industry. Their importance may well increase in the future as new generations become more business conscious.

REGIONAL DISTRIBUTION

Tanneries exist in all Member States except Luxembourg. The contraction of the leather industry has affected northern European countries more severely but is presently also having an impact on the southern Member States. Most European tanneries are located around the Mediterranean Sea, Italy accounting for almost three quarters of the total. Spain follows with 285 tanneries and a share of 8%. France, Greece and Portugal host respectively 176, 150 and 130 establishments.

In some Member States, tanneries are regionally and/or locally concentrated: Santa Croce sul Arno, Ponte a Egola and Solofra in Italy, Vic and Igualada in Catalonia (Spain), Alcanena in Portugal, Graulhet and Mazamet in the south of France, and Backnang in Germany are examples of areas with a high concentration of tanneries, often playing an essential role in the local and/or regional socio-economic life.

In most of the larger countries there has been significant rationalisation of the industry. In Merseyside in the United Kingdom, for example, there were 40 tanneries in 1945 but only 4 survive today. In the case of Germany, a rationalisation of the tanning industry has restored the viability of the industry. The success of the leather industry in Germany has been partly based on its upstream link with the German chemical industry and many new raw materials have been tested through this link. Downstream, the presence of a major high quality automotive industry and footwear industry has boosted demand conditions.

ENVIRONMENT

In profitably recovering a by-product of the meat industry which would otherwise have to be landfilled, the tanning industry helps to maximise the use of a renewable natural resource.

Leather tanning can be a source of considerable environmental impact. Air and water pollution, widespread odours, disposal of waste and the damage to sewage systems are among the problems that have been experienced in the leather industry.

Only 20% of the weight of a rawhide finally becomes leather leaving behind liquid effluents, solid wastes and by-products. Some of those could again enter the production chain as raw materials for gelatine, glue, leatherboard, grease, etc.

Water pollution may arise from spent or washed-out chemicals used in the process and therefore require appropriate treatment.

Source: COTANCE

Treatment plants, however, generate a different form of residue (generally sludge) which also has an impact on the environment. Recent research developments have proven that on a scientific level there is no observable effect of chromium containing sewage sludge when disposed on agricultural land, thus allowing its use in agriculture in replacement of chemical fertilisers or as a soil conditioner.

Solid waste arises from operations such as cleaning, scrapping, splitting and trimming. These residues, if not re-used, have to be disposed in landfills.

It is worth noting that part of the waste is inherited from operations upstream of the tanning process, deriving from improper hygienic conditions of animals when presented to the abattoir and salting and other chemical preserving operations after skinning.

The later washout of salt or chemicals may cause problems with effluent quality, as few waste water treatment systems are designed to remove such substances.

The concept of environmental protection and of a sustainable development is being integrated into the management strategies of EC tanneries. Recognising that pollution prevention is often cheaper than to apply "end-of-pipe" solutions, the industry is developing cleaner production technologies in experimental projects, often in cooperation with other EC tanners. In certain regions of the EC where there is a concentration of tanneries, such as Santa Croce sul Arno (Italy), Graulhet-Mazamet (France), Alcanena (Portugal), EC tanners are joining forces to tackle environmental issues together leading to the development of large effluent treatment plants.

The EC leather industry has taken positive steps towards improving environmental performance and minimising waste through the implementation of cleaner production processes. Investments in this field made by the tanning industry can be estimated at 2% to 4% of the sector's turnover or to some 150-300 million ECU per year.

The environmental regulatory framework in Member States sets almost equivalent burdens to tanners. However, in some countries, industry operators might be forced to assimilate faster new constraints as their national standards become more stringent. One example of such "first mover" initiatives, that subsequently have to be assimilated all over the EC, is the ban of PCP (Penta-Cloro-Phenol) in Germany. PCP, that is used as a treatment to prevent moisture absorption by the raw material, is dangerous to human health under long exposure and potentially causes toxic emissions when incinerated. Initiatives of this kind may cause problems for some countries and companies which are not ready for the implied changes.

The optimum for the EC tanning industry regarding environmental performance is to maximise the utilisation of all inputs, identify uses for any possible by-products, minimise waste and treat the inevitable residues.

Research and development is being financed by the EC tanning sector to find viable solutions to environmental problems in leather production, thus contributing to the global effort of sustainable developments in the leather industry.

REGULATIONS

Sector specific regulations are more frequent at local, regional or national levels rather than at EC or international level. Most regulations affecting the leather sector tend to be of a horizontal character and the particular provisions concerning tanneries are often subsumed into a global framework.

At EC level it is possible to distinguish three main areas where the leather industry is particularly addressed:

Trade related regulations: The EC common customs tariff in Chapter 41 provides for the import duties on leather. Those range from 3% to 7% and are among the lowest in the world. The General System of Preferences grants to developing countries a preferential access to the EC market, suspending the duties up to certain ceilings.

Technical regulations: The Commission has issued a proposal for a footwear labelling directive, laying down the means to be used for footwear labelling referring also to the constituent materials of it and thus defining leather. This draft directive takes over the definition of leather elaborated by the International Council of Tanners (ICT).

Ecological regulations: Apart from general legislation regarding health and safety and environmental protection which applies to all branches of industry, the tanning sector pays particular attention to an EC proposal for a directive laying down limits for chromium in sewage sludge to be used in agriculture.

At an international level the Uruguay Round of GATT negotiations may help determine future trade policy in the leather industry.

OUTLOOK

Leather production in the EC is expected to fall in the short term as there are no signs of recovery in the worldwide recession in the leather trade. The non-completion of the Uruguay Round leaves the general framework for trade somewhat vague, adding uncertainty to the leather industry. Cheap leather imports will continue to increase and exports are not likely to grow significantly because of a lack of reasonable access to the largest potential market, Japan.

In the medium term, the prospects for the EC tanning industry will depend on its ability to adapt to the changing international economic environment.

The EC leather industry will have to face increased competition from developing countries in the purchase of raw materials and in the markets for finished leather. Normal commercial developments in the USA, Europe, Australia and New Zealand will lead in the medium and long term to a situation where no untanned hide or skin will leave those countries. Environmental reasons also support the case for immediate processing either fresh or wet-blue raw materials as it obviates

the need for salting and thus the need for the reverse process which requires the disposal of a heavy load of salt into waste water.

In the longer term, the buoyancy of demand relative to supply is expected to maintain the upward pressure on hides, skins and leather prices. The demand for various luxury leather products such as leather upholstered cars and high fashion garments will depend on the growth and distribution of wealth in high income countries. An increase in the demand for leather footwear is expected to be concentrated in lower income regions of the world.

Population growth in Asia (where per capita incomes also rise faster than the world average) will be an important factor in the expansion of world demand for meat and the availability of derived leather articles. Asia's share of world hide production will have increased from some 13% in 1970 to an estimated 25% by the year 2000. Asia and Latin America NICs will become vast new consumer markets for leather with the expansion of their leather articles manufacturing industry.

Wood processing
NACE 46

In 1991, the woodworking industry reached a production value in current prices of 34.9 billion ECU, an increase of 27% compared to 1985. Hit by recession in the early eighties, the woodworking industry has been growing at a faster rate than average manufacturing since 1986. Over the period 1992-1995, demand in the primary and secondary processing of wood industry is expected to grow by 2.9% per year.

INDUSTRY PROFILE

Description of the sector

According to the NACE definition of sector 46, woodworking can be divided into two parts, namely the first processing of wood (NACE 461) which includes sawmills and planemills and the second processing of wood (NACE 462 to 466). The second processing of wood includes:

- semi-finished wood products (Nace 462): particleboard, fibreboard, and plywood;
- wooden building components (Nace 463): carpentry, joinery and parquet flooring;
- wooden containers and pallets (Nace 464);
- other wood manufactures (Nace 465);
- cork, basketware and wickerwork, brushes and brooms (Nace 466).

In view of the typically SME character of these activities in all the EC countries, the output of these groups is considerably underestimated by the majority of statistical analyses since they generally ignore smaller businesses (less than 20 people employed).

Main indicators

In 1991, consumption in current prices amounted to 42.7 billion ECU, an increase of 1.9% compared to 1990. Production amounted to 34.9 billion ECU, an increase of 3.9% on 1990. Sawing, planing and drying of wood represents 16.9% of total wood products production, semi-finished wood products 23.1%, wooden building components 34.9% and other wood products 25.1%.

The trade balance improved in 1991, especially in the subsectors 461 (sawing, planing and drying of wood) and 462 (semi-finished wood products). The woodworking industry employed about 436000 persons in 1991.

Recent trends

In constant prices, apparent consumption and production in 1991 had increased by 28% and 27% respectively since 1985. Extra-EC exports have remained stable since the 1989 jump, albeit with a very slight decline. Employment since 1985 has fluctuated around 430 thousand persons, and in 1991 was 1.7% higher than 1985 at 436 thousand.

Foreign trade

Extra-EC imports, after rising continually from 1985 to 1990, declined by 5% in 1991. The ratio extra-EC exports/extra-EC imports, after having reached a level of 23% in 1985, has remained stable at a level of roughly 20%. Intra-EC trade increased constantly during the period 1982-1991, amounting to 5 billion ECU in 1991 and represents 34% of total imports.

MARKET FORCES

Demand

Since the products of the woodworking industry are very heterogeneous, these products have different types of buyers, i.e. industrial or final consumers.

Demand for the products of the woodworking industry largely depends on two sectors: the building or construction industry on the one hand and the furniture industry on the other hand. Since these two sectors are highly cyclical, demand for the products of the woodworking industry depends heavily on the evolution of general income and interest rates.

The expected general economic recovery is not yet likely to influence construction activity in Europe in the near future. The building volume is expected to experience a further slight reduction due to high interest rates, a surplus in buildings in many countries and the general cut-backs in state-subsidised construction. This decline is in contrast to the expected general economic growth rate of 2% which indicates that the trend of a decreasing contribution of the building sector to gross

domestic product continues. The expansion of renovation and maintenance activities has partly compensated fluctuations in new construction volume output during recent years. Industry experts anticipate a decline in the construction of new dwellings as well as in commercial and public building.

The year 1991 was not a very good one for the furniture industry. Except for Germany and the Netherlands, growth rates were just enough to balance inflation rates in nearly all the countries. The worst situations were encountered in France and the United Kingdom. Luckily, many countries increased their exports to Germany to satisfy the rapidly expanding demand. Except for Denmark and Portugal, whose exports increased strongly, the other countries' overall exports rose by moderate rates. The growth of imports was remarkably high in Germany, Portugal, Greece and Spain. Apparent consumption increased in nearly all European countries (except for France, the UK and Denmark) and in general, was covered by an increase in imports which was more significant than the increase in production.

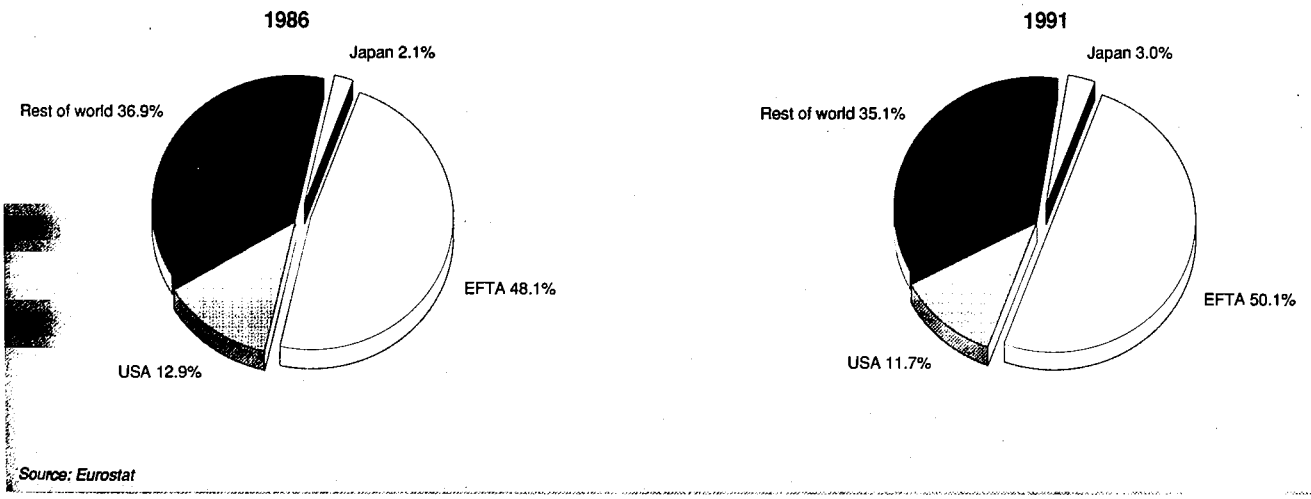
Supply and competition

The deficit in the Community trade balance can be explained by the dependence of important subsectors on tropical hardwood (and on sawn timber), imports of plywood from south east Asia (especially from Indonesia), hardboard from South America (especially Brazil), and the imports of wood products from the countries of central and eastern Europe at extremely low prices.

Although imports of raw materials like tropical hardwood will continue, an improvement in the trade balance of the sector can be achieved through a consolidation of the industrial system within the EC.

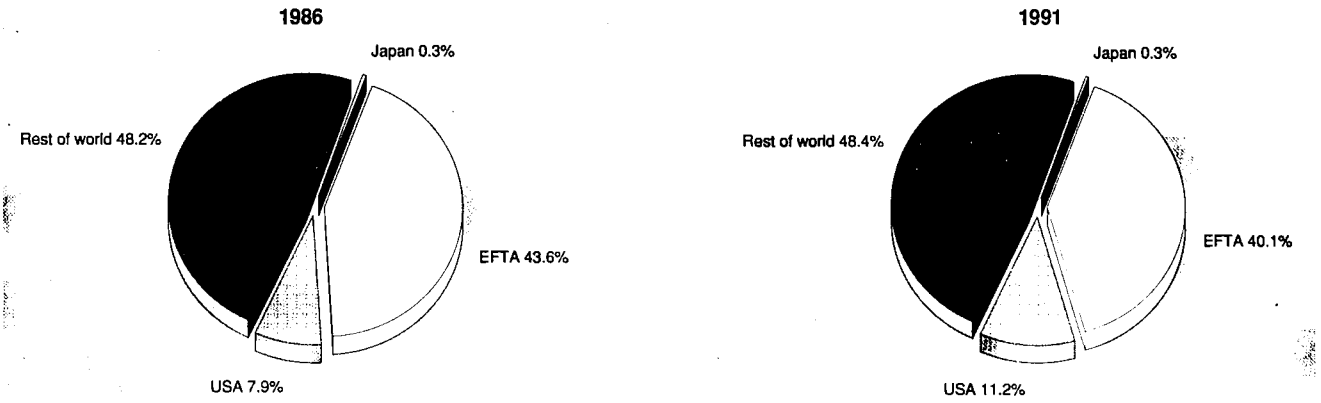
Moreover, depending on the Community's forestry policy, an increase in the domestic supply of wood may be achieved through the use of marginal land. As there are important surpluses of agricultural products within the EC, there is a tendency to convert agricultural land into forestry areas. This could lead to a further improvement of the trade balance of the EC woodworking industry and would also have a positive ecological impact.

Figure 4: Wood processing
Destination of EC exports



Source: Eurostat

Figure 5: Wood processing
Origin of EC imports



Source: Eurostat

Trade flows among Member States are more significant than extra-EC exports. This may partly be explained by the importance of transport costs which affect the trade in wood and wood products. In the period 1987-1991, the value of intra-EC trade increased by an average of 8.7% per year.

In the past, competition has been affected by a large number of technical barriers to trade between Member States (nationally oriented standards that have already been in existence for a long time, major differences in the procedures for technical approval, etc.). In the light of the integration of the EC market in 1993 the sector will be affected by the results of discussions on the short term implementation of European standards and technical reference documents. This technical integration is expected to result in an increase in trade between Member States.

The political and economic developments in the countries of central and eastern Europe will have important consequences, since these countries have very large wood reserves and a low wage labour force.

INDUSTRY STRUCTURE

Companies

The woodworking industry, including the manufacture of wooden furniture, has around 242 thousand companies, 94.2% of which are enterprises with less than 20 employees representing 46% of employment and 34% of turnover. Companies with more than 99 employees represent 0.6% of the enterprises but they realise 36% of turnover.

Strategies

Since woodworking started as an artisanal activity, the family structure of its small and medium-sized enterprises is still very important. The industry enjoyed a rapid growth between 1960 and 1974.

The woodworking industry went through a major crisis commencing in the second half of the 1970's, like most sectors of European industry. This crisis lasted until the beginning of the 1980's. Due to substantial investment efforts since 1983, the EC woodworking industry is heading for overcapacity problems in the beginning of the 1990's, despite achieving a balance in the late 1980's. This balance, in part, was due to a significant increase in the demand for products of the woodworking industry, as to meet this increased demand, the enterprises of the woodworking industry made substantial investment. Since new machines normally outperform older ones, new investments resulted in a rationalisation of the production process and an improvement of the efficiency and productivity.

As demand slowed down in the beginning of the nineties, investments were focused on the introduction of new products (e.g. oriented strand board, medium density fibreboard) and new production technologies.

In order to cope with extra-EC competition, many small and medium sized enterprises have adopted a strategy of diversification and specialisation.

ENVIRONMENT

Wood is a renewable raw material. Its transformation into finished products requires a minimum of energy and doesn't pollute air, water or soil. Some discussions have however arisen on the use of tropical timber, the recycling and disposal of packaging waste and the tax related to CO_2-emission. This evolution is certainly not unique to this sector, but has to be

Table 5: Wood processing

seen in a much broader context, in which the whole of Europe is beginning to think "green".

Protection of tropical forests

The deforestation of the tropics is an extremely alarming situation which gives rise to general concern. The most important reason for this deforestation is the circle of poverty, population pressure, over indebtedness and economic underdevelopment which results in an increasing demand of land clearance for farming, industrial purposes and infrastructure at the expense of the forests.

Unqualified and destructive timber exploitation is an ecologically irresponsible action. In order to preserve the biological variety and protect endangered animal and plant species as well as to prevent erosion, it is necessary to turn large areas of forest into nature reserves where any kind of commercial exploitation is prohibited. The tropical forests must be protected, but adequate account has to be taken of their ecological, economic and social functions. This requires land planning which designates protection forests, commercially exploited forests and areas for agricultural, industrial and infrastructure purposes.

Environmentally sound and sustainable forest management schemes can contribute to a large extent to the preservation of forests. The European woodworking industry fully supports the introduction of these schemes. Generalised bans and boycotts do not necessarily contribute to the preservation of tropical forests. On the contrary: they may accelerate the deforestation of tropical areas due to the increase in poverty that could result from them. The ITTO guidelines for sustainable forestry, which have been adopted by all producer and consumer countries, constitute the first internationally recognised criteria for environmentally sound, sustainable forest management. It is essential to achieve the implementation of these guidelines before the target date 2000 agreed upon within ITTO.

The measures agreed upon in this context should be implemented in collaboration with competent environmental organisations. An important incentive for the realisation of sustainable forestry is the introduction of an attestation of origin. An attestation scheme can be established on a country basis or on a case by case basis. The interests of the wood producing countries of the Third World have to be considered appropriately when coordinating international measures for the protection of tropical forests. In the problem zone of the tropical forests, ecology and economy are no irreconcilable contrasts.

Recycling and disposal

During recent years, national as well as European authorities have begun to focus on packaging and packaging waste. Within the range of packaging materials, wood takes a specific place. As already stated, wood is a renewable raw material. Compared to other materials, wood needs only little energy for processing and therefore helps to reduce the use of valuable energy resources.

Woodwaste cannot be considered as real waste, since it can be and is used to manufacture other materials such as particleboard, fibreboard, and laminated wood etc. If this use of woodwaste is not possible, it can be used for energy production. For the time being, woodworking companies produce the necessary technical warmth, and heat the workplace, mainly from bark and woodwaste. Modern firing installations have reached a very high technical standard and, from an environmental point of view, have to be regarded as being highly efficient.

Based on the arguments above, wood is a well suited packaging material. It can be recycled to produce other materials, or can be used to produce energy. Treated or coated wood packaging can be burned in suitable firing installations together with household wastes.

The woodworking industry continues to argue for the re-use of timber packaging materials for energy production as one of the solutions for recycling.

CO_2-reduction policy

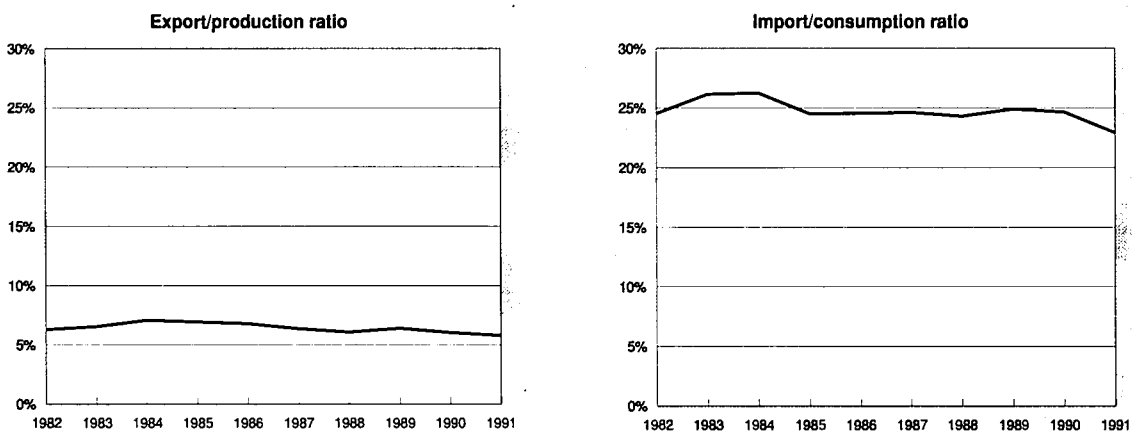
In the past, after considerable effort, the woodworking industry has managed to achieve some good results in the reduction of energy consumption. This branch of industry has an acute awareness of the necessity to reduce the emissions of CO_2 to protect the atmosphere on earth. Therefore, it will aim for further reduction, and support political concepts consistent with that purpose if they can be realised in an economic way and be combined with the necessary political measures.

The raw material wood should be promoted more extensively. This includes an increasing forest area as this leads to improved CO_2 absorption and helps to redress the balance against the disappearing of tropical rain forests.

Product promotion could include, for example, specific orders from public authorities for, say, anti-noise barriers along roads and railway tracks made from wood or wood based materials, as part of a positive attitude towards the use of wooden constructions.

Finally, the positive and expandable role of the thermic use of wood waste is important. This helps restrict the use of

Figure 6: Wood processing
Trade intensities



Source: Eurostat

other non-renewable energy sources, that are less "CO_2-friendly".

REGULATIONS

There are relatively few technical regulations in the woodworking industry, leading to the concept that the "single European market" is already practically realised. The "construction products directive" and the related European standardisation activities have helped. A similar effort is being made on the market of biocidal products (including wood preservatives), where an EC-directive is being prepared and should allow the removal of barriers to trade in this field. Finally, a lot of discussions are on-going related to the "phyto-sanitary" field and plant protection.

The following items are of specific concern for the woodworking industry.

German "Gefahrstoffverordnung"

In 1986 Germany notified a "decree on dangerous substances", introducing, between others, a requirement that wood based materials and furniture made thereof should not emit a concentration of more than 0.1 ppm of formaldehyde in a "testing chamber". This caused detailed opinions/observations from different Member States. Between 1986 and 1991 the subject has remained under discussion.

On 12 February 1991, the German government notified its "Prüfverfahren für Holzwerkstoffe" (test methods for wood based panels). These can be considered as the implementation of the formaldehyde regulation in the "Gefahrstoffverordnung". Again detailed opinions/observations were discussed by six Member States and the EFTA Secretariat as well as by the Commission itself.

In spite of this, a final decision was taken on the regulation, when, at the end of October 1991, the German government published the test methods for wood based panels in the "Bundesgesundheitsblatt".

Compared to the initial proposal of the German authorities, some beneficial changes were introduced. The main request of industry, that the results of the "derived test methods" (such as perforator and gas analysis values) should be considered as equivalent to the tests in "large chambers", was met.

In principle, however, industry remains opposed to this regulation and requires a lot more clarification.

Regulations related to wood dust

In some countries, there are very stringent regulations on the exposure to wood dust in workplace, due to its presumed risks for workers.

Presently, wood dust does not appear on the EC-list of carcinogenic substances at work places, because no direct relationship between exposure to pure wood dust and certain types of cancers of the higher respiratory system has been proved. Research, however, continues, the Industry has launched a research programme to be performed at the Cancer Research Centre in Heidelberg. The programme, which will be co-financed by the Commission of the EC, will take approximately 3 years. It is expected to provide vital scientific evidence in the wood dust debate.

German "Verpackungsverordnung"

The German "Verpackungsverordnung" (regulation on packaging waste) came into force on 1 August 1991. The main implications of this regulation are:

- from 1 December 1991 all transport packaging such as pallets and crates have to be taken back and recycled;
- from 1 April 1992 it should be possible for a consumer to return the "Umverpackungen", i.e. the packing material used for theft avoidance or used for publicity;
- from 1 January 1993, used selling packaging will have to be taken back by retailers and industry to be recycled and there will be an obligation for deposits on certain one way packages.

According to the this "Töpfer-law", recycling is equivalent to "material recovery". This poses specific problems for wood material as a "material recovery" is not always possible. The German law does not allow for energy recovery.

As a consequence, recycling systems for wooden packaging in Germany had to be developed on a very short term. The "Grow" label is already used for vegetable and fruit crates and will shortly become applicable to pallets. It still is difficult and costly to find industrial consumers of recycled wood.

As other countries, like France, already have a national law concerning packaging waste or are developing one, the problem is also being dealt with on the European level. The proposal for a European Directive does authorise energy recovery. This clearly is the best solution for certain woodwastes.

Volatile organic compounds

The Commission of the European Communities has developed a proposal for a Council Directive concerning the limitation of the emissions of organic solvents from certain activities and industrial installations. The aim of this directive is to reduce the emissions of organic solvents from certain industrial installations and processes. It forms part of a strategy for an overall reduction of the emission of volatile organic compounds in the Community.

The proposal covers two activities of the woodworking sector, namely coating of wooden surfaces and wood impregnation. It is based on the principle that all enterprises, using more than one ton of organic solvents per year, should apply a strict management plan. Those using more than 5 tonnes per year should also reduce their emissions considerably.

It could therefore have important implications for a significant number of SMEs in subsectors of the woodworking industry, such as furniture, joinery, and parqueting, etc. The discussions on this subject continue.

Customs tariffs

On December 16th 1991, the EEC signed the Association or Interim Agreements on trade and trade-related matters with Hungary, Poland and the Czech and Slovak Federal Republic. To apply these agreements from March 1st 1992 on, a number of Council Regulations had to be issued. These regulations were published in the Official Journal L 56 of 29 February 1992. They are summarised as follows:

- Council regulation 517/92 removes Hungary, Poland and the CSFR from the list of countries in annex to the EC regulations on import arrangements for products in State-trading countries and on common rules for imports from State-trading countries;
- Council regulation 518/92 (Poland), 519/92 (Hungary) and 520/92 (CSFR) on certain procedures for applying the Interim agreements on trade and trade-related matters, lay down specific provisions concerning general rules or common rules for imports and on the protection against dumped or subsidised imports from countries not members of the European Community. It specifies the procedures to be followed for applying safeguard measures that are provided for in the Treaty;
- Council regulation 521/92 opens and provides for the administration of Community tariff quotas and ceilings for certain industrial products originating in Hungary, Poland and the CSFR. Until 31 December 1992, imports of certain

Table 6: Wood processing
Expected real annual growth rates

(%)	1992-93	1992-95
Apparent consumption	2.9	2.9
Production	3.4	3.4
Extra-EC exports	-1.5	-1.4

Source: Cei-Bois

products originating in Hungary, Poland and the CSFR will be subject to Community tariff quotas or ceilings.

Customs duties on imports applicable in the Community to 4403 10 10 (poles of coniferous wood, injected or otherwise impregnated to any degree, not less than 6 m nor more than 18 m in length and with a circumference at the butt end of more than 45 cm but not more than 90 cm) originating in Hungary, Poland and the CSFR shall be progressively abolished:

- from the 1st of March 1992: 50% of the basic duty;
- one year later, elimination of the remaining duties.

Customs duties on imports originating in the EC and applicable in Hungary, Poland and the CSFR will be progressively abolished and reduced to zero by the end of the year 2000.

SKILL SHORTAGES

Due to the very fast evolution in production techniques, the sector is experiencing increasing difficulties in finding properly trained staff. This implies that considerable attention will have to be paid to higher training standards in this field, as qualified executives are required, as well as skilled workers. Furthermore, the absence of sound information concerning the material 'wood' in most architectural and engineering courses is a shortcoming with a direct negative influence on the state of knowledge of the specific behaviour of timber in the building sector.

OUTLOOK

Average real annual growth for the period 1992-1995 is estimated at 2.9% for consumption and 3.4% for production. Extra-EC exports are expected to decrease by 1.4% annually until 1995.

The increasingly stringent requirements with respect to health and environment will increase the costs of the industry. Additionally, European standardisation may lead to increased extra-EC imports. Nonetheless the implementation of European standards will have a beneficial impact on trade between Member States. Furthermore, the agreement signed in May 1992 between the EC and EFTA, substantially increases the available market by creating a European Economic Area of 400 million consumers.

Written by: Cei-Bois
The industry is represented at the EC level by: European Confederation of Woodworking Industries (Cei-Bois). Address: Rue Royale, 109-111, B-1000 Brussels, tel: (32 2) 217 6365; fax: (32 2) 217 5904.

Sawing and first processing of wood
NACE 461

Although more than half of EC consumption of sawn, planed and dried timber is imported, the restructuring of the industry in the early 1980's has had a favourable impact on EC production, and may lead to a decrease in extra-EC imports in the 1990's. Structural changes have taken the form of increased vertical integration and/or the merging of small production units. This trend is expected to continue in the coming years.

INDUSTRY PROFILE

Description of the sector

The first stage in the processing of wood falls under NACE 461. This code groups the companies engaged in the following activities:

- saw milling;
- planing of wood;
- drying and seasoning of wood.

Main indicators

The improvement of the trade balance in 1991 was due largely to a sharper decrease in consumption than in production. As a result, imports (12%) decreased more than exports (7%) in 1991.

Production in 1991 amounted to 5912 million ECU and represented 17% of total production of the wood processing industry.

Employment has remained stable since 1988 at a level of about 80,000 people, representing 18% of total employment in the wood processing industry (NACE 46).

Recent trends

Apparent consumption, after a constant rise from 1985 to 1989, decreased in the beginning of the 1990's. Production rose sharply in 1988 (+12.4%) slowing considerably thereafter. Figure 3 illustrates the production of 1990, followed by weak growth in 1991 and 1992.

During 1985 to 1991, extra-EC exports declined at an average rate of 1% per year, a trend that is expected to continue in the coming years.

Foreign trade

The negative trend in the trade balance is reflected in the very low extra-EC export/extra-EC import ratio which has averaged 5% for the last decade. The share of intra-EC trade in total imports remains low albeit increasing slightly at the beginning of the 1990's.

Extra-EC imports mainly come from the EFTA countries (46% in 1991) and North America (21%). Although the import penetration rate remains very high (50.7%), EC producers have been successful in substituting extra-EC imports since 1984.

MARKET FORCES

Demand

Only 5% of EC production is exported while 8% of EC production is directed to the final consumer. The large majority of EC production goes to industry, more specifically to the pallets industry, the carpentry industry and the furniture industry. This situation will continue in the near future.

The maturity of the market has been masked by recent temporary effects, such as the economic growth in the eastern part of Germany and the huge projects that took place in Spain associated with the Seville exposition.

New products are emerging based on new techniques, such as gluing which will increase value added. There is important automatisation taking place in the large sawmills, and more specifically, in the softwood sector.

Supply and competition

Inside the European Community, there is strong local competition. In addition, there is significant pressure from foreign competition, more specifically in the saw milling sector which supplies the pallets industry, where cheap products are entering the EC market coming from Poland and Czechoslovakia. A considerable amount of imports are also coming from Scandinavia, North America and eastern Europe.

Factors such as lower labour costs, exchange rate developments (especially the US$), and the better availability of raw materials, play an important role in the competition taking place in EC and extra-EC markets. Factors such as higher produc-

tivity, trade practices, trade policies and technological advantages have only a marginal impact on competition.

INDUSTRY STRUCTURE

Companies

Some 3700 enterprises employing more than 0 persons operate in the first stage of the processing of wood in the EC as a whole. Altogether, about 80 000 persons were working in these companies in 1991. however, the sector is dominated by small and medium sized enterprises, so that total employment is likely to be considerably larger than the official figures.

Strategies

The investments that took place in the course of the 1980's contributed to the reorganisation of the industry, a necessity caused by the strong competition from non-EC producers. There were three main types of structural changes: the closure of non-profitable enterprises, the merging of small production units and an increased tendency towards vertical integration. Moreover, there is a growing demand for highly qualified personnel.

Investment focused on plant modernisation and existing investment projects. Investments are principally taking place inside the EC. There is a tendency for large companies to disinvest, mainly because of cash problems. Furthermore, there are a number of mergers and acquisitions taking place in the sector.

The main strategy for the enterprises of the first processing of wood is to produce goods with a higher value added. The enterprises tend to be subcontractors to the second processing of wood, instead of remaining simple raw material suppliers. By producing more custom-made goods for the second processing of wood, the EC enterprises are able to improve their competitiveness vis-à-vis extra-EC competitors.

Due to their geographical proximity, the enterprises of the first processing of wood can also respond in a more flexible way to the needs of enterprises of the second processing of wood (e.g. just-in-time delivery).

OUTLOOK

The decrease in consumption which began in 1991, will continue in 1992. In 1993, consumption will stabilise and increase slightly afterwards. Production, which has increased since

1985 (in constant prices), is expected to increase further in the period 1992 to 1995 at an average of 2.7% per year. EC production will continue to substitute for extra-EC imports. Extra-EC exports are expected to decrease as attention is focused on the EC market.

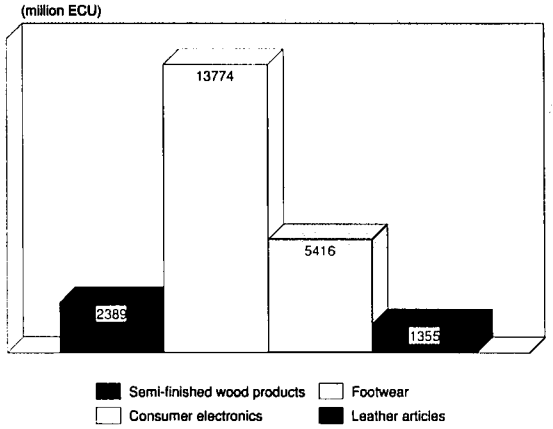
Written by: Cei-Bois
The industry is represented at the EC level by: European Confederation of Woodworking Industries (Cei-Bois). Address: Rue Royale, 109-111, B-1000 Brussels, tel: (32 2) 217 6365; fax: (32 2) 217 5904.

Semi-finished wood products

NACE 462

The manufacture of semi-finished wood products is the second largest woodworking sector, representing 23% of the total value of production in the secondary processing of wood. Approximately 1600 firms are involved in the manufacture of semi-finished wood products, employing about 67 000 people.
The average annual growth rate for the period 1992 to 1995 is estimated at 3% for consumption and 3.2% for production.

Figure 1: Semi-finished wood products Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

This group mainly covers wooden board material (particleboard, fibreboard, and plywood), which is in turn used as an intermediate product in the furniture industry or in building (the 'industry' circuit), or as a finished product (the 'do-it-yourself' circuit). Besides raw boards, there are also surface improved panels (boards covered with veneer, PVC or melamine resin impregnated paper).

NACE 462 also includes the enterprises that impregnate wood with chemical preservatives.

Main indicators

Apparent consumption in current prices amounted to 9 648 million ECU in 1991. Total consumption of raw wooden board material is divided into particleboard at 45%, fibreboard at 32% and plywood at 23%. EC particleboard is leader of the semi-finished wood products.

Production represents 23% of total production of the wood processing industry. Particleboard production in value represents about 50% of total production of wood based panels in the EC. In volume, the share of particleboard in total production is about 80%.

This sector employed 67 000 people in 1991, which represents 15% of total employment in the wood processing industry.

Recent trends

Apparent consumption in constant prices has increased constantly since 1982. In 1991, consumption was 25.6% higher than in 1985. Production has followed the same pattern (except for a decline in 1986), as have extra-EC exports (except for 1990 and 1991 when there was a slight decrease in exports). On the other hand, employment decreased from 1983 to 1986 and then stabilised at a level of about 67 000 persons.

Foreign trade

The EC trade balance, which steadily deteriorated from 1982, improved for the first time in 1991. The share of intra-EC trade in total imports reached 46% in 1991, following steady improvement during the last ten years.

The ratio extra-EC exports/extra-EC imports has remained stable during the last few years, with exports representing about 23% of imports.

The EFTA countries are the major trading partners for the subsector of the semi-finished wood products.

MARKET FORCES

Demand

The important gap in the particleboard market between production capacity and demand has made it very difficult for manufacturers to recover their heavy investments costs. Chipboard production is practically fully automated and the investment threshold, especially for the continuous lines, is high. Important modernisation and concentration has taken place during the last few years and the industry has reached a very high level of technology and efficiency. This ensures that the industry continue to match high quality standards and growing competition in the near future.

The trend in the buyer's preference has been to replace solid wood, tropical wood, plastics and other wood based panels by medium density fibreboard (MDF), especially for furniture manufacturing. MDF acts as a good substitute material for more expensive types of solid wood. Thin MDF is a strong competitor and a potential substitution product for thin plywood and hardboard. Since thin plywood is mainly produced in Indonesia, European competition is not affected by it.

The development of new applications will continue to gather momentum. Since the extension of the thickness range, and the improvement of moisture resistance and fire retardance, more and more applications are opening in construction, furnishing and interior fitments. The possibility of forming MDF into moulded parts is the latest innovation in the field of MDF technology. The door industry is increasingly discovering the usefulness of MDF, and not only for door skins. Window frames are the next target area.

For plywood, the trends in buyer's preference remain stable. The sector has a saturated market due to substantial imports. There is little substitution occurring and the importance of product innovation remains negligible.

Oriented Strand Board (OSB) is a relatively recent type of wooden board material, at least in Europe. It is mainly used in the construction industry because of its mechanical properties. OSB also acts as a substitution products for plywood.

Supply and competition

Overcapacity has lead in many cases to the closure of mills. The EC industry has signalled its willingness to remain competitive. The necessary condition, however, is that extra-EC competitors respect the prevailing rules for international trade and competition. Large imports into the Community, from East European countries and countries benefiting from the Generalised System of Preferences (GSP), at very low prices are a real threat for the industry. The emergence of the single European market will be very difficult for the industry if imports from these countries are not controlled fairly. Pressure from foreign competition is favoured by exchange rate variations as well as less environmental friendly log harvesting methods. Pressure by foreign competition is also the result of low labour costs, trade practices and trade policies, such as dumping from countries of central and eastern Europe and the GSP countries or the US request in the context of GATT to reduce import taxes on wood to 0%. Technological advantages are not considered a factor affecting competition in EC and extra-EC markets.

Source: Eurostat

The deficit in the Community trade balance for semi-finished wood products is the consequence of large inexpensive wood reserves outside the EC (North America, Scandinavia and eastern Europe) and the huge import of plywood from North America and South East Asia and hardboard from South America and eastern Europe. For the plywood sector, the most important competitive advantages of the EC plywood manufacturers over the large single-product manufacturers in the USA and Indonesia is that the European industry specialises in the manufacture of small series of special, custom-made goods from very different types of wood.

For particleboard and MDF, there is a strong competition within the EC. For plywood and hardboard, there is a strong competition from outside the EC.

In the fibreboard sector the number of companies switching from the so-called wet to the dry process is expected to increase further due to strict regulations regarding environmental protection. Currently, replacement investment required to meet these regulations automatically results in an expansion of capacity, and hence may give rise to surplus capacity.

Oriented Strand Board (OSB) is mainly produced in the UK and France and the product has reached a high standard of acceptability in these and several other European countries. During this decade it is expected to become an important product in the European panel industry.

The realisation of the Single European market in 1993 offers many opportunities to the sector, as normally all barriers to trade will be removed. The creation of a European economic space could also contribute to the development of a flourishing market. Furthermore, the political events in the countries of central and eastern Europe and the resulting demand from radical economic changes, offer the possibility for further expansion of economic activities in the industrialised countries.

INDUSTRY STRUCTURE

Companies

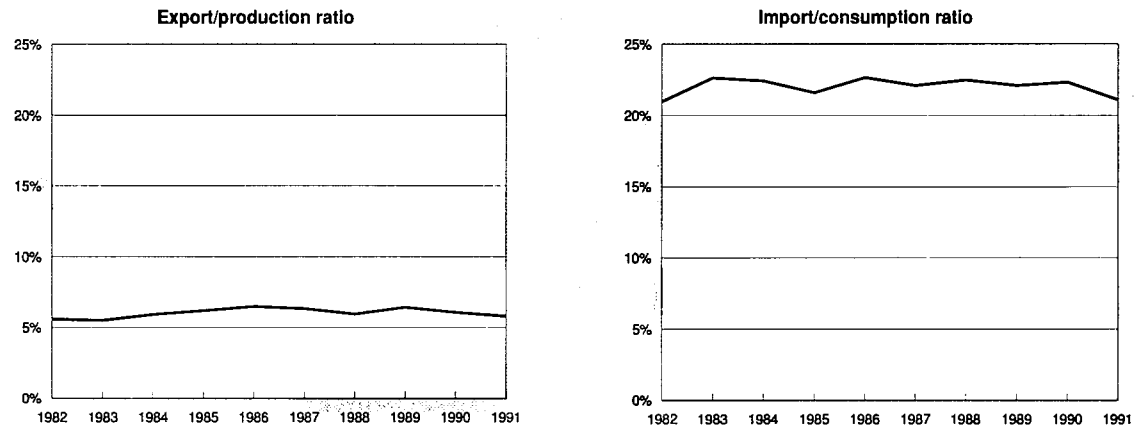
According to estimates about 1 600 firms are involved in the manufacture of semi-finished wood products. The particleboard industry accounts for about 120 companies, with an employment close to 20 000 persons. Total employment in the industry is around 68 000 persons, which means that the average number of employees per firm is 40, which is high compared to the other subsectors of the woodworking industry.

Strategies

The chipboard industry is a capital-intensive sector. Production is practically fully automated and the investment threshold, especially for the continuous production lines, is high. These circumstances imply that an average chipboard firm exceeds the SME dimension of the sector and that the added value in the case of this activity is lower than in the rest of the woodworking industry, where the high percentage of labour input raises the value added. The sector has gone through a major restructuring and it is apparent that concentration has taken place.

In the fibreboard sector, the nature of investment is to develop new products, to modernise existing products, to increase capacity and to switch to eco-friendly production methods (for example: converting from the wet process in the hardboard

Figure 5: Semi-finished wood products
Trade intensities



Source: Eurostat

industry to the dry process in the MDF industry). As far as firm structures are concerned, there are several new joint investments by board manufacturers (in France and Portugal) concerning MDF, but there are as yet no major changes in hardboard.

Until recently, the plywood sector was rather labour-intensive. Technological development and computer applications in production control and the operation of machinery have, however, lowered production costs to a great extent, and have at the same time enabled a substantial reduction in the percentage of wood waste. The sector is still highly suited to product diversification (with a greater utilisation of European wood species), certainly given the production methods that allow the manufacture of small series of special, custom-made goods. The nature of investments, carried out by the European companies themselves, is to modernise and to find new product developments.

REGULATIONS

Customs tariffs

The common external tariff on imports coming from outside the Community is the same for particleboard, fibreboard and plywood, and has been maintained for some time now at 10%.

The association agreements signed on 16/12/1991 between the EEC and Hungary, Poland and the CSFR changed the regulations formerly applicable to these countries.

Customs duties on imports applicable in the Community to particleboard and plywood originating in Poland, Hungary and the CSFR were abolished on the 1st of March 1992. Council regulation No 521/92 implies that fibreboard originating in Hungary, Poland and the CSFR will benefit from a suspension of customs duties on imports within the limits of annual Community tariff quotas amounting to 4.8 million ECU for fibreboard originating in Poland and the CSFR, and 8.05 million ECU for fibreboard originating in Hungary.

Annual import quotas on imports of particleboard and plywood originating in the Republics of Croatia and Slovenia and the Yugoslav Republics of Bosnia-Herzegovina, Macedonia and Montenegro, have been fixed from 1 January to 31 December 1992 by Council regulation No 545/92. This regulation was published in the Official Journal of the EC No L 63 of 7 March 1992. The annual ceiling for particleboard is 39,546 tonnes, while for plywood the annual ceiling reaches 153,925 m3. As soon as these ceilings have been reached, the levying of a customs tariff of 10% may be reintroduced by the Commission, by means of a regulation.

Table 6: Semi-finished wood products
Expected real annual growth rates

(%)	1992-93	1992-95
Apparent consumption	3.0	3.0
Production	3.2	3.2
Extra-EC exports	1.9	1.9

Source: Cei-Bois

OUTLOOK

Consumption as well as production in real terms for the sector of the semi-finished wood products is expected to grow in the coming years. The average growth rate for the period 1992 to 1995 is estimated at 3% for consumption and 3.2% for production.

In the particleboard industry, the outlook for 1992 is not a very optimistic one as depressed conditions continue in the Scandinavian countries and there are significant signs of slowdown in countries of central Europe, such as Germany. Only the relative optimism in the US economy as well as in the UK are likely to have positive implications.

In the fibreboard industry, the MDF industry represents a production potential of more than 3.5 million m3. In comparison to particleboard (30 million m3) and sawn timber (67 million m3), the share of MDF in the market of wood and wood products still appears quite moderate. Despite of this, the European MDF industry will increasingly open up export markets for its products outside the EC and EFTA, especially for special MDF boards.

The sector is facing a number of risks, including the additional costs associated with the increasingly stringent requirements with respect to health and environment, competition with imports, and the threat of overcapacity. However, the political reforms in the countries of central and eastern Europe offer an expansion potential of exports and possibly joint-ventures.

Wooden building components
NACE 463

The manufacture of wooden building components accounts for 42% of the production value of the second processing of wood, making it the main subsector in the European Community. It depends heavily on trends in the building industry. A substantial opportunity has emerged in the field of renovation work, making the sector less dependent on cyclical new building construction.

INDUSTRY PROFILE

Description of the sector

This sector, in the NACE definition, bears the title "manufacture of carpentry and joinery components and of parquet flooring". The sector produces wooden doors, frames, rafters, wooden façade components, partitioning and other walls, wooden screens, staircases, parquet flooring and glued laminates.

Even the "wood treatment" industry can be considered as belonging to a large extent to the building related sectors. This branch of industry, which was in the past principally geared towards the impregnation of railway sleepers and poles for electricity distribution and telephone connections, has to a large extent switched over to the delivery of protected wood for building and external uses.

Main indicators

Apparent consumption in current prices in 1991 amounted to 12.5 billion ECU.

Production increased by 6.8% in 1991 compared to 1990 to reach 12.2 billion ECU. Production of wooden building components represents about 35% of total production of the wood processing industry and 42% of the second processing of wood, making it the main subsector of the woodworking industry.

The EC-trade balance, which was positive in 1982-86, turned negative in 1987, and has worsened rapidly in the period 1988-91.

This sector employs about 163 000 persons, representing 45% of total employment of the second woodworking process.

Recent trends

In 1991, consumption in constant prices was 36% higher than in 1985, while production increased by 30%. Extra-EC exports, on the other hand, decreased by 17%. These exports started to decline in 1985, contributing to the progressive deterioration of the trade balance, and are expected to continue to decline in the coming years.

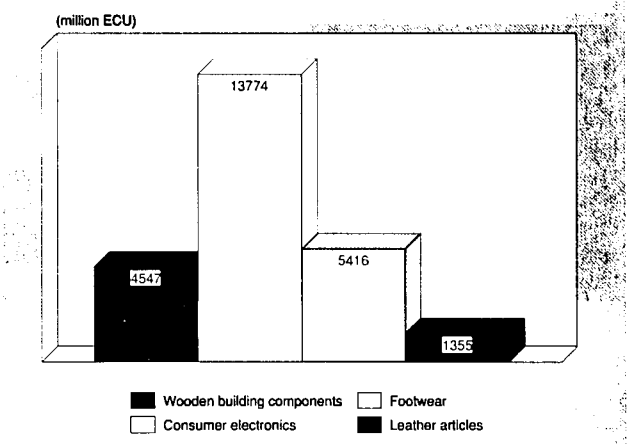
Employment has remained relatively stable since 1982 at about 162 000 employees, with the exception of the years 1985 to 1987 when employment slipped to 150 000 people. Employment is expected to increase in the future.

Foreign trade

The negative trend in the trade balance, which started in 1987, is reflected in the extra-EC exports/extra-EC imports ratio which, after being high in the first half of the 1980's, weakened considerably. In 1991, the exports/imports ratio was 55%, compared to the level of 168% achieved in 1982.

The share of intra-EC trade in total imports decreased compared to the beginning of the 1980's, declining to 50% in 1991.

Figure 1: Wooden building components Value added in comparison with other industries, 1991



Source: Eurostat

Extra-EC imports mainly come from the EFTA countries (46.7%), Yugoslavia (7.6%) and from the OPEC countries (7.5%).

MARKET FORCES

Demand

Demand in the sector depends heavily on trends in the building sector. The recent trend in buyer's preferences, in a market not confronted with saturation, is to use more softwood. During the past decade renovation has expanded significantly, and particularly the demand for wooden building components. This development has made the subsector less dependent on new building construction. In the market for the construction of private housing, the single EC market will not significantly impact the demand for building components, since well-defined regional markets will continue to exist within Europe. This is largely due to the specific climatic conditions and local building traditions and styles, rather than any specific standards laid down by the various local authorities.

Wooden joinery and parquet flooring in private housing has benefited from growing consumer demand in recent years.

Source: Eurostat

The demand for wooden building components is becoming more dependent on characteristics such as thermal and acoustic insulation, than the more traditional properties associated with wood, particularly in the non-residential building sector.

Supply and competition

International competition remains rather limited because of existing differences in climatic conditions and building traditions. Transportation costs are also a limiting factor for international trade, since most products are heavy and voluminous.

Nevertheless, pressure from foreign competition does exist, mainly due to lower labour costs. Other factors such as exchange rate developments, better availability of raw materials or technological advantages are less important.

The wood treatment industry is also considered to be a sector related to building. Treated wood is used in relatively new market applications, such as in agriculture, vineyards and horticulture, fruit-growing, enclosures, playgrounds and hydraulic engineering,. The significance of wood treatment for the general woodworking industry is especially apparent, since this process has enabled the use of wood to be possible in applications where previously rapid biological attacks have excluded its use. Thus wood is gaining market share from competitive building materials in non-traditional markets.

Products such as fire-resistant wooden doors may, initially, appear unusual. However, the high degree of dimensional stability of wood provides these doors with a competitive advantage over metal or synthetic products, since the latter deform more rapidly at high temperatures.

Producers of wooden window frames experience competition from substitution products made from other raw materials, such as aluminium and PVC. However, wooden frames still have the largest market share in the EC with 40%, well ahead of aluminium and PVC.

INDUSTRY STRUCTURE

Companies

The ideal enterprise for coping with specific climatic conditions and local building traditions and styles is a small to medium-sized enterprise that optimises its size in accordance with clearly determined geographical limits and technical specialisation.

Strategies

Recent investment has concentrated on modernising plant and increasing capacity (e.g. in Germany, due to the five new Länder). Investment is being predominately undertaken by the European producers themselves, foreign investment is not important.

Producers tend to specialise considerably and the sector is characterised by a lot of acquisitions, particularly in Germany.

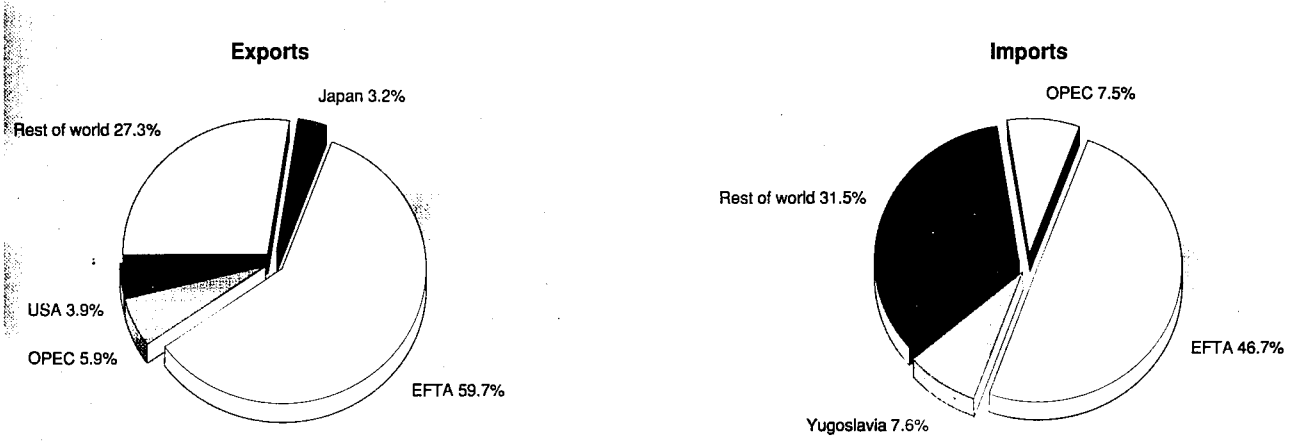
Most manufacturers of wooden building components work on a local or regional scale, because of the differences in climatic conditions and building traditions. However, by conforming to the European construction products directive, many enterprises will be able to expand their potential market to the European Community.

REGULATIONS

Very specific for wooden building components is the Council directive No 89/106 on the relationship of the laws, regulations and administrative provisions of the Member States to construction products, better known as the 'Construction Products Directive'. This directive entered into force in all Member States on June 27, 1991 and deals with the whole family of 'Construction products' instead of individual components. The directive states that a construction product is fit to trade if it can be proven that the product, when used in a construction, satisfies the relevant essential requirements.

There are six essential requirements for which the "Standing Committee on Construction", set up to implement the directive, is still preparing the "interpretative documents".

Figure 4: Wooden building components
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

Construction products fulfilling all essential requirements can obtain the CE-mark, which implies that they can be used and traded in all Member States without additional control.

To obtain the CE-mark, the product will have to either comply with a European standard or, in the case of new and innovative products, have technical approval. Standards for wooden construction products are being prepared within five technical committees of CEN, the European Committee for Standardisation. Technical approval will be issued by EOTA, the European Organisation for Technical Approval.

Before being able to implement the Construction Products Directive in practice, some major problems such as the reaction-to-fire performance of construction products still have to be solved and it is hoped that the system will be fully operational by the end of 1992.

OUTLOOK

Consumption in the EC for the period 1992-1995 is expected to grow annually by 5.1% (real growth rates). The average real annual growth rate for production for the same period is estimated to be 4.3%. As a result, extra-EC imports are expected to increase their market share. This may be compounded by the increasing standardisation at the European level which will lead to uniform products, and hence increase extra-EC imports.

Exports are expected to decline by 6.7% in 1992 and less severely in the following years.

In the future, European standardisation and the Single Market should give producers the opportunity to expand within the European market instead of depending on the local market. Activity in the renovation market will ensure the sector is less dependent on the cyclical new construction industry.

Other wood products
NACE 464, 465, 466

Production and consumption in the industry have improved consistently since 1982 despite increasing competition from the low wage producers of Eastern Europe and the Far East. The industry is characterised by a large number of SMEs with relatively stable employment. There has been significant investment in recent years to automate as much of the production process as possible in order to compete more effectively with imports. However, the trade balance has continued to deteriorate.

INDUSTRY PROFILE

Description of the sector

This chapter covers several of the smaller subsectors of the woodworking industry. The most important is wooden containers (Nace 464) which comprises boxes, crates, pallets, barrels, cable drums, etc.

Nace 465 groups together miscellaneous wood manufactures. The most important products are wooden frames for paintings, photographs, mirrors and similar objects.

Nace 466 includes the manufacture of articles of cork, basketware, wickerwork and other articles of plaiting materials (except case and wicker furniture) and the manufacture of brushes and brooms.

Main indicators

In 1991, the current value of production of these subsectors added up to 9.1 billion ECU, which represents 21.3% of the total production of the woodworking industries (excluding wooden furniture).

The sector is very labour intensive, more than some of the other woodworking sectors. Employment amounted to 127 612 or 29.3% of the total employment in the woodworking industries in 1991, proportionally more than its 25% share of total production of woodworking industries.

Wooden containers and pallets account for 3.1 billion ECU or 34% of the production of the "other wooden products" sector. This compares to a brushes and brooms production of 0.9 billion ECU (10.0% of "other wooden products"). While on average the sector exports some 10% of its output to markets outside the EC, exports of wooden containers remain limited as shown in Table 2.

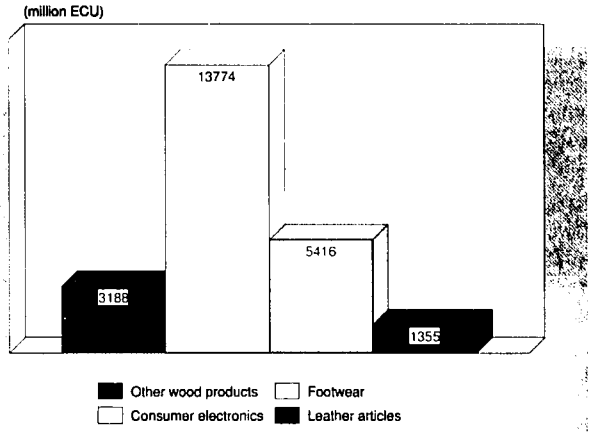
The value added of these subsectors adds up to 3.2 billion ECU, roughly one-third of the consumer electronics industry. The breakdown by Member State is shown in Figure 2.

Recent trends

Apparent consumption grew constantly during the period 1982-91. Until 1986, however, this growth was rather limited. From 1987 until 1989, there was an important increase in the level of consumption, followed by moderate growth in 1990 and 1991.

EC producers were initially slow to react to the upswing in consumption, however, and there was a remarkable rise in extra-EC imports in 1987. EC production responded to strong demand at home with big increases in 1988 and 1989 . Extra-EC imports, however, have been taking a continuously higher share of EC consumption since 1987. Extra EC-exports, on the other hand, were still at the same level in 1991 as in 1985.

Figure 1: Other wood products
Value added in comparison with other industries, 1991



Source: Eurostat

Employment declined steadily from 135 439 in 1982 to 122 589 in 1988. There was an important rise in employment in 1989, followed by a slight decrease in 1990 and 1991.

Because of the slowdown in economic growth and international trade, demand for wooden containers decreased in 1990 and 1991.

Foreign trade

Although most of the subsectors dealt with in this chapter are exposed to strong competition from extra-EC low wage countries, the import penetration ratio is relatively low at about 13% in 1991 up from 11% in 1982. The share of production that is exported to non-EC markets has averaged a steady 10% throughout the eighties.

External trade in wooden containers and pallets is of limited importance but has nevertheless increased noticeably since 1989. Extra-EC imports now cover 2% of the consumption of wooden containers and pallets. These increased imports mainly consist of cheap pallets made in East European countries, like Poland, Hungary and Czechoslovakia.

The trade balance for wooden containers and pallets, which was still largely positive at the beginning of the eighties, has gradually worsened and showed only a very small surplus in 1991.

Most trade (62.3%) takes place within the EC. This figure might be overstated, however, as some international movements of pallets are "invisible" since consignments of empty pallets are included in the customs statistics, whereas loaded pallets are not.

Although the EC brushes and brooms industry is experiencing severe competition from China and Eastern Europe, the external trade balance remains positive. Differentiating with regard to product lines, there is a positive trade balance for industrial brushes, paint brushes and rollers, domestic brushes and brooms. The trade balance is negative for toilet brushes and fine hair brushes. Articles of plaiting materials are mainly imported from countries in the Far East, such as South Korea, Taiwan, the Philippines.

MARKET FORCES

Demand

Since the products dealt with in this chapter are very heterogeneous, these products have different types of buyers, i.e. industry or final consumers.

Wooden containers are mainly bought by industry. Here, demand for these products relies on demand for other products which are transported and stored in containers or on pallets. Since most products can be transported either in a wooden container or on pallet, demand for these packaging materials depends largely on the general macroeconomic situation.

Since trade, intra-EC as well as extra-EC, is intensifying, there is a potential stimulus for sustained growth for the sector of transport-related packagings like wooden containers and pallets. For the moment, however, demand for wooden containers is rather weak due to the slowdown in economic growth and international trade.

Wooden containers are used to improve manoeuvrability of goods during their transportation or storage.. This requires light structures that are able to withstand rough handling. Standardisation of pallet dimensions makes them highly suitable for repeated and different uses.

With the exception of industrial brushes, most brushes and brooms are bought by final consumers. Industrial brushes are sold by direct sales contact between the supplier and the in-

Source: Eurostat

dustrial client. Personal hygiene products (tooth-brushes, hair-brushes, and make-up brushes) are distributed by specialist chains, pharmacies, and supermarkets. Household brushes are usually offered to individuals by supermarkets; the same applies to paint brushes and rollers. It is worth noting that large distribution centres also import products directly from outside the EC.

Wooden frames for photographs, paintings, mirrors, etc. are also mainly destined for final consumers. These products are distributed by large distribution centres as well as by small specialised businesses, like photographers, art galleries and gift shops.

Demand for bottle corks comes from the wine, champagne and beer producers. Cork is also used for insulation and, recently, for flooring.

Supply and competition

Since 1990 demand for wooden containers has weakened due to the general slowdown in economic growth and international trade, putting pressure on supply to lower profit margins.

For all the subsectors under observation, internal EC competition remains rather limited. Foreign competition from extra-EC countries, however, is fierce in all product lines. The major extra-EC competitors are not the other industrialised countries like USA and Japan, but low wage countries in the Far East and Eastern Europe.

It is clear that lower labour costs are the main competitive advantage of these extra-EC competitors. They also have a lower regulative burden (lower social and environmental costs).

Because of the relatively low degree of complexity of the production process, it is difficult for EC producers to realise technological advantages. Even with the highest possible level of automation, the lower labour costs of the extra-EC competitors is often of overriding importance, especially when combined with dumping practices. The EC brushes and brooms sector has already been involved in anti-dumping procedures regarding Chinese brushes.

Since 1990, there has been a sharp rise in the imports of pallets from Eastern Europe (especially Poland) at extremely low prices that barely cover transportation costs. These imports are a serious threat for the survival of EC pallets producers. European standardisation of pallet dimensions, however, has led to increasing extra-EC imports.

Most of the extra-EC imports of brushes and brooms come from China and Eastern Europe. China has a quasi-monopoly where imports of paint brushes are concerned. Imports of brushes from China and Eastern Europe have disrupted EC production on more than one occasion. Products from these countries are often offered at dumping prices. The EC industry hopes that trade agreements with these countries as well as certain structural changes in their markets will rectify the situation.

Availability of raw materials often plays an important role, too. China has a quasi-monopoly for pig hairs, used in paint brushes. Articles of straw, cork and other plaiting materials are mainly imported from South-East Asia. Eastern Europe has large reserves of wood that is suitable for the production of pallets.

Production process

The raw materials used for the production of wooden containers and pallets are mostly local types of wood. Pallet dimensions have, to a large extent, been standardised. The handles of brushes and brooms are mostly made of wood or plastic. The hairs can be synthetic fibre, animal (pig hair) or vegetable (coconut fibre).

Although the degree of complexity of the production process is relatively low, some automaton is possible. During the second half of the 1980's, the wooden containers sector undertook important investments in automation and rationalisation.

Because of external competition, EC producers of brushes and brooms need to acquire high-performance machinery. The automation of production means acquiring high-performance machines which introduce the fibres, attach them to the frame and adjust the packing material all in one cycle. In this way, toothbrushes and nail brushes, etc. can be produced in very large quantities. With these types of brushes, the packaging and labelling operations are also performed automatically. The manufacture of paint brushes, particularly fine brushes, is less automated, although here too, significant progress has been made.

The workforce still has an important role to play in the case of certain operations (for example, the manufacture of paint brushes). In addition, automation has generated an increasing need for people with technical knowledge of machines and tools.

INDUSTRY STRUCTURE

Companies

Most of the enterprises in these subsectors are SME's. The number of enterprises employing more than 20 people is estimated at 5200 of which 1400 are in the wooden containers sector. Among the subsectors dealt with in this chapter, wooden

containers is the most capital-intensive. The size of the enterprise is also relatively larger.

Strategies

The major strategy for all the enterprises of these subsectors is to rationalise and automate the production process as much as possible in order to be able to face the competition from extra-EC low wage countries.

For the producers of wooden containers, specialisation in custom-made packagings helps to minimise competition from low wage countries which mainly produce standardised products. Because of geographical proximity, EC producers can respond in a more flexible way to the needs of their customers (i.e. special dimensions, just-in-time delivery).

Producers of wooden containers and especially pallets are working out systems for recycling (see also environmental section in overview). This should provide them with a competitive advantage over the producers of plastic and metal pallets.

REGIONAL DISTRIBUTION

The firms in the wooden containers industry are mostly located in the vicinity of available raw materials and/or major transport centres, such as harbours and airports. The brushes and brooms industry is mainly concentrated in Germany (33%), UK (23%), Italy (17.5%) and France (16.5%). Portugal is the most important producer of cork.

OUTLOOK

After a slowdown in 1991 and 1992, production and consumption will grow at a steady pace. It is expected that consumption will grow faster than production. This means that extra-EC imports will increase their market share. Extra-EC exports, on the other hand, will probably diminish.

The risks for the wood product subsectors are increasing imports from low wage countries in the Far East and Eastern Europe and from European standardisation which may lead to increasing extra-EC imports (i.e. pallets). Opportunities for EC producers will come from specialising in custom-made packagings, work out systems for recovery (energy recovery, production of particleboard, repeated use, etc.) and environmental measures (i.e. CO_2 tax) which will affect production of wooden products less than production of substitution goods in other materials (i.e. plastic, metal), which are more energy-consuming.

Pulp, paper, printing and publishing
NACE 47

The EC pulp, paper, printing and publishing sector has undergone notable changes over the past decade. All the branches of the sector are moving towards a more international structure, through concentration. The international slowdown curbed activity growth in the sector in 1990 and in 1991. High interest rates increased the cost of capital investment in the upstream subsectors of the industry such as pulp and paper production. Downstream, the publishing sector experienced lower returns on advertising, while book sales stagnated. The whole industry is increasingly affected by environmental legislation and consumer action. Despite these challenges, the industry is expected to grow by around 3 to 4% in the next few years.

INDUSTRY PROFILE

Description of the sector

The pulp, paper, printing and publishing industry includes the production of pulp, paper and board (NACE 471); the converting of paper and board (NACE 472); printing and allied industries (NACE 473); and publishing (NACE 474).

Pulp, paper and board production covers all manufacturing of paper and board products from virgin pulp or waste paper. Paper and board converting covers all subsequent processing of paper and board products into packaging, stationery and hygienic products. Printing and publishing covers all activities related to the manufacturing and selling of books, magazines, newspapers, brochures and other printed matter.

Main indicators

In 1991, production of the pulp, paper, printing and publishing industry rose by 5.4% in value and by 2.6% in constant prices. The increase in consumption of 2.8% in 1991 in real terms, was slightly stronger than the expansion in production. Consumption decreased in Benelux, Denmark and France. All other countries experienced growing consumption, notably Germany, Italy and Spain.

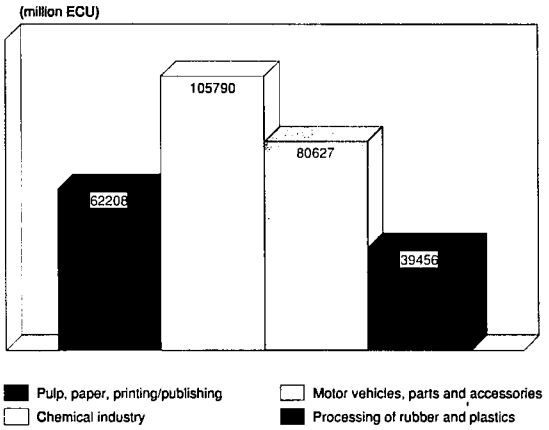
Recent trends in employment in the pulp, paper, printing and publishing industry show diverging developments among the EC member states. In 1991, employment increased in Germany, Greece, Spain and the Netherlands, but decreased in France and Italy. A major reduction of employment took place in the United Kingdom where 18 000 jobs or almost 5% of the sector's workforce were lost. Nevertheless, employment in the EC for the sector as a whole went up by 2.7%.

As shown in Figure 2, Germany, France and the United Kingdom have the largest pulp, paper, printing and publishing industries in the EC.

Recent trends

After averaging growth rates of 4% in real terms between 1982 and 1985, EC production growth in the pulp, paper, printing and publishing industry picked up to more than 6% annually in 1989, before moderating in 1990 and 1991. Real consumption growth followed the same trend as that of production. This slowing trend was particularly evident in the paper converting, and the printing and publishing subsectors while output growth continued to rise at a relatively fast pace in the pulp and paper subsector.

Figure 1: Pulp, paper, printing and publishing
Value added in comparison with other industries, 1991



Source: Eurostat

Restructuring throughout the industry led to a 6% reduction (80 000 units) in employment over the 1982-1986 period. However, high level in activity since mid-eighties has more than offset this decrease with annual gains in employment averaging 1.4% between 1985 and 1989 (versus declines of 1.3% for the period 1982-85). Overall, 88 000 jobs were created between 1986 and 1991 in the pulp, paper, printing and publishing sector.

International comparison

Although they are mostly smaller than their competitors in the USA and in Scandinavia., EC manufacturers have built up a large and viable industry in the pulp and paper production and in the converting sectors.

Total EC output in the pulp and paper industry amounted at 48.7 million tonnes in 1991, of which 10.7 million tonnes of pulp and 38 million tonnes of paper. Total EC output was less than half of US output but was 20-25% higher than the Canadian and Japanese. EC output in the paper converting industry is closer to that in the USA: 40 billion ECU against 52 billion ECU. In printing and publishing, total EC sales of

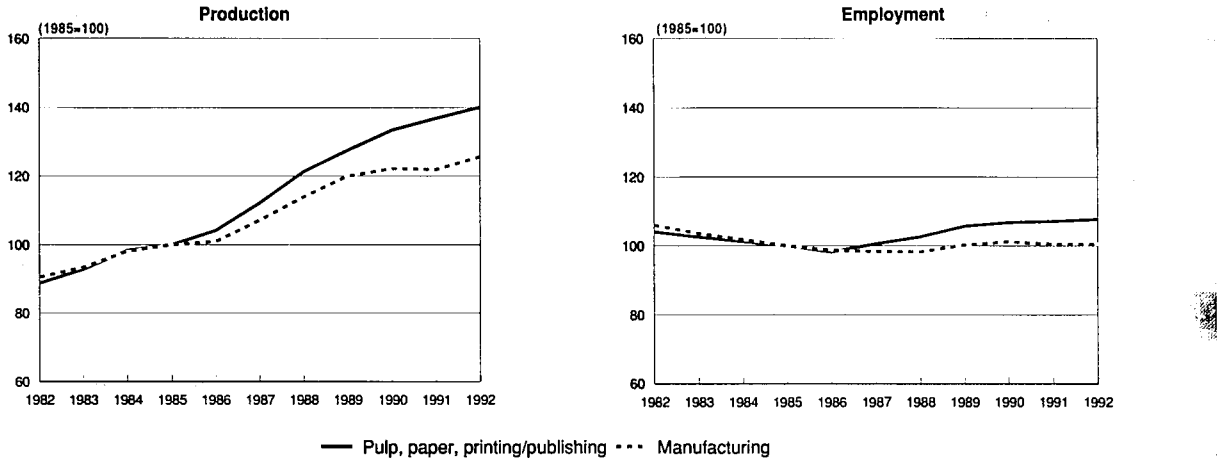
Figure 3: Pulp, paper, printing and publishing
Production and employment indices compared to EC manufacturing



1992 are estimates
Source: Eurostat

90 billion ECU are more than two thirds of the roughly 130 billion ECU US sales in this industry. Due to language and cultural diversity, the EC publishes about five times more book titles a year than the USA.

Foreign trade

The 10 billion ECU trade deficit for the sector as a whole is due entirely to the 13 billion ECU trade deficit in pulp and paper products. Paper converting shows a slight 0.3 billion ECU trade surplus and printing and publishing activities generated a 4 billion ECU trade surplus.

In 1991, the trade deficit of the EC pulp, paper, printing and publishing industry decreased by 5% or 500 million ECU. The improvement in the trade deficit came primarily from weakening import growth. EC export growth has been steady since 1986. Imports, on the other hand, which were expanding at double digit growth rates in 1988 and 1989, decreased for the second year in a row in 1991.

Most EC exports continued to be oriented to EFTA countries. Since 1986, exports to the USA have decreased by almost 30%. The EFTA countries are an even more important supplier to the EC accounting for nearly 70% of EC imports. These imports are primarily pulp and paper related products from Sweden and Finland. Since 1986, however, the EFTA's share in total imports has decreased slightly, partly as a result of direct investment in production facilities in the EC.

Intra-EC trade has stabilised since 1990 after growing steadily since the early 1980s. High domestic EC trade growth in the paper converting and in the printing and publishing sectors has been offset by decreasing trade volumes in pulp and paper production.

MARKET FORCES

Demand

Demand for paper products is strongly related to GDP growth. Stationery and packaging products are principal supplies to the service sector (offices, transport and distribution) and as such they directly reflect performance in these sectors.

In the early 1990s, demand for periodical printed matter has been affected by decreasing advertising revenues. The book sector is suffering from saturation in the markets of Northern Europe. Some expansion could still be generated in southern Europe.

Supply and competition

The booming 1980s led to large investments in the pulp and paper production facilities. With the slowdown in activity in the late eighties, however, these sectors experienced overcapacity in several paper and board grades as well as in market pulp. These very new and advanced paper mills are expected to be fully used when the economic activity picks up in the early to mid-nineties.

As in all oversupplied markets, prices have been put under downward pressure. The pressure on pulp and paper prices has had obvious effects in the paper converting industry, increasing competition among the converters. Clients, in foodstuffs-packaging in particular, were increasingly organised on a pan-European scale in order to strengthen their standing in negotiations with paper converters.

As a result of stagnating book sales, various publishing houses are suffering from overcapacity as well. Average print runs for major book releases have been gradually reduced and a number of glossy magazines have not survived the economic slowdown of 1990-1991. Revenues of daily newspapers were

further eroded by the drain of advertising money to the audio-visual media.

INDUSTRY STRUCTURE

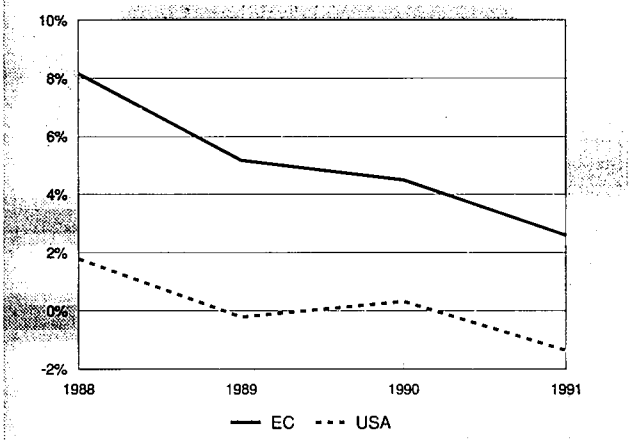
Companies

Several acquisitions by Scandinavian giants such as STORA, SCA and Kymmene have reduced the number of main EC pulp and paper producing and converting companies. These major firms now own 50% to 60% of the EC paper production capacity. Some of the remaining EC companies have merged, such as Arjo Wiggins. Others, such as KNP, might consider merging with EC partners in the near future. The existence of large international companies do not prevent a large number of small and medium sized companies from thriving.

The EC printing and publishing market is dominated by the German Bertelsmann and the French Hachette. Both are world players in their field. Yet, most of the EC industry is fragmented in line with national markets. There has been some degree of concentration, but within national borders.

Regarding the sector as a whole, the EC market is also fragmented: the top 500 companies represent only 34% of total turnover and 29% of total employment. 80% of all companies have less than 10 employees, and 40% of sales are generated by companies employing less than 100 employees.

Figure 5: Pulp, paper, printing and publishing International comparison of production growth at constant prices



Source: Eurostat

Strategies

The strategies of major EC companies in the pulp and paper production and converting sectors are mostly aimed at further integration. Spurred on by their Scandinavian competitors, many of them have diversified throughout the paper production chain. The only area that the EC has hardly touched is forestry, due to the absence of large wooded areas within the Community. This could change somewhat when forestry of fast growing eucalyptus wood in the southern EC countries picks up.

Small and medium-sized EC paper companies tend to carve out niches in highly specialised areas with high added value production. They produce high quality paper and board grades and related products for special applications. Their main focus is to install the latest equipment which facilitates flexible and high quality production. Flexibility is crucial in a market with rapidly fluctuating profit margins on the different paper grades.

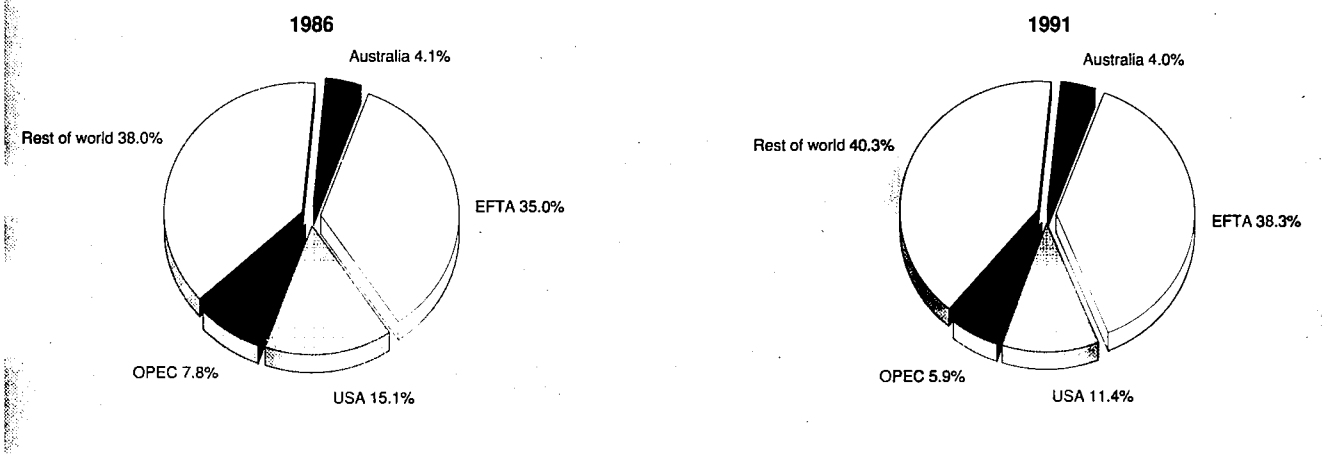
EC printing and publishing companies aim for further concentration and globalisation of activities. Among others, this implies an appropriate response to the new technological challenges of the audio-visual media. Some of the major publishing houses, Bertelsmann and Hachette notably, want to become global multimedia groups in line with their biggest competitor, Time-Warner in the USA. Publishing increasingly includes not only printed matter but also, electronic news services, CD-ROM information and interactive CDI devices.

REGIONAL DISTRIBUTION

EC pulp production is concentrated in the United Kingdom, Belgium and Italy (around 600 000 tonnes per year), Spain and Portugal (around 1.4 million tonnes per year) and Germany and France (about 2 million tonnes per year). The main paper grades such as newsprint and supercalendered paper are largely produced in Germany, France, Italy and the Netherlands. Paper and board converting takes place mostly in the three major EC member states, the United Kingdom, France and Germany. Some foodstuffs packaging related activities are located in agricultural areas.

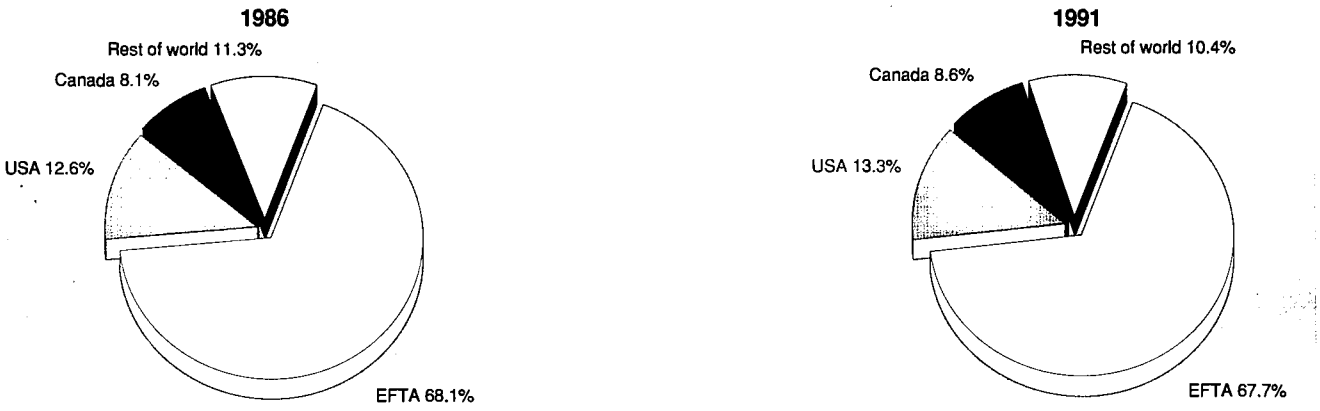
Printing and publishing activities are by nature distributed throughout the Community. Even the ongoing concentration of ownership in the sector has had relatively little effect on

Figure 6: Pulp, paper, printing and publishing Destination of EC exports



Source: Eurostat

Figure 7: Pulp, paper, printing and publishing
Origin of EC imports



Source: Eurostat

concentration of local printing and publishing facilities so far.

Due to the growing predominance of the English language, notably in academic publishing, the UK market is crucial for EC publishers. Many continental publishing houses are thus boosting their presence in the United Kingdom by acquiring local companies or by setting up new UK subsidiaries.

ENVIRONMENT

A number of ecological issues directly affect the business of the paper production and converting industries. Most importantly, the paper production industry faces EC and national legislation on waste paper recycling and on emission controls in the production processes. The paper converting industry faces an EC packaging and packaging waste directive which sets minimum recovery and recycling rates for packaging material. EC manufacturers are gearing up to reorganise production and distribution in such a way that these requirements can be matched.

The publishing and printing industry is not directly affected by this legislation, but it does feel the pressure from public campaigns for greater consumer awareness. As a matter of policy some publishers of magazines and corporate presentations have decided to use 'environmentally friendly' paper to show off an innovative image.

OUTLOOK

The coming years will probably bring moderate improvements to the various segments of the pulp, paper, printing and publishing industry. The overcapacities built up in pulp and paper production will fade out as soon as demand will picks up sufficiently. This cyclical phenomenon is strongly influenced by general economic growth, which is generally expected to pick up by 1993. In order to cope more efficiently with fluctuations in the markets for various paper grades, producers will have to use more flexible production techniques.

Demand for the paper converting industry could benefit from emerging market economies in Eastern Europe, while low costs in production and in distribution in this area could prompt companies to transfer production units from western to eastern countries.

One of the most significant challenges for the coming decade will be the industry's response to new EC and national environmental regulations, as some of them, like the EC packaging legislation could fundamentally alter the market for these products.

The printing and publishing sector is also showing signs of maturity. The period of high growth is over, and the main strategies focus on consolidation and restructuring. It now appears that new electronic media will not replace but rather complement the written media. Nevertheless, a redistribution of revenues and investments will inevitably favour the audio-visual sector at the expense of the traditional industries.

Pulp, paper and board
NACE 471

The performance of the pulp, paper and board industry in 1991 compared positively with other industrial sectors, although it fell short of the high growth rates recorded in the 1980s. Regarding the restructuring process, 1991 was quiet, but it was only an interlude to the expected resumption of wide-scale mergers and acquisitions in the coming years. The three key issues facing the industry were overcapacity, world trade and the environment. Persisting overcapacity in production continued to put a downward pressure on prices in 1991. As a result, new production facilities were not fully used, and plans for major investments were postponed. The emergence of new markets in Eastern Europe and the creation of new trading blocs in North America and Europe continue to modify the picture of world trade. Environmental legislation and public action of pressure groups are becoming the main concern for the sector. The future performance of the paper and pulp industry will depend on its ability to address these concerns.

INDUSTRY PROFILE

Description of the sector

The products of the industry are divided in three categories: pulp, paper and board.

Market pulp is woodpulp for paper making produced for sale in competition with similar pulp from other producers. It excludes pulp for use by the producing mill or other mills which it owns or controls, situated in the same country. However, it includes pulp shipped to affiliated firms in other countries.

Paper and board comprises products as printing and writing paper, sanitary and household paper, wrapping and packaging paper and board, and various sorts of specific quality paper.

The final use of these products is mainly threefold: in communications, for printing, writing and drawing; in the packaging industry, for transportation, storage and presentation of traded goods; and in a variety of special applications, like hygienic paper, nappies and fiduciary paper (money, cheques), or technical use in filters and insulation.

In this monograph, paper and board together will always be referred to as "paper".

Main indicators

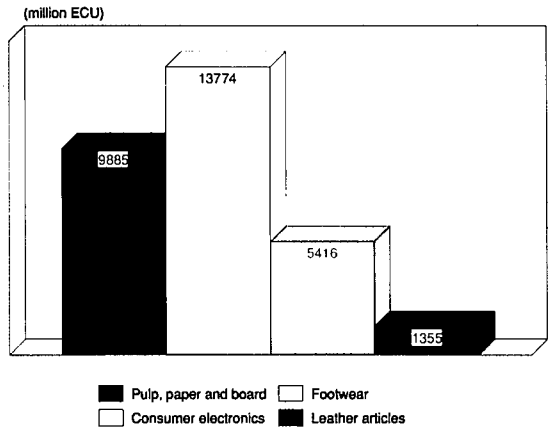
Production in current prices rose by 2.9% in 1991, after nearly 4% in 1990. Germany is the main EC producer, followed by France, the United Kingdom and Italy. The breakdown by major product line shows the importance of waste paper, which accounted in 1991 for about 60% of total production value of the industry, followed by chemical pulp and mechanical pulp with 17% and 11% respectively.

Employment in the sector suffered from the slowdown in production, with a reduction of 2 000 jobs (1%) in 1991. The breakdown by country shows that employment decreased in most EC countries except in Germany and in the Netherlands, where it rose by 1.6% and 3.1% respectively.

Recent trends

After experiencing 7% and 8% growth in 1987 and 1988 respectively, real production in the pulp and paper sector slackened to 4% in 1989 and 1990, before rallying to 5% in 1991. As a result, the industry grew by 5.4% over the 1985-1991 period, against 4.8% over the 1982-1985 period. Between 1982 to 1991 total output in the pulp and paper sector rose faster than EC manufacturing as a whole: 5.2% against 3.4%.

Figure 1: Pulp, paper and board
Value added in comparison with other Industries, 1991



Source: Eurostat

The trend of employment contrasted with that of production. The number of jobs in the pulp and paper sector decreased steadily since the first half of the 1980s (except in 1988 and 1990, as a result of the upward phase of the business cycle), from 208 800 in 1982 to 186 200 in 1991, a level which has more or less since been maintained. This plummeting of employment in the first few years of the 1980s illustrates the deep restructuring process which occurred in the sector.

International comparison

In 1991, total EC pulp production stood at around 10.7 million tonnes, while paper production reached 38 million tonnes. With 48.7 million tonnes in 1991, the EC is the world's second largest producer of pulp and paper, after the USA (130 million tones). Japan and Canada followed, with 40.7 and 39.7 million tonnes respectively. As far as pulp is concerned, the EC is only the fifth largest producer in the world after the USA, Canada, Japan and Sweden. On the other hand, the EC is the second largest producer of paper after the USA, and followed by Japan, Canada, Finland and Sweden.

Foreign trade

Despite the international economic slowdown, EC exports of pulp and paper bounced back by 4% to 2.5 billion ECU in 1991. Although import volumes rose in 1991, imports fell by 4%, as a result of a drop in imports prices of more than 7%. Intra-EC trade grew rapidly in the second part of the 1980s to reach double the 1982 value in 1991. The ratio of extra-EC imports/EC consumption remained relatively constant.

The EC pulp and paper industry has a widespread range of export markets. The EFTA countries hold the largest individual share of extra-EC exports (28.6% in 1991), followed by the USA (13.1%), whose share has decreased by about one quarter since 1986. As for extra-EC imports, the EFTA countries, in particular Sweden and Finland, account for about three quarters of total imports, a share which has remained stable over the 1986-1991 period. The only significant variation in supplies was the rise of Canada as second largest exporter to the EC.

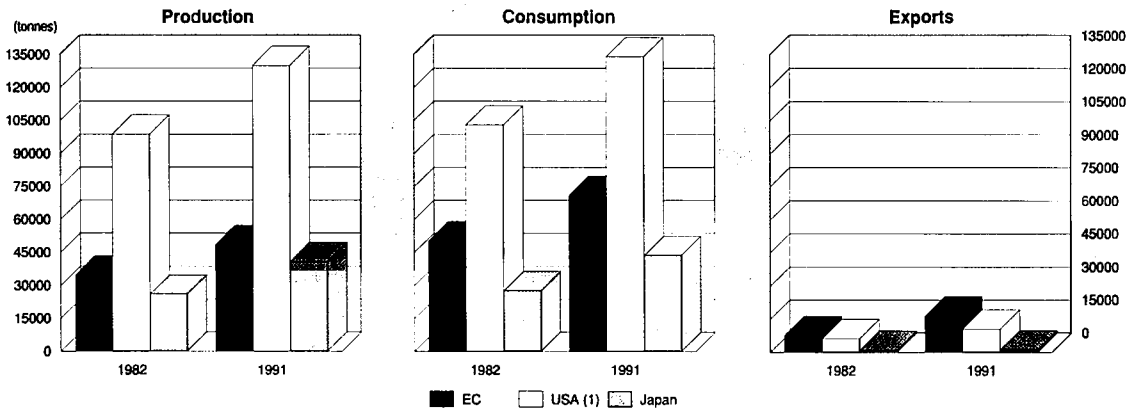
MARKET FORCES

Demand

The principal customers of the paper and board production industry are the paper and board converting industry, the printing industry and final consumers. The market power of these three groups in influencing prices has inevitably grown with the current oversupply on the market. In particular, the market power of the printing industry and final consumers is increasingly demonstrated in the field of environmental issues. Effective campaigns by green pressure groups are forcing the paper and board production industry to adapt to new standards.

Despite the boom in German demand of pulp and paper due to the unification process, demand in Western Europe slackened in 1991, in line with the general slowdown in activity. In the United Kingdom, growth in domestic demand was even negative. The German market continued to be the largest European market, and the fact that no kraft pulp production is allowed in Germany still generates considerable imports of these raw materials. The EC is the largest single importer of

Figure 4: Pulp, paper and board
International comparison of main indicators in volume



(1)1990 figures rather than 1991
Source: CEPI, API, CCPA, PPI

pulp in the world. A short description of the activity for each subsector is given below.

Newsprint

Newsprint is largely made from waste paper and mechanical pulp. Although belonging to the category of uncoated graphic papers, newsprint can be lightly calendered, for instance in order to facilitate the increasing use of colour in newspaper advertising. Newsprint is used in letterpress, flexographic or offset printing. Newsprint consumption is directly related to the revenues of printed advertising. In this respect, depressed spending on advertising in 1991 led to lower demand for newsprint. In Western Europe (EC and EFTA), apparent consumption of newsprint went down by 1.4% in 1991 compared with 1990. Production fell even sharper, by 5%.

Uncoated graphic paper

These grades include directory, heavily filled and supercalendered paper. They are used in rotogravure and offset. A distinction is made between uncoated mechanical and uncoated woodfree graphic paper. Production and consumption of uncoated mechanical slightly decreased as did the trade volume. On the other hand, production in uncoated woodfree in the EC and EFTA increased by 4.4% in 1991, while consumption rose by 3.9% and exports by 5.6%.

Coated graphic paper

A distinction is made between coated mechanical printing paper and coated woodfree printing paper. The coated mechanical grade is made with a mixture of mechanical and chemical pulp and used to print catalogues, magazines and advertising material. The coated woodfree grade is made almost exclusively of chemical pulp and it is used for high-quality 'glossy' printed products. The coated graphic paper grades did well in 1991 with rising production (+3.0%) and consumption (+4.7%). Growth in imports outstripped growth in exports.

Non-graphic grades

Non graphic grades include kraftliner paper, corrugated board materials, packaging paper, folding boxboard and greyboard. Kraftliner is used for the outer lining of corrugated board. This product is essentially produced in France, Spain and Portugal. Most of these non-graphic grades experienced slight increases in production and consumption.

Hygienic and sanitary products

Main final products of this grade are hygienic paper, napkins and industrial wipes. Production and consumption of these grades grew by around 2 to 3% in 1991 but exports fell sharply by 6% (EC and EFTA).

Supply and competition

Within the EC, market pulp production is concentrated in Portugal, Spain, France and Belgium. Newsprint is produced mainly in Germany, France and Italy. Most of the EC kraftliner production is in France and most uncoated graphic paper is produced in Germany, the United Kingdom, Italy and Spain.

Paper and board

Overcapacity is the industry's current biggest problem and it is particularly acute in the printing paper segment. In 1991, some of the most advanced and largest paper mills in Europe were running at only 80-90% of their potential capacity. This is too low for adequate returns on investment in this highly capital intensive industry.

The present situation is directly related to the outstanding growth of the 1980s. Confident with double-digit growth figures and cheap loans in those years, many companies in the EC, Scandinavia and North America decided to build new, larger and more efficient paper mills. These machines are now a source of huge capacities in a market which, although growing, can not absorb all the new supplies. Recent and planned capacity increases have consistently exceeded growth in European market demand.

Source: CEPI

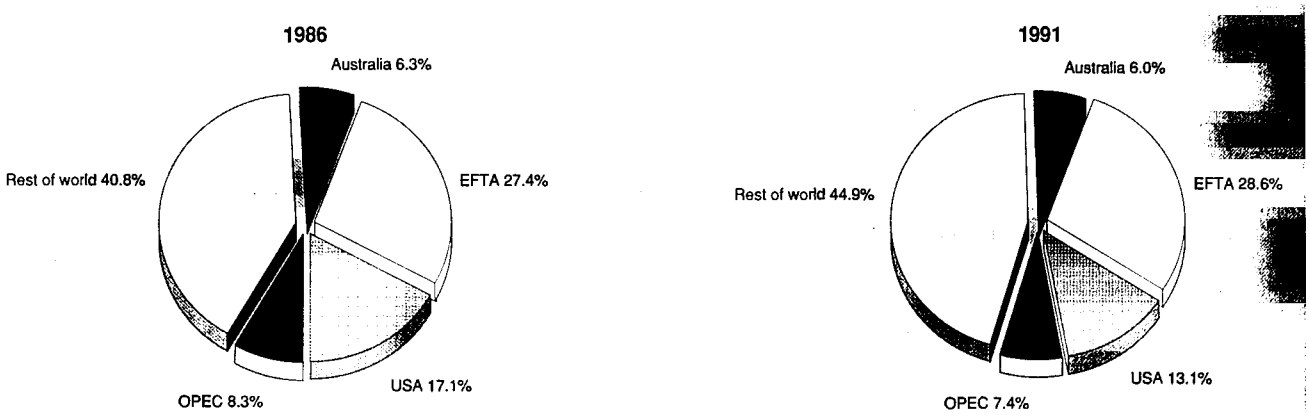
Steeply increased interest rates and a general economic slowdown have now created a bad situation for many of the world's larger, and often heavily indebted, companies. Smaller manufacturers, who have been more cautious in the past, are in a slightly better position.

The gradual abolition of EC frontiers, both in legal as in practical terms, has a further impact on internal EC competition. In this process, access to the German market remains crucial. Although this market is well served by German based, and partly Scandinavian owned production facilities, the country's high labour costs encourage strong competition from efficient French and Dutch producers.

The international competitiveness of the EC paper and board industry is generally good. Its productivity stands out positively against competitors in the USA and Scandinavia. EC industries have invested less in super-capacities and more in flexible production techniques. At the moment this strategy is proving to be vital to overcome rapidly changing market conditions for the various grades of paper products. Otherwise, the competitiveness of EC paper industries is a relative concept since many outside competitors moved into Europe. Some 50-60% of the EC production capacity is foreign owned with Swedish and Finnish companies as the main shareholders.

The EC paper industry is also gradually adapting to Community-wide economies of scale. National EC producers previously concentrated on the manufacturing of all paper and board grades for the national market. This resulted in rather small nationally oriented production facilities, which had a high degree of product diversification. Through a series of mergers and acquisitions, these producers are now seeking economies of scale comparable to those of their main competitors in the world. Many EC manufacturers have focused on niche markets, specialising in higher added value products,

Figure 5: Pulp, paper and board
Destination of EC exports



Source: Eurostat

such as carbonless paper, thermal paper and watermarked paper. Most of them have no integrated links with wood processing plants, and buy pulp on the world market.

The European paper and board industry had a difficult year in 1991 and 1992 will see only slight improvements. However, this hardly affected its international competitiveness since the situation of its main competitors was not much better.

The US paper industry remained badly affected by the persisting economic recession. Much of US paper production is volume oriented which makes it less easy to adapt to changing market conditions.

The Canadian pulp and paper industry is hit by legislative developments in its main market, the USA. An increasing number of US states demand by law that newsprint, for example, be made partly from recycled wastepaper instead of virgin fibres. Canada therefore is searching new outlets for its virgin-based pulp product, notably in Europe.

The Finnish pulp and paper industry was drawn into that country's deep economic recession although Finnish machines belong to the world's most advanced state-of-the-art technology. As a result of large investments most companies are heavily indebted. The Finnish industry also suffered from disruption in its former imports of annually 5 million m^3 of wood from the former Soviet Union. Furthermore, Finland has also lost the major Russian export market for their paper products.

As for the Scandinavian countries in general, the EEA treaty between the EC and EFTA which enters into force in 1993 will not change much in the paper industry. Under existing trade agreements, EFTA countries already enjoy a zero tariff for paper imports into the EC.

The Japanese market, although important, is largely self-contained and of limited direct relevance to European producers. The Far Eastern paper market is the fastest growing in the world, notably in the ASEAN countries and South Korea. One of the potential main suppliers in that area will be Indonesia. The Indonesian government policy is actively aiming to become a world leader in paper and pulp production. It is not yet fully clear how European producers are placed to compete on the Asian market.

Pulp

The prices of various grades of pulp were subject to highly cyclical changes after 1986, the year when steep price rises began. In 1989, the peak year, prices for Northern Bleached Softwood Kraft (NBSK - the prime grade) had risen between 55 and 75%. By 1990 these prices had dropped again by 35%. In 1991 they were slipping further for most grades.

Analysts attribute these large fluctuations mostly to an initially tight market in the latter part of the 1980s and subsequent overshoot in pulp capacity development. In response to a booming demand for paper in most parts of the world, many pulp mills were delivering pulp not only to their regular customers and integrated paper production units but also to many outsiders who increased capacity. Most pulp mills were running at full capacity.

A logical reaction to these developments was to increase pulp producing capacity by larger and more efficient pulp mills, often accompanied by restructuring of the industry at large. Some of these new production capacities have now been established. They are often so big that the advent of one mill (with an average annual capacity of 400 000 tonnes) has an immediate effect on world market prices. In 1991 it became clear that a number of planned new production units were no longer economically justified.

Production process

The pulp, paper and board manufacturing industry is traditionally linked to the forestry and wood processing industry. Due to lower costs of transport and the main raw material (cellulose), dependence on the supplying industries is decreasing. The original vertical integration of forestry, pulp mills and paper manufacturers is gradually replaced by more horizontal integration: big conglomerates in Europe and elsewhere are shaping up to produce every conceivable paper-related product from a variety of raw materials. This increasingly includes recycled paper.

The EC pulp and paper sector is highly innovative, and it modernises its machine park at a fairly rapid rate. Scale advantages and efficiency gains still continue to increase productivity. But despite this trend, the unit labour costs and the total unit costs continue to rise. Labour costs rise slightly because the industry workforce needs continuous training and ever higher technical education. Total unit costs increase even faster because of the high levels of investments needed to stay competitive. The level of indebtedness of many major EC producers is significant.

INDUSTRY STRUCTURE

Companies

The number of paper and pulp companies is still gradually decreasing and their average size is getting bigger. Nevertheless the level of concentration within the EC is still low compared to the situation in Scandinavia and the USA. The five largest companies in the EC are Arjo Wiggins Appleton (UK), Bührmann Tetterode (NL), KNP (NL), Papierwerke Waldhof-Aschaffenburg (D) and Jefferson Smurfit (IRL).

The major events in recent years were the 1990 takeover of the EC's largest firm, Feldmuehle Nobel (D), by the Swedish giant Stora, and the merger of Arjomari (F), Appleton (USA) and Wiggins (UK) in the same year.

The years 1989-1990 were marked by increased acquisitions by Scandinavian and US companies within the EC and some regrouping among EC companies. The US largest paper company, International Paper, bought Zanders (D) Cookson Graphics (UK) and Laurent-Espaly (F). In 1989, the Swedish SCA bought Reedpack (UK). Kymmene of Finland bought Chapelle Darblay (F). The Irish based Jefferson-Smurfit internally restructured its US operations and acquired some smaller mills throughout Europe and the USA. 1991 was a quiet year as far as mergers and acquisitions were concerned.

Strategies

Practically all top European (EC and EFTA) paper manufacturers have been involved in major restructuring activities in the past years. Because of the overcapacity, industries are now less convinced that bigger is better. The financial world is also less keen to finance the mergers and takeovers of already firmly indebted companies. Nevertheless it is more than likely that the relative calm of 1991 is not more than a pause in an ongoing process. However, further restructuring should not necessarily entail expansion of scale. In many market niches the industry needs smaller and more flexible production units which are increasingly closer to their markets.

REGIONAL DISTRIBUTION

Within the EC, market pulp production is concentrated in Portugal, Spain, France and Belgium. Newsprint is produced mainly in Germany, the United Kingdom, France, the Netherlands and Italy. Most of the EC kraftliner production is in France and most uncoated graphic paper is produced in Germany, the United Kingdom, Italy and Spain

ENVIRONMENT

Although the industry was among the first to acknowledge the importance of monitoring the 'eco-balance' in its production processes and actively recycles a large proportion of paper, it has become the target of several hard hitting protest campaigns.

Protest campaigns of international environment organisations focused on four main issues: the bleaching method using chlorine and chlorine compounds necessary to obtain a flawless white colour in quality paper; the quantity of forest wood used in paper production; the degree of recycled paper to be used in the production process; and the high and growing per capita consumption of paper in the Western world.

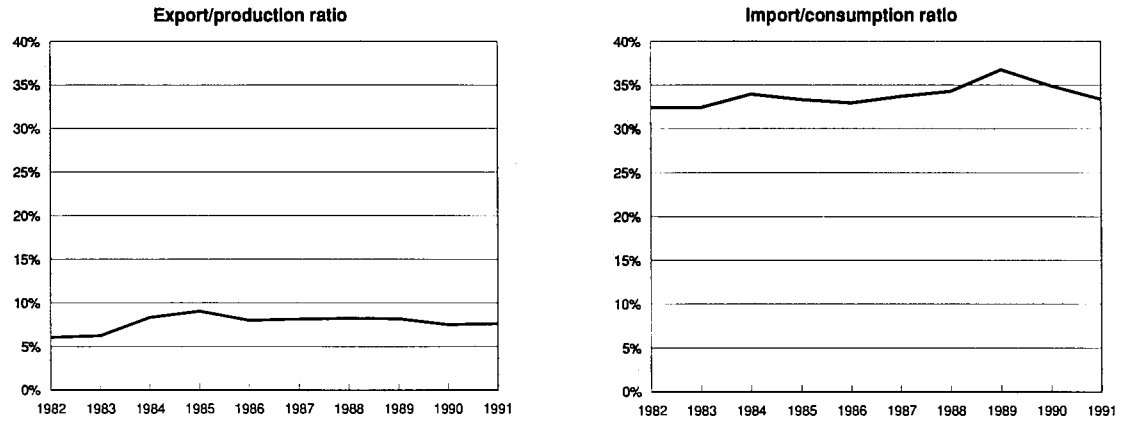
In response to these pressures and a growing consumer awareness, the industry has a strong case to present. Firstly, the pulp and paper industry is one of the few which actually regenerates its raw materials. Sustainable forestry is employed in Europe where at least two trees are planted for every one that is harvested, with the result that forests in Europe are actually increasing. Secondly, the industry has switched largely from the use of pure chlorine gas to the much less harmful chlorine-dioxide as the main active ingredient in the bleaching process. Thirdly, the industry already recycles almost half of the paper consumed in Europe and is still stepping up this activity. There are however other effective methods of waste disposal besides recycling such as energy recovery in state-of-the-art incineration plants.

REGULATIONS

The European Community is presently developing a regulation which will affect the pulp and paper industry. The industry fully supports this pan-European effort of harmonisation, rather than the development of national legislation, because the latter risks to hamper international trade without actually improving the environmental impact of global pulp and paper activities.

A proposal for a packaging waste directive which aims to increase the amount of waste to be recovered places increased responsibility on manufacturers to assist in waste disposal. In Germany legislators have already set very high recovery standards and forbid incineration for packaging waste. The impact of this policy in this crucial market may influence pending EC legislation.

Figure 7: Pulp, paper and board
Trade intensities



Source: Eurostat

One major effect of the German legislation which has already been demonstrated is its important effect on the waste paper market. Waste paper prices have become so low that collection by private enterprises is not attractive. In certain cases prices have even become negative because municipalities no longer knew what to do with their growing stocks. All these direct and indirect market developments will have to be carefully considered in the development of waste management policy, integrated prevention and pollution control, eco-labelling, eco-audits, etc.

OUTLOOK

The keyword for the development of new pulp and paper production lines in the coming years is flexibility. Unstable supply and demand developments among the different paper grades make it crucial that modern facilities produce flexibly the kind and quantity of paper which the market is willing to absorb. The industry will see new restructuring activities in the years to come.

As for the market situation, it is expected that demand will pick up again by early 1993 to alleviate some of the pressure on prices. However, since considerable capacity increases are still planned, the overcapacity will not be easily lifted. To sum up, the current slowdown in growth seems to be cyclical rather than structural. The emergence of market economies in Eastern Europe will have some impact on the EC pulp and paper market, but later rather than sooner. In the short run, it is likely that demand in Eastern Europe will grow particularly in lower grades such as newsprint. In the long run, new production facilities in these countries might serve European consumers.

Paper and board converting

NACE 472

The paper and board converting industry reached a new record high with a total production value of 44.3 billion ECU in 1991. The economic performance of the sector is strongly influenced by the pace of economic activity in general. The effects of decreased consumer spending in 1991 were partly compensated by the opening of new markets in Eastern Europe. The packaging market in particular experienced a revival associated with the reunification of Germany. Over-capacity in the paper production sector, however, resulted in downward pressure on prices which spilled over into the paper converting sector. The converters suffer from high wages and the reduction of working time for their 410 000 employees.

INDUSTRY PROFILE

Description of the sector

The paper and board converting industry covers all processing of paper and board into final applications in packaging, communications, and other special uses. The industry manufactures a wide variety of products in packaging, often in combination with plastics and metal foils, in stationery and office supplies, wallpaper, labels, hygienic material etc.

The distinction between the paper and board manufacturing and the paper and board converting industry is not easy to make. Increasingly, the major European paper producing manufacturers integrate forward into the production chain. As such they become active in both production and converting markets.

Main indicators

The size of manufactured goods made of paper and board increased steadily in the EC during the 1982-1991 period. The trade balance has always been of small proportion, although positive. In more recent years, a trend towards a reduction of the trade balance has taken place due to rising imports, although the main trade flows (75%) take place within the EC. Employment has been stagnating in 1991 and 1992.

The breakdown by country shows that the largest producer within the EC is Germany, with about 30% of total value added in 1991, followed by the United Kingdom (23%), France (18%) and Italy (10%).

Recent trends

From 1986 onwards, both production and employment in the paper and board converting industry outpaced the growth rate of the manufacturing sector as a whole. Average growth rates during the 1982-1991 period were at 4% for both production and consumption, although consumption grew faster in the 1985-1991 period. Extra-EC exports grew more strongly (9.8% per year) during the 1982-1985 period, before slowing (4.3% per year) in the latter half of the 1980s. Extra-EC imports growth, on the other hand, weak in the first half of the 1980s and grew rapidly (9.3% per year) in the 1985-1991 period. Overall, growth in extra-EC imports has been higher than in extra-EC exports during the 1982-1991 period.

International comparison

The paper and board converting industry is defined as widely diverging in its activities in the EC. It is difficult to make clear comparisons between Scandinavia, North America and Asia. The EC is the second largest producer of paper and board after the USA. In 1991, EC production was about 70% of that of the USA, and about 40% higher than that of Japan.

As in Europe, the prosperity of the paper-derived products industry in other regions is closely related to the health of the economy at large. Thus, the persistent recession in the USA has had a negative impact on the sales of packaging products.

Foreign trade

Trade in most goods of the paper converting industry is limited. In packaging products, the volume/weight (i.e. corrugated board/containers) ratio makes transporting over longer distances particularly uneconomical. For other packaging materials, i.e. bags, sacks, folding boxes, this is no longer valid due to container transport systems. For hygienic products, office products, labels, envelopes, the volume/weight ratio is less relevant, and they are exported to distant markets in Asia and South America. Most production is organised as close as possible to the market to keep costs low. Both ratios of exports/production and imports/consumption reach a level of 6 to 7%.

Given the importance of geographical proximity for trade of paper and board, the main trading partners are the EFTA coun-

tries, which account for a share of about 42% of extra-EC exports and about two thirds of extra-EC imports; the USA take only about 7% of total extra-EC exports and about 15% of total extra-EC imports.

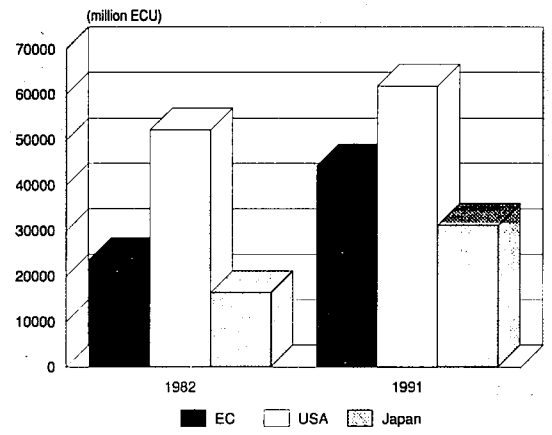
MARKET FORCES

Demand

The 1991 market situation for the different product groups of the industry was as follows.

Packaging products represent most of the industry's production (55 to 60%). It includes corrugated and solid fibre board, folding and rigid board boxes and containers, paper packs and carrier bags and other wrappings of consumable items. Demand for packaging products continued to grow at high levels in the EC. The industry received an extra impulse by the unification of Germany, which already was the most important market. It was a particularly welcome boost since most EC Member States experienced lagging demand. Uncertainty arises out of the different environment legislation in the EC Member States.

Figure 4: Paper and board converting
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Household and hygienic paper goods represent the second largest segment of production in the industry. It includes high quality products containing cellulose, cotton tissue and crepe paper, which are used in nursing, baby care and feminine hygiene. Demand for these products has grown exceptionally in the past two decades. Demand for products of slightly less added value, such as travelling, kitchen towels, and toilet paper has grown rapidly as well. It seems that after this period of strong growth, the market for these products has reached certain saturation levels in the EC although consumption per capita of various goods still lies below the US average. Some growth of demand may still be possible in southern EC Member States.

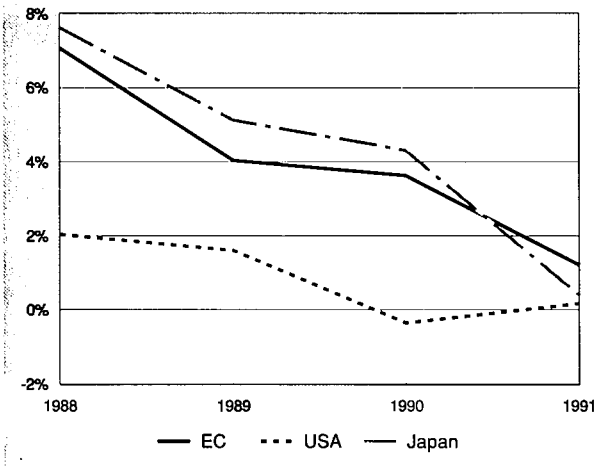
Stationery and office supplies represent the third largest segment of production in this industry. It includes envelopes, labels, printing and copying paper, and products for special applications such as fax paper. Shifts in consumer patterns and the emergence of new technologies has taken away demand from mail-related stationery such as envelopes to electronic transmission-oriented stationery such as fax-paper and computer printing paper. Overall demand for office supplies is still gradually rising. Although some long term effects are expected of a transition to an electronic 'paperless office', most analysts believe that stationery consumption in the EC will still expand.

Supply and competition

Overcapacity and the resulting pressure on prices in the paper and board manufacturing industry had an impact on the market for paper converting goods. But lower costs for the converting industry's raw materials have not led to higher profit margins as labour costs, transport and energy costs increased dramatically. The converting industry's customers have been able to negotiate lower prices for the end products. These customers include increasingly integrated retail trade chains which have considerable market power. Moreover, the industry is faced with steeply rising operating costs as a result of higher costs of labour and the financing of large capital investments.

The principal customers of the packaging industry are distributors, retailers and food processors. These customers are shaping up for the European Single Market and have much to gain with increased scale advantages and integration of international operations. There are indications of heightened

Figure 5: Paper and board converting
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

levels of cooperation among the principal players in this field. In the process they become more powerful negotiating partners for their suppliers in the packaging industry. A similar trend takes place in the hygienic and stationery products sector.

The EC paper converting industry is gradually adapting to EC-wide economies of scale. The pace of restructuring is largely determined by the activities of non-EC manufacturers on the EC market. Major Scandinavian groups such as STORA, SCA, MoDo and Iggesund have been very active acquiring both paper mills and paper converting production units throughout the EC. The advent of the Scandinavians in the EC market had an important positive impact on the productivity of the EC-based industry as a whole. Their introduction of new production techniques and process innovations has been quickly followed by a substantial part of the EC industry. Labour costs and general productivity, now compare positively against Scandinavian and perhaps even better against North American industry.

Production process

In some of its branches the paper and board converting industry is integrated with the paper and board production industry. But as a whole it still remains essentially a separate and moderately fragmented industry of small and medium-sized firms. Originally these two sides of the branch were clearly separated in an upstream side closely related to forestry and bulk paper production and a downstream side related to packaging and other applications, often on a smaller scale. Today, bulk paper producers are integrating forward into the production chain. In competition with their Scandinavian counterparts, the large EC paper manufacturers acquire smaller converting production units. In doing so they gain efficiency, secure market shares and guarantee a steady demand for the raw materials.

These integrating forces led to synergies in new capital investments and a reorganisation of labour. As one notable result, it had a positive effect on labour productivity. The productivity index went up almost 20% from 1985 to 1991.

INDUSTRY STRUCTURE

Companies

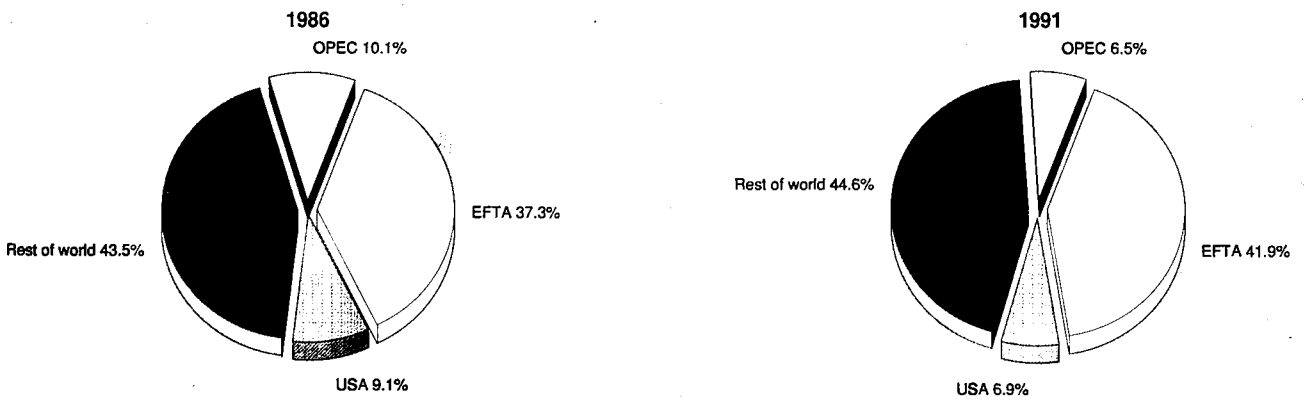
Most of the major EC companies in paper and board converting are the same as those listed in the previous monograph on paper and board production. The same is true for the main competitors in Scandinavia and North America. Forward integration of these companies and a rapid rate of mergers and acquisitions in the years preceding 1992 led to higher concentration levels.

The number of enterprises remained relatively constant at some 4 900, of which many were specialised small and medium-sized companies.

Strategies

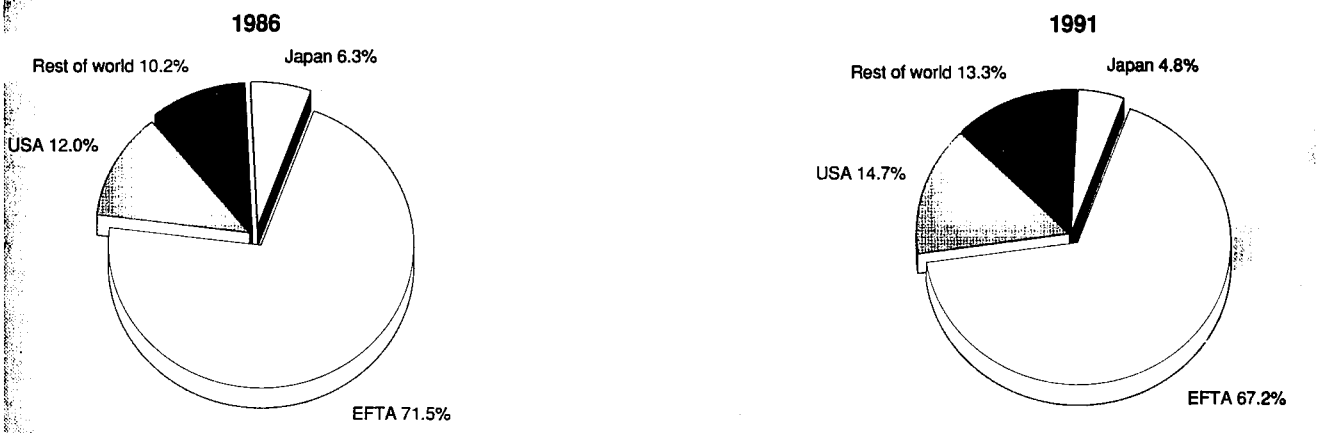
The strategies of the EC paper converting industries are guided by the integrating forces from mergers and acquisitions which thrived in the late 1980s but which have been temporarily slowed down. Continued inward investments of Scandinavian and North American producers within the EC are forcing EC producers either to join them or to cooperate among themselves. The general expectation is that when business picks up again somewhere in 1993 the concentration of the industry will receive a new boost.

Figure 6: Paper and board converting
Destination of EC exports



Source: Eurostat

Figure 7: Paper and board converting
Origin of EC imports



Source: Eurostat

REGIONAL DISTRIBUTION

As the bulk of EC paper production, most EC paper converting is concentrated in the United Kingdom, Germany and France. Some of the specialised packaging industries have settled close to foodstuffs production areas in southern Europe and smaller countries in the North such as Denmark and the Netherlands. The biggest market, both for packaging stationery and hygienic products is Germany. This market has become even more crucial for EC producers after the reunification in 1990.

ENVIRONMENT

Ecological issues in public relation campaigns are starting to become a matter of serious concern for producers of paper related products. A growing number of packagers and retailers switch to environmentally friendly products. Applications in packaging are well suited to contain recycled fibres. Already more than 80% of paper and board packaging, mainly corrugated containers, is made from recycled fibres.

The packaging industry is currently most concerned with legislative developments in several EC member states and the proposal for a packaging directive recently adopted by the European Commission. Early in 1992, Denmark, the Netherlands, Germany and France implemented legislation to set minimum amounts of packaging waste which are to be recovered by manufacturers. The other main element of these new laws are minimum amounts of packaging waste which need to be recycled into the production process.

OUTLOOK

The paper converting industry will face a moderate improvement on 1992 performance in the coming years. Most experts think that the overcapacity in bulk production could diminish by 1993 which would allow some restoration of prices and profits. Equally important will be the resurgence of restructuring activities.

Technical developments are due in the coatings of paper for special applications. New methods for paper coating will increase the use of paper-based packaging and wrappings both in industrial applications as in food transport.

New opportunities could be offered by the opening of new markets in Eastern Europe. Tied closely to the transport and trading of consumable items the demand for packaging products seems set to grow with increasing competition and consumer choice. But the spending power of consumers in Eastern Europe will take several years to grow significantly. The new trading accords with some of the Eastern European states allow increased exports of certain goods to the Community. Since local production of EC-standard packaging material is hardly available, this might also trigger additional demand for the EC packaging industry. Stationery and hygienic products will probably profit less from these market openings.

Printing and publishing
NACE 473, 474

Printing and publishing, with all its historical and cultural importance, is a mature sector of moderate and steady growth which benefits from a reduced susceptibility to movements in the economy by comparison with other media. Nevertheless, the industry is currently undergoing a technological revolution which could bring the whole of paper-based production into question.

INDUSTRY PROFILE

Description of the sector

The printing and publishing sector encompasses all the stages necessary to transform a piece of creative work into a manufactured product available for distribution to the public.

The finished products of the printing and publishing sector are diverse and include books, encyclopaedias, daily and periodical press, maps, and musical scores.

Main indicators

In most EC countries, consumption and production doubled between 1982 and 1991. Since 1991, however, overall EC consumption growth has been checked, reflecting the recession in the United Kingdom, the largest printing and publishing producer in the EC. Growth in consumption in south European countries such as Italy, Spain and Portugal, on the other hand, held steady.

As shown in Figure 2, the United Kingdom, France and Italy together account for 57% of the value added of the sector in Europe, with the United Kingdom dominating with 22%.

Recent trends

The EC trade balance with the rest of the world remains in surplus both in value and volume terms. Following a period of marked volume growth, the balance has stabilised since 1985 as exports performed less well.

Figure 3 shows the remarkable growth of production for the printing and publishing sector during the 1982-1992 period. Also employment in the sector has been rapidly growing after a temporary slump in 1986.

International comparison

With a population slightly higher than that of the United States, Europe publishes five times as many titles, 250 000 a year. From 1982 to 1986, the number of titles published rose in Europe by 10%, while production over the same period fell in the United States and Japan.

The USA remain the world leader in printing and publishing. In 1991 US production was worth 36% more than that of the EC and nearly doubled that of Japan, which had the fastest growth during the 1982-1991 period.

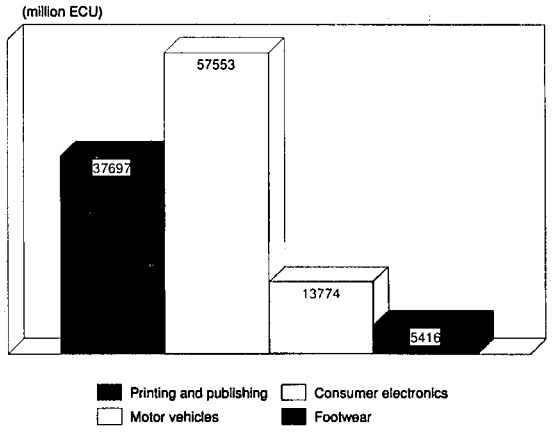
Foreign trade

EFTA is the EC's main partner in the printing and publishing sector both for imports and for exports, surpassing trade with the USA.

In fact, although language considerations do predominate in matters of trade, new markets are developing as economic frontiers expand. Within the EC, the United Kingdom has benefited most from the changes in the structure of trade, closely followed by the Netherlands. The United Kingdom is becoming a crucial centre for European publishers, as well as an important entry point for American printers and publishers wishing to establish themselves in the European market.

Intra-EC trade is growing at the expense of commerce with the rest of the world. Trade intensities are very low in the printing and publishing industry: the export/production ratio is about 4 to 5% and the import/consumption ratio is around 2%.

Figure 1: Printing and publishing
Value added in comparison with other industries, 1991



Source: Eurostat

MARKET FORCES

Demand

Developments in the book trade depend on a complex variety of factors, including economic and social aspects such as demographics, education, leisure trends and the number of public libraries.

Books do not follow the rules which generally dictate the economic performance of other products. The book, in fact, is one of those basic products whose evolution takes place over the long term in keeping with demographic circumstances. And every European country has seen a reduction in its birth-rate.

Stagnancy in new school entries intensifies this trend, as a reduction in the number of children has not been offset by a wider provision of education.

The situation appears most favourable in the United Kingdom and France, where a slight rise in population is forecast. Meanwhile, the average birth rate in Europe has stabilised around at 1.9 children per couple; the corresponding figure for the rest of the world is 3.6.

Analysis of consumption trends for books reveals a marked difference between the South and the North, with Southern Europe characterised by relatively weak reading habits.

Books represent 27.5% of leisure spending in Italy, compared with 18.7% in 1981, but only 46% of the population can be described as "readers", among whom 70% read less than five books a year. In Spain, 63% of the population does not read for leisure.

There exists a strong correlation between the level of education attained and the tendency to read. 93% of graduate Italians read regularly, compared to a figure of 26% for those less qualified.

While reading ranks behind television and radio, nearly 50% of Britons read one book a month. Despite such a high consumption rate, the level of buying is very low: of the 56% of regular readers, only 60% actually purchase their books. This situation is due to the importance of public libraries - seven times more numerous in the United Kingdom than, for example, in France.

Overall, Europe is a mosaic of contrasts. In addition to major cultural differences, we can highlight:

- the ageing of the readership in Northern Europe linked to demographic factors, as well as regular consumption of books due to improvements in living standards and the cultural importance of reading in these countries;
- increased importance given to reading in the cultural habits of Southern Europe due to improved education. This now means that the most committed readership is among the young.

Despite national disparities throughout Europe, it would appear that two sectors of editorial activity are emerging to cater to

the interests of the main groups and larger small and medium-sized businesses - youth and educational publishing.

For a long time, children have been considered prime consumers; seen as the readers of tomorrow, they have spearheaded the youth sector as a major arena for socio-cultural activity. Educational success is a key factor for professional development and one of the main sources of parental concern. Encyclopaedias and dictionaries, as part of the educational publishing sector, also represent a rapidly-expanding market.

Supply and competition

Two separate phenomena have given rise to talk of a "publishing crisis" in Europe. On the one hand, stagnant sales have held down the number of titles published. On the other, the titles that have been published testify to editorial dynamism and healthy competition.

The apparent contradiction between these two phenomena has led to what some see as a crisis of over-production, resulting in a reduction in the size of average print runs. Stagnation or even reduction in the number of copies published emerges as a widespread phenomenon.

In Germany, the average print run for a contemporary novel never exceeds above 5 000 copies. Those countries with the most vigorous publishing sector are the ones most hurt by cutbacks in average print runs.

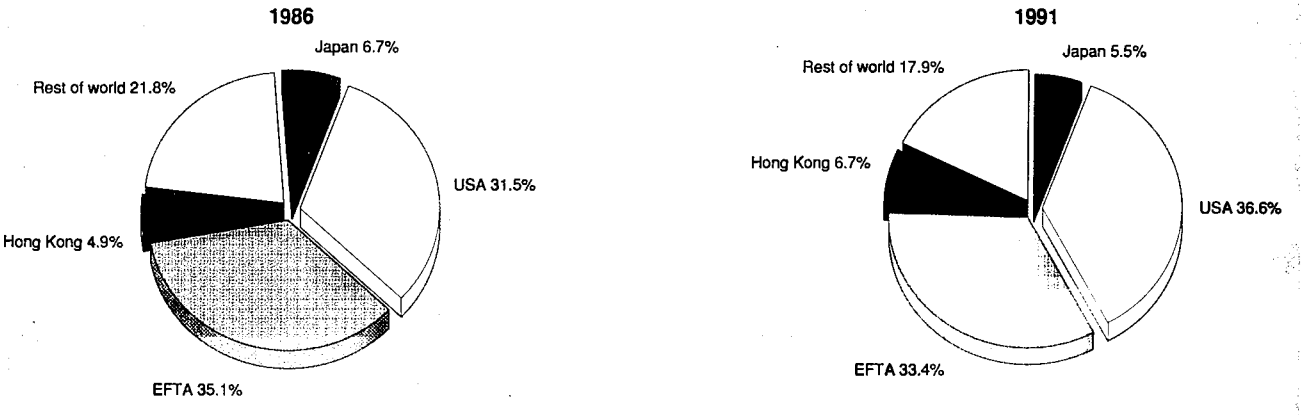
The countries where production has grown most are the United Kingdom (with 68% growth between 1976 to 1986) and Spain, with a growth rate of 50% over the same period.

The number of titles published gives some indication of the expansion of the market; the percentage of new titles gives a further indication of market health.

Accordingly, Germany exhibits a high number of published titles, but a low ratio of new titles (27% of the total in 1989). France and Italy come in the middle, with the ratio of new titles to overall published output roughly balanced. Finally, the Netherlands, Spain and the United Kingdom exhibit strong market vitality, with new titles accounting for some two-thirds of total published output.

Commercially speaking, new titles are a high-risk area for publishers, whereas reprints reduce uncertainty and hold down fixed costs on a larger number of units over a longer period. The strategy of differentiation practised by the major publishing groups can be seen, to some extent, as "competition by attrition", with each publishing house attempting to secure maximum shelf space in retail bookseller outlets and, by definition, crowding out its competitors.

Figure 7: Printing and publishing
Origin of EC imports



Source: Eurostat

The reduction in average print runs and price rises are related. In practice, the average production cost of a book falls in relation to the number of copies published. Lower print runs therefore push up average unit costs.

Book prices do not obey the laws of supply and demand. In fact, eleven EC countries have adopted different forms of single-price arrangements. Only in Portugal is there a system of free pricing for books. On the other hand, books benefit in general from lower value-added tax rates. These range from 0% in Italy, Portugal, the United Kingdom and Ireland to 22% in Denmark.

Book publishing has been affected by developments in audio-visual media, but the press has been affected even more. Advertising revenue, the principal source of finance for the press, has fallen dramatically over the last ten years, with advertising spending in the press dropping from 77% in 1980 to 41.6% in 1990. Over the same period the corresponding figures for TV advertising revenues rose from 15.8% to 25.1%. Nevertheless, in spite of forecasts that dailies, weeklies and periodicals would disappear as a result of the rise of audio-visual media, the principal newspapers have maintained their profit level over the last ten years.

The market for the press in southern European countries is relatively underdeveloped, with fewer than 118 000 copies per thousand inhabitants compared to 129 000 in France.

In addition, the press is highly competitive. In European countries on average, ten daily titles together account for more than 50% of national circulation. This situation is most pronounced in the United Kingdom, where that percentage is reached by the combined circulation of only four titles.

The 1990s will be witness to a major upheaval in printing and publishing as the very notion of paper -based media is progressively challenged. A CD-ROM (Compact Disc -Read Only Memory) is capable of storing up to 550 million characters - the equivalent of about 25 000 printed pages - and has become a vital storage medium for activities such as archiving, data banks and directories.

Meanwhile, the CD-I (Compact Disc- Interactive) has a storage capacity capable of storing and reproducing sound and images as well as text. The CD-I also permits interactive audio-visual applications via a simple remote control device. Units are already on sale in the USA, and the launch of CD-I on the UK market was planned for June 1992.

Given this enormous text and image data storage capacity and know-how, CD-I publishers will play a major role in these markets: when it comes to targeting the public at large, the industry will be critically dependent on publishers.

Production process

The printing and publishing sector is characterised by strong value added and a high dependence on skilled personnel. In Germany, where manpower is particularly expensive, printing labour costs can represent 36% of total costs in Germany.

The main stages in the manufacture of a book are: editing the work following acceptance of the author's manuscript; a technical stage where typesetting and pagination allow a calculation of the costs of production and the raw materials needed; return of the composed text to the publisher in proof form; initial correction; layout and illustrations with preparation of a "dummy" copy for the printer; checking printer's final proofs; printing a predetermined number of copies; distribution of the requisite number of copies to points of sale; and acceptance of returns or unsold copies at the publisher's expense.

In the course of the last few years, computer-assisted publication (CAP) and desk-top publishing (DTP) have generated professional interest. Computerisation of design and manufacture has allowed considerable gains in time and cost, but CAP will add to salary costs in the short term, since the process requires new skills from the workforce. CAP seems to be better adapted to limited print runs and, as a result, is more cost-advantageous to smaller publishers than to the major groups.

In hardware terms, computerisation opens up the possibility of creating new forms of published product such as CD-ROM and CD-I. For example, a 9-volume dictionary weighing 50 kg can now be captured on a 6 cm disc weighing a few grams and the entirety of its information accessed in a matter of seconds.

In the printing sector, most firms now use electronic systems for composition and image processing. Photo composition has now replaced hot metal as the main technology. Micro-publishing (desk-top publishing) has also brought about considerable changes in the sector by facilitating PC-driven integrated text and image processing.

These technological innovations imply improved qualifications for staff and increases in productivity. Output per employee has thus risen from ECU 59,000 in 1980 to ECU 73,000 ECU in 1989 (at constant 1985 ECU values).

A special feature of publishing is the cost burden of "returns", i.e., unsold copies. This burden is all the more difficult to bear in a period of recession. Books which are not sold are returned and destroyed/recycled.

Part of the problem is that available sales space tends to remain constant, whereas the number of titles on the market continues to grow. Inevitably, this disparity leads to a reduction of the time a book is on display, and its overall life-span. Volume and speed of returns has affected some publishers disproportionately, with several experiencing rates of return of over 60%.

Both the printing and the publishing industries require an increasing level of capitalisation. The best-known example is in dictionaries and encyclopaedias, where long production and commercialisation lead times presuppose financial resources to absorb heavy cost burdens both during the period of investment and to cover the costs of promotion and publicity to launch the title on the market.

INDUSTRY STRUCTURE

Companies

Europe's publishing sector is highly fragmented. Most groups have activities beyond merely publishing, covering a wider range of economic activities such as printing, press and publishing, bringing together a range of activities of creation and manufacture of paper-based media. Fewer than 10% of all printers operate independently of a publisher.

The main groups such as Bertelsmann (D) and Hachette (F) range even farther afield, and are involved in multi-media activity.

The trend towards concentration by acquisition and merger is not equally marked in every country, but it is growing everywhere.

In Italy, the three main groups are Mondadori (30% of the market), Rizzoli (12%) and Fabbri (10.5%).

In the United Kingdom, the two publishing giants are Pearson and Reed which, between them, have 31% of the domestic market.

In the Netherlands, where 500 publishers serve a population of 15 million, three houses dominate: Elsevier, Wolters-Kluwer and VNU, which together control two thirds of the nation's publishing activities.

In Spain, five groups - Planeta, Anaya, Plaza y Janes, Circulo Lectores and Salvat - represented 38% of the market in 1983.

In France, five main groups control three-quarters of the market. La Cite and Hachette hold two-thirds of the national market between them - a situation without parallel elsewhere in Europe. That said, French publishing as a whole is characterised by modest levels of globalisation and poor sales of French language books on international markets (as compared with the performance of Anglo-Saxon publishers).

Strategies

The two main aspects of strategy are concentration and globalisation.

Publishing groups are developing both vertical (publishing and distribution) and editorial (diversification) strategies in these new areas as well as in traditionally profitable areas, the net result being to favour economies of scale. However, small publishing houses have a capacity for creativity and flexibility which allows them to stay in the market.

Publishers, in the strict sense of the term, tend on the whole to be medium-size in Europe, with the exception of the major Dutch groups Elsevier and Wolters-Kluwer.

Mixed books/press houses are becoming more numerous, as a result of growing synergy between the two activities: newspapers and magazines remain the most reliable media for book promotion. Thus, Mondadori acquired control of L'Espresso, a famous Italian weekly magazine, in 1989.

The most prestigious names belong to the multi-media groups: Bertelsmann, (D), Time-Warner (USA), Paramount (USA), News Corporation (AUS) and Hachette (F). These groups have a presence in all of the main mass media markets - books, cinema, television, press - and all have extensive international connections.

Globalisation strategies are pursued in general by way of subsidiaries or by acquisitions. In practice, publishing groups -acknowledging their limited knowledge of international markets and the cultural differences implicit in language and business practices - are more likely to expand by economic rather than industrial or commercial means.

Bertelsmann and Hachette are the most international of the major global groups. Between now and the mid-1990s, however, they will in all probability be joined by groups like Pearson and Reed, which have made no secret of their intention to diversify away from their pronounced Anglo-Saxon orientation.

Meanwhile, the Single European market is obliging publishers to consolidate their position in Europe: what is at stake is not so much Europe itself, but the principal European languages which predominate on world markets: English, Spanish and, to a lesser extent, French.

Expansion both in Europe and throughout the world is nevertheless limited by the national character of information. None of the multi-media groups has a major position across Europe in the three main media - press, TV and radio.

REGIONAL DISTRIBUTION

The United Kingdom is a key market for European publishers, largely due to the growing importance of the English language and the influence of the major UK publishing houses. The United Kingdom acts as a springboard for American publishers and printers wishing to access the European market.

While UK publishers have invested only modestly in Europe, continental Europeans have boosted their presence in the United Kingdom through a series of acquisitions and establishment of new subsidiaries.

London is at the cross-roads of a number of trade zones all of which target Anglo-Saxon markets. French and Hispanic language zones remain natural areas for France, Belgium and Spain, which, by and large, have successfully retained their special trade relationships with those respective language areas.

ENVIRONMENT

Paper consumption in developed countries is of the order of 120 kg a year per inhabitant. Paper and pulp is the second main consumer of forest products in the world, after the lumber industry. Demand in the OECD countries for wood pulp, paper and cardboard is projected to grow substantially in volume, from 150 million tonnes today to some 200 million tonnes by 2010.

The use of recycled paper is increasing. Furthermore, contrary to popular belief, paper production is rarely harmful for woods because they need to be cleared regularly.

REGULATIONS

As a cultural product, books ought to remain affordable to consumers. For this reason, most European countries apply conservative measures on pricing, Portugal being a notable exception. These measures would appear to be crucial to the continued existence and development of the distribution networks needed to keep books available to the public and, by extension, for the survival of literary creativity in all its diversity.

In the United Kingdom, the Net Book Agreement governs the fixing of book prices. It is for the publisher to decide whether his books should be sold at a free or an imposed price. In practice, only textbooks tend to be sold at free market prices.

In Germany, publishers themselves operate the rules on price fixing. In Germany, bookshops are bound by a collective contract with 1 700 affiliated publishers to respect the fixed cover price. A similar arrangement operates in Italy. In France and Spain, legal provisions exist to enforce the obligation to sell at the published cover price.

One way out of the problem is to purchase and sell rights on a pan-European level; this, of course, would entail larger investment on the part of publishers.

It will be difficult, especially in the case of more internationally-oriented publications such as English-language encyclopaedias and technical and scientific literature, to maintain an imposed price which differs according to the country concerned. The logic of the Single Market calls for the application of a European price, possibly corresponding to the published price in the country with the lowest applicable value-added tax.

OUTLOOK

The publishing sector is best described as a mature sector posting regular if moderate year-on-year growth. Because of its peculiar mix of historical and cultural factors, the publishing market is relatively immune to economic swings.

The cultural habits of consumers are the key to future development in the sector. Its evolution depends on socio-economic factors such as demographic trends, education, industrialisation, political trends (as in Spain, Greece and Portugal) and, not least, tradition.

New technologies now seem to be complementing rather than substituting for the written word: in fact, those countries which have emerged as the prime consumers of images are also those which remain most attached to the written word.

The most promising subsectors of the publishing industry are those connected with knowledge, teaching and professional

Table 5: Printing and publishing

training - such as dictionaries, encyclopaedias, textbooks, practical guides and books aimed at the youth market.

The application of new technologies in publishing - either as production aids or as new media per se - is still at an embryonic stage. New products derived from books or developed from synergy between different media - sound, images, text and data - can be expected to multiply on and stimulate global markets.

Printing
NACE 473

Comprising more than 60 000 firms and employing some 670 000 people, the Community's graphic industry handles a turnover of over 50 billion ECU. The industry consists mainly of small enterprises, as 85% of them employ fewer than 20 persons.
The graphic industry is a modern, high-technology industry which, by keeping up with the latest manufacturing processes and investing heavily in new machinery over the last few years, has placed itself at the forefront of technical progress. Image processing in modern printing is now carried out by computer or computer assisted equipment. This technology does of course require highly skilled workers.

INDUSTRY PROFILE

Description of the sector

Printing firms produce a wide variety of products ranging from simple visiting cards printed in one colour to bulky, four-colour direct mail catalogues. The smaller firms work mainly with local clients for whom they produce personal or commercial printed matter whereas bigger firms often deal with a more widespread clientèle and supply for example printed advertising material, books or continuous stationery. Some large firms run both a printing and a publishing house which specialise in newspapers and magazines.

Those larger firms which have gravure printing, print and/or publish magazines, catalogues and long-run advertising material very often for the international market. Of course, this variety of markets goes together with a great variety of results; the economic health and vitality of the markets can vary substantially because of the impact of economic, cultural and social factors on them.

Recent trends

Despite the economic growth of the last few years and the positive effect on employment and production, the graphic industry in Europe is now developing differently from country to country. Germany, for example, is benefiting from its present economic growth, partly because of the increase in demand from the new East-German Länder, whereas the United Kingdom and other EC countries are suffering from a slowdown in economic growth. Countries close to Germany have also benefited from its unification as they have won contracts which German firms have been too busy to accept. On the whole, though, in 1990 the growth of the graphic industry exceeded that of the Community's economy by about 1%. In 1991 extra-EC exports reached nearly 1.5 billion ECU, whereas extra-EC imports were 0.7 billion ECU.

Foreign trade

No detailed figures can be given on the trade in graphic products or the structure of that trade because the external trade statistics do not distinguish between the trade of printing firms and that of publishing houses.

The production of graphic products in EC Member States is mainly determined by the internal demand. The export rate, that is the percentage of the industry's turnover achieved by exports, is in general below 10%. This relatively low rate is due to several characteristics of the industry, such as the need for frequent contacts with the client, the great need for communication during the work, linguistic barriers or the relatively high costs of transport. Exports concern mainly large runs or special contracts, such as catalogues or other printed advertising, books or newspapers. Exports are in general made by a small number of large firms working in gravure or web-offset.

Most of the external trade with non-EC countries is made with other Western European countries. The amount of printed work done by EC printers for outside clients has indeed increased considerably in recent years. Trade with Eastern countries remains low but is expected to develop substantially in the near future. Exports to non-EC countries are about twice as important as imports.

MARKET FORCES

Demand

In the graphic industry there is a direct link between demand and production because this sector supplies mainly to order. Printing firms are rarely able to manufacture for stock as other industrial sectors can.

Demand for printed products is influenced by a number of demographic and economic factors such as population growth, composition of households, training and education as well as economic growth. The graphic industry, just like the publishing sector, is above all a supplier of products which disseminate information and knowledge and cater for leisure activities. Despite the low growth of population, the number of households and managerial jobs continues to grow as does the proportion of income available for education and information. All this continues to stimulate the demand for newspapers, magazines, periodicals and books. Consequently, the number

of books printed has never been so high. New technologies have opened up new and ever growing markets, such as for computer manuals and educational material. On the other hand, private demand represents only a small part of the graphic market.

The advertising expenditures of the economy as a whole is one of the most important factors influencing demand and production in the graphic industry. Almost two thirds of the industry's turnover depend directly or indirectly on advertising. Any political decision affecting advertising, in general or in particular also affects the graphic industry and consequently can jeopardise employment. The printing of catalogues, advertising brochures, pamphlets and company reports is ever increasing as are advertising inserts in newspapers.

Commercial printing has now become an important part of graphic production. Individuals, municipalities, industry, commerce and insurance companies are now big clients for printed products of all kinds, including stationery, visiting cards etc.

These products, printed on separate sheets remain one of the main activities of the small printer who is often limited to local custom. Larger printers will deal with continuous forms and a more widespread clientèle. The demand for continuous business forms is constantly increasing , mainly due to the growth in electronic data processing used for example in electricity bills and insurance certificates. The continuous forms market is expanding substantially in some countries, partly because of increasing electronic treatment of information, whilst the market is suffering from a harsh crisis in other countries, such as Italy.

Labels, packaging products, wall calendars, illustrations and postcards form yet another sector of the graphic industry. These products are often printed by specialised firms.

The upward trend in overall demand has been stimulated by the development of new and existing products. At the same time, printers are now trying to cater for special requests. Quality standards are rising visibly, particularly in creativity and design by electronic means and improved equipment for colour printing. Multicoloured pictorial information is increasing for advertisements, magazines and company reports, and newspapers are also now making use of colour.

Progress in technology has also led to a number of electronic data processing functions being carried out at the client's office, for example, articles are often now drafted on the client's computer. The printer then has to transfer the information - off-line and on-line - to and from the client.

Information needs are satisfied by an increasing variety of electronic means and communication devices. Nevertheless, the permanence and high degree of information stored in the printed product have enabled it to retain its position as a simple, easy, accessible and efficient means of communication. A number of printed products are complemented by electronic media and vice versa (for example, specialised magazines). The necessity to process and exchange information efficiently will continue to increase.

Supply and competition

The publisher remains one of the printer's main clients, as he accounts for about 40 to 50% of production. The printing of newspapers is almost exclusively carried out for publishing firms. Furthermore, in this area, publishing houses and printing houses often form a legal entity and belong to one owner. The printing of newspapers accounts for roughly one-fifth of the total printing production.

Publishing houses are also important clients of the magazine printer. In countries such as Germany, widely circulated magazines are invariably published by printing houses which are owned by publishing houses. In other countries like the United Kingdom and France such a situation is rare: printing and publishing represent two distinct and different activities. These

Source: Eurostat

publishing houses are dealing increasingly on the international markets. Other types of publications, such as specialised magazines, religious, scientific or professional are printed for independent publishers or for publishing houses linked to printing houses. The production of periodicals accounts for about one-fifth of the total print production. Book printing follows a similar pattern to that of periodicals. Book publishers - independent or linked to printing houses - are not the only ones to order the printing of books, paperbacks or hardbacks; industry, public authorities and other organisations are also ready clients. Book printing accounts for about one-tenth of the total printing production.

The market for printed advertising material consists of a wide range of goods, such as direct mail catalogues, prospectuses, advertising inserts, posters or leaflets. The structure of this market is as diversified as its products as a large proportion of the clients are made up of direct mail companies, commerce and industry. Political parties and other organisations are also big consumers of printed advertising material. This sector has grown considerably over the last few years, stimulated mainly by the development of new forms of advertising, such as direct mail. The production of printed advertising material accounts for a quarter of the total printing production.

Printed matter for individuals and professionals is often taken on by the small printing firms. These cater for the municipalities, various organisations, industry, commerce and local individuals to whom they supply visiting cards, business forms, headed paper, invoices, transport tickets and cheques.

These small firms often print in single sheets, whereas the larger or more specialised firms deal with continuous printing and produce different types of continuous forms, completed on computer by the clients themselves. The production of this printed matter accounts for about one-fifth of the total printing production.

The tenth of the printing production which has not been attributed to any of the above categories accounts for various products such as calendars, fine-art prints, postcards and greetings cards, cartographic products etc. Alongside these printed products the sector also produces rubber or polymer stamps, reprographic products such as photocopies, overhead foils and microfilms.

Alongside these printing firms can be found suppliers of services who often take the place of printers when these cannot cater for exact needs. This is why composition and word-processing are sometimes carried out by trade typesetters; the same applies to reproduction (image processing) and to finishing. Services such as the design of printed matter and the production of layouts and dummies are also offered to the client. In the future, firms who will offer new services through desk-top-publishing processes will complete the existing structure of the graphic industry.

Production process

Printing has traditionally been a high wage industry, reflecting the above-average levels of skill required from its labour force. Printers have also often been among the first to benefit from improved working conditions - shorter hours, longer holidays and other advantages. In half the Community countries the working week is 37.5 hours or less. In most others it is not more than 40. Only Portugal still has a basic week of 44 hours.

At the same time, wage costs have a considerable impact on total production costs and have even increased in the last few years. Furthermore, important investment costs need to be made to ensure that the necessary qualified personnel is available. Despite all this and the swift technological developments in recent years, which have enabled new markets to be won, employment has remained relatively stable in the graphic industry.

Current developments in the industry indicate a close link between the printing sector and the development in communication and information technology. Innovations in equipment and graphic machinery have put the industry in the forefront of technological progress, an industry where equipment has a major impact on the type, the quantity and the flexibility of the work carried out as well as on the professional skills and the organisation of the work in general. Many aspects of the print production process are now commonly automated, measured and controlled by computers. In the last few years, there has been a substantial increase in investment in new printing machinery in several Community countries.

There have been particularly fast changes in the sectors of pre-press and reproduction. Even small printing and reproduction firms now use totally electronic pre-press systems with word and image processors. Photocomposition is the dominating technology and is progressively taking over the old system of hot-metal composition. The latter is still used, however, in certain specialised jobs.

Desk-top-publishing has also brought about a number of changes. Generally speaking, desk-top-publishing allows combined processing of both text and image. This new development means that a number of customers are now able to do their own keying work which in turn has led to ever greater demands

in photosetting especially in capturing, processing and converting the very varied information found in printed matter. A number of customers have tried to accomplish these operations themselves but have had to face the fact that such systems require the experience of a professional typesetter and that the cost is often underestimated.

Upstream of the printing process, reproduction has also undergone a number of important changes due to the rapid developments in micro-electronics. Photomechanical reproduction by camera which was once quite common has already been widely replaced by electronic image processing. Such systems process and convert image-data through electronic whole-page transmission; after the lay-out of the page with the text, the illustrations are mounted electronically. These very expensive systems are installed in the large printing firms and in reproduction firms dealing with colour magazine and catalogue printing. Other less expensive systems, such as powerful personal computers are now being used for colour separation. In this area, technological progress is comparable to that found in composition. In fact, there are now very definite signs that the two areas of composition and reproduction will eventually merge.

Equipment and production techniques now used in printing and in finishing have also been influenced by the arrival of the micro-processor. The latter is being increasingly used to control such functions as tension of the paper web, ink flow, machine control, labelling and despatching. To a great extent these two areas also show signs of merging. Certain printed products, such as books, are already being produced by what is known as on-line finishing, in other words the printing and binding are carried out on the same production line.

The use of electronics in information and communication now play a significant role in printing as a whole. The effect is quite obvious in the transmission of information from client to printer as this is now, more often than not, carried out through electronic media. The transmission of information within a printing house - for example, in newspaper printing, from the editing department to the printing floor or in the case of magazine printing, from one printing department to another - is becoming quite common.

On the other hand, publishing firms have tried to evaluate the impact of this new technology in communication on printed products and are looking into ways of becoming more involved in these areas. Publishers and printer-publishers have often invested in such areas as data-processing units, data banks, videotext and even local radio stations, whereas the printers tend to remain faithful to purely technical operations.

Taking into consideration that most equipment manufacturers now offer similar techniques and know-how in all European countries, if not world-wide, the technological progress of the graphic industry can be considered to be similar in all the EC countries.

INDUSTRY STRUCTURE

The graphic industry in the EC is made up of small and medium-sized companies. A typical printing firm employs fewer than 20 employees, as some 85% of all the firms belong to this category. The remaining 15% are nearly all firms employing between 20 and 500 workers. Only a very small number of printing firms employ over 500 workers; in Germany this category stands for 0.3% of all the firms and this percentage is even lower in a number of other countries.

ENVIRONMENT

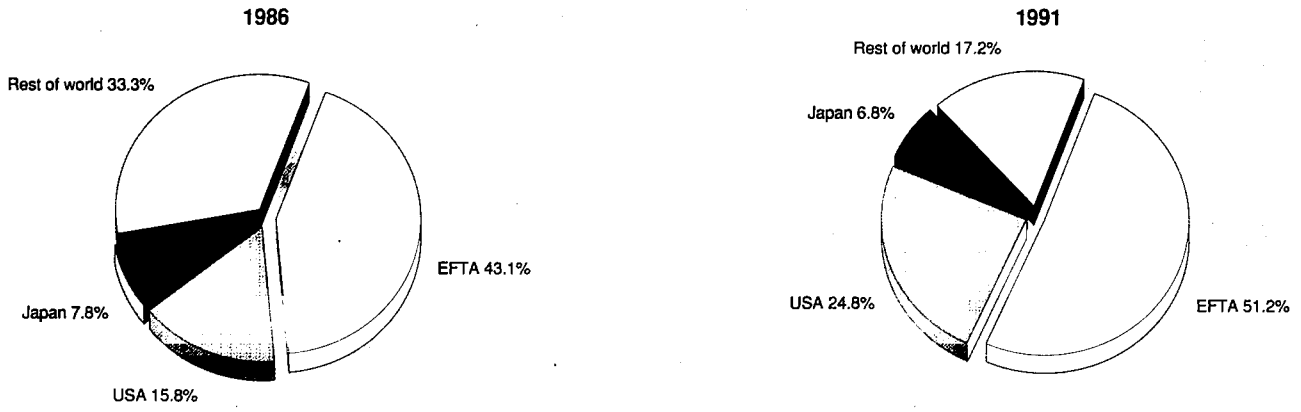
The European graphic industry is an industrial branch which has only a marginal impact on the environment. Nevertheless, the industry is devoting increased resources to meeting the stricter environmental requirements. For example, it has invested large amounts of money to limit emissions caused by web-offset printing, to improve the quality of water and to encourage the recycling of waste.

In some EC countries the graphic industries federations collaborate closely with government departments to agree on the best measures for environmental protection. At international level, the international association for the graphic industry, INTERGRAF, is co-operating with the EC Commission to define appropriate directives in this area. To maintain fair competition, the Single Market requires the harmonisation of laws and directives in all EC Member States, and this also in the field of the environment.

REGULATIONS

The European graphic industry is following very closely the debates concerning the EC draft directive on tobacco advertising. Present terms could well lead to a total ban on advertising of tobacco products. Besides the total ban on featuring the brands of tobacco products in ads, the EC Commission is considering the following measures: limitation of direct advertising; restriction of the advertising activities of mail order houses and retailers of consumer goods; limitation of advertising for medicines not requiring a prescription.

Figure 2: Printing
Origin of EC imports



Source: Eurostat

Besides the economic considerations against the advertising ban, there is also the legal consideration. It is Intergraf view that products manufactured legally should be allowed to be advertised legally.

OUTLOOK

The future outlook is for a continuing high rate of change affecting all parts of the printing industry. This change will not be conditioned by technological progress only, although this will surely bring further automation both on presses and in print-finishing lines.

Thanks to advanced technology, customers will increasingly require on-demand printing, i.e. the printing of very small runs of specialised works, instead of speculating on future sales and keeping expensive published works in stock. Customer demand will also affect the way printing companies are managed with an increased requirement for certification according to the Total Quality Management Concept.

In the longer term, environmental concern will lead to the use of new materials, certainly in the printing process (ink formulations, for instance) and perhaps also in end-products.

Rubber products
NACE 481, 482

The rubber products industry consists of two main subsectors: the manufacture of tyres and the manufacture of industrial rubber products. In the world tyre market the EC is now neck and neck with the USA. After slow but positive production growth in the 1980s, the industry is now experiencing a period of stagnation but there are good prospects for recovery in the years to come.

INDUSTRY PROFILE

Description of the sector

The rubber industry comprises two main subsectors, the tyre and inner tube industry and the production of industrial rubber products (which includes some products for consumers).

The tyre and inner tube industry includes the manufacture of tyres and tubes for passenger cars, trucks and buses, agricultural vehicles, earth moving and mining machinery, bicycles and motor bikes, and other applications.

Industrial rubber products are pipes, hoses, sealings, belts, profiles, foam, soles, glue, etc. which are manufactured for such end markets as vehicles, machinery, electrical engineering, construction, the chemical industry, the food and drink industry, the medical sector and sporting goods.

The rubber industry is to some extent connected with the plastic processing industry (NACE 483): both process polymeric material based on hydrocarbons. The bigger enterprises in the sector of industrial rubber products are often active in the plastic processing branch too. The processing machinery for both branches is similar; the rubber industry uses mixing equipment in addition because the raw material is mixed by the manufacturers themselves.

Main indicators

Both demand and production of rubber products stagnated from 1989 onwards. In line with the weakness in demand and production growth, employment did not show any improvement. Due to rationalisation efforts of the industry, employment in the rubber products sector remains at around its 1986 level.

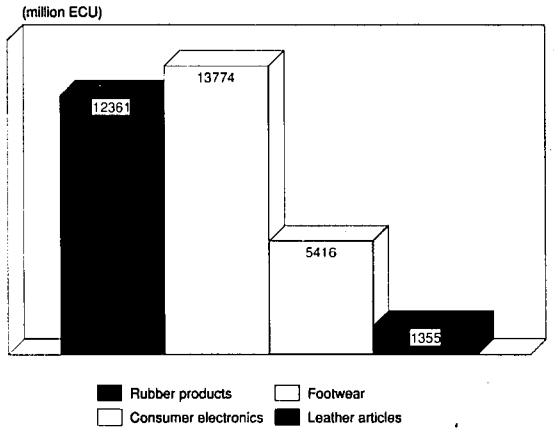
Growth was sluggish in 1992 due to low growth rates in its end markets especially in the car manufacturing sector, which accounts for more than two thirds of the demand for rubber products.

Germany is by far the largest producer of rubber products in the EC, accounting for about a third of total value added in 1991. France is the next largest producer, with about one fifth of total value added, followed by the United Kingdom and Italy, both of which account for about 15% of total value added.

International comparison

The US tyre market remains the biggest in the world but EC-based tyre producers are now the world leaders. The same situation also holds for industrial rubber products. Figure 4 shows that the EC had the biggest increase in production volume in the 1982-1990 period, followed by Japan. Production growth in the US tyre industry has been stagnating since 1988.

Figure 1: Rubber products
Value added in comparison with other industries, 1991



Source: Eurostat

Foreign trade

In 1984 and 1985 there was a remarkable upswing in extra-EC exports. Extra-EC imports, however, steadily increased every year from 1982 to 1991 by more than 8% on average with the result that the trade balance decreased. Throughout the eighties, the share of intra-EC trade in total imports stayed constant.

Among the export markets of EC rubber products, the EFTA countries account for roughly one third of total extra-EC exports, followed by the USA and the OPEC countries. Japan's share is negligible and even decreased in the 1986-1991 period.

As for extra-EC imports, Japan is an important supplier of rubber products, and its importance is increasing. The share of the EFTA countries decreased between 1986 and 1991 and was only marginally bigger than Japan's in 1991. The importance of Malaysia as a world rubber producer is confirmed by the fact that this country more than doubled its share of total extra-EC imports during the 1986-1991 period.

MARKET FORCES

Demand

The tyre market for original equipment (OE) is a highly competitive market with a limited number of customers who exert a strong market pressure on the suppliers. The replacement market is entirely different with a huge number of customers. Most of them are individual car owners, some are commercial organisations like rent-a-car firms or transport enterprises.

The ratio between OE tyres and replacement tyres depends on the development of car production and on the total fleet of vehicles. In periods of overall economic growth, for example, high car sales may boost the share of original equipment up to about one half of the total tyre sales; during periods of recession or stagnation, the ratio is about 40:60.

Industrial products account for almost 40% of the volume of total EC production of rubber products, while tyres account for about 60%. Sales values are about the same for both sectors due to a higher specific value of industrial products.

Taking tyres, tubes, and industrial products for motor vehicles altogether, the automotive sector covers about 70% of the rubber products market. Although tyre replacement demand is not as closely connected with income developments as the demand for new cars, in periods of recession there is a tendency to reduce the driven distance per vehicle, privately and commercially.

The rubber industry participated in the booming car market in the late 1980s. The boom continued in Germany in 1990 and 1991 as a result of German reunification, with positive side-effects also on the French and Italian car production. The weakness in the car market in 1992, however, had a negative impact on that part of the rubber industry which supplies the outfitting of new cars.

Substitution processes have taken place in some areas of industrial rubber products in the last decade. Rubber has been substituted by plastics especially in the profile, hoses, pipes, and sealings sector or in the production of toys or soles. Presently, the situation has in some cases reversed and re-substitution has taken place. The plastic tyre which was introduced some years ago did not achieve a breakthrough. Its

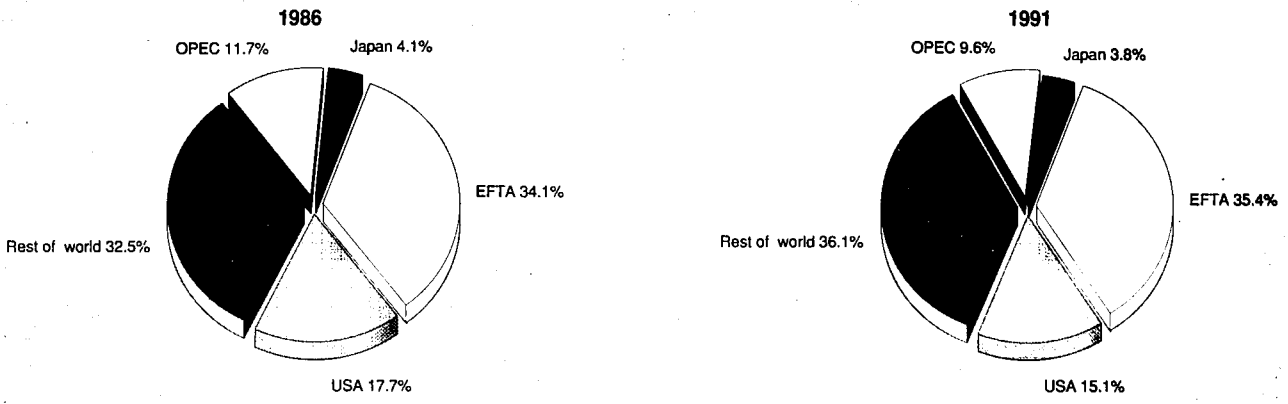
Destination of EC exports



Source: Eurostat

application is, according to experts, limited to very specific purposes. Rubber has replaced metal in some hoses and window frames in cars.

To counterbalance substitution attempts, intensive research and development activity was undertaken partly on raw material and partly on rubber products. Composites consisting of rubber and metal, rubber and glass, rubber and plastic, were developed and produced. One of the most well known inventions was the new tyre developed by Continental in the 1980s. But its introduction on a wider scale is still forthcoming.

Supply and competition

Tyres form a highly competitive market. Production capacity often exceeds demand and there is a constant pressure on prices. This is particularly true for OE tyres. Car manufacturers accept the cheapest offer under certain quality and specification conditions to reduce their own costs. Worldwide procurement of tyres is possible and acts as a permanent market discipline for the suppliers. The price-setting margins are restricted and the tyre industry complains all over the world of low prices and low profits. The replacement market does not face such stiff competition, but wholesalers and retailers also take advantage of the competitive situation as long as the demand by car owners is not restricted to specific brands.

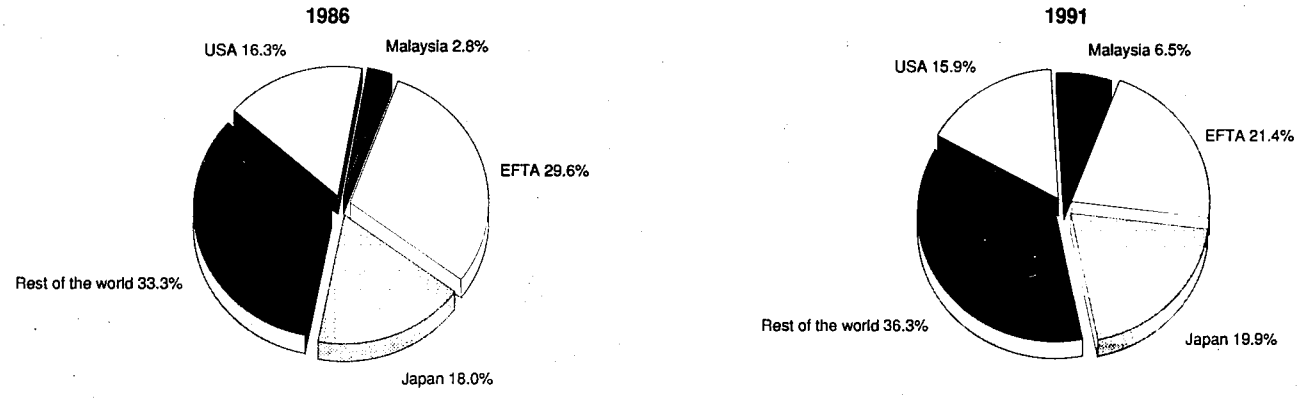
The industrial rubber sector is a much more specialised branch with less opportunity to take advantage of economies of scale than the tyre sector. Even the supply of parts to the automobile sector involves a high degree of specialisation and differentiation. The consequence is that competition between suppliers is less strong than in the tyre sector and the globalisation of procurement is limited because of the necessary consultations between customer and supplier.

Production process

The rubber industry processes natural and synthetic rubber. For tyres the production input is shared about half and half in volume terms; for technical rubber products production, much more synthetic rubber is used, depending on the specifications of the product. An important raw material for tyres is carbon black, besides other textile and metal components.

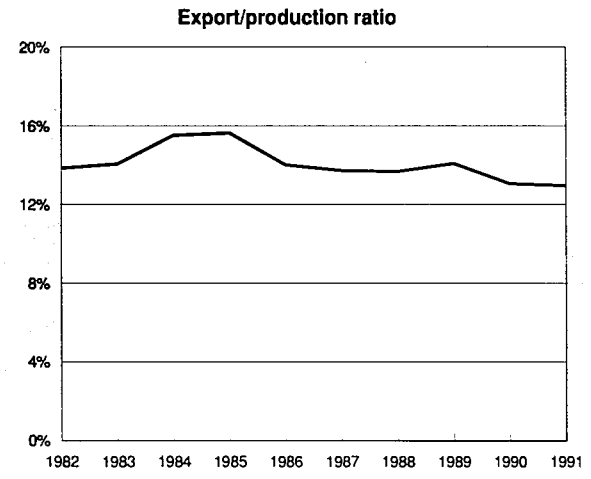
Natural rubber is imported mainly from Southeast Asia, while synthetic rubber is supplied by the chemical industry. The unfavourable price and profit situation in the market for OE tyres leads to constant efforts to bring down costs, especially

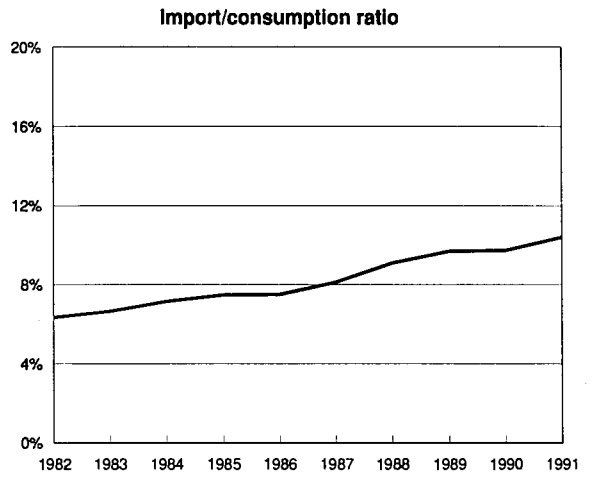
Figure 7: Rubber products
Origin of EC imports



Source: Eurostat

Figure 8: Rubber products
Trade intensities





Source: Eurostat

labour costs, by automation. If these technical developments achieve a breakthrough, and the labour employed gets more and more only controlling and supervising tasks, then a major change in productivity would follow.

INDUSTRY STRUCTURE

Companies

The largest tyre manufacturers normally produce industrial rubber products as well. In addition, there are many small and medium-sized enterprises which produce technical products or products for end consumers only. Small and medium-sized enterprises dominate the rubber and plastic products industry (there are no separate figures available). As far as rubber is concerned, all tyre producers have more than 100 employees, but there are many producers of industrial rubber products or consumer products which employ between 20 and 100 persons. The three largest European tyre manufacturers are Michelin (F), Pirelli (I), and Continental (D). European tyre manufacturers account for 36-40% of the world market.

Strategies

There are at least three ways to react to the challenges resulting from intense competition: first, higher investment in cost-reducing processes; second, increased research and development activity; third, mergers and acquisitions and/or alliances.

Investment activity in the EC showed an upward trend until 1990. Due to reduced expectations, investment decreased in 1991 and it was expected to do so in 1992 as well. The main aim for investment activity is an increase in productivity and reduction in costs (especially labour costs). When the tyre business was booming, expansion was an additional objective. Innovation activities aimed at new products or at new processes, and production methods are other strategies for keeping up with the competitors and are partly in line with diversification. Among the active tyre producers worldwide none is restricted to making tyres.

As the car market became increasingly international, tyre manufacturers have had no choice but to adopt a worldwide strategy. The concept of dominant position at both national and EC level has disappeared. Several structural changes have taken place in the recent past that have reshaped the structure of the world tyre industry, aimed at increasing the size of the largest groups: Bridgestone (J) took over Firestone (USA), Michelin took over Uniroyal-Goodrich (USA), Pirelli acquired Metzeler (D), Continental took over Semperit (A), General Tyre (USA), and Uniroyal-Englebert (USA). Fulda (D) was acquired by Goodyear (USA) and Dunlop (UK) by Sumitomo (J). On the fate of the East German Pneumant, no decision has been taken so far. The latest attempt by Pirelli to take over Continental in 1991 failed. It remains to be seen whether in the long run these two firms will establish some sort of alliance to compete on the world market with the three largest firms: Bridgestone, Michelin and Goodyear.

The industrial rubber industry supplies a large number of sectors, and some rubber producers are now tailoring their production to the needs of the main local client industries. The Italian industry, for example, tends to specialise in sole components for footwear, while the German rubber industry tends to specialise in conveyor belts for the mining industry.

ENVIRONMENT

The main environmental issue for the rubber industry is the recycling, incineration or disposal of scrap tyres and rubber products. Retreading used tyres is a widespread recycling method which has many positive aspects from the ecological point of view. But this does not solve the problem of disposal: at the end every tyre and rubber article has to be incinerated (for example in cement mills) or disposed at dumps. There were attempts to make a chemical recycling by pyrolysis in order to get hydrocarbons but it turned out to be to expensive and generating itself air pollution.

The EC (particularly Germany) is in a leading position worldwide as far as research on and development of ecological techniques are concerned. In the long run this could lead to export opportunities either in the form of machinery or plants or in the form of licences for ecological incineration of tyres.

OUTLOOK

Growth in the automobile industry will be sluggish in the near future but in the medium term prospects for stronger growth are good. In the truck tyre sector the growing traffic as a consequence of the realisation of the single EC market will lead to increasing demand for tyres too. The replacement tyre market acts as the stabilising element; there is always some growth as long as the number of registered cars is in-

creasing. Other industrial rubber products will grow more or less in line with general industrial growth.

The year 1993 is likely to bring some recovery in consumption which will continue in the following years until 1996. For production and extra-EC exports, only the years after 1993 will see growth. One of the underlying assumptions is no significant increase of demand from eastern Europe.

Plastics processing
NACE 483

The recession in Europe and the rest of the world has had a negative effect on the EC plastics processing industry during 1991. In 1992 the manufacturing output of plastics goods in the EC is expected to grow at the same rate as GDP (2%), while the extra-EC trade balance should rise in 1992, compared to the weak 1991, by 6% approximately. The main challenge for the plastics processing industry, as for other sectors, will be to help solve the problems of managing waste.

INDUSTRY PROFILE

Description of the sector

Consumption of plastics material in the EC plastics processing industry is approximately 26 million tonnes. The main branches of the industry are plastic films (6.2 million tonnes), polyvinylchloride (3.5 million tonnes), polyurethanes (1.6 million tonnes), fibre reinforced plastics/composites (900 000 tonnes), and expanded polystyrenes (535 000 tonnes). The industry employs around 800 000 persons. Its main business is to convert plastic resins and compounds into products. The sector operates a range of different technologies, such as injection moulding, compression extrusion, blow moulding extrusion, hand lay-up of fibre reinforced plastics and coating. They also carry out ancillary operations such as decoration by printing, hot stamping and a variety of subassembly operations.

Plastics converters may produce finished articles which are used by other industries like food and hygiene packaging, or building articles, or distributed to consumers. They may also be custom processors who produce components on a subcontract basis for other manufacturers or they may be in-house operations integrated into the manufacturing process. The major markets for plastics are building, packaging, electrical and electronics, automotive, furniture, and agriculture.

Production of plastic films, largest subsector of the plastics processing industry, reached 6.2 million tonnes in 1992 in western Europe. Plastic films are mostly based on polyethylenes but also on polypropylene, PVC, PET or coextruded resins (polyamides, ethylene-vinyl acetate, etc.).

In 1990, the production of polyurethanes in western Europe reached 1.6 million tonnes, of which rigid foams accounted for 450 000 tonnes. The key end markets for polyurethane are furniture, transport and construction which together account for two-thirds of polyurethane consumption.

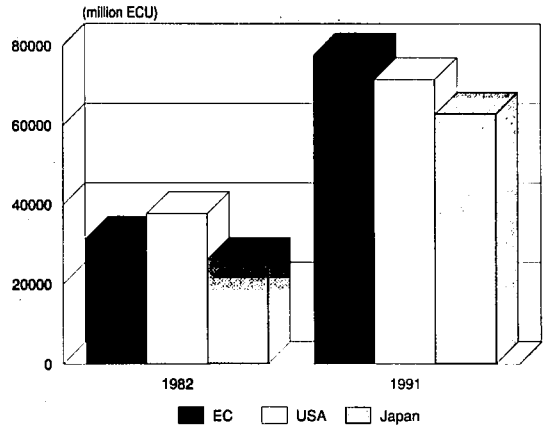
The main constituents of fibre reinforced plastics/composites (FRP/C) are reinforcing fibres dispersed or imbedded in a continuous matrix (polymer). Glass fibres represent over 98% of the total tonnage of reinforcing fibres used. The remaining 2% is shared between carbon and aramid fibres. The total EC glass reinforced plastics (GRP) production in 1990 reached about 990 000 tonnes, three quarters of which were obtained by thermoset matrix and a quarter by thermoplastic matrix.

Expanded polystyrene represented an output of 535 000 tonnes in 1991 in western Europe. In addition, a large part of the plastics converting industry is also devoted to the manufacture of bottles, drums, pipes (875 000 tonnes), profiles, window frames (400 000 tonnes) and calandered products (wall and floor coverings).

Main indicators

Both consumption and production strongly increased during the 1982-1991 period, respectively by 7.5% and 7.1% per year. Extra-EC imports grew at a spectacular annual rate of 13.4% during the second half of the 1980s, that is three times more than extra-EC exports. The trade balance remained stable during the 1982-1991 period, at a level of around 2 to 2.5 million ECU. During the same period, employment in the plastics processing industry grew by 36%.

Figure 1: Plastics processing
Value added in comparison with other industries, 1991



Source: Eurostat

International comparison

The USA, EC and Japan remain by far the largest producers and consumers of plastic materials. In absolute terms, this was expressed in 1991 in the following production and consumption: USA (28.5 and 27.4 million tonnes); EC (28.5 and 24.9); and Japan (12.8 and 11.6). Germany accounts for about 40% of total EC production and consumption.

Foreign trade

The value of the plastic products exported from the EC increased less rapidly than what was imported. From 1982 to 1991 the value of exports has been multiplied by 2.1 and the value of imports by 3.3.

During the 1985-1991 period there has been a decrease in trade between the EC and the USA, as well as a reduction of imports from EFTA countries. This was balanced by an

increase of the imports from China, which is becoming an important supplier of the EC.

Trade with extra-EC countries grew more slowly than the production. On the contrary intra-EC trade increased faster than production.

MARKET FORCES

Demand

Products made by plastics processors range from such mass-produced items as small injection mouldings and continuously produced low density polyethylene packaging film to such specialised ones as composites used in space-shuttle components. In short, virtually every product manufacturer uses, or can use, plastic components.

There is an extensive and diversified demand for plastics goods. Consumer goods and technical applications are characterised by continuous developments.

Demand for plastics can be subdivided in six important markets: building (window frames, insulation, etc.); packaging (food, beverages, etc.); electrical/electronics (offices, telecommunications, etc.); automotive; other transports (railways, shipping, aircraft, etc.); and other markets (agriculture, leisure, toys, household, garden, etc.). The first five sectors deliver to other industries, while the last one directly to consumers via distribution outlets such as department stores.

Many industries use components made of various types of polymers. The energy crisis increased the need for low weight materials. For example in the automotive industry plastics have been replacing more and more metal parts. Another example is given by the packaging sector, where plastics have been replacing glass for bottles (soft drinks, mineral water, milk, etc.) and jars (yoghurts, etc.). The man-made properties of more than 5 000 polymers, blends, alloys and combinations enhanced the design and manufacturing of goods (compact discs, televisions, medical instruments) which would not be possible without various types of plastics.

Plastic films

The major end uses of plastic films are printed films for automatic packaging, shrink and stretch films for overpack-

aging (i.e. pallet hoods and covers or collation films), film for agriculture and horticulture (greenhouses, silage, mulching), films for construction and for shoppers, carrier bags, refuse bags and heavy duty sacks. Almost three-quarters of these films are printed, generally by flexography. Thus printing is an activity almost as important as extruding in this sector of the plastics converting industry.

Polyurethanes

Rigid polyurethane foams show the most potential for growth relative to the more mature flexible market. The key end markets for rigid foams are domestic appliances, mostly refrigerators, which take 90-100 000 tonnes, and the construction industry which takes 250-270 000 tonnes of rigid polyurethane panels. Insulating panels for refrigerated trucks and containers is also an important end market.

FRP/C

The FRP/C industry is a very young and fast growing branch of industry. During its early years in the 1950s the only technologies known were manual hand lay-up and spray lay-up. The first mechanisation appeared only in the 1960s, while pultrusion and winding were introduced only in the 1970s. Even nowadays new techniques are introduced.

In 1990, the breakdown of total EC production of thermoset GRP by manufacturing technique shows that manual techniques still account for about 35%, followed by automated techniques like sheet moulding compound (SMC) and bulk moulding compound (BMC) with about 34% and continuous lamination (about 11%). The percentage of manual techniques used varies greatly among Member States, accounting for more than 80% of production in Greece, Ireland, Portugal and Denmark and for less than 40% in Belgium/Luxembourg, Italy, Spain, France and Germany.

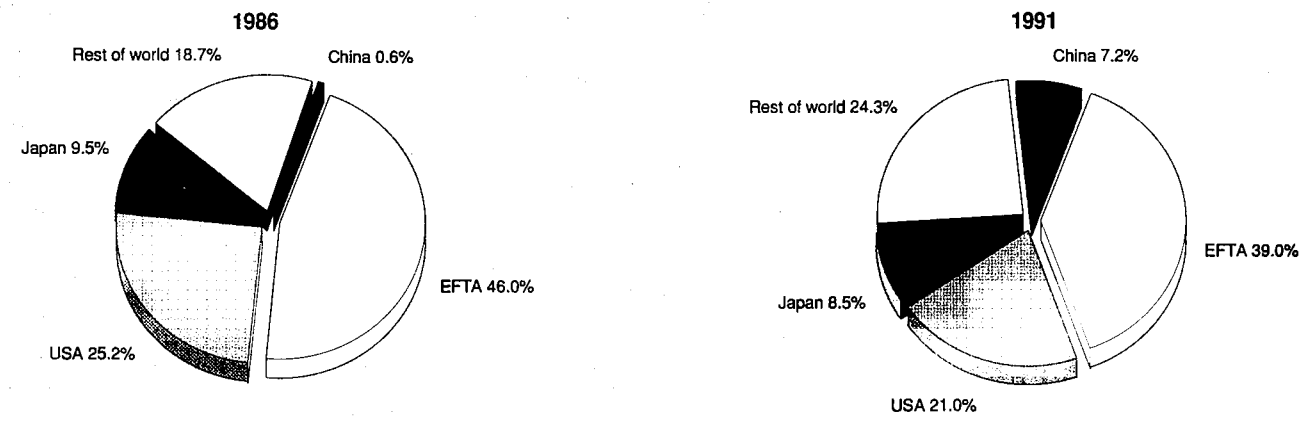
Supply and competition

The existing capacity of polymer production, mostly in the hands if the main petrochemical groups, is in general in accordance with the demand for raw materials by processors.

The plastics processing industry is mainly composed of small and medium sized companies. On one hand for the procurement of raw material, the medium-sized plastics processor has to deal with strong polymer producing companies, and on the other hand he has to sell his plastic products through large scale industries like carmakers, manufacturers of electrical and electronic equipment and department store chains.

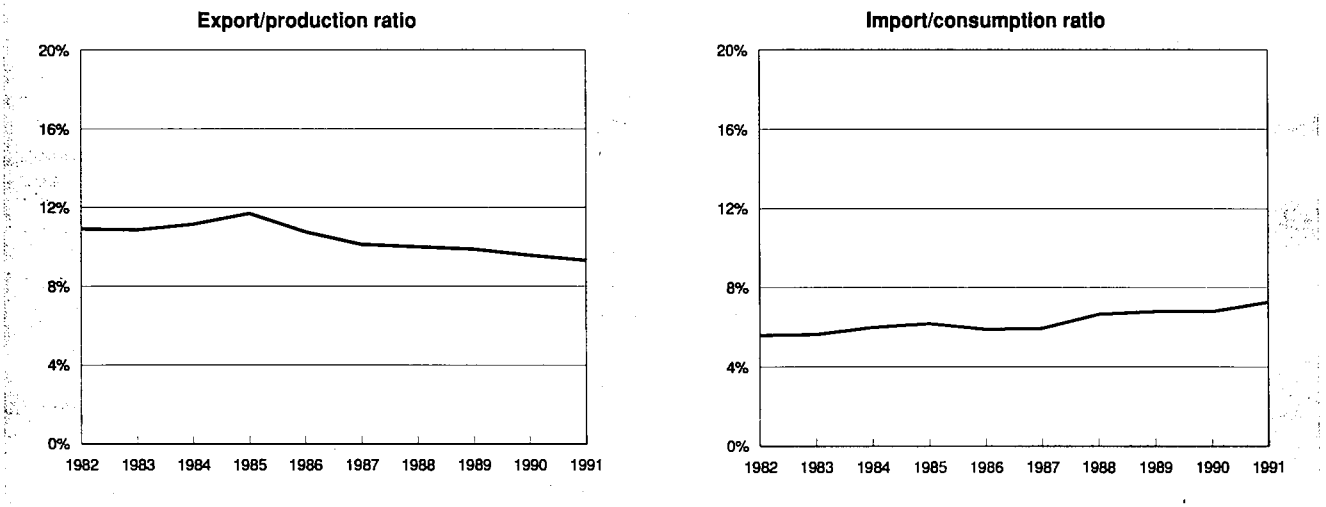
The highly advanced technology in the European processing companies enables them to export about 9.5% of their total production in spite of the high transport costs for plastics

Figure 7: Plastics processing
Origin of EC imports



Source: Eurostat

Figure 8: Plastics processing
Trade intensities



Source: Eurostat

products. The same happens to the imported goods where extra EC imports account only for about 7.3% of total EC consumption. Another reason for this is that plastics processors are often working as subcontractors to other industries and therefore need to be in the "just-in-time" distance. Nevertheless, competition from Far East Asian countries, is becoming in some cases a threat.

Production process

The plastics processing industry utilises a variety of production methods and plastic materials. For every production method, a skilled labour force and important investments in numerically controlled machines are necessary. Professional training is therefore very important for the plastics processors in the EC.

Plastics are increasingly needed because they offer a complete freedom of design, because they are tough, safe, and low in energy content. Plastics lead to many new applications in consumer products as well as in hi-tech applications.

INDUSTRY STRUCTURE

Companies

There are approximately 20 000 plastics processing firms in the EC. The sector experienced a consistent growth during recent years. This was not only achieved by an extension of the sales of the existing companies, but mainly of new companies joining the sector.

Table 5: Plastics processing

Other transports	1 531	1.9
Other markets	28 610	35.8
Total	79 963	100.0

Source: EuPC

In spite of being a sector of small and medium sized companies, the plastics processing industry in Europe has also larger companies such as: Plastic Omnium (F), Wavin (NL), Alphacan (F), Rehau (D), CMB Packaging (F), BPI (UK), Schöller (D), Autobar (UK), Allibert (F), Klockner (D), Peguform (D), Freudenberg (D), and subsidiaries of Hoechst (D) and Solvay (B).

The biggest companies in the field are establishing links within the EC and eastern Europe and are looking for partners.

ENVIRONMENT

The plastics industry is prepared to accept its fair share of responsibility for the environmental impact of plastics but other essential partners in this work are: supply and user industries, retailers, consumers, governments and the waste disposal authorities. Recognition must be accorded to the environmental benefits they can impart from their initial conception through their service life, for example by saving energy and to their ultimate manifestation as waste, ensuring that their full potential for reuse is exploited. There is no single solution to the problems of plastics waste management and material recycling or chemical recycling, incineration and landfill all have their part to play to different extents and according to particular local circumstances. The preferred hierarchy of solutions should be in the following order: 1) Resource efficiency and waste avoidance; 2) Material recycling/product re-use; 3) Energy recovery/recycling; 4) Thermo-conversion; 5) Landfill.Industry itself can assist to help eliminate litter by avoiding overpacking. However, public discipline has a major part to play and public agencies should help improve public education in this field. Degradable plastics are for many reasons not a solution to litter problems, or indeed to plastics waste management questions in general.

OUTLOOK

Due to environmental concern, the industry can foresee the development of products made of recycled plastics. It can also expect concentrations in different fields such as subcontracting for cars and consumer electronics. This young industry is working at heightening public awareness of its many initiatives to contribute to a cleaner environment. The best growth opportunities may come from newly accessible markets

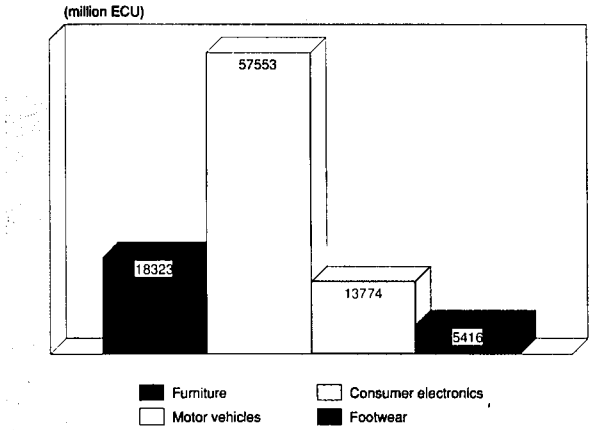
Furniture
NACE 316.6, 467

Competition in the EC furniture industry is fragmented; the sector is composed of small or medium-sized enterprises. Concentration, however, is increasing, both in manufacturing and distribution and particularly in northern Europe. Four countries, Italy, Germany, Belgium and Denmark, have highly competitive furniture industries.
Demand for furniture is cyclical and highly elastic. It is dependent on a series of indicators over which the industry itself has no control, including consumer confidence in the economy as a whole. The industry is very vulnerable to shifts in the economic climate.

Figure 1: Furniture
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The products of the furniture industry are highly diversified and are classified according to the main composing material. Non-metal furniture, for example, accounts for 78% of production. Products are differentiated between dining/living room, bedroom/bedding, kitchen and office furniture.

Office and shop furniture accounts for approximately 15% of production. Two main product groups can be distinguished in the production of office furniture: seating and other types of office furniture (desks, tables, cupboards and cabinets). Production of seating amounts to about one fourth of total production of office furniture.

Main indicators

After a decrease in the early 1980s in all parts of the sector except office furniture, production levels for the industry as a whole have grown steadily, although growth rates have been slowing more recently. Production growth of 13% (in nominal terms), in 1988 was down to 6.6% in 1991. Consumption growth has outpaced production growth by a small percentage due to weakening export growth in the latter half of the eighties. The slowdown in export growth has also contributed to the deterioration of the EC trade balance since 1989, although rising import growth is a more significant factor. Employment in the EC furniture industry is at its highest level since 1982.

The largest share of the furniture industry is devoted to the manufacture of household furniture, specifically dining and lounge furniture. Office and shop furniture makes up approximately 50% of the metal furniture sector in some countries, including the Netherlands. Total production of office furniture in the EC reached about 6 960 million ECU in 1991. The largest producers were Germany (37%) and Italy (19%).

The countries with the highest value added are Germany and Italy, followed by the United Kingdom and France. Together these four countries account for over 80% of total value added.

Recent trends

Compared with overall EC manufacturing, the furniture industry experienced above average growth from 1985 to 1991, in contrast to the early eighties when furniture production growth lagged behind that of total manufacturing. In particular, office furniture has profited from the general economic upturn since 1982, showing the largest growth rates in the industry.

Before 1986, employment in the furniture industry declined, although at a lesser rate than for total manufacturing. In the late 1980s, however, and in line with production growth, employment in the furniture industry grew faster than overall EC industry employment such that by 1991, employment had regained its 1982 level.

Exports at constant prices for the furniture industry grew at a faster rate than overall EC exports before 1985. This pattern for exports was influenced to a large extent by increased exports to the USA. Since 1986, EC export growth has varied considerably, with virtually no growth in 1986 and 1987, a strong performance in 1989, and a weaker performance thereafter.

Furniture consumption showed no real growth until 1986, after which it began to grow at 6% per year on average, spurring production. Office furniture showed the highest growth rates. Growth rates for the different types of household furniture vary by country. In the United Kingdom consumption of bedroom furniture has the highest growth rate, whereas in Germany, kitchen furniture is the fastest growing subsector.

International comparison

The US furniture sector has expanded more rapidly than that of the EC since 1982, although both regions have grown more

than the furniture industry in Japan. In addition, strong demand growth in the USA before 1989, stimulated export growth in the EC. The EC's continuously positive trade balance suggests its strong competitive position relative to Japan as well as the USA, both of which have trade deficits in the furniture sector due to higher consumption demand than domestic production.

Foreign trade

Extra-EC imports grew considerably faster than extra-EC exports at the end of the 1980s and the beginning of the 1990s. This is reflected in the development of the trade balance and the ratio of exports to imports, which both increased until 1985 and then fell steadily. Intra-EC trade is important, averaging a steady 75% of total imports. Metal furniture accounts for approximately 30% of total imports and 20% of extra-EC exports.

The EFTA countries are is the primary market for exports, as well as the primary source of imports. Eastern Europe is also a major supplier.

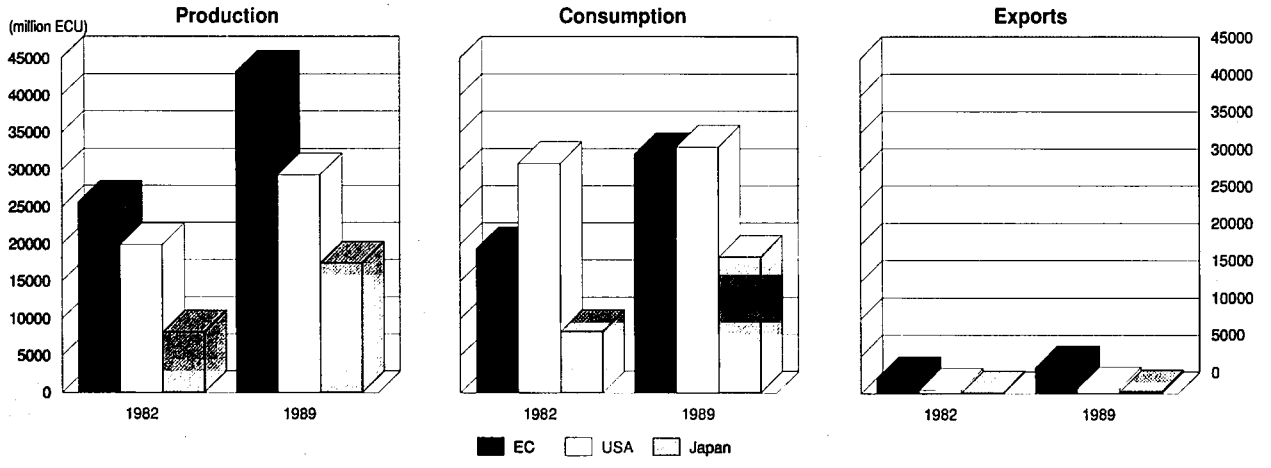
In general trade has grown more rapidly than production, although extra-EC export growth stagnated in 1990 and 1991. Extra-EC exports are a small percent of production compared to intra-EC demand, so this situation did not have a large effect on the overall performance of one industry. Net exporters within the EC are Germany, Italy, Belgium and Denmark, while France and the United Kingdom are net importers.

MARKET FORCES

Demand

Demand for household furniture is primarily connected with growth in the number of new households. Furniture sales are also closely related to trends in overall consumer expenditure and in the housing market. Consumption is also related to consumer confidence in the economy in general. Demand is highly cyclical; purchases tend to be postponed during recession and periods of high real interest rates, making the furniture sector highly vulnerable to changes in the economic situation.

Figure 4: Furniture
International comparison of main indicators at current prices



Source: Eurostat; OECD, Industrial statistics, and Foreign trade by commodities

Other factors which determine demand are changes in life styles, cultural aspects, the furniture renewal rate and the intensity of advertising and marketing, which tends to be very low in the industry.

Supply and competition

The furniture industry is fragmented and is dominated by a number of small independent firms. In recent years, however, large groups have acquired some of the smaller firms, especially in northern Europe. Increased concentration is not yet a factor in Greece, Spain and Portugal, where the manufacturing process is still predominantly artisanal. Germany also tends towards small firms; the average firm has 125 employees and only nine German enterprises have over 1 000 employees.

Retail firms are much more highly concentrated than manufacturing firms, giving the retail sector a firm position vis-a-vis the industry. Internationalisation is expected to increase, although currently only one furniture company in Western Europe, IKEA, in considered to be an international firm. Large trading companies are usually department stores, mail order companies and companies divided into branches. The increased market power of retailers has put prices, and therefore profit levels, under pressure. Larger firms will have a competitive advantage in the future, especially with the advent of the Single European Market.

Four EC countries have highly competitive furniture sectors: Italy, Germany, Belgium and Denmark, all countries with an export surplus. Their position is largely explained by individual local factors, including the level of demand, production factors, distribution networks, etc. For example, the Italian retail system forces manufacturers to be flexible, and results in originally designed furniture to fit specific demand. This necessary domestic innovation strengthens Italian companies on the international level.

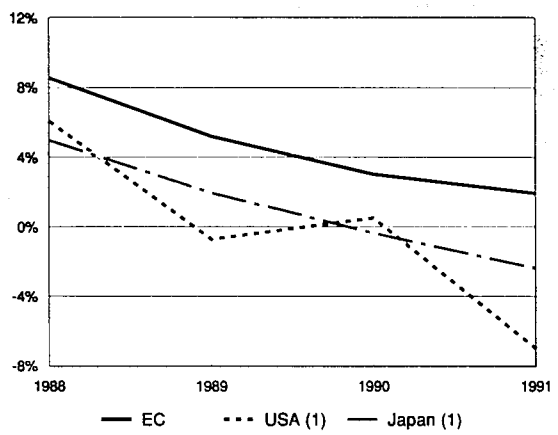
Competition from the United States and Japan in this area is negligible, and imports from East Asia (ASEAN), although increasing, are still only about 3% of total imports. The cost of transportation of the industry's products hampers international trade, although solid wood furniture, furniture in ready-to-assemble form and furniture components have strong international demand.

Eastern Europe has always been an important supplier for the West European market. Due to the economic crisis in these countries, production and supply have been reduced strongly, creating some supply problems in Germany which depends heavily on imports from Romania. Currently only Poland and Hungary are capable of producing goods for exported. Imports from Eastern Europe will continue to decline, although most of what is produced in these countries will be exported due to lack of domestic demand.

Production process

The production of furniture has for a long time been a process artisanal in character; industrial manufacturing of furniture is relatively recent and the production process is still labour intensive. Labour productivity and unit labour costs are therefore of particular importance to this industry. Both have risen

Figure 5: Furniture
international comparison of production growth at constant prices



(1) 1991 for Japan and US are estimates
Source: Eurostat, Department of Commerce, Bureau of Economics Analysis, USA,Statistics Bureau, Japan, OECD, Indicators of Industrial activity

in the past decade, with the unit labour costs increasing slightly faster.

For several subsectors of the furniture industry, raw material input costs can also be very high. In the metal furniture industry in the Netherlands, for instance, these costs amount to 47% of turnover (51% of total costs).

In spite of the labour intensive nature of the furniture industry, technology has been moving the production process towards increasingly automated manufacturing in response to increased national and international competition. Major productivity improvements have been in the production and assembly of rectilinear furniture from coated panel boards.

INDUSTRY STRUCTURE

Companies

The furniture sector is comprised of around 65 000 firms, most of them medium sized. For technical and market-related reasons, a high degree of specialisation is required. However, forces like the Single European Market and the ongoing power of furniture retailers in setting prices are forcing the furniture industry to make strategic choices which include increased concentration.

The number of firms varies regionally. In Spain, where the production process is largely artisanal, the number of manufacturers is around 12 000, whereas in Germany the number is around 1 500.

Strategies

Strategies in the furniture industry will come from the need to face the increased concentration of the distribution sector

Table 5: Furniture

(1) Excluding metal furniture (Nace 316.6)
Source: Eurostat

and the associated increase in the market power of retailers, franchises, and cooperatives. It is much more difficult to establish cooperatives in the production sector itself and thus is more competition among manufacturers than retailers.

Cooperation is particularly strong in Denmark, Scandinavia and Germany, whereas franchising is more frequent in the United Kingdom. If this tendency continues, European firms' international competitive positions could be threatened. Domestic competition strengthens a firm's efficiency and ability to read changes in market demand, as can be seen from the fact that the four countries with the most competitive industries also are the highest exporting countries in the EC.

REGIONAL DISTRIBUTION

In every country of the EC the furniture industry is present, but in varying degrees of competitiveness and concentration. As previously mentioned, the northern countries and Italy have a fairly developed manufacturing industry, whereas in Portugal, Spain and Greece, the sector is quite artisanal nature.

In general, large-scale enterprises are not numerous, although they do exist in nearly every country.

ENVIRONMENT

Environmental issues for the furniture industry fall into two categories: process problems and the use of specific materials in the products.

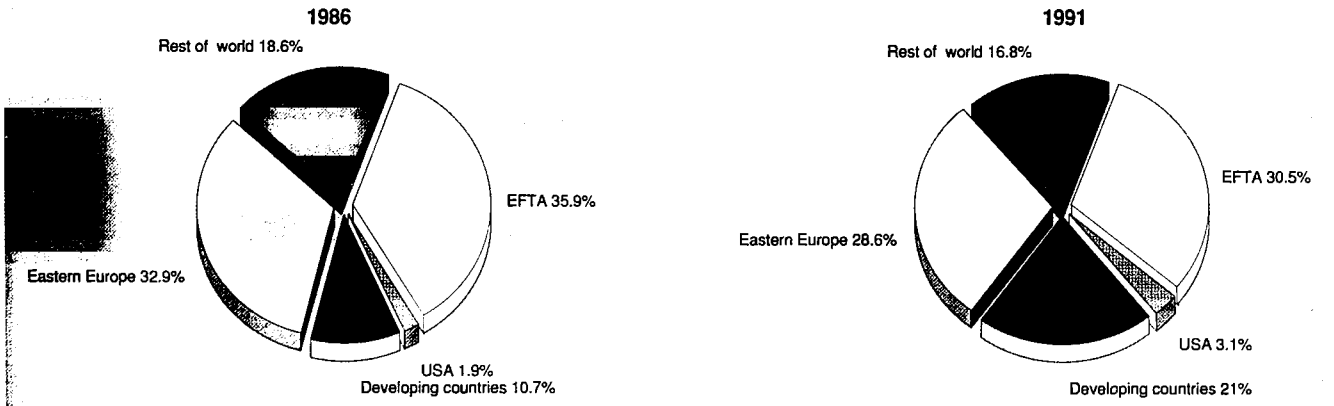
Emissions from finishing materials like stains, glazes and lacquers may cause problems and result in government intervention. The use of plastics in the upholstered furniture industry may be under pressure as well due to the increased concern about certain materials like polyurethane and PVC.

REGULATIONS

Safety of products and protection of design are the two main elements which are affected by legislation.

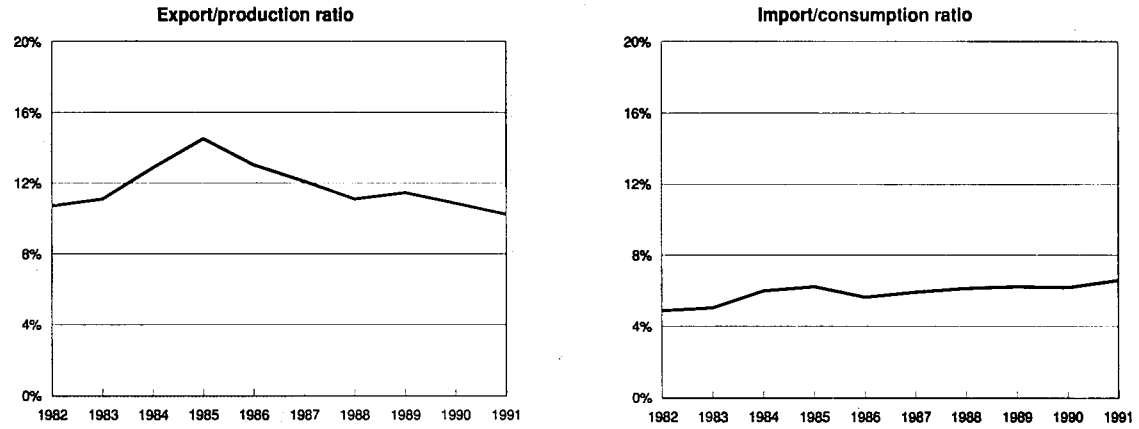
Fire safety is an area of high concern. The EC Commission is drafting a proposal for a directive on the fire safety of

Figure 7: Furniture
Origin of EC imports (1)



(1) Excluding metal furniture (Nace 3166)
Source: Eurostat

Figure 8: Furniture
Trade intensities



Source: Eurostat

upholstered furniture. For instance, it should not be possible for furniture to be set on fire by a burning match or cigarette.

Design protection is one of the key elements of the success of the European furniture industry, and adequate protection of design and models is essential to the industry.

OUTLOOK

The outlook for the furniture market is generally favourable. Due to the growing number of households, as well as the gradual recovery from the general economic slowdown at the start of the 1990s, real growth rates are expected to be 3% to 4% per year in the medium-term. Additional factors supporting growth are high replacement demand and more inherited capital. Prospects for office furniture are particularly promising because of the growth of the service sector and the gradual recovery of investment in the EC.

Counter forces are the saturated market, which will spur competition among the producers, and possibly high interest rates. Output could grow along with demand, but the prospects for exports are less encouraging.

In summary, the furniture industry faces a number of challenges in the future: the growing power of the retailers (e.g. IKEA); the search for Europe-wide brand products; the increased concentration of the industry; the reorganisation of production (automation, logistics, sub-contracting).

Jewellery
NACE 491

The jewellery sector had a difficult year in 1991, with production and consumption in real and in nominal terms declining, although prices for precious metals and diamonds remained stable. The value of diamond sales declined in 1990, although the number of pieces purchased increased slightly, implying increased purchases of lower valued pieces. The outlook for 1993 is more promising, as it is expected that general economic growth will increase after the slowdown at the beginning of the 1990s.

INDUSTRY PROFILE

Description of the sector

The jewellery sector is divided into six subgroups:

- precious metal or precious plated ware;
- goldsmiths' and silversmiths' wares;
- fancy (or "costume") jewellery;
- diamond cutting;
- precious and semi-precious stones;
- coins and medals.

The difference between precious and fancy jewellery is sometimes difficult to determine. An article made of base metal and coated with precious metal set with imitation stones would be regarded as costume jewellery, but high-quality plated metals may also be set with natural stones, and the designation of costume versus precious jewellery is unclear. The industry includes articles made of precious metals (particularly silver) that are not worn on the person.

At the retail level, it is customary for the industry to have close ties with the clocks and watches industry as well as with antiques not necessarily made of precious metals.

It should be noted that Eurostat data on production and employment used in the monograph show the relative volume of the industry in each country and trends in production and employment. However, the absolute figures are underestimated, as units employing less than 20 people are not taken into account by official statistics, and because of high taxation of jewellery in most EC countries. Small firms can account for more than 40% of production for a country.

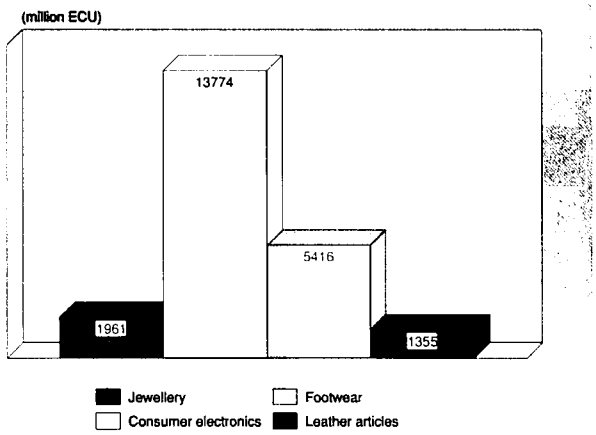
Main indicators

Production in current prices and in real terms grew slowly in 1990 and declined in 1991. For the largest EC producer, Italy, jewellery production declined in real terms by 7% in 1991, and for the EC as a whole, by 6.6%.

Although the growth of gold jewellery fabrication also slowed down in 1990, output from East Asia declined as well, and for the first time in three years the EC's output was higher than that of East Asia. Despite the relatively stable prices of gold, silver and diamonds in 1991, the jewellery industry was vulnerable to the effects of the recession in the USA, and the slow economic growth in the EC and Japan.

Gold production in Italy reached the level of 415 tonnes in 1991 compared to 381 tonnes in 1990 (9% growth), while total gold fabrication in Germany, France and Spain increased 15% during that time. The largest producing countries are Italy, Germany, France and Belgium. Italy alone produced 70% of EC total gold production in 1990.

Figure 1: Jewellery
Value added in comparison to other industries, 1991



Source: Eurostat

Gold and silver traded at low price levels in 1991 compared with the early 1980s. The price of gold went down from 392 USD per ounce to 355 USD in August, 1991. Traditionally, instability raises gold and silver prices, but neither the Gulf War nor the attempted Soviet coup affected the price. Silver prices declined at first, but later rose to the early 1991 price of 4.10 USD per ounce. Diamond prices, which are strongly influenced by the De Beers Central Selling Organisation, remained fairly stable during 1991.

In evaluating apparent consumption, care must be taken in analysing the figures for the following reasons:

- the interval between production and sale is often long and stock levels fluctuate significantly;
- production figures are underestimated by the exclusion of firms with less than 20 employees. Apparent consumption is derived by subtracting exports and adding imports to production, so apparent consumption figures are highly dependant on production figures.

Therefore consumption is likely to be underestimated by a large amount.

Import and export figures, however, will cover most trade because of the high value of the products involved, above the minimum for statistical declaration.

Source: Eurostat

As a result, apparent consumption for even the largest producing countries, such as Italy, could be negative. This is readily understood when one considers that the enterprises included in the production figures employed in 1988 some 12 000 people, whereas it is estimated that total industry employment in Italy is actually around 40 000.

An indication of the market can be found when looking at retail figures. Euromonitor estimates for 1988 showed a market of 8.1 ECU billion (9.6 billion USD) for precious jewellery and of 1.3 billion ECU (1.6 billion USD) for costume jewellery. Using the retail sector margins, the comparable consumption figure calculated equals 5 billion ECU, three times apparent consumption.

France and the United Kingdom are traditionally the major markets for costume jewellery in the EC. Germany has recently witnessed an upsurge in demand for costume jewellery which places the German market alongside the United Kingdom and French markets in importance. German consumers, more than other Europeans, had a bias for real jewellery during the 1960s and 1970s. Costume jewellery became more fashionable at the end of the 1970s, but demand decreased in 1991.

Imports are a small percent of consumption in the EC. Italy is a large importer of raw materials and semi-finished products, which are exported after further production. EC export growth was negligible in 1991, reflecting the less favourable economic situation world-wide. Costume jewellery exports have been declining since 1989.

Employment figures show very little change in the numbers employed between 1985 and 1991, but accurate figures are difficult to obtain due to the large number of very small firms in the industry, and of self-employed workers.

Recent trends

The demand for gold for the purpose of jewellery fabrication rose markedly, from 54% of total gold production in 1980 to 87% in 1990, which had a not able effect on the price of gold. The market for costume jewellery in particular expanded during the 1980s. On the basis of estimates at the retail level for the EC (Euromonitor) and for Japan (Japan External Trade Organisation) and at the industry level for the United States (Department of Commerce) the total value of the market for jewellery in the late 1980s was roughly divided into 80% precious jewellery and 20% costume jewellery.

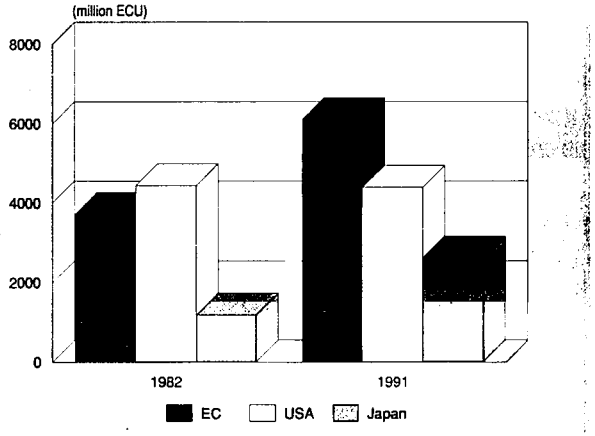
The substantial fall in industry employment in the early 1980s was caused by the slump in economic activity and by increasingly capital-intensive production methods. These methods have allowed for greater production without a dramatic increase of the labour force.

International comparison

According to the World Gold Council, in 1988 around 38% of Italian adults bought at least one article of gold jewellery, compared to 34% in the United Kingdom, 18% in Germany, 14% in France and 15% in other EC countries. In Japan, a comparable figure was 33% of all female adults. In the 1980s these figures showed a rise in almost all countries, but the growth has been especially strong in Japan, where in 1986 this figure stood at 21%. In the USA, sales are under pressure, due to a 10% luxury excise tax applied on the portion of retail sales over 10 000 USD, effective on January 1, 1991, which especially affects high end products.

US demand shrunk in 1991, resulting in difficulties for some retail chains. Total turnover in 1991 has been estimated be-

Figure 4: Jewellery
International comparison of production at current prices



Japanese production presented for 1982 and 1989
Source: Eurostat, US Dept of Commerce, US Industrial Outlook 1992, OECD, Industrial Structure Statistics, Japan External Trade Organisation, Your Market In Japan, 1990

tween 15 billion to 18 billion USD in retail prices. At the industry level, the market for precious jewellery in 1991 was estimated at 6.2 billion USD and for costume jewellery at 1.7 billion USD, continuing the decline of 1990.

In Japan, demand shrunk 2% in 1990. Japan is still considered a growth market, however. The total market in Japan has been estimated at 2,500 billion Yen at the retail level (13.7 billion ECU). Japan itself is facing competition from East Asian countries in the costume jewellery market. Japanese manufacturers are increasingly using the workforce in those areas; bullion and diamond materials are being shipped to East Asia, from which finished or semi-finished products in turn are imported.

According to De Beers, world retail sales of diamonds reached 32 billion USD in 1990.

Foreign trade

The most significant general feature of the trade figures is the volatility of the figures over the years. It should be noted that all values are in ECU. As most international trade takes place in dollars, the ECU values are influenced by fluctuations in the dollar rate. The appreciation of the yen during the 1980s had an overwhelming impact on EC exports to Japan; by 1990, exports to Japan in ECU value were well over nine and a half times the 1980 figure in ECU.

In 1991, extra-EC exports considerably exceeded extra-EC imports. The trade surplus amounted to 4.3 billion ECU, which was an increase from 1990. Much of this, however, was due to falling imports. The breakdown of EC imports by country of destination emphasises the importance of Italy as a producer of jewellery. For Italy itself, exports are very important, accounting for 70% of production. Italian exports mainly involve high priced products.

The trade deficit for costume jewellery amounted to 252 million ECU in 1991, with exports to countries outside the EC of 218 million ECU and imports of 470 million ECU. The largest exporter and importer of costume jewellery is France.

Exports from Thailand have been accelerating over the past ten years, placing it in the position of second largest exporter of jewellery in the world after Italy, with the potential to become the largest. Exports of polished diamonds look particularly promising for Thailand.

For intra-EC trade, the Single European Market will mean that national tariff and quota restrictions will disappear, restrictions mainly found in trade with Spain, Portugal and Greece. EC import tariffs for jewellery range from 3% of CIF value for types of precious jewellery to 8.5% for costume jewellery. For countries falling under the GSP or the Lomé convention there are no tariffs.

In 1991, France and the United Kingdom were the most important consumers of EC exports in Europe. The European export market decreased 2.5% in 1991, continuing the development of 1990.

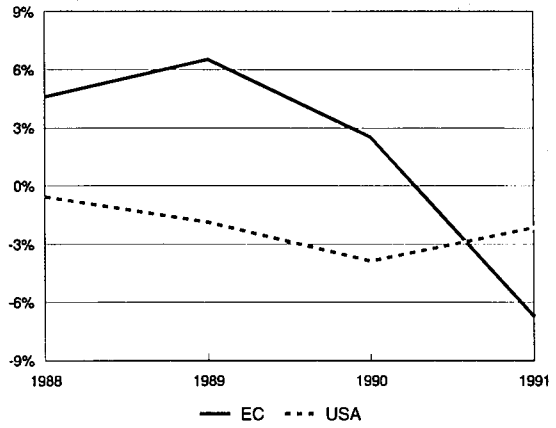
France is the most important intra-EC importer of costume jewellery, followed by Germany, the United Kingdom and Belgium. In 1991, the European export market declined 6.5%. Extra EC exports decreased by 7.5%.

MARKET FORCES

Demand

In 1991, demand for heavier, bulky items increased; ethnic jewellery also grew in popularity, particularly gold mixed with coloured enamel. In the EC, polished gold remains the most popular choice for general jewellery, although textured gold is gaining popularity for more 'avant garde' designs. Earrings are the most frequently bought item.

Figure 5: Jewellery
International comparison of production at constant prices



Source: Eurostat, Census of Manufacturers

Diamond rings continued to dominate the retail sales of diamond jewellery throughout the world. Especially in those countries where diamond engagement rings are traditional, this domination is pronounced. For instance, in the United Kingdom, where 70% of brides receive a diamond engagement ring, rings account for 83% of the total value of the market. In the USA, however, despite the strong tradition of diamond engagement rings, rings accounts for only 61% of total value. This is a result of the increasing popularity of men's diamond jewellery and of high priced diamond bracelets. In Germany and Spain, where engagement rings are not a tradition, rings account for only 52% and 41% of total value, respectively. In Germany, high-value necklaces form a very important category. In Spain, earrings are particularly popular. Sales promotion by the De Beers Corporation in Japan has been very effective, firmly establishing the position of diamond jewellery in the engagement ring market. In Japan, 77% of brides receive a diamond engagement ring. As a result, rings account for approximately 76% of total value in that country.

Purchasing of jewellery is highly seasonal, with one-third of diamond jewellery being bought in December. The rising demand for precious jewellery is a result of growth in the standard of living and personal disposable incomes. National differences can also be quite large. These are influenced by the amount of disposable income people are prepared to pay for luxury items. For instance, Dutch consumers' spending on precious jewellery is relatively low, whereas Italian consumers' spending is high.

The majority of purchasers are women, but the percentage of men buying jewellery is rising. Much of this is for gifts, but there is also an increasing portion of men wearing jewellery. Younger groups in the population are the leading purchasers.

The following factors are likely to stimulate demand for more costly jewellery:

- the ageing population. The percentage of people between 30 and 40 years old will rise in the 1990s. These are the people who buy costly jewellery; younger people tend to buy less expensive fashion accessories;
- the demand for unusual and natural materials;
- the current ornate and luxurious fashion trends.

Among the discernible trends are:

- Far Eastern, Indian and African styles;
- folkloric, heraldic and Art Deco themes;

- increased use of natural raw materials;
- floral and animal motifs.

The last two trends emerge out of a general concern for ecology and nature.

Supply and competition

There is little branding in the precious jewellery sector, which makes analysing competition at an industry level irrelevant. It is more significant to determine competition at the retail level. Manufacturing for costume as well as precious jewellery is highly fragmented, with many small, artisanal companies. At the retail level there is also fragmentation, but in the 1980s some retail chains gained importance: including Ratners (parent company of Ratners and H. Samuel) in the United Kingdom, Magic Moment and Gold Market in Italy.

Precious jewellery is sold mainly through specialist jewellers, whereas costume jewellery is sold through a variety of outlets: department stores, chemists, clothing shops and jewellers.

Competition in the costume jewellery industry is coming mainly from East Asian countries, especially Hong Kong, South Korea, Taiwan and Thailand. Usually these countries operate at the less expensive end of the market, but product quality is improving. Competition from East Asia takes place mainly through price.

Production process

Most of the enterprises in the precious jewellery industry are artisanal in character. Therefore it is difficult for the industry to keep up with fast growing demand, as was the case in the 1980s. In comparison with costume jewellery, however, the

precious jewellery industry has the advantage of not being under the influence of fashion trends: designs last much longer.

The manufacture of costume jewellery includes a broad variety of products: brooches, ear-rings, necklaces, bracelets, rings, hair ornaments, hat ornaments, shoe ornaments, cuff-links, tie-clips, etc. To maintain market position, manufacturers of fashion jewellery are urged to produce up-to-date designs. In theory, new collections are introduced 2 to 4 times per year, but in practice new ranges appear much more frequently. This makes short distribution lines necessary, giving local EC producers an advantage over overseas manufacturers. Much costume jewellery is shipped by air because of the need for quick delivery.

Costume jewellery is very sensitive to fashion trends, which make high mark-ups necessary to compensate for the risk of goods becoming unsaleable.

INDUSTRY STRUCTURE

Companies

Jewellery manufacture, for both precious and costume jewellery, is highly fragmented. For example, Italy's industry has 6,500 businesses, employing 40,000 people (estimated). The largest are all privately, generally family, owned and managed.

Primary precious jewellery firms include Lyon Alemand Louyet (France), Engelhard (France), Trattamente Ceneri Auroargentari (Italy), Uno a Erre Italia (Italy), Rosy Blue (Belgium), Lens Diamond (Belgium), Franz Golz (Germany) and Guthmann & Wittenauer.

Among the costume jewellery companies with the highest sales are Bijoux GL (France), Moranduzzo Dario (Italy), Modern Creation Muenchen Reisegepack (Germany), and Rudolf Zenner (Germany), among others.

Strategies

The use of brands is rare in the jewellery industry. The few existing brands tend to be active in the costume jewellery sector, mainly originating from enterprises with well known brand names in other industries such as cosmetics or clothing (Kenzo, Moschino, Fiorucci) which branch out into jewellery. Distribution, therefore, plays an important role in competition and strategy.

Precious jewellery is mainly sold through speciality jewellers, but there are a growing number of multiple and non-specialist outlets. However, once demand picks up, independent jewellers should fare better. For costume jewellery sales outlets are much more diverse, with special emphasis on the tax and duty free shops. With the Single European Market, this type of outlet will disappear for intra-EC travel, but the European Commission has given the duty free stores until the year 2000.

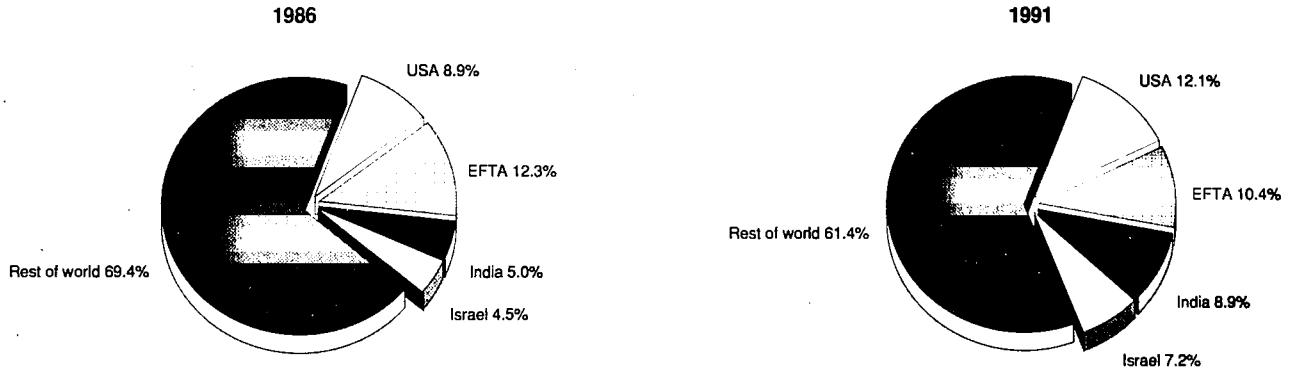
Most of the enterprises of the industry are too small to follow rigid strategies apart from following the market. As competition with foreign industries increases, however, more emphasis could be placed on quality.

REGIONAL DISTRIBUTION

The industry has a great need for specialists and therefore remains concentrated in places where the infrastructure has been built over many years. By further specialised aggregation, some locations lend themselves to higher-quality jewellery, some to quantity production, and some to production of larger silver articles.

The main manufacturing centres in Italy are Arezzo, Vicenza and Piedmont. In Germany about 75% of the trade is based in Pforzheim, with Idar-Oberstein being an important centre of the gemstone industry. Other centres are Schwabisch Gmund, Hanau and Kaufbeuren. In France, Paris and Lyon account for a major part of the industry, as does St. Amand.

Figure 7: Jewellery
Origin of EC imports



Source: Eurostat

In the United Kingdom the main centres are London, Hatton Garden, Birmingham and Sheffield (the centre for cutlery and a large portion of the table-silver industry). In Belgium, Antwerp is the centre of the jewellery industry. Belgium ranks among the major diamond cutting centres in the world, along with India, Israel and the United States.

REGULATIONS

Regulations in this industry refer only to the precious jewellery, as there are generally no specific standards or restrictions for fancy jewellery.

Currently, four systems of grading are in use for polished diamonds, associated with the Gemological Institute of America (GIA), the International Diamond Council (IDC), the Scandinavian Diamond Nomenclature Committee (ScanDN) and the International Confederation for Jewellery, Silverware, Diamonds, Pearls and Stones (CIBJO). Proposals have been made to arrive at one international standard. Although all organisations are confident of reaching a successful solution, an agreement has still not been reached.

On October 8, 1990 the European Commission accepted the Green Paper on standardisation (published January 28, 1991). Early in 1992, the Commission gave a communiqué summarising the reactions on the Green Paper. All this has to lead to directives in the spirit of the "new approach" (the Commission only providing general guidelines and prescriptions for a product).

OUTLOOK

Demographic changes will affect the market. The proportion of persons 45 to 65 years old in the population is forecasted to grow 4% by 1995, which should stimulate demand for higher priced items. The proportion of people aged 15 to 24 years is forecasted to fall 12%, which will lead to more competition in the lower-price end of the market.

Forecasts for the jewellery sector depend heavily on the price of gold. Along with the expected moderate economic growth, the gold price may move upwards. But several scenarios are possible here, including a further decline in price should the mining industry not decrease production. After the active years of 1988 and 1989 and the successive slowdown in 1990 and 1991, growth is expected to be 3% to 4% for the jewellery industry.

Source: NEI

The costume jewellery industry is very sensitive to developments in the world economy. As the prospects for general economic developments are for slow growth, the outlook for the costume jewellery industry is also moderate.

Furthermore, competition is expected to intensify as a result of the advent of the Single European Market and of production in East Asia. Another threat to domestic EC manufacturers is the assembly of imported pieces into products by importers. Subcontracting to manufacturers in the Far East is also growing. These developments put pressure on prices.

One possible response of manufacturers is the development of brand names. At the moment, brands are mostly absent in the sector, which increases vulnerability to imports. Developing brands could offer significant opportunities, although more for distributors than producers, due to the higher level of concentration among distributors. Brands could also differentiate between East Asian and European manufacture on the basis of quality; East Asian imports compete on a price basis, and with the demographic changes expected in the near future, price will be less important than quality.

Musical instruments
NACE 492

There has been an increasing demand for musical instruments in the 1980s as a result of changing lifestyles and the development of musical culture among the general public. Asian imports account for a large portion of the supply of electronic instruments; Japan is particularly strong in the supply of up-market, sophisticated instruments. Current trends in EC production are likely to continue into the 1990s with the emphasis on traditional, high-quality instruments, the gradual development of electronic instruments, and increasing activity in the restoration of old instruments due to the growing share of 30 to 40 year old people in the EC and the accompanying changing lifestyles.

INDUSTRY PROFILE

Description of the sector

The products of the musical instrument industry are highly diversified and can be summarised in the following groups:

- pianos (upright and grand pianos);
- organs;
- woodwind instruments (saxophones, oboes, flutes and clarinets);
- brass wind instruments (trumpets, trombones);
- string instruments (violins, cellos, violas and bases);
- fretted instruments (non-electric guitars, mandolins, banjos);
- percussion instruments (drums, cymbals);
- electric pianos, electric keyboards, portable keyboards;
- synthesisers;
- other instruments (accordions, rhythm machines, mouth organs, harpsichords, pipe organs);
- accessories and parts (bows, strings, bridges, components for electronic music).

Musical instruments include both traditional instruments (early or modern), and electronic instruments.

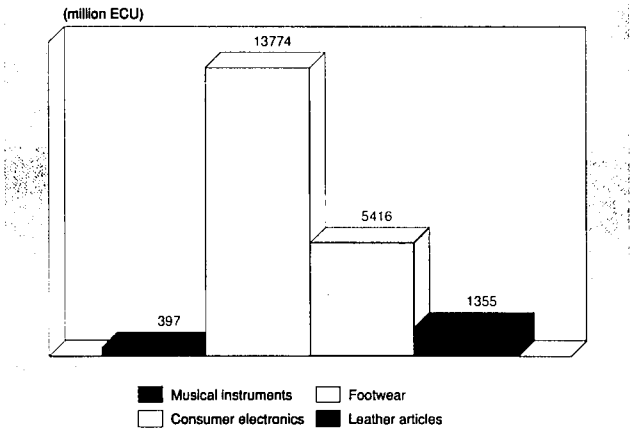
Demand for pianos keyboards and related instruments accounts for two-thirds of the market.

Main indicators

Consumption of musical instruments increased in 1991, after a decrease in 1990, and production reflected the improved demand with a similar growth. The EC is a net importer of musical instruments. In 1991, the balance of imports over exports deteriorated slightly as EC exports grew slowly compared to EC imports. These indicators do not reflect perfectly the market for musical instruments, as resale and rental, which are significant in all European countries, must also be taken into account.

Employment fell in 1990 and 1991, compared to growth in 1989. Many countries, however, only report employment for firms with 20 employees or more. In Germany alone, 30% of the working force is employed in firms with less than 20 employees. When taking into account that labour force reduction is more difficult in small companies than in large ones the decline in employment in recent years is likely to be insignificant.

Figure 1: Musical Instruments
Value added in comparison with other Industries, 1991



Source: Eurostat

Production of musical instruments varies on a regional basis. The bulk of European production comes from Germany and Italy, which together account for 78% of EC production. Germany (West), however, suffered a decrease in production at constant prices from 1980 onwards with only a temporary recovery in 1989. Italy's production grew until 1991, with a setback only in 1990.

According to some market reports of Germany and the United Kingdom, there is a trend towards the use of more traditional, acoustic instruments. A renewed interest in jazz in some countries is creating more demand for pianos and wind instruments. The largest growth of the market, however, is still to be found in new electronic products.

Recent trends

EC production at current prices grew 37% between 1985 and 1991. In constant prices however, total production recovered slowly from the decline in the early 1980s, with a slight relapse in 1990. In 1991 there was a substantial rise in production.

The growth rate of value added has lagged behind production growth. Investments by EC producers picked up in 1988 and again in 1989 according to German figures. Investment in the USA also grew in 1988, but fell back in 1989.

In the 1980s many firms, both cottage industries and larger concerns, went out of business as a result of commercial and financial difficulties. The number of people working in the industry fell from 19,300 in 1980 to 13,800 in 1991, with a temporary increase in 1989. The evolution varies from country to country. Employment is mainly concentrated in Germany (48 % of the total), Italy (18%), the United Kingdom (13%) and France (11%). The greatest job losses since 1980 have occurred in Italy, the United Kingdom and Spain. Although Germany and France have also experienced declining employment, the decreases were smaller and steadier. Since German figures refer only to firms with 20 employees or more, this fall is likely to be lower when the small firms also are taken into account.

International comparison

With production at 962 million ECU, the EC was the largest world producer in 1991 for the sixth consecutive year. Japan suffered from a decrease in production after high growth in 1990 while USA production declined for third year in a row.

Foreign trade

The EC faces stiff competition for high value, modern products, especially from the East Asian countries of Japan, South Korea, China and Taiwan. In the field of traditional instruments, competition is also present from other Europe countries including those in Eastern Europe, Austria and Finland. Increasing labour costs had a negative impact on EC competitiveness at the end of the 1980s and at the beginning of the 1990s. Asian countries have succeeded in gaining a firm foothold in the EC market by selling good quality products at lower prices.

Throughout the 1980s, imports grew steadily mostly in electronic instruments, pianos, wind instruments, and accessories and parts. EC producers are faced with an absolute decline in market share; the share of the EC market being supplied by non-EC producers has grown from 40% in 1980 to 50% in 1991.

In 1991, exports of musical instrument accounted for 30% of total production: the same ratio as in 1980. The EC balance of trade figures showed a deficit throughout the 1980s. Exports consist mainly of string instruments, accordions, organs, and accessories and parts. In 1991 extra-EC exports continued to grow after the recovery in 1989. Intra-EC trade has grown faster than extra-EC trade since 1988, a reversal of the trend in the 1980s.

MARKET FORCES

Demand

The EC has a large market, estimated at 1 335 million ECU in 1991. However, the consumption of musical instruments in the EC remains low compared to the United States, due to the fact that the market is made up of individual national markets with specific characteristics. There is, however, a trend towards greater uniformity in the electronic instruments sector.

Several basic factors are likely to have a favourable effect on the musical instrument market all of which are linked primarily to demographic developments.

The decreasing number of 5 to 20 year old people in the total population will, in the long term, lower total demand for musical instruments and, in the short term, lower growth of demand for easy electronic instruments like portable keyboards. The increasing number of 30 to 40 year old people means more purchasing power and more interest in acoustic instruments in the future.

The rise in purchasing power and changing life styles, have also revived interest in music-making.

Supply and competition

Despite its large home market, the EC musical instrument industry is losing its competitive position. Import penetration continued after a temporary standstill in 1990. During the second half of the 1980s the yen depreciated, making Japanese products relatively cheaper in the EC, whereas EC exports to Japan grew more expensive. In 1990 the yen appreciated, which is reflected in weaker imports, but in 1991 the Japanese currency again fell in value against the ECU.

The development of electronic music instruments has lead to a wider range of products. These electronic instruments have an advantage over traditional music instruments in that they offer new ways of making music, in an easier and more accessible way for non-professional musicians makers. However, a part of the market for traditional instruments has been lost, mostly in the segment of musical instruments which were designed to be played at home. In the professional market the trend in live music towards more sophisticated shows and video clips has lead to a demand for easy compatibility of instruments.

Production process

European firms concentrate on products in the top of the market range. High quality production implies smaller production runs and instruments made-to-order, consistent with an industry which is geared to an experienced clientele rather than the general public. The EC industry, with its specific national features, also plays an important role in transmitting European musical culture through the instruments it manufactures: pianos and violins in Germany, woodwind instruments in France; guitars in Spain; and some piano and brass instrument manufacturing in Britain.

INDUSTRY STRUCTURE

Companies

The EC musical instrument industry suffers from two major structural handicaps. Firstly, the industry is fragmented, with many small and medium-sized firms. Secondly, the EC lacks multinational firms similar to those of the United States and Japan. That situation has led to restructuring and mergers in all EC countries.

An important development, which will raise the competitive pressure in the high quality market, has been the decision of Yamaha, the world leader in musical instruments, to set up localised production plants in the EC. Yamaha recently took control of Kemble (UK) piano company and brought the Premier (UK) drum company. Premier percussion ranked 16th in sales in 1990 and had some 220 employees. Yamaha also acquired an interest in Schimmel (D). This should strengthen its presence in the EC, and allow Yamaha to offer better service and to respond more quickly to local preferences.

The South-Korean company Samick has plans for a piano assembly plant in Germany. Samick is the second largest piano maker in the world and has the worlds largest guitar manufacturing facility. Daewoo also has some interest in a German manufacturer.

The shift in markets and the development of new markets have encouraged a number of companies, mostly Japanese and South Korean with core activity outside the market for musical instruments, to enter the market. An increasing use of computers in synthesisers and Public Address (PA) systems facilitated the entry of computer manufacturers.

The development of new electronic instruments has mostly hit the lower quality market, while EC companies still have a name for high quality products. Steinway pianos, Selmer saxophones, Buffet-Crampon clarinets and Hohner accordions and mouth organs continue to be regarded as the best available.

There are only a few large companies in the EC musical instrument industry. They include: Hohner, Steinway and Sons, Schimmel, Schreiber and Vogtländische Musikinstrumente (D); Bontempi and Roland Europe (I); Selmer, Buffet-Crampon (F); Boosy & Hawkes (UK).

Strategies

Owing to large investments during the early 1980s in the Italian industry, productivity improved considerably, causing a significant drop in employment. Production value in constant prices increased rapidly during the same period, while productivity figures for Germany and the United Kingdom have deteriorated since 1987. The overall trend for the EC has been a relatively steady rise in productivity.

Several structural factors influence the industry's operations. First, high labour costs are a major handicap for an industry that has to compete with foreign companies which are sometimes larger and use more efficient and more flexible production methods, in particular Japan, Korea, Taiwan and other East Asian countries. However, within the EC the value added per employee increased in real terms from approximately 24

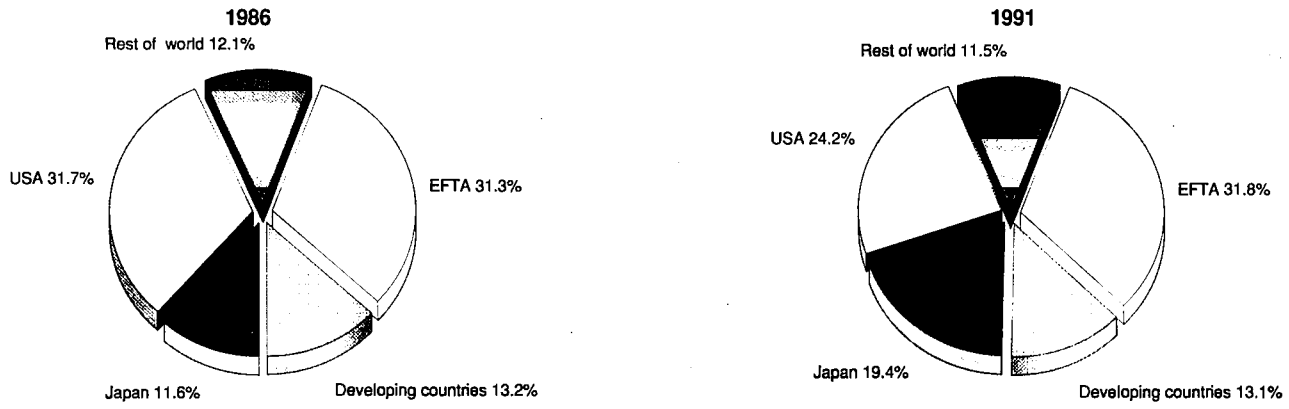
Destination of EC exports



Source: Eurostat

100 ECU in 1982 to 28 700 ECU in 1991 as a result of increasing production and a decreasing work force.

Two other factors, the small size of the European firms and a tendency toward national specialisation, result in independence and individualised production among EC manufacturers. Therefore, investments in production and marketing are low for the sector as a whole, except for one or two larger companies which have achieved reasonable profitability levels. The case of electronic musical instruments is an illustration: investments in the EC grew initially but are still not sufficient to match the sums laid out by Japanese, Korean and American firms.

Poor financial resources and predominantly artisanal production have restricted the introduction of automation in the EC in contrast to the persistent streamlining efforts made in Japan, South Korea and the United States. These countries have achieved large production runs by using computer-aided design and micro-computer and software developments to produce musical instruments at lower costs. In addition, American and Japanese firms have introduced greater manufacturing flexibility by subcontracting the manufacture of electronic components. This has given them a further advantage over their European counterparts, who cannot achieve this level of flexibility. The limited financing and automation capacity of the European firms shows up in the investment figures. Although the ratio of investment to value added rose from 6.2% in 1982 to 9.5% in 1988, it has always been one or more percentage points lower than the overall, economy-wide ratio.

Despite the EC's disadvantages compared to its international competitors, it has a few dynamic firms with good technical and human potential which are beginning to pay off, especially in the concentration on top-of-the-line products.

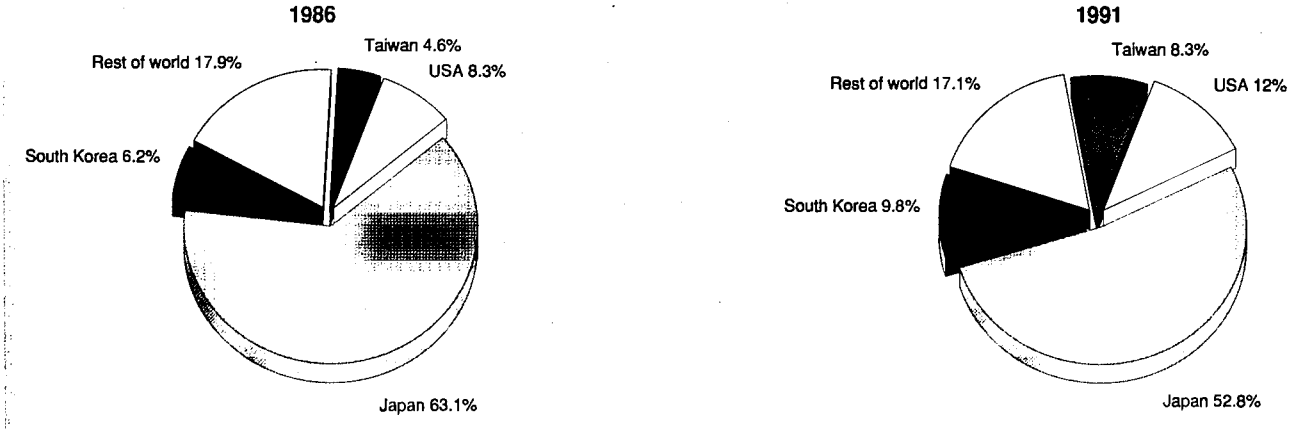
REGIONAL DISTRIBUTION

Certain regions have gained worldwide reputations as producers of superior products. These include Paris and Mirecourt in France, Berlin, Bayern, Hessen, Sachsen (Vogtland) and Baden-Württemberg in Germany, and London in the United Kingdom.

ENVIRONMENT

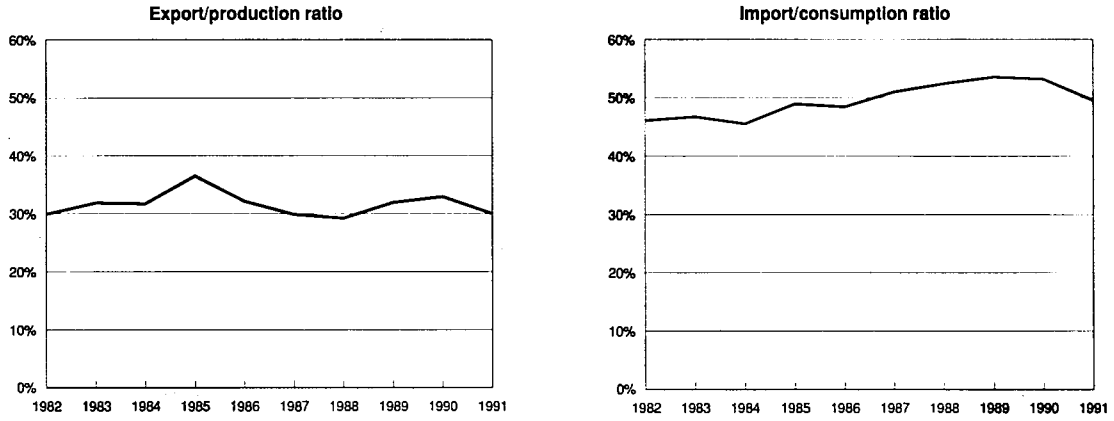
The musical instruments industry is relatively non-polluting. There are a few areas of concern to be addressed, however. First, the use of wood in pianos requires high quality wood

Figure 7: Musical instruments
Origin of EC imports



Source: Eurostat

Figure 8: Musical instruments
Trade intensities



Source: Eurostat

and adds in a minor degree to the decline of forests. Second, the modern electronic musical instruments use plastics. But this is of more concern to the plastics processing and plastics producing industries. Given the long life of instruments, these problems are negligible. Overall, the musical instruments sector is considered a clean industry.

OUTLOOK

The production of musical instruments in the EC grew markedly in 1991. This growth reflects favourable domestic demand. These circumstances are likely to continue for the early 1990s. Demand should reflect a gradual return to acoustic music as well as a steady development of new applications for electronic music.

Given the market forces discussed above, expectations are for further growth in demand to boost EC production, accompanied by some growth in employment figures.

Growing demand will also attract more imports from East Asian countries. Technological advances in electronics coupled with computerisation have enabled the Japanese firms to develop a strong competitive edge in terms of price and quality over EC firms.

In spite of certain advantages, the EC musical instrument industry is likely to face a number of difficulties in the next few years, owing to the nature of its professional structure and its lack of flexibility in responding to the latest consumer trends, which favour high-quality, reasonably-priced, all-electronic products. Parallel markets, such as the second-hand piano market, which often distort competition, may also cause problems.

Toys
NACE 494

In 1990 and 1991, EC toy production suffered an economic slowdown in many countries. In 1990 the depreciation of dollar and yen also contributed to the troublesome situation for the EC industry. The industry has since recovered from difficulties due to deficiencies in its industrial structure and increasing competition from East Asia. Many of the products from East Asia are made for the large, US based, toy enterprises. The EC toy industry is becoming more concentrated under the influence of international competition and concentration on the retail side of the distribution channel. Video games were a booming sector in the early 1990s, and are likely to be a growing sector in the near future. The declining EC child population will put downward pressure on sales, but with more parents in higher income brackets, toy and game purchases will have a higher value added. The major challenge for the EC toy industry is to become more aware of market demand, and to concentrate on fulfilling consumer wishes.

INDUSTRY PROFILE

Description of the sector

The toy industry consists of manufacturers of the following products:

- cars and vehicles for children, such as pedal cycles, scooters, hobby-horses, pedal cars, dolls prams and similar toys;
- dolls of all types made of plastic or other materials, accessories and spare parts for dolls;
- other toys and scale models such as wooden toys, trains and electrical circuits, weapons, projectors and other optical toys, musical toys, model kits, construction games, miniature models made of cast metal, toys for babies and toddlers, figurines, structures with characters, soft toys and all other toys made of plastic, metal fabrics, rubber and other materials;
- articles for parlour games, table-tennis equipment, billiards, video games.

Sporting goods are also included in NACE 494 and in statistical charts, but will be dealt with in a separate chapter.

Main indicators

The toy and sporting goods industry produced goods worth ECU 6 billion in 1991. Apparent consumption for the EC's large domestic market reached ECU 9.6 billion in 1991. The negative trade balance reflects the lower production of toys and sports goods compared to consumption, although extra-EC exports grew during the 1980s. The market value for toys is around ECU 6.5 billion at retail prices.

Employment in the EC industry declined strongly during the 1980s to 71 thousand in 1991 from 89 thousand in 1982. Only Greece experienced a growth of employment. The trend of declining employment ended for all EC countries in 1989, after which the level stabilised between 70-71 thousand. Countries with a large number of small and medium enterprises have been hit hardest, with Italy suffering the highest decrease.

Since 1986, video games have been the strongest performing sector. The introduction of the Game Boy from Nintendo, a small hand held console that can accept a number of game cartridges, has pushed the growth rates even higher. In 1991, the video games sector grew especially strongly in Germany, Spain, France, Belgium, Luxembourg, the Netherlands and the United Kingdom, to reach a value equivalent to approximately 25% of total market value of games and toys. In several of these countries the growth of the toy market can be fully attributed to video games. The increase in sales of video games has affected the other toy sectors only marginally, however. Many video games are bought for boys at an age where they traditionally stopped playing with other toys, so video games are not a substitute for other toys.

Board-games have been gaining interest from the public, as a result of more leisure time, higher disposable incomes and to a certain extent more emphasis on family-oriented activities in response to parent concerns regarding television watching.

France is the largest producer of toys in the EC. Production reached ECU 1 921 million in 1991. During the 1980s, France succeeded in strengthening this position. Germany is the next largest producer, with production of ECU 1 541 million. The production value of the other major producers, the United Kingdom, Italy and Spain, increased overall since 1985, although at a lower pace than in France and Germany, and their production values declined in 1990 and 1991. The German market was an exception to the trend of declining production and slow growing sales in 1990, with increases in production and sales of 6% and 11%, respectively. In 1991 only Germany, France, Denmark and Portugal (a very small producer) re-

corded production growth, whereas in all EC countries toy consumption grew.

Recent trends

In the second half of the 1980s apparent consumption was especially buoyant, with annual average growth rates above 10%. Demand growth was more than fully met by imports: and the import/consumption ratio increased from nearly 22% in 1982 to over 39% in 1991. The troubled situation of small toy manufacturers selling primarily on a national basis during the 1980s is evident when the development of the toy production and industry employment in real terms are compared to those of overall manufacturing. Production in real terms in the EC rose by 1.8% a year during the 1982 to 1991 period. This compares to a growth in prices of 5.4% thus growth is due largely to price increases rather than volume expansion.

International comparison

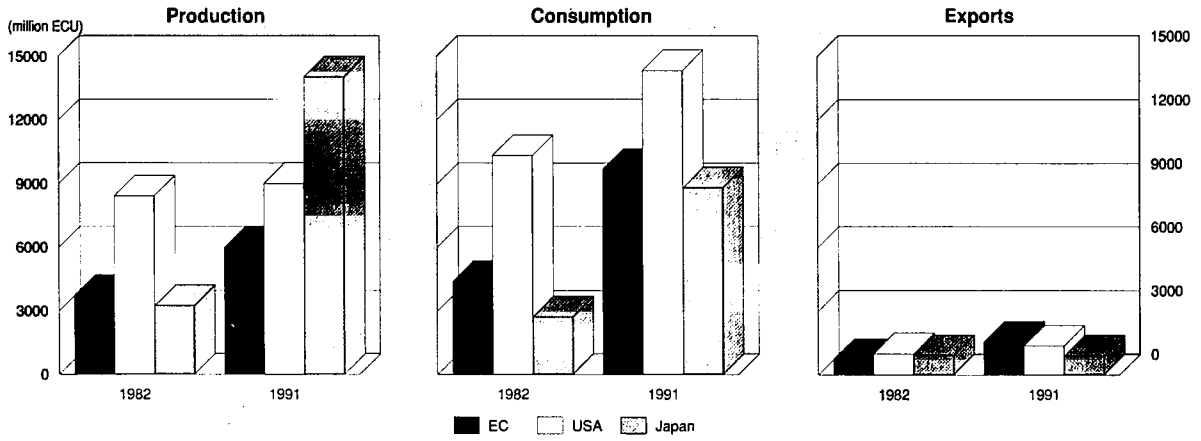
The EC is the third largest producer of games and toys in the world after Japan and the United States. While EC producers are gaining market shares relative to the USA they are losing their comparative advantage relative to Japan. Much of the fluctuation in positions is due to the variability of exchange rates. The figures in real terms, however, indicate a relatively more flourishing toy manufacturing industry in the EC than in the USA. The US market is the largest in the world. The USA has a large trade deficit in toys as a result. The apparent consumption of games and toys in the EC is one-and-a-half times lower than in the USA owing to a much lower unit consumption and lower average prices.

Foreign trade

The discrepancy between exports and imports of toys continues to widen. The export-import ratio dropped to 22% in 1991 from 50% in 1985. The trade balance also deteriorated to almost 3 billion ECU in 1991. Both extra EC exports and imports grew during the 1980s, but the latter at a much higher rate than the former.

Although the situation has improved slightly, the Europeans hold only a small share of the American market which is the most promising in terms of size and growth potential. EC exports accounted for 3.6% of US toy imports accounts in 1990, whereas the East Asian NIC's accounted for 52.5% and Japan for 36.7%. The USA has also become less important

Figure 4: Toys and sporting goods
International comparison of main indicators at current prices



Japan consumption and exports are 1988 data
Source: Eurostat, US Dept. of Commerce, US Bureau of Census, UN Trade Statistics Yearbook, Census of Manufacturers"

as a destination of EC exports. EFTA countries remain the most important geographical destination for EC exports.

Extra-EC exports of toys and sports goods are highest in Germany and France. For both countries, extra-EC exports are roughly equal to intra-EC exports. For Italy, the Netherlands and the United Kingdom intra-EC exports are significantly larger than extra-EC exports. Production in the United Kingdom is particularly export-oriented, due to a strong presence of affiliates of primarily US multinationals, which use their British branches to export throughout Europe.

Imports from Taiwan and Hong Kong have dropped dramatically. For the most part, this trade has shifted to China and Japan. Imports from China grew about 57.5% from 1989 to 1991. EC imports from East Asia are mainly the products of worldwide successful toy companies.

Extra-EC imports of toys and sports goods made up 53% of the EC market in 1991, compared to 27% in 1980. The EC industry's export capacity represented 66% of production in 1991 with 25% covering extra-EC trade.

Nine EC countries exported more than half their total exports to other EC countries. The five largest producers of toys have less reliance on intra-EC trade than the other countries. In Belgium/Luxembourg, Ireland and the Netherlands, 80% of total exports is intra-EC trade.

Imports are mostly extra-EC. Only five countries imports are more than 50% intra-EC. Portugal alone shows a high share of intra-EC imports (84%). The importance of imports from third countries is due to the heavy competition from East Asia. The main extra-EC importers are Germany and the United Kingdom, while France is the main intra-EC importer followed by Germany.

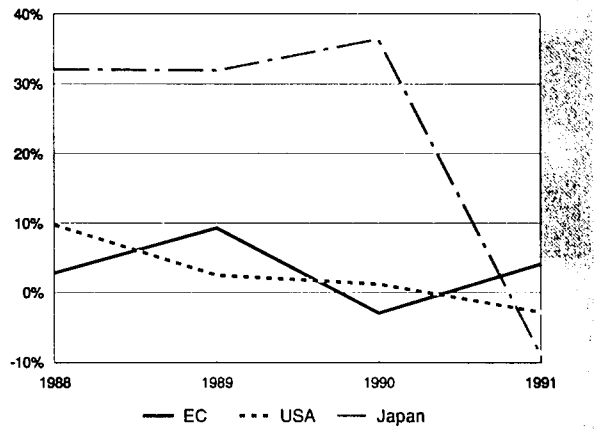
All EC countries are net extra-EC importers. In intra-EC trade Germany, Spain, Ireland, Italy and the United Kingdom are net exporters. Germany however, experienced an intra-EC trade deficit for the first time in 1991.

MARKET FORCES

Demand

Major determinants of toy and game consumption are the level of real disposable income and demographic changes. Rising income stimulates toys and games purchasing. This is relevant when comparing low GDP per capita countries like Portugal and Greece with the richer countries like Germany. Growth is more likely in the low, but rising income countries.

Figure 5: Toys and sporting goods international comparison of production growth at constant prices



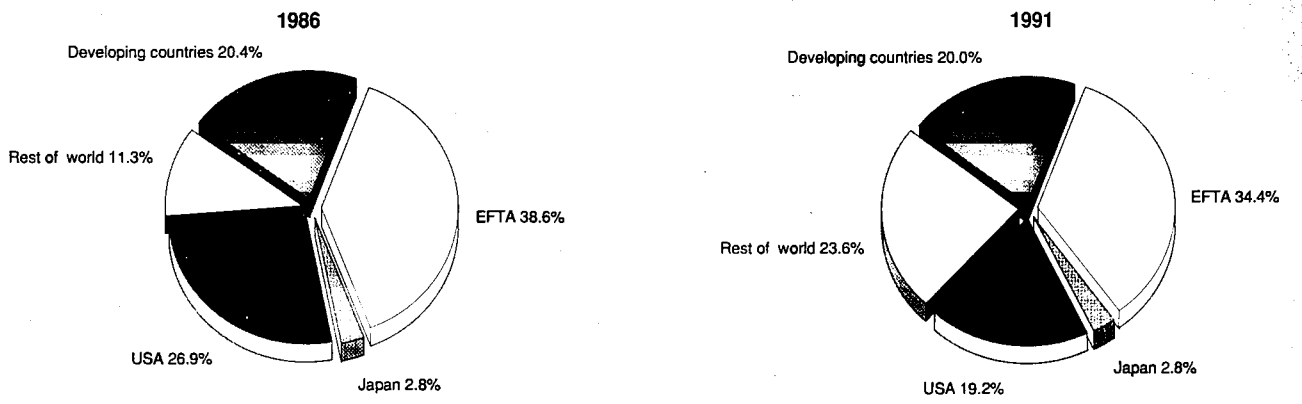
Source: Eurostat, census of Manufacturers

An important factor which will negatively influence apparent consumption in the near future is Europe's shrinking child population: it is expected that the population between 0 and 15 years of age will drop by 0.3% per year between 1990 and 1995. This decline will be moderate due to the counter force of people in the baby boomer generation, who will become parents in the 1990s. In some countries, such as the United Kingdom, this could be a stimulating force for infant toys. Furthermore, there is stiff competition from other leisure products such as clothes, records, cassettes and travel for teenagers.

Women are still much more important buyers of toys than men. The reputation and image of toys in safety, quality, "playability" (a toy being used more than once or twice) are as important as income.

The number of toys received per child per year and the amount spent on these toys has been increasing, as a result of the higher average age on which parents have their first child.

Figure 6: Toys
Destination of EC exports



Source: Eurostat

On average, these parents have a larger disposable income than in their early twenties.

The significant differences in access to commercial TV time from country to country also greatly influence consumer demand for toys. Demand is particularly influenced by TV advertising in the United Kingdom and Italy, less so in Germany.

Market prices could come under pressure as the importance of large retailers like Toys 'R' Us grows, with the currently large spread in prices for the same toy becoming smaller. However, the competitive nature of the toy market in general has ensured that prices have risen in line with the inflation rate. There are exceptions, including increasing prices for board games, and decreasing prices for video games.

Supply and competition

Toy manufacturers are in a weak competitive position both on EC markets and internationally. This is underscored by the growing market share of non-EC producers. While in 1980 net imports were 15% of apparent consumption, they grew to 38% of apparent consumption in 1991. This strong growth in apparent consumption, which has almost doubled in the last decade, allowed EC producers to expand their production. Additional efforts are necessary, however, to improve industry's position relative to American and Japanese multinationals.

The difficult situation in which the Community toy industry finds itself can to a certain extent be attributed to the characteristics and trends of the domestic market outlined above. However, other factors which are symptomatic of the state of the industry are also responsible for the weak competitive position of the EC toy industry as a whole.

The high wage costs in Europe are a major handicap for the EC toy industry in relation to foreign competitors, most of whom have relocated to East Asia. China and Korea have become the hub of international subcontracting because of the low labour cost. The handicap of high labour costs is particularly penalising in a sector where assembly operations are numerous and difficult to automate for small production runs.

Owing to their small size, most EC companies have a low investment capacity. Lack of financial resources is a basic handicap in the bid to compete with other producers.

In addition, because of insufficient production runs due to the patchwork nature of the EC market and the small size of firms, no benefits can be achieved from economies of scale comparable to those made by American multinationals. The latter companies offer a single world-wide range.

Production flexibility is a major advantage for toy manufacturers, since they have to deal with a cyclical market influenced by fashion trends. The EC toy industry has a low production flexibility. Flexibility obtained by home-based piecework and national subcontracting, which are widely developed in the EC toy industry, particularly in southern Europe, is not sufficient. EC manufacturers have very little access to international subcontracting compared with American and Japanese multinationals in the sector, who often have more than 50% of their products manufactured in Taiwan and Hong Kong. There are, however, clear indications that EC manufacturers are beginning to follow the pattern set by these competitors.

Weak international managerial capacity is also a problem. Ignorance of foreign distribution channels is a serious obstacle for small and medium sized EC firms with international ambitions. Their marketing approach is much less developed than that of foreign multinationals. Few EC firms now have the capacity to develop a licensing policy or to open up factories abroad.

Although the EC toy industry suffers from a number of disadvantages compared with its competitors, it nevertheless includes a number of young, dynamic firms capable of holding their share on both domestic and international markets. The success of such firms is based on creativity, quality products, and ability to transmit European culture through the traditional toys it offers, for instance, educational toys. These aspects form the first of three key factors, which have proven to generate global success for a toy company:

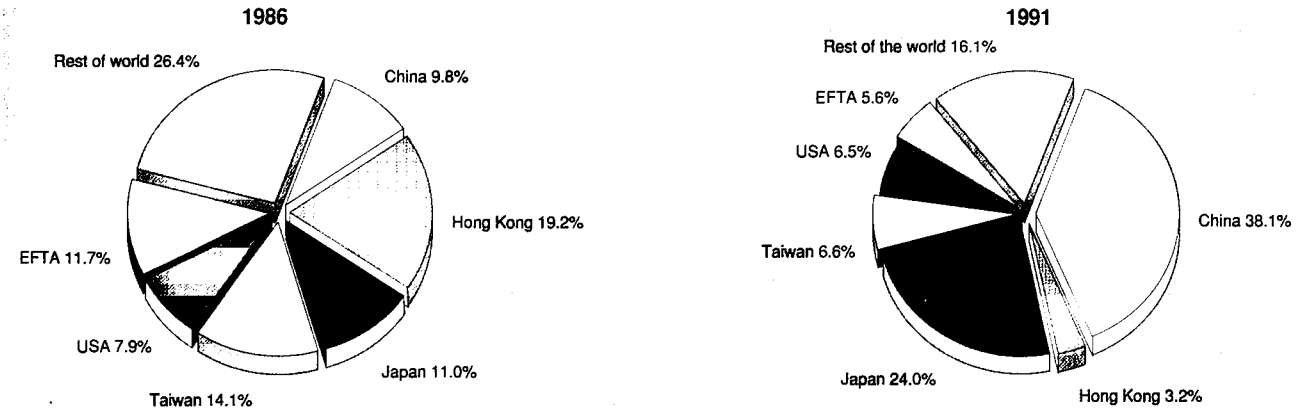
- Innovation in product development;
- Creation of 'concepts' which can greatly enhance the appeal of a toy;
- Effective advertising and promotion.

Production process

The strengthening of the EC's competitive position is clear from the growth in productivity which exceeded production growth. The share of value added in production has remained constant, so compared to other industries the toys industry has shown a not unfavourable performance.

Although the toy and sports goods production value is 60% of apparent consumption in the EC, product development takes place mainly at the headquarters of the world leading toy companies in the USA and Japan.

Figure 7: Toys
Origin of EC imports



Source: Eurostat

A large part of the success of international toy companies can be attributed to the use of third-party manufacturers, often in low-labour cost countries. Outward processing has become vital to the production process of the toy industry.

A key element in the toy industry is the licensing of product and the licensing of characters. These two forms of licensing account for approximately one quarter of the value of toys sold. Counterfeiting is on the rise, however, and the introduction of an international code is desirable to areas which must compete with counterfeits, sueh as the EC.

INDUSTRY STRUCTURE

Companies

In general, the European companies specialise in traditional toys, whereas companies located in other countries produce fashion toys which require high publicity costs and have a short economic life cycle.

The EC toy industry suffers from two main structural handicaps. The first is the high fragmentation of firms in the sector, because of the vast spread of different products. It is estimated that 80% to 90% of the firms operating in the sector on a full-time basis (excluding seasonal activity) employ fewer than 20 salaried workers.

The second problem is the absence of multinational firms comparable to American and Japanese groups, with the exception of Lego. This explains also why production is so dispersed. The main American multinational firms are Hasbro, Mattel, Fisher Price and Kenner Parker Tonka. In Japan, Bandai and Tomy are the leading multinationals.

The pressure of competition in the sector caused a number of companies, including some medium-sized companies, to go out of business in the 1980s.

Furthermore, the emergence of the superstore concept, with the example of the US Toys 'R' Us chain, means concentration on the retail side as well. The Toys 'R' Us chain is one of the few that are operating internationally. The outcome is a concentration on the supply side of toys into the hands of fewer, more professional, internationally operating companies.

The weak industrial structure has led to a fall in profitability levels in EC companies since 1980. This is mainly due to rising costs of production, marketing and advertising, which are difficult to pass on to the consumer because of strong competitive pressures in the sector.

Large companies in the toys industry are Lego from Denmark with around 3 000 employees in Denmark alone, Geobra Brandstätter (D), Ravensburger (D), Gebruder Märklin (D), Tonka France (F), Smoby et Majorette (F), Mattel Toys (I), Samosa and Burago (I) and PEG Perego Pines (I). The American Company Hasbro employs 3 200 people in the EC, spread among different subsidiaries over the EC countries, illustrating the importance of the US toy companies for the EC.

In the sector of video games the world leader is Nintendo (Japan), followed at a clear distance by Sega (Japan). Nintendo has completely conquered the Japanese and US markets, where one household in three owns a video game set.

Strategies

The toy industry is constantly trying to develop a new toy or game that could boost sales, like the introduction of Trivial Pursuit in the 1980s.

The business strategies of the successful companies have proved beyond question that ownership of manufacturing plant is not a cornerstone of business success. It is a necessity for a manufacturer to use the least expensive labour available when the production process is highly labour-intensive. All the world leaders have followed this strategy. The Lego company has a somewhat exceptional position inasmuch as it produces in Denmark and Switzerland, which have especially high labour costs. The explanation is the high level of automation and the need for high precision manufacturing.

In a market noted for unpredictable and large fluctuations of demand, flexibility in manufacturing and a marketing-oriented approach are necessary for companies to gain a competitive edge. To be flexible, most of the internationally successful toy companies use a mix of manufacturing plant and third-party contracted manufacturers.

REGIONAL DISTRIBUTION

The industry is highly concentrated geographically. Some 95% of the firms, accounting for approximately 90% of EC production, are situated in Germany, Italy, France, the United Kingdom and Spain. Within those five countries, firms are often located in a particular region: Bavaria and Baden-Württemberg in Germany, Lombardy in Italy, the Jura and Rhône-Alps (Ain) in France, and the Alicante and Barcelona provinces in Spain. Each country has its own specialisation:

- Germany: plastic toys, model trains and paper toys;
- Italy: bicycles, dolls and board games;
- France: die-cast and mechanical toys, board games and stuffed toys;
- United Kingdom: metal and plastic miniatures, table and board games and die-cast.

Each country has a production advantage. Germany is known for technical know-how; Italy's structure allows great flexibility and high product quality; France has particular knowledge in plastics transformation.

ENVIRONMENT

Although there is not much polluting activity in the production process of toys, the higher public ecological awareness does and will have impact on the demand for toys. Wooden toys benefit from this development. Recycling is an important issue in environmental policy and will have its effect on the toy industry as regards the packaging of toys. This is already true for Germany, where packaging of toys regulations have become more stringent.

REGULATIONS

The most important regulation in this sector is the EC toy safety directive of May 3 1988, published July 16 1988, which came into effect January 1 1990. Toys which fulfil the demands of the directive get the "CE" mark. This does not apply to toys which were already marketed before January 1 1990, however. There are physical, mechanical and chemical requirements. Furthermore toys have to be made of inflammable or slow inflammable materials and toys have to have clear indications and/or instructions for the consumer on how to handle the product. Normally, if the product fulfils the standards of the European standards institutes CEN and CENELEC, the toy will comply with requirements of the safety directive.

EC packaging requirements are also of importance, especially those which refer to the packaging of toys imported from countries outside the EC to meet the EC's safety standards.

OUTLOOK

The EC toy market is not likely to expand much in the coming years, given the prospect of a further decline in the child population and stiff competition from other leisure products. An exception is Germany, where the outlook is more promising

Table 6: Toys and sporting goods
Expected real annual growth rates

Source: NEI

as a result of increasing leisure time, more interest in toys and games and the reunification.

Electronic toys will have strong growth for a few years, after which the future for this part of the market is quite uncertain, due both to the possible development of a bad reputation for these games with parents, and to saturation. It is expected that almost all growth in the toy market in from 1991 to 1995 will be in the video game segment.

The main problem for the European companies is to transform from product oriented enterprises to marketing oriented ones. Furthermore, cooperation will be necessary to cope with small scale production and to become more flexible. In this way international competition would be feasible, especially with large East Asian companies. Competitivity will also depend on which of two development strategies is chosen: leadership in traditional toys in the luxury and middle markets, or a strategy of marginal opportunities at the bottom end of the market to gain a foothold. The increased ages and incomes of parents, in addition to a cultural nostalgia for traditional toys. may affect this decision, but mass-produced toys are still expected to do well.

Sporting goods
NACE 494.2, part of 451, 453

The EC market for sporting goods grew quickly in the 1980s but with highly differing rates between product ranges. In general, the more fashion-led consumption in the 1980s has stimulated the industry, but has also increased competition (particularly from abroad); putting prices under pressure. Furthermore, production could not follow demand, as competition from abroad has put prices under pressure. As a result, outward processing became more and more important. This trend is likely to continue.
The demographic trend towards a growing proportion of the population over 25 years old is leading to shifts in demand patterns: year-round recreation activities, higher quality products, and more individualistic sports are becoming more attractive.

INDUSTRY PROFILE

Description of the sector

Sporting goods are covered by NACE 453 and by part of NACE 451 and NACE 453 for sports footwear and sports clothing, respectively. Detailed statistics are not available at this level of aggregation except for trade. Moreover, sporting goods manufacturers produce other goods such as toys, camping equipment and products which originally for sports but which are now employed for other uses as well. For example, the importance of fashion and casual wear is becoming ever more prevalent. It is increasingly difficult to discern between goods and clothing for use in sport activities and for leisure. This sector is therefore very difficult to quantify. Apart from trade figures, there are no statistics for the sporting goods industry (i.e. none for production, employment and investment) and much of the tables and figures in this chapter reference NACE 494, toys and sporting goods.

Main indicators

Margins in the sporting goods sector are usually a mark up on the producer price of 50% to 100%, which gives a rough guide to estimate the amount of production in the EC. Estimates for the market volume in France and the United Kingdom in 1991 amounted to 25 billion FF and £2.5 billion respectively, a total of approximately 7 billion ECU. This would mean some 4 billion ECU at producer prices. This estimate takes equipment as well as clothing and footwear into account. The figure covered under NACE 494.2 should be much lower, as this covers mainly sports equipment. A high estimate would be one-third of total value, some 1.3 billion ECU for France and the UK only. This figure could be doubled, when two other major producer countries, Germany and Italy, are taken into account.

The production of sports clothing has been growing slowly during the second half of the previous decade. In Germany, the average nominal increase was approximately 2% per year. The production in 1989 was nearly 376 million ECU, whereas sports footwear amounted to 87 million ECU. German consumption of all sporting goods categories is estimated to have totalled 3.8 billion ECU in 1989; of which 12.5% consisted of sports articles, 65% sports wear and 22.5% sports footwear. Italian output of sportswear in 1987 amounted to 772 million ECU (excluding swimwear). Demand reached 1,438 million ECU at retail prices. French output of sportswear reached 461 million ECU in 1987. For 1990, market estimates for sportswear amount to 2.1 billion ECU in 1987 at retail prices.

Recent trends

Demand for sport goods is generally rising, albeit at different levels and growth rates in individual EC countries, depending on their economic performance. The long period of economic growth in the 1980s combined with a more positive attitude towards sport (the fitness boom) has produced high growth rates. Markets have been saturated, however, during the general economic slowdown at the beginning of the 1990s.

High degrees of saturation are already detectable in the large markets, (i.e. Germany, France, the United Kingdom and Italy), as well as in other countries with high purchasing power. These markets are more susceptible to fashion trends and to technical innovations such as all-terrain bikes.

Production of sports clothing in particular is presently done mostly through outward processing. As a result, many European manufacturers are also importers. Sports footwear production has declined according to market surveys; output has shifted to lower labour cost markets.

International comparison

From 1986 to 1990, the US Dollar was at a low value in relation to other major currencies, stimulating US sporting

goods exports (annual increase of 20%). In the USA, according to the official census of 1982, there were 1,452 companies engaged in the production of sporting goods.

The Japanese government is trying to increase consumption in their economy. As a result, the government has taken steps to gradually shorten work hours and increase leisure time. This development has given foreign manufacturers of leisure products and sporting goods major opportunities. The Japanese sports equipment market has experienced 6% growth in real terms from 1986 to 1991. Japan has roughly 1 500 manufacturing companies with some 28 000 employees.

Foreign trade

The EC recorded a trade deficit for the sixth consecutive year in 1991. The deficit grew due to stagnating exports, while imports from outside the EC rose to 1.3 billion ECU. The cover ratio (exports over imports) fell to 0.56, which is much below the levels recorded during the most of the previous decade. Although trade within the EC expanded, it did so at a slower rate than overall imports, resulting in a declining share of intra-EC imports in total imports. The dependence on non-EC countries becomes ever more prevalent.

During the years 1990 and 1991, exports came to a standstill after experiencing temporary growth in 1989. Exports to the United States were down for the second consecutive year and amounted to 144.2 million ECU in 1991. Exports to Japan rose 5% in value to 136.2 million ECU, despite the depreciation of the Yen. Growth figures in the second half of the 1980s were on average much higher. The chief exporter was France, followed by Germany, Italy and the United Kingdom.

Following a decline in 1990, imports grew 17% in 1991, an increase which is consistent with the figures for the years 1985-1989. EC imports from the United States rose the same percentage in 1991, and those from Japan a slightly smaller percentage. In real terms, however, this could actually be the reverse, as the US dollar appreciated and the yen depreciated. The main importer was Germany, followed by the United Kingdom, France and Italy.

Intensified marketing efforts, notably by countries in Far East, South East, and South Asia, as well as by the USA and the EFTA nations, have led to increasing international competitive pressure. The main supplier countries outside the EC include Japan, Taiwan, South Korea, USA and China. China's rising

share of imports reflects the move of manufacturers from Hong Kong to mainland China.

Intra-EC trade occurs mainly between countries where most sporting goods manufacturers are based and where the population has high purchasing power. These are the large countries already mentioned as the largest extra-EC importers and exporters.

The trend in sports footwear shadowed that of sporting goods in general, showing a deficit in 1990 of 294.6 million ECU. Of importance was the increase in imports from the United States, an expansion of 76.6% to 43.1 million ECU. Additionally, the United States reduced reliance on EC imports by 17.7%. Italy and Portugal were the only two EC countries to display positive trade balances: the Italian surplus attaining 207.3 million ECU. The United Kingdom showed the most serious deficit, some 169.8 million ECU.

MARKET FORCES

Demand

Factors affecting demand are:

- increasingly influenced by "lifestyle": fashion and leisure usage of sports clothing and footwear;
- sporting activities are increasingly evolving from competitive team sports into recreational activities for the individual;
- overall economic development, resulting in a moderate growth of personal disposable income;
- the continuing positive public attitude towards sport;
- sports equipment is much less susceptible to changes in fashion; furthermore, sports equipment tends to be more durable than clothes or footwear;
- demographic factors will be important: the proportion of people more than 25 years old will increase in the coming decade.

The generally good economic climate (at least in the long term), and the tendency of consumers to engage increasingly in activities with a sporting "touch" (due to growing amount of spare time and higher disposable incomes) have been positive factors for the development of the sporting goods industry.

But the sporting goods market is also susceptible to the peaks and troughs of the business cycle. Sporting goods tend to be discretionary items (i.e. they are among the first purchases to be postponed during recessionary times).

Supply and competition

Factors affecting supply are:

- growing concentration in trade and industry, with increasing market power wielded by a few multinationals;
- small businesses try to survive through a high degree of specialisation and by co-operation in production and distribution;
- competition by non-EC suppliers, notably from the Far East, East and South East Asia, continues especially in the lower price sectors.

The European sporting goods industry has until now been characterised by a large number of small and medium enterprises (SME's). In response to the growing concentration of large companies, these SME's seek cooperation in the whole of the EC. Furthermore, the market power of dealers is strengthened by the creation of European-wide distribution networks.

The increasing competition from the USA, Japan, East and South East Asia has been one of the negative factors for the development of the sporting goods industry. The other are the three consecutive mild winters between 1987 and 1990 for winter sports equipment, and growing environmental awareness which curb the expansion of certain sport activities such as motor sports and hunting.

Production process

The largest manufacturers of sporting goods in the EC rank among the world's leaders in product and production technology. Through constant R&D expenditure these manufacturers endeavour to use state-of-the-art materials and technologies. Small and medium-sized enterprises try to secure market niches, but in particular small businesses from Spain, Portugal and Greece still have much progress to make in the use of modern production methods. This applies to both sports equipment and clothing.

Two major market groupings of products can be distinguished:

- up-market items with high quality and strong brand names;
- simpler and cheaper products (mostly imports).

Internationally recognised European brands/manufacturers do not generally enjoy a competitive edge. With the exception of suppliers from the USA and Japan, many newly industrialised countries with advanced production methods produce first-class sporting goods and have been gaining growing shares in the European market, particularly in the lower and middle price categories.

INDUSTRY STRUCTURE

Companies

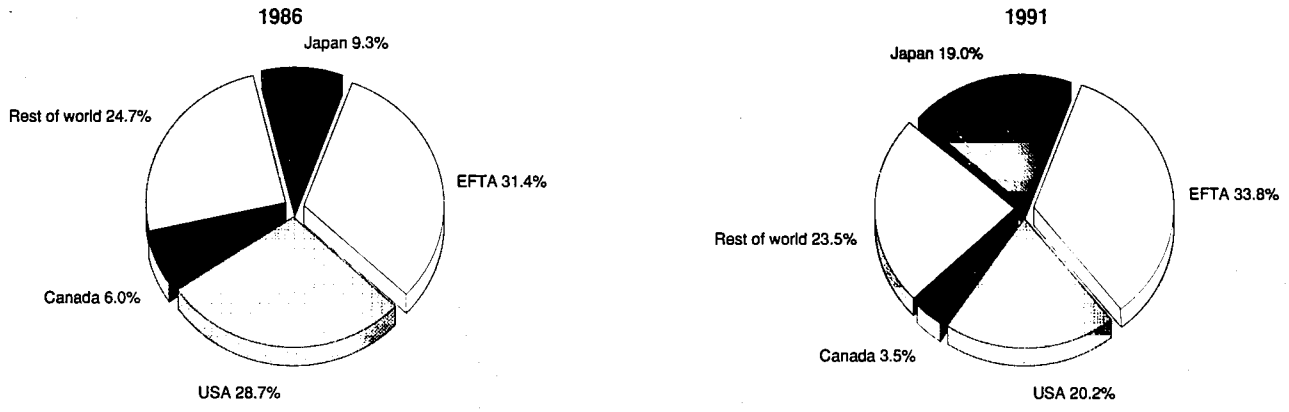
The main product groups and brands/manufacturers in the EC are:

- Adidas/Puma: sports clothing and footwear;
- Rossignol, Salomon: skiing and tennis equipment, golf clubs and equipment;
- Lacoste: tennis equipment, leisure clothing;
- Bogner: leisure clothing;
- Kettler: sports and fitness equipment;
- Dunlop/Slazenger: tennis equipment and clothing;

Strategies

The sporting goods market is in some segments highly competitive, and manufacturers have been seeking ways to improve

Figure 6: Sporting goods
Destination of EC exports



Source: Eurostat

their performance. In the 1970s and 1980s, numerous manufacturers pursued a policy of diversification and produced not only their core products but also sports and leisure clothing and footwear for highly varied activities. Profits tended to decrease after extensive diversification. This meant streamlining the product ranges, focusing on the companies' strengths, and disposing of loss-making divisions.

On the other hand, the dynamic behind the diversification has been inter alia the recognition of the higher rewards from other products. For example, running shoe brands could move into the sector of golf shoes. Furthermore, an all too high dependence on a specific season is also an incentive to diversify the product range.

Finally, the recognition of demographic changes by the companies has made them consider sports where consumers other than the young (male) adults are active. The increase in the older population sections with high purchasing power and a strong interest in sport has, for example, led to an increased interest in golf.

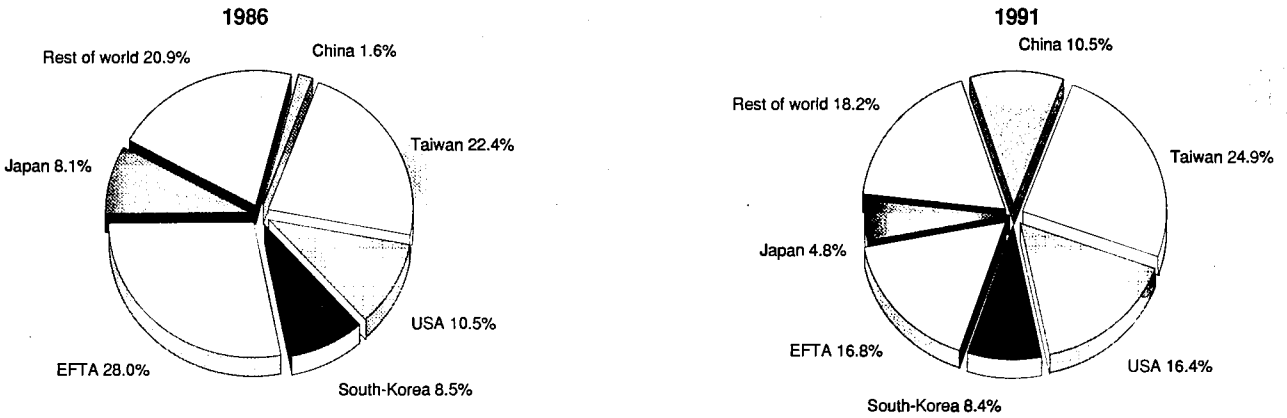
In sum, companies will tend to diversify in the future, but not as unconditional as in the past. A prime example is Adidas, which driven by the financial troubles in the 1980s, now has entirely abandoned the Adidas branded leisurewear sector and concentrated on key products. In 1990, a strategy which concentrated on key products, more outward processing, centralisation of functions and improved logistics proved successful.

REGIONAL DISTRIBUTION

The major producer countries in the EC are Germany, France, the United Kingdom and Italy. Figures about the number of companies engaged in sporting goods manufacturing can only be indicative, as it depends on small differences in interpretation if a company is considered to be in the sporting goods sector. This is especially relevant of the clothing sportswear sector. However, the most companies seem to be engaged in the sports clothing sector, and the fewest in the sports footwear.

Within countries the geographical pattern can be very different. In Italy, most of the manufacturers are based Lombardy and in Spain a majority of manufacturers are located in Catalonia. France and Germany, by contrast, have companies widely spread throughout the country.

Figure 7: Sporting goods
Origins of EC imports



Source: Eurostat

The chief countries of origin for the main product groups are as follows (main non-European origin countries):

- gymnastic and athletic equipment: UK, France, Germany, Finland, Norway (USA, China)
- tennis rackets: Belgium, Austria, France, Germany (Taiwan USA)
- golf equipment: UK, France, Germany (Taiwan, Japan, USA)
- table-tennis equipment: France, Germany, Sweden, UK (China, Japan)
- leather balls: Italy, UK, France, Germany (Pakistan, China);
- roller and ice skates: Austria, Switzerland, (Canada, China)
- cross-country skis: Austria, Finland, Italy (CIS)
- alpine skis: France, Austria, Finland, Italy, Switzerland, Finland, former Yugoslavia, (USA)
- aquatic sports equipment (incl. windsurfing): France, Austria, Switzerland, Italy, Germany (USA, China)
- leather sports gloves: Italy, France, Germany, Netherlands, Hungary (Pakistan, South Korea, Canada, USA)
- track suits: Italy, France, Germany, Portugal, Turkey, former Yugoslavia, Denmark, UK, Switzerland, Poland (China, Pakistan, India)
- ski suits (woven): Italy, France, Germany, Austria, Greece, Portugal, former Yugoslavia (China)
- ski boots: Austria, Italy, Germany, France, Switzerland, former Yugoslavia (South Korea)
- sports footwear: Italy, France, Germany, UK, Austria, Portugal, Spain, Switzerland, former Yugoslavia (China, Indonesia, South Korea, Taiwan)

ENVIRONMENT

Normally, sporting activities do not spring directly to mind when one thinks about environmental protection. Furthermore, a distinction should be made between the environmental hazards caused directly by the sporting goods industry and those hazards in which tourist services, for example, are responsible for.

Some of the outdoor activities are finding opposition though, especially by the environmental movement. The arguments are that some outdoor activities could be detrimental to the direct environment of the sport area. The general public does not consider them as a hazard to the environment.

On the other hand, recent efforts have been made to protect the environment in the concerned areas. National sporting associations and local and/or regional authorities are involved to protect the environment by local regulaitons for doing sports (i.e. minimum of snow for skiing, special routes for cross-country skiing).

However, other sports will benefit from the heightened ecological awareness and to compensate for stress of overcrowded and polluted cities. Cycling, windsurfing, and trekking are just a few examples.

REGULATIONS

Apart from import restrictions, there are no EC directives which are of direct importance to the sporting goods industry. This does not mean, however, that the industry would not be interested in EC policy. On the contrary, The following areas of EC law and policy are at the forefront of their interest:

- harmonisation of product standards;
- competition policy and distribution arrangements;
- intellectual property rights (strongly tied to GATT policy);
- import quotas; e.g. alleged dumping of Asian products has led the cycle manufacturers, for example, to ask for import restrictions on cycle imports;
- consumer protection.

OUTLOOK

Development of demand is likely to profit from technical developments and fashion trends. Production, however, will not rise as fast as demand because outward processing of especially clothing will continue. To this can be added the high potential of market penetration by fashion companies.

Generally, the successful firms will be those focusing on R&D, in market monitoring and on pursuing a niche strategy. Furthermore, brand images will play an ever more important role.

Table 5: Sporting goods
Expected real annual growth rates

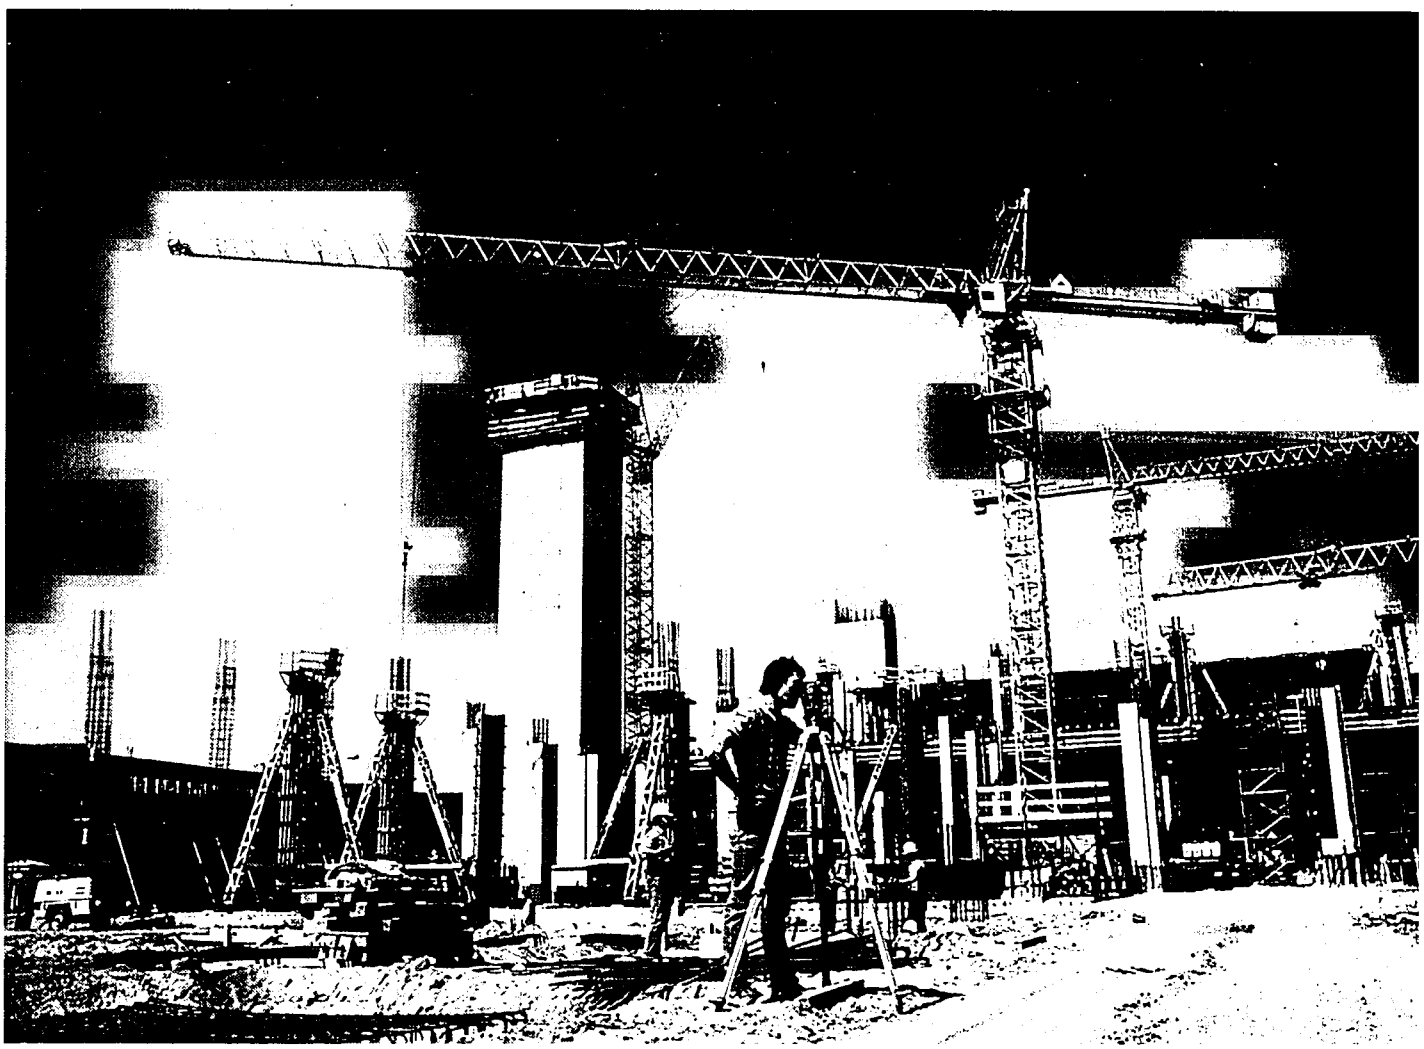
(%)	1992-93	1992-96
Apparent consumption	3.0	4.0
Production	2.0	2.3
Extra-EC exports	3.0	4.0

Source: NEI

Competition from imports has already had a considerable effect on the industry and is expected to continue in the next five years. Improving competitiveness will be done by more outward processing in the clothing segment, and by investing in the latest production equipment.

In the sports shoes sector, considerable effort will be given by brand leaders to maintain their market shares, especially in the countries where recessionary trends are visible.

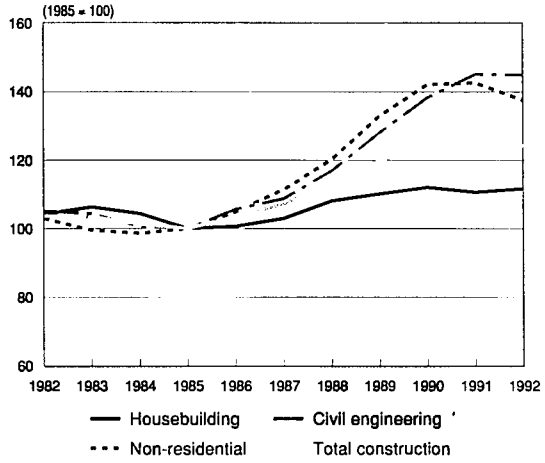
Written by: FESI and Netherlands Economic Institute
The industry is represented at the EC level by: Federation of the European Sporting Goods Industry (FESI); Address: PO Box 1160, D-5340 Bad Honnef 1; tel: (49 2224) 76 381; fax: (49 2224) 75 940.



Construction
NACE 50

The construction industry accounts for the largest share of all investment by public bodies and private undertakings in fixed assets and in private and public housing construction. Its output is relatively labour-intensive, so that it is one of the industrial sectors which gives the greatest employment. On the other hand, it uses a great deal of materials, so that its sales have considerable consequences for the output of other industrial sectors.
Despite relatively mobile production processes at locally changing building sites, the sector has a low capability for adjusting to changing demand through geographical mobility. Hence, apart from the few very large construction firms, foreign operations are only of secondary importance. Competition is more extensive in local and regional markets. However with the progressive completion of the European internal market, transnational competition might grow in the future.

Figure 1: Construction
Index of investment in construction in the EC



Source: FIEC

INDUSTRY PROFILE

Description of the sector

Construction activity takes place as building activity, as civil engineering activity, or a combination of both.

Building activity deals with the construction of new buildings for various kinds of uses and users. In addition to buildings for private undertakings (administration and production buildings) and for the various public bodies, this sector builds a considerable share of multi-storey dwellings and family houses. It also meets growing demand for the modernisation and repair of these buildings.

In civil engineering, construction firms engage in the construction of transport infrastructure (roads, railways and airports), hydraulic engineering (mainly rivers, canals, harbours, streams, sluices and dams), irrigation and drainage and waste water disposal. They also engage in the erection of purifying plants and construction involving bridges, tunnels, shafts, drilling, excavation works, and land improvement.

The boundaries between building and civil engineering are fluid. In the construction of new buildings, civil engineering works are also required, while in civil engineering, additional buildings frequently have to be constructed. The larger construction firms therefore offer both building and civil engineering services on an extensive scale.

Recent trends

There has been a change in output trends in the various branches of construction since 1991/92. While private commercial and public sector building and civil engineering are stagnant

or even declining after a decade of considerable growth, a revival is taking place in housing construction which in the 1980s experienced a lower rate of activity despite increasing demand for housing.

While the economic state of the construction industry in the EC follows the local economic trends of each Member State, it cannot be adequately and solely explained by this consideration. For example, while growth in construction was been more pronounced than that for the general economy in Germany and Portugal in 1992, in other countries it will fare worse.

The decline in almost all civil engineering branches since 1992 in nearly all the European countries shows very clearly the dependence of business activity in this sector on public expenditures on infrastructure works. Nearly all countries in Europe have considerably reduced their investment budgets in order to stem state indebtedness. These cuts have been especially severe in Spain and Italy.

International comparison

The EC is the largest construction market in the world. In volume terms, the EC market is around a third greater than the US construction market and around 10% greater than that of Japan. On a world scale, 1991 was a year of generally stagnating or slightly declining construction activity.

The main areas of activity in construction vary in these three large markets. In the USA, housing takes the largest share of construction and since 1991 has once again grown strongly. In Japan this applies to public sector building and civil engineering, and in the EC to investment in repairs and modernisation.

In Japan, investment in fixed assets in the form of buildings was relatively the highest with around 18% of GDP, compared to only 12% in the EC and approximately 10% in the USA. Until 1990/91 the growth rates for investment in all these markets exceeded the growth rates of GDP. Since 1991/92, they have been lower in all these markets. Only the construction markets in Germany and Portugal constitute a partial exception.

The future development of the construction industry in Japan and the USA will depend on growing demand for public sector building and civil engineering investment. In the EC it remains to be seen to what extent planned large-scale transport infrastructure projects and postponed civil engineering works will cause further delays or increases in production as a consequence of government budgetary and financial policies.

In transnational business operations the efficiency of the European construction firms can be clearly judged by their presence in the growing world markets. Thus, European construction firms meet approximately half of the transnational volume of orders executed in the growth markets of Europe and Africa and around a third of the Middle East markets. There they are in competition with US construction firms.

In these markets, with a share of less than 10%, competition from Japanese construction firms is of small importance. In the Asian market, on the other hand, the shares of Japan and the USA are more important, each having approximately a third.

Foreign trade

Transnational business operations amount to only around 5% of the total volume of construction and are carried out by only a few large firms. However, these conduct almost two-fifths of their construction operations abroad.

In the transnational business operations of construction firms there were clear signs of growth for 1991-92 in selected European markets, although viewed overall the European market is showing no signs of growth. These developments are due especially to increased competition, particularly among the large firms which work abroad mainly through local subsidiaries. At the same time, cross-border activities due to the Single Market also increased for small and medium-sized enterprises.

MARKET FORCES

Demand

Economic and technological structural change is giving rise to constantly increasing new needs in the EC. Demand is likewise increasing for alternative investment, especially in the form of modernisation and the repair of buildings. There are, however, widely differing demand and output conditions in the individual construction branches and EC Member States, according to whether the contractors depend on public sector or private sources of financing for their projects.

A restrictive budgetary policy, such as prevails in most countries, is therefore limiting both public sector demand for civil engineering and private demand for publicly assisted housing construction.

Growing interest rates and declining direct public assistance is leading to correspondingly smaller demand and output in the construction of flats. With a rising need for rental housing and continuing low profitability from investment in housing construction, growth in this construction branch can be expected only following an appropriate allocation of budgetary resources. This development will be replicated in 1992 mainly in the trend in housing construction in Germany. Therefore, the re-establishment of profitable market conditions for rental housing is important.

In the case of the remaining construction areas, financing costs and changes in them, along with profitability of building use, have had a much greater influence on construction output than changes in market volumes, production costs and capacity utilisation.

During the 1980s it was the service sector which assured an increasing dynamic in non-residential building which accounts for around one third of total construction. Since 1991, it has been these kinds of uses which have leading to individual production collapses in the relevant construction branches.

The demand for civil engineering develops mainly in a countercyclical fashion, as demand is accelerated or delayed by the budgetary, financial and economic situation of the relevant decision-making public bodies. Moreover, many projects come to the execution stage only after several years of planning, decision-making and procurement procedures. They then extend over several years of financial and technical accounting.

In modernisation and repair, growth trends are continuing in all construction branches. These construction activities are acquiring an increasing importance in relation to total building production, as well as for medium-sized and larger construction firms.

Few additional effects on demand, on the other hand, can be expected from innovations in building products and processes. This will come rather through innovations in new transport, communications and environmental technologies in the user fields which need new construction facilities to make these innovations a reality.

Supply and competition

The preparation for and the completion of the European internal market improve the competitiveness of construction firms engaging in cross-border business operations in the EC. Improved approval conditions for construction firms and materials to which they are accustomed in their home markets, better opportunities for participating in public tenders, and the elimination of formal obstacles to the transnational move-

ment of construction equipment are making a significant contribution to this development.

Both overall and regionally, the construction operations of non-European construction firms in the EC are of little importance today. This applies both in quantitative terms and also to their impact on competition in construction in the EC.

Because of their supply capacity, most of the small and medium-sized construction firms operate only in partial markets and are therefore faced with specifically regional demand. Only the larger construction firms are in a position to re-arrange their capacities according to shifts in demand in the regional markets and in their individual sectoral partial markets.

This can lead to excess regional demand or supply in individual construction branches which makes it difficult to see the development of the general demand on the market as a whole. At the same time, this leads to special regional developments in costs and prices.

Production process

For construction firms, building materials and labour constitute the main cost factors. In the case of building materials there is close integration with the up-stream sectors of industry, such as the stone, sand, steel, chemical and wood-working industries. This integration is developing towards an increasing amount of prefabrication prior to delivery to the construction site.

The productivity increases expected from this are however also shifting parts of the value created by the construction industry to the supply sectors.

Because of their relatively small use of fixed assets, the financing costs of construction firms are structured differently from those of the other sectors of industry. Thus, fewer interest burdens arise in construction in connection with the financing of fixed assets. These burdens arise more in the pre-financing of construction projects during the execution phase and up to payment of the final account.

While the first factor favours the more rapid expansion of production capacity, large accounts receivable due to production conditions restrict expansion of business activity especially during periods of high interest rates.

The use of labour in the construction industry is influenced more by the structural impact of increased technological and commercial requirements than by a quantitative decline in production. The more recent production decline has therefore shown little effect on the level of employment in this sector, as the demand for qualified personnel is increasing and can be met only with difficulty.

INDUSTRY STRUCTURE

Companies

In the EC, construction is carried out to a large extent by small and medium-sized enterprises which represent more than 80% to 90% of European construction firms according to the definition of "SME". Their market share varies however from one country to another and also from one construction branch to another. Thus, their number in Belgium and Italy is relatively large, whereas it is smaller in France, the United Kingdom and particularly in Spain. In many civil engineering branches, for example bridge and tunnel construction, concentration of market shares is more pronounced than in most of the branches of general and road construction.

The large European construction firms work in several different building and civil engineering branches. They adjust the main areas of their business operations to developments in the individual partial markets. This applies also to the European and extra-European foreign markets, in which they carry out a considerably greater part of their production than the small and medium-sized construction firms.

Strategies

The structural changes in the construction markets of Europe call for adjustment measures on the part of construction firms: specialisation in the case of medium-sized construction firms operating at regional level, and further diversification in the case of larger firms. Some of the latter are increasingly extending their activity into non-construction services.

Production by several independent firms is thereby being brought together in one common individual service, usually in the course of the execution of the works as a main contractor along with sub-contractors, or as joint ventures. The present trend is for an increase in main contractor orders at the expense of joint ventures.

In addition to these project-related forms of cooperation, closer enterprise integration is also taking place through purchasing, participation, or cooperation agreements as part of preparations for the European internal market.

Thus, the larger firms can react more quickly to shrinking partial markets through mobility on a nation-wide scale, through additional diversification, and especially by integrating sub-contractor services of more specialised small and medium-sized firms into their offers.

In civil engineering the small and medium-sized firms, which specialise mainly in certain civil engineering branches, are scarcely in a position to engage in such product and service adjustments. Additionally, because of their small range of geographical mobility, they are compelled to resort to quantitative adjustments when their predominantly public sector clients shift the main areas of their infrastructure investment.

REGIONAL DISTRIBUTION

To a far greater extent than is the case with the other industry sectors, the regional distribution of construction capacity is the result of client location criteria. The method of production is entirely related to the construction site and pushes construction firms towards greater geographical mobility.

Small and medium-sized construction firms are capable of doing this only in their local and regional markets. Construction capacities are therefore dispersed according to demand for construction. For the most part, the predominantly small and medium-sized firms adjust to changed demand situations less through geographical mobility than through the establishment or reduction of production capacity.

A general or branch-related recovery of construction in individual areas of the EC will lead only conditionally to a general stabilisation, as available production capacity, especially of the small and medium-sized enterprises, can hardly be mobilised to move to the areas of demand.

In public sector civil engineering, and especially in transport construction, the regional distribution of production capacity is determined by the financial capabilities of the territorial authorities, particularly through the inflow of financial resources from outside, e.g. resources of the European Structural Funds for infrastructure works.

At the regional level even civil engineering capacity for investment in the protection of the environment is guided by the demand for these construction services and especially by the economic structures of the areas with greater environmental investments. In other regions supply bottlenecks can arise, if additional investment in the protection of the environment is required with the aid of civil engineering services.

ENVIRONMENT

Practically all branches of construction are increasingly confronted with environmental problems. New construction in effect transforms the use of land such that it brought within the scope of environmental regulations. In most cases, it is the construction industry's clients and the local supervisory authorities which must take the final decision as to how to address the environmental implications arising from new construction. The construction industry has many organisational or technological alternative solutions for such interventions, but in many cases they are turned down by clients because these solutions may be associated with higher costs.

On the other hand, an increasingly large part of the output of the construction industry is needed for environmental measures of a preventive or repair character. Thus the disposal of polluted water, for example, is carried out almost exclusively through use of these production services. This depends entirely on demand from public sector and private customers.

The structural policy of the EC is operating to an increasing extent in indicative fashion, as for example when, through the financial resources of the European Structural funds, measures for the protection of the environment are proposed at an early stage in the regions of Europe, in which there is also a backlog of demand in other infrastructure areas.

REGULATIONS

With the progressive completion of the European single market, harmonised and harmonising EC regulations are replacing the diverse national regulations and standards for the construction industry. This applies both to regulations for transnational use of building materials and temporary use of construction equipment and machinery, to the way in which contracts are awarded, and to the principal conditions of the contract. Common regulations on personnel use and its conditions are also appearing.

Although public procurement directives apply only to larger projects, they define tender and award procedures in general. In the same way the Construction Products Directive promotes not only transnational trade in these products but also construction abroad generally.

OUTLOOK

Regional economic structural change on the one hand and technological structural change on the other is giving rise in the EC to lasting new needs for land, the short-term, medium-term and long-term demand for which depends on the financing capabilities of the public sector and private clients.

Reduced expectations regarding the general trend of incomes and high financing costs are at present preventing these needs from developing into a corresponding demand.

More and more medium-sized and (though with some hesitation) large construction firms see a new field of activity in modernising and repairing buildings, and the market and productivity potential of this has not yet been exhausted.

In civil engineering new areas of special emphasis are coming more clearly to the fore, e.g. investment in the protection of the environment, the improvement and technological renewal of existing infrastructure facilities and the area of trans-European networks covered by proposals from the EC Commission, with consequential changes in the structure of construction operations and the composition of the labour force.

The especially dynamic development in the new German Länder will continue after 1992, as the expansion and reconstruction of the public infrastructure there will develop independently of general developments regarding interest rates, costs and budgets.

Despite rising needs for infrastructure installations, continuing restrictive budgetary policies in most countries of the EC are creating bottlenecks in demand which are pushing construction firms towards more sustained and increasing activity abroad. This is being facilitated to an increasing extent by the completion of the European internal market, and it assures greater transnational competition.

Building
NACE 501

The building sector is considerably influenced by the overall economic situation, by both current trends in economic activity and expectations of future trends arising therefrom. The response of the public authorities, in terms of their economic, monetary, credit and fiscal policies, also plays an important part in determining the condition of the industry.
During 1991 and 1992, a combination of conflicting short and longer term expectations, together with generally restrictive measures taken by the public authorities particularly in the area of monetary and credit policy, was reflected in an overall reduction in the level of demand. A small increase in output did not fully compensate for previous reductions, despite there being urgent requirements to be met in most regions.
Among small and medium-sized enterprises, competitive pressures have eased following a reduction in capacity. Among large construction enterprises, by comparison, competition is more intense. Growth in overseas markets is still so slight that firms are focusing their activities even more on national and European markets. There is little evidence so far of the expected easing of competitive pressures as a result of transfer of production capacity to markets of Eastern Europe.

INDUSTRY PROFILE

Description of the sector

The building industry is responsible for the construction of new buildings for various use by both private and public sector clients. Meanwhile modernisation and rehabilitation work is assuming greater importance for the industry.

Construction plays a vital part in relation to different aspects of economic activity both public and private. Given that the need for buildings is always growing, building plays a key role in the economic and social development of all countries of the EC.

Because of the growth in value and volume of its use of raw materials, components and equipment, what happens in this sector is crucial for several other industry sectors at the same time: construction materials, timber processing, ceramic products, sanitary ware, the chemical industry and mechanical engineering, among others.

Levels of demand for the products of a range of other industry sectors also are influenced, directly or indirectly, by the level of activity in building, through either contractual or technological links: for example, furniture, office equipment and soft furnishings.

Because it uses labour-intensive production processes, the building sector of construction is still one of the industry sectors employing the largest number of personnel.

Main indicators

The economic situation in construction in the countries of the EC tends to reflect the overall trend in economic development in those countries. However, the economic growth trend does not provide a sufficient or certain indication of what is happening in construction: for example, in 1992 the rate of growth in construction output in Germany and Portugal was higher than that of the economy as a whole, while in other countries the level of activity in construction was still relatively lower than observed in other sectors of industry and commerce.

Meanwhile, however, the structural change which is occurring, as a result of developments both economic and technological, throughout the EC countries, has prompted a growing need for new buildings. This is particularly the case in those regions and countries - notably Spain, Portugal, Ireland and, most recently, Germany - where structural change is being experienced in especially large measure. However, new building activity in these countries is not fully reflecting the growth in construction needs, on account of both economic and budgetary constraints.

Nearly as great an increase is being experienced in the need for replacement investment, more especially in modernisation and rehabilitation of buildings, particularly in Spain, France and Italy. In these countries this branch of construction is making up for the recession in new building work.

Direct grant measures intended to encourage construction of buildings for rent, which public authorities have taken in the past, have not met with the results that were expected. However, in response to a growing need for rented accommodation, these measures have been reintroduced, with the backing of a suitable amount of budgetary resources, despite their past lack of success. This situation is reflected especially in measures taken in Germany and France. In the Netherlands, by comparison, such measures have been considerably reduced.

International comparison

The easiest way to make international comparisons of construction industry performance is to compare the commercial activity of construction enterprises carried out beyond their own national boundaries. Any broader comparison of construction market conditions and performance may be misleading because it can take into account only some of the complexities arising from differences in market size, construction needs, size of firms and the composition of demand.

The record of cross-border activity illustrates clearly the capabilities of European construction firms, especially in growing markets. European firms account for very nearly half the volume of orders placed in the growth markets of Europe and Africa, and a third in those in the Middle East that also are growing. In these markets they compete mainly with American firms, whose share is around two-fifths in Europe, one-third in Africa and a half in the Middle East.

Competition from Japanese construction firms in these markets is insignificant: they account for barely 10% of orders. In Asian markets, however, both Japan and the USA play a more significant part, amounting to roughly one-third of orders for each country, while European firms account for no more than one fifth.

Meanwhile, European construction enterprises are always well-represented in the part of the American market occupied by non-national contractors, their share of which is around two thirds. The role of Japanese firms in this market is growing, but in 1990 their share was still no more than one fifth. In addition, major European construction enterprises occupy an important place in construction activity in the USA carried out by the home-based industry, by virtue of their share holdings in American construction firms.

Foreign trade

In contrast to the years up to 1990, 1991 and 1992 have seen a rise in the volume of overseas work carried out by construction companies. Even so, this work still represents no more than around 5% of total construction work, and is only of significance to a few large construction companies for whom overseas work accounts for roughly a fifth of their turnover.

However, this does not tell the full story of the overseas activity of these companies because, for some years now, they have been increasing their financial stake in foreign firms to such an extent that they have come to be viewed, in some cases, as local companies.

The rising tendency of building activity abroad is most pronounced in the case of Spanish firms, with lower but still pronounced increased rates of activity in the case of French and Italian firms.

MARKET FORCES

Demand

Measures taken by governments have affected the construction industry both directly - by the priority given to public investment in construction in government spending, and by means of assistance for initiatives in the private sector - and indirectly - by favourable tax arrangements and fiscal and monetary policies.

In several countries, restriction of government spending has had direct and immediate negative consequences for investment in public works, especially in Spain where, after substantial growth in public investment up to 1990, demand for construction of public buildings has fallen by nearly a third.

In spite of opposite tendencies in public spending in Germany and France the outcome has not resulted in proportional growth in the demand for building construction. In 1991 and 1992, the increased German budget deficit brought about a substantial increase in infrastructure investment, especially in the new Länder, whilst demand for public buildings has remained unchanged. In France budgetary policy has at least not had any recessionary effect on the demand for public buildings.

The general development of incomes has on the whole had a rather indirect effect on the demand for building construction, especially multi-storey housing and new single-family dwellings. For instance the increase in real incomes has led to increased requirements in the quality of housing. Increased demand for accommodation is particularly evident in regions where economic growth is attracting additional population.

At the same time, however, the emergence of increased financing costs is squeezing anticipated returns from this sector in comparison to other forms of investment, and putting this type of long-term investment at a disadvantage vis-à-vis other forms of investment.

The factors which influence the multi-storey buildings sector are completely different from those which affect demand for other products of the building construction industry. In this area, variations in financing costs produce a more marked effect over the rate of production of buildings than either changes in the size of the market, production costs or the overall level of the capacity of the industry.

Up to now, it has been principally the substantial development of the services sector of the economy which has been behind the strong growth observed in the commercial building sector - shops, offices, hotels and restaurants, nursing homes, and private leisure centres, - which accounts for nearly half of total private non-residential building. Apart from a few regional focal points, however, the services sector has shown less growth in 1991 and 1992 compared with other years, and this has been followed very quickly by marked falls in output in the various relevant sectors of the industry.

More than half the total of public investment in building construction is carried out at local government level, where it is not the level of demand for building which will be decisive but rather the financial predicament of regional and local authorities.

In this case, it is incentive programmes concentrated at regional level which are most likely to bring about improvements in the infrastructure. Notably this is true of Portugal, and in 1992 to a lesser extent for Spain. Germany's eastern Länder are also benefiting from such programmes, following some initial uncertainties.

Throughout the EC, except in the areas noted above, the rate of growth in the public works sector in 1992 has either fallen back or even become negative.

As far as housing modernisation and improvement is concerned, a positive growth rate is being maintained in nearly all EC countries. This sector is assuming greater and greater

importance for the building construction industry as a whole. Up to now building modernisation and improvement work has been largely the preserve of small construction companies. However, possibly as a result of the recession, a growing number of medium-sized enterprises, and even some large construction companies, are discovering a new field of activity whose potential has not yet been fully explored, quantitatively or qualitatively, by comparison with what has been achieved elsewhere in terms of growth of productivity.

As far as building construction is concerned, one cannot expect any further increase in demand resulting from innovations either in construction products or in production methods. For the present building construction differs from other industry sectors in that the product is significantly influenced by architects who stand between producer and client.

Supply and competition

For small and medium-sized construction enterprises competitive pressures have returned to normal following a reduction in total production capacity. Among large enterprises in the industry, on the other hand, competition is on the whole reduced. The growth, noted above, that has taken place in foreign trade in construction has directed the energies of these firms more towards overseas and particularly non-European markets. Experts had expected an easing of competition as a result of a shift in production capacity to the markets of Eastern Europe, but this has not yet happened to any significant degree. Indeed, it looks more and more as if one might expect building construction capacity of the countries of Eastern Europe to come onto Western European markets.

The industry's clients, for whom it provides buildings for a wide range of uses, are drawn from all sectors of the economy, both private and public. In none of these sectors, however, does the industry face any particularly strong market leverage on the client side. Even public sector demand for building construction is normally decentralised among a large number of authorities.

Following privatisation of public services, the market leverage of the State is being further reduced, even at local level.

However, some reversal of this trend may occur as a result of an increase in leasing of public buildings, given that some leasing institutions have considerable commercial strength which they could exercise.

The level of activity within the EC of construction enterprises from outside the EC is insignificant, whether at Community or regional level. Foreign investors often employ contractors who subsequently award the work to European contractors.

The process of completing the Single European Market is helping to bring about an improvement in the competitiveness of building firms enabling them to extend their operations into other EC countries. This is coming about especially as a result of easier market entry both for these firms and also for the construction materials which they are accustomed to use in their national markets.

Furthermore, former obstacles to cross-border movement of firms' construction plant and equipment are now being removed.

The activities of trade associations at European level, relating to completion of the Single European Market, are bringing about a better understanding of the fundamental parameters of different markets, especially in the area of public and private law, and at the same time reducing risks that have up to now considerably hindered construction firms wishing to compete in non-national markets.

Production process

The rising trend in total European building construction workload recorded over the past several years has continued in 1992, albeit at a slightly slower rate. Statistics show a real growth rate of around 3%.

However, this statement is of little significance for the analyses carried out and decisions taken by firms in the building industry, given that it relates only to the overall trend while growth is at different rates in different European countries and different branches of construction.

Most SMEs operate only in a limited part of the market, and therefore depend very heavily on trends at regional level. Only the large construction enterprises are able to re-allocate their resources in response to shifts in demand in different regions and sectors in which they have an interest.

It is therefore changes in the structure of market sectors in the different countries which provide the best basis for assessment and decision-taking by individual firms.

Major inputs and their productivity

Compared to other sectors of industry, building is labour-intensive and depends heavily on primary materials. On the other hand, it requires very little investment in fixed assets. Productivity improvements will be achieved mainly by the use of appropriate materials, effective management, and the skill level of the workforce.

As far as construction materials are concerned, there is close interdependence between the following sectors: aggregate, metals, chemicals and timber-processing. Firms wishing to improve productivity by using better quality and more expensive materials will seek to extend this interdependence by making more use of off-site prefabrication.

One may also note similar developments in transport, where better management together with prefabrication measures have led to productivity improvement.

Furthermore, growth in the flow of orders from main contractors to sub-contractors is marked not only by greater complexity of such orders but also by the exploitation of potential for increases in productivity by means of co-operation between more specialised firms in the same sector of the industry.

By comparison with other sectors of construction, the building sector requires, in relation to its output, much less investment in capital assets, consisting mainly of mobile plant and vehicles. On account of this, it has relatively less potential for productivity improvements.

Generally speaking, this arrangement is beneficial, when one thinks that the financial resources and financing costs of these assets are markedly lower. Lower capital requirements make it easy for new firms to enter the market place and for existing firms to increase their production capacity more quickly.

At the same time, reduction in production capacity is equally easy. However, the reduced need for capital, especially for capital subscribed by the proprietors of the enterprise, can in the case of expansion quickly expose weaknesses of the enterprise, if increase in the scale of its operations leads it to have to make payments in the short term to a large workforce and for heavy investments in materials, while on the other hand payments for the work done fall due only in the medium or long term.

The increase in leasing of construction plant and vehicles again highlights these relationships, if one considers on the other hand the reduced need for capital and for meeting the costs of financing, but on the other hand the threat to solvency from growth of production capacity or of the scale of operations of the enterprise.

The building sector has a very large workforce. As a result, fluctuations in production in this sector exert a strong influence on the total level of employment in the different national economies.

For example, in countries faced with a decline in construction activity the level of employment was relatively low in 1992 not just in construction but overall. In most EC countries, however, numbers employed in construction have increased, more especially in Germany and Spain, though in Italy and Portugal numbers have stayed at the same level.

Variations in numbers may however hide substantial qualitative changes in the make-up of the workforce, as firms are faced with increased commercial and organisational pressures in view of stricter standards and as a result of important changes in production techniques especially in respect of the use of prefabricated components.

Enterprises are experiencing more and more difficulty in finding personnel suitably qualified for commercial and technical positions in construction, which they have an urgent need to fill.

Staff and office workers are assuming greater importance compared to numbers of operatives on site, where the proportion of skilled workers is increasing.

Compared with other sectors, building construction employs a proportionately greater number of older workers (over 50 years old), which makes it ever more urgent to recruit a new generation of workers, and to improve skills. If this does not

happen, the effect of the fall in the number of skilled workers as more reach pension age will be even more acute.

The difference in wage costs in building construction between different EC countries, and in the balance between pay and other labour costs are relatively less important than the difficulties of finding sufficient numbers of suitably qualified personnel.

PRODUCT FEATURES OF THE INDUSTRY

Technological conditions

A rapid introduction of technological improvements which have already been developed is hindered by the fact that they must be capable of adaptation to building work on building sites; building sites which are invariably different in every case and are characterised by varying environmental conditions and contractual relationships.

In spite of remarkable progress in, for example the area of energy-efficient buildings, new advances in building processes, new materials and plant and site organisation are not discernible today.

By virtue of production methods employed on different building sites, the meteorological conditions lead to an adverse effect on building production particularly in the northern areas of the EC. Two exceptionally mild winters, have therefore resulted in a real increase in building production in these regions which in turn has brought about economies.

Non-residential building

After the high rates of increase in construction of private non-residential building, in the years up to 1990 and with weaker increases in 1991, an equally large decrease in new building activity has been estimated in this sector for all EC countries for 1992, with a further substantial decrease anticipated for 1993.

This correlation is very evident in sharply reduced investments in the private sector in the United Kingdom (with significant differences between industrial construction and commercial developments) and in the Netherlands, France and Ireland. There the market situation is also characterised by considerable supply surpluses. Outside the EC, this development can also be seen in Finland, Sweden and Norway.

Only in Germany is increased private investment leading to a growth in demand in this sector of the industry. In particular, in the new German federal states, investments by German and foreign firms are increasing rapidly.

In the public sector of the construction industry, on the other hand, the decreases for 1992 will be less marked than in the private sector, with similar falls anticipated in 1993. Exceptions to this trend can be found in Germany, Spain and the Netherlands.

Multi-storey housing construction

After two years of declining building volumes, a slight increase in demand for multi-storey housing construction may be expected in 1992; however, this is expected to be followed by a rather larger fall in 1993. Although, this development may be characterised by a further divergence between individual countries both inside and outside the EC. Finland and Sweden in particular are expected to suffer dramatic decreases in activity in this sector. Only the United Kingdom and Germany are expected to witness increased output in 1993.

The high pressure of demand for rental accommodation should have made considerably higher increases likely, particularly in Germany and above all in the new federal states. To date, private investments in particular are lacking in this product sector; in the new federal states this can be explained because the rents are regulated at a very low level with a still very high rate of interest.

In the Netherlands the recent considerable drop in new construction in multi-storey housing construction is mainly due to the high interest rates and the increasing fees for transfer of ownership.

Building modernisation

As in the years up to 1991, in almost all EC and EFTA countries, increased demand for the modernisation and renovation of residential buildings may be expected. In many countries this should even offset the decline in new residential construction.

Exceptions were the United Kingdom and the Netherlands in 1992. However, as these market sectors recover in 1993, Belgium and Italy are expected to decline.

Despite the urgent and extensive repair and modernisation required in the new German federal states, increases in this sector continue to show a shortfall due mainly to a lack of private investment.

INDUSTRY STRUCTURE

Companies

More than in other sectors, the building industry in the EC is characterised by a very heterogeneous structure with regard to the sizes and concentration of firms and their geographical distribution.

The size structure continues to be characterised by a multitude of small firms; about 80% of building firms in Europe employ less than twenty employees. The number of building firms with more than twenty employees is estimated at approximately 40 000.

The proportion of the total building construction turnover of a country, on the other hand, is more clearly shown by the economic significance of the large building firms with over 500 employees; it amounts in Italy to 18%, in Belgium 13% and in Germany 24%; on the other hand it is as much as 36% in France, 42% in the United Kingdom and 48% in Spain.

It cannot, therefore, be surprising that according to "Le Moniteur" of the 40 largest construction companies in the EC, 11 have their head office in the United Kingdom, 9 in France, 5 in Germany and 4 each in Spain and Sweden. Building construction in Italy and Belgium is sustained above all by smaller firms, in Germany mainly by medium-sized and in France and the United Kingdom above all by large firms.

Strategies

According to the size of the firm and its geographical region of operation, the cost-performance relationship shows considerable deviations. This obliges the firms to increase productivity, above all through increased used of prefabricated elements, increased mechanisation, plant hire and improved organisation of building sites with the cooperation of suppliers and sub-contractors.

The investment by building firms in plant and equipment fluctuates considerably from country to country, but compared to the costs of personnel represent a smaller proportion of overall costs when expressed in terms of depreciation. Increases in productivity usually arise through more efficient use of personnel and plant and equipment.

This correlation also becomes recognisable in the increasing use of leased plant and equipment and vehicles, through which technological improvements and plant inventories can be more rapidly put to use.

Changes in the product structure can be seen increasingly in specialisation by medium-sized, regionally active building firms and diversification in larger firms. The latter are increasingly extending their area of activity in non-building trade services, in particular with the development of real estate and its management, such as, for example, hotels and office buildings. This development is particularly marked in the United Kingdom and can be considered as a cause for a noticeable surplus of supply in these sectors.

A particular feature of the performance structure of this sector is the combination of the production work of several independent firms jointly in one single project, in general through the conclusion of contracts between main contractor and subcontractors or as a joint venture. The bigger the building contracts the more this kind of cooperation between firms in the same sector occurs.

As a current trend, an increase in the main contractor approach at the expense of joint ventures is evident. Building firms of all sizes are involved in this. This trend can be considered both as a consequence of increased specialisation and further diversification within the production sector.

In addition to these more project-related forms of cooperation between firms, outright purchase or takeover of firms as well as participation or cooperation agreements are also increasing. In these cross-border interrelationships, France, Germany, the United Kingdom and the Netherlands are particularly involved. These activities aim above all at the building markets in Spain, Portugal, Belgium and Germany. Their growth can be ex-

plained in particular by the preparation for and completion of the Single European Market.

REGIONAL DISTRIBUTION

The building site-related production method of operation obliges building firms to be more geographically mobile. With small and medium-sized firms this mobility is limited however to their local and regional markets. In addition, a marked geographical dispersion of building firms and, therefore of the whole building capacity continues to occur. Significant upward trends in the construction economy therefore, tend to result in company collapses rather than geographical shift of building resources which are in themselves mobile. Following the subsequent reduction in construction capacity, the necessary resources are then lacking during the economic recovery particularly in regions with an urgent need to catch up in building investments.

A general or sector-related upturn of building production in individual regions of the EC then reveals an unbalanced situation, since the available resources, particularly of the small and medium-sized firms, can hardly be mobilised in the regions most in need.

The consequences of this are, on the one hand, regional increases in building prices and, on the other the emergence of larger firms to fill the shortfall. This situation applies in 1991-1992 above all to Spain, Portugal and Germany.

REGULATIONS

The preparations for and completion of the Single European Market are affecting output, in addition to the diverse direct and indirect effects on building construction supply and demand, in particular through Europe-wide effective regulations.

The guideline for building products harmonises the conditions of authorisation for such products. It thus simplifies not only cross-border trade in such products, but also the building activity of the firms in their non-national European markets. The greater EC internal competition to be expected from this is, therefore, also related to building production overall.

The directives for coordination of the award procedures for public procurement are more far-reaching and have a more direct effect on EC internal competition in the building sector, since the government demand for building construction covers a significant proportion of the total output of the industry; particularly because private buildings which are mainly government financed are equally affected.

The threshold of 5 million. ECU limits these effects, however, to a sector of the building construction demand, in which there is either already strong cross-border competition between large building companies or this competition was previously limited for other reasons.

OUTLOOK

The economically and technologically-based structural change in the EC countries is characterised by an increase in demand for new construction and this, above all, in regions in which structural change is particularly marked.

Dampened expectations regarding the general development of income and high financing costs are hindering present day needs for corresponding growth in building construction output. New advances in technology are not evident. The technological improvements already initiated in larger building firms are being increasingly introduced in smaller firms. Productivity improvements can therefore only be achieved through improved organisation in building site procedures and increased off-site fabrication. In this way an increasing proportion of work let to general contractors on a turnkey basis is noticeable throughout the EC.

Medium sized construction firms all well as, to a lesser extent large firms, are paying increasing heed to the renovation and repair sector of the market which remains to be fully exploited.

Civil engineering
NACE 502

Civil engineering delivers mainly public infrastructure installations, so that its business activity depends primarily on demand from the various public bodies. The production capacity of this sector thus depends less on the general trend in incomes than on the budgetary policies of these public bodies.
A decline of business activity therefore emerged in 1992 after several years of considerable growth rates. This decline is clearly due to diminishing state investment.
This heavy budgetary dependence is beginning to loosen in several areas of civil engineering. This tendency can be seen in the clear increase in private forms of organisation for public sector tasks, beginning with services and factory operations, and followed by associated infrastructure investment which can be carried out also with private sources of financing. This applies especially to the fields of transport, communications, waste and waste water disposal as well as to water and energy supplies. As a result the use of potential demand in these fields is less limited by budgetary constraints.
Also of value to civil engineering is the impact of major technological developments in transport, communications and the environment. Civil engineering production capacities on a large scale are required for their practical introduction. This impact is more far-reaching than technological developments in civil engineering itself.

INDUSTRY PROFILE

Description of the sector

In civil engineering, construction firms are active in the construction of transport infrastructure (roads, railway lines and airports), in hydraulic engineering (mainly rivers, canals, harbours, streams, sluices and dams), in irrigation and drainage, disposal of waste water and erection of purification plants, construction of bridges, tunnels and shafts, drilling, excavation works and land improvement.

Like the building sector, civil engineering makes extensive use of materials and is very labour-intensive, but additionally to a greater extent than building it makes use of plant. However it is less integrated with the other industrial sectors of the economy through client and supplier relationships. Hence changes in its production capacity have fewer downstream effects on general economic development.

Recent trends

Since 1992, after several years of strong growth in civil engineering production, there has been a decline in nearly all civil engineering branches in most of the countries of Europe. This clearly shows the dependence of business activity in this sector on public expenditures on infrastructure projects.

Nearly all countries in Europe have considerably reduced their investment budgets in order to check state indebtedness.

These cuts have been especially severe in Spain and Italy. In Spain the enormous investment efforts made in public sector infrastructure from 1988 to 1990 with growth rates of 20% to 25%, and an increase of 9% in 1991, have been followed by a decline in business activity of around 6% for 1992.

In France this decline is making itself felt mainly at local levels. Only on-going national large projects have helped to prevent a major decline in overall production.

Only Germany and Portugal represent exceptions to this general tendency towards decline. A special feature of both among the countries of the European Community is a great backlog in needs in Portugal and in the new German Länder. In East Germany extensive additional state expenditures from the Fund for the "Revival of the East" benefit mainly civil engineering, especially investment in transport infrastructure.

The decline in non-residential building is also having an impact on civil engineering, as a quarter of investment in non-residential building is accounted for by civil engineering works, such as supply piping, factory purification plants, pipelines, and drainage. Increasing requirements for protective measures against emissions give reasons to expect that this decline will be reversed from 1993 onwards.

Similarly spectacular growth rates are appearing outside the European Community, more recently in Sweden.

International comparison

The market situation of European civil engineering firms in foreign markets shows features similar to developments observed in building, especially as many large construction firms cover both sectors in their production.

The competitiveness of European civil engineering firms is shown mainly by their heavy involvement in various branches in foreign markets. Thus of the ten civil engineering firms most active in foreign markets worldwide, European firms are involved with seven in hydraulic engineering, with six in waste and waste water disposal, and with five in energy supply.

Foreign trade

In the transnational business operations of the civil engineering firms there are definite signs of growth for 1991-92, mainly in Europe, although, from an overall point of view, the European market is not registering any increase. This correlation follows from increased competition, especially among the large firms in this sector who work abroad mainly through local subsidiaries.

It is to be assumed that this development in the markets for public infrastructure works in Europe has already been influenced by the Public Procurement Directives.

European firms are also increasingly active in overseas markets for civil engineering, such as the Middle East and Asia. So far this has not been negatively affected by the fact that bilateral and multilateral financing institutions are abandoning project-related forms of financial assistance. This applies also to the European Development Fund which is increasingly limiting its support for individual projects in favour of promotion of deliveries of materials and technological co-operation.

Extraordinary rates of increase were achieved by Spanish civil engineering firms in the otherwise declining markets of Central and South America. A part of Spanish civil engineering capacity is also being used on an increasing scale in neighbouring Portugal.

MARKET FORCES

Demand

The demand for civil engineering services develops mainly in counter-cyclical fashion, as demand is accelerated or delayed by the budgetary and financial and economic situation of the relevant decision-making public bodies. Moreover, many projects come to the execution stage only after several years of planning, decision-making and procurement procedures. They then extend over several years of financial and technical accounting.

For an assessment of the development of demand it is necessary to know the special features of this sector especially in comparison with building. They arise almost exclusively from the kind of services provided and from the special requirements of predominantly public clients. France can be mentioned as

a typical example, as two-thirds of civil engineering production there is awarded by public clients.

In road construction, both the local authorities, for example, and the central government bodies decide on the projects. Their decision depends to a large extent on their own budgetary and financial situations. Thus expectation of loss of receipts can lead to short-term delays, while receipts which turn out to be higher will not, however, rapidly lead to an acceleration of projects.

Civil engineering depends less directly on the general trend of wages and salaries than on the budgetary possibilities of the various public bodies, which for their part are very much affected by the general trend of incomes.

It is difficult, especially in the short-term, for the demand for civil engineering services to be derived from the need for infrastructure installations or the relation to existing ones. This applies to the needs for transport infrastructure as well as for supply and disposal facilities. By contrast, specific developments in demand are more a consequence of political priorities for public investment and the budgetary framework.

During budgetary bottlenecks, politically decided large projects can therefore be spread out in time with corresponding consequences for the demand situation in the relevant branches of civil engineering. These interconnected factors can be clearly seen from the budgetary and finance laws in France, Spain and Denmark, in which, despite obviously continuing needs, civil engineering investment was spread out over time. The same can be seen with opposite effect, as in Belgium where the decrease of the 80's was reversed for the first time in 1992.

In civil engineering also, the benefits of additional demand cannot be expected at present from innovations either in production or processes. In some fields of transport, and in communications and environmental technologies, the services of civil engineering are required for the operational introduction of technological innovations on a large scale. As a result there is a considerable demand pressure on this sector.

Supply and competition

The market power of public clients operates more noticeably in civil engineering branches than in building. To be sure, demand in civil engineering also comes from many public bodies - as, for example, railways, telecommunications and airports - which operate in part autonomously in relation to their parent territorial bodies and which decide investment projects.

Nevertheless many civil engineering branches depend entirely on this public sector demand in their relevant branch. This applies especially to road construction and civil engineering works involving pipe-laying for supply and disposal facilities.

Noticeable, politically supported improvements in the public procurement system temper the possible use of this public sector market power and enhance competition. In the case of large projects the public procurement directives are operating in this direction. But these endeavours are also increasingly in evidence for small and medium-sized projects, though only with regional and local impact.

A typical example is the development in Denmark of a selective extension of open tendering to kinds of tasks and projects which were not previously put up for tender, coupled with the establishment of independent advisory procurement boards in which representatives of the various parties concerned participate.

Production process

Civil engineering, like building, is very labour-intensive compared with other industrial sectors. However, as opposed to building, it operates in most production branches with a greater use of plant. Improvements in productivity are therefore to be achieved both through the organisation and the qualifications of personnel as well as through fixed assets corresponding to the specific tasks.

However, in comparison with building, civil engineering reacts less flexibly to short-term fluctuations in the economy because of the higher amount of specialised fixed assets in the relevant branches of civil engineering. Adjustment through shifting a firm's production capacity from one construction branch to another in many case requires restructuring the equipment used.

Main contractor and sub-contractor contracts are less frequent in most civil engineering branches than in the building sector, because in these fields there are scarcely any services which could be more efficiently provided by various specialised firms.

The employment trend in civil engineering shows tendencies comparable to those of building. As a result there is an increasing demand for highly qualified personnel both on the technical and business sides of the firms.

Small reductions in employment due to declining construction production relieve this sector at present of the necessity of seeking highly qualified employees who, after personnel cuts lasting many years, become one of the main problems of the sector with every major enlargement of production.

FEATURES OF CIVIL ENGINEERING

Development of transport infrastructure

The largest part of construction work in this field still has to do with the renewal and enlargement of existing roads and rail links of national and, increasingly, transnational importance. With around one third, it also comprises the largest share of civil engineering production.

Special efforts in the field of new construction are being made principally in the countries with comprehensive plans for the development of transport. This is the case in Great Britain and France with new motorways, city ring roads, and the further development of the high-speed rail network.

In the development of high-speed rail routes, similar efforts are being made in the case of investments by the German Bundesbahn and the Italian state railways with corresponding effects on production in this branch.

In Spain infrastructure investments for the Olympics and the World Exposition were a special focus of investment until 1991. The decline in civil engineering production in this branch because of a very restrictive Spanish budgetary policy is probably temporary, as the linking of the new route networks to the rest of the Spanish rail network, with its different operating standards, and to the European high-speed rail system will bring about such a sustained demand pressure that renewed growth at a relatively high investment level is inevitable. Also the second national road plan will have a bearing on this development.

In Belgium, however, up to 1992, demand which has been increasing for years has not brought about such growth either in rail or road construction.

In Portugal the largest share of public sector investment expenditures went into the development of the main highways and the motorway network. There are signs of further growth there, because large-scale projects are close to execution: a bridge over the Tagus and a new international airport for Lisbon. Here resources from the European structural Funds are clearly having an effect.

In Ireland these resources of the European structural Funds will be effectively utilised only from 1992 due to lengthy planning preparations. There too they will be used mainly for development of the main highways.

In Denmark electrification of the main railway lines is being continued. In road construction future growth will be in the context of the planned Oresund crossing and the associated investment in road links.

Bridges, tunnels and shafts

Construction projects involving large-size bridges and tunnels form part of the development of transport infrastructure. An outstanding example of this is the Channel tunnel which is putting other plans for large-size tunnels and bridges in the shade.

Hydraulic engineering

This civil engineering branch is receding into the background in the countries of the European Communities during 1992. This trend is discernible even in the Netherlands which traditionally carries out large hydraulic engineering infrastructure works. The long-planned flood-protection works on the waterways cannot provide sufficient compensation in capacity, though they are leading to a slight increase in this production branch.

Different tendencies are being shown only by France, though on a considerably reduced scale in 1992, with its development of harbours, and by Portugal with its investment in national water distribution. Previously planned major hydraulic engineering projects have been postponed in Spain.

Waste water disposal and investment in the protection of the environment

There are general signs that the whole area of water supply and waste water treatment and disposal is a significant growth area for civil engineering in the European Community. This is especially noticeable in Belgium, Denmark, Great Britain and Portugal. The directive 92/271 establishing our obligation to treat waste water in municipalities with more than 2,000 inhabitants will assist this development.

While the civil engineering branch is still lagging behind road construction in quantitative terms, small and medium-sized civil engineering firms are benefiting from increasing demand at local and regional level. Even in markets which are in general decline there are signs of a sustained rise in investment in waste and waste water disposal facilities. However there is a real decline in Ireland because of a reduction there in resources from the European structural Funds for road construction.

Energy supply pipelines and excavation works

There was scarcely any change in 1992 as regards the situation in excavation works, insofar as they did not come under other civil engineering branches like road building. Production is being maintained, particularly in some regions of Germany through the recycling of industrial land.

Only in Ireland can considerable additional infrastructure investment in gas supply be recorded. It is being supported in particular by the European Structural funds. A gas pipeline across the Irish Sea is being indicated as a future large-scale project.

Modernisation and repair

As in building, the modernisation and repair of public and private infrastructure is accounting for a constantly growing share with increasing growth rates. Interest chiefly centres on bridge repairs, improvement of transport infrastructure, and renewal of faulty waste water disposal pipes.

These investments provide a sustained demand, especially for small and medium-sized civil engineering firms operating at local and regional level.

INDUSTRY STRUCTURE

Companies

Like building, civil engineering is variously structured, depending on size of firm and geographical distribution. Approximately four-fifths of the firms in this sector employ fewer than 50 workers. But around half of the workers of the sector taken as a whole are in firms with more than 500 employees.

In civil engineering, firm sizes are more closely related to the various branches than in the building sector. Thus road works and sewage disposal are carried out principally by firms of up to 50 employees, while construction of bridges, tunnels and shafts as well as extensive excavation works are carried out by firms with more than 1 000 employees. As a result, firms of varying sizes are affected in different ways by reductions in infrastructure investment, and this is hidden in the overall growth figures.

This is very clearly shown for France in 1991 and 1992 where infrastructure investment by the local bodies was considerably reduced, and this especially affected the small and medium-sized civil engineering firms. While the continuation of large-scale projects, such as the TGV Nord compensated for this development in the overall figures, it benefited mainly the larger firms.

As scarcely any sub-contracting firms operate in this civil engineering branch, a continuing concentration can be observed in this field which is already far advanced in France where more than a third of this business is accounted for by firms with more than 1000 employees.

Because of the general decline of construction in this sector, the establishment of new, specialised civil engineering firms is not taking place on the same scale as previously.

Strategies

Depending on the special nature of their products and services, the individual civil engineering branches are characterised by various combinations as regards the intensity of their use of personnel, materials and fixed assets . Hence strategies for productivity improvements focus on personnel, with the consequence of dismissals in the countries where demand has declined the most.

As in building, civil engineering is generally less intensive in its use of fixed assets than the other sectors of industry. Because of the decline in civil engineering production in 1992 and because of reduced estimated demand - in the public sector and demand as a result of private non-residential building - investment in fixed assets in this sector has also definitely diminished.

The production structures of this sector are also determined by the main investment areas in public sector infrastructure. This kind of change can hardly be matched by the small and medium-sized firms specialising mainly in specific civil engineering branches with adjustments in products and services or even only with little geographical mobility.

As civil engineering services involve less complex detail as to execution and equipment than building, the executing firms are for this reason more specialised in their relevant branch of civil engineering. Forms of co-operation among main contractors vis-a-vis sub-contractors are also less frequent than in building.

For the same reason it is to be assumed that integration of firms through purchase, merger or partnership agreements take place less frequently in civil engineering than in building. However there is no detailed documentary evidence of this.

REGIONAL DISTRIBUTION

Most civil engineering works call for great mobility on the part of the civil engineering firms for constantly changing construction sites and projects. This factor leads to larger migratory movements between the regions and, increasingly, the national markets in the European Community.

In public sector civil engineering, especially in transport construction, geographical differences show up according to regions and Länder because of the varying financial capabilities of these territorial bodies. But this applies also in the context of large-scale projects, such as the Channel Tunnel and the associated peripheral public sector investment, especially in transport construction.

As against this, regions with lower levels of economic activity are falling badly behind in civil engineering, with consequential, further disadvantage for their infrastructure. This is shown very clearly in the case of the Spanish regions which did not form part of the main areas of investment during recent years up to 1992 and have now been hard hit by the budget cuts.

Even the distribution of investment for protection of the environment depends on the economic structure of the territorial areas. Areas with older industry require larger environmental protection investment, in Germany, for example, in a proportion of 10 to 1 for North Rhine-Westphalia and the new Länder on the one hand and for Schleswig-Holstein on the other.

In civil engineering the resources of the European structural Funds show a clear impact with regional differences, especially in Portugal, Ireland, Greece and Southern Italy.

ENVIRONMENT

The construction of new and the development of existing transport infrastructure, particularly in road construction, comes up against environmental limits both in remote and populous areas because of its great use of land and its impact on the landscape. In civil engineering this leads in many cases to delays in carrying out investment already decided on.

So far there is no prospect of a solution which, though part of production in this sector, would offer improvements in the environmental situation during the development of transport infrastructure.

As against this, civil engineering is the sector where production operates more effectively than in the other sectors of industry on behalf of environmental protection measures in the sense of on-site prevention and repair. This applies in particular to the construction of waste water disposal and purification installations and also to measures - which are sometimes extensive - involving soil exchange in the case of contaminated ground.

The selective assistance of the European Community to regions with older industry is giving rise to growing demand for renewal measures which can be carried out by civil engineering, as soon as this assistance begins to take effect in the direction of new kinds of use and activities as well as private and public sector investment.

The scale of these infrastructure works is evident in districts in Lorraine and parts of the Ruhr area. However this experience is far from sufficient to permit a clear assessment of the required scale of future measures of this kind in the new German Länder.

REGULATIONS

Civil engineering is also being influenced by the preparations for and the completion of the European internal market in addition to the diverse direct and indirect effects on supply and demand in civil engineering, the regionally targeted resources of the European structural Funds, and, above all, by Europe-wide regulations of direct effect.

The Directive on Construction Products does not have the same importance for civil engineering as for building. However it also harmonises for this sector the approval conditions for these products and thereby simplifies not only transnational trade in these products but also construction operations by firms in non-traditional markets.

More far-reaching and of more direct consequence for competition in civil engineering within the EC are the directives on public procurement. However, an aggregate value of more than 5 million ECU limits the impact to a segment of demand for civil engineering in which either strong competition among large construction firms already exists or this competition has hitherto been limited for other reasons. The greatest part of the mostly smaller regional and local projects are not affected by it.

OUTLOOK

New areas of emphasis in civil engineering are coming increasingly to the fore, for example, investment in protection of the environment and he improvement and technological renewal of existing infrastructure facilities with consequential changes in the structure of construction enterprises and the composition of the work force.

In the field of financing, a rising need for infrastructure investment of transnational significance is forcing a discussion of reform of financing, especially with the participation of private investors who could free themselves from the restrictive constraints of state budgetary policy. This applies in particular to investment in transport in a pan-European context.

Developments in the new German Länder have triggered a special dynamic, as it has been possible for the development and repair of public infrastructure in the Eastern Länder of Germany to take place in large measure independently of the general trends in interest rates, costs and the budget, because of a considerable injection of public resources. However the expected impact on European-wide supply structures has failed to materialise.

In the other countries of the European Community there is no sign yet of an end to restrictive budgetary policies. This trend will continue to dampen demand pressure arising from the need for infrastructure facilities.

It is also causing structural shifts in the restricted investment volume, especially at the expense of construction of transport infrastructure. This demand bottleneck is also leading to a sustained and rising activity abroad of the civil engineering firms which is being increasingly facilitated as a result of the completion of the internal market and therefore ensures greater transnational competition.

Written (in German) by: Prof. Dr. Wolfgang Hagedorn
The industry is represented at the EC level by:
European Construction Industry Federation (FIEC). Address: Avenue Louise 66, B-1050 Brussels; tel: (32 2) 514 5535; fax: (32 2) 511 0276; and, European International Contractors (EIC). Address: Postfach 2966, D-6200 Wiesbaden; tel: (49 611) 77 22 68; fax: (49 611) 77 22 85.

Industrial engineering

For the industrial equipment manufacturers of the EC, 1991 was marked by an increase of 9% in the current value of orders and by a number of transactions in the final stages of negotiation which helped to maintain business at a level comparable with that of the first months of 1992. These results compare favourably at world level, where there has been a marked up-turn in business, mainly as a result of major programmes of investment undertaken in several key sectors in the industrialised countries.
The energy, petrochemicals, oil, gas and communications sectors embarked upon major programmes of investment, either by increasing capacity and rationalising obsolete production units in order to improve their production costs, or by extending infrastructure networks, particularly in the rail sector and in telecommunications. Major programmes of investment were also dedicated to the protection of the environment and to improving the quality of life. In this respect, the EC industry made numerous investments aimed at reducing pollution, often on the basis of procedures developed by industrial equipment manufacturers.

INDUSTRY PROFILE

Description of the sector

Industrial engineering largely consists of supplying services: feasibility studies, technical process studies, market research, location studies, architectural and civil engineering studies, staff training, supply of capital equipment and systems, etc. The relative importance of these different activities varies considerably depending on the industrial sector concerned and the type of contract.

Owing to the specific nature of the activity, industrial engineering does not feature as such in any statistical records. In order to make up for this lack of data, the European Committee of Plant-makers (EUROPLANT) introduced a model for gathering data on the sector's activities. This system has not yet been adopted by all the EC countries, however it permits to discern certain patterns within the sector.

Main indicators

According to reliable estimates, the world market for the major industrial equipment manufacturers was worth around 118 000 million ECU in 1991, representing a slight increase by comparison with the previous year.

During 1991, the industrial equipment manufacturers of the EC had an order book of which the estimated value was 48 000 million ECU, representing a 9% increase in current value over the previous year. This increase has been reflected - to varying degrees - throughout all sectors of the EC countries. It has been particularly marked in Germany, the United Kingdom, Italy and France. These four countries account for some 90% of the total number of orders, of which approximately 35% stem from the EC market.

Recent trends

The early 1980s were particularly favourable for the industrial engineering sector, as firms embarked upon the final phase of several major industrialisation projects in the developing countries. After the historic slump in the period 1984-1986, a significant revival of the world market began following huge investment programmes generally linked to the energy sector and to large infrastructure networks. The effects of this revival were felt most in the industrial regions.

Following the large-scale rationalisations undertaken in 1984-1986, which were reflected by a marked fall in employment and an end to activity in the declining building industry, the sector experienced a period of stability in employment in 1991, and even a slight increase in the appointments of specialist staff to carry out specialised jobs on the work site.

International comparison

On a world-wide scale, the distribution of market shares of industrial equipment manufacturers, as shown in Figure 1, reveals no significant change from previous years. EC plant-makers remain at the top of the ranking, closely followed by the US industry. Japanese plant-makers are well behind, controlling a 14% share of the world market. US engineering firms, however, are still the world leaders in terms of both technological capability and size.

MARKET FORCES

Demand

It is interesting to note that the distribution by sector of contracts reveals a tendency towards concentration around those client industries with high technological value and considerable capacity for investment. The distribution by sector of contracts undertaken in 1991 is shown in Figure 2. The oil, gas and petrochemicals sector, which accounts for 32% of the total number of orders for the EC industrial equipment

Table 1: Industrial engineering

manufacturers, has channelled most of its investments into petrochemicals (some 50%) and refining (over 40%). The main reasons for this investment are: to put new products on the market which are more compatible with environmental requirements; to improve the output and profitability of production units which have become technically obsolete; to remove possible risks to human safety and health.

In general, the tendency for most of the EC's plant-makers to focus increasingly on the internal market, following the decline of the markets in the developing countries which occurred in the mid 1980s, enabled them to adapt their structures to a changed market and to develop new technologies situated in rapid growth sectors. In this regard, it is interesting to note that around 35% of orders originated within the EC market which continues to offer favourable prospects. By contrast, the share of orders from the developing countries decreased slightly as a result of events in the Gulf which influenced decisions to invest or even led to the suspension of contracts in many countries bordering the region.

Supply and competition

At world level, competition remains very fierce and technical advantages remain very slight due to a policy of research and development which is strongly sustained by both American and Japanese industrial equipment manufacturers. Factors relating to price and reference to similar techniques currently constitute the main criteria for assessing competitors.

It is notable that, in recent years, Japanese engineering companies, which are usually subsidiaries of major Japanese business groups, have consolidated their presence in Europe, particularly in Germany and Great Britain. These subsidiaries are playing an increasing role in the preparation of projects intended for markets in bordering countries, and in many cases, are seeking European partners who are willing to enter into consortia or joint ventures, to share the risks of these projects. Japanese engineering companies are also increasingly looking to European industry to supply equipment and machines or to provide assembly services. This is particularly true in the case of projects financed by European loans.

Production process

The sector has not undergone fundamental modifications in recent years, but numerous operations are taking place which aim to increase the size of companies, by a policy of technological complementarity, or to identify synergies by developing networks of alliances.

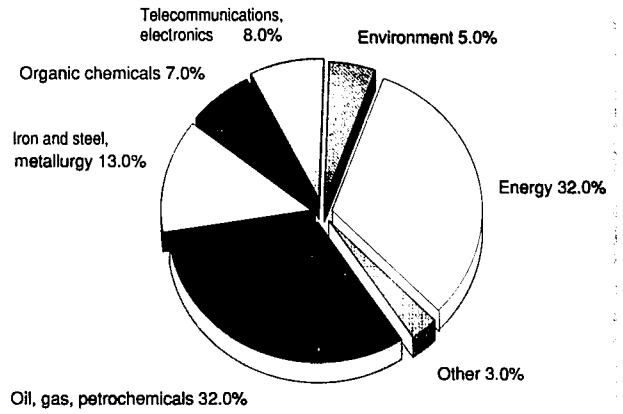
In many cases, technological cooperation, between equipment manufacturers designing systems, on the one hand, and industrial group investors on the other, has increased and has enabled new or more effective procedures to be developed. The major trends in technological development have focused on computerised production control techniques, the organisation of preventive maintenance and procedures for improving the quality of the industrial and urban environment. Particular emphasis has also been placed on procedures for the removal of pollution from industrial installations.

INDUSTRY STRUCTURE

Companies

A large number of plant-makers are first and foremost machine manufacturers. All the major mechanical and electrical engineering firms in the EC are active in the industrial engineering sector, and carry out a large part of their activities within the framework of large-scale industrial projects. Among the largest ones, one can recall Ansaldo, Fiatimposit and Nuovo Pignone (I), Mannesmann, Siemens and Krupp (D), Spie Batignolles, Alsthom and Air Liquide (F), Cockerill Mechanical Industries (B) and Fives Coil Babcock (UK).

Figure 2: Industrial engineering
Breakdown of contracts by industrial sector



Source: Europlant

OUTLOOK

Towards the end of 1992, a significant fall off in the volume of projects and number of orders is to be expected worldwide and certainly in the industrialised countries which have, until now, provided the impetus for growth. However, it is anticipated that the market outlook for industrial rehabilitation and for the infrastructure development programmes will, by contrast, remain positive.

Moreover, ecological pressure, mainly in the industrialised countries, will speed up measures for the protection of the industrial and urban environment and will be reflected by investment programmes which are careful to comply with the regulations increasingly produced by supranational consensus.

Finally, the imminent completion of the Single Market and the gradual creation of a European Economic Space also constitute factors favouring the development and accomplishment of the major infrastructure projects which are necessary to ensure their functioning. Furthermore, the technical assistance programmes provided by the EC for the countries of Central and Eastern Europe undoubtedly requires the restoration of their economies and, in particular, their infrastructures, to which priority must be given in order to establish a market economy. In this perspective, the EC's equipment manufacturers have already made preliminary contacts. Obviously, the implementation of these projects calls for a climate of confidence and political and social stability together with the provision of adequate sources of finance; the European Bank for Reconstruction and Development is without doubt the appropriate instrument to fill this role. Moreover, the re-establishment of peace in the countries bordering the Gulf should bring about a revival of the process of industrialisation in several oil-producing countries with which western equipment manufacturers have constant links.

E15

Distribution
NACE 61-65, 67

The EC distribution sector is undergoing considerable restructuring. Changes include concentration, reduction in the number of traditional wholesalers, transformations in the retail sector and a tendency towards diversification and internationalisation. Moreover, the future of the distributive trade sector will be influenced by the completion of the internal market and the opening-up of Eastern Europe.
The sector represents about 14% of output and employment in the European Community. These figures have remained relatively constant over the last ten years, showing that the distribution sector has grown in line with economy.

INDUSTRY PROFILE

Description of the sector

The industry is divided into two subsectors: wholesale distribution and retail trade.

Wholesale distribution (NACE 61) is defined as "units exclusively or primarily engaged in the resale of goods in their own name to retailers or other wholesalers, to manufacturers and others for further processing, to professional users, including craftsmen, or to other major users".

Retail distribution (NACE 64 and 65) is defined as the distribution to final consumers of:

- food, drink and tobacco;
- dispensing chemicals;
- medical goods, cosmetics and cleaning materials;
- clothing;
- footwear and leather goods;
- furnishing fabrics and other household textiles;
- household equipment, fittings, appliances, hardware and ironmongery;
- motor vehicles and cycles;
- motor fuels and lubricating oils;
- books, newspapers, stationery and office supplies;
- photographic, optical, jewellery and other retail distribution.

These definitions describe the function and product areas characterising wholesalers and retailers. They do not cover the fact that many organisations perform both functions, or that the ownership of wholesalers and/or retailers may reside in operators from another subsector of the supply chain (such as manufacturers), or that manufacturers in some areas carry out their own wholesaling and retailing and are not thus covered by the statistics for the latter sector.

A further important point is that the definition of wholesalers ignores the increasingly wider role that many operators within the sector are playing. For example, the change in manufacturing to tightly-managed production techniques (such as Just-In-Time) means that the whole distribution chain is becoming more sophisticated, and that wholesalers are also taking on functions such as packaging, quality control and administration. None of these is included in the NACE definition, but they nevertheless affect the contribution to the economy of the sector as well as the profile of the wholesaler.

INDUSTRY STRUCTURE

There is great change occurring within and between the subsectors of the distribution industry. This change can be summarised as:

- concentration, expressed in terms of a reduced number of larger operators, and closer vertical links between manufacturers, wholesalers and retailers;
- a general reduction in the number of traditional wholesalers, bearing in mind the fact that the concept of wholesaling seems to have different meanings within different Member States;
- a series of transformations in the retail sector, with significant differences between Member States. Overall a slower increase than before in hypermarkets, a rise in franchising and a proliferation of forms of distance selling are prominent features;
- a tendency towards diversification of activities into other service areas and some specific moves towards internationalisation.

The concentration phenomenon is more evident in northern Member States, with not only a rationalisation in the direct retail sector, but also the emergence of purchasing groups and voluntary chains to benefit from economies of scale.

Wholesaling is often thought of as an activity of the past, in that the traditional operator now often finds himself squeezed out either through a manufacturer's wish to control distribution himself or through the large retailer's practice of upstream extension.

However, some forms of wholesaling are on the increase, such as wholesaler-owned voluntary chains and specialist operators who focus on specific end-users (such as schools and hospitals). "Traditional" wholesaling does survive in raw materials and bulk products because of the logistics involved.

Geographic variance remains of great importance in the structure of the distribution industry. The structure of retailing continues to evolve, with marked differences between the north and the south of the Community. In the north, concentration and larger outlets are the new trends. In the south, smaller shops remain very prominent.

An interesting trend is emerging within the retail sector, whereby,

- retail groups are the typical operators in food retailing;
- voluntary chains feature in non-food retailing; and,
- franchises are moving into services (travel, financial services etc.) as well as goods.

Diversification of activities is occurring, whereby producers (typically non-food) set up retail operations, or where retailers offer services such as travel, financial services, restaurants, etc.

Internationalisation tends to occur towards neighbouring Member States at first, because of cultural similarities. Non-food retailers are the operators most prone to internationalise, with great attention having to be paid to national consumer tastes. The Euro-consumer does not yet exist, even if consumption patterns are moving closer together.

REGIONAL DISTRIBUTION

The most obvious influence of geography on the sector is in the different definitions of what a wholesaler is, and in the role of the small retail outlet.

In Germany, for example, wholesaling tends to be thought of as the distribution and procurement activity of manufacturers. In France, the tendency of manufacturers to subcontract sales activities and of retailers to subcontract buying, results in wholesaling being seen as a large growth sector. The Dutch import-export agencies, which are major economic operators, contribute to that country having the feeling that the sector is dynamic, while in the United Kingdom, a more restrictive view is taken, namely that of the old-style "middle man" between manufacturer and retailer, now in decline.

Taking these differences of perception into account, the major feature of geographical variance in wholesaling is that the northern Member States exhibit much more evidence of a blurring of activities between manufacturer, wholesaler and retailer then do those in the south.

As for retail, large food and non-food shops are steadily increasing their dominance of the market in northern Member States (including France) while the small operator survives tenaciously in Italy and Spain. The overall importance of the small outlet should not be underestimated; for example, the 80 largest food retailers in the Community do less than 60% of the total business.

Concentration in retailing is thus correlated with the level of economic development of the Member State, except for Italy, which retains its high number of small shops. Franchising and non-shop retailing are also notable for some geographic variance, explained in the monograph on retail distribution.

ENVIRONMENT

Traditionally, the distributive trades have been seen as pure intermediation functions, only operating in response to supply impulses, and therefore not at all involved in the environmental debate. This view, however, is set to change. Distributors, especially purchasing centres in the retail sector, are increasingly playing a pivotal role in translating trends in consumer preference into final demand and are thus able to boost the sales and the production of so-called "eco-goods".

Moreover, more and more distributors are taking on new functions, including packaging. This activity entails a series of environmental issues which has to be taken into account by the sector.

OUTLOOK

The changes inherent to the sector itself (concentration, increased used of technology, vertical integration and diversification) must be seen together with extraneous developments such as the creation of the Internal Market by 1 January 1993 and the potential opening-up of East European markets.

While the achievement of an integrated EC market will require a European distributive systems (and the Community's actions in the transport, competition, investment, structural funds and enterprise policy areas are helping this to come about), operators in the distributive seetor face two conflicting pressures in seeking to meet the challenge. The first is the inereased competition from other Member States as the concentration and integration in the sector, encouraged further by cost reductions following the completion of the Internal Market, forces them to broaden their horizons and seek cross-border opportunities. The second feature is the continuing requirement to respect local culture in delivery of services, a feature which reduces the scope for rationalisation and internationalisation.

The key may thus be effective streamlining of operations through technology, enabling the operator to carry out more activities at an overall higher level of sophistication. Electronic Data interchange (EDI), Electronic Point-of-Sale (EPOS), and Direct Product Profitability (DPP) techniques are used widely as essential tools in upgrading activities.

The problem is, of course, for smaller players, who may find that the required investment in technology is too great for them to support.

The opportunities created for logistics planning and management by the abolition of internal frontiers should contribute to expansion in physical distribution activities. Taken together with the liberalisation in road transport, this area should see major change. This will in turn produce a situation where distribution strategies will influence consumption patterns and where marketing activities typically performed by manufacturers may be taken on by distributors and traders.

Lastly, reduced consumer spending on retail goods will reinforce the battle for market shares and therefore influence the present structure of the industry.

Written by: Commission of the European Communities, DGXXIII

Wholesale distribution
NACE 61

Wholesale trade is a hidden force in the European economic process. It employs approximately five million people (4% of the EC working population) and consists of 600 000 businesses. It provides the integration of different added-value functions that have to be performed to distribute products from manufacturer to users: composition of catalogue, sourcing, storage, assembly, re-packaging, distribution, support and financial services. The position and power of wholesalers in the distribution chain depend on their ability to create unique added value for suppliers or buyers. Based on the distribution dynamics, wholesalers have three strategic options: distribution partner for suppliers, sourcing partner for buyers and integrative wholesaling. The Single European market and the opening of the Eastern European market create many opportunities among which the need for European wide distribution networks, integrated chain management to create total quality for buyers, and alternative distribution modes. The European wholesale trade has a strong base to face this challenging future.

INDUSTRY PROFILE

Wholesaling is nowadays a difficult activity to define. Its function has evolved over time and different types of wholesale organisations still coexist in various phases of development stages. However there is still, according to the NACE 61, a definition of wholesale distribution:

This class includes units exclusively or primarily engaged in the resale of goods in their own name to retailers or other wholesalers, to manufacturers and others for further processing, to professional users, including craftsmen, or to other major users. The goods can either be resold in the same condition or after undergoing the kind of processing, treatment, packing or repacking to which they are usually subjected by the wholesale dealer. Generally speaking, the latter's role involves, on one hand, the storing of goods and, on the other hand, taking title to or having the right to dispose of the goods in question. In addition to a breakdown according to range of goods, there are classifications based on other criteria which are also useful for the wholesale trade, e.g.: breakdowns according to economic links, geographical area of activity (importexport, transit, domestic trade) etc.

Wholesale trade provides the integration of different added-value functions that have to be performed to distribute products from manufacturers to users. In Figure 1 we show the interface fields in which wholesalers have to perform in their role as integrators of different functions.

Wholesaling is more and more the excellent execution of integrative management because many of the functions can be contracted out to specialised third parties. The wholesaler will always perform the most critical function for the buyers by himself. Transport and distribution, for instance, are contracted out by many wholesalers while the composition of the assortment is performed inhouse. Storage could also be contracted out, but is rarely done. Functions with capacitylike characteristics (i.e. functions that are performed with standardised methods and which require high volumes to realise low unit cost) often can be contracted out while functions with special designed features often have to be performed inhouse. The latter truly create the added value for the buyers. The position and power of wholesalers depend on their ability to create unique added value for suppliers and buyers in the distribution chain.

The integrative role of the wholesale trade is focused on the transformation of processes surrounding purchasing (creation of large volumes, sourcing, storage, catalogue composition, material management) into those surrounding sale (market-oriented assortments and services, commercial support, distribution, customer service, training). Wholesale trade is therefore bridging differences in the distribution chain between place, time period, quantities, capacities and price requirements. The functions performed or integrated by wholesalers are described more in detail in Figure 2. Successful wholesalers integrate existing functions (purchasing, storage, distribution) according to a developed marketing formula and with the help of resources, into a unique set of values. This formula should be focused on either market/client segments or functions and consistently implemented.

Wholesale trade is a very diverse service industry. It performs its integrative role throughout the total economic process from raw materials to final enduser products. And the integrative

Figure 1: Wholesale distribution
Wholesalers, the integrators of different service functions

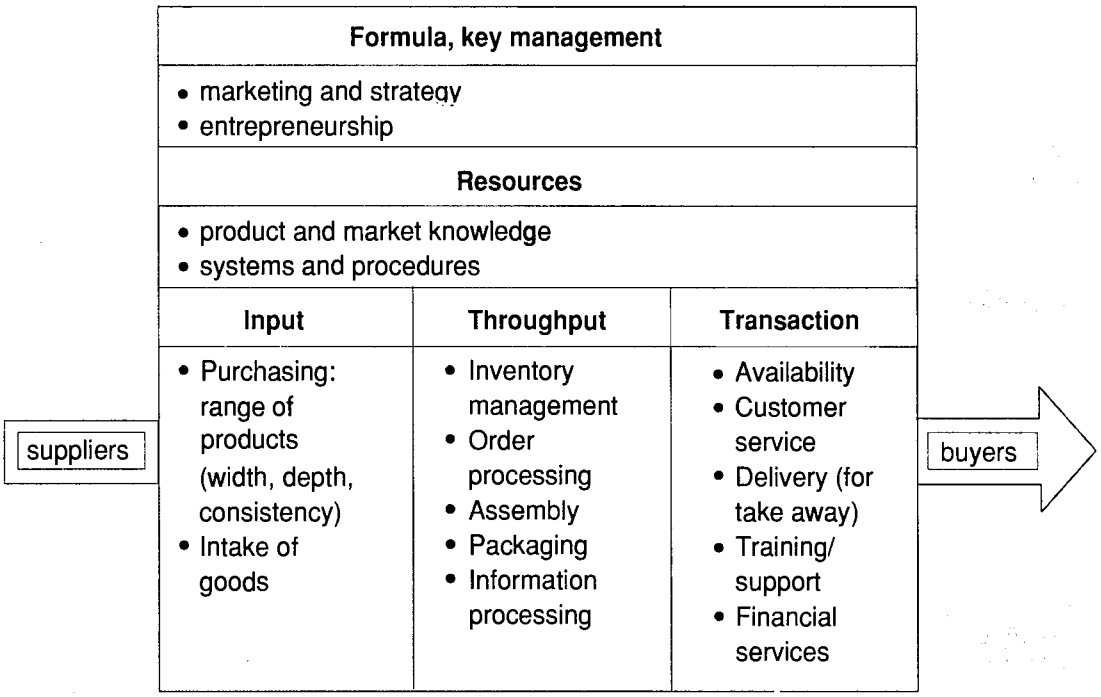
Figure 2: Wholesale distribution
Wholesale trade functions



Source: A.T. Kearney

role can be fulfilled by different types of businesses, in some cases integrated with the supplier or buyer organisation. The following examples can be given of segmentation dimensions of the wholesale trade business:

- product orientation: raw materials, semifinished goods, non-food and food consumer products;
- geographic orientation: international trading houses, importers, exporters; for the domestic markets distributors and cashandcarries, can be distinguished;
- functional orientation: logistics service providers (physical distributors), commercial traders (agents), financial brokers and the fullservice wholesaler;
- ownership: integrated wholesalers (sales companies, purchasing departments/companies) and independent wholesalers.

In real life wholesale businesses are combinations of the previous mentioned dimensions. The functions integrated or performed by the wholesale trade are unavoidable functions in the economic process. Therefore the fulfilment of the functions can be found within independent wholesale businesses or upstream, downstream the distribution chain with sales companies of suppliers, or the purchasing department of buyers.

The wholesale trade employs approximately 5 million people, which is 4% of the EC working population. The differences between the Member States are minor: Greece 3%, Denmark

5%, Netherlands 6%, Germany 3%, United Kingdom 3%, France 4%, Spain 3%, Belgium 3%, Portugal 2%, Ireland 4%, Luxembourg 4%. Female employees account for approximately 30% of the EC wholesaletrade workforce. For the individual Member States this percentage varies between 22% (Portugal, Ireland) and 36% (Germany).

The turnover generated by the wholesale trade in the EC is between ECU 1 500 and 2 000 billion. Given this total turnover 35% to 45% of the EC GDP is related to wholesale trade. There are some Member States where wholesale trade is a historical economic force shown by the turnoverGDP relationship: Netherlands 70%, Belgium 60%, Denmark 55%. Turnover has grown the last years in most Member States with 3 to 4% annually. Important growth sectors were capital goods and agricultural products.

More than 600 000 businesses are involved in wholesaling in the EC. The larger part of these businesses is smallscale. About 70% 80% employ less than 10 persons. And less than 5% of the businesses generate 30% 40% of the total turnover. These large businesses can be found in the steel and electrical sectors. Wholesale trade businesses in the southern countries, in particular, operate on a very small scale: Spain, Greece,

Portugal and Italy. In Germany and France concentration has taken place to a certain extent.

The structure of the wholesale trade is largely due to the rather low entry barriers for new businesses: minimal legal requirements, no specialist education is required and the necessary startup investments are relatively low. Many wholesale businesses therefore start every year but at the end of some years many have failed. Research has shown that half of all new wholesale businesses fail within the first five years of their existence. In Table 2 a list of the largest EC wholesalers is given. The selection has been made out of the Euro top500 companies of the European Business Press Group. Thirteen companies of this top500 had wholesaling as primary business activity.

MARKET FORCES

Wholesaler functions are performed at different stages in the process from raw materials to end-use. This process can be divided among the supply and distribution chain. Raw materials and semifinished products typically apply to the supply chain, while capital goods and consumer goods apply to the distribution chain. In both chains different requirements are asked for regarding logistics, commerce and finance. The customer service requirements, in the distribution chain for instance, differ greatly among the three distribution options as shown in Figure 3.

The structure of the supply and distribution chain is based on the efficiency and effectiveness rules of distribution. The smaller and more numerous the buyers, the more distribution levels that are necessary for effective distribution. The price levels depend on the multiplier which are determined by the distribution-flows in the total market. These price levels are more or less balanced and justify the lines of supply. Therefore, a wholesaler will not in the long run supply large buyers because the margin is too small and suppliers will not distribute to the mediumsized buyers because this will require too much sales effort. The wholesale trade is directive in the distribution chain because it gives direction to the lower levels, distributes directly to endusers and industries. And by this very fact the wholesale trade influences direct deliveries from suppliers to endusers.

The European economy is going through a change process that can affect the distribution chain and the position of the wholesaler largely. The most important changes are:

The integrated value added chain is dismantled. Shifts take place downstream and upstream leading to concentration and specialisation of production units. Assembly, for example, or customisation of packaging will be outsourced to third parties near the customer base. This creates added value opportunities for wholesalers.

Distribution is becoming for many industries a key factor for success, especially in mature businesses where product quality and specifications very quickly become standards. The only discriminating factor will be the variable features of the products (customer service, availability) provided by distributors.

The industry focuses more on corebusiness and searches for specialised partners to take care of distribution and customer services.

New parties enter the market for distribution services: specialists in warehousing and physical distribution that provide European distribution services to large manufacturers. These logistics service providers do not interfere with the commercial process (as wholesalers do) but often these suppliers themselves take care of marketing and sales or plan to do so. These specialists are ready to take over the logistics activities of industry and wholesalers because they have their information systems in place and have locations throughout Europe. They are often part of large transportation companies willing to invest in the creation of these services. Their margins are substantially lower compared to the wholesale trade.

Although wholesaling is local business, internationalisation and concentration through mergers and acquisition will continue for reasons of economies of scale in sourcing, warehousing and formula exploitation. And the large suppliers operating at the European level ask for distribution partners that can supply European wide distribution services.

Professionalisation of management techniques, profiling, and market approach will continue at all levels: commercial profiling, development of formula, use of management techniques which are already used in other business sectors (Direct Product Profitability (DPP), market segmentation, private labelling).

Suppliers and buyers require improved integration of business processes in order to realise higher levels of customer service at reduced cost. The developments in EDI provide excellent opportunities to link the business processes of the different players in the distribution chain. The use of bar-coding, scanning techniques and online computer links will impact cost efficiency, human resource policies and the need for large investments (in the initial phase) to a large extent.

REGULATIONS

The EC regulations will affect, directly or indirectly, wholesale trade in Europe. The sector will be directly influenced by a set of already adopted measures concerning VAT harmonisation, product liability, the status of trade agents, exclusive agreements, safety, technical standardisation, and competition.

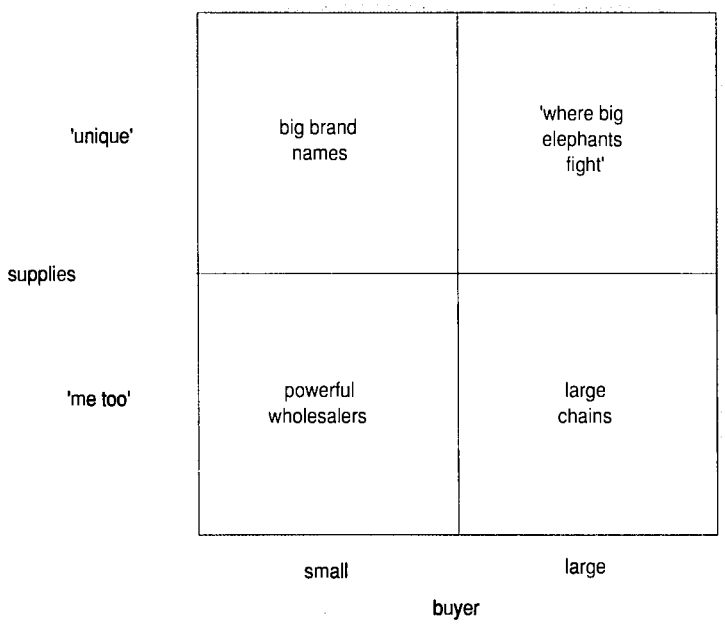
Turning to VAT harmonisation, under the terms of the agreement of June 25, 1992 (Directive 92/680/EEC), from January 1, 1993 the Member States must have a standard VATrate of at least 15% and abolish the higher VATrates. They will be allowed to maintain the zerorate and the extralow rate (1% and 4%) which were existing on January 1, 1991, but will not be allowed to introduce new reduced rates, except for Spain and Luxembourg which will be able to apply new extralow rates. The VAT will be collected in the country of destination. This means that pre-financing is not anymore necessary for companies selling products in other Member States. Definite decisions on this part have not yet been made.

The internal market will also entail harmonisation of the rules regarding product liability. The regulation (Directive 85/374/EEC) speaks of a reversal of the burden of proof: the plaintiff will no longer have to prove fault on the part of the defendant. Another change is that not only the manufacturer is considered to be the producer, but also the importer of products from outside the EC is deemed to fulfil the same role. This regulation will lead to increased costs (supplementary insurance premiums, higher claims for damages, increased number of claims) for:

- wholesale companies which import products from nonEC countries;
- wholesale companies which market goods whereby the consumer cannot discover the identity of the producer;
- wholesale companies selling goods under their own brand name;
- wholesale companies which change some part of the goods.

Directive 86/653/EEC regulates the position of the independent trade agent. The purpose of this regulation is to stimulate freedom of establishment of agents within the EC. This directive regulates the relationship between principal (i.e. machinery producer) and agent including their mutual rights and obligations, such as providing each other with appropriate information and compensation and the ending of the agreement.

Figure 4: Wholesale distribution Power matrix



Source: A.T. Kearney

Contrary to agents and producers, distributors are not very well protected in the EC. Only in Belgium and in Finland are distributors actually protected and entitled to legal indemnity. Although a more positive jurisprudence towards legal indemnity for distributors is developing, the distributors are still at a disadvantage as compared to the producers with respect to legal protection.

Exclusive agreements between producer and distributor are not allowed in the EC because protection of territory is prohibited. The EC council directive 83/83/EEC lists some conditions under which an exclusive agreement between supplier and distributor is exempted: bilateral agreements between one supplier and one distributor, concerning the resale of goods (not services).

Directive 89/655/EEC requires that all existing, new and secondhand work machinery and equipment comply with the minimum on safety and health. The consequences of this directive are simplified intra-community trade, decreased costs and therefore increased exports. The harmonisation of the safety requirements is envisaged through the introduction of the EC label.

In 1992 the European Commission published a Green Paper on reform of the Community's efforts in the field of technical standardisation. The aim is the creation of uniform standards in sizes, weight, qualifications, safety, hygiene and veterinary requirements and all other technical standards which are specific to certain sectors. This harmonisation will simplify and stimulate international trade. The European Commission has now proposed the creation of a European Standardisation Forum, increased participation of interest groups and advocates greater visibility and implementation of European technical standards.

The European Commission stimulates free competition. Concentration of industries creates economic advantages but should not limit free competition. The EC therefore prohibits mergers leading to possible unfair competitive positions (Directive 89/4064/EEC). Mergers between companies that have to be examined by the Commission have the following characteristics: the aggregate worldwide turnover is more than 5 000 million ECU and the aggregate Community-wide turnover of at least two of the companies concerned is more than 250 million ECU.

Besides controlling the wholesale service industry through directives, the EC acts as a stimulator of alliances to share knowhow and cooperate on technological innovations. The European Interest Grouping is the first EC legal entity which enables European companies to cooperate on a legal and European base.

In addition, the EC works indirectly as a catalyst for the wholesale service industry through the liberalisation and harmonisation of transportation and financial services, making international trade easier and financially more attractive. Cost advantages because of the liberalisation and harmonisation could be partly counterbalanced through increased preliminary controls and certification.

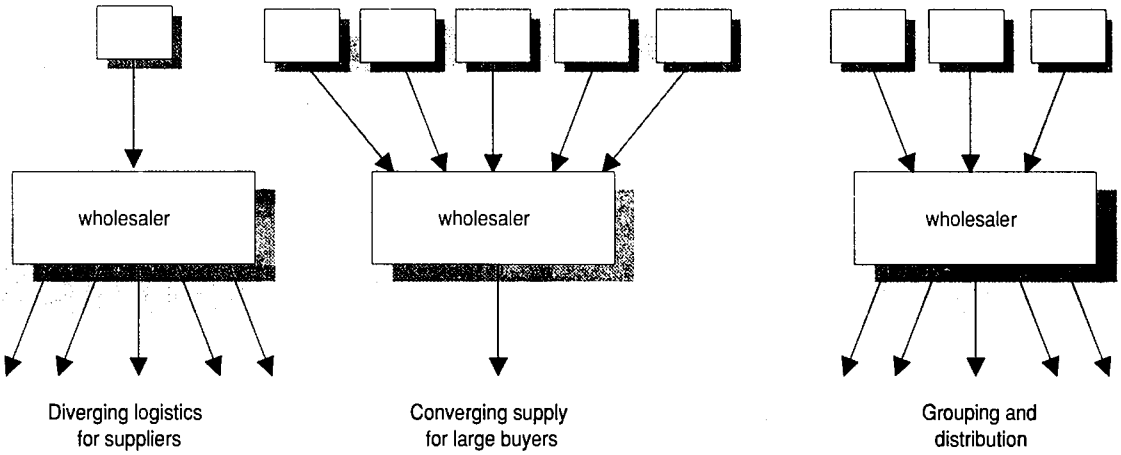
STRATEGIC OPTIONS FOR WHOLESALERS

In the distribution chain a power struggle is going on. In Figure 4 we describe the position of the wholesale trade with the help of two dimensions: purchasing power of buyers and 'unique product' proposition of suppliers. The four areas where the relative power position of the players in the distribution chain differ are:

- the area of the large brand suppliers;
- the area of the large purchasing chains;
- the area of the wholesalers;
- the area where large brand suppliers share margins with large purchasing chains.

The situation in many markets differs largely. In the food market for example, the big brand suppliers and large retail stores struggle for dominance. The wholesale trade has, except for some specialisation, completely disappeared. In the electrical materials market, the independent wholesalers are dominant although the brand suppliers become stronger and stronger. Another example is the toy market where chains have taken over the position of the wholesalers. In capital

Figure 5: Wholesale distribution
Different market situations require different strategies



Source: Eurostat

goods it is still the wholesaler/importer (which can also be the sales companies of the manufacturers) that directs the distribution chain.

In this power struggle wholesale trade has the largest added value for medium and small sized buyers who do not themselves have the facilities and volumes to buy, import and export directly from suppliers.

The strategic options of the wholesale trade depend on the market situation. In a market situation where many buyers exist as well as many suppliers of 'me too' (or non differentiated) products, the role of the wholesaler is typically the 'independent specialised' one. This market situation requires the typical wholesaler, who has a complete catalogue, to perform the requested logistics services well and has good sourcing channels to cover more or less all his clients' needs.

If, however, the market situation is different in the sense that only a few, unique, suppliers exist and many small buyers, the wholesaler should be a distribution partner for these suppliers. In this case, the wholesaler is specialising in logistics services such as storage, distribution, information (EDI) and customisation.

In the third case, when there are a few large buyers and many me too suppliers, the opposite happens: the wholesaler is a sourcing partner for the buyers, taking care of wellorganised supply, product selection and efficient sourcing.

These three market situations require three different strategies (see Figure 5).

Option I Distribution partner for suppliers

Based on the market situation with many buyers and a few unique suppliers, the wholesalers provide distribution services to the manufacturers:

- make products available as 'widespread' as possible (European distribution);
- offer customer services throughout Europe to the buyers;
- have uptodate EDI systems with online links in the suppliers information systems;
- provide inventory management;
- provide market information to suppliers.

The suppliers have often branded products and therefore take care themselves of marketing. They need a partner to cover the logistics operations and distribution.

Option II Sourcing partners for buyers

When many metoo suppliers share the market and only a few large buyers dominate the demand, the strategy calls for a sourcing partnership with these buyers, offering on a tailormade base:

- global sourcing of products;
- account management;
- storage facilities and inventory management;
- integration of supply with the buyers' justintime needs.

The wholesaler in this case becomes an integrated part of the purchasing department of a selected number of buyers.

Option III Integrative wholesaling

In the many buyers/many suppliers situation, the wholesaler fulfils the total range of consolidating and integrating functions in the field of commerce, logistics and finance. Critical are:

- the creation of catalogues and their updating;
- effective usage of Direct Product Profitability mechanisms to know the profitability of products and client groups;
- highquality EDIsystems to create quick response services;
- creative and innovative power to update the services offered, add new products and services and to professionalise the organisation on a permanent base.

In real life these three strategic options can be implemented within one wholesale company for its different market segments. The organisation has to fit the implementation of the three different strategies in the organisational principles which means separate management procedures and systems.

REGIONAL AND INTERNATIONAL COMPARISON

All Member States have their own distribution infrastructures and trade history. Therefore we cannot speak of one EC wholesale service industry. The scope of this monograph does not permit an indepth analysis of the differences, but in the following paragraphs, some characteristics are described.

France

The wholesale trade holds a strong position in the French economy, especially in the international trade business. Concentrations have taken place resulting in the emergence of large, multidimensional trading houses with specialised divisions. These international trading houses are strong in food and capital goods. In the domestic market cooperative structures have emerged between regional wholesalers to share resources. Typical for France are also the wholesale centres where a variety of wholesale companies work together and present themselves together to the market. The French wholesale trade is especially strong in nonfood consumer goods and industrial supplies. In the food market its position has been taken over by the large retail chains.

Germany

The wholesale trade position in Germany is comparable to that in France. A strong concentration has taken place during the last years, which is why the average wholesale company in Germany is larger than in the other EC Member States. The wholesale trade in Germany is especially strong in industrial supplies. In food its position has been taken over by the strongly concentrated retail sector. Large parts of the national imports and exports are organised by international trading houses. Often these trading houses have historical links with the steel industry. The concentration and the links with powerful industries have made of the German wholesale trade a professional service industry with a respected reputation in the labour market - professional in the sense that substantial investments are made in systems and procedures to create new added value services.

United Kingdom

The wholesale trade in the United Kingdom is especially strong in nonfood consumer goods. The concentration in the retail business has limited their role in the food market. It is, however, true that, contrary to the other Member States, food wholesalers in the United Kingdom started voluntary retail chains to counterbalance the power of the retail giants. In the exports and imports business, independent merchants play an important role as well as the international trading houses. These trading houses are mainly important for the import of machines, means of transport and agricultural products. Merchants and trading houses are involved in approximately 4050% of the exports. For imports this is much less (15%).

Italy

Italy has primarily a smallscale distribution (infra)structure in which the wholesale trade serves to link manufacturers and retailers. In 1987 Italy had three times as many wholesale businesses as Germany. Wholesalers in Italy are spread amongst all market sectors. They are mainly focused on the domestic market. International trade is taken care of by the producers themselves or foreign trading houses and importers. The situation is changing slowly because foreign trading houses and distributors (from the US, Japan, Germany, France) are investing in Italy.

Netherlands

Just like Germany and France, the Netherlands has a strong wholesale sector. Wholesalers are very much internationally oriented and offer overseas producers European distribution. They also play an important role for imports and exports; approximately 6070% of the imports are organised by the wholesalers and 30% of the exports. There are some large international trading houses with strong Asian links. Strong wholesale sectors are capital goods and agricultural products.

Belgium

The majority of Belgian wholesalers are small or medium sized, often familyowned firms with a local area of operation. In the international trade larger wholesalers organised in cooperatives play an important role.

Denmark

Probably Denmark has the highest concentration in wholesale trade. A few large wholesalers and trading houses (for international trade) dominate the primary distribution level. Food and nonfood consumer goods are their main markets.

Ireland

Ireland has, like the SouthEuropean countries, a fragmented distribution structure. Therefore the wholesale trade is also in Ireland an important linking pin. The international trade is dominated by the English trading houses.

Southern Europe

Spain, Portugal, Greece are characterised by a very fragmented distribution structure. Retail and wholesale trade are smallscaled and have a traditional orientation. In all sectors wholesaling plays an important role. Concerning imports, wholesale trade holds a strong position in capital goods, whereas for exports it is strong in textiles and agricultural products. In Spain the concentration process has started, initiated by foreign investments.

Eastern Europe

Eastern Europe does not have a specific wholesale culture. Large stateowned departments took and take care of the distribution of goods and materials. The larger European wholesale concerns invest in Eastern Europe to build up a wholesale market for foreign products. They have the international trade and distribution logistics knowhow that the stateowned companies lack to a large extent. Wholesalers who open up subsidiaries in Eastern Europe have to face the limitations of poor infrastructures and almost nonexisting communication networks. Eastern Europe is for many wholesalers and trading houses a challenging market.

Japan

The distribution of machinery in Japan is influenced by its history and its social structure. The large trading houses, Sogo Shosha, are economically and politically powerful business entities. Their primary role is to provide links between various industrial sectors and parties, which are in turn able to benefit from trading houses' information networks and financial ties. Although Japanese multi-levelled distribution structure is very effective, the EC distribution structure tends to be more cost-efficient. However, in Japan distribution fulfils a strategic function, perceived as being as important as technology. This makes Japanese producers more powerful (and threatening) in the Japanese market.

USA

The distribution structure for machinery in the USA is more or less similar to that in the EC, although distributors in the USA focus more on satisfying customer needs and service requirements. The market focus makes producers and distributors organise distribution according to the grouping of client's needs. Distribution in the USA is used as a strategic tool to realise corporate objectives.

OUTLOOK

The European wholesale trade has a strong base for the future. It performs functions that have to be performed at some stage in the supply and distribution process. In some market sectors it holds a strong position, in others its functions have been integrated with suppliers or buyers. For the next years the European wholesale trade faces some interesting challenges:

The Single European market is expected to boost the European economy. Besides, manufacturers are concentrating on their core business leaving the other business processes to specialists

with local, technical and logistics knowledge. Both facts are developments that can contribute to a strong future position of the wholesale trade.

The Single European market and the opening of the Eastern European market will require European distribution networks. Logistics service companies are building up these networks which include sophisticated communications networks. Wholesalers have to take part in the creation of these European wide distribution networks through alliances, mergers or acquisitions.

The integration of the levels in the supply and distribution chain means that the borders between companies become fluent. Systems have to be integrated, procedures and commercial policies coordinated in order to improve the total quality for the buyers. Suppliers and buyers will therefore reduce the number of business partners they are working with. The intensified relationships will require investments and management time which will force a reduction of business relations.

The dynamics in the supply and distribution chain will force wholesalers to make strategic choices: logistics partner, sourcing partner or integrative wholesaling. The European wholesale trade is facing challenging opportunities but these require specialisation on a market segment, on specific wholesale functions for a selected number of business partners. Focus on the business process of the customer and find ways to add value to this process will be the key factor for success.

Concentration will continue in retailing. European retail chains will emerge that integrate wholesale functions in their own organisation. Alternative distribution forms will arise with the help of the continuing developments in EDI. Direct computer links between buyers and suppliers or public sales information systems will make the representatives of the wholesale companies redundant. The wholesale trade will be forced to innovate its services on a continuous base focused on adding value to the business process of its buyers or suppliers.

Written by: A.T. Kearney Management Consultants
The industry is represented at the EC level by: Federation of European Wholesale and International Trade Associations (FEWITA). Address: Rue Froissart 123, B-1040, Brussels; tel: (32 2) 231 0831; fax: (32 2) 230 0078.

Retail trade
NACE 64, 65

Retailing is an important and significant force in the European economy, representing, for many manufacturers, the means of access to consumers. Although the retail trades in Europe strongly reflect national characteristics, a number of common themes can be identified. Core market development has occurred alongside diversification into other retail and services sectors and geographical markets. At the operational level, retailers have increasingly adopted the marketing concept as they seek to increase sales. These developments have also necessitated investment in the means to control costs and to manage the operation more efficiently.

INDUSTRY PROFILE

Retailing is a dynamic and complex sector involving a range of company types of varying scale, operating in a variety of product sectors and through a diverse and changing network of outlets and selling techniques. This dynamism and the traditional lack of attention paid to the retail sector makes national comparison of statistics relating to the retail trade difficult. Despite the existence of NACE classifications, national statistical offices and major trade associations produce data based on a range of different definitional criteria.

Commonly data is collected on the basis of a variety of definitional aspects which mix features such as type of business (e.g. independent, multiple chain), type of establishment (e.g. department store, hypermarket), selling technique (e.g. mail order, self-service) and product range (e.g. food, clothes).

The NACE 1970 classification of 'Retail Distribution' encompasses classes 64/65 and is essentially based on the product groups sold, namely:

- food, drink and tobacco (641/642);
- dispensing chemists (643);
- medical goods, cosmetics and cleansing materials (644);
- clothing (645);
- footwear and leather (646);
- furnishing fabrics and other household textiles (647);
- household equipment, fittings and appliances, hardware and ironmongery (648/649);
- motor vehicles and cycles (651);
- motor fuels and lubricating oils (652);
- books, newspapers, stationery and office supplies (653);
- other "non-food products" (654/655, 656).

Under the new scheme of NACE Rev 1, due to come into operation in 1993/94, "Retail Trade, except of motor vehicles and motorcycles; repair of personal and household goods" is found in Division 52 of Group G. This classification has moved the motor trade to a new category, defined more detailed product groups, and incorporated second-hand goods retailing and repair businesses into the retail trade category. The NACE Rev 1 involves the retail sale of:

- non-specialised stores (521)
- food, beverages and tobacco in specialised stores (522)
- pharmaceutical and medical goods, cosmetic and toilet articles (523)
- new goods in specialised stores (524)
- second-hand goods in stores (525)
- non-store sales (526)
- repair of personal and household goods (527)

Retailing is the final link in the distribution channel between the consumer and the product manufacturer for the majority of consumer goods. In its simplest form, retailing is the activity which makes goods and services available for purchase and consumption by consumers. The role of retailers in the distribution channel varies with such factors as the characteristics of the products and service concerned, and the type and nature of business relationships with others involved in the channel. Traditionally retailing does not in itself create goods and services, and consequently the activities performed by retailers reflect this role. Increasingly, however, retail activity now adds value to products and services and enhances them in the eyes of consumers.

Notwithstanding the problems of comparative data in this sector, the retail trades are a significant contributor to the European economy (Tables 1 and 2). Best estimates from Eurostat suggest that retail sales in the twelve member states amount to around 1300 billion ECU. This turnover is generated by almost 3.3 million businesses and 13.2 billion employees.

To view the retail trades as a single homogenous international entity is naive. Despite the growth of cross-border retail activity and the international transfer of retail concepts, management techniques and retail and manufacturer brands, retailing is still predominantly an industry with strong national characteristics.

The diversity of retailing can be illustrated by reference to two dimensions: organisational form and selling techniques. These are often confused in statistical series. The type of firm or business organisation operating in the retail sector can be one of several types:

- independents,
- corporate chains,
- contractual chains,
- consumer co-operatives.

The importance of these categories varies from country to country and in different retail product sectors.

Independents are companies in which the owner is typically directly involved with the day to day management of the operation, therefore there is generally little scope to operate many outlets. The majority of businesses engaged in retailing are independents, but in terms of market share the unaffiliated or 'true' independent is generally in decline.

Corporate chains may be privately owned, publicly quoted or government controlled organisations. This type of organisation operates a number of establishments or 'branches', and is generally becoming the dominant organisational type in most countries, particularly in northern Europe.

Contractual chains allow any type of organisation to contractually combine with others for various activities. Historically the benefits of co-operation in the buying function stimulated contractual chain formation, but most of these contractual chains now also involve marketing and other management activities. Contractual chains commonly take three forms. Voluntary chains are groups led by wholesalers to which retailers affiliate. Spar and Vege are examples of voluntary chains in the food sector which operate in a number of European markets. In contrast, retailer buying groups comprise groups of retailers collaborating for buying and marketing activities. These collaborations may involve both independents and corporate chains. In the food sector Leclerc and Intermarché (France), Edeka (Germany), and Crai, Selex, and A.O. Conad (Italy) are typical examples, whilst in the non-food sectors Intersport (sports goods) Euro-Active (photographic equipment) and Expert (electrical goods) represent this form of organisation. In the last decade, franchising, in which one organisation (the franchiser) offers another (the franchisee) the opportunity to benefit from its marketing and operational systems via a contractual relationship, has grown rapidly in most countries. The European Franchising Association identifies over 2 200 franchisers in the EC (excluding Greece and Luxembourg) with almost 106 000 franchisees and a turnover of over 50 billion ECU.

Consumer co-operatives are organisations owned by consumers operating under specific national legislation defining a co-operative. This ownership pattern provides co-operatives with a distinct, highly democratic, administrative structure. The fortunes of consumer co-operatives within the EC have fluctuated. Major difficulties have occurred in France and Germany, whilst these organisations remain significant forces in Denmark and Italy.

A second, yet distinct, dimension of retailing is the selling technique employed. This dimension has several aspects, the importance of which again varies from country to country and with retail product sector. Aspects of selling technique include:

- nature of sales point,
- sales method,
- scale of outlet,
- product range,
- location.

Nature of Sales Point: the majority of retail sales occur via fixed retail outlets or stores. However, for certain product groups and in certain markets, itinerant outlets and non-store retailing should not be discounted. Non-store retailing involves mail-order, door-to-door selling, vending machines and home selling and is more important for non-food lines.

Sales Method: in fixed retail outlets traditional counter service has been replaced in many cases by self-service sales techniques. This has implications for store layouts, staffing and customer service.

Scale of Outlet: for fixed retail outlets statistical distinctions are often made on the basis of size, particularly in the food trades. In spite of a broad international consensus that super-

Table 3: Retail trade

markets are self-service stores with a sales area in excess of 400m^2, conflicting definitions arise for larger units. For example, whilst the French define hypermarkets as stores of over 2,500m^2 with a high proportion of floorspace devoted to non-food, German definitions distinguish between self-service warehouses in excess of 5 000m^2 and consumer markets of 1 500m^2 and above, whilst the British superstore definition of over 25 000ft^2 (2 323m^2) does not take into account any expected proportion of non-food floorspace.

Product Range: distinctions are also drawn between specialists (retailing a single product group), niche retailers (retailing very narrow product lines) and mixed retailers (retailing a number of product groups, often referred to as 'scrambled merchandising').

Location: locational distinctions may involve the physical location such as in-town, edge-of-town or out-of-town sites, and also locational features such as controlled environments, for example, shopping centres.

Although often confused in statistical series, organisational form and selling technique are two separate features of retailing. Independents and corporate chains may both operate self-service and counter service stores of different sizes in different locations.

MARKET FORCES

The demand and supply issues in retailing may be addressed by reference to trends in retail sales volume and the operational strategies of retailers. At the operational level the emphasis has been upon both enhancing sales and controlling costs. Both of these have been aided by the application of technology and the development of management skills in the retail sector.

Consumer demand for the services provided by retailers is shown in part by changes in retail sales volume (Table 3). Indexed sales figures for the 1985-1991 period reveal national differences in growth in total retail sales volume. Such figures alone however disguise fluctuations from year to year and between retail product groups. Annual changes in retail sales volume of two or three percentage points are not uncommon as retail sales are very vulnerable to changes in consumer confidence. Britain is a case in point, where strong credit-driven growth in the mid 1980s disappeared at the turn of the decade. Similarly, differential demand is observed between retail product groups. Food, as the largest retail sector, tends to mirror the overall changes in retail sales volume and is less prone to dramatic swings in sales volume. Other non food sectors such as clothing and household goods are more prone to fluctuations in volume, for as non-essentials they are more dependent upon consumer confidence, and disposable income. Purchases of these produces can be postponed or eliminated more readily than those of food products.

The adoption of the marketing concept has been fundamental to the drive to enhance sales. The retailer is the closest of all the institutions in the distribution channel to the consumer and is increasingly using the knowledge derived from this position to develop activities more suited to consumer needs. Companies in the sector have recognised that consumers' perceptions of organisations and store formats is central to the retailing business and have responded accordingly. In general terms one observes a trend from a mass or generalist retail offer to a specialist retail offer. For example, in mail order

retailing this is reflected in the trend towards specialogues at the expense of general mail order catalogues. The aim is simply to apply basic marketing principles of segmenting the market, identifying target customers, their motives and values, and providing a retail offer to meet these needs.

This does not mean that the mass or generalist retail offer is totally inappropriate. For some consumer groups and purchasing decisions, and in certain environments, this type of offer meets consumer needs. The growth and spread of the large scale food store (whether hypermarket or superstore) shown in Table 4 is testament to this. In the large store sector, which is commonly associated with mass retailing, specialisation is taking place. Large store specialists are developing in most retail product lines (furniture; DIY; garden centres; clothing; shoes; records; toys), and many department store companies are adjusting their product ranges, effectively becoming large textile specialists.

The targeting of consumer groups and development of specialist retail offers is particularly visible in smaller store formats. A number of consumer values have been identified and specific formats have emerged to serve these needs. Amongst these values and corresponding retail formats are:

- the limited line discount store, which provides for customer requirements for low prices via stores retailing limited product ranges consisting of a few lines sold at low prices in sparsely decorated and staffed outlets;
- the convenience store, which provides for customers seeking to conserve time in their shopping habits. These stores carry relatively wide product ranges, but with limited lines usually consisting of a single major brand per line. Store decor typically stresses efficiency, and accessibility is at a premium via store location and long opening hours;
- the specialist store, which provides for choice through narrow product ranges but with considerable depth of lines and brands. Staff are generally capable of providing expert advice on the products carried as the customer motive for visiting these stores is to make a choice within a pre-determined product group;
- the style shop, which provides exclusivity or design originality via quality products in stores which carry few lines. Store fittings are of high quality and customer service in its various forms is also high;
- the branded goods store, which provides assurance to consumers who value the reputation of a single brand. These stores only carry the single brand which is what the customer values;

- service shops, which provide the customer with a skill or service usually in a short time period;
- locally specific shops, which respond to the consumer's wish for impulse or emotion-based purchases following a particular experience. The product range, theme and location of these stores are closely linked to a particular experience.

In all these store formats, the product range, store ambience and customer service levels are specifically tailored to meet the needs of identified consumer values.

Whilst marketing oriented activities such as these seek to increase sales and build customer loyalty, other operational activities are concerned with managing cost structures. For all retail organisations the largest element of costs is the cost of purchasing the product for resale. Consequently, great emphasis is placed upon maximising buying power benefits through scale or efficiency. As scale is related to the volume of products sold within a product range, sales growth via internal development, acquisition or collaboration provides the potential for greater power. The breadth of product ranges and number of brands stocked also influences power as sales volume is concentrated or dispersed over the lines or brands. Finally, efficiencies in decision-making primarily through centralisation or the co-ordination of purchasing provides for greater buying power.

Closely associated with the costs of buying, particularly for retailers with a high stock turnover, is management of the delivery and distribution of products to stores and customers. A clear trend in Europe is a move towards the centralisation of physical distribution, where suppliers deliver to a central point for redistribution rather than direct to the store. Often this process may involve the sub-contraction of this activity to specialist third party distribution companies.

A third element of cost structure which has changed significantly over time is employment structures (Table 5). Retailing is a major employer, particularly of females, and increasingly of part-time employees. Employment ratios however vary from nation to nation as do hourly labour costs. The trend towards part-time employment allows greater control over labour scheduling, matching staff levels with peak trading times which aids the control and management of labour costs.

The twin pressures for improved marketing and control are clearly reflected in changes in supply chain management in European retailing. Whilst buying terms and conditions are still the subject of debate between suppliers and retailers, in many sectors supplier relationships have become more collaborative than confrontational in nature. Co-ordination of the supply chain, enhanced by improved information on product movement, has grown. In addition, as retailers have incorporated the marketing philosophy into their approach to the business, they have increasingly regarded themselves as brands in their own right. The combination of activities, products and services offered by retailers "add value" to the basic product offering and provide a means of differentiation from competitors. The growth in retailer advertising reflects this trend, as does the development of retailer brand product ranges. The availability of retailer brand product lines again varies from sector to sector and between countries, but in most cases the role of the retailer brand has changed, particularly in the food sector. The original market position of these brands in food was as a low price/lower quality alternative to manufacturer brands, but as these brands carry the retailer's name and are unique to the store, they have been repositioned and their quality improved and increasingly they are associated with new product launches. This role has necessitated a change in the relationship with suppliers with a greater emphasis on quality control and product development.

All of these operational issues have been aided by the introduction of technology in retailing and the development of management skills. Initially technology investment was driven by the desire for better management of assets and the associated productivity improvements. Increasingly however a number of retail businesses are appreciating the potential for information technology to aid marketing and strategic management decisions. The acceptance of universal standards which allow item identification, data transmission and electronic processing have been central to the adoption of technology in retailing. For example, without agreements on bar-code standards, investment in item identification equipment such as scanning (Table 6) could not take place. Investment in such technologies has provided the information infrastructure upon which application technologies such as EFTPOS and EDI are based. These application technologies provide the information basis for improved management of the company.

Technology alone however will not manage a business. Managers must still make decisions based on the information provided by technology. As the information available to managers has increased and changed in nature, management styles and structures have evolved to maximise the benefits. Although management styles differ, there is some evidence of a trend towards centralised decision making, whether at regional or national level. One could argue that the growth of franchising and the changing membership conditions of buying groups and voluntary chains represents a similar step amongst independent businesses to create a more uniform image and benefit from economies of scale and replication.

INDUSTRY STRUCTURE

Companies

The largest retail companies in Europe are now of significant size in terms of turnover to be ranked alongside businesses in the production sector of the economy. Given the size of the food sector, the majority of the largest companies are predominantly food retailers, although mail-order companies such as Otto Versand and Schickedanz-Quelle feature in any listing of major companies. Of these major companies the vast majority have either diversified operations or have made important international contributions to turnover. The exceptions to this observation are the British food retailers Tesco and Argyll which are essentially domestic based 'core' business operations.

The retail sector is accustomed to rapid change and this is reflected in the changing fortunes of these major companies over the past decade (Table 7). At the start of the 1980s a list of the largest retailers included the German and French co-operatives, which have since run into financial difficulty and have been dissolved, and a number of department store based businesses (Karstadt, Kaufhof, Vroom en Dressmann (now Vendex International), Hertie and Nouvelles-Galeries). The relative importance of most of these companies has since declined, to be replaced by food retailers.

Also apparent from any listings of the largest companies is that a number of them (Metro, Carrefour, Intermarché, Auchan, Asko and Argyll) have effectively been formed since the 1960s. These companies have grown rapidly through the introduction of new forms of retailing (e.g. the hypermarket, large store discount outlets) and growth through acquisition and collaboration. The largest organisation in 1991/92, Metro, has its origins in wholesale and cash-and-carry retailing, but through the acquisition of Kaufhof and others now has a major retail contribution to total sales. This contribution is likely to be reinforced by the major shareholding held in Asko.

Strategies

As they have grown in size, retailers have increasingly developed clear corporate strategies to maintain growth and survive within the marketplace. One basic strategy has been to seek product market dominance. Growth is sought within the existing 'core' product market as companies seek to increase their share of sales through new outlet development, or co-operation with or acquisition of others operating in the market. Within every country and retail product market in the EC examples may be found of companies employing this route to growth. The clear consequence of this strategy is product market concentration with a greater share of sales attributed to single organisations or collaborative groups.

An alternative strategy is to diversify beyond the original activities of the business into related or new product markets. This may involve a redefinition of the existing retail product market as existing ranges are widened to encompass related products or services. Similarly, other segments within a known product market may warrant attention. An established hypermarket operator for example may develop smaller store formats

such as discount or convenience stores. Possibly the most risky option is to diversify into new unrelated retail product or service markets of which the company has no experience or knowledge. Generally the diversifying business will have management expertise in one retail sector which is felt appropriate to the new sector. The consequence of this option is that the organisation develops a portfolio of different retail businesses. For example the largest seven DIY retailers in Europe are now subsidiaries of retail organisations with their main activities in other retail product markets.

A further type of diversification is geographical diversification involving activities outside the domestic market. Internationalisation in retailing takes a number of forms. At one level there is technology transfer where a retail format or innovation - such as the limited line discount store, the convenience store or hypermarket - is developed in a number of national markets. This transfer may or may not be directly linked to a single company. In addition certain retail activities such as buying and management systems may involve an international dimension. The formation of international buying groups in the late 1980s reflects this trend. For most, however, retail internationalisation is associated with a business itself operating in a foreign market. As Table 8 shows, a significant volume and proportion of sales is now accounted for by the overseas activities of retailers operating in a range of product markets. It is noticeable that many of Europe's largest retailers feature on this list. The management involvement in international operations will range from a financial stake in existing companies, to franchising, and everyday management control.

One consequence of these strategic trends is a clear growth in the scale and complexity of these organisations - which may now operate a range of store formats, often in different product and geographical markets. The changing retail environment further reinforces the importance of management information systems and management skills. Whilst some of these organisations remain private businesses and finance expansion through cash flow and bank loans, an increasing number are turning to the stock market for funds. This is particularly true of British and Dutch companies, but increasingly true of French corporate chains. Finance derived from such sources requires a return on investment which again places pressures upon firm control and management.

REGIONAL DISTRIBUTION

Within all the markets of the EC, regional differences in consumer tastes, particularly for food products, necessitate some product range adaptation by retailers. Also there are differences in access to certain types of retail facilities between rural and urban areas throughout the Community.

At a national level there are clear differences in the retail structure between northern and southern Europe. Essentially in southern Europe the retail trade is characterised by a larger number of business and outlets, lower turnover per business and person employed (Table 9) and lower levels of retail concentration. The independent business sector, whether acting alone or in some form of contractual chain, dominates the sector. The trends observed in northern Europe, however, are present in southern Europe, often inspired by retailers from other nations, hence the presence of French food retailers in Spain and to a lesser extent Portugal and Greece.

ENVIRONMENT

The concern over ecological issues in Europe generally has some impact on the retail sector. First the growing demand for 'green' or environmentally sound products (such as cosmetics, washing powders and paper products) has been taken into account in product range selection. A potentially greater impact however is in the area of packaging and packaging waste. This issue has come to the fore in Germany with legislation placing the responsibility for recycling packaging materials upon manufacturers and retailers, but is also on the political agenda in a number of other countries. In Germany, the Netherlands and France a number of leading retailers have already begun to take an active role in waste disposal.

REGULATIONS

The regulatory framework affecting retailing in the EC largely takes place at national level. The scope and range of policies specifically directed at the retail sector varies from country to country, and broad legislative activity to regulate industry in general (e.g. taxation and social protection legislation) affects retailing. In most countries retail-specific legislation has tended to be reactive rather than proactive, formulated in response to particular problems and political pressures rather than forming part of an overall strategic approach to the retail sector. In general legislation exists to control unfair competition, whether through monopoly control policy or the regulation of discriminatory and restrictive practices; to monitor establishment of retail businesses and premises; and to protect consumers.

The scope and effect of legislation is varied across the Community. Legislation to control the growth of large stores exists in a number of markets, with the effect of slowing growth (France and Germany) or preventing growth (Belgium); differences in sales tax and excise duties have lead to cross-border shopping in a number of markets, such as on the Danish-German border and the Irish-Northern Ireland border; and competition policy has prevented proposed mergers in the United Kingdom and Germany.

At Community level, various aspects of the Single Market will influence the retail trade. The mutual recognition of national product safety standards along with the removal of border controls will influence the sourcing, transport and movement of product; fiscal harmonisation (particularly of VAT) will potentially affect final prices to consumers; whilst aspects of the social charter will influence employment structures.

OUTLOOK

Retailing is an important sector of any national economy and will remain so in the foreseeable future. As retail internationalisation in its various forms increases over the next decade, similarities in the retail formats and management techniques seen in different countries will grow. This will be particularly noticeable in southern Europe as the retail trade 'learns' from the northern countries. Despite these trends, retailing will however retain distinct national characteristics.

In most countries and retail product markets the dominance of large organisations is growing. Scale will remain a key issue in retailing and contractual chains will provide an important means of achieving some of the benefits of scale for independent businesses. For many of the larger organisations national market shares in their retail product sectors are approaching limits which may attract the attention of public policy agencies. Continued growth through acquisition in these sectors may also be limited by a dearth of target companies. Increasingly then, attention will be focused on diversification and internationalisation as a strategic route to growth, and upon marketing and management control activities to increase the return from existing operations.

Tourism

NACE 661, 665, 667, 771

The tourism industry is better viewed as a market than as a sector, as it impinges across a wide variety of services and industries, including not only accommodation, restaurants and travel services, but also craft industries, the entertainment industry, banking, business services, and the activities of local authorities in relation to national parks, historical monuments etc. The demands of European tourists have shifted discernibly over the last decade. Travellers are now more independent and better informed, and seek greater flexibility in their travel arrangements and a better quality of service at destinations. In general, today's tourists also have more time and more money leading to more frequent breaks and growth in long-haul holidays as tourists have become both more adventurous and more environment conscious. Industry operators have in large part reacted appropriately in evolving new tourism products and many southern Member States are in general successfully diversifying from, or enhancing, their traditional beach products. The outlook is for continued rapid growth in EC tourism revenues, but at a slower pace than overall international tourism.

INDUSTRY PROFILE

Description of the sector

Few industries have as pervasive an impact on local communities throughout the world as travel and tourism. The tourism industry is a widespread, complex network of businesses engaged in the lodging, feeding, travel arrangements and entertainment of tourists. A tourist is defined as a visitor staying at least one night in a place other than that corresponding to his usual environment. The main purpose of such a visit may be primarily pleasure, primarily business or a mixture of the two. Tourism is most commonly associated with "pleasure", rather than business, although within "pleasure" trips a distinction between "pure" tourists and visits to friends and relatives (VFR) is often made. The official World Tourism Organisation (WTO) definition of "tourist" omits the "excursionist" who does not stay overnight in the country or place visited, although this visitor is an increasingly important customer of the European travel and hospitality industries.

The diversity of the tourism sector is such that it is often better understood as a market rather than a sector in the sense that it impinges on may different parts of the economy. The most important of these include the lodgings subsector, catering, the sports and entertainment industry, travel services, and transport and craft industries. Within a wide definition of tourism, all of these subsectors, with the exception of lodging, also rely on other sectors, of which particular niches concentrate on tourism. The most important of these related sectors is transport, which is covered in chapter 22. This chapter examines the following subsectors:

- hotels (NACE 665);
- non-hotel accommodation (NACE 667);
- restaurants (NACE 661);
- travel services (NACE 771).

The average breakdown of tourist receipts, although this varies widely across different tourism outlets is accommodation (32%), food and beverage (25%), local transport (9%), recreation and entertainment (6%), shopping (24%) and other activities (4%). Tourism-related employment across the subsectors travel, shopping, entertainment, accommodation and meals is not distributed according to the distribution of expenditure on these items. The hotel and catering sector is particularly labour intensive and is likely to account for over 50% of tourism industry employment even though it only generates about a third of the expenditure.

The diversity and the fragmented nature of the tourism industry in the EC is a disadvantage when collecting and aggregating statistics, particularly on the individual subsectors. Discussions to develop a "Standard International Classification of Tourist Activities" (SITCA) are currently in progress between Eurostat and the World Tourism Organisation.

Main indicators

Revenue from international tourism in all EC countries represented 76.2 billion ECU in 1989, equivalent to 1.6% of EC GDP. Official data on domestic tourism is less easily available

and not easily aggregated across EC Member States. However, with the exception of the Benelux countries, Eurostat estimated that all tourist activity generated over 4% of GNP in each Member State in 1988 and as high as 9.4% in Spain, indicating that domestic tourism expenditure is even more important than international receipts.

Data from the European Travel Intelligence Centre indicates that in volume terms domestic travel is the more important, with only one in five trips across Europe being to foreign destinations. The proportion for EC Member States only, however, is likely to be higher.

Many of the businesses that comprise the EC tourist industry are characterised by a high proportion of casual and family workers, many of whom escape the official statistics. Employment is also highly seasonal which distorts the information available. Within the tourism sector, up to 3.3 million full-time and part-time workers are employed in the hotel industry, which makes it the biggest single employer in the EC. The hotel sector is a particularly important employer of female staff and part-time and temporary workers. Part-time workers form 20% to 30% of the total workforce in the sector, depending on the Member State.

Comparable data on the economic contribution of travel and tourism in the different EC Member States, and other European and non-European countries, is available in the latest World Travel and Tourism Council (WTTC) report "Travel & Tourism in the World Economy". Its contribution to European and world economic growth is considerable whether measured in terms of total sales, value added, capital investment, tax contributions, or employment.

According to the WTTC Report 1992, travel and tourism is Europe's largest industry, directly employing around 14 million people in the EC. The industry sells for an estimated worth of 600 billion ECU a year for the EC. It generates a value added of 290 billion ECU, equivalent to around 6% of EC GDP. The WTTC also estimates that annual growth in gross output of the tourism industry in West Europe averaged 10.4% from 1987 to 1990.

Recent trends

International tourism in the EC grew rapidly during the second half of the 1980s. In the 1985-90 period the value of international tourism expenditures by EC Member States increased by 70% to 77.5 billion ECU. The fastest growth in expenditures is evident in emerging markets of southern Member States, particularly Italy, while growth was slower in the more mature northern Member States. Receipts from international tourism in EC Member States grew more slowly from nearly 58 billion ECU in 1985 to almost 80 billion ECU in 1990.

International comparison

While international tourism expenditures by, and receipts for, EC Member States are much higher in both absolute and relative terms than the USA or Japan, to some extent this reflects the greater multiplicity of international borders and contiguous countries in the EC. Using World Tourism Organisation (WTO) arrivals data, there were eight European countries ranked among the top ten international destinations in 1990. Five of these were in the EC: France (first), Spain (third), Italy (fourth), United Kingdom (seventh) and Germany (eight). Similarly five of the top ten tourism spenders were also EC Member States.

While Europe remains by far the world's most popular destination for international tourists, it has been steadily losing market share through most of the 1980s. Preliminary data for 1991 shows a further sharp drop, although the effects of the Gulf War and the economic recession in major markets suggest 1991 was an atypical year.

Table 3: Tourism

The WTTC 1992 report estimates that one out of every ten workers in the EC are employed in the tourism sector compared with one out of 13 in other countries of Western Europe and one out of 12 in Eastern Europe. These figures compare with one in 15 worldwide, one in 13 in North America, and one in 10 in Japan.

Foreign trade

There are no official statistics comparing extra-EC tourism revenue and expenditure, although it is apparent that both have been growing in recent years. The most important markets for tourism into the EC are the EFTA countries, Japan and the USA. Long-haul travel out of EC origins, in particular to the Far East and to North America, has increased substantially in recent years. For example, between 1985 and 1990 arrivals in the USA from the EC's four major tourism generating countries - Germany, United Kingdom, France and Italy - increased from 7.6 million to 13.6 million. In absolute terms Austria and Switzerland are the most important extra-EC destinations, particularly for Germans - there were an estimated 12.7 million West German arrivals in these two countries in 1990.

The importance of international tourism varies widely across Member States. In absolute terms the most important destinations are France and Spain which respectively account for 20.7% and 20.6% of all tourist receipts in the EC. Italy and the United Kingdom are also major destinations in absolute terms. Some Member States are more reliant on tourism than others. The less developed countries (Portugal, Spain, Greece and Ireland) all depend on international tourism to generate more than 3% of their GDP, compared to an EC average of 1.6%. Similarly, tourism receipts generated almost a quarter of exports in Spain and Greece.

As an import, tourism is most significant in the balance of payments of Germany and Denmark where its share of goods and service imports is around 8% against an EC average of 5%. Germany accounts for over one third of the total international tourist expenditure of EC members while the United Kingdom and France are the other important spenders. In per capita terms, Denmark, Belgium/Luxembourg and Germany top the list of spenders. Thus, international tourism is re-distributive of wealth within the EC in that the industry generally makes a net positive contribution to the balance of international payments for the poorer Member States, including Ireland as well as the Mediterranean countries and a net negative contribution to the accounts of the richer northern Member States.

Expenditure on international tourism as a proportion of private final consumption was highest in Denmark, but was also high (in excess of 4%) in Ireland, the Netherlands, (West) Germany and Belgium-Luxembourg. It remains particularly low, despite recent growth, in Spain, France and Portugal.

MARKET FORCES

Demand

The demand for holidays is influenced by a variety of factors which affect the decision whether to take a holiday, what type or length of holiday and where to take it. The most important of these factors include: income, particularly the level of discretionary income; available free time; age and family circumstances; comparative price levels in different destinations; attractiveness of other destinations; profession (particularly farmers and the self-employed); and second home ownership.

Table 4: Tourism

The percentage of the population which takes at least one trip a year of one night or longer away from home is about 60% in Europe overall, but the level of trip-taking varies widely from country to country, ranging from as high as 87% in Iceland to 51% in Portugal, and even lower in the countries of Eastern Europe. The proportion of Europeans who take a leisure or business trip abroad tends to be considerably lower, ranging from 62% in Luxembourg to 13% in Portugal. The average share of all Europeans who travel abroad is around 26%. However, the level of travel abroad is actually higher than domestic travel in some markets, notably Belgium, Luxembourg, the Netherlands and West Germany. The vast majority of trips made by Europeans abroad are to neighbouring destinations, another reason for their high level in the Benelux countries. Domestic travel also tends to decline in favour of foreign travel as the market becomes more travel experienced.

The level of trip-taking is very much affected by income, educational and social status. Those with high disposable income tend to travel more frequently, rather than limiting themselves to just one trip per year. In addition, business travel - which is becoming increasingly important in these markets - is usually much more frequent than leisure travel. Northern Europeans are by far the most enthusiastic outbound travellers, especially those for whom foreign destinations are quickly and easily accessible by private car or other surface transport.

The level of trip-taking is much lower in southern Europe. The Mediterranean countries are popular holiday destinations in their own right, offering plenty of sunshine and opportunities for beach holidays, which are still the favourite choice of holidays for the majority of Europeans. In addition, southern Europeans have traditionally spent their main summer holidays in their own countries. Traditions are changing, as witnessed by the growth in outbound travel from a number of the southern European markets over the past few years. In the less mature European markets, the cost of travel is also an important deterrent to foreign holidays.

In general, the level of holiday-taking rises more than proportionately with income. Results of a recent survey by Mintel into European lifestyles indicate that expenditure on holidays and home improvements predominate, if respondents' disposable income were to rise by 25%. High income generating countries also tend to be high tourist generating countries, of both the domestic and overseas varieties, although low income generally reduces the propensity of tourists to travel outside their own countries.

Similarly trends in international holiday-taking are closely linked to economic growth patterns in origin countries, often with a lagged effect into the following year. A recent Economist Intelligence Unit (EIU) report ("International Tourism Forecasts to 1999") estimated that for most countries about 90% of all fluctuations in travel growth rates around the long-term average can be "explained" by the relative cost of travel abroad and fluctuations in income growth rates.

The World Tourism Organisation (WTO) has identified a number of "mega-trends" which it expects to influence tourism demand, in the absence of a major catastrophe, over the next decade. These include a significant increase in long-haul tourism, a continuation of the growth of air travel unless rail travel is modernised quickly, a faster growth of organised travel compared with individual travel, an expansion of late bookings and bargain-hunting, an increase in hotel occupancy, greater short-break tourism especially that related to business travel, less day tourism as leisure time outstrips economic growth and, finally, an increase in special interest tourism. However, large segments of the travel trade still over-concentrate on a few mass markets and largely sun oriented products, leaving ample scope for further marketing of alternative tourism products.

More free time has also contributed to the growth of the tourism industry. In all EC countries collective arrangements ensure at least four weeks holidays for the majority of workers, with a further 7 to 14 days public holidays. In comparison with 15 to 20 years ago, this represents a substantial increase in the proportion of time available for vacationing. Along with rises in average incomes, this increase has contributed significantly to the growth of the European tourism industry, through an increase in second holidays and short-breaks as well as through a greater incidence of holiday-taking. Growth in incomes has also led to increases in the number of second homes. In Greece, Spain, Italy, the Netherlands, Denmark and France, over 10% of holiday-makers use second homes for holiday accommodation. Generally, the acquisition of sec-

Source: European Travel Intelligence Center, European Travel Monitor Luxembourg

ond homes indicates a reduced propensity to spend on conventional holidays abroad with most second homes being in the same country. However, the EC is in the process of drafting new proposals to harmonise laws relating to time-shares and second homes across Member States. This should lead to an increase in the proliferation of second homes owned in Member States other than ones own.

Short-breaks and second holidays not only tend to be taken in the off-season, but the growth in these supplemental breaks, as the number of vacation days available increases, appears to lead to a slight shortening in the duration of the main peak-season holiday. Short breaks accounted for 32% of foreign trips in Europe in 1991, compared to 28% in 1990. Short leisure breaks accounted for 19% of all international trips in 1991, up from 14% in 1988. The implication of this trend is that seasonal variation in holiday-taking will be reduced and growth in tourism expenditure can take place with relatively low additional capital investment.

Travel statistics often distinguish between "pure" holiday travel, visiting friends and relatives (VFR) and business travel. Business related travel is probably the fastest growing segment of the travel market. General business travel is not usually regarded as part of the tourism industry, although it is probably the most important component of airline and hotel demand. Business travel is determined by factors such as the level of economic activity rather than being influenced by the marketing and product development activities of the tourism industry. Expanding niches within the business market can, however, be regarded as tourism-related: incentive travel in particular, but also conferences and extensions to business trips which incorporate a strong leisure element.

The rapid growth of the tourism industry in Europe slowed substantially in 1991, as a result of a variety of factors including the Gulf War, unrest in the Balkans and recession in some of the major originator countries such as the United Kingdom, the USA and Australia, with the Japanese long-haul market also depressed by the wealth effects of the stock market decline. Thus, the major slowdown was in the lucrative long-haul market, where advance bookings were particularly affected by the Gulf War. In contrast, however, domestic and short-haul tourism in Europe was less affected as tourists, rather than forego their vacation plans, travelled to destinations closer to home.

Weather is an important factor in almost all "pure" holidays. Alongside institutional factors such as the timing of school and work holidays and long-standing traditions, the importance of the weather has contributed strongly to tourism long-standing problem of seasonality. However, there are changes in traditional patterns taking place which indicate that holidays are becoming more evenly spread (both across time and countries) and that there is scope for further spreading. These changes include a greater awareness of health issues and of the dangers of too much sun, resulting in a reduction in beach holidays and greater interest in sport and educational holidays. Furthermore, additional short-breaks and second holidays are generally spent in one's own or a neighbouring country. Finally, changes in the traditional north-south mass market package holiday pattern are taking place, because southern Europeans are becoming wealthier and travelling more, because business travel flows have increased and because a variety of factors combining to change the holiday patterns of northern Europeans.

Changes in population age structure also strongly influence the nature, incidence and timing of holidays during the 1990s. Traditionally those aged over 55 have been less likely to take a holiday than most other age groups. Thus, the ageing of Europe's population might be expected to result in a reduction in tourism demand, but there is strong evidence to suggest that the over 55s tourism market will be among the most lucrative tourism market segment over the next decade.

The USA has a population of 250 million people, many with a European heritage which is frequently utilised as a major marketing tool to attract US travellers to Europe. While it is also one of the world's largest and most active travel markets, a high proportion of travel is domestic. In 1988 out of an estimated 12 billion trips, only 14.4 million were to overseas

Table 8: Tourism

destinations, just over half of them to Europe, mainly to EC countries. Europe's share of USA outbound travel has fallen in recent years. While the volume of US overseas departures increased substantially during the late 1980s, Europe's share has remained largely stagnant since 1985. It has fallen particularly sharply in 1991 as a result of a combination of factors including the impact of the Gulf war, the weak USD and the economic recession. This decline highlights the volatile nature of the US market which is particularly susceptible to exchange rate fluctuations and political developments. A similar demand trough was experienced in 1986.

The outlook for US travel to Europe, leaving aside volatility aspects, is for some, but not rapid, growth. Factors which could potentially constrain the growth of US travel to Europe include: the declining share of the population that could be characterised as having a "European heritage"; southward and westward geographical shifts of the US population; and lack of discretionary income and time in the fastest growing population segments (people in their late 30s and 40s who are tied down by high interest rates and dependants).

Business travel between the USA and Europe should continue to grow alongside the growth in international trade of goods and services, while ongoing moves promoting closer European unity will both stimulate business as US companies seek to assert their presence in the market and streamline travel by easing airline regulations and border controls. On the supply side, developments such as the growing importance of strong US carriers (United and American Airlines) in the airline sector and increased liberalisation will put downward pressure on fares and widen the number of US cities with direct access to Europe. Much the same factors affecting the demand for US travel to Europe in the 1990s are also affecting Canadian demand - decline in the relative size of the older population age-groups, population increases in the 1970s and 1980s being driven by non-European immigrants and population shifts towards British Columbia in the west.

Japanese outbound travel expanded very rapidly during the second half of the 1980s, doubling between 1985 and 1990 to over 1.1 million trips, and falling back in 1991. Europe's share of this growing total remained stable, with the exception of 1991. It occupied a third place behind destinations elsewhere in Asia and in North America. Like all long-haul travel, Europe bound travel from Japan is sensitive to fluctuations in economic growth and to fears about security. These factors are reflected in the decline in European arrivals from Japan in 1991, but this should only be a temporary interruption of continued growth. The factors behind the growth of international tourism out of Japan during the 1980s should continue to operate in the medium term. These include: growth in Japanese incomes; greater availability of leisure time and a change in attitudes to leisure and work across demographic groups; changing attitudes to overseas travel among the Japanese, aided by the appreciation of the Yen; links between overseas travel and Japanese overseas investment; government initiatives including overseas travel promotion campaigns, easing of restrictions, the use of fiscal incentives, air transport policy and the campaign against workaholism; and, promotions by EC tourist agencies.

The EFTA countries are also important source markets for EC tourism. In general they are relatively mature markets with similar demand characteristics to the more affluent EC Member States. The level of trip-taking is high, particularly the proportion of foreign travel. In 1990, the WTO ranked Switzerland, Austria and Sweden 9th, 10th and 11th, respectively, in the world in terms of expenditure on foreign travel. However, in common with many EC Member States, long-haul travel out of Europe by residents of EFTA countries is likely to increase during the 1990s.

Supply and competition

Supply is in general more than adequate to meet demand. There is clearly no shortage of travel agencies or tour operators from which to choose. The suppliers of the travel and tourism industry, i.e. airlines, hotels, etc., are cyclical industries and this can have repercussions on the availability of seats and rooms, particularly at peak seasons. On balance, consumers are in a buyer's market and this is reflected in price-setting and margins.

Production process

The main inputs of the industry are accommodation in a variety of forms (hotels, holiday villages, self-catering villas and apartments, caravans and campsites, entertainment facilities, and seats on aircraft, trains, coaches and rental cars). All services must meet the quality expectations of an industrialised world consumer market, although there is scope for a wide range from hotels without star to five star hotels and a similar range of transport options. There is constant demand for quality improvements at every level.

Almost all sectors of the tourism industry are labour intensive. Female participation is high, with percentages of between 45% and 65% in most Member States. The only exceptions are Spain and Greece where female participation falls to about a third. Employment of short-time and seasonal staff is also high. There is an overall correlation between the country's level of development and the annual working hours in the tourism sector with Germany and Portugal as the two extremes (under 1800 hours and over 2000 hours respectively).

The employment pool of young workers will shrink in the near future. The expected increase in the mobility of labour within the EC may help to alleviate the problems of regional shortages of skilled staff, but worries about labour shortages remain. One of the most serious threats to the hotel and catering sectors is that harmonisation of labour conditions will push up costs and prices in certain countries. There is currently a wide divergence, not only in weekly working hours, but also in wage rates. These differences in length of working week will have an effect on how labour is ultimately redistributed. Some of the labour shortage may also be compensated for by increased productivity and technological advances. Considerable new technology has been introduced into all segments of the tourism industry in recent years. However, the general impact has been on improved quality of service rather than on labour content reduction.

INDUSTRY STRUCTURE

Companies and strategies

Estimates by the World Travel and Tourism Council indicate that investment in the tourism industry in the EC in 1990 was around 74 billion ECU, equivalent to around 12.6% of gross output, although investment levels, despite the development of Euro-Disney, are likely to have fallen sharply in the more pessimistic climate of the early 1990s. While continued growth in investment in tourism infra-structure can be expected in the medium term, it is likely to be slower than during the second half of the 1980s. Opportunities for investment will be provided by the moves towards greater economic integration within the EC, accompanied by the expansionist trends of most of the major players in the tourism industry. However, most investment is likely to be in product development and in additions to existing infra-structure rather than in greenfield investment. Thus, the high level of take-overs, mergers and inter-selling of tourism assets and management contracts between major players in the industry can be expected to continue over the next few years.

In many of the less developed Member States EC structural funds provide an important boost to tourism investment. The increasing importance of EC wide legislation in areas such as environment, health and safety, competition policy and in tourism itself will also influence investment trends. In particular closer attention is being paid to environmental sensitivity in the planning of major new investments. The opening up of Eastern Europe will provide opportunities for investment outside the EC, but it is likely that the funds diverted to the east will be mainly from developing resorts outside Europe rather than from the EC. Investment in tourism infra-structure in eastern Europe is already quite high - the WTTC estimated 1990 investment at 76 billion USD, 81% of EC investment. The European Commission's strong policy focus on the opening of new markets through alternative forms of tourism (rural tourism, cultural tourism, youth, third age and social tourism) will also provide opportunities for new developments. The Commission's efforts to reduce the consequences of mass tourism, which they expect to become more acute in the next few years, through endeavouring to spread holidays over the year, will also open some new possibilities for the EC industry. There has already been considerable investment in new products aimed to both capitalise on the demand for new forms of tourism rather than beach holidays and to improve the spread of arrivals through the season.

REGIONAL DISTRIBUTION

The tourism industry has traditionally been regionally concentrated, generally in seaside or mountain regions. In Spain, for example, 30% of international tourists visit Catalunya while the Mediterranean coast is one of the high tourism generating regions within France, Emilia Romagna in Italy, the islands in Greece and Algarve in Portugal. The major European cities also tend to be magnets for tourism concentrations, in particular London, Rome and Paris.

ENVIRONMENT

There is a strong inter-relationship between tourism and the environment. On the one hand the environment in all its aspects (clean air and water, uncongested core areas of historic cities, thriving wildlife habitats, healthy indigenous cultures, etc.) are all key tourism resources, and often undervalued. On the other hand, growth in tourism has already contributed to deterioration of these assets and can potentially contribute to further degradation. Excessively concentrate growth in tourism has already contributed to destructive depletion of ground water reserves, elimination of coastal vistas, destruction of habitat for rare species, disruption of nature, destruction of historical buildings and so on. For example, water discharges from activities along the Mediterranean coast has had serious effects on, among other things, the bathing water for the 100 million tourists visiting the Mediterranean every year.

Europe's mountains are among the most threatened wilderness, mainly due to the rapid growth of skiing activity. Artificial snow machines, requiring millions of litres of water, make sudden changes to the water levels in feeder lakes and disturb the biological sediments in the lakes. Increased bed capacity affects local resources of small mountain villages. These must quite suddenly meet increased demand for water, sewage disposal (a large number of rural communities throughout Europe do not yet have structured sewage treatment facilities), communications (television, mail, telephone), and fast roads offering attractive transfer.

Two broad types of environmental impact with which the tourist industry must be concerned were identified in a recent report on Tourism and the Environment by the Economist Intelligence Unit (EIU). Destructive tourism, where the industry itself causes damage to the environment, includes overcrowded beach resorts in Mediterranean coastal areas lacking adequate infra-structure to deal with resultant 'loads, overvisited cultural sites leading to destruction of artefacts, and damage to alpine mountain areas from over development of ski-resorts. Anti-tourism development, on the other hand, relates to destruction of the environment by other industries which impacts negatively on the tourism industry. Examples include the impact of acid rain on forests and closure of beaches due to radioactivity or oil spills. Leaving wider environment considerations aside momentarily, tourism may continue, and in many cases has continued, to flourish despite environmental deterioration. A "shear" point exists, however, where the attractions of certain products will falter because of risen visitor aspirations or of the extent of destination deterioration.

However, industry umbrella groups, many national tourism organisations and the EC Commission are responding to the problems posed by environmental issues. The response from operators, however, is relatively muted, to some extent reflecting the small size and short-term horizons of most operators. Greater concern for environment issues is evident among many of the larger hotel groups.

In its 1990 report, the world wildlife fund, referring mainly to conservation of natural areas, accused the tourism industry of being slow to get involved in beneficial environmental projects. The flexibility with which large tour operators, airlines and even international hotel chains can shift between destinations enables them to take a more casual stance than would be justified by the long-term implications of their actions.

In preparation of the Earth Summit in Brazil, the World Travel and Tourism Council and six other umbrella organisations jointly collaborated to provide information on tourism's potential to enhance the environment.. The WTO has also developed twelve environmental rules which have been adopted by the industry organisations. These include:

- identify and minimise product and operational environmental problems, paying particular attention to new projects;
- pay due regard to environmental concerns in design, planning construction and implementation;
- be sensitive to the conservation of environmentally protected or threatened areas, species and scenic aesthetics, achieving landscape enhancement where possible;
- practise energy conservation;
- reduce and recycle waste;
- practise fresh-water management and control sewage disposal;

- control and diminish emissions into the air;
- monitor, control and reduce noise levels;
- control, reduce and eliminate the use of environmentally unfriendly products such as asbestos, CFCs, pesticides and toxic, corrosive, infectious, explosive or flammable materials;
- respect and support historic or religious objects and sites;
- exercise due regard for the interests of local populations, including their history, traditions, culture and future development;
- consider environmental issues as a key factor in the overall capacity development of travel and tourism destinations.

The EC Commission has used channels other than legislation to help improve the environmental record of Member States. These include financing of more environmentally-friendly product development through the Community Support Framework, funds for improving infra-structure in coastal resorts through programmes such as ENVIREG. The Tourism Unit of Directorate General XXIII is currently funding a research study on tourism and environment, and has also recently sponsored 23 practical pilot projects on "sustainable tourism". Campaigns and policies aimed at improving the seasonal spread of tourism arrivals also contributes to the amelioration of the potential damage of tourism on the environment.

Public awareness of environmental issues in relation to tourism are increasing, putting pressure on many segments of the tourism industry to react. A survey of German tourists by the Studienkreis für Tourismus indicated that the importance of environmental concerns among German tourists had more than doubled over the period 1985-88. Awareness centred mainly on environmental problems such as bathing water and dirty beaches, which had a direct impact on holiday enjoyment. These concerns have been reflected in changing tourism tastes and in product development. Two poles of "environmental" tourism can be identified. Firstly, there has been growth in various forms of agri-tourism or nature-based tourism which generally involves tourists taking holidays in uncrowded, generally rural areas rather than in the more popular and, in high season, often overcrowded conventional tourism resorts. Properly managed this type of tourism generally does little or no damage to the environment and in most cases is "environmentally sensitive" in that it depends quite strongly on the quality of the environment if it is to be sustained. At the other end of the eco-tourism spectrum are holidays which are deliberately designed not only to capitalise on environmental attractions but also to put minimum stress on the environment and to reduce the consumption of natural resources to an absolute minimum. The EIU report asserts that environmental consciousness is not a fashion which will pass, but one which will grow in strength and predicts fivefold growth in environmental tourism during the 1990s. On this basis the competitiveness of European destinations is likely to suffer as there are relatively few undisturbed natural areas remaining in Europe by comparison with the other continents.

Nature and adventure travel are among the fastest growing sectors of the tourist industry. The emergence of "ecotourism" or nature tourism coincides with the still increasing concern with environmental issues among people in general and in politics. Three holiday-maker types, who in increasing amounts are involved in nature and environment can be distinguished: the open air holiday-goer; the nature lover; and, the nature investigator. The contents of the product is mostly defined by a variety of nature oriented possibilities, in which relaxing and simply being in nature are most important to the holiday-maker. Social, cultural and historical aspects are of minor importance.

The first group consists of consumers with no interest in environmentally conscious forms of tourism and consequently definitely not in nature oriented recreation. Around a quarter of the tourists belong to this group. The second group, best described as nature lovers or open air holiday-makers, are interested in general nature oriented activities such as exploring by foot or bike, and making long beach, mud flat or nature walks. It is a fairly amorphous group, characterised by a certain limited amount of environmental awareness which also shows up in their needs for tourism/recreational supplies which satisfy an amount of criteria concerning environmental consciousness. This group can choose from a wide range of tourism recreational supplies which in some way meets these satisfactions. Over 60% of these consumers belong to this group. The third group, nature investigators, attach value to nature oriented activities (conducted forest walks, nature lectures, observing flora and fauna, etc.), besides the above mentioned activities. Their choice of tourism/recreational supplies are obviously more restricted. They visit nature parks, historical parks and gardens, bird sanctuaries, cultural historical monuments, campground accommodations in nature and visitor centres. Almost 10% belong to this group.

If managed properly, ecotourism allows travellers to experience cultures previously inaccessible, it brings revenues to remote regions and can contribute to making conservation economically viable. It is largely the presence of tourists that convinces national authorities to protect natural zones. A problem is of course that this huge demand to do "off-the-beaten-path" tourism to natural areas create a problem due to the fact that many natural parks are not yet equipped to benefit and to mitigate the negative effects.

REGULATIONS

A wide range of local, national and EC regulations impact on the tourism industry, although few are specifically designed with the tourism sector in mind. In particular, the industry's lobby groups having achieved favourable consideration in some aspects of the VAT and excise duty harmonisation process may now focus on derogations or special treatment in forthcoming Directives implementing the Social Action Plan - the tourism industry has a heavy reliance on low-paid, on female and on part-time workers. For this reason regulations on worker's residence permits and on the recognition of vocational qualifications across the EC are also of interest.

The tourism industry, particularly in Ireland and in the southern Member States have benefited considerable from EC-funded investment in recent years. Such investment has also been of benefit to rural areas and to declining industrial areas. Such granted aid has caused little concern in other service or industry sectors, nor has it attracted attention from competition authorities, since it is based on regional policy considerations.

Developments in consumer policy are about to have an increasingly important bearing on the tourism industry. The EC is presently developing a body of legislation aimed at improving protection for tourists. Areas covered include time share agreements, unfair terms in consumer contracts, distance selling, denied boarding compensation for airline transport, package holidays, rules governing computer reservations systems (CRS) and access to justice abroad. A directive exists on package holidays and Council has adopted a regulation establishing common rules for a denied-boarding compensation system in scheduled air transport. There are also regulations on the access to CRS and further measures are expected. The remainder of the areas mentioned are at earlier development stages.

The directive on package holidays comes into force on January 1, 1993, and is a cause of tension among different sections of the industry. It places liability for consumer compensation with tour operators, who complain that, apart from the directive containing ambiguous terminology, stricter hygiene and safety regulations should now be applied to the hotel sector. For

example, the regulations in the recommendation on protection of hotels against fire are non-binding. While the concerns of the tour operators are valid for some countries, in many Member States hotels are already subject to strict national and local legislation on health, safety and other hygiene requirements. It should also be noted that tour operators in some Member States are already required to lodge funds with national authorities in the advent that refunds to clients are required.

At present environmental regulations do not weigh heavily on the tourism industry. While planning laws are particularly strict in some Member States they are relatively lax, or inadequately applied, in others. Inspired by EC pressure this is already changing - for example, in some cases funding of tourism investment from the European Regional Development Fund in Greece has been threatened because of inadequate consideration to the environmental impact of certain developments.

OUTLOOK

The World Tourism Organisation (WTO) projects international tourist arrivals in the year 2000 to fall somewhere between 592 and 690 million suggesting an average annual growth rate in the 1990s of between 4.5% and 4.8%. Given the slowdown in tourism expenditure in recent years and the expected recovery in the world economy towards the end of 1992 and into 1993, a higher growth rate of close to 6% is expected over the next four years. However, it is also expected that EC Member States will continue to lose share, particularly of main holidays, to extra-EC destinations in the Far East and in Eastern Europe. This will be offset to some extent by continued growth in short-break holidays and growth in international tourism expenditures in the southern Member States.

Employment	3.0	3.0

Source: Fitzpatrick Associates, Economic Consultants

As a generating region for international tourism many West European countries may also come up against a ceiling limitation to foreign travel during the latter half of the 1990s. As a tourist receiving region western Europe is a mature destination with limited capacity to absorb ever-increasing numbers of tourists in its principal tourist attractions, a particular problem given the increasing concerns of tourists about congestion and over-crowded resorts.

Restaurants
NACE 661

The restaurant sector includes a diverse range of establishments from fast food take-away to haute cuisine. Rising levels of disposable incomes and greater female labour force participation, alongside changing tastes and increases in tourism expenditures have all contributed to a steady increase in restaurant revenues. Entry and exit barriers are relatively low with the result that the industry is predominantly populated by small independent establishments, although the rapid growth of fast food chains, particularly franchise outlets, has provided a high degree of uniformity in that subsector. While the use of new technology, mainly in food preparation, has been increasing attraction, the retention of workers is a growing problem in many Member States. The outlook for the industry is, however, relatively buoyant and the factors which have driven recent growth should continue to operate in the 1990s.

INDUSTRY PROFILE

Description of the sector

Among the most vibrant and visible commercial sectors of the EC, restaurants are present in virtually every local community. As a sector, restaurants are important to the EC economy and to those of its Member States, but they play their most significant role in their contribution to the local economy of almost every village, town and city in the EC.

There is substantial variation within the restaurant sector, from fast food outlets to high class restaurants, providing very different markets with a variation of the same service, the provision of ready to eat food. Most restaurants are stand alone operations, although some are an integral part of the services provided within other sectors, principally hotels but also including public houses, railways, ferries and night-clubs. There are also other service branches specialising in the provision of food including contract caterers, work canteens and messes and convalescent homes. However, while the type of operations are diverse, the sector is dominated by family restaurants.

There is a fine distinction at the margin among the sub-segments of the restaurant industry. Unlike hotels, most grading of restaurants tends to be unofficial, often relatively subjective and generally only applies to the top end of the market.

Main indicators

Eurostat statistics on restaurant turnover exists for only 8 EC countries and is particularly dated in the case of Denmark. Restaurant turnover has increased in recent years, continuing on an upward trend which is already well established, although there are variations across different Member States. Within this overall increase, turnover in the fast food and take-away sector has been growing most rapidly, although again there are substantial variations across countries with meals in bars and public houses showing the fastest growth in both the United Kingdom and Ireland. Surveys undertaken by Foodservice Consultants Society International (FCSI) across ten European countries appear to indicate little restaurant turnover growth during 1991, but with a slight upturn towards the second half of the year.

Also data on official employment in the restaurant industry is available for only a limited number of EC Member States. The evidence indicates that the trend in employment is upward but increasing much less rapidly than turnover. However, the FCSI survey results suggest that employment fell somewhat during 1991, reflecting relatively poor turnover performance, but that most respondents were optimistic about increasing employment numbers during 1992.

Restaurant services are not internationally traded although an important market for their services are foreign visitors on holidays or business trips. Estimates for expenditure by tourists on food vary from 20% to 25% of their total expenditure.

MARKET FORCES

Demand

The demand for restaurant services is influenced by a variety of factors including disposable incomes, demographic factors, changing consumer tastes and the level of tourist activity. The propensity to eat outside the home is most strongly, and positively, linked to increases in disposable income. As a result the general trend in demand for restaurant services in recent years has been upwards. Nevertheless, often seen as a luxury, private expenditure on eating out is vulnerable to dips in disposable income and the eating out market provides a good barometer of the economic climate, being one of the first industries to suffer from adverse developments in incomes or consumer sentiment. This is evident in the fall-off in the United Kingdom during 1990 and 1991. Overall, however, and reflecting this linkage, the proportion of total consumer spending on eating out has risen over the second half of the 1980s and it is estimated that the EC average is around 5%. The estimate hides substantial variations between Member States. In some cases these differences reflect the importance of the tourism sector, the proportion is above average in Spain and Portugal, while in others it reflects traditional attitudes to eating out. If the EC catering industry is to follow the USA, where it is often cheaper to dine in a fast food or family restaurant than to buy equivalent ingredients and cook at home, then the tendency for locals to choose to eat out on the basis of cost and convenience will become more es-

tablished. Already in the EC eating out has become both more commonplace and relatively less expensive.

The growth of tourism is clearly a major source of business for the consumer catering industry in the EC. Even when staying in self-catering accommodation the tourist tends to eat out rather than cook for himself; when staying in hotels and similar establishments there may be no choice but to go to restaurants and cafes. In common with many other companies who deal in the totems of popular culture, the large fast food firms view the relatively young and increasingly affluent populations of South Europe as providing the best prospects for continued growth in Europe in the 1990s. On the other hand the UK fast food market is regarded as stagnant with a decline in market share for hamburger and pizza restaurants which appear to have reached market saturation point. The main growth area in the United Kingdom during the 1980s, according to a recent report by Marketpower, was in meals served in public bars. Relatively rapid growth in demand for ethnic restaurants, particularly those with cuisine which is not well represented at present, is also expected across the EC.

The increasingly rapid spread of communications media, through satellite TV for example, aided by the growth of international tourism flows has accelerated the trend towards greater internationalisation of the restaurant market. Nowhere is this more evident than in the growth of US-type food outlets serving hamburgers and pizza. Increasing numbers of ethnic restaurants in many European cities are also appearing as internationalisation trends are coupled with increased confidence and a sense of experimentation of consumers. Conventional food service styles, products and concepts are being rendered obsolete by 1990s lifestyles. The youth market is dominated by fast food, but there are significant trends also towards, inter alia, health foods, pasta and the replacement of red meat and red wine by their white counterparts and by fish.

One exception to these trends is the resurgence of regional cuisine, especially in France and Germany. However, the overall trend is towards homogenisation, with the fast food-led multiples changing eating culture, even if France, Spain and Italy are working hard to preserve their own national culinary identity in the face of the US-inspired attack.

In cities and towns the national economy tends to influence the performance of restaurants. The performance of in-store cafeterias is closely related to the index of retail sales while unemployment, inflation, interest rates and other economic indicators all influence the performance of restaurants. While many meals consumed in restaurants are related to the working and travel patterns of customers, "dining out" is also an important leisure activity throughout Europe and as such is affected by the general levels of expenditure on leisure. Restaurants also compete with other leisure activities including cinema, theatre, home video and sports for the discretionary spending of the consumer.

Supply and competition

The key competitive factors in the restaurant industry are food quality, price and decor. Entry and exits barriers in the restaurant sector are negligible at most levels of the industry. As a result and because of the localised nature of competition in most cases, there is little danger of monopolistic practices emerging and strong competition is evident both within and across segments of the industry.

Take-away and fast food has been the main growth area in the European restaurant sector in recent years. US firms are providing the driving force behind this growth. Having expanded initially in the United Kingdom, they are now spreading throughout mainland Europe, where they are facing increasing competition from indigenous companies.

One of the critical issues facing the restaurant sector within the EC over the coming decade will be the availability of labour and the ability of the sector to compete with other industries in offering a worthwhile career to staff. Because it is dominated by family owned enterprises the concept of "employment" in much of the European restaurant sector is blurred. Very frequently husband and wife will work together in a restaurant and they may be helped by their children or other family members whose remuneration may be "in kind" rather than through cash payment. Throughout the EC, however, owners of family restaurants are discovering that their sons and daughters are being attracted into other areas of employment.

Where employment is regulated, pay and conditions in EC restaurants tends to be towards the minimum for each Member State. There are of course exceptions, but generally employment conditions in restaurants involve long and unsociable hours, relatively low levels of basic pay and a reliance by employees on gratuities and service charges. Pay and conditions tend to be best where agreements have been reached between employers and trade unions but these agreements also tend to be confined to the larger and more structured employers. Staff turnover in restaurants is high and there is a lack of structured training in several countries.

As demographic patterns develop and family sizes decrease, particularly in the northern Member States, the restaurant sector is likely to experience staff and skill shortages. This is already evident in the United Kingdom, Germany, Benelux, France and Denmark where restaurant chains are seeking to recruit part time workers, students and senior citizens as well as immigrants from outside of the EC. The problem is not as serious in southern Member States and it is possible that there will be migration of restaurant workers from Greece, Spain, Portugal and southern Italy to fill vacancies in northern Europe. However, such migration patterns in an increasingly integrated EC labour market is likely to add to pressures to improve wage and other working conditions in the less developed Member States.

Competition in the restaurant sector is similar to that in other services which are dominated by small individually-owned enterprises. The cost of entry to the business is relatively low and this encourages entrepreneurs to enter a local market,

particularly when restaurant business is seen to be growing. The establishment of restaurants is however governed by regulations in all Member States. These include the granting of planning permission, the certification of the premises by the local health authority and in some states the granting of license to sell alcohol. Generally regulations governing restaurants are not seen as barriers to competition, but the policy of some EC governments in relation to restaurant services along motorways could distort free competition in the market. The policy in Germany was the subject of dispute between McDonalds and GfnBAB which franchises motorway catering. Fast food outlets have traditionally sought to attract passing trade using "drive thru's" - Burger King, for example is improving its "drive thru" facilities by introducing the "video drive thru" which permits customers to see their order on a video menu as it is being placed. Future mergers to create national or supranational chains are also unlikely to distort competition in the sector.

Competition within the sector is complex and differs across market segments and locations. Price elasticity tends to be lower at the top end of the market where competition is based on reputation, image and a perceived high quality of food and service. These competitive criteria also exist in the broad segment of family restaurants in which marketing and advertising is rarely undertaken. Location is of course a key factor but ambience, quality of food and personality of the proprietor are also important. Price becomes a more important factor when the reputation of the restaurant is more confined to the local community.

While quality, image and location are important competitive factors in towns and cities, price takes on greater significance particularly in "in store" cafeterias and restaurants, in coffee shops and in the fast food sector. Overall the trend has been for prices to move in line with inflation but strong local competition has kept price increases below inflation in larger cities throughout the EC.

The relatively minor position of corporations and chains in the European restaurant sector and the American base of some major players make it difficult to comment on profitability. Statements from Hotrec, the EC hotel and restaurant association, and from national associations of restaurant owners indicate however that there has been a relatively high level of business failures among EC restaurants over the past decade and that the lack of expansion by the vast majority of restaurants reflects lack of profitability. For nine out of ten European restaurant owners the business is a "way of life" which is sufficient to provide a modest standard of living for a family. In the case of some of the major players such as the retail stores, restaurants provide a service which attracts customers and make a contribution to the overall profitability of the enterprise.

Production process

The preparation and service of food is labour intensive. The raw materials tend to be supplied in a fresh state, prepared by hand, cooked by traditional methods and served to diners at their tables. Pressures on the availability of skilled staff as well as high labour costs are however forcing the industry to look towards technology as a means of reducing unit costs. While progress in the area has been slow there are indications that automation and technology are playing a more significant role in the preparation of restaurant meals. These trends are most evident among restaurant chains and larger enterprises.

The bulk preparation of food and its storage under frozen or chilled conditions has been attractive to the catering industry for many years and has been practised successfully in hospital catering and in the provision of meals in industry and institutions. Frozen products, including meat, fish, potatoes and vegetables is used extensively in the fast food and "quick service" sectors and there has been a widespread development of freezers and regeneration cookers.

The chilling of foods after cooking and their service within a few days of chilling is also growing in popularity because of more efficient chilling and regeneration equipment. "Cook Chill" systems are now being used in cafeterias and in other popular restaurants in Europe as a means of reducing unit costs. The principal advantage of the "Cook Chill" system is that food can be prepared in batches to tight specifications and these "batches" can be used to compile meal menus. The ability to cook food in bulk and to "hold" it for several days has enabled restaurants using this system to reduce their staff requirement particularly at night or over week-ends.

Another system of cooking food in advance is *sous vide* which originated in France and is growing in popularity at all levels of the market. Under this system dishes, which can include delicate sauces, are cooked and preserved in a plastic pouch which is chilled, for regeneration prior to serving. The system has enabled caterers to expand their menu by having additional dishes under storage or chefs to prepare sauces in batches for use at a later date.

Electronic technology has assisted in the volume preparation of foods by offering greater control over traditional cooking media such as ovens and gas or electric ranges. The "combination oven" which can cook foods in several ways, is a product of this technology which has enabled designers to add "cooking cycle programmes" and electronic probes which measure temperature and moisture content of the food during the cooking cycle. Microwave ovens are also enhanced by electronic controls. Energy costs in restaurants are relatively high and this has led to greater emphasis on energy efficient cooking with the advent of halogen elements in electric ranges and induction cookers providing the most promising developments.

The choice of energy is a source of continuous debate within the sector with chefs traditionally expressing preference for gas because of its controllability while electricity is becoming increasingly competitive because of technological developments with energy-efficient cooking elements.

Some larger restaurants have installed computerised billing and stock management systems and there has also been considerable investment in electronic air conditioning and air recirculation systems.

The principal "stock in trade" of restaurants is food in a raw or semi prepared state. At all levels of the industry there is increasing demand for conformity to specification and continuity of supply. The "Quality" system has been employed informally by the vast majority of restaurateurs over the centuries and still works effectively today. It is based on a long term relationship between restaurateur and individual suppliers of meat, fish and vegetables. The butcher, fishmonger and vegetable supplier will invariably reserve their best quality stock for the local restaurant because of its purchasing power, the regularity of its demand and the product knowledge of the buyer.

Among corporate-owned restaurants, however, quality is achieved through more formal structures. Detailed specifications are drawn for each food item and there is a greater emphasis on partially processed or prepared foods which are frequently supplied in a frozen state. A growing number of corporate-owned restaurants now operate just in time systems similar to those operated by the manufacturing industry.

INDUSTRY STRUCTURE

Companies

While becoming increasingly dominated by big chains, as the growth in the fast food and take-away sector outpaces

average growth, all EC countries continue to offer an enormous range of family run restaurants and cafes that are central to the appeal and character of the industry. The increase in market share of the chains has, however, been at the expense of the traditional independently-run operations in addition to capturing overall market growth. The Marketpower study of the UK restaurant market also estimated that the catering market was becoming increasingly concentrated, with one in five private sector outlets either owned by a group, part of a consortium or operating as a franchise.

The sector includes chains of restaurants often owned and operated by conglomerates and multinational companies and it also embraces the fast food subsector which is growing rapidly throughout the EC and is largely controlled by American companies operating through local franchises. The largest catering group in the EC, McDonald's, fits this profile perfectly. Fast food restaurant chains are both multiple retailers and a production enterprise. In both the facets of their activities they have similarities with multinational multiple retailers and with multinational manufacturing enterprises. Like the retailers, expansion across national borders has occurred first and most substantially in the wealthiest EC Member States. Prominence is given to the names of the outlets and they are promoted and marketed like fast moving consumer goods. Alongside the name, uniformity of formula or format (decor, furnishings, staff uniforms, menus etc.) are key elements in the image and marketing of the chain, although concessions to national and local tastes are increasingly being made.

By far the most significant group of restaurants has little to do with corporations or "brands". Typically these restaurants which represent more than 90% of the sector across the EC, are family-owned and employ less than ten people, some of whom may be casual or part time employees. The local family restaurant tends to offer dishes based on local or regional cuisine. More and more this cuisine is offered outside of its country of origin. It is no longer unusual to find, for instance, restaurants serving Italian cuisine in France, Greek restaurants in the United Kingdom or French restaurants in Germany. A trend throughout Europe has also been the success of restaurants offering regional cuisine outside of their own regions - for instance Tuscany dishes in Veneto or the cuisine of Andalucia in Catalonia.

Family-owned restaurants span the full spectrum of dining out in Europe from simple take-away "fish and chips" shops in the United Kingdom to the award-winning restaurants of the famous French chef-patrons. The gourmet segment of the market is dominated by family-owned restaurants throughout the EC and in most countries it is the personality, reputation and skill of the patron who may be the chef or the maitre d'hôtel on which the success of the enterprise is based. Many such family-owned restaurants at the top end of the market are relatively large concerns employing up to 100 people and some, like the Roux Brothers in the United Kingdom and Paul Bocuse in France, have developed ancillary enterprises. More typical even at this level, however, is the restaurant serving 50 dinners each evening, owned and operated by a

single proprietor and employing a staff of around 20. Where corporations have become involved in gourmet dining they have tended to do so in conjunction with hotels. The four and five star hotels of Europe pride themselves on their dining facilities and each will offer at least one restaurant serving gourmet food. The scale and variety of the food offered in hotels is also expanding. More hotels are now operating ethnic restaurants, offering an international menu and informal dining in brasserie and coffee shop styles.

Strategies

Investment by corporations has been most obvious towards the lower end of the market, particularly in the areas of popular catering, transport catering and fast food. Groups like Forte's Little Chef (UK), GIB (DK), Quick (F), GfnBAB (D) and Autogrill (I) have developed successful chains of restaurants close to motorways and associated restaurants can also be found in towns and cities. These chains tend to be national rather than transnational and a dominant EC-wide restaurant chain has yet to emerge. Many people in the industry believe however that associations and mergers will take place following the completion of the Internal Market and that the first "European" restaurant chain is likely to emerge along the motorways of the EC.

A transnational restaurant chain may also emerge through the retailing sector. Supermarkets and department stores already operate large chains of cafeteria style restaurants in France, Germany, Benelux, United Kingdom and Italy. The expansion of these stores within the EC would lead to the expansion of their restaurants also. Karstadt, Hertie and Kaufhof operate large restaurant chains in Germany and the Casino supermarket chain operates the largest group of restaurants in France with 238 outlets. Other large scale retailers involved in restaurants include GB-Inno-BM of Belgium. In addition individual restaurateurs have opened restaurants offering their own national or regional cuisine in larger cities of Member States. The EC capitals for instance are the location for restaurants in the style of virtually all Member States.

Investment by corporations from outside of the EC has been an increasingly important phenomenon since the early 1980s. This has been confined almost entirely to the fast food sector and has been spearheaded by the American chain McDonald's which had around 1 140 outlets in the EC at the end of 1990. Other chains which originated in the USA like Burger King (360 outlets), Kentucky Fried Chicken (340 outlets) and Pizza Hut (over 300 outlets) have also been making an impact on this segment of the market. Burger King and Pizza Hut are now owned by UK companies, Grand Metropolitan and Whitbread respectively.

Fast food (selling packaged, cooked food and drink at a counter to be consumed on the premises or taken away) and fast service (limited menu restaurants providing table service and take-away as in pizza chains) has been the fastest growing segment of the EC restaurant industry for more than a decade. Its popularity can be attributed to the European acceptance of American dining culture particularly among young people, to the expertise of the American chains in the areas of product

development, location of outlets, staff training, consistency in quality, and to changing living patterns in Europe. Fast food and fast service have been most successful where there are large groups commuting over relatively long distances, living outside of a family structure, living in an urban environment and operating under time constraints. The principal food products served in this sector include hamburgers, chicken, pizza, pastry, fish and potatoes. Entrepreneurs in each of the EC countries have established national and regional fast food chains which compete with the US-originating franchised outlets and in this area the United Kingdom with Wimpy, Casey Jones, Pizzaland and other chains has achieved considerable success as has France with Quick, Accor, Groupe Le Duff, la Croissanterie, Pomme de Pain and others.

Investment in the EC restaurant sector has also come from entrepreneurs from outside of the EC who have opened "ethnic" restaurants in almost every member country. Thousands of restaurants owned by immigrants and offering Chinese, Indian, Thai, Vietnamese, Argentinean, Indonesian and other cuisine are scattered throughout the EC, are seeing their market share increase.

The FCSI survey results indicate that, in general, investment by the industry during 1992 will be mainly aimed at improving information, reducing costs and attracting new customers, rather than increasing capacity. The main area where respondents expected to authorise more capital expenditure was on information technology.

REGIONAL DISTRIBUTION

Restaurants are ubiquitous in Europe and may be found in every village, town and city. The concentration and level of competition tends to be related to population densities - cities and larger towns have more restaurants per head of population than do villages and rural areas but the exception lies in areas of tourism interest which tend to have a large number of restaurants competing for tourism business.

ENVIRONMENT

The interest in healthy food will present a challenge to caterers in the next few years as will the demographic shift to an older population which, to-date, has not been a target of the large catering chains.

Restaurants tend to be kind to the environment, and are becoming even more so. Waste is largely biodegradable and easily disposable while cooking systems are generally environmentally friendly. Some concern has been expressed regarding CFC gasses used in refrigeration but this issue is now being addressed by refrigeration manufacturers. The fast food sector, however, is a major contributor to litter problems in many Member States. Some chains have taken steps to ameliorate litter problems - McDonalds, for example, now use bio-degradable packaging rather than expanded polystyrene.

Restaurant consumers have also expressed concern about the production methods used in the food raw material and while this has not as yet adversely affected the sector, some restaurants are winning popularity by guaranteeing customers that all dishes are prepared from organically-grown produce and that poultry and fish are not the product of intensive growing systems. Consumers are also showing preference for foods which are perceived to promote health and this demand has led to the creation of new style cuisine based on a healthy diet. Eurotoque, the EC association of chefs, has been active in promoting a positive approach by restaurant owners towards the environment.

REGULATIONS

There are a wide variety of national and EC regulations which impact on the restaurant trade. The most important include compliance with hygiene regulations and certification by local health authorities, regulations relating to working conditions, and in some cases the granting of a licence to sell alcohol. Hygiene regulations across the EC are in the process of being harmonised, EC labour legislation is constantly influencing conditions of work, particularly in the less developed states. Ongoing proposals for a directive on packaging will also affect the industry. Harmonisation of VAT rates (and excise duties on alcohol) will also have differential impacts on restaurants across the EC over the next five years.

Restaurants services are not included in the list of goods and services to which Member States may apply a reduced rate of VAT. However, the Member States which were applying a reduced rate to restaurant services at 1 January 1991 are allowed to continue to do so at least until the end of 1996.

OUTLOOK

The restaurant sector in the EC has been growing throughout the 1980s and this overall growth is likely to continue during the 1990s. The rate of growth will however be influenced by tourism trends, economic growth, national characteristics and demography.

Growth in intra-EC travel and in the number of visitors from outside the EC will increase demand for restaurant facilities. Those countries whose tourism is expanding are therefore likely to experience a higher rate of growth in the restaurant sector. Expenditure on restaurant meals is also related to economic conditions, although during the 1980s a growing share of household expenditure was devoted to eating out. Disparities in GDP and private consumption expenditure growth rates will create higher levels of demand for restaurant services in those Member States whose economies grow fastest. Much eating out is discretionary expenditure and is susceptible to income squeezes, as evidenced in some Member States during 1991. However, the outlook to the mid 1990s is for a recovery in GDP growth across most EC Member States - Business International forecast average GDP growth across the EC at around 2.5% per annum over the 1992-96 period. Increased spending on eating out somewhat above this level is expected.

Employment growth is expected to be below that of turnover. The level of automation is likely to increase, motivated by cost-cutting, service improvement and problems with attracting staff. Restaurateurs are also likely to seek other service innovations reducing labour usage, while the relative importance of less labour intensive segments, particularly fast food outlets, will increase.

Table 5: Restaurants, snack bars, cafes and other eating places
Expected real annual growth rates

	1992-93	1992-96
Turnover	2.0	3.5
Employment	1.0	2.0

Source: Fitzpatrick

National growth rates will also be affected by the prevailing tradition of dining in restaurants, which varies widely across EC Member States. Social attitudes towards eating out are changing and as the EC becomes more integrated the dining tradition is likely to spread somewhat throughout the EC.

Different segments will also grow to varying extents across Member States. For example, in relation to the size and wealth of France and Spain and the present under-representation of international chains there are good opportunities for expansion by these companies, while continued economic austerity will constrain growth of eating out in Greece.

Countries with an emerging youth population will also see more rapid growth in fast service and fast food restaurants and those with an ageing population will see more growth in health food and leisure style restaurants. As more people move into urban areas there will be fewer family meals, greater consumption of snacks and small meals and more dining in restaurants as a leisure activity.

Hotels
NACE 665

The hotel sector comprises of a disparate variety of establishments in terms of size and range of services provided. Demand for hotel services is predominantly from tourists, with business travellers also accounting for a substantial proportion. Fragmentation of demand trends in recent years has resulted in growth, on the one hand, of bonded hotels providing a uniform product at different price/quality levels, and on the other hand, of hotels striving to differentiate their product. Concentration in the industry is growing as large hotel chains increase market share, while smaller hotels are increasingly joining voluntary associations. The outlook is for relatively slow growth during the first half of the 1990s.

INDUSTRY PROFILE

Description of the sector

The hotel sector comprises establishments which vary widely both in terms of size and services provided. At one end of the scale there are small, mono-located, family-run enterprises providing accommodation services and at the other are large hotels, frequently part of a chain, operated in a highly professional manner and providing a wide range of services. Such services might include restaurant and banqueting, public bar, health and leisure facilities, bureau de change, shopping facilities, business secretarial services and conference facilities. The incidence of hotels supplying accommodation only is now relatively small, with a discernible trend towards larger establishments providing a broader range of services and, as a result, the extent to which the business of hotels impinges on other service sectors is increasing.

Main indicators

Official statistics on hotel turnover and value added in different EC countries do not exist. Nor are there consistent definitions of hotels and similar establishments across countries, making aggregations and inter-country comparisons difficult.

Eurostat data indicates that the hotel industry is most important in Italy and the United Kingdom which have considerably more hotels than the other Member States, although the UK estimate includes inns and guest houses. Definitional differences are reflected when beds are used as an indicator of capacity. Italy had an estimated 1.6 million beds in 1988 compared to 1.0 million in France, 0.8 million in West Germany and 0.7 million in Spain (see Table 3).

Recent trends

Despite definition differences a trend increase in the volume of turnover in the accommodation services of hotels is evident from guest flows. Over the period 1985 to 1990 guest flows through hotels and similar establishments rose in most Member States, the exceptions being Spain, which experienced a slight decline, and the UK, where a sharp decline in bed nights from domestic residents was recorded. The most rapid rise was in Portugal, by an estimated 28%, and the smallest in Greece, 4%. Increases of 18% to 20% were recorded in most northern Member States.

Analysis of available bed nights indicates an increase in the supply capacity of the industry. Hotel guest-nights increased in most Member States over the 1988 to 1990 period, a continuation of the 1980s trend. While the number of foreign guest-nights fell in some countries, most notably some southern Member States, this was more than compensated for by rises in domestic guest-nights. A decline in both business and tourist demand led to some contraction in 1991, but growth is expected to resume in 1992.

The increase in the number of beds and bedrooms was against a background of a slight decline in the number of hotel and similar establishments. This reflects the industry trend towards larger units. Occupancy rates were above 60% in 1990 in each of the eleven EC Member States surveyed by Pannell Kerr Foster (PKF), ranging from 63% in Belgium to 78% in Italy.

Data collected by PKF on average room rates across different European countries places France's hotels as the most expensive, followed by Spain and Italy. Prices in EFTA countries tended in general to be higher than in the EC with particularly high average rates in Austria, Finland, Norway and Switzerland. Price levels and changes in the EC's capital cities, however, reflect local supply and demand imbalances and local property prices. Analysis by Business International indicates that the prices of hotels, particularly in the moderate/comfortable category, rose very sharply in Europe's major cities during the second half of the 1980s, with substantial differences across locations.

Official employment in the hotel industry is only available for the accommodation sector as a whole and then only for nine of the twelve Member States. The trend in overall employment is upward reflecting industry growth and the limited possibilities for capital substitution. The overall growth in total employment masks a decline in the number of self-employed persons, again reflecting the relative growth rates of larger chain operations at the expense of smaller traditional hotels. However, the high level of employment in the United Kingdom relative to its low number of bed-places highlights the problems of comparability using official data. These data problems are currently being addressed by Eurostat.

International comparison

Horwath International analysis of the overall performance of hotels across all the worlds regions indicates that income before fixed charges and revenue per room were highest in Europe in 1990. However, Horwath data relates mainly to chains.

Foreign trade

Available data on hotel-nights does not facilitate a breakdown into intra-EC and extra-EC "exports" and "imports" of hotel bed nights. However, most Member States distinguish between residents and non-resident guest nights, with the strongest growth in most Member States being non-residents guest-nights.

MARKET FORCES

Demand

The most important consumers of hotel services are tourists, accounting for nearly half of turnover (30% individual travellers and 19% group tours) in 1990 in Horwath International's hotel sample. However, while most group tours use hotels, a relatively high proportion of independent tourists use non-hotel accommodation. These include camping and caravan sites or, in the case of VFRs (visiting friends and relatives), family homes. Business travellers accounted for around 29%, rising to 40% if conference participants were included. Smaller hotels have substantially less business emanating from the group tours and conference market segments.

The distinction between tourist and business components of market demand is important because they are affected by different factors. While both are affected by the general level of economic activity, business travellers, and in particular the conference market, are more sensitive to economic downturns than tourists. International and domestic business demand is higher in northern European Member States reflecting higher GNP levels.

Recent analysis by stockbrokers Kleinworth Benson in the Economist Intelligence Unit's (EIU) Travel and Tourism Analyst suggests the service sector and its level of concentration are important components of the demand for domestic business travel. Large service firms tend to have a greater number of branches than their manufacturing counterparts and generate substantial travel within the firm by personnel from a broad range of functions such as accounting, finance, personnel, training, development, design and merchandising as well as traditional sales and marketing functions. Based on their analysis Kleinworth Benson suggested faster growth in domestic business travel in mainland EC states than in the United Kingdom in the medium term.

Closer integration of the EC Internal Market, and subsequent cross-border expansions will continue to increase the importance of inter-EC business travel. Traditionally, business travellers have been less price sensitive than tourists and while this still remains the case recent tightening of the economic environment has made firms more conscious of their travel budgets and costs.

General income levels are an important determinant of overall tourism demand and hence of demand for hotel services. In more prosperous northern Member States second annual holidays are now commonplace while in the southern Member States international tourism has recently grown. Such trends reflect rising incomes and increased leisure time. Increased frequency of holiday-taking spreads seasonal tourist flows and favours hotels relative to the other popular forms of accommodation. In addition, with increasing female participation

Source: Pannell Kerr Foster, Eurotrends 1991

in the workforce and a tendency towards smaller families, a growing proportion of the European households have two incomes and historically high levels of disposable income. Thus, many hotels have increased average occupancy rates through the promotion of off-season short-breaks, particularly at week-ends.

The relative importance of international versus domestic demand varies widely across Member States. France, Greece, Italy, Portugal, Spain and to a lesser extent the United Kingdom and Ireland attract substantial numbers of foreign tourists. Traditional factors, such as climate and income levels, affect the habits of domestic holiday-makers across Member States with relatively greater usage of hotel accommodation in northern Europe. A slight reversal of the traditional north to south tourism flows has been evident in recent years reflecting increased international holiday-taking by southern Europeans and the declining relative importance of sun and beach holidays. Both of these trend should boost hotel demand somewhat at the expense of other accommodation.

Trends towards cheaper and independently organised holidays will adversely affect hotels at the upper end of the market although lower grade hotels will also face competition from non-hotel accommodation. On the other hand the ageing of the European population and continued growth in the importance of long-haul and business travel augur well for hotels at the upper end of the price-quality range. Not all independent tourists seek budget accommodation and many hotels at the upper end of the market are cooperating with other suppliers and adapting their product offer to attract the more lucrative segments of this market.

Within the tourism segment, international tourism is more vulnerable to economic conditions. The US market is particularly noted for its volatility, reacting strongly to political events such as the Gulf War and to the relative strength of the US dollar vis-à-vis European currencies. Having recovered slowly during the latter years of the 1980s after a sharp and mainly politically inspired decline in 1986, the number of US visitors to Europe fell substantially in 1991. The fall was mainly as a consequence of the Gulf War but also in response to the continued weakness of the US dollar and the downturn in the US economy. Visitor numbers from Japan, having doubled in the preceding five years, also fell reflecting similar nervousness about political developments and the wealth effect of stock market falls on potential travellers. Long-haul travellers are also much more likely to use hotel accommodation and in particular hotels at the upper end of the market. Long-haul origin markets are particularly important to hotels, particularly those at the upper end of the market. Tourists from EFTA countries are more likely to use budget or non-hotel accommodation than their long-haul counterparts, while initial flows from eastern Europe may also favour non-hotel accommodation.

Supply and competition

Characteristics of the hotel industry affecting competition include ease of entry and exit, the often localised nature of competition, and competition between segments within the industry and by non-hotel establishments supplying similar services. These factors ensure that, in general, monopolistic positions are rarely attained; exceptional hotels at specific locations, such as The Gleneagles in Scotland, may however be able to maintain excess margins. Thus, increasing competition through mergers of large chains in the European market

Source: Horwath International

is not a cause for significant concern on the basis of inter-hotel competition at the present time.

Economic power is important in negotiations between the industry and upstream suppliers, such as major tour operators, but the need to maintain goodwill and quality standards generally tempers excessive exercising of power. Similarly, the emergence of anti-competitive practices through increasing vertical integration are less likely because of the volatility of the tourism demand, the "contestable" nature of the industry and the high degree of interdependence between its various segments. One issue causing concern is the use of Computer Reservations Systems (CRS), which are dominated by the main airlines, generating fears that clients seeking accommodation will be initially directed to airline-owned hotels. The EC has already agreed a regulation covering this topic and industry umbrella groups have been liaising to discuss difficulties.

The nature of the hotel industry is such that imbalances between supply and demand are generally localised in either time or space and invariably lead to variations in prices and in profit levels. Surpluses and shortages in "time" are most common. Thus, in 1991 a general downturn in tourism demand resulted in good deals for consumers but substantial losses for many hotels, particularly in the United Kingdom where hotel re-possessions reached a record high. Similarly, seasonal variations in demand for hotel rooms result in generally lower prices (or additional value-added in terms of special incentives) in many rural and resort hotels in the off-season, while many urban hotels are also capitalising on the growing short-break market to boost overall occupancy in hotels which are filled by weekday business travellers. Capacity imbalances in particular locations may also result in variations in profits around normal margins, while in certain cases, for example major sporting fixtures such as the Olympic Games, where both time and supply constraints put very strong upward pressure on prices.

The prices of hotels, particularly in the moderate/comfortable category, rose very sharply in Europe's major cities during the second half of the 1980s. The increases in price vary widely across cities reflecting different supply and demand conditions. Data collected by Business International indicates that the price of a single room in the moderate/comfortable category in Madrid rose nearly sixfold between 1985 and 1990. Price levels and changes in the EC's capital cities, however, reflect local supply and demand imbalances and particularly local property prices. In absolute terms, London hotels were the most expensive over the period 1985-90, followed by Paris.

Operating profits in recent years have generally been higher in chain-affiliated hotels than in their independent counterparts and this gap is expected to widen. Analysis by Kleinworth Benson in the United Kingdom indicates very substantial differences in trading margins and profits per room between affiliated and unaffiliated hotels. The importance of scale, particularly marketing-based economies, is being recognised by many small hotels and increasing numbers are becoming affiliated to voluntary associations or taking the franchising route. Horwath International analysis suggests profit levels expanded alongside demand in European hotels during the second half of the 1980s.

EC hotels cannot compete with most of their extra-EC counterparts in terms of price alone. The labour intensive nature of the industry ensures that hotels in less developed countries such as the Far East and Africa have a strong competitive advantage. Thus, EC hotels are often reliant on the tourism strengths of their location. Quality is also important. For example, in East European countries, cheaper prices are gener-

ally counter-balanced by quality considerations, not alone of the hotels in these locations but also of other local facilities. Improvements in this respect mainly as a result of ongoing investments by the major chains will remedy many of these deficiencies in the more developed East and Central European countries. The cost of travel to many non-EC destinations is also a prohibitive factor, as demonstrated by the increasing popularity of Asian locations. Reductions in the costs of long-haul travel can be expected to divert more tourists from competing EC resorts in the medium term. In addition there are worries, particularly in southern Member States, about potential cost increases as a result of ongoing EC integration reducing competitiveness relative to neighbouring destinations such as Turkey and Cyprus, although recognition of these concerns has been an aid to HOTREC in achieving concessions for hotels on VAT rate approximations and may arouse similar sympathies on the expected implementation of the Social Action Plan.

Production process

The services provided by hotels vary widely across the industry. At one extreme hotels may simply provide accommodation only, although this is relatively rare and a mixture of accommodation, restaurant food and retailing of alcoholic beverages is most common. However, the variety of services being provided is wide and includes banqueting, health and leisure facilities, a variety of business services, shopping, bureau de change, conference facilities, laundry facilities and touring services.

The hotel industry has traditionally been highly labour intensive, including substantial use of part-time and female workers. Increased automation is, however, apparent, particularly in northern Member States where problems with labour retention and the attraction of new workers are sharpest. The introduction of the 5 day or 40 hour week, night shift compensation, with weekends and holidays to enjoy, lure people away from labour intensive jobs with unsociable hours. Many hotels and chains have introduced innovative programmes to tackle recruitment and retention problems. These programmes involve improving the image of hotel work, implementing better working conditions, and evolving training and reward systems geared at enabling personnel to move within the industry with clear career paths. They also entail improved co-operation with schools in terms of curricula and their selection of candidates. While the Single Market process will increase the reservoir of labour available to the hotel industry, greater mobility and higher expectations may accentuate staff retention problems.

Increased use of technology - yield management and CRS, front office systems, in-house entertainment, improved kitchen equipment - is contributing to greater skill requirements for hotel staff rather than displacing labour. Among the most important of these is yield management. This involves applying basic economic principles to pricing and controlling room inventory for the purpose of maximising revenues. What makes contemporary yield management different from traditional pricing practices is the frequency and scope of the decision-making process. Advances in computer technology support immediate measurement of market forces and the practical application of economic theory. These techniques make it possible to update prices for all future arrival dates to match the market's demands each day and to tailor prices to different demand segments. Leisure traffic is normally price sensitive and books early, while business travellers are less price (but more quality) sensitive and tend to book late. Yield management enables the anticipation of late demand and the offer

of an appropriate number of rooms at the higher rates these guests are willing to pay. Yield management systems are also useful for market information purposes, indicating where business comes from, when it is repeated and allows deduction of the crucial factors affecting decisions.

Driven by economic developments, the spread of large chains, the growing complexity of the industry's market and the availability of sophisticated management information systems there is a growing trend towards more professional management in the industry. This is reflected in labour saving strategies, such as the increasing number of hotels offering buffet breakfasts.

INDUSTRY STRUCTURE

Companies

Generally the hotel industry is fragmented but the importance of large hotel chains has increased considerably over the last decade. While many of these chains have brought a homogeneity to the industry in many European countries, the structure and importance of the hotel industry differs across Member States.

Nevertheless in terms of bed places offered there is considerable concentration in the European market. The top ten chains operating in Europe provide as much capacity as the next forty chains combined. It should be noted, however, that while the incidence of bonded chain hotels is increasing, in some cases these are run by independent hoteliers on a franchise basis. Pressure for increased size comes from economies of scale in marketing, greater ability to meet the trend toward market segmentation with a complete range of differentiated services and advantages in covering a range of major destinations in any specific area. The strength of the chain to invest in CRS is another factor which will shape the industry in the coming decade, although advances in technology will increasingly enable smaller hotels to avail of CRS.

In identifying the world's top hotels the International Hotel Association (IHA) distinguishes between three different types of hotel company - corporate chains, with a strong brand identification, professional hotel management companies (HMCs) and voluntary chains and associations. There is overlap between these categories. For example, Best Western, a voluntary group is included among the corporate chains because of strong brand image while many of the larger corporate chains have their own HMCs which may run the hotels of other groups in certain locations - Scotts Hospitality have recently come to an agreement with Marriott Corporation to run 13 UK hotels formerly marketed as Holiday Inn properties using the Marriott's budget brand Courtyard and the right to develop further properties using other Marriott brand names.

By global standards the top EC hotel companies are not as large as North American based chains, but are larger than their Asian counterparts. The 1991 listing of the world's top corporate chains in 1990 by the International Hotel Association (IHA) included eight North American based chains in the top ten, although the top corporate chain, Holiday Inns, is owned by a UK brewing conglomerate, Bass Plc. Similarly, the top ten second tier management companies listed by the IHA included only one EC company, the UK-based Queens Moat Houses Plc. However, reflecting the continued importance of small hotels in Europe the IHA listing of voluntary chains and associations had six EC-based companies, including the top three, among the top ten in the world.

Strategies

The most important developments in the hotel industry in recent years have been the expansion of the chains/voluntary associations and segmentation of hotel properties into branded

products each aimed at specific clientele. While different levels of service and quality across hotels has always been a feature of the industry, segmentation within the major hotel chains has resulted in increasingly distinctive products. It is also argued that too many brands within some chains may lead to customer confusion. Segmentation in Europe is not as advanced as in the USA but has increased substantially, to the extent that nearly all major hotel chains now have a range of differently specified products. For example, the French-based Accor/Wagon Lits group, which has a presence in nine EC countries, has a highly developed set of branded products, ranging from the four-star Sofitel to the one-star Formule 1. Through its recent acquisition of Wagon-Lits the expanded company now owns the latter's stable of brands, including the budget chain Primo 99.

The fastest growing segment of the market are the budget and "no-frills" establishments. Greater economic cohesion within the EC, and demand from Eastern Europe, are expected to contribute to increased demand for low-cost, no-frills establishments. As well as Formule 1, other budget and no-frills chains include the French sister companies Campanile and Premiere Classe, Forte's Travelodges and Holiday Inns' Garden Court. Segmentation is not solely based on simple price/quality features and includes resort hotels and those specialising in the growing conference market.

Consistent delivery of good service, particularly for business travellers, is the key element to maintaining loyalty as repeat business is the most cost-effective way of generating profits. Marketing, sometimes in partnership with other hotels or upstream services is a key strategy element in generating new business, but as articulated by Thomas W. Storey, executive vice-president of Radisson Hotels International "We have calculated it costs 15 USD to get a new trial guest and 2.50 USD to get a repeat guest".

While business travellers and some sections of the long-haul tourist market tend to find the uniform hotel product reassuring, many leisure travellers look for something more distinctive. The discussion on demand trends in the industry suggests that there is need for a wide range of products to catering for increasingly diverse forms of demand. The more a hotel can differentiate itself from its neighbour, for example by reflecting the special character of its surroundings, the more it is likely to appeal to the discerning guest. Similarly, with the growing importance of short-break holidays many hotels are becoming the central element in a package of accommodation and leisure activities designed to attract short-break guests, particularly in the off-season. Many resort and medium-sized hotels are also adding attractions such as fitness centres and other forms of all-weather entertainment.

Catering for new and alternative forms of tourism, such as activity holidays, also requires many hotels to re-think their strategy vis-à-vis non-hotel accommodation. Evolving packages to attract these new tourism market segments may involve coordination with other tourism and leisure facilities in the locality and other forms of accommodation. Cooperation between hotel groups is also a feature. For example, in order to improve its marketing in Europe Radisson has co-operated with SAS hotels, Mövenpick Hotels and Concorde Hotels. Similarly, cooperation between smaller hotels has resulted in segmentation, generally with a stronger leisure dimension, through the formation, or expansion of existing, voluntary chains.

While the top hotel groups in the EC are predominantly EC-owned, in general large hotel chains are international in character. Two of the top chains, Hilton and Holiday Inn, originated in the USA but have recently been purchased by UK companies. In post-1992 Europe the financing and building of hotels will ease with free movement of capital. The political and economic

changes related to the completion of the EC Internal Market and to German reunification should have a positive "ripple" effect on hotel investment. However, there are factors, a less buoyant demand outlook than during the late 1980s and the effects of the recent downturn in demand, which suggest many investments will be in existing premises. In addition there is probably already a sufficient number of hotels in most major EC locations to cater for increases in demand, suggesting most investment will be in the form of conversions and extensions of existing properties.

Discernible trends indicate takeovers are the preferred expansion mode. As current players seek further economies of scale and/or expansion into new markets, takeovers provide a better entry point than starting from scratch on unfamiliar territory. There have been a number of high profile mergers over the last year including that between Accor and Wagon-Lits, although a proposed merging of Air France and Lufthansa's luxury Meridien and Kempinski chains has been scaled back. Extra-EC hotel chains such as the US-based Marriott Corporation, ITT Sheraton and Radisson and Far Eastern chains such as Nikko, Seibu Saison and Aoki are also seeking to expand into Europe. Seibu Saison have recently purchased Scandinavian Air System's 40% share of Inter-Continental hotels having originally brought SAS in as a partner when they purchased the groups from Grand Metropolitan, while Aoki almost purchased Swissôtel. In general and with a view to the longer-term, Japanese investment has tended to aim for vertical expansion - hotels, restaurants, leisure facilities etc. - rather than a significant market share in a particular sub-sector, although the slump in stock market prices in Japan has slowed the flow of investment to Europe.

Similarly EC-based chains are expanding more across national borders as the gear up for closer European integration. For example, during the second half of the 1980s the UK hotel and hotel management company Queens Moat Houses expanded from a mainly UK base to the extent that 45% of its business is now in continental Europe. Encouraged by saturation in their domestic market, US chains are also likely to increase investment in the EC to improve their share in a market on which they are not in a leadership position. With increasing investment from large chains there is a danger that this concentration may threaten the competitive position of the many small, independent hotels and restaurants that create the uniqueness of the European tourism product. Such fears may be misplaced and smaller independent and efficiently run hotels should be able to establish themselves in their own profitable niche. Retaining traditional ambience and intimacy with their clientele are important marketing characteristics, but small hotels should pay adequate regard to modern marketing, technological and management practices. These practices may include investments to upgrade quality, and cooperation with other tourism enterprises and other hotels in promotion, reservations systems and information systems.

Airport locations will continue to provide prime locations for both expansion and the development of new hotels, although increasing emphasis on high-speed rail links should draw both business and leisure travel from the airlines, suggesting that railhead locations will also see new investment. Continued growth in business and leisure travel will also stimulate new investment in hotels at large business parks and in resort areas. Even Spanish resorts which have suffered from stagnant demand during the second half of the 1980s may see further investment as new demand from Eastern Europe materialises - Iberotel, for example recently announced that they were concentrating on development in the Mediterranean rather than the Caribbean and the Far East. Increased investment in budget hotels may also see traditional European heavy construction giving way to prefabricated units.

The opening-up of Eastern Europe is attracting considerable investment funds as there is a substantial supply deficiency, particularly of three star hotels. Some investment may be diverted from EC countries although it is expected that the bulk of the diversion will be from developing countries (with the exception of Asia). Another concern is that while elimination of restrictions on mobility of capital may encourage the large-scale investors, small operators may well continue to be hampered by the reluctance of banks and other financiers to inject cash into an industry which many do not understand. This will add to the concentration of the industry and the weakening of the independents.

REGIONAL DISTRIBUTION

Location has traditionally been considered the most important element governing the supply of hotel services. In general, hotel location follows demand rather than stimulating it, although there are exceptions. Thus, hotels are predominantly located in cities, specialising in business travellers, and in resort areas, specialising in tourist traffic. These factors, particularly the latter have led to significant variations in the distribution of hotels across Member States and within Member States. For example, the largest hotel in the EC is located in the Canary Islands.

ENVIRONMENT

Regulatory pressure on the hotel industry in relation to environmental issues is not extensive at present. There are three major pieces of environmental legislation which are, or will when they are adopted, affect the hotel industry. These are the requirement for an environmental impact assessment which is required for large projects, liability for damage caused by waste and the obligation to clean up contaminated land. The latter two are not yet in force and in general their impact will not be excessive. However, there is an expectation that regulatory pressure may increase with requirements for improved waste management and more consideration to how well hotel structures blend in with their surroundings.

The International Hotel Association (IHA) recently held a conference on hotels and the environment where the president Helga Holgersen warned of stringent regulations if hoteliers did not work to improve their environmental records. Identifying the environment as a key tourism asset and also noting that hotels may save on costs and gain in consumer goodwill, the IHA has identified environmental issues as a key concern for its members. An annual "environmental award" is presented each year in association with American Express, while more recently twelve environmental new year resolutions for 1992 have been drawn up. These resolutions cover the spectrum of environmental issues affecting hotels including care in planning and designing new projects, energy conservation, waste management, emission of pollutants and sensitivity towards ecological habitats, local populations and culture/heritage issues.

There are a number of key areas where hotels can improve their environmental record. In particular the construction of new hotels in terms of energy conserving design, materials chosen, location and blending with surroundings. With hotels already designed there is also considerable scope for improved waste management both through recycling and energy conservation. As with the yield management systems which are contributing to better pricing, management information systems are also enabling better control of costs including those with environmental implications. Demand size management (DSM), for example, is increasingly being used to control expenditure on energy costs and to extract more out of existing facilities. Attention to such details has been motivated by escalating power plant construction costs, excessive lead time to build new plants as well as the public's increasing environmental concerns (pollution, ozone depletion and greenhouse effect). With regard to such aspects the IHA is working

Table 13: Hotels
Expected real annual growth rates

(%)	1992-93	1992-96
Turnover	5.0	4.0
Employment	3.0	3.0

Source: Fitzpatrick Associates

on an environment code for existing hotels and for new construction. Hotels groups are also cooperating to promote good environmental practice. Hilton, Inter-Continental Hotels, Marriott, Meridien, Ramada and Sheraton are among a number of groups which recently signed an environmental charter for the industry covering areas such as waste management, product purchasing, air quality, energy conservation and noise pollution.

REGULATIONS

Hotels are subject to a wide variety of regulations both on local, national and European level, relating to health and safety, hygiene, sale of alcohol, planning permission and consumer protection. At EC level there is a range of measures which indirectly affect the hotel industry, such as the Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC), a body of measures covering the protection of workers, workers' residence permits, environmental regulations and data protection legislation. The industry is more directly affected by the 1986 Council Recommendation on fire safety in hotels (86/666/EEC). The Package Holiday Directive stipulates in article 5 that the package tours organiser is liable to the consumer for the proper performance of the contract, in all aspects including hotel safety (without prejudice to the right of the organiser to pursue other supplies of services). The result is that those in the industry responsible for organising tours are applying pressure and calling for more binding regulations on hotel safety. Also, while some are calling for standard classification system for hotels, a number of hotel organisations are resisting.

Regulations on competition policy, particularly on abuse of a dominant position and state aids also potentially affect the hotel industry. However, as noted the hotel sector is generally regarded as relatively competitive and has not been the subject of attention from competition authorities. With regard to state aids, the hotel industry in quite a number of Member States, particular those in the south, received substantial state aid for infra-structural investment. This has not been contested by other sectors or hotel interests in other Member States - often part-funded by the EC 's European Regional Development Fund such finance is generally regarded as regional aid and as such allowable under existing regulations.

Initially, proposed changes on VAT harmonisation would have increased hotel prices and reduced competitiveness relative to extra-EC destinations. This was a particularly worrying prospect for Mediterranean Member States whose hotel prices were also under pressure from prospective EC legislation on other areas, particularly in relation to working conditions. Furthermore, these Member States faced direct competition from non-EC Mediterranean destinations such as Cyprus, Turkey, Malta and north African countries. Swayed, among other things, by these factors, hotel services are now included among a list of goods and services to which the Member States may apply a reduced rate of VAT.

OUTLOOK

The hotel industry has experienced relatively steady growth over the last decade, with temporary downturns, such as in 1991, reflecting the underlying vitality of their demand base. Over the next decade global demand for both tourist and business accommodation will continue to grow at a relatively rapid pace. However, the EC's share of global tourism revenue is likely to decline slightly while the EC hotel industry will also face stiff competition from alternative forms of accommodation and from more adventurous and more demanding tourists. The industry has the capacity and the flexibility to tailor its products to suit changing demand, as evidenced by the substantial changes which have occurred over the last decade. Value for money is another emerging criterion among EC tourists but adoption of new technology should enable hotels to provide better service and more targeted marketing while keeping costs from rising, although there will be pressure on labour costs from both a regulatory end and from dwindling supply. Growth in guest-nights in 1992 should pick up substantially in 1991 and remain steady, at 4% per annum over the following three years.

Written by: Fitzpatrick Associates
The industry is represented at the EC level by: Confederation of the National Hotel and Restaurant Associations in the EC (HOTREC). Address: Blvd Anspach 111, Bte 4, B-1000 Brussels; tel: (32 2) 513 6323; fax: (32 2) 502 4173.

Other accommodation
NACE 667

The other accommodation sector is made up of a large number of diverse types and sizes of establishment, dominated by the smaller operator. The demand for this type of accommodation is predominantly from tourists and tends to be domestic in nature. Growth has continued in the other accommodation industry as demand has moved away from traditional package holidays and towards more independent ones. Concentration within the industry is very low and the range of products in terms of cost and quality is very diverse. There is very little regulatory pressure and many of the smaller establishments, which are not recorded, can operate without constraints. Overall relatively slow growth is expected during the 1990's however some areas where new products have been developed will fair better than the traditional establishments.

INDUSTRY PROFILE

Description of the sector

The non-hotel accommodation sector encompasses a wide variety of establishments in terms of type, size and services provided. This sector includes camping sites, caravan parks, hostels, guest houses, bed and breakfast, social tourism establishments, rural tourism establishments, apartments, second homes, time-shares and integrated resort developments. Services offered by this sector range from simple accommodation with basic amenities to integrated resorts with restaurants, bars, shopping malls and health and leisure facilities. This diverse sector tends to overlap with the hotel sector. At the lower end of the sector small bed and breakfast establishments provide accommodation and simple meals. At the top end of the sector European organisations provide integrated resorts and timeshare accommodation. The former overlap with the hotel sector at the lower end of the market while the latter compete with the mid-range hotels. Within the separate categories of the non-hotel sector the services provided vary widely. Thus campsites may provide restaurants, bars, swimming pools and other leisure amenities or just basic facilities.

Main indicators

Due to the diversity and size of the sector official statistics on the turnover and value added in different EC countries do not exist. The use of different definitions of other accommodation throughout the EC make it difficult to make comparisons and obtain main indicators for this sector. Eurostat data on other accommodation provides detailed information on camping and tourist village accommodation establishments. However, data on other categories such as holiday dwellings and social tourism establishments are far from complete. Much of the data on camping and tourist villages is based on classified campsites and therefore under estimates the number of establishments and bed places.

France followed by the United Kingdom and Italy have the largest number of camping and tourist village establishments (see Table 1). However, the figure for Germany is based on tourist villages. Research by GFK Marktforschung Gmbh ("Camping and caravaning 1989"), indicates that Germany is also a main market and has an additional 2 000 campsites. Spain has the largest number of holiday dwellings, however, this figure must be treated with caution as it includes a large number of small establishments.

While the paucity of the data hinders cross sector comparisons, Eurostat data indicates that most of the bed places provided by the non-hotel accommodation sector are located in campsites and tourist villages. France provides the largest number of bed places followed by the United Kingdom and Italy. Whilst Spain has a very large number of holiday dwelling establishments it provides slightly fewer bed places than the United Kingdom (see Table 2).

Incomplete and slightly dated data on overnight stays in camping sites, from a GFK report on camping and caravaning, indicates that this sub-category of the other accommodation industry is most important for France, followed by Italy and Germany. Comparable information for the United Kingdom and the Netherlands is not available and the data for Portugal, Greece and Ireland are considered seriously under-recorded.

Self-catering accommodation, which includes rented flats, villas, chalets, cottages and single rooms is reported to represent the largest sub-category of non-hotel accommodation. Since a large proportion, perhaps 50%, of self-catering accommodation is let unofficially, it is impossible to obtain exact numbers. The data that exists suggests France, Spain,

Italy, Greece and Portugal lead in the provision of such accommodation.

Approximately 460 000 European families constituting 1.5 million holiday takers own their own timeshare in over 700 holiday resorts. Most of these timeshares are situated in Spain followed by France, Portugal, the United Kingdom and Ireland. This category also includes gîtes which are generally rural properties let as holiday homes. France has the greatest number of gîtes followed by Germany and Italy (see Table 4).

While Spain has a relatively small number of gîtes it has over 90 000 officially classified furnished flats. In the United Kingdom, Ireland and Germany, bed and breakfast accommodation is very popular. Again there is little accurate data on the number of establishments and many of them are unrecorded.

Recent trends

It is difficult to gauge developments on an EC wide scale due to the lack of accurate information. Eurostat figures on growth in the number of bed places provided by camping and tourist villages indicates that the number in Spain increased by almost 50% between 1985 and 1990 while the number in Greece rose by over 20%. Over the same period the number of bed places fell by almost 70% in the Netherlands and by almost a third in Germany.

Social tourism accommodation increased between 1985 and 1990. In Belgium there has been steady growth, in Italy strong growth in the mid 1980s was followed by a steady decline, whilst the limited data for the United Kingdom indicates strong growth.

The timeshare sector has also shown strong growth with the number of households owning timeshare holidays in Portugal increasing by fourfold and the number in Spain nearly doubling.

International comparison

Usage patterns of non-serviced accommodation in the EFTA countries are comparable to those of the EC states; EFTA countries generally have high standards of accommodation with Scandinavian countries, particularly Sweden, noted for chalet style accommodation located in forest surroundings. Though no EC comparable data are available for the USA, the touring market there is very large. Americans have pioneered the recreational vehicle market and standards and levels of provision for mobile tourists in the USA are very high.

Foreign trade

There is insufficient data to ascertain a breakdown of non-hotel bed nights in terms of "imports" and "exports". Even if this data were available the large number of establishments that are unrecorded would undermine its accuracy. The proportion of "camping tourists" from outside each member state is typically in the range 30% to 40%. The ratio in Greece and Luxembourg is believed to be considerably higher.

MARKET FORCES

Demand

Demand for non-hotel accommodation is strongly linked to tourism demand, much more so than for hotels. Most of the non-hotel accommodation users are leisure travellers, with business travellers tending to use this type of accommodation when hotel accommodation is unavailable. The low level of business demand results from the nature of the accommodation which is generally booked well in advance, by the week rather than the day, and is at the lower end of the accommodation market.

Increasing incomes and discretionary leisure time are predominant factors determining the propensity of people to take holidays and use other accommodation. Both disposable income and available leisure time increased in the EC Member States during the 1980s. These changes have stimulated the demand for other accommodation. Much of the demand for other accommodation, particularly camp sites and rented accommodation, comes from family groups and tends to be linked to domestic tourism.

For a variety of reasons including income levels, the weather and the attractiveness of their own country as a tourist destination, the nationals of southern Member States of Greece, Portugal, Spain, Italy, and France are more likely to holiday in their own country. Thus much of the demand for other accommodation tends to be domestic in nature. In northern Europe, particularly Germany, the United Kingdom and the Benelux countries, there is higher demand for foreign holidays as travellers seek better climate and cheaper holidays.

The demand for other accommodation tends to be highly seasonal in nature and essentially limited to the warmer months, although winter sports generates demand for self-catering accommodation, particularly in the French Alps. There has been growth in activity and sporting holidays reflected by the overall increase in leisure and health and fitness of Europeans. Approximately 10% of all holidays taken in Europe are built around a specific activity or sport. This seasonality results partly from the nature of the product, thus camping and caravaning holidays are more suited to the summer months, as well as to institutional factors such as school holidays which determine when families can take their holidays. Holiday parks of the style developed by Sun International ("Sunparks") and Neckermann ("Center Parcs") have proven a highly successful formula by providing facilities such as sub-tropical swimming pools, saunas and high standards of catering able to generate high occupancy level throughout the year. Such formulae are also tailored to the growing popularity of short-break holidays.

The demand for other accommodation tends to be linked to the independent traveller and the trend away from package holidays towards the "go as you please" holidays should favour the other accommodation sector. The demand for campsite accommodation is strongly correlated with the use of cars as the transport mode. A recent survey by the European Travel Monitor considered the mode of transport used for international trips. This indicated that international tourism from Luxembourg, the Netherlands, Germany and Belgium tends to be car based and therefore more likely to use other accommodation. Very few international tourists from Ireland, Greece and the United Kingdom use car for even part of their travel, which indicates a lower demand for other accommodation. The opening of the channel tunnel is likely to stimulate international car travel between the United Kingdom and mainland Europe, which should in turn increase demand for the non-hotel accommodation industry as UK residents avail of the opportunity to tour Europe without incurring the expense of car-hire.

Citizens of Denmark, the Netherlands, France, Belgium and Luxembourg tend to have higher caravan ownership and would therefore tend to have a greater demand for campsite and caravan park accommodation.

The demand for social tourism accommodation is most prevalent in France and Belgium where a certain part of the population who are unable, generally for financial reasons, to go on holidays are encouraged to do so. Under social tourism schemes accommodation is made available for people in low incomes, pensioners, large families and the handicapped. The schemes either provide holiday vouchers or aid for constructing tourist facilities. In France vouchers are distributed by the Agence Nationale pour les Chèques-Vacances (ANCV). These vouchers are accepted by 30 000 establishments and more than 2.5 million French people benefited from the scheme. In 1990, 190 million FF or two fifths of the expenditure was spent on other accommodation with the majority spent at social tourism establishments and rural gîtes. There is still potential for growth in social tourism since there is

latent demand for this type of holiday and for the associated accommodation.

The rapid growth in short break and week-end holidays has led to an increase in the demand within some sectors of the other accommodation market. Generally this sector will not benefit to the same extent as the hotel sector since many of the establishments are not suited for short breaks, and would not attract the higher income groups that can afford second holidays. The demand for caravan parks, campsites, holiday apartments is not likely to rise significantly. Integrated resorts and bed and breakfast style accommodation are more suited for short breaks and demand for this type of accommodation has increased as a result of the growth in the short-break market.

At present demand from eastern European countries is very low. It is expected that tourism flows from these countries will increase rapidly as their economies improve. However the low income levels in these countries will lead to a higher proportion of holiday makers using non-hotel accommodation, with the demand for budget accommodation such as campsites increasing.

The majority of EC holiday makers travel to the seaside, over 50% in 1985, and their holidays are very weather dependent. Nearly a quarter of all Europeans spent their holiday in the country. These holidays tend to be less weather dependent. Rural tourism has shown stronger growth than sun and beach tourism. In France where rural tourism has been promoted by the government 80% of visitors are travelling independently, 20% are foreigners, and 30% are on short-breaks.

The demand for non-hotel accommodation amongst long-haul travellers is generally very low. The industry has therefore not suffered as much as the hotel industry from the decline in US visitors associated with the Gulf War and the recession in the USA. The growth in long-haul tourism originating in the Member States is unlikely to have much impact on the non-hotel accommodation sector since many of these tourists would not have used this type of accommodation.

Supply and competition

The supply of other accommodation varies dramatically within segments of the industry. Integrated resorts and timeshare developments tend to be capital intensive with organised management structures. Similarly apartments and villa based establishments tend to be capital intensive and many of them are marketed through travel agents and as part of package holidays. At the lower end of the scale campsites and caravan parks tend to be less capital intensive whilst temporary accommodation in bed and breakfast establishment may be provided by altering the use of existing buildings rather than constructing new ones. Barriers to entry in the integrated resort and timeshare markets exist in terms of the high set up costs and the long lead in time associated with purpose built resorts.

At the lower end of the market, in particular campsites and caravan parks, the set up costs are much lower and market entry is easier.

The supply of other accommodation tends to be seasonal in nature and a number of caravan sites and non-hotel accommodation establishments operate at full capacity in the summer while providing limited or no accommodation in the winter. There therefore tends to be over capacity for much of the year and shortages at peak times. In contrast integrated resorts, theme parks and timeshare accommodation provide service all year round and use significant price differentials in order to spread demand.

The supply of social tourism accommodation is dependent upon state funding and many of these establishments are in need of modernisation and upgrading. This segment competes with the commercial accommodation sector and is seen by some as unfair subsidised competition. However, this type of accommodation is aimed at a particular market segment and is designed to stimulate latent demand rather than divert existing holiday-makers.

A number of non-hotel establishments providing similar services to hotels, tend to compete with hotels towards the lower end of the market. Thus tourists might be faced with the choice of hotel or self-catering apartment. Competition within the bed and breakfast market has lead to improved quality and has thus brought about more direct competition with hotels.

Tourists in the non-hotel accommodation sector are clearly becoming more demanding and expect higher standards of comfort and facilities (e.g. sanitation, catering and sports facilities). In France, for example, around one fifth of camping sites have a swimming pool and/or at least one tennis court. The trend is therefore to improve the quality of the facilities and services supplied by the industry. There is, however, still considerable divergence both within and between Member States.

(1) Estimates
Source: European Caravan Federation

Competition in the non-hotel accommodation varies between Member States. In some Member States the market tends to be mainly domestic and the consumers choose between different regions. The other accommodation sector in southern Member States tend to attract a higher proportion of foreign visitors. It is estimated that nearly 70% of campsite users in Greece are from abroad. There is therefore an element of competition, particularly between other accommodation situated in coastal areas where the foreign tourists are sun seekers and less concerned by the cultural and heritage aspects of their holiday.

The opening of borders with eastern Europe has increased the competition for non-EC accommodation. This new market appears to be diverting visitor flows away from EC Member States. ETIC data indicates that nearly 7 million international trips were made from EC countries in 1990. A recent report for the EC Commission by IPK Munchen found that east European countries such as Hungary, Poland, Romania, Czechoslovakia, and Bulgaria generate healthy balance of payments surpluses on their tourism accounts.

Production process

The services provided by non-hotel accommodation vary widely across the industry. At one extreme campsites and caravan parks may provide a pitch or area of land as well as basic amenities, other establishments such as self catering apartments may provide accommodation while integrated resorts often have restaurants, bars, shops and health and leisure facilities. The variety of facilities and services being provided means that the production process differs significantly throughout the industry.

Campsites and caravan parks tend to be the most land intensive. Generally the industry is not as labour intensive as the hotel industry, since there are fewer services for the residents and there is usually an element of self catering. Many of the workers tend to be part-time, for example at campsites and ski resorts, and in the smaller establishments, such as bed and breakfast, family and female labour is used. The integrated resorts tend to be more labour intensive and the skills are similar to those in the hotel industry.

The majority of the establishments are not technology intensive. Some sectors such as theme parks which provide other accommodation use computer reservation systems (CRS), as do the apartments and villas which are marketed as part of a package holiday. Many small operators rely on local adverts or links through tourist agencies. Smaller pensions and bed and breakfast rely upon guide books and literature rather than travel agents.

INDUSTRY STRUCTURE

Companies

The pattern of campsite and caravan park ownership varies within the EC. In France, municipal authorities have traditionally been a major force in the ownership of camping sites but more recently the private sector has increased its presence and now has 54% of sites and 60% of pitches. Private sector sites are overwhelmingly in the hands of small businessmen typically running just one site although some of these may operate a number of sites within a region. The industry is very fragmented and dominated by a large number of small enterprises. There are a number of larger players who run organised campsites where the camping equipment is provided on site. For example Haven Spain and France Holidays, a subsidiary of the Rank Organisation which also owns the Butlins holiday resorts, offers 37 parks in Spain and France varying in size from under 250 to over 500 pitches. Similarly Keycamp holidays offers 75 campsites throughout Europe including mobile homes.

The integrated resort sector of the non-hotel accommodation industry has developed over the last 10 to 15 years. This represents a much more concentrated sector. The leading developers of health and leisure centres have been Dorent in Germany, Gran Dorado, Sun Parks and Center Parcs in France and Benelux, and the Sandcastle Centre and Center Parcs in the United Kingdom. The concept is highly developed in the Netherlands where the market is dominated by Center Parcs, in the United Kingdom the demand is still uncertain. In 1990 there were over 400 000 villa rentals and nearly 2.1 million visitors in the Benelux properties.

Club Med is an upmarket tourism product designed for those who enjoy activity holidays. It is based on a system of holiday villages and Club Med currently has around 105 holiday villages with a capacity of close to 68 000 beds in 34 countries around the world. Europe accounts for 55 villages and 38 390 beds (see Table 10).

The new Euro Disney resort in France is the largest theme park to have been developed in Europe and offers non-hotel accommodation including 14 rustic lodge sites with over 1 000 rooms and 400 wooden cabins. France has a further 35 recreational parks and 30 aqua parks. In the United Kingdom many of the theme parks are geared to day trip or the short break market and generally don't include accommodation, examples of this are Blackpool Leisure Beach and Alton Towers in the midlands.

Social tourism initiatives tend to be concentrated in Belgium and France. The VVF (Villages Vacances Familles) in France provide subsidised accommodation and has a capacity of 186 villages with a total of 67 000 beds and an annual turnover of 190 million FF. VVF was largely instrumental in setting up Euro-villages, which now has members in France, Belgium, Germany, Switzerland, Italy, Spain and Portugal.

Strategies

The general strategy within the other accommodation industry has been to improve the quality of the accommodation and facilities. Campsites now offer swimming pools, sporting facilities and even cinemas and discos.

The concept in the more sophisticated integrated resorts has been to transfer the ambience and environment of tropical resorts to northern European locations. These resorts also tend to be of a higher quality than the traditional resorts with swimming pools, tennis courts, restaurants and comfortable accommodation.

These resorts also tend to be more activity based with numerous sporting and leisure facilities, and most importantly of all a guaranteed environment all year round. The primary target group is families with small children.

The success of the timeshare establishments is largely due to their ability to offer exchange location. This initiative means that the owner does not have to return to the same resort every year. They are able to exchange their accommodation for another resort by using the services of the exchange companies. For example the owner of a timeshare in Tenerife may choose a holiday in France

REGIONAL DISTRIBUTION

Traditionally the location of other accommodation establishments has followed demand rather than leading it. Unlike hotels, other accommodation tends not to be concentrated in major cities, but is rather located away from these centres. This reflects the close ties with tourism traffic and in some cases the industry's dependence on climatic factors. The distribution of other accommodation establishments varies from country to country and depends upon the nature of demand and the type of establishment. Camping and caravan sites, and to a lesser extent second homes and timeshare accommodation, are generally located in coastal areas.

The emphasis for many of the other accommodation not found near the coast is rural areas. These include caravan and campsites as well as farmhouse accommodation. Theme parks such as Center Parcs and Sun Parks are not as dependent upon their location as they are activity based and generally self contained. Center Parcs in the Netherlands and the United Kingdom tend to be located in rural and forest areas.

ENVIRONMENT

In general the non-hotel accommodation sector has developed without major damage to the environment. Many of the subcategories such as rural tourism, camping and caravaning depend upon their location and environment as a major selling point. There is however scope for other accommodation establishments to become more environmentally friendly. Since

many of the users are independent travellers there tends to be a high proportion of car usage associated with this type of accommodation. A green paper from the EC indicates that the use of car as opposed to rail or bus increases congestion, produces more pollution and is a less efficient use of energy. At 25% occupancy levels railways use less than half as much energy per passenger kilometres as small engined cars. There may be scope to develop alternative modes of transport or to spread the peak season so that some of the negative environmental impacts associated with the car are reduced.

Under new EC legislation, an environmental impact assessment is required for large infrastructure projects. Since many of the non-hotel accommodation establishments are either small in nature or not capital intensive this is unlikely to have an impact on these areas of the industry. In the case of the development of integrated resorts and timeshare resorts there may be a need to increase environmental awareness. However, these resorts benefit from a clean environment and it is in the interest of the developers to ensure that any new developments blend in with their surroundings.

One area where the non-hotel sector has had a detrimental impact on the environment is in overcrowded holiday resorts where a large number of apartment blocks, generally linked to package holidays, have been crammed into coastal locations. Examples of these may be found on the Costa del Sol in Spain, in the Algarve in Portugal as well as on a number of Greek Islands.

There exists therefore a potential to improve the environmental record of some of the other accommodation sectors. The construction of new establishments might be controlled in terms of density, materials chosen, location and more sensitivity to the regions heritage and natural/historic environment.

REGULATIONS

Caravan parks and campsites are affected by a number of regulations both locally and nationally. These regulations vary across Member States but tend to cover the use of the parks in terms of the maximum number of pitches, the minimum size of the site, adequate drainage of the site, access to and within the site, car parking provision associated with the site as well as toilet and water facilities. In Ireland, for example, the minimum number of lettable pitches is 20, the density of the pitches should not exceed 20 per suitable acre, there should be one car parking space per pitch, a suitable hard standing service for caravan pitches and a set number of toilet facilities and water outlets depending upon the size of the park. In Spain the camping regulations are under the authority of the autonomous region, in Italy there are some common requirements nation-wide as well as regional legislation on the campsites within each region.

Regulations generally limit the proportion of fixed facilities that may be allocated to holiday parks, 15% to 20% is a typical ratio. The attractions to the operator of developing fixed facilities lie in the higher rent and profit levels available. There are a large number of parks which cater for fixed facilities, the caravan and mobile home owners usually pay an annual rent for the site. These parks are not regulated in the same way as touring or tourist parks since they are not open to tourist, they are however subject to similar regulations.

Caravan parks and campsites along with other accommodation establishments are governed by national regulations covering sanitary services, fire services and safety, food hygiene, and where appropriate licensing regulations related to the sale of alcoholic beverages. As well as these national regulations there may be a number of local regulations with which the establishments must comply. Examples of these include government planning and development acts, and local by-laws on access roads, and sewage disposal.

Generally the non-hotel accommodation is regulated in terms of the amount it may charge for the facilities it provides. The scale of charges for different types and sizes of accommodation are normally regulated at a national level.

Some of the larger accommodation providers within the other accommodation industry may be affected indirectly by EC regulations. The recent directive on package holidays may well affect a number of the suppliers providing apartments, villas, chalets or other accommodation as part of inclusive tour packages. Within the package holiday directive tour operators may be held liable if customers are not satisfied with their accommodation or if the facilities are not a true reflection of those advertised.

Forthcoming consumer legislation on access to computer reservation systems (CRS) may affect the way in which package holidays incorporating other accommodation products are sold. A proposal for a Council Directive on timeshare has been submitted on 2 July 1992. One of the fundamental problems is that national legislation cannot cover sales practices in another jurisdiction. In the United Kingdom the Office of Fair Trading (OFT) investigated the techniques involved in the sale of timeshare accommodation. The recommendations from the United Kingdom and Spain include the development of more acceptable practices including a cooling off period and the option to withdraw from the sale within seven days. The UK's minister for consumer affairs is now discussing the matter with the European Commission in order to seek the establishment of European law pertaining to timeshare sales throughout the EC.

Regulations on the harmonisation of VAT, will increase the price of non-hotel accommodation and reduce competitiveness relative to extra-EC destinations. However like the hotel sector the rate of VAT applied over the transitional period will be at the reduced rate which has not been agreed yet but will exceed 5%.

OUTLOOK

It is difficult to provide an outlook for the non-hotel industry as a whole. While the demand for other accommodation in some Member States has experienced relatively steady growth over the last decade, for example in France, Spain, Greece and Italy, in others, such as Germany and the Netherlands, growth has been more static.

There is also variation within different sectors, with lower growth and in some cases a decline in the traditional holiday resorts in Spain and Portugal, and strong growth in theme parks and integrated resorts in northern Europe. While the development of timeshare accommodation slowed towards the end of the 1980s the number of owners is forecast to grow from approximately half a million in the early 1990s to around 1.5 million by the year 2000.

Over the next decade global demand for non-hotel tourist accommodation will continue to grow at a relatively rapid pace. Increased leisure time and disposable income coupled with more diverse products is likely to lead to an overall increase in demand. The general movement away from traditional resort holidays may adversely affect some areas of the

industry but generally increased growth will result from the shift towards more independent holidays and the demand for more adventurous holidays.

The shift towards new, higher quality and year round products is likely to continue. The use of CRS and the development of activity and theme holidays around non-hotel accommodation packages will attract new clientele and ensure that value for money is maintained without a loss in quality. Growth in guest-nights in 1992 should pick up substantially on 1991 and remain steady, at 6-7% per annum over the following three years.

The industry is represented at the EC level by: Confederation of the National Hotel and Restaurant Associations in the EC (HOTREC). Address: Blvd Anspach 111, Bte 4, B-1000 Brussels; tel: (32 2) 513 6323; fax: (32 2) 502 4173.

Travel services
NACE 771

Although 1991 was a difficult year for many companies involved in the travel services branch of the travel and tourism industry, there are indications that the public is turning more towards the trade to book travel arrangements. However, as travellers become more sophisticated in their demands, the inclusive tour package (IT) is losing favour to individually tailored products. Trends in both the business and leisure travel markets suggest value for money is an increasingly important criterion. The future success of individual companies in the sector will depend largely on their ability to meet these changing demands and this, in turn is likely to be linked to their ability to stay ahead of technological developments in the field and to strengthen their presence throughout the EC by acquisitions, mergers and other collaborative ventures.

INDUSTRY PROFILE

Description of the sector

The activities of the travel and tourism industry do not fit readily into standard international definitions. Operations and activities of the travel services branch which can be said to comprise retail travel agencies, tour operators, ground handling services and even car rental are often indistinguishable from other related sectors of the industry. As car rental is covered in chapter 2415, it is not discussed in this chapter on travel services. There is considerable vertical integration in the European travel industry. Hotels, airlines and other transportation companies all can and do have their own tour operating subsidiaries, developing either fully inclusive tour packages or partial package arrangements to help fill airline seats or hotel rooms.

Moreover, the majority of travellers, whether business or leisure, do not use the services of tour operators or travel agents to make their travel arrangements. They either book their transportation direct with airlines and other suppliers, or travel by private car, the dominant mode of transportation in Europe. A significant share of hotel and other accommodation reservations are also made directly. In addition, other organisations provide part of the services available from companies in the travel services branch. These include motoring associations, tourist offices and non-profit bodies such as trade unions, clubs, company staff associations and media groups. In some EC states, there are "social tourism" organisations which provide low cost holidays.

The difficulties in evaluating the importance of even the core sector activities are compounded by the fact that relatively few companies release operating figures, let alone consolidated results. The industry can be measured in terms of number of sales passengers/clients or volume of sales. The latter terminology is also confusing, since there is frequently no distinction made between real turnover and sales volume. Passenger figures in relation to travel agency sales cannot be readily equated with the number of holidays sold by travel agents, since the real value of the agent's sale is only the commission. Employment poses further problems, since employment in the tour operating and ground handling service sectors is highly seasonal and, therefore, fluctuates widely with no common conversion factors for part-time to full-time jobs.

The distinction between business and leisure travellers has always been difficult to identify and is becoming more so with the disappearance of border controls. Balance of payments data are generally used to measure the currency flows generated by travel and tourism. Often they provide an inaccurate measure since data collection methodology and analysis vary widely from country to country. With ongoing liberalisation of exchange controls, it has become even less useful.

Profiles of the leading travel and tourism groups in the travel services branch illustrates that the industry generally not built on a combination of the three core sectors (tour operating, retail travel and ground handling), nor even with an emphasis on one or two of them. In fact, only one of the top ten groups in the industry in the EC is wholly focused on this sector.

Main indicators

The only comparable data on the economic contribution of travel and tourism in the different EC Member States, and in the other countries, concerns the travel and tourism industry as a whole. A good source of information is the latest WTTC Report "Travel & Tourism in the World Economy". The 1992 edition is the second of an annually conducted study commissioned by the World Travel & Tourism Council from the WEFA group (Wharton Econometrics & Forecasting Associates). It estimated that there were 14 million people employed in the travel and tourism industry in the EC in 1990, generating gross output of 590 million ECU of which 290 million ECU was value-added.

According to the European Travel Monitor there were over 200 million outbound trips in 1991, over half of which involved some kind of bookings through the travel trade. About 30% are fully inclusive tour packages (ITs), usually off-the-shelf programmes developed by tour operators, and 23% of trips involve either part package arrangements, or transportation and/or accommodation booked through a retail travel agent. An additional 12% or so concern arrangements for transportation or accommodation booked directly with suppliers, and the remainder are fully independent trips, which have no prebooked arrangements.

Relative shares vary widely across markets but in general, the share of fully inclusive package tour arrangements has been slowly declining since the late 1980s, in favour of partly booked trips. This trend has been particularly marked in the low budget sector of the market, notably for trips from northern Europe to the traditionally popular sun and beach holiday spots in the Mediterranean.

Airline ticket sales channelled through IATA's (International Air Transport Association) Bank Settlement Plan (BSP) also provide an indication of the use of travel agents. The net sales volume of airline tickets issued by the BSP around the world in 1990 was 26.6 billion USD. Countries in Europe generating the highest sales volume through BSP were the United Kingdom, Germany and France. However, the decision by IATA to broaden the customer base of the BSPs and to encourage participation by other travel industry service suppliers such as railways, shipping lines, car rental companies, etc. means the figures are not totally reflective of travel agency sales alone.

Data on turnover in travel agencies and tour operating enterprises is available from the European Community Travel

Agency Association (ECTAA) for a limited number of EC states. This indicates that turnover is highest in the United Kingdom, although the relatively low level indicated for the former West Germany casts some doubt on comparability.

Recent trends

Data on travel agency operations do not always distinguish between wholesaling and retailing activities. In a number of EC countries, there is little difference between a tour operator and a retail agent. Figures released by the European Community Travel Agency Association (ECTAA), the grouping of national travel agents' associations within the EC, indicate that the retail travel agency sector is expanding slowly. This evidence is not conclusive, however, and may reflect increasing membership of national organisations.

On the other hand, analysis of travel agency sales of airline tickets indicates significant growth both in the volume and the number of locations. The United Kingdom, however, is an exception, in that significant growth in sales was accompanied by a decline in the number of locations.

The apparent increase in number of travel agencies in the EC has been accompanied by growth in employment in some Member States, particularly in Spain, Italy and Portugal.

The recession and Gulf War had a significant impact on the airport bookings sector in 1991. This sector, which accounts for between 20 to 30% of the total market, is very high yield. But sales through airport offices and concessionaires were

down by 15 to 20%. Nevertheless, rental operators are seeking to extend their airport presence in anticipation of a return to a period of air traffic growth.

International comparison

Europe attracted close to 62% of worldwide international visitor arrivals in 1991, or 277.4 million, down 2% over 1990. Despite continued growth in arrivals and revenues, Europe's relative share of world tourism has been declining since the early 1960s. While data from the World Tourism Organisation (WTO) indicates that western Europe's share rose between 1980 and 1985, it fell back rapidly over the latter half of the decade to 52% in 1990. Five EC countries are in the top ten international tourism spenders, with Germany number two in the world after the USA.

Foreign trade

European inbound tour operators, handling incoming business from overseas markets, claimed increases in revenues and client numbers of up to 30% from 1987 to 90, although the Gulf War and the economic recession in major markets like Japan and the USA resulted in a decline in inbound visitor arrivals in Europe in 1991.

In the majority of cases, global estimates of travel to Europe can only be extrapolated from national visitor arrivals' and outbound travel statistics. Most visitors to Europe cover more than one country on their trip and are often counted twice by one country in Europe such as when they use the same country as gateway and departure point. So individual destination arrivals cannot just be added together. Airline statistics, where available, cover all passengers and not just those resident in the respective source markets, and visa statistics are difficult to obtain and frequently unreliable. Moreover, a significant share of long haul visitors do not use the services of the travel trade.

EC countries generated about 72% of the total international trip volume of 202 million from all European countries in 1991. This was 1.4% down compared to the previous year. The EFTA countries and Eastern Europe accounted for 14% each. Foreign travel accounted for an estimated 21% of trips (1990 data), although the relative share of foreign trips varied sharply from market to market.

In terms of destination share of travel and tourism, EC countries attract an estimated 58% share of all European trips. Although there has been a decline in Europe's share of worldwide international tourism, the region's importance as a tourist destination for travellers from outside Europe has continued to grow year by year.

MARKET FORCES

Demand

The final consumers of the travel services product are all those who take holidays or who travel on business although there can be intermediaries, such as clubs and associations, or corporations buying on behalf of their travelling staff. Official data on travel demand are difficult to compare country

by country. Private sector sources of statistical information do exist, but these data are generally confidential, reserved for paying clients.

60% of the Europeans take at least one trip a year, of one night or longer away from home. The level of trip-taking varies widely from country to country, ranging from as high as 87% in Iceland to 51% in Portugal, and still lower in the countries of Eastern Europe. The proportion of Europeans who take a leisure or business trip abroad tends to be considerably lower. The average share of all Europeans who travel abroad is around 26%, although the level of travel abroad is actually higher than domestic travel in some markets, notably Belgium, Luxembourg, the Netherlands and West Germany. Domestic travel tends to decline in favour of foreign travel as the market becomes more travel experienced.

The level of trip-taking is very much affected by income, educational and social status. When income rises travelling tends not to be limited to just one trip per year. In addition, business travel is usually much more frequent than leisure travel. In the less mature European markets, the cost of travel is also an important deterrent to foreign holidays, especially for markets located at great distances from the popular holiday destinations, like Greece and Portugal.

Most business travellers use the services of the travel trade for airline travel, though it is fairly common for corporations to deal directly with hotel chains when they can get a better deal for room accommodation, and with the railways and car rental companies for ground transportation. New technology is opening up the tourism industry, as well as improving communications. This can have both negative and positive effects. On the one hand, it is easier for people to book their own travel directly with airlines, hotels and other suppliers. On the other, travel agents are better able to respond to the increasing demand for more tailor-made products. While dedicated software enables access to information on travel and accommodation to the travel section of large corporations, only travel agents and airlines can issue tickets. This has helped maintain the role of travel agents in the face of technological developments but in the medium term there may be pressure for allowing large corporate access to blank tickets. Similar constraints have lessened the impact of information systems such as Minitel on travel agency sales, although Air France flights can be booked directly with tickets purchased at airports.

The extent to which Europeans planning holidays in or outside their own countries will use a travel agent depends heavily on how they plan to travel, what type of accommodation they will use and whether they speak the language and/or are familiar with the destination country. The majority of domestic holidays bypass the travel services branch completely, with people travelling by car to their destination and staying with family, friends, in their own or rented holiday accommodation.

A number of different factors have affected demand for travel and for travel services. Price is among the most important, as are political factors, the different taxes on travel, notably on air travel, and exchange rate fluctuations.

Increased airline liberalisation will allow greater access to markets by a greater number of carriers. It will put downward pressure on fares, compensating for possible VAT increases, but on many routes it is difficult to see fares falling below current levels. The increasing liberalisation of air transport in Europe in the run up to 1993 generated increased competition, resulting in an enormous passenger traffic growth generated since the mid 1980s. This has caused severe capacity constraints and delays at airports, dissuading some people from travelling by air.

Health risks and environmental damage are also examples of factors affecting tourism demand. There have been increasing concerns over dirty beaches and polluted bathing waters in the Mediterranean and other popular tourist resort areas and a desire for improved quality. Some travellers have shunned tour operators and destinations that have received bad publicity over their environmental record.

A lack of suitable products has impacted on demand from certain sectors of the market, particularly older people. The travel trade is well aware of the ageing of the European population, but the 55-plus age sector of the market is not always well understood.

There has been a wide range of new products and programmes introduced on the market over the last few years in Europe. These have both helped to stimulate travel and tourism to less developed regions and to encourage a better off-season utilisation of facilities. However, most of these new products have been targeted at people who already travel at least once a year away from home for holidays or other leisure purposes. Few have addressed the issue of people not travelling at all. The result has been an increase in number of trips per person travelling and notably, an increase in trips abroad. But the share of Europe's population that does not travel has changed very little. One of the fastest growing sectors is the short break market or trips of one to three nights. The bulk of short break travel does not use the travel services branch, but there has been strong growth in the commercial sector. Not just tour operators, but also airlines and hotel groups have launched their own programmes. Rural and urban tourism have also registered above average growth in the last couple of years, both in domestic and international markets. And in general, travellers are becoming more adventurous and activity oriented.

Shifts in demand towards long-haul travel are a two-edged sword for the travel services industry. On the positive side long-haul travel arrangements are more likely to be booked through an agency, but on the negative side the economics of long-haul charters are such that they are often relatively less profitable (more expensive "empty-legs" to cover at the beginning and end of the season). Increases in long-haul travel into Europe will benefit ground-handlers and car-hire.

Supply and competition

Supply is in general more than adequate to meet demand. There is clearly no shortage of travel agencies or tour operators from which to choose. The suppliers of the travel and tourism industry (i.e. airlines, hotels, etc.) are cyclical industries and this can have repercussions on the availability of seats and rooms at peak seasons. On balance, consumers are in a buyer's market and this is reflected in price-setting and margins.

Travel services for corporate travellers on business trips can cover a wide range of products, not just transportation tickets and hotel reservations. Car rental, theatre and restaurant bookings, visas, the provision of travellers' cheques and foreign currency are all part of the package of services offered. There are also increasing expectations for these services, in terms of price advantages and quality, since corporate travellers provide frequent high yield business.

Demand for travel services from leisure travellers is met by tour operators and/or retail travel agents. Car rental bookings are either handled by travel agents, or direct by suppliers. The tour operator is effectively a wholesaler combining travel, accommodation and ground handling services in a single package. The increasing independence and sophistication of leisure travellers are reflected in the product range.

The travel and tourism industry is highly price sensitive in most EC states. This appears to be less the case in countries where the industry is more fragmented. The price/quality trade-offs are also not the same for all groups and all nationalities. Pressure on prices comes from the nature of the demand, but also from the nature of the production process. The industry gains pricing advantages from bulk buying. But it has to ensure

Table 7: Travel services
Leading travel and tourism companies in the EC according to turnover, 1991

(million ECU)	Turnover 1991	Financial year ending
TUI	2 590	10.91
Wagons-Lits	2 171	10.91
Thomson	1 644	12.91
NUR	1 220	10.91
LTU (2)	1 130	12.91
Club Méditerranée	1 115	10.91
DER	1 056	12.91
ITS	963	10.91
Havas	958	12.91
Owners Abroad	916	10.91

(1) Figures for Club Méditerranée and Wagons-Lits are provisional. Figures released by TUI, NUR, LTU, DER, ITS and Havas are not consolidated in accordance with EC or international standards. TUI includes turnover of all groups in which it has less than a 100% stake pro rata to the turnover. This probably overstates the TUI performance. Figures for the other groups are more closely correlated with normal consolidation practices
(2) LTU has since acquired Thomas Cook from the Midland Bank.
Source: The Western European Package Travel Industry; EIU 1992

that once it has factored in its own operational costs staffing, catalogue production, advertising, computer reservation systems, travel agents' commissions the end result is a product which is still competitive with the product the consumer could put together himself.

Competition forces operators to keep price increases to a minimum, and this is achieved through bulk buying of seats and rooms, in some cases owning several stages in the production process, and by switching more capacity to and promoting more heavily lower cost destinations.

Production process

The main capital good employed, except in cases where the travel company owns its own aircraft or accommodation, is access to computerised reservation systems (CRS). The cost of these can range from a few thousand ECU to tens of millions, depending on the solution adopted. There is constant pressure to upgrade technology. Leading operators aim to provide real time connections with the consumer through travel agents (or their own sales outlets) with instant confirmation of bookings. In addition to the costs of CRS access, hardware costs and expenses for dedicated data lines, travel agencies in some Member States also require substantial finance for government "loading" schemes.

Besides the employment of quality management, the travel agency industry EC wide attracts counter staff who are generally relatively unskilled and badly paid. The industry attracts labour because of its glamorous image and the perceived possibility of free or low cost foreign travel. Labour turnover tends to be high as this perception is frequently not realised, or the realisation is not sufficient to compensate for the disadvantages of the job. Major travel agencies train their own staff, but much training is on the job, or through familiarisation trips to destinations or on courses run by tour operators. The tour operator sector and ground handling companies require seasonal workers, generally with human relations and language skills, to work at destinations during the season. No labour cost data are available and value added concepts do not apply.

Product innovation in the business travel sector takes the form of improvements in comfort, speed of service and of travel, and in flexibility at competitive prices. One significant new development in the industry in the last five years has been the merger of networks among business travel agents, as an alternative route to international expansion. EC travel agents are prominent members of these. The two largest are Business Travel International (BTI), incorporated in the Netherlands, and Internet. The EC members of BTI in mid 1992 were Holland International (NL) and its Belgium subsidiary Transintra, El Corte/Ingles (E), Hogg Robinson (UK), Havas Tourisme (F), Hapag-Lloyd (D), International Travel Bureau (IRL) and Kuoni Travel (I). The European members of Internet are ABR, DER and Rominger of Germany and Gastaldi Tours of Italy.

Innovations in the travel agency sector for the leisure traveller are primarily in improved computerisation. For the tour operator, there is constant innovation through the addition of new accommodation, new destinations and new products like short breaks, one-day plane trips, visits to Euro Disney, and to sporting and cultural events.

INDUSTRY STRUCTURE

Companies

There are no composite figures on the turnover of the travel services branch, nor on employment or number of companies, though it is clear that the sector is growing over the EC as a whole. Travel agencies and many tour operators are members of trade associations, but travel agency membership may be by branch or by parent company, so the figures are not homogenous. The EC travel agents association, ECTAA, groups the national associations. The European Tour Operators Association (ETOA), which comprises mainly inbound interests, and the International Federation of Tour Operators (IFTO), which comprises entirely outbound interests, include mainly the largest companies as members.

Major changes among the leading European travel and tourism groups in the last few years suggest that there has been increased concentration in the tour operating and retail agency sectors. This is reflected in the shares of the leading operators in individual EC countries, notably the United Kingdom, Germany and France. But, in fact, impressions might be slightly deceptive as far as the whole of the EC area is concerned.

In 1991, according to an EIU Special Report, "The West European Package Travel Industry", the top ten groups, in terms of turnover and excluding companies in the travel agency business only, accounted for 63% of the estimated 18.65 million ECU turnover of the top 50. Another study from Dafsa/Eurostaf suggested that in 1986, the top ten groups in the same categories accounted for 65% of the total turnover of the top 50 groups.

As the data are not strictly comparable, these figures can only be taken as broad indicators, and the difference cannot be regarded as statistically significant. The number of groups in the top half represented 86% of the top 50s' turnover in 1991, which was almost the same as 5 years ago (84%). The only clear shift appears to be among the three leading groups, whose share has actually dropped from 34% to 30% over the same period.

There are a number of non-profit organisations in the sector. These include organisations such as Villages Vacances Familles (VVF) in France, the Deutsches Familienwerk in Germany, Loisirs et Vacances in Belgium, and IGS in Spain. Several of these have significant leisure travel operations, including tour operating. VVF is the largest.

A number of the major travel companies are owned by public sector enterprises. The largest are DER (owned by the German Railways) and CIT in Italy (by the Italian Railways). There are also a number owned by or affiliated with state-owned or state-controlled airlines, in particular Air France, Alitalia and Iberia.

Strategies

Despite the relatively constant pattern of concentration, there has nevertheless been considerable change at the top in the travel industry over the last five years, largely as a result of acquisitions. Growth in the domestic markets of the leading companies has been slowing, particularly for the tour operators. The growth in the tour operating business is currently in Spain, Italy and Portugal. German travel companies are finding growth in the five new states of eastern Germany. According to the German travel trade magazine, Fremdenverkehrswirtschaft (FVW), these markets accounted for 5.1% of German passengers and 4.5% of German-sourced tour operating turnover of the leading four companies TUI, NUR, LTU and ITS in 1991. There has been no consensus on strategies, however. A company-by-company description of the top ten highlights this clearly.

The top ten groups hold varying interests, not only in the three core areas of the travel services sector (tour operating, retail travel and ground handling), but also in related services, including hotels and catering services, car rental, airlines (owned by the group, e.g. in the case of the German LTU, for flights to holiday destinations, or through minority participation, e.g. the French Club Méditerranée), or railway sleeper services (in the case of Wagons-Lits in Belgium). Not two of the top ten groups look alike because of different specialisation. The top ten includes TUI (D), Wagons-Lits (B), Thomson Travel (UK), NUR (D), LTU (D), Club Méditerranée (F), DER (D), ITS (D) and Havas Tourisme (F).

The picture of who chooses to invest in this sector of the industry is also equally varied. TUI is controlled by a group of travel agencies (DER, Hapag-Lloyd, ABR and others); Wagons-Lits is now owned by a hotel group (Accor); Thomson by a printing and publishing group (Thomson of Canada); NUR is owned by a retailing chain (Karstadt); LTU by its founders and by the Westdeutsche Landesbank, as a significant minority shareholder; Club Med is a publicly listed company with a number of financial institutions, as well as American Express of the USA and the Japanese Seibu Saison group, among its minority strategic shareholders; DER is a subsidiary of the German Railways; ITS is another subsidiary of a retailing chain (Kaufhof); Havas is controlled by a communications group and has a property company as a significant minority shareholder; Owners Abroad is a publicly listed company in which institutional investors have significant minority stakes.

All the companies in the top ten, except DER, have made major acquisitions in the last five years. In some cases, the acquisitions were in domestic markets (Thomson, Owners Abroad, LTU, Club Med, Havas) but in others, they were in other EC and non-EC countries.

EC acquisitions include TUI's purchase of a substantial minority holding in Arke Reisen of the Netherlands; a restructuring of TUI's interests in France with a subsequent increase of its stake in Viajes Ecuador of Spain by Wagons-Lits; purchase of a controlling stake in Travelplan of Spain by ITS and by ITS' subsidiary, Holland International, of a controlling stake in Transcontinental and Transintra of Belgium; purchase of the Belgian Sunsnacks by NUR. LTU and Club Med have entered into a joint venture. There has also been some major divestment, such as by Havas Tourisme of its travel agency interests in Belgium.

The travel services branch has been highly segmented by national market until now. Only two of the market leaders, Wagons-Lits and Club Med, have brand names which are recognised EC wide, and only these two and DER operate in most EC countries. As of mid 1992, two, Owners Abroad and Thomson, were not represented in any way in the core sectors outside their own domestic markets.

In expanding into other EC markets, the competition for market shares and for the companies these groups have been buying comes from other European groups, and mainly other EC groups. There are only a handful of large non-EC groups in this field. These include American Express; Kuoni Travel of Switzerland; NRT Nordisk of Sweden; SAS Leisure of Sweden; and Hotelplan/Interhome of Switzerland.

The fact that there are a number of companies operating both as tour operators and retail travel agencies incoming and outbound in a several EC countries highlights the fact that regu-

lation does not seem to be a major reason why many EC travel and tourism groups have not expanded outside their own national borders. The main reasons would seem to be cultural barriers to transplanting their products and the fact that domestic markets have been expanding fast enough to satisfy the companies' need for growth. But there are major regulatory differences in areas such as consumer protection and conditions of market access. These are addressed by the EC Package Travel Directive, due to take effect on January 1, 1993.

Significantly, travel agencies which are essentially selling someone else's products, allowing them to adapt the products offered to local market needs, have expanded into other EC countries much faster than tour operators. The latter generally have to develop a tailor-made local product which accommodates local tastes in food, eating hours, type of accommodation, transport mix and quality, all of which are highly variable.

REGIONAL DISTRIBUTION

Many of the medium sized firms only have a regional catchment area. Specialists in some segments, such as coach holidays, can operate profitably from a local base. Although there are areas where the density of travel agencies is lower, this is not a major issue. On a Member State basis the density of travel agencies is highest in Germany and lowest in France.

Many tour operator products are available by mail and bookings can be made direct by phone and through viewdata systems. This method of distribution is especially popular in France and notably, for last minute sales bargains. It is expected to become more widespread as viewdata ownership expands throughout the EC.

ENVIRONMENT

There is evidence that the final consumer is becoming increasingly sensitive to the impact of travel and tourism on the environment, although this is not yet true in all countries. In Germany and the UK, where the package travel markets are the most developed, it is now common for large companies to appoint executives responsible for the company's environment policy and for the monitoring of destination hotels' energy conservation and other environmental practices. Hotels which do not comply with basic minimum standards can be struck off a tour operator's hotel listing. Catalogues are increasingly being printed on recycled paper and tour operators issue clients with guidelines as to how to preserve and protect the local environment at holiday destinations.

Travellers are more and more aware of the impact of tourism on the destinations they visit, although this concern has not yet translated into apparent concern over the type of transportation chosen to travel on holiday i.e. rail as opposed to car or plane.

Major tour operators also work behind the scenes, particularly in developing countries, to help local authorities plan sustainable resort development. Thomson has also been heavily involved in encouraging the recycling of some of the Balearic islands' mature resorts. The main specific regulatory pressures inside the EC come from environmental impact assessment or land use requirements for tourism developments. Regulations on night flying also affect the industry.

REGULATIONS

One of the main regulatory issues affecting the industry is increased consumer protection legislation, mainly through the EC Package Travel Directive, that comes into force on January 1, 1993. This will impact EC companies very differently because it is only a start towards harmonising highly varying national situations, and one which also leaves considerable discretion to the Member States in the implementation process. Other issues include the future of duty-free sales in the EC, the imposition of VAT on the industry's products, airline deregulation, environmental limits on resort developments, and transport policy.

OUTLOOK

While the average holidaymaker's yearning for sunshine, allied to a certain price-sensitivity, will ensure the traditional Mediterranean favourite resorts continue to top the popularity lists, the two-week inclusive package holiday (IT) geared to lying on a beach in the sun will probably not be enough to satisfy the market's increasingly sophisticated demands in the medium term future.

IT sales can be expected to stagnate, or decline, for short haul travel, although long haul travel could become more and more organised since it is often less expensive to take a long haul package than to try to organise such a trip independently. Choice of destination could increasingly be determined not simply by market demand or tour operator programme availability, but by capacity restraints and bottlenecks in destination countries and on airline routes.

Changing demographics will also have an impact on travel demand. But some of the greatest changes in the market are likely to be not so much demographic as psychological in nature. Personal values, such as having fun, relaxation and self-fulfilment, are becoming more important.

With increasing leisure time - a shorter working week, more part-time employment and more flexible working hours - this is likely to stimulate demand for travel and use of the travel services sector. However, while air travel is finally starting to filter down to the masses - reflected by the growth in the increased traffic through Europe's regional airports - there are still an estimated 40% of Europeans who do not travel at all. A significant share of non-travellers probably would like to travel if there were no economic or timetabling constraints. A number of new products need to be developed and measures taken, either by local or national governments, to stimulate this sector of the population.

The future success of individual companies in the sector will depend largely on their ability to meet this need for new products, as well as changing demands from increasingly sophisticated European travellers. This, in turn is likely to be linked to their ability to stay ahead of technological developments in the field and strengthen their presence throughout the EC by acquisitions, mergers and other collaborative ventures.

The European car rental market remains highly fragmented in terms of the customer base. Opportunities exist for expansion through both increased penetration in established markets and expansion into eastern Europe. However, in the short-term the focus is likely to be on improving customer service to improve board loyalty, particularly with business travellers.

Transport services
NACE 7

Transport is essential for the working of the economy. It is part of the whole production process from input to delivery to the customer. Its importance extends well beyond that of its 4% share of Gross Domestic Product. Transport services mirror economic activity and interaction. Increasing European integration will lead to more interaction and thus to more transport demand, of which service suppliers will benefit. Common policies for transport will help create a competitive environment. More competition will force the suppliers to invest heavily in modern equipment. Large investments in transport infrastructure are currently in progress. This will create the conditions and opportunities for integration and growth in the future.

INDUSTRY PROFILE

Description of the sector

The transport services industry is primarily engaged in the conveyance of goods and passengers either directly or indirectly. Direct involvement relates to the actual conveyance of goods and passengers by various modes of transport. Indirect involvement relates to such services as handling when changing modes, traffic guidance, travel arrangement, freight brokerage, storage, etc.

NACE 7, the transport and communications industry, comprises the following two-digit classes:

- NACE 71: railway transport;
- NACE 72: other land transport, including urban transport, road transport and pipeline transport;
- NACE 73: inland waterway transport;
- NACE 74: sea transport and coastal shipping;
- NACE 75: air transport;
- NACE 76: supporting services to transport, including inland waterway ports, sea ports and airports;
- NACE 77: travel agents, freight brokers, storage and warehousing;
- NACE 79: communications, including postal and telecommunication services.

It should be noted that the categories above, apart from NACE 79, relate to companies which have as their primary activity transport services. Apart from these companies, however, transport also takes place in other economic units (own account transport) which is not captured in value added and employment statistics for NACE 7. When measuring physical transport activity (e.g. in passenger-km or tonne-km), however, transport in these non-NACE 7 units is included. For example, companies active in manufacturing regularly transport on their own account, as they do not want to rely on external transport services. Similarly, in family households, the use of the private car is not in itself an economic activity.

This leads to a situation where economic transport statistics only relate to companies with transport as their primary activity (excluding own account transport), whereas physical transport statistics relate to total transport (including own account transport). Interpretation of statistics can lead to paradoxical results. The share of own account transport, therefore, should be kept in mind.

Telecommunications and postal services, which comprise NACE 79, are covered in separate chapters in this book.

Recent trends

Total gross value added at market prices generated by the EC transport industry amounted to some 176 billion ECU in 1990, which is approximately 4% of EC GDP (own account transport not included). But the importance of transport in the economy goes well beyond its 4% share. Transport is part of the production process, a fact which is being recognised by a growing number of businesses. "Just-In-Time" delivery is such an example of how transport can be part of the production process. Transport and communication will also play an important role in gaining the benefits of European integration, as they enable interaction between Member States.

The importance of transport as an economic activity varies considerably by Member State. In countries like Germany, France, Ireland and the United Kingdom, the transport share in GDP is below the EC average. For Belgium, Denmark, Greece, Italy and the Netherlands, the share in national GDP is above 4.5%.

Transport value added in 1990 was double the figure for 1980. During the 1980s, value added rose by 7.4% annually (nominal growth). When taking real growth figures for value added into consideration, growth in the beginning of the 1980s amounted to only 1.2% (EC-7; 1980 to 1983). In 1984, a strong recovery in real growth occurred of 4.5%. Since then, growth rates declined again to about 1.7% annually (EC-7; 1984-87).

Employment in transport services amounted to 5.2 million people in 1990 (when including communication services: 7.6 million), which is 4.0% of total EC employment. When looking at the development of employment presented in Table 1, it is obvious that the sector encountered serious problems during the beginning of the 1980s. Between 1980 and 1982, employment declined by 1% per year, with a strong recovery in 1983. Employment rose fairly steadily to 1989, before declining substantially in 1990.

Inland transport services, the total of rail, road and inland waterways, account for 46% of total employment in transport and communication (see Table 3). Sea and air transport take a share of 7%. Direct transport services thus total 53% of

total transport activity. Indirect transport services, the supporting services and other auxiliary services have a share in total employment of 18%. The remainder, 29%, relates to employment in communication services.

In passenger transport, the private car has become the primary mode of transport. This type of transport, takes between 75 and 90% of the market, leaving 10% to 25% to railways and buses and coaches (see Table 4). Over the years, railways and buses and coaches have lost market share to private cars. In general, the use of private cars reaches a saturation level in total passenger transport demand when this market share approaches 90%. Congestion, pollution and a need for low cost public transport generates a minimum requirement of railways, bus and coach services. In general, these needs are met with public transport services which are usually run with the help of government subsidies.

For international passenger transport, airlines have become an important mode for both business travel and tourism. Growth in passenger air transport has been very high during the 1980s, causing congestion problems in the airways and for airports. With high speed rail services, the railways are becoming more and more competitive for medium range distances.

The bulk of goods transport is done by road haulage. This mode takes a share of about 78% in total goods transport activity (air transport and shipping not counted, due to lack of comparable data). Railway services account for about 17%, whereas the remainder (5%) is done by inland shipping. During the 1980s a shift can be noted in this modal split. Rail services and inland shipping lost share to the advantage of road haulage. Road haulage has benefited a great deal already from increasing integration. With its relatively high flexibility, it is quickly able to meet new demand requirements. Furthermore, it seems that growth in the transport of bulk goods, the core business of rail and inland shipping, remains low. Rail and inland shipping do have opportunities, however, in unitised cargo (containers).

Another trend is the increasing importance of air freight transport services. Especially in the field of high value goods and perishable goods, air transport has a competitive advantage with its high speed of conveyance. This service is currently being integrated more and more with express mail service companies.

International comparison

The share of transport and communication in GDP in the EC is similar to that of the USA and Japan (about 6% of GDP including communications services). In absolute numbers, the USA's transport and communications sector is the largest: at 238 billion ECU it is slightly larger than the 223 billion ECU for the EC12 in 1987. The Japanese transport and communications industry, with 128 billion ECU, is small when compared with the USA or the EC.

The distinction between transport and communication for the EC and the USA reveals that between 1980 and 1987, both transport and communication for the EC maintained a share in GDP of 4% and 2%, respectively. In the USA, a shift can be noted: the transport sector lost 0.5 percentage points during this period, while communications increased 0.2 percentage points.

Growth in the three world regions between 1980 and 1987 is also different. Real growth in transport in the EC was higher than in the USA (1.5% versus 0.7%). For the total of transport and communications, Japan surpassed both American and European growth rates.

Foreign trade

Table 6 shows the international payments for EC transport services by branch. Exports in 1989 totalled 76.9 billion ECU and imports, 76.4 billion ECU. Intra-EC trade represented 40% to 42% of total trade. Road freight, rail and inland waterway transport (presented together under the heading "other transport") determine the largest part of trade. In world trade, 43% to 45% is done by "other transport"; in intra-EC trade, 52% to 55%. The larger share in intra-EC trade can be ex-

plained by the greater importance of sea freight in world trade (about one-third of total trade).

On average, intra-EC trade and total trade developed similarly throughout the 1980s. Trade figures for air transport services reveal very strong increases. During the 1980s, growth was on average above 9%; intra-EC trade was actually above 11%. Growth rates for sea freight services were below 5% on average; serious declines in the service trade occurred in 1983 and 1986/87 as a result of economic recessions.

TECHNOLOGICAL PROGRESS

In all subsectors of the transport and communications industry, progress in technology is substantial. It relates to the following items:

- the development of new information and communications technology ("telematics"), leading to new communication services.
- the application of telematics enables considerable improvements in transport service quality. Issues such as vehicle monitoring, goods and parcel tracing, container handling, etc. have become possible due to new applications of information and communication technology (e.g. Electronic Data Interchange).
- several research programs like DRIVE (Dedicated Road Infrastructure for Vehicle safety in Europe), IRIS (Integrated Safety Information and Navigation System) and EURET (Research and Technological Development Programme in the field of Transport) have been carried out with the purpose of improving traffic safety and integrating transport on an European basis.
- energy efficiency and reduction of exhaust emissions.

ENVIRONMENT

For certain emissions of air pollutants, transport is the most dominant source. Transport is responsible for about 80% of carbon monoxide emissions in the EC. For nitrogen oxides and hydrocarbons, transport causes 50% to 60% of all man-made emissions. Furthermore, transport emits 40% of all emitted particulates. Another pollutant is lead, emitted by automobiles burning leaded gasoline.

OECD data reveal a downward trend of polluting emissions by the transport sector in the Netherlands. This is the result of the growing use of more efficient engines, which have better fuel combustion and fewer emissions. The German transport sector was able to reduce carbon monoxide emissions and stabilise hydrocarbon emissions. In France, Italy and the United Kingdom, however, the trend for polluting emissions by transport is still upward.

These developments seem to be at odds with the use of cleaner technologies in most countries and with tighter emission standards, both of which have reduced emissions. Despite this, total emissions continued to grow, as the growth in transport has outpaced reductions in emissions. Furthermore, the stock of transport equipment is renewed only in a gradual way. Cleaner means of transport do not yet constitute a large part of the total stock, but will unquestionably grow in the short- to medium-term. The effect of emission reductions, therefore, must become significant in the coming years.

Table 7: Transport services
Energy consumption and emissions by mode of transport

	Air	Rail	Tram	Bus	Car

REGULATIONS

Most of the EC transport market is currently regulated on a national basis and therefore relatively fragmented. Whereas the domestic markets are regulated, the international markets are almost deregulated. In 1985, a ruling of the European Court obliged the Council to work out a common transport policy along the same liberal lines that hold for the rest of the economy under the rules of the EC.

The implementation of the common transport policy involves two elements:

- freedom to provide services and eliminate competition distortions;
- improvement of infrastructure and production means.

The latter element relates to large investments in infrastructure and new innovations in means of transport. The Community contributes to a number of infrastructure-related projects: the high-speed rail network, the Brenner transit route, the combined transport network of Community interest, the trans-Pyrenean links, the Scandinavian links. These projects fall within the first three-year action programme (1990-1992).

However, this Community programme has limited funds, and there are several projects of a pan-European dimension which are not funded by the Community: e.g. the Channel Tunnel, the Trans-European Motorway, the construction of the Rhine-Main-Danube Canal.

Innovation in transport means is led by European R&D programmes aimed at traffic safety, reductions in energy consumption and in exhaust emissions. The harmonisation of technical standards is currently going on in view of the Single Market programme.

Concerning the first element (freedom to provide services and eliminate distortions of competition), the Commission has made several proposals regarding the establishment of the conditions for cabotage. Most progress has been made on intra-EC road transport. Bilateral authorisations for transport between countries are replaced by EC authorisations after January 1, 1993. The transport ministers have also decided to eliminate all quotas as of the same date. From then on, permission to enter the market will depend on qualitative criteria. On January 1, 1990, the old tariff system within the Community was replaced with a new one which is based on free price fixing.

In inland shipping, there is already a liberal situation on the Rhine River, but initiatives will be taken to extend this to other waterways. Initiatives have also been taken to allow cabotage: each ship with an EC-flag is allowed to provide services within other Member States. This will increase competition on the European waterways.

The railway directive of June 1991 aimed at increasing the access to the railway market by "denationalisation" of track infrastructure as much as possible at the beginning of 1993 and onwards. Free access to the entire EC railway system, however, is only allowed to private companies involved in combined transport. Existing national railways from different countries are allowed to link up under the agreement, giving them access to each others' network. This applies to both freight and passengers. However, in rail transport, cabotage

is not really feasible, as rail companies are forced by technical network differences to transfer transport to another company at the border. New infrastructure with harmonised technical standards may enable the introduction of rail cabotage in the distant future.

As regards the shipping market, in June 1992 the transport ministers decided to deregulate the market in four stages between 1993 and 1999. The first three stages refer to the deregulation of the EC sea freight market. The fourth and last stage concerns the deregulation of the EC market of passenger traffic by sea. There are however some exceptions concerning Greece (temporarily) and strategic goods.

Since 1987, European airlines have been subject to a process of deregulation, which has taken place in three stages. The third stage will be operational as of 1st January 1993. Although it is the most far-reaching package so far, the programme will not bring about a completely deregulated EC air transport market in 1993. It still includes safeguards with regard to the free settlement of fares and a transition period for the introduction of cabotage. Cabotage will only be introduced in April 1997. In the meantime cabotage under condition will prevail.

In the field of regulation aimed at environmental protection, measures concentrate on emissions of exhaust gases and particulates. The general aim is to reduce the burden for the environment caused by the transport sector. The standards for carbon monoxide (established in 1985) depend on engine size and have become effective during the 1988 to 1993 period. One of the consequences of this policy is the use of three-way catalytic converters in gasoline-fuelled automobiles.

Policies in passenger transport aim at reducing private car use to the benefit of public transport. This is being done to alleviate congestion problems on the networks in and between major conurbations in the EC. Additionally, it is beneficial to environmental protection initiatives.

Until now, intra-EC transport has been considered international transport and therefore exempt from value added taxation and excise duties. With the establishment of the Single Market, transport between Member States will become "domestic" and thus subject to one "national" system. In view of the Single Market, the European Commission wants to introduce value added tax and excise duties on international transport services. However, opposition from Member States and the sector itself have postponed initiatives for drafting regulations by the Commission. The Commission has not yet proposed a single VAT rate.

OUTLOOK

The prospects for the EC transport industry are quite positive. With increasing European integration, transport demand is likely to grow both in terms of the volumes of goods and passengers and in terms of the distances to be covered. It is not likely that such growing demand will be covered by own account transport. On the contrary, externalisation of transport and logistic services from existing industries will cause in itself a growth in professional transport services.

Another contributor to growth may be the opening up of the East European economies. It is expected though that during the first years of economic restructuring, only marginal growth in transport demand may occur. Transport suppliers from these countries may not be able to compete with EC companies yet and thus will not be a threat.

Large investments in infrastructure are currently made to extend the network capacity of the various transport modes, as existing networks operate at or above capacity levels. This will create new transport possibilities which are necessary for the growing integration of the EC market.

The Common Transport Policy aims at liberalising and harmonising the EC transport market, and improving the industry's efficiency. This will enhance competition and improve the quality of service offered under the condition of further economic growth.

The growth prospects differ of course for the different modes of transport. Given the long term character of the developments in rail transport, moderate annual growth rates are expected. Freight transport by rail (1%) is expected to grow slower than passenger transport (2%). Road passenger transport is likely to grow a slight 1% per year given the fact that private car use has not yet reached its maximum. Road freight transport is expected to grow much faster (4%) due to the liberalised market and new opportunities, although, tighter environmental regulations will act as a counterforce. Inland waterways transport will maintain its upward trend with moderate growth rates. Seaborne trade is expected to grow slowly in the short term, but faster in the medium to long term. Recovery in depressed markets like transport of steel and iron takes time. Air transport is considered to be a structural growth sector. However, the strong growth figures of the late 1980s are not expected to return in the short or medium term. Rates of 4% for both passenger and freight, however, are attainable.

Railway transport
NACE 71

Railway companies are controlled by single national operators, which precludes competition between individual railway companies and between railway companies and private firms. To increase competition and profitability some countries intend to privatise their railway. Moreover, in 1991 the EC Transport Ministers made the first step to liberalise the EC rail transport market in order to increase competition. The railway sector seeks to increase its competitive power by developing high-speed rail services, which should ultimately (with the aid of the EC) result in an integrated European high-speed rail network.

INDUSTRY PROFILE

Description of the sector

Rail transport services consists of companies which are exclusively or primarily engaged in the transport of passengers and freight by rail. This sector also covers equipment and supplies for numerous activities, including the private railway sector. Not included are: (a) railways which only serve one town (NACE 721.1), (b) repair workshops for locomotives, carriages and wagons (NACE 362.3), (c) local railway companies which operate regular bus services (NACE 721.2) and (d) sleeping cars and restaurant cars (NACE 666). In fact, the single railway companies of the Member States are making up the whole EC rail transport sector.

Throughout the eighties, passenger traffic has increased while freight traffic and employment have decreased. Passenger traffic grew at a virtually constant rate; the rate of reduction in the employment level declined slightly at the end of the reference period. Freight traffic moved downward until 1988, whereas during the period between 1988 and 1990 a very modest average annual growth rate was achieved. However, the number of tonne-kilometres performed in 1990 was less than in 1989. It should be stressed that these total freight figures conceal a structural change away from low value added heavy products to higher value products carried in containers or on road units (combined road/rail traffic). Although the total tonnage of rail freight declined annually with 0.9% between 1985 and 1990, the latter type of traffic grew by around 7.5% per year; its share in total rail freight transport increased from 7.5% in 1985 to about 11% in 1990.

Regarding both passenger and freight traffic as well as employment, Germany's DB, France's SNCF and Italy's FS are the top-3 railways in the EC, accounting together for nearly two-thirds of the total passenger traffic of the EC railway companies and for three-quarters of total freight traffic. SNCF is the single biggest company in passenger traffic; DB is the largest in freight.

As to passenger traffic, the majority (SNCB/NMBS, DB, DSB, RENFE, FS and NS) of the EC railway companies revealed an increase in their passenger traffic in 1990, varying from 2.2% (SNCB/NMBS) to 8.8% (NS); the remaining companies showed decreases (CH, SNCF and CFL and CP) ranging from 1.7% (CH) to 7.1% (CFL) or remained stable (CIE and BR/NIR).

For most of the companies (CH, RENFE, SNCF, NS, CP and BR/NIR) freight traffic was lower in 1990 than in 1989. The decline varied from 1.5% (CH) to 7.6% (CP); SNCB/NMBS, DSB, CIE, FS and CFS) grew with in the range from 1.2% (NS) to 5.2% (CIE). DB freight traffic remained unchanged in 1990.

Data on international passenger rail transport could only be obtained for intra-EC passenger traffic. The information, representing numbers of passengers refer to 1988 and 1989 only. Intra-EC traffic passenger turned out to be only 1% of the total passenger flow. As it can be safely assumed that intra-EC traffic holds the greater share in the total international rail passenger flows of the EC Member States, it can be concluded that international passenger rail traffic plays only a subordinate part in the EC.

Regarding freight traffic, Table 4 reveals that international trade in six Member States accounts for more than 50% of all freight transport. Besides Belgium and Italy, the quantities involved are limited. With the exception of Greece, most international traffic is intra-EC. This also applies to France, Portugal and Spain with international shares varying from 11% to 25%. Germany's rail freight traffic is also 25% international. However, less than half of it is intra-EC traffic. Due to its insular position, the UK has virtually no international freight transport by rail.

The major intra-EC flows are between Italy and France, Belgium and Luxembourg, Belgium and Germany, Germany and France, Germany and the Netherlands and between France and Belgium. These flows account for one-third of total intra-EC rail freight traffic.

MARKET FORCES

Demand

Past developments have not been in favour of the demand for rail transport. Increased private car ownership hit passenger rail traffic severely. Recently, however, the development of high-speed rail services has provided an opportunity to divert traffic from air to rail. Air traffic's comparative advantage over rail transport i.e. speed, is under pressure, because airports and air corridors are increasingly congested, causing considerable delays. The train, which is cheaper than the plane, will become particularly attractive for journeys between 400 and 600 kilometres. For example, on the stretch Paris-Lyon, air traffic's share declined from 30% to 9% after the introduction of the TGV. Moreover, in some EC countries, policy is recently explicitly dealing with influencing the demand for rail transport. Current concern with congested roads, airports

and airspace, as well as with pollution due to road and air traffic, are underlying this change in policy.

Structural changes in the economic structure in the EC countries away from transport-intensive industries such as coal and steel which are of particular relevance to rail transport hit the railway industry severely. Technical and organisational developments in other industries (just-in-time stock management and sophisticated distribution networks) caused a further growing demand for quick, flexible and reliable deliveries of relatively small quantities. These developments were detrimental to rail transport, because of its relative inflexibility and high transhipment. Moreover, lack of integrated, interborder coordination is not stimulating the demand for international rail transport.

Supply and competition

Railway networks are controlled by single national operators. Rail transport services in the Member States can be characterised, to varying extents, by state regulation, the importance of non-commercial obligations and political objectives. Large subsidies from the state generally cover operating losses and/or investment (see Table 5). The special nature of the rail transport system largely precludes competition between railway companies or free market across national boundaries. In order to increase competition and profitability, however, some Member States - Germany, the Netherlands and the UK - intend to privatise their railways. In the UK, this gave rise to interesting developments; four companies disclosed plans for exploiting the government's planned deregulation of British Rail. On the passenger side, Orient Express Hotels, the Virgin Group and Britain's largest private bus company Stagecoach Holdings plan to operate railway services. On the freight side, National Power, the electricity power generator wants to run coal trains to its power stations.

Apart from individual Member States, the EC is seeking to liberalise the EC railway industry. In June 1991, the EC Transport Ministers opened the door to liberalisation when they agreed upon the Directive aimed at increasing access to the EC railway market.

In 1990, labour costs were nearly 55% of total operating costs; the subsidies totalled on average more than 40% of the operating revenue of the EC railways. At the same time, the EC railway companies suffered a joint loss of six billion ECU. With 4.8 billion ECU, DB and FS contributed together amply to this deficit. The 1990 deficit was twice as high as in 1989.

Unit labour cost grew with an average annual rate of about 6% between 1985 and 1990; for total unit cost this growth rate was higher at more than 7%. The discrepancy between the development of the unit labour and total unit cost has particularly occurred since 1988.

Because the "production" of the rail transport services sector is expressed in two different units (passenger-kms and tonne-kms) while employment data are not broken down accordingly, neither total, nor separate (for passenger and freight traffic) data can be produced. However, the basic developments shown in Table 1 indicate an increase in labour productivity in the EC rail transport services sector during the period from 1985 to 1990; the number of passengers increased, whereas the employment level decreased and number of tonne-kms declined.

The international comparison reveals the different function of the railways in the EC, the USA and Japan. Considering the relation between passenger-kms and tonne-kms performed, EC railway companies are important to both passenger and freight traffic. In the USA freight traffic is predominant, whereas in Japan the emphasis is clearly on passenger traffic.

Employment in the EC railway industry is respectively three and one-half and five times as high as in the USA and Japan. Given the passenger-kms and tonne-kms performed, EC railway employment can be considered high.

Railway density in the EC and Japan is virtually similar; in the USA it is 40% lower. The EC railway network is less electrified than the Japanese one, 41% versus 57%. In the USA, electrification is insignificant.

ENVIRONMENT

Railway transport is a relatively "clean" mode of transport, particularly as far as air pollution is concerned. Electric traction allows for different energy sources to be used, preferably toward less polluting primary energy. Available data on cost

and investment in the environment in the transport sector indicate that these are by far the lowest in the railway sector.

REGULATIONS

In June 1991, the EC Transport Ministers agreed upon a directive aimed at increasing the access to the railway market by the "denationalisation" of the track infrastructure as much as possible at the beginning of 1993 onwards. However, the directive is only the first step in the process towards total deregulation of the EC railway market. Free access to the entire EC railway system, however, is (under certain conditions which have not yet been worked out) only allowed to private companies involved in combined transport combined transport, which accounts for only about 5% total freight transport by rail. Consequently, the accessibility for private newcomers will only be marginal, whereas passenger traffic is totally excluded from the agreement.

Existing national railways from different countries are allowed to link up under the agreement, giving them access to each others' network and to the networks of railways in countries separating them. This applies to both freight and passenger traffic. In addition, national railway monopolies would be able to account separately for infrastructure and operating cost.

In late 1989, the Union International de Chemins de fer (UIC) launched the P.A.R.I.S. (Pricing, Accounting and Rolling Stock Interchange Simplification) in order to create recommendations to increase international rail competitiveness and revenues in passenger traffic. The prevailing price structure, therefore, should be removed. It is rigid, complex and unable to respond to specific market conditions and it also makes revenue accounting and settlement slow and inefficient. Further rolling stock interchange rules should be simplified to be better understood and more geared to market conditions. The programme consists of two stages. The first stage ended in September 1990. Recommendations on pricing, accounting and international route management were submitted and ratified in October 1990. Then the second phase was launched, including the implementation of the recommendations from the first stage and to come to further recommendations.

TOWARDS AN INTEGRATED EUROPEAN HIGH-SPEED RAILWAY NETWORK

In 1989, the Community of European Railways (CER), comprising the Railway Authorities of the EC countries and those of Austria and Switzerland, published a blueprint for an integrated continent-wide high-speed network across all European countries to enable rail to compete more effectively against airlines on many major intercity routes. In December 1990, the EC Commission adopted the proposals and the Transport Ministers gave the scheme a favourable welcome. The creation of an optimal Community railway network hinges on new or upgraded infrastructure in 14 key rail corridors, covering a total of 30 000 route-kms (30% new 250-350 km/h infrastructure and the rest upgraded tracks for at least 200 km/h). It was thought that the recommended system could be operational by 2010. This seems optimistic considering the time taken to activate and finish current projects. In addition to the infrastructure investments, technical harmonisation is a prerequisite to maximising the potential of the high-speed train in the next century's European passenger market. Standardisation, for example, will be required for: (1) the electrification system (currently four different systems are operational in the EC: see Table 8); (2) the signalling system (virtually each country has presently its own signalling system) and (3) rolling stock (very different technical concepts are underlying the rolling stock, momentarily in use in the various EC countries.

There is still a long way to go before a fully integrated European high-speed network will be operational. Nevertheless, the projects currently carried out on a national basis, such as the construction of high-speed lines (e.g. in France, Germany and Spain), the upgrading of existing lines for higher speeds and the ongoing construction of the Channel Tunnel offer prospects for the realisation of such a network.

OUTLOOK

Rail's future share in the (growing) European transport services market will depend on its ability to meet customers requirements concerning speed and flexibility.

As for freight transport, the short- and medium term prospects are limited in this respect, because of its relative inflexibility. Moreover, the integration of the European railway system and deregulation of the EC railway market are primarily long-term processes, leaving the market in the short- and medium insufficiently integrated and accessible. Moreover, deregulation of the EC transport market in general will increase competition especially with the relatively more flexible road haulage industry. Therefore, the diversion of freight from road to rail are considered less probable than vice versa, although environmental considerations and congested roads may counteract this process.

Table 9: Railway transport
Expected average yearly growth rates

	1992-1993	1992-1996

Tonne-kms	1.0	1.0
Employment	-1.5	-1.5

Source: UIC, Paris

With regard to passenger traffic, the prospects for rail traffic are better. Improved railway services on the one hand and current concern with congested roads, airports and airspace as well as with pollution due to road and air traffic may favour rail transport. Moreover, high-speed rail services will be increasingly competitive with air traffic on distances between 400 and 600 kilometres.

With relatively the best prospects, passenger traffic by rail is expected to grow at a faster rate than freight traffic. However, no dramatic development for either of category of traffic is expected in the short- and medium-term, given the long- term characteristics of the developments that would favour rail transport. Passenger traffic, therefore is expected to grow by 2% per annum, both in the short- and medium-term; For freight transport an annual increase of 1% is predicted in the short- and medium term.

Furthermore, the rationalisation process is expected to continue, which will further reduce the employment level in the EC railway industry. The forthcoming privatisation of the railways in Germany, the Netherlands and the UK will also contribute to this decline. Privatisation of the Bundesbahn will for example cost 30,000 jobs. The rate of decline assumed to be similar for the whole forecasting period at approximately 1.5%.

Written by: Netherlands Economic Institute
The industry is represented at the EC level by: Comité de liasion européen des commissionaires et auxiliaires de transport du marché commun (CLECAT). Address: Passage International 14, Residence Pallas B.10, B-1000 Brussels; tel: (32 2) 218 1788; fax: (32 2) 218 8125.

Public transport
NACE 721

Public transport has become important (especially in urban areas) as a solution to traffic congestion and pollution. Large investments are currently being made to improve public transport services, especially in the field of light rails. There is also a tendency to make public transport more commercial, where cost-based pricing and improved efficiency will be necessary. Increased competition of publicly owned transportation with private transport is gaining attention.

INDUSTRY PROFILE

Description of the sector

Public transport consists of units engaged in passenger transport by city underground, surface and elevated railways, tramways, (trolley-) bus and motor coach services. Services are provided by way of regular transport which means transport on scheduled routes following a fixed timetable. Also special regular services exist, that cater for specific categories of persons to the exclusion of other passengers (e.g. workers, school children, airline passengers). The provision of services is limited geographically to urban and suburban transport and transport in regions and conurbations.

Main indicators

For public transportation in major urban areas Germany is the largest country in terms of passenger journeys: in 1989 nearly 6 000 million passenger journeys were made. Also in terms of vehicle kilometres Germany is one of the biggest next to the United Kingdom. Both countries account for 1 000 million vehicle kilometres.

Bus service is by far the most widespread mode in public transport in the EC. In urban and suburban public transport it accounts for about 60% of passenger trips, 59% of vehicle fleets and about 90% of all transport systems. Measured in terms of fleet size, route length and number of routes the largest operating bus systems are to be found in the large European cities like Copenhagen, Paris, Athens, Rome, Madrid, Birmingham and London. Commuter rail or local train services follows far behind with 18% of passenger trips and 28% of vehicle stocks. Underground railway ranks third with 13% of passenger trips and only 8% of total vehicle stock. Light rail is not of great importance in the EC. It accounts for only 7% of passenger trips. Finally, the least significant public transport mode is trolley buses with only a marginal share in total passenger trips.

When looking at national bus and coach services Italy with 80 billion passenger kilometres ranks first in 1989. Germany follows suit with 53 billion, whereas France and the United Kingdom rank third and fourth respectively. In vehicle kilometres Italy and the United Kingdom show up as largest.

MARKET FORCES

Demand

As indicators of demand, Table 3 presents the number of passenger journeys and the population served for the major urban areas. The 106.7 million people living in the EC's largest cities completed 21 073 million journeys in 1989. Table 3 also indicates the number of passenger kilometres and the population served for national bus and coach services. For these services some 300 billion passenger-kilometres were made in 1989, serving 325.9 million people.

In order to make an estimate for service coverage, Table 3 shows the demand per head of population served in the various EC countries. Its interpretation must be done cautiously as local or national circumstances can influence the indicators substantially.

For urban transportation, the ratio in Table 3 reveals a high coverage in Italy, Portugal and the Netherlands. In Greece service coverage in urban areas is also relatively high. In Belgium, on the other hand, the indicator shows a very low coverage in cities. In terms of national public transport, a high ratio is shown for Denmark, Italy and Belgium. In Greece and the Netherlands, on the other hand, service coverage seems low.

Supply and competition

Table 4 presents some indications of supply of public transportation in the EC Member States. For all modes in major urban areas, the number of vehicle-kilometres per capita served indicates a relatively high service provision in countries like the United Kingdom, Denmark and Italy. The ratio amounts

Source: UITP/TMG

to 50 vehicle-kilometres per capita or above in these countries. A moderate service provision can be found in France, Greece, Ireland and the Netherlands with the ratio between 40 and 50. A relatively low service provision can be identified in Belgium, Germany and Portugal (ratio below 30). Concerning national bus and coach services, the ratio indicates a high service supply in Denmark, Italy and the United Kingdom, whereas it is low in Portugal, Spain and France.

When looking at the financing structure for bus operations in the EC Member States (Table 5), it shows that in some countries, fares account for the largest part and in others subsidies dominate. This is very much correlated with the underlying financing philosophy of public authorities in these countries. In the United Kingdom and Ireland and to a lesser extent Spain, Portugal and Germany, revenues are mainly from fare collection. In the remaining countries, a more subsidy oriented revenue system prevails: operations are financed by way of subsidies from collective means.

In general it can be stated that local bus operations tend to have lower fare revenues. In Ireland for example, Dublin Bus recovers 83% of total costs from fares, whereas Bus Eireann receives 96% from fares. Belgian public transport operators in urban areas cost recovery from fares was about 30% to 40% versus a range of 25% to 55% for regional bus operations. German bus operators achieve a cost recovery from fares of about 60% in urban areas and about 80% in regional areas. For Dutch bus companies, fares account for 25% of total costs in cities and 40% in regions.

An interesting cost recovery system has been introduced in France. Apart from fares and subsidies, a special taxation exists: the "versement transport". It is charged to business establishments with more than nine employees in areas with a population of more than 30 000. Fares effectively account for 50% of total costs, the taxation finances another 30% and the rest is received from other collective sources.

Production process

Measuring productivity in public transportation is difficult, although some indications for local bus transport can be derived. Conclusions however, can not really be drawn as

indicators are sensitive to specific circumstances of location such as the average distance between stops and the length of lines.

In terms of vehicle kilometres per employee in local bus transport, high ratios can be found for operators in Brussels (30800 vehicle kilometres per employee), Hamburg (HHA: 20200), Bonn (19700), Rotterdam (18600), London (16500) and Liverpool (16400). Rather low ratios are identified for operators in Hamburg (PVG: 4100), Athens (ILPAP: 6100), Luxembourg (7500) and Amsterdam (8700).

Another indicator could be the number of passenger journeys (in thousands) per bus. Exceptionally high figures are calculated for operators in Naples (604), Lisbon (510) and Milan (390). Lower but still high ratios can be found for operators in Munich (301), Berlin and Athens (over 280), Rome (266) and Barcelona and Madrid (about 250). Relatively low figures are obtained for operators in Belgian cities, some French, German and English cities, the largest Dutch cities and the city of Luxembourg.

ENVIRONMENT

Strategies of public transport operators are very much dominated by public transport policies of national governments and the European Commission. These aim at stimulating the use of public transportation and discourage private transportation (cars). The reasons for such policies relate to the existence of road congestion and air pollution. In large urban areas, congestion and pollution from cars have become an especially

serious problem which can be alleviated by public transportation. Discouragement of private transport is usually done by way of heavy taxation on cars and fuel, which revenues could be used for subsidising public transportation operations and investments.

In its Green Paper on the Urban Environment the European Commission has suggested the following actions:

- encourage city authorities to incorporate public transport and road construction into their plans for land use and transportation;
- promote innovation in public transport, environmental-friendly vehicles and advanced traffic management systems by way of contributing to the cost of pilot projects and monitoring their effects;
- encourage EC-wide exchange of information in urban traffic management to maximise the benefits of a wide range of experiences;
- consider in detail the potentials for using economic instruments in private car transport such as road pricing and pay-tolls for the right to enter city centres.

One of the issues in executing public transportation policies is the principle for fare collection. This relates to the extent of cost recovery from fares and to the system of fare levels. In general, fare systems are based on zonal rates.

Certain modern fare collection systems operate by using modern micro-electronics. This requires the sales of so-called smart cards (i.e. cards with magnetic strips or micro-chips on which a number of "units" are stored). Customers consume units while using the network. Such modern systems are already in use in Hong Kong and Singapore. The advantage of such systems is that the use of electronics enables a good tracking of transport demand, as data on each trip can be stored on computer. Such tracking opens possibilities for in-depth analysis of traffic demand to improve the service quality and to identify bottlenecks very quickly. It can also enable proper division of fare revenues in case of multi-operator fare collection (e.g. cards valid for more network systems). A problem though is that introduction of these modern systems imply large investments.

In view of the Single Market becoming effective in 1993, not very much will change in public transportation. The only important issue could be the procurement of new vehicles. At present there is a marked tendency for local procurement. But this is likely to change as foreign suppliers should also get access to national markets. The building of new infrastructure like underground systems and light rail systems should also be open to foreign bidders.

Source: UITP/TMG

Large investments are currently being made in public transportation. For example, expenditures on new vehicles in Western Europe are running at about 4 000 million ECU a year with replacement rates averaging about 5%, but ranging from 2% in Belgium and the United Kingdom to 8% in the Netherlands.

Total investments in urban rail systems (both underground and light rail) through the 1990s is expected to be around 31 000 million ECU. Large programmes exist in France (e.g. extension of the RER network in Paris, new systems in Strasbourg and Rouen), Germany (e.g. integration of East German networks in West German networks may amount to 12 billion DM), United Kingdom (e.g. extension of the Jubilee Line in London and the Metrolink in Manchester, light rails in Birmingham, Sheffield and Bristol) and Italy (e.g. underground in Naples).

REGULATIONS

Competition between operators in public transportation hardly exists. This is due to the regulatory environment in which they operate. The environment varies from one Member State to another. In the next paragraphs the main features in the various countries are summarised.

Belgium

The responsibility for public transportation by bus is with the three regional governments of Flanders, Brussels and Wallonia. The national bus company and the urban public transport companies are reorganised into quasi-commercial regional companies owned by the regional government. Five local subsidiaries are created, which operate under "contrats de gestion" for four to six years providing monopoly power within the area. The regional public transport company decides on fare levels and the allocation of subsidies to operating companies. It also coordinates various activities such as ordering vehicles, a common statute for personnel, common services between operating companies, etc. Operating companies determine timetables and can decide on subcontracting operations externally.

Denmark

Danish county councils (except Aarhus and Fyn where the local authority is responsible) have created regional transport companies for the management of all regular public transport within the area. In general, these companies organise, plan and market the services offered. Operations are generally licensed out to (mostly private) companies. Revenues go to the regional transport company; deficits are financed by the county council.

In the Capital Region (Copenhagen and surroundings) the situation is different. A new law came into force on January 1st, 1990 engaging the Capital Region Public Transport Company in general transport planning, network preservation and integration of fare structures with those of the railways. Currently it is licensing out bus services in long term contracts by way of competitive tender procedures. By April 1st, 1994, 45% of all bus services should be licensed out in this way.

Other local rail services are operated under agreements with local governments. Agreements related to service levels to be provided and fares and subsidies to finance the services. A particular example is the metro service in Copenhagen.

Germany

Local and regional authorities in Germany control and coordinate public transportation solely by determining routes and fare systems and deciding on the licensing of services to private companies. In practice companies active in this field cooperate extensively with each other. Licenses can apply to all modes of transport, but the period of validity can vary. Subcontracting to other operators is allowed. In principle, fares must be set

at a cost covering level. Where this is not possible, subsidisation will be defined by the authorities. The State Government investigates the possibilities for deregulation.

Competition between bus and railway has always been strictly avoided. The Deutsche Bundesbahn itself operates various rural bus services through its subsidiary Geschäftsbereich Bahnbus (GBB; split in 25 regional companies) as a replacement for former rail services.

In former East Germany, the old situation was a very heavy involvement of public authorities in public transport operations. The situation is currently changing towards the present system in the western part of Germany.

France

In the Ile de France area (Paris and surroundings) the Syndicat des Transport Parisiens governs the main operators (RATP and SNCF) plus another 80 small operators belonging to professional associations. The STP defines policies, route coverage and revenue structure (fares versus subsidisation). Existing services cannot be moved from one operator to another. For new services, an operator can be chosen. Operators are allowed to subcontract service operations to others.

In the rest of France, the "départements" are responsible for regional bus transport. Usually bus services are provided under monopoly franchise contracts guided by administrative coordination of these services. In urban areas the "autorité organisatrice" controls local transport. This body determines itself service structures and fare levels and grants single area monopoly contracts for a limited time period. Three major groupings (Transexel, Transcet and CGFTE) control most of the operators in the market.

Greece

Prefectures govern Greek regional and local bus transportation. They grant public transport licences to cooperative associations in the regions. A cooperative consists of individual bus owners providing buses and drivers, and revenue collection staff for fare collection. In Athens, three government owned bus companies run the public transportation services within the city under the control of the separate public body OAS. Thessaloniki and Rhodes have systems slightly different from the prevailing system in the country. In Thessaloniki, a private operator has a license for 21 years duration to operate services; in Rhodes city a municipal operator runs the services in the city proper under the guidance of the prefecture.

Spain

Spanish authorities, usually the municipal council, grant concessions of between 8 and at maximum 20 years for the operation of a network of scheduled local bus services. The authorities determine the route structure and fare levels. Special regular services are allowed on condition that they do not compete with scheduled services.

Urban transport is provided by 185 companies, of which 28 are municipally owned and three are labour cooperatives. Private companies also operate in 129 of the 134 small sized towns (less than 100 000 inhabitants). In four of the five large cities (population above 0.5 million) the municipalities take charge of public transport themselves.

Source: TMG/UITP

In inter-urban bus services, regional authorities grant concession rights to private operators. In case the service crosses the regional boundary, the concession is granted by the national government. Concession conditions are generally the same as those for urban transport.

Passenger services by rail are mainly provided by the state railways RENFE. In some regions, however, the regional government owns the network. Sometimes services are provided by way of a concession to a private operator using this network. Metro services (Barcelona, Madrid and Valencia) are provided by either state owned or municipality-owned organisations.

Ireland

Irish public transport is operated by the state-owned holding company CIE. This company owns three subsidiaries: Dublin Buses for bus services in the Dublin city region, Provincial Buses (Bus Eireann) for inter-urban and rural services and local services in the two major towns outside Dublin, and the Railways for all rail services including the rapid transit line in Dublin. The government is currently considering to introduce competition in the provision of transport services. A new authority is likely to be created for putting out to tender particular services and issuing licenses.

Italy

Public transport in Italy is governed by a concession system. In general, concessions are granted for long durations under monopoly conditions. In larger cities, the concession usually goes to the (generally municipally owned) local public transport company. Regional authorities provide long term franchises for longer-distance services and services in rural areas.

In some cases, national authorities issue concessions for inter-regional and other long-distance services. These concessions can be granted to any operator, either private or publicly owned. The body issuing the concession usually determines services, timetables and fares.

Luxembourg

In Luxembourg four networks exist in public transportation. These are:

- Luxembourg City Buses (AVL) for local and out of town services in the city of Luxembourg under the control of the city government;
- RGTR: a number of private operators providing bus services under the control of the Ministry of Transport;
- bus networks in the cantons of Esch-sur-Alzette under the control of a syndicate of cantonal authorities;
- CFL: the railway company provides not only rail services but also bus services on formerly existing railroad links and on routes determined by the Ministry of Transport.

The core body is the Ministry of Transport. It determines fares, timetables and services, coordinates the provision of services throughout the country and it grants 10-year concessions to operators with automatic renewal.

Portugal

Most public transport in Portugal is provided by public sector companies. Some local and regional bus services are in private hands under a concession agreement granted by the national or local government. In 1990, a law was passed to deregulate public transportation.

In Lisbon, Oporto and Coimbra, services are provided by companies owned by the municipality. For Lisbon and Oporto commissions have been established to control the implementation of a public transport plan. This plan should regulate the public transport system in the area.

In the rest of the country, the government strives for complete deregulation by imposing only qualitative restrictions in licenses for operators. Control over maximum fares is retained. Local authorities are authorised to supplement the network with subsidised services.

Netherlands

Dutch public transport is a fully monopolised system via a licensing procedure under the Passenger Transport Act. In urban transportation municipalities grant licenses to either the local public transport company (nine largest cities) or the regional public transport company (45 cities). Licensing in inter-urban and regional transport is governed by the Ministry of Transport. Licenses are granted to 16 regional bus com-

panies, which are all 80% subsidiaries of the state-owned holding company "Aandelenbezit Streekvervoer" since 1982.

Since 1988, private operators have the possibility to compete with the regional transport operators. Measures are taken to privatise bus companies. As a result, these companies engage in coach services and road passenger services. The Ministry of Transport continues its policy to stimulate public transportation, but more and more requires efficient cost-based operations and limitations to subsidies.

United Kingdom

British public bus transport on long distances has been privatised to a great extent. The then National Bus Company and Scottish Bus Group were split into 71 separate companies in order to get smaller more flexible entities offering long distance coach services. These companies should be able to compete with each other by way of pricing and service provision. While this has led to improvements in efficiency and quality, it has also resulted in reduced service quantity.

In local areas, services are also run on a commercial basis in which the operator determines fares, routes and timetables. In addition there exist subsidised services on certain routes. For London however, subsidisation prevails as London Regional Transport (LRT) compensates losses incurred by the bus and underground companies. Some services are provided by other bus operators under concession agreements with LRT.

Train services are generally provided by British Rail under a legal monopoly. In some local areas, however, a local network is operated by separate institutions.

OUTLOOK

Traffic congestion and environmental problems have initiated a new attention for public transportation. Especially in urban and suburban areas public transportation has become a priority issue and this is likely to increase. There is also a tendency to privatise public transportation activities to some extent. In this respect, private capital could become important next to publicly available capital.

These tendencies are not only characteristic to EC public transportation. Also in North America and South East Asia, attention to public transport has grown as a consequence of traffic congestion and pollution. Commuter rail has re-emerged in US and Canadian metropolitan areas and large investments are made to create new systems and improve existing systems. In Japan, commuter services in main conurbations have evolved into profit making private companies offering good services to the public.

Large investments will be needed in infrastructure (new underground lines, light railways), fleets (modern buses, vehicles for rail services), modern fare collection systems (smart cards) and service quality (comfort, service-reliability and flexibility).

Investments in railways and trolley bus systems are at an advantage as these are the least polluting systems. Light rails transport in particular seems to have made a comeback. On the other hand, research and development in buses is increasingly aimed at reducing exhaust pollution (e.g. in the Netherlands, the use of natural gas is tested). In addition, there is a need for investments in multi-modal facilities, such as park-and-ride, and passenger information facilities (e.g. at home via modern telecom-services like teletext or videotex).

Fare policies in view of privatisation tendencies are inclined to move into a situation where subsidisation of public transportation is no longer necessary. Hence, more cost-based pricing systems and efficiency improvements will get more attention in future. By contrast, policies also encourage people to use public transport rather than cars by way of low fares. By increasing costs of private car transport, the fares for public transport can be more cost-based, but can also remain relatively low.

Another development which will continue, is the further integration of public urban transport systems with other modes of transport. In some countries, good connections have already been created with the railways network. Furthermore, local railway networks have been connected with important airports. Examples are Schiphol Airport in Amsterdam, Zaventem Airport in Brussels, Charles de Gaulle Airport (via RER) and Orly Airport (via VAL) in Paris, Heathrow and Gatwick airports in London, Düsseldorf and Frankfurt airports.

Road passenger transport
NACE 722

The road passenger transport sector is primarily composed by bus and coach services. The private car remains the most important competitor of this transport mode. Taking into consideration the recent French experience, the high-speed trains do not compete seriously with road passenger transport. From air transport more competition can be expected on the medium journeys market.

INDUSTRY PROFILE

Description of the sector

The road passenger transport sector includes companies exclusively or primarily engaged in the operation of taxi-cabs, chauffeur driven hire cars, regular and occasional motor coach services, etc. Apart from collective forms of transport services, a large part of the industry consists of coach services for tourism.

Main indicators

Table 3 shows that Italy has recorded the largest number of passengers-km in 1990. The importance of this transport mode in Italy is also reflected in the high number of enterprises which are involved in road passenger transport. These enterprises are relatively small in number of employees if compared - for instance - with the Netherlands. Compared to the other member states, the Dutch enterprises are also larger in terms of the average number of coaches per company.

Recent trends

During the 1980s the development of road passenger transport has differed from country to country. Italy recorded the highest growth rates, whereas the transport mode lost importance in Germany and the United Kingdom. In other Member States only small growth rates have been reached.

The small growth rates or even declines in the use of this transport mode are reflected in small growth rates of the stock of buses and coaches. Since 1984 the EC stock only increased by an average rate of 1.5%. Italy, the United Kingdom, Spain and France were the main EC countries stimulating the growth of stock.

International comparison

Also in the USA and Japan the development of the stock of buses and coaches - with annual growth rates of 1.4% and 1% respectively - reflects a limited growth of this transport mode. Among other factors, the intense price competition among American airlines has caused people to favour air transport instead of coach services.

In passenger-km, the four largest EC countries do not differ very much from each other. In all four countries the share of private cars as a transport mode has further increased since 1980. Rail is more popular in France, while road passenger transport is more popular in Germany, the United Kingdom and Italy.

MARKET FORCES

Demand

A growing demand for private mobility and the absence in some countries of adequate alternative public transport, are the main factors behind the popularity of private cars. Even high raises of excise duties on fuel prices have neither influenced car ownership nor car use.

In most EC countries, transport by private cars has been increasing faster than overall mobility. The highest share of private cars in total passenger transport has been reached in the United Kingdom (88.3%). The southern EC countries like Italy, Portugal and Spain are likely to record further growth of private car use. The use of buses and coaches within these countries has increased less than total passenger transport. A continuation of this trend is expected for the near future within these countries.

A large proportion of coach services is closely related to tourism. Tourism coach service in combination with accommodation arrangements (inclusive tours) is very popular among lower and medium income households and also among senior citizens. Operators, however, are trying to attract other market segments by offering high quality services on long-haul routes.

Especially during the economic recession of the early 1980s, coach services have made a strong progress as holiday transport mode. Since the mid-1980s, the share of long-haul coach services has stabilised in most countries. For example, in the Netherlands the share of buses and coaches for foreign holidays has been fluctuating around 14%, just behind aeroplanes (15%).

Supply and competition

In Spain and Germany, competition from the improvements in domestic rail networks and the introduction of high-speed trains could become a threat. In France, however, where the TGV is already operative for ten years the high-speed trains could not stimulate overall demand for railway services in 1990. Passenger transport by buses and coaches, however, recorded a 2.5% growth in the same year. The high-speed train seems to be more a competitive threat for regional air services than for the passenger transport by buses and coaches.

Fuel, depreciation, maintenance and wages are the main cost factors for the operators.

INDUSTRY STRUCTURE

The road passenger transport sector varies considerably from one Member State to the other. Although some very large

Source: European Conference of Ministers of Transport

operators are active, the majority of the enterprises are small-sized. Medium and large sized operators tend to work more in the international market, in contrast with smaller companies which operate in national and regional markets.

Large operators in the EC markets are National Express in the United Kingdom, De Jong Intratours and Beuk in the Netherlands, Iberbus in Spain, GTI in France and Deutsche Touring (subsidiary of the German railways) in Germany. In some Member States, governmental or semi-governmental organisations play a role in long-distance transport.

On the European level, 40 operators of international regular services are members of Eurolines. Their membership of this organisation allows them to cooperate in arranging and publicising their services. Another example of such an organisation is Europabus which operates in Germany.

The greater part of the investments made by enterprises is for replacement of depreciated coaches. The intensifying competition and high customer requirements forces the enterprises to operate with high-quality buses and coaches with a broad variety of all modern features (e.g. air conditioning, air pressure suspension systems, video facilities, catering etc.).

ENVIRONMENT

Road passenger transport can be considered as one of the most environmentally friendly transport modes. In fact, it contributes to reducing private cars traffic and therefore road congestion and air pollution.

The amount of air pollution caused by road passenger transport itself and the energy consumption are clearly much lower (on a per capita basis) than the in the case of private cars.

REGULATIONS

The EC legislation has established three types of international coach services: occasional, shuttle and regular services. Occasional and shuttle services are basically tourist services. International regular services are subject to similar rules for national services (timetables, set routes and prices).

There is also a category known as special regular services, which mainly consists of the carriage of employees to their place of work and carriage of school children.

Only international occasional services are free from the requirement that prior authorisation must be obtained to run the service, from the States of departure, destination and often

the States in transit. Only the Member State where the vehicle is registered has to authorise the service. In national coach transport, the categories of service vary from country to country and within certain States there is no category of shuttle services.

The EC Council of Transport Ministers has recently adopted the regulation on the freedom to provide intra-EC services for road transport by coach and bus. Under this regulation, an authorisation is no longer required for most occasional services and for shuttle services if accommodation is included (inclusive tours). For regular services, however, authorisation is still required.

A proposal for a regulation on the conditions under which non-resident carriers may operate national road passenger transport within a Member State, has recently been adopted. The new freedom allows operators to provide certain non-regular services under the same conditions as resident carriers as from January 1, 1993 and all such services as from January 1, 1996.

The degree of regulation of coach services varies greatly between Member States. Certain Member States, such as the United Kingdom, have a very liberal system, where basically only qualitative controls govern the operation of a service (Transport Act). The Netherlands also have a relatively free system (Passenger Transport Law) for coach operations. Regular bus services (public transport) is strictly regulated. On the other hand, in Spain the 1987 LOTT legislation prescribes very detailed provisions governing all road passenger transport.

Furthermore, a Directive has come into force on 1 January 1990, strengthening the existing provisions for becoming a passenger transport operator. In particular, it specifies precise minimum financial requirements to ensure the viability of existing and potential operators and it makes the passing of a written examination compulsory for new entrants.

A parallel development to opening the EC market which will be of great assistance in raising standards of coaches and in ensuring the transparency of the market, is the introduction of a system of star rating for coaches. The International Road Transport Union (IRU) has set up this system and runs it. The number of stars awarded to a coach indicates to the tour operator and potential customer the quality of a coach.

OUTLOOK

The growth of passenger mobility within the EC will further stimulate road passenger transport. The growth rate of this transport mode, however, will be lower than overall mobility growth, as private car use, especially in the southern EC countries, has not yet reached its maximum. Attempts by national governments to discourage private car traffic in order to reduce road congestion and air pollution by cars, are not likely to have significant consequences for the ownership and use of private cars in the short term. The opening up of Eastern Europe has already and will further create new attractive tourist destinations for coaching. Investments in high-speed trains is not expected to threaten the road passenger transport in the coming years. The sector is likely to grow by 1% per annum in the 1992-95 period in terms of passenger-km.

Written by: NEI
The industry is represented at the EC level by: International Road Transport Union (IRU). Address: Centre International, 3 Rue de Varembé, Bte 44, CH 1211 Geneva 20; tel: (41 22) 734 1330; fax: (41 22) 733 0660.

Road freight transport
NACE 723

Since 1982 road freight traffic has increased at an average annual rate of 4.4%. The period 1986-1990 accounted for the largest growth rates with an average of 5.7% per year. Favourable developments in the world economy had a positive impact on the volume of goods transported by road. The development pattern of the road transport industry is very similar across the Member States.
Developments for both intra-EC traffic and third-country transport volume have been positive. The freight rates for international transport have been under pressure because of the growing number of internationally active road transport companies.
The single market will bring about a better capacity utilisation of the European road haulage industry and lead to a further growth of intra-EC traffic. Community policy aims at eliminating physical barriers and harmonising taxes within the EC. In close connection with the EC policy on infrastructure and pollution the European Commission will give special attention to the less developed areas in the EC.
Although the opening up of Eastern Europe will tend to favour both passenger and freight traffic by road, its impact on the EC road transport sector is not expected to be substantial in the short-term.

INDUSTRY PROFILE

Description of the sector

The goods-haulage sector includes units exclusively or primarily engaged in the transportation of goods - regular or otherwise - by lorries or similar vehicles e.g. tractors, articulated vehicles, lorry-trailer combinations and road trains.

The market for merchandise road transport is organised by a national regulatory framework. Community measures and bilateral agreements between Member States. International road transport in the community is submitted to bilateral authorisations which are gradually being replaced by multilateral authorisations before being completely removed.

Main indicators

It is estimated that total road transport increased by 3.6% in 1990, to a level of 826 billion tonne-kilometres. This represented a slowdown compared to growth rates in 1989 and 1988.

With the exception of the Benelux, all the EC countries showed comparable market shares for total and domestic road freight operations. The proportion of domestic traffic in total road freight traffic for the EC is 80% and varies according to Member States from 79% in France to around 94% in the United Kingdom. For the Netherlands and Belgium, domestic road transport is less important than international haulage (44% and 39% respectively). With 18%, the Netherlands holds the highest market share in international EC road freight transport.

In 1990 the total amount of tonne-km achieved by intra-EC merchandise road transport among EC countries was estimated at 166 billion, accounting for 20% of total tonne-kilometres.

International comparison

The EC total fleet of 15.6 million vehicles is smaller of that of the USA and Japan, respectively 43.6 and 22.2 million vehicles.

Total road traffic between the Netherlands and Germany is very intense at 7.9 billion tonnes/km from the Netherlands to Germany and 7.4 billion tonnes/km in the opposite direction. The same intense road traffic can be observed between Belgium and France, as well as between Germany and the Northern part of Italy.

Transport increased exceptionally fast in Spain and Portugal. While in 1989, total international road traffic increased by 8.9%, transport to the Iberian peninsula grew by more than 20%.

MARKET FORCES

Demand

The eastern European countries are currently unable to cope with a substantial increase in road traffic. Road maintenance, upgrading and the construction of new motorways are necessary to prevent congestion and to ensure rapid flows of goods and passengers. Implementation of these measures require both considerable investments and time. The TEM (Trans-Euro-

pean Motorway), prepared and carried out under supervision of UNO, has the objective to come to an integrated Pan European road system. The TEM-project is not expected to be completed before the turn of the century. The deregulation of the road transport market in Eastern Europe is a long-term process.

The Single Market will increase competition and encourage the European road haulage industry to innovate and upgrade its services in order to meet developments in demand by shifting from general haulage to a wide range of specialised and sophisticated transport services. Hauliers will be engaged more in distribution than just in physical transport. Increased competition and the pressure to innovate will entail a process of concentration and co-operation. On the other hand an increase in the demand for specific services offers prospects for specialisation.

Finally the use of information and communication technologies, e.g. Electronic Data Interchange, Tracking and Tracing systems, makes market growth possible, which is in line with the possibilities that come with the single European market. The use of ICT itself has a stimulating impact on the market growth, since the services offered by the players in the transport market can be of better quality (like Just In Time) and/or cover a far wider range than a simple long haul.

Supply and competition

As far as national road traffic is concerned, it can be noted that of all Member States, the United Kingdom had the highest share in the total tonne-km of road traffic (21%), followed by Italy with 19% and Germany with 18%.

On the supply side the trend in the 1980s has been one of steady growth, accelerating in the last few years. Liberalisation and harmonisation will affect the supply side in several ways. Trade between Member States and thus intra-EC road traffic will increase. However, competition between hauliers from different EC countries will intensify, pushing freight rates downwards.

Comparison of market shares confirms the strong competitive position which the Netherlands hold in intra-EC road freight, in relative as well as in absolute terms. Belgium also is well placed on the intra-EC market. The intra-EC market shares of Germany and France are also high, but compared to their national traffic their contribution to intra-EC traffic is of minor importance. Spain is the only other country where intra-EC traffic is significant to the sector. The United Kingdom can be expected to increase its intra-EC market share after the opening of the Channel tunnel. That increase will probably affect competition between transport modes - sea and air freight - more than competition between UK and other road hauliers because the latter also stand to profit from the Channel tunnel.

Production process

Figure 1 shows the development of costs for hauliers of some EC countries. Total cost inflation was highest in Germany at an average yearly growth rate of 3.4%, followed by Denmark and France with 3.2%. As fuel costs decreased for all countries in the 1982-1989 period, the greater part of cost inflation must be attributed to wage increases.

"Source: ERECO, Europe in 1996; based on national statistics

The average carrying capacity of semi-trailers (based on Germany, France and Belgium) has increased from 22.7 to 23.7 tonnes between 1986 and 1989, whereas the average carrying capacity of lorries and trailers has remained unchanged at 1.8 and 7.0 tonnes respectively. These low figures are of course due to the large number of small lorries. Based on seven countries of the EC, figures show that 7% of the lorries have a carrying capacity of 7.0 tonnes or more. Moreover, these lorries account for 45% of the carrying capacity of all lorries.

However, the picture changes when we look at the use of these vehicles. The average of tonne-km per vehicle in 1989 was 51 200. Greece, France (due to the large number of vans) and Ireland and Portugal have lower than average utilisation-rates. Denmark, Spain, and Italy are operating more or less on the average, whereas the other EC countries are all clearly operating above average. Germany, Belgium and the Netherlands have all utilisation rates of approximately 100 000 tonne-km per vehicle.

INDUSTRY STRUCTURE

Profile

The market is highly fragmented into many small transport companies. In most EC countries the number of road transport undertakings is slowly decreasing, which indicates a move towards some co-operation between companies or concentration in the sector.

Member States differ considerably in the number of hauliers, the evolution of this number, and the distinction made between own account transport and transport for hire and reward. Member States have different market access rules for long distance and short distance haulage respectively.

The road-transport sector is characterised by small and medium sized operators in the south of the EC and larger operators in the north-west. The turnover by single company is highest in Belgium. Luxembourg is not fully comparable because the country is so small and the part of the turnover that is realised in cross-border transport relatively large.

Of the other countries, the Netherlands and Belgium have a transport sector that is more than proportionate compared with Germany, France and the United Kingdom.

Strategies

The lack of sufficient investments in road infrastructures becomes a serious threat to the haulage sector. Apart from the problems facing road traffic in the Austrian and Swiss Alps, competition from the railways may increase. The investments in railway transport are developing fast, with investment in high-speed trains as well as in the improvement of the overall quality of railroad transport. The Channel tunnel will lead to changes in transport flows and logistic locations as well.

However, the balance in the modal split for freight traffic in 1990 remained undoubtedly in favour of road transport, with percentages varying between 53% and 90% (and far over 90% for the EC countries not mentioned in Table 3). Only in Germany and in the Netherlands is there a very substantial part of freight transported by other means.

The differences can be partly explained by the low degree of efficiency of alternative transport modes (Italy), by the low level of public investment in rail and inland waterways (Greece, Denmark) and on topographical grounds (Greece).

REGIONAL DISTRIBUTION

In 1989, the total amount of international transport between EC Member States was 557.9 million tonnes. EC countries in the north-west region - the Netherlands, Belgium, France and Germany - accounted for 84.6% of the total transport to

other Member States and 88.9% of total transport from other Member States.

ENVIRONMENT

One of the most important problems concerning road traffic is air pollution; it harms the environment, may modify climate and contributes to acid rain. Among the major air pollutants are: Sulphur dioxide (SO_2), Nitrogen oxides (NO_X), Carbon monoxide (CO), Particulates (Aerosols), Lead (Pb) and Carbon dioxide (CO_2). Both gasoline-driven and diesel vehicles emit carbon monoxide, hydrocarbons, nitrogen oxides and carbon dioxide, though diesel vehicles emit CO and NO_X at lower rates. Furthermore, gasoline vehicles emit lead, and diesel vehicles emit SO_2 and particulates.

Transport in the EC, including private cars, contributes a considerable part of carbon monoxide emissions (some 80%). The percentage shares of individual countries fluctuate between 60% and 95%, and vary greatly from year to year. Additionally, 50% to 60% of the emissions of hydrocarbons and nitrogen oxides stem from traffic. The contribution to the emissions of particulates and sulphur dioxide is lower. Whilst most emissions are produced by private cars, the emission of particulates originate mainly from diesel engines - important for freight traffic. New EC standards for heavy vehicle emissions, Euro I and Euro II, will reduce emissions by these vehicles by 55-65%, except for CO_2.

The EC commission has come up in 1991 with ideas for a combined tax on energy and carbon. Its purpose is to stabilise the emissions of the greenhouse gas CO_2 in the year 2000 on the level of 1990. The tax should begin in 1993 with a charge of US$ 3 per barrel of crude oil, rising to US$ 10 in 2000. This means that gasoline and diesel fuel prices would raise with 6% and 10% respectively. No final decision has been reached yet.

REGULATIONS

The issue of authorisations, the fixing of tariffs and driving times, the imposing of technical standards and taxes on motor vehicles, are actions that can affect the supply side of the market, for instance, the number of vehicles on the road. From January 1st 1993 onwards, all bilateral authorisations, transit and Community quotas will be replaced by Community authorisations, but these won't be subject to quantitative restrictions. From then on permission to enter the market will depend on qualitative criteria. On January 1, 1990, the old tariff system for international journeys within the EC was replaced with free price fixing.

By improved co-ordination, the EC is trying to improve the observance of social measures, e.g. to extend its span of control, to prevent drivers from neglecting the measure dating from November 1985 which regulates their hours of driving.

Other EC measures that may affect the road transport of goods are associated with the EC policy concerning environment and infrastructure. Other measures are especially aimed at improving the infrastructures of the economically less developed areas.

Another important aspect of goods transport is cabotage, which was not permitted in road haulage by any host state in Europe until recently. The decision which the EC transport Council has made about cabotage therefore constitutes a real breakthrough. During the transitional period (1990-1992) a quota of 15 000 allowances with a validity of two months was distributed among the member states. Furthermore cabotage is submitted to certain rules of the host Member State. However, cabotage only accounted for 0.1% of the combined domestic markets of the member states in the first year of operation (mid 1990 - mid 1991).

As to the future of cabotage, a final decision is due by end 1992. However, there remain strong opposing forces to a general introduction of cabotage. This is partly related to the differences in taxes and tolls. However, in the Benelux countries cabotage will be effective after the amendments of the national laws in the three countries.

OUTLOOK

The liberalisation and harmonisation of the EC transport market, the presumed ensuing growth of economic activity and a shift in demand towards fast and flexible transport will affect the volume of total transport. Environmental regulation, Eastern Europe, investments in road transport and other modes of transport and information and communication technology are other important aspects.

For hauliers, the European integration may produce some general advantages such as an increased transport volume, more third-country transport, less empty return loads, simplified foreign settlement, and co-operation with foreign transporters.

Table 8: Road freight transport
Expected annual growth rates

(%)	1992-93	1992-96
National goods traffic	3.0	3.0
Intra-EC goods traffic	4.0	5.0

Source: NEI

Intra-EC traffic will grow significantly faster than national traffic. One reason is that hauliers can react to future developments faster than other modes of transport because the rerouting of existing capacity requires little investment. however, saturation of roads will form a threat to the expansion of the road haulage sector.

Finally, the use of new information and communication technologies could give transport companies a competitive edge over non-users. The developments in this field are fast, and only keeping track of them requires already considerable effort.

After a slowdown in 1991 and 1992 due to the general weakness of the economy, the EC road haulage industry is expected to grow at average annual rate of 3 to 5% per year in the medium term.

Inland waterways transport
NACE 73

About 40% of all transport between EC Member States is transported by inland waterway. After a crisis in the beginning of the 1980s, demand gained momentum again during the latter part of the decade. However, overcapacity hampers the development of the sector. Scrapping and modernisation policies are successfully improving the situation. Together with increasing demand (especially in the transport of hazardous goods and unitised cargoes) the prospects for inland shipping are modestly positive.

INDUSTRY PROFILE

Description of the sector

NACE 73 includes units exclusively or primarily engaged in the transportation of passengers and goods on rivers, canals, lakes, lagoons and within river ports. Tugs and push boats operating on inland waterways also belong to this NACE heading.

The sector of inland waterway transport consists of companies operating ships of various sizes to convey goods throughout Europe on the available inland waterway network. As passenger transportation is limited to some ferry boats across rivers and boats for river cruises, this part of the sector is practically negligible. Most inland shipping operates with unscheduled services. Operations using fixed time tables rarely exist.

Next to companies operating ships as their primary activity (professional transport), there are companies active in manufacturing that operate ships on their own account (own account transport). These companies want to have complete control on the availability of inland water transport facilities.

Main indicators

In terms of tonnage transported, the country with the largest volume is the Netherlands. Germany ranks second with a total tonnage of some 220 000. Belgium follows with about 95 000 tonnes and France is in fourth position with some 60 000 tonnes. In the other countries of the EC, inland shipping is a marginal activity. In the United Kingdom and Italy, only domestic shipping takes place; in Greece, Portugal, Spain and Denmark, inland shipping is virtually non-existent.

When measuring transport activity of inland shipping in terms of tonne-kilometres, the ranking changes. Germany takes first position followed by the Netherlands. France ranks third and Belgium fourth. The remaining EC Member States have marginal figures.

The majority of inland shipping activity is accounted for by goods transported on the Rhine River. Nearly 300 000 tonnes are transported annually on this main artery of inland transportation for the European continent. The river is the most important connection between the large ports in the Le Havre-Hamburg range (e.g. Rotterdam and Antwerp) and the European hinterland. Dutch and German inland shipping operators benefit from this advantageous situation.

National differences occur when looking at the distribution of goods traffic. In Italy and the United Kingdom, inland shipping is purely a national phenomenon, as there are no inland waterway linkages with other countries. In other countries, domestic transport is also relevant. This is especially the case in France, where half of inland shipping concerns domestic transportation.

The Netherlands is clearly an exporter country: some 40% of inland shipping relates to exports, whereas about 20% is imports. For Germany, the situation is reversed: about 40% of inland shipping relates to imports, whereas some 20% is exports. In Belgium, imports account for nearly 50% of total inland shipping (measured in tonnes), while exports account for nearly 30%.

Total tonnage in transit throughout the EC amounted to some 65 000 tonnes. The Netherlands with over 30 000 tonnes is the most important transit country, followed by Germany with another 15 000 tonnes. For Luxembourg, transit traffic is the most important traffic category: in terms of tonnage 82% is in transit; in terms of tonne-kilometres it amounts to 97%.

Table 4 gives an indication of the type of products that are transported by way of inland shipping. The sector specialises in the transport of massive bulk products, such as sand, ores, coal, chemicals, and oil. These can be basically distinguished in dry bulk and liquid bulk. The largest volumes of goods transported relate to petroleum products (17%), iron ore, iron and steel waste, etc. (13%) and crude and manufactured minerals (33%). In practically all countries, crude and manufactured minerals are the most important type of goods transported.

For example, in Germany about 25% of total inland shipping was crude and manufactured minerals, in France about 50%, in the Netherlands around 35%, in Belgium around 25%, in Luxembourg about 15% and in Italy about 40%.

Most of inland waterways transport throughout Europe takes place within the EC. Transport to and from non-EC countries mainly relates to transport links with Switzerland (Rhine) and the East European countries along the Danube and the Elbe rivers.

Recent trends

Average growth in total tonnage transported throughout the EC during the period between 1985 and 1989 amounted to about 2% per annum. This means an important recovery from the very depressed situation at the beginning of the 1980s. Annual rates however, fluctuate considerably. In 1987, a drop in tonnage transported of about 0.8% occurred, whereas in 1988 growth soared to 6%. Also, large differences exist for the individual member states. In Germany, average growth between 1985 and 1989 amounted to only 1.1%. In the Netherlands, on the other hand, total tonnage transported increased by 4.0%. Italian inland shipping is rapidly decreasing. France encountered a serious drop in total tonnage.

When looking at total tonne-kilometres, the EC total is about stable at 55 billion km. For the Netherlands, there has still been a growth of 2.3% on average during 1985 to 1989, whereas Germany and Belgium show growth rates between 0% and 1%, respectively. Italy, France and the United Kingdom, however, experienced a declining trend.

MARKET FORCES

Demand

Over the years, demand growth in inland shipping had been fairly limited. This was shown by the relatively low growth rates presented earlier. In other types of transportation, growth rates of demand were higher. This was due to the fact that the majority of goods transported related to traditional bulk products as inputs for traditional industries (e.g. refineries, steel industries, chemical plants), where growth rates of industrial activity have been moderate.

These industries are in need of cheap transportation for bulk goods. Speed is not really important, as long as there is a continuous flow of vessels transporting it. Interruptions of this flow should be minimal and not distort the production process in the plants.

There has been a structural tendency to reduce the volumes of goods to be transported. This has been done by transferring the initial processing of raw materials to the origin. As a result, total tonnage of raw materials reduced and the tonnage of processed materials increased. However, the increase does not compensate the decrease: e.g. instead of transporting a

tonne of crude oil, less than a tonne of processed crude is transported.

Another problem on the demand side is that there is a tendency for monopsony power: demand is with a limited number of large industries, which are able to exchange information on the inland shipping market. In the Netherlands, for example, the transport of sand and gravel has been controlled by a cartel of sand and gravel traders and producers. Furthermore, some industries have arranged long-term transport contracts with shipping companies at guaranteed prices. In addition, some industries have their own vessels (own account shipping). They only need professional shipping to meet with peaks in their transport demand.

In the last five to ten years, unit cargoes like containers and roll-on roll-off (e.g. equipment for agriculture, cars and trucks) have become more and more important for inland shipping. This is due to a need with shippers to have reliable and cheap transport facilities for non-bulk products without the need to move these products in a fast way. Also unit cargos can be easily handled in multimodal (combined) transport concepts: a combination of rail, road and inland waterway transport. Such packaging of non-bulk goods is likely to continue and allow inland shipping to diversify away from traditional bulk tonnage.

Another tendency is that inland shipping has become important for the transportation of dangerous cargoes, such as highly poisonous or explosive chemical products. These substances require a high level of safety and safety standards from the transportation service providers.

Supply and competition

Inland shipping is capable of meeting the industry's requirements for bulk transportation which is cheap, energy-efficient, safe and reliable. The application of modern information and communication technology allows modern transportation concepts like Just-In-Time delivery and door-to-door transport chains. Some advantages offered by inland waterways in comparison to other modes of transport is the relatively low burden for the environment as the energy use per tonne is very low and the absence of grave bottlenecks in the used network.

The EC inland waterway fleet has a carrying capacity of 12.2 million tonnes. The Dutch fleet accounts for 49% of the total capacity, while the German fleet holds second position with 25%. The Dutch fleet has increased by 20% in ten years time, whereas the fleets of other countries has diminished. Overall, the EC fleet carrying capacity has been reduced by 6.2% between 1980 and 1990.

The fleet is characterised by the existence of a large number of private owners mostly operating only one vessel with the owner's family living on board. In general these vessels are old and relatively small in size and not in line with the latest technological standards. These ships are not demolished as the owners operate at or below economic cost prices, accepting very little or even negative returns. Large shipping companies exploiting fleets of 20 to 100 vessels mainly operate on the Rhine and its branches. Their fleets are generally large modern units enabling a high productivity and shorter turnaround times.

The existence of small family-owned vessels which have not yet been scrapped and the introduction of modern large sized vessels has caused a structural imbalance between supply and demand. Overcapacity, therefore, has become a structural phenomenon in inland shipping. During the 1980s overcapacity was estimated at some 20% of the EC fleet.

Overcapacity has had a negative effect on the evolution of prices on the free market. Already during the 1930s price regulating systems and cargo sharing systems had been introduced, basically to guarantee ship owners a minimum income. This social policy led to maintaining the overcapacity problem.

REGULATIONS

To remedy overcapacity problems, national governments have introduced capacity-regulation systems. In May 1989, the Council established principles for an EC-wide capacity-regulation policy which is also followed by the Swiss authorities. It entails:

- measures to set up and coordinate the functioning of national scrapping schemes by harmonising the basic principles and procedures throughout the EC;
- provisions to prevent the impact of a coordinated scrapping action from being cancelled out by limitations on the bringing into service of new vessels.

The purpose of capacity regulation is twofold. Firstly, it should bring down the total carrying capacity of the fleet by deleting old tonnage. Secondly, it should modernise the fleet by introducing modern large-sized tonnage.

These policies have already been effective. Table 6 reveals a larger reduction in the number of vessels than the reduction in carrying capacity. This implies that the average ship size has increased while average ship age reveal a considerable reduction.

On the Rhine River, a free market situation prevails. The Act of Mannheim of 1868 guarantees free shipping on the Rhine and its arteries for all ships with flags belonging to countries signatory to the Act (Germany, France, the Netherlands, Switzerland, Belgium, and the United Kingdom). The Commission is in favour of including the Rhine-regime in its EC Transport Policy. However, a complicating issue is that Switzerland is not currently a Member State.

In view of the Single Market, initiatives are taken to allow cabotage: each ship with an EC flag is allowed to provide services within other Member States. This will increase competition on the European waterways. Price and capacity regulating systems are not favourable in future EC transport policies and are likely to gradually disappear.

THE NETWORK

The Rhine, being navigable over a distance of 1,000 km from Basel in Switzerland to the North Sea at Rotterdam is clearly the backbone of the EC waterway system. Other rivers like the Meuse, the Schelde and the Elbe are interconnected with the Rhine by means of canals navigable for vessels of at least 1,350 tonnes, (classified as a Europe, class IV, standard vessel). Furthermore, a coherent network has been created by waterways navigable for units with a loading capacity from 1,350 to 10,000 tonnes (pushed convoys on the Rhine and certain other sections) which covers most of Germany, the Netherlands, Belgium, Luxembourg and the northern and eastern frontier zones of France.

This network will be extended to Eastern Europe in 1992 if the capacity of the Rhine-Main-Danube Canal also supports the large size vessels. Except for this route, a northerly transit to Eastern Europe between the Netherlands and Germany is also possible through the Mittelland canal. It is not yet clear what measures will be taken to improve its capacity.

In the French hinterland, the rivers Seine and Rhône, being navigable for pushed convoys of 5,000 tonnes, play an important role. However, to date, these rivers are only connected with the main European network by narrow canals. Networks in Italy and the United Kingdom basically relate to the Po River in Northern Italy and navigable rivers and canals in the UK (e.g. Thames, Humber, Clyde).

Although no major bottlenecks exist, investments in new infrastructure continue to be necessary. Increasing ship size requires enlargement of locks and canals, the deepening of waterways and adaptation of inland water ports. Modern navigation facilities are also needed along the waterways.

OUTLOOK

Demand for inland waterway transport is likely to maintain its upward trend at moderate growth rates. In view of economic integration, transport demand among Member States will increase in terms of both volume and distance to the benefit also of inland waterways. In the field of hazardous goods transport and unitised cargoes, inland waterways are likely to gain.

The developments in Eastern Europe will affect traffic in two ways. Firstly, positive developments emanating from German unification and the opening up of the Eastern European econ-

Table 7: Inland waterways transport

omies. New market opportunities and intensifying trade will occur, but in the short term these effects may be limited. Secondly, negative developments may occur as fleets from East European countries enter West European markets, especially via the Rhine-Main-Danube canal. However, ship sizes are small and service standards can not really meet Western requirements.

Concerning capacity, the EC scrapping system is likely to be successful. Together with the present trends in demand, a new equilibrium between demand and supply can occur in the near future. This will allow better prices and better utilisation of ships.

Over the past five years, the EC merchant fleet declined considerably as did carrying capacity (cwt), entailing a significant drop of the EC share in the world fleet and its carrying capacity. Although the EC's container capacity, measured in twenty-foot equivalent units (TEUs) increased, its share in the world's container capacity dropped. Remarkably, in recent years the EC fleet has developed more or less in line with the world fleet and its capacity. The foreseen gradual recovery of the world economy and developments within the EC will contribute to a further improvement of the position of the EC shipping industry. The developments within the EC concern the deregulation of the EC shipping market and the creation of an EC shipping policy aimed at achieving an efficient and competitive EC shipping industry, enabling EC shipowners to regain a major role in world shipping. Some European liner companies are actively engaged in extending European distribution networks to meet new requirements for intermodal transport and value added services. A large part of the tanker and bulker fleets will have to be renewed in the 1990s, which may cause the EC to improve its position in bulk transport.

INDUSTRY PROFILE

Description of the sector

The sector includes units exclusively or primarily engaged in the transportation of passengers and goods in sea-going and coastal vessels. Also to be classified under this heading are units exclusively or primarily engaged in the transportation of passengers and goods and in the operation of sea-going tugs. Deep-sea transport refers to shipping on long sea routes, coastal shipping or short-sea shipping refers to the conveyance of passengers and goods between national or European ports, including those on the Black Sea, the Mediterranean and Moroccan Atlantic ports.

Between 1986 and 1991, world seaborne trade grew by nearly 5% in volume; over the past two years the growth rate was lower, namely 3.0%. The seaborne trade's various products showed a similar development pattern, although their pace of development varied widely. Over the period between 1986 and 1991, most products increased at an average rate of 3.5% to 4% per year; grain grew at a lower rate, whereas crude oil grew almost twice as fast. Despite a slowdown in its development, crude oil maintained also over the past two years a significant growth; for coal and "other goods" the pace of growth declined recently, whereas the seaborne trade in oil products, iron ore and grain declined between 1990 and 1991.

Table 2: Shipping
Average yearly rate of change of seaborne trade

(%)	1986-91	1989-91
Crude oil	7.0	6.5

Bulk products allow for the greater part of seaborne trade. In 1991, liquid bulk's share was 46%; the three main dry bulk commodities accounted together for 28% and the share of the remaining dry bulk (which is part of "other goods" in Table 1) is estimated at 5%. In tonne-miles bulk traffic held a total share of nearly 80% of the world's total seaborne traffic in 1991.

It is estimated that about one-third of the world's bulk traffic (in tonnes) has its origin or destination in Europe. The overwhelming part of these flows, 90% is inbound. Nearly half of it is comprised of crude oil and oil products, 18% coal and 16% iron ore, the rest is grain and "other bulk". Oil and oil products have their origin for 75% in the Middle East. Coal is mainly coming from the US, Australia and South Africa with a joint share of 75%. The main sources of iron ore are South America and Australia, allowing together for 60% of Europe's total iron ore imports by sea. Europe's grain supplies are mainly (80%) originating from the United States and South America. "Other goods", reflected by the liner trades, are spread evenly between inbound and outbound trade to Europe, where such trade reached 5464 million TEUs inbound and 5449 million TEUs outbound. Inbound and outbound trade with the USA accounted for the greatest shares: 24% and 21%, respectively. Regarding inbound traffic, the non-European Mediterranean countries followed the USA closely with 19%.

In 1989, the international seaborne trade within the EC amounted to about 216 million tonnes or 18% of the total international trade of the EC. About 80% of extra-EC flows was inbound.

The United Kingdom had the greatest share of intra-EC trade, with nearly 33%, followed by the Netherlands with 18%. Italy and France held the largest shares in the extra-EC trade, 19% and 17%, respectively: the Netherlands and the United King-

EC 11	169 500 (1)	216 300 (1)	793 200 (1)	202 300	1 211 800 (2)

(1) Essentially, these flows should be identical. Most probably the difference is due to the fact that some of the airports by sea (outbound) arrive through transhipment by another mode of transportation (road,rail,inland waterways) at their destination. Consequently the importing country does not consider this trade as "seaborne". Hence "outbound" is higher than "inbound" the foregoing "outbound" reflects the intra-EC seaborne trade.
(2) In order to avoid double counting intra-EC trade has been added only once to the sum of the "in- and outbound" extra-EC trade. As intra-EC "outbound" is considered to reflect the intra-EC trade 216 300 has been added to the sum of the extra-EC trades.
Source: Eurostat

dom followed with 15% each. For all EC countries, inbound traffic is dominant in the extra-EC seaborne trade.

In 1989, between 40% and 60% of vessels involved in international trade to and from the EC were registered in an EC Member State.

Between 1987 and 1992, the world's merchant fleet remained virtually unchanged. However, its carrying capacity (cwt) and container capacity (TEU) increased. In particular, the growth of container capacity was quite significant. During the past two years, both the world fleet and its capacity revealed an acceleration of their pace of development. This is also true for the various vessel types. Although their development varied considerably, the container fleet increased fastest.

A comparison of the development of the various fleets with the development of the relevant commodities shows that the world trade in crude oil developed faster than the oil tanker fleet. For dry bulk products, particularly over the period 1990 to 1992, the opposite was the case. The relative increase in the capacity of the dry bulk fleet, together with a significant decline in the demand for these vessels due to the worldwide crisis in the iron and steel industry, caused a considerable decline in the freight rates. The rates in the liner trade are also under constant pressure because of excess capacity. The rapid increase in container capacity in relation to the development of "other commodities" has enhanced rather than relieved the pressure on the rates. Excess capacity is expected to subsist, the container capacity, will not be drastically reduced. The fleet is relatively young and active, so there are no extensive scrapping programmes. Instead, replacement of first and second-generation container vessels will not entail significant withdrawals from the market. Although less effective and economic in the main east/west arterial trades, the older vessels are useful in the feeder trades and in supporting secondary services to and from the developing world.

In 1992, the aggregate capacity in service of the top 20 container carriers totalled 1 403 000 TEU, representing a 41% share in the world's total slots in operation. This was an improvement of their position over 1991, when they allowed for 1 246 000 TEU or 39.8%.

Asian carriers dominated the rankings. They did not only occupy nine of the top 20 places, but five of them were also among the world's top 10 liners. The Asian carriers together accounted for 698 000 slots, or nearly half of the top 20 operating capacity. Sea-Land and APL are representing the

US in the top 20 with a joint operating capacity of 202 000 TEU (14.4%). ZIM Israel Navigation and UASC, the remaining operators are European; in 1992 their aggregate operating capacity was 398 000 TEU (28.4%). Five of them, including the third largest carrier in the world (Maersk), are based in the EC, allowing for a combined 323 000 slots in operation (23%).

With regard to the individual top 20 carriers the change in ranking of leading firms is remarkable; in 1992 Evergreen lost its leading position to Sea-Land Service. Evergreen's operating capacity remained virtually unchanged, whereas Sea-Land increased its capacity by 22.5%. CGM showed strong growth at 47%. As a result it moved from 20th to 16th position. Other operators with significant increases in their operating capacity were MOL (24%) and Cosco (21%). In contrast, due to a considerable decline in their operating slots, two companies dropped from the top 20: Gearbulk and Star Shipping, both breakbulk companies. Their operating capacity declined by 24% and 32%, respectively. They were replaced by UASC and MSC.

The top 20's order book totalled 194 000 TEU, which is nearly 14% of their joint operating capacity in 1992; it is 55% of the total foreseen new capacity (347 000 TEU as of May 1992) of the world's container fleet. The greater share of this, 231 000 TEU or 7% of the world's current slot capacity, is due before 1993.

During 1991, considerably less new capacity was ordered than in 1990: 145 000 TEU versus 189 000 TEU. Companies adopted a more cautious approach for various reasons, such as the uncertainty surrounding international trade as a result of the Gulf war, deepening economic recessions in the Far East, North America and Europe and low ocean freight rates due to overcapacity. These factors resulted in the delay and/or scaling back of several orders.

The development of the EC fleet could not keep pace with that of the world fleet. Unlike the world fleet, the EC fleet declined over the past five years. The decrease totalled more than 18% (4% per annum). The drop in the carrying capacity was less, namely 15% (3.2% per annum), whereas container capacity increased by nearly 13% (2.5% per annum). The USA and Japan were also facing a considerable decline in their merchant fleet over the reference period. In the USA, the number of ships declined by more than 38%; the carrying capacity was reduced by 3.5%, while container capacity increased by 12%. Remarkably in Japan the fleet as well as its carrying and container capacity declined. In particular the reduction of the carrying capacity by one-third is noteworthy. Contrary to the developments in the EC, the USA and Japan, the "open registry" and "other" categories showed growth in both their fleets and their fleet capacity. As to the capacity in particular the increase in container capacity was particularly significant, 72% for the "open registry" and 48% for "other countries".

The developments over the last five years entailed a decline in the EC's share in the world merchant fleet from over 19% to less than 16%. Its share in the capacity of the world fleet declined from 18% to 14.5% (cwt) and from 30% to 25% (TEU) between 1987 and 1992. These shares do not deviate much from those in 1990, indicating that during the period from 1990 to 1992, EC fleet capacity developed more or less in line with that of the world fleet and its capacity.

With the exception of Denmark, Ireland and Luxembourg, the merchant fleet as well as the carrying capacity of all Member States declined over the period 1987 to 1992. Belgium shows the greatest reduction. Its whole private fleet was transferred to Luxembourg which explains Luxembourg's growth in 1992. Other countries facing considerable reduction in their fleets were Spain, France and the United Kingdom. Spain's fleet was reduced by one third, the fleet reduction of France and the United Kingdom was about 28%. In the United Kingdom, the carrying capacity declined by more than one half (54%); for Spain and France this capacity was reduced by one third. Spain, France and the United Kingdom were also facing a decline in their container capacity. The same applies to Greece. In the remaining Member States the container capacity increased. Apart from Ireland and Portugal, with very small container capacities, the major increase in container capacity occurred in Denmark (75%), Italy (69%) and the Netherlands (42%).

Furthermore, it appears that Greece holds the greatest share in the EC fleet (26%), followed by Germany and Italy, each

accounting for about 15%. Greece also shows a much higher share in EC carrying capacity (46%), Italy is second with 11%, followed by Denmark and Germany with 8% and 7%, respectively. By contrast, Germany accounts for the largest share in the EC's container capacity (34%), followed by Denmark (17%) and the Netherlands (13%). Differences in the fleet structure by Member State allow for the differences in ranking on the basis of carrying or container capacity.

The composition of the fleet varies widely by Member State. The fleets of Belgium and Greece consist for the greater part of tankers and bulk carriers; contrarily in Denmark, Germany, Spain and Ireland, general cargo and container vessels account for more than 60% of the fleet.

For the EC as a whole, general cargo vessels hold the greater share. The same is true for Japan, where general cargo vessels account for more than half of the fleet. In the US, tankers are the main vessel type. Also deserving mention is the very low share of container vessels in the Japanese fleet.

National governments and the European Commission want to maintain an EC fleet not only for strategic and commercial reasons but also because of its contribution to the European economy in terms of income, employment, and balance of payments, etc. Employment of nationals has decreased from about 250 000 crew members in 1980 to about 118 000 in 1990. The decrease is due to the movement away from EC flags to open registers where manning costs tend to be low as well as to a rationalisation process.

In 1990 EC nationals of their respective Member State made up 85.2% of the total employment of the EC shipping industry. This share varies considerably by Member State. It is relatively low in Belgium, Germany and particularly in the Netherlands, where it ranges from 40% to 68%; for the United Kingdom and South European countries these percentages are much higher. In Spain, Italy and Portugal no foreigners are employed at all.

In 1992, the principal EC liner companies transported a total of 455 000 TEU, equivalent to 95% of the capacity of the EC's container fleet or nearly 54% of the total container capacity of the EC fleet. As for the separate companies, Maersk is by far the largest EC liner company. It is the third largest container operator in the world. Its capacity is more than twice the operating capacity of the three other EC carriers, appearing in the top 20 (Nedlloyd, P&O Containers and Hapag-Lloyd), ranging from 50 000 to 60 000 slots.

The scarce and fragmented financial information on EC liner companies indicate that revenues from shipping are only making up a part of their total revenue. CMB and Hapag-Lloyd showed the highest shares for shipping in their total revenue: 70% and 57%, respectively in 1991; by contrast, for P&O the contribution of shipping to total revenues was only 18%, for EAC 24% and for Nedlloyd 37%. As far as data permitted for employment it can also be concluded that often not more than half of the labour force employed by the major EC liner companies is related to shipping activities.

The order book for the ten main EC liner companies totalled 91 000 TEU in 1992 or more than 7% of the operating capacity. Seven out of the ten companies under consideration have placed new building orders. The German companies accounted for more than half of them. The planned extension of the Maersk fleet is very modest due to considerable investments in the recent past.

MARKET FORCES

Demand

In general terms, both manufacturers and retailers need a reliable and continuous flow of products at a reasonable price. Regarding major bulk commodities, which are inputs in the oil refineries (crude oil), the iron and steel industry (iron ore and metallurgic coal) and electric power plants (steam coal) the customers are largely in control of the flows to secure their regular supplies. They operate on a global scale. Regarding general cargo and containerised cargo in particular, customers are moving increasingly toward a global strategy.

Supply and competition

The shipping industry is very fragmented: there are major diversified liner companies as well as one-vessel captain-owners. Apart from large producers who carry their own cargoes there are important owners specialised in bulk shipping or in the rental or leasing of ships.

European short-sea trades, including intra-EC seaborne trade, still have the characteristics of regional markets. Mediterranean trade consists mostly of national traffic, which is reserved to the national flags, and international traffic across

Source: European Community Shipowners Associations

the Mediterranean to North African countries (subject to bilateral agreements). Therefore, in these trades there is a lack of competition. By contrast, in and around the North Sea there is fierce competition between short-sea fleets due to the UK's national trade being open to all flags. The Federal Republic of Germany, the Netherlands and Denmark dominate international short-sea trades.

Short-sea owners dominate specialised trades under European flags, many owners of larger vessels having opted out of the trade under these flags. Specialised trades include chemical vessels, liquid-gas tankers, reefer trade, car carriers, the carriage of heavy lifts, and chartered containers. Markets for liquid-gas and reefer trades are much less volatile than those for tankers and bulk carriers, because owners either charter their vessels to the traders or join the freight pools of the large operators.

Regarding general-cargo North-South trades with many developing countries (particularly those in Africa and Latin America), conference trade is often divided in accordance with the 40:40:20 formula of the Unctad Code, whereby the national carriers in the trade between two countries each have a share of 40 percent, the remaining 20 percent to be divided among cross traders. The Unctad Code applies to conference carryings only, but some developing countries want to bring their whole liner trade within the scope of the Code, which would enable them to regulate the share of non-conference lines, generally referred to as outsiders.

Many liner companies, both conference members and outsiders, are operating on the principal East-West routes and although the world's largest container operators are involved in this, trade market shares of more than 10% are rarely achieved. Most of the shares are in the range of 2% to 9%. Furthermore, in the (for the companies) relevant North-South trade, the shares vary from 10% to 20%. Consequently, no single liner company is dominating the trade; the market is very competitive, which is enhanced by the prevailing excess capacity in the liner industry.

To cope with the fierce competition as well as in order to meet the ever increasing needs of the clients, some carriers are aiming at giving a global dimension to their operations. The forthcoming unification of Europe has further encouraged the concept of globalisation as a drive for greater penetration in the Single Market.

Globalisation involves "one-stop shopping" (i.e. door-to-door transport) and "no sweat arrangements". One-stop shopping refers to geographical coverage of the transport service; no sweat arrangements refer to the so-called value added services (i.e. integrated transport and ancillary services).

The response of the major EC liner carriers to the global and European challenge is very different. Nedlloyd and P&O have built up large transport networks and restructured them in line with the growing importance of intra-European trade. Container logistics on a worldwide scale and inland activities (storage, distribution and transport) on a European scale are underlying Nedlloyd's policy, which aims at being present in the whole transport chain with the view to provide a full logistic package. In 1988, therefore, Nedlloyd Road Cargo, Nedlloyd Air Cargo and Nedlloyd Lines Agencies were established. In addition, acquisitions were obtained in countries like Germany and the United Kingdom.

P&O follows a similar policy. It invested in key areas of surface transport industries and follows a strategy of acquisition. Furthermore, it developed P&O European Transport Services (POETS) grouping together European haulage and distribution activities. Unlike P&O and Nedlloyd, CMB, Delmas and Hapag-Lloyd continued to focus on their core transport activity and to enhance door-to-door operations for their deep-sea service clients. CMB has taken steps to become a leading door-to-door operator for the European market. Its deep-sea strategy is concentrated on North-South traffic. Delmas will become a global operator; Hapag-Lloyd concentrates on intercontinental door-to door transport, although they currently do some distribution in Europe for Far Eastern clients.

As for non-European carriers, Sea-Land is the only carrier from outside Europe whose activities have acquired a truly European dimension. In line with its intercontinental network, Sea-Land is aiming to strengthen its intra-European network. For haulage on European roads, Sea-Land reached a joint venture with Frans Maas as part of a policy of forming alliances to enter the EC market.

REGULATIONS

There are variations among Member States regarding their approach to shipping; the Mediterranean countries are generally well placed in bulk shipping and (with the exception of Greece) rely strongly on state-ownership, particularly in the liner trades. The northern Member States have a long tradition of privately- owned liner companies which have often developed into diversified groups. Many of these companies have reduced their stake in the bulk trades. There are, particularly in the United Kingdom, still many independent or

Source: Nedlloyd

oil-company-controlled tanker and dry-bulk shipping companies, but most of their deep-sea tonnage is registered abroad.

Governments have offered throughout the years incentives to owners to keep their vessels under national flags. Nevertheless, an increasing number of vessels owned by EC nationals have been transferred to open registers. Initially, these registers were used to avoid tax liability, but in the last few years cost reduction (particularly of manning costs) has been the main motive. The main open registers are those of Liberia, Panama and Cyprus. EC owners with high labour costs under national flags would have been forced out of most trade if no cost-saving measures had been made by their governments such as investment allowances and government-supported research to advance automation and innovation.

Some countries have tried to mitigate the owners' plight further by creating offshore registers or similar schemes which allow employment by foreigners at lower wages and of nationals at reduced levels of taxation, often in conjunction with a permission to reduce crew levels. France has such an offshore register in Kerguelen, the Netherlands in the Dutch Antilles and the United Kingdom in Bermuda and the Isle of Man. In 1988, Denmark introduced a separate international register for Danish vessels, and Germany authorised a similar scheme in 1989.

These initiatives have now been followed with a proposal from the European Commission to introduce EUROS as a Community register. EUROS would operate in parallel to the existing national registers (i.e. vessels already entered on national registers could as an option of the shipowner also be registered in EUROS), in which case such shipowners would be entitled to the financial and fiscal benefits that would be provided through EUROS with a view to improving the competitive position of EC fleets.

The decline of tonnage under EC flags due to the open registers and protectionist practices of non-EC countries, the ageing of the EC fleet and the drop in employment underlie the development of an EC shipping policy. A start of such a policy was made in 1986, when the Council adopted four major regulations: 4056/86/EEC, 4057/86/EEC, 4058/86/EEC, which are exclusively focused on the protectionist policies and practices of non-EC countries, and 4055/86/EEC, which refers both to non-EC countries and EC Member States. The principles underlying these regulations are fair and free competition.

The main purpose of Regulation 4056/86/EEC was to set down rules in the context of a general shipping policy and to demonstrate their importance for the achievement of the EC's shipping policy objectives. It applies to international maritime transport services other than tramp vessels. Regarding liner conferences, the Regulation was aimed at stability, guaranteeing regular and reliable services to transport users.

Regulation 4057/86/EEC refers to unfair pricing practices in maritime transport; the need for the Regulation was caused by unfair pricing (continuous under-pricing) practices of non-EC countries. These practises are detrimental to the competitiveness of EC shipowners in international liner shipping. The regulation allows for a redressive duty to be imposed on the foreign shipowners concerned.

Regulation 4058/86/EEC is aimed at safeguarding free access to cargoes in ocean trade. The regulation provides for a procedure applicable when certain trade practices by a non-EC country threaten to restrict free market access by Member States' shipping companies. Regulation 4055/86/EEC applies the principle of freedom to provide services to maritime transport between both Member States and non-EC countries.

This regulation provides for the phasing out or adaptation to Community legislation of agreements between a member state and a non-EC country containing cargo clauses. This practice would seriously affect the trading interest of all countries by substantially increasing transport costs. Adjustment to Community law of agreements concerning trades not governed by the United Nations code of conduct will have to be completed by 1 January 1993.

Further mention should be made of the deregulation of the EC shipping market, implying the freedom of cabotage (i.e. the freedom of a Member State to operate on the domestic market of all the other Member States). On the 23rd of June 1992, the Transport Ministers of the EC Member States adopted in principle the regulation applying freedom to provide services to maritime transport within Member States. The text provides for a series of derogations for different trades in certain areas of the Community.

The following maritime transport services carried out in the Mediterranean and along the coast of Spain, Portugal and France shall be temporarily exempted from the implementation of the regulation:

- cruise services until 1 January 1995;
- the transport of strategic goods (oil, oil products and drinking water) until 1 January 1997;
- services by ships smaller than 650 GT until 1 January 1998;
- regular passenger and ferry services until 1999.

Island cabotage in the Mediterranean and cabotage with regard to the Canary, Azores and Madeira archipelagos, Ceuta and Melilla, the French islands along the Atlantic coast and the French overseas departments is also exempted until 1 January 1999.

This derogation shall be extended for Greece until 1 January 2004 for regular passenger and ferry services and services provided by vessels less than 650 GT.

In those areas outside the geographical scope of the above mentioned derogations, the liberalisation will be complete as from 1 January 1993.

OUTLOOK

Developments within the EC are expected to favour the EC shipping industry. To begin, the advent of "Europe 1992" and the resulting gradual deregulation of the EC shipping market will stimulate economic growth in the EC with an expected increase in the Community's share in world trade. Secondly, the four regulations adopted by the Council of Ministers at the end of 1986 aimed at increasing the competitiveness of the EC shipping industry towards non-EC countries may contribute to less protectionism and to fairer pricing in the liner trades. Thirdly, the clearly expressed aim of the EC to achieve an efficient and competitive EC shipping industry should also enable EC shipowners to regain a major role in world shipping using ships registered in the EC. The proposed EUROS register should contribute to that end.

Some European liner companies are actively engaged in extending European distribution networks to meet the new requirements for intermodal transport. A large part of the tanker and bulker fleets will have to be renewed in the 1990s, which may entail problems in private financing (i.e. financing by banks), given the risks and the huge amounts involved. The availability of both finance and reputable shipowners may enable the EC to play again a larger role in bulk transport. The vessels involved will be of proven design (there being no new technology under consideration) but there may be a new tendency towards larger vessels.

As a result of foreseen positive development of the world economy and the deregulation of the EC market, seaborne trade is expected to grow in the short to medium-term. Some markets, however, such as the iron and steel market are still depressed and the recovery process as well as the liberalisation of the EC market will take time, the development of the seaborne trade in the world is expected to be slightly faster in the medium-term than in the short-term.

Table 12: Shipping
Expected average yearly growth rates

(%)	1992-93	1992-96
World seaborne trade (tonne-miles)	3.5	4.0
EC fleet: CWT	1.0	2.0
TEU	5.0	5.0
Employment: EC shipping Industry	-5.0	-4.0

Source: Netherlands Economic Institute

The development of the world economy and implementation of the measures aimed at stopping the decrease of the EC fleet are also expected to have a greater impact on the medium-term rather than on the short-term. Carrying capacity has declined considerably over the past five years (though more recently this process seemed to have come to a standstill) is expected to develop at a much slower pace than container capacity, which revealed continuous growth in recent years. Although foreseen EC measures will have their main impact on container capacity in the medium-term, there are also countervailing powers which could cause a slowdown of the growth of the container capacity, in particular current excess capacity. As a result, the medium term development of container capacity is not expected to be faster than in the short run; growth is assumed to be identical in the short- and medium-term.

For employment, a strong downward development is expected to continue. Because of the reasons mentioned above, a slow down of the decline in the employment level of the EC shipping industry is foreseen.

Air transport
NACE 75

EC airlines operate on a global scale. Consequently they are facing competition from a great number of non-European airlines. Competition is particularly strong on the North Atlantic routes, where the EC carriers have to cope with US mega-carriers, for which Europe has become a target for further growth. Moreover the EC airlines are facing increasing competition, because since 1987 they have been subject to a process of deregulation of the EC air transport market. At the beginning of January 1993 the third and last phase of deregulation programme will become operational.
The strategic response from the EC airlines to an increasingly deregulated, competitive global market has been cooperation, aimed at getting access to markets which are currently closed. Fundamental to this strategy is the forging of links with local and/or regional carriers together with the establishment of international alliances to generate traffic.

Figure 1: Air transport
International comparison of airlines

INDUSTRY PROFILE

Description of the sector

The air transport industry consists of companies which are exclusively or primarily engaged in the transport of passengers and freight by air on scheduled or chartered services as well as helicopter and air-taxi services, local pleasure-flight operators, etc. and the town offices of airline companies.

Air traffic (excluding military air movements) is broken down into commercial and general aviation. General aviation, which will not be considered further here, includes private planes, air taxis and aerial surveying flights. Commercial aviation is divided between passenger travel - including carrier and charter traffic - and air freight, which includes regular air freight, courier transport and air mail.

In the present monograph attention is concentrated on scheduled passenger and freight traffic. In particular the national carriers of the EC Member States are covered, representing about two thirds (in passenger-km) of passenger traffic and virtually total freight transport (in tonne-km) carried out by EC carriers.

Main indicators

Both the growth rates for passenger and freight traffic as well as for employment were much lower over the period 1989-1991 than between 1985 and 1991. This was due to a stagnation in demand, which started in 1989 as a result of a declining economy. The situation aggravated further in 1991 when during the six weeks of the Gulf War air traffic declined dramatically. Although the situation improved afterwards, the 1991 performance of the EC carriers in passenger and freight traffic were respectively nearly 5% and 3% less than in 1990, while employment declined by more than 3%.

As for employment it should be stressed that its 1991 reduction was also the result of a rationalisation process, aiming at improving the sector's productivity level. The joint effect of the development of the factors dealt with before caused the labour productivity passenger-km/employment of the EC air transport to grow at an average annual rate of 2.7 over during the period 1985-1991, though it declined in 1991 by 1.2%.

Passenger traffic

British Airways, Lufthansa and Air France are the top-three EC scheduled airlines, accounting together for nearly 60% of both the total number of passenger-km and revenue of EC carriers. British Airways is the single largest EC carrier in passenger transport. Remarkable is KLM's fourth position.

Nearly 90% of EC passenger transport by air is international. However, the south European airlines show shares which are below 90%. This is particularly true for Iberia, Air France/UTA and Olympic Airways, showing shares of 77%, 79% and 84% respectively; for TAP and Lufthansa these shares are around 90%, whereas for the remaining west European airlines the international shares vary from 94% (British Airways) to 100% (KLM, Luxair and Sabena).

More than one fifth of total passenger-km are performed within Europe, which is equivalent to nearly 24% of the internationally achieved passenger-km. In terms of passenger flows these shares are 36 and 52% respectively.

International revenue from passenger traffic is nearly 85%. In terms of passenger-km this share being higher, the revenue per passenger-km accruing from domestic traffic is higher than from international traffic: 0.146 versus 0.096 ECU. However, revenue per passenger-km from international traffic varies considerably by route. Within Europe it is higher than for domestic traffic (0.186 ECU), while on other international routes it is considerably lower, around 0.065 ECU. This ex-

plains the fact that the share of the revenue accruing from European traffic is nearly twice the European share in the total number of passenger-km performed.

Freight traffic

Although in tonne-km performed Lufthansa, Air France and British Airways are the three biggest EC freight carriers with KLM holding the fourth position, in terms of revenue KLM ranks second and British Airways fourth. In tonne-km the top-three freight carriers allow for 64% of total freight carried by EC companies (66% in terms of revenue). The single biggest EC freight carrier - both in tonne-km and in revenue - is Lufthansa.

With 96% of the tonne-km performed on international flights, freight traffic is even more international than passenger traffic. For the individual carriers the shares vary from 91% for Iberia and TAP to 100% for Aer Lingus, KLM, Luxair and Sabena.

European freight traffic is relatively insignificant. This is particularly true when measured in tonne-km, only 4% (just under 10% in terms of revenue). Hence revenue on air freight comes overwhelmingly from outside the EC. The revenue per tonne-km on these routes is about one third of that on routes within Europe. In 1991 freight revenue totalled 15% of total revenue.

Investment

In 1991 the EC fleet increased by 10% percent to a level of 1026. New types added to the inventory were the MD11 (Alitalia and KLM) and the BAe 146 (British Airways). About 75% of the additional aircraft was destined for the short-haul fleet (B732, MD80s and Airbus 320). It is worth to note that in 1991 more than half of the short-haul fleet was in compliance with the Chapter 3 noise standards The long-haul has mainly been extended with B747.

In 1991 British Airways and Lufthansa had the biggest fleet with 226 and 217 units respectively. Air France followed with 158 planes. These three airlines accounted together for 69% of the EC fleet.

In 1991 all the AEA members together placed orders for 64 new planes, which was considerably less than in the three preceding years; both in 1988 and 1989 over 200 new planes were ordered and in 1990 the orders for 148 new units were placed.

At the end of 1991 the order book of the EC airlines contained 318 units. British Airways and Alitalia allow together for nearly half of this number. The order book comprises 161 Boeings, 105 Airbus, 51 McDonnell Douglas types and one BAe ATP. A total of 93 orders refer to next generation aircraft still in the project stage, the Airbus 321 and 340 as well as the Boeing 777.

International comparison

The internationally operating US and Far East airlines achieved in 1990 respectively 65% and 115% more passenger-km per employee than the European carriers, indicating significantly higher labour productivity than in the EC. European airlines are facing the highest share of labour cost (36%) on total costs, closely followed by the US airlines, whereas Far East airlines' share of labour cost is considerably smaller. As regards the load-factor the EC carriers hold an intermediate position with 68.5%; it is lower than that of the Far East carriers (74.5%) and significantly higher than that of the US airlines (62.3%). Unlike the Far East airlines, most of the EC and US airlines are facing severe financial problems. In 1991 the European airlines suffered a joint loss of about one billion ECU. Within the EC British Airways and KLM hold currently the strongest financial position, though the profits of KLM are under heavy pressure, due to its 20% stake in the currently highly unprofitable Northwest Airlines. In the USA excess capacity together with free competitive pricing lead to fare wars, causing bankruptcy for three major US airlines (TWA, Continental and USAir) as well as for the smaller America West Airlines. These companies are allowed to continue their operations under the protection of Chapter 11 of the US bankruptcy code. In addition Delta and Northwest Airlines posted considerable losses over the first six three months of 1992 and so did American Airlines.

MARKET FORCES

Demand

Given the global scope of air transport, the world's general economic situation is an important factor of the demand for air transport services in general and so is - as the Gulf war has demonstrated- the international political situation. The specific demand for services of the EC air transport industry depends on the competitive position of the EC carriers towards non-European airlines. In addition to the short haul, demand for air transport is also influenced by developments in surface transport modes, particularly railways.

Supply and competition

EC airlines operate on a global scale. Their joint network links most EC airports with 174 cities in the rest of the world; their intercontinental traffic accounts for more than 70% of total passenger-km. Consequently they are facing competition from a great number of non-European airlines. Competition is particularly strong on the North Atlantic routes, where the EC carriers have to cope with US mega-carriers. Europe has become a target for further growth of US airlines. These airlines can rely on massive domestic markets which are not open to European carriers. Contrarily the US carriers have access to all the major European destinations, in some cases with valuable concessions to establish European hubs, served by smaller aircraft and filled-up with local traffic. With current shares of more than 10% American Airlines and United Airlines brought about within the space of one year (July 1991-July 1992) a radical change in the market on the North Atlantic

routes. They also intensified and changed the shape of competition on these routes. Besides considerable fare reductions, other marketing tools have been used. such as frequent flyer programmes and more comfortable travelling conditions (comfortable seats, more space etc.).

Within the EC the second phase of a three-phase deregulation programme is currently being pursued, meaning that the EC air transport market is not yet subject to free competition. Bilateral agreements between EC countries still "organise" this market, although increasingly more international routes are served by three airlines (80 in 1991, whereas 350 international routes were served by only one airline and 200 by two airlines). However, route competition in the EC can not be simply measured by the number of airlines serving a specific route, because air traffic in Europe is a mix of point-to-point and intercontinental, European and/or domestic transfer traffic. On average 25% of the passengers carried in the EC are transfer passengers. Hence airlines serving the same route compete within the route for both the point-to-point and transfer passengers; outside the route a variety of airlines may compete for the transfer passengers.

Furthermore, particularly within Europe on journeys between 400 and 600 km., the airlines are subject to competition from railway transport. The development of a high-speed European rail network will make rail even more competitive with air on such short journeys.

INDUSTRY STRUCTURE

Companies

Among the top 20 IATA member airlines there are six EC scheduled airlines: the top three EC scheduled airlines - British Airways (7), Lufthansa (11) and Air France (13), together accounting for nearly 60% of the total passenger-km performed by the EC, and further KLM (15) Alitalia (18) and Iberia (20). Apart from Aeroflot (the number of passenger-km of which has been reduced by nearly 40% since 1990), the top six IATA members are US airlines and so are number 8 and number 10. Unlike the European airlines the US airlines are mainly serving their domestic markets. In international traffic, therefore, British Airways ranked first and Lufthansa fourth.

As for freight traffic, EC airlines held high positions in the IATA top 20: Lufthansa (2), Air France (4), British Airways (6) and KLM (7). In international freight traffic Lufthansa held even the first position; Air France was second, whereas British Airways and KLM were fifth and sixth.

Strategies

Strategic response from the EC airlines to an increasingly deregulated, competitive global market has been cooperation, mainly in the form of collaboration and partnership among established European national carriers together with major airlines from the US and other continents. These partnerships aim at getting access to markets which are currently closed. Examples are the KLM/Northwest Airlines partnership and the attempt of British Airways to acquire a minority stake in USAir, which would enable British Airways to get access to the US market, whereas USAir, which is mainly involved in domestic traffic, would get the opportunity to extend its international operations. Companies seek at the same time cooperation with regional airlines (Lufthansa and Lauda Air) and with other national airlines (Sabena and Air France).

The partnerships comply with the concept of "hub and spoke", that central airports are fed by traffic from regional airports and vice versa. The large European airlines are developing domestic or short-haul intra-European services to feed their long-distance business from their main hubs. Fundamental to this strategy is the forging of links with local and/or regional carriers together with the establishment of international alliances to generate traffic.

Further cooperation is increasingly sought in capital-intensive areas such as computerised reservation systems and automated ticketing. Computerised reservation systems provide a marketing edge by giving airlines detailed information about their markets. This allows them to improve flexibility by facilitating the optimisation of the configuration of planes, routes and available seats as well as providing a wide range of other services at the same time as booking a ticket. Access to, if

not ownership of, these systems is thus of paramount importance.

Moreover European airlines are responding to increased competition -particularly with US carriers- by introducing a wider range of marketing weapons. In addition to the "traditional" fare reductions mention should be made of frequent flyer plans and measures to make travelling by air more attractive, for example by making seats more comfortable and/or by creating more space for the air traveller.

ENVIRONMENT

Air transport can affect the environment in two ways: through the generation of noise and through the emission of toxic gases.

Although no reliable quantitative data on the contribution of air transport to environmental pollution exist, circumstantial evidence in the form of cost of air pollution in the EC indicates that, within the whole transport sector, air transport ranks second, but far behind number one, the road transport sector.

With regard to noise generation the air transport industry succeeded in reducing the 95 decibel take-off noise. Nowadays only 0.8 million people are living in areas exposed to this noise level as against 19 million in 1970.

As to air pollution the toxic gases involved are carbon dioxide, (the principal "greenhouse" gas), carbon monoxide, unburned hydrocarbons and nitrogen oxides. Energy conservation programmes gave rise to an immediate reduction (50% since 1970) in the carbon dioxide emissions, whereas the development in combustion technology led to a significant decline in the emissions of carbon monoxide and unburned hydrocarbons of respectively 90% and 70% since 1970. The research is currently aimed at reducing the emissions of nitrogen oxides which have been virtually unchanged over the past 20 years, because modern combustion technology involves higher temperatures and pressures making it less easy to control the volume of nitrogen oxides.

Furthermore, airlines try to diminish emissions from sources other than aeroplane engines, such as from ground vehicles and from aircraft maintenance. With respect to aircraft maintenance opportunities are being pursued to reduce chemical emissions and effluents.

REGULATIONS

Since 1987 the European airlines are subject to a process of deregulation. The EC Commission launched a three-stage liberalisation programme to encourage competition and reduce fares on the European air transport market. The liberalisation process should ultimately result in a fully deregulated EC air transport market, allowing EC carriers to operate all over the Community, offering all sorts of services at fares which can freely be set. The deregulation policy concentrates on three areas: capacity, pricing and market access.

Between 1987 and 1991 the set of proposals for the first and second stage were accepted. Recently the EC transport ministers agreed on the package for the third stage in the liberalisation process, which will be operational as of 1st January 1993. It includes still safeguards with regard to the free settlement of fares and a transition period for the introduction of cabotage i.e. the freedom of an airline from one country to operate unconditionally domestic flights in another country. Cabotage will only be introduced in April 1997.

In the meantime "consecutive cabotage" will prevail which means that EC airlines can offer national services within other Member States provided the following conditions are met: the flight originates in the country where the airline is registered and that it will not pick up more passengers than half of its seat capacity in the stopover in the foreign Member State. Together with consecutive cabotage the seventh freedom right will be introduced, allowing EC airlines to compete on international routes between other Member States without the currently prevailing condition that the flight should originate from their home countries. The EC airlines' right to set their fares has been limited by safeguards against over-pricing and

price cutting policies aimed at forcing smaller competitors out of the business.

OUTLOOK

The deregulation of the air transport market is promising for a rapid development of passenger and freight transport by air. However, future growth rates are not expected to reach the levels attained between 1985 and 1990, when they totalled 6.9 and 8.4% for passenger and freight transport respectively and 3.3% for employment. The air transport sector is currently facing a number of temporarily and structural problems. In particular congestion due to Europe's inadequate airport and air traffic control (ATC) infrastructure is a structural problem which limits airport capacity in relation to demand. These infrastructural deficiencies cannot easily be removed. Environmental constraints on new airport projects and on new runways at existing airports will severely limit such developments. A fully integrated air traffic flow management system (based on Eurocontrol) is not expected to be fully operational before 1995. Finally the EC airlines will be subject to ever increasing competition from non-European airlines, not only from the USA, but also from the Far East. Furthermore on the short-haul airlines will be subject to more competition from surface transport, particularly from high-speed trains.

The signalled problems are not expected to be drastically relieved during the forecast period. At the same time the deregulation process will continue, entailing gradually more traffic. It has been assumed therefore, that the growth rates for the medium-term will be slightly higher than for the short-term.

Postal and express services
NACE 790

In the past decade private operators have been able to seize the market for (non-reserved) high value added services. They created efficient networks with large capacities enabling high quality and reliability. These were the features asked by the users, which the traditional postal administrations were not able to cope with. Now the situation is changing considerably: postal administrations are becoming more market oriented; private operators have difficulties in maintaining the high quality networks and start to extend their services. Further policy initiatives put forward by the European Commission in its Green Paper will cause changes in the positions of both postal administrations and private operators.

INDUSTRY PROFILE

Description of the sector

NACE 790 includes all units exclusively or primarily engaged in transmitting sounds, images, documents and packages for the benefit of the general public. Apart from postal and express services this NACE heading includes telephone, telegraph, telephotography and telex services.

In this monograph the postal and express services are dealt with in more detail. In particular it concerns the activities of Postal Administrations of Member Countries and private operators. Postal Administrations are also involved in financial services like postal giro offices (NACE 812) and post office savings bank branches (NACE 813.1).

Essentially the market for postal services consists of three segments: letters, parcels and express. The distinction between letter services and parcel services is either determined by weight (e.g. above 2 kilos is a parcel) or by contents (letters carry 'communication'; parcels carry 'goods'). Express services include express letters (documents) and express parcels (packages).

Letter services can be categorised in three main areas:

- Standard letter services for letters, post-cards, printed papers and small packets with or without priority delivery;
- Subsidiary letter services, which include registered letters, recorded letters, certificate of posting/advice of delivery, special delivery, direct bags ("M-bags"), post office boxes and post restante;
- New letter services, such as postal electronic mail, document exchange, remail, "hand delivery", "city mail" and unaddressed direct mail.

Postal administrations mainly provide letter services under a monopoly (reserved services). In general a concession is granted to the postal administrations, in which they have special and exclusive rights for offering these services. The provision of the service is then obligatory. Parcel and express services are offered in a free competition environment (non-reserved services), where postal administrations dominate in parcel services and private operators in express services. For some non-reserved services postal administrations have been charged to provide them also (obligatory non-reserved services).

In financial services postal administrations offer the following types:

- postal payment means (money orders, postal orders and cheques, "valeurs declarées");
- girobank operations (tele-payment, interior accounts/deposits/pay-out, foreign currency, mortgage);
- savings bank operations (home savings and common funds investment);
- other payments (pensions, welfare services, licences, taxation and public payments).

Main indicators

The largest postal administration in the EC is to be found in France. This administration accounts for 32% of total EC turnover in 1988. The German postal administration ranks second with ECU 9 billion, but may have become bigger now since the German unification.

Recent trends

Between 1985 and 1989, services provided by postal administrations (measured in number of items handled) grew by 6-8% annually in Italy, Portugal, United Kingdom and Spain. At the other end of the spectrum, Ireland, Greece, Denmark and Germany posted slow growth in the 2-3% region. For Japan volume growth between 1983 and 1987 amounted to some 4.6% on average.

Express services have grown much faster. The European market for express and courier services has been increasing at a rate of 30-40% a year in the last few years.

This caused a considerable shift in the market for postal services. The traditional carriers, the national postal administrations, have been confronted with increased competition in the non-reserved services from international operators aggressively moving into the market, especially in the field of parcels and express services.

International comparison

Comparing postal administrations in the EC with those in the USA and Japan reveals that the EC administrations with a total of some ECU 39 billion have the largest turnover. In the USA total turnover amounted to ECU 30 billion, whereas in Japan turnover was ECU 9.5 billion.

On average each EC citizen received 260 mail pieces in 1990 (243 in 1988). In the USA however, the number of mail pieces received annually by citizens is much higher: 650 pieces in particular due to high direct mailing activity. In Japan the average amounts to about 160 pieces.

Source: Green Paper /Sofres/CEC-estimates/NEI-estimates

Within the EC there are large differences in the average number of mail items received. In Denmark and the Netherlands this number is the highest: over 400 items per year. On the other hand in Greece and Portugal the average is below 100 items annually. Figures for Japan reveal that in Tokyo mail received per capita amount to 388, whereas in some rural prefectures this is less than 60 pieces.

MARKET FORCES

Demand

Customers of postal services are either businesses and organisations or individuals. Some 80% of all mail originates from businesses and organisations, of which about 45% has the same group as destination. About half of the mail from individuals is destined for businesses and organisations. The other half goes to other individuals. For parcel services the distribution is slightly different. Businesses and organisations send about 85% of all parcel items, the bulk of which (70%) is received by individuals. About two thirds of parcels sent by individuals is destined for other individuals.

For postal administrations the market is rather evenly spread over various end users. An important outlet is the publishing industry sending periodicals to its readers by mail: it account for about one fifth of the shipments made. Other important segments are mail ordering and advertising (direct mail).

The largest users of services by private operators (mostly parcels and express shipments) are industry and mail ordering companies. Industry constitutes about a quarter of total shipments, whereas mail ordering takes another 20%.

During the seventies and eighties mail ordering has developed considerably into an important competitor of retailing. Postal services have benefited of this growth as they have been able to meet with requirements such as customer communication, catalogue distribution, statement sending and goods distribu-

tion. There is a tendency however, that private operators more and more take over this market from public administrations by providing better service quality and reliability.

Advertising by mail (direct mail) has also become of considerable importance for postal services over the years. An increasing share of advertisement budgets is spent on direct mailing activities. But in this market segment also, postal administrations seem to lose market shares to the private operators.

Distribution of publications by mail remains important for postal administrations. They can offer cheap mailing services at preferential tariffs. Private operators are not really able to compete with this low value mail services, unless other requirements become important (e.g. a guarantee to deliver the next day).

Industry has more and more demanded a high reliability of postal services. It is thus prepared to pay for service quality, a segment which has been picked up by private operators.

Supply and competition

Reliability and service quality have become the major factors for private operators to exist. Postal administrations with their monopolies on letter mail services seem to have neglected these factors in the past. This has allowed private operators to capture the market with high value added postal services,

Table 4: Postal and express services

whereas public administrations with their obligation to provide reserved services stuck to low value added postal services. Private operators account for about 45% of turnover in the market with only some 5% of total shipments.

Large private operators have increasingly offered a range of services exceeding pure postal services. This change on the supply partly reflects changes in production management in the manufacturing industry, with increasing need of just in time deliveries and door to door transport. In addition, an enlarged range of services is also results from excess capacity. Having created networks with large (air freight) capacities to enable fast deliveries all over the world, private operators were hit by over-capacity as growth rates remained below expectations. Hence, companies being called 'integrators', started to extent their service package to transportation and distribution services. Some companies have even developed into suppliers of complete logistic chains for manufacturing companies which wanted to externalise their transport and distribution activities.

Production process

The production process of postal services can be divided in five stages: collection of mail, sorting for destinations, transportation, final sorting and delivery of mail. Mail delivery is the largest cost items with 60% of operational costs. Next comes transport and sorting for destination with a combined share of 25%. Mail collection makes some 10% of total operational costs, whereas the remainder (5%) goes to final sorting for delivery.

A good network is of crucial importance for postal services. The complexity of the interactions between all the different points in a network demand a good logistics chain. For in-

ternational mail the problem is even more complex, as domestic networks have to be matched. Essentially there are two network systems: the hub-and-spoke system, in which a region is serviced from a central "hub" via "spokes" with local centres; and the spider's web system, in which local centres interact directly with each other.

Productivity is very different between the postal administrations of the EC countries. On average postal administrations have a turnover per employee of 21 500 ECU. Private operators on the other hand show a turnover per employee of over 57 000 ECU. Differences highly depend on the type of services offered.

Network quality and productivity are among the factors that cause wide ranges in tariffs for what, apparently, are the same services. In 1990 the rate for sending a letter weighing up to 20 grams within the country was ECU 0.19 in Spain and ECU 0.57 in Ireland (adjusted for purchasing power differences). Sending a 100 grams letter cost only ECU 0.37 in Greece, but ECU 1.51 in Italy. Private operators demand far higher charges; customers pay for a higher service quality.

A good indicator for service quality in postal administrations is the percentage of domestic mail not delivered the day after collection. In small countries like Denmark, Netherlands and Luxembourg this rate is well below 5%. In Germany, a very large country relative to the previous ones, the Bundespost manages to limit the rate to 10%, which equals the set aim within the Conference of European Postal and Telecommunication Administrations (CEPT). In Italy however, more than 80% of mail is not delivered the day after collection. This testifies the notorious service quality of the Italian postal authority and may even explain the 40% deficit on mail service operations and the larger market share of private operators in Italy.

INDUSTRY STRUCTURE

Profile

Private operators can be classified into two categories: companies operating internationally, such as the big four 'integrators': DHL, Federal Express, TNT and United Parcel Services (UPS). They offer services which go beyond postal services and integrate various forms of transport and distribution. The second category consists of domestic companies, e.g. Kühne & Nagel (D), Jet Services (F), TAT Express (F) and Securicor (UK). On a local level small companies offer express services within city or conurbation areas.

The boosting market for express services has attracted companies active in other fields of transportation and forwarding. For example (scheduled) airline companies like KLM, Lufthansa, British Airways and Air France have attempted to enter this market by offering cheap -otherwise redundant- cargo space in their aircraft. But also freight forwarders and railroads have started express services. Postal administrations have set up their own international express service EMS in order to get some crumbs from this high value market.

Recently however, the large private operators were confronted with a tough year and have experienced a considerable setback

in activity due to recessionary tendencies. Rationalisations and closure of activities in certain areas even led to job losses.

Strategies

Postal administrations have been forced to commercialise in recent years. This was not only due to the competition with private operators, it was also initiated by the tendency to privatise public activities and a need for reducing budget shortages. Already in the United Kingdom and the Netherlands postal administrations proved that postal services can be a profitable operation: Royal Mail and PTT Post realise surpluses on mail services. Similarly, the Japanese Postal Service has been able to generate profits from 1981 onwards by improving services and operations efficiency and expanding business activities without resorting to postal rate increases.

In some countries, the profitability of financial services provided by postal administrations is high, sometimes well above 10% of the turnover in that sector. This enables a partial and sometimes full compensation of losses on postal services.

Apart from commercialisation on the demand side, public administrations have also tended to economise on the supply side. This has been done by way of large investments, especially in automatic sorting of mail in the sorting centres. Also the efficiency of operations in the network has been improved by a more cost-based attitude.

In the private sector market for intercontinental parcel and express shipment services there is only room for a limited number of operators. It is therefore likely that mergers and strategic alliances will take place in the medium term. These will involve integrators, carriers and forwarders, but also postal administrations.

Already one of these alliances has become effective: TNT together with five postal administrations in the Netherlands, Germany, France, Sweden and Canada started the joint venture GD Express Worldwide. In this joint venture the five administrations combine their EMS services with the international express network of TNT. Other postal administrations can joint in, but TNT will maintain its 50% share in the venture. This alliance is attractive for postal administrations as they do not have to depend any more on various bilateral agreements; TNT on the other hand benefits from the good sales and distribution networks of the postal administrations. Besides this TNT has already lost a competitor: Federal Express also uses TNT's network for its activities in Europe.

REGULATIONS

In each country governments have arranged legislation in which postal administrations should provide universal postal service at affordable tariffs. Provision requirements differ from Member state to Member state. For example in Spain inter-city express services are reserved (intra-city and international services are not reserved).

In the non-reserved service the market should regulate itself. For reserved services however, some body should be responsible for regulating the market. In the past the regulator was also the operator: the postal authority. But nowadays Member states have separated the regulatory authority from the operational function by establishing a body under the responsible ministry.

In an international perspective, postal authorities cooperate in various organisations, such as the Universal Postal Union (UPU) of the United Nations and the Conference of European Postal and Telecommunications Administrations (CEPT). The former is a worldwide organisation providing the basic framework for international postal services. The latter includes not only the EC authorities, but also those from EFTA, Eastern Europe and Turkey. In CEPT various issues have been agreed (e.g. the 'péréquation tarifaire' which is the use of a standard tariff in domestic markets for letters below 20 grams irrespective of distance).

In view of the Internal Market the EC is developing a common policy for postal services throughout the Community. This will require a lot of policy harmonisation in the various Member states. Issues in this respect are the definition of reserved and non-reserved services, principles of cost-oriented tarification and competition. Ideas have been presented by the European Commission in its Green Paper.

Private operators will benefit from the lifting of custom barriers within the EC. It will reduce their operation costs and allow them to improve service quality. However, their position is highly dependent on the legislation currently in force and the envisaged legislation changes. For example changes in the definition of non-reserved services could harm them in the core of their activities. Currently the International Express Carriers' Conference submitted a complaint concerning a new system of terminal dues for international mail agreed between EC postal administrations. Another point of concern is the intended impediments on remail activities.

REMAIL

A special issue in postal services is the remail service. This is a cross-border mail service offered by private operators. The most common type of remailing is the A-B-C mail: a private operator collects international mail of a large customer in country A, transports it to country B from where it is posted for delivery in third countries C. A second type is A-B-B mail, in which the mail is posted by the private operator in country B for delivery in B. The third type is A-B-A, in which the private operator posts the mail for delivery in country A.

Remailing challenges the monopolies of the postal administrations, because services can compete with the postal administrations involved. Especially in the A-B-A case the monopoly of country A is challenged, as mail which is effectively domestic has become international mail. The postal administration in B however benefits as it will collect the full revenues leaving only the terminal dues for the postal administration in A.

The basis of remail has evolved from a market need for good quality services and the weaknesses of the terminal dues system for international mail agreed in the UPU. It started with the mailing of publications with an international distribution. In the 1970s the KLM airline initiated its Publications Distribution Service in cooperation with the Dutch postal administration. Express companies like TNT (Mailfast) and DHL (Worldmail) gave another impulse in remailing, as they had to find new and profitable freight next to their express shipments to have an optimal usage of their planes. Since then remail has developed into a service of wider scope, e.g. in international direct mail advertising and even in traditional letter services.

OUTLOOK

The outlook for postal services varies with the type of service offered. For traditional letter services the growth trend will be of a stagnant nature. This is due to competition from modern communication means such as facsimile, electronic mail and EDI. In parcels and express services growth is likely to be very high. The integration of the European market implies increased interaction (in terms of traffic and trade) between the Member States. This increased interaction will be mainly with industries requiring high quality services. Further there is a trend in industry to go back to the core business implying externalisation of transport and distribution to the benefit of the integrators.

Another strong growth market is likely to be with advertising (direct mail) and mail ordering. This will be a market with strong competition between postal administrations on one hand and private operators on the other.

Of crucial importance for the competitive position is the application of modern technologies. Private operators are already at a high level, but some postal administrations seem to be far behind and may need a large investment program to come at par level with the private sector.

Another important issue is the regulatory environment. A community policy for postal services will seek to reduce the present lack of harmonisation in legislation concerning reserved and non-reserved services, to introduce a more cost-oriented tarification system and to apply free market principles where possible.

In this respect the cross-subsidisation from financial services to postal services is likely to disappear. In the Netherlands this is already the case as Royal PTT Nederland NV has established PTT Post as a separate business unit, whereas financial services (the former Postgiro) has effectively become a private sector bank (Postbank). In addition, the post offices have been transferred into a separate business unit as well, in which the post office becomes more of a retail outlet for commercial and non-commercial services, rather than a place to buy stamps and send letters and parcels.

Sea ports and other sea transport facilities
NACE 763

Supporting services to sea transportation are highly heterogeneous in nature. Services are provided by port authorities and private companies depending on the regulatory environment in the port and the extent of subsidisation in national port policies. Competition among ports is very severe and the only way to keep ahead of competing ports is to invest heavily in modern infrastructure, suprastructure and facilities. A Common Port Policy may change the competitive environment.

INDUSTRY PROFILE

Description of the sector

This group in the NACE classification includes all supporting services to sea transport and coastal shipping. In effect these are sea ports and other sea transport facilities. Examples of service types are tugs at sea, pilotage, lighthouse operations, buoys and other navigation facilities, stowing, stevedoring, loading and discharging of sea-going vessels, and operation and maintenance of sea harbours, piers and docks.

Main indicators

In the 118 major seaports in the EC, as defined in the MERC World Ports Database, a total traffic of about 2 000 million tonnes of cargo was handled in 1990. The largest volumes have been handled in the United Kingdom with some 408 million tonnes in 23 ports. The Netherlands ranks second with 358 million tonnes, of which the major part is handled in the world's largest port, Rotterdam (288 million tonnes).

Only limited information exists on the importance of ports for the national economies. For the port of Rotterdam, total value added in 1989 was estimated at 9.9 billion DFl., about 2.5% of Dutch GDP. Employment related to port activities was estimated at 290 000, of which 69 200 directly involved in port services. Total value added for the port of Antwerp in 1989 was estimated at about 188 billion Belgian francs., about 3.4% of Belgian GDP. Direct employment in the port of Antwerp amounted to some 64,000 people.

Recent trends

In 1988 and especially in 1989, growth figures for cargo handled were very high in some ports: Brugge-Zeebrugge had an increase of 28% in 1989, Calais handled 23% more cargo, Thessaloniki registered a strong recovery in 1989 (+30%) after a decline in 1988 (-12%). Other ports with strong growth in 1989 were Leixoes with 13% and Tarragona with 14%. Felixstowe had a very good year in 1988 (+33%), but experienced minor set backs in recent years.

Growth rates for 1990 are less pronounced due to the slackening growth in world trade. Some ports encountered serious reductions in activity, such as Livorno with a reduction of 20%, Dover with 25% and Southampton with 23%. The latter two ports were severely hit by recessionary tendencies in the UK economy. A port of particular interest is Rostock in former East Germany: cargo handled in 1990 in this port was 36% below 1989 tonnage.

International comparison

Whereas in the 1960s and 1970s European ports were among the largest ports in the world, in the 1980s ports in South East Asia and Japan have taken over positions in the world top 10 seaports. Japan in particular has entered the top 10 with ports like Kobe, Chiba, Nagoya and Yokohama. Singapore has reached second position with large volumes of general cargo (mainly in containers) and liquid bulk (mainly oil). There are presently no American ports among the world top 10.

The only European port which was able to maintain its position in the world ranking was Rotterdam. In 1992 this port celebrated its thirtieth year as the world's largest port. Total traffic handled in Rotterdam amounted to 288 million tonnes, which is still about 100 million tonnes ahead of Singapore in second position. The majority of traffic handled through Rotterdam is liquid bulk (oil, oil products, chemicals, etc.) with some 135 million tonnes. Dry bulk comprises 94 million tonnes, mainly consisting of iron ore and coal for the German steel industry. In general cargo, Rotterdam has been the largest container port in the world for years, but has now given up this position to Singapore and Hong Kong.

Antwerp, the second largest European port, moved to the ninth position in the world's top 10. It has a growing share in container traffic, but is also strong in other types of general cargo handling. Antwerp is an important competitor for Rotterdam. The third largest European port is Marseilles with some 92 million tonnes in 1990. Traffic through this port consists mainly of oil.

The largest ports in the United States of America are Philadelphia, Corpus Christi and Houston. Their size is on the order of 60 to 70 million tonnes handled per year, which makes them of medium size in comparison with European and Japanese ports. The most important type of goods handled is liquid bulk, which is essentially oil and oil products.

MARKET FORCES

Demand

Demand for seaport facilities and services comes primarily from transportation activities. Transport companies are in need of such facilities in order to handle the goods from one transport mode to another. The demand for these companies (in effect the demand for transport services) comes from shippers wanting their goods to be transported and thus depends on the economic activity in the hinterland of the port.

Supply and competition

The variety in the supply of seaport facilities and services is very wide. It concerns not only the handling of cargo from one mode of transport into another, but also storage of goods, distribution facilities, customs clearing, towing and berthing of ships, food and fuel supply services, customs handling, etc.

During the 1980s there has been a tendency to incorporate the broad variety of services with the transportation services themselves. Hence, transport companies have changed into service providers offering the complete logistic chain from one door to another: the door-to-door concept. Due to automation and electronic data interchange techniques (e.g. INTIS in Rotterdam) transportation and handling processes have become highly efficient. This enables transport companies to meet with increasing demand for just-in-time delivery systems of industries.

INDUSTRY STRUCTURE

Port traffic

Most of the EC's largest ports can be characterised as importing ports as incoming traffic is much higher than outgoing. There are only few ports where exports exceed imports: Calais, Rouen, Algeciras-la-Linea and Tyne. Similar situations exist in the USA and Japan. In the USA, only Duluth is effectively an export harbour; in Japan, Tokyo can be characterised as such.

The breakdown by type of traffic in Table 4 shows which is the dominant traffic through the EC's ports. In each Member State, one or a few ports specialise in liquid bulk traffic. These are essentially the locations for import of oil and oil products. Examples are Le Havre and Marseilles in France, Wilhelmshafen in Germany, Trieste in Italy, Sines in Portugal and Southampton in the United Kingdom. Similarly, specialisations exist for dry bulk traffic. Ports like Bremerhaven and Lubeck in Germany and Limerick in Ireland handle practically only dry bulk goods. Finally some ports can be characterised as general cargo ports, such as Brugge-Zeebrugge, Calais, Dublin, Valencia and Felixstowe.

Strategies

The Port Authority of Rotterdam has presented large investment plans. Investments should enable the port to reach a volume of traffic handled of 400 million tons by 2010. Investments should be directed to attracting high value added services, for which high skilled workers and specialists will be needed. Total investment budget amounts to some 11 billion Dutch guilders, of which 7 billion will come from the central government. In addition, private companies will have to invest another 20 to 25 billion Dutch guilders in suprastructures and facilities. Among these plans are ideas to increase the number of container handlings in Rotterdam to 9 million TEU by the year 2010. This Delta 2000-8 plan is a joint initiative of the port authority and the largest container stevedore, ECT.

Other issues in the development of the port of Rotterdam are also relevant. Very important for Rotterdam will be the construction of the Betuwe-lijn, a freight-only railroad which should connect the port with Germany. Another issue is the opening of the Rhine-Main-Danube canal, enabling Rotterdam to extend its hinterland connections to the countries bordering the Danube and the Black Sea. Furthermore, the transformation of certain parts of the port area into specialised port locations are envisaged, (e.g. distribution centres ("Distriparks") and new installations for fruit and vegetable handling).

In Belgium, large investments are also envisaged. In Antwerp the Left Bank development will cost about 37 billion Belgian francs. Further plans exist to enlarge the container terminal costing about 13 billion Belgian francs, and to renovate docks and locks at another 13 billion Belgian francs. In addition the Belgian government wants to deepen the Westerschelde, Antwerp's seaway to the North Sea, and the Port of Zeebrugge at a total cost of 10 billion Belgian francs.

Europe's largest ports not only have investment plans. Smaller ports also want to improve their position by investing in infrastructure, suprastructures and operation facilities. An example is Bordeaux's study entitled Port Avenir 2000. Another example relates to Barcelona and Valencia. These ports have initiated major container terminal developments in view of attracting direct liner calls. The port of Piraeus also has ambitious plans: the current terminal facilities will evolve into a pure passenger and cruise terminal, whereas the cargo handling facilities will be relocated to a new area west of the city.

REGIONAL DISTRIBUTION

With Rotterdam, Antwerp, Hamburg and Le Havre, most of the EC's largest ports are to be found in the Le Havre-Hamburg range. These ports are the most important gateways to industrial and consumption areas on the European continent. This hinterland can be reached easily by way of a high standard infrastructure in terms of road, rail and inland waterways. The Rhine River is especially important for the port of Rotterdam. Without this connection and its good geographical location on the North Sea, Rotterdam may not have evolved into the world's largest port.

Ports in the United Kingdom and Ireland have the domestic market as their hinterland. Good connections exist from UK ports to the major industrial areas. These connections mainly consist of motorways and railways. Inland waterways have over the years become less important. Current plans exist for its revival. An important activity of UK ports (especially in Scotland) relates to the offshore activities on the North Sea. A port like Aberdeen, for example, highly depends on service provision to oil rigs in the North Sea and on oil handling coming from the North Sea oil wells.

In the Mediterranean, Marseilles and Genoa are important ports, especially for the import of oil and oil products. Their hinterlands can be found in the southern part of France (e.g. Lyon and surroundings) and the North Italian industrial areas (e.g. Milan and surroundings), respectively. Other goods handling activities are very dispersed over the broad variety of small ports along the coasts of the Mediterranean, Adriatic and Aegean Seas. Some ports are emerging though. Algeciras-la Linea in Spain, for example, has become far and away the leading container transhipment port in the Mediterranean and has ambitious development plans to maintain this position.

ENVIRONMENT

Port authorities are more and more concerned about environmental issues in their ports. Operators will have to comply with environmental legislation becoming stricter year by year. But this is not seen as a negative point. Shippers more and more want their products transported in an environmentally responsible way, as they do not want their names combined with negative publicity from environmental accidents. They even tend to demand transport facilities which are ahead of national legislation. This forces port operators to do heavy investments in environmentally sound handling facilities.

REGULATIONS

The supply of seaport facilities and services must be distinguished in the provision of infrastructural and suprastructural facilities and handling services. Facilities are generally managed by a port authority, whereas handling services are mostly in the hands of private companies. The situation however, differs very much from country to country. Port authorities and companies can be either publicly owned or privately owned (or a combination).

In general, three types can be distinguished concerning the principle of exploiting port facilities:

- fully centralised ports, where exploitation is in the hands of the port authority. This authority is a state body. It does not exclude collaboration with private companies, but decisions on investments are mainly with this body. Examples are most Spanish ports, Italian ports, some ports in France and Denmark.

- decentralised ports, where the port authority is a municipal or collective body. Examples can be found in Belgium, the Netherlands, Germany, the United Kingdom and Portugal.

- fully private ports, where the port authority is a private company. Examples can be found in the United Kingdom, where Associated British Ports is the owner of 21 ports throughout the country, in Germany (e.g. Wilhelmshafen), Greece and Spain.

A very difficult issue is port pricing. Various principles of port pricing are used and depend effectively on the extent of subsidisation defined in national port policies. An extreme principle is that port pricing should be such that all costs of the operations together with depreciation and financing costs of infrastructure and suprastructure have to be recovered. The other extreme is that port services are public services to be priced at marginal rates. Cost recovery is then made from subsidisation originating from public budgets.

In practice, port pricing is generally made on the idea that costs from operations and suprastructures should be recovered. Investments in infrastructure are generally subsidised by central or local governments. The deviations are however large, which causes onerous competition among ports.

The European Commission is currently developing guidelines for integrating ports into trans-European transportation networks. A Common Port Policy could complement maritime and infrastructure policies and harmonise the terms of competition among EC ports. In particular it may address the distortions from financial support by public authorities and the recovery of infrastructure costs from its users.

Another issue is cabotage. For the transport sector as a whole, cabotage will become important in the future. New regulation will allow domestic transport by operators from other Member States. This may cause shifts in transport flows throughout the EC and, as a consequence, shifts goods handling through EC ports. Some ports will benefit; others will be harmed. It is likely that small ports may encounter problems as traffic flows could concentrate in major hubs.

PASSENGER TRANSPORT

In most ports in the European Community, passenger traffic is negligible or even non-existent. For some ports, however, it is the main activity. The ports along the Channel depend heavily on ferry traffic between the United Kingdom and France. The opening of the Channel Tunnel by 1993 is considered a major threat to the ferry operations on the Channel and as a consequence to the ports along the Channel.

Furthermore, some ports in the Mediterranean have important passenger facilities for ferry links. Important examples are in the south of Italy, where ferry connections exist with Greece and the countries in Northern Africa. Also, Greek ports generally have passenger facilities providing for domestic inter-island ferry links in the Aegean Sea.

Finally, mention should be made of the ports in Northern Germany and Denmark. From these ports, important ferry links exist with Sweden and Norway. Copenhagen is currently building a new passenger terminal due for 1994 enabling the handling of 10 vessels simultaneously.

An important issue in passenger transportation is the existence of duty and tax free sales on ferry boats and in passenger terminals. The European Commission is inclined to abolish these sales on ferry links between Member States. This would harm the passenger transportation sector severely as a substantial share of their revenues are from sales of duty-free goods. Abolition has now been postponed until 1999.

CONTAINER TRANSPORT

Container traffic emerged from the need to unitise general cargo items into manageable units of equivalent size. For this purpose the twenty-foot container was developed which could be easily filled with general cargo for transportation and easily stripped when reaching its destination. During its development, containers of different size emerged, but the standard unit of measurement has remained the twenty-foot container. Traffic flows are thus expressed in Twenty-foot Equivalent Units (TEUs).

In 1991, total container handling in ports throughout the world amounted to some 90.7 billion TEU (86.1 billion in 1990: +5.3%). Expectations by the Japanese Container Association indicate a further growth to about 115 billion TEU in 1995, an annual growth of about 6% on average.

The largest container ports are currently Singapore and Hong Kong, handling over 6 million TEU in 1991. These ports have been able to become major hubs in the Southeast Asian region for container traffic flows, where the large container line companies are calling. In 1991, both ports show growth rates of over 20%. Japanese ports, however, show relatively low 1991 growth rates in container handling, varying from only 3% for Kobe to some 10% for Yokohama. In the USA, the ports of New York and Los Angeles encountered reductions of about 5%, whereas Long Beach realised an increase of some 10%.

Looking at the ports in the Le Havre-Hamburg range also relatively low growth rates are shown. Rotterdam is clearly losing market share to the benefit of Hamburg and Antwerp. In 1991, the volume of containers handled in Rotterdam increased by only 3.6%, whereas in Hamburg and Antwerp this volume increased by 14.3% and 17.2%, respectively. This shows the severe competition among ports in this range to attract container traffic and become the major hub in Western Europe.

Port authorities and container handling companies make heavy investments to create an attractive infrastructure where containers and container ships can be handled as fast and as reliably as possible. Modern container terminals operate with highly automated container location and tracing systems. An example is the Maasvlakte-terminal of ECT in Rotterdam, where modern straddle carriers can trace containers automatically. Large gantry cranes also need to comply with the increasing ship size: the largest ships (of so called 'post panamax size') carry up to 4500 TEUs.

OUTLOOK

The outlook for cargo handling depends heavily on the prospects for world trade and world shipping. As world shipping is fairly depressed, especially in bulk transportation, the future for cargo handling is bleak. In the short term, growth in European ports may amount to about 1.5%, whereas in the medium term annual growth rates may not exceed 2.5%.

The outlook for container handling in ports is more optimistic. It is expected that general cargo growth will be above the

Table 6: Ports
Expected annual growth rates

(%)	1992-93	1992-96
Cargo handling	1.5	2.5
Container handling	4.0	6.0

Source: NEI

total cargo average. Furthermore, within general cargo substitution from ordinary cargo to containerised cargo is likely to proceed. Container handling growth rates are thus expected to amount to about 6% on average. Some ports, however, will be able to establish higher growth rates. This will depend on the increasing tendency to create large trunk lines between major hubs in various regions throughout the world. From these hubs, feeder lines will service container traffic demand in other ports in the region.

Written by: Netherlands Economic Institute

Airports and other air transport facilities
NACE 764

The airports throughout the EC heavily compete to become major hubs for international and intercontinental flights for both passengers and freight. Capacity problems disturb the competition process. The timing of investments in capacity extension will influence the competitive advantage of an airport. In view of the future liberalisation of the EC aviation market a shake-out of airline companies can occur. Some large companies will remain each deciding on which airport is going to be its home base or major hub.

INDUSTRY PROFILE

Description of the sector

Supporting services to transport (airports and airfields) includes units exclusively or primarily engaged in the activities essential to air transport, without transporting passengers or goods themselves. Classified in this group, are units exclusively or primarily engaged in the operation of civil airports and airfields (public and private), radio beacons and radar stations. Also included are units taking care of air routes and air traffic control. This monograph deals with airports only, for which limited statistical information exists.

Main indicators

SRI measured employment in total aviation related activities in 1988 at 426 000 people. Excluding aviation employment, total non-airline employment in the EC can be roughly estimated at some 115 000 people, 27% of total aviation related employment.

Looking at passenger transportation by air to and from the major EC cities, growth rates average at 6.8% per annum between 1983 and 1990. The largest growth was observed for Stockholm's airport Arlanda (9.2%) and for London Gatwick (7.7%). Relatively slow increases were measured for Paris-Orly, the Rome airports, Athens, Luxembourg, Palma Majorca, Zurich and Copenhagen.

Freight handled at airports in the major EC cities increased by 6.6% on average during 1983 and 1990. Strong growth with percentages above 10% per annum were recorded by the airports of Maastricht (24.2%), Manchester (17.2%), Cologne (16.9%), Brussels (12.7%), Luxembourg (12.6%) and London Gatwick (10.5%). Minimal growth (below 4%) occurred in Athens, Paris-Charles de Gaulle and Copenhagen.

On average passengers handled on airports in the main European cities in 1991 diminished by 5.2%, following the effects of the Gulf war. The most serious reduction occurred for the Stockholm Arlanda airport (-13.9%). Other airports with considerable reductions were those of Rome, London Gatwick (also due to a change in the London Traffic Distribution Rules) and Copenhagen. Amsterdam was the only airport which was able to maintain the number of passengers handled.

For freight the drop in activity in 1991 was less dramatic. Total tonnage handled at the airports was reduced by 1.8%. Differences between airports are however large. Strong declines were observed for Madrid (-15.9%), Frankfurt (-5.3%) and the London airports (-5.5%). On the other hand, Brussels and Cologne airports show increases above 12%, for Luxembourg growth amounted to 7.5%, Amsterdam was able to increase the volume handled by 4.2%.

International comparison

The world's largest airport city is New York. At its three airports nearly 75 million people have been handled throughout 1990. About 40% goes through the J. F. Kennedy airport, which handles most international traffic. New York is also the most important freight centre in the world with 1.7 million tonnes.

In South East Asia the largest airport city is Tokyo handling some 60 million passengers and 1.4 million tonnes of freight in 1990. Its major airport for international flights and freighting is Narita, which was newly built some years ago.

When comparing volumes of passengers and freight handled in the three world regions, the USA clearly takes the largest share (about 60% in passengers and about 45% in freight). In this country aviation has developed into the major transportation industry for domestic connections. The bulk of passenger and freight flows through USA airports are movements within the country. For freight, developments are particularly influenced by express freight services.

The share of EC airports amounts to some 30% in both passengers and freight. A major part of this concerns intra-EC or intra-European traffic.

The large South East Asian airports handle about 10% of passengers and 25% of freight. In Japan, traffic is dispersed among a lot of regional airports due to capacity problems. In the future some may become major hubs for both intra-regional and intercontinental traffic. Freight handling at Asian airports is particularly relevant for high value electronics shipped to the European and American markets.

MARKET FORCES

Demand

The strong growth in demand for passenger air transport is mainly due to the increasing globalisation of trade and the growing internationalisation of companies. This has led to an increasing demand for fast and reliable air transport for business people. The growth in freight also relates to the growing need for express freight services. This is particularly the case for high value goods (of limited weight) like electronic products, and goods for which fast transport is crucial (e.g. perishable goods and urgency goods).

Especially airports in Portugal, Spain and Greece heavily depend on charter flight handling. In Northern Europe some airports specialise in charter flights (e.g. Manchester, Maastricht). However, these specialisations are often due to other reasons than business policies. For example, until 1991, charter flights from London were deliberately assigned to Gatwick in order to alleviate capacity problems at Heathrow.

Supply and competition

Airport capacity is determined by several factors, such as runway layout, number of runways and gates at the terminal and number of positions on the apron. Also, within the terminal the check-in capacity depends on the access to the airport, the number of check-in counters, the capacity of the baggage handling system and the use of modern electronics. Further, juridical conditions are of relevance, such as restrictions on night flights, customs control capacity, etc.

Most EC major and medium-sized airports operate just under or even at capacity levels. For some airports, such as Barcelona, Milan Linate and Rome Fiumicino, capacity problems are really severe. To get over the critical state of the present situation at Milan Linate enlargement works are expected to increase capacity by about 30%.

Production process

The services provided at airports form part of logistic chains. Passengers travel from one location to the other using air transport as a part of their total routing. Air transport involves adequate connections with other transport modes, lounges for waiting passengers, customs facilities for international flights. Further the passenger wants sufficient facilities such as bars, restaurants and shops in order to while away necessary waiting time.

Airlines also require services: they need weather forecasting services, fuel provision, flight catering services, maintenance facilities. In particular they need an adequate check-in procedure in which the passenger and its accompanying luggage is well administered and allocated to the correct flights. Of particular relevance is security services. Adequate security monitoring of passengers and their luggage has become extremely important.

Finally, government requirements need to be mentioned. These relate to facilities enabling law enforcement, customs control and air traffic control.

Similar requirements exist for freight forwarding at airports. Services also form part of logistic chains in particular for industries. These more and more require modern logistic concepts like Just-In-Time and Door-to-Door transportation. Such facilities are comparable to those for sea ports.

INDUSTRY STRUCTURE

Profile

Europe's busiest airport is London-Heathrow. With a total number of passengers handled of some 40.2 million in 1991. The second busiest is Frankfurt with 27.3 million, followed by Paris-Orly (23.3 million), Paris-Charles de Gaulle (22.0 million), London Gatwick (19.0 million), and Amsterdam and Rome (both 16.5 million).

In terms of freight handling the largest airport in Europe is Frankfurt with over 1 million tonnes in 1991. Next come -in descending order- London-Heathrow (660 000 tonnes), Amsterdam (630 000 tonnes), Paris-Charles de Gaulle (590 000 tonnes) and Brussels (315 000 tonnes).

When looking at the number of aircraft movements the same airports occur. London-Heathrow ranks first with 360 000 movements in 1991. Next is Frankfurt with 312 000, followed by Paris-Charles de Gaulle at 250 000. Stockholm and Amsterdam are in fourth and fifth position with 223 000 and 206 000 movements respectively.

Strategies

Capacity problems are the main current concern in airport strategies. Capacity problems especially occurred on air routes and in air traffic control and the number of aircraft that can be handled simultaneously at the airfields.

Another issue of strategic importance is 'safety first'. Terrorism has forced airport authorities to considerably improve safety facilities. Further, as 70% of airline accidents occur during take off and landing, high standard safety conditions are required in air traffic control on the airfields.

Capacity problems and safety provisions together with the need to keep ahead of competition forced airport authorities to invest heavily in new facilities and service improvement. They try to attract new traffic by offering high quality services to all users of the airport. They also try, in cooperation with regional authorities, to attract economic activity. For example there is good cooperation between regional authorities in the Ile de France region and Aéroports de Paris. Another example is Amsterdam-Schiphol. Together with regional and local bodies this airport drafted a strategic plan until 2000 for the development of both the airport and the region into a main port similar to the port of Rotterdam.

To mention a few of the investment initiatives by airports, the Italian Ministry of Transport has made a national airport

plan for the development of its airports. This plan not only envisages to invest in the large airports in Rome and Milan, but also in the small regional airfields. The Airport Authority of Copenhagen is drawing up a master plan for a substantial enlargement of facilities including a second terminal due for 1997. Munich has recently started operations at a completely new airport abandoning the old one near Riem. Athens has resumed plans for a new airport at Spata. Lisbon's terminal expansion is nearing completion.

ENVIRONMENT

Environmental issues are of major concern for airports. Restrictions have been imposed on noise levels of planes taking off and landing.

Other ecological issues have also the attention of airport authorities. Restrictions exist for operations during the night. Some airports even do not allow night flying. Further, restrictions are imposed on emissions of aircraft engines. Finally, various airport services become more and more aware of their ecological responsibility. This relates for example to maintenance and repair services for aircraft, fuel provision services and catering services.

REGULATIONS

In the EC, the legal structure of airport authorities varies widely from one Member State to another. There are six main types of airport statutes:

- public establishments (e.g. Aéroports de Paris, Copenhagen Airport Authority);
- airports owned and managed by joint stock companies (e.g. Frankfurt: 31.7% Federal Government, 42.5% State of Hessen, 25.8% City of Frankfurt; Amsterdam-Schiphol: 76% State Government, 20% City of Amsterdam, 4% City of Rotterdam);
- public airports managed as concessions by public institutions (Marseille, Nice);
- public airports managed as concessions by private companies (e.g. Aeroporti di Roma SpA in which Alitalia has a 51% stake);
- airports owned and managed by a private company (e.g. British Airport Authority plc managing the three London airports plus Southampton and three Scottish airports);
- state operated airports under a national airport authority (e.g. in Spain, Greece, Belgium, Portugal and Ireland).

In order to implement an EC airport policy the Commission has made a categorisation of airports throughout the Community. Category 1 airports are the major hubs or capital airports such as London, Paris, Frankfurt and Amsterdam. Category 2 covers the larger regional airports, such as the airports of Marseilles, Hamburg, Shannon, Luxembourg, Barcelona and Manchester. Finally the category 3 airports are those remaining offering international services. Airfields for domestic services only will not be subject to EC policy.

DUTY AND TAX FREE SALES

Duty and tax free (DTF) sales have become highly important for airports as a source of revenues. Passengers want to benefit from low priced alcoholic and tobacco products available in the DTF shops on the airports. NEI estimated total DTF-sales on EC airports at about 1.3 billion ECU in 1988, of which 56% relates to passengers travelling within the EC. DTF-shops operate under concession agreements with the airport authorities. Income for airports from these agreements amounted to about 480 million ECU in 1988.

The European Commission envisages to abolish DTF-allowances for passengers travelling within the EC. To overcome the loss of concession income, landing and passenger charges would have to rise by 13 to 25%. Airlines will have to pass these higher charges to the traveller by increasing their fares, possibly causing a negative effect on traffic demand especially in the market for Inclusive Tours.

The effects may aggravate due to related developments. Firstly, airline companies, especially charter airlines, will lose revenues from on-board DTF-sales. They, on their turn, will also cause a cost push on fares to overcome this. Secondly, the European Commission wants to impose value added tax on fares and excise duties on fuel for flights within the EC. The combined result may be that fares increase to such an extent, that substantial reductions in demand occur. These problems have led to a postponement of abolishing DTF-allowances within the EC until the 1st July 1999. In the meantime the DTF-industry will develop a system of vendor control, in which the vendor will check compliance with DTF-allowances. This system is necessary as customs control for travelling within the EC will disappear.

Financial services

NACE 81, 82, part of 83

Throughout the world, banks and financial institutions face a complete upheaval in their industry and professional practice, as a result of deregulation, changing professional demarcation and globalisation. The development of information and communications technologies is a major force for change. The 1980s saw the emergence and continuation of many aspects of this transformation. The 1990s will be the decade in which to adapt to them.

INDUSTRY PROFILE

Description of the sector

The financial sector was traditionally split up into various activities which the authorities kept strictly separated, prohibiting diversification. However, distinctions between commercial banks (the role of which is the financing of industry and the granting of consumer credit), investment banks (which concentrate on the top line of enterprise), and brokerage houses were largely removed. Progressive liberalisation of the financial professions within the EC has allowed banks to play a direct role in the sale of shares and bonds, as well as in related activities. At the same time, links between the banking and insurance professions have grown. Some insurance companies now offer credit services and payment facilities, while banks offer insurance products.

Main indicators

In the twelve countries of the EC, the importance of the financial sector in terms of value added grew markedly, reaching 6.83% in 1988, an increase of more than 1% from 1985.

The United Kingdom and Luxembourg are particularly important in the financial sector, which represented 16.21% and 17.80% of national added value respectively in those countries in 1988. This can be partially explained by the relative importance of national markets established in those countries. The relative importance of the assets of the financial sector also accounts for the greater size of the Luxembourg and UK markets.

Growth of the financial sector does not, however, imply proportional growth in employment. Financial institutions generally have too many employees, inasmuch as productivity grows steadily.

International comparison

In total balance sheet terms, the three main banks in the world in 1990 were Japanese. These Japanese banks were followed by ten European banks and three American banks in the top 20. The domination of the Japanese banks is a result of their strategy of increasing assets to the detriment of profitability and personal resources. The comparatively poor performance of US banks is the result of restrictive regulation which limits the field of activity of the banks both geographically and commercially. The US banking system is extremely fragmented and poorly diversified.

European financial markets are of such size as to compete with both the USA and Japan. Bank deposits in the EC were 1.5 times those of the USA and three-quarters those of Japan. Market capitalisation of domestic shares on European financial markets accounts for one-fifth of the global total and two-thirds of New York capitalisation.

Foreign trade

Growing internationalisation of banking services and activities linked to shares and bonds prompted a significant expansion of international financial services markets. Between the end of the 1960s and the beginning of the 1980s, there was particular growth in Euro-currency and Euro-credit operations (carried out directly by banking establishments of major stature), as well as traditional trade-linked operations and new forms of Eurobonds.

Since the beginning of the 1980s, there has been a reorientation towards basic share operations, especially the underwriting of international bonds and the provision of brokerage services linked to international transactions in nationally-quoted shares.

constitute one of the most important branches of the financial services sector. Provision of banking services has grown considerably since the 1960s, with the result that many countries are reaching saturation point. Banks are often only able to secure new customers by directly luring them away from competitors.

In the case of financial services to industry, however, three main trends can be identified. The first is increased growth in demand for very specific services tailored to the management of assets and liabilities, based increasingly on computerisation, and working via a wider range of instruments, among them options and new fixed-term instruments. The supremacy of the banks has been challenged by large companies, with their own systems of financial management.

Secondly, intervention by the banks in the management of businesses, and the growth in demand for services offered by commercial banks for financial restructuring and reorganisation, mergers and acquisitions, take-overs and leveraged management buy-outs has been increasing.

In addition, small and medium-sized enterprises with a solid track record but which are unable to meet the criteria for an official market quote revived demand for risk capital companies, as well as the opening up of new segments of the official stock markets, such as secondary markets or unlisted securities.

Financial services linked to shares (especially the issuance of shares, brokerage services, share transactions and portfolio

management) have become the most important segment of financial markets since the beginning of the 1980s.

Around 1982, when balance sheets and capital were most exposed to liquidity and country debt risks, a clear reorganisation took place, oriented towards stock-market based operations, in particular underwriting international bond issues and international transaction brokerage. There was, in addition, an unprecedented development of new forms of off-balance-sheet operations, especially international issues on money markets, and exchange rate risk coverage instruments. However, this involved an increase in speculation.

Supply and competition

Whereas previously concerns about potential conflict of interest regulated policy, it is now considered necessary to move towards diversification by allowing financial institutions to work in a wider range of areas and with a wider range of products in order to promote competition and boost efficiency in the financial sector. Financial institutions, which were extremely specialised, therefore acquired more flexibility and incentive to exploit new possibilities which had opened up as a result of increased demand for financial services. Institutions still retained some of their tendency to specialise, however.

While competition in new products and, to a lesser extent, price competition, grew in importance, geographical competition - the traditional network of banking outlets - weakened for the most part from the end of the 1970s, as home banking and automated banking increased. Product competition became particularly intense in household savings, with the appearance of a greater number of more and more diversified players, both from within and without the banking system. These included credit institutions, insurance companies and co-operative investment organisations.

Diversification and intensification of competition were helped along by the deregulation which occurred in all European countries from the mid-1980s, specifically,

- an end to monopolies accompanied by free negotiation in brokerage, which led to a reduction in commissions;
- reorganisation of the market for treasury stocks, with the appearance of specialists in most countries whose role was to stimulate the market and assure its liquidity;
- creation of secondary markets;
- computerisation and the subsequent improvements in market liquidity and the precision and speed of information;
- creation of markets in ancillary products, notably the United Kingdom's LIFFE and France's MATIF, taking their respective places as fifth and sixth largest derivative markets in the world.

In addition, all countries undertook major reforms of their currency markets, including the issuing of credit notes negotiable on the market in national currency. Businesses can now finance their needs by issuing treasury bonds. Banks can also enlarge their field of operation with deposit certificates. National treasuries facilitate management of their debt by issuing negotiable gilts.

Changes that have taken place on money markets have prompted the appearance of instruments used to convert loans into negotiable debt certificates. This innovation, inspired by experience in the United Kingdom and the USA, is beginning to be implemented in France and does not yet exist in Italy and Germany.

For individuals, there has been a increase in co-operative management products and savings, especially in France. Total assets of investment funds in Europe rose from 196 billion ECU in 1985 to 518.2 billion ECU in 1989.

Production process

The decade of the 1980s was marked by the removal of intermediaries, and led to the development of markets and innovative new products. However, reduced activity on the part of intermediaries does not appear to be irreversible. A collapse of the stock markets could quickly turn the situation around. It would therefore be more useful to consider the emergence of greater competition between networks of intermediate financing and those of direct financing, with agents choosing between the two sources.

In the context of the development of new systems of financing, new regulation on the functioning of markets is essential to maintain the stability of the system and reinforce investor protection. The entire supervisory process with respect to capital markets has therefore been expanded. Monetary authorities have strengthened their prudential control on financial in-

stitutions through the application of liquidity and solvency ratios and the elaboration of new international standards. The Cooke ratio will, as of 1993, oblige banks throughout the world to respect a proportion of 8% between assets, reserves and provisions and total commitments according to the nature of investment risk.

Deregulation led to an explosion in market activity and a proliferation of products, but an indispensable factor was the availability of enhanced computer technology and telecommunications, which allows instant access to movements on the global marketplace. The explosion in "remote banking" is itself a direct consequence of technology. The automation of transactions between bank and customer runs parallel to a general automation of transactional operations.

From the point of view of costs, computers as a mass processing tool permit significant increases in output. Productivity related to administrative functions is growing in the banking sector in the order of 5% to 7% a year. At the same time, by minimising manual intervention, using real time operations, keeping customer files up to the minute, reducing delays and making deadlines more reliable, computers are an important quality tool, as well.

The consequences of this change in organisation of work are to be found in the globalisation of tasks as opposed to compartmentalisation; in the overall responsibility of partners for good practice, reasonable costs and a satisfactory outcome of the operation; in the improvement of working conditions; and in the increase in the number of possibilities for employees to maintain direct contact with the customer.

New technologies presuppose new staff skills. Financial establishments which hired great numbers of untrained staff during the race for expansion in the 1960s and 1970s are now faced with major investments for training and for underwriting redundancies. In addition, the additional costs of investing in computerisation have a deleterious effect on profits of banks and insurers. Set against a background of growing competition, the way institutions handle such changes will be crucial in the years ahead.

INDUSTRY STRUCTURE

Companies

The traditional fragmentation of the European banking sector will result in the effects of competition being intensified, especially in the case of stockbrokers. The largest of the European banks still only represent about 2% of the market in terms of either credit, deposits or turnover. In comparison, major firms in manufacturing industry, hold market shares of between 15% and 45%.

In the insurance sector, the concentration is higher, with fewer than 600 companies accounting for 80% of premium income. There is however a movement towards mergers and acquisitions, both in banking and insurance, as geographical diversification is accepted as a prime means of moving outside saturated domestic markets. The principal obstacle to such mergers and acquisitions remains the regulatory climate applied by the authorities. Attempts to acquire foreign networks also run up against social and cultural obstacles. Consumers tend to prefer to put the management of their affairs into the hands of a local banker or insurer. Accordingly, the infrequency of mergers and acquisitions tends to push up costs - these can equate to 20 or 30 times annual profits - but such moves are necessary if banks and intermediaries are to bolster their asset position and solvency ratios.

Despite this, mergers and acquisitions in Europe have grown spectacularly the last five years. Between 1985 and 1989 the cross-holdings between banks have almost quadrupled, while those between insurers have doubled.

Table 3: Financial services
Mergers and acquisitions in the financial sector

1986	3.5	13.5
1987	3.7	22.3
1988	7.7	29.3
1989	12.0	38.0

Source: CEC

Strategies

Closer cooperation between banks and insurers has been the most notable strategic aspect of recent years, although these two sectors still account for a small proportion of all mergers and acquisitions. There are a number of potential advantages, including the improvement of client service and commercial efficiency with the extended range of products offered. Banks are able to make their cumbersome branch networks more profitable, and insurers avoid having recourse to independent agents and the expensive distribution networks they imply. Also, there are significant potential operational synergies, such as administrative and information technology savings, rationalisation of distribution, joint financial management and the use of complementary distribution networks. Institutions can also profit from increased financial strength, which allows entry into activities requiring greater capital resources. Banks can in fact increase their capital ratios by merging with insurers, which tend to have better ratios.

At an international level, the trend towards greater integration of financial systems takes the form of increased cross-border participation in other companies, as well as an expansion of international markets, especially Euro-currencies, Euro-bonds and Euro-stocks. The need for convergence is high, however, whether in market development, techniques and instruments or applicable codes of conduct. On a more technical level, the need for convergence is also apparent in payment systems and in information for clearing, regulation and current accounts.

REGIONAL DISTRIBUTION

In Europe, London remains the centre of the international financial marketplace, both in terms of stock market capitalisation and volume of transactions. London's pre-eminent position can be explained by the extent of deregulation and the role of the SEAQ international transaction system which deals with European shares.

UK experience has speeded up the pace of innovation in other European countries. New ideas spread rapidly to France as of the beginning of the 1980s, helping maintain the competitiveness of the French financial system. In some countries, like Italy, a growing burden of public debt made former financial market organisation systems obsolete. Improved liquidity in the publicly-quoted stock markets became an essential precondition for attracting foreign capital.

Germany only felt obliged to modernise its financial markets only comparatively recently; reforms there have to date been limited, because of a previously-relaxed system of regulation, and the existence of a decentralised network of regional stock markets which acted as a brake on the development of Frankfurt as the prime exchange.

REGULATIONS

The EC Second Banking Directive (89/646/EC) sets out the minimum conditions to be fulfilled to participate in banking

activities: minimum capital, professional competence, professional qualifications, share structure, and observance of a number of prudential ratios, notably the Cooke ratio.

The Council of Ministers has adopted a common position on a directive liberalising investment services in the securities field which is designed to give a European passport to financial intermediaries. This directive together with the accompanying directive on capital adequacy will enter into force on 31 December 1995.

In the field of insurance, two directives have been adopted, one on industrial risks and the other on life assurance.

OUTLOOK

Since the 1970s, competition has intensified considerably in the vast sector of financial services. Banks, stock brokerage houses and other providers of financial services have become highly competitive enterprises using modern management techniques and commercial strategies.

Market forces now play a decisive role in the functioning of financial systems which had for long been protected and subject to restrictive regulation.

Fundamental changes to supply and demand in financial services, the emergence of new information and communications technologies, increasing internationalisation and inter-penetration of national markets: all are factors which have served to intensify competition.

After 10 years of financial innovation, there are still imbalances in the reforms taking place across Europe.

For financial services and insurance, the Single Market remains a concept whose impact will probably not be felt until around 1995 at the earliest. In fact, savings, financial services and insurance are already global areas for major firms. Individuals, meanwhile, tend to remain attached to locally-available services provided by local companies.

NACE 81

Banking deregulation and progress towards the creation of a pan-European banking sector have reinforced competition and changed the face of wholesale banking as margins on credit to large businesses tighten. The effect of this competition is all the more pronounced in that banking in Europe is lightly concentrated, with mergers and partnerships increasing. Banks have also had to face changes in demand structure towards a series of high value-added products. As a result, maintenance of prices and margins is now dependent on more than innovation and improvement of product quality. Quality of service is the factor that now creates the crucial difference between different networks.

INDUSTRY PROFILE

Description of the sector

Banking is a sector which has traditionally been sheltered by national authorities. In essence, it serves the two functions of accepting deposits and translating them into loans to the enterprises, to the public authorities and to consumers, into investments, and of managing payment mechanisms to serve economic growth. The special nature of banks, however, is being eroded by the trend towards deregulation: some banks' activities are becoming increasingly similar to some of the activities of the other financial institutions with which they compete. More than 150 different activities can now be identified in the banking sector as banks increasingly diversify into share activity and strengthening links with the securities and life insurance sector.

Recent trends

On the whole, 1990 saw annual results plummet throughout the banking sector worldwide. Among those hardest hit were the three leading Japanese banks - DKB, Sumitomo Bank and Fuji Bank. Each was heavily committed to collapsing stock and property markets. In Europe, UK banks were hard-hit by the recession, with 1990 results down by 13.2% at Midland Bank and 11.2% at National Westminster. The German banking sector was the only one to remain healthy due to an explosion in credit demand caused by the reunification. Dresdner Bank results were up 30%.

International comparison

Japanese banks dominate the world market in terms of reserves, with six Japanese banks in the world top ten (see Table 5). This is the result of a decade of exceptional growth during which Japan's banks pursued an aggressive policy of market share expansion that culminated in their moving into first place worldwide in terms of deposits. Aggregate deposits held by European banks are equivalent to no more than three-quarters of deposits in Japan, although European deposits are 1.5 times higher than in the USA. Japan's growth aspirations in this sector have suffered a setback, however, in the wake of the current severe economic crisis which has depressed solvency ratios in particular.

Foreign trade

Internationalisation of credit institution activity is a function of balance sheet totals and the proportion of worldwide commitments. Overall, this has grown in relative terms over recent years. Belgium, the United Kingdom and France are the countries most open to the rest of the world. Meanwhile, Japanese banks have pursued a strategy of establishment in Europe along the lines of their successful strategy in the USA, where they account for some 15% of bank assets.

MARKET FORCES

Demand

European banks began a process of profound change in the 1980s. By the end of the 1980s, however, demand for credit slowed in a low-growth recessionary climate and earlier trends towards an increased number of bank outlets were radically curtailed. At the same time, banking density reached record levels in most European countries (around 90% on average): France, with 2.5 bank accounts per person, is the most densely banked country in Europe.

This is paralleled by the current phenomenon of structural marketplace simplification which has impacted on credit as well as savings. Between 1986 and 1990, the market for commercial paper more than doubled, from 367.9 billion USD to 866.9 billion USD.

The growth of share activity allows businesses to go directly to market for their cash-flow needs. Elsewhere, the pattern of savings is changing; the development of UCITS, co-operative savings banks offering high interest rates on short-term deposits, etc. has resulted in savings being diverted from the banks. Attitudes towards saving differ widely between Member States. Italians set aside 20% of their income for savings on average, whereas the percentage is only 4% in the United Kingdom. Inversely, the rate of consumer indebtedness is 2.5% in Italy and 14% in Germany.

Two major trends are apparent in the sector: stagnation at the level of bank deposits and sustained growth in savings and credit. This twin movement is linked to high levels of bank penetration, now running at 90% for Europe as a whole. The number of bank outlets per capita in Europe is the highest in the world. Belgium, Spain and France in particular have high rates.

Innovation is a prime factor in revitalising demand. Customer demand has moved towards high-quality service. Banks have responded with services such as increased flexible credit. Multi-option facilities targeting the corporate sector offer more flexible fund management via single credit contract, foreign currency financing or special drawing facilities. Both firms and individuals look to banks to provide guaranteed rates of interest and exchange rate; as a result, banks are developing more complex instruments to satisfy demand. The role of innovation in stimulating demand is illustrated by the success of rollover credits which offer clients permanent credit lines.

Supply and competition

Overcapacity, allied to deregulation and weak economic growth, has led to strong competition among European banks. The generalised deregulation has removed many traditional barriers between the different financial sectors, both in the European and in the world markets. The almost complete abolition of exchange controls has led towards a simplification of currency transactions by way of the disappearance of geographical borders. The decompartmentalisation of the various money markets has culminated in the establishment of conditions conducive to a genuinely global money market.

One consequence of deregulation has been the development of intermediary products which permit non-bank investors and borrowers to complete transactions without going through financial institutions, previously mainly the banks. In concrete terms, large volumes are now moved about without involving the banks.

Banks have also had to face greater competition in their efforts to attract funds which would otherwise head towards the markets. The boom of high interest-bearing current accounts in Europe and in the USA - and in France of a particular type of UCITS like the SICAVs - has resulted in increases in the cost of bank funds. While European countries were going through a deflationary phase, real interest rates were being maintained. As a result of this increased competition bank margins have been squeezed, particularly in the case of major corporate clients.

Another consequence of deregulation and tougher competition has been an increase in risk. Arguably, the first sign of trouble came with the crisis of the major Latin American countries in the early 1980s. The USA was the hardest-hit, as evidenced by a string of bank failures, which has continued in the late 1980s and early 1990s because of the collapse of certain economic sectors like the property market and the textile industry, and the general recession. In Europe, the result was not major bankruptcies, but increases in debt provision which squeezed margins further. Provision for country risk cover varies widely from country to country.

More recently, the 1990 crash in the property market following a wave of speculation has also played a part in the increase in bank bad debt provisions also in Europe and in Japan. The Midland Bank closed its property department at the beginning of 1991.

In general, the slowdown in growth has hurt banks severely, all the more so since new competitive pressures have forced banks to undertake more risky transactions. The United Kingdom is one of the countries most affected. At the beginning of the 1990s, the number of company failures hit a record level, and banks had to increase their bad debt provisions. Faced with growing risks, bank supervisory authorities have been obliged to find new ways of dealing with risk in order to maintain the solvency of the banking system. The most important weapon at their disposal is known as the "Cooke Ratio", which corresponds grosso modo to the EC solvency ratio, which has become mandatory as from the 1st January 1993. This obliges every bank to maintain a balance between the total of its own funds and the total of its risk assets weighted according to the riskiness of each category of assets. In this way, both internal and external growth depends on a bank's ability to boost its reserves. The Cooke Ratio was adopted in July 1988 and was fixed at 8% applicable as of the end of 1992, also the Community solvency ratio was fixed at 8%. Overall, European banks are in a better position than their Japanese and American counterparts who have been involved in recent years in a balance sheet race which has seen commitments increase at the cost of solvency.

The changing economic climate has checked growth in the banking system and has brought to light structural weaknesses. Principal among these is an inflation in general costs which, together with declining net banking product, have reduced operating profits. In most European banking groups, investment in information technology is growing between 15% and 20%, but this has not been completely offset by workforce cutbacks. With the increased use of home banking, automatic teller machines and telebanking, it is essential that banks continue to prune the excessive staff. Redundancy strategies are being adopted, but these are often difficult to implement given the important role of collective labour agreements in the banking sector and the sizeable share of banking in total employment.

Overall, European banks exhibit poor levels of profitability. Mediation margins in the EC have dropped by more than 30% over the last three years, to the lowest in the world after Japan.

In total balance sheet terms, the Japanese banks maintain their position at the top, but the European and American banks have recovered part of their lost positions.

Production process

Technology and computerisation are of crucial importance for banking productivity and the development of new activities. The growth in market activity in this sector must be attributed mainly to technological progress which has resulted in instant access to information for operation. The development of home banking is a direct consequence of technology. As of the beginning of the 1980s, banking entered the computer age, with marketing of specific services such as long-distance banking by computer. A high degree of interbank compatibility has resulted in France developing one of the largest automatic teller networks in the world, with one machine for every 1 500 customers. On the other hand, customers are now familiarised with card services, and expect something new, such as genuine one-stop agencies featuring automated disc-storage, cheque printing, information and advice. Apart from automatic cash dispenser, telebanking now includes a variety of video text services. There is a definite trend towards total transaction automation between bank and customer.

Computerisation is a processing tool that can produce major productivity gains. Estimates show that administrative productivity is growing annually at about 5% to 7%. However, investment in computerisation represents a heavy financial burden. In the decade 1980-1990, bank spending for computers rose by nearly 30%.

In addition, banks show an increasing tendency to centralise their technological resources, concentrating their information technology system in a limited number of centres, typically on a group or regional level.

The cost of acquiring a new customer is very high, at around 1 156 ECU high according to a recent study. Adding one point of market share is estimated to cost between 1 billion and 2 billion ECU in investment.

INDUSTRY STRUCTURE

Companies

The banking sector in Europe is not concentrated. The larger European banks do not represent each more than 5% of the market in terms of credit, deposits or balance sheet total, compared to market share of up to 45% for manufacturing industry leaders in the EC.

Strategies

Banks are developing along pan-European lines, but their impact is still marginal.

European groups are developing two broad lines of strategy, often in tandem. The first line lies in diversification, whether in the sale of insurance products, acquiring shares in manufacturing industry (as German banks are doing), offering a

wider range of various financial services (leasing, factoring, forfeiting, etc.) or dealing in securities both on the stock exchange and over the counter. The most notable development over the past few years has been the emergence of "bancassurance". This has led to numerous agreements between banks and insurance companies - in Germany, between Allianz (Europe's premier insurer) and Dresdner Bank; in the United Kingdom, between Commercial Union and Midland Bank; in France, an entity run by Groupe des Assurances Nationales (GAN) which brings together the Crédit Industriel et Commercial (CIC) and the Banque de l'Union Européenne (BUE); and, in the Netherlands, the NMB-Postbank and Nationale Nederlanden merger.

The second strategy is the creation of mergers or alliances between banks. As mentioned above, through its German operation, Barclays Bank has shown itself to be one of the most aggressive institutions on the European scene. In Italy, the adoption of the Amato Law in 1990 paved the way for major restructuring and modernisation, exemplified by the Cassa di Risparmio di Roma acquisition of Banco di Santo Spirito, and of 65% of Banco di Roma. Increased concentration in the banking sector can be anticipated across the board, but a distinction should be made as to the impact of concentration on large networked banks. In effect, the large banks serve a mass market where productivity gains can be registered, whereas smaller merchant banks specialise in asset management and engage in activities with less of a need for economies of scale. There is, as well, a proliferation of strategic alliances at the European level. BNP, Dresdner Bank, Credito Romagnolo, Commerzbank and the Banco Bilbao Vizcaya have signed partnership cross-holding agreements similar to the strategic alliance already in place involving Crédit Lyonnais, Commerzbank and Banco di Roma.

The move towards concentration in the European banking sector mirrors a similar trend in the USA and Japan. In Germany, the eight major banks control half of all banking assets; in Japan, the half-share is accounted for by 12 banks and in the USA, by 35. Despite the fact that US banks are still subject to legislation which compartmentalises banking activity and erects geographical barriers to expansion, one quarter of the 12 500 existing banks should disappear by the year 2000, with the loss of some 250 000 jobs. Concentration will take longer to achieve than in Europe, but it will come. In Japan, the banking sector is already very concentrated, with three of the top twelve banks ranking high in world ratings in terms of balance sheet total. Nevertheless, concentration is likely to become even more pronounced, and the number of national banks could drop from ten to eight, four of the top ten having already merged between themselves into two new banks, with regional banks declining from 145 to 100. Previously, Japanese banking strategy consisted in cultivating strong asset growth; today, the accent is on profitability through concentration and growth of own resources.

REGIONAL DISTRIBUTION

French banks dominate this sector in terms of total balance sheet and asset base, although their performance in terms of Net Banking Products (NBP) and growth are only average. Three German banks appear on the list of Europe's top 10 banks in terms of balance sheet total, and Germany has as well a fast-growing network of medium-sized banks. UK banks have all the features of mature enterprises: they are large, well capitalised, but with static turnover, NBP and asset growth. Few Italian banks figure among Europe's largest banks. Capitalisation and NBP are average but NBPs and reserves are exhibiting strong growth, although volume is growing rather less rapidly than in Spain. Spanish banks lead the field in terms of growth rates but at the expense of their profitability. The banks themselves are still of modest size, but growth potential in terms of reserves and NBPs is significant. Banks in southern Europe are increasing in both size and dynamism. In terms of total balance sheet growth, three out of Spain's four top banks are in the European top 20.

Europe has high levels of banking activity, with the number of outlets per capita the highest in the world, outpacing Japan and North America. Belgium, France and Spain exhibit rates higher than the European average. Italy has less than 1 000 banks with a total of more than 15 000 branches, but has one of the lowest rates of density in Europe.

REGULATIONS

There are practically no barriers left to entry in each Member State, in accordance with the provisions of the Second Banking Directive (89/646/EC). This imposes a minimum capitalisation of 5 million ECU and provides that the status and integrity of managers and shareholders be vetted by national authorities. Holdings in non-financial companies cannot exceed 15% of the company's capital. Banks have to abide for a wide set of harmonised rules like the solvency ratio, the limits to the large exposures, the consolidated supervision, etc. Some barriers may be laid down against third countries' banks, but all the treatment of the latter is now discussed in the framework of the GATT negotiations.

Unlike US legislation (the MacFadden Act), most European countries apply no restrictions on mergers, with the exception of Greece and Portugal. Italy, in its Amato Law of 20 November 1990, eased restrictions on groupings and banking concentration, but maintained some limits to the acquisition of public banks. However, the measures taken in 1992 concerning the privatisation of the public sector, have repealed most of these limits.

The solvency of credit institutions is an important aspect of banking law. The Second Banking Directive invokes a solvency ratio (to reserves) of 8%, echoing the Cooke Ratio introduced by the Bank for International Settlements for all of the world's banks. On the other hand, the EC Directive limits banks' diversification into areas outside finance.

In almost all European countries, financial intermediaries are now empowered to set their own terms for remuneration of deposits and charges for banking services. Only in France there are statutory restrictions on terms of remuneration for current accounts.

OUTLOOK

The bank/customer relationship is changing. Clients now expect from their banker the widest possible range of financial services, and banks have to position themselves to provide

these services. In the course of this transformation, there has been protracted debate on the respective merits of two kinds of bank: on the one hand, the so-called "universal" or "one-stop" bank which purports to meet the totality of client needs; and, on the other, the "niche" institutions which specialise in a particular segment of the market. These two types of financial institution should coexist in Europe in the years ahead, with the number of universal banks increasing at a slow pace. Few banks at the present time offer the entire range of banking services to its clientele.

In addition, growth in Europe's banking sector will come about through a commitment to higher added value, with quality of service constituting the key difference between one network bank and the next. For the time being, strategic alliances and mergers and acquisitions involving banks from different EC Member States are the exception rather than the rule. In future, however, one can anticipate accelerated moves to bring banks from different European countries together.

Insurance
NACE 82

The insurance sector in Europe is characterised by strong overall expansion, although growth appears to be slowing somewhat in the countries of northern Europe. Markets are moving slowly towards deregulation, although obstacles remain at the national level. This deregulation extends beyond insurance itself and into the sector of global financial services, notably in the form of "bancassurance" which, as the term implies, is a mix of traditional insurance services and banking. The sector as a whole is still oriented towards domestic markets, but it is becoming progressively international.

INDUSTRY PROFILE

Description of the sector

The NACE classification defines the insurance industry as embracing all units "exclusively or primarily engaged in insurance", i.e. converting individual risks into collective risks. Compulsory social security is not included.

Insurance is thus defined in terms of the economic function of converting and mutualising risks. NACE 82 distinguishes three classes of insurance according to the type of risk:

- units engaged in several types of insurance (composites), comprising the following two types of risk;
- units engaged in life insurance, where the risk covered relates to eventualities linked with the duration of human life;
- health, casualty, injury and accident insurance (or non-life insurance), where the risk covered is defined in opposition to the previous category.

Reinsurance is not regarded as a separate category: it is assigned to one of the above three classes according to the type of risk reinsured. Not all countries allow composite insurance undertakings and the creation of new ones has been banned under Community rules for a number of years. The breakdown is thus confined in some instances to two classes: life insurance and non-life insurance.

Much of the analysis in this report is drawn from the report "European insurance and the single market", published by Eurostat in 1992.

Main indicators

Total gross premiums written in the Community were 275 billion ECU in 1990, of which 132 billion were in life insurance and 143 billion in non-life insurance.

The three leading European countries in terms of both overall premium income and premium income by sector (life and non-life) are Germany, the United Kingdom and France. The immense size of the insurance market in the United Kingdom (larger than its counterparts in France and Germany) is somewhat offset in qualitative terms by the lesser degree of protection it affords in terms of social and retirement protection.

The non-life insurance sector represents around 56% of European gross premium income from all sources, compared with 44% for life insurance. The life insurance sector, however, is growing at a faster pace than the non-life sector in all EC Member States (in 1985 the relative share was only 37% for life insurance and 63% for non-life insurance).

Although reinsurance is not considered as a specific activity by the NACE classification, its market share and the proportion of premiums retained by national insurers are essential indicators of insurance activity. They are evaluated from the rate of accepted reinsurance and the premium retention ratio.

The rate of accepted reinsurance measures the proportion of gross premiums written which is accounted for by reinsurance. The few existing data suggest a low rate of reinsurance, generally less than 5% in life insurance and a higher one (though again very variable according to the different countries: it can vary from 3% in Portugal to 19% in the United Kingdom), in non-life insurance.

The premium retention ratio expresses the percentage of total gross premiums written which is retained by the insurers: the remainder represents premiums ceded or retroceded. The retention ratio is very high in life insurance, where reinsurance is fairly rare: for the EC as a whole, it stands at around 96%. In non-life insurance, however, it is lower (about 80%).

Recent trends

The life insurance sector is experiencing strong growth. Even in mature markets such as the United Kingdom and Germany, life insurance business is growing at a rate of two to three times GNP growth. Insurance markets in Italy, Spain and Portugal are less developed, but are also expanding at annual rates in excess of GNP growth. By way of example, life insurance premiums in Spain represented 1.27% of GNP in 1987 and 3.4% of GNP in 1990.

(1) Forecast
Source: Arthur Andersen, "Insurance in a Changing Europe"

Overall, non-life business is expanding more slowly than life insurance, but it has also attained growth rates in excess of annual GNP growth.

Despite growing competitive pressures, however, the European insurance industry as a whole has achieved high growth margins. This is confirmed among other things by statistics on density of insurance. In 1989, average EC density of insurance was below 891 USD, i.e. less than half that of the USA and one third that of Japan. There is considerable north/south disparity within the Member States. Density of insurance is modest in Spain, Portugal, Italy and Greece (averaging below 406 USD). The north is dominated by the United Kingdom, the Netherlands and Germany, where density levels are in excess of 1 200 USD.

International comparison

Compared with its two main competitors, the EC insurance market is slightly larger than that of Japan (238 billion ECU in 1988) but far smaller than that of the USA (456 billion ECU in 1988) which remains the world's biggest market. In terms of market share, in 1988 the USA had 42% of the world market (thought to be some 1 090 billion ECU), whilst the EC and Japan had 23% and 22% respectively.

Each of these three markets is also very differently structured. Whereas the American market is still largely dominated by the non-life sector (some 64% of all operations), the Japanese market is very much dominated by life insurance which accounts for nearly 75% of all business. The structure of the EC market is thus somewhere between these two patterns, but the trend is clear: European insurance is moving further and further away from the American model and closer to the Japanese one.

Foreign trade

In the non-life sector, some 40% of insurance companies derive more than 5% of their premium income via foreign branch activities while, in the life insurance sector, only 25% of companies report similar penetration. In both sectors, these percentages are expected to increase in the years ahead.

The share of foreign-source premium income remains modest in most EC Member States. The exception is the United Kingdom, which is the leading exporter of insurance services in the EC: 44% of UK non-life business and 16% of UK life insurance business derives from non-domestic sources. Lloyds of London (an £11 billion insurance market) derives two-thirds of its premium income from non-domestic sources. The UK insurance sector is traditionally oriented towards the USA and former British colonies, with its continental European business being more restricted. In continental Europe, Switzerland is a very strong presence in the insurance sector. France has also expanded its non-domestic business throughout the EC and has consistently increased its market share in the Member States.

Although they maintain a European presence, neither US nor Japanese insurance groups seem poised to acquire a substantial share of European insurance business in the short term. They are only active to any significant degree in the United Kingdom.

MARKET FORCES

Demand

In the insurance sector, consumer behaviour differs radically depending on whether the policy concerned relates to life or non-life business.

As far as the life sector is concerned, the ageing of Europe's population has played a decisive role in the growth of premium volume. The need for comprehensive insurance coverage increases with advancing years, especially when social security benefits relating to pensions and medical treatment appear progressively inadequate. The Italian and Spanish pension systems (and to a lesser degree the French system) are verging on bankruptcy. In an effort to compensate for the erosion of state benefits, the public is turning increasingly towards life insurance-related products.

Greater life expectancy and a lowering of the legal retirement age have had the combined effect of increasing the average length of retirement to a period equivalent to a quarter or one fifth of human life. The legal or accepted retirement age in every European country is now between 60 and 65 years (except Denmark, with a retirement age of 67 years). The effective retirement age now tends to be the same throughout the EC and is below the age prescribed. In addition, there is a growing propensity on the part of retirees to insure themselves more comprehensively. Incomes of elderly persons measured in units of consumption now exceed the average income of the working population in certain Member States.

Further, the proportion of the working population in all the EC Member States has declined as a result of major pressures on the labour market. In effect, these pressures have encouraged older workers to stop work earlier and delayed the entry of younger workers into the job market.

Improvements in living standards emerge as an essential factor in the shifting patterns of non-life insurance consumption. The population insures not only itself but also its growing number of possessions. In this respect, it is worth noting that the number of cars in the United Kingdom increased from

5.6 to 22 million units between 1960 and 1990. For the EC, demand for passenger cars increased from 3 million units in 1960 to more than 12 million units in 1989. There are also now 150 million homes. Non-life insurance is coming to be regarded as a commonplace product. Here, a distinction has to be made between mandatory insurance coverage on the one hand (car insurance, workplace accident insurance, and so on) and other categories of insurance (life, health, etc.) which are currently marketed. It is above all in the former category that price sensitivity plays a key role. Financial considerations are thus major determinants of consumer choice in both the life and non-life sectors.

Supply and competition

The European market can by divided roughly into two different structures. The continental European market is more highly regulated, less innovative, and characterised by exclusive brokers. The authorities not only exert financial control over the sector but also apply a priori hands-on regulation. These highly-regulated systems are found above all in Belgium and Germany and, to a lesser degree, in Italy and France.

New players have entered the insurance sector - the most significant competitive challenge coming from the banking community. The countries which pioneered "bancassurance" are the United Kingdom, France and Spain; in other European jurisdictions, banks are only now beginning to enter the insurance marketplace. While the banks insurance market share to date is insignificant, the growth potential is very high. It is estimated that by 1995, the share of banks in individual life insurance business will be around 10% of the market in terms of insurance proper and a further 10% as distributors of insurance. In France, 70% of new business written in 1989 was sold via banks or other financial institutions. In Germany, the Deutsche Bank recently set up its own insurance company.

By contrast, non-life business appears less vulnerable at present to the influence of banks entering the marketplace, primarily because non-life business presupposes specialist knowledge and a large distribution network.

Freedom of establishment has not only facilitated market entry on the part of domestic groups, it has also boosted the presence of foreign insurers. The advent of foreign institutions has had the effect of further stimulating competition in national markets. While banks are comparatively inexperienced in matters of insurance; foreign insurers are fully conversant with every aspect of the marketplace, both in terms of innovative products and competitive pricing.

In the wake of heightened competition and a progressively more exigent marketplace, insurers have been forced to become more innovative in terms of the products and services they offer. Overall, the tendency has been towards the development of insurance coverage that is increasingly flexible in character. As an illustration of this, classic (fixed premium) life coverage has been losing ground to policies based on a unit-linked life approach, where the policyholder opts for premium payments which suit his budget and, as required, revises premium instalment levels during the subsequent life of the policy. Such policies continue to offer a guaranteed fixed amount payable on maturity. In some countries, however, there are already variants which offer life insurance linked to investment - implying a financial as well as a technical risk. In such cases, no fixed amount is guaranteed at maturity. In addition, if the investment portfolio underperforms, the implications for the insured party can be serious.

The success of such products will depend on the overall economic climate, the performance of the stock markets and the willingness or ability of insurers to assume this additional risk. It is estimated that unit-linked policies will grow at the rate of 15% on a yearly basis; this compares with annual growth for other categories of insurance products of between 5% and 9%.

The years ahead will see the emergence of completely new insurance products. As a case in point, environment-related coverage is expected to experience fast growth in the order of 10% to 14% annually. Experience in the USA has demonstrated that penalties for environmental infringement can be vary significantly, hence the need for innovative insurance coverage.

Production process

In a unified and deregulated market, tariff structures increasingly reflect management and distribution costs. Management costs and tax prepayments can represent substantially increased insurance premiums. Keeping these costs down necessarily entails the introduction and development of administrative procedures which are as cost-efficient as possible. The various approaches open to them include:

- agents: independent professionals who represent one or more insurance companies and who are remunerated on a commission basis;
- brokers: independents mandated by the client and without any link to an individual insurer; remunerated on a commission basis;
- salaried employees (particularly in the life sector);
- independents: mandated by an individual insurer and remunerated on a commission basis.

The preferred strategy varies from one country to the next. Agents and brokers dominate the market in continental Europe. In Germany, for example, they are responsible for more than 75% of policies sold, whereas the corresponding figure for Italy is closer to 80%. Until now, the use of intermediaries (agents, brokers, independents) has tended to be the rule, but costs are high as a result of the generous commissions paid.

As far as operational costs are concerned, marketing and distribution costs rank immediately after policy payments in terms of size. At Generali, for example, distribution costs represent more than double administrative overheads. Not surprisingly, new and less expensive modes of distribution are being explored, among them: retail chain store sales, including sales desks set up in supermarkets; and sale by correspondence (typically by direct mail or telemarketing).

INDUSTRY STRUCTURE

Companies

In 1988 there were about 4 800 insurance companies in the EC, 2 850 of which operating non-life insurance, some 780 operating life insurance and 350 composites.

The average size of insurance companies is measured in terms of gross premiums divided by the number of undertakings. In the EC, the average size of life insurance companies in 1988, in terms of premium written, was nearly 100 million ECU, that is more than twice that of the non-life insurance undertakings (about 45 million ECU).

This is slightly larger for life insurance than the average size of American companies (85 million ECU), but far smaller for non-life insurance (120 million ECU). Japan is altogether a special case: it has only a hundred or so companies for a market comparable to that of the EC. Japanese companies thus achieve an enormous average size of 4.3 billion ECU for life insurance and over 1 billion ECU for non-life insurance.

In 1988 almost 790 000 people were employed in the insurance industry in the EC. This figure applies to the insurance industry in the strictest sense, excluding the intermediaries - brokers and agents - who are sometimes added.

Most of the leading groups in Europe have a total premium income in the range of 3.5 billion to 7 billion ECU.

France	51 to 60	600
BR Deutschland	41 to 50	800
Italia	41 to 50	260
España	Below 40	450

Sources: GDV, ABI, FFSA, ANIA, VVN, OFAP, UNESPA

With the exception of the Spanish group Euroseguros, the number one insurer in each country is also among the leading insurance companies at European level. Despite the merger of UAP (F), Victoire (F) and part of BNP (F) in 1990, and Nationale Nederlanden's (NL) merger with NMB (D), Allianz (D) remains the undisputed market leader in Europe.

In most European countries, the state holds equity in the major insurers. In effect, it is extremely difficult for the state to disengage from the insurance sector which has an important influence on financial markets. In certain countries, including France, the state views the insurance sector as an instrument of investment policy and formally accords insurers the status of "institutional investors".

Strategies

Insurers have recognised the importance of internationalising to better spread risks and to grow in a saturated marketplace. Since 1987, there have been a number of cross-frontier take-over actions, and more are expected.

In the course of the next five years, the market share of national insurance companies should decrease across the board. In southern Europe, this process should be rapid to the extent that domestic insurance companies have adapted only slowly to the pan-European marketplace and are expected to service no more than 50% of their home markets by 1995. With the exception of Assicurazioni Generali, Italian insurers are very reliant on their home market and are not expected to play a major role in other European markets. The same holds true for Belgium. Insurance companies in France, Germany, Switzerland and the United Kingdom have proved to be extremely aggressive in their take-over strategies; a substantial portion of European premium income is now destined for those countries.

Table 5: Insurance
Total consolidated premium income

11 - 14.5	1	3.2
Over 14.5	1	3.2

Source: Eurostaf

The process of "internationalisation" is largely underpinned by strategic alliances, mergers and take-overs - hostile or otherwise. In the insurance sector - and, more especially, in life insurance - setting-up a new network in a foreign context is extremely difficult. Insurance is a product which is sold rather than bought, and the consumer usually prefers to deal with a local/national entity which he knows and trusts. Decades are required to build brand loyalty. The mergers and acquisitions strategy is fundamental to attaining the critical mass that is vital in a progressively competitive marketplace characterised by spiralling overheads.

Bancassurance represents another strategic route which relies heavily on mergers and acquisitions. For the insurers, tying into the banking community is advantageous in terms of volume of customers accessed through banking networks. This marks a radical departure, to the extent that the insurance industry has traditionally operated through independent agents rather than interfacing directly with its customers. Accessing the ready-made sales/distribution network offered by the banks is also less expensive than operating via intermediaries to whom a more generous commission structure applies.

Over the course of the last few years, a number of major links were forged. As of 1986, Allianz had diversified geographically by linking with VIA (F), RAS (I), Bizrosito (H) and Fireman (USA). In addition, Allianz has taken a position in Dresdner Bank, the country's second-largest bank, which now markets Allianz products in the five Länder of the former German Democratic Republic. In July 1989, Victoire acquired Colonia, the number two non-life insurer in Germany. This enabled Victoire to double its critical mass (turnover went up by 196%), to secure geographical diversification, and to reinforce its position in both insurance and reinsurance. UAP and the BNP have signed an agreement which provides for reciprocal marketing. In the agreement, each acquired 10% of the equity of the other. In addition, UAP is present in Belgium (Royale Belge), in Spain (GESA) and in the United Kingdom (Sun Life). Nationale Nederlanden's merger with NMB Postbank has not only reinforced its financial position, it has also created substantial synergy.

These and similar moves have increased the financial muscle of the companies involved but they have also cut into the financial resources of the acquiring company resulting in a dilution of equity for the shareholders in cases where the operation in question has entailed fresh capital. It is for this reason, perhaps, that strategic alliances are preferable to take-overs. A case in point involves AMB (D), Fondiaria (I) and Royal Insurance (UK). The three companies have co-operated for many years and have now grouped their European interests. In 1992, they created the European Partners for Insurance Cooperation, bringing into being a holding company which

groups the European operations of the three outside their respective national territories.

It might be expected that the prospects offered by the Single European Market would tempt Japanese and US insurers. Both groups, however, have proved to be sufficiently preoccupied with their own domestic and highly-protected markets. Neither seems poised to launch a programme of international expansion in the immediate future.

REGIONAL DISTRIBUTION

Within the Community three countries dominate the market: the United Kingdom (74 billion ECU in 1990), Germany (71 billion ECU) and France (59 billion ECU). These three account for 74% of total operations within the EC.

These three markets remain dominated by non-life insurance but to differing extents: Germany is closer to an American-type market, very much dominated by non-life insurance (60%). Non-life insurance is less preponderant in the United Kingdom (52%), while France is somewhere in between (55%).

Just two Member States have an insurance market which is dominated by life insurance: Spain (63%) and Ireland (58%). But many other markets are still characterised by a strong prevalence of non-life insurance: Portugal (over 80%), Italy and Luxembourg (both almost 75%) and, to a lesser degreè, Belgium, Denmark and Greece.

In the industrialised nations of northern Europe (the United Kingdom, Germany and the Netherlands), premium income corresponds to 5% or more of national wealth. In southern European countries (Portugal, Spain, Greece) this percentage is much lower.

Further, insurance products differ widely in the various EC Member States in terms of category and distribution. These differences can be explained in terms of disparate fiscal treatment and the level of state involvement in the industry. Some countries - such as Belgium, Italy and Portugal - impose mandatory tariffs for automotive insurance, for example, whereas others (such as Spain, Ireland or the Netherlands) maintain an infrastructure that is more open and competitive.

REGULATIONS

The insurance business is traditionally subject to stricter regulation than that which applies to banking or other financial services. Most regulations require policy clauses to be standard and, in certain sectors of the industry, prices are predetermined.

Regulations also provide for prudent management of resources invested by the insurer on behalf of its customer base. Exercising due control over investments emerges as one of the main priorities of regulatory control. Specifically, the following principles are evoked:

Table 7: Insurance
Tax treatment of insurance premiums in European jurisdictions, 1989

Source: Fédération Française des Sociétés d'Assurances

- congruence: commitments denominated in a particular currency must be covered by assets denominated in that currency;
- localisation: commitments and risks must be balanced on a country-by-country basis;
- liquidity: insurers must at all times be in a position to honour their financial commitments to their policyholders;
- yield: over time, returns on investment must match the yield specified in the policy issued.

Certain countries have introduced specific measures to encourage the consumption of life insurance products. In Germany, for example, 80% of life policies are on a tax-deductible guaranteed-yield basis (as opposed to 20% which are unit-linked). In other countries, life insurance premiums are still taxable (Belgium, Italy, Portugal). In Europe as a whole, premiums paid are as a rule deductible in part for purposes of income tax; exceptions to this rule are found in Denmark and the United Kingdom. Added value is generally exempt, except in Spain and Norway. As a rule of thumb, it can be said that life insurance business is comparatively modest in those countries where premiums are taxed.

At Community level the process of completing the single insurance market is already well under way. This process is based on a series of directives aimed at harmonising national laws (on authorisation, the establishment of subsidiaries and branches, supervision, or technical reserves), and securing the freedom for EC companies to establish themselves in another Member State: all this has already been achieved (the so-called "first generation" directives).

The "second generation" directives try to secure the freedom to provide services, whereby an EC company may conclude a contract with a client based in another Member State when the company itself has no base there. Progress towards the freedom to provide services varies at present according to the class of insurance and type of risk: it already exists in non-life insurance for large risks (essentially industrial risks excluding the private market), while it has been approved but is not yet effective in life insurance.

A future series of "third generation" directives will introduce a single licence for insurance undertakings in the EC, which will signal the completion of the single market in this sector.

The process of deregulation described above must necessarily be accompanied by measures to promote fiscal harmonisation. Failing this, deregulation could result in an exodus of insurance companies - or their financial resources - in favour of jurisdictions with a more favourable tax climate.

OUTLOOK

The insurance landscape has changed since 1990. In essence, the following factors are expected to irrevocably transform operations of the 4 600 insurers scattered throughout the EC:

- auto insurance promises to develop in Europe along the lines identified in the USA. Today, it accounts for 35% of commercial risk, but this figure should reach 50% by 1995;
- the Single European Market for insurance is still a concept rather than a reality. Its full impact is predicted to be felt no earlier than 1995;
- by 1995, banks will capture in excess of 10% of life business within the EC and be responsible for a further 10% in terms of marketing and distribution;
- cross-frontier activity will grow in the course of 1993, primarily in the form of European insurers penetrating the potentially-lucrative markets of southern Europe;
- competition will increase as will demand/price elasticity. Niche opportunities will emerge in the non-life sector. Environmental coverage policies will grow at the rate of 10% to 14% annually. In the life sector, unit-linked and investment-linked policies are expected to grow by 15% annually (as compared with 5% to 9% yearly growth for other categories);
- market concentration will increase, notably in the life insurance sector in the United Kingdom and the non-life sector in Spain. Within the next decade, Europe will be dominated by a small number of large pan-European groupings (Allianz, UAP, Winterthur), with a number of parallel groups continuing to be active as specialists in niche markets;
- key parameters for success will be quality of service, application of information technologies, quality of management and on-the-job training.

Financial intermediaries
NACE 831, 832

European financial marketplaces have gone through a period of change since the beginning of the 1980s. Technological innovation, notably in terms of computerisation and modernised communications, has gradually given rise to a global marketplace operating 24 hours a day across the three main trading zones comprised of the USA, Japan and Europe. Deregulation of European financial markets has also boosted competition and resulted in improved price structures and resource allocation systems. These progressively deregulated markets have inevitably been characterised by increasing internationalisation. The planned single European financial market, able to compete with the US and Japanese markets, is rapidly becoming a reality.

INDUSTRY PROFILE

Description of the sector

The term "intermediaries" is applied to those operators who act as go-betweens for lenders in the first instance and borrowers in the second. Their role consists in transforming the funds made available by the lender into the form sought by the borrower.

Intermediaries thus contribute to a better allocation of resources, help ensure stock market liquidity of stocks and enhance negotiability. Intermediaries bring greater efficiency to the financial system by stimulating competition and reinforcing market mechanisms, in particular by: increasing the number of competing enterprises in the various financial markets; extending consumer and borrower choice both nationally and internationally by launching a wide variety of new financial instruments; exploiting improved information technology to impart increased market transparency; upgrading overall financial system efficiency by exploiting deregulatory measures; attracting foreign borrowers and investors; introducing efficient new technological infrastructures (such as new systems for payments, information transfers, negotiation and clearing); strengthening links with other international markets; contributing to market security and stability; and boosting price competitiveness.

The end of the monopoly of brokers gave rise to the creation of sizeable financial intermediary groups. These groups operate in corporate finance, in stock markets and in collective savings management. Banks also have a major presence on these markets. The progressive liberalisation of financial services in the EC has afforded them the possibility of intervening directly in the stock market as well as in related markets.

Main indicators

In every country, progressive changes in financing techniques have gone hand in hand with rapidly increasing capitalisation. London has retained its supremacy because its market capitalisation is the equivalent of that of continental European markets combined. The Milan stock exchange trails behind the main European exchanges (United Kingdom, Germany, France), with capitalisation equivalent to a mere 10% of that of Paris. Growth in transaction volume testifies to expanding markets and increasing professionalism.

Recent trends

The proportion of stock market holdings to gross domestic product more than doubled in the German and UK markets between 1982 and 1989. In Paris, the ratio increased from 5% to 33.2%. The Paris Bourse exhibited the strongest growth between 1982 and 1989, rising to a level approaching that of Germany. London, however, still holds the dominant position.

Growth in the bond market, while less spectacular than in the stock market, remains significant. Its weighting by reference to GDP doubled in France in the period 1982-1989, but grew only by 8% in the United Kingdom, which was hit particularly hard by the crash of 1987.

Growth in market capitalisation does not offer a clear indication of market development, however, since it is in part due to a nominal factor: asset valorisation. To arrive at a clear picture, stock market indices have to be taken into account. Nevertheless, real growth in stock market capitalisation is impressive, doubling in Germany and the United Kingdom and increasing fourfold in France over the period 1982-1989.

International comparison

In 1991, US financial markets had the strongest performance. The Dow Jones index rose by 10.2% over the year as a whole, despite a cooling of the economy. This was due to US monetary policy, which held interest rates down over the period and bolstered investor confidence with low inflation rates. The Japanese market went in the opposite direction, with a dramatic fall in 1991, as Japan showed the worst reaction to the recession. The reaction in European markets was somewhere between these two extremes. Despite German reunification, Europe was hard-hit by the recession and interest rates were maintained at a high level.

Foreign trade

Internationalisation is a by-product of deregulation and the revolution in communication technology. The resulting interdependence among markets has had two results: issuers have increasing recourse to foreign markets to raise capital, while investors have tended to internationalise their portfolios.

Over the last decade, there has also been significant growth in currency investments. Germany, the Netherlands and the United Kingdom, traditionally more liberal on exchange controls, lead the field in this respect.

The volume of transactions in foreign shares slipped back in all markets in 1991, dropping by a factor of two within the EC as a whole. In Tokyo, 1991 transaction volume represented only one-third of the 1990 total.

MARKET FORCES

Demand

The 1970s were marked by major shifts in the economic system, including the abandonment of fixed exchange rates and the emergence of current account imbalances consequent upon successive oil price shocks. The 1980s saw the development of capital markets organised along both national and international lines. The explosive growth in stock market activity was particularly pronounced between 1982 and 1989, with real capitalisation (deflated by the stock index) doubling in Germany and the United Kingdom and increasing fourfold in France. Against this background, the role of financial intermediaries became progressively important, their principal role being to ensure market liquidity and spread. Financial intermediaries have to be responsive to the demands of both investors and borrowers: investors are anxious to secure optimal placement of their funds, namely placement which offers best yields at least risk. On the other hand, borrowers are anxious to secure capital at optimal (i.e. lowest) cost.

The problems are currently exacerbated by an economic climate characterised by very high real interest rates. In addition, increased interest rate volatility and the progressively international character of currency exchange flows have intensified the need to protect against interest and exchange rate exposure risks.

There has also been an increase in the demand for services involving management of corporate assets and liabilities. This demand has increased above all in situations involving financial and corporate restructuring, notably in the wake of mergers and acquisitions or management buy-outs.

Supply and competition

The emergence of new types of demand has stimulated financial innovation and spawned new high-yield investment products across the full spectrum of money management markets. Innovation in the US served as a model for changes instigated in Europe since the end of the 1970s. London has proved to be the European market most affected by the wave of reforms, followed by France and Italy - where market reforms were initiated and supported by the public authorities. Germany was only slightly influenced, and reform there is still in its early stages.

Reforms of money, stock and auxiliary markets in the United Kingdom, France, Italy and Germany have seen expansion in savings, stock market quotation and the reinforcement of regulatory provisions. Hand in hand with these reforms came the gradual removal of exchange controls, an essential precondition for the modernisation and internationalisation of

European financial markets. Since 1985, the various European stock markets have undergone a major reorganisation, the main aim of which was to improve efficiency while ensuring stability and investor protection. Key trends include:

- an end to brokers' monopoly and freeing of commissions. France and Italy saw a crumbling of stockbrokers' monopoly and the creation of investment houses;
- a reorganisation of the market for treasury stocks, with the consequent adaptation of a secondary market in such stocks to reflect the needs of investors;
- the creation of secondary listing in Italy (1978), the United Kingdom (1980), France (1983) and Germany (1987), allowing medium-sized businesses unable to meet the conditions for full listing to improve their access to capital;
- the computerisation of stock markets and market operations in all European exchanges as of 1986. This technical innovation has boosted market liquidity by making information more rapid and more precise.

Stock market efficiency was improved by the creation of new futures and options markets such as LIFFE and LTOM in London as of 1982, MATIF and MONEP in Paris as of 1986 and 1987, and DTB in Germany as of 1990 - all of them influenced by the Treasury Bond Futures Market in Chicago. The aim of these markets is to afford investors some protection against fluctuations in interest rates, exchange rates and stock market prices. They have experienced rapid growth in terms of transaction volume.

In addition, there have been major (albeit less so in Germany) reforms with the issue of negotiable debt stocks on national currency markets and, on occasion, denominated in foreign currency. Collective management products appeared in Europe towards the end of the 1970s and grew rapidly in those countries with low rates of return on savings accounts.

Developments on money markets have led to the emergence of new instruments designed to allow the transformation of loans into negotiable debt stocks. This innovation, based on experiences in the USA and the United Kingdom, is new to France and still unknown in Italy and Germany. It offers financial institutions a more flexible means of managing their assets.

The trend towards financial innovation over the past decade has brought about a fundamental change in the structure of international financing. The growth of capital markets has brought greater diversity to financing and challenged the quasi-monopoly of the banking system. Equally, between 1983 to 1986, there has been a general reduction in financial intermediary charges (other than in the United Kingdom). Since 1989, only Italy has been immune to this trend, which is attributable to the increasing appeal of the financial markets. It is a trend that could reverse itself, however, in the event of a stock market decline.

The trend towards capital market deregulation goes hand in hand with increased competition between the different exchanges. Key competitive elements in modern capital markets are stock exchange transaction taxes, brokers' fees and the delivery-clearing system. In the case of Paris, stock exchange taxes have had the effect of restricting liquidity, mainly because they make transfers and receipts from abroad more expensive. Paris is seriously threatened by the prospect of its European competitors moving towards abolition of such taxes. Some countries, including Spain, abolished such taxes in 1989 and 1990, following London's lead in 1986. Germany is soon to do away with stamp duty.

In 1991, financial intermediaries suffered overall as a result of decelerating growth which brought a fall in the number of transactions on European exchanges. This is evidenced in gross issue volumes which reflect market liquidity. From 1985 to 1987, share issues grew on average 65% in Germany, 40% in France and 110% in the United Kingdom, but this trend was reversed after 1988, following the 1987 crash and the subsequent depressed state of the market. In 1991, this pessimism was fuelled mainly by the Gulf War, the coup in the Soviet Union and a recessionary US economy. In France, for example, the number of transactions fell by 6.5%, prompting a decrease in tariffs: average transaction charges fell by 9% in France.

Table 5: Financial intermediaries
Transfer transaction costs (taxes, stamp duties and commissions), 1991

Belgique/België	N/A (stamp duty 0.35 to 0.70%)

Production process

Competitive advantages differ at the level of European exchanges and financial intermediaries as a result of two main factors: the time taken to transmit information (i.e. the status of information technology modernisation); and the delay in clearing. Shorter clearing times would result from a switch from paper-based clearing to electronic systems - a process that is far from complete. Paradoxically, the London exchange, which brings together all the international markets, is the least advanced in this respect.

The efficiency of inter-exchange communication is another competitive advantage: London's Reuter information system competes with NASDAQ of the USA.

There are currently two kinds of financial intermediary: the market-maker, predominant in London, who ensures market liquidity by operating against the posted price; and the intermediary who contributes to the establishment of a median price by centralising orders.

The progressive institutionalisation of share dealing suggests a shift towards two distinct market structures in future: a decentralised system of market-making (as in London), or a centralised system based on specialists (as in Paris).

Part of the intermediary's role, other than generating liquidity, is to ensure market transparency. This can be achieved by adherence to formal rules of conduct, based on six principles. The financial intermediary must:

- have the resources necessary to provide the service offered to the client; this implies competent and informed partners and adequate internal organisation for originating, transmitting and executing orders;
- be able to provide information commensurate with his clients' needs;
- make every effort to carry out his clients' instructions to the best of his ability and with due despatch. In addition, in the case of limited offers, he must ensure a fair distribution among his clients;
- respect market rules of transparency and security;
- set up a system to monitor all in-house dealings;
- anticipate possible conflicts of interest and resolve them fairly if and when they arise.

INDUSTRY STRUCTURE

Companies

The end of broker monopoly resulted in the establishment of major groups of financial intermediaries which operate in corporate finance and markets or collective savings management. Such diversification can give rise to conflicts of interest between the different services offered and, in particular, can be conducive to risks of insider trading. As a result, monitoring the major groups is a difficult matter. Most European countries have drawn up lines of demarcation between the various activities in the sector. For example, Italy's Amato law requires such activities to be farmed out to subsidiaries. Reforms across Europe have opened up financial markets to new players. The major banks have strengthened their positions in every market - either directly, as in Germany, or by participation in quoted companies, as in France, Spain and Italy.

Strategies

The increase in collectively managed savings in Europe as a whole is evidence of the growing importance of the banks. Consistent growth in the sums managed suggests that Europe could soon emerge as the global market leader in this respect. Within Europe, France takes the lead, accounting for about half the sums managed in this method. Italy is one of the few EC countries to have seen the amounts managed fall over the last four years.

The second major change in capital markets took place against the background of worldwide internationalisation, which forced financial centres to modernise. In this respect, the benefits of an integrated European market have not gone unnoticed. A benchmark report prepared by Paolo Cecchini for the European Commission shows that potential gains could reach 22 billion ECU. More and more, investors would pay less for an increased volume of services, and companies would be able to access lower-cost capital, thus enhancing their competitive position against their non-European rivals.

The trend towards a financial Europe is justified by the increasing financial needs of European businesses which cannot be met within the limited scope of their domestic capital markets. Meanwhile, savings trends are changing: since 1987, most European countries have experienced a revival in savings rates. The creation of a single financial market could result in three different scenarios, each of which would offer new development opportunities to European financial intermediaries.

First would be a strategy which breaks down barriers to market-makers in different markets. This route could be of interest to the most important of these firms, opening up all the exchanges to them and allowing them to develop off-market transactions. Some national authorities are opposed to this idea, however.

Second, there could be mutual recognition of nationally-organised markets, while nevertheless maintaining their specific national character and organisation.

Finally, European integration into a single market for the main traded stocks could complement the second strategy, allowing the creation of a market of 200 to 300 key European stocks of international standing while respecting the specificities of each national exchange.

The Euroquote plan for a European exchange has been under review since January 1991; this should permit Europe to play a key role as the third time zone between the USA and Japan. Eurolist will comprise 300 major European stocks chosen by reference to market capitalisation; these will be traded simultaneously in national currency on the various national exchanges. At the same time, a European share index will be calculated.

National exchanges are now experiencing growth in demand for ECU-denominated products. Italy, France and the United Kingdom have developed ECU-denominated lending over recent years and an increase in ECU derivatives is anticipated. ECU futures have been traded on MATIF as of October 1990 and LIFFE as of March 1991. Internationalisation and institutionalisation of ECU-denominated portfolios appears to have a bright future.

REGIONAL DISTRIBUTION

In Europe, London remains the hub of international financial market activity, both in terms of market capitalisation - about

715 billion ECU in 1989 - and the monthly volume of trading (50 billion ECU in 1989). Paris is the second financial centre in Europe, albeit far behind London, but with capitalisation of 242 billion ECU and a monthly traded volume of 2.2 billion ECU in 1989. Paris modernised when broker monopoly ended in January 1992. The Japanese investment house Nomura, Morgan Stanley of the USA and UK broker Kleinwort Benson decided in April 1992 to set up on the Paris market as a means of developing their trade in shares and options.

The relative weight and wealth of stock markets as a proportion of GDP also points up London's dominance (90% in 1989) ahead of Paris (33% in 1989). London's position in Europe is partly due to the SEAQ system launched in 1985, which covers 340 important stocks on twelve exchanges as traded by 53 market-makers. 85% of transactions on this international market relate to European shares. Thus, London accounted for 50% of trading in the ten most active stocks going through the Paris monthly clearing market. Similar phenomena are seen throughout the EC. Italy has started to modernise its market. On the other hand, the Netherlands, which maintains close contacts with London, has been hard hit by competition from the SEAQ.

REGULATIONS

Financial intermediaries face an additional challenge as a result of market modernisation. It is generally accepted that this challenge consists in four areas of risk: interest rates; exchange rates; trading; and technical risks connected to telematics or computers.

The emergence of new and sophisticated financial products and increasing market volatility have resulted in increased risk. Deregulation and professional restructuring represent an additional risk arising out of the multiple roles of market operators. The various authorities have had to reinforce their supervision of the markets. COB in France, CONSOB in Italy, CNMV in Spain, the Belgian Banking Commission and the VvdE in the Netherlands have all had their powers extended in recent years. On the other hand, Germany and the United Kingdom appear to be more attached to a system of self-regulation by professional associations operating in the sector. The UK Financial Services Act provides "self-regulatory organisations" with the requisite authority to carry out monitoring and control. Control is an essential element in ensuring the credibility of a financial marketplace. In the United Kingdom, the system of market supervision is highly decentralised, with each professional organisation responsible for the conduct of its own members. In Germany, there is no real supervisory authority; instead, stock markets are controlled by the Länder. This structure has come about largely due to the position of the banks in the German financial sector. In Spain, the National Committee of Stock Exchanges assumes responsibility for the supervision and inspection of the four exchanges (Madrid, Barcelona, Valencia and Bilbao). Unlike the rest of Europe, the Spanish Central Bank carries out supervision of operators.

OUTLOOK

In 1991, European stock exchanges were affected by the upheavals of the Gulf war, the Soviet coup attempt and recession in the USA. At the same time, the recession which hit Europe as of 1991 provoked pessimism on financial markets. Forecasts for 1992 do not suggest any improvement, with growth projected at 1.5% overall and slightly above that figure in the principal European financial centres. Even the prospects of European monetary union and a consequent rise in savings and trade are still not enough to stimulate market activity. Several years of high interest rates are still expected.

Generally speaking, a decade of financial innovation has resulted in an imbalance in the level of financial market reforms across Europe. Although changes have contributed to a process of internationalisation of capital markets to the benefit of every country, increased fluidity has only been obtained at the cost of high real interest rates.

Real estate
NACE 833, 834, 835

The property markets of Europe are facing vacant office blocks, falling rents, structural overcapacity, and investor uncertainty. The virtual disappearance of some investors, such as the Japanese and the Swedes, has put a burden on the rest of the market. Only Germany appears to be moving forward.

INDUSTRY PROFILE

Description of the sector

The various professions active within the property sector attest to the dual nature of the industry implicit in its primary and secondary markets. Certain activities relate to primary demand and the completion of property development, whereas others are exercised by intermediaries or financial advisers who ease the functioning of the secondary market. In the first category are builders/developers, together with consultants specialising in feasibility studies. Real estate agents form part of the secondary market, with their expertise in surveying and valuation of properties, and role in sales transactions and estate management.

In addition, the property sector may be divided into two separate compartments: residential property and commercial property, whereby the latter includes offices, shops and factories.

Recent trends

Following spectacular expansion at the end of the 1980s, the property sector experienced a substantial downturn in 1990, with the exception of Germany, where highly speculative market conditions fuelled strong growth. London experienced the worst fall in rents, primarily as a result of high vacancy levels in the City. In Belgium and the Netherlands the market remained stable, with rents increasing particularly in Brussels and Amsterdam. Brussels is particularly attractive to many companies anxious to benefit from proximity to developments within the EC and its institutions. Markets in Spain and Portugal continue to expand, especially in the case of Barcelona.

All of Europe's capitals have gone through an adjustment phase, however, and prices everywhere have stopped rising. Cyclical developments in the various cities are not always concurrent. It is estimated that by the end of the first quarter of 1992, London had almost completed its cyclical adjustment, whereas significant drops in prices are still anticipated for Paris, Madrid and Lisbon.

International comparison

The transactional value of the US market is estimated at some 1 000 billion USD a year - nearly 7.5% of GNP - with almost half of this accounted for by new construction. This translates into total cumulative value (1990) of an estimated 8 770 billion USD. The US real estate market, however, is less dynamic than the European market due to structural oversupply. In 1989, despite large reductions in construction, vacancy rates rose 9% to 19.5%. During that same year, growth in construction in Europe had no effect on vacancy rates, which remained at an average of 2.5%. The US market has been in the throes of a major recession for several years, with some real estate prices plummeting by 50% over a four-year period. By contrast, the Japanese market, confronted by problems of over-population and over-concentration of activities in certain areas, is approaching saturation point - and prices continue to rise.

Figure 1: Real estate

Foreign trade

The proportion of international investment in the property market continues to increase. It is estimated that, by 1995, foreign investments flowing into Europe will grow to 12.5 billion USD annually. The share of investment in Germany is growing, although the main target market remains the United Kingdom. The London and Paris markets were both buoyed between 1988 and 1990 by Japanese, German and Scandinavian (especially Swedish) investors. The subsequent recession in the property market coincided with a withdrawal of foreign investment and a process of retrenchment into national markets.

Japanese real estate investments overseas were estimated to average 2 billion USD a year in the early 1990s, compared to 11 million USD in 1985. At the end of the decade 1980s, 75% of Japanese property investments were in office blocks, commercial properties and hotels. The remaining 25% was invested in golf courses, apartments and private hotels. Total EC real estate investment was evenly distributed between Germany, France and the United Kingdom.

MARKET FORCES

Demand

The property sector in Europe comprises several markets: office properties; commercial properties; industrial properties; and domestic properties.

In general, the health of the property market is closely linked to economic conditions. A slowdown has the direct effect of bringing down demand both for rented and bought office properties. That said, the rental market is less dependent on economic fluctuations. Unlike the real estate sales market, it is not bound by investment logic: whereas purchase is an investment, rental is the consumption of real estate. Therefore, interest rates are a crucial factor in the development of the property market, but less so in the rental market.

Property is taxed at three levels: transfer duties; various local taxes; and land revenue taxes.

Transfer duties are levied at the time of sale of a property. At present, France has the highest such taxes in the world, at almost 18% in Paris, compared to between 6% and 12% in most other European capitals. London and Frankfurt are the exception, with transfer duties of 1% and 2%, respectively. In Germany, land taxes are treated as business revenues and are correspondingly highly competitive.

The level of infrastructure provision and planning also influences demand. The three regions of Greater London, the Rhine-Ruhr and Ile-de-France comprise the principal focuses of wealth of the EC. These are the three vertices of the "Golden Triangle". Paris and London are among the best provided-for regions of Europe in terms of services, and have the best infrastructure. The airports of London and Paris respectively deal with 40 and 31 million passengers a year.

Certain factors have a particular effect on the different property markets. In the office property market, the shift in business demographics towards the services sector puts pressure on commercial properties to the detriment of industrial sites. In addition, the demand for offices is becoming more sophisticated, with the development of large luxurious American-style complexes, such as the Quartier de la Défense in Paris.

The domestic property market, on the other hand, is still a sector which appears resistant to the kind of factors noted above. In this case, other, sometimes less pragmatic and more personal, factors are at work.

Supply and competition

With the slowdown in economic growth and rising interest rates, Europe is presently experiencing a reduction in demand. Portugal and Spain saw growth rates respectively of 3.9% and 3.5% in 1990, whereas growth slowed in other continental European countries and stood at 1.6% in the United Kingdom. Reunified Germany was an exception, with a growth rate of 4.2%.

Currently, the matching of property sector supply to demand has slowed. This can be explained by the length of the production cycle: it takes several years to construct a building. There is now Europe-wide overcapacity, and there has been an increase in vacancy rates everywhere other than in central Paris and Berlin. Outside the centre of Paris, there is again a situation of oversupply, with 60 million m2 of property standing empty in the suburbs, while Berlin is a highly speculative market, where reunification has brought about an increase in demand.

Overcapacity in property has been even more pronounced to the extent that foreign investors, notably from Japan and Sweden, have suddenly pulled out. Japanese investors, concerned at their rates of return -especially the Cooke ratio - have pulled out, and the Swedes had to weather a domestic stock market crash.

Sales agents were the first to be hit by the property recession. Having been drawn in by seven years of market growth, they counted on the rapid and highly profitable turnover of properties and borrowed, in some cases up to 100%, from the banks. The recession brought major losses, aggravated by the withdrawal of the banks.

1991 was marked by lower economic growth and by uncertainty linked to the Gulf War; the year saw a drop in profitability in the property market.

In general, it is necessary to make a distinction between central business districts and outlying areas. In central business districts, lower demand has enabled structural shortages to be reduced and, as a result, rent growth is stable, although at lower rates than during the 1980s. London is an exception: the number of vacant office properties there is very high, in contrast to other business centres in European capitals.

Outlying areas, on the other hand, are experiencing a more severe recession. These areas are more high-risk, with construction anticipating demand. Examples are the Paris suburbs and the outlying areas of Madrid.

The property investment market has gone through the same sort of change, but in a more pronounced way. Investors have preferred to postpone their activities while markets are gripped by uncertainty. The degree of speculation which has characterised the investment climate over recent years brought about a severance of the link between supply and demand, exacerbating the current recession.

In 1990, the domestic property market saw an average growth in rents of 11%. In the longer term, however, this market

was the least profitable. Since 1985, rents have gone up by 14% a year on average, although Lisbon was an extreme case with a rise of 233%. The commercial property market saw rent rises of 10% in 1990, compared with a previous growth rate since 1985 of 22% annually. The industrial property market was more dynamic in growth terms than the rental market, with growth rates of 13% in 1990 and 16% in the period since 1985. In this area, the best performers were Spain and Portugal, following their entry into the EC.

OFFICE VACANCY RATES BY CITY, 1989

Production process

Supply of offices is fed simultaneously by the arrival on the market of new buildings (60 to 65% of supply) and the recycling of older ones. Few markets have a primary sector coexisting with a secondary sector to such a degree. This secondary market allows property to be used as an investment base, as it guarantees a measure of liquidity. This role as an investment base is more pronounced in office property than residential property. The latter has more of a community character, and is often the subject of regulation designed to preserve its social utility. This in turn holds down yields on capital investment. This closed-circle structure accords particular importance to the role of intermediaries. They exist to facilitate transactions (and ensure market liquidity), performing an essential role in affording investors continuity between primary and secondary sectors. Another consequence of this special configuration is that the various players in the marketplace can either simultaneously or successively adopt opposing roles: buyer and seller, provider and consumer.

Satisfying end-user demands presupposes activity on the part of developers, investors, financial backers and consultants. Each is in competition with the next - both over the character of the product and the means whereby it is acquired, i.e., purchase, rental, or leasing. Professional competence in this sector takes a number of forms:

- local market knowledge: the ability to put a precise value on a site and its possibilities, and to define a product suited to the needs of the end-user. This factor can only be provided by local experts, and has acted as a brake on internationalisation of the sector as a whole;
- manpower resource deployment: this activity is an integral feature of the sector. It should be pointed out that high levels of productivity are present: consultants achieve rates of 150 million ECU per employee in the larger firms within this sector, a productivity level comparable to that recorded in heavy industry. In terms of sales, volume exceeds 350 billion ECU at the level of 300 employees and above;
- financial expertise: the professions in the property market are closely linked to the world of finance, which explains the presence of banks in the sector. Financing of the product, in addition to production and sale, presupposes management.

As in every service activity, communication capacity plays a major role. The profession is able to intervene rapidly, which is a key element for success. This is seen, for example, in the auction process, where investor reaction must be immediate. In such conditions, the larger institutions, with their hierarchical structure and their prudential constraints, are at a disadvantage in the race to obtain business.

INDUSTRY STRUCTURE

Companies

Within the EC, property professionals represent a workforce of around 120 000 authorised practitioners. Most agencies are small in size and operate at a local level.

There are two categories within the property profession: developers who construct buildings on land which they already own with a view to their sale or rental, and intermediaries who make markets in the product and counsel those involved.

There are four types of developer: independent developers (who make up only a small part of the sector); subsidiaries of banking or financial groups, almost all of which have in-house development divisions which act both as a channel for the distribution of credit and a profitable activity in themselves; subsidiaries of public works and construction authorities. Again, all of the majors these days have development arms; and institutional developers, an example being the association of around 15 insurers and bankers in the Société Française d'Investissements Immobiliers.

At the intermediary level, the approach to the market is characterised by an increasing professionalism at the level of estate agents, an increasing role for consultants and a progressively

Table 4: Real estate

national/international structure. In this context, three types of intermediary can be identified:

- estate agents and administrators specialised in marketing and renting to end users, (as opposed to developers targeting institutional investors);
- consultants, whose number and importance increases as products become more sophisticated and the sector more international. These usually take the form of small, independent practices. Their role is important because, as we have seen, decisions on development, investment and acquisition are wholly dependent on market conditions
- market-makers who buy in order to resell. These are the speculators who exploit market imbalances to their own advantage, notably in the form of undervalued purchase prices. In addition, however, they also act as a buffer, mitigating the impact of major differences between supply and demand. Their ability to play this role depends on their capacity to carry a property over a period.

Strategies

One striking characteristic at the present time is the emergence of widely divergent strategies on the part of developers. Until recently, developers tended to adopt similar strategies; they were typically small-scale and unambitious, finding it difficult to operate on an international level in such a conservative profession. The current trend, however, is towards the integration of upstream and downstream activities: development proper upstream, and commercialisation downstream.

One can also identify a growing tendency to extend the range of products offered in an attempt to reduce dependence on the vagaries of a single market sector, a case in point being developers originally specialised in housing who reposition for profit deriving from the boom in office property.

Two major strategic groups of developers can thus be identified. Some have elected to diversify into complementing development activities such as administration, hotel chain management or even insurance, which do not share the cyclic nature of property development. Others have opted to remain specialised, but have diversified their product portfolio and attempted to become more international in scope.

For several years now, intermediaries have tended towards the Anglo-Saxon model of consultancy. This strategic transformation, which sees an increased presence of banks in the marketplace, has facilitated globalisation of the property market. The main consultancy offices assume the role of go-between by opening up their domestic marketplace to foreign partners. This development also admits a larger volume of transactions, regardless of the size of the market. In fact, while the office markets in London and Paris are more or less the same by volume, there may be (depending on the period in question) between ten and twenty times more transactions in London than in Paris.

As far as estate agents are concerned, the present recession in property has pointed up their inadequate financial resources. Developing these resources has emerged as a priority objective, and agents are working more closely with the banks to permit themselves to work on projects for which no immediate client has necessarily been identified.

Despite growing globalisation of the property market and the increasing sophistication of products - both of which developments aim at responding to demand increasingly along the lines of the Anglo-Saxon model - consumers tend to remain more attached to traditional national models. In general, the prestige properties offered by major public works groups serve more as a shop-window for their skills than as merchandisable products aimed at the consumer of the future.

REGIONAL DISTRIBUTION

Most real estate activity is concentrated in northern Europe, in an area which is bounded by Paris, London and Frankfurt and which includes the Brussels area. London and Paris have the greatest number of offices in Europe, with a total surface area of around 32 million m^2. Other European capitals typically average around 5 to 6 million m^2. The greater part of Europe's wealth is concentrated in Paris and the Ile de France, Greater London and the Rhine-Ruhr region. Economic growth in these focal points - against a background of almost stable employment - depends on a major increase in value added per capita. And that increase, in turn, depends on development of the services sector as a replacement for manufacturing industry within the economy.

In this respect, London is the most service-oriented market, with services accounting for 69% of value added, although Paris is close on London's heels. Germany's regions, on the other hand, have a less-developed service sector; an exception to this is perhaps Düsseldorf, where a number of Japanese companies are based. Value added in Germany is generally attributable to the manufacturing sector.

The main cities in southern Europe reveal expanding property markets, as economic growth prospects outpace the existing property market. Italy is a special case, in the sense that foreigners have great difficulty in penetrating that country's property market. In fact, data which would permit a determination of real property values in Italy are practically non-existent.

REGULATIONS

The regulatory provisions which attach to the real estate profession vary widely from country to country within the EC. Generally speaking, regulatory provisions apply mainly to estate agents. Certain countries - Denmark, Spain, France and Italy - have erected major barriers to entry into the profession; elsewhere, professionals are subject to the provisions of common law.

With the exception of Greece, Portugal and Denmark, each EC jurisdiction has a professional charter. Harmonisation of regulations on a European level is pending.

OUTLOOK

In 1991, the repercussions of the Gulf War, together with other political and economic uncertainties, had an adverse effect on the property sector, resulting in a general stagnation or decrease in prices and transactions. Germany, largely due to reunification, seems the only country to have emerged from this situation with increased demand and prices - but there remains a risk of over-heating in the market.

In the medium term, if economic upturn is achieved as forecast, there should be a turnaround in currently reduced demand. Growth rates promise nevertheless to be slower than in the 1980s, with marked differences applying between central business districts and outlying areas for which development prospects appear less promising.

Business services
NACE 83

Business services is a fast growing sector whose demand is fostered by technological change as well as by a trend towards increasing externalisation of some activities in industry. Though the sector is not concentrated, M&A activity recently accelerated in anticipation of the Internal Market. The sector's prospects are good and the Internal Market should boost cross border activities which remain very limited so far.

INDUSTRY PROFILE

Description of the sector

Business services are defined as those intermediate services which are used during the production and the preparation for distribution processes and are supplied by specialised firms to other enterprises in order to increase efficiency, productivity and competitiveness. Therefore, inhouse supplied services are out of the scope of this study. Services such as trade, transport and telecommunications are covered in separate chapters.

Business services can be classified in subsectors on the basis of several criteria. The most widespread classification, and probably the most useful one, is based on the function performed for the account of the customer firms. Business services substitute functions (activities) of the production process which otherwise would have been performed by the customer firm in its premises, usually in a specialised department (accountancy, technical services, marketing services etc.).

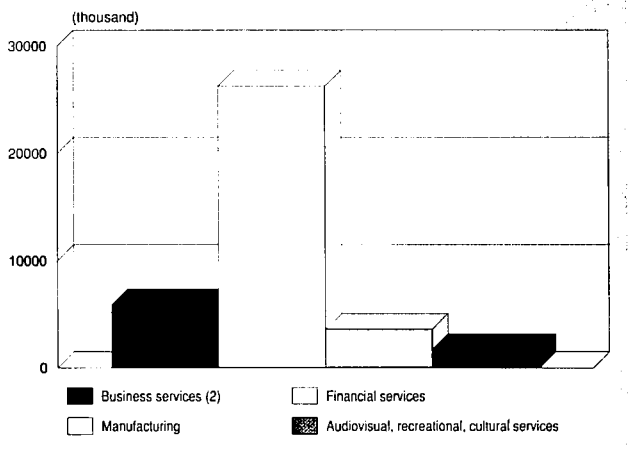
According to this classification, business services can be grouped as:

- management and administration services (management consultancy, legal services, accounting, fiscal advise etc.);
- production services (architectural, engineering, operational leasing, repair and maintenance, packaging, quality control etc.);
- research related services (contract research, etc.);
- personnel related services (vocational training, labour recruitment, supply of temporary labour, etc.);
- information and communication services (data banks, software services, technical computer services, advanced telecommunications services, express mailing, etc.);
- marketing services (advertising, sales promotion, market research, direct marketing, public relations, export promotion, fairs and exhibitions, etc.);
- operational services (industrial cleaning, security services, linguistic services, etc.).

Main indicators

From the most recent available data it is estimated that the sector's turnover represents about 6% of the European Community's GNP. More specifically, from data supplied by professional associations, it is estimated that, in 1990, business services in the EC achieved a turnover of 236 billion ECU. Yet, although these figures come from a reliable source, they should be interpreted with some caution. On the one hand professional associations don't cover all the firms operating in the sector, and on the other, it is not unusual for individual firms to subscribe to several professional associations as many firms are engaged in a wide range of service activities.

Figure 1: Business services
Employment compared to selected sectors, 1990



(1) Excluding Italia
(2) NACE 83 and 84
Source: Labour force surveys, Eurostat

Business services constitute one of the fastest growing sectors of the European economy. Indicative of this dynamism is that during the 1980-85 period, the sector achieved faster annual growth (14.6%) than the average for goods and services (10%). Moreover, this growth was the fastest among all market services. Growth differs between individual Member States, reflecting, mainly, differences in industrial market organisation. With this respect Italy posts the most rapid expansion and France the slowest. The sector's fast growth over the 1980s resulted in a considerable improvement of its share of total market services from 12.2% in 1980 to 13.9% in 1985.

It is estimated, that within European Community, 5.5 million people are employed in business services, a figure which represents 5% of the total EC employment. Even during the recession periods after 1973, when the employment situation in the EC considerably worsened for all services, and despite the sensitivity of these services to recessions, business services exhibited exceptional employment growth in comparison to the service sector as a whole. The sector's rapid rise in employment over the 1980s is explained by the externalisation process, innovations in service management and increased demand due to expanding economic activity.

Foreign trade

The analysis of trade in services is generally somewhat limited by lack of data. A few comments can nevertheless be made on international trade in business services. The relative share of the sector in total trade in services is growing over time. Intra- EC trade remains limited so far but is expected to grow considerably in the future. The EC shows a positive trade balance, a factor which suggests that it is internationally competitive in this sector. However, imports are rising faster than exports.

MARKET FORCES

The fast growth of demand for business services observed during the past two decade can basically be explained by the process of externalisation of economic activities, in combination with technological changes. These developments, in turn, are attributed to the ever increasing complexity of the production and distribution systems and the widespread adoption of information related functions by the firms.

Source: Professional Associations - Sectoral studies

The technologydriven changes required new skills, which small and medium sized firms could not easily afford. Hence, the necessity to meet the challenges of new technologies have resulted either in a continuously increasing externalisation of functions previously performed internally, a tendency witnessed, in particular, in the small to medium sized firms, or in the internal development of the necessary capabilities exploiting thus the resulting economies of scale and scope mainly by large firms.

This was, in fact, the situation encountered after 1973, when the introduction of information technology in the organisational structure of all economic sectors drew heavily on services provided by specialised business services firms, in particular software houses, management consultancy and marketing. This tendency was most pronounced in US compared with Europe.

INDUSTRY STRUCTURE

The sector is composed of a large number of small companies and, at the same time, a limited number of very big, mainly international, firms. In general, firm size tends to be small for most business services for which quality and specialisation are overwhelmingly important and for which few scale economies can be identified. sub sectors in which a large number of firms employ more then 50 employees are consulting engineering, accountancy, market research, testing, inspection, quality control and some operational services.

Though the sector is not very concentrated, a number of mergers and acquisitions have been occurring recently as firms aim at improving their competitive positioning in anticipation of the completion of the Internal Market. Small local or national firms are thus linking up with similar parties in other Member States, in order to increase their pan-EC presence. This tendency is expected to accelerate in the future, under the impetus of deregulation and the emergence of a dynamic information sector.

OUTLOOK

A common market in services is one of the most important prerequisites for the creation of a fully integrated European market. Yet, markets for business services are among the least integrated in the Community, even though the Rome Treaty guarantees the freedom to provide services.

Although free movement of services is facilitated and accelerated by the development of international information and communication networks, service markets remain primarily national markets. Indicative of this phenomenon is the fact that, in a sector as apparently internationalised as computer services, revenues from other Member States on average only account for about 5% of turnover. The situation is even worse for other business services sub-sectors.

The White Paper on the Integration of the Internal Market proposes general initiatives to cope with the situation. These strategy guidelines remain to be translated into detailed measures. However, implementation obstacles remain, stemming from differences in national legislation and national attitudes.

In general, we can say that although many problems remain to be solved the internal market is expected to have a positive impact on business services through increased demand, more competitive supply and additional employment. At the same time some negative effects through a greater concentration of supply and distortions of competition cannot ruled out.

It is expected, that the measures taken in the framework of the Internal Market will affect positively growth in business services. At the same time, the moderate overall economic expansion expected in the coming years will affect negatively the sector. In total, it is estimated that these two factors will cancel each other and that the performance of the sector will be similar to that of the past years, that is, an annual rate of growth, in the area of 10-15% and an increase in employment in the area of 2-4% depending on the sector and the country.

Written by: Panayota VORLOOU, Commission of the EC, DG III

Advertising, direct marketing and public relations

NACE 838

Advertising, marketing and public relations services experienced considerable growth and development during the 1980s. The market has been powered by greater awareness of the benefits of advertising and by the availability of effective new direct marketing techniques. Some market momentum was lost towards the end of 1990. This was, in part, a result of slowing economies and financial recession. The success of direct marketing helped combat the slow decline among more traditional advertising services, including above-the-line advertising.

INDUSTRY PROFILE

Description of the sector

At approximately 70 billion ECU turnover in 1990, this services sector is among the most important in the EC services market. Advertising accounted for approximately 64% of turnover, direct marketing 35%, and PR services the remaining 1% in 1990. The sector is engaged in communication services that promote an idea, product or service. Effective communication of information requires creative thought, idea development and focus on a given universe of people (the prospective customer group could be the public or a subgroup). Advertising agencies, direct marketers and public relations specialists all have one thing in common: an ability to deliver vital information effectively.

Advertising

In advertising, it is important to give the advertised product extra value over alternate products. Slogans and branding are aimed at lifting the product's image. This allows the marketer to maintain a higher price than private label products can carry, and to pay for the advertising from that margin. Advertisements are placed where they will be seen. People assimilate advertising messages in the same way as other information, partially consciously and partially subconsciously. The main media include: television; radio; cinema; newspapers; magazines; periodicals; and posters.

Direct marketing

Direct marketing is aimed at reaching people directly, as the name implies. It often involves delivering a personalised advertising message to individuals. Unlike advertising, the effectiveness of direct marketing can be measured. This allows for some experimental and exploratory mailings to be made to small numbers of people to discover the efficiency and effectiveness of an idea. An important advantage of direct marketing is that advertisers can select specific groups of people from established lists. Mail order catalogue companies were among the first to develop direct marketing technology. The number of users has since expanded horizontally and vertically throughout industry and among such diverse groups as public services and politicians. Business to business requires specialised media including trade journals and trade fairs. Direct mail can be particularly successful for business to business promotion.

Public relations

Public Relations (PR) agencies are used by companies mainly to deliver sensitive information to the public or other interested parties, including the press. They are also used to lobby institutions to achieve policy changes. Owing to the diversity of businesses with which most agencies deal, agents are generally knowledgeable of common business problems. They can also help their clients to adapt to a rapidly changing regulatory and marketing environment.

Main indicators and recent trends

Provisional estimates for 1991 anticipate that the billings turnover for 1991 will be only marginally higher than 1990's approximately 70 billion ECU (not including more than 30 million ECU for mail-order sales). Added value was just over 10 billion ECU, and the services employed roughly 155 000 people in 1991.

Advertising

Advertising agencies define turnover or "billings" in terms of the amount of money they spend with the media on their clients' behalf. Gross earnings are a fixed percentage, normally 15%, of billings.

Advertising services require between 0.4 and 1 million ECU of billings per employee. This provides roughly 60 000 ECU

to 150 000 ECU of gross fee income per employee. Production centres and media in the advertising industry engage approximately 500 000 full-time equivalent salaried and wage earning personnel. However, most of these are double-counted from other monographs. About 10% (50 000) are exclusively included in this sector. In advertising, roughly 10% to 15% of the total workforce is self-employed. These are mainly photographers, illustrators, designers, copywriters, and translators.

It is not possible to accurately separate the number of people involved in advertising from the number in direct marketing. Advertising has a higher average wage cost than direct marketing because of the amount of highly specialised work involved. Direct marketing workers have by comparison low wages, except for specialist consultants.

Direct marketing

The European Direct Marketing Association (EDMA) has divided direct marketing into three sectors: print direct marketing; telemarketing; and new technologies (include interactive telecommunication channels).

Interactive telecommunication expenditure is small in relation to direct mail and telemarketing, but as more Europeans use personal computers and gain increased access to E-mail, Teletext, Minitel and other telecommunication systems, the market will expand. Direct response advertising through media, such as television broadcasts, newspapers and magazines is included in advertising media expenditure.

In direct marketing the emphasis is on keeping the cost per operation as low as possible to make the service attractive to companies. Mechanisation has helped to make processes more efficient. It is therefore possible to keep work force costs at less than 5% of the turnover of total billings. On this basis, it is estimated that direct marketing services in the EC employ about 40 000 full-time equivalent persons for the service (value added) aspect of the business.

The proportion of expenditure on advertising and marketing are changing considerably. A great amount of direct marketing business is now in the advertising and marketing expenditure system, often it replaces more costly salesperson promotion.

Public relations

According to CERP's 1991 European Public Relations Survey, there are some 44 900 public relations professionals in the EC and 52 760 in Europe. EC spending on public relations services reached an estimated 6.3 billion ECU in 1991.

Public relations professionals are divided between those who are employed by and handle the public relations programmes of a company, organisation or public institution, and those who are employed by an PR agency or consulting firm and offer their services to a variety of clients. Agencies only account for between 5% and 10% of the total PR carried out in the EC. Many companies are starting to use professional PR consultants rather than in-house resources. For some, this is the first time they have used a specialist, having previously relied on a member of their own management team to do the PR work.

International comparison

Advertising expenditure in the USA over the last decade has been far greater than in Europe. Since 1984, Europe has been catching up, largely due to exchange rate variations. The Gulf War and the recession have affected US turnover since 1990. Expenditure for 1991 was estimated at 120 billion ECU.

Similarly, the advertising expenditure in Japan has been affected by currency exchange rates. It dropped in ECU terms during 1990, but otherwise showed a fourfold increase over the past 10 years. 1991 turnover was an estimated 10 billion ECU.

There are no official figures on the market size for PR in either USA or Japan. Estimates suggest they are in the order of two to 14 billion ECU in the United States and about thirty times less than that amount in Japan.

MARKET FORCES

Demand

Advertising

The major products advertised are commodities. Major products include: alcoholic drinks; baby care products; food and beverages; non-prescription drugs (OTC); perfumes; cosmetic products; sanitary products; toiletry products; toothpaste; motor vehicles; tyres; tobacco products; financial services (banks, insurance); public services; pet foods; pharmaceutical products; and fund-raising.

Besides having their own advertising department, major international companies usually use advertising agencies. Large commodities companies tend to be the major investors in advertising services. Owing to an expansion of private label business (a store's own brand), by large chain-stores, marketers of leading brands have been obliged to increase advertising expenditure to position their brands as highly competitive products. A concentration of vendors has resulted from an increase in the proportion of larger stores compared to small shops. This has tended to work against the commodities marketing corporations.

Small and medium sized enterprises are often unable to maintain their own advertising departments or hire an advertising agency to conduct advertising campaigns. Many use below-the-line advertising (without an expensive creative element) and direct mail.

Direct marketing

Direct marketing is replacing a considerable portion of company representatives' time because it is so much less expensive. Whereas a company sales representative can only visit a few clients, averaging less than a dozen per day, direct marketing can reach numbers far in excess of this. Whereas in the 1970s companies concentrated on the visit approach in the 1990s it is increasingly carried out at a distance. Direct marketing services' demand is increasing because they are so cost effective.

Supply and competition

There are no regulatory barriers to starting an advertising agency in any EC country. However, it is not an easy field

to penetrate. Securing the main accounts of new clients is an obvious but very difficult means of expansion.

Client loyalty is indeed a major barrier to new entrants. Large corporations frequently retain the same advertising agency for periods of more than a decade. The reasons for this include the use of clients' sensitive commercial information by the agency. Other reasons are the understandings that exist between senior managers and their agency counterparts and the time-scale that creative campaigns take to prove successful.

Major commodity companies often offer competitions when they wish to change their main account. The headquarters of international companies often choose only one agency for their global business strategy. The marketing subsidiaries in the various regions are required to use the services of the local office of this agency. Often creative services are supplied by the agency's main creative centre and only copy-writing and media campaigns are handled by the local office.

Profit margins in above-the-line advertising are maintained by the agency fee as a percentage of billings system. However, many small agents who do below-the-line work can choose lower margins to be more competitive. In direct marketing, competitive pricing forces are also at work, although the main emphasis is on obtaining a high percentage yield in sales.

High volume printing is tending to go to countries with the lowest production costs. There is also a trend of direct mail being mailed from countries with the lowest tariffs. Freight and courier companies have been bidding for a part in the postal services market by undercutting the prices of public postal services.

Production process

In the print medium, newspapers and news journals can now publish simultaneously in several countries using electronic printing methods. Major newspapers and magazines are increasingly targeting larger international audiences.

The mode of direct mail communication (or "admail") is either via telecommunication channels or by post. Mailings often involve use of computer-assisted mail-merge technology. Modern computer technology has provided marketers with the possibility to automate the direct marketing process, and to achieve very low promotion costs in comparison to other techniques. Print as circulars or inserts, leaflets, flyers, catalogues, and direct response advertisements placed in newspapers and magazines are the main forms of direct marketing. In order to maximise the chances of a successful campaign, the marketing company follows a specific process. First, potential consumers must be identified. This often involves finding databases containing lists of people that fit the consumer profile. Then, a message that will capture the interest of those readers must be developed.

INDUSTRY STRUCTURE

Companies

Forced restructuring in the early 1990s has caused some major advertising agencies to expand into new areas such as direct marketing and promotional services, increasing the overall competitive strength of these companies.

Many major advertising companies have invested heavily in the emerging direct marketing business. There are a few thousand companies including SMEs, and on top of that many self-employed, which number about 20 000. There are more than 1 000 telemarketing service companies, most of which are SMEs.

In advertising, the list of major companies does not change much from year to year. Companies wishing to achieve a position in the top ten would find it easier through acquisitions

of other agencies rather than by organic growth. Euro RSCG moved into first place by acquiring stock in other companies. The top 25 agency networks accounted for a little less than half all sales in 1991 according to the trade journal Advertising Age.

There are some 4 705 public relations agencies or consulting firms in the EC. A PR agency is normally registered by law and handles only public relations assignments for its clients. A PR consulting firm is usually not registered and may specialise in other related services such as media relation, public affairs, and sponsorship.

The size of PR agencies is usually small. There are only eight PR agencies that have more than 100 employees each, most of which are UK-based.

Strategies

Major advertising companies are often involved the formulation of the strategic plan of a client. Several major advertising agencies have chosen to expand into direct marketing and promotional services because their clients are increasingly seeking promotional methods which can be better focused and therefore more effective and often less expensive. Often they acquire established direct marketing concerns rather than attempting to build their own services. They are then able to expand the direct marketing service to their existing clients as well as serve the customer base of the acquired company.

Advertising does not have to be capital intensive. An agency can start up using funds provided by its clients. The main investment of many advertising companies is its creative teams. When it comes to direct marketing considerable investment is needed for the automated processes and computer technology.

REGULATIONS

Regulations affect advertising and direct marketing to an important extent. Advertising standards have been applied in some countries, and consumer watchdog institutes act as Ombudsmen for the public. Advertising companies are obliged to work within the national advertising Code of Conduct.

Government regulations have a strong influence on the business in some commodity sectors. Regulations vary from country to country. They concern mainly methods of advertising, the amount of media advertising and the promotion of certain products. Tobacco advertising is affected by a considerable amount of regulation. Direct marketing and promotion expenditure is affected by government regulations in Germany and the Netherlands

The 1980 EC Directive concerning Television Without Frontiers established a framework for European distribution of TV and radio. TV broadcasting has been deregulated, leading to an increase in TV advertising expenditure in some countries. The removal of trade barriers was the prime reason for the change, but contributory factors were the latest technological developments in cable and satellite transmission. Some stations under government control are now allowed advertising, e.g. RTBF in Belgium.

The French television broadcasting industry has undergone major changes in recent years as a result of new regulations. There are now seven companies attracting significant advertising revenues. They comprise TF1 (previously state-owned), A2 and FR3 (both public stations funded by a mixture of licence fees and advertising) and three new commercial channels, Canal Plus, TV5 and M6. Italy may need regulation to limit the number of TV stations. Besides the state-owned channels RAI, Canale 5, Italia 1 and Rete 4 there are 900 local TV stations of variable quality funded by local businesses using advertising time. In the other direction, very significant developments have taken place in the United Kingdom, where some independent local broadcasting companies will not have their broadcasting license renewed because another company has been chosen in their broadcasting area.

Direct marketing may be affected by an EC Directive which concerns the freedom of information and right to use direct marketing methods to promote products. There are concerns about the control of personal information and its potential misuse by public or private organisations. The lobby groups for the direct marketing industry also have the same concerns. Special lists (Robinson lists) containing the names of those people who do not wish to receive direct marketing are used in most countries to stop unwanted mailing and codes of ethics already exist in the industry. The EDMA, FEDIM and EAT are trying to have modifications made to the draft directive since in its present form it could prove to have a damaging effect on industry.

OUTLOOK

A contraction of companies in some industry sectors resulting from the Single European Market dynamics, should not have a negative influence on advertising expenditure. On the contrary, bigger players should mean more advertising will be used.

Advances in computing technology will continue to have a great impact on advertising, and direct marketing. The evolving interactive systems such as personal computer electronic mail and Teletext should replace in part or supplement traditional advertising and direct marketing methods. A caveat to consider is new legislation in this area concerning circulation of computerised information.

Direct marketing costs are increasingly becoming attractive to many companies implying greater shares of gross national products to be spent on advertising and promotion services. Barring an EC Directive limiting direct marketing, this activity should be the major promotion tool of the sector within five years. The ease with which information can be transplanted makes this a highly effective means of reaching potential customers.

Legal services
NACE 835

In 1991, legal professionals accounted for 63% of the 500 000 employed in this sector. The fee income of the sector was estimated at approximately 40 billion ECU. Legal services are continuing to expand into corporate business affairs, especially concerning activities associated with mergers and acquisitions, competition law and the internal market. Because the legal profession has developed independently in each Member State, its organisation differs from country to country.

INDUSTRY PROFILE

Description of the sector

The sector covers all professional and support staff working in the liberal legal profession in the EC Member States. The description and statistical details which follow do not relate to those employed in the public sector, i.e. commerce and industry and central and local government, including the prosecution service, nor does it include the judiciary.

Legal service providers include legal counsels, lawyers, public notaries, professionals specialised in business matters, patent agents and bailiffs. Directive 77/249 of March 1977 on the freedom of lawyers to provide services lists a general designation of persons described under the term lawyer. Fiscal advisers also give legal advice in some countries, although it is the exclusive province of members of the legal profession in Denmark, Spain, Greece and Germany.

The services of lawyers fall very broadly into four areas: negotiation; preparation of documents; legal advice; representation before the Courts, Tribunals and administrative bodies.

Not all lawyers operate in the same manner throughout Europe, however, and spheres of activity vary considerably. Work includes:

- court practice (civil and criminal), including preparatory advice and investigation;
- preparation and negotiation of contracts;
- purchase and sale of property (domestic and commercial);
- company law including mergers and acquisitions;
- intellectual property law;
- consumer and social security law;
- preparation of wills and winding up of estates of deceased persons;
- tax planning and investments.
- Notaries deal mainly with the preparation of deeds and legal documents. Their work includes:
- purchase and sale of property (domestic and commercial);
- company formation and changes to statutes;
- preparing contracts (including those of marriages);
- making translations of legal documents;
- preparing documents for the sale of motor vehicles;
- preparing wills;
- preparing other legal documents.

Sheriff officers and judicial officers (bailiffs) have the job of executing judgements concerning property and financial matters. Duties range from debt collection and property recovery to delivering legal documents and auctioning property in cases of bankruptcy. In some countries, huissiers (highly

qualified bailiffs) are involved in managing property, selling insurance and offering legal advice.

Main indicators

The sums of money passing through lawyers, notaries and bailiffs accounts are far greater than their fee incomes because they handle money matters for clients. It is therefore not of great value to know the turnover of the sector.

Official fee income data does not exist for every country in the EC, so the estimate of 40 billion ECU comprises both local estimates and official Eurostat data. It allows a comparison of the value of legal services with other service sectors. No major fee income study has been done for the EC, so the figure could be lacking accuracy.

Average annual fee income per fully employed professional varies a great deal in the EC. The ratio from the highest to the lowest band is roughly 5:1 (not including individual high and low extremes). The differing rates depend on several factors. Two important factors are the cost of living (particularly general office expenses), and the ratio of demand to supply. Overall the Latin notaries have the highest fee incomes, lawyers are second, and bailiffs are last.

It is estimated that a legal services office needs at least 40 000 ECU fee income per legal professional per annum to be viable in most countries of the EC. In the southern European countries the annual fee income can be lower. There are significant variations in earnings within countries. Fee income of lawyers in major cities are greater than those of practices in smaller towns. For example, the rate in London per solicitor is £128 000 (approximately 183 000 ECU). In the north of England the average rate drops to £74 000 (approximately 106 000 ECU) per solicitor according to the Law Society statistics for 1989-90. The figures mentioned are gross fee income.

Estimates show that lawyers in the United Kingdom (mainly in the London area) have by far the highest average fee income of lawyers in the EC. The southern European countries have the lowest income per fully employed professional, and many lawyers are unemployed, particularly in Spain and Greece. There is no numerus clausus to contain the number of people studying to become lawyers. In the more lucrative Latin notary profession there is a numerus clausus.

Lawyers have three ways of billing clients: remuneration by the hour, as a percentage of the value of the case (not permitted by law in some countries), and by service. The method of payment chosen often depends on the sum of money involved in a case. For example, it would be unlikely for many commercial companies to accept to pay 10% of a very large sum of money under dispute. Percentage fees charged by lawyers normally reduce as the case amount increases. A percentage banding method applies. For example, a case amount below 3 500 ECU might be charged at 10%, between 3 500 and 7 000 ECU might be charged at 8% and so on. Unless a code exists which involves only one billing mechanism, lawyers must inform their clients which system applies in the calculation of fees. For hourly rates, unless the lawyer has informed the client and obtained an agreement of the rate before starting the work, the national bar's guideline rate applies. It is also usual for many lawyers to modify their fees according to the economic means of clients.

In case of dispute over a fee, the national bars assess the hours of work chargeable by the lawyer. Lawyers must provide proof of work done. The problem of disputed fees mainly concerns the Belgian and Dutch bars. In time this should diminish as these lawyers become more professional in the billing aspect of their business. Many national bars are trying to help their members to improve their business organisation.

The major achievements of national bars of lawyers have been in tidying up billing practices by developing codes of conduct. In Belgium some bars have accepted a fee code recently formulated by the national order of advocates. The code suggests that hourly rates should be BF 3 000 per hour, not including expenses (just over 72 ECU), for 1 200 chargeable hours per annum (300 days at 4 hours per day). Lawyers do not have to follow the rate formula, however. Many lawyers charge less, especially those practising outside Brussels. Many also work more than eight hours per day. Moreover, most would not apply this rate for tasks such as letter writing.

A relatively high fee rate charged per hour does not necessarily mean a high income. In the Netherlands, the suggested rate for a lawyer by the local bar in The Hague was 265 guilder (118 ECU) in 1992. However, lawyers practising in the Netherlands generally do not earn more than those in Belgium, though their basic hourly rate is higher per capita, and the Belgian lawyers outweigh them significantly in number (Belgium has almost one lawyer per 1 000 people whereas the Netherlands has 0.65 per 1 000). The Dutch lawyers do not take as many cases to court as their counterparts in Belgium, and they rely on a large amount of legal aid assignments. The same applies to lawyers in other countries which have a code of ethics which avoid court action whenever possible.

Many trainee lawyers do not become lawyers at the end of their training period, but go into other occupations (such as banking and commerce), where they can apply their knowledge of the legal system. Trainees receive pay in every country of the EC, compared to trainees in countries such as Austria who must work without pay (earnings go into the lawyers' pension fund).

MARKET FORCES

Demand

The economic recession of the early 1990s had varying effects on the legal profession from country to country. In the United Kingdom, lawyers concentrating on conveyance were badly hit by Britain's property market slump, while in Belgium, lawyers' activity increased.

Bailiff activity can also be affected conversely during recessions as the number of bad debtors increases during these times. Payment difficulties often place small firms in the hands of receivers. Bailiffs then become involved in the liquidation procedures. Bankruptcies have increased in many countries in recent years, and there are concerns that the post-1992 EC market trends will lead to higher levels of SMEs failing. Unemployment has also affected the ability of private citizens to pay mortgage and other debt. Another major activity of bailiffs is delivering legal notices. Their involvement in the legal process increases with the number of cases that go through the legal system.

The notaries sector did well while property markets grew faster than inflation due to speculation. Property sales slumps have negatively affected income from this activity.

Supply and competition

Numerus clausus' limit the number of notaries in all Latin notary countries, as well as the number of huissiers, bailiff officers and their assistants. There is a small notary body in London with only 25 members. In the rest of the United Kingdom solicitors perform notary functions. Notary acts are covered in a solicitors education in the United Kingdom and Ireland. Lawyers have no numerus clausus. Legal services market conditions de facto regulate the number of lawyers in most EC countries.

REGIONAL DISTRIBUTION

The activities of lawyers and notaries vary significantly from country to country. In the United Kingdom, Ireland and Denmark, lawyers do notary work. In the southern European countries and in Germany, the notary is a professional and public

Source: Law Firms in Europe and Legal Business (April 1991)

legal official appointed by the state. Duties include bringing together disputing parties in an attempt at reconciliation and supervising any agreements which they reach. In "written law" countries (not including Denmark and Portugal) where notaries are public civil servants, they have the statutory power to authenticate various legal documents. German notaries' functions differ by Länder. The notary will be either a simple notary (Nur Notar), a notary-solicitor/advocate (Anwaltsnotar), or a notary-civil servant (Richternotar). In most countries of the EC, bailiffs are liberal professionals. Germany, Denmark and Italy are exceptions. There the function is carried out by state and commune employees. The Union Internationale des Huissiers de Justice et Officiers Judiciaires (International Association of Sheriff Officers and Judicial Officers) is working towards greater harmonisation of this part of the legal services profession.

Belgium

The civil law structure of the Belgian legal system has a relatively high number of lawyers, notaries and huissiers per capita. Most are in small practices or are sole agents, although there is a shift towards the establishment of larger groups. There are 29 separate, autonomous bars of lawyers throughout the country.

There are 520 bailiffs in Belgium (required training: law degree) which are divided across 27 jurisdictions. These bailiffs are ministerial or public officers and their duties range from the preparation of incident reports, the serving of writs, the execution of legal judgements and the collection of debts.

Denmark

Denmark is the one Member State with only one type of legal professional providing private legal services. There are 3 714 lawyers working in a centralised legal system. The size of practices of Danish lawyers is similar to those of Belgium, with many single practitioner and small firms. Legislation now allows corporate practices. A small minority of Danish law firms practise abroad. The number of other EC national lawyers practising in Denmark is insignificant. All lawyers practising in Denmark are members of the "Dansk Advokatsamfund" which has statutory powers of regulation. Danish court judges perform many acts carried out by notaries in the Civil Law countries.

France

The decentralised French lawyers' system has more than 180 autonomous bars throughout the country. On January 1, 1992, the profession of "conseil juridique" was fused with the profession of "avocat", under the title of "avocat". The "conseil juridique" had formerly been unregulated and embodied about 4 900 members, many employed in large units. The number of avocats now exceeds 23 000. A small group of avocats have a monopoly of practice before the Conseil d'Etat and the Cour de Cassation.

Notaries in France number about 7 500. They fulfil the classic role of the Latin notary, and some general advisory work. The bulk of their work is property transfer, similar to notaries in Belgium. In some parts of France notaries also act as estate agents. A separate profession of "avoué", with about 350 members, provides a legal appeal service in France.

There are nearly 3 000 bailiffs in France which collect approximately 40 billion French francs annually. To enter the profession, candidates must have a law degree and pass a special exam.

Germany

The main legal profession in Germany is the "Rechtsanwalt", which numbers nearly 65 000 lawyers (including the former East Germany). A part of German notaries are only notaries, not exercising the profession of the solicitor/barrister (Nur-Notar). In some former Prussian Länder, lawyers are also appointed to notary tasks (Rechtsanwaltsnotare). In Baden-Wurttemberg the Notar is employed in the civil service and performs notary services and probate (hereditary) services. Specialised legal experts also exist. These include patent attorneys (Patentanwalt), tax advisors (Steuerberater) and auditors (Wirtschaftsprüfer). Multidisciplinary partnerships between Rechtsanwälte, Steuerberater and Wirtschaftsprüfer are possible.

Greece

German law influenced Greek civil law. There are about 23 000 lawyers, or "dikigoro". There are about 60 bars, but Athens, Thessaloniki and Piraeus bars account for about three-quarters of all lawyers practising in Greece. Greece has a relatively high number of notaries, 25 000, in comparison to all other EC countries. Notary duties in Greece are mainly state controlled.

Ireland and the United Kingdom

Ireland has a legal system similar to that of the United Kingdom (other than Scotland). The legal profession consists of two branches, namely barristers, who represent clients on the instruction of solicitors, in Court proceedings, and solicitors, who provide a wide range of legal advice and services (including a right to represent clients in Court), in addition to offering services similar to those provided by notaries. There are 860 practising barristers and 3 600 practising solicitors in Ireland. Solicitors admitted to practise in Ireland may be admitted to practise in England/Wales and Northern Ireland without the necessity of passing an aptitude test or completing an adaptation period under the EC Diplomas Directive. Similar provisions apply to solicitors admitted to practise in England and Wales and Northern Ireland to practise in Ireland. There are also reciprocal arrangements for barristers with the bars of England/Wales and Northern Ireland.

Italy

In Italy there are approximately 59 700 lawyers (avvocato) and trainees (procuratore). There is a six-year period where a new lawyer has the title of procuratore. There are proposals to place all lawyers under one title, avvocato. There are 160 bars all of which are autonomous and self-regulatory. Italy's 5 000 notaries have functions which are civil and commercial in nature. A large amount of legal work of a commercial and taxation nature is carried out in Italy by "commercialisti" or "ragioneri" (accountants).

Luxembourg

Out of the total 434 lawyers on the Roll for the legal year 1991-92, 60 or 15% were from other Member States. Law in Luxembourg is basically influenced by France and Belgium therefore law students pass their degrees mainly in France and Belgium.. The new law regulating the profession of avocat which goes back to 10 August 1991, granted the profession a quasi-monopoly of law practice for both Court activities and non-Court activities.

There 32 notaries and 19 bailiffs in Luxembourg. No partnerships between lawyers and notaries are allowed. The law also prohibits MDP's between lawyers and other professionals.

Netherlands

There are approximately 6 854 lawyers in the Netherlands. Partnerships between notaries and lawyers can exist in the Netherlands. Many law firms in the Netherlands are accordingly combined practices of advocaten and notarissen. There are approximately 1 000 notaries in the Netherlands and about 7 000 assistant notaries and support staff. Tax advisers (belasingsadviseurs) are also able to practise with lawyers. The "Nederlandse Orde van Advocaten" has statutory powers of regulation. There are 19 local bodies under this umbrella organisation. Lawyers in the Netherlands can advertise their services.

The "deurwaarder", of which there are 220 not including an additional 200 deputies, is more or less the equivalent of the bailiff in France and Belgium. In the Netherlands, these bailiffs represent creditors before the "kantongerecht", or district court, for sums of money up to 5 000 florins and are specialised in the collection of debts before legal proceedings begin.

Portugal

In Portugal, only the 10 312 lawyers, or "advogados", can give legal advice and practise at the courts. The "Ordem dos Advogados" is the national bar. "Solicitadores", which number about 900, practise in fields such as registrations and as "avogados" auxiliary. There are 384 notaries employed by the Portuguese state.

Spain

Spain has approximately 58 000 lawyers (abogado), a high number per capita. although many do not have a practice law full-time. Numbers have fallen in recent years. Regulations have limited the size of Spanish practices to 20 professionals. There are approximately 6 000 "procuradores" for procedural representation before the Spanish courts. These may merge with "abogados" in the future. There are only 2 000 notaries in Spain.

United Kingdom

In the United Kingdom overall, there are 65 803 lawyers of which most are solicitors (58 010). Almost 90% of these lawyers practise in England and Wales where there are 7 160 barristers and 51 000 solicitors. In Scotland there are 283 advocates and 5 773 solicitors while in Northern Ireland there are 350 barristers and 1 237 solicitors.

INDUSTRY STRUCTURE

Some English and Dutch law firms employ hundreds of lawyers, whereas in other EC countries such developments are forbidden, or have never developed due to fragmented bar structures and protection of the profession. The largest firms of solicitors are in London. These firms tend to be very active internationally in Europe and throughout much of the world. Solicitors in the United Kingdom can now practise in limited liability companies.

Foreign lawyers can also compete for business in the United Kingdom, and London has attracted many foreign law firms. From 1 January 1992, these lawyers could enter partnerships with English solicitors.

Belgian lawyers' firms have yet to establish themselves internationally, but Brussels, as the main seat of the EC institutions, has attracted lawyers from other parts of the EC. These do not usually practice in the Belgian courts, but are engaged mainly in EC law.

The German system was the first to open its doors completely to competition. Lawyers wanting to set up practices have relatively easy access to the German bars formerly closed to outsiders, but very few lawyers have exploited this development. Many foreign lawyers entering the German legal system work at building up clients in the commercial enterprise sector. In 1987, regulations changed to allow for larger firms of lawyers to develop.

France has attracted several foreign legal firms, but the French have been slow about penetrating the systems of non-French speaking countries. Some larger firms of avocats are developing, but most firms are still small practices.

In Italy large legal firms are emerging in major cities such as Milan and Rome. There are few solo foreign lawyers practising in Italy.

Most Greek lawyers practise either alone or in small units; partnerships between lawyers were forbidden until recently, which has prevented the growth of practices. The Greek shipping industry has attracted a few foreign lawyers.

REGULATIONS

Currently there are no regulatory structures for the legal profession at EC level, but the CCBE is working to achieve change. Its principal aim is harmonisation of the legal profession within the EC. A CCBE council for advice and arbitration exists to settle disputes between lawyers or between bars and Law Societies throughout the EC. It will act as the joint body within the EC to supervise international practice of the profession throughout the EC. To promote the study of all questions affecting the profession of the law and to develop solutions designed to coordinate and harmonise the practice of the profession. The CCBE has already produced a Common Code of Conduct applicable throughout the EC.

Each member state governs its legal profession under its own statutes. Legal professionals must consider their role as one of providing services of a very specialised nature to clients. The legal systems of the EC countries are of three types: a Scandinavian system (only Denmark), a Common Law system (United Kingdom and Ireland) and a Civil Law system in continental countries of the EC.

Lawyers have had to fight to establish the right to practise throughout the EC. Initially, some legal professionals argued that the Treaty of Rome did not concern legal services. A series of cases has modified the European Court's and other bars' points of view. Currently the only Directive dealing with lawyers' freedom to provide services is the Directive of 22 March 1977. This is a limited measure to cover temporary provision of services. A new EC Directive on establishment being drafted should be in force soon. At a CCBE plenary session held in Dublin in May 1991, most legal representatives for EC countries accepted the new draft Directive. Those representing France, Spain and Luxembourg opposed some of the draft document's contents. A new draft has since been prepared. The CCBE and the Commission of the EC have informally discussed the draft Directive. The Commission will undertake work on proposals only if a larger majority of the delegations represented by national bodies support them, if governments do not object, and if proposals are progressive concerning mobility in the EC.

On December 21, 1988, the EC Council adopted a Directive concerning the recognition of Higher Education Diplomas. This allows lawyers to have their qualifications recognised in all EC countries. Aptitude tests are helping to assess the level of migrants' qualifications.

There is much debate within the profession about various aspects of European integration and the evolution of a "European bar". In practical terms the integration of the legal professions in Europe is still at a very early stage.

OUTLOOK

There will be greater movement of lawyers within the Single Market, but it will probably be limited because of language barriers. Aptitude tests help assess the level of competence of legal professionals wishing to practise outside the country in which they received their professional training. However, the establishment of multi-national practices (MNPs) is beginning to increase. This growth in MNPs should follow a similar pattern of development as the accountancy services sector where international companies have large numbers of professional partners. A future challenge for the legal profession will be to bring legal systems in each country of the EC closer on common nomenclature for legal terms and to standardise legal practices across the EC. This will be a difficult task, as the practices have sometimes been used for centuries

Legal professionals, qualified to work throughout Europe, must learn the deontology and legal language of the professional services in other countries. The smaller countries of the EC may eventually have more of their legal professionals prepared to work in other countries because they tend to have most multilingual professionals. This includes cross border assignments and relocation.

In the EC, overall income from legal services increases between 5% and 10% annually, and all indications suggest that this growth will continue in the long-term. Growth areas include divorce settlements, the commercial sector, legal aid, the environment, the health care sector, accident litigation (large scale disasters), and legal advice. One area that could provide major growth for legal services is the medical profession. Before the 1990s, many medical professionals in the EC did not have to worry about malpractice suits, but this is changing, and could offer significant opportunities for legal professionals.

Accountancy services
NACE 836

A small number of multi-partner international firms, which serve mainly large corporations, provide accountancy services to large international corporations and financial institutions. A plenitude of small practices supply accountancy, tax, and bookkeeping services to small businesses, and occasionally to subsidiaries of large corporations.
Six major accountancy firms make a very important part of this sector's turnover. Combined turnover has grown faster than inflation over the past decade. This reflects growth in EC economies, and an increase in revenues generated by accountancy firms from tax and management consulting services. The estimated turnover for accountancy services was roughly 40 billion ECU in 1991. More than half a million persons are employed full-time in the sector. A little more than one fifth of these are professionally qualified accountants, and are members of professional organisations represented in the Fédération des Experts Comptables Européens (FEE).

INDUSTRY PROFILE

Description of the sector

Accountancy services are offered by accountants and accountancy firms to commercial companies, associations, non-profit organisations, public bodies and private individuals. In the Panorama of EC industry 1991-1992 the accountancy services monograph referred only to professional accountants. Data included statistics for accountants working as company employees (not considered accountancy services) and qualified accountants who have continued their membership of professional organisations, but carry on non-accountancy activities. The 1993 edition covers all personnel, including professional accountants and support staff, working in accountancy firms or independently.

In order to offer certain accountancy services, it is often a legal requirement that the provider holds a professional qualification and belongs to a recognised accountancy body. Table 1, below, lists such professional bodies in the EC.

Eurostat data exists for accountancy services. However, these data contain an element of management consultancy services provided by members of the accountancy profession. Specialised trade journals provide some data braking down fee income by category of activity. There are no official data for the number of firms offering accountancy services in the EC. It is estimated that there are tens of thousands of such firms in the EC. The majority are very small practices which consist of one to five persons. The range of services offered by each of the small firms generally tends to be limited, but the range of services provided by small firms as a whole is large. There is a large group of firms, numbering thousands, which have more than five persons but less than 100 persons. There are relatively fewer accountancy service firms with above 100 persons in the EC. Many of these latter firms were formed by grouping smaller practices together.

The largest firms, known as the "Big Six", each have very large numbers of people working for them. The largest accountancy service firm in the world, KPMG, has reached worldwide employment levels above 75 000. A large proportion of these, 34 200, work in Europe. These firms have personnel located throughout the world in hundreds of offices, each of which has partners, professional accountants, technical and other support staff. The "Big Six" firm with the smallest number of offices in Europe is Arthur Andersen. KPMG has the largest number of European offices, 401 in 1992. Thus, the major firms are an aggregation of many small practices.

Source: European Accounting Focus

Some are newly established offices and others were previously independent practices which were acquired or merged, and thereby integrated into a group.

Although self-employed accountants can and do work internationally, this activity tends to increase as the size of the firm increases. Larger firms also have greater scope than small firms to offer a wider range of services. They often have several highly specialised niche services within their overall structures. As in other sectors, small firms tend to concentrate on a limited number of market segments, whereas large firms can offer a more comprehensive , full service approach. However, the small firm section as a whole coverts the full spectrum of services offered. Irrespective of their size, accountancy firms do not necessarily provide all of the accountancy services required by each of their clients, even though they may offer an extensive range of services.

A sub-professional level of accountancy services exists. It consists of firms which do not employ professional accountants and only offer services such as bookkeeping, data processing and payroll services. The overlap between such services and human resources services was taken into account when calculating employment and turnover data. Care was taken to adjust the estimates accordingly.

Activities of the accountancy service firms include services such as: accounting; statutory audits; merger audits; contribution audits; public sector audits; insolvency practice; legal advice/expert witness; representation of clients; investment services (including advice); tax advice; and consulting (marketing, strategy, information technology, etc.).

The type of services provided by an accountancy firm to each of its clients varies. Legal requirements sometimes require the involvement of professional accountants or firms, whereas other services are not subject to such requirements. Such requirements vary from country to country and/or as a result of the legal form of the client. Some companies are exempt from the audit requirement if their turnover is below certain thresholds, or if they have certain legal form. Cooperatives, private limited liability companies, partnerships and associations are often exempt from many of the accounting and auditing obligations imposed on publicly quoted companies.

Services other than those required by law have been an important source of growth for the accountancy services sector. In some countries, accountants act in a fiduciary capacity for clients, handling investments and similar financial matters. In recent years management consultancy has been one of the sector's major growth areas. Management consultancy is covered in a separate monograph in this chapter.

In several countries, some of the bigger firms derive less than half of their income from accountancy and auditing. The situation differs significantly from one country to another, largely due to the differing legal requirements imposed by Member States in relation to auditing, as well as because of market developments. Services other than accounting, auditing and tax advice are becoming of increasing importance.

Main indicators

At one end of the scale, the bigger firms are expanding their services to provide more global advice in areas such as strategy, marketing and research. At the other extreme, many of the smaller practices concentrate almost totally on traditional accountancy services. In their case, management consultancy, marketing and research services account for less than 5% of total fee income.

It is not easy to separate the value of non-accountancy services from others, because data is not available for every firm in every country. However, some "fee split" data is available from professional associations and specialist publishers. Specialist publications include "European Accounting Focus", published by Intellectual Property Publishing, and "Accountancy" the journal of the Institute of Chartered Accountants in England and Wales.

The research carried out by the specialist press into fee structure and income often covers little more than the "Big Six", and never more than fifty firms.

Germany, France and the United Kingdom account for about three-quarters of the EC market for accountancy services. The southern European countries have the greatest growth potential.

Accounting and auditing services form the core of the firms' activities. These two services, which are often combined into a single service category, account for about two-thirds of turnover. Tax advice is the next most important service, accounting for about one-fifth of the turnover. Management consultancy generally accounts for between 10% and 15%. Lastly, legal advice services often relate to matters such as transfer pricing, corporate legal structure, insolvency, and occasionally debt collection and factoring.

International comparison

The "Big Six" firms head the league tables in practically every country in Europe. Of the EC countries, Greece is the only country where one of the "Big Six" is not in first place. This is because the State body, Soma Orkoton Logiston (Institute of Public Accountants), until recently enjoyed a monopoly to practise all regulated activities reserved to the accountancy profession, including accounting and statutory audit. This will change in March/April 1993 as a result of a presidential decree of July 1992. The biggest accountancy service firms in EC are in the United Kingdom. The operations in the United Kingdom of Coopers & Lybrand and KPMG each employ almost seven thousand staff. A dozen firms each have more than one thousand staff. This contrasts significantly with the other three of the largest EC countries.

In France KPMG has a twenty-seven office operation which is only fractionally smaller than its practice in the United Kingdom. There is a big drop down to Arthur Andersen's French based firm, which has only a little more than two thousand persons. Another three firms each have over one thousand staff.

In the Italian market Arthur Andersen is the biggest firm with a relatively small staff of just over six hundred people. The "Big Six" head the field, and below them is Ria & Mazars which has only just over one hundred staff.

According to the tables published in European Accounting Focus, the major accountancy firms in Germany are not as big as those in the United Kingdom and France. KPMG heads the accountancy league table in Germany, well ahead of the other "Big Six" firms.

The US market is roughly the same size as the EC market despite having slightly fewer inhabitants. Fee rates are somewhat higher, even with a weak dollar. In the mid-1980s the US market was significantly larger in ECU terms because of the exchange rate at that time.

In Japan, the development of the accountancy profession has taken place during the last hundred years. The "Big Six" accountancy firms have achieved a strong position in the Japanese market through acquisition and mergers with local firms and through organic growth. The largest Japanese accountancy firm, Tohmatsu, became part of the Deloitte Ross Tohmatsu network. The top four firms in Japan are associated with the "Big Six". There is a reluctance among many major Japanese companies to use services provided by accountancy firms, especially consultancy: instead they tend to use employees.

MARKET FORCES

Demand

The range of services provided by accountancy firms is changing from being largely accounting and auditing to a much broader spectrum, including management consultancy. This includes investment planning and corporate strategy. Nonetheless, auditing has been an area of major development. Since the 1980s there has been significant demand for acquisition studies and merger audits.

Legal requirements oblige many companies to have their annual financial statements audited. A properly approved auditor or firm of auditors must state whether the financial statements they have audited give a "true and fair view" of the results of the company's activities and its financial position, and whether accounts comply with the relevant legal provisions.

The purpose of the independent external audit is to lend credibility to financial information, thereby enhancing the effectiveness of economic decisions made on the basis of it. In addition, many companies and other entities not subject to the statutory audit requirement voluntarily request contractual audits, in view of the benefits that accrue from this service. Finally, there is growing demand for audit-related services, which involve the issuance of special-purpose reports and opinions of the application of certain defined procedures.

Tax advice services include tax planning or tax compliance. The former consists of advice on the application of taxation law. Tax compliance relates to the preparation and presentation of the various returns and declarations required by law, and assistance to clients in their dealings with the relevant authorities.

In the past, many small companies, self-employed people and small shops are unable to do any part of their own accounting and bookkeeping and therefore depended on the services of accountants. However, because computer hardware and accountancy software programmes have fallen so much in price, nearly every business can afford the investment required. Nonetheless, many businesses continue to use accountancy service firms in order to make better use of their own resources and to have access to specialist expertise.

Professional accountants are either the leading, or significant, providers of insolvency services in those countries where they may act in this capacity. Their role may be that of liquidator, receiver, or administrator. Clients may also turn to accountants for strategy advice before a critical or unredeemable stage is reached in its financial position. For this reason, the service provided is often known as "insolvency and corporate recovery."

Supply and competition

In every EC country, the profession is organised in one or more bodies (see table 1), which enjoy a degree of autonomy from the State which varies from country to country. Self-regulation has nevertheless always been a key factor in the organisation of the profession. In Greece, where regulated accountancy services were provided until recently by a civil service agency, the introduction of EC directives is leading to the creation of an independent body similar to those in other Member States in 1993. In some countries there are several organisations of which an accountant may be a member and which award professional qualifications. Not all organisations represent properly qualified professional accountants.

The process of qualifying as a professional accountant is a long one, requiring both theoretical knowledge and practical experience. The entire process can last from six to seven years, or even up to ten or fifteen years in some countries. Many of those working in lower positions in accountancy firms are doing so to gain the practical experience necessary to qualify as a professional accountant. Most people working in the accountancy services sector are not professional accountants. They include support staff and technical staff as well as trainee accountants.

In the EC approximately 300 000 persons are members of professional organisations belonging to the Fédération des Experts Comptables Européens (FEE). About one-third of these persons work in the accountancy services sector. Most of the remaining 200 000 members of professional bodies represented in FEE, are employed as accountants in industry, commerce, education and public sector. Some retain their membership of professional accountancy bodies even when they carry out different functions.

There are several associations representing accounting technicians having lower qualifications. At present, these exist at national level only. The remainder of those who work in the accountancy services sector, numbering hundreds of thousands, do not belong to any organised body. In some countries, only those accountants or auditors working in public practice may be members of the relevant professional bodies. In others, all those having the appropriate qualification, be they in public practice, in industry, commerce, education, the public sector, unemployed or retired, or working abroad, can retain their membership of the professional bodies. There is a trend towards more accountants becoming members of organised bodies.

When a person becomes a professionally qualified accountant, this often marks an important point in his or her career: he or she may become eligible to move into jobs requiring higher qualifications. Some opt to stay with the company they trained in, others open their own practices, and some use the qualification to move into other senior management positions. There are no restrictions on the number of accountancy firms which may be established in EC countries, nor is there any limit or numerus clausus restricting the number of professional accountants. The number of accountancy firms in the EC has increased throughout the 1980s. The larger firms have tended to decrease in number because of mergers and acquisitions.

Source: KPMG, European Accounting Focus and Accounting

The largest firms have many office locations and their staff generally serve clients within close proximity of their offices. Large international accountancy service firms often have separate offices to deal with international clients and, in addition, a centrally coordinated team acts as a consolidator of information. With many offices spread throughout most countries, these firms are also able to assist clients who have multiple business units spread throughout a country.

The bigger the accountancy firms are better equipped to provide international accountancy services to major international companies. Differences between countries as regards legal requirements and other regulations tend to create problems. The assistance which accountancy service firms can provide in coping with these differences makes them extremely valuable to multinational corporations.

INDUSTRY STRUCTURE

Companies

The large accounting firms have thousands of partners, and their full-time employees normally amount to about ten times the number of partners. Accountancy service firms have a high ratio of staff to partners in comparison to other businesses and many professions. The "Big Six" accountancy firms have roughly 9 000 partners between them in Europe. Their total staff numbered 142 300 in 1992 according to European Accounting Focus. Smaller firms of professionally qualified accountants generally have a higher ratio of qualified staff to support staff. Many accountancy firms have grown considerably in size as a result of mergers with other major firms and acquisitions. Beneath these six firms there are fourteen accountancy firms which had more than 20 million ECU of fee income in 1991 (Table 3).

Strategies

The major accountancy firms have many partners partly because their networks in Europe are made up of independent locally established firms with locally qualified accountants. Partnerships are offered to people who join the firm bringing with them clients, or to personnel whose careers develop within the firm. Acquisition of smaller firms is a quick way of gaining clients. The acquired firms benefit from being part of a large international group. In some smaller countries many major accountancy firms have chosen not to get involved with local firms. Portugal is a good example; several international firms developed Portuguese practices from scratch.

One of the "Big Six", Arthur Andersen, has been in the forefront in developing the non-accountancy services area of activity. In some countries more than half its turnover comes from management consultancy services. Its success in this sector has not escaped the attention of other firms, many of which are now trying to increase their share in consultancy services.

Accountants practising alone and very small partnership firms often concentrate on smaller, often private, companies, sole traders, clubs, associations and individuals. This constitutes a large proportion of total demand for accountancy service. Local offices of large firms and small firms can also opt to specialise in niche practices or develop broad range service structures.

REGULATIONS

Accounting and auditing services are highly regulated in the EC. Regulations are both numerous and complex and vary from one country to another, despite the attempts made at Community level to bring them closer together. These regulations fall into two main categories:

- Regulation of the services themselves including rules governing the manner in which the services should be provided;
- Regulation of the accountancy profession and of its members working in this sector.

Regulation of services

Many of the services provided by the accountancy profession have been regulated for a long time in most European countries, often in different ways. These services include statutory audit, accounting, public sector audit, contribution audit, insolvency practice, etc. National regulations define the type of work to be carried out, when, under which conditions and by whom.

Statutory audit is the only service provided by the accountancy profession which is regulated in all EC countries in the same way. It is also the only service which has been subject to specific EC directives. As a result, all companies above certain minimum thresholds must now prepare and file financial statements audited by an independent expert. All the other services have, until now, kept their own national specificities. Certain services are regulated in some countries, but not in others; some services are reserved to one profession in certain countries but are shared between several professions in other countries, or even forbidden to the accountancy profession in others. Consequently, the range of services provided by the profession varies significantly within the EC as does the degree of competition which exists in each of these markets between the accountancy profession and other professions.

Regulation of the profession

In addition to the services it provides, the accountancy profession itself has been regulated for a long time in European countries. Because the economies of the Member States developed in different ways, the regulation of the profession differs from one country to another. The degree of self-regulation, which historically has been very significant in the profession in many countries, has decreased in the recent past, mostly as a result of the implementation of EC directives.

In a majority of Member States, the profession has been created and organised by law or by public authorities. Even in those countries where the profession has been privately organised, it enjoys official recognition by the State, which entitles its members to carry out regulated activities. Regulation, be it public or private, applies to a number of areas such as the definition of professional titles, protection of the titles, membership requirements, minimum levels of education and train-

ing, continuing education, ethical standards or codes of conduct, technical standards, additional licensing requirements for specialised areas of practice, rules for establishment of professional firms, etc.

In the EC, only limited attempts have been made to harmonise these rules. This has resulted in the Eighth Company Law directive on "the approval of persons responsible for carrying out statutory audits of accounting documents". The directive established minimum education and training requirements for statutory auditors, be they individual or firms. However, Member States remained free to impose more demanding requirements, and many did.

Another directive applying to the accountancy profession is the First Mutual Recognition directive which, when implemented, allows professionals from other Member States to seek recognition of their qualifications so as to be able to carry out regulated activities without having to requalify. In the case of the accountancy profession, Member States can require migrants to pass an aptitude test on local laws and ethical requirements. Although such a regime previously existed in some countries such as Belgium, France, Ireland, Luxembourg and the United Kingdom, it is new for others. This new system should have come into force early in 1991, but its implementation has been delayed in a number of countries. However, it is already obvious that it will not generate significant flows of accountants across EC internal borders. Despite making it easier for professional accountants to establish themselves abroad, differences remain between national laws and regulations with which accountants must be familiar. These differences will continue to restrict the free movement of accountants within the EC.

OUTLOOK

Future prospects are excellent for the accountancy services sector. It is likely that regulations will lead to a tightening up of accountancy practice and the raising of standards. The accounting-related company law directives have already led to an increase in demand for accountancy services in many EC countries. They have also improved the comparability of published financial reports. To a large extent growth in the accountancy services sector will depend on growth of the economies within the EC Member States.

Small accountancy firms that have offices in only one or a few EC Member States may benefit from legislation to facilitate the cross-border provision of services. However, it is considered that this will not have a significant impact before the end of the century.

Developments in Central and Eastern Europe have also brought increased demand of accountancy services. Accounting and the accountancy profession are essential elements of the infrastructure of market economies. As the countries in Central and Eastern Europe undergo a process of transition towards market economies, they need the services of professional accountants from the EC and other market economy countries. Initial demand is for services including advice on changes in the regulatory environment, privatising state-owned enterprises and attracting foreign investments.

Written by Campbell Management Consultants
The industry is represented at the EC level by: Fédération des Experts Comptables Européens (FEE). Address: Rue de la Loi 83, B-1040 Brussels; tel: (32 2) 231 0555; fax: (32 2) 231 1112.

Market research
NACE 839.1

The EC accounts for 42% of the world market for market research. Eight of the world's top 10 market research companies have their headquarters in the EC. There are more than 1500 companies and consultancies in the EC offering market research services. They employ more than 30 thousand permanent employees and 100 thousand freelance interviewers, researchers, self-employed consultants and sub-contractors. In 1990, the market research market amounted to more than 2.2 billion ECU in the EC.

INDUSTRY PROFILE

Description of the sector

Market research analyses the markets for all kinds of products and services, and provides a link between consumers, customers, the general public and the market. It is used by marketers to: identify and define opportunities, threats and problems; initiate, modify and evaluate marketing activity; and improve understanding of marketing processes.

According to a study made by ESOMAR, 52% of all EC market research is commissioned by manufacturing companies, 14% by companies in the services sector, 9% by government bodies, 5% by wholesale and retail organisations, 5% by advertising agencies, 4% by research organisations and the remaining 10% by others. The purpose of market research is to understand consumer demand. Attitude surveys provide suppliers of goods and services and potential suppliers with information about what people want and why they want it.

Market research enhances economic efficiency by enabling companies and other organisations to provide the goods and services that customers want by investigating their needs, beliefs and behaviour. This helps companies to avoid wasting resources in developing and producing undesirable products, or to avoid communicating the benefits of their goods and services inadequately.

Market research specifies the information required to address these issues; designs the method for collecting the information; manages and implements the data collection process; analyses the results; and, communicates the findings and their applications.

Main indicators

The total European market accounts for 46% of worldwide expenditures on market research: 42% in the EC and 4% in other European countries. This compares with a share of 36% for the USA and of 7% for Japan in 1990.

Within the EC, nearly two thirds of the total market research expenditure is accounted for by three countries: France, the United Kingdom and Germany. The first two account for 24% of the European market each, and Germany accounts for another 22%. The contribution of former East Germany, which is for the first time included in the German figure, is estimated at approximately 5% of the total German expenditure. Spain continues its rapid upward movement and replaces The Netherlands in fifth place. In broad terms, the most rapid growth continues to be seen in Southern Europe, particularly Spain and Portugal.

Despite the growing internationalisation of markets, about 88% of EC market research is still conducted for national clients although many of these may be subsidiaries of multinational corporations domiciled elsewhere. Sub-contracting to foreign research organisations when coordinating international studies accounts for around 5% of research companies' business. About two thirds of this is accounted for by two countries: the United Kingdom (39%) and France (25%). There are no hard data on the source of foreign clients or the destination of sub-contracted revenues. However, industry reports suggest that the proportion of intra-Community research is increasing.

Recent trends

The market research market grew rapidly between the 1950s and the 1980s. Growth is currently slowing due to the worldwide recession. Although it is difficult to find accurate data on market research turnover figures, since the distinction between market research information, market consultancies and related disciplines is sometimes difficult to make, it is estimated that the real annual growth rate of this sector over the past five years was in excess of 10%.

(1) Estimate based on average of comparable countries
Sources: Trade associations and ESOMAR estimates; other countries' data not available

The 1991 ESOMAR study on the size of the research industry in 1990 showed an 11% growth in the size of the market within the EC, from 185 billion ECU in 1989 to 224 billion ECU in 1990. The ESOMAR study covers 20 European countries and uses data and estimates provided by national market research societies, trade associations, expert industry watchers, and the world's major research groups and chains. These turnover totals exclude market research conducted "in-house" by marketing companies, advertising agencies, governmental organisations, academic institutions and other organisations conducting "in-house" market research.

MARKET FORCES

Demand

Traditionally, manufacturers of packaged consumer goods were the main users of market research. Companies which market services (finance, leisure etc.) have become a sector of growing importance to market research suppliers. The increasing pace of development in technology, growth in the information industry, diversification of life-styles, and proliferation of media has made marketing research ever more necessary to monitor changes in the market place. In recent years, thus, a much wider range of business and non-commercial organisations (including public sector and government) have used market research to aid their planning, decision making and policy formation.

Research can be categorised by type of product or subject, by frequency of research (ad hoc versus continuous research), by type of research (qualitative versus quantitative), or by mode of information collection (telephone interviews with questionnaire, one-on-one face to face interviews, focus group discussions, desk research, mail survey and so on). Face-to-face interviews clearly account for the majority of quantitative research expenditure in the EC: 72% compared to 20% telephone interview studies and 8% mailed questionnaire studies.

Almost three-quarters (73%) of market research studies are related to consumer products and services. Ad hoc research

outweighs continuous research by 56% to 44%. Most of the latter is panel research (74% of continuous research and 34% of the total). The other 26% of continuous research is split evenly between omnibus research and other continuous research. About 80% of market research expenditure in the EC is from quantitative research, 15% from qualitative research and 4% from desk research and secondary activities.

Relatively small countries with a highly developed infrastructure tend to favour telephone questionnaire studies (Denmark) or mail studies (Netherlands). For qualitative research, focus group discussions clearly account for the majority of the research expenditure in the EC (approximately 59%) compared to 41% for in-depths interviews, with variations between countries due to cultural factors.

Supply and competition

The structure of the market research industry is remarkably similar across the EC Member States. Generally, the market can be split into three parts: media market measurement: audit shops and scanning (the analysis of consumption from computerised tickets shops); specialised market research by multinational research companies and local unaffiliated companies. These latter include specialised quantitative research, ad hoc research and qualitative research.

The evolutionary process in the market research market indicates that when a national research market first develops, it relies heavily on omnibus studies, brand barometers, qualitative and small-scale quantitative research. Subsequently, there is a major leap in development in which a retail audit and/or consumer panel (together with media research services - especially television audience measurement) is established. These syndicated continuous services, generally offered by one or two dominant suppliers, then claim a significant proportion of spending on market research. This leaves relatively little for the ad hoc research sector, which is more geared to problem solving and the identification of opportunities.

When a market reaches a certain size and stage of maturity, an equilibrium is established, in which continuous research captures about one-third of total expenditure. Other regular services (e.g. advertising tracking, quality of service monitoring) add a further semi-contractual sector, partly substituting for ad hoc studies and partly reflecting overall growth in the information market.

Other geographic variations stem from broader economic and market influences. In smaller countries, less research on new product development is undertaken as the major R&D activities and corporate headquarters are often located elsewhere. This leads to more research involving the screening of concepts, products or communications approaches that have been developed and more thoroughly researched in the larger EC markets.

Market research has developed from consumer marketing origins and tends to be relatively less widely used in those countries where the emphasis is more on industrial products. There have also been different patterns in the post-war evolution of markets and of marketing. Furthermore, restrictions on television advertising (and hence, related research) in a number of countries have contributed to this differential use of market research across the Community, as have the varying levels of retail trade concentration (broadly, more concentration in the north than in the south). The overall effect of these, and other, factors is that compared with the level of economic activity in the country, the market research market is particularly well developed in the United Kingdom and the Netherlands and somewhat less so in Germany and France. The exceptional British results during the last few years may be explained by two factors: a long tradition in market research and a universal language.

There are considerable differences in costs and prices across the EC countries, largely reflecting differences in salaries and social costs. Other factors explaining these cost and price differences include: the degree of competition in the local market; the enhanced efficiency that comes with greater experience in certain types of research; a mix of research and data collection methods; and the geographic dispersion of population

In an ESOMAR survey designed to discover how research prices vary from one country to another, research institutes were sent detailed specifications for six different surveys and asked to state what price they would quote to a client for carrying out each of these six studies. Averaging across all six projects, France and Italy emerged as the most expensive

countries, and Belgium, Greece, Portugal as the least expensive. In 1991, the rank order in terms of average research costs from the most to the least expensive was as follows: France, Italy, Germany, Ireland, United Kingdom, Denmark, Spain, the Netherlands, Belgium, Greece, and finally Portugal.

Investments

In a predominantly people business, capital investment has historically been a relatively insignificant component, apart from in the continuous research sector. However, the advent of the micro-computer has revolutionised market research and the level of necessary investment. Changes in data collection methods have increased investment needs. Computer-aided interviewing especially by telephone has involved the commitment of substantial sums to the installation of facilities typically comprising 20 to 100 telephone booths with appropriate telecommunication and computing equipment.

In the continuous research sector, single-source data from panels that record product purchase and media exposure have required considerable investment in developing and placing scanning devices, "people meters" to record television viewing and other high-cost electronics. Data derived in this way, as well as data from other sources, increasingly form part of computerised databases for marketing management information systems (decision support systems).

Over the past decade, more EC research companies in the ad hoc sector have begun to emulate US research firms in the standardising and branding of research products. This, too, involves investment, although typically in the time of first-rate research technologists and innovators. Significant investment in designing, testing and validating new research techniques, and subsequent marketing investment in communicating the benefits of these techniques to customers is only possible if the costs can be amortised by the application of the same technique across many countries and over time.

INDUSTRY STRUCTURE

Companies

Eight of the top 10 world market research companies and two of the world's three major market research chains (networks of independent companies) have their headquarters in Europe.

The industry is characterised by considerable fragmentation and intense competition. Barriers to entry are low except in the high-tech high-investment areas of market and media measurement (around 35% of total market research expenditure).

Pre-tax margins have historically averaged 5% to 6% of turnover for ad hoc research organisations. This is considered to have risen a little higher in recent years. Substantially higher margins are made by research companies with multiclient services and a contractual customer base.

Strategies

Several companies have restructured their services to survive in the rapidly changing market. A number of mergers and acquisitions have taken place often as part of the creation of major marketing services corporations. This has led to a reduction in the level of American ownership of EC market research businesses. Another effect has been to increase industry concentration and to produce eight major research holding companies in the EC.

The other major structural change process is horizontal specialisation. Increasingly, market research organisations throughout the EC are setting up specialist divisions or operating subsidiaries that concentrate on key business sectors (e.g. media, health care, automotive, travel, finance) or research specialisations/problem areas (e.g. qualitative, advertising, customer care).

Vertical integration has always been a feature of the European market research industry. All but the smallest companies have combined a client service function with a data handling facility (data collection, preparation, processing and printing). However, there are signs that this vertical integration is beginning to be questioned by some companies, especially where personal interviewing fieldwork is concerned. The USA market for instance has long been characterised by an ownership separation of research companies from fieldwork suppliers.

REGULATIONS

Market research is, like many service industries, dependent on self-regulation. For instance, the ICC/ESOMAR International Code of Marketing and Social Practice is applied by all ESOMAR members and by the national marketing research societies in all the EC Member States. This Code, which guarantees the respondent's anonymity, specifies responsibilities towards respondents, the rights of respondents, relations with the general public, the mutual responsibilities of clients and researchers, and reporting standards. The Code is particularly relevant in the light of EC proposals for data privacy legislation. For the time being, such restrictions can vary from one EC Member State to another, with many countries offering an exemption to market research in recognition of the fact that it deals with aggregated and anonymised data and not with personalised data.

Other restrictions which vary from country to country can affect the right to conduct and publish public opinion polls, particularly in the run-up to government election. Although political opinion-polling constitutes only about 2% of the entire market research industry and actual pre-election polling ac-

counts for less than 0.3% of the total market research turnover, it naturally attracts a lot of media and public attention.

Another regulation which may affect the market research industry is the proposed EC Directive on Temporary Employment. This directive would affect most freelance interviewers, and may ultimately drive up market research prices. Indeed, at present, legislation on social security and benefits still varies widely between EC Member States.

OUTLOOK

With the proliferation of sources for marketing data, companies will have smaller market research departments, if any at all. It will, however, be increasingly necessary for researchers to provide an interpretative service to help marketers understand the implications of market research data for marketing strategy. This trend is already evident with the increasing number of researchers acting as consultants to companies.

Parallel to this is the growth in automation and technological developments within the market research sector - an unstoppable trend which means that market research companies will need greater capitalisation to be able to invest the necessary funds in the latest technology to remain competitive. This is evidenced by innovations such as television audience meters and scanners developed by the largest research chains. This trend, together with the increased need for international research, has led to the growth of international research chains and the possibility for buyers to go to one head office to commission a research project in several countries or regions.

Growing areas for research are customer satisfaction, branding and research into corporate image, business to business, finance, retail and utility sectors and legal research - sectors that have only recently started using market research systematically. Studies suggest that expenditure on most types of market research is likely to increase rather than decline over the next five years. This will be markedly so in the case of main areas of research activity such as usership and attitude studies, product testing, advertising and concept development and evaluation, and advertising campaign tracking, particularly with the proliferation of different types of media, new publications and TV stations.

The opening of new markets such as Eastern Europe means that large research chains must also have available funding to set up offices in regions where facilities such as faxes and computers cannot always be taken for granted. In the short-term, demand for market research in Eastern Europe is not expected to increase significantly. However, as the demand for market research is related to the productive investment rate, the potential demand is significant in the longer term. The growth of demand will also depend on variables such as qualification standards, and will be strongest in countries where the labour force is most qualified.

The completion of the Single Market will lead to an increased and new type of demand for market research services, but will also mean a need for a greater harmonisation of statistics across the Community in order to improve the comparability of survey findings.

Finally, the client-research company relationship is likely to be affected by Total Quality Management (TQM) and Service Quality demands. Many companies are adopting TQM and cultivating service quality, and so research organisations must also expect to do the same to offer consistently high and reliable quality in their services.

Management consultancy

NACE 839.1

Management consultancy has shown vigorous growth during the 1980s. The Gulf War and recent slowdown in growth in the industrialised countries, however, have sent many service sector industries tumbling. Management consulting has not been immune as many companies cut-back on external services. Full employment in the sector fell by approximately 5 000 full-time persons over the past two years to its present level of 50 000. Turnover for the sector is estimated at 7.5 billion ECU for 1991.

INDUSTRY PROFILE

Description of the sector

Management consulting consists of providing information, advice and expertise on a whole range of specialised management functions in an independent, objective manner. Services are performed by specialised personnel with considerable experience in the specific branches in which they work. Consultants include people with backgrounds in banking, computing, economics, general management, accounting, law, management communications, management planning, marketing and sales, market research, personnel selection, quality assurance and control, stock markets, and technology transfer.

The services provided by management consultants include: corporate strategy and development of organisations; administrative and financial systems; management of human resources (including recruitment of executives and temporary managerial staff); management of production and services (including technology, organisational support management, research and development and quality control); marketing and corporate advertising and promotion; information and management technologies and systems; project management; and economic and environmental impact studies.

The development and installation of information and management systems forms an important part of management consultancy activities (approximately 35%). This service is very similar to the computer-based management schemes developed by computer software houses. Management consultancy firms are increasingly involved in helping companies to develop information technology and apply computer tools.

Management consultancy services also often overlap with services covered by other monographs in this publication. A main area of overlap is contract research, particularly ad hoc market studies which often form part of strategic analysis projects. Accountancy companies offer management consultancy services in the European market, and many US ones are among the major suppliers of this service.

This overlap occurs to a lesser extent with consulting engineering firms, and concerns production, or computer-based production, organisational support, project and programme management, and also economic and environmental impact studies.

In the absence of any reliable national, Community or professional statistics, the data supplied by the association FEACO characterises the trends taking place within the sector. FEACO figures represent between 40% and 70% of the activities of the sector.

Main indicators

Technology and market globalisation are high on the list of factors affecting an increased demand in management consultancy in the 1980s. No complete data exists for this profession. However, the consolidated turnover of FEACO members was approximately 3.42 billion ECU in 1991. The membership's turnover has fallen in straight years since 1989, when it was 3.53 billion ECU. Prior to that, growth in turnover was between 10% and 20% annually.

MARKET FORCES

Demand

Private industry is the main user of management consultancy, according to FEACO. Private industry accounts for more than

60% of its member's commissions. The private business services sector accounts for roughly 20% to 25%, and trade, between 5% and 10%. The public sector is very small (civil services, public authorities, and governments) although the importance of public authorities as buyers of management consulting services is higher on average in France and the Netherlands. There is also growing demand for consultancy by certain public services (in particular, health, education, and transport).

The development and introduction of information and management systems remains the main area of activity. Strategy definition is a very commonplace management consultancy activity. An important part of strategy studies recently have focused on the single European market. Others concern strategies for developing business in the Eastern European countries, or the wider global market.

For some specialised markets experts from outside of the EC might be used. Exports (5% to 25% according to country) are mainly to developing countries.

Three trends are predominant within the management consultancy sector:

- recourse to management consultancy is becoming increasingly common practice, at least among companies with more than 500 employees;
- the use of strategy or systems consultancy is becoming increasingly recognised as an intangible/strategic corporate investment;
- consultants who formerly intervened from time to time concerning improvements of performance, productivity, are being used to promote quality and the optimisation of resources in all corporate functions, key factors in finding the competitive edge.

The break-up of the Soviet Union has had an important affect on the development of Eastern European business consultancy. These include political risk studies, industrial infrastructure analyses, legal system assessments, investment analyses and market analysis. A smaller market exists for consultants to work directly for Eastern European authorities. The former East Germany currently provides about 15% of the turnover of German consultancy firms. To a large extent this growth has compensated for cutbacks in consultancy assignments in the United Kingdom which has been in recession.

Supply

The majority of management consultancy in the European Community is carried out by local consultants. When contracts are offered to non-EC consultants by foreign companies they often use the services of EC based consultants to provide them with information rather than hiring consultants from their own locality.

The level of remuneration (consultancy fees) for consultants is 500 ECU to 1 500 ECU per day. Government bodies awarding contracts to consultants often pay around the 500 ECU per day mark. For large specialist firms fees asked can be more than 2 000 ECU per day. The higher rate is justified by the wealth of experience in those practice.

INDUSTRY STRUCTURE

Companies

The majority of consultancy companies are small practices. They are often partnerships of specialist consultants. A large volume of consultancy is undertaken by larger firms, particularly audit companies. The amalgamation phenomenon is continuing with large practices growing more quickly than medium-sized ones. In the top auditing consultancy practices, KPMG, Price Waterhouse, and Arthur Andersen in particular, have strengthened their market positions by developing management consultancy services.

Strategies

Many companies (US/UK auditing and strategy consultancy practices) have trading partnerships and loose arrangements with other consultants who work for them in specialised areas. The idea of developing multidisciplinary professions to be more competitive is increasing in the larger firms. Medium-sized national firms, on the other hand, are looking to strengthen their alliances with consultants in other countries to help cope with the competition from large networks. Following a spate of activity in the late-1980s, mergers and acquisitions within this sector have declined.

REGULATIONS

There are no regulations specifically affecting management consultancy, or regulating the type of persons engaged in the profession. There is also no requirement for consultants to

be a member of any professional association. In fact the EC market is currently open to all consultants wishing to work internationally. The only force stopping non-EC consultants from carrying out assignments in Europe would be their failure to gain travel visas.

A move towards certification is in the pipe-line. This is seen as being important where public authorities are concerned. Consultancy firms invest frequently in the training of consultants, but there are some public courses. Qualification and certification procedures are being developed especially in France, the United Kingdom, the Netherlands, Denmark and Italy. The attempts to comply with international standards (ISO) confirm the way in which the sector is maturing.

OUTLOOK

Since mid-1990 market growth has weakened reflecting the economic downturn. However, the development of market economies in Eastern European countries following the virtual collapse of communism will present further opportunity for new growth. This will need to be largely supported by International finance from developed market economies before EC consultants will be affordable to developing businesses in those countries in the short-term. The slowing down of demand and the maturity of the EC sector in the medium-term should lead to more competition and possibly further mergers and alliances between the major consultancies.

Owing to the nature of this service sector it is not possible to predict growth rate values for the next five year period. A great deal of management consultancy is ad hoc and often cannot be planned for until firm contracts are made. Nevertheless, many management consultancy practices have been increasing staff levels in the third quarter of 1992, which comes from more than just optimism. Most already have a clear idea of what lies ahead of them in the next year. Some that are retained for a range of management services including financial auditing have written management consultancy into the budgets.

Architects and construction economists
NACE 837

In general, the denomination of "architect" applies to persons who are working in construction. Besides this type of architects, there are specialists such as interior architects, landscape architects and town planners. Although the importance of these, especially of town planners and landscape architects, is increasing in most EC countries, they are not considered in this chapter. This chapter deals only with architects working in construction projects and construction economists.

INDUSTRY PROFILE

Description of the sector

Architects and construction economists are classified under section 837 of NACE, called technical services. Both are working with and within the construction industry.

The functions of architects and construction economists are to design building, including the elaboration of construction programmes, to use their specific knowledge concerning building techniques and physics, and to use their awareness and utilisation of general as well as project-specific official rules and regulations in the context of a construction project.

Architects influence the economic scope of a construction project. They are, however, also responsible for the aesthetics and the quality of the buildings.

Some of these aspects also characterise the profession of construction economists although the weighting of the aspects differs. The profession of construction economists has a tradition of more than one hundred years in France, Ireland and the United Kingdom and somewhat less in Spain and Portugal. The role and services of the construction economist varies from country to country according to domestic tradition and education systems. In France, Ireland and the United Kingdom, construction economists are educated as quantity surveyors while in Spain and Portugal, they are trained as technical architects.

In Belgium, Denmark, Germany, Greece and the Netherlands, services within construction economists traditionally have been rendered by architects and sometimes by structural engineers. As a response to the market, professionals specialising in construction economics in countries without a surveyor education have established their own professional societies or divisions. In Belgium and Denmark, applicants must participate in post-graduate training programmes before they are accepted by the professional society as construction economists.

The profession of construction economist, also known as quantity surveyors, developed with the increasing demand for construction. The profession is a speciality within the construction sector. Quantity surveyors are working in various fields including building construction, civil and structural engineering, mechanical building and engineering services, petrochemicals, cost and production engineering, planning and urban development, landscaping and interior design. The difference between their work and that of architects is that they mainly deal with the costs and valuation of projects and not with the physical part of the building construction. Their tasks include project and quality management, risk management within construction, feasibility studies and investment appraisal, cost information, calculation and control, bills of quantity and specifications, contracts between clients and contractors, time scale, monitoring progress, payment and accounting as well as managing the facilities and maintenance.

Other services provided by architects and construction economists include giving expert evidence in arbitrations and disputes, preparing statements of expenditure for tax and accounting purposes and assessing the replacement value of construction projects for insurance purposes.

Main indicators

For both professions there are no data available about turnover and value added. The activity in this sector, however, mainly follows general economic developments, and in particular developments in the construction sector.

(1) Estimates
Source: CEEC

The total number of construction economists registered in the national professional associations within the EC was around 48 000 in 1988. In 1990, there were about 237 000 architects registered in the national professional registers. The total number of architects within the EC has increased since 1983.

Germany (West) is the country with the highest number of registered architects among the Member States. It is followed by Italy, the United Kingdom and France. Greece has the highest number of architects per million inhabitants, at more than 1200, followed by Denmark and Germany (West) respectively with a little more than 1100 architects. The proportion of registered architects between the EC and the USA is approximately 1.7:1.

In contrast, most construction economists in the EC are registered in the United Kingdom and Spain. These two countries account for more than 80% of all registered construction economists within the EC.

MARKET FORCES

Demand

Both architects and construction economists work for the construction industry. Demand for this type of service thus comes both from the public sector and from private enterprises. The major public clients are central governments, local authorities and nationalised industries. Private clients are private developers and owners of commissioned private housing estates, commercial offices, shops and industrial estates. Independent architects or small architectural enterprises are also hired by private households for the planning and construction of residential buildings. Both the public clients and the clients from private industry mainly cooperate with larger architectural offices and construction economist businesses.

The demand for construction activity is influenced by income, interest rates, prices, employment and public expenditure. Especially in the private residential building sector, factors such as personal disposable income and mortgage rates can limit building activities. In contrast, public sector construction activity is mainly constrained by the need to balance government budgets. Finally, the demand for architectural and construction economist's services by the private non-residential building sector depends upon the trends in interest rates. In the second half of the last decade, the growth in private non-residential building largely compensated the decrease in public non-residential building activity. This largely contributed to the growth in the services of construction economists.

Considering the shortage of dwellings in almost all EC countries, the market for architectural services is still far from saturated. Moreover, expenditures on total repair and maintenance are expected to continue increasing, because it is necessary to improve the quality of the old stock of houses and flats.

The prospects for public sector related construction activity are dimmer, however, given the need for most EC countries to reduce their budget deficits. High interest rates also restrict demand for construction in the private sector.

Supply and competition

The number of architects varies a lot from country to country. The range is from around 300 per million inhabitants in Spain to more than 1000 in Denmark, Germany and Greece. The same (but with a smaller range) holds for construction economists. Although the ranges are quite large, there does not seem to be inadequacies between the supply and demand for architectural and construction economists' services in the EC Member States.

The variability in the number of architects and construction economists across countries reflects the fact that the rules for the construction of buildings vary across EC countries. There are also a few countries, in which less qualified professionals are able to do more demanding services than in other countries. This, however, may change once the services directive takes effect. This directive allows every professional to offer his services in a foreign EC country. But the regulations for charges are not included in this directive, such that the national regulations sometimes still apply. This gives a competitive edge to the countries with lower labour costs. The directive also stipulates that public procurement contracts in the building sector above 5 million ECU can be awarded only after an open or limited tender. This will increase the awareness of the costs and benefits in terms of quality of services as well as the need for a transparent basis of agreement, especially when dealing with cross border business.

INDUSTRY STRUCTURE

Companies

A characteristic of both professions is the huge number of small independent firms with less than 10 employees. The United Kingdom is the only EC Member State in which the average number of employees per firm is more than 10. The same applies to the structure of the market for architects. In Germany and the Netherlands, about 90% of the architectural enterprises have less than 10 employees.

Strategies

The growing competition between Member States will influence the strategies of both professions. Small enterprises which only supply part of the services required by the clients are already facing strong competition from firms, such as large building firms with their own planning offices and firms which offer the complete management and coordination of projects. This means that the smaller firms and the independents have to specialise in fields where the larger enterprises are not working, or cooperate more with the larger enterprises than was the case in the past. The completion of the Single European Market will provide new opportunities for cooperation. In cases where foreign enterprises are commissioned with work abroad, they will need local experts who know the specifics of the national construction markets and their regulations.

Another reason for the foundation of big enterprises is the liability. A lot of projects are of such a size that it is necessary for the planners to spread their liability risks. Then, it is reasonable to found enterprises in forms of private or financial companies, if that is allowed by local laws.

The relatively old stock of residential and non-residential buildings and the old structure of the major EC city centres opens another possibility for architects and construction economists to expand their services in the sectors of rehabilitation, maintenance and inner city regeneration. A third part of the professions' strategies could be to work in new fields. In this context, construction economists are starting to offer their work in the sectors of civil, heavy and process engineering.

Table 3: Architects and construction economists Independent private practice of construction economists, 1989 (1)

(1) Estimates
Source: CEEC

REGIONAL DISTRIBUTION

The location of the offices of architects and construction economists does not necessarily depend on the demand for their services. But it is an advantage for both professions to have offices in the regions and cities where their services are needed. Especially the larger firms who are mainly working for the non-residential building sector tend to locate in areas and cities where high demand is expected, i.e. in large agglomerations with a fast rate of economic development. This development is further encouraged by the fact that it is in these regions that one usually finds the appropriate infrastructure for industry. In general, however, both professions are able to react quickly to changes in demand, as it is easy for them to open branch offices in regions where this seems to be necessary.

ENVIRONMENT

A big challenge for both architects and construction economists is the already damaged environment. New forms of energy saving and emission reduction are necessary in the construction sector. New materials are being developed, and some are still being discovered. Architects and construction economists can play an important role in this area in convincing their clients of the advantages of more environmental friendly construction. This stretches from the explanation of long term cost advantages to the use of new materials. Some efforts in this direction are currently being made, especially by architects who are planning houses with winter gardens, suburban and rural settlements with their own heating system, or with new systems for producing electricity such as wind power stations.

REGULATIONS

Architects qualifications are defined by the EC Directive 384 of 1985. The professional training for architects varies from country to country. Starting with the decision for the EC directive on architects in 1985, college diplomas and certificates from each Member State are recognised in other Member States on a reciprocal basis. Therefore, at least four years of study at university level are required. This directive has produced the basic preconditions for all architects to set up business in the EC country of their choice and exercise their profession.

Since the only countries which offer a specific professional education in construction economics at university level are Ireland, Portugal, Spain and the United Kingdom, no real regulations for construction economists exist at the EC level. In most of the other Member States, both architects and engineers to some extent deal with construction economics. The regulations for the profession of the construction economists are based on the directive on Mutual Recognition of Diplomas.

But, for both professions, the services directive is important. This directive opens the market for services within the EC and frees competition across national borders. The aim of this directive is to promote price competition on the markets for services.

In addition to the directive for services, the directives for the allocation and liability for services are worth mentioning. The first one allows juridical persons to participate in public tenders which are subject to open bidding procedures. However, the public authorities are able to plan their own building projects. The directive for liability if forced upon the construction industry, represents an increased financial burden for the construction sector. According to that directive, liability will be 20 years. The result of such a directive would be an increase in costs and less construction. For these reasons the construction industry would prefer a directive specifically dealing with liability in construction including adequate consumer protection.

The work of architects and construction economists will also be affected by the construction products directive, though to another extent. This directive provides for the harmonisation of the entire set of technical rules in the building and construction industry. Accordingly, there is a guarantee of free trade and unrestricted use of products within the European Single Market. The product's conformity with harmonised specifications should protect the consumer. In accordance with the building coordination directive, public orders from a threshold value of over 5 million ECU must be subject to open bidding procedures throughout the EC.

OUTLOOK

The development of both sectors is dictated by future trends in construction activity within the Member States. With the start of the Single Market in 1993, the prospects for the professions of architects and construction economists are in general positive. Both professions will, however, face increased competition in the coming years, which will influence the structure of each branch.

The independent architects for instance will face keen competition from foreign enterprises in their own countries. Public sector related work can only be realised in cooperation with engineers, or undertaken by large enterprises in which architects work together with engineers and construction economists. This tendency is supported by the building coordination directive which makes it possible to award both planning and building work to a single contractor. This favours non-specialist firms like general contractors which are already well known in Denmark and the United Kingdom. In general, it is possible that the allocation of contracts by public authorities to architects will decrease in the next few years. The small independent architectural enterprises may thus start to work more and more as sub-contractors to large private companies. For projects in foreign countries, cooperation with national enterprises will be necessary and new international relations will need to be established. In general, thus, one can expect to see a growing tendency to form partnerships with financial and private companies, to limit the risks of independent architects and construction economists. Concerning the scope of the work of construction economists, the latter are likely to continue to expand their activities into civil and heavy engineering.

Engineering services
NACE 837

In 1988, EC engineering services accounted for approximately 400 000 jobs and a turnover of 20 billion ECU. However, given that engineering services frequently determine the choice of material and equipment to be used in a project, the strategic importance of the sector exceeds by far its small share of the construction industry.
During most of the 1980s, the sector was severely hit by the decline of its traditional export market, namely developing countries. However, in the late 1980s, this decline was offset by renewed Western demand and the emergence of intra-EC trade.
Prospects for the 1990s look rather bright thanks to stricter environmental regulations, the development of Eastern Europe, technological change and the building up of European transport networks.

INDUSTRY PROFILE

Description of the sector

Engineering services are defined as the intellectual services, which aim at optimising investment projects in industry, construction and infrastructure, at all stages of a project from its conception to its actual functioning. These services are provided by individual consulting engineers, design consultants, or by engineers employed by constructing firms, design firms, or public agencies. Their main objective is to optimise investment projects by proposing the lowest cost - highest productivity engineering solutions, consistent with the particularities of the specific markets. The consulting engineer studies the feasibility of projects, conceives the designs, executes the designs in detail, procures contractors and suppliers, administers contracts and supervises constructions and/or installations.

Engineering services embody two main categories: engineering design services and construction services. Engineering design services are defined as the essential intellectual activities needed to optimise the whole investment project. Construction services are defined as the essential intellectual activities required for the optimal management of the construction phase of a project and are also labelled construction management.

In turn-key projects, services offered include the construction itself and the final inspection of the project.

Engineering services apply to residential buildings i.e. office and commercial buildings, hospitals, schools and universities, retail facilities, leisure facilities, or non-residential buildings, i.e. utility facilities such as transmission lines, power plants, transportation facilities (roads, bridges, airports, etc.), public work facilities such as water and sewer systems, industrial plants such as refineries, processing and manufacturing facilities, other projects (e.g. mining).

Main indicators

The size of the sector is somewhat difficult to estimate because engineering services are generally not reported separately from the construction industry as a whole. Table 1 shows employment and turnover for the members of the EFCA professional associations. In 1991, affiliated firms employed 187 000 persons and their turnover totalled 13.3 billion ECU: Estimates for the sector as a whole point to 450 000 jobs and sales worth approximately 30 billion ECU.

Engineering services thus represent less then 5% of the construction industry but the economic significance of the sector is far more important. These services indeed play a crucial role in the process of investment and tend to forge forward and backwards linkages in national economies. As they set the techno-economic specifications of investment projects and determine both the civil engineering part as well as the materials and equipment to be used, engineering services fix the technology dimension of the investment. They thus play a vital role in the diffusion of new processes, materials and technologies throughout the economy and constitute an important link between R&D and production. Engineering services are a crucial determining factor for efficiency, productivity and competitiveness. They also constitute an important source of demand for equipment and materials. It is estimated, that out of the total contract value of industrial projects, 60-70% account for the equipment and material purchases, whereas the bulk of total cost for infrastructure projects account for civil works.

The links between engineering services and demand for material and equipment are particularly important for the balance of payments of exporting countries. Unlike other services, exports of engineering services generate a demand for equipment and materials, which tend to be purchased from the contractor's country of origin. This can be attributed to the fact that engineering services firms tend to influence the selection of the contractors and the sourcing of the machinery equipment. In the case of France, it is estimated that exports of capital equipment linked with foreign contracts for the provision of engineering services are several times greater than the fees earned for the provision of the engineering services. For the US, a survey conducted by the National Contractors Association in 1975 came up with a fifty per cent estimate of foreign contract value flowing back into the US economy. These export benefits are particularly strong in the case of engineering contractors, who assume full responsibility for the project, i.e. design, construction management and construction itself.

Historical trends

Engineering services, as part of the services supplied to the manufacturing sector, can be traced back in the 18th century when they first emerged in the UK as a result of the separation of design from construction.

The international market of engineering consultancy led primarily by British engineers, developed considerably during the first half of the twentieth century.

After world war II, the international market for the engineering services was dominated by US firms. However, European engineering design and construction firms were alongside steadily expanding their international activities.

In the sixties and early seventies, international aid programs, massive foreign direct investment and heavy public infrastructure spending in third world countries created a significant export market for engineering services in the developed countries. The general expansion of the international construction market, experienced during the seventies, allowed some developing countries, e.g. India, Brazil Yugoslavia etc., to start building up national capabilities of engineering services and to emerge as competitors in the international markets.

The steep oil price increase in 1973 and the resulting accumulation in oil revenues, opened new markets for huge infrastructure and industrial projects and hence for engineering services. The major oil producing countries, particularly those of Middle East, initiated large scale development programs, including highways, housing, military facilities and industrial plants.

The picture changed markedly in the early eighties. The engineering services sector entered into a prolonged period of declining demand, with the US. steadily loosing ground in the international market, in favour of Europe and Japan. The worldwide recession, sustained inflation and high interest rates slowed down world investment. In addition oil exporting countries, witnessing considerable decline in their oil revenue as of 1986, curtailed sharply their investment programs. The situation further worsened when the backlog of accumulated debt of less developed countries reached a critical level, forcing these countries to further squeeze their new construction projects.

A marked demand recovery, which started in 1987, in combination with positive business prospects opened in Eastern European markets, and the anticipated increasing demand related to the rebuilding of war-torn infrastructure and oil installations in Iraq, Kuwait and Iran, raised market expectations in 1992.

Foreign trade

The bulk of trade in engineering services until 1986 has been a one way flow from developed to less developed countries. More specifically, in 1986 the less developed countries accounted for 87% of total imports of design services and for 76% of foreign contract awards. Moreover, these percentages showed remarkably small changes over the 1980-86 period. On the other hand, trade between developed countries was very limited. However, since 1987, a North to North trade has been developing, which gains ground continuously, increasing its share from 13% in foreign design and 24% for contract awards to 44% for both activities. This is to a large extent attributed to the intraEC trade, which increased from 6% in 1982 to 16% in 1989 for design services and from 15% to 23% for foreign contract awards.

The increased intraEC trade of the past years, indicates that there has been forces at work leading to an increased mobility of designers and contractors across the borders. These forces are related to the prospects and expectations created by the steps towards the completion of the Internal Market, the opening of the Eastern European markets, and the decision for the construction of a number of large infrastructure projects in the EC.

The decline in export towards less developed countries was offset by an increase of demand in the developed countries so that a recovery in overall export activity is clearly observed with an average annual rate of increase of around 16% in nominal terms (according to an IDOM study of September 1992) during 1986-89.

In conclusion, the international demand for engineering services has been declining throughout most of the 80's, whereas a recovery characterises the last years of the decade. However, this recovery is mainly due to the emergence of a European and North American market for these services. More precisely, Europe and North America displaced MiddleEast and Africa and became, together with Asia, the leading markets. A special feature of these new developments is that, whereas Asia is a stagnant market, North America is particularly fast growing. Since 1990-91 and especially 1992, the market in Europe has been stagnant with declines in northern Europe due to the recession.

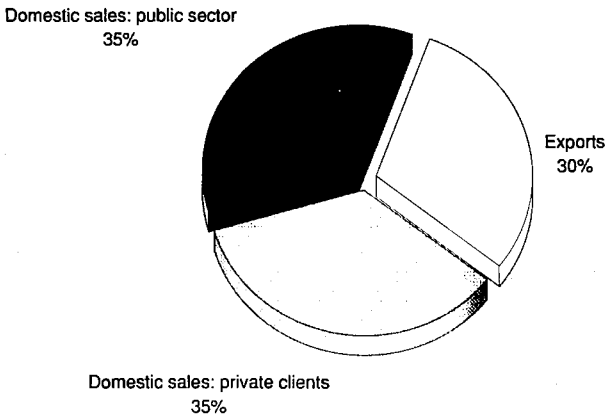
MARKET FORCES

Demand for engineering services is closely related to three main factors: public and private investment, technological progress and the availability of finance. All these factors, however, are connected with the general economic activity.

Based on EFCA data and Engineering News Record (ENR) data, several features of demand for engineering services may be singled out.

The EC engineering consultancy firms derive 70% of their turnover domestically and 30% from foreign countries, especially from the less developed countries. The intra-European trade was limited until 1987 when non-EC engineering consultancy firms, mostly USA firms, were more active in the (across the border) European consultancy market than the EC engineering consultancy firms themselves. However, intra EC

Figure 1: Engineering services
EC sales by major end market, 1988



Source: CEBI/CEDIC

trade seems, however, to have increased over the past several years.

From the domestically generated turnover 50% is derived from private clients and 50% from the public sector. What is more interesting is that, on the average, public authorities and entities in the EC Member States cover 70% of their needs in engineering services by in-house production and only 30% is assigned to consultancy firms. The externalisation of these services could prove decisive factor for the development of EC engineering services sector.

If we take the large EC firms represented in the Top 200 International of design firms (Engineering News Record), the share of total production exported range from 63% to 72%, which means that the large EC designers are highly export oriented.

INDUSTRY STRUCTURE

In the 1960's, engineering design services were closely related to trade in engineering equipment. In West Germany some 80% of projects were awarded to West German suppliers of equipment. For Japan the corresponding proportion was 63%, for France and Italy 50%. However, due to an externalisation process, engineering design firms entered into a dynamic process towards their independent operation. Thus, it has become a sector in its own right. The driving force towards this development was the need for unbiased independent information. However, there is evidence that this externalisation process has not weakened the derived demand link between engineering services and exports of materials and equipment.

Concerning the size distribution, the sector is highly concentrated, due to the existence of some giant integrated engineer constructors. The largest engineering firms in the world are Canadian and American. European firms, however, are more numerous in the list of the Top 200 International. In 1989 out of the 200 largest design firms, 94 were European and from these, 71 were domiciled in the European Community. The same is also true for international contractors. Out of 250 leading international contractors, 115 were European and from these 84 ere located in the EC.

Large firms coexist with a large number of small specialised design and construction firms (even traditional one-man firms), which, in most cases, only operate on the domestic market.

OUTLOOK

The expected global economic recovery in the course of 1993, which will affect, more or less evenly, all the regions of the world, combined with technological progress, which will mark the decade of the 1990's, offer a good probability for growing exports of European engineering services.

In short and medium term, there are some significant factors at work which are expected to fuel more design billings and contract awards throughout the decade. These factors are:

- emergence of large scale construction markets around the world due to increased industrialisation in Asia, Africa and Latin America;
- harmonisation of environmental regulations and stricter environmental control in industrialised Europe and USA;
- huge needs of Central and Eastern European countries for reconstruction of their economies and for environmental projects;
- the completion of the European internal Market which will necessitate the building up of a Europe wide transport network and will initiate numerous projects within the framework of the EC structural funds;
- the technological change, which creates the market for technologically advanced projects increasing, the engineering services content of investment.

Projecting the past trends into the future, the probability is very high that EC's leadership position in the world market for engineering services will continue in the coming decade. The US, the only rival which could challenge the leading position of the EC, has been systematically loosing ground over the past years.

The industry is represented at the EC level by: European Federation of Engineering Consultancy Associations (EFCA). Address: Avenue de Cortenberg 79, Bte 7, B-1040 Brussels; tel: (32 2) 732 4990, fax: (32 2) 732 5125.

Geodetic surveying
NACE 74.2

There were close to 65 000 individuals working in the geodetic surveying profession in 1991, of which more than half were in France and Germany. The long-term prospects for geodetic surveying are promising. A trend towards larger companies offering a more diverse range of services will heighten competition for smaller-sized operations which must continue to innovate and adapt to hold onto their share of the market.

INDUSTRY PROFILE

Description of the sector

Geodetic surveyors measure the size, position and three-dimensional shape of the earth's surface, sub-surface and sub-marine features. Measurement systems can be land-, sea-, air- or space-borne. Much of the geodetic surveyor's work is in the management, analysis and structuring of acquired data. The trend towards an automated and computer-based approach will allow easy assimilation of results into the client's database.

The following areas of expertise come within this broad description: national and international mapping; large and small scale mapping; measured building surveys; tunnelling and mining surveys; measurement and location of underground structures and services; cadastral and boundary surveys; industrial and engineering surveys; setting out for construction; monitoring and deformation surveys; land and geographic information systems, cartography; ocean bed, coastal and river surveys; measurement of marine resources; maps, plans and navigation charts; surveying services.

In many Member States, urban and regional planning, land and building valuation, soil testing, land management, and management of development can also come within the scope of the geodetic surveyor, although not necessarily as part of a traditional definition of his activities.

Main indicators and recent trends

Just over half of the total employees in geodetic surveying work in the public sector, although individual states come between the two extremes of Germany (West) (80% public sector employees) and Belgium and Denmark (both 80% private sector employees).

Between 1980 and 1990 there has been a 130% increase in the numbers employed within the industry in the countries where comparative figures are available.

The United Kingdom has seen 25% of turnover being generated outside of the EC in recent years with a strong position in Middle Eastern markets but this is probably an overestimate now following political troubles in the region. With the exception of the Netherlands and Belgium, no other Member States have a significant market outside of the EC.

MARKET FORCES

Demand

Geodetic surveyors provide a service to developers, builders and contractors, architects, planners, lawyers, engineers, geophysicists and oil companies. The list is a growing one as more people in earth sciences, for instance, start to benefit from the services and skills of the profession start. Satellite positioning systems have opened new markets where conventional techniques would not have been considered due to cost. However the apparent ease of operation of such systems means that often for low precision work the geodesist is involved more in the role of a consultant than a practitioner.

Table 1: Geodetic surveying

Marked differences exist between Member States in the amount of workload derived from the private and public sectors. Belgium, Denmark, France, Greece and the United Kingdom have a larger proportion in the former and Italy, Luxembourg, Germany, the Netherlands, Portugal and Spain a larger proportion in the latter. Cadastral surveys and other public sector works show a fall in demand balanced by an increase in engineering and industrial surveys and large scale mapping. By contrast, expertise in geographic information systems and database management is more and more sought after.

Supply and competition

There is widespread market saturation. Luxembourg has not quite reached this position but Spain stands alone in having too few qualified surveyors to meet demand. The institution of a new degree course, mentioned elsewhere, is aimed at filling this gap.

Within each country, profit margins have been reduced considerably and in the expanding areas of land and geographic information systems computer software companies are competing for work. They are also competing in the labour market for well qualified geodesists at a time when most predictions

are of a shortage of suitable personnel. Member States at present face little competition either from other member states or from outside the EC. One exception to this is the United Kingdom where American companies have been involved in recent takeovers. Spain and, to a lesser extent, Luxembourg and Portugal meet competition in their home markets. The competitor's strengths are often a larger company structure and computer-based technological advantages.

The main disadvantages for outside competitors are the regulations necessitating membership of professional bodies (which still pertain in many countries) and the language barrier.

INDUSTRY STRUCTURE

Companies

It is not possible to rank with any certainty the largest companies operating in this sector because individual turnover figures are so hard to come by and staff figures have changed dramatically amongst some of the larger companies. However, the following companies (in no particular order) are amongst the largest operating in the EC: Racal Surveys (UK), Engineering Surveys/Clyde Surveys (UK), B.K.S. Surveys (UK), Mason Land Surveys (UK), Hansa Luftbild (D), Starkstrom Anlage Gesellschaft (D), Egle Vermessungsbüro (D), Grontmij (NL), Inpark (NL), Oranjewoud (NL), and Eurosense (B).

There are roughly 6000 separate enterprises operating in the industry. Approximately 90% of these employ less than 10 geodesists. Belgium, Germany, Denmark, Greece and Ireland all have a high proportion of very small companies and in Belgium self-employed status is the normal situation. The United Kingdom and the Netherlands have a more equitable spread of company sizes. Larger companies are generally either specialised, for example in aerial photogrammetry and remote sensing (Hansa Luftbild) or part of a bigger field such as civil engineering, offering geodetic surveying within their operations (Oranjewoud). Some large companies, however, do offer a range of services purely within geodetic surveying (Engineering Surveys/Clyde Surveys).

Strategies

The most general strategies are towards diversification of services offered, collaboration with associated professionals particularly in the field of information technology and an attempt to keep abreast of the latest technological developments. It is only the last of these which has progressed to any large extent.

Lesser themes include efforts to achieve quality accreditation and a change in personnel structure towards less qualified field operatives and more qualified staff at a managerial level.

REGIONAL DISTRIBUTION

Although regional differences occur in the nature of the work undertaken, the distribution of geodesists is highly correlated with the population distribution overall. The service provided is still strongly tied to the land itself and hence the industry polarises where land is being exchanged, monitored or developed. As the emphasis moves towards providing expertise with land information systems, more freedom of location and other factors will emerge.

ENVIRONMENT

Geodetic surveying places little burden on the environment although many of the industries which it serves do, and these industries come under increasing regulatory pressure as a result. An example of this is the restriction of activity in mineral exploration in Ireland. There is a trend towards the use of computer-based mapping and design packages for environmental purposes but these are often used by people outside the geodetic surveying community.

Areas of activity where geodetic surveyors capitalise on an ecological or environmental market include, nearshore and inland hydrography for waste sedimentation studies, photogrammetry to aid the restoration of historic monuments, photogrammetry and remote sensing for landscape vitality measures (e.g. crop health) and global environmental monitoring (e.g. heat emission) and digital mapping for visual impact analysis.

It should be noted that many of these areas are beyond the scope of the average geodetic surveying company and are normally the province of government departments and specialist organisations.

REGULATIONS

The most important regulations are those concerning cadastre. Some countries such as the United Kingdom and Ireland have an essentially descriptive system of land registration and the geodesists role is a minor one. Elsewhere, the law recognises boundaries based on survey measurements. These measurements are carried out by a specialist organisation (e.g. the Administration du Cadastre et de la Topographie in Luxembourg) by public servants (cadastral surveyors) or by licensed geodetic surveyors. In the last case, this work will often form a substantial part of a geodesist's activities. The differences in cadastral law between countries (and also between regions within one country such as exist in Germany) mean that this sector of the market sees little competition across borders.

EC regulations concerning recognition of qualifications for migrant workers are being addressed by the Comité de Liaison des Géomètres-Experts Européens (CLGEE). A detailed report of education for geodetic surveyors within the EC was published in 1988 since when both Belgium (4 year courses at the University of Gent and at the University of Liège) and Spain (approval of a 5 year high degree course) have implemented changes towards compatibility with other Member States. The CLGEE is striving to harmonise qualification standards and achieve mutual recognition of diplomas. Some cross-border commissions have already resulted from these initiatives. EC directives concerning public service contracts have had no significant effect to date.

In Denmark, Germany, France and Italy the profession is afforded legal protection. In Belgium, the Netherlands, Ireland and the United Kingdom no such legislation exists. Elsewhere there is a position between these extremes.

OUTLOOK

The outlook in the short term is hard to forecast and is strongly linked to a widespread economic uncertainty. German unification and the inherited cadastral system in eastern Germany are handicaps to economic development and serve to increase the uncertainty there. Ireland's small economy and large national debt is unlikely to see rapid growth.

The long term future for geodetic surveyors is good and will rest largely with their ability to adapt to change. Many of the traditional skills in data acquisition are becoming less relevant with the advance of automated systems. However the processing, structuring and manipulation of these data within land and geographic information systems for resource management, planning and other projects is becoming increasingly important. Geodetic surveyors will need to capitalise on their strengths in this area.

Collaboration with information technologists and moves to fewer and larger companies offering a more diverse service will increase although there is a place also for small sized companies who invest and can offer a state-of-the-art product.

Early experience in Eastern Europe suggests that much work will be available for people who can offer professional expertise as an entry into the market but they will have to rely on a large degree of personal resourcefulness and management skill in order to be successful.

Industrial metrology is a growth area where the surveyor's measurement skills are competing with long established methods. It is to be expected that some surveyors will choose to specialise here and increase their market share.

The fortunes of the geodetic surveying industry will always be closely tied to activity in the construction industry.

Linguistic services
NACE 839.3, NACE 935

Linguistic services include translation services, interpretation and the teaching of foreign languages. These services have been in high demand in recent years due to the growing internationalisation of the world economies. There were approximately 11 500 persons employed in this sector and registered in one of the EC's key national professional associations in 1991, but the actual number of individuals exercising this profession is much greater. The provision of translation, interpretation and language teaching services in the EC is not yet regulated, and in many countries there is no specific criterion to have access to this profession. The coming years will see major changes in the structure of demand for linguistic services, with greater needs for technical expertise and increased demand for the "non-traditional" languages.

INDUSTRY PROFILE

Description of the sector

Translation and interpretation services, as well as language teaching services, are part of the linguistic services sector. Translators and interpreters are included in NACE 839.3. Language teachers are part of NACE 935, called "private tuition".

The translator has the duty to translate texts from one language to another. Translation covers an extremely diversified market. In all realms of human activity translation is required. These range from commercial and industrial affairs, scientific matters, legislative, press and audio-visual subjects to literary works. There are two basic types of translators: the literary translator, who only translates literary texts, and the techno-scientific translator who undertakes all other required forms of translation. A third, more limited category comprises conference translators who - sometimes also belonging to one or both of the above types - are engaged temporarily by intergovernmental organisations to translate conference documents as they are produced.

Interpretation services also cover a wide range of areas. Interpreters directly translate spoken words from one language into another. There are three different types of interpretation services. The first is simultaneous interpretation, such as that which is done during international conferences with the help of modern communication technologies. The second is whispered interpretation. In this case, the interpreter whispers the translations into the ear of his client. This form of interpretation is normally used if somebody is making a speech which needs to be directly translated for another person. The third form of interpretation services is consecutive interpreting. In this case, the speaker stops talking after a few sentences to let the interpreter translate, and then resumes his conversation and stops again after another few sentences. This form of translation is mainly used in bilateral talks.

Language teaching covers all language courses which are organised by public institutions, private enterprises and individual teachers. Besides the normal language education that is given during school time, there are private language schools which organise language courses for advanced vocational training.

In all three professions, (translation, interpretation and teaching) the professionals generally work either as independents, or are public sector employees. Only very few are employed on a full-time basis by private sector enterprises or intergovernmental organisations.

Main indicators

The total number of translators and interpreters registered in the national professional associations of the major EC countries was around 11 500 in 1991 (Table 1). Most of these work as free-lance translators. For example, the share of free-lance translators and interpretation is almost 100% in France, about 90% in the United Kingdom and about 85% in Belgium. It is mainly in Germany and Italy that one finds a greater share of employed translators, at around 50% in Germany and 40% in Italy. The national professional associations, however, estimate that only a quarter of all persons working as translators are registered as members of their association. The reason is that most of these national associations have only existed since the mid-eighties. In all reporting countries, however, the number of registered translators increases year by year.

The average yearly turnover of a translator who is working full-time is between 35 and 50 thousand ECU. The salary range is quite large because translators are paid per line translated. Another reason is that the price of translation per line varies from country to country. A third reason is that the level of experience of the translator can vary. More experienced translators are able to translate faster than beginners. Since there are no figures available relative to the number of interpreters and language teachers, one can only estimate the average yearly turnover of a full-time working interpreter and a full-time working language teacher. This is estimated to be between 55 and 90 thousand ECU for a free-lance interpreter, and between 30 and 65 thousand ECU for a free-lance language teacher.

International comparison

Germany is the country with the highest number of registered professionals of all Member States, followed by the United Kingdom and the Netherlands (Table 1). The total estimated turnover of translation and interpretation services in the EC is much higher than in Japan and the USA, due to the variety of languages that exist within Europe and the close relationships between countries in Europe. As a result of its close export relations with the EC, translation is also important in Japan (Table 2).

MARKET FORCES

Demand

In general, demand for linguistic services has grown with the globalisation of industry and the closer cooperation of national governments in international organisations like the EC, the OECD, the United Nations bodies and others. But even private undertakings with international relations need the services of translators and interpreters from time to time.

At present, more than 50% of the demand for translation services come from the commercial and industrial sector, about 20% correspond to demand for scientific translation and less than 30% correspond to legislative and other translation, including press, audio-visual and literary translations. During the eighties, the demand for literary translation was decreasing or stagnant in a few EC Member States (Table 2).

Interpretation services are mainly used during international conferences or gatherings, and can be contracted both by the public sector and by private enterprises. Given that these conferences are not scheduled on a regular basis, and can take place in various locations, the interpreters must be very flexible. This is the reason why most of the users of such services do not have in-house staff of interpreters. This is also the reason why most of the interpreters are independent workers.

The structure of demand for language teachers is very different. Large enterprises of the business sector and the national and international institutions need language teachers for vocational training purposes. Some have their own teachers for in-house tuition. Smaller companies, however, tend to use private lan-

guage schools. Demand for independent language teachers thus mainly comes from small businesses or private persons who need to learn a foreign language in a short period of time.

The demand for linguistic services is, in principle, not related to the general economic development of a country. However, private enterprises tend to reduce their in-house staff when the economic situation deteriorates. When this happens, there are more possibilities for independent translators and interpreters to get free-lance work awarded by large public or private enterprises. The same phenomenon is observed in intergovernmental organisations.

Supply and competition

As mentioned above, there are two types of translators, interpreters and language teachers: free-lance workers and salaried workers.

Traditionally, the free-lance translators are members of a professional association and work in their own premises. They deal either directly with the client, or through the intermediation of agencies or translation businesses. These agencies normally have no in-house translators, and subcontract free-lancers. Limited numbers of supernumerary in-house translators are recruited by United Nations bodies and other intergovernmental organisations based in Europe.

In recent years, government agencies and intergovernmental organisations have increasingly resorted to out-contracting of translation services to free-lance, due to an excess demand for such services and a need for specialised skills in translation (legal, financial or other) and because this is considered less costly than salaried employment. Salaried translators generally work for international institutions or large enterprises with international relations.

Most free-lance translators only work part-time. Nevertheless, there are still quite a few translators who are registered as unemployed in most EC countries. For example, more than one thousand unemployed translators were registered in Germany in 1991. But the number of unemployed translators has been decreasing in almost all EC countries since 1988.

Although the unemployment rate of translators is quite high, there is still not much competition between translators. Larger volumes of translation which require multilingual knowledge are mostly done by translation companies employing translators with different native languages. Free-lancers tend to specialise in non-traditional languages, work for smaller projects or in specific areas of expertise. Compared to in-house translation, free-lance translations are very competitive in most EC countries.

There is no real inadequacy between the demand and supply of interpreters within the EC. Even if more interpretation into English, French and German is required than into the

other languages, there is also a greater number of interpreters which work in these three languages. Specialisation in certain sectors (especially in the technical field) and the knowledge of exotic languages can enable free-lancers to avoid competition. But, in general, the free-lance interpreter is always in competition with the in-house interpreting staff of public administrations, or international organisations such as the EC and the OECD.

Language teaching services are offered by individual professors, private schools of all sizes and free-lance teachers. Competitors for these services are enterprises which offer telephone tutorials or training programs such as books, videos, records, tapes and compact discs. This latter form of learning foreign languages is cheaper and offers more flexibility to the pupil than scheduled courses.

INDUSTRY STRUCTURE

Companies

Most of the persons working as translators, interpreters or language teachers are free-lance. The few full-time employed professionals that exist mainly work for large companies which have their own in-house translation, interpreting and language teaching services, for public administration or intergovernmental organisations.

Private translation, interpreting and language teaching companies are usually large companies. Most employ more than one hundred full-time translators and award contracts to independent free-lance professionals. The largest European companies in the translation sector are located in the United Kingdom. These are Interlingua T.T.I. Ltd., Randall-Woolcott Services Ltd. and the Longman Group UK Ltd.. In the language teaching sector, Linguarama Ltd., London and Elsevier Languages from the Netherlands are the largest European enterprises. Two other language schools are also important within the EC: Berlitz, which has its headquarters in Princeton (USA), and E.F. with their headquarters in Lund, Sweden.

Strategies

Considering the growing market for linguistic services, the free-lancers and the enterprises working in that business will tend to face stronger competition in the future. Stronger competition means shorter deadlines, more translation into new languages (such as those of eastern Europe), stricter quality requirements for technical translations, and more translation into specific software demanded by the clients.

These future demand trends will require an even greater flexibility and better training of the professionals. In particular, the technical standards of translators will have to increase. Computer assisted translation is already being used. This means that the translated texts are typed in specific software packages and provided on diskettes. The use of translation machines, working with systems provided by firms like Systran (used by the Commission of the EC), Siemens-Nixdorf, Rank Xerox or Intergraph, or the access to translation data bases such as "Eurodicatom" makes the work of the translators faster and more efficient. But the creation of such a modern infrastructure is expensive. Only the larger institutions and enterprises are able to afford such tools. Moreover, computer assisted translation is only possible if there is less emphasis on quality. This provides enough opportunities for free-lance translators who do high quality translations. Free-lance translators also have the possibility to specialise in certain areas. Since more specialist translators are required, and since there is a demand for a greater use of technology, the firms which have modern equipment tend to give short term contracts to the free-lance translators and ask them to work on their own premises.

REGIONAL DISTRIBUTION

The professionals who work in the linguistic service sector are concentrated in the regions where large enterprises or international organisations are located. The EC Commission and the OECD are the two international organisations in the EC which have the largest staff of translators and interpreters. This means that a great part of all employed translators and interpreters are working in Paris, Brussels, Luxembourg and Strasbourg. Since the EC and the OECD cannot translate everything in-house, many free-lance translators have their premises close to these institutions. The same holds for interpreters, who also tend to locate near the capital cities. There also tends to be a greater concentration of translators and interpreters in areas where the major international companies are located. This is the case for instance in Berlin, Hamburg, Düsseldorf, Frankfurt, Munich, Milan, Barcelona, Amsterdam and Rotterdam.

REGULATIONS

The role of translators and interpreters is recognised by two international documents:

- The UNESCO recommendation on the protection and improvement of the legal and social status of translations and translators, adopted in Nairobi in 1976.
- The relevant provisions and recommendations regarding translators and translations set forth in the Final Act of the Conference on Security and Co-operation in Europe, adopted in Helsinki in 1975.

Both these documents recognise the important role that translators and interpreters play in the promotion of cultural exchanges, international relationships and the furtherance of science, technology and economic progress. But they do not include any regulations for the professions nor the education process.

In most EC countries, there are either no or unsatisfactory regulations of the translators' and interpreters' legal status, apart from the international or national copyright laws that apply to translators. Only a few EC countries regulate admission to the practice of the profession of translator and interpreter. There is no official job profile. Professional training is not necessary. There is no protection of the title of "translator" and "interpreter", nor codification of the rights and duties of the profession, and there is often no law which regulates the practice of the profession of translator and interpreter.

In most EC countries, the legal situation is the same as in the United Kingdom: the civil law is decisive in such matters as negligence, libel and performance of contract. Some countries like Germany have already enacted legislative measures to regulate interpreting and translation in legal and administrative proceedings. But, in general, the public has no guarantee that a person offering his/her services as an independent interpreter and/or translator does in fact possess the requisite qualifications, although membership of one of the officially recognised international associations (see below) is considered to offer an assurance of quality. There are only a few EC countries in which the interpreters and translators registered in the national professional associations are required to have a university degree. But in some countries it is possible to pass an academic education which finishes with an academic, legally protected title. The existing EC Directive about the acknowledgement of academic education is the only regulation which would be valid for the profession of the interpreters and translators. It is not yet adopted as national law in all EC countries.

OUTLOOK

The demand for translation or interpretation services in the so-called "traditional languages" is almost satisfied within the EC, and has reached maturity. But there will be major changes in the structure of demand for translation, interpretation and teaching services in the coming years. The opening of eastern Europe offers new possibilities for the profession. For this, a good knowledge of east European languages is necessary. More professionalism and greater degrees of specialisation will be required by the sector's clients. The use of artificial intelligence is increasingly necessary. Free-lance translators and interpreters may then start to face increased competition from translation companies which are well equipped with computers and different in-house specialists. The market is, however, still large enough for free-lance translators and interpreters who are able to speak at least one exotic language and have special knowledge in a certain branch.

Publishing services
NACE 839

The publishing services sector is growing very rapidly, influenced by the pace at which technology is advancing. The customer base of publishing services is broadening. They range from non commercial concerns such as hobby clubs to major international commercial enterprises. This sector overlaps into other service sectors, which include computer consultancy, below the line advertising consultancy, and secretarial support services. The estimated turnover of publishing service companies was roughly 5 billion ECU in 1992, and they employed almost 50 000 persons in total.

INDUSTRY PROFILE

Description of the sector

Publishing services vary considerably from one company to another. They range from the provision of consulting to offering desktop publishing services. Consultants help industry to integrate desktop publishing software and hardware into current processes for advertising and other document development.

Design engineering, press relations, management services, marketing, and advertising departments of many companies are currently using desktop publishing systems. Often they make the basic document electronically and pass the file to a publishing service company for improvements before printing.

Recent trends

Within the EC desktop publishing developed fastest in the United Kingdom. However, the availability of programs in other major national languages soon followed, and allowed France and Germany to catch up. Initially software programs were available in only a few European languages. This did not stop professionals in other countries from using them and producing documents in their native languages.

The major desktop publishing software producers now write programs in many national languages in a bid to increase their penetration of the global market. Following the collapse of communism in Eastern Europe Ventura has taken the initiative to produce Ventura Publisher in Polish, Czechoslovakian, and Cyrillic (for the Russian market). Ventura is also developing Ventura Publisher in Kanji for the Japanese market.

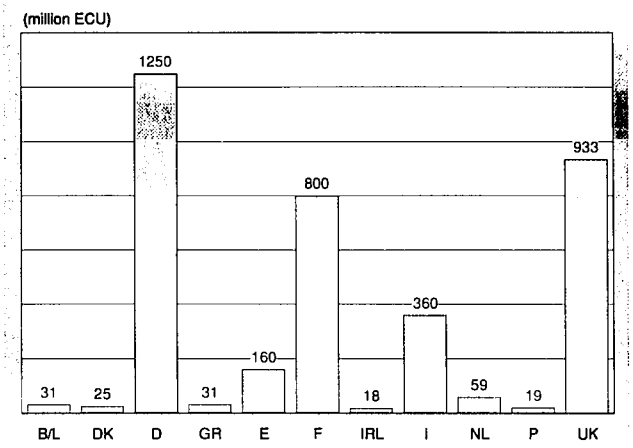
International comparison

It is difficult to estimate the size of non-EC markets for publishing services owing to a lack of statistics. The USA has a sophisticated publishing service market. The EC lags behind the USA in desktop publishing and design services. Japan despite being a developer of very high-tech equipment has delivered a good performance in computer design is trailing a long way behind the EC in the development of desktop publishing service companies.

Foreign trade

There is very little trade of publishing services. The service companies involved sometimes have production carried out in a country with lower costs, especially for regular large production volume publications. Extra EC imports and exports are very small, taking data for the whole printing sector these are less than 2% of the internal market turnover. Cross border business within the EC is also minor, amounting to less than 5% of the turnover of the sector.

Figure 1: Publishing services
Value added by Member State, 1991



Source: Eurostat

MARKET FORCES

Demand

Many printing press businesses have now computerised their production processes. Relatively inexpensive and more efficient computerised systems have helped many to make the decision to convert. There is a polarisation in the demand for final finish of documents.

For some customers printing on a laser printer (300 dots per inch) gives an acceptable quality. Often this demand comes from persons and companies not using this type of promotion or communication tool before.

Those professional customers converting from the older technology often require the best possible finish and have 2 540 dots per inch bromide films made before printing. Professionals also enhance pictures in documents, often to give them a crisper look, using specialised desktop publishing program extensions.

Customers often require using the flexibility of the electronic publishing system which allows documents made at the pre-printing stage in several formats so that they can choose the one they think is best. The text for a document, nearly always generated by word processor, is transferred to desktop publishing software to enhance the way it looks. Style sheets, automatically set, present information in a given style. Very few key strokes are necessary to change style sheets. In fine tuning a document font types and character sizes can change to achieve the most suitable result.

Supply and competition

There are no major pan-European desktop publishing service companies. Most companies in this relatively new market sector only serve a limited locality in their own country. Competition is slight. Although many can conduct direct marketing campaigns few are resorting to this to increase business. Many companies looking for a desktop publishing service would use "yellow pages" directories or similar business and service guides to find details of services available in their locality.

Companies offering a full professional service are fewer than those offering processing and production at 300 DPI. Increasingly the latter subcontract pre-printing to printing companies, if they have to produce a high quality document.

There is currently very little price competition mainly because the emphasis on the desktop publishing experts creating the document to the requirements of their clients within predefined budgets. However, prices have fallen on average by

more than 25% in real terms as the sector branch has gone through expansion.

Production process

Computer technology is rapidly replacing technologies involving manual techniques prevalent in the mid-1980s. Most of the companies in the sector are new. Many only started business in the mid-1980s. Some business service companies with longer histories have altered business plans to get into the flourishing desktop publishing services market. Many computer consultants have become more involved in desktop publishing than other activities.

Other professionals attracted to desktop publishing include those that previously involved in translating, printing, typing, word processing, copy-writing, and proof-reading. Publishing production professionals, photo composers, page layout specialists and photo engravers, have had to move with the times by making investments in electronic printing. In the last three years most converted from manual to computerised page layouts. These include: PC picture publishing, PC art, computer aided design (CAD), and desktop publishing.

Most desktop publishing companies are very small enterprises. Their main work is to layout documents from manuscript or electronic text using professional desktop publishing packages, and subcontract the production. Many use only four main tools: an Apple Macintosh, IBM compatible or other PC, a scanner, computer software including desktop publishing programmes, and a laser printer.

Some have made investments in higher or additional cost pre-printing equipment. This includes film making and bromide, and Cromalin proofing equipment. Often desktop publishing involves incorporating pictures, graphs and tables into a document, and this sometimes needs special scanning or filming equipment and software to create files in tagged image file format (TIFF).

PageMaker has offered colour picture desktop publishing software for several years. This has meant that Apple Macintosh has been the computer system chosen by many printing companies for desktop publishing. In 1991, Xerox's subsidiary Ventura launched some very professional colour printing products for its IBM compatible PC customer base.

Specialised computer programs are available for making multi-coloured pictures. These programs allow PC users to make colour separations and retouch images. Examples are Ventura Separator, Ventura Photo Touch and Ventura ColorPro.

Professional picture publishing programs and scanners are expensive. For example the normal retail price of Picture Publishing Plus software plus scanner is about 8 000 ECU in 1992. The unit price of some sophisticated drum and flat bed scanners is more than 20 000 ECU. Less effective hand held scanners, which cost less than 100 ECU per unit, serve the other end of the market.

Although scanning photographs or drawings has been the main method of making electronic pictures, programs now exist to make picture files from video films. "Multimedia" computer

EC	34 440	5 670	9 520	49 630

Source: Campbell Management Consultants' estimates

programs provide pictures by the latter method. An editor can also buy picture files. Many electronic picture libraries and software companies sell electronic pictures. Documents containing line drawings, data tables and graphs must merge files or parts of files from other PC programmes.

Professional printing companies generally produce the final documents because they have the equipment for high resolution film or bromide production and large print-run capacity. Higher resolution desktop printers have recently become available. Eventually this may change things for small print-run printed matter, especially newsletters.

Moreover, even photocopy machine technology has developed to the extent that the newest generation of professional photocopiers integrate printing and binding of documents. This process involves a computer terminal linked to the photocopy machine.

There are many desktop publishing programs. They range from programs designed to make single page layouts to those for long documents. Printing professionals mostly use Ventura Publisher and PageMaker. Of the two, Ventura Publisher is the main desktop publishing software used in Europe.

Companies not requiring so much sophistication or text adjustment during the desktop publishing can use other programs. These programs include Timeworks Publisher, Express Publisher, Newsmaster, Avagio, Finesse, and Page Plus. Each of the major computer operating systems, DOS, Windows, UNIX, OS/2, and Macintosh requires separate desktop publishing programs.

IBM compatible computers are now becoming the standard for the computer industry and users are changing from DOS operating systems to Windows. Apple Macintosh was the major computer system for desktop publishing until just a few years ago.

PC art and picture publishing packages to create layouts are newer products for desktop publishers to work with. Some of them have existed for several years. PC art computer programs such as Art Works, Illustrator, FreeHand and CoralDRAW, all in second or third generation versions are relatively inexpensive (about 200 ECU per single user software in 1992). These programs help operators, lacking flair for drawing, to produce very professional drawings.

Printing companies that have resisted the conversation to the higher technology are unable to offer much flexibility or radical last minute changes. The desktop publishing market is growing organically as trade associations, clubs and various companies begin producing magazines, newsletters and other printed material for their members.

REGULATIONS

There are no EC regulations governing this sector. National regulations which concern the computer and printing industries apply to publishing services. Companies involved in desktop publishing must observe copyright and trademark laws.

OUTLOOK

Desktop publishing software has penetrated the professional publishing domain and the mass market. Picture publishing, although available to the public, is more for the desktop publishing professionals at 1992's prices. The data files of pictures are often very large - often more than 40 megabytes - which limits the amount of home-made picture files used to make professional quality printed matter at 2540 dots per inch (DPI).

Computer technologies under development will allow the replacement of internal hard disk stores (drives) by larger capacity portable storage devices. External hardcards and tapes allow transportation of very large files. Floppy disks currently restrict files to a maximum size of 1.2 megabytes. Electronic picture libraries are likely to grow in demand. However, there will always be a need for photography, especially for news media.

Desktop publishing is likely to go on expanding well into the next century. Industry forecasts the annual growth rate for this sector in double figures over the next five years. Growth is strong across the whole EC market.

There is a possibility that many companies currently using service companies could opt to use in-house resources for desktop publishing if hardware prices continue falling. Publishing service companies would then have to concentrate upon smaller businesses which are not able to allocate staff or justify the expense of under-utilised equipment.

Written by: Campbell Management Consultants

Temporary work services
NACE 839.3

Over the past four decades, temporary work services have progressively changed into a sophisticated, professional service industry providing instruments for labour management. The industry has turned itself not only into the main tool for helping businesses fill temporary shortages in their workforce, but also into personnel recruitment advisors since temporary workers often find permanent employment through their temporary assignment.

INDUSTRY PROFILE

Description of the sector

Temporary work companies hire temporary workers and put them at the disposal of a third party (i.e. triangular relationship). Key to this relationship is the fact that they receive their salary from the temporary work companies but their work-orders on assignments from the third party.

Client firms call upon the services of temporary work companies when they have temporary shortages of labour. The hourly cost of temporary labour may at times be higher than that of permanent workers, but since temporary labour is usually resorted to for short, well defined periods or for specific tasks, the cost is borne only for effectively supplied hours of labour. The alternatives of overtime or a permanent reserve of extra manpower would be more expensive. Temporary work companies bear the cost of recruitment, selection, payrolling, statutory social security insurance, etc.

For temporary workers, temporary work companies satisfy particular individual needs and preferences. However, a growing number of jobless workers also resort to temporary work companies to find a temporary occupation with the expectation of finding permanent positions at a later stage. It is now estimated that an average well over one-third of temporary workers find permanent jobs as a result of temporary contracts. The actual proportion varies widely between different EC countries.

The ageing European workforce and the increase of females in the workforce also have an effect on the temporary work services sector. These developments have been associated with a greater desire for more flexible and temporary working arrangements.

Main indicators

The importance of temporary work is shown by the number of people who are active in the sector each working day. The United Kingdom, France, (West) Germany and the Netherlands (in order of rank) are the largest employers of temporary workers in the EC.

Overall, it is estimated that well over a million persons a day in the EC work through temporary work companies. In the USA, a country with a comparable workforce, this figure is estimated to be somewhat lower. Market penetration in the USA is generally lower than in the EC, especially if one takes into account that the temporary work services sector is non-existent in Italy and Greece, and still not very developed in Luxembourg and Ireland.

International comparison

The temporary work services sector in general has shown double digit growth in past years. Most of the business in this sector is done in Belgium, France, Germany, the Netherlands and the United Kingdom (see Table 2). On average, it is estimated that growth has been approximately 15% per year in countries where temping is well developed, but even higher, around 20%, in countries where the sector is less developed. With the arrival of the current more or less recessionary period in many countries, growth has come to a halt, or at least slowed to a pace that corresponds to economic growth in general. The sector is still quickly growing in importance in Spain and Portugal. In these two countries, temporary work companies have only recently been legalised, or tolerated in the case of Spain (the temporary work services sector has not been officially legalised yet).

Total turnover in this sector was estimated at 17 billion ECU in the EC in 1991. Turnover for the USA, in comparison, is estimated at approximately 16 billion ECU for the same year. The world market is currently estimated at approximately 35

billion ECU. These estimates are based on statements made by national federations, since no regular statistical surveys are held in this sector in the EC or other countries.

MARKET FORCES

Demand

Demand for temporary work services is, to a large degree, dependent on the general economic situation of a country. The enormous growth in recent years clearly stemmed from the growing need for more flexible labour contracts. The favourable economic climate, however, also helped to boost growth. The current situation is somewhat reversed: the more developed temporary work markets show saturation signs, and the stagnation of economic growth or even recession in some countries has also slowed growth to a minimum. Markets which are heavily effected by these trends are, for example, the United Kingdom and Denmark. It is expected that, in general, growth will slow to a pace more in line with general economic activity.

The fields in which temporary workers fulfil their assignments tend to differ between countries. In France and Germany, for example, the majority of temporary workers are blue-collar workers. In the United Kingdom and Portugal, temporary workers are primarily active in the administrative or commercial fields, as is the case in the USA. In some countries, such as Denmark, this is due to restrictive regulations. The differences are further illustrated by Table 3.

The length of the contract that is desired by clients varies. This length is usually dependent on the function which the temporary worker will fulfil for the client. If the temp is called to replace someone who is ill or on holiday, contracts are usually short: ranging from a day to several weeks. However, if a temp is called for because of an unfilled vacancy, or because the client is not certain whether the development of his business will allow him to hire an extra worker permanently, contracts can be extended to months or even a year or more. Contract duration is often limited by national regulations, but the maximum period varies per country.

Client companies often treat temping contracts as if they were trial contracts. They increasingly tend to offer a permanent contract to workers who have worked for them through a temporary work companies.

Temporary work is male-dominated in the EC: almost two-thirds of all temporary workers are male. The only countries known to deviate from this pattern are the United Kingdom and the Netherlands, where the proportion of male and female temporary workers are fairly equal. Figures for the USA show exactly the opposite: more than two-thirds of the temporary workers are female.

Temporary work tends to attract primarily those from a younger age group. In most countries, approximately two-thirds of the temps are under 30 years of age.

Supply and competition

Market coverage in terms of active population per establishment is highest in the Netherlands, the United Kingdom and France. In these countries, there is one office for every 4 000 to 5 000 potential temps. Differences in market coverage are large, as can be illustrated by comparing this last figure

to that of Portugal or Spain: there the number of persons a branch office serves is much higher. These differences will diminish with the further development of the sector in these last two countries.

Naturally, market coverage figures also give an indication of the degree of competition in the different EC markets. In general, competition is fierce in well developed and/or stagnating markets (such as the United Kingdom) and moderate in less developed and/or growing markets (such as Portugal). The large differences in regulations provide a natural barrier to cross-border activities.

The degree of differentiation in supply varies from country to country, depending on market demand and regulations, but does not seem to differ very much within any particular country. An exception is a specialisation in client markets (intermediating for medical staff only, for example), which does appear regularly.

Prices and other terms offered being more or less the same, competition takes place through elements such as response time to a client request, distance between client office and temporary work companies, past performance of temps hired and other client services offered.

INDUSTRY STRUCTURE

Companies

Temporary work business is basically local business. Most companies operate through a network of local offices. Offices are located either near potential clients or near potential temps. This differs from country to country.

The six largest temporary work companies operating in Europe are (in alphabetical order): Adia (CH), Blue Arrow (UK), BIS (F), ECCO (F), Randstad (NL), and Vendex (NL). Their estimated total market share in the EC is 35%. In the USA it is estimated that the four largest companies hold 30% of the market. Temporary work companies of EC origin account for well over 80% of the EC market.

Many temporary work companies operate under more than one name in the same market. Some have the same management, others operate more or less independently. Franchising is known to be practised by, for example, Manpower and Adia.

The market leader differs per country; regularly, the leading position is held by a business with its home base in that country. Examples are Randstad in the Netherlands, ECCO in France and Interlabor in Belgium.

Basically, all temporary work companies operate on a local scale, whether they are a small, independent one-office company or an office of a larger (multi)national temporary work business enterprise.

A relatively new phenomenon is the emergence of costbased government temporary work companies, notably in Belgium (T Interim) and the Netherlands (START). They have gained a considerable share of the market. At the same time their operation has proven to be beneficial to the acceptance of organised temporary work in these countries, and thus to the market size.

Strategies

In past years temporary work companies (particularly the larger enterprises) have diversified into less related services such as security, contract cleaning and maintenance, language services, business information and financial services. The present trend is more focused on efficiency and upgrading, while expansion is strongly geared to services related to personnel management and internationalisation. In their efforts to improve the efficiency of their operations and the quality of their services, temporary work companies are investing heavily in computer systems and networks. The trend towards upgrading is illustrated by the fact that many temporary work companies are shifting towards temporary workers with higher educational qualifications and more experience.

The major temporary work companies are expanding their businesses internationally. Internationalisation not only takes place in EC countries (whether or not by acquisition) but also outside the EC, notably in the USA and East Asia (including Japan).

The expansion into personnel management areas is to be found in services such as personnel management for small and medium-sized enterprises, recruitment (including head-hunting) and training of personnel. This is triggered by the fact that the distinction between permanent and temporary employment is becoming less pronounced (the contract of well over one-third of temporary workers later results in a permanent contract for the employee).

In those countries with a liberal regulatory regime, a shortage of qualified temporary personnel is becoming a major obstacle to growth. This shows the importance of education and training now provided by an increasing number of temporary work

companies. Typing courses, word-processing training and low-level technical courses are forms of training that figure regularly in their programme. Specific training tailored to the job or the individual is also common.

The issue of quality accreditation has also made its entrance into this sector. The countries in which the sector is well developed have started efforts in this direction recently. It is a result of a more competitive situation in these countries, combined with the trend in business towards a higher level of client service. Companies try to offer rapidly available and flexible services while still complying to the high quality standards demanded.

REGULATIONS

Organised temporary work is widely practised in the majority of the Member States. There are, however, considerable differences in regulation between EC countries. Two Member States, Greece and Italy, prohibit the operation of temporary work companies and the conclusion of temporary work contracts. In those countries where temporary work companies are forbidden, illegal practices are known to exist. Although temporary work companies are still officially forbidden in Spain, they are tolerated in practice. Regular discussions take place between the government and employers' organisations and trade unions about the possibility of legalising temporary work companies. There are two federations in Spain and the number of agencies is estimated to be over 200. In Portugal, regulations have been changed, resulting in a more liberal climate for temporary work companies. Several multinational temporary work companies have already opened offices in these two countries or are planning to do so.

Several countries restrict the use of temporary workers in one or more business sectors. For example, Denmark maintains a general prohibition except for the commerce and office sectors. The Netherlands and Germany prohibit temporary work in some areas (blue-collar workers) in the building and construction industry. Belgium prohibits temporary work in the construction industry as well as furniture removal and storage.

A number of other restrictions and requirements are common to most regulations in Member States, the most important being: registration of temporary work companies; limitations to the conditions under which temporary work is allowed; limitations to the duration of contracts (varying from 3 to 24 months or no restriction); and requirements for wage levels and social security conditions.

An indicative summary of the degree of regulation is shown in Table 5. It must be noted that the statements 'liberal' and 'restricted' should be seen relatively; the statements are meant to compare the EC countries to one another. If the USA were to be judged on this basis, the regulatory regime would be considered liberal.

OUTLOOK

The expectations for growth vary from country to country. Growth seems to be quickly slowing to a moderate (e.g. France), zero (e.g. the Netherlands) or sometimes even negative (e.g. the United Kingdom) figure. Economic recession and full employment both tend to reduce turnover. The sector seems to thrive best in a climate of moderate or brisk general economic activity.

In those countries where temporary work companies are well-developed, competition is strong; moderate growth sectors may still be found in high-tech industries such as robotics, informatics, bio-chemistry, etc.

In the countries where the sector is less developed, measures leading to a more liberal regulatory regime could still provide large growth impulses for the sector. Competition there is much weaker.

The large variety of national regulations within the EC have caused the Commission to examine possible harmonised regulatory schemes for the sector, in view of the increasing mobility of the labour force after 1992. It is not certain whether the Commission will submit EC-wide regulations upon the sector, or regulate cross-border activity only.

The industry is represented at the EC level by: Confédération Internationale des Entreprises de Travail Temporaire (CIETT). Address: c/o FRES, 36 Mortimer Street, London W1N 7RB, United Kingdom; tel: (44 71) 323 4300; fax: (44 71) 255 2878.

Industrial cleaning services
NACE 923

The EC market for industrial cleaning services reached 18 billion ECU in 1991, a 5% increase in real terms over 1990. The three main end users of industrial cleaning services are government, private businesses and hospitals. The rate of penetration of industrial cleaning services is still fairly low at about 45%, indicating that the sector could continue to enjoy rapid growth in the coming years.
Like other EC markets, the industrial cleaning services sector is currently experiencing mounting competition and a progressive move towards internationalisation. Changes in the regulatory environment in Europe will also have a major impact on the future of this sector.

INDUSTRY PROFILE

Description of the sector

The service activity considered in the present chapter comprises the cleaning, by specialised firms, of buildings whether they are used for administrative, industrial or commercial ends. Services provided by cleaning contractors are the following: inside cleaning of buildings such as offices, factories and workshops, inside cleaning of means of transportation (buses, trains, planes, metros, trams, ships),tanks, and small building maintenance. The following activities may also be provided by cleaning firms, but are not covered in the present chapter: security services, waste management services, evacuation of asbestos, laundry, dry cleaning, and pressing.

In some EC Member States, chimney sweeping, facade cleaning (but not restoration), the maintenance of areas around buildings and general sanitation are also part of industrial cleaning services.

Main indicators

In 1991, overall turnover of cleaning contractors in the EC was about 18 billion ECU (see Table 1). In real terms, the sector grew by 5%.

The main reason for this rapid growth in industrial cleaning services is the rising market penetration of cleaning contractors. The degree of market penetration, extremely important for business services, measures the share of the total potential market that is actually sub-contracted to specialised service contractors. The rate of market penetration by cleaning contractors is calculated based on several estimates, among which the sales of cleaning products and materials. At present, the rate of penetration in Europe is estimated at roughly 45%, for a total market value for industrial cleaning services in Europe of close to 40 billions ECU.

The low rate of market penetration in Denmark and in the United Kingdom (see Table 2) explains the relatively low turnover achieved in those countries, compared to other countries with a similar level of development.

Market penetration is constantly increasing over time. The so-called "in-house" cleaning services represent the most important development opportunity for cleaning contractors. According to a British survey, the contracting-out of services formerly performed in-house represented, in 1990, more than 75% of the cleaning contractors' new markets, whereas the cleaning of new buildings only represented around 10% of market growth.

There is no sign of market saturation in the EC. The growth rate of this sector in countries with a high market penetration (Germany) s similar to those with an average (Belgium) or low (Denmark) rate of market penetration.

Recent trends

In 1991, the public authorities contracted out the equivalent of 5 billion ECU of industrial cleaning services. This represents one third of the branch turnover (see Table 3). In the public sector, the rate of market penetration is systematically higher than in the private sector, with the exception of Luxembourg.

The public procurement of industrial cleaning services is increasing in the EC, especially in the United Kingdom where the government sector has changed its policy towards the contracting out of services to private firms.

Office cleaning is traditionally much more important, in terms of turnover, than other market segments. It is also the segment of the market in which in-house cleaning is estimated to be the most important, which indicates that the future growth potential of cleaning services to private firms is still very important. Many private or public companies indeed do not yet contract out the cleaning of their premises, except perhaps for some exceptional and/or unusual work (window cleaning, cleaning of carpets floors, etc.). In-house cleaning may, however, be limited certain segments of industry which have specialised facilities or controlled environments (nuclear power stations, agri-food industries, dust-controlled rooms, etc.).

Hospital cleaning, which represents between 3 and 6% of the market (except in Spain, where the figure is 20%) must be separated from the other market segments in so far as its features are very specific. It comprises, on the one hand, the cleaning of common spaces and the cleaning of rooms, with features quite similar to hotel cleaning (day-time work, full-time and with longer average working time) and, on the other hand, the disinfection of more sensitive areas such as operation rooms. This latter task generally requires specific techniques and skills.

In-house performance of cleaning services by private or public hospitals is estimated to be more important in the first sub-segment of the market than in the second. Rooms and public spaces are indeed often still cleaned by the hospital's own staff.

MARKET FORCES

Demand

Two trends recently appeared on the cleaning market: the demand for quality and a broader range of services. It is, however, still difficult to either quantify or measure their impact on the industry.

Quality requirements

Cleaning service customers are more and more demanding in terms of quality. These customers often ask that objective criteria be used to establish the price for a defined level of quality. This raises serious problems in the case of industrial cleaning services because of the high subjectivity attached to the concept of cleanliness. It is, indeed, extremely difficult to measure quality in the cleaning sector. Some projects towards the establishment of quality measuring systems have, however, been carried out. A Dutch cleaning institute (VSR) for instance has developed a relatively sophisticated system which can be applied to approximately 25% of the market in this country. It consists of a generating very precise list of criteria based on a range of errors established in advance with the client. The level of quality, according to this list, is controlled periodically. This statistical account is used to define what is an acceptable level of quality for the client and is registered with the contract. In France, the international technical centre for cleanliness (CTIP) is also trying to define a means of quantifying cleanliness and the technical means to achieve the desired results.

The clients' natural requirements for high quality are, however, in contradiction with a fairly wide-spread attitude which consists of systematically choosing the lowest-priced tenderer. The process "low price/poor service quality/dissatisfaction of the client" is thus engaged, seriously damaging both the quality of the services performed and the profession's image.

A first solution comes from the contractors themselves, who try to make their clients aware of the problem as the contracts are being drafted.

A second is provided by the professional organisations which, in addition to organising communication campaigns, have been promoting the setting up of minimal professional requirements necessary to have access to the market and exercise to the profession (see the section on the regulatory environment).

Supply of broader support services

Another trend that seems at present to be limited to the British market and, to a lesser extent, to the Dutch one, consists of the extension of the contractors' activities to the provision of broader support services that include, in addition to cleaning, security services, catering, the building maintenance, and the care of surrounding areas, etc. This trend is the consequence of the requirements expressed by some big clients, especially the British public sector, who are seeking to simplify sub-contracting by limiting the number of contractors.

It is, however, not yet possible to measure the impact of this trend on the market or on the profession. It is also impossible to appreciate whether it will extend significantly to other EC markets.

INDUSTRY STRUCTURE

Companies

The EC cleaning industry in 1991 was made up of more than 35 000 companies. This number is constantly increasing as a consequence of the dynamism of the branch.

Structurally, the sector is characterised by a large number of handicraft and small companies, employing less than 20 workers. Broadly speaking, more than 90% of the cleaning contractors in the EC employ less than 100 people, except in Germany where the market is more concentrated and where 15% of the companies employ more than 1000 workers. It must be noted however that the relatively low average working time in this country directly affects the level of employment.

Strategies

The trend towards a greater concentration of the market through mergers or acquisitions is evident in all EC countries.

Total	28 463	31 809	33 572	34 849

Source: FENI

It is, however, hard to put numbers beside this trend as the establishments often retain their previous name after the operation, which usually only affects the capital ownership.

On the other hand, more and more big groups are seeking to diversify their activities by entering the cleaning services market and taking over existing cleaning companies. This has been the case in particular of large temporary work service companies, and of companies such as the French Compagnie Générale des Eaux.

The big groups are also growing in importance in terms of employment and turnover. In France, more than half of the workers are employed by firms with more-than-500-employees (which represents less than 100 firms) and the 40 "over-1000" companies account for one third of the turnover of the sector.

REGIONAL DISTRIBUTION

Cleaning contractors are naturally located in industrial and urban areas, close to their clients. The industry is in effect characterised by the necessity for the contractor to be established very close to its clients. This results in a high fragmentation of the industry.

The firms which develop activities in several regions usually operate via a network of local agencies, linked to the mother company through regional or national subsidiaries.

Most of the big groups are established in several countries (EC and non-EC). The internationalisation of the groups, however, is hard to measure since, because of the proximity requirements, these large groups often enter new markets by taking over national companies. The latter thus remain essentially national establishments. The cross-border provision of cleaning services is quite rare and limited to neighbouring regions or to very specific contracts.

EMPLOYMENT

Recent trends

The cleaning industry is one of the EC's largest employers, with more than 1.8 billions of workers in 1991. Employment grew by more than 4.5% between 1990 and 1991.

Employment is traditionally made up of women and blue collar. It seems, however, that these two characteristics lost some of their importance in 1991, though it is still is too early to conclude that a trend has been established.

Non-EC migrant workers represent up to 48% of the workers in this sector in Belgium, and between 15 and 20% in Germany, France and the Netherlands. In the other countries, non-EC migrants represent less than 6% of the workforce.

Organisation of the work

The cleaning industry is characterised by the importance of part-time work. The average working time is quite low - be-

Source: FENI

tween 3 and 4 hours a day. Cleaning services are indeed performed outside of the usual working hours, when the clients' buildings are relatively unoccupied.

Contractors must therefore concentrate their workforce on two relatively short periods: in the morning and in the evening. Most of the workers (60%) are occupied in the evening. "Day-work" is limited to some specific situations (hotels and hospitals) and represents only 10 to 20 % of all cleaning activities. Night work is very limited in this sector.

Full-time work is quite atypical in the cleaning industry, as the "work day" is most frequently split into two non-consecutive periods: morning and evening.

Labour costs

The minimum hourly wage for unskilled workers in the cleaning industry (see Table 6) is quite homogeneous across countries in the EC. Wages are close to 5.5 ECU/hour except in Portugal and in the United Kingdom which are in fact estimates. The gross wage appears to be quite high in Denmark, but this results from the fact that the social contributions are distributed differently between employees and employers.

The total cost of labour, i.e. including both the wages and employer contributions, varies significantly from one country to the other. It ranges from 2.8 ECU/hour to 14.7 ECU/hour. This mainly reflects differences in national and professional (guaranteed by the collective agreements) social protection systems, which result in considerable variations in the share of employer contributions in gross wages across countries.

Work time and training

In order to promote greater professionalism in the cleaning industry, employers are aware of the necessity to increase work time. At the same time, they intend to develop vocational training initiatives especially for the lower levels of professional qualification.

Beyond its direct effects on the quality of the services, this strategy aims both at keeping workers in the company or, at least in the industry, and at stimulating their professional motivation by offering them the opportunity to have a professional career in this industry.

REGULATIONS

Social legislation

The cleaning industry is highly labour intensive, which makes labour-related costs an extremely important factor in the determination of the price of the service. Labour costs represent between 75 and 85% of the companies' turnover. Companies are therefore directly affected by social regulations. The organisation of work is, however, very peculiar to cleaning activities and often requires the adaptation of the social laws to its features. For instance, any regulation limiting part-time work would have a major impact on the cleaning service sector.

The social statute of workers in the cleaning industry is generally defined by sectoral collective agreements, at the national or regional level, except in the United Kingdom where agreements are made at the company level.

One of the most constraining social regulations for cleaning contractors is the obligation in most EC countries to keep all or part of the workers at a given site in the case of a change in the owner and contractor. The terms of this transfer of employment varies across the Member States. This principle however results in a strong reduction of competition as it considerably reduces the means of manoeuvre of the new contractor.

Professional regulation

Except in Germany, the access and the exercise of the profession are completely free in the EC Member States. Because the sector is a fairly dynamic one, many new cleaning companies are created every year. Most of them are small (less than 5 employees) and managed by people who neither have a basic knowledge of management rules nor basic professional skills. This makes the "life expectations" of these firms quite short, and many do not survive beyond one year.

A study carried out in Belgium in 1990 showed that, of the 1959 companies that were created between 1986 and 1990, only 1017 were still existing in 1990. Of these, 381 had been created more than 5 years before; 872 remained just one year in the market and then disappeared and 185 did not even survive a complete year. This phenomenon constitutes a major concern for the profession as it damages quite seriously both the market and the profession's image.

Most small companies have a tendency to tender at unrealistic prices (sometimes lower than the total cost of labour). Furthermore, they often do not have a sufficient financial capacity to be able to face the difference between the date at which they are paid by their clients and the monthly payment of their social obligations. This explains why so many companies become bankrupt after only a few months of existence.

Beyond its social consequences, this problem damages the whole profession and often results in a return to in-house cleaning by the client who initially out-contracted these services.

The profession has tried to react in most of the European countries, and national organisations of cleaning contractors are trying to impose minimum standards with which firms must comply to be allowed to enter the market.

The solutions adopted by the industry representatives differ from one country to the other, depending on the national legislative system and habits. These minimum standards for instance take the form of "quality labels" in France and in Germany (respectively "Marque professionnelle" and "Guterschutzgemeinschaft"), and are based on the commitment by contractors to respect minimal professional rules and to adopt certain codes of behaviour. These systems have been established by the profession itself but the labels are granted by independent authorities.

In Belgium, discussions are underway to establish a kind of "identity card" or professional label for companies in the industry.

French and Dutch organisations are also actively working on the definition of "quality insurance" systems adapted to cleaning features and based on ISO standards 9000.

OUTLOOK

From an economic point of view, the completion of the single European market offers good opportunities for the companies in this sector.

Beyond the opening up of public procurement of services, which should have favourable effects on the cleaning industry, and the complete liberalisation of services provision, which will facilitate the establishment of new firms in the sector and encourage the growing internationalisation of this industry, cleaning companies should benefit from the cooperation tools offered by EC law, especially the European Groups of Economic Interests.

The creation of a European company statute should also facilitate the internationalisation of cleaning companies in a near future.

One major concern must, however, be mentioned: the distortion of competition that can result from differences in labour costs. The current situation shows large differences in unit labour costs across countries. This may result in an artificial delocalisation of companies, eager to benefit from lower labour costs in certain regions. This could seriously damage the regional, economic and social landscape of these regions. However, because of the proximity requirements, this phenomenon would be limited to cross-border regions, and to a limited number of long distance or very specific contracts.

Written by: FENI

The industry is represented at the EC level by: Fédération Européenne du Nettoyage Industriel (FENI). Address: Avenue des Nerviens 117, Bte. 48 bis, B-1040 Brussels; tel: (32 2) 732 1342; fax: (32 2) 735 0787.

Security services
NACE 839.3

The security services sector in Europe had a turnover of approximately 7 billion ECU in 1992 employing some 424 550 people of which some 314 410 persons were employed by the 4635 private security companies operating in the EC. About three-quarters of security activities are subcontracted with the remaining quarter handled by corporate security divisions.
Many Member States are working hard to improve the quality of the services provided. Some individual firms have already been certified in accordance with ISO standard 9001. Quality improvement in the education and training of employees has in some Member States resulted in forms of cooperation with the regular police in the field of preventive supervision. The growth potential of private security services is good, both in the conventional sector and in terms of diversification of the security services provided.

INDUSTRY PROFILE

Description of the sector

The term "security" comprises a variety of specialities within the sector. This monograph is mainly based on data concerning the "manned guarding" sector, but also provides some information on related and ancillary specialities.

The sector of the production of electronic and technical equipment, for example, manufactures detection systems offering a variety of possible security applications, as well as exchange units capable of handling many types of signals and forwarding these to central alarm stations via telephone or permanent lines.

We are witnessing the dawn of the "electronic age". Wireless transmission from detection systems to a central alarm station may mean lower installation costs and can in some cases positively affect the risks of sabotage etc.; it may also prove the best solution in case of objects needing temporary protection (as in the building sector).

Even the technical advantages of the space age are noticeable in the security services sector. Today, tracing systems are being applied which can, by using satellite communication, accurately trace any object on earth equipped with a signal code emitter to within a few metres. This represents a great step forward in combating crime, (e.g. in the case of VIPs taken hostage). Furthermore, this development can also play an exceptionally useful role in improving the security of, for example, shipping traffic after a calamity has occurred.

Satellite tracing systems also contribute to the improvement of efficiency in international land, sea and air transport by allowing continuous spotting of the transports. This helps to coordinate the deployment of materials and/or ensure proper monitoring.

As an extension of the production sector of security equipment, the technical installation sector constitutes a logical speciality. It ensures the installation of security equipment in buildings, on grounds and to an increasing degree in private homes. This sector is developing very fast.

In the construction of new office and industrial buildings, a clear increase of so-called "smart buildings" can be observed where building automation plays an essential part. Often the technical installation comprises not only the security equipment: elements like air-conditioning, automatic access control, lift service programs etc., are also included in the technical infrastructure.

The central alarm station forms a vital link in the above-mentioned sectors. Equipped with state-of-the-art security equipment and usually manned by a team of at least two, it receives the signals from technical systems installed at the clients' premises and handles them according to a scenario agreed previously with the client. Depending on the type of occurrence, assistance is called in from the police, fire units, technical emergency services or the alert verification team of a private security organisation.

The central alarm station is also increasingly seen to give active response to certain signals because today's data network infrastructures allow remote control of technical processes. Systems can be switched on or off at a distance, the degree of distance being basically irrelevant. Visual images can also be transmitted via this method.

In the EC, over 1500 central alarm stations are operational with an estimated 4.5 million connected installations. This sector has considerable growth potential. It appears likely that middle-class households, too, will increasingly decide to purchase professional security equipment linked to a central alarm station. Considering technical developments, the purchase of "domestic equipment" will in principle suit all purses.

Transportation of cash and valuables is a specialised sector in which over 50 000 security employees, manning approximately 9 000 armoured vehicles, are employed by 180 special transportation firms. It is believed that the distribution of coin will be fully transferred to this sector, as well as the running, servicing and refilling of a number of cash dispensers.

MARKET FORCES

Demand for manned guarding services

All over Europe, the beginning of the nineteenth century saw the advent of night security services, usually on a small scale, active locally and often established in industrial areas. Not until after the Second World War did a substantial growth occur due to a number of factors: increasing industrialisation and the prosperity it brought, increased crime, weakened social supervision by the environment (family, church, etc.); increased awareness by entrepreneurs of the necessity of protecting their own belongings instead of considering the mere responsibility of the authorities or the police. Preventive security activities were carried out by security staff employed by the company itself as well as by employees of the contracted private security organisation.

The growth of the private sector was greatly enhanced because businesses frequently chose to concentrate on their own field and hive off disparate tasks. After industrial cleaning maintenance and catering, security activities were also increasingly subcontracted. Besides subcontracting, we find the birth of the "externalisation" concept meaning that "corporate" security guards are transferred to a security organisation specially selected for a particular purpose. In this new form, the existing security activities are continued on a contract basis. This tendency may be compared to the process of privatisation of government tasks.

Annual growth in the security services sector is 10% on average. This growth is occasionally the result of incidents, such as the Gulf War, when heightened threats of terrorism compelled entrepreneurs to take additional security measures.

The existence of an extremist terrorist group in a country can strongly affect the level of prevention within companies. But security is also seen to contribute to the continuity of the production or labour process and as such represents important support for a company's continuity criterion.

Preventive security has become a profession. The duties have grown more complex. Where in the past they were mostly concerned with porter services, mobile surveillance and the like, present-day security guards perform extremely useful and critical tasks within the framework of the total management of extensive projects involving a wide range of crucial security functions.

In large industrial plants and exhibition operations, security guards are in charge of not just access control but also fire

Source: CoESS

prevention and sometimes fire protection; they perform tasks in traffic control and parking supervision on the grounds and provide First Aid. For all these purposes, they man control rooms from where the security of the production process in the widest sense is monitored.

Another reason for the growth is the diversification of the security services sector. The uniforms (often an element of identification), recognisability, mobility and up-to-date communication equipment represent an infrastructure that allows private security organisations to explore new fields of activity such as operating bridges and locks in water-abundant areas, management of nature reserves or preventive supervision in the recreational sector (campsites, beaches). Other activities include environment-screening in cooperation with companies or public authorities.

In many countries there is some form of cooperation with public authorities. For example, budget inadequacies of the police have contributed to the development of cooperation in which the police play a supervisory role. A common example is the security check of passengers in many international airports where private security guards screen passengers under the supervision of the regular police force. Less familiar are forms of cooperation (e.g. the overseeing of detainees, traffic control, parking supervision in city centres and intendancy in public transport particularly in large cities) where drug abuse has especially caused criminal acts to multiply. Security guards are also used to protect military objects and perform preventive activities in prisons.

Supply and competition

In many EC countries, much is being done to improve the quality of the service. Quality is increasingly becoming a measurable element which relates to:

- quality/expertise of the company management;
- quality of the organisation, procedures, etc.
- quality of the performing staff (schooling/training);
- quality of the terms of delivery.

In the countries where relevant legislation exists these rules are often seen to contribute to the quality aspect. Indeed, competition among security firms is first of all a matter of quality aspects and much less a question of rates and on-charging. In those countries where competition has focused on the cost price of the service, we also find that this policy leaves no room for financial investments in quality improvement. Although no unequivocal standard has as yet been established, it seems likely that the international quality standard for services (ISO 9000) will be applied as a certificate of quality assurance.

Several security firms have so far been certified according to this standard and no doubt more companies will follow their path.

INDUSTRY STRUCTURE

A survey held in 1992 among the members of CoESS showed that this service sector employs 424 550 people.

The subcontracting percentage in the EC Member States averages 74% (314 410). The remainder (110 140) employed in a corporate situation. In the EC, an average 124.9 out of each 100 000 inhabitants work as a security employee. The turnover of the 4 365 private security firms in the EC amounts to 6 684 million ECU, with an average annual turnover of 21 259 ECU per employee.

There are 4 365 security firms in the EC. The average work force is 72 employees per firm. In non-EC European countries, the average company size is 74 employees in the 457 security firms established in these countries. An overview of the company size of security firms can be given for the following EC countries: United Kingdom, Germany, Spain, the Netherlands and Italy.

In addition, about 33 600 security employees are being employed in non-EC countries by a total of 457 security firms. Their total turnover is 1 014 million ECU which means an annual turnover per security employee of 30 164 ECU.

REGULATIONS

In various ways there are considerable dissimilarities in the laws and regulations. These laws and regulations are, of course, subject to change. The information supplied below was valid in late 1990 and early 1991. It describes a number of marked differences in laws and regulations.

Most European countries have some form or other of laws or regulations. One noticeable exception is the United Kingdom where no government rules exist whatsoever. Germany too, considering the extent of the sector there, takes a position of its own. This country does have some incorporated legislation but no specific legislation.

A number of duties are performed on a standard basis. In some countries the array of duties is quite wide. In Sweden, the tasks include the production of identity cards and assistance in fire-fighting. In Germany, a considerable amount of activities are connected with the maintenance of public order. In Spain, part of the duty is to pursue and arrest lawbreakers.

All European countries (excluding the UK) have mandatory licence and practical requirements which are generally the same. Although such harmonisation exists, a number countries enforce special requirements, including:

- Compulsory third-party liability insurance (Belgium, France, Portugal, Spain and Switzerland);
- Belgium and France apply restrictions for those who have previously been employed professionally in the police force or have been in the military. Italy and Spain, on the other hand, make it a requirement to have accomplished one's military service to be allowed to work as a security guard;
- In France it is not possible to enter the security services sector after a bankruptcy.

The requirements and the duration of the various types of schooling in Europe are quite diverse. In Germany there is no unified concept. In the Netherlands, however, schooling is organised quite thoroughly as compared to the other European countries.

Laws and regulations with regard to equipment (uniform, weapons, identification and the use of dogs) are on the whole similar in all countries. Wearing a uniform is compulsory in most countries, but is optional in four countries. The uniform shall not resemble the police uniform.

Carrying arms is permitted with the exception of Denmark, the United Kingdom, the Netherlands and Norway. In some countries, the laws and regulations with regard to arms are contained in the Fire Arms legislation of the country in question. In other countries, a separate article is included in the Security legislation.

In most countries employees in the private security services sector are obliged to carry an identity paper; Austria is an exception. In Spain security guards can easily be recognised by a badge that each guard is required to wear.

As for government supervision, Belgium, the Netherlands, Portugal and Spain stipulate annual reporting to the Ministry in charge. In Sweden and Norway, supervision is in the hands of the police.

The amount of possible sanctions varies widely. In the Netherlands there is only the possibility of withdrawing the licence. Belgium, Denmark, France, Norway, Portugal, Spain and Switzerland have, in addition to that sanction, the possibility of imposing fines and/or imprisonment.

Other noticeable clauses include:

- security firms are not to concern themselves with or intervene in political or labour conflicts (Belgium and France);
- In case a person resists against removal, a certain amount of violence may be used (Finland and Sweden);
- The wages of a security guard must not be lower than the starting salary of a police officer (Greece);
- In Austria, approval from the Prime Minister is required if someone wishes to exercise other activities simultaneously with security activities;
- In Spain, each private security organisation is assigned an exclusive number. This number must be mentioned on any document and in any publication the firm produces.

OUTLOOK

Growth in the private security sector appears encouraging. Quality control, increase of sub-contracting, diversification of the security sector and cooperation with public authorities will lead to greater expansion of private security companies in the EC.

Most of the growth, however, will be affected by well organised, large and mostly international operating security organisations, who are willing to invest in an adequate infrastructure of the organisation and quality control program, including the improvement of education and training of their security employees.

Car rental
NACE 844

The West European car rental market had a value of 4.5 billion ECU in 1991. The largest market by far is Germany. The biggest car rental company in Western Europe is Avis, followed by Hertz, Europcar, Budget and Eurodollar. The evolution of the car rental market is closely correlated with a country's economic activity. There is generally extraordinarily strong price and service competition. The market potential is far from being exhausted. During the next few years an average annual growth rate of 5% is expected for the car rental market in Western Europe, with the business segment growing more slowly, and the leisure segment growing faster than average. The five big companies will be able to gain market share at the expense of the numerous small and medium-sized firms.

INDUSTRY PROFILE

Description of the sector

The car rental branch deals with the commercial rental of motor vehicles (passenger cars and trucks) without driver. Car rental with driver is not the subject of the following analysis; it is included, together with the taxi business, in NACE 722.

Commercial car rental is provided by companies either exclusively or in combination with other business activities. The majority of the big companies of the sector are in this business exclusively, in part also in combination with car leasing. The small and medium sized companies, however, combine the car rental business with other activities, especially with petrol stations, motor vehicle dealerships and garages. Mostly, the car rental business is then not the major activity.

Main indicators

The Budget Report estimates the total West European car rental market at a value of 4.5 billion ECU in 1991. Germany has by far the largest market in the EC, with 36.7% share over five countries for which data are available. The United Kingdom follows with 17.2%, France (14.1%), Italy (5.5%), and the Netherlands (2.3%).

The market of the six countries covered in the report (the five EC countries mentioned above and Sweden), is estimated to grow by 5% on average in nominal terms over the coming years. The German market, due primarily to reunification, grew by 27% in 1991. Excluding Germany, the market volume in the six major countries would have declined in 1991. The Gulf War and the economic slowdown, especially in the United Kingdom, must be seen as the causes of the decline. The entire fleet size increased by 13% in 1991.

MARKET FORCES

Demand

The three most important factors affecting the growth of the European car rental market are general economic growth, airline traffic growth, and customer attitudes. According to the "Budget Report on Car Rental in Europe", a 1% increase in disposable income leads to a more than proportional growth in demand for car rental, namely 1.8%. Due to the firm link between car rental demand and economic growth, the Budget Report considers car rentals to be a good indicator of economic activity. On the basis of the estimated growth rates of GNP in the countries under consideration, a real expansion of the car rental market of close to 5% is expected for the period 1991 to 1996.

20 to 30% of all car rentals are estimated to occur at airports. The International Air Transport Association (IATA) estimates that in the period 1991 to 1995 airline traffic in the countries covered (incl. Sweden) will grow by an annual average rate of 4%. The Budget Report expects the deregulation of the European airline industry to result in more air passengers and less service, especially in the leisure sector.

The Gulf War showed that many business trips are unnecessary, and effectively not begun, with extensive negative effects on the car rental industry. Business airline travel is therefore likely to grow more slowly in the future than assumed above. Above average will be the growth of the leisure market, induced by an increase in disposable income, deregulation, and lower prices. Furthermore, the European tourist is becoming increasingly independent and enterprising, a tendency which benefits the car rental industry. The greatest benefit will accrue to South and East European travel markets where transport systems have not been fully developed yet.

A clear pricing policy and a constant high level of service are becoming increasingly important, a trend which favours the big car rental companies with evenly high performance standards and large station networks. The big companies will therefore be able to gain market share at the expense of small and medium sized firms.

The rental time differs from country to country; it ranges from 2 to 3 days in France, Germany and the United Kingdom, to 3 to 4 days in Italy, and to 5 to 7 days in the Netherlands. Many renters have reduced the length of their trips, possibly because of deteriorating economic conditions. The average

distance per hire remained the same, at 150 kilometres, with the exception of Italy where it is at 450 kilometres. The demand for oneway rentals varies substantially, from 33% of all rentals in France to 3% in Italy. Rental activity is strongest during the summer months (May to August), whereas it is markedly weaker in the winter months (January and February).

Supply and competition

There is generally extraordinarily strong price and service competition in the car rental industry. It is led by the big companies which court the business sector as well as the leisure sector with a most flexible pricing policy oriented on partial cost thinking. At the same time the performance standards (car plus service) are substantially expanded and improved. The Budget Report confirms that in the 6 countries under consideration average rental fees per day for a Ford Escort declined by 12% from 1988 to 1991. Comparing the cost of owning a car with the cost of renting one on weekends shows that up to a utilisation rate of 44 weekends per year renting the car is cheaper or at least not more expensive than owning the car. The Budget Report lists additional advantages of car renting, namely higher quality and reliability, time saving, petrol costs saving by using the shortest route, and adaptation of the rental car to special requirements.

The partial-cost oriented pricing policy of the big car rental companies is possible because of the effects of rationalisation and declining costs resulting from the size of the companies, and also and importantly because of the financial and/or contractual ties to the automobile industry. The sale of used cars, which are bought at large discounts, yields high profits and subsidises the rental business. Table 3 shows the share holding interests of motor car manufacturers in the major international car rental groups.

INDUSTRY STRUCTURE

Companies

The five big car rental companies in Europe are Avis, Budget, Eurodollar, Europcar and Hertz. Avis, Budget and Hertz operate worldwide with international networks in many countries. Eurodollar and Europcar are trying to establish global presence through cooperation. Eurodollar is the major licensee of the American Dollar group, and Europcar has marketing agreements with National in the USA, Tilden in Canada and Nippon in Japan.

The Budget Report estimates the car rental fleet in Western Europe at 610 000 cars. In 1990, Avis and Europcar together were the market leaders. In 1991, Avis surpassed Europcar and became market leader; the other three big companies followed closely.

After Hertz, Avis is the second biggest car rental firm worldwide; Avis Europe, in which the Belgian Lease International and to a lesser part General Motors and the American parent company Avis Inc. hold shares, is the market leader ahead of Europcar. In 1991 its pure rental turnover amounted to 175 million ECU.

Avis relies primarily on its extensive station network at airports and train stations in Europe. Exclusive contracts exist with the French, Belgian and Luxembourg railroads. In addition, there are cooperation agreements with most of the big travel agencies, many airlines (Lufthansa!) and hotel chains. At present Avis tries to establish ties with the East and West German railway companies. Avis, like the other big companies, provides a number of special services for the business customer, the major client. A computer system supports fast and flexible management decisions. With its "super value" programme in 1991, Avis was the first of the major car rental firms in Europe to offer leisure travellers special discount rates.

Hertz, the largest car rental company worldwide, is owned by Park Ridge Corporation, in which Ford Motor Company holds a majority equity share. The company relies primarily on its strong airport presence: it has 2 000 airport locations worldwide. Travel from the USA, where Hertz is market leader, is a cornerstone of its business. In the United Kingdom Hertz also has an exclusive agreement with British Rail, and additional cooperation agreements exist with the national railroads of the Netherlands.

Source: The Budget Report on Car Rental in Europe.

Hertz has specialised in the business segment of the market. The company has numerous fly-drive agreements with airlines, e.g. its "Business-drive" programme in partnership with British Airways. In combination with British Rail Hertz introduced its "Intercity-drive" programme. In 1991 a number of products were introduced for the leisure traveller, like the "Holiday-saver" programme in Europe. Since 1991 Hertz has been selling its used cars directly to the final consumer or user, respectively, rather than to wholesalers.

Europcar was created in 1989 by a merger of InterRent, a 100% Volkswagen subsidiary (market leader in Germany until then) and Europcar, the leading car rental firm in France and the United Kingdom, a subsidiary of the Belgian-French travel firm Compagnie Internationale des Wagons-Lits et du Tourisme. In Europe, Europcar has cooperation agreements with National Car Rental of the USA, Tilden rent-a-car of Canada and Nippon-rent-a-car of Japan. 1990 and 1991 were years of reorganisation, rationalisation, and network adjustment.

Europcar is extraordinarily active in East European markets; it entered the Soviet market in 1989, and the East German market in 1990. In addition it has licensees in Czechoslovakia, Hungary, Yugoslavia and Bulgaria.

With counters in about 260 airports in 79 countries, Europcar's share is around one third. In 1991 the company became the leading concessionaire at London Heathrow airport.

During 1991 the non-airport segment of the market was more intensively courted with the programmes "Cost cutter", "Business drive" and "Super drive". Especially for the visitors of Euro-Disneyland the company started the pan-European promotional campaign "Join the countdown to Euro-Disney".

Budget is the third largest car rental company worldwide with a fleet of 250 000 vehicles and 3 600 outlets in 140 countries. It operates its own network (in Belgium and in France), as well as a franchise network. Despite difficult market conditions, its own network grew at a rate of 15% in 1991.

Franchise partner in Germany is Sixt AG, which in recent years achieved second place with low-price strategies and a rapid pace of expansion. For 1992, a turnover of 263 million ECU was planned, a 20% increase compared to 1991. A new segment which Sixt thinks promising is the rental of heavy tractors and trucks (in excess of 9 tons). Budget was the first company to introduce all-inclusive rates. Within this all-inclusive rate it is the only company to offer personal insurance. Budget must also be considered the price leader among the big car rental firms.

The company focuses on the leisure segment of the market. Its "Holiday drive" programme is the best known leisure car rental programme.

Budget's fast pace of expansion was based on the mix of corporate and licensed operations. Especially the various local market segments could be reached with franchise partners. One specialty is the provision of luxury cars. Of all car rental firms Budget maintains the largest Mercedes fleet and is the biggest customer of Mercedes in the world.

Eurodollar International is the European franchisee of the American group Dollar Rent A Car Inc. Dollar in turn belongs to Chrysler Corporation, which also owns Thrifty Rent A Car.

Eurodollar has own and franchised outlets in 20 European countries. In 700 locations in Europe it offers more than 70 000 vehicles (worldwide this figure is 125 000 in 1 800 locations). In 1991 the French, Dutch and Italian franchisees were taken over by Eurodollar International. Through cooperation with Autohansa in Germany the franchise network was expanded there; an extension of the network is planned to Eastern Europe, the Middle East, and Africa. In early 1992 a new franchisee started in Poland. The sharp expansion, especially in the business segment, has diminished the originally strong dependence on the UK market.

Together, these five large companies represent 51% of the market in Western Europe. The remaining share of the car rental market is accounted for by a great number of small, medium sized and larger firms of local, regional and nationwide importance, which in turn frequently enter horizontal cooperation arrangements in order to raise their efficiency.

Strategies

Economies of scale and financial and/or contractual interrelationships with the automobile industry create structural competitive advantages for the large car rental companies. They use these advantages consistently and efficiently in order to safeguard and expand their market shares. The beneficiary is the car renter who enjoys very low rental fees.

In this way the airport business has fallen almost entirely into the hands of the big car rental companies; small and medium sized firms have no chance here. Price comparisons suffer from the very low degree of standardisation within the individual EC countries. The sector is in the process of providing a solution for the standardisation of services and quality levels. This should render the market more transparent and more competitive.

The numerous small and medium sized car rental firms focus on the non-airport segment of the market. This consists of the rental of substitutes for accident damaged cars (turnover share approximately 50%), the rental for business purposes (app. 30%), the rental to tourists (app. 15%) and the rental for other private purposes (app. 5%).

The sales prices of the small and medium sized firms are not always based on exact cost calculations, but are oriented on market prices. As this frequently results in prices which fail to cover costs, the car rental division is often being subsidised by other activities of these smaller firms.

Frequently there are still, especially in the countryside, local supply monopolies or oligopolistic constellations which make cost-covering prices possible. The increasing regional expansion of the large companies' networks, however, results in increasing price and service competition here, too.

REGIONAL DISTRIBUTION

No statistics are available about the regional distribution and the density of the car rental networks in the individual countries. If the ratio cars/million people is taken as an indicator of the density of networks, the United Kingdom ranks first with 2 357 cars per million inhabitants, followed by Germany (1 913), France (1 746), the Netherlands (1 416) and Italy (713) (see Table 1). The car rental networks are the densest in the large cities and metropolitan areas as well as in coastal and vacation regions. As a part of their expansion strategies, the big car rental companies are in the process of extending their networks also to medium sized and even smaller towns.

ENVIRONMENT

The car rental activity has positive and negative effects on the environment. Positive environmental considerations include the use of train for long distance travelling, the smaller size of rented cars compared to the own car, and the use of relatively new cars in rental fleets:

The combination train and rented car can replace the use of one's own car for the long distance travelling. The rented car is then used at the point of destination. The environmental damage and the resource use of the railroads, in terms of person-kilometres, is much lower than that of one's own automobile. Besides, the substitution of the train for the car ride results in less traffic especially on motor ways, contributing

to a decline in accidents and emissions. The economic costs of car accidents, in particular, are considerable.

Other environmentally beneficial effects of rental car use include substitution of as a rule much smaller, leaner rented cars for the relatively powerful own car, and regular maintenance and inspection of the relatively young car rental fleets

In all of these instances exhaust emissions are reduced. With respect to the strength of this effect, a pronounced north-south gap may exist among the EC countries, as the car rental firms in the Southern vacation countries frequently have older, poorly maintained cars in their fleets.

Environmentally damaging factors include the use of aeroplanes for long distances instead of one's own car. Exhaust emissions of aeroplanes, in terms of person-kilometres, are much higher than that of automobiles.

Another element is the creation of demand for the service "car rental" through a large variety of services, ubiquity and low prices. This consideration has relevance especially in the vacation countries.

A quantitative and qualitative weighting of these various effects on the environment and thus an overall assessment is not possible. Furthermore, each of the factors mentioned carries a different weight in the individual EC countries.

OUTLOOK

The service "car rental to drivers" offered by private firms has an essential place in all modern economies. In numerous cases it is a true alternative to the use of one's own automobile or truck, usually in combination with the use of the railroad or the aeroplane. Its use is closely correlated with the mobility of private households and business as well as the degree of utilisation of the highway network. Mobility in all EC countries is rising and this trend is expected to continue in the medium and long term. As a result, the car rental business will most likely continue to register high growth rates. Experts are forecasting a doubling of the German car rental market over the next ten years. This forecast is based on growing business travel in the wake of the completion of the EC internal market, on economic growth in Eastern Europe as well as continued expansion of Europe-wide tourism. There is evidence that 43% of business travellers are now using rented cars, more than double the figure of a year ago. Furthermore, growing concern for the environment has resulted in a switch to public means of transportation plus a rental car at the point of destination.

Leasing
NACE 84

In the early 1960s, the rental sector in various European countries was enriched by a new variant which has proved to be very successful. The idea of equipment leasing, imported from the USA, very quickly gained general acceptance. Today, leasing is one of the most important form of renting capital goods in Europe, followed by renting itself. In some EC countries, leasing is responsible for around 30% of investment in plant and equipment.
Even though leasing has experienced a cyclical weakening in some EC countries, over the next few years a continuation of the positive trend in leasing can be expected, not least because of the effects of the single European market and the growth of new markets in eastern Europe. If those EC countries that have not allowed private automobile leasing, approve this rental form, strong growth in leasing is likely.

INDUSTRY PROFILE

Description of the sector

The word "leasing" is used throughout the world to designate certain forms of medium to longterm commercial renting of merchandise. The only exception is France where this form of renting is know as "credit bail". In English speaking countries in particular, equipment leasing is less easy to differentiate from traditional forms of renting elsewhere, since here, for example, a "for lease" sign is used to signify accommodation. Furthermore, the difference between leasing in the narrower sense is quite different from hirepurchase, renting or other rental forms, which is largely due to different taxation and civil law systems throughout the EC. If one disregards the renting of living space, it is easier to define the difference between renting and leasing in the EC countries. Renting then includes the short term transfer (also on an hourly or daily basis) of, for example, vehicles or construction equipment, on payment of a fee. The differentiation between hire purchase and equipment leasing is hard to make. A high proportion of English and French leasing contracts would be classified in Germany as hire purchase or even as hidden instalment buying with all the consequences for accounting and taxation.

In genuine leasing, unlike in renting, the regulations of the individual countries for accounting, taxation and relating to common law usually play a major role. Since most commercial and civil law codes in EC countries were developed at a time when leasing in its present form did not yet exist (the first leasing firm was founded in the USA in 1952), there are still on the most part no corresponding legal definitions of leasing. Only in France was leasing ("credit bail") put on a legal footing as long ago as 1966. Since ministerial decrees and court rulings have throughout the years taken the place of a legal definition, the resulting legal framework conditions covering leasing vary a great deal in individual EC countries. Market shares for leasing in the individual countries therefore vary considerably, and cross-border leasing has played a relatively limited role.

In most countries, equipment leasing has crowded out the traditional medium to long-term forms of renting; even the manufacturers of office machinery and EDP equipment, who traditionally made relatively frequent use of traditional producer renting, have today mostly switched to leasing, either through their own leasing firms or through distribution leasing, i.e. through an outside leasing firm. Disregarding the rental of dwellings, which is not the subject of this analysis, leasing is by far the most important of all rental forms, followed by renting itself, which supplements leasing through the provision of short term contracts.

NACE 84 includes: renting, leasing and hiring of agricultural machinery and equipment (without permanent staff) (NACE 841); renting, leasing and hiring of construction machinery and equipment (without permanent staff) (NACE 842); renting, leasing and hiring of bookkeeping and office machines, electronic data processing equipment and cash registers (without permanent staff) (NACE 843); hiring of consumer goods (NACE 846); renting, leasing and hiring of other movables (without permanent staff) (NACE 847).

This chapter will focus on leasing, which dominates the rental market, before genuine renting and hiring. The renting of cars and other means of transport without driver (NACE 844 and 845) is considered in a different monograph.

Main indicators and recent trends

In the larger EC countries, equipment leasing existed since the early 1960s with particularly rapid development since the

mid 1970s. In the meantime, the United Kingdom, Ireland and Spain, with leasing shares of around 30%, have almost caught up with the USA, the pioneer in leasing, where the share of leasing in overall equipment investment was 32% in 1990. Despite the already relatively high market share of leasing in most EC countries, doubledigit growth rates have been common. According to figures from LEASEUROPE, annual new business of leasing firms rose thirty times over from 1972 to 1990.

The idea of leasing as an investment and financing alternative has had a remarkable career. In the first years of leasing, both in the USA and Europe, the manufacturers of capital goods dominated the market. They employed leasing as a marketing instrument; in some instances new office equipment in the 1960s was only available on a rental basis. Gradually leasing firms independent from manufacturers established themselves in Europe, often as bank subsidiaries, and the leasing option received further refinements. In the mid 1970s the independents overtook producer leasing in new business generated. Especially in contract design, several innovations were introduced.

Mainly, two contract types exist today, one with full payout (full amortisation) and the other with nonfull payout (partial amortisation). In the latter case, the lessee only uses the capital equipment for a portion of its normal service life, and there are normally one or more additional users. The leasing rates are therefore only calculated at a fraction of the purchase value. This type of contract is used almost always in relation to motor vehicles. It also used to be very widespread in computer leasing, although the rapid decline in prices has meant that leasing firms no longer lease as many computers due to the commercial risk involved. A particular form of partial amortisation contract is the terminable leasing contract (operating leasing). The prevalence of operating leasing varies among EC countries, being relatively high in the United Kingdom and relatively low in Germany.

International comparison

The trends in leasing in non-European industrial countries are similar to those in the EC. The leasing ratio in the USA is 32%, in Australia 33%, but only 9% in Japan. Although the market share of leasing is low in Japan, growth is very strong. New business in Japan has been estimated at around 60 billion ECU, compared with 95 billion ECU of the European market.

For the leasing market in the USA, various estimates exist. Leaving aside long-term industrial hire purchase business, the current leasing ratio should be at about 20%.

In the countries of Eastern Europe, leasing is not yet widespread; Bulgaria, Czechoslovakia, Poland and Hungary made the greatest advances.

MARKET FORCES

Demand

The European leasing markets also attribute their three-decade long expansion phase to the constant extension of the services they offer. Leasing companies soon abandoned the initial orientation upon office machinery, to include construction and manufacturing equipment and finally road vehicles. Presently, leasing companies offer nearly all commodities from typewriters to jumbo jets. At the same time, their dependency on large corporations as well as on banks and insurance companies has declined.

With increasing standardisation of leasing contracts and checks on creditworthiness, as well as with the widening of sales channels (e.g. via retailers or bankers,) leasing firms have been able to offer competitive prices to small and medium sized companies in practically all economic sectors. Thus, leasing rapidly achieved a foothold in the various service industries as well as in the trades. Today, the services sector ranks number one or two in most EC countries in the list of the most important lessee sectors.

Since the early 1980s, auto leasing to private persons, which had not been very wide-spread, made advances in Germany and France as a result of the massive sales promotion campaigns of auto manufacturers. Especially in times of sluggish auto sales, the car makers offered very attractive leasing conditions. In these countries, private leasing has gained a dominant position over medium sized personal loans from banks and savings institutions. Today, private households are in third position in the rental sector rankings in France and Germany (see Table 2).

Supply and competition

At the end of the 1980s capital goods manufacturers countered the success registered by independent leasing firms with their modern contracts was countered. Many of them founded leasing companies with an independent legal status and adopted

some of the contract ideas of the independent competitors. This period also saw a strong expansion of automobile leasing in Europe. A variety of major road vehicle manufacturers employed leasing as a marketing instrument in sales promotion campaigns. The boom in vehicle leasing has continued to the present day in most EC countries. Step by step, office machinery and EDP have lost their dominant position in the European leasing market. Today, in most EC countries, road vehicles occupy first place for leased goods.

With growing market share, the established European leasing firms expanded their services in the 1980s, achieving a stronger profile visàvis pure financiers and small newcomers. Today, renowned leasing firms are experts in investment, finance, law and taxation. Full-service contracts can include all commercial and technical services. For big-ticket leasing, especially in cross-border trade, some leasing companies also function as packagers and consultants.

Their product and market knowledge as well as their speed in reacting have meant that the European leasing companies, despite occasional detrimental taxation and depreciation regulations in several countries, have not experienced a permanent decline in sales.

REGULATIONS

EC countries not only define leasing differently, yet also have a wide variety of civil law, fiscal and accounting rules. In addition there is no standardised supervision by governments or central banks.

The rental sector in France has a somewhat unusual organisation. "Credit bail" is the most widespread form of renting, with its own laws. A "credit bail" transaction is only present when at the outset the renter is granted an option to buy. The law stipulates, moreover, that the purchase of goods for the purpose of renting is the precondition for a "credit bail" transaction. The law thus specifically excludes manufacturers from leasing. Firms such as Peugeot, Renault or IBM have therefore set up special finance companies in order to comply with these requirements.

Alongside "credit bail", France also has more diverse companies that offer other forms of leasing contracts (e.g. "location simple"). These companies do not have the importance of established "credit bail" firms. The latter are aided by legal regulations that guarantee market entry limitations, refinancing advantages, etc. On the other hand, they are subject to strict

government controls and rules on advertising, and, as finance companies, are treated as banks.

In the United Kingdom leasing is not subject to any specific regulations or restrictions, as is the case in Germany, the Netherlands and Denmark. An unusual aspect of British finance leasing is that the lessee can enter the leased object on the assets side, an element taken from US law. Not all sides see this as an advantage. In the United Kingdom, operating leasing is considerably more widespread than in most other EC countries, which is partially attributable to differences in definition. According to the accounting conventions decree SSAP 21, finance leasing contracts are those agreements transferring all the major risks and advantages from the possession of the leased object to the lessee. All other leasing contracts are treated as operating lease contracts.

In Denmark there is no specific leasing legislation. Leasing investments show in the balance sheets of the leasing firms; special tax codes for leasing are nonexistent. At the beginning, leasing in Denmark faced considerable acceptance problems and had to adjust to frequent changes in treatment by taxation legislation. Even today, big ticket leasing is still in its infancy.

In Germany, the lessor is accountable as the legal owner of the leased object and not the lessee. As a rule, both contracting parties see this as an advantage, and that is one of the reasons why hire-purchase and other rental contracts which do not conform to the edicts on leasing, are comparatively rare in Germany. Operating leasing is understood in Germany to mean short and medium term leasing contracts in which the lessee has the right to discontinue the agreement at any time. This form of contract is used especially for motor vehicles and in the construction equipment sector.

In the Netherlands, due to the tax code and government support stipulations, true leasing does not exist, as a rule, but rather hire purchase.

Spain and Portugal have, like France, introduced laws and relatively tight regulations for leasing. Spanish law obliges leasing firms to operate as stock companies and comply with minimum equity provisions. Two thirds of the companies are bank subsidiaries.

In Italy there are still no specific rules on leasing, although these are under preparation. The current trend is for the incorporation of leasing firms within financial institutions from which the leasing firms expect an improvement of their long-term refinancing.

Belgian law on "locationfinancing", that corresponds to the French system of "credit bail", obliges the lessee to enter the leased goods on the assets side; private leasing is not permitted. The leasing ratio is still below average at 8.3%, primarily due to the dominance of smallticket leasing.

The characteristic feature of the leasing market in Ireland is the relatively favourable fiscal situation and diverse subsidies, e.g. from the Industrial Development Authority. Moreover, the GPA group, which is by far the world's largest aircraft leasing firm, has its headquarters in Shannon.

The first leasing company in Greece was set up in 1987, with eight additional firms having been established since then. The law places them under the control of the Bank of Greece. The conditions for leasing are relatively disadvantageous; leasing of buildings, trucks and busses is not allowed and the depreciation rates are unfavourable.

OUTLOOK

It is impossible to make halfway precise medium or long term forecasts for the renting business and specifically for leasing, although one can indicate some trends. From 1992 to 1995, the rental sector in the EC countries will grow, on the whole, at the same pace as the economy's gross investment in plant and equipment (excluding housing construction). Spurred on by the economic recovery, several countries will even register higher growth rates, i.e. through increases in the market share of leasing. In this, vehicle investment will play a decisive role. With the EC single market and the new markets in eastern Europe, the need for road vehicles will continue to grow. In this segment, leasing should be able to increase its high market share. The available forecasts on increases in air travel and the resultant need for aircraft will spur aircraft leasing. In the last few years, leasing of aircraft has already been able to register substantial market share gains. More recently, however, the economic problems that several airlines have been experiencing translated into fewer aircraft orders.

The traditionally high share of renting and leasing in the areas of EDP, office machines and telecommunications should also see further rises in view of the rapid technological development and the still increasing market permeation of these devices. There are, however, trends in this market segment that are having a dampening effect on leasing, such as downsizing and the continuing decline in hardware prices. Finally, especially in unified Germany, machinery and industrial plants will ensure a continued expansion for the leasing branch. Up until now, private leasing has only existed in half the EC countries; in some places, this form of leasing is not permitted. Should this situation change, possibly with the completion of the single market, leasing growth will accelerate considerably. Due to intensified national and international competition, the movement towards concentration on the leasing markets should continue, also in the form of cross-border cooperation and takeovers.

Information services

The economic value of technical activities in the processing, exchange and communication of information is growing substantially as modern economies evolve from an industrial age to the information age. Information services make up a fast growing market which totalled 135 billion ECU in 1991 in the EC. The sector is characterised by the increasing importance of software which has become a fundamental part of the cost and competitiveness of other subsectors such as telecommunications. The provision of information services takes place in a wide range of competitive environments, from the national monopolies controlling basic telecom services to the deregulated computing services market. For several years, however, the sector has been increasingly liberalised and the trend will continue throughout the 1990s.

INDUSTRY PROFILE

Description of the sector

Information services encompass telecommunications, software and computing services and electronic information services (i.e. on-line and off-line queries to data banks).

Telecommunications are part of NACE 79 (communication), which also covers courier and postal services. Software and computing services and electronic information services form NACE 839.2 (computer services) although the distinction between the two sectors is not clear. The forthcoming revision of the NACE classification (NACE/rev. 1), however, will be more detailed with a specific class for telecommunications (forthcoming code 64.20) whereas computer services will be split into several classes including a specific class for database activities (forthcoming code 72.40).

Main indicators

The world market for information services amounted to 500 billion ECU in 1991, of which telecommunications services accounted for 330 billion ECU and software and computing services, 170 billion ECU (of which about 10 billion ECU corresponded to electronic information services). If equipment related to information services is added, the current world market for information technology and information services can be estimated at 900 to 1000 billion ECU.

At the European level, information services represented 135 billion ECU in 1991, of which telecommunications accounted for 80 billion ECU and software and computing services, 55 billion ECU (of which around 3 billion corresponds to electronic information services).

In the EC, the information business (equipment and services) already accounts for more than 5% of GDP. This contribution will grow in the future, mainly due to the rapid development of the telecommunications sector. In year 2000, telecommunications alone should account for more than 7% of the GNP of the EC. At that time, the world market for information technologies and information services will approach 2000 billion ECU, with a projected contribution to GNP of more than eight percent. But this is only the sector's direct contribution. The economic value of the applications of information technologies and its effect on the productivity of administrative and infrastructure is many times larger. In Europe, more than 50% of GDP is in one way or the other affected by the availability and use of advanced information technologies.

The electronic tools of the information age - personal or business computers which can communicate with all sorts of information bases - have already and increasingly will transform our lives. Sectors such as education, health care, transport, rural development will share the benefits of the development of information and communication services. Telecommuting with resulting impacts on employment and energy saving, distance education and training, help to the physically disabled, environment and disaster management, and health care, to name but a few, will develop thanks to information technologies and related services.

Foreign trade

USA and Japan have taken a commanding lead in information technologies and consumer electronics. Europe's trade balance in electronics with the rest of the world shows a deficit of some 30 billion ECU. As far as the balance for services is concerned, estimations are more hazardous. Telecommunications, for instance, have a mechanism for sharing revenues between countries which depends on the usage of the networks in the countries and the tariffs applied in the different countries participating in the communication. In some cases, part of the revenue goes to the owners of intercontinental infrastructures (like Intelsat, for instance). The EC currently has a surplus in relation to the US in telecommunications services (about 300 million ECU in 1988). As far as other information services are concerned, it is believed that the Community is in deficit with respect to the US, particularly with regard to electronic information services such as data banks. Non EC suppliers of software and computing services tend to operate on the EC market through subsidiaries and associated firms established in the EC, thus contributing to employment and value added in the Community, which nevertheless still posts a trade deficit.

MARKET FORCES

Demand

For the sake of simplicity, demand can be divided into two main categories: corporate users and residential users.

Corporate users are driven by price/performance considerations and are fast developing into knowledgeable customers with growing bargaining power, particularly in the telecoms sector. They have become, in Europe, as vocal as their American counterparts about the fact that their needs must be met both functionally and economically.

Although residential users do not have requirements as wide ranging as those of the corporate users, they are very interested in the provision of services that combine convenience, ease of use and low cost. An example in the information services market is the rapid development of videotex (Minitel) services in France. Penetration of these markets requires however strong marketing efforts to generate broad acceptance.

Supply and competition

A major difference between telecommunications and other information services is that telecoms have traditionally evolved in a regulated environment featuring national monopolies, while other services, from their emergence on, have developed in a competitive environment.

Throughout the EC, telecoms are still primarily under the control of the national main operators, which still account for 95% or more of total revenues. Deregulation has opened competition in areas like mobile communications services and valued added services, which grow much faster than basic telephone services but still represent a low part of global revenues (telephone accounts for more than 85% of the revenues). In the emerging global communications environment, the major telecoms operators are vying to reposition themselves on the international scene and to meet this objective

are concluding all sorts of partnerships or acquisitions. New entrants have already made inroads in the market, mainly in value added services, mobile communications and video distribution, in expectation of further de-regulation.

In software computing and electronic information services, environment is non-regulated and calls for market forces to organise the competition. These sectors are undergoing significant changes in terms of supply and competition with new competitive pressure coming from large groups of different origins (professional services, manufacturers, end-users, consulting and audit firms), the accelerated trends towards the supply of global solutions and the expected arrival of new powerful entrants in spite of higher entry barriers.

The profile of the enterprise of the service branches and the regulatory situation, particularly in the telecom sector, are described in further details in the respective chapters.

OUTLOOK

The decade to come will see the advent of the "information age" following the "industrial age".

After several, yet unsuccessful attempts of convergence between data processing and telecommunications, convergence is starting to become a potential reality as distributed intelligence develops. Transmission, at almost any bandwidth, is about to become particularly cheap. This will give the potential to abolish distance, not only for voice, but for video and for the transmission of vast volumes of non-coded information. Today, we are able, commercially, to transmit 2.4 Gigabits per second on inexpensive optical fibres over a distance of 50 kilometres without need for regeneration, that is at very low cost. This capability, known as capacity-distance achievement, is expected to continue to double every year into the next century.

Software will be a major force in the development in all the information services sectors concerned. In the telecom sector in particular, costs will increasingly come from the software developments required to operate and manage the networks and to provide the many high functionality services that will emerge on the new infrastructures ("intelligent networks"). Tools and methods for the development, documentation, renovation and maintenance of software will therefore play an important role in the development of the information services sector.

Eastern countries, within their difficult race to catch up with western economies, will represent privileged markets for information services (and infrastructures obviously) and will certainly welcome the opportunity to so leapfrog development and benefit from the new technologies. Telecommunications, particularly, will have to be developed substantially to allow for the economic development of the countries. Some of the Central European countries have already engaged in deregulation and privatisation schemes for their telecommunications sectors, going sometimes further than Western European countries themselves (e.g. Poland).

In the future, the EC information sector, in particular software computing and electronic information services, will continue to try and overcome the challenge of operating in a market fragmented by different cultural, linguistic, legal and fiscal environments. The provision of (electronic) information services in "minority" languages, typically those of the merging Eastern countries, is very expensive.

In conclusion, information services is a sector where Europe is rather well positioned and has several winning cards to compete successfully and improve its market positioning. Nevertheless, in the context of growing international competition, Europe will be facing major threats and European actors should have a more aggressive strategy, notably outside Europe.

Software and computing services
NACE 839.2

With a steady 20-25% growth rate per year over the 1985-1990 period, software and computing services is a strategic and very large market which affects almost all economic sectors. The software and computer services industry is characterised by a complex and dynamic range of goods and services in a rapidly changing environment where technologies play an important role. The industry is undergoing significant change as the two-digit growth rates of the market attract new and powerful entrants.

INDUSTRY PROFILE

Description of the sector

Software and computing services is a heterogeneous sector and is thus difficult to define. The sector can, however, be categorised into five broad areas of activities:

- consultancy, including strategy and management consulting as well as the development and management of information technology;
- processing services where the traditional service bureau is notably decreasing while sophisticated activities such as facilities management, value-added network services and on-line information are rapidly increasing;
- professional services which include technical assistance, business software, industrial and technical software, training and education;
- software packages including systems software, tools and applications packages;
- systems integration (SI) which essentially consists of putting together the best mix of software and hardware to solve a customer's SI problem; large SI contracts are often let on a fixed price basis and demand considerable expertise if costly delays and overruns are to be avoided.

Main indicators

The software and computing services revenues of the 12 EC Member States are estimated at about 50 billion ECU in 1991. The market is expected to grow at 10-12 percent per year from 1990 to 1995, much reduced from the average annual growth rate of 22% over the past five years (1985-1990).

Systems integration and software packages, the latter being driven mainly by the microcomputing, are the two fastest growing segments of the sector. Software packages is also the largest segment, with about a third of the sector's total revenues in 1990, and its importance is forecast to rise during the coming years. It is followed by professional services with nearly 30% of income in 1990.

The world market for software and computer services totalled 150 billion ECU in 1990. The US market share decreased from 56% in 1985 to 50% in 1990 and should continue to shrink until 1995 in favour of other main areas.

Foreign trade

Foreign trade is a difficult notion to handle in the field of software and computer services, due to the fact that suppliers tend to operate outside their country of origin via the intermediary of local subsidiaries and associated firms. This is why no distinction is made, in Tables 5 and 6, between actual exports and sales by a subsidiary based in a foreign country. With regard to the international activity of suppliers, American firms lead the world market, with particularly strong positions in consultancy, software packages and facilities management. Their local presence is continuously growing in Europe while, to date, few European software houses have made an impact outside their home country. In terms of foreign trade, according to the consulting firm EIC, the trade balance between the US and Western Europe shows a deficit of 2.5 billion ECU in 1990. With the rest of the world, the Western Europe trade balance is slightly positive and reaches 0.75 billion ECU.

MARKET FORCES

The software and computer services industry is undergoing significant changes in terms of end-user requirements, and accelerated trends towards a global solution offered by the suppliers. Technological changes are also playing an important role in the development of this industry.

Demand

As demand matures, users' requirements can be divided into two main segments according to the expected value added to final client. The high-end or strategic segment includes systems integration and high value added professional services (development of strategic information systems for clients). It represents roughly 30% of the total software and computer services market. The other segment (70%) includes software packages, processing services, systems operations and other "commodity-like" professional services.

The skills needed to compete in each segment are different: high differentiation in the high-end segment, low cost or efficient supplier in the low-end. Specifically, the high-end requires an international presence to help international clients successfully implement their information systems in their international location. It also calls for a good understanding of clients business in order to supply tailor made solutions and not only tools and products. In some cases, the supply of strategic services also calls for a unique external supplier capable of assuming total responsibility for cost/time/performance of the projects from the early stage of their inception to the final phase of their implementation at users' site in order to gain time and money. Nevertheless, some customers are hostile to such vendors' attempts to control and would rather continue to deal with different suppliers.

Despite change in the products and services requirement by end-users, few major changes occurred in the breakdown of

software and computer services by end-users sectors in 1990. The finance sector (banking, insurance, financial services) is still one of the major end-use segments, together with the manufacturing sector (discrete and process manufacturing). During the first half of the 1990s, demand from sectors such as communication, transport and retail are expected to grow slightly above the average. On the other hand, the demand from the defence sector will be affected by large cuts in military budget.

Supply and competition

Together with the diversity of products and services offered, the software and computer services sector is characterised by the large variety of actors playing in this domain. Six strategic groups of competitors can be identified according to their core business:

- independent software and professional services companies (CGS, Sema Group, Finsiel, Eritel);
- software packagists (or publishers) (SAG, SAP, Microsoft);
- audit firms (Arthur Andersen and other Big Six);
- strategy and management consulting firms (Bossard, Roland Berger, McKinsey);
- data processing departments or subsidiaries of end-user companies;
- hardware vendors (Siemens, Olivetti, Bull, IBM).

The competitive borders were clearly drawn amongst the six strategic groups of competitors from the beginning of the data processing industry up to the 1980s. Hardware manufacturers and software editors had the lion's share of the package sector while professional services companies dominated the sector of computing services and software development. Finally, the Big 6 and other strategy and management consulting groups were well entrenched in the consultancy and audit business.

Several factors are accelerating the restructuring of the sector, tending to eliminate that strict partitioning of supply. On one side, the market begins to show some signs of maturation and profitability differences between players are widening. On the other side, the nature of supply is changing as suppliers endeavour to offer global solutions and to be a unique interface for their clients. Competitive responses to these changes depend on strategic group.

For hardware manufacturers, a shift in focus to more "service-oriented" has started in the second half of the 1980s and will certainly accelerate in the 1990s. Several factors account for such a change. The move away from proprietary systems and the fact that hardware is being viewed as a commodity have affected industry profitability and margins are increasingly transferred from the hardware to the services and software. In addition, hardware manufacturers need to retain their installed base of customers and want to enlarge their market base to the SMEs which are primarily looking for "turn-key" solutions and complete services.

As hardware manufacturers and the audit firms move aggressively into their core business, professional services companies need to evolve quickly to adapt their service range by enlarging it to the new markets and the increasingly competitive environment. The key area of battle for them is the consulting sector, where both are clearly absent (or uncompetitive). Audit firms have built up their competitive advantage with their existing international network and their high visibility with clients. This advantage is becoming less significant, however, as they consider moving into other strategic segments (system integration and development, package). Improving their competence in such areas is a survival condition for these audit firms.

The problem of software editors is similar to that of the hardware manufacturers. Services are essential to sell a product today. In the past, most of their efforts were concentrated in product development and marketing, leaving their partners (software and services companies) to integrate their products into a client's management information system (a higher value-added activity with a higher potential of profitability). The need to differentiate, along with the necessity to "verticalize"/"integrate" value-added activities, is forcing them to move outside their core business (product development and marketing).

Production process

Technology will be evolving fast during the 90's, driven by the demand as well as by supply. On-going standardisation will accelerate under market pressure, notably with respect to the operating system environment (UNIX, MS-DOS/WINDOWS) or system development tools (SQL, programming language such as C, C++). These industry-wide standards will, however, co-exist with other industry de facto standards of some hardware manufacturers (e.g. IBM's OS2 or AD/Cycle).

New generation products must be able to work under various systems architectures and hardware environments and application portability is becoming a crucial factor for new product development along with the increasing networking capability in future systems, necessitating the mastering of network technologies such as cooperative processing, distributed data bases. Multimedia systems will be introduced more and more in many end-use segments driven by the availability of affordable hardware equipment and optical devices (hypertext, image converters).

A major change is expected to occur in the software production process where, from the early stages of software industry, software engineers have faced the challenge of being both efficient and flexible in designing and developing software, a common problem to any industry where there are differences in customer's needs, shortages of skilled workers or competition based on price and innovation. During the 1990s, the answer could be the ability to better industrialise the software production process, relying on standardised designs and reusability of software basic components (or interchangeable components). This new approach will open up new ways for greatly improving programmers' effectiveness and productivity, much more than the current craft-oriented and job-shop software approach.

The rapid pace of these technological changes is exerting a high degree of pressure on every actor in the sector, forcing them to invest more and more in technology development, costly systems and tools, as well as in new market expansion enabling them to amortise the high costs involved.

INDUSTRY STRUCTURE

Companies

More than 16 000 companies are present in the field of software and computer services in Europe (including hardware vendors and non European firms). Only a few of them (40 to 50) employ more than 1000 employees representing 0.3% of the number of companies but 43% of the market.

European firms are traditionally well positioned in the professional services segment (CGS, Sema Group, SLIGOS, LOGICA) while the software packages segment have always been dominated by the US (ORACLE, Computer Associates, Microsoft). Except IBM (7%) no company holds more than 2 or 3% of the European market.

Strategies

The main actors are resorting to mergers and acquisitions to expand internationally and to become providers of a full range of services. However, each strategic group of competitors adapts this strategic thrust according to its current competitive positioning. For hardware manufacturers, acquisitions are used

to enter new unfamiliar markets and to learn from the acquired companies rather than controlling them, while internal development, relying on existing resources and skills, is adopted in systems integration. Professional services companies play a market share game in Europe. Entry strategies into new geographical markets are mostly based on the acquisition of local firms although few have decided to move into the consulting sector by external growth. Packagists are entering systems integration and professional services segments to minimise their risks and increase the overall profitability of their traditional core segment. This move, which is essentially achieved internally, is eased by the "natural adaptation needs" of most important package during their implementation.

Audit firms prefer internal development when entering the information technology (IT) services market. A pioneer of such moves is Arthur Andersen in the middle of the 1960's, which was soon followed by other majors. End-user firms diversify into the IT services market, particularly in the sector of processing services and to a lesser extent the software package sector, by internal and external development (Daimler-Benz/Debis, BMW/Softlab). As information technology is becoming a board-level issue, strategy consulting firms extend their skills, mainly internally but also through small acquisitions, and develop strategic IT planning and approach for their clients.

OUTLOOK

In the context of growing international competition, Europe will be facing major threats during the 90's which could have important impacts on its future competitive positioning and a more pervasive but real economic impact on other economic sectors in which information technology and software technology are critical (banking, insurance, transportation, electronics and defence).

Despite the competitiveness of European firms in the professional services, Europe is clearly threatened in other main areas of the software and computer services, such as consultancy, packages and processing services (notably facilities management). In the sector of professional services, European firms are also facing competitive pressures and some of them are facing the threat of being acquired by other European and international large groups.

Nevertheless, Europe has several important winning cards to compete successfully and improve its market positioning: strong competence in methodologies and telecommunications capitalised through some European research and development projects (software factory, broad band communication); good competitive positioning in some high value-added activities like systems integration; dynamics of the Single European Market;

Major European groups of software and computer services could improve their competence in the sector of consultancy, notably with regard to strategy and management consulting, in order to gain the same understanding of their potential clients' strategies as the large international American groups (the Big 6).

In the field of software engineering, Europe can rely on its advance in new formal methodology to develop new generation of CASE tools (Computer Aided Software Engineering) facilitating the re-use of software or the re-engineering of old systems. In the same manner, under the dynamics of the single market, Europe can have its own line of software products responding to the specific needs of European firms and ad-

ministrations (accounting, taxes, custom system, social security, health,..).

Other large and pan-European systems can be also initiated at the European level, helping European firms improving their basic competence on software process and technology, and systems integration.

Edited by: Sema Group

The industry is represented at the EC level by: European Computing Services Association (ECSA). Address: Avenue de Cortenberg 79-81, Bte. 7, B-1050 Brussels; tel: (32 2):736 6003, fax: (32 2):736 6006.

Electronic information services

The electronic information services industry includes the provision of financial and company data, market research, business information and news services. According to a joint IMO/EIIA survey of professional hosts and database providers in the EC, the industry generated revenues of some 3 150 million ECU and employed 22 000 people in 1990. The expansion of the electronic information services market in Europe is generating the creation of "transnational" information products. The industry is experiencing an increasing number of joint ventures and cooperative agreements in an effort to develop and serve a pan-European marketplace.

INDUSTRY PROFILE

Description of the sector

Over the last decade, the European Electronic Information Services market has been moving away from its traditional base, founded in the areas of science and technology, towards the domain of specialised information services. These services include amongst others, financial and company data, market research, business information as well as news services.

However the emergence of this market has not been along clearly defined lines. Consequently, the European Electronic Information Services market is somewhat ill-defined, and information about the industry arises out of a collection of irregular non-official industry statistics. One of the major difficulties involved in the measurement of the industry, is the fact that electronic information by-passes export and import regulations, and may go unrecorded in national trade statistics. Additionally, on-line databases which may be accessible internationally through a complex system of gateways, networks and host computers, make the tracking of cross-border information flows virtually impossible.

Nevertheless, despite these apparent obstacles and problems, the following sections will attempt to present an overview of the current state of the European Electronic Information Services market and key trends, both in terms of demand and supply, based on available sources of information. These sources whilst drawn from the industry at large, also include the work of the IMO (Information Market Observatory), which operating under DG XIII in Luxembourg, is charged with improving the understanding of the European Electronic Information Services market.

Main indicators

Table 1 shows some results of a joint IMO/EIIA (European Information Industry Association) survey of professional hosts and database providers in the European Communities.

This survey put the revenues of the suppliers of these services at some 3 150 million ECU in 1990. This shows a 12.5% increase as compared to 1989. This growth whilst significantly lower than for previous years, and attributed to the approaching economic downturn in the UK, is nevertheless higher than for the European economy in general.

The number of people employed by EC-based host and database organisations was 22 000 in 1990, an increase of 3.5% compared to the previous year. The highest growth rate is coming from the sales and marketing functions (more than 10%), whilst data-gathering and editorial functions represent the largest human resources function, with over 40% of the total.

Regarding mode of delivery, ASCII services account for 78% of the on-line sector, and also showed the fastest growth between 1989-90 with 15.1%, reaching a total of 2 054 million ECU. Professional videotex service revenues, which are estimated at about 450 million ECU (including telecommunication costs) account for around 17% of all on-line services in the EC. Including revenues from other unclassified on-line activities, total on-line revenues resulting from all activities are put at 2 638 million ECU in 1990, which is an increase of 13.1% from 1989. By comparison total off-line services increased by 5.9% to 316 million ECU in 1990.

Within the on-line sector, real-time services represent some 59% of the total, growing by 15% over 1989. Over the past three years (1988-90), the proportion between real-time and retrospective services has remained fairly consistent. Optical media (notably CD-ROM), shows a growth of some 31% over 1989-90, and has a market value of 30.5 million ECU in 1990. With respect to subject of interest, financial and business oriented information services, which arise mainly out of real-time services, represent 96% of the market. Scientific, technical and medical subject areas (STM), have only a 2% market share, and a relatively weak growth rate, at a little over 5% between 1989-90.

Geographic distribution of turnover showed that in 1989, around one third of revenues were generated in the same Member State as the hosts/distributors whose services/products

they were purchasing. The remainder was evenly split between intra and extra-EC trade. In 1990, there was a significant growth of intra-EC trade of some 25%, at the expense of exports beyond the EC, with national consumption remaining at the same level. However, the export performance figures need to be considered in light of the fact that the US dollar weakened significantly against most European currencies over this period.

SECTOR ANALYSIS

ASCII

Table 2 shows world production and distribution of electronic databases, from which the concentration in the highly developed economies of North America and the European Community, can be clearly seen. However, despite the greater population size (US population, 244m, EC, 343m), and a comparable economic base (US GDP 4 300 billion ECU, EC GDP 4 200 billion ECU), there are nearly twice as many database producers and host services in North America as in Europe. In the high revenue-generating area of business databases, North America produces three times as many databases as Europe.

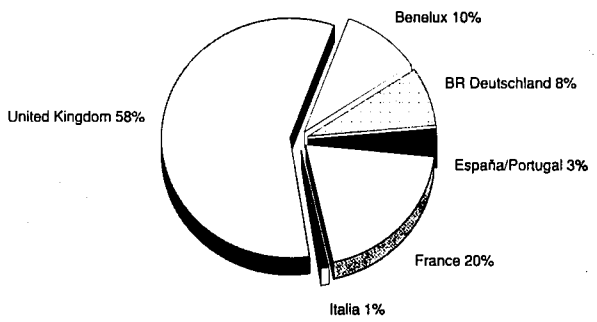
Further details of national ASCII markets, as well as turnover by type of service/product are shown in Tables 3 and 4.

Videotex

The European videotex service market is still very much dominated by France (87% of installed terminals and 80% of videotex service revenues), although other Member States are also making efforts to match the mass dissemination of videotex terminals as achieved by France Telecom. Details are shown in Table 5. The European videotex market is characterised by separate national approaches to videotex development, which has affected standards, terminal distribution policy, as well as procedures for billing customers. Thus there are three different videotex standards in operation, CEPT 1, 2, 3, with only six national videotex networks currently supporting multi-standard services.

One of the key trends in the videotex market has been the growth in the demand in the professional and business sectors. Again France dominates this market through its inherent market size, although only half of French videotex users are considered professional, and account for only 27% or 73 million ECU of videotex revenues attributable to the service providers (telecommunication costs not included). Elsewhere, the ratio

Figure 1: Audiotex
Share of EC installed lines, 1990



Source: Probe Research

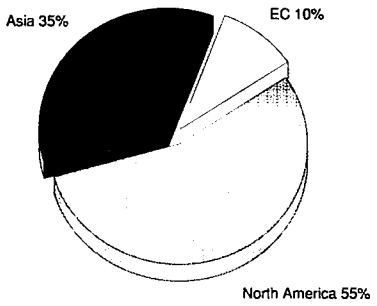
of professional users is much higher (see Table 6), and in the UK for example, travel and stock exchange services are successful applications. However, as with audiotex, there still remains several barriers to the growth and development of international videotex traffic, namely, differing national standards, lack of user awareness and services with a pan-European interest.

Audiotex

Audiotex is defined as those services where information is provided through interactive on-line access to a database using voice or tone recognition. Recently the European audiotex market has been stimulated by a degree of deregulation in the European Telecommunications market. This has allowed a new range of premium rate services (PRS) to be made available. The main advantage of PRS services is that users are charged directly by the network operator, and therefore there is no need to subscribe in advance to those audiotex services required, which in effect encourages demand.

Within Europe the level of market development is very uneven, with the UK, France and Netherlands accounting for more than 90% of the 1990 market, which has been valued at 530 million ECU. Estimation of future market trends are difficult,

Figure 2: CD-ROM
Installed base of CD-ROM drives by continent



Source: Infotech

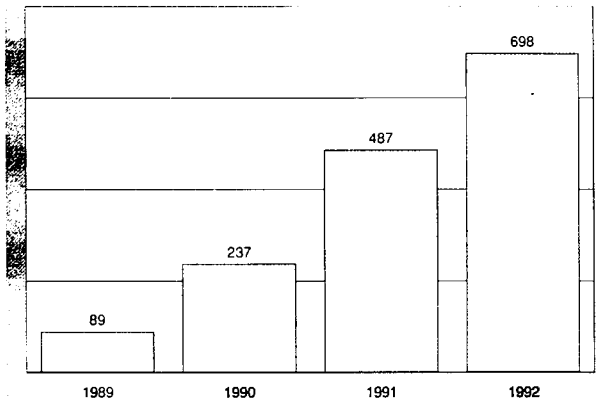
given that there are a variety of barriers which hinder development, particularly in terms of PRS services. However, even from a technical point of view, there are currently no facilities to support the development of European transborder audiotex services, since no interconnections of PRS are available, and there is no single and common free-phone number. Some indication of the European market is given by the 1990 audiotex share of installed lines as seen in Figure 1.

Optical information media

The optical media market, of which a major component is represented by CD-ROM, has shown rapid growth rates in previous years, which makes the collection, validation and processing of data for the production of statistics especially difficult. Although growth in the turnover of the optical media sector between 1989 and 1990 was high at 31%, with revenues of some 30.5 million ECU, the sector is nevertheless still quite small in the EC.

The installed base of CD-ROM drives within Europe compared to North America and Asia is low (see Figure 2), and therefore the European market for CD-ROM is still underdeveloped.

Figure 3: CD-ROM
CD-ROM titles published in Europe, 1989-92



Source: CD-ROM Facts and Figures 1992 (TFPL Publishing)

Worldwide the production of new titles available on CD-ROM has increased steadily over recent years. Although the rate of increase varies according to the source, it can be assumed to be more or less doubling annually. Details of the evolution of the number of European titles given by the organisation TFPL's "CD-ROM Facts and Figures" are shown in Figure 3. One interesting finding by the Optical Publishing Association suggests that by the end of 1992, more than 6 400 commercial titles will be available worldwide. If correct, this means that by 1993 there will be more databases available on CD-ROM than on-line in ASCII mode.

INDUSTRY STRUCTURE

Europe has a number of competitive strengths in the world markets for professional information services. Partly, and not least of which, is the presence of several world-ranking information and media conglomerates within the EC. These companies, notably Reuters, Reed International, Maxwell Communications Corporation, Pearson-Financial Times, Elsevier and VNU, have been active in the field of information services for more than a decade. In addition, Europe is characterised by some large and established markets for professional electronic information services in key areas such as chemicals, pharmaceuticals and financial services.

On the other hand, the European Electronic Information Services market by comparison with North America's, remains relatively underdeveloped. The reasons for this, not only lie in the fact that the European market is more fragmented and heterogeneous, but also that national markets are dominated by national operators. Thus, database services have tended to develop along national lines and national languages. Another weakness arises somewhat paradoxically out of the existence of an efficient supply of traditional (non-electronic) business and professional information in many EC countries. This has the effect of negating the perceived need for electronic information.

OUTLOOK

The electronic information services market in Europe not only faces the challenges of American and increasingly Japanese competition, but also those challenges from within: technological change, diversification and changes of ownership.

The expansion of the pan-European marketplace is also beginning to create "transnational" information products. As a result, there is an increased tendency for joint ventures and co-production arrangements. The creation of a pan-European marketplace is essential for the future of the European information industry. This will be achieved only by:

- the elimination of legal and administrative barriers;
- the convergence of national telematic infrastructures (especially with respect to videotex and audiotex networks);
- the harmonisation of government owned primary data collections.

Such initiatives as the European Commission's IMPACT 2 programme will facilitate the creation of such a marketplace, especially with respect to balancing development between the richer and the less favoured regions. However, it is also important to balance technological and market development with user requirements, through more user friendly access systems.

Telecommunications services
NACE 790

Revenues generated by telecommunications services in the EC totalled 80 billion ECU in 1989. The market is still largely dominated by basic voice services which account for about 85% of total turnover, but other services are expanding rapidly. Total growth during the second half of the 1980s averaged 7% per year, but exceeded 20% for data communication and 50% for mobile communication. The development of the sector will be spurred by changes in information technologies but also by increasing use of digital technology in consumer electronics. The supply of telecom services is still predominantly controlled by national monopolies. Though value added services have been deregulated in most of the Member States, basic services are still monopolised by national operators in nearly all countries. Liberalisation is however prodding the restructuring of the sector.

INDUSTRY PROFILE

Description of the sector

Telecommunications services cover: point to point interconnection (interconnection of persons with each other, of persons with computers and machines, or of machines with each other); and, point to multipoint distribution (distribution of information from one point -man or machine- to a large number of addresses).

The information transmitted can be voice, data, or images (fixed or full motion). Until recently, each of these types of information required the use of a specific network. However, recent networks like ISDN (Integrated Services Digital Networks) allow for the integrated distribution of voice and data.

The transmission can be on line, or real-time, as in the case of telephony. It can also be deferred, when the addressee is not available. The information is stored then and either forwarded at a later stage or retrieved by the addressee (voice mail or mailbox services).

Beyond the pure transmission of information, which is referred to as basic service (telephone, telex), a whole sector of value added services (VAS) has emerged and is bound to develop substantially. Thanks to the digital revolution, the information can be processed, adapted, stored and forwarded as required.

Voice mail or mailbox services already belong to this kind of services, as do protocol conversion services that allow the interconnection of applications activated on two different computer systems.

Mention should also be made of the extension of the videotext, which opens up the value added services market to residential users and small firms. The service is most highly developed in France which, in 1987, had over 90% of all capacity installed within the EC.

Over the coming decade, existing basic infrastructure will start giving way to essentially new services, featuring vast amounts of built-in intelligence. One such example is automatic translation from one language to another to support real-time communication between individuals from different countries.

Access to the services is offered on dedicated networks: Public Switched Telephone Networks (PSTN), Data Networks (PSDN) like X25 networks (Transpac / Datev), and progressively, ISDN.

"Private" networks, most often based on leased capacity (leased lines), allow enterprises to avail of their own transmission and networking capacities on an exclusive basis. Virtual networks share capacities while the user accesses the network when required only (instead of on a permanent basis), while having the impression that he is the sole user.

Networks are becoming increasingly "intelligent" and will become platforms for the provision of brand new services.

The majority of communications are currently established between access points belonging to the fixed infrastructure. A major growth area in telecommunications, though, is the mobile communications sector, where demand currently exceeds capacity, and which is the leading edge of the "universal" network which would allow an addressee to be called in and to call from any part in the world through a combination of fixed and mobile links. Cellular communication being put into place now, is, paving the way for the mobile and cordless communication, freeing the user from being tethered to the network.

Main indicators

In 1991, the world market for telecommunications services totalled 330 billion ECU for a corresponding investment in telecommunications equipment of 83 billion ECU. Growth in total telecommunications services has averaged 7.3% per year since 1986, ranging between 5% for telephone, to about 20% for data communication and more than 50% for mobile communication services.

In the EC, revenues generated in telecommunications services totalled some ECU 80 billion ECU in 1989, with over 900 000 persons employed. Telephone still accounts for the vast majority of the services, with more than 85% of the total, while telex and telegraph, on the decrease, represent less than 2%. The other services account for the remaining 13 %.

Mobile communications, with some 5 to 6 million subscribers in Europe, are expected to reach some 20 million by the late 1990's, particularly with the implementation of the Pan European Digital Cellular System (GSM) and the second generation cordless telephone.

Japan	50.0	40.7

(1) Estimate - rounded figures
(2) Data for reunified Germany.
Source: SEMA GROUP, using UIT data

The networks provided for some 132 million main lines in 1989, a level comparable to that of the USA. Penetration rates ranges between 18 and 56 main lines per 100 inhabitants depending on the country, with an average of about 43 for the EC, against 50 in the USA and 40 in Japan.

Telex services are operated on a separate network which covered about 660 000 lines in the EC in 1989. The number of lines is decreasing in most of the European countries as companies switch to other systems to transfer documents (micro-computers, fax, etc.). Investments in telecoms are substantial. They ranged from 4 to 14% of GDP according to the Member State in 1989.

Foreign trade

International telecommunications services are regulated by a mechanism by which revenue is shared among the countries and carriers involved in the communication. The revenue, based on usage, also depends on the tariffs in the different countries. The European Community had a trade surplus with the United States of around 300 million ECU in 1988. As far as individual Member States are concerned, given that residents in high-income countries generally make longer and more frequent calls, high income countries tend to show a trade deficit in telecommunications services.

National traffic, that is among the Member States of the Community, accounts for more than 90% of total traffic, leaving less than 10% for international, of which intra-European traffic is but one part. By comparison, long distance traffic accounted for more than one third of overall telecommunications services revenues in the USA in 1988.

MARKET FORCES

Demand

Rapid technological progress has an enormous influence on the nature of demand for telecoms services. Until recently, telecommunications essentially meant telephony. Emerging information technologies has allowed for increasingly efficient generation, processing and storage of computer generated in-

formation. Data processing and consumer electronics have both accumulated, on the local level, a fantastic amount of capability which, so far, has been restricted to local usage and passive distribution. The computer is no longer a terminal in the usual communication sense. Comprising an ever expanding network of functional devices, the 60 million personal computers in the world can potentially function as telecommunications switches.

The same holds for the video sector in consumer electronics. As video goes digital, video and computer technology will merge. Smart video, digital video, desktop video or video computer, all describe the same concept of extremely powerful computing machines, which will process not only data, but full motion video. They will, of course, operate interactively and, of course, must be networked globally. To provide interconnection for this local intelligence is the major challenge of the information age.

Telecom users can be divided into two main categories with differing needs and monopsony power: corporate users, and residential users.

Corporate users are driven by price/performance considerations and are developing considerable bargaining power. Advanced users are beginning to ask for broad band capabilities. Communication facilities matching the capabilities of local area networks will be more and more demanded. European users are now becoming as vocal as their American counterparts about the fact that their needs must be met both functionally and economically. If they can't get satisfactory responses from established telecommunications operators, they will increasingly look for alternative answers.

In most cases, residential users, unlike corporate users, cannot afford to subscribe to costly new services, but welcome the provision of services that combine convenience, ease of use and low cost. The penetration of advanced telecommunications services at the household level will take more than just making them available at low tariffs and will require marketing effort to generate broad acceptance. Itemised billing and call transfer,

for instance, have already gained some acceptance in certain countries of the Community.

Supply and competition

Due to the current regulatory situation, supply is still primarily controlled by the main national operators in most of the countries of the Community. In general, basic services continue to be entrusted to the main operator. The United Kingdom, however, has opened the competition for basic services, with Mercury as main contender of British Telecom, and contemplates opening the competition further.

Value added services are generally open to competition, as are, on a concession basis, mobile communications. In the latter case, the combination of limited capacity and fast growing demand have entailed high tariffs. Capacity is increasing, however, and the implementation of the new pan-European cellular system is expected to greatly improve the situation.

As the major operators endeavour to re-position themselves on a deregulated market, technological know-how, R&D and marketing have become key competitive factors. Long distance, particularly transatlantic, tariffs have decreased as a consequence of competition and forced the operators to progressively re-balance their tariff structure, reducing the cross-subsidies which were traditionally the rule between the profitable long distance communications and the local communications.

Productivity, as expressed by the number of main lines per worker, increased during the 1980s. In countries such as the United Kingdom, Spain, Belgium and Ireland, staff cuts were necessary to achieve those productivity gains. More recent staff cuts include the 18800 people let go by British Telecom in 1991, and an estimated 16000 in 1992.

Two main inputs are purchased by the telecom operators (TO) for the production of telecommunications services: telecommunications equipment (switching, transmission equipment), often supplied by large multinational groups, and software, provided either by equipment producers or by specialised software houses.

INDUSTRY STRUCTURE

Competition is still limited by current regulations, but the liberalisation that has already taken place and the prospect of further such steps sharpen the appetite of new entrants.

Telecom operators on one side, like AT&T, the American RBOC's (Regional Bell Operating Companies), USA long distance carriers or the Japanese NTT, are all eyeing the large and profitable European market or have already entered into joint-ventures, or undertaken acquisitions or cooperation agreements. The following examples show the diversity of activities and countries targeted.

AT&T: agreements with several European carriers on Virtual Private Networks; agreement with PTT Netherlands; increased service activity in all major European countries; individual contracts with national operators in specific sectors (e.g. USA direct services);

SPRINT: joint-venture with British Waterways for the establishment of the third UK carrier;

Bell Atlantic: agreements in Denmark (second GSM licence); in Spain (cooperation with IBM in network management); and in Czechoslovakia (cellular, public switching);

Bell South: agreements in France (cellular, cable TV) and in the UK (paging);

NYNEX: agreements in France (Network control, telemarketing); in Germany (software services); in Hungary (banking software) and in UK (cable TV franchises); and

Pacific Telesis: cooperation with Mannesman consortium (Cellular D2 Network); agreements in the UK (personal communication network, cable TV).

In the reverse direction, European operators are vying for size and market share on the international market, through direct investment (e.g. stock acquisition by France Telecom in Argentina, Poland and Mexico operators, British Telecom or Cable and Wireless investments in the USA, STET in North and South America, and Deutsche Telekom in Eastern Europe) or through agreements with customers or other operators overseas to supply them with global networking and network management services.

Potential new entrants on the "traditional" telecommunications scene are also to be observed among cable operators (traditional or new comers like utilities providers) which are waiting for the regulations to allow them to provide telecommunications services. Conversely, some telecom operators are eyeing the cable TV market.

Projects for pan-European broad band networking are also under elaboration, like METRAN or GEN in the traditional framework of operators cooperation or HERMES, an initiative put forward by a consortium of European railways from 11 countries, of large private companies (Daimler Benz AG, Compagnie de Suez) and of foreign carriers (Sprint International, Nynex International). Both projects are taking longer than foreseen and are experiencing difficulties in the process of negotiations among so many partners.

Despite all these projects and new ventures, the impact on the concentration of telecoms operators in the Community has been weak, with telecommunications services mainly in the hands of the traditional operators. The only exception so far is the United Kingdom where British Telecom accounts for 85% of the total market, the rest being shared between Mercury (13%) and other smaller operators (2%). Turning to value added services, all the EC markets but Italy, Luxembourg and Greece are liberalised, but the market shares of private suppliers remain very small (usually at about 1%). Similarly, France, Spain, Germany, and Portugal have already granted licences to private mobile radio operators, but their share is negligible. So far, only the United Kingdom has granted licences for the for the development of telepoint, private mobile radio (PMR) and PCN networks.

REGULATIONS

The sector is facing major regulatory changes as a result of increasing liberalisation. Two kinds of move have been made so far in Europe:

- partial or total privatisation of telecom operators and the introduction of competition in the provision of services;
- liberalisation and opening to competition the provision of telecom equipment.

Most countries have so far kept the provision of basic services under state monopoly, whereas value added services have generally been opened to competition. Provision of services in this context must rely on the principle of equal access to basic networks and networks of third parties to allow for the provision of these services. This is the "open network provision" policy which the EC has been promoting for years.

The other liberalisation promotion favoured by the EC has been the opening of the telecom equipment market, so far largely restricted to national suppliers in Europe. This is slowly coming into force, but decades of close relationships and habits cannot be overcome rapidly and progress is limited so far.

Table 11 gives a summary of the regulatory situation in Europe, particularly the main operators, the services which have been liberalised, and the terminal markets open to competition.

Privatisation has already been conducted in the United Kingdom and it is foreseen in 1993 in countries such as Belgium, Denmark, Germany, Ireland, and Portugal.

Pursuing its push towards a European deregulated market, the European Commission has adopted, in 1991, two long awaited directives: one on leased lines, lifting the technical restrictions imposed by the operators on the interconnection of leased line networks to the public network (Open Network Provision, applicability to leased lines); and the other on satellite communications, breaking up satellite communications monopolies for both TV and other communications purposes.

The enforcement of the latter implies a thorough revision of the Eutelsat, Intelsat and Immarsat conventions, and agreements from individual member states to allow direct access to capacity.

OUTLOOK

Telecommunications are undergoing a profound and rapid evolution. With and beyond the extension of current services, new services will appear and transform the economy, allowing new approaches to employment (teleworking, telecommuting), to education and training, to the assistance to the physically handicapped or to the environment and disaster management systems, to name only few.

Among the major trends currently underway are the development of broad band services (for large volumes of data and full motion picture), multimedia services, mobile and cordless services and network management services (intelligent networks).

The opening up of Eastern Europe is another major area of development. Although the countries of Eastern Europe currently lag in terms of telecommunications services, these markets have the potential to develop quickly by benefiting right away from new technologies (like, for instance, France did in the 1970s with the digital technology). Optical fibre, now or soon as cheap as copper, can be used for local networks, and mobile/cellular technology can be an economic and rapid solution to urgent needs. Eastern countries are about to or intend to liberalise and deregulate their telecommunications and call for a rapid assistance to built up their networks and operations. Various operators have already responded in investing (in Poland, for instance) or will do so in the coming years. German presence is also significant in the Central European Countries.

Finally, as has been mentioned earlier, competition in the telecom services sector is about to change profoundly and the operators are endeavouring to position/reposition themselves on the international scene in preparation of the global communications world of tomorrow.

Education
NACE 93

Total public expenditure on education represents approximately 10% of total public expenditure in most EC countries, compared with figures of 13% or so in the USA and Japan. Europe's future will be built essentially on the quality of its human resources and therefore on the past and future ability of its member states and economic participants to develop and disseminate training at school level (teaching in the kindergarten, in primary and secondary schools and at university level), and to accompany professional careers in relation to all common and specific economic and social factors. Through its content, organisation and the quality of its results creating expertise in each member country, education is the first way of satisfying demands and changing conditions in the labour market. In this sense, it is the most important investment in every country.

INDUSTRY PROFILE

Description of the sector

The structure and evolution of the teaching sector reflect the way in which each country has attempted to build in historical components of its main demographic and economic factors (mainly in terms of activity and jobs), taking the best possible account of foreseeable and estimated developments, and the extent to which they have succeeded.

Its organisation is different according to countries, since each has organised its own education system giving different priorities to technical and professional teaching, incorporating part time education at very different scales, and defining diploma types and levels in a specific manner, particularly in higher education corresponding to nonhomogeneous theoretical ages.

Also, the importance of private education is very variable within the various education systems. This sector includes all structured teaching activities in schools or universities which issue diplomas at any level.

This sector's characteristics makes it relatively dynamic, and atypical of other activity sectors.

Recent trends

Table 1 shows the two main trends essential for understanding the main developments in education in Europe.

The first trend relates to demographic changes in the EC Member States, characterised by a general weakness. Thus between 1980 and 1990 the growth rate in West Germany was negative (average 0.2% per year); it was close to zero in Belgium, Denmark, Italy, Luxembourg and the United Kingdom, about 0.5% in Spain, France and Portugal, and 0.9% in Ireland during the same period.

Logically, this lack of demographic vitality is combined with a relative ageing of the population of the Member States. For example, the proportion of the population under 15 years old to the population between 15 and 65 years old in West Germany changed from 27% in 1980 to 21% in 1990, from 34% to 25% in Italy, and from 42% to 31% in Spain.

This is obviously a difficult trend which affects all Europe, and in which the less developed countries (particularly in Southern Europe) are reducing their differences with the more developed countries. It has a strong influence on the size of the educated population and on their proportion in the total population.

The second main trend relates to increasing school attendance. A significant increase in the educated population is caused by a relative diversification of some syllabuses (secondary technical and professional education, tertiary education) in order to take advantage of needs in the job market and technical developments. However, this increase also depends on the increased time that students need to spend in the education system (increased higher education but also protection against unemployment and a political desire of many countries to increase the opportunity for as many students as complete their secondary studies).

These two opposing trends work together, with the second only partly compensating the negative effect of the first.

Portugal is a special case because, despite its demographic growth which is average within the community, it is distinguished by its fairly stable school attendance ratio.

Referring to Table 2, the most significant point concerns the very large increase in the number of students registered for tertiary education. Over the last 15 years this growth was 60%, whereas the number of students receiving primary education decreased by more than 23%. In this case we can clearly see the effect of smaller classes in the education system, in an age group at which school attendance is compulsory.

The drop in the total school population is almost equal to the difference between the increased number of higher education students and the reduced number of primary students.

According to the OECD, in 1987-88 about four million people were employed in the education sector in the EC (taking into account only primary, secondary and special education and excluding the administrative personnel). About 1.5 million people worked in primary education schools, about 2.4 million in secondary schools and 0.1 million in special schools.

Developments in education for girls

The proportion of girls within the 524 year old population in the community is 49% (1985). This ratio is almost identical in all countries.

The proportion of girls receiving full time education within this same period was 49%. Their education ratio is therefore the same as their proportion within the 5 to 24 year old population.

This total number hides some disparities: up to 17 years old girls are proportionally more numerous than boys, although this changes later. After 18 years old there are more boys than girls in West Germany, Greece, the Netherlands and the United Kingdom. In Ireland and in France, girls are more highly educated than boys up to 19 years old, whereas in Belgium this is true up to 20 years old.

The general trend is undoubtedly towards seeing the same ratio in the education system as their proportion within the population.

However, one should note that the unemployment rate for girls is higher than that for boys (24.3% compared with 19.6% for the under 25 years of age in 1987). This difference may be partly due to the difference in the school leaving age, but is no doubt also partly due to traditional - but reducing practice of hiring boys rather than girls in what are still predominantly male work environments, or due to potential maternity risks, etc.

Private education

In Europe, private education, in other words education that is not directly under the authority of the State, is given varying degrees of importance by country as a function of education level and the type of relation with the State, particularly concerning financing.

Thus, the proportion of private education in Belgium and the Netherlands is very high, due to the fact that it is entirely covered by public funds. There are also hybrid formulas in which State participation methods vary. The higher the amount paid to private school financing by the State, the larger the proportion occupied by private schools in the education system.

There are many reasons explaining why the private sector exists and the varying support given to it. These include religious and historic factors or image - related factors along with a possible difference in quality, and special training.

The pedagogic environment

Table 4 shows the trend towards a relative reduction in the number of students per teacher, such that some age groups

benefit from better teaching ratio. There are two reasons for this. The first is pedagogic, based on the principle that teaching efficiency improves when there are fewer students, while the second relates to the logic of adapting to demographic changes.

These numbers hide important differences in that they are national averages whereas there are reduced numbers of students per teacher due to population drops in some areas, and at the same time there are sometimes large increases in suburban areas. This urbanisation phenomenon, almost complete in countries in Northern Europe (97% urbanisation ratio in Belgium) is continuing in other countries, particularly in the South (for example the urbanisation ratio of 32% in Portugal). It will result in further adjustments in the number of students per teacher, and will be affected by some hysteresis.

SECONDARY SCHOOLS

This is the sector in which there are the largest differences between teaching in the various countries.

These differences are related to teaching matter (general or polyvalent compared with technical or professional), and also to its organisation (full time and part time or apprenticeships).

In 1987, general or polyvalent full time education (full time in all countries) represented 41% of all education in the second part of secondary education for the entire community. This ratio was 25% for West Germany and Italy, 96% for Portugal and 42% for France, compared with 72.2% in Japan and 100% in Canada and USA.

These differences are the result of national policies which heterogeneously encourage the introduction of technical and professional components into education and therefore preparation for entry into the labour market.

Quantitatively, the senior secondary education across the community provides secondary education representing its concern with professional needs but also showing up differences in selected approaches.

HIGHER EDUCATION

The challenges faced by the European community (trade competition, research and development, demography,...) have already resulted in a relative drop in the proportion of unqualified labour. This trend will undoubtedly continue. For example:

- between 1980 and 2000, the population of technicians in Denmark is expected to increase from 10% to 30%.
- in Germany over the same period, the demand for university graduates will increase by 1 600 000.
- in France between 1982 and 2000, the proportion of students with at least a level 5 degree (first degree issued after two years at university) will increase from 11% to 21%.

There are differences between Member States partly due to the initial situation, characterised in the case of Greece, Portugal and Ireland by a relatively low proportion of students. In these cases, there is a catching up effect, and also a political objective of creating the ability to meet the main economic and social challenges.

The ratio used here is biased due to the fact that the reference population, due to its ageing, is not identical in composition over the two periods. The proportion of women having received higher education increased from 40.40% in 1975 to 46.40 % in 1985 (more than 50% in France and Portugal) therefore approaching the proportion of girls in the 5-24 year old population.

Higher education is also characterised by the level of diplomas obtained by students (see Table 7).

Globally

There are important differences between the percentage of the highest level graduates (6 and 7) in community countries and the equivalent values in Canada, Japan and the USA. In 1987, the level achieved in the EC was less than in the countries mentioned. Different efforts therefore need to be made in the different countries in order to reach the same level of higher education as in the USA, Canada and Japan.

Graduates

Qualitatively, related to changes in high level abilities related to new technologies, it is interesting to note the ratio of natural sciences and engineering sciences taught in universities (excluding non-university education which exists in some countries - for example Engineering Schools in France).

Scientific characteristics of the higher education

Table 8 shows the diversity of situations in EC countries related to two aspects:

- the historical and cultural aspect, which partly explains the ratio that each country assigns to engineering sciences and natural sciences in university education compared with the total number of programs, and the ratio for each of these sciences.
- the socio-economic aspect, concerning the importance given to engineers in economic activities: as this increases, the engineering function is better recognised and rewarded; the case of Japan is significant in this respect.

Overseas students

There is a very big difference concerning the presence of foreign students in higher education, both in absolute and relative terms.

There is a very strong correlation in terms of origin, between the representation of some continents and the history of the country (former colonies, common language, which is obvious in the case of France, Belgium, and the Netherlands. Apart from France and Belgium, the geographic mobility of students is still low, both globally and between countries in the community. In this case, origin is undoubtedly related to:

- the fairly limited knowledge of the characteristics and possibilities of higher education in other countries;
- the non-existence of a genuine community work market;
- the fear of additional financial costs;
- lack of understanding of the language.

ECONOMIC FACTORS

Education is generally considered as a public consumer item, with a price close to zero and which, in any case, does not reflect the costs to produce it. However, it is sometimes considered as a private consumer item for which the price is fixed freely by schools.

Education is also an investment item since it prepares the future of the individual and the nation.

The complexity of the education concept and the various perceptions that it covers make economic and qualitative evaluations difficult and inaccurate, and also make comparisons between countries difficult.

In order to compare education expenditures between countries, we need some common points: the concept of Purchasing Power Parity specific to education, recently developed by the OECD, allows to convert different foreign currencies into a same unit by taking into account the relative purchasing power of different currencies. Using this method, the relative effects of education expenditures and their changes may be analysed more precisely.

The two main indicators that are used are the total public expenditures for education per student as a percentage of the GDP per student (Table 10), and the total public expenditure for education as a percentage of the total public expenditure (Table 11).

(1) Taking account of Purchasing Power Parity
Source OECD : Education expenditures, coast and financing trench analysis, 1970-1988

Public education expenditures schematically follow two main expenditure types: capital expenditures (facilities, infrastructures), and current expenditures (mainly salaries and in some countries subsidies to private education). By definition, the latter are higher and represent the majority of expenditures (between 85% and 99% depending on the country). Their elasticity is low, meaning that any capital expenditure can only be a supplementary expense and appears to be treated as such.

In general, public teaching expenditures are proportional to the Gross Domestic Product (6.2% for Ireland, 4.1% for Portugal, 4.8 for the United Kingdom, 6.9% for the Netherlands, 4.0% for Greece in 1987). However these major differences are influenced by the catching up trend for less developed countries in which the demographic component has had a real influence on education expenditures up to the end of the 1980s.

In 1987, this proportion varied between 3.8% for Greece and 6.9% for the Netherlands, namely a ratio of 2. The same ratio was 2.7 in 1970.

In general, the table shows a wide dispersion for this indicator, however, this is not surprising considering the difference in the development level of the observed countries. It is interesting to note that the countries with the highest levels in the early 1970s (the United Kingdom and the Netherlands, and the United States and Canada on the other part) are precisely those which dropped during the period under consideration. The reverse phenomenon is true for countries with the lowest ratios, particularly Greece and Portugal. It is therefore possible to talk about a catch up phenomenon for the countries lagging behind, itself contributing to convergence of the observed ratios since differences are reduced.

These countries would therefore increase their efforts in the education field as a function of the economic development level achieved.

The first indicator (Table 10) shows a difference between less developed countries in the EC and the more economically advanced countries, although the difference between these two groups tended to reduce between 1970 and 1988. The fundamental reasons are unchanged - demographic changes, and efforts made to reduce the differential by countries such as Portugal which increased by 100% between 1973 and 1988. Greece only maintains its level of 50% percent relative to the Netherlands. This indicator has been fairly stable in other countries, except in the United Kingdom which experienced a major drop, representing the relative disengagement of this country's Government from financing education in general, in particular since the middle of the 1980s.

It also appears - taking account of the Purchasing Power Parity method - that a fairly constant relation has been maintained in recent years between public expenditures per student and the GDP per capita.

The second indicator (Table 11) shows another approach to public education expenditures. The trend for the European countries studied is almost always downwards, which would no doubt be a concern if part of this trend were not due to the influence of a relative reduction in the educated population.

EC countries classified as less developed generally have lower values than the other Member States or than the USA and Canada. This also confirms the fact that education expenditures are a function not only of the development level, but also of priorities and choices defined by governments. The case of West Germany is undoubtedly partly a result of demographic changes and of efforts made in education in the 1960s.

Convergence of this indicator over the same observation period (1970-1988) is a result of lower values recorded for all countries.

This variation is also due to a less important relative increase in education expenditures relative to other items in national budgets.

Nevertheless it is not easy to interpret this relative reduction as a sign of an increasing efficiency of education systems, since this efficiency cannot be measured in terms of education or diplomas only, but must include socio-economic effects.

Considering demographic changes in European Community countries and the ratio of 18 to 25 year olds within the total population, it is interesting to note the attitude of the various

(1) Taking account of Purchasing Power Parity
Source OECD : Education expenditures, coast and financing trench analysis, 1970-1988

governments towards higher education. This comment is particularly important in that European institutions are strongly encouraging the development of higher education and the mobility of European students by the implementation of EC programs. Three trends have developed over a long period (1970-1988): the trend characterised by Portugal which made a major effort in its higher education and with an average ratio over this period of 11.4%, the trend in Ireland, Greece and Italy where the ratios were between 5.5% and 7.3%, and finally that typical of other countries with ratios of between 1.5% and 2.1% which appears to characterise an apparent maturity of financial efforts made for this level of education.

In as much as higher education is increasing in all countries studied, this would appear to mean that - still using the Purchasing Power Parity method - it is difficult to place real expenditures in a genuine continuum; there are signs of individual efforts (major infrastructure or education projects) succeeded by periods of stability. Faced with the importance of the challenges to countries, it may be important to consider the public financial effect dedicated to higher education within a long term view essential to its efficiency. Unfortunately, measurements of this efficiency can often only be made based on economic and social results observed several years after the expenditures were made.

The catching up effort made in education in general is thus confirmed in higher education.

EC POLICIES AND FINANCING

The developed world is inexorably advancing into a qualifications society where everyone seeking secure employment will require a qualification, where activities which in the past did not require special skills or knowledge now require such, and where the unqualified will be largely excluded from the labour market. The Community has taken these radical changes as well as the special needs of the post-1992 workforce into account when it decided on a number of strategic policy actions and programmes.

In this context, the Community has implemented a number of programmes to stimulate and encourage recognition of education and to improve its quality by increasing exchanges of information and experience and encouraging mobility of students and knowledge.

The major EC industrial training programmes are:

- COMETT, which assists with the development of transnational education by cooperation between companies (particularly small and medium sized companies) and universities in industrial and technological fields. COMETT aims to exploit, in particular, the continental dimensions of the Internal Market, plus EFTA, in an area characterised by increasing economies of scale, particularly via transnational, sectoral and regional networks and training projects. The programme has so far financed 7000 training courses, involving 150 000 persons, 10 000 firms, 2 400 universities and 4 000 other organisations.
- ERASMUS, contributing to increased mobility of students receiving higher education with recognition of study credits within the Community, and cooperation between universities (university cooperation programs, the implementation of the "ECTS" (European Capitalisable Credit Transfer System" experiment with a 1990-1992 budget of 192 million ECU.
- LINGUA, designed for the promotion of foreign languages through teachers and relations between students - 200 million ECU for the 1990-1994 period.
- EUROTECNET is an innovation promotion program within the professional training field, taking account of technological transfers and their consequences on employment, work and qualifications. It contributes to the development of new abilities and qualifications. EC support was 7.5 million ECU for 1990-1993.
- FORCE, which provides incentives for institutions and enterprises in the Member States to invest in continuing vocational training and the promotion of wider access to training and development of transnational measures at EC level. It is organised to work interactively with the objectives and actions carried out by ESF (European Social Fund), the EUROTECNET and COMETT programs, IRIS networks. Some 24 million ECU were allocated for 1990-1991, plus 61 million ECU from the ESF.

Note also the existence of:

- EURYDICE, an information network about education within the EC for which the public consists of responsible national, regional and local authorities.
- YOUTH FOR EUROPE which facilitates student exchanges.
- YOUNG WORKER EXCHANGES (18 to 28 years old), designed to complement and enrich their professional training in other Community countries.
- IRIS, European youth training program network.
- PETRA, an action program for training and the preparation of young persons for adult and professional life (transnational partnership projects, youth initiation projects). This program had a financial budget of 40 million ECU for the 1987-1992 period.

OUTLOOK

The above information and comments raise a number of questions about future developments in this sector.

The first development initiated throughout the Community concerns developments in higher education. In this respect, it is worth mentioning the obligation of European education systems to:

- increase the proportion assigned to scientific and technical programs in order to satisfy the needs of senior technicians and engineers in the various economic sectors;
- increase relations between these economic sectors by making more use of engineers and research workers from industry in education or by increasing common projects;
- search for more harmonisation projects between universities and countries, while maintaining individuality, on syllabuses and teaching programs in order to improve collective vitality.

Some progress has already been made in these various fields, and this must not be only increased and consolidated, but also made better known and shared; the various EC projects contribute towards this.

The second development concerns globally improving the efficiency of education systems. It is obvious that this efficiency may be measured individually by granting diplomas; in reality its effect as an investment will be felt throughout the subsequent career.

A major effort must be undertaken concerning these two dimensions in order to integrate all education techniques as far as possible (remote education, interactive computer assisted education,...), to allow teachers to concentrate more on their main objective: to take the necessary steps to ensure that future workers learn how to learn and make a self-training effort that will stand them in good stead for self-adaptation throughout their professional careers.

Related to the above point, and taking account of actual difficulties generated by viscosity in the education system related to the labour market and resulting in about 15 million unemployed in 1990 (annual average), there is a more and more urgent need to make efforts in two directions. For the young, methods of reinserting them into school activities (giving them the opportunity to approach, or to be comparable with those that have been able to follow standard syllabuses), or to include them in training programs to make them operational and satisfy the needs of various economic sectors. Major efforts have been made, frequently encouraged by the necessity to cope with practical situations and with a real concern for foresight. For other job seekers who have already had a professional activity, experience has shown that reconversion problems are better solved when they are anticipated.

The example of a number of companies who have implemented reconversion operations (possibly leading to diplomas), sometimes months or years before a reduction in the workforce materialises, demonstrates the benefits of formulas which undoubtedly require public assistance, but also a confirmation of their will and commitment.

Finally, we should emphasise the influence, which will increase in future years, of the arrival into the secondary education systems of the smaller numbers of students currently in the primary education system. The question of a reorganisation or redeployment of infrastructures and teaching facilities and in terms of numbers and abilities of teachers has already arisen in some countries and will arise in others. It is a controlling factor in the ability of all education systems to efficiently manage the situation with respect to the qualitative and quantitative development of higher education. In short, capital education resources and teachers must be provided to match these needs as well as possible, reducing differences between EC countries in order to optimise competitiveness and social harmony within the EC.

Written by: Quaternaire Développement

Health care services
NACE 95B1, 95C1

Spending on health care amounted to 390 billion ECU in the EC in 1991. The sector provides employment for approximately 6.9 million persons. The rapid increases in health care expenditure during the mid-1980s alarmed governments. This resulted in spurious health care cost containment programmes being implemented throughout the EC. The challenge beset today's governments is to contain health care costs, while increasing services, without reducing quality. This implies that some organisational changes and new policies must be made over the next few years. Public and private hospitals for instance are now becoming familiar with efficiency and quality evaluations.
During the 1990s, emphasis will be placed on transferring part of the institutional sector budget to the more cost effective home care and community care sector. In some Member States, there is also still a need for substantial investment in health care. Even in the countries with the best developed health care systems, additional money will be required to provide for services in areas where the system has always been lacking, e.g. full reimbursement of medical supplies for the chronic ill.

INDUSTRY PROFILE

Description of the sector

There are many healthrelated services. They comprise hospitals and clinics, registered nursing homes, special treatment centres, polyclinics, first-aid centres, health centres, dentists, paramedical centres, home medical supplies and nursing services, mobile medical equipment services, leased high nursing care services, primary care provided by general practitioners, specialist medical and surgical cabinets, psychiatric institutions, rehabilitation services, community nurses, chemists, drug stores, pharmacies and parapharma medical supplies services.

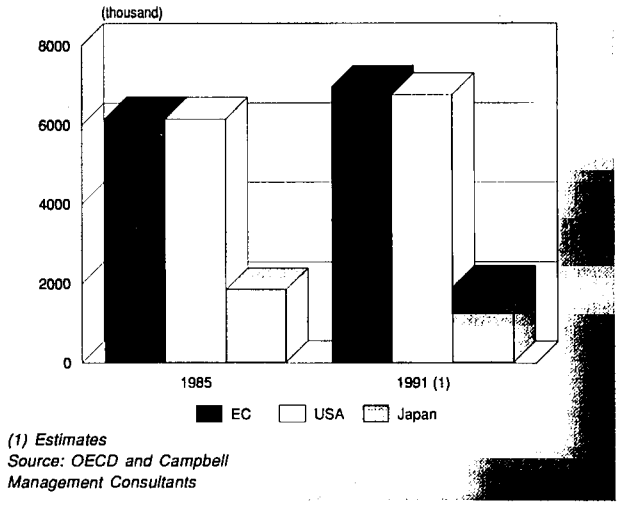
Because of the overlap between health care and social care, it is difficult to draw a line between the two. This also poses a major problem when it comes to assessing health care expenditure. This is the reason why health care expenditure data often differ from one official source to another.

Private hospitals account for an important percentage of institutional care services. Many had their roots as charitable hospitals, founded by religious bodies, when the institutional system was in its infancy. Today many of them are included in national health care plans.

Private commercial enterprises are newer to the system and provide additional hospital, clinic, day centre, and nursing home facilities (in the United Kingdom almost entirely private); they are mainly a result of developments in health insurance paid to private sickness funds or commercial insurance companies. In most European Community countries they are an important part of the health care system, which would be unable to cope without them. In Italy private hospitals are an important part of the hospital system working under convention (law 833/78) within the national health service (SSN).

The home-care and primary care sector in its present form is new. Home-care probably existed before hospitals. Family doctor practices, which provided almost all primary care in the 1960s, are being replaced by health centres. There is also an important trend of specialised physicians leaving the institutional environment and opening practices in the community.

Figure 1: Health care services
International comparison of employment



(1) Estimates
Source: OECD and Campbell Management Consultants

Main indicators

The main sources of revenue for the sector are national public health insurance plans and private health insurance contributions. Organisation of the former is very disparate across the EC. Public health funds are collected through sickness fund agencies (e.g. ziekenfonds and mutuelles), national insurance contributions or by taxation. Private health insurances are paid by persons who opt for additional or alternate coverage to national health provision.

Other sources of revenue are contributions which are not reimbursable, made by patients directly to care providers or drug and medical supplies dispensaries. These payments amount to a substantial sum, and are often unaccounted for in estimations of health care expenditure. In some countries it is not necessary to make payments for most health services whereas in others payments must be made by the patients or their relatives and then reclaimed through sickness funds.

Private health insurances work in a similar way. Sometimes there are agreements between private and publicly owned hospitals to settle accounts directly, and other times the patient must pay directly and then claim from a private insurance body retrospectively.

Day hospital care, enabling the patient to be sent home after a minor operation is slowly spreading in the EC. In parallel, institutions which provide care for chronically ill patients and the elderly have had a sharp increase, corresponding to rising needs of an ageing population. More recently, some public hospitals in France have expressed interest in working with hotel groups. These would provide facilities next to hospital complexes to cater for aftercare of patients who have undergone minimally invasive surgery such as laparoscopic surgery.

International comparison

The EC as a whole spends more per capita on health care than Japan, but significantly less than the USA. Currency exchange rates affect the comparison, however. Expenditures per GDP are also not particularly good indicators of the state of nations' health care programmes, but can be used to show how health care expenditure is developing.

Ironically, the better systems get at treating people with life-threatening illnesses, the more times these people will go through the system. In the 1950s for instance, when many health care systems were at an early stage of development, patients with heart disease, cancer, chronic kidney failure, and diabetes often died early. In the 1990s they can be successfully treated and sometimes cured. The health care system has thus tended to become more expensive, and more difficult

(1) Estimates
Source: OECD estimates

to fund. Moreover, as more new treatments become available, some requiring high cost technology, there is a greater demand for them, and this adds to the problem of spiralling costs.

However, even with these improvements a large group of people still fail to get full treatment. This is another important measure of health care status. Apparently, a minority of people fail to obtain treatment in some health and social security systems because of their financial income status. Whereas most people receive excellent care, some minorities get virtually none. This applies both to Europe and to the USA.

Health care concerns more than just hospitalisation. Primary care, convalescence and the access to other services such as those offered by dentists, opticians, and aids for the infirm are also very important. There is still a long way to go for some members of European society to have fair treatment. This applies to the chronic ill such as diabetics, ostomates, and incontinent people. Diabetes, the major chronic disease, is often poorly diagnosed according to health experts due to inadequate screening. Recently many national screening programmes have incorporated blood glucose monitoring. However, the majority of insulin dependant diabetics in the EC do not receive full reimbursement for all of the supplies they use, while other, chronic ill, people get the whole or majority of the cost paid by the health care system.

Clearly the very large sum of money involved in health care has prevented some authorities from providing full support. The United Kingdom has one of the best programmes for people with chronic health and hygiene problems in terms allowing them access to necessary supplies free of charge. Some sickness fund based health care systems fare poorly in this area, e.g. those of Belgium and Germany.

Because of these different approaches to health care financing, a large gap has opened between EC countries. The quality of health care varies as a result. The systems with the poorest general performances are those which developed using mainly publicly run national health services. The United Kingdom, a pioneer in national health care provision, was the best service in Europe just after the Second World War. However, by the 1970s, in the hospital environment it began to fall behind standards set by other countries, such as Belgium, Denmark,

Source: OECD estimates

France, Germany, Luxembourg, and the Netherlands. This is because countries with "reimbursement per act or service" systems have allowed an almost unlimited use of health care resources. Consequently, as the systems required more money, individuals and their employers were made to pay more into it according to demand, not subject to maximum budget constraints.

Foreign trade

Within EC countries and with other countries, it is difficult to assess exports of health care services, i.e. facilities for the benefit of non-residents, when they pay for this out of their own purse. The export of health care services payable by social security organisations within the EC is limited by Community regulations. It includes migrants and patients residing near borders, emergency care during international transits (E111), and where treatment is authorised by the patient's own social security organisation (E112) because it is not available locally. Some centres of excellence rely upon patients travelling internationally to be able to maintain continuous specialty services or further develop pioneering work.

Private clinics provide services for residents of many extra-EC countries. These are either covered by international agreements or individual financing. Often they are due to historic relationships, especially with ex-colonies. Examples include Algerians and Moroccans treated in France, Libyans in Italy, and Latin Americans in Spain. These patients seek particularly the services of highly specialised private clinics which offer superior treatments to those found in hospitals in their own countries. Commonly they are affluent members of societies in those countries.

MARKET FORCES

Demand

Demand for continued improvements in health services mainly by health care professionals is one major reason for cost increases in health care in every country within the EC. This has resulted in improved quality of life and an increased life expectancy of individuals living in the EC, which is the system's main aim.

Health care in the 1990s often makes routine use of technologies unimaginable only two decades ago, and could not have been achieved without sending costs spiralling. Other factors contributing to growth in health expenditure are multiple. Some main ones are: the public seeking more health services from the system, the development of new services including screening programmes, the development of professional personnel in the sector, increased capital investments, and increasing costs of better treatments and medical supplies.

In some countries commercial enterprises are encouraged to participate in the provision of all aspects of health care (includes France, Spain, Germany, Greece, and more recently, the United Kingdom and Ireland). Whereas in others they are prevented by law or de facto from owning hospitals, (includes Belgium, Luxembourg, and the Netherlands). In the other countries (Denmark, Portugal and Italy) commercial clinics have to compete in environments where the major emphasis is on developing national health care through the establishment of publicly owned hospitals.

Private hospital chains probably consider the obvious barriers against them in some countries to be unfair, and not in the spirit of the single European market. Since state monopolies are being dismantled elsewhere the private professional hospitals could consider that they are being unfairly discriminated against.

Any idea that hospitals should be non-profit making, because they may trade quality of service for profits, is also unfounded. The reality is that the latter provide very high quality services, which are often charged "cost plus" to the patient's health insurance company. Many leading physicians work in private professional hospitals. The greatest danger of qualitylapse is more in the public hospital sector where the number of patients seeking treatment is unlimited and budgets are controlled by lump sum allocations.

The control of quality should be a legal one, which is the direction currently being taken in most countries to ensure good practice. Throughout the 1990s the legal profession has increased its participation in discussions and conferences on this subject. Health authorities are having to dismantle some protection they have built up for hospital staff, and make them accountable for all of their actions. In the United Kingdom, Crown protection of the national health service (NHS) is no longer in force; formerly no patient in the United Kingdom could sue the NHS.

Cost containment of health care in Germany was attempted in 1987 when the Bundesrat passed a law to not allow hospitals to have retrospective calculated claims for medical acts. It was thought by many observers that several least efficient hospitals would go out of business after this act. However, most were saved because of oil prices falling. This had the consequence of reducing heating bills, which is an important part of hospital expenditure for hospitals in the northern part of Europe.

Many German hospitals still rely heavily on making profits on the sums they get for convalescence following surgery. Even patients that have been operated on using minimally invasive surgery are kept more than eight days following surgery in most German hospitals, in stark contrast in other countries patients which are treated using the same techniques are sent home after two or three days.

Developments in the United Kingdom are currently providing important opportunities for private enterprises. After many years strongly supporting centrally controlled publicly owned facilities, the conservative government has opted for a system of decentralised power. It aims at achieving greater efficiency by allowing market forces to find some lowest common denominators, and do away with nugatory practices of the civil service based system. Hospitals which can fulfil certain conditions, which prove they can be self-governing, have the option of becoming trusts within the NHS.

Already more than 150 hospitals and other services have become NHS Trusts, and many primary health centres are now fund budget holders on a capitation basis. Services remain available to all, paid for mainly out of general taxation and mostly free at the point of use. Local health authorities are now purchasers of services and hospitals public or private are providers.

NHS Trust hospitals have the power to make all of their own managerial and financial decisions, and must compete for business against other hospitals, although central government is still setting targets for patient waiting lists and national returns on the capital employed. Units providing high quality, value for money, services will be more successful in attracting contracts and funds to provide services for patients.

They may even choose to make subcontracts for some services. If a service offered by private initiative is less costly than the equivalent national health service facility it would be selected. Patients would be transferred from the latter to the former by the budget holder, or by the NHS Trust hospitals' managers.

INDUSTRY STRUCTURE

Companies

There are currently more than three thousand owners of commercial enterprise health care services. Most have been formed

by small groups of medical professionals. In Italy there are almost 700 owners (natural and juridical persons) of commercial enterprise health care services. However, bigger investors are getting involved. This started with health insurance companies, and has gone on to include all types of company from capital venture groups to water companies. Several private hospital chains run by financial groups with money from finance centres or insurance companies have been established within the EC.

The largest EC private health care group is the French chain Compagnie Générale des Eaux which owns 60 institutions. With Clinivest and Alphamed this chain owns almost 7% of all private clinic beds in France. Through its subsidiary, American Medical International, it has acquired 18 institutions located in England.

The combined turnover of more than 435 million ECU placed CGE just ahead of the British company, BUPA. BUPA had a turnover from health services of just over 290 million ECU in 1991. BUPA has expanded its health service and insurance operations in Spain through its newly acquired subsidiary, Sanitas which had a turnover of 245 million ECU in 1991 .

REGIONAL DISTRIBUTION

The EC health care institutional environment contains a panoply of facilities. They have the titles hospital or clinic. They range from large high tech purpose-built hospitals to an older generation of hospitals housed in buildings of a bygone age (sometimes even former workhouses). Clinics vary in character. Often they are indistinguishable from hospitals (sometimes they are prevented by law from being called hospitals).

It would be inaccurate to say that private clinics are generally inferior or subordinate to public hospitals. Where inferiority exists, it is often one of size or the variety of services. However, many well equipped major facilities in Europe are privately run.

Hospitals have obtained fair compensation per medical act or for bed occupancy from the health (or sickness) insurance funds. In these systems, most health care costs are funded through employees' and workers' and their employer's health care insurance contributions. Individuals who are self-employed are encouraged to cover themselves adequately for hospitalisation for which there are sometimes obligatory minimums, and primary care coverage can be optional.

The sections below describe the health care industry structure by country.

Belgium

All private hospitals in Belgium are non-profit making. They compete on an equal footing with publicly owned hospitals. Most were founded by religious bodies. A minority were started by groups of doctors or associations. Private "for profit" hospitals have been largely forced out of the system by hospital funding regulations which prevent them from benefiting from state subsidies for equipment and construction.

Considerable investments have been made to rebuild the Belgian hospital system. The average size of hospitals has increased. This is largely due to a cost containment measure, taken by the Ministry of Health and Social Affairs in 1987, to close the smaller hospitals. At primary care level the general practitioner's coordination, the Yellow and White Cross association and others offer community nursing services. Paramedical and primary care services are increasingly being organised by private professional groups.

In Belgium, hospital physicians, general practitioners and specialists in the community are paid on a fee basis, which can be fee for service or a fee per capita. Some physicians choose to supplement their income from hospitals by running their own cabinet in the community. Other hospital staff are salaried. Sick fund societies manage reimbursement claims for most of the population.

Self-employed have the choice of whether they wish to have full or partial coverage. Companies in Belgium are increasingly offering group insurances to their employees as perks. This allows extra hospital costs, such as private rooms, other comforts plus all non reimbursed medical products, to be recovered by the insured.

Luxembourg

Approximately 40% of the private hospitals in Luxembourg are not "for profit" enterprises. Private health insurance in Luxembourg amounts to a few percent of the total health care expenditure. Hospital staff are employed on a salary basis, whereas general practitioners work on a fee per act basis.

The public also uses the services of some hospitals in countries surrounding Luxembourg, particularly Germany.

Denmark

Denmark has a national health service funded by general taxation. Practically all treatment is provided by publicly owned hospitals. There is one private hospital and about a dozen of X-ray clinics under private control. The private insurance market has declined because practically the whole population have their complete hospital costs paid. Most primary care is provided by general practitioners. Most work in group practices. Hospital personnel are salaried whereas medical professionals working in the primary health sector charge fees per act.

France

France, which has the largest number of private hospitals in Europe, also has the greatest number commercial enterprise private hospitals. About half the country's health provision comes from the "cliniques privées". Of the approximately 200 000 beds in the private hospital sector roughly 54% are owned by commercial enterprise (2% of these are psychiatric institutions). Private hospitals tend to be much smaller than public hospitals in size, and it has often been said they are less intimidating for some people.

The French state's commitment to the national hospital programme has been to establish public hospitals (centre hospitaliers) in every major town in France. About 40 of these are very large complexes with university affiliations. Public hospitals are autonomous and can try to borrow money from private companies for capital investments. They often apply for government subsidies when they run into liquidity problems.

Private hospitals tend to concentrate on offering specific therapies which provide sufficient profitability. This is illustrated by the very low percentage of long stay beds in the private sector. But there is a trend to increase the private sector in this area. The data for medium stay patient entries, from the Ministry of Social Affairs and Employment, shows that more patients are treated in private hospitals than in public hospitals.

In France, hospital doctors can be salaried or charge fees per service for their services. Many work for several establishments simultaneously, and some also practice in the community. However, the level of fees they earn is regulated for about 95% of them. Practically every person in France is covered by health insurance. Some workers pay into additional health insurance schemes to have full reimbursement for all services.

Germany

The state and local governments account for less than half the hospitals in Germany. Private hospitals compete on an equal footing. They obtain funds through a dual financing system. Funds for capital items are provided by the state and local governments, and other income comes from earnings against treatments. These are agreed between hospitals and local sickness fund organisations. This is calculated on a sum per day basis. Many hospitals, public and private alike, compete for specific surgery or medicine services.

Less than a third of the German private acute care hospitals are commercial enterprises. Many are small and specialised clinics. There is an evolution in the number of parapharma hospitals run by commercial enterprises. The private sector is now expected to rapidly develop home-care services. Home dialysis, including nursing assistance, is now provided by medical supplies companies.

Almost seven million Germans (roughly 10%) were covered by additional private insurances in April 1990. The number was five million in 1985. The health care system is financed by sickness fund associations, private insurance and state and local government. Hospital doctors are either paid salaries or fees per medical procedure or surgical act; the hospital they work for decides its payment policy. General practitioners charge fees which vary according to the nature of the service they are providing, on a fee per act basis.

Greece

Greece has a health insurance system which is similar to that of Portugal. Approximately 95% of the population are covered by an insurance fund. There are 35 funds. With these funds there are four major ones. The largest is the IKA (2.56 million employees and workers and 2.62 million of their families). Second is the OGA (1.91 million agricultural workers and 0.59 million of their families). TEBE follows (0.48 million artisans and 0.82 million of their families), and the government has the fourth largest fund (0.19 million directly insured plus 0.27 of their families and retired civil servants). Voluntary hospitals, private clinics are licensed to provide additional health care services. Provision of health care in Greece is improving.

Ireland

Ireland has a national health care service which covers its entire population. One fifth of the population is covered by additional private health insurance besides national health insurance. In recent years the Irish national health care service has made efforts to contain health care costs. Ireland's very young population has a very different demand to that of countries with older populations. Instead of geriatric facilities it needs paediatric centres.

Italy

The Italian National Health service came into being in 1979, replacing a sickness fund service. Sickness fund offices still have an involvement in collecting contributions for old-age pensions, but sickness social insurance INPS (Istituto nazionale previdenza sociale) is the only state organisation entitled to collect contributions. Health care is organised on a regional level. Of the private hospitals, 90% are agreed by the national health service to provide services to national health service patients. They work within a convention made by local health units (USL).

An Italian law of December 1991 requires that there are 6 beds per 1 000 inhabitants, of which half a bed allocation must be for rehabilitation or long-stay. The standard applies to public and private hospitals. But private hospital bed numbers are calculated at 50%, not to reduce too much of the system's flexibility assured by their essential contribution. These private hospitals are paid on a daily rate basis and must be profitable to continue.

Italian private hospitals that are accepted in the plan are reimbursed by local health units for services that they provide to patients insured under the national health service plan. By law this payment should take 90 days to be reimbursed. However, payment can take seven months in some areas of the country. Private insurance patients are a valuable source of additional funds of free private hospitals and clinics. The 10% of private health care institutions providing specialised and general acute care treatments are licensed but not within the convention to provide services within the Italian national health service plan. These hospitals have to conform to the laws in force to be licensed, but not those concerning conditions settled to obtain a convention with a local health unit.

They are expanding because the average Italian is increasing private health care coverage. There are approximately 1.5 million private policies providing coverage for approximately 3.7 million people. Generali is the main insurance group involved in the private insurance system in Italy. It accounts for roughly 14% of private policies. RAS, SAI, and Fondiaria have respectively 9%, 7% and 5%. The remaining policies are divided among many insurance companies.

Netherlands

Health care in the Netherlands is decentralised and organised to a large extent by sickness funds and local authorities. There are more than 70 of these. Public and privately owned hospitals operate under the same conditions. A part of their budget is given by the Ministry of Health, and the rest is from reimbursement given by ziekenfonds (sickness funds).

Nearly half the health care services in the Netherlands are voluntary or religious; the latter, although called private, are not commercial enterprises. Most new major private hospital investments have been made by Dutch universities. Community care is provided mainly by the Cross Associations (private and religious in character) which run many nursing homes (verpleeghuis).

The Netherlands has the most developed nursing home system in the EC. General practitioners provide most primary care. They are nearly all self-employed. Some have grouped to form health centres, and obtain subsidies from the central and local governments. Not every person has the same rights concerning coverage. Persons with higher than average incomes are not entitled to full reimbursement by the national system; however, their hospitalisation is mostly free of charge. As far as payments go fees and costs of products must be paid by the patients, but most are recoverable from the ziekenfonds retrospectively. Reimbursement rules also vary from one locality to another.

Portugal

The Portuguese health care system is largely run by the public authorities. In the 1980s significant investments were made in upgrading the hospital sector. Several new major hospitals were built during the 1980s to ensure the Portuguese population a health service comparable with the rest of Europe. Private hospitals contribute about 20% of the total number of beds which amounted to about 54,000 in 1990.

A significant number of hospital beds in the Portuguese private clinic sector belong to institutions of religious and social security character. Some specialised services such as dialysis centres have been set up by private companies, e.g. WR Grace; these do not have beds. More than 200 health centres and more than 1 500 medico-social clinics provide the country's primary care services.

Spain

Hospital ownership in Spain is divided between several owners. The major publicly owned hospitals have either regional or municipal status. These are supplemented by private hospitals owned by the Red Cross, universities, religious concerns and private companies. The number of private hospitals is much greater than the number of public ones, however, in terms of bed numbers they account for only about one third.

Private enterprise hospitals in Spain, of foreign and local ownership, account for about 15% of all beds. Many have closed since the late 1980s owing to the Ministry of Public Health and Social Security's policy to make the public hospitals more efficient by increasing bed occupancy rates. However, this has allowed many new investors to establish themselves by buying up failing private hospitals.

Towards the end of the 1980s the British private health group, BUPA (a provident society), decided to invest in Spain. It owns, Sanitas, one of Spain's major private health care groups. Another major group is the 'La Alianza' hospitals in Catalonia.

Physicians in Spain are paid salaries or fees per service. There is a well developed family doctor establishment, working either for the social security or the state. Primary care is also provided by private centres, emergency centres, outpatient clinics. Some dialysis centres are run by commercial companies, and the Ministry of Health and Social Security allows companies to provide a peritoneal dialysis home service on a fee per day basis.

United Kingdom

The United Kingdom has a national health care service which provides for the whole British population. Its public sector is going through a process of decentralisation of hospital management, by offering many hospitals 'trust status'. The private and not "for profit" (independent) sector is now able to compete for services against publicly owned hospitals.

BUPA, Britain's largest health insurance company (with about 50% of the UK's private health care market), has increased its scope. Besides offering health insurance for private treatment it now has its own hospital and nursing services. The independent sector comprises some charitable institutions, private enterprise hospitals and nursing homes. Among others manufacturers of commodity products such as alcoholic beverage and hotel groups are participating in the rapidly growing registered nursing homes' sector, which caters for Britain's old and infirm.

Primary care in the United Kingdom is being organised into health centres. These are rapidly replacing single practices. Most general practitioners are paid fees on a per capita basis, but a few are salaried. However, in health centres they can also apply to the become fund holders. This allows the doctors to keep budgets and select where their patients should go for treatment.

Medical supplies companies offer services such as home parenteral nutrition, and peritoneal dialysis, e.g. Baxter Healthcare and Fresenius. Baxter also owns some dialysis centres through a subsidiary company.

REGULATIONS

Laws forbid hospitals to make profit in Belgium, the Netherlands, and Luxembourg. There are no very small private cooperative hospitals in Belgium or the Netherlands either. This is because Belgium has a regulation which says that the minimum number of beds a hospital may have is 150. It must also provide a certain minimum in terms of the scope of services. In the Netherlands hospitals must have a minimum of 180 beds, unless they are within 15 km of another hospital, whereon they must have a minimum of 120.

In Italy private hospitals are accepted within the national health care hospital plan which works according to a convention of six beds per 1 000 patients per annum. This is not aimed at limiting short-term treatments, but at controlling the number of beds in areas. It served to reduce the number in areas of over capacity upon its inception. Private hospital beds are counted at only 50% because their presence is judged essential. This rule may seem out of place within the next few years as laparoscopic surgery and other minimally invasive therapies replace traditional surgery which required more time to convalesce.

Private clinics in Greece, which account for about one fifth of the country's health care expenditure, are facing a law which threatens to close about 95% of them according to the Greek private clinic association. Greek law forbade the establishment of further private clinics between 1982 and September 1990. The same law prevented existing clinics from increasing their number of beds.

For economic reasons, Greece's private clinics had to reduce their overall bed number by 8 000 beds to become 15 512 beds by the end of 1982. During this period the public hospital sector only increased its bed number by 2 900 beds. The law, since December 1991, authorises the establishment of new private clinics, but the minimum requirements of services which must be provided are roughly three times greater than those before the embargo.

The investment necessary, being so large, resulted in no new registrations before June 1992. The current private clinics must also increase services to meet the new standards within 18 months of the December 1991 law.

The CEHP, UEHP, and UIHP would like to see more freedom for patients to seek hospitalisation at a hospital of their choice within the EC. An obvious problem is the disparities existing among health insurance systems within the 12 Member States. In the short-term it is unrealistic to expect someone in Portugal to make the same contribution to health insurance as someone in Germany.

It is also unrealistic to accept massive movements of patients within the European Free Space until greater equality of health provision has been achieved. On the other hand patients should not be prevented from seeking treatment anywhere in the EC, and having their national health insurance cover considered. Agreements already exist between countries, although these contain cumbersome administration formalities and restrictions for the main part.

OUTLOOK

In the early 1980s governments in Europe and the USA began closer monitoring of the mounting costs, and most instigated health care cost containment measures. These have affected many aspects of health care provision programmes. In particular they have led to rationalisation of some services and greater control of expenditure by increasing public institutions' expenditure. Circumstances vary importantly from one country to another, and demand is tied to factors such as age structure and general nutritional status of a population.

Future demands on health care systems will depend on these two factors very importantly, among many others. By 1990 a great deal had been learnt about controlling health care costs. One major finding was that the systems needed better management. This management needed to focus on value for money. The idea is being developed even further.

Another important consideration is that deinstitutionalisation can bring benefits to patients able to convalesce at home; it allows them to recover in their own often more agreeable surroundings and hence reduces institutional costs significantly. This is at an early stage of development in Europe. In contrast, the USA it is at an advanced stage of development.

Changing policies of health ministries will increasingly allow private enterprise to become involved in the provision of certain health-related services, although they are not being given the same consideration in every country. The clearest example of a country with a very positive interest in the development of the private health care sector is the United Kingdom's NHS. It is undergoing the most radical change since its formation. The idea of "money following patients" is a radical departure from earlier arrangements. The other major EC countries, Italy, France and Germany all appear to favour the development of private health care.

Evidently, privately run health-related services are increasing in scope and also in number. A new direction for private enterprises will be to examine niches opportunities in the acute care sector. They would protect their stake by investing in the best technology available.

Health care services need not be stationary structures, nor do they need to be capital intensive. A good example of the former is the mobile screening service of BUPA in the United Kingdom. The General Electric Company has participated in a similar venture in Germany. Smaller scale hospitals can achieve savings by hiring the services of mobile units. This may be a good business strategy for the short-to-medium-term, but could have limitations in the longer-term if there is a concerted trend toward closing small hospitals.

On the other hand, home intravenous therapy and peritoneal dialysis programmes organised by medical supplies companies Kabi Pharmacia, Baxter, and Fresenius, appear to have better longer-term potential. The home-care sector, which is only at its initial stages of development, will continue to expand in the EC.

A new peer infrastructure is needed for doctors, and it may be difficult to change professional habits. Some hospital physicians will not wish to temporarily pass the control of some patients to doctors in the community, while the patient is still under the care of the hospital. It may also be difficult for some physicians to accept to place high-tech medicine in the hands of primary care doctors and community nurses.

The primary health care sector will need a good overhaul to cope with secondary care. There is a need for greater professional competence at community level. Some retraining will be necessary. Doctors in the community will need to have greater contact and guidance from central hospitals. Dismantling more of the institutional structure and consolidating it into larger units will continue to be met with resistance by hospital personnel.

The idea of having large supra-regional centres of excellence supported by many dependent hospitals has a great deal of merit, but small specialised surgery and medicine clinics can also play an important role. The private sector will continue to invest in the expansion of registered nursing home facilities across the EC. More than 100% growth can be expected in this service over the next five-year period.

The UEHP states "the European private hospitals', clinics', and nursing homes' sector must maintain and strengthen its commitment to provide its patients with the high quality medical technical and human assistance, performing quality control and revision (quality assurance) within its structure, according to standard methods designed to guarantee homogeneous results".

Audiovisual services
NACE 971, 972, 973, 974, 345.2

While the European audiovisual industry exhibits continued growth, this performance varies widely from country to country. The rapid expansion in recent years of southern Europe continues, yet Europe as a whole registered problems in 1991.
The proliferation of television channels exacerbated the problems of some countries and led to increased US programme content. The European production sector appears unable to benefit from global market growth: cinema attendance figures are declining, and some countries have had to introduce special measures to combat the problem.
Europe's audiovisual hopes are now pinned on High Definition Television (HDTV) and multimedia developments. In both instances, Europe's future depends on countries being able to pool their product and market strategies coherently. Europeans will have to learn to cooperate, especially by developing audiovisual production partnerships.

INDUSTRY PROFILE

Description of the sector

Audiovisual products can be defined as images and sound put together and recorded or transmitted for the entertainment, information and/or education of the consumer. They take various forms, from reels of film to video-cassettes, and include radio and TV programmes.

The audiovisual sector thus groups four main sub-sectors: film production (NACE 971); film distribution (NACE 972); cinemas (NACE 973); radio and television broadcasting (NACE 974). The music recording sector, although being part of NACE 345, is also considered within this chapter.

The already close links between these sub-sectors of the industry have intensified over recent years. A film - usually developed for the cinema and, as a result, a product aimed at that sub-sector - can extend its life-cycle via broadcasting, perhaps several times, on television and by being recorded on video-cassette.

The speed with which a motion picture moves from one medium to another obviously depends on agreements between the cinema sub-sector and television. Another factor entering into the equation is how many homes are equipped with recording hardware (VCRs). The emergence of pre-paid specialised channels and subscription and cable channels (such as Canal+) has changed the negotiating balance between the cinema industry and television, and has led to cinema/TV co-productions (as in the case of Channel 4 in the United Kingdom).

Main indicators

The global market for the audiovisual industry, including equipment and services, was estimated in 1990 at about 195 billion ECU. Average growth at constant 1990 prices was 6.5%. Audiovisual equipment (such as television sets, compact discs and VCRs) represents the bulk of this total, accounting for 54% of the whole.

On the services side - which is the prime focus of this study - TV broadcasting recorded a turnover of about 82 billion ECU in 1990, outpacing the film industry, whose share was only 4% of the world market. This pattern, repeated and reinforced over the last five years, seems to be becoming more pronounced.

The annual growth rate in cinema receipts - 1% between 1985 and 1990 - trails TV receipts, up 7.4% a year on average over the same period. In the short term, the trend towards cable, satellite and specialised channels will only exacerbate the difficulties faced by the film industry.

Recent trends

Continuing change over more than a decade has totally transformed the European audiovisual sector. Virtually total deregulation of the sector has led to a proliferation of TV channels, an increasing supply of programmes and radical changes in conventional financing methods. Advertising revenue has gradually taken over from licence-fee income.

In the past ten years, as many new TV channels have come on stream as during the entire previous history of the industry. By the end of the 1980s, commercial channels outnumbered public channels.

These two events have conspired to provoke a major upheaval in the European audiovisual sector. The number of hours of

programming necessary to meet market demand has multiplied tenfold over the course of several years. Nevertheless, this growth in the number of channels has not fed through to growth in programme production. In effect, the principal beneficiaries of growth in the number of channels have been US programmes which have been exploited in subsidiary European markets. It is anticipated that European programme production will not benefit from the knock-on effects of increased programme demand until the viability of the new channels has been firmly established.

It must be noted, however, that the scarcity of international-class programmes being produced is a contributory factor in Europe's trade deficit in this area.

Some of the characteristics of TV production work against its diffusion on a large-scale: non-reproducibility; low productivity gains; more support for new technical media than for production per se; a short-lived product which in many cases does not outlive its first broadcast (news programmes, game shows); pre-production methods of financing which discriminate in favour of programmes which are a priori profitable; and prohibitive redistribution costs which favour imported products. These few observations help explain the low level of internationalisation of European productions.

In practice, it is rarely easy to opt from the start for production on an international scale, given that producer and distributor are both confronted by obstacles common to most countries: language on the one hand and, on the other, consumption patterns such as the optimal length of TV films or the optimal number of episodes in a series, and so on.

European co-production could represent an extremely short term remedy to production shortfalls, but this is by no means easy to put in place. Experience has shown that groups which are accustomed to autonomy and non-accustomed to cooperation often experience difficulties in working together. What is more, the success of a TV film in the ratings will more often than not hinge on its leading characters: finding stars who are identified as such in all European countries - let alone in the entire world - is a daunting task.

MARKET FORCES

Demand

Changing consumption patterns across Europe are linked to changes in penetration of audiovisual equipment into the average household. Europe leads the USA and Japan as a potential market for audiovisual equipment but, predictably, there are marked differences between countries. The French and Italian markets, for example, are much less dynamic than those of Germany and the United Kingdom.

In terms of the different kinds of equipment, video-based hardware, especially camcorders and VCRs, is the fastest-growing. Increasingly, integrated VCRs are sold with new TV sets.

European households are approaching saturation point for many items of equipment. One result has been changed patterns of televisual consumption. As other, currently less well-equipped countries see this pattern emerge in the years to come, there will be a degree of market homogenisation which will serve only to intensify the problems facing the European cinema industry. To put it another way, cinema and television will be brought closer together through co-productions or broadcasting agreements.

The advent of HDTV must be viewed as a threat by the film industry. Image quality and stereo sound will reinforce the current tendency to consume cinematographic products at home -all the more so as the number of available channels continues to grow.

Television

The television market is made up of: terrestrial broadcasts, cable transmissions and satellite television. Within these sub-sectors, a distinction must also be made between public TV on the one hand and commercial channels on the other.

The European market represents approximately one-quarter of the global income of TV networks, trailing far behind North America (46.7%). European growth rates, however, are more healthy. Italy and France, both of which have recently experienced major deregulation, have seen their respective shares of the world market grow by 18.9% and 17.5%.

Europe is the market that has evolved most rapidly over the last five years. With average annual growth of 10.6%, it is far ahead of North America (4.7%) and Japan (4.5%). Europe's market share has risen from 21% in 1985 to 25% in 1990.

Other regions such as China, Latin America and India have also grown at the same time. Satellite distribution has spawned new markets with large numbers of potential consumers; in the long term, this could drastically change the economies of production and lead to a further internationalisation of consumption in the form of an increase in co-productions.

Most income - even these days - is generated by terrestrial broadcasting. In 1990, cable TV garnered only 20% of total income. However, this pattern is likely to shift in the years ahead, nowhere more so than in Europe, where the number of channels is increasing rapidly. Income generated by cable TV is growing at double the rate of income from terrestrial networks. The structure of TV financing has also altered as terrestrial networks evolve and monopolies and duopolies are replaced by a market economy. Advertising has become a key source of income: even some public networks have had to resort to it, applying the same economic arguments as their commercial counterparts. This has inevitably triggered debate on the role of public television in the case of those public channels whose output is virtually indistinguishable from that of commercial broadcasters; France's A2 (public) and TF1 (private) channels are a case in point.

Since 1988, public financing has accounted for some 20% of total funding, including taxes or licence fees in countries where those exist, as well as government credit and regional contributions. It follows that advertising is the principal source of funding for these channels. In the case of encoded subscription channels such as Canal+, the financial structure is, of course, entirely different, since it is primarily dependent on fees paid by subscribers. In 1990, Canal+ income was, for the first time ever, greater than the total amount of licence fees paid in respect of all the public channels in France.

The share of public financing shows a pronounced downward trend in almost all European countries. In 1990, terrestrial channel income rose slightly more than 10%, whereas public financing rose only 4%.

Cable television

Overall, cable TV in Europe has grown slowly and revealed wide differences between countries. Three countries seem particularly dynamic in this respect: Germany, with almost 7 million households connected in 1990; the Netherlands (4.1 million); and Belgium/Luxembourg (3.2 million). With the exception of Switzerland - which, with 1.6 million subscribers, features in the list of top European cable TV countries - all the other European countries are in what can best be described as an intermediate situation, with development prospects which are more or less promising.

In this context, France is perhaps a special case: although the possibility of supply already exists, demand has yet to emerge. In October 1991, from a total of 3.8 million available connections, only some 20% (700 000 subscribers) were connected, far below the penetration rate of the encoded Canal+. It seems that the successful privatisation of TF1 and the commercial success of Canal+ have failed to encourage French viewers to move to cable. The 1992 target of two million new cable subscribers will probably not be met, even if current growth rates do testify to increasing interest.

The proliferation of cable channels has had a clear impact on household demand for programmes. In most European coun-

tries, cable has expanded considerably, posting growth rates in excess of 30%. France and Germany lead the field in this respect, with average annual growth from 1985 to 1990 of 93% and 35% respectively (although the actual number of households connected remains undisclosed). Germany seems to have the most cable subscribers, with some 10 million in 1992; this compares with an aggregate of some 15 million in the other EC Member States.

Forecasts for the growth of cable over the next five years show three distinct European areas: first, the area comprising those countries nearing saturation where, consumption should level out, i.e., Netherlands, Belgium, Luxembourg; second, the area comprising Germany and Nordic countries such as Finland and Denmark, already well cabled and with continuing annual equipment growth of over 10%; and third, the area grouping France and the countries of southern Europe, which are still poorly equipped and which represent significant development potential.

The United Kingdom represents a special case: one of the weakest markets in Europe, its forecast growth rates suggest that it will remain so for the foreseeable future. The entire future of UK cable TV hinges on private operators and the success of the Astra and BSB satellites.

As in the case of terrestrial broadcasting, cable channels are experiencing serious financial difficulties. Financing is essentially derived from household subscription income, with advertising representing only 10% of total revenue. There are two explanations for this: a commitment by many cable networks to reduce advertising to a minimum; and the size of the current market which reduces the interest of advertisers in this type of medium.

In future, however, larger audiences could revive advertiser interest. If this happens, it will cause a further upheaval in the advertising market, similar to that caused when the emergence of commercial stations prompted the substitution of TV for other advertising media. In fact, a sort of double competition could emerge - between different media and within the medium itself.

Satellite broadcasting

Another phenomenon in recent years has been the growth in satellite reception, as evidenced in most European countries by the number of individual satellite reception dishes purchased and installed. Growth in the individual or collective dishes will continue over the coming years, fuelled by price reductions and the availability of more powerful satellites which cost less and are less cumbersome to install.

The United Kingdom is Europe's healthiest market. There, the sluggish launch of cable and the attractions of US programming have worked in favour of satellite reception.

This broadcasting mode (for which numbers of households are still undisclosed) represents direct competition to cable reception. In Japan and the USA, where over 3% of households are now equipped with dishes, cable operators have had to encode their transmissions to avoid satellite viewers being able to receive their broadcasts directly.

Film and video

The structural problems of the European film industry in recent years have been a particular cause for concern. Throughout the 1980s, cinema attendance rates dropped markedly, going from 750 million in 1981 to 564 million in 1990. This trend continues.

Film output has paralleled this trend as outlets became more scarce. In the course of a single decade, the number of feature-length films produced fell and only 416 features were made in 1990. Finally, the number of cinema houses continues to decline, as does their average seating capacity.

The situation would be less worrying were it evenly applicable to all the players in the market. However, while the European film industry is going through a difficult period, its US counterpart presents an enviable picture of robust financial health.

Two elements have changed fundamentally in the course of the last few years: film consumption patterns and video consumption. The erosion of cinema attendance has come about as a result of changes in the client base allied to a lack of adaptation of the product. The cinema-going public has become progressively family-oriented and increasingly more haphazard. In order to maintain revenue, the film industry has had to reorient itself to meet the demands of cinema audiences which are made up of out-and-out cinema buffs on the one hand and, on the other, casual cinema-goers for whom a visit to the cinema is simply one among many alternatives. Given such a mix of clientele, the problem of building loyalty is immediately obvious. Meanwhile, family-oriented consumption has moved to the home, facilitated by the increasing availability of equipment for reproduction and recording.

The upshot is that, in order to maximise profitability, producers have been obliged to diversify their revenue sources to take account of the proliferation of television channels and the increase in mass-market video. In Europe, video took off comparatively recently, its growth having been initially delayed by the comparative non-availability of domestic reproduction equipment and the slowness of the film industry to adapt.

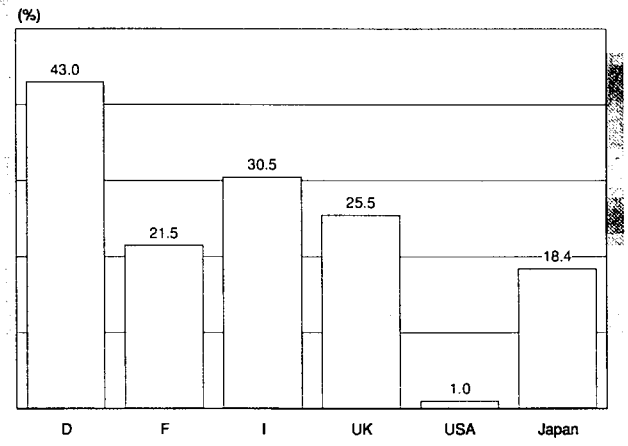
On the basis of global box-office receipts in recent years, it emerges that a sustained recovery is taking place in Japan, after a marked fall of 11% in 1987. 1990 growth of 3% has brought the industry back up to 1985 levels. The contrast is even more marked in the USA. Between 1985 and 1990, US box-office receipts in constant dollars rose by nearly 34%.

The decline in European film audiences is exacerbated by a fall-off in competitiveness. As for television, the trade balance continues to deteriorate - to the benefit of the USA. The national film industries in Europe account for less than 20% of total receipts, compared with 70% for films from the USA. Japan, despite having a poorer reputation than Europe as a film-making nation, has been more resilient than Europe in this respect: 42% of the films shown are made locally, with 55% imported from the USA.

It is difficult to make a positive case for European attempts in recent years to penetrate the North American market. Such successes as there have been proven to be very limited. This is probably because protectionism in the USA market is very effective, but it is also attributable to the need for dubbing, problems in accessing distribution networks and, not least, because European productions rarely betray international ambitions. Film and video are thus experiencing the same problems as television: strong penetration by US products and poor positioning abroad by European producers.

However, whereas the growth in the number of television channels has had the effect of benefiting programmes from

Figure 3: Audiovisual services
Public financing of networks, 1990



Source: Various

abroad, the same situation does not apply to the film industry. In film, dependence is due primarily to the commercial aggressiveness of US distributors and, even to a greater degree, to the fact that Europe does not always make the most of its internal market.

To generate profit from products which are increasingly costly to make, US film producers can draw on a market of 249 million consumers - sufficient to amortise their product. Europe, on the other hand, has a potential consumer base of 326 million but, for the time being, has failed to overcome the obstacle of regional differences. In fact, the national or regional flavour inherent in some productions usually prevents them from targeting a European market, let alone an international one.

Faced by this challenge from a USA that is perfectly organised in terms of both production and distribution, Europe has no other option than to strengthen its own enterprises. At present, Europe's network of small and medium-sized producers are no match for the majors. Clearly, such a fragmented structure can only stand up to global concentration by developing effective intra-European partnerships.

The probable direction the industry will take scarcely gives grounds for optimism, be it the advent of HDTV - which will further upset a troubled industry - or the growing presence of Japanese electronics companies aiming to synergise mass market hardware and video software.

Convergence of film and video techniques, notably during shooting, should promote productivity gains within the industry. Until now, productivity gains were mainly derived from distribution. The development of more luxurious and more comfortable multi-screen complexes has proved a vital step in adapting to the needs of the new consumer. It is also conceivable that a number of players totally new to the audiovisual scene could emerge, lured by prospects of profitability implicit in new technology.

INDUSTRY STRUCTURE

Strategies

The stakes are high in the audiovisual market. Not surprisingly, therefore, a number of manufacturers have recently adopted strategies designed to secure themselves a slice of a potentially lucrative market.

More than ever, the audiovisual market now comprises interlinked segments: the interface between equipment and the consumption of services; VCR and video cassette, interactive compact disc or multimedia software; and the link between the various media available to a product (films shown in cinema houses, on television and, finally, in video-clubs or at home).

These overlapping structures attract to the market firms which have widely disparate aims but which view themselves as indispensable to the audiovisual sector. These players can be classed into five groups, each with its own inherent logic.

Product logic

Product logic dictates that consumer equipment groups (Matsushita, Sony, Thomson, Philips, Siemens) have a presence in all the new segments. The aim is to avoid over-dependence on programme producers becoming a major element in equipment supply. Consumer electronics groups, to achieve their aims, have therefore to seek strong complementary links with television and cinema, and avoid outright competition.

While seeking to renew the existing stock of equipment with new products and multimedia products, these firms must improve their expertise by controlling the provision of programmes. This is behind the recent acquisition by some of the electronic giants of cinema distribution networks or production companies.

This logic is fundamental to strong competition surrounding HDTV between Europeans, Americans and Japanese, each set on its own standard.

Information technology logic

In an attempt to secure a place in the consumer electronics market, the main groups (IBM, Bull, Apple) have adopted a two-level strategy: equipment market penetration based on cheap domestic micro-computers, and mastery of programme production in multimedia.

The strategy here is to assimilate audiovisual consumption as a whole and micro-computer consumption by insisting on the advantages of information technology for service, maintenance or accounting applications.

Programme logic

While it cuts across most of the other approaches, this logic is particularly relevant to traditional film or TV companies. In essence, it is a question of their financial well-being. In the case of TV, these companies are threatened with the loss of a large part of their income from advertising. In the case of cinema, they face the prospect of continued decline in cinema attendance.

Source: Idate, Afma, Goldman Sachs

For all of them, the obligation is to improve the quality of their programmes, an impossible task unless there are major developments in European co-production and the targeting of international markets.

Network logic

Audiovisual, computers and telecommunications are distinct sectors which are nevertheless very close to each other; in practice, reference is often made to the "communications" sector as grouping all three.

Telecommunications companies (AT&T, NTT, British Telecom, France Télécom) all see audiovisual as a logical extension of their core activities. The ideas of networks, cable, telecommunications and satellites are all integral to their sector.

The logic of these players is to extend transmission hours so as to generate profits as quickly as possible from their major infrastructural investments. Once technical issues have been resolved (e.g., coaxial cable or fibre-optics, high or medium power satellites), the profitability of the sector will hinge predominantly on programme quality. It is therefore understandable that these players, who currently run networks, should invest in becoming producers. France Télécom, spurred on by HDTV, was among the first to invest in that technology as a means of presenting industry professionals with attractive demonstration products.

Multimedia logic

Multimedia is as yet a technology of the future, although it is already well-established in professional circles, especially in training. There is every indication that multimedia should rapidly become mass-market. Technical standards are being negotiated and should soon produce a world multimedia standard. Thereafter, even if the possible applications are of interest to players from different backgrounds, it can be expected that major programme producers such as Time Warner, Disney, Murdoch, Berlusconi, CLT, Havas or Hachette will be in the vanguard in developing synergies with their other media activities.

OUTLOOK

For cinema and television, the years ahead promise to be turbulent. The convergence of computers, telecommunications and audiovisual technologies will rapidly give rise to a new market phenomenon: multimedia.

In addition to integrating a number of existing technologies -sound, image, data and video - on the same support, the multimedia revolution will require producers to adapt to other forms of know-how.

It is difficult to predict at this juncture who will emerge victorious. That said, for the domestic, image-based sub-sector, existing enterprises in the audiovisual sector will have a significant competitive edge.

The second key focal point in the next decade will be HDTV. Here, there is more at stake than the audiovisual sector alone. HDTV offers Europe a chance to reposition itself as a leader in mass-market consumer electronics equipment such as television receivers, decoders and satellite dishes. Additionally, the performance of equipment manufacturers has always had a knock-on effect on programme production, inasmuch as hardware supply and software availability are inseparable.

The difficulty for Europe will be to achieve a rapid consensus on a European HDTV standard in order to provide industry with a stable technological base. Accordingly, priority must be accorded to elaborating a timetable for the introduction of European HDTV while at the same time safeguarding as far as possible the diverse interests of those players already committed to the project.

By 1995, average annual growth should match recent trends of around 6%. However, this growth will disguise setbacks in several market sectors: the growth of cable and specialised channels; growth in satellite reception; and the expansion of video to the detriment of the cinema industry.

Film and video
NACE 971, 972

The European film industry is currently undergoing a difficult period. Attendance has dropped sharply since the start of the 1980s, the number of feature-length motion pictures made annually is in decline, and the number of cinema houses has progressively decreased.
The overall situation is in marked contrast to the robust health enjoyed by the motion picture industry on the other side of the Atlantic - at least up to 1990.
The problems facing the industry at present appear to reflect not only a decline in film output but also difficulties of adaptation to new marketplace conditions, notably the problems of attracting new audiences and accommodating profound changes in consumption patterns. In the longer term, the real question to be addressed may well be how European producers can adapt to these changing conditions and respond to intensified competition from US and Japanese groups.

INDUSTRY PROFILE

Description of the sector

There are five main groups of activity in the film and video industry:

- Production destined for cinema or video consists of assuming responsibility for the entirety of a project from its initial financing through to selection of the optimal distribution channels.
- Technical aspects of the industry relate to the provision of specific services such as post-production, lighting, printing and duplication.
- Distribution to cinema houses is increasingly affected by large networks at the expense of smaller, independent distributors.
- Video publishing is still largely dependent on cinema output in terms of the titles issued.
- Recent years have seen the emergence of a new breed of operator in the guise of companies whose objectives are to acquire audiovisual rights attached to a product and to sell these rights in a designated geographical area for a limited period of time.

The above activities, which are comparatively easy to define in terms of their objectives, are very broadly integrated into overall strategy. As a result, it is extremely difficult to identify viable statistical data for each of the above. No global statistics are available with respect to employment in the film production and distribution industry; the same holds true of video publishing.

Box office receipts emerge as the most reliable economic indicator of the film industry. In 1990, receipts for the EC as a whole amounted to about 2.07 billion ECU.

Main indicators

In recent years, the European film industry has been characterised by three major and related trends: firstly, falling cinema attendance which has depressed box-office receipts; secondly, digressive output in terms of feature-length films; thirdly, increasing availability of home video cassette playback capability has triggered substantial growth in video sales.

For the five largest European countries (i.e. Germany, France, the United Kingdom, Italy and Spain) taken together, box-office receipts declined by some 13% over the period 1985 to 1990.

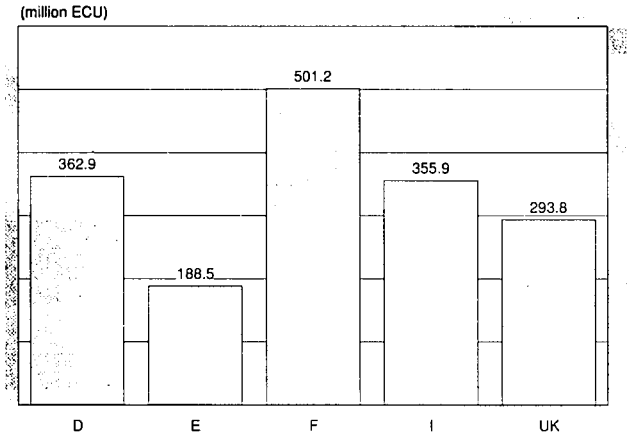
Figure 2: Film and video
Cinema income in the five largest EC Member States, 1990



Source: Screen Digest

The five largest European film producer countries made an aggregate of 433 films in 1985; by 1990, this number had fallen to 410.

Today, film producers acknowledge that a growing portion of their revenue derives from sales and rental of video cassettes. For the five European jurisdictions noted above, the video market in 1990 was valued at 2.38 billion ECU.

Recent trends

Since 1990, there has been a pronounced divergence in growth patterns in the video market as opposed to cinema box-office. Cinema attendance has been progressively eroded in the majority of European countries. Between 1981 and 1990, attendance fell from 750 to 564 million - a drop of some 25%. At the same time, the number of cinema houses fell from 20 513 to 16 728 over the 1985-90 period.

It is difficult to identify a clear trend in terms of the number of films made: these averaged out at 450 per year for the period 1981-1988, but fell strongly in 1989 and 1990. That said, it would be premature to conclude on the basis of these erratic production figures that the recent drop in output reflects a genuine adaptation to new market conditions.

Box-office receipts exhibit a corresponding downturn, although this trend appears to have levelled off recently. The changing pattern which emerges for 1988 to 1990 should be noted. To a large degree, this would appear to reflect a loss of competitiveness in the European film industry, the slight upturn in attendance being attributable in the first instance to imported product.

Growth patterns in the video market reveal a totally different picture. The various indicators available show pronounced differences from one national market to the next, but nevertheless demonstrate an unequivocal upwards trend in the medium term:

International comparison

The downwards trend in cinema attendance in most European countries since the 1960s is in contrast to the remarkably stable attendance figures recorded for the USA and, since 1987, for Japan.

Foreign trade

The dwindling international competitiveness of the European film industry is a further cause for concern. Revenue generated by national production represented on average 19.5% of total revenue in 1990, whereas 70% of total revenue was generated by films of US origin. In Japan, too, there is a similar disequilibrium, albeit less pronounced: there, US product accounts for some 55.1% of total revenue, with the domestic film industry generating 41.4%. By contrast, US-made films account for 97% of receipts in North America.

Consequently, there is a major trade imbalance in Europe: in 1988, for example, the EC trade deficit in this sector amounted to some 500 million ECU in terms of films and 570 million ECU in videos.

Further, the weakness of intra-European trade in the film sector is well-documented: European film output is piecemeal, with films which attract a pan-European audience being the exception rather than the rule.

Most analysts predict that US productions will continue to harvest a larger slice of revenue in foreign markets in the course of the next few years. Estimates suggest that US productions will account for in excess of 55% of box-office receipts by yearend 1992.

MARKET FORCES

Demand

Demand can be assessed according to two different criteria: attendance; and distribution channels and financing.

From the outset, it is important to recognise that the film industry has many different audiences: useful distinctions are made between habitual and sporadic cinema-goers cut across social, cultural and economic barriers.

In short, there is a cinema public which views attendance as a "night out", whereas another cinema public spends a night out (specifically) "at the movies". This polarisation has largely replaced the traditional "family audience" which, today, represents only a very modest share of box-office receipts.

This pattern is not without economic impact. A certain type of cinema audience (often in groups and attracted to films of the "blockbuster" variety) will undoubtedly favour big-budget productions. In this category, US productions clearly boast an undeniable edge.

Perhaps the most significant technological development within the sector is the emergence of high-definition television (HDTV), a new mode of film distribution which offers cinema-quality image reproduction on domestic TV receivers and, as such, represents a potentially serious competitive challenge to traditional cinema houses.

It goes without saying that the development of HDTV receivers will go hand in hand with the development of high-definition video product. This being the case, the film industry must face up to the challenge in much the same way as it did when television originally came on the scene: in other words, it must convince the public at large that cinema still offers a qualitatively better product in terms of image, special effects and viewing comfort. This is imperative if it is to retain a significant market share. In any event, the advent of HDTV will undoubtedly reinforce public perceptions of the relative appeal of television and cinema.

What must also be taken into consideration is the financial pressure on cinema houses: on the one hand, they are squeezed by falling attendance whereas, on the other, they are in urgent need of funding to modernise their premises.

A further major consideration impacting on demand is in respect of distribution channels: increasingly, revenue derives less from cinema performances and more from onwards sales to TV networks and video houses.

Over time, film production houses will certainly experience a growth in these outlets. At the same time, however, consumer patterns are changing at such a pace that cinema house operators are facing a transformation: there will be progressively fewer cinema houses in Europe but they will be more sophisticated and more luxurious. The emergence of large multi-cinema complexes clearly documents that this trend is inexorable.

The video sector has blossomed as more and more European households purchase or rent VCRs, often on the strength of reduced-price lease-purchase deals. The increased availability of film on video has also led to a structural distortion of traditional markets: video equipment rentals now account for a progressively lower share of the European market.

Supply and competition

The canons of conventional economic analysis are difficult to apply to a industry as idiosyncratic as the film industry. Industry analysts repeatedly stress that the success or failure of a given film cannot be predicted with any degree of certainty; in other words, the film industry cannot be assessed in conventional economic terms.

This may be true. Nevertheless, an analysis of the economic structure of the US film industry reveals certain key elements that may account for the current domination of this sector by the USA.

The principal factor exerting a positive influence on the US film industry is the immense size and comparative homogeneity of the North American market.

What also emerges is that the North American market - unlike its European counterpart - is virtually impenetrable to foreign films. The linguistic barrier represents a formidable obstacle: US audiences seem as little disposed towards viewing films in the original language as they are to accept the loss of quality implicit in dubbing.

Above and beyond these cultural problems, however, US companies have been successful in setting up efficient marketing and commercial structures in Europe, whereas the same can by no means be said of European firms in the North American marketplace.

Moreover, the financial resources available to US producers constitute a major plus in terms of competitiveness. With precious few exceptions (some German and Italian studios), European film producers are small-to-medium sized enterprises which face perennial funding problems when attempting to get projects off the ground. There is a marked contrast between Europe's myriad small producers and the Hollywood giants such as Warner, Paramount, Columbia or Disney, all of which boast annual turnover in excess of 1 billion USD. It follows that the US majors can embark on big budget movies which will be worldwide box-office successes.

In the long term, Europe's film industry runs the risk of being caught between a rock and a hard place. The rock is the financial muscle of the major US studios which enables them to turn out products for the mass market. And the hard place is Japan's powerful consumer electronics industry which has now recognised that access to film libraries will be the key to longer-term marketplace dominance and, as a result, has espoused vertical integration strategies.

Production process

Making a full-length feature motion picture is a long and complex process which entails mobilisation of technological and artistic resources of the highest order.

Technological innovation impacts directly on the production process. The key development in this respect is perhaps the advent of "electronic cinema", that is:

- synthetic imaging for special effects;
- gradual convergence (possibly over the next four to five years) of new video and existing film production technology;
- new distribution technology which, some analysts predict, will ultimately result in celluloid copies being replaced by digital data transfers between distributors and operators.

Overall, computers seem set to play an increasingly important role, particularly in animated films, where synthetic imaging comes into its own. It must be conceded, however, that technological advances, however impressive, have not as yet resulted in transforming the industry from its traditional labour-intensive roots (division of tasks, hierarchies of competence, etc.).

In terms of output, various models co-exist within the industry:

- Productivity gains are relatively weak in the case of full-length feature production and, in any event, relate only to certain aspects of the production process (computer-assisted special effects, montage and video sequences).
- Productivity gains are achieved in animated features by division of work along Taylorian lines and, additionally, by reducing image quality (lower number of frames per second and simplification of designs and animation).
- Productivity gains at the consumer end of the industry are generated as a rule by the establishment of multi-screen complexes which permit overheads to be apportioned and by recourse to distribution networks which depress transaction costs and permit more cost-effective advertising.

INDUSTRY STRUCTURE

Companies

On the technical side, firms tend to be small and to offer services which predominantly reflect the particular expertise of their founder or a nucleus management team.

On the whole, European film production companies are also on the small side, although there are a number of large production companies which tend to be linked more often than not with TV programme distributors and to offer a mix of film and video production services. Cases in point are Bavaria Film in Germany, Reteitalia in Italy or SFP in France.

In practice, the largest European production groups tend to have their own studies which boast in-house technical facilities.

The trend in Europe at present is towards the establishment of large distribution and operations networks. There are pronounced differences from one country to the other: in France, Gaumont, Pathé and UGC control 20% of the nation's screens but have a virtual 100% monopoly in Paris. In the United Kingdom, Rank is the leading distributor (with 80 houses and 300 screens). In Germany, UFA is in the number one spot (120 houses and 320 screens). In Italy, Fininvest is the only group at present to have developed a geographical strategy with regard to distribution.

Strategies

Three essential strategic considerations deserve comment: first, recognition of film production as an integral part of the multi-media strategies pursued by the communications industry; second the advent of mass-consumption electronics; and third, the growing physical presence of major US production studios in the European marketplace.

A number of televisual distributors are also extremely active in film production - notably Canal+ and Bouygues in France, Fininvest in Italy and Bertelsmann in Germany. The film industry constitutes a potentially lucrative market for such groups as long as they can exploit the distribution networks that they already own in order to target a larger audience more cost-effectively. There can be no doubt that films - despite differences from one country to the next - represent an optimal means of building a faithful customer base.

This does not necessarily mean that the film industry is becoming a hostage to the dictates of televisual distribution; in fact, the above-mentioned and other major distribution groups view the film industry as merely one aspect of a comprehensive portfolio of audio-visual services which they can offer. Accordingly, some of these groups have actively positioned themselves within the video publishing market.

Another major development in this sector has been the emergence of equipment suppliers as key players within the industry. Recent acquisitions of a controlling interest in major Hollywood studios - such as by Sony at Columbia or Matsushita at MCA - confirm this trend, as does the interest shown by Philips in expanding into the sector.

It seems highly probable that conquering world HDTV markets will hinge on access to filmed material. For the moment, the focus is on HDTV hardware but, in the final analysis, it will be access to film libraries that will determine the respective success or failure of the various high-definition standards currently being developed.

Squeezed profit margins in respect of hardware mean that future profits will essentially be generated via software. This fact underpins Japan's interest in the film industry.

Controlling film distribution networks is a strategic priority within the industry. Not only is network control fundamental to the success of a given film on the cinema circuit, it is also a precondition of downstream revenue generated by video sales and TV broadcast rights.

Of particular interest in this context are the aggressive distribution strategies adopted in Europe by leading US operators. For example, Warner has recently commissioned 30 multi-screen complexes in the United Kingdom and Ireland, earmarked 80 million USD for investment in Germany and announced plans to expand in Spain.

In the longer term, it appears that US domination of European film production could be paralleled by domination in the distribution sector. If this were to happen, the effects would be cumulative: cinema houses would be owned by major US studios which had direct outlets for the films they themselves produced.

REGULATIONS

The majority of the EC Member States have put in place support programmes for their respective domestic film industries.

Support comes in various guises - direct subsidy, selective financial support, grants for screenwriters, fiscal incentives, or measures regulating subsequent TV broadcasting and TV distribution quotas.

Financial support for the film industry is substantial. In France, for example, state aid accounted for some 15% of the aggregate film production budget in 1990. This being so, industry professionals are anxious to maintain the derogations in favour of the film industry currently enshrined in the General Agreement on Tariffs and Trade.

OUTLOOK

In the immediate future, a major question mark hangs over the ability of individual European countries to meet two distinct challenges.

The first challenge is to halt the decline in cinema attendance which has been recorded over the past three decades. Certain countries, such as the United Kingdom or Germany, now appear to have succeeded in this respect. Luring audiences back into the cinema houses has been achieved principally by modernising existing facilities and introducing the concept of the multi-screen cinema complex.

The second major challenge is to recapture a substantial part of lost share in domestic markets. This would appear to be a much more difficult task, notably because of the problems

most European film producers face in targeting pan-European audiences. That said, the increased incidence of European co-productions offers a ray of hope in this respect.

The growing importance of the video industry and televisual distribution as a source of financing for the film industry is the only certain development in an uncertain marketplace.

Television
NACE 974

Four important issues characterise the European television industry at present. First, the globalisation of the communications industry, including television, is at the heart of so-called multi-media strategies whose results so far have been well below declared objectives.
Second, the range and power of European communications groups result from concentration in production rather than in financial terms. Concentration has a twin aim - to respond to the need to diversify into multi-media and to use external growth to achieve a dominant position in the market segment or segments concerned.
Third, the current drive towards internationalisation has imparted a European dimension to the television industry. This is primarily due to relatively restrictive national regulations and the activity of centralised advertising space purchase agencies.
Finally, the audiovisual industry in Europe is still highly fragmented, with cultural and linguistic environments only impacting on the creative aspect of high-quality television. Meanwhile, programmes in general are dominated by the American model, with series production, light entertainment and game shows all aimed at mass audience distribution.

INDUSTRY PROFILE

Description of the sector

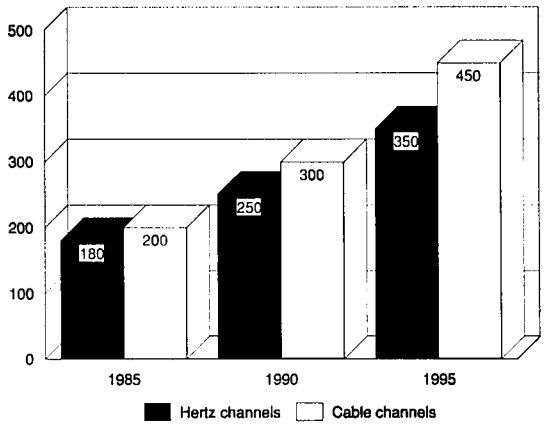
The television industry can be divided into two main sub-sectors: production and broadcasting.

Production

TV products, by their nature, are extremely diverse; they include drama, sports, game shows, light entertainment, news and current affairs and children's programmes. It is also worth noting the important place occupied by motion pictures.

Producers nowadays include audiovisual professionals, communications groups, manufacturers, institutional investors and industrial technicians.

Figure 1: Television
Distribution of television programmes in Europe



Source: Carat TV

Costs, which continue to rise, come in three stages: the acquisition of rights, royalties and trade marks and the payment of producers; technical overheads; and general overheads.

Financing comes in the form of either direct or indirect public funding, start-up capital or risk capital.

Broadcasting

These days, there are two ways of bringing pictures to the consumer: via the airwaves (terrestrially and by satellite) and via cable. The perennial problem of compatibility between PAL, SECAM and NTSC standards will surface once again with the advent on the market of high definition television (HDTV) and its own array of standards - including Europe's MAC, D-MAC, and D2-MAC.

The channels operating today can be grouped in three main but overlapping categories: they are either public or commercial, national or transnational, and general or specialised.

Broadcasting operators include governments, major communications groups and what could be termed multi-media groups.

The resources needed to meet escalating overheads come from various sources: taxes, sale of advertising space, exchanges

or barter, sponsorship, subscription and pay-per-view. Their respective weighting depends on the type of TV concerned.

Recent trends

The European television industry has recorded average growth rates of 6% over the 1980s. It represented a 42.2% share of the world audiovisual market in 1990, with a value of around 82 billion ECU. This share is poised to grow further by 1995.

Production

The 1980s saw European production sacrificed in favour of bargain imports from the USA. Falling audience ratings, relative increases in the cost of imported US programmes and the approaching exhaustion of film library stocks (in France, the current percentage of repeat broadcasts is 58%) are some factors that encourage to think that the situation might change soon.

That said, four major questions remain to be asked. Will we see the emergence of genuine European demand? Language barriers mean that the answer is far from clear.

In light of the attractions of vertical integration, will production be externalised - in other words, will independent producers be encouraged? Given the requirements of government authorities and the economic weight of the sector, it might be assumed that the answer will be yes.

Will channels have the financial muscle to invest in both equipment and in programmes? Pay-per-view and the increase in advertising revenue ought to, and probably will, bring this about.

Will the line between cinema and television markets be redefined? The growing power of the networks, the massive scheduling of film programmes, falling cinema attendance and the increasing role of television in film financing and production strategy - all of these favour a long-term convergence of cinema, video and television.

The development of programme production is a prerequisite of success, given that television is the key market for producers.

Given the slow reaction of the EC, this will not be simple, not least since producers are working in a rapidly-changing environment. In effect, the audiovisual sector is subject to all manner of restrictions, necessitating major restructuring. The borders between cinema, video and television are coming down. Major technical changes are taking place. Production costs are rising, and broadcasters are reducing their financial commitments.

Broadcasting

Deregulation and technical development have come together to foster major growth in the number of television channels in the EC: 75 in 1985 and 123 in 1992 (see Table 10).

Deregulation started in 1954 in the United Kingdom and is continuing in other European countries. It is prompted by the inappropriateness of rules originally drawn up when television was in its infancy and still a state monopoly.

The main thrust of deregulation is to amend legislation in order to ensure that a restricted market is opened up to the private sector. The principal result has been a progressive dismantling of the monopoly of state television.

Technological progress has put an end to a "shortage" of frequencies and increased the impact of new modes of broadcasting such as cable and satellite, breaking down traditional boundaries in the process.

The major development in the run-up to the next century promises to be the advent of high-definition television. HDTV cinema-quality images are purported to be so good as to make the commercial development of HDTV seem inevitable: in-

Source: CIT Research Frost & Sullivan

creased screen size, better colour definition, improved brightness and contrast scales, stereo sound and digital images all contribute to a dismantling of the traditional frontiers between cinema and television.

Technological progress has resulted in substantial changes in the task of broadcasters, notably by making them more dependant on producers and by necessitating major investments.

Faced with rising overheads, financial resources inevitably have to be adapted. In Europe, these represented about 17.5 billion ECU in 1990, and are expected to rise to 26.5 billion ECU in 1995.

Advertising, the source of revenue likely to experience the most substantial change, already contributes the major part of television resources, often at the expense of other media.

International comparison

Production

Three main factors characterise international trade in television programmes:

- One-way traffic from the major exporting countries: in Western Europe, 45% of imported programmes come from the USA, 15% from the United Kingdom, 7% from Germany, 5% from France and 28% from the rest of the world.
- The predominance of drama productions and light entertainment in exported programmes.
- The weak share held by co-productions.

The USA has the lion's share as far as TV drama is concerned, providing 75% of series in Spain, 64% in Italy and 14% in the United Kingdom; the USA is also responsible for 60% of films imported into Europe. The Japanese dominate in animated cartoons.

Each country has its own speciality: cultural programmes from France, religious programmes from Italy and educational programmes from the United Kingdom.

Broadcasting

Even without potentially large-scale commercialisation of HDTV in the years ahead, the world audiovisual market can be expected to expand. This is predicated on the current rate of household spending on equipment such as TV receivers and VCRs, together with major growth in spending on video products.

Penetration rates for satellite dishes and cable reception are constantly growing and are still far from saturation point.

Year-on-year growth in total revenue of television networks is estimated at in excess of 5%. The share of public financing is now growing only slowly if at all, whereas advertising revenue continues to climb. Finally, subscription income to cable channels is growing in tandem with market penetration.

Foreign trade

Europe nowadays is a dominated market in TV terms to the extent that European television networks are massively dependent on programmes made in the USA. These imported programmes were valued at 766 million ECU in 1989, out of total spending in the order of about 1200 million ECU.

Import volumes differ according to the country concerned: imports of US programmes were valued at 103 million ECU in Italy, at 240 million ECU in the United Kingdom, 331 million ECU in France, 309 million ECU in Germany and

Source: OMSYC

135 million ECU in Spain. By contrast, total exports were calculated as 453 million ECU (Italy), 336 million ECU (United Kingdom), 145 million ECU (France), 118 million ECU (Germany) and 81 million ECU (Spain). The US/Europe balance of trade in TV programmes thus massively favours the USA.

MARKET FORCES

The structure of the European television market will, in the long term, be conditioned by strategies deployed by two main groups of players: on the one hand, consumers and broadcasters and, on the other, US producers, independent producers and new arrivals in the market.

Demand

The increase in household ownership rates for colour TV receivers and VCRs and the growth of satellite and cable TV reception, the increase in broadcasting times and major technological advances such as HDTV and the video disc - all conspire to bring about increased demand, not only in quantitative but - primarily - in qualitative terms.

This increased demand will be all the more difficult to harness as supply diversifies, as pay TV establishes a larger market share, and as the TV market becomes more international.

Over the period 1989-1999, annual growth in TV programme demand is projected at be around 37%. This breaks down as follows: repeat showings 145 000 hours in 1989 and 187 000 hours in 1999; programme purchases 168 000 hours in 1989 and 254 000 hours in 1999; in-house productions 148 000 hours in 1989 and 159 000 hours in 1999; co-productions 19 000 hours in 1989 and 35 000 hours in 1999.

To cope with this demand and generate viewer loyalty from a paying audience - either through advertising or subscription revenue - broadcasters will exert pressure on producers, all the more so as their margins are weak.

Broadcasters will take advantage of the disappearance of boundaries between television, cinema and video to become producers themselves; this will give rise to the establishment of multi-media groups and an increase in concentration in the sector. Nevertheless, there will be casualties along the way, as witness the demise of France's TV channel La Cinq.

Supply and competition

Technological advances and deregulation will result in a proliferation of TV channels and a demand for TV programmes that will multiply by a factor of 25 over the next ten years.

It remains to be seen how the supply side will react. As of right now, prospects seem rather bleak. Broadcasters seem concerned exclusively with ratings. And, here in Europe, they have only recently come to recognise the problems they face at the hands of US and Japanese producers.

Production process

The need to develop programmes is growing and will be a crucial factor in any successful European audiovisual strategy.

Set against the current background of broadcasters searching for a different identity, programme quality - and therefore the investment needed - are prime considerations.

Source: OMSYC

There appears to be a remarkable correlation between development budgets and ratings success. This also applies to those programmes which are most successful in export markets.

As far as product development is concerned, three main trends are noteworthy: upstream, the sector is becoming more industrial and more specialised; increased recourse is had to market research; and developed prototypes are not always brought to market.

The need for bigger development budgets has been clearly recognised by different players in the European market. Ways of selecting promising projects have also been developed. That said, mobilisation of financial resources is in itself not enough -what is also required is access to promising creative talent.

INDUSTRY STRUCTURE

Companies

Institutional and private investors, national and multinational communications groups, manufacturers and industry professionals are all involved in the sector.

Producers can be split into two groups: independents and multi-media groups.

Independent producers have been accorded a growing role in the light of recent EC policy decisions, but they remain largely nationally-based.

Multi-media groups have their roots in other media, but are now developing audiovisual activities. European players include Hersant (F), Hachette (F), Bertelsmann (D), Amaury (F), Fininvest (I), Havas (F) and the global empires of Murdoch and (formerly) Maxwell operating in Europe.

As for broadcasting, the number of television channels has grown considerably in recent years (see Table 10).

Strategies

Production

Public TV channels have come under pressure from regulatory authorities, rising costs and increasing specialisation. They have now tended to assume the role of specifiers.

Commercial channels have hived off their production activities more and more to independents. It is they who define a large part of production strategy, usually confined to a national scale.

In Germany, the independent sector first saw the light when a second national channel (ZDF) came on stream. It is based around the major studios and about 80 medium-sized enterprises. The emergence of the private sector has called existing organisational structures into question, and the sector has yet to stabilise.

The independent sector in Spain, after a long period of underdevelopment, now takes a major role in production, following the appearance of new players on the market.

In France, the sector is weakly concentrated, with only 13 companies having more than 50 employees. It would appear that some form of regrouping is called for, presumably based around current production groups.

The structure of the sector in the United Kingdom approximates to that of France and exhibits the same problems and strategies.

Italian producers usually exercise a dual role as producers for both cinema and television. This is an advantage in the medium term, as is the fact that international partnerships are more advanced in Italy than other European countries.

The Americans cannot be ignored: they are no longer able to function purely autonomously and have to look for new market outlets for their product. Finally, the Japanese, by acquiring major studios and their film libraries, have emerged as potentially important European players.

Broadcasting

The larger European broadcasters face the temptation to integrate vertically. There are two factors which induce them to resist: the compelling economic logic behind the separation of the roles of broadcaster and producer; and the regulatory environment which governs relations between the two sides in many countries.

This has the following strategic consequences: first, a partial externalisation of production; second, a search for optimum value from own resources; and third, a development of intellectual property rights management for all broadcasting support activities.

REGULATIONS

Over and above the usual statutes relating to any activity -upholding public order, decency and so on - television is also subject to broadcasting quotas, a general commitment to respect certain rules governing the relationships between producers and broadcasters, and detailed provisions as regards advertising content.

The quota situation differs greatly between countries. None at all exist in Denmark, Greece, Luxembourg or Germany. In other countries, the situation varies, as shown in Table 11.

Aside from debate on the opportunities or restrictions occasioned by quota systems, it has to be said that they constitute a barrier for the majority of the players in the market.

In order to limit vertical integration - with its aim of creating a real audiovisual programme market and improving intra-European broadcasting and financing - regulation of the links between producer and broadcaster have been put in place in France and the United Kingdom. Such regulation does not exist in other European countries.

As far as advertising is concerned, different forms of regulation in different countries prescribe: the duration per hour of advertising spots; the admissibility or otherwise of advertising during broadcast of films; and the advertising in certain sensitive sectors.

In addition to national rules, the EC directive on broadcasting and the provisions of the convention on trans-frontier television also apply.

OUTLOOK

The audiovisual industry in Europe is in a transitional phase between television dominated by the public sector and television governed by the laws of the marketplace.

Prospects for growth and profitability, as well as the promotional possibilities inherent in the media, will encourage new country players such as Japan, as well as groups from other sectors, to invest in the industry.

Although there is still room within the sector for new participants, the costs of entry in terms of annual investment and the financial risks involved will accelerate concentration in the sector in the medium term.

The most urgent question still to be resolved is how the television industry will adapt to the demands of the post-1992 Single European Market in terms of free movement of goods (standardisation) and services (programmes), people (creative and technical personnel) and, not least, capital.

Table 11: Television
Broadcasting quotas in Europe

Belgique/België	60% of TV films and series EC output, or francophone for the RTBF
España	Public service TV: a certain volume of Spanish production by 'contractual agreement'
España	TVE/Cinema: one-third Spanish films
France	50% French language originals and 60% European
Italia	40% rising to 50% European, with a majority Italian
Ireland	35% Irish production
Nederland	10% Dutch culture for pay TV
United Kingdom	No quotas since 1983, but industry self-regulation. 86% EC programmes

Music recording
NACE 345.2

The recorded music sector was adversely affected by the recessionary climate which prevailed in all the industrialised nations in the course of 1991. In the USA, 1991 record sales were down 11% by comparison with 1990. In the United Kingdom - the Member State which heads EC rankings in the music sector - sales were off 7% by comparison with the previous year.

INDUSTRY PROFILE

Description of the sector

The recording industry is a highly capital-intensive sector which presupposes substantial investment commitments. Five companies currently hold more than 80% of the world market. These five majors can be grouped in three categories: mass-market consumer electronics (Philips and Sony), multi-media groups (Warner and Bertelsmann) and distributors (Thorn-EMI).

Recent trends

The traditional products of the recorded music industry were 33 and 45 rpm (revolutions per minute) vinyl discs and audio cassettes. Since the early 1980s, however, technological innovations have radically changed the quality of recorded music and prompted swingeing changes in consumer buying preferences.

Laser-based compact discs (CDs) have gradually replaced their vinyl counterparts. Following a reduced demand for traditional formats, the principal labels had progressively reduced or totally eliminated vinyl output. Thus, some companies no longer manufacture 33 rpm discs, whereas other labels now typically press a modest 3 to 4 thousand vinyl copies even in the case of the most popular recording artists.

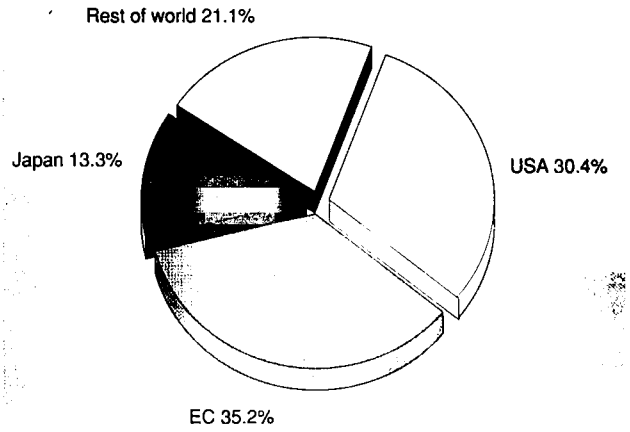
Images have impacted on the music scene, notably in the form of music-video broadcast on dedicated TV music channels. More recently still, the laser video disc has emerged, offering a permutation of image and high-quality CD sound.

The digital-sound compact cassette is being launched in the course of 1992 in the form of Philips' DCC (Digital Compact Cassette) and Sony Corporation's Mini-Disc.

International comparison

In the absence of precise data, it is difficult to effect a direct comparison between EC and non-EC markets. In the recorded music sector, competition is international: the five leading companies are multinational in character and each owns a number of national labels.

Figure 1: Music recording
World market share by country, 1991



Source: IFPI

That said, European groups such as Polygram, Bertelsmann or Thorn-EMI have performed strongly in world markets. At the beginning of 1992, it was estimated that they had captured some 52% of the world market.

MARKET FORCES

Demand

By its very nature, recorded music is a product for which demand is difficult to quantify and anticipate. Records are consumer end products which have an extremely broad-based market, the majority of which is at an average 25 years of age. Demand can be quantified by reference to such parameters as global sales development, market share by country and by hardware support systems.

Since the beginning of the 1980s, the market has grown by some 3.5% on a yearly basis, with the most important growth occurring between 1986 and 1989. The latter fact is no doubt attributable to the advent of the laser disc in 1982 and, more particularly, to a progressive reduction in the cost of both the discs and the laser-based hardware support systems.

The recession which set in as of 1990 has affected the world's industrialised nations and has also impacted on the recorded music sector. Between 1990 and 1991 sales fell 11% in the USA and 7% in the United Kingdom. France and Germany - despite 15% growth in the wake of reunification with the former DDR - both anticipate falling sales in the course of 1992.

Consumption of recorded music on playback systems is, by and large, exclusive to the industrialised countries of the world, the three principal market blocs being the EC, the USA and Japan.

Table 1: Music recording
Distribution of aggregate EC sales by product category

(%)	1980	1985	1986	1987	1989	1990	1991

CDs	0.0	2.6	5.6	10.9	27.2	33.0	42.9

(1) Vinyl, CD and cassette
Source: IFPI

Within the EC, the United Kingdom is the largest consumer, followed by Germany and France. Together, these three countries represent over 70% of total EC consumption. The comparative weakness of the other EC markets is explained in part by their size and in part by their level of economic development.

These percentages do not take account of the volume of pirate copies sold in the respective markets. In Italy, for example, the IFPI estimates that pirate copies represented 13% of market volume in 1990; in the USA, the corresponding figure was 4%. The losses associated with pirate copies in Europe is about 300 million ECU, a figure which represents about 10% of European sales.

The increase in CD consumption is linked to ownership of the appropriate playback hardware. In the EC, the number of CD players sold in 1982 was below one million; this figure rose to 1.7 million in 1986 and to 3.2 million in 1987. This explains the surge - albeit somewhat belated - in compact disc sales: CD's share of the EC sound recording market rose from 2.6% in 1985 to 10.9% in 1987, and then boomed to about 43% in 1991.

Demand is a function of the support hardware purchased, but it is also conditioned by the type of recorded music available. The vast majority of recorded music is pop music or variations on classical music. A rough estimate reveals a ratio of 9:1 in favour of pop as opposed to classical recorded music sold, although in the USA classical music accounted for as low as 4% of overall sales in 1991.

The impact of publicity in all its various forms cannot be denied. In this respect, the key media are radio and television, although television is less important than might be assumed. Nevertheless, experience in France has demonstrated that permission to advertise recorded music on TV was hailed as a major breakthrough by the recording companies.

Advertising campaigns mounted by the recording companies are strongly reliant on proven formulae. Thus, in 1991, compilation albums accounted for 16% of album sales in the United Kingdom. In addition, the sale of boxed albums featuring the collected recordings of an individual performer or group has emerged as a viable strategy for stimulating demand and boosting profits.

International industry events such as MIDEM have also helped promote broader acceptance and consumption of recorded music. In this case, the recorded music is underpinned by music-video- presentation.

Supply and competition

In the recorded music business, supply adapts very rapidly to demand. A simple comparison between domestic consumption of CDs in the principal markets and annual production capacities reveals the existence of substantial over-capacity. Worldwide, annual capacity in 1989 was in excess of one billion CDs with a consumption of 770 million units in 1990.

Within the EC, competition is waged among five large firms which, together, hold some 80% of the EC market. In 1991, according to CEO Alain Levy, Polygram had a 24.5% share of the EC market.

The smaller independent labels often do not have the financial muscle to underwrite large-scale production or to assume the financial risks inherent in launching a new recording.

Distribution equates to between 25 and 35% of production costs and, as such, is beyond the financial resources of the smaller labels. This being so, the general practice is for the smaller houses to subcontract distribution to the larger firms by way of catalogue sales, on the grounds that risks are increasingly spread as the number of catalogue outlets increases.

Since its recent acquisition of Virgin Records, Thorn-EMI now has a catalogue featuring 825 000 titles. For their part, the smaller labels rely on a quick commercial turn-around and, accordingly, subcontract operational phases both upstream and downstream of the recording phase.

Production process

The production process comprises origination, recording, publishing and distribution.

Origination stage costs vary. Essentially, this phase relates to performer contracts, the value of which will necessarily fluctuate depending on the relative status of the performers concerned.

The costs associated with the recording stage, i.e., sound recording and mixing, also vary depending on the desired end product. These costs can fluctuate between 10 and 30% of total production costs in the case of a compact disc. The leading labels all maintain their own recording studios.

Publishing stage costs relate principally to recording royalties. The producer, in issuing the recording for public consumption, assumes all potential profits and losses.

"Pressing" denotes serial reproduction of the recording. Like recording studios, pressing facilities represent an essential input to the production process. Pressing and surface treatment

of the product absorb between 15 and 25% of the total production costs of a CD.

Manufacturing compact discs presupposes leading-edge technology and a commitment to substantial investment. The five major labels have integrated the disc pressing stage and now have facilities in all major markets. As of 1990, there were more than 60 pressing facilities in 17 countries worldwide.

Small, independent pressing firms have typically diversified their production into micro-groove, cassette and CD video production in a bid to optimise return on investment.

Distribution is a key stage in the recorded music industry. The distributor is a direct client of the publisher who, in effect, has no contact whatsoever with the end user (other than via promotional activities).

In the course of the last 15 years, distribution patterns have altered considerably: small distributors are now disappearing from the scene to be replaced by larger distribution infrastructures. As an illustration, there were 50 small distributors in Paris in 1992, down from 150 a decade and a half ago. Typically, the small distributors specialise in niche markets, leaving mass markets to the larger houses.

The prime distribution channel is via large chain stores which tend to exhibit a restricted choice but an attractive pricing structure. A second distribution channel has emerged in recent years in the form of "multi-specialist" stores which, to all intents and purposes, are effectively music supermarkets. Here, the choice is extremely wide-ranging (e.g., in excess of 100 000 titles at Virgin). In both the above cases, the volume of sales is such that distributors are in a strong position to negotiated preferential discounts.

The third distribution channel comprises medium-sized record chain store outlets which offer customers a quality service at cut-price rates. Examples are Nuggets in France or Our Price in the United Kingdom.

The final distribution channel comprises the sales outlets of the record companies themselves. Virgin Megastores and Thorn-EMI's HVM outlets sell both from their own lists and those of other labels.

Table 4: Music recording

INDUSTRY STRUCTURE

Companies

The recorded music industry is characterised by a marked concentration of firms, with five multinational groups sharing 80% of the global market. Additionally, there are many companies in each country (particularly in the United Kingdom, where there are about 1500 companies).

The five groups in question and their main labels are: Sony Music, notably via BS (Japan); Polygram (NL), controlled by Philips; EMI, notably via Thorn-EMI and, as of 1992, Virgin (UK); Warner Music (USA); BMG Music, notably via Bertelsmann Music Group (D).

Concentration within this sector has been intensified in the wake of a number of acquisitions which, by definition, have resulted in the disappearance of some of the smaller independent houses: between 1987 and 1992, there was a ten-point fall in the number of independents. The most recent major development in this respect came in March 1992 when the Virgin Music Group was acquired by Thorn-EMI in a takeover valued at around £550 million.

The five leading producers are diversified groups; as such, they accord varying levels of importance to their music business.

Geographically speaking, firms in the recorded music sector are from three main countries or regions of origin - Europe, Japan and the USA. To a considerable degree, however, this distinction is specious inasmuch as each of the major houses publishes titles in a great variety of national markets and, moreover, maintains production facilities (notably pressing plants) throughout the principal consumer markets.

Strategies

In essence, the main players in the recorded music sector follow one of three broad strategies. Respectively, these are based on control of the production process, catalogue content, or advanced technology.

Table 5: Music recording
Share of world market

(%)	1987	1992 (1)
CBS	19.5	19.5
Poygram	17.3	17.5
EMI	15.9	20.5
WEA	14.1	15.5
BMG	11.0	14.0
Other	22.2	13.0
Total	100.0	100.0

Source: Eurostaf

Control of production

Control of production means integration of upstream activities such as recording and pressing and downstream control of distribution. This strategy is reserved to those firms which have the commensurate financial resources.

The majors have integrated the pressing phase, either by forging links with other industrial groups - as is the case with Philips/DuPont de Nemours or Thorn-EMI/Toshiba - or by other means, such as equity participation. The shining example of downstream integration is undoubtedly that of Virgin Megastores, which were excluded from the takeover by Thorn-EMI.

Catalogue content

The publisher's catalogue or list comprises the full range of titles made available to distributors. Lists can be short and tailored to niche markets, which is the case with the smaller independents, or extensive - which is the rule among the majors. Anticipating a takeover, Virgin signed extremely expensive contracts with leading performers in order to boost the value of its portfolio: 35 million USD with The Rolling Stones and 30 million USD with Michael Jackson.

Advanced technology

The technological challenge consists in the continuing development of new products to boost demand and obviate market saturation. The recording industry will this year launch new pre-recorded formats (DCC and mini-disk) which promise to achieve precisely that over the longer term.

To ensure that the copyright owners are not disadvantaged by the new technology (i.e. through private copies), a new system of protection (SCMS) has been incorporated to limit the number of copies that can be made from the pre-recorded original.

REGIONAL DISTRIBUTION

It should be noted that, taken together, the United Kingdom, Germany and France represent more than 70% of the EC market.

The Netherlands is one of the smaller EC Member States and, as such, exhibits only a modest share of the total EC market. That said, market penetration is high: the Netherlands is one of the largest per capita consumers of CDs and one of the best-equipped countries in terms of playback hardware.

REGULATIONS

Generally speaking, recorded music is a product which conforms to commonly-accepted commercial standards. On the other hand, by its very nature as a creative product, protected by intellectual property legislation, producers must take into consideration the moral and economic rights of all the contributors (authors, composers, performers).

Each country has its own regulatory provisions in this respect, that are currently subject to EC harmonisation. Usually, in each country collecting societies manage the rights of the creators.

The music industry is facing the problem of piracy and private copying. In the former case, the copies in question are made with a view to fraudulent sale and without due remuneration of the authors concerned. Copying for private use is, as such, free from prohibition. In a bid to curb illegal copying, some Member States have established a royalty on sales of blank cassettes and hardware equipment.

OUTLOOK

Despite the recessionary climate, the recorded music sector should continue to grow in importance in the years ahead.

In geographical terms, the leading firms in this sector are predicting market growth in the countries of Eastern Europe, together with increased market demand in Latin American and Southeast Asia.

On the technology front, the introduction of DCCs in 1992 should stimulate demand. According to some analysts, DCCs could secure between 4 and 5% of the market in the course of 1993.

NEW PUBLICATION ON SERVICES

eurostat

What are services in Europe ?

Services in Europe are :

1 - *Commerce*

2 - Transport activities

3 - *Hotels, Restaurants, Catering, Travel agencies*

4 - Credit institutions

5 - *Insurances*

6 - Information, Communication, Business Services

7 - *Audiovisual*

What does the publication contain ?

The publication contains :

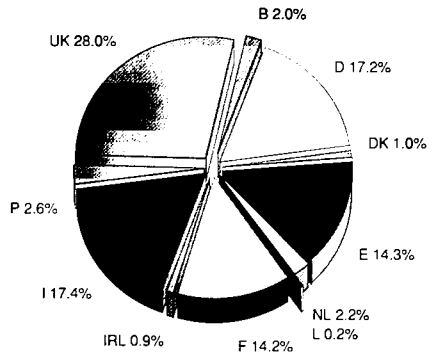
AN OVERVIEW ON SERVICES IN EUROPE

The aim is to give a general description of services through information derived from the National Accounts.

With **more than 30 diagramms**, this chapter outlines in **50 pages** the composition of Services, compares market services at international level in terms of **value added at market prices and employment**.

Methodological comments are also included.

The relative share of countries in the «HORECA» branch of market services in Europe in 1990 According to total employment (excl. GR) ***(extracted from the publication)***



BUSINESS STATISTICS ON SERVICES

This chapter is divided into seven sectoral parts. It provides **200 pages of key figures**.

Four economic variables have been selected from the MERCURE data base: **number of enterprises, turnover, gross value added at market prices and employment**.

A selection of data has also been extracted from other Eurostat data bases to offer a large overview of sectorial statistics.

Where is the publication available ?

This publication is available at the:

OFFICE FOR OFFICIAL PUBLICATIONS OF THE EUROPEAN COMMUNITIES, L- 2985 Luxembourg

*The projects related to the **MERCURE** Information System on Services are conducted by the **D4 Unit : "Services and transport"** headed by Mr. Lancetti*
Eurostat, Bâtiment Jean Monnet, Unité D4, L-2920 Luxembourg
