The opinions expressed in this publication are those of the authors alone. Under no circumstances should they be taken as an authoritative statement of the views of the Commission of the European Communities.

Panorama is commissioned by the Unit "Competitiveness and general questions of industrial policy" of the Directorate-General for Industrial Affairs of the Commission of the European Communities (DG III), with the cooperation of the trade and professional associations of the European Community.

All professional associations/organisations known to the Commission which represent industry at the European level were asked to contribute material on their sector. At the end of each monograph, addresses and telephone and fax numbers of the respective professional association concerned are indicated.

The many consultants and associations that contributed to this edition of Panorama are listed at the very end of the publication.

Questions about the content of the Panorama of EC Industry should be directed to the association concerned or to the Commission service responsible for this publication:

Message from Jacques Delors

President of the Commission of the European Communities

With the completion of the internal market on 1 January 1993, the Community turned a page in its history.

New stages in its development, including the establishment of the European Economic Area, the quest for agreements with the countries of Central and Eastern Europe and the renewed attempt to conclude the GATT negotiations, will soon be reached and will ultimately enable the economic and commercial frontiers of the Old Continent to be extended even further.

We must welcome the fact that these major accomplishments have come about during what has been a short period of time in the Community's existence.

The successful construction of these landmarks, indispensable as they are for better integration of Europe's tremendous economic potential, is indisputable proof of the dynamism which characterizes the action of all European citizens.

The Community will now have to consolidate these successes internally by implementing the Treaty on European Union, and in particular by pressing ahead with economic and monetary union, the positive effects of which will strengthen the competitive position of Community firms wherever they do business.

The considerable expansion of the internal dimension of the Community market, together with the harmonization of technical product requirements and the freedom to operate on the basis of common rules, now provides our firms with an environment comparable, if not superior, to that of our major competitors in the world at large. There can be no doubt that this will allow our firms to adopt the strategies they need to meet the challenges ahead with success and confidence.

Despite the progress already made, we should not underestimate these challenges, foremost among which is the slowdown in global economic activity. To overcome them, the Community will have to continue with policies combining rigour and imagination on the part of both governments and individuals. And this in a context where firms are having to come to terms with global competition and with new constraints, linked in particular to the need to protect the environment, to explore new technologies and to anticipate major industrial changes.

It is against this background that I am particularly pleased to present this fourth edition of the Panorama of EC Industries. This European Commission publication has the great merit of being an essential reference work for many people from the business, political and academic worlds, as well as of contributing to improving our knowledge of the various sectors of Community industry.

I would invite everyone for whom better knowledge of the various aspects of our industrial activity is indispensable for their own work and discussions to draw from this publication the information and inspiration they need.

Jacques Delors

Preface by Martin Bangemann

Vice-President of the Commission of the European Communities

Since 1 January 1993 operators in the Community have been able to do business in the largest domestic market in the world. In the space of a few years, the European Community has managed the remarkable feat of creating a single market from twelve separate, national markets. This success has been possible only because Member States and firms recognized a large home market as being essential to maintain international competitiveness.

Following the removal of border controls and technical trade barriers, businesses can now supply a single product for the whole of the single market. Manufacturers no longer have to produce for twelve separate markets. This increases competition enormously on the European home market. European firms must respond to the increasing pressure of competition by being increasingly cost-conscious if they are to continue to be successful in the market place. Nor is it any longer enough to measure success by the yardstick of Europe alone. The international competitiveness of European firms has to be gauged against our competitors on world markets, since these are the relevant markets for most products. Only manufacturers who produce to world market standards have a real chance of success.

The primary objective of the European Community's industrial policy is to increase the international competitiveness of European firms. To achieve this we must not rely on copying our competitors, for this would only lead to dependence on them. We must rather build on the economic strengths which undoubtedly exist in the Community. Above all, these include demanding standards and a skilled workforce. Even more important, however, is a business environment geared towards competition so that there can be fair competition between European firms. Government intervention and maintenance subsidies prevent the necessary structural change and so intensify structural crises. That is why strict discipline as regards subsidies is one of the most important pillars of industrial policy, even during an economic slowdown. A return to the old race to subsidize serves no-one, not even those receiving the subsidies. European industrial policy must accelerate structural change and promote the widespread use of new technologies. Here the Community authorities should not try to usurp the role of market forces. But wherever government action is necessary, it must be taken with the specific objective of increasing productivity and offering incentives for technological innovation. The 'European way' is based just as much on the belief in the free play of market forces as on government responsibility for maintaining and increasing international competitiveness. The inclusion in the Maastricht Treaty of the "Industry" chapter now makes this clear for all to see.

The success of European industry will not come solely from mastery of the latest technologies. International competitiveness depends increasingly on the capacity to optimize production processes. The largest productivity reserves are found in improved organization of work and structuring of operations. Nowadays the key to economic success no longer lies only in the ability to invent, but also in the capacity to translate inventions into mass production more rapidly and efficiently than the competition. That involves flexible production processes and closer cooperation between manufacturers and suppliers. Small and medium-sized firms are just as important to the economic success of the Community as are large firms. Highly-specialized suppliers are as dependent on the success of large European firms on world markets as large firms are reliant on rapid and reliable subcontractors. This can gradually lead to a development partnership which will be one factor in ensuring the competitiveness of European industry. The internal market offers European industry new prospects for the future. What we must do now is try to realize them.

Martin Bangemann

Introduction by Riccardo Perissich

Director-General for Industrial Affairs
of the Commission of the European Communities

Businesses and governments must share the responsibility for meeting the challenges and responding to the opportunities presented to industry by the global economic situation. This presupposes that individuals must have access to as much information as possible so that they can judge the merits of the policies adopted.

In 1992 the European Information Association awarded "Panorama of EC Industry" its "Award for Excellence" for official publications containing information on Europe.

This award confirms that "Panorama" has now become a standard reference document and a working tool for a very large number of businesses and business analysts.

Its success is without doubt the result of the originality of its production process, based as this is on close cooperation between the European trade associations representing the different sectors of industry and the Commission's specialized departments and units, which work daily with the associations to promote the competitiveness of Community industry.

This fourth edition of "Panorama" is published at a time when the Community has reached a fundamental milestone in its process of integration.

The completion of the internal market in 1993, in which Directorate General III of the European Commission has played an extremely active part, represents the realization of a major objective of Community action and the successful completion of deliberate efforts to build the largest integrated market in the world.

Anticipation of the benefits of the Single Market has already led to profound changes in the structure of the Community's industry and service sectors, making them more flexible, better adapted to the new demands of competitiveness, and more in line with the wishes of Europe as a whole for healthy competition.

Taking advantage of the particularly favourable economic climate at the end of the 1980s, most sectors were able to adapt their strategies to better coverage of Community markets and increased operational efficiency.

However, the changes already implemented will have to continue in order to meet the challenges posed by the creation of the European Economic Area, the gradual opening-up to the market economy by the countries of Central and Eastern Europe and the conclusion of the GATT Agreements.

Businesses will have to be active in their pursuit of these important changes, despite the deterioration in company profitability caused essentially by the slow-down in economic activity affecting the economies of the industrialized countries. This is the background against which Community action on industry, whose principles were set out in the Commission communication "Industrial policy in an open and competitive environment", will have to be broadened to encourage completion of the work outstanding.

This new edition of "Panorama" reflects the progress already made on industrial competitiveness and international opening-up of markets, and takes account of the uncertainties thrown up by the latest economic developments.

For many sectors it was difficult to prepare forecasts, but they will contribute to clarifying future prospects and facilitating business decisions. Forecasts were produced thanks to the joint efforts of the authors of the monographs, trade associations and Eurostat (the Statistical Office of the European Communities), whose contribution and statistical knowledge greatly helped the authors in their work.

As in previous editions, efforts have been made to increase sectoral coverage and harmonize statistical information so as to supplement existing sets and analyses. This is particularly true of service sectors, for which better quality information is now available.

A large number of associations have updated and expanded their previous year's contribution. Many others have provided statistics or partial reports. All the associations whose names appear at the end of the sectoral studies were consulted on the contents of the texts now being published and were thus able to make comments and observations.

This particular feature is an essential element in the production of this book and gives it a unique character compared with other publications dealing with industry. It also explains why the opinions expressed in a number of analyses do not necessarily coincide with the views held at the Commission and therefore commit only the authors, whose names are given at the end of the monographs. A number of the sectoral analyses were written by experts or by the Commission departments responsible for industry.

Overall responsibility for this edition falls to the Unit for competitiveness and general industrial policy questions in the Directorate-General for Internal Market and Industrial Affairs of the European Commission, which contracted the technical coordination and editing to an outside consultancy.

A number of changes in presentation in the work as a whole and its various chapters have been made in order to make the text clearer and bring it more into line with the wishes of a large part of the readership.

As in each edition, the special issues in the first part of "Panorama" cover questions of topical interest. Thus, the monographs deal with progress on completion of the Single Market, the problems of the defence industry, urban transport, cooperation between SMEs, and the growth of mergers and acquisitions in the Community.

The sectoral analyses should be read independently of each other, bearing in mind that while every effort has been made to achieve consistency of information, statistical data cannot be cumulated across sectors.

I would like to thank all the contributors and those who played an active part in producing the fourth edition of Panorama. I can assure them that DG III is particularly pleased with the final result.

Riccardo Perissich

Panorama 1993 time frames and statistics

Panorama 1993 provides a comprehensive picture of industry and services within the European Community. It is intended for all those requiring an update on the present situation and probable future developments in the manufacturing and service industries in the EC.
Panorama opens with a "special features" section, which takes a global approach to a number of horizontal subjects of topical interest. The main part of the book - the industry reviews - provides a microeconomic survey of EC industry and services, tracing the major developments in production, employment, trade and structural change and includes, in most cases, detailed statistical data and forecasts.

Time frame

The industry reviews and forecasts were written during the second and third quarters of 1992. Time series run from 1982 onwards, and the latest data is limited to 1991. Gaps in the data were filled by estimates wherever information was available, and these estimates are footnoted in the tables.

All figures for 1992 are estimates. Forecasts, if available, were provided by the associations or consultants involved in the compilation of individual reports.

Industry classification system

The selection and ordering of industries and services included in Panorama is based on the NACE coding system. This system classifies economic activity in terms of the nature of goods and services produced or by the nature of the production process employed. It is arranged on the decimal system and is subdivided into divisions (1-digit codes), classes (2-digit codes), groups (3-digit codes), sub-groups (4-digit codes) and items (5-digit codes). Panorama is primarily focused on the '3-digit' level.

More detailed information on the NACE codes is contained in the General Industrial Classification of Economic Activities within the European Community published by Eurostat (1985 reprint of the 1970 edition). This publication is available from the usual outlets for Community publications.

Although most chapters are headed by the appropriate NACE code, some do not have a NACE code indicated as the sector represents too small a fraction of the total NACE group. This is particularly common in the service sectors.

Revisions to the NACE classification have been incorporated in a Council Regulation (OJ L293, 24th October 1990) and will start being used for data collection over the next few years. One of the objectives of this revision is a further breakdown of some service and industrial categories. Even when a NACE code appears beneath the sector title this should be regarded with caution. In some cases the NACE classification does not exactly coincide with the industrial sector under discussion. Each chapter includes a preliminary section explaining the sectoral coverage in the chapter in question, and indicating the extent to which this deviates from the NACE classification. There are cases where an overlap occurs between sectors and therefore data cannot be cumulated.

Statistical data

The statistical data in Panorama should be regarded with caution, particularly for the more recent years where data have often been estimated. The two main sources of data are Eurostat and the professional associations. Data sources are indicated for each statistical table.

For manufacturing industries each chapter includes a summary table containing the main indicators for the industry. These cover apparent consumption (defined as production + imports - exports), net exports (the trade balance of the Community with the rest of the world), production and employment.

Data in the tables are in current ECU unless otherwise stated. Indices (reference year: 1985=100) have been calculated for production and trade data providing easier reference for trend changes. The productivity measure used in certain monographs is based on value added at factor cost in 1985 prices per person employed.

Every effort has been made to include data for all 12 Member States. All figures are on a pre-unification basis, and exclude East Germany unless otherwise stated. However, where data are not available for the EC-12, country coverage is clearly indicated in the footnotes appearing below each table. Production figures for the USA and Japan derived from their respective censuses of manufacturers have also been included. To compare the Panorama of EC Industry with the US Industry Outlook, Eurostat can provide you with a table correlating NACE to the US SIC.

Production and employment

Data for production and employment come from annual enquiries conducted by Member States to **all firms with 20 or more employees**. The exceptions to this are Spain and Portugal where the coverage is for firms of all sizes. Figures are generally available at the NACE 3-digit level. The production data exclude VAT, and the employment data relate to persons employed excluding home workers. The definitions are standardised, and so the figures are comparable across industries and countries.

Estimates are not supplied to Eurostat by Member States for the firms not covered by the enquiries, and the figures under-report actual employment and production. Where this is significant, either industry association sources are used or a note is made in the commentary. Derived statistics which are calculated from both production and trade statistics will also be affected. Apparent consumption will be understated, and import penetration ratios and export rates will be overstated.

Gaps in Eurostat's data for production and employment have where possible been filled by estimation. Denmark provided

final data up to 1990; Germany, Spain, Luxembourg, the Netherlands, and the United Kingdom up to 1989; and the remaining countries provided data up to 1988. EC totals contain estimates for missing countries, and these are not specifically footnoted.

Estimates are derived from short-term indicators such as indices of production, producer prices and employment. Data for 1991 are based on indicators for the early months of the year, but also take into account independent sectoral forecasts. Eurostat's estimates are only made for the NACE 2-digit and 3-digit level. Gaps in industry association figures at the 4 or 5-digit level have normally not been filled due to the scarcity of statistics at this level.

Exchange rate conversion and deflators

All data are reported in ECU, and national currencies have been converted at the average exchange rate prevailing for the year in question. The exchange rates used for the conversions are stated in the 'Annex' section at the end of the 'Highlights' chapter. Producer price indices have been used to deflate production and value added data. In cases where the corresponding NACE 3-digit index has not been available, the NACE 2-digit index has been used. For Portugal, where such indicators are not yet available, the corresponding retail price indices have been taken.

Trade data

The trade data are reported in terms of Community trade flows with the rest of the world. In most cases, these data are based on Eurostat figures. Export valuations are generally fob (free on board, i.e. excluding freight and insurance costs) whereas import data are cif (i.e. inclusive of carriage, insurance and freight). Import statistics may generally be regarded as slightly more accurate than export statistics due to greater ease of data collection in the former case.

All trade figures are in current ECU. For comparative purposes, the ratio of exports to imports (X/M) has been calculated for each set of trade data.

Trade figures for Spain and Portugal before 1984 have been estimated from non-Eurostat sources.

Table of contents

Chapter 5: Non-metallic minerals

Chapter 6: Chemicals

Chapter 7: Metal products

Chapter 8: Mechanical engineering

Chapter 9: Electrical and electronic engineering

Chapter 10: Electronic engineering

Chapter 11: Transport equipment

Chapter 12: Instrument engineering

Chapter 13: Food, drink and tobacco

Chapter 14: Textiles, leather, footwear and clothing

Chapter 15: Wood processing

Chapter 16: Pulp, paper, printing and publishing

Chapter 17: Rubber and plastics

Chapter 18: Other manufacturing industries

Chapter 19: Construction

REVIEWS AND FORECASTS: SERVICE SECTORS

Chapter 20: Distribution

Chapter 21: Tourism

Chapter 22: Transport services

Chapter 23: Financial services

Chapter 24: Business services

Chapter 25: Information services

Chapter 26: Social services

Chapter 27: Audiovisual services

Q U E S T I O N N A I R E

FOR THE ATTENTION OF READERS OF PANORAMA OF EC INDUSTRY

This is the fourth edition of "Panorama of EC Industry" published by the Office for Official Publications of the European Communities. We would be grateful if you could complete this short questionnaire which will enable us to adapt future editions of Panorama to your needs.

Please mark the appropriate response(s)

1) How do you know about Panorama?

Advertisements	( )

Special Features

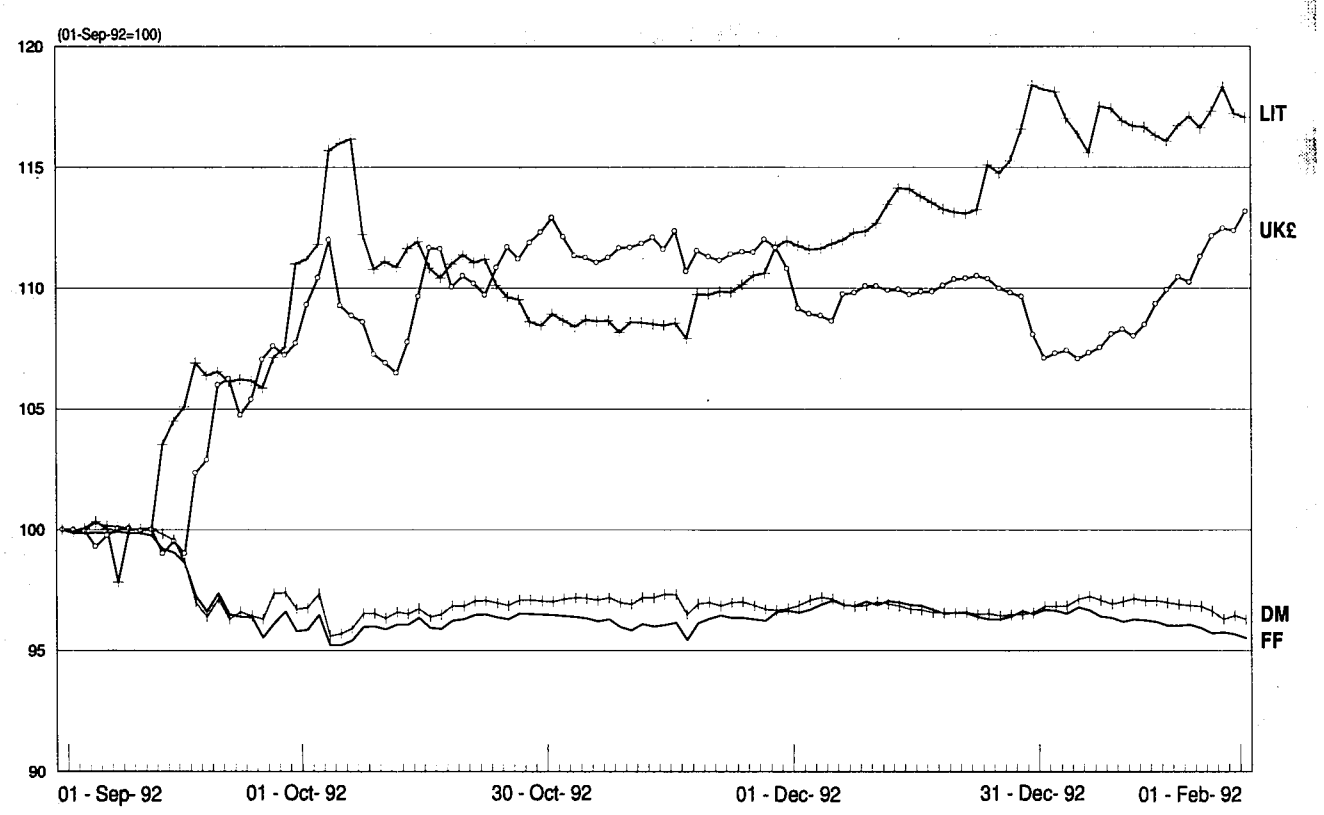
Highlights

INTRODUCTION

This fourth edition of the Panorama of EC Industry was prepared during the second half of 1992, in the midst of major turbulence on exchange rate markets and declining business and consumer confidence. In 1993 and beyond, Europe's industry will have to face a new set of challenges, while policy makers address a number of issues that could not be resolved before the end of 1992, as had originally been planned:

- The Maastricht Treaty, which shapes the new Europe, is still awaiting ratification by some of the Member States.
- The UK pound and the lira, which had to drop out of the EMU at the end of September, have not yet rejoined, despite Italy's hopes to bring the lira back into the system as soon as possible. During the first months of 1993, speculators were still putting pressure on some of the system's weaker currencies, sometimes doing so successfully (as with the Irish punt), other times less so (with the French franc).
- By the end of 1992, no agreement had yet been reached within the framework of the Uruguay Round. The change in US administration mid-January leaves little prospects of a rapid conclusion to the Uruguay Round.
- The modernisation of the economy of the East German Laender is proving to be much more expensive than had originally been anticipated. It is draining resources in Germany and leaving little room for a monetary expansion in the EC in early 1993.
- Chaos is what best characterises the present situation in the former planned economies. The unstable political situation in the countries of Eastern Europe discourages foreign direct investment in these regions.

Figure 1: Changes in exchange rates of selected currencies against the ECU



Source: DRI Europe

Furthermore, the US economy continued to post only moderate rates of growth at the end of 1992. Hopes of a stronger recovery began to subside as President Clinton seemed to step back on some of his election promises. As always when economic conditions are poor, the possibility of protectionist measures arises. Should some of the world's governments yield to pressures for increased protection of what are viewed as "strategic" industries, world trade growth prospects would be dampened, which would threaten the recovery.

In Japan, the economic situation was still deteriorating in the early months of 1993, with little hope of a recovery before the second half of the year at best.

Europe's industry has been affected unevenly by these various factors. Some sectors seem to have continued navigating virtually unaffected by the storm whereas others, already hurt by the growth recession of the early 1980s, by the unfavourable exchange rate developments in the mid 1980s, and by the enhanced competition from new suppliers on the world market, experienced a serious blow. Among these casualties, are the iron and steel and computer industries and defence.

In these troubled times, this *Panorama of EC Industry* attempts to give a clear picture of the present state of Europe's industry, of its relative strengths and weaknesses, and of the ways businesses themselves are trying to cope with the current problems. In the first part of this *Panorama*, a number of issues of particular relevance for Europe's industry today are discussed. Such issues include recent trends in cross-border mergers and acquisitions, and in direct foreign investment (both within the EC and by EC companies in the rest of the world), the impact of the completion of the Single Market on European industry and an analysis of the EC firms' relative performance in patented technologies. In the second part of *Panorama*, Europe's economy has been broken down into over 180 industrial and services sectors, each of which is the subject of a special chapter.

The present article provides an overview of the key issues that are discussed in this fourth edition of the *Panorama*. It compares the relative performance of sectors in Europe over the past five years, highlighting those factors that will influence these sectors future growth potential. The analysis has implications for both future restructuring needs or policy. In many of areas, the Commission of the European Communities has already developed an action plan, which is outlined wherever appropriate.

THE EC ECONOMY IN 1993 AND BEYOND

In September of last year, Europe's currency regime fractured and came close completely to breaking apart under the strain caused by high German interest rates resulting from the cost of unification. The prospect of the French referendum on Maastricht provided the trigger that set attacks on one currency after another, starting with the most vulnerable (the lira and sterling) and progressing to the peseta, the Irish punt, the Danish krone and even to the fundamentally strong French franc (Figure 1).

These repeated attacks on the EMS currencies further undermined business confidence, dashing hopes of a rapid recovery in the beginning of 1993. Still, it is the long-term impact of these currency movements, more than the short-term one, that is most alarming. Indeed, the short term-impact on growth of the turmoil in the money markets has not been that considerable. The EC economic outlook had already started to darken considerably over the summer of 1992, with evidence accumulating of an incipient recession in Germany and a deepening recession in the United Kingdom. The problem - high real interest rates - has now become so deeply rooted into the system that even if interest rates were to come down significantly in the early months of 1993, the EC economy would not be able to switch immediately from a recession mode to one of rapid growth.

The present state of the EC Member States' economies and the prospects for 1993 and beyond are discussed in greater depth in the special feature on "Sectoral Prospects", in the first part of this book. This situation can be summarised as follows:

- Germany, hit by high interest rates, rapid labour cost increases and the D-Mark's appreciation, will see its economy contract in 1993. The German economy is suffering from the unwinding of the unification boom and from the deterioration in its competitiveness relative its main trading partners. Most economic indicators for Germany point to a negative rate of growth this year: order books are falling, business confidence, as measured by the EC's business tendency surveys, has come down to a worrying level, industrial production is declining in many sectors and unemployment is rising. This, combined with the high level of interest rates, is expected to make fixed investment one of the main casualties of the recession. Although residential construction may hold up due to the shortage in housing, the outlook for business fixed investment is actually quite poor. Even the service sectors, which had held up fairly well until now thanks to the unification effect, will not hold up indefinitely.
- The French economy is one of the soundest in the EC at present. Its currency, despite the fact that it has been repeatedly under pressure from speculators, is fairly valued against the D-Mark and possibly even somewhat undervalued. High interest rates, however, are preventing the economy from benefiting from its underlying soundness. This keeps growth under the minimum level required to stabilise unemployment, which is a major cause for concern for policy makers in an election year.
- In Italy, the budget deficit and the privatisation plan dominate the agenda. The planned cuts in public spending and the increases in revenue will dampen consumer spending, while the business sector is in the midst of restructuring. The lira, which had still not re-entered the monetary system

Table 1: EC macroeconomic trends

in the beginning of 1993, is expected to only re-enter with a wider fluctuation band and if there is a clear presumption that the new parity is "fixed but adjustable".

- In the United Kingdom, problems continue to accumulate as the weak economic growth of the past few years has sent the deficit sky-rocketing - it is now in the 7-8% range as a share of GDP. Inflation will likely rebound as soon as the economy recovers. The UK pound will not likely rejoin the EMS in the near term such that the economy ought to be able to maintain its competitiveness vis-à-vis the rest of the EC through continued devaluation of the sterling. The faster projected growth in real UK GDP this year is, in fact, principally a reflection of stronger projected growth in real net exports.

Elsewhere, the picture is not much brighter:

- In the USA, there is growing confidence that real GDP growth will be in the 2.5-3% range this year, and that it could rise well over 3% in 1994 provided that the new President introduces the package of fiscal stimulus that he promised during the election campaign. However, this is unlikely to be sufficient to lead the world economy out of the present growth recession or to solve the difficulties of those of its sectors which are presently calling most vehemently for increased protectionist measures (such as the steel sector and the aerospace industry).

- In Japan, the economic situation also continues to deteriorate rapidly. The chances of a speedy Japanese recovery have faded, and there is now little hope of much improvement before mid-to late 1993.

RECENT PERFORMANCE OF EC INDUSTRY

Figure 2 ranks 89 sectors of Europe's industry based on their average annual rate of growth in production over the period 1986-91. The bars in Figure 2 have been shaded according to whether the sectors are typically "capital goods producing sectors", "intermediate goods producing sectors" or "consumer goods producing sectors".

Generally speaking, the sectors which experienced the fastest growth over the 1986-91 period have the consumer goods producing sectors, and to some extent, intermediate goods producing sectors. Several segments of the food and drink sector recorded particularly buoyant growth, a large part of this being accounted for by German unification. In contrast, the capital goods producing sectors are among the "moderate growth" sectors, with two notable exceptions: telecommunications equipment and office and data processing equipment.

The relative weakness in the capital goods producing sectors' occurred despite the recovery of business fixed investment in the EC over the period, and is a major cause for concern given the need to maintain a modern and productive capital base in the economy to remain competitive in increasingly global markets.

By far the fastest growing sector over the 1986-91 period was the manufacture of automotive body parts. This sector recorded average growth of close to 10% per year in real terms, mainly reflecting the rapid growth in automotive vehicle sales in the late 1980s and the set-up of Japanese transplant operations in several EC Member States, in particular, the United Kingdom and Spain.

Most of the other rapidly growing sectors, such as the manufacture of pharmaceutical products, the processing of plastics, the manufacture of office machinery and data processing equipment and the production of telecommunications equipment, are high technology sectors for which demand has grown rapidly both within Europe and worldwide over the period considered. Nevertheless, in some of these sectors, the rate of growth of production in the EC, as illustrated in Figure 1, was not sufficient to prevent sometimes serious losses in market shares, as described below.

There are also some less technology intensive market segments among the fastest growing sectors. This is the case of the secondary transformation and treatment of metals, the manufacture of soft drinks, textile finishing and the manufacture of pulp, paper and board. Changes in household consumption patterns combined with generally faster growth in real disposable incomes in the EC in the second half of the 1980s encouraged the rapid expansion of the packaging sector. This boosted demand and production of sectors such as the processing of plastics, of pulp, paper and board, and the manufacture of glass and glassware. The rapid growth in the secondary transformation and treatment of metals also reflects the rapid growth of the transport equipment sectors over the period, in particular, the automotive industry and the aerospace sector.

Among the "rapid growth" sectors, which experienced an average annual rate of growth in production between 4.5% and 6% over the period, are many sectors whose demand is related to construction activity. This is the case, for instance, of the concrete, cement and plaster sector, the manufacture of household textiles, of wood manufacture, carpets, linoleum and floor coverings and even of the manufacture of domestic electrical appliances. Indeed, the construction sector itself, which is not shown on this figure, experienced rapid growth in most EC Member States over the period thanks to improved economic conditions in general, to relatively low interest rates (this followed a period of very high real interest rates in the early to mid 1980s), to the revival of business fixed investment and to the high level of demand for new housing in Germany due to the inflow of refugees from the East. Construction activity nevertheless started weakening in 1991-92, and the short term prospects for this sector are particularly downbeat. The coming years will thus see much slower growth of all sectors related to construction activity, irrespective of any price competitiveness effect.

Also among the rapid growth sectors over the period 1986-91 are some "basic" consumer goods sectors such as soaps and detergents, fish and seafood, other food products, animal and poultry, the slaughtering and preparation of meat and fruit and vegetable processing. This again partly results from the German unification effect: in 1990 and 1991, the production of the food and drink sector in Germany grew respectively 12.5% and 8.8%, due to strong growing demand from the eastern Laender.

Most of the remaining food and other "basic" non-durable consumer goods producing sectors posted a growth in output which ranged between 2.5% and 4% over the period, mirroring the moderate growth of demand for such "mature" products.

Finally, among the "slow growth" sectors and the sectors whose output declined between 1986 and 1991, are many basic products related to the textiles and clothing industries (such as the cotton and wool sectors, the tanning of leather, and also the production of textile machinery), and equipment related to basic infrastructure investment by the public sector (such as railway equipment, the manufacture of transmission equipment, and the manufacture of boilers).

Figure 2, however, does not give a good idea of which sector have been the "high performance" sectors over the past 5 years from an international perspective, nor of which sectors are likely to continue posting rapid growth over the coming years. There are some sectors - even among the fastest growing ones - for which EC producers have experienced losses in market shares both at home and abroad. There are also a number of "slow" or "medium" growth sectors in which EC producers have, in fact, posted a very healthy performance over the past five years, expanding their market share at the expense of other world competitors.

Given that the uncertainties that characterise future trends in the EC economy mainly result from external developments rather than from domestic developments, it is the sectors that are most trade intensive that are likely to be most vulnerable over the coming years. In particular, European Industry must overcome:

- the absence of an agreement within GATT;
- increased competitive pressure from a number of trading blocks (Eastern Europe, China, and various countries in the Far East);
- rising protectionist pressures in the USA;
- the structural problems of the US economy, and the cyclical downturn in Japan,

The analysis in the next sections aims at providing a better assessment of the relative performance of EC-based producers over the past five years compared to their world competitors.

Tables 2 to 7 classify sectors into six broad categories, depending on their average annual rate of growth of production over the period 1986-91 and the share of output that is exported.

In Table 2 are those sectors which have posted very rapid growth in output over the past five years, and which are also characterised by a high export intensity of production. These sectors are thus highly sensitive to changes in world economic conditions - in particular to changes in demand trends or to changes in the world competitive environment. Within this category, are office machinery and data processing equipment, telecommunications equipment, electric lighting equipment and medical and surgical equipment. All four sectors posted average annual growth in excess of 5% per year over the period 1986-91, and export more than 15% of their total output outside the EC. Table 2 also provides a measure of the import penetration ratio, measured as the share of imports in domestic production This rate of import penetration is particularly high in two sectors, office machinery and medical and surgical instruments, indicating that, although EC industry exports a high share of its production in these sectors, foreign producers also control a high share of the EC's internal market.

Table 3 lists those sectors which experienced buoyant growth over the past five years (i.e. in excess of 5% per year on average), but which are less export-oriented (the share of exports in production is less than 15%). These are sectors for which the rapid rate of growth in production between 1986-91 reflects more a strong rate of growth of domestic demand within the EC than a rapid growth of export markets. Among these sectors are several market segments of food and drink, which benefited from buoyant demand in unified Germany in 1990 and 1991, and a number of sectors linked to packaging and to construction activity. As in Table 2, however, we also find among these sectors a set of industries for which the rate of import penetration is very high, such as pulp, paper and board, wood sawing and processing, or cycles and motorcycles. In some cases, this reflects a lack of natural resources within the EC, but in others such as for cycles and motorcycles it does reflect competitiveness problem of the EC in global markets.

Table 4 lists those sectors which have experienced rapid but not buoyant growth over the past five years and which also have a high rate of export intensity. This list includes such sectors as aerospace equipment and repair, sound recording and reproducing apparatus, and, again, sectors linked to construction activity such as household textiles, carpets, linoleum and floor coverings. Most of the sectors are also vulnerable to competition from abroad, as the rate of import penetration

in these markets exceeds the export intensity ratio - sometimes by quite a high factor.

Table 5 provides a list of "medium growth - mainly domestic demand driven" sectors which posted growth between 3% and 5% per year on average between 1986 and 1991 - and which exported less than 15% of their output to non-EC destinations. Among these are several food and related products, as well as heavy construction materials. All these sectors are expected to post slower growth in the coming years than had been the case in the late eighties, due to the general slowdown in economic activity, in particular in EC construction activity, and to the unwinding of the German unification effect, which has brought the rate of growth of basic consumer goods producing sectors such as food and drink back to "normal".

In Table 6 are sectors which grew at rates of growth significantly below the average for the EC manufacturing industry (i.e., by less than 3% per year on average between 1986 and 1991), and which are also highly export oriented. The comparatively slower rate of growth of these sectors, which are highly dependent on export markets, reflects either a slow growth of demand within the EC and worldwide or persistent losses in market shares of EC producers both domestically and abroad. The high rate of import penetration in some of these markets does seem to indicate that some of these sectors suffered from major losses in market shares over the past five years, either because of bottlenecks in supply or because of a loss in competitiveness relative to the other world producers.

Finally, in Table 7 are those sectors which are both slow growing and little export oriented, i.e. sectors for which either demand has grown only slowly over the past five years, or which have lost out to non-EC producers on the home market.

To provide a better assessment of the relative performance of the EC sectors over the 1986-91 period, and to identify those sectors that have been or will continue to be exposed to the greatest competitive challenge, we have calculated a "vulnerability" index which measures the relative change in the EC's net trade position vis-à-vis the rest of the world. This index is defined as the change in the rate of export intensity between 1986 and 1991, minus the change in the rate of import penetration over the same period.

A high negative value of the vulnerability index thus indicates that there has been a deterioration in the net trade position of the EC vis-à-vis the rest of the world between 1986 and 1991, whereas a positive value indicates that the net trade position of the EC (measured in volume terms) has improved between 1986 and 1991, either because export intensity has risen more than the rate of penetration of imports, or because there has been an absolute decline in the rate of penetration of imports over the period.

Table 8 ranks those sectors which have posted the strongest deterioration in their net trade position vis-a-vis the rest of

the world between 1986 and 1991, while Table 9 lists those sectors which have seen a relative improvement in their net trade position over the period considered.

Figure 3 indicates, for each of the above-mentioned sectors, whether the change in the net trade position results from a change in import penetration, from gains (or losses) on the export side, or from a combination of both. Figure 7 shows the performance of the various industrial sectors according to a combination of two criteria, namely the export/import ratio (X/M) and the share represented by exported goods in relation to output. This gives an idea of both the intensity of trade (mainly due to specialisation within sectors) and the competitive position of those sectors.

Trade creation

In the upper right-hand quadrant of Figure 3 are those sectors for which both export intensity and import penetration have increased over the period considered - i.e. sectors for which there has been a as "trade creation" effect over the past five years. These are:

- Sound reproducing and recording equipment
- Miscellaneous textiles industries
- Ready-made clothing
- Manufacture of leather products
- Cotton industry
- Distilling of ethyl alcohol
- Railway equipment
- Dressing and tanning of leather

In most of these sectors, the EC has actually improved its net trade position vis-à-vis the rest of the world - the exceptions being sound reproducing and recording equipment, and ready-made clothing (see Table 8). In all other sectors, the rise in the EC's export intensity has exceeded the rise in EC import penetration over the period, which denotes a relative improvement in the competitiveness of these EC sectors on world markets. In the case of sound recording and reproducing equipment and for miscellaneous textiles, the picture is mixed since in both cases the rise in import penetration has largely exceeded that of export intensity. This reflects the increased speciali-

sation of the EC industry in certain segments of these markets, along with losses in market shares in the "mass" market segments.

Increased competitiveness of EC industry

The second quadrant of Figure 3, in the lower right-hand side of the chart, groups those sectors for which the rise in the export intensity of EC production was accompanied by a decrease in import penetration. The sectors which fall in this quadrant have thus seen their net trade position improve significantly over the period considered. The only sector which falls in this category, however, is the textile and sewing machinery sector which, despite its improved net trade position, has seen no growth in output in the EC over the period 1986-1991 and even experienced a slight decline.

Losses in competitiveness

In the upper left-hand quadrant of Figure 3 are sectors which suffered both from an increase in the rate of penetration of foreign producers in the EC market, and from a fall in the export intensity of domestic production. These are sectors in which EC-based manufacturers have lost significant market shares both at home and abroad for a number of reasons, these reasons range from uncompetitive cost increases, to un-

favourable exchange rate developments, inadequacy of demand and supply, and, in some cases, capacity problems within the EC which caused exports to switch from foreign markets back to the domestic market. Among the sectors in this list are all of the previously mentioned "vulnerable" sectors, except sound reproducing and recording equipment and ready-made clothing for which the export intensity of EC output did increase over the period, as indicated earlier. It is thus these sectors that EC policy makers and the business sector itself will have to focus their attention on if the EC industry is not to lose out completely to foreign producers in what are mostly "dynamic" market segments. Indeed, most of these "highly vulnerable" sectors are sectors for which demand has been growing in excess of 4% per year on average in real terms over the period 1986-91. These are:

- Office & EDP equipment
- Cycles and motorcycles
- Medical & surgical equipment
- Household textiles
- Motor vehicles parts & accessories
- Toys and sports goods
- Optical instruments
- Knitting
- Steel tubes
- Mass-produced footwear

Trade destruction impact

In the lower left-hand quadrant of Figure 3 are sectors for which both the rate of import penetration and the export intensity of EC production have decreased over the period considered. There has thus been a "trade destruction" effect, which is largely explained by the slow overall rate of growth of demand, which has taken place alongside an expansion of domestic production capabilities and an increase in intra-EC trade. Among these sectors are:

- Wood sawing and processing
- Semi-finished wood products
- Slaughtering and preparation of meat
- Grain milling

In addition to the sectoral vulnerabilities identified through the above analysis, the recent deterioration in the economic situation of the OECD countries and the developments in Eastern Europe have created additional problems in a number of sectors, which are not yet apparent from this analysis of trade flows between 198691. The three main "problem areas" are pulp and paper, basic chemicals and the steel industry.

In the first two sectors, it is the rapid turnaround in demand in the early 1990s, combined with the fact that the companies in the sector launched massive investments in capacity expansion during the 1980s when the business climate was much sounder, which are at the origin of the problems experienced by these sectors now. This over-investment has created world-wide excess capacity problems and has sent both prices and profits falling.

In the steel industry, rather than an expansion of production capacities within the EC, it is the massive inflow of steel products from Eastern Europe at a time of falling EC demand and the depreciating dollar which explain the difficulties to which the sector is confronted today. Since the peak of the market in 1989, prices have fallen by 25-30%, and now stand near the 1982 levels. Steel imports from Eastern Europe have, in the meantime, increased by close to 20% per year on average, reaching a total of 2.7 million tonnes in 1991. This has seriously hit the profitability of EC steel producers.

The products imported from the central European countries are essentially destined to the construction sector, as these consist of products such as wire rods and concrete reinforcing bars. These low value-added products account for about 6% of the EC's iron and steel consumption. The inflow of low-priced imports from the East has nevertheless led to a significant decline in EC production from 1990 onwards.

The problems currently faced by the EC steel industry are more structural than cyclical. Indeed, EC demand for iron and steel is expected to remain approximately stable over the coming years, in view of the slow projected economic growth and a continuation of past trends in steel use per unit of GDP. There is, in fact, in all industrialised economies a gradual substitution of steel by other materials, such as plastics. At the same time, the EC's external trade balance, which was 2.7 million tonnes lower in 1991-92 than had originally been forecast by the Commission (COM(90) 201 final of May 7, 1990), is expected to continue to shrink. The widening of the deficit in 1991-92, was due both to a 2 million tonne shortfall in exports (compared to what had originally been forecast), and to higher rise in imports than previously anticipated (by 0.7 million tonnes). The shortfall in exports mainly reflected lower exports to the USA (due to the falling dollar) and to the former Soviet Union.

A contraction of the markets for iron and steel products in Eastern Europe and the CIS will inevitably result from the falling level of economic activity in these regions in the short run, and, in the longer run, by a move away from metal products in line with what has been observed in the industrialised countries. This will likely divert an even greater share of steel production from these countries to the EC. At the same time, mounting protectionism pressures in the US put this export market at risk for EC producers.

Within the EC, it thus appears indispensable to launch a new phase of restructuring, which would be aimed at eliminating excess capacities in critical areas. In a recent communication (SEC (92) 2160 Final), the Commission of the EC outlines the strategy that ought to be followed by all actors in the iron and steel sector in order to achieve the necessary restructuring. Although the Commission stresses the fact that the initiative lies with the companies themselves, it nevertheless proposes a specific package of measures to reduce the adjustment costs for these companies. In particular, financial incentives will be granted by the EC to reduce the social costs linked to the restructuring, such as the reconversion of the labour force. It is estimated that approximately ECU 240 million will be devoted over a three-year period to the problem of the reconversion of employment. Financial assistance to offset the capital costs of restructuring (contribution to the fixed costs or related to the closure of some installations) will also be available, but will have to originate from the CECA budget and be agreed upon by the Council level.

On the external front, the Commission insists on the need to maintain a "fair and loyal" trading environment at world level, and is negotiating with the other world countries on that basis. A strict monitoring of trade flows, and of the price at which the products are being sold will be undertaken in order to take action where necessary in a timely fashion. Safeguard clauses will be negotiated with some main steel producing countries, in particular with the countries of Eastern Europe, in order to avoid dumping.

The Commission finally hopes to be able to contribute to the decision of which production capacities will have to be dismantled, in order to ensure that it is the least effective ones that are eliminated and that the restructuring takes place in an orderly fashion. The communication includes suggestions as to how the choice of capacities to close could be made.

THE EC'S POLICY RESPONSE

The main concern identified in the previous section are the negative trends in the net trade balance of a number of industries and losses in relative market share of EC producers both at home and abroad. The completion of the Internal Market should provide the basis for improved competitiveness of the EC industry by creating new market opportunities and through the greater competition that will ensue from market integration. Beyond the measures set out in the Internal Market programme, which depend on timely transposition into national law and effective implementation in each Member State for their impact to be maximised, the Commission presented its proposals for measures to accompany industrial change in its document on the future financing needs of the Community (COM 92/2000). The European Council at Edinburgh decided on the future allocation of Community resources between the different policies. Community efforts in the field of adaptation to industrial change will be concentrated in five main areas: trans-European networks, research, development and technology policy, small and medium-sized enterprises, human resources - in particular through the implementation of a new Objective Four of the European Social Fund to cover those already in employment and through specific programmes financed under the European Regional Development Fund.

More detail on the specific challenges facing each sector of Europe's industry, as well as on the various measures that have been adopted or that are proposed either by the Member States or by the Commission in order to enhance the competitiveness of given sectors or facilitate trade - such as the harmonisation of norms and standards and the opening-up of previously restricted markets - are discussed in greater depth

in the industry and service sector monographs in the second part of this book.

CONCLUSION

This analysis has focused on identifying those sectors of EC industry that will be confronted with the biggest challenges over the coming years. This was done by analysing their trade performance over the 1986-91 period, a period characterised by the launching of the single European market programme. It may appear somewhat discouraging to find that, despite the restructuring efforts made by EC industry during the second part of the 1980s, and despite the unquestionable benefits brought about by the single market programme whose main aim was to facilitate the restructuring of EC industry around its stronger companies and to reduce production costs, there is still a long list of sectors experiencing difficulties in world markets. The fact that some of the sectors that have been losing market share both in the EC and abroad over the period 1986-91 (see Table 8) grew rapidly in terms of production over that period (such as the medical and surgical instruments sector, or the cycles and motorcycles sector) nevertheless provides motives for hope. On the other hand, it is important to keep in mind the fact that, because the creation of the single market has been a gradual and slow process, all the benefits of the programme have not yet been reaped by EC industry. The list of "problem" sectors that was drawn up in 1985 was, in fact, much longer than the one presented in Table 8. The coming years will thus hopefully see the list become shorter and shorter, as the benefits of the single market work through the economy. Because the international economic climate is so uncertain, however, policy makers have to remain vigilant.

The world's largest industrial groups

INTRODUCTION

This chapter introduces the Top 200 industrial groups in the world and the Top 200 groups in Europe (including both manufacturing and services) classified according to 1990 turnover (consolidated figures). Where possible, 1991 figures are included in the listings. Turnover does not include excise taxes. Profits are shown as the consolidating company's share of total net income (after taxes). Figures have been converted to ECU using the 12 month moving average exchange rate during each company's fiscal year. Employee figures show either a year-end or yearly average number, as published.

A large number of groups have very diversified activities. When broken down on a sector basis, groups have been put in the sector which accounts for the greatest share of their turnover. Concerning breakdown by region and country, the criterion is that of the group's origin.

In a global economy characterised by multinational companies present in several continents and with ever more diversified activities, the criterion of location loses its significance in many cases.

All figures are extracted from the Commission's Data Base on Large Enterprises (DABLE).

THE WORLD'S LEADING INDUSTRIAL COMPANIES

The slowdown in the global economy in 1990 was strongly felt by the world's 200 largest industrial groups.

Total turnover of the 200 largest industrial groups in 1990 reached 3 078 billion ECU, exactly the same turnover as in 1989 (in current value). The growth rate for the period 1986-90 was 6%, hiding a growth rate of 8.1% for the period 1986-89.

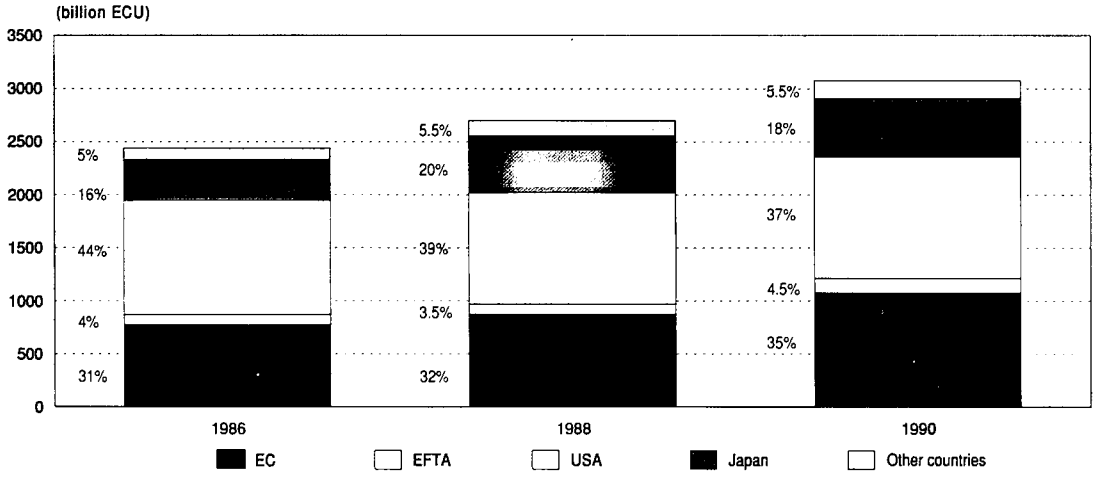
In addition, figures reported for 1991 indicate that the growth rate achieved by the same sample of enterprises will not exceed inflation.

Employment growth was less than one percent in 1990 compared to a rise of 6% since 1986. Fourteen out of the 25 biggest employers are European firms, twice as many as the seven American representatives in this list (see Table 3).

The 25 biggest sales increases are evenly distributed across Europe, USA and Japan each of which have eight companies in the Top 25.

Missing from the rankings, as a result of the Gulf War, is Kuwait Petroleum, number 93 in last year's list.

Figure 1: The 200 largest industrial groups in the world
Turnover growth at current prices



Source: DABLE

Comparative achievement of the Community groups

The American industrial groups represent 37% of the global turnover of the Top 200. EC groups are just behind at 35%, EFTA groups at 4.5%, the Japanese groups at 18% and other countries' groups at 5.5%.

The trend since 1986 shows a continuously weakening presence of American groups in the absolute number of companies in the Top 200 as well as in their share of global turnover. The statistics show that the Top 200 of 1986 included 79 American groups with 45% of total turnover; in 1988 the Top 200 had 71 groups with 39% of total turnover and in 1990, 68 American groups had 37% of total turnover.

Japan's spectacular rise in the first half of the 1980s seems to have slowed by the end of the decade. Japan had 40 groups in the Top 200 in 1990.

Table 1
The Top 200 of world industry

(number of companies)	1986	1988	1990
EC	61	62	67
EFTA	12	14	12
USA	79	71	68
Japan	36	43	40
Other	12	10	13

Source: DABLE

The leading position of Europe is now clearly established. EC's share of turnover rose from 31% in 1986, and 32% in 1988 to 35% in 1990 with respectively 61, 62 and 67 groups. EFTA's share remained static. In terms of the number of groups in the Top 200, the EC and EFTA overtook the USA in 1989 for the first time (76 against 72). In 1990 the gap widened: 79 European companies for 68 American ones. Furthermore, Europe pushed the USA into second place in turnover terms in 1990: 39.5% against 37% (see Figure 1).

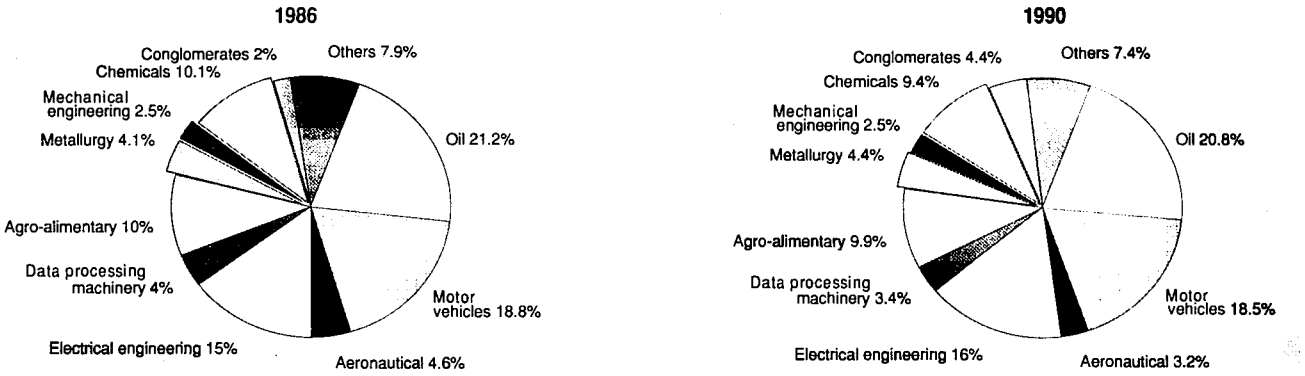
Figure 6: The 200 largest industrial groups in the world
Turnover by sector



Source: DABLE

Falling margins everywhere

Aggregated profits for the global Top 200 companies tumbled by 19% in 1990. The overall net profit/turnover ratio slipped from 4.1% in 1989 to 3.4% in 1990. The biggest fall was in the USA (from 4.7 to 3.6%) and the smallest in Japan (from 2.8 to 2.5%) (see Figure 2). It is already apparent that the profit drop in 1991 will be greater than in 1990.

Among the 25 largest profit earners the USA have twelve representatives. The EC occupies eight places in this list (see Table 3).

An exception to the malaise are the pharmaceutical giants. Four out of the top six of the most profitable companies are from the pharmaceutical sector.

The number of Top 200 companies reporting losses rose dramatically in 1990 to fifteen: seven American, six European and two Japanese. In 1988 and 1989 there were only seven. Considering that four out of the 1991's top seven racked up losses (General Motors, Ford, IBM and IRI), the loss reporting companies could be doubled in 1991. Philips reported the largest loss in 1990 (2 billion ECU), followed by General

Motors (1.6 billion ECU), Occidental Petroleum (1.3 billion ECU) and Michelin (0.7 billion ECU). In 1991, General Motors recorded the largest loss ever reported by a non government-owned company (3.6 billion ECU).

Figures 3, 4 and 5 show the development of the net margin (net profit/turnover ratio) by sector and by economic area for the Top 200 companies. These three graphs show clearly that the recession has been felt by almost all sectors all over the world in 1990. Preliminary figures for 1991 are not encouraging either.

Sector profiles

What began as a gentle decline in overall margins in 1989 progressively worsened during 1990. Startlingly, margins even turned negative for the American automobile sector and for EC's electrical engineering sector.

The distribution of turnover by sector did not significantly change in the period 1986-1990 (see Figure 6). In the following categories the groups are classified by the sector of activity which best represents the company as a whole (the conglomerates, i.e. groups with very diversified activities have not been considered).

Petroleum refining

Tumult in the Middle East restrained petroleum supplies. The result was a sparkling year for the oil companies. The biggest beneficiary was Royal Dutch Shell that passed Exxon as number one in the oil business. All the US oil companies moved to a lower place on the list in 1990 compared to 1986 and the share of the US groups in the total turnover was down 5% since 1986. On the other hand, the number of US representatives in the Top 200 remained unchanged at eleven. EC companies came up from seven representatives in 1986 to eight in 1990, accounting together for 37% of the total turnover (34% in 1986).

The biggest jump on the list was achieved by Petroleos de Venezuela which rose from the 115th place in 1989 to 47th place in 1990.

The average number of employees per company diminished from 49 000 in 1986 to 46 000 in 1990.

Motor vehicles and components

Europe and the USA both have 36% of turnover in 1990.

Profits dipped worldwide in 1990. In the USA margins began to decline in 1987 to the extent that, for the big three (General Motors, Ford Motor and Chrysler), they became negative in 1990. In 1991 the situation worsened dramatically: all four American representatives in the Top 200 were in the red: General Motors experienced the biggest loss ever reported by a non-government owned company and Ford Motor, the biggest loss in its history.

Total employment for the four US majors in 1990 was down by 9% compared to 1986. The eight Japanese representatives saw a rise in employment of 30% and the eight from the EC, of 9%.

Early indications in the accounts of Japanese carmakers (fiscal year end March 1992) point to considerable drops in profits. Nissan even warns of a future loss.

Electrical engineering / electronics

The relative importance of this sector in the Top 200 improved by 1% in 1990 compared to 1986. However, the number of groups diminished by 3 to 28 (one Japanese company more but four less Americans). It is therefore not surprising that the US share in turnover felt from 27% in 1986 to only 18% in 1990%.

The seven EC groups totalled 22% of turnover in 1990, 1% less than in 1986. The number of employees, however, was reduced by over 4%. Philips lost seven places in the ranking of the world's 200 largest industrial groups and made a loss in 1990 of 2 billion ECU.

Japan made up 37% of total turnover in 1990, 2% more than in 1986. For the eight Japanese groups that are both in the 1986 and in the 1990 Top 200, the number of employees soared by 41%. The slowdown of the economy touched the

Japanese electronic sector in 1991, resulting in lower annual profits.

The most spectacular performance in this sector comes from the three Korean groups: Samsung, Lucky-Goldstar and Daewoo. With 21% more employees, they doubled their total turnover in five years and claimed 16% of total turnover in 1990. The Samsung group is now the third electronics group in the world after General Electric and Hitachi. The highest rate of growth, however, was obtained by Sony with an average annual growth rate of 25.2% that brought the company from the 98th place in 1986 to a rank of 45th in 1990.

Data processing and office machinery

The data processing and office machinery sector is represented in 1990 by six companies. NCR fell out of the Top 200.

In both years IBM occupied first place. In 1986, IBM's turnover was 14% bigger than the total of the next six others

combined. By 1990 however those six together had 5% more sales than IBM.

Japan's strength in this sector is underestimated because in this analysis the groups have been put in the sector which accounts for the largest share of their turnover keeping companies as Toshiba, NEC and Canon out of the data processing and office machinery sector.

Aerospace

This sector is largely dominated by American companies. Japan is not present in the Top 200. The EC managed to take 20% of the Top 200 in 1990 especially thanks to the steep climb of British Aerospace from rank 187 in 1986 to rank 63 in 1990 (average annual growth rate of 33.2%). All the other companies lost places in the 1990 list. France's Aerospatiale bailed out of the Top 200.

Chemicals

Twenty-six companies of the Top 200 belong to the chemical industry. For six of these companies, the main activity is the manufacture of pharmaceutical products.

EC companies produce 45% of total turnover of this sector at the Top 200 level, 3% more than in 1986. The American companies lost 3% and now account for 38% of total turnover.

The top positions in the list of the most profitable companies in the Top 200 are occupied by two American pharmaceuticals: Merck (net margin 23.2%) and Bristol Myers Squibb (16.9%). (See Table 3).

Metallurgy

The EC dominates the metallurgy sector at the Top 200 level after years of heavy losses and considerable restructuring. In 1986, eight out of the fourteen companies figuring in the 1986 Top 200 made a loss. The results were all positive in 1990 although not as high as in 1988 and 1989.

Also the growth of employment is higher than the average of the Top 200 companies: +13% since 1986 for the eleven companies represented in the Top 200 in 1986 as well as in 1990.

Agro-Alimentary

The agro-alimentary industry produced 10% of the total sales of the world's largest 200 industrial companies in 1986 as well as in 1990.

This sector is dominated by the USA and Europe. Since 1986, the USA has lost three companies in the Top 200 and 7% of

total turnover while the EC has added four companies and 9% of total turnover. The EFTA share remained stable at 9%.

In 1990, Philip Morris surpassed Unilever and Nestlé to become the biggest thanks to an average annual growth rate of 13.4% for the period 1986-1990. Kraft General Foods turned in a rate of 23.2% and Conagra one of 16.1%.

EUROPE'S LARGEST MANUFACTURING AND SERVICES COMPANIES

The 200 largest manufacturing and services groups (excluding distribution) in Europe achieved an overall turnover of 1 886 billion ECU in 1990.

The EC accounted for 172 companies and EFTA for 28, generating respectively 89% and 11% of total turnover in the 1990 Top 200. Growth of total turnover was 4.3% in 1990. The average annual growth rate for the period 1986-1990 was 8.2%.

A breakdown by country is shown in Table 5. Germany had the largest share in turnover in 1986 as well as 1990 with 42 companies in both years, but lost some ground in its proportion of total sales. Since 1986, the United Kingdom lost 12 representatives in the Top 200 and its share in total turnover slipped 3.6%, allowing France to take over the second place. Italy and Spain both considerably improved their positions. However, in a global economy, characterised by multinational companies, the criterion of location loses some significance in many cases.

In the list of the 25 largest growth rates in 1990, the first three places are occupied by utilities. France and Sweden are well represented in this list with respectively seven and five companies.

End of record profits

Profits of the Top 200 fell by 20% in 1990, in line with the world trend. No sector was spared. After years of improvement, net margins and financial performances deteriorated in 1990 for all sectors. This is shown by the net profit/turnover ratios and the net profit/net worth ratios in Figures 16 and 17.

In 1990, 13 companies had net income levels exceeding one billion ECU (see Table 6), the top four being Royal Dutch Shell (5 billion ECU), British Telecommunications (2.9 billion ECU), IRI (2.4 billion ECU) and British Petroleum (2.3 billion ECU).

Among the Top 25 companies with the highest absolute profit levels, the remarkable performance of the UK enterprises must be underlined. There were 13 UK companies in the Top 25 largest profit-earners, compared to 4 for Germany and France and 3 for Italy.

The highest return on sales was realised by Glaxo (27.8%) and Guinness (22.4%). Nine of the 25 companies with the highest return on sales were active in the service industries (see Table 6).

In 1990, a total of twenty companies in the Top 200 reported a loss, doubling the 1989 total. The transport sector was particularly battered with seven losers: the Deutsche Bundesbahn suffered the heaviest blow (2.4 billion ECU). Other big losses were reported by another German state-enterprises: Deutsche Postdienst, the Dutch companies Philips and KLM, and the French companies Machines Bull, Michelin, Thomson and Air France. Volvo is the only EFTA company in the Top 200 with a significant loss.

Employment falls

Employment growth among the Top 200 came to a halt in 1990. The total number of employees tailed off by 2.9% in

1990 (meaning a loss of almost 450 000 jobs) after years of growth (2.2% in 1989, 3.7% in 1988 and 2.4% in 1987). The biggest employer in 1990 was the Italian national conglomerate IRI, followed by the German groups Daimler-Benz and Siemens, all reaching figures in excess of 350 000 employees (see Table 6).

Sector profiles

In this section, groups classified by sector of activity and based in the EC or in the EFTA countries are analysed. The groups are classified by the sector of activity which best represents the company as a whole. In some cases groups have been classified as a conglomerate. VEBA's 1990 group sales, for example, came from the following activities: electricity (20%), chemicals (19%), oil (21%), trading (31%), transportation (6%) and other services (3%). Other groups among Europe's Top 200 classified as conglomerates are: IRI, INI, OIAG, Hanson, BTR, Preussag, Anova and BET. Conglomerates share in total turnover went up from 5.3% in 1986 to 7.6% in 1990 (see Figure 18).

The biggest sector at the Top 200 level is the oil sector with 14.1% of total sales, followed by motor vehicles (12.2%), chemicals (11%) and electrical engineering/electronics (8.8%). Those percentages are only slightly different from 1986 (see Figure 18).

Petroleum refining

The increase in oil prices pushed sales up 11.4% in 1990 (ENI is not taken into account due to its very diversified activities). The average annual growth rate for the period 1986-1990 was 2.7%.

The top of the hierarchy of Europe's oil companies remained unchanged in 1990. The state-owned French company Elf Aquitaine rose from the 21st place in 1989 to the 12th place in 1990.

The profit fall was hardly felt by this sector. On the contrary, most of the European oil companies had better results in 1990 than in 1989. The number of employees rose by 5%.

Motor vehicles and components

As a result of the decrease in car demand in most European markets, Europe's carmakers had a difficult year in 1990. Total sales rose by only 3.4%, while profits dropped by 54%. In 1991 sales were merely 1% higher than in 1990 and profits dropped by a further 10.7%. Germany's car industry, however, which accounts for 55% of Europe's total turnover, realised 7% more sales in 1990 and 4.7% more in 1991, mainly due to the extraordinary boom in car demand following the reunification.

The biggest rises in Europe's Top 200 were obtained by FIAT moving ahead from place 13 in 1986 to place 5 in 1990, and BMW, from place 55 to place 37 over the same period. The Swedish carmakers stalled on the list. Volvo, the only loss maker in 1990, has lost 17 places since 1986. Saab-Scania sold a big part of its car division to General Motors and plunged 62 places in 1990.

Metallurgy

German groups generated 53% of total turnover (49% in 1986). Sales rose by 3.2% in 1990 and the number of employees by 10%.

After years of heavy losses and considerable restructuring this sector saw a remarkable progression in the results since 1987. In 1988 all companies showed a profit. In 1989 net margin even exceeded 4%. In 1990, however, profits dropped by 44%.

Chemicals

Leaving pharmaceuticals aside, the chemical industry has been affected by a general fall of profits. The first ten companies all saw a regression in turnover. Thanks to pharmaceuticals, the chemical sector achieved the highest net margin (see Figure 16). The five pharmaceutical companies in the Top 200 (Sandoz, SmithKline Beecham, Roche, Glaxo and Schering) have enjoyed an average annual growth rate of 9.4% during the period 1986-1989 (3.3% for employment). Sales went down in 1990 by 1.5%, while profits rose by 7.4%, resulting in a net margin in 1990 of 11.9%. Glaxo was Europe's most profitable company in 1990 with a net income to turnover ratio of 27.8% (see Table 6).

Agro-alimentary

Growth of Europe's largest food companies was only 1.6% in 1990, while profits fell by 17%. The Anglo-Dutch number one of this sector, Unilever, did not suffer the same general malaise. It saw its sales increase by 9.6% and its profits by 11.8% in 1990. Guinness was number two in the European list of the 25 most profitable with a net margin of 22.4% (see Table 6).

The British dominated the agro-alimentary sector with 12 groups out of 22. Five British groups, however, realised lower

sales in 1990 than in 1989. External growth is no longer a common situation, except for the Swedish group Procordia whose turnover soared by 70% in 1990 while its ranking jumped by 62 places.

Average annual growth rate of employees 86-90: 3.1%.

Electrical engineering/electronics

The relative importance of this sector at Top 200 level dimmed by half a percentage point to 8.8% over the period 1986-1990. In 1990 growth was only 1.7% and the number of employees diminished by 0.4%. Moreover, its net margin was only 1%. These figures are largely due to the weak performance of Philips (sales down by 1.8%, employees down by 10.5% and a loss of 2 billion ECU). In 1991 Philips was out of the red, but employment was again down, with 65 000 jobs slashed in the last two years.

Ericsson saw its sales rise by 9% and its profits by 40%. Siemens benefited from the opening of the East (1990 sales up 4.8% and profits up 6.3%), with an even stronger performance in 1991 (sales up 15.3%, profits up 19.1% and employment up 7.8%).

Mechanical engineering

The mechanical engineering sector had nine representatives in the Top 200 in 1990, i.e. two less than in 1986. Linde and AGIV were newcomers in 1990.

The average annual growth rate of the seven largest companies was 11.4% for the period 1986-1990. Employment rose in the same period by an average of 4%. The net margin was low in 1990 (1.9%), although better than in 1989 (1.3%).

The service industries

In the 1990 European Top 200 there are 43 service industry companies, i.e. nine companies more than in 1986. Their total turnover is 360 million ECU, or 19% of global turnover (see Table 14).

Among the Top 200, the average number of employees of the companies in the service industry was 87 000, less than half of the average number employed in the manufacturing companies (194 000).

Energy

Electricité de France maintained its number one position throughout the 1986-1990 period. The fastest growth was recorded by the Belgian companies Tractebel and Electrabel and the Italian ENEL.

Strikingly, the turnover of the four gas companies was 6.5% lower in 1990 than in 1986.

Telecommunications

Telecommunications services accounted for 24.5% of the 1990 global services turnover, especially because of the recent separation of Deutsche Telekom from Deutsche Postdienst and France Telecom from La Poste in 1987. These splits make a year on year comparison meaningless.

Growth of the telecom companies is undeniable: 11.5% in 1990 with a net profit/turnover ratio of 8.3%.

Transportation

In 1990, total turnover at 61 billion ECU was divided as follows: air transport, 47%, with 5 companies; rail transport, 36%, with SNCF, Deutsche Bundesbahn and British Railways; and water transportation, 16%, with P&O and Nedlloyd.

As for air transport, the five companies in the European Top 200 are Air France, Lufthansa, British Airways, Alitalia and KLM. Both turnover and employment climbed 15%. Air France, after having absorbed its major French rivals Air Inter and UTA became the biggest airlines in Europe. Apart from British Airways, all lost money in 1990, even those companies outside the Top 200 such as Iberia (INI), SAS, Swissair, Finnair and Sabena.

The accounts of 1991 show big losses continued for all companies, except KLM and Swissair.

A big shake out seems to be very likely in the coming years.

The distribution sector

The distribution sector is not represented in the preceding categories. In 1990, the United Kingdom had the most representatives (25) in the distribution Top 100, followed by France (23) and Germany (22).

In the distribution Top 25, however, Germany dominates with seven companies, followed by France and the United Kingdom with five each. The Swiss have six companies in the Top 100. The Netherlands also score well with four in the Top 25.

The distribution Top 100 annual average growth rate for the 1988-1990 period is 9.8%. The corresponding rate for employment is 6.7%.

In terms of turnover, the United Kingdom occupies only third place, with 19.5% of total turnover. France's growth rate of 17% for the last two years put them in second place with 22.4%, due to the merging of businesses. The biggest share is for Germany with 25.2%.

The fastest growing company, France's Pinault at the 39th place, was not represented in the 1988's Top 100. In 1991 Pinault continued its advance.

Table 19 shows the 1990 Top 50 and their corresponding 1988 figures.

Cross-border mergers and acquisitions in the EC

THE OVERALL PICTURE IN 1991

The rising trend of cross-border mergers and acquisitions (M&A) throughout the 1980s stalled in the first two years of the 1990s. KPMG, a firm of accountants and management consultants that monitors global M&A figures, calculates that the value of all cross-border M&A around the world in 1991 was less than half the value in 1990, which was itself down on 1989's figure: $130.6 billion in 1989; $117.8 billion in 1990; and a mere $51.9 billion in 1991.

The causes were not hard to find: the Gulf War turned most financial centres into ghost towns in the first quarter of 1991; and a severe economic recession made capital scarce and expensive in the two most active M&A markets - the UK and the USA. The recession in these countries, which started in 1990, was prolonged through 1991 partly by uncertainty over the elections due in both of them in 1992. Other factors, such as the tension at the Uruguay Round of trade talks carried out under the auspices of the GATT, plus the uncomfortably fluid state of what was once the Soviet Union, also played a part.

Historically, M&A activity has been closely linked with the ups and downs of the business cycle. Activity fell off in the recession of the mid-1970s, and again in the early 1980s. The unprecedented length of the continuous period of economic growth in the 1980s assured a build-up to unheard-of levels of M&A activity. It was inevitable that there would be a dramatic fall as soon as the boom years ended.

Activity in Europe declined in 1991 less than it did in North America. KPMG's figures show that cross-border sales of European companies in 1991 were 56% of the value of such sales in 1990. In North America, 1991 sales were only 37% of 1990's. For the first time for several years, the value of EC sales ($23.3 billion) exceeded the value of North American sales ($20.3 billion).

The EC was also a much more active cross-border acquirer than North America (acquiring $10 billion more than North America in 1990, and $21 billion more in 1991). Indeed, in 1990 both the UK and France individually spent more on cross-border acquisitions than did the United States. And in

Source: Acquisitions Monthly/AMDATA III

1991 France spent $12.5 billion, considerably more than either the United States ($7.3 billion) or the UK ($6.3 billion).

Within the EC, French companies have been particularly conspicuous for the past four years both as cross-border acquirers and as cross-border targets. They have regularly come in second to the UK in rankings of European cross-border buyers and sellers. Of KPMG's ten biggest cross-border deals in the world during 1991, four involved French buyers and eight involved European Community buyers - the four French deals plus one German, one Dutch, one Anglo-Dutch, and one Spanish/American deal. France was a less popular target in 1991 than in earlier years, but the Swiss multinational Nestle's purchase of Perrier has given it a good start to 1992.

For the clearest indication of the extent of the decline in M&A activity in Europe in 1991 it is best to look at the UK. There, M&A statistics have been gathered more consistently and for longer than anywhere else. Table 2 shows that M&A in the UK in 1991 was lower than in any year for the past five years. UK acquisitions in continental Europe were only just above those in 1987, the last year before the EC's 1992 programme really grabbed the business world's imagination.

There were no outstandingly popular sectors in 1991, although there were one or two (like pharmaceuticals) which bucked the downward trend. Among KPMG's top ten deals for the year there were two in insurance: a French consortium's purchase of the American company Executive Life - at $3.75 billion the biggest cross-border deal of the year; and the French company Axa's purchase of a 49% stake in the American company Equitable Life. And there were two deals in the oil and gas sector: Royal Dutch Shell bought the Guangdong Petrochemical joint venture in China; and Elf Aquitaine bought (jointly with Enterprise Oil) the North Sea assets of Occidental Petroleum.

STATISTICAL INCONSISTENCIES

Unfortunately, KPMG's picture of cross-border deals during the year is not a unique picture. There are other databases from reliable producers that paint a very different picture, and there are a number of good reasons for the differences.

First of all there can be disagreements about quite simple things - such as the value of deals. Take the Elf Aquitaine/Occidental Petroleum deal. KPMG includes it as one of its ten biggest cross-border deals of the year - at a value of $891 million. Acquisitions Monthly's AMDATA data base records the deal at £796 million. For that to be the same as KPMG's dollar figure the exchange rate would have to be $1.12 to the pound - a rate that never existed throughout the whole of 1991. IDD Information Services record the Occidental deal at £860 million. M&A Europe, produced by IMC Business Communications in Geneva, considers it as a joint Elf Aquitaine/Enterprise Oil deal with a value of $1 480 million (see Table 1).

And this was a widely publicised deal. When it comes to smaller private deals - which are particularly significant in continental Europe - numbers are often simply not available, or if they are they are largely guesswork. As Coopers & Lybrand, a firm of accountants and management consultants, says in a recent report on M&A in Germany, "Very often figures that one sees are merely based on assumed purchase prices derived by using rule of thumb multiples of either sales or profits".

Then sometimes there are problems over how deals should be categorised. When in 1991 the British company ICL bought Nokia-Data, the loss-making computer division of Finland's Nokia group, some data gatherers categorised it as a UK/Finnish deal; others saw it as a Japanese purchase of an EC business, since Fujitsu owns 80% of ICL, and much of Nokia-Data's business is inside the Community. The categorisation was no easier when ICL subsequently bought half of the European computer-services subsidiary of America's Bell Atlantic.

Potential Community member Sweden creates some special problems. The busily expanding Asea Brown Boveri (ABB) can be considered to be either Swedish or Swiss; and when Tetra Pak paid over $2 billion for Alfa Laval nobody was sure whether it was a cross-border takeover or a purely domestic affair. Tetra Pak and Alfa Laval are Swedish, but Tetra Pak's headquarters are in Switzerland and its business is everywhere.

Confusion also arises over the dating of deals. Should they be dated at the time when the deal was first announced, or at the considerably later time when it became fully effective? The impact that this decision can have is clearly illustrated by the European car industry. M&A Europe says that M&A spending in the car industry in Europe was "slashed" in 1991 to "a meagre" $500 million, down from $12 billion over the previous two years. According to IMC the biggest cross-border deal in the European car industry in 1991 was worth only $131 million.

Then turn to another authoritative source - IDD's Mergers & Acquisitions Analysis - and it lists Volkswagen's £3.45 billion purchase of the Czech car company Skoda as the biggest cross-border European deal of all in 1991. IMC did not include the deal in its 1991 figures because it had already included it in its 1990 figures: the deal was first announced in August 1990, but did not come fully into effect until June 1991.

Such a huge deal can make a huge difference. Include it, and the car industry does not seem to have gone into such a deep dive into the doldrums in 1991. More especially since Fiat signed a letter of intent to purchase a majority of the Polish car-maker FSM in October 1991, a deal that was worth $2 billion when it was completed in 1992. But a letter of intent was not enough to include Fiat's Polish deal in either IMC or IDD's 1991 figures.

Moreover, if the Skoda deal is included in 1991, and so is the German insurance company Allianz's $3.1 billion purchase of America's Fireman's Fund (a deal that was announced in August 1990, but which came into effect on the second day of 1991), then the picture of acquiring and target nations for the year changes dramatically too.

Suddenly, Germany becomes one of the most acquisitive nations in 1991 (by value - see Table 3), and question marks are raised over the argument that Germany became obsessed with its reunification of East and West at the expense of wider interests. Also, on the basis of the Skoda deal alone, Czechoslovakia becomes the second most popular target nation in Europe in 1991 - after the UK.

In terms of totals too it makes a difference. IDD reports that there were 1 334 cross-border deals around the globe in 1991, down 22.3% from 1 716 in 1990. KPMG reports that there were 1 793 deals in 1991, down 34.2% from 2 725 in 1990. IDD's smaller number of deals were worth £40.8 billion (compared with KPMG's larger number of deals which were worth the smaller amount of $51.9 billion). The value of IDD's deals in 1991 was one-third less than the value in 1990; KPMG's was down by more than a half.

A number of consequences flow from these inconsistencies. For a start, not too much should be read into the upturn recorded by some gatherers of M&A data towards the end of 1991. Then, although there was undoubtedly a decline in activity in 1991, nobody can be sure how steep it was. What can be said with reasonable certainty is that the value of deals declined more than the number of deals - i.e. the big widely-publicised (and often hostile) deals fell away rapidly, while small friendly mergers continued at a not very significantly altered pace.

JOINT VENTURES

The decline in M&A activity was not entirely due to the changed economic environment. It was at least partly the result of a discernible shift in corporate philosophy. Companies have been increasingly eschewing the full merger, or the acquisition of control, in favour of less expensive, less ambitious joint ventures. This marks a turning away from the popular belief in conglomerates - in the idea that the only way to benefit from another company is to own it and to control it.

Joint ventures are also referred to as "corporate partnerships". They involve loose agreements between two or more companies designed to help them exploit jointly a market opportunity. Joint ventures have been particularly popular in the electronics industry where Japanese technology has often been combined with European market access to help reduce normally high development and marketing costs to the benefit of both partners.

According to KPMG, joint ventures and minority participations (stakes of less than 50% in another company, often held as part of a strategic alliance between the two companies) have withstood the recent poor economic climate better than mergers and acquisitions. In the first nine months of 1991, the number of cross-border joint ventures recorded by KPMG fell by only 20% on the first nine months of 1990, while the number of cross-border mergers and acquisitions fell by 37%. KPMG says that "acquisition is increasingly seen as only necessary when it relates to a core part of the business and it is essential to have outright control. Outright acquisition is very expensive and there are situations in which companies no longer see it as viable."

Joint ventures may indeed make increasingly sound strategic sense to a large number of companies looking to expand in Europe. Nevertheless, in some cases joint ventures may represent not just the better option in entering a particular market; they may represent the only option. For despite the efforts of the EC to create a level playing field for takeovers across the Community, there remain considerable barriers to entry for companies wishing to make cross-border contested takeovers. Those barriers apply particularly to takeovers of quoted companies, and they divide continental Europe from Anglo-Saxon financial markets.

BARRIERS TO TAKEOVERS

Many contested takeovers do not take place for the simple reason that nobody really believes that they can happen. Whatever its shortcomings, the unsuccessful hostile bid by Italy's Pirelli for Germany's Continental tyre company in 1991 will have confirmed the view that German companies are impregnable for as long as they have the support of the big German banks. On the other hand, the successful bid by Switzerland's Nestle for France's Perrier may have reinforced the impression that France's capital markets are fast becoming Anglo-Saxon. Nestle played the Perrier takeover very much by the Anglo-Saxon rules that it had honed in its takeover of Britain's Rowntree a few years earlier.

In its 1990 report on barriers to takeovers in the European Community, Coopers & Lybrand identified two types of barriers to takeovers of public companies: "structural" and "technical". The firm defines structural barriers as being impediments to contested bids that arise from the structure of the ownership of shares and "the broad culture of how each market operates".

In Italy, for example, only eight out of over 200 listed companies have issued more than 50% of their shares to the public. That means that they remain tightly controlled by small cabals of like-minded industrialists and financiers who are not minded to give up control. Coopers could only identify one contested bid as ever having taken place in Italy, and that was for a minority stake. (Credit Lyonnais' purchase of 48% of Credito Bergamasco in 1989.)

Technical barriers are specific measures which directly impede the passing of control by contested takeover. By their nature, they can be removed in a short space of time by regulatory or legislative action. Dutch companies are particularly adept at building technical barriers which restrict the voting rights of ordinary shareholders and concentrate power in shareholder groups that are friendly to management.

Coopers & Lybrand found structural barriers to be strong in France, Germany, Italy, and Switzerland; while technical barriers were strong in Germany, the Netherlands and Switzerland. The consultants found the UK to be "the one example of a market in which both structural and technical barriers are weak for the majority of listed companies."

Coopers then described clearly the fundamental difference in this respect between the UK and other EC countries:

"As a general observation we find that only in the UK have directors a clear duty to shareholders. In all other countries studied [the major European economies], we have observed a commitment of management to act in the interest of the continuity of the company - though in some countries stronger than others - thereby taking into account the interests of all stakeholders and not merely their shareholders.

"At the same time, we found that only in the UK the concept of 'hostile takeover' is perceived to be an integral part of the financial market, while the other countries are very much conducive towards 'agreed takeovers'.

"This finding confirms that a free market for takeovers can only exist when shareholders have the major say in the decision on the company's future ownership. Indeed our study reveals that in all countries studied, except for the UK, many barriers to takeovers have effectively made the position of the shareholder less dominant. Thus an environment of agreed bids has evolved where contested bids could hardly succeed."

This dilemma is Europe's dilemma: does it want to move further towards the shareholder-dominated model which even

Source: KPMG

its greatest proponent (the UK) is having doubts about after the corporate irresponsibility that it encouraged in the 1980s? Or does Europe want to move away from its fixation with the level playing field beloved by the British, inventors of the cricket pitch and the tennis lawn?

Barriers to the takeover of private companies are much more limited than those discouraging the takeover of public companies. Most of them relate to the relative ease (or otherwise) of finding out about potential targets, or to the unwillingness of private companies in some countries to be bought by any company (like a UK quoted company) that will have to reveal the purchase price to the public. The strength of the intangible barrier put up by an absence of information should not be underestimated.

COUNTRY BY COUNTRY

Combining both domestic and cross-border deals, the UK (as always) stands head and shoulders above the rest of Europe in the amount of M&A activity during 1991. IDD reckons that there were 1 178 deals completed in the UK in 1991 (domestic and cross-border) worth some £21 billion. Comparable figures for 1990 were 1 491 deals worth £27.6 billion.

AMDATA has slightly different figures for the UK. It reckons that there were 1 189 deals (both domestic and cross-border) in the UK in 1991, worth £18.2 billion - compared with 1 524 deals worth £27.7 billion in 1990. There were 341 acquisitions by UK companies of companies abroad (value £3.3 billion), and there were 264 foreign acquisitions of UK companies (value £6.5 billion), the favourite sector of acquirers in the UK being the oil and gas industry.

On the continent, IDD reckoned that the busiest nation in 1991 was Italy. Italian companies, it claims, made 288 purchases (domestic and cross-border) worth £1.24 billion - "well ahead of Spain, France and Germany by value and number". AMDATA also has Italy high up the list of cross-border acquirers and targets in 1991. As an acquirer only the UK and France beat it; as a target only the UK, France and Sweden.

From KPMG's data - which covers cross-border deals only - Italy is way down the list of European Community acquirers (see Table 4). First in 1991 was France with 220 deals worth $12.5 billion, followed by the UK with 285 deals worth $6.3 billion. Italy is also low down the list of EC target nations for the year.

Source: IDD Information Services

Notwithstanding the equivocal data on Italy, 1991 was a year when M&A interest was particularly sharply focused on Germany and Spain. Coopers & Lybrand reckoned that there were a record 2 895 deals involving German companies in 1991, most of them inside Germany where the Treuhandanstalt continued with its task of privatising the former "Kombinat" in the eastern part of the country. By the end of the year almost 50% (some 5 200 companies) had been privatised.

Foreign companies accounted for only 10% of the privatisations in eastern Germany, with France, the United States and the UK the busiest buyers - in that order. Foreigners were particularly active in the construction and building materials sector. Almost half the European cross-border deals in the sector recorded by M&A Europe for 1991 were purchases in either the former East Germany or in Czechoslovakia.

Interest in Spain was sparked by general international excitement about the 1992 Barcelona Olympics, the Seville Expo, and the 500th anniversary of Christopher Columbus's departure for the New World. However, far more significant to deals in the longer-term than these grand events was a new law introduced in 1990. It required Spanish companies with more than 50 employees to file annual audited accounts. As such they become a matter of public record, available for examination by any hopeful suitor. Together with the removal of protectionism at the end of Spain's transitional period of entry into the EC at the end of 1992, this should be enough to keep the country in the forefront of EC M&A activity.

INDUSTRY BY INDUSTRY

Pharmaceuticals was one industry in Europe that remained reasonably immune to recession in 1991. Cross-border deals in the sector increased, buoyed up by the fact that - recession or no recession - European populations get remorselessly older and more health-conscious.

The oil and gas industry was also noticeably active, thanks to the almost single-handed efforts of France's Elf Aquitaine which featured as a buyer in six of the seven biggest cross-border deals in the sector. The biggest deal by far was Elf's joint purchase with Enterprise Oil of Occidental Petroleum's North Sea assets.

Despite an almost halving in the value of deals between 1990 and 1991, the food, beverages and tobacco sector was still the busiest in cross-border M&A in Europe. Apart from some rationalisation of the UK brewing industry, there were no particularly big deals in the sector. But many big names (Unilever, PepsiCo, Nestle) were busily further consolidating their positions in Europe with a number of relatively small deals. The seemingly insatiable French giant BSN was again particularly active, cementing deals during the year in Czechoslovakia, eastern Germany, Greece, Ireland, Italy and Spain.

The media sector was also busy with the dissolution of the Maxwell empire at the end of the year accounting for much of the interest. And as usual there was plenty of activity in the banking and financial services sector. Much of the interest there was focused on Spain, where a restructuring of the banking industry led to the divestment by the big banks of non-core businesses (of which they had more than a few), and to a number of strategic stakes being taken in the biggest Spanish banks by banks from other member countries.

CONCLUSION

Future M&A activity is highly dependent on the levels of economic growth in the major economies of the world. There are, of course, certain special situations and opportunities that apply only in recession, and that can be sure to keep corporate financiers occupied whatever the economic climate. For example, in recession some buyers are tempted to go looking

for irresistible bargains; others buy defensively in the hope of improving their own profitability; and yet others (often groups of managers) buy bits and pieces spun off by big corporations as they rationalise and digest the excesses of earlier booms.

There are other more positive forces that apply in both good times and bad. Companies continue to put strategies into effect that reposition them competitively to take account of the changing corporate environment. Coopers & Lybrand identify three areas where this applies:

"Highly regulated sectors such as pharmaceuticals, media and transportation, will continue to rationalise throughout the world as regulatory barriers are removed. In Europe, companies in capital-intensive industries, such as chemicals and steel, will have to consolidate in an effort to reduce fixed costs. There will also be pressure on businesses in labour-intensive industries to relocate to lower-cost areas, such as southern and eastern Europe."

Anything beyond this is in the hands of the pilots of the western world's major economies.

Inward and outward foreign direct investment in Western Europe

INTRODUCTION

Foreign direct investment (FDI) and the activities of multinational corporations (MNCs) are playing an increasingly important role in the international integration of the world economy, even though this integration affects different parts of the world to a different extent and in different ways.

Three important developments can be discerned in the development of FDI over the last two decades - trends which are likely to persist for some time:

Growth: Worldwide FDI is growing faster than other economic indicators like production or international trade.

Regional shifts: FDI is becoming more and more concentrated in developed countries, especially in the USA and Europe. Simultaneously, MNCs from Japan as well as from several European countries have been growing faster than those from the USA and the UK, who have traditionally dominated FDI.

Growth patterns: External growth, i.e. through acquisitions of already existing companies, is becoming the dominant mode of MNCs' expansion strategies, in contrast to internal growth, i.e. through the setting up or extension of subsidiaries.

DEFINITIONS AND STATISTICAL PROBLEMS

FDI can be defined as cross-border transfer of capital through which an investing enterprise creates a new foreign company, (partly) gains control of an already existing foreign company, or develops the business of an already affiliated foreign company. The affiliation of the foreign company, i.e. some kind of managerial relationship, is important since this is the criterion which distinguishes FDI from international portfolio investment. Thus, FDI is closely related to the activities of MNCs.

This general definition allows for a great variety of detailed statistical definitions. The benchmark definition of the OECD includes the following transactions: the purchase of shares or other original capital, reinvested earnings, the net increase of loans and credits, minus disinvestments. The affiliation of a foreign company is usually assumed if the investing company holds 10% or more of the voting power.

However, most countries use their own definitions, which deviate more or less from each other, as well as their own methods of collecting data. The statistics of some countries do not include reinvested earnings. This is the case for instance in the Netherlands and France, to name only the most important. Some countries do not define a minimum threshold, like the Netherlands, or use a 20% ownership threshold as the criterion, like Germany and France. The different treatment of investment in real estate or of short term loans poses further problems. Finally, some countries like Greece and Ireland do not produce FDI statistics at all.

A further important problem is that of indirect FDI e.g. through intermediary holding companies and special financial institutions. Intermediary holding companies which belong to a foreign company and own other foreign companies at the same time play an important role in the UK, the Netherlands,

Data on US affiliates is for 1989, taken from Bureau of Economic Analysis
Data on Japanese affiliates is for 1990, calculated from JETRO data
Data on total employment is for 1990, taken from OECD
Data on Germany is for 1990, taken from Deutsche Bundesbank
Data on France is for 1989, taken from Service des Statistiques Industrielles
Data on Italy is for 1989, taken from R.Cominotti and S.Mariotti: Italia multinazionale 1990, Milano 1991
Data on United Kingdom is for 1989, taken from Central Statistical Office
Data for Spain is for 1990, estimates based on a current research project
Data for EC and total Western Europe are estimates for 1990, based on the figures presented here plus additional national sources

Luxembourg and Switzerland, and their treatment in national statistics varies greatly. Finance companies or so-called special financial institutions through which MNCs finance international as well as domestic operations are frequently found in the Netherlands, where they are completely excluded from FDI statistics.

Eurostat has tried to tackle the problem and started to harmonise data available from national statistics of the twelve EC countries. This is obviously a very difficult task. A comparison of "harmonised" bilateral FDI data as given for the investing country and the targeted country show tremendous differences or asymmetries. FDI outflows and inflows often are a multiple of the respective other.

All data presented here have to be interpreted with caution. For this reason, this report will refrain from calculating and presenting exact percentage figures on sectoral or regional FDI distribution as well as, e.g., on growth rates.

Outward investment stock

Since statistics on FDI *flows* are difficult to interpret, we will present some other data first. The above definition of FDI refers to flows, i.e. annual values of capital transferred across borders as reported in the balance of payments. Another method of measuring FDI is to assess FDI stock or FDI position at a certain point of time, i.e. the (book) value of the assets owned by the investing company in its foreign affiliates. Data on FDI stock also poses severe statistical problems, but national definitions are nevertheless more homogeneous.

Data on outward FDI stock is available for the seven most important European investing countries (cf. Table 1). The by far most important investor is the United Kingdom, followed by Germany, the Netherlands, France, Switzerland, Italy and finally Sweden. There are significant differences in the regional distribution of the countries' foreign investment. The United Kingdom is the only country where the USA (40%) has attracted more FDI than Europe (30%); it is also the country with the highest share of FDI in developing countries (14%). For all other European countries, perhaps with the exception of the Netherlands where data on FDI stock in European non-EC countries is lacking, Europe has attracted over half of the FDI stock. The EC alone has attracted more or less half of FDI stock of most European countries, but only little more than one quarter of that from the United Kingdom.

This data shows the distinctive orientation of MNCs from the United Kingdom, which, following a long tradition, are much more globally oriented. MNCs from other European countries, on the other hand, are still, despite high growth rates in the USA for most countries, heavily oriented towards Europe.

Data on industry structure of FDI stocks is only available very selectively and on different bases. To give an example - data sometimes refers to the industry of the investing company and sometimes to the industry of the foreign affiliates. Consequently, data will not be presented here in detail. But some general remarks can be made. The share of investment in manufacturing affiliates is considerably higher in overseas investment than in investment in European countries, where commercial affiliates are much more important. For the UK and also for the Netherlands, oil companies which usually act on a more global basis account for a major share of FDI. Finally, it seems that a considerable share of the UK's FDI is being undertaken by trusts and other conglomerates which manage their subsidiaries at arm's length. This means that foreign affiliates of these companies are much less integrated into a unique company strategy, hence on an operative level UK companies are less internationalised than statistical data would indicate.

Employment at foreign owned manufacturing affiliates

For inward FDI, probably the best indicator for the level of internationalisation can be derived from employment figures. Head count leaves much less space for varying definitions. Table 2 shows data for the manufacturing industry of the most important European countries, along with an estimate for the EC and total Western Europe. Germany is the country with the most employees at foreign owned companies, followed by the UK, France, Spain and Italy. In Western Europe, there are about 4 million persons employed at majority owned manufacturing foreign affiliates, 3.7 million of them in the EC. About half of these employees are working at non-European companies, especially American but also Japanese and Canadian but also others. Foreign penetration of the manu-

facturing sector is especially high in Spain, and also in several smaller countries like Ireland, Austria or Belgium. It is low, for instance, in Italy.

Global developments

Over the last decades, world-wide FDI has grown much faster than world production or international trade. This has been especially true for the period between 1983 and 1989, when - according to UNCTC calculations - worldwide FDI outflows grew by 29% annually. In 1990 and 1991, this growth slowed down again.

During the 1950s and 1960s, FDI was dominated by MNCs from the United States and the United Kingdom. The 1970s and 1980s, on the other hand, have witnessed a tremendous growth of FDI by corporations from other European countries and from Japan. Table 3 shows "harmonised" Eurostat data for inward and outward FDI flows of the three regions of the Triad, and reflects the tremendous growth between 1985 and 1989. EC(12) has doubled outward FDI, and inward FDI has even grown fivefold; in 1989 both reached about the same level. Japan's outward FDI has grown almost fivefold, while inward FDI has remained negligible. Contrary to this, US inward FDI has more than doubled, while outward FDI remained at a low level. The situation of the US looks somewhat different if one includes reinvested earnings (cf. Table 4). Recent data for Japan also show that the extremely high growth rates of the 80s did not persist in 1990 and 1991; nevertheless, Japan remains a large net foreign investor (cf. Table 5).

Source and notes: see country tables

The high growth of FDI in the second half of the 1980s is primarily a result of the boom in international M&A activity. The fact that MNCs today are primarily expanding through external growth, i.e. acquisitions, and only to a very small extent through internal growth, i.e. green field investments or expansions, also has an impact on MNCs' internal structures. MNCs' structures are becoming more polycentric. This is due to the fact that acquired companies have strong points and potentials of their own, such as access to markets, management abilities, technology, or R&D capacities - sometimes, they are even MNCs in their own right. This development towards more polycentric company structures is supported by the "philosophy" of many companies to develop a triad structure and to become an insider in the three most important regions of the world economy, North America, Europe and Japan, i.e. to develop the ability to behave like a national company in each of the three regions.

For most European MNCs, except those from the UK and the Netherlands, Europe has always been at the core of their internationalisation strategies. Due to a boom of M&A activities, FDI flows between EC countries have grown enormously in the second half of the 1980s (cf. Table 3). This growth has slowed down in 1990 and 1991 (cf. country data as presented below). European MNCs are restructuring their European activities and developing a more unique approach including European intra-company divisions of labour. They achieve this by utilising the different locational advantages for different kinds of activities and production in different

parts of Europe and the EC. In this respect, they are following a strategy MNCs from the USA have pursued for a long time. One third of the turn-over of US manufacturing affiliates in Europe are exports to other European countries.

The opening of Eastern Europe poses completely new challenges to MNCs. Selected data available on FDI outflows to Eastern European countries displays high growth rates, especially since 1989. Hungary and the Czech Federation of the CSFR are receiving the largest shares of FDI inflows, particularly when their relatively small size is taken into account. Among the investing countries, Germany and the USA hold the leading positions.

FDI flows of European countries since 1985

Data on FDI outflows and inflows as given in the balance of payments are presented in Tables 6 and 7. For many European countries, annual figures fluctuate enormously. FDI is a long-term phenomenon, though FDI figures for one or two years might only reflect a small number of large take-overs that just fell into that period. Similarly, low FDI figures for a year or two might reflect the absence of large take-overs and perhaps even the sale of parts of the companies that had been acquired in the previous period.

FDI flows should not be mixed up with foreign affiliates' investments in fixed assets. Since FDI is only one way of financing foreign activities of a company, besides e.g. taking up loans on the local market, FDI is strongly influenced by changes in interest rates or exchange rates. This means that changes in FDI flows during the last one or two years generally should not be interpreted as indicators of a general and long term shift in the structure of FDI flows, even if these changes are immense, such as in the UK in 1990 and 1991.

Comparing the three-year periods 1985-87 and 1989-91 in Tables 6 and 7, FDI outflows have increased significantly for most European countries, the notable exceptions being the United Kingdom, Switzerland and Norway, where data for the last years shows no clear tendency. FDI inflows of EC countries have also grown in this period, most significantly of its new members Spain and Portugal. Among the EFTA countries, only Sweden shows a clear increase of FDI inflows. For most European countries, FDI outflows are more or less constantly higher than FDI inflows, with some important exceptions: In 1990 and 1991, the UK became a net importer of FDI while Austria only recently became a net exporter. Spain and Portugal (and probably also Greece and Ireland, where no data is available) have always been net importers of FDI.

EC countries

BLEU

The BLEU, receives slightly more FDI than it invests abroad. Both inward and outward FDI have been growing strongly since the mid 1980s. It should be noted that banks and other financial institutions located in Luxembourg, and which are

large recipients of FDI, are not included in the data presented in Table 8.

Denmark

Outward FDI has been higher than inward FDI during the whole period since 1985, and both have been growing in the longer run. The EFTA countries have traditionally been the most important foreign direct investors into Denmark. But in 1991, the share of the EC had risen such that the Community accounted for about half of FDI outflows as well as FDI inflows. Outward and inward FDI in manufacturing have also been growing, accounting for less than a quarter of outward and over one third of inward FDI in 1990 and 1991 (Table 9).

Germany

FDI outflows have been growing tremendously over the last years, while FDI inflows have more or less stagnated since 1985 (Table 10). While until 1988 the USA received about half of Germany's FDI outflows due to a wave of acquisitions, outflows have concentrated on EC countries since 1989. The privatisation of East German enterprises, so far, has not led to a higher penetration of the German economy by foreign MNCs. The share of investment or employment guaranteed by foreign investors to the privatisation agency Treuhandgesellschaft is less than 10% of total guarantees.

Spain

FDI flows of Spain show a continuous and high growth (Table 11). Inward FDI has grown more than sevenfold between 1985 and 1991, and outward FDI has grown even seventeen fold over this period. Spain has been an important importer of FDI since the end of the 1950s, while the internationalisation of Spanish companies is a new phenomenon. Spain is the biggest European net importer of FDI, with net inflows amounting to over 8 billion ECU in 1990 and almost 9 billion ECU in 1991. Spain's most important FDI partners for inward as well as for outward FDI are the other EC countries.

France

French outward FDI has increased enormously in the second half of the 1980s, and in 1990 French outward FDI was higher than that of any other European country (Table 12). 1991 outflows showed a decrease. In manufacturing, the chemical and food industry showed the highest growth rates. Inward FDI has been growing too, but has not reached the level of outward FDI. More than half of inward as well as outward FDI were connected with other EC countries.

Greece

Data on outward FDI is not available for Greece. Data on inward investment refers to "entrepreneurial capital" which includes foreign capital inflow either for direct investment or for working capital approved under the foreign investment

law. Capital inflows of this kind have more than doubled since 1986, reaching 727 million ECU in 1990. A regional breakdown is not available.

Ireland

Unfortunately, Ireland does not provide data on FDI, even though the Irish manufacturing industry is highly dependent on foreign companies, and Ireland's Industrial Development Authority subsidises these investments. About half of grant-aided foreign investment is coming from the USA. The very high FDI outflows to Ireland the statistics of several European countries are showing in the beginning of the 1990s are primarily going to the newly established Free Banking Zone in Dublin (Table 13).

Italy

Annual values of Italian FDI outflows as well as inflows vary considerably (Table 14). In the medium term perspective, outflows and inflows seem to be balanced. In 1991, outflows stayed at a relatively high level while inflows dropped by more than half. The concentration of FDI to and from EC countries is higher than for most other European countries.

Netherlands

Both inward and outward FDI have grown since the mid 1980s, the level of outward FDI being considerably higher than that of inward FDI (Table 15). Neighbouring BLEU as well as the UK where some Dutch MNCs have a second headquarters (like Royal Dutch Shell and Unilever) are the most important

FDI partners. Outward FDI to EC countries grew slightly above average, accounting for more than half in 1990 and 1991. Inward FDI from EC countries dropped considerably in 1991, leading to an overall decrease in total inflows for the first time since the mid 1980s.

Portugal

Outward FDI of Portugal, especially in the manufacturing sector, is still negligible. Inward FDI, since the end of the 1980s, has seen a real boom (Table 16). Even though FDI inflows in manufacturing have grown much slower than total inflows, accounting for about one fifth in 1991, the data illustrates that Portugal has become an interesting location for export manufacturing not only for low skill and labour intensive industries, which had been important for many years, but also for capital intensive industries, the joint venture of Ford and Volkswagen being the most prominent example.

United Kingdom

Until the end of the 1980s, outward FDI of the UK had been considerably higher than inward FDI, and both had been growing continuously since 1985 (Table 17). The imbalance was due to high FDI outflows to the USA, while net outflows to EC countries were much smaller, and the EFTA region, due to high FDI inflows from Switzerland and Sweden, even was a net investor. In 1989, the latest year for which data is available, manufacturing accounted for over half of outward FDI and around two fifth of inward FDI, which are considerably higher shares than those of other countries. In 1990, net outward FDI to the USA stopped completely, and, for the first time, the UK became a net importer of FDI. In 1991, inward FDI decreased while outward FDI stayed at about the same level.

EFTA countries

Finland

The strong growth of Finnish outward FDI, of which manufacturing accounts for about half, reflects the enormous internationalisation of a small number of Finnish MNCs. EC countries have become the main destination, while neighbouring Sweden is still the most important single country (Table 18).

Norway

Inward and outward FDI flows of Norway do not show a clear tendency (Table 19), reflecting the variability of investments in the oil industry. Negative inward FDI flows in 1991 are basically the result of some disinvestments by British oil companies.

Austria

Starting from a low level, outward FDI flows of Austria have grown considerably since the mid 1980s, indicating the beginning of an internationalisation process of a small group of Austrian companies. Inward FDI flows have remained notably low, even though many MNCs - especially from Germany and the USA - operate in Austria.

Sweden

Sweden's outward FDI has been growing enormously since the mid-1980s; but it dropped in 1991, due to a decrease of FDI outflows to EC countries, which attract the major part of Sweden's FDI (Table 20). Inward FDI has always been much lower than outward FDI, but in 1991 inward FDI from EC countries grew considerably. The shift of FDI flows from and to EC countries can possibly be linked to the changed macroeconomic paradigms of the Swedish economy.

Switzerland

Data on outward and inward FDI flows of Switzerland do not display a clear trend. Usually, outflows are higher than inflows (Table 21). In 1990 and 1991, over half of Switzerland's FDI outflows went to EC countries. In 1990, the USA

The Single Market after 1993

The date of 1st January 1993 marked a further historic landmark in the development of the European Community. It heralded the start of an EC market without internal border controls, with wide-ranging benefits and changes for citizens and for businesses operating in the Community.

Whilst a few decisions remain to be taken notably in the company law and direct taxation field, the basic legal framework for the Single Market based on the Commission's 1985 White Paper programme has been agreed, thus respecting the deadline embodied in the Single European Act of 1987 which obliged Member States to create "an area without internal borders in which goods, persons, services and capital can freely circulate". Future work will focus on ensuring the efficient and proper functioning of the Single Market. This will involve the close cooperation of Member States' authorities, the Commission and other Community institutions, business and citizens in exchanging information and experience through mechanisms and procedures already established or which are being set up. The Commission will play an important role in smoothing out difficulties which may arise.

The Treaty establishing the European Economic Area will shortly enter into force. This Treaty extends to the EFTA states except Switzerland the relevant Community legislation concerning the free movement of goods, capital, services and people, thus creating a free trade area covering some 375 million consumers. In many areas, Community legislation (e.g. public procurement and financial services) will apply throughout the EEA from the date of its entry into force. The EEA will cover most of the "acquis communautaire" including most internal market measures except those dealing with the abolition of border controls. EFTA countries will apply EEC rules on state aid, transport, competition, consumer and environmental protection, statistics, public procurement and company law. The EEA will not bind EFTA states to participate in the Common Agricultural Policy. There are special arrangements for certain sectors, such as food, fish, energy, coal and steel and some countries have derogations to delay implementing obligations. A special EFTA Surveillance Authority will ensure that the EFTA countries abide by the rules and that the same competition rules as applicable within the EC are also applied by the EFTA side. Cooperation will be intensified in the flanking policies like research and development, environment and social policy.

SINGLE MARKET DECISIONS

As at 31st December 1992, decisions had been taken on 95% of the Single Market measures foreseen in the Commission's 1985 White Paper programme.

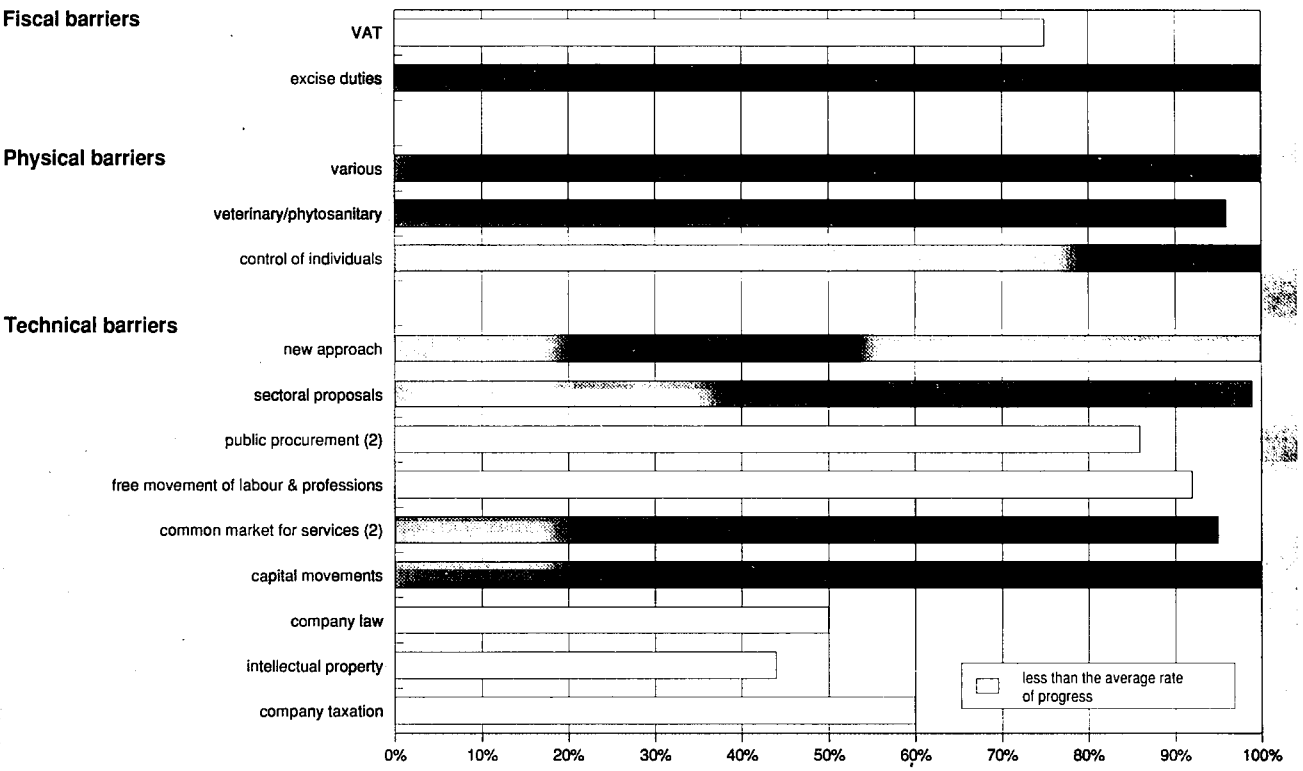
All the decisions to enable the free movement of capital have been taken. In the veterinary and phytosanitary field, all the decisions have been taken to harmonise the conditions for placing animal and plant products on the market and for displacing the necessary health controls away from the internal borders to inspection points on the territory. In the area of free movement of goods, new VAT and excise duty regimes have been introduced. These replace controls at the internal borders by, for example, in the case of VAT, a system based on cooperation between national tax authorities; customs documentation has been abolished on goods circulating in the Community or put in free circulation in a Member State; all the technical harmonisation measures foreseen in the White Paper have been agreed, and so has the legislation for opening up competition in the field of public procurement. In the services sector, all the decisions foreseen in the financial services sector and the transport services sector (with the exception of the definitive cabotage regime for the road transportation of goods) have been taken, though certain measures will not enter into force immediately (e.g. third non-life insurance and life assurance directives enter into force on 1st July 1994; similarly in the fields of, for example, maritime and road cabotage (of passengers), transitional measures have been agreed to enable certain Member States to adapt to a system of open competition).

In the area of intellectual property, it is expected that the remaining decisions will be taken early in 1993 to enable the Community trade mark to be introduced; similarly that all Member States will ratify the Convention on the Community Patent to enable its entry into force. It is regrettable that certain decisions have not been taken in the area of company law - notably the setting up of a European company statute and the harmonisation of laws relating to take-over bids, and on direct taxation designed to eliminate the imposition of double taxation in cross-border dealings. Nevertheless, if one or two pieces remain to be agreed to complete the legislative programme, the framework is largely in place and awaits only the finishing touches.

In relation to the free movement of persons, all Community citizens will have the right of residence in a Member State other than their own, and will be able to freely circulate in the Community. Restrictions on cross-border purchases of duty paid goods have been removed, although a traveller may be subject to a control on the territory, and asked to justify that the excess spirits and cigarettes above certain stipulated indicative limits (at which level trade in such goods might be suspected) are for personal use (e.g. for a family wedding). Whilst sales of duty free purchases will be permitted until 1st July 1999 in respect of intra-Community travel, controls to administer such sales will be carried out at the point of purchase and not by customs at the internal border. Measures for the mutual recognition of professional qualifications have entered into force and comparative tables published of national vocational training qualifications in a wide range of non-regulated professional sectors.

The legislative programme necessary for the abolition of border controls on goods was first set out in the Commission's Communication of December 1991 (see COM(91)549), and in subsequent Communications of May and June 1992 (SEC(92)877; SEC(92)1085). By and large all decisions en-

Figure 1: State of Council decisions taken on the Single Market, 31 December 1992 (1)



(1) The table shows the percentage of decisions taken by the Council based on the 1985 White Paper Programme: 264 decisions of the 282 proposals (261 final adoptions, 3 common positions), 18 decision remaining of which 5 are being given high priority for adoption.
(2) Common positions: capital adequacy, investment services, public procurement excluded sectors
Source: Commission of the European Communities

abling the removal of internal border controls on goods have been taken, though certain accompanying measures at Community level relating to particularly sensitive goods and issues (strategic goods, cultural goods, animals accompanying travellers) need to be finalised. Checks at land and sea borders on persons circulating in the Community are being abolished between the Member States party to the Schengen Agreements, but checks will still be made by certain Member States at the internal borders for the purpose of controlling illegal immigration, given their geographical situation and where the immediate introduction of new controls on the territory would be more cumbersome for citizens than the minimum checks necessary at the internal border. Internal border checks on persons at airports are to be removed by 1 December 1993 in the Schengen area.

FUTURE PRIORITIES

The priority is now to ensure that the Single Market works properly and efficiently. This requires, first, that the Member States' authorities transpose all the directives currently in force and enforce them uniformly.

With respect to this first point, the transposition situation by Member State as at 31 December 1992 is as follows: 233 directives have entered into force of which 194 require national transposition measures. The rate of transposition has risen to 75%.

A second requirement is that remaining or additional legislative measures to complete the framework are adopted by the Council and implemented: notably in the fields of company law, direct taxation and energy.

A third requirement is that the necessary European standards for the full implementation of the "new approach" directives and public procurement directives are developed by the Community standards bodies as soon as possible.

The fourth requirement is the uniform policing of the Community's external border, close cooperation between, for example, national tax authorities, and an efficient and effective system for removing from the Community market either dangerous goods or those which do not comply with Community legislation. Measures involving the exchange of officials particularly in the taxation and customs fields have been set up to foster mutual confidence, and telematic networks introduced or improved (e.g. VIES, SHIFT) to enable the storage of data and rapid exchange of information between Member States' authorities and with the Commission. In addition, "contact points" in Member States are being designated to deal with problems relating to the coordinated removal of dangerous goods. In order for the benefits of the Single Market to be fully achieved, it is necessary to develop fully integrated trans-European networks in the transport, energy distribution and vocational fields as well as those in the data transmission field. Work is continuing on the basis of a programme of priority networks established by the Commission in consultation with interested parties.

Programmes and policies articulated in the 1985 White Paper have resulted in fresh strategic perspectives that have radically transformed the business environment by imparting a pan-European dimension rooted in market transparency, a viable legal framework and a new dynamism born of deregulation:

In the wake of harmonisation and the removal of cross-frontier controls, the Single Europe affords the corporate sector access to a marketplace of 340 million consumers - a marketplace which is characterised by an unprecedented level of compatibility in terms of both goods and services. New possibilities have emerged with respect to cooperation between individual

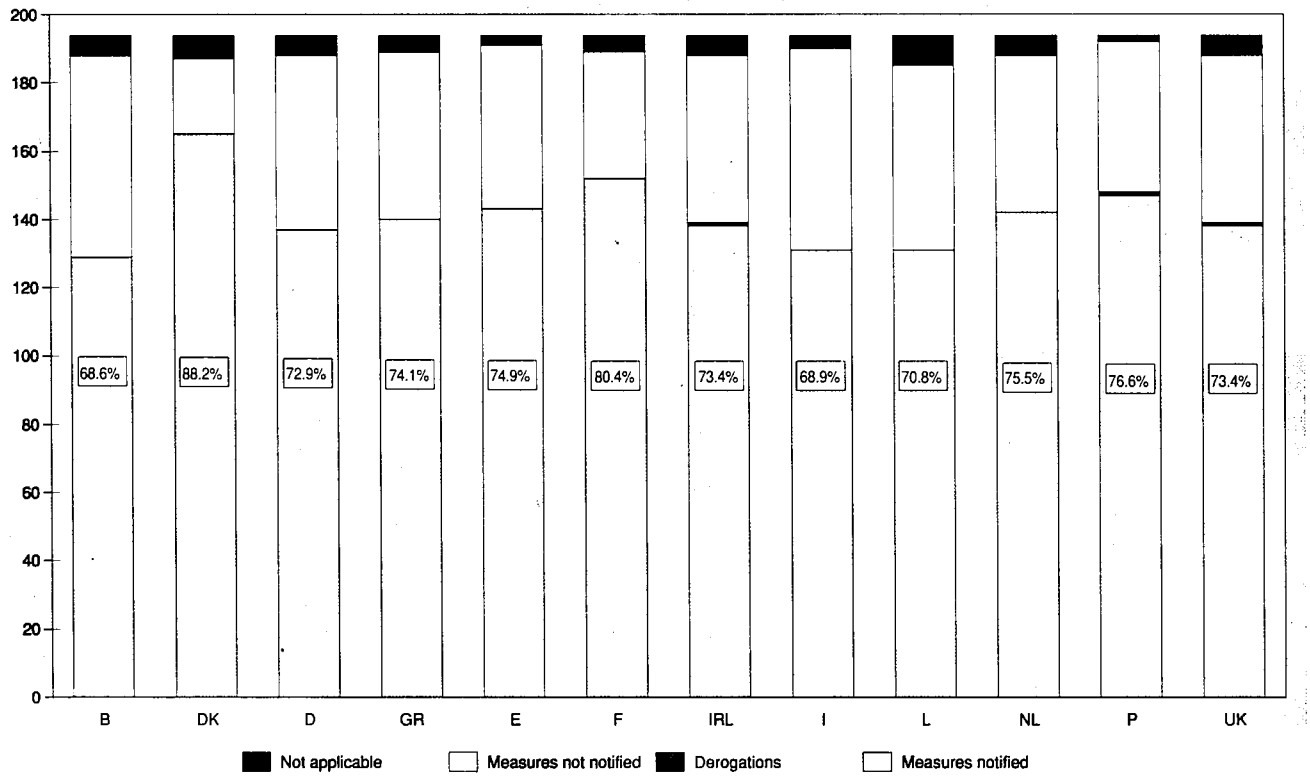
Source: Commission of the European Communities

firms and recourse to services provided by operators in other EC Member States, whereby the sole competitive yardsticks are price and quality. The impact of this new economic area has already been demonstrated both at the corporate level, where intra-EC trade has grown from 50% in 1981 to 60% in 1992, and in terms of intensified cooperation between EC firms.

The Single Market affords companies the possibility of operating within a stable and established legal framework which largely eliminates distortions to trade. Transposition and implementation of EC rules into Member State law has resulted in private sector firms and public sector operators acquiring rights and obligations which are enforceable, in the first instance, at the level of national tribunals. Artificial barriers rooted in national law have also been largely eliminated, the most notable change being undoubtedly in respect of public procurement. At the consumer level, there is a new confidence that pan-European harmonisation of regulations, test methods and certification standards will ensure that goods and services comply with health and safety requirements. Meanwhile, new provisions on external EC relations and fair trade guarantee that European companies are shielded against unacceptable commercial practices.

Figure 2: Breakdown of situation by Member State at 31/12/92 (1)



(1) Measures notified as a share of total is displayed

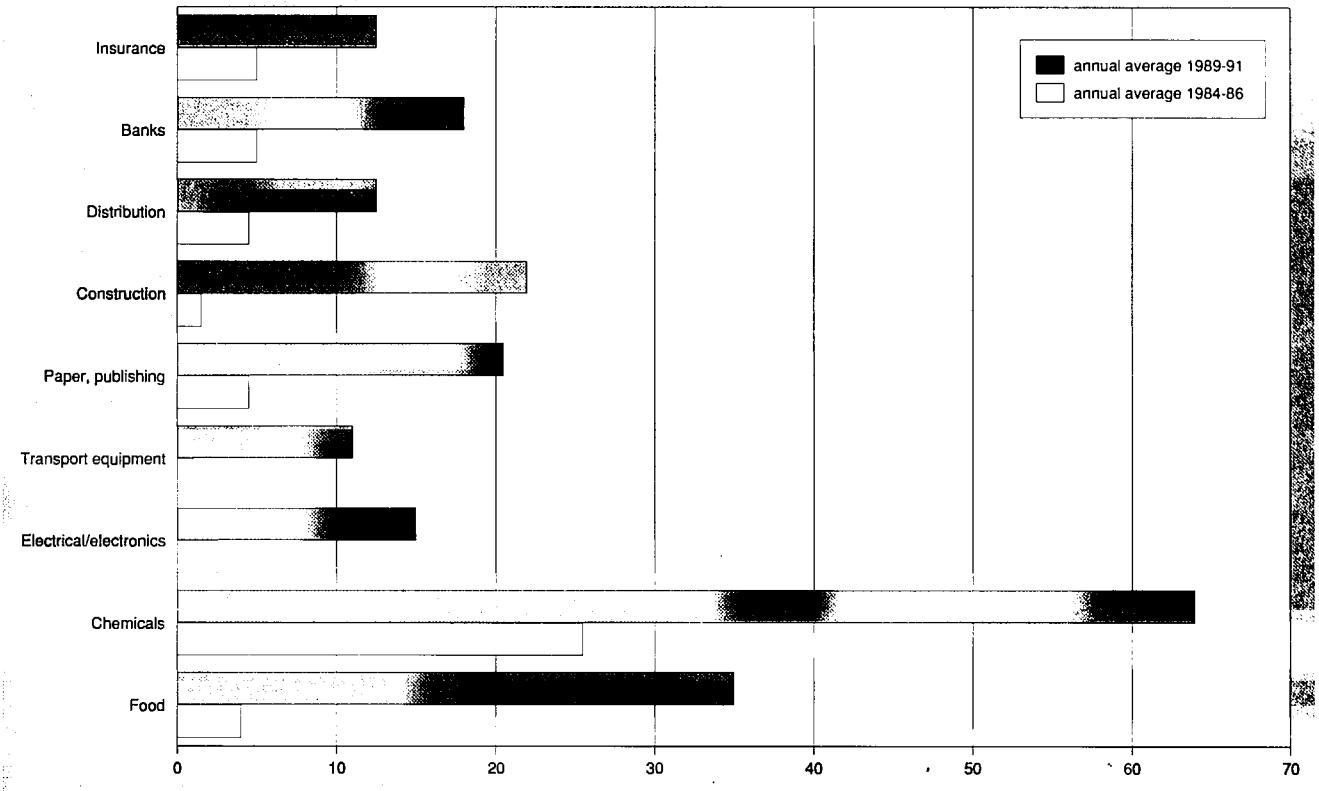
Figure 3: Intra-EC mergers and acquisitions of majority holdings by sector



Source: Commission of the European Communities, Annual Reports on Competition Policy

Finally, the Single Market promotes and protects private initiative and boosts innovation. Community rules have abolished frontier controls and eliminated attendant formalities, rendering superfluous some 90 million customs declarations every year. Customs and transit documents issued by one EC Member State are now recognised by the other eleven Member States. Even more important, however, is the fact that the removal of border controls obliges each Member State to take account of its Community partners when implementing new rules at national level so as to preclude distortion of intra-EC trade.

These aspects of the Single Market have already had an impact on corporate strategy and on the policies adopted by the public sector in the Member States, not least in fiscal matters. On the other hand, progress in this area only serves to highlight significant shortcomings at the social level.

The 1st January 1993 was considered a deadline by business and citizens, inside and outside the Community. The challenge was to put in place the legal framework for the Single Market, removing the physical, technical and fiscal barriers to the four freedoms of movement. This deadline has largely been respected. Many measures have been in force for some time, the remainder will enter into force in due course. The challenge in the immediate future is to make the Single Market work smoothly through effective implementation and enforcement. The open, competitive environment will present challenges for each sector of industry and for each business. 1992 is behind us; the real challenge of the Single Market is just beginning.

The use of modern electronics in urban transport

Developments in advanced telematics and information equipment

THE TRANSPORT SECTOR CHALLENGE

The rapidly growing European economy has brought with it an even more explosive growth in mobility.

Europeans spend more than 500 billion ECU on road transport products and services every year. More than 10% of the average family budget is devoted to transport. Car ownership has been increasing steadily by 4% a year. and there are now some 120 million cars in Europe. International traffic increases by 5% a year, whilst on main motor ways freight traffic increased by more than 10% in 1990 alone. It has been estimated that a 1% growth of the GNP generates 1.5% growth in passenger transportation and up to 3% growth in the transportation of goods.

Economic growth in the European Community has recently been about 2.5% per annum. Coupled with the freedom of movement of persons and goods in 1993, this implies that much higher increases in transport flows can be expected.

In certain cities, traffic demand can no longer be satisfied. In Paris the average speed has dropped to about 10 km/h and in London to about 18 km/h. Once the journey has been completed, finding a parking space is often no easy task: In Paris there are only 720 000 legal parking places for 4.2 million cars, so it is difficult to find even prohibited parking space. Quite a significant proportion of downtown traffic is due to people merely looking for a parking place. In large cities and city centres, traffic needs to be managed, and more attention should be paid to public transport as the most promising alternative to guarantee an acceptable level of mobility.

On the 2nd of December, the Commission adopted the white paper, "the future development of the common transport policy". The new global approach identifies the transport challenges of the future and the eventual responses of the Communities for coping with them.

At this crucial period when developing the competitiveness of Europe is at the top of the agenda, the transport system faces major deficiencies: traffic congestion, accidents and environmental problems are worsening. The social problems are accumulating. Waiting in traffic jams for instance costs a German driver 65 hours a year. The cost of congestion delays in Europe is estimated to be around 15% of total transport costs - at around 500 billion ECU per annum. Finally, in the EC countries alone, approximately 55 000 have been killed, 1 700 000 injured and 150 000 permanently handicapped through road accidents on average in each of the years of the 1980's. Apart from the human suffering, the financial cost of all this lies around 50 billion ECU per year.

Therefore, important efforts to increase the performance of the road network are urgently required. There are, however, severe obstacles to the expansion of traditional infrastructure, such as the scarcity of space (especially in the urban environment) and resources as well as environmental reasons. Existing approaches to solving road traffic problems such as current traffic management schemes, civil engineering improvements, engine management technology and Community Directives on vehicle standards are important, but have limited effect in the face of rapidly increasing traffic.

The major challenge in the future in the short term but also in the medium and long terms, is the substantial improvement in the utilisation and operation of transport networks through the application of information technology and telecommunications. Investment in this "new" approach, called Advanced Road Transport Telematics (ATT), is required and has potential of substantial benefit.

EXPECTED BENEFITS OF ATT SYSTEMS

ATT systems are expected to be beneficial to different groups in the community:

To road users:

- Increased road safety
- Reduced travel time
- Availability of better information and other services
- Improved travel comfort

To road operators and administrations:

- Improved traffic control and monitoring
- Assessment of new strategies & policies

To industry:

- Creation of a new important market
- Stronger European competitiveness

To society:

- Reduced pollution
- Reduced number of accidents
- Reduced congestion

To Europe:

- Facilitate the single European market 1993
- Strengthen the European competitiveness
- Further European social cohesion

THE NEED FOR EUROPEAN COLLABORATION

In view of the forecast increase in international traffic, these systems will have to be introduced all over Europe in a co-ordinated way.

Transport patterns on road infrastructures are changing rapidly, and do not take into account national borders. This makes the operation of on-vehicle equipment installed with minimum common functionality a high priority in all regions and cities in Europe.

The telematics and automobile industries are already well aware of these aspects, but this awareness is only a first step and much more effort is required to arrive at an approach where compatible solutions acceptable to European citizens and industry are found.

However, the rapid technological changes and differences in user requirements represent a major challenge to achieve a satisfactory level of European compatibility and interoperability. The collaboration in the development of common functional specifications and European standards is essential for the development of a compatible network for all services in an "open" system. This requires appropriate flexibility in the integration of existing and new developments in the stages of testing and implementation at different national and regional environments. The different situations and problems at both the technical and institutional level must be taken into account allowing sector actors - and in particular local, regional and national authorities responsible for the infrastructure - to decide their investment and strategies. A common conceptual framework and agreement on basic principles at European level is a prerequisite for meeting user requirements, fair competition and the management of risks of the considerable investments required.

This European approach will benefit both the users and industry.

EC R&D INITIATIVE

Following favourable opinions from the Economic & Social Committee, from the European Parliament and from the Council of Ministers, DRIVE was formally adopted as a Community research programme in June 1988, for a period of three years (1989 - 1991). Within the budget of 64 million ECU, 72 projects were retained for a total amount of over 1000 Man-years.

Following the successful operation of this programme, a new initiative extending it to a new phase (DRIVE II), shifting the accent from "exploring options" to "preparing for the implementation", has been launched for a new period of three years (1992 - 1994). With a budget of 120 million ECU, 56 projects including a large number of "demonstration projects" are actually working for a total amount of over 2000 man-years.

The main objectives for the use of ATT is threefold:

- improving the safety in road transport;
- maximising road transport efficiency;
- reducing the environmental impact of road transport.

The EC envisages a common European Integrated Road Transport Environment (IRTE) in which drivers are better informed and "intelligent" vehicles communicate and co-operate with the road infrastructure itself. The aim is to come to the overall design of traffic management and safety systems which will represent a significant advance over those currently available.

DRIVE is not a stand alone initiative: It works in close co-operation with PROMETHEUS, CARMINAT and other programmes under the EUREKA initiative and with several national development programmes.

ECMT RESOLUTIONS

In May 1990 the council of ministers of transport of ECMT (European Conference of Ministers of Transport) passed a resolution on transport, computers and telecommunications. Here the ministers recognised that the problems of transport on European roads are becoming worse and that it is not possible to address these problems simply by building more roads. The conference took into consideration how important efficient transport is to the economics of the Member States, the impetus already given to the exploitation of Information technology and Telecommunications in programmes such as DRIVE an PROMETHEUS and resolved:

- to monitor on an on-going basis the developments with respect to computer and telecommunications applications to the transport sector;
- to promote studies on the legal and administrative problems arising with respect to these applications, especially where the question of safety is concerned;
- to carry out comparative studies on public and private funding mechanisms, both national and international, whereby the infrastructure and services associated with these applications can be developed;
- to engage initial analyses of scenarios for introducing computer and telecommunications applications in the transport sector.

In May 1991, The Council of Ministers of ECMT acknowledged the valuable work carried out on the subject of harmonising traffic messages and their transmission in close co-operation with EC within the DRIVE project RDS-ALERT. The council recommended that the draft pre-standard for traffic messages and their communication should be followed in all European field trials and that wide circulation should be given to the corresponding resolution so that the proposed pre-standard can be brought into the public domain and can be freely used in the implementation of trials and in the development of equipment.

In November 1991, the Council of ministers of ECMT considered its response to DRIVE II and recommended that:

- national policy-making authorities give full support to pilot experiments conducted under the DRIVE II programme;
- officials from central government play an active role in designing and conducting DRIVE II experiments in order to promote and assist in preparing, performing and assessing such experiments, and to establish a practical system of co-ordination with other public authorities involved, notably at local or regional level.

In June 1992 at the Athens meeting, all ECMT ministers, after having spent substantial time to a special demonstration concerning the major action lines of DRIVE, expressed their satisfaction with the progress of the work carried out in the different DRIVE projects.

LOCAL INITIATIVES WITH TRANSPORT AUTHORITIES - POLIS AND CORRIDOR

The involvement of local authorities, infrastructure providers and the participation of the real final users is a must in setting up integrated pilot projects. With this in mind, two "bottom up" initiatives were launched in order to incite awareness of local, regional and national authorities on the ATT capabilities and to help in the exchange of ideas and the development of common future plans. They are:

POLIS (Promoting Operational Links with Integrated Services through road traffic informatics between European cities) which is a network for urban area pilot projects administered by the cities themselves. More than forty (40) European cities are involved in the POLIS network, either under the "participant" mode (for cities that committed themselves to set up and fund the major part of an R&D pilot project) or the "follower" mode (for cities that are interested in following closely the pilot projects of other cities without wanting to take the lead themselves in the setting up of an R&D pilot project).

CORRIDOR is a collaboration network for all actors (national and regional road administration, motor way companies, IT&T industry, service providers and operators) involved in the process towards the implementation of new ATT services on European motor ways. The infrastructure owners, in most cases national or regional road administrations, will play a crucial role as investors in road-side infrastructure. The initiative provides a framework for the exchange of experience in planning and conducting inter-urban pilot projects containing cross border traffic flow and/or cross border traffic information flow. 13 European regions and representatives from all national administrations and EFTA countries participate in this framework. In this way CORRIDOR is contributing to the realisation of the Single European Market.

THE IMPLEMENTATION - ERTICO

The Commission of the European Communities has promoted the creation of a private-public organisation, open to all interested European organisations, with the objective of contributing to the co-ordination of on-going ATT projects in Europe and to provide support and guide-lines for implementation.

On November 13, 1991, an international non-profit making organisation in the form of a Belgian Société Cooperative was incorporated in Brussels, for which the name ERTICO SC was chosen (European Road Transport Telematics Implementation Co-ordination Organisation)

The objective of ERTICO is to encourage, promote and assist with the co-ordination of ATT implementation in European transport infrastructures, assuring a smooth transition from pre-competitive R&D to market driven investments.

The main tasks of ERTICO are to:

- conduct strategic planning;
- analyse needs and markets for ATT;
- conduct ATT systems engineering resulting in Common Functional Specifications;
- follow and assess continued research results;
- follow and assess field trials;
- promote common specifications, standards, laws and regulations;
- initiate and participate in implementation projects.

SYSTEMS ENVISAGED

Driver information increases safety and travel comfort

A first area where advanced telematics can offer a great help is the information of the driver.

Many accidents and a lot of time lost in traffic jams can be avoided by informing the driver accurately and in good time so that he can take this information into account and adapt his way of driving or decide on an alternative route.

- Well organised data transmission systems between meteorological institutes and information providers can greatly enhance the accuracy of the information on local weather conditions.
- Artificial intelligence based systems will be able to quickly and accurately detect road accidents, incidents and congestion. Telematic systems can bring that important information to the drivers with the shortest delay by means of in-car displays or warning systems or using variable message signs along the road.
- Information about actual traffic flow will be available in the relevant traffic control centres. Advanced telematic systems can also make this information available to the road users in such a way that it can be easily utilised by individual drivers.
- Advanced telematic systems make it possible to connect information centres of different modes of transport together in order to make all this information (travel times, schedules, fares, park & ride facilities, ...) available to the candidate traveller at home or in the office and at public places in order to allow him to better plan his trip and to choose the most suitable mode of transport.

Enhanced traffic control increases efficiency

A second area for improvement is within traffic control centres.

Signalised intersections are one of the most important components of any urban traffic control system because, to a great extent, overall traffic efficiency, safety, cost of operation, capacity, and environmental impacts depend on their design and operation.

Delay is the parameter which defines the level of service of signalised intersections. It is also a measure of driver discomfort, frustration, fuel consumption, and lost travel time.

Traffic signal optimisation is a complicated process that determines cycle time, green split, phase sequence, and offsets between the signals (in the case of signals co-ordination). It is obvious that traffic signal optimisation can lead directly to reduction of delay. Two approaches are mainly used to reduce delay and fuel consumption. They are optimisation of cycle time and green split for isolated intersections, and co-ordination of signalised intersections within a network or along an arterial.

ATT systems can play an important role in automatic traffic data collection as the input for traffic control systems in which sophisticated algorithms and strategies allow immediate adaptation of the traffic control system for an individual intersection as well as for a whole urban network to the real demand.

Freight management systems enhance efficiency

One of the most important sectors of road use is the commercial vehicle fleet. Efficient routing of commercial vehicles produces very significant economic benefits.

Telematics and neural networks can significantly contribute to a pan-European freight management system which will establish unprecedented levels of information availability on vehicle and load locations with direct data communication to drivers for delivery and pick-up instructions and creation of customs documents. This would lead to an opportunity for making significant improvements in the efficiency of goods transport by road.

Hazardous goods monitoring enhances safety

One area of transport safety lies in the movement of dangerous loads. ATT systems such as automatic identification combined with automatic location and continuous tracking have great potential in providing accurate logging of movements of loads and identification of their nature. Similar considerations apply to the security of both dangerous loads and valuable cargo.

Public transport: the most promising alternative

As stated earlier, certain cities have such serious and wide spread congestion problems that traffic demand can no longer be satisfied. If nothing is done, this will inevitably result in a lower quality of life in the city as mobility decreases. This congestion is mainly due to the use of private cars for home-office travel taking a large amount of road space for only one or two persons. Use of private cars for this purpose needs to be reduced. This can be achieved by attracting people naturally to another mode of transport. On the other hand, city authorities might need to practice demand management strategies strictly to reduce car traffic in certain areas. In these cases, in order to guarantee the same level of mobility to individual citizens, the only alternative is to make sure that an attractive public transport system offering sufficient capacity is available before the application of measures restricting demand. An attractive public transport system must offer sufficient capacity with modern comfort, should be more reliable (enhanced real time control), easy to use (better information for passengers), with reduced travel times (less loss of time at stops due to the use of electronic payment systems, better interchange facilities between different transport modes) and adapted to the needs of the traveller (by increased efficiency, comfort and flexibility using non-fixed itineraries providing a demand responsive service and avoiding congestion.

ATT can be applied to an integrated Public Transport overall management system based on a V.S.C.S. (Vehicle Scheduling and Control System, in French S.A.E.: Système d'Aide à l'Exploitation) where all the buses have an on-board micro-processor which determines their exact location. The control centre interrogates all the buses in turn which then respond with their location, load, mechanical status, information on fare collection, etc. The central computer compares the real position of each vehicle with the theoretical situation as foreseen in the timetable, and calculates (here expert systems in real time can be applied) possible measures in order to restore the service to normal in case of delays or incidents. The operator can then send instructions in digital form to the vehicles concerned which are then displayed to the concerned drivers. The central computer registers all the operational data to be used for statistical purposes. These statistics can then be used as input for the refinement of future timetables.

Telematics and informatics will play a major role in the following functions concerning the general management of Public Transport undertakings:

- Strategic planning: demand analysis, network improvement, operations improvement.
- Management information: information on bus operation, information to the managers on the day-to-day variations in demand and their causes.
- Maintenance: development of a data base in order to gain the necessary know how for improvement of vehicle reliability, improved Artificial Intelligence base maintenance planning and diagnostics.
- Fare collection: smart cards can be used as the basis for a more user friendly fare collection system, easier to use by the traveller and allowing for the operator a much more detailed information gathering about origin and destination of users.
- Passenger information: psychological studies reveal that waiting for a bus for 3 minutes not knowing when it will arrive gives much more stress than waiting for 10 minutes knowing in advance that it will arrive in 10 minutes. This is the foundation of passenger information: To put the user at ease, it is essential to give him maximum information 1) before the trip starts to help the passenger in organising his trip, and 2) during the trip information about the actual bus journey: bay assignment, actual waiting times, route identification, destination (outside and inside the vehicles), interchange facilities, disturbances, etc. The information about current actual operation is available in the V.S.C.S. centre and can thus be made accessible to the users by means of interactive displays at bus stops, stations, at home and also inside the vehicles. At bus stops the actual waiting time can be displayed. The major difficulty to overcome here is the development of new cost effective displays to permit the generalisation of such displays to practically every stop without overloading the operator's budget.
- Operations management: all the major operations management tasks such as scheduling (establishment of timetables, assigning vehicles, drivers and rostering drivers) and management of crew and vehicles can largely be assisted by informatic tools with the possible use of Artificial Intelligence.

At strategic level it is of the utmost importance that urban traffic control systems take into account the needs of public transport. Telematic systems can interconnect and integrate both systems and give public transport a certain priority within the general traffic strategy adopted by a city.

In general, the application of integrated computer based bus operations management systems will have the following direct and indirect effects:

Commercial effects: Service improvement resulting in turnover increase and improvements in:

- running speed
- regularity - punctuality
- user information
- supply adequacy
- demand responsiveness
- multimodal and multiservicing facilities
- fare facilities (smart cards)
- increase in operation efficiency
- revenue/expense coverage improvement
- resource saving:
- staff due to productivity increase
- buses due to more hours/bus (less breakdowns and down time)

Profitability of routes:

- patronage knowledge
- fare collection
- strategic planning

Energy savings:

- higher speed (running and operating)
- depot management
- better safety: due to better maintenance and on-line diagnostics
- better security: due to continuous surveillance and alarm systems
- whole management efficiency
- common language flexibility simulation

External effects:

- contribution to economy
- industrial and software suppliers
- better service - mobility
- urban development

- energy saved

Environmental impact (indirect):

- air pollution
- noise pollution

Safety and security are also at stake as on the one hand maintenance methods and on-line diagnosis will lower the incidence of accidents for buses which are already much safer than private cars (in France 18 fewer accidents with equivalent kilometrage). In this case, any traffic substitution in favour of public transport saves human lives.

On the other hand, rapid communication and "silent alarm" possibilities and close contact with police and emergency services will reduce criminal acts drastically. This is an important fact since "small criminality" seems to have found its playground around public transport facilities at stops and in the vehicles.

MAJOR BUILDING BLOCKS FOR THE IRTE

Radio data systems (RDS)

The development of in-vehicle information systems in recent years has been based almost entirely upon broadcast radio. Broadcasting of radio information about road or traffic conditions has been common practice for several decades. However, several drawbacks need to be overcome:

- the listener is not only obliged to accept messages which have nothing to do with his trip, but is also forced to hear them repeatedly;
- he needs to capture "his message" amongst a variety of non-interesting messages;
- he is obliged to listen to the programme broadcasting this type of information;
- he needs to understand the local language.

A special system (ARI) has been developed in Germany making use of identification signals for broadcast messages to motorists. This system was introduced in Germany, Switzerland, Austria and Luxembourg, but didn't succeed to spread all over Europe.

On the other hand, the RDS (Radio Data System) is already standardised by the broadcasting organisations co-operating at European level within the EBU all over Europe and fitted in many car radios. It is used to broadcast on a side band data together with frequency modulated radio programmes. Its main application is the automatic tuning of receivers. The driver sets the radio station of his choice and from then on there is no need for tuning his radio again when entering another broadcasting zone during his trip.

A promising application of this system is the RDS-TMC (Radio Data System - Traffic Message Channel) that allows the transmission of signals identical with the identification signals in the ARI system but that also presents other interesting functions that can solve the drawbacks of voice broadcasting mentioned above: traffic messages are no longer broadcast in the form of sound, but digitally according to a so-called TMC computer code. The messages are reconstructed in the vehicle using a special RDS-TMC receiver unit that contains a micro-computer, a database for the standardised international data set, the respective national location sets and an integrated circuit producing synthesised speech from decoded digital data. The system can restore the information in the form of short speech synthesis messages or as printed messages on a display.

In such way the system is language independent and can be presented directly to the driver or even integrated into an autonomous navigation aid system which can be improved using RDS location coding.

The system is, however, limited in its transmission capacity (some 130 bits/s). In the future, Digital Audio Broadcast (DAB) systems will allow to broadcast much more information. Approximately 8 kbit has been reserved on each stereo program which could be used for services like RDS-TMC and extra services such as paging, and other information such as weather forecast, water levels, stock market, etc.

Groupe spécial mobile (GSM)

Due to the growth of analogue mobile radio throughout Europe, the CEPT (Conférence Européenne des Postes et Télécommunications) set up GSM to define a second generation system. The result is the pan-European digital cellular mobile radio system commonly referred to as GSM (Groupe Spécial Mobile).

The infrastructure necessary for the GSM cellular radio system is presently being installed and will assure full coverage for mobile telephony purposes all over Europe by 1993 - 1994.

The advantages of GSM as a communication medium between moving cars and a traffic control centre are:

- The ready availability of a radio channel implies that the driver can be in contact with the traffic centre in any place at all times. Many important applications such as emergency calls can only be realised by means of a radio link.
- GSM is a digital system providing several types of data services which could be used as building blocks for a dynamic route guidance system. The maximum user data rate available is 9600 bits/s.
- GSM defines a pan-European standard.

GSM is already operational in many European countries and is expected to cover the whole territory by 1994.

This infrastructure can also be used in order to achieve two-way communication between vehicles and control centres, but with an important difference from conventional cellular telephony where calls are made on a one-to-one, or point-to-point, basis. Only one channel for each cell (representing less than 1% of the total GSM capacity) is needed to broadcast information to all equipped vehicles in the cell, while the uplink with data from the vehicles uses a multiple access protocol to distinguish individual vehicles.

The system will be compatible with UMTS, the future generation of pan-European cellular radio.

Due to the nature of its concept, with "cells" covering a diameter varying approximately from 5 km to 35 km, GSM can also be used for rough location of vehicles.

Navigation systems - route guidance

The task of the driver in a moving vehicle consists not only of operating the mechanics of the machine, but also the even important task of "navigation" which can be quite complicated especially in an unfamiliar environment: the driver needs determine the car's position, the itinerary, read the map, take the initiative to detour in case of road works or traffic jam,... This gives an extra burden to the driver which can endanger the safety of driving.

Positioning systems

Recent developments in communication techniques have lead to the implementation of services directly accessible to private users. Remote telephone communications and vehicle positioning are the most promising. Several systems are actually available:

LOCSTAR is a satellite based combined radio positioning and (data) communication system in the EUREKA programme.

DATATRAK and TRACKER are commercial positioning systems developed in the UK.

- LORAN-C and DECCA are commercial exclusive radio positioning systems, widely used for maritime navigation purposes.
- DATATRAK, LORAN-C and DECCA are available at the moment but do not fully cover the European territory.
- GPS (Global Positioning System) is a satellite based system developed for the United States for military purposes. It is also available for civil applications, however, with a lower degree of accuracy (but still within one hundred meters).
- GPS is already used for vehicle location purposes in fleet management applications. However, full coverage in urban areas, where buildings may cause transmission loss and interference with reflected beams can occur, remains problematic.

Autonomous navigation systems

Autonomous systems are able to give navigation advice to the driver based on the knowledge of the vehicle's position and of the road network. TRAVELPILOT developed by BOSCH and CARIN developed by PHILIPS, both rely on a combination of dead reckoning and map matching in order to maintain the vehicle's position.

Dead reckoning uses the electronic compass and the wheel sensors to respectively determine direction and distance travelled. Since slight inaccuracies of these sensors add up over long distances, the position becomes increasingly inaccurate and therefore is periodically corrected by using an additional procedure called map matching: the in-car computer seeks to match the route determined by the sensors with a possible route on the digital map. If the car is found to be slightly off the road, its position is updated by "electronically relocating" it back onto the street network.

The driver inputs his destination and the in-car computer matches this information with the digital map available on CD-ROM. The system then computes the shortest route between the current position and the destination, and this information is conveyed to the driver in the form of turning advice at each intersection, either by voice output or by means of a simple pictogram on a small display.

Autonomous navigation systems can:

- provide an easy way to find a destination in an unfamiliar environment;
- replan a route following a missed or wrong manoeuvre;
- allow for different route choice criteria (shortest, most scenic, etc.);

These systems go some way to alleviating traffic problems since shorter routes should result in "less time on the roads", thereby reducing environmental pollution. The most important feature, however, is the help provided to the driver in facilitating his task and therefore improving safety.

Dynamic navigation and route guidance systems

By design, the routing provided by autonomous navigation systems is based on static information and does not take the prevailing traffic situation into account. Consequently, these systems can be made more powerful when supplemented with "up to the minute" traffic data. Generally, traffic information is only available for a few important streets in a city, i.e., those covered by sensors. Comprehensive traffic information must therefore come from a different source such as the cars themselves. With its on-board sensors, each car will monitor its own progress as it traverses the links which constitute the planned route and anonymously send its "floating car messages" to the traffic control centre. These messages are very short and contain journey times as well as data concerning stop-and-go traffic and turning manoeuvres. This, however, implies a two-way communication link between the vehicles and the control centre through which cars receive information about current and predicted travelling times for the important links of the road network, and other data concerning availability of parking spaces, park & ride schemes, etc.. On the other hand, the same cars transmit to the control centre their own "floating car messages", acting as a traffic sensor and contributing this way to give the control centre an overall picture of the traffic in the whole city. Different technologies can be used for the link between the car and the control centre. EURO SCOUT uses infra, red beacons installed all over the city. Micro-wave beacons could fulfil the same function, both provide only intermittent and short range communication with the mobile, thus requiring high data rates. Another approach is taken by SOCRATES, using GSM allowing for continuous communication authorising much lower data rates.

The information available this way in a dynamic route guidance system enables the in-car computer to improve on the performance of an autonomous navigation system by supplanting the shortest route by the fastest.

Dynamic route guidance systems affect also the task of the traffic manager, who gains rapid access to a substantial amount of information about prevailing traffic jams and incidents. This knowledge enables him to improve his traffic control strategies by optimising the traffic control system.

THE MARKET: COSTS AND BENEFITS

The total financial investment for the implementation of the global ATT services will have to take into account:

- the cost of the preparation of infrastructure, where public investment will comprise the major part;
- the cost of the proper ATT infrastructure itself, where public and private investment will be shared depending on the implementation strategies adopted by the national governments of the member states;
- the cost of the in-car equipment, where private investment will form the major part.

For each Member State, the ratio of public to private investment will depend on the State's policy and strategy. Some countries would not want to go beyond the basic infrastructure equipment level, while others clearly accept that the public investment can reach a higher level, for example in the services operators domain. Most countries have not yet formulated their policies for some or all of the ATT services.

The infrastructure investment

It is clear that private investment will depend both on the prior provision of the necessary public investment (in the preparation of the infrastructure) and on the existence of a potential market demand for services to users. As it is difficult for all of the European countries to have a precise idea of their own investment on ATT implementation, the following figures are based on some data available in countries which have been used to produce a forecast scenario in terms of systems which could be implemented on major urban areas and inter-urban motor way networks. Some figures concerning freight & fleet applications have been included in the figures for the inter-urban area.

ATT applications which have been clearly identified for short and medium term implementation in medium and large cities are:

- Adaptive traffic control
- Public transport management
- Parking management
- Route guidance
- Tunnel control

Table 1: Cost of implementing the ATT systems in large cities

Country	Number of inhabitants (millions)	Number of cities by size (inhabitants) 0.3 million	0.3 to 1 million	1 to 5 million	5 million	Cost estimate (million ECU)
Belgique/België	10	4	1			70
Danmark	5	1		1		40
BR Deutschland	75	10	8	6		330
Hellas	10		1	1		40
España	38	5	4	2		140
France	55		3	1	1	200
Ireland	3.7	1	1			20
Italia	57	4	7	3		190
Luxembourg	0.37		1			10
Nederland	14	1	3			40
Portugal	10	1		1		30

- Integration of ATT systems

and, possibly:

- Road pricing

Cost estimates

The figures in Table 1 are taken from the CEC DG XIII C4 IRIS report. The average cost estimates for cities have been calculated mainly from estimates from the UK, and vary depending on the size of the city (7 million ECU per site for cities of 0.3 million inhabitants and over to 140 million ECU per site for cities of more than 5 million inhabitants). For each country, the number of towns or cities of the above sizes have been estimated. Using these numbers cost estimates of the total cost of implementing ATT systems in each country excluding Road Pricing have been prepared. These cost estimates do not include the costs of the ATT systems which may be installed in smaller towns.

On road pricing equipment, it is the Netherlands which has produced the most detailed studies and estimates of this type of application. It is estimated that the total cost of providing road infrastructure for the Randstad (a highly populated area consisting of several cities with a total amount of about 5.10^6 inhabitants) would be 150 million ECU, i.e. 30 million ECU per million inhabitants. For the whole of the EC, the cost estimate using a similar method of calculation would be around ECU 1.83 billion.

Since the same vehicle will generally be used to circulate within the urban environment as well as for inter-urban trips, Tables 2 and 3 consider both urban and inter-urban motorways.

ATT applications which have been clearly identified for short and medium term implementation on motor ways are:

- Basic infrastructure
- Traffic data collection
- Weather and environment monitoring
- Automatic incident detection
- Traffic control
- Driver information (variable message signs and video terminals)

Referring to the list of ATT applications, the average unit costs which have been suggested for dual carriageway motor ways are indicated in Table 2. To make a rough estimate of the unit cost per km of ATT equipment, a set of assumptions has been made, which are summarised in Table 3. Based on these hypotheses, the estimated cost for the implementation of ATT equipment on interurban motor ways is of approximately 0.4 million ECU/km.

Table 2: Average unit costs for dual carriage motorways

Basic infrastructure (cable, trench & emergency telephone)	80 kECU/km
Traffic data collection	30 kECU/km
Weather station monitoring	100 kECU/site
Automatic Incident Detection	200 kECU/km
Variable Message Signs	300 kECU/site
Automatic Toll Collection	50 kECU/site/lane
Traffic Control Centre	1000 kECU/site

Source: IRIS Report, CEC DG XIII

Table 3: Assumptions for the road infrastructure network

Length of European motor way network	20 000 km
Length of toll motor way network (EC & EFTA)	15 600 km
Weather monitoring station	every 50 km
Automatic incident detectors	every 500 m
Variable message signs	every 10 km
Automatic toll collection for 6 lanes	every 20 km
Traffic control centre	every 200 km

Source: IRIS Report, CEC DG XIII

If, however, it were accepted that Automatic Incident Detection is only necessary on half the motor ways and Variable Message Signs are only required every 20 km, the average cost becomes 0.25 million ECU/km. Taking the above estimates into account, one can conclude that the total investment required to provide ATT systems on the European motor way system is likely to be between 5 and 8 billion ECU.

In-vehicle investment

In Europe, the development of ATT which is already under way in conventional automotive functions for cars, and on

Table 4: Estimated market size for in-car equipment in France in 2000

the interdependent developments in component miniaturisation, fixed network telecommunications, and mobile telecommunications services, will be the key enabling elements of ATT.

As the number of vehicles increases, it will be reasonable to assume more interaction within the systems and consequently more benefits. In this context, there might be the possibility that sales of ATT services will be much higher than sales of ATT systems. In fact, the demand for inter-active driver information, navigation and safety systems might lead in 20 years time to 90% of the vehicles being equipped with processors, communications and interface devices. The number of vehicles in Europe is estimated to reach the number of 190 million by the year 2010.

A recent report for the French Ministry of Transport has made some estimates of the European market for in-car equipment by the year 2000, that are reported in Table 4.

If we consider that the market penetration of these devices by the year 2000 is about 10% of the final market, which could be 90% of the 190 million cars over 20 years, then the final market for in-vehicle equipment can be estimated to be more than 50 billion ECU. The above mentioned cost estimates for cities, motor ways and in-car equipment can be combined to give overall estimates for the whole European market (Table 5).

Cost/benefit analysis

A comprehensive cost/benefit is difficult in this domain, especially because the implementation approach of ATT systems is based on average need at European level and not on a detailed country per country approach where the implementation strategy has to be matched to the real problems of traffic safety or traffic efficiency. However, it has been possible to provide some figures for the return on investment and to estimate other benefits due to efficiency improvements (e.g. in term of reduced time delay or saving of human lives).

Revenues from the market of services

Estimates of revenues from the marketing of services were given in the above mentioned study for the French Ministry of Transport, and are reproduced in Table 6.

Table 5: Estimated infrastructure investment costs

Infrastructure investment and in-car investment cost	(million ECU)
Cities	4 000
Motor ways	5 000 to 8 000
Total	9 000 to 12 000
In-car investment

Non commercial benefits: efficiency, safety, environment

One of the major aims of the Advanced road Transport Telematics systems is to increase the efficiency of road transport and road safety by the implementation of RTI systems where critical traffic problems cannot be resolved by more classical solutions.

Studies have been carried out by the European Road Transport Community to either measure or estimate the benefits of applying ATT solutions to these problems. Although it is very difficult to give precise figures, typical estimates of percentage reductions in time delay or accident savings, derived from these studies are supplied in Table 7.

Some of these figures will be verified by different pilot projects in DRIVE II. Unfortunately, pilot projects are in general devoted to only one system, making it impossible to conclude on the combined effect of several systems.

ATT and environment

ATT systems can result in potential benefits to the environment. A combination of ATT systems is, however, necessary, some aiming at improving efficiency, others aiming at reducing traffic demand.

It is also important to include these technological measures in a broader package of measures including also regulatory and policy measures to meet the requirements regarding the environment.

Although it is very difficult to get relevant information on the benefits of ATT on the environment, Table 8 gives a rough impression of the potential benefits of some ATT applications on the global (emission of greenhouse gases and depletion

Defence-related industries in the EC

INTRODUCTION

With an estimated production of 50 billion ECU and a workforce of about 800 000 people, the EC defence industry would easily rank among the top 20 EC manufacturing sectors. However, any such comparison is hypothetical because virtually all defence-related industries are already represented in the statistics of other, civilian, sectors.

In 1991, the EC defence industry consolidated on the adjustments and changes of 1989-1990. A series of mergers, acquisitions, internal restructuring and redundancies significantly altered the industry. Within the EC, defence procurement continued to fall in real terms and was on average 12% lower than in 1989 for major weapons. Reductions in defence spending hit hardest in heavy equipment for land forces and shipbuilding. But even technologically advanced armament development projects (upon which new military strategies focus) were at stake when EC governments reconsidered their budgetary priorities. Most EC defence contractors were actively expanding their civilian operations in order to be prepared for a much smaller defence market.

INDUSTRY PROFILE

The European defence industry has many ties with the civilian sector. The overlapping between the two areas in Europe are so numerous that it is often preferable to use the term "defence-related" industries. In this chapter, civilian industries related to the most significant production activities of military equipment are discussed. In Europe, this broadly includes five major

groups of activity: aerospace, electronics, shipbuilding, land vehicles, and weapons and ammunition.

Precise production figures for 1991 are difficult to obtain, due to the fact that few European defence-related manufacturers publish the defence share of their total sales. In 1989 the total defence turnover of these industries was estimated at 55 billion ECU. With defence sales steadily decreasing, the 1991 figure was probably close to 50 billion ECU.

Estimates of the total EC workforce more or less dependent on defence sales vary between 1 and 1.5 million. Recent studies which focus only on employment directly generated by defence contracts quote some 850 000. During 1990 and 1991, a series of restructuring measures was announced in most major defence-related companies, totalling a workforce reduction of some 50 000.

Total military expenditure by EC Member States was 144 billion ECU in 1991, of which almost half went to personnel. Spending on major weapon systems amounted to 28 billion ECU, or less than 20%. Total EC exports of major defence systems by the six main exporting EC member states amounted to 3.4 billion ECU in 1991 according to a SIPRI estimate. This was down 15% from 4 billion ECU in 1990.

Real expenditure on defence equipment rose significantly in the EC from 1980 to 1987, but started to decline in 1988. The decline was particularly strong in 1990, the year after the fall of the Berlin wall and the effective end of the Cold War.

This development added to the declining situation on the world export markets. These were affected by a winding down of Cold War conflicts and arms races on Third World territory. On the supply side, EC exports have been hit by growing competition from US suppliers and emerging defence producers such as China, Brazil and Israel led to lower European sales in crucial markets in Asia and the Middle East. The Gulf war in 1991 provided a slight one-off boost for producers of ammunition, missiles and spare-parts. Nevertheless, the overall effect was negative. Significant exports to Iraq were cancelled. After the war, some Arab countries such as Saudi Arabia and Dubai rearmed at a significant scale but often rewarded US rather than EC contractors.

INTERNATIONAL COMPETITION

European industries see decreasing export markets directly affecting the budgets for new product development. European industries therefore, are increasingly pooling R&D resources and developing new products jointly. For most defence contractors, however, the situation in the US is not much better. In 1992 the Bush administration announced that, in five consecutive years, the defence budget would be reduced by 10 billion dollars. Major production and development programmes were already cancelled in the 1988-1991 period. US defence employment was estimated at 3.5 million in 1991. Industry analysts calculated that, given budget reductions, 500 000 to 1 million jobs would be lost up to 1997. Big US defence manufacturers like McDonnell Douglas and Lockheed will probably keep their lead in the world defence markets but will also face significant production overcapacity.

Japanese industries are gradually moving as suppliers of some of the core technologies used in Western armament systems. High speed integrated circuits, for instance, can be produced cost effectively by a few factories only, and most of them are Japanese. Japan has developed a significant defence pro-

duction capability without building a defence industry. More than in Europe, Japanese defence-related industries have their main strengths and profit earners in the civilian markets.

World trade in defence products declined as a result of overall reductions in defence spending. World trade statistics on defence are collected by two institutions, the US Arms Control and Disarmament Agency (ACDA) and the Stockholm International Peace Research Institute (SIPRI). According to 1992 SIPRI statistics, the total volume of world defence trade more than halved from 1987 to 1991. From 1990 to 1991 the trade volume decreased by 31%. Particularly depressed were Third World markets which, in 1991, imported almost one-third of what they absorbed in 1987.

This directly affected EC export sales as intra-EC trade has never been a sizeable proportion of European defence exports. Between 1987 and 1990, intra-EC trade never accounted for more than 700 million ECU and sometimes even less than 300 million ECU. Total EC defence exports ranged between 4 and 7 billion ECU annually over the period 1987-1991. The main EC export markets are the Middle East and South East Asia.

According to SIPRI statistics, defence trade from the six major EC exporting countries went down considerably from 6.2 billion ECU in 1987 to 3.4 billion ECU in 1991. The volume of French exports decreased most, and UK sales showed a similar pattern. Contrary to the trend, German trade went up from 1990 to 1991 as a result of the reunification. In 1991 much of the old East-German armaments stocks were sold on the second-hand market. In 1992, there were no prospects for a quick recovery of the defence export markets.

DEMAND

Market developments in 1991 continued to be dominated by the decrease in defence budgets. In many respects this trend was even accelerated. By the end of 1990 and the beginning of 1991 the virtual end of the Cold War had encouraged most EC governments to consider taking a "peace dividend" from the defence budget to allocate funds to more acute public expenditure needs. Growth of the defence budgets came to a standstill and some countries implemented reductions of a few percent in real terms.

The new security environment will have multiple effects on the pattern of defence equipment expenditure. Main armament systems (combat aircraft, warships) will be kept in service for longer periods. Funds initially foreseen for the development and production of new systems will increasingly be devoted to maintenance and upgrading of system components.

The changing strategic missions of NATO will have a devastating effect on the equipment budgets of land forces. Large numbers of tanks and other heavy land-based equipment were useful as a barrier to a large scale Soviet attack. There is hardly a place for them in the 'new world order' where the emphasis is on fast and mobile crisis containment.

Military personnel lay-offs are costly and come at the expense of equipment expenditure. Social security payment schemes for the large numbers of lay-offs in the EC armed forces will in the first couple of years enlarge rather than reduce the proportional size of personnel expenditure. Certain equipment expenditure will be postponed or cancelled altogether.

Military R&D is likely to be cut less than overall defence budget cuts. Although some major development programmes were cancelled, indications are that the major EC member states (France, UK) want to give military R&D a higher priority than in the past. However, big development programmes such as the European Fighter Aircraft which require huge R&D investments will be more difficult to defend politically.

Governments will also become more cost conscious. Despite a long history of protected national defence markets, many governments have already implemented competitive procurement procedures. Recent studies on public defence procurement show that an increasing number of EC governments use competitive tendering methods to award defence equipment contracts. As US suppliers have often been cheaper in the past, this could have consequences for the competitive position of European suppliers.

SUPPLY

The European defence industry is gradually moving to a higher degree of integration and concentration. The traditional inclination of individual member states to sustain a self-sufficient defence production capability is no longer attainable. R&D and unit costs of the principle armament systems have become so high that efficient cooperation and risk-sharing is the only way for defence manufacturers in Europe to stay in the front line of technological and product development. This risk-sharing includes not only the joint development of key technologies but often also implies building up financial buffers through share swapping or other methods.

Most major defence contractors now cooperate on a large scale in order to spread risks and secure markets. For instance, Aérospatiale announced that in 1992 it would generate more than three-quarters of its total sales in cooperation with the German DASA, both in civilian Airbus and in a range of defence projects. Cooperative projects will increasingly involve real work sharing, whereby each participant takes on

only a part of the production process, and specialises accordingly. This may contrast with the principle of juste-retour which has been the hallmark of defence cooperation in the past two decades. It implied that each national industry had a right to a share of the workload equivalent to its government's contribution. Although such arrangements will remain as a guiding principle they will often be too costly. Even among the major EC member states it has become clear that it is impossible to sustain a full range defence industrial capability on a purely national basis.

However, some of the more ambitious European cooperation projects are threatened by participating governments which are reconsidering their commitments. As it appeared end-1992, the European Fighter Aircraft programme could be seriously pruned. Other projects, such as the UK-Italian helicopter EH 101, could be more successful in particular because its function complies with new military strategies.

In addition to increasing concentration and cooperation, another striking pattern on the production side is the growing importance of specialised subcontractors. Most of the added value of today's weapons system is found in state-of-the-art electronic, precision-mechanic and other components. These specialised suppliers are at the leading edge of technological developments and are often able to combine military with civilian production. As a consequence, their profit margins grow and the dependency relationship with the main contractor is modified. In turn, the main system manufacturer is gradually transformed into an overall project manager and assembler. His profit margins decrease and he is less able to individually bear the financial burden of major weapon systems development and production.

In terms of technology, it is worth bearing in mind that military manufacturing increasingly involves technologies, production processes and components available in the civilian domain. In order to avoid unnecessary production costs most defence manufacturers are making use of what the civilian market has to offer.

INDUSTRY STRUCTURE

The profile of the European defence-related industry is still largely shaped along national lines. The three major EC member states, the United Kingdom, France and Germany have large supplier industries. The size of these markets is such that they host technologically advanced manufacturers in most sectors. British Aerospace, Thomson-CSF, GEC, DASA and Aérospatiale are the dominant players in Europe with considerable shares in export markets in the rest of the world.

Somewhat smaller are the industry groups of Italy and Spain, which have achieved significant market positions at home and sometimes even abroad. Alenia and Agusta in Italy and CASA in Spain have carved themselves niches in European markets for attack helicopters and transport aircraft. Nevertheless, these companies are of below-critical size to continue product development on their own. They need cooperation with other European partners to stay abreast in the defence field.

Indigenous industries in smaller EC member states such as Belgium and the Netherlands managed until recently to be competitive in very specialised product areas. FN in Belgium was a well known small arms producer supplying US forces, and HSA in the Netherlands was on the leading edge in naval anti-missile electronics. However, these and other comparable companies had to give up their independent position and join with big competitors. Other EC member states such as Greece and Portugal import most of their defence equipment or have local assemblers producing US equipment under licence.

Anticipating decreasing defence markets from 1989 onwards, the European defence-related manufacturers have regrouped by a series of mergers and acquisitions. In addition to the scale aspect mentioned in the previous section, another major reason for rising concentration was external growth. In the still nationally secluded European defence markets, the obvious way to expand (or not to decrease) is by buying the market share of competitors. These moves centred around industrial conglomerates in the four major EC member states. After two frantic years in 1989 and 1990, the mergers and acquisitions activity continued in 1991, though at a slower pace. There were continuing talks on cooperation projects but the persisting decline in defence sales left few manufacturers with enough cash to buy in new production capability. Instead, the year 1991 was marked by internal restructuring and workforce reductions.

In France, Thomson-CSF in missiles and defence electronics and GIAT Industries in land-based equipment were most active in acquiring smaller defence contractors in Belgium, the Netherlands and France itself. Thomson-CSF's attempt to buy a major share of Texas-based LTV's missile division failed in 1992 after strong political opposition to the proposed takeover in the USA. The strategy of these French defence contractors is to become market leaders in specialised defence niches. Other French defence contractors such as Dassault, Aérospatiale and Matra tried similar strategies but had less solid market positions in defence, in particular through their heavy reliance on export sales to the Middle East. Future prospects for these companies seem best in civilian markets, Dassault in its business jets, Aérospatiale in Airbus and Matra in its thriving space and transport activities.

In Germany, the Daimler-DASA grouping of MBB, Dornier, MTU and TST is at the centre of defence restructuring. The German government's preoccupation with the costly unifica-

tion and its determination to save significantly on defence spending has left the country's defence industry few illusions about future contracts. Mid-1992, the German government announced its intention to cancel participation in the production phase of the multi-billion European Fighter Aircraft project. By end of the year it appeared that the project will continue but will be seriously pruned. DASA's strategy is largely aiming at reducing, as quickly as possible, its defence exposure. Besides its major participation in the Airbus consortium it aims strongly at the emerging market for regional airliners. Plans on the joint development of a new regional aircraft were made with Alenia and Aérospatiale. Daimler is also close to acquire a controlling stake in Fokker, the Dutch regional airline manufacturer.

In the United Kingdom, the dominant players British Aerospace in aerospace and GEC in defence electronics restructured mainly internally. There was some movement pending in 1991 when GEC was considering to launch a takeover bid for British Aerospace. In-house, GEC cut more than 11 000 jobs in its electronics and shipbuilding production. In 1991, British Aerospace completely regrouped its missiles, electronics and aerospace divisions and reduced its workforce by some 12 000. In 1991, all British Aerospace defence divisions were merged into one operating unit. Other UK defence producers went through similar changes. VSEL and other shipyards shed several hundreds of jobs.

In Italy, Selenia and Aeritalia were regrouped in 1990 in the Alenia concern, all part of the IRI industry group. The new group ranked fifth in size among European defence contractors but it remained unclear whether the group would keep its present reliance on defence sales.

In other EC member states, such as Belgium and the Netherlands, smaller and specialised defence contractors were sold, significantly reduced their workforce, converted drastically to civilian production or closed down altogether. The latter applied in particular to smaller ammunition manufacturers, but also to land vehicle and heavy equipment producers.

REGIONAL DISTRIBUTION

The production of defence equipment is strongly concentrated in the four main EC member states, in particular in France and the United Kingdom. Among the EC top 40 defence producers, which generated some 40 billion ECU of total defence sales in 1989, 40% originated in the United Kingdom, 33% in France, 14% in Germany and 10% in Italy. Companies from these four member states added up to 97% of the EC total defence sales.

Within EC member states, several regions have built up a high degree of reliance on defence sales. Some combine such activities with advanced civilian aerospace and electronics production. Such is the case with most parts of the Southeast of England, the French concentration of aerospace industries around Toulouse and the province of Bavaria in Germany. These regions seem apt to modify their focus without too much trouble. In the coming years there will also be more job losses among the technologically advanced industries but these will continue to be the main contractors of future defence equipment.

Other regions are more linked to civilian sectors which are themselves in decline, such as shipbuilding. These regions include parts of the North of the United Kingdom, the French province of Brittany and the German area around Bremen. These will have greater difficulties in finding new outlets for their industrial activity.

OUTLOOK

The present outlook for the European defence-related industries up to the year 2000 is that trends which started in 1989-1990 are likely to continue. Defence spending by national governments seem to become more and more subordinate to other budgetary priorities. Major development and production programmes will probably be scaled down and export markets may continue to decrease. The ability of European defence industries to cope with such loss of business will depend on a successful reduction of their defence exposure. But not all alternative civilian markets will offer enough opportunities.

Major alternative civilian outlets include the aircraft and aeroengine markets which are still expected to grow at 5% annually. It also includes, to a lesser extend, the spacecraft and satellite markets.

The defence-related sectors which will continue to loose more markets and jobs are the traditional sectors which used to be geared towards the Cold War-scenario requirements. These include heavy land vehicles, ammunition, construction works and shipbuilding. The pace of decline will be faster in these sectors and could imply production reductions of 10% and more annually.

Some specific defence related markets have good prospects under the present circumstances. These include in particular all types of simulation equipment which allows superior training levels at low operating costs. There will also be a growing need for equipment used by the flexible (air)mobile intervention units which seem to become the cornerstone of a future European defence strategy. Such equipment would include various helicopters, transport planes, battlefield reconnaissance systems and anti-missile defence systems.

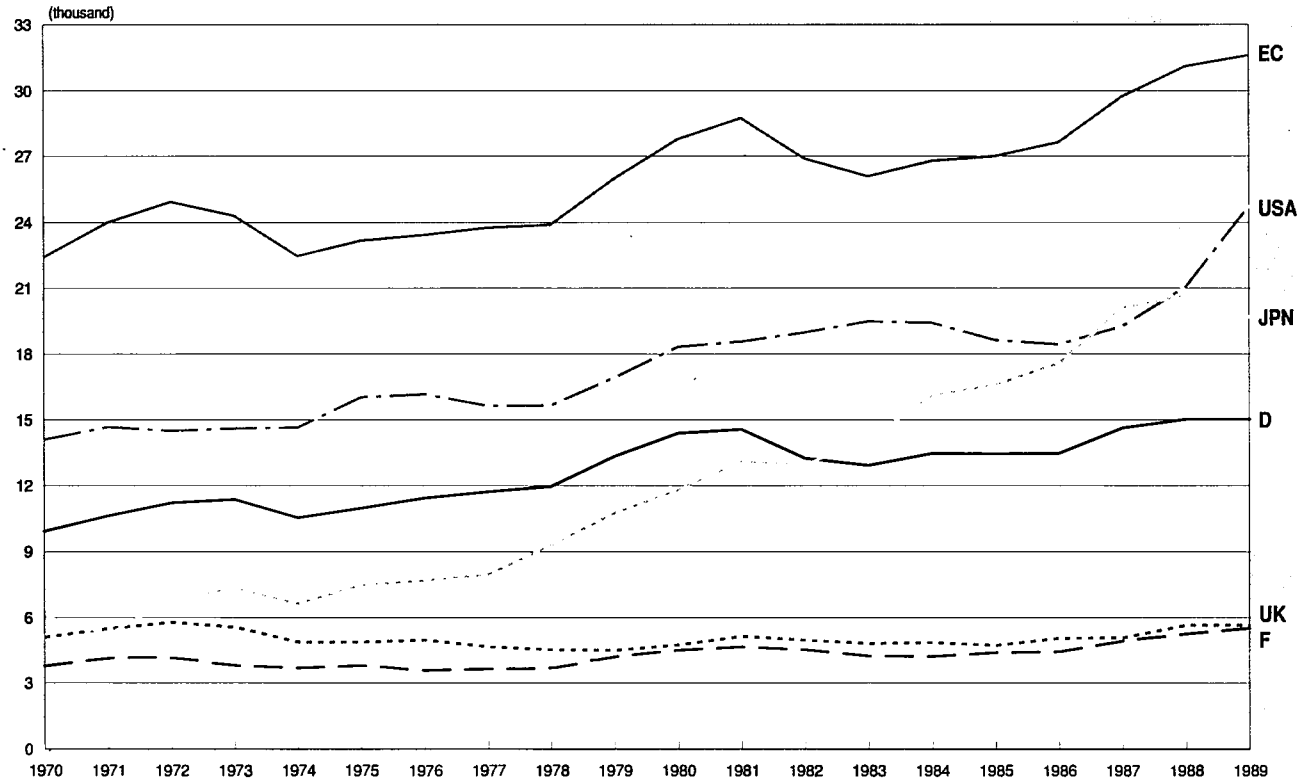
EC performance in patented technologies

INTRODUCTION

The study focuses on the performance of the European Community in the race for innovations. The competitive position in new technologies is measured by the number of inventions of a certain quality applied for patent. The number of inventions applied for patent is a widely used R&D output indicator. It is of economic relevance because the right to produce and to market is claimed with the patent application. In the next section the data base and the methods used are explained. The third section deals with the EC performance in all fields of technology, and with the EC specialisation by area of R&D compared with the American and Japanese industry. In this context, the share of the different EC countries in the production of new technologies will be discussed, and the most ingenious EC companies will be identified. The EC performance will then be analysed in more detail, by focusing on fields of technology believed to be especially promising for the future. Following the well known "hit list" of sunrise industries, the following fields of technology were selected: biotechnology, new materials, information and communication technologies, and environmental protection. Within these broader areas, the analyses will be differentiated by subfield of technology and by strongly rising and strongly declining technologies. The last section summarises the findings.

Figure 1: All fields of technology
Inventions (1) by country of origin



(1) With patent applications in at least two countries

MEASUREMENT APPROACH AND DATA BASE

The innovation process takes place in different phases: (i) perception of a problem and/or a scientific breakthrough, (ii) research and development of new solutions, (iii) securing marketing rights for the new products or processes, (iv) preparation of the production and market introduction, and (v) start of the production of new products or of existing products with the new production process. This implies that the position of the EC in the race for innovations can be measured at different stages and in different ways. If only market success is of interest, one measurement approach would be to identify new products or processes and to measure their production or degree of application by country. It is, however, both difficult and expensive to obtain reliable statistical information on the implementation of new technologies in this way. Official production and trade statistics normally give precise information only in a relatively late phase of the diffusion process of new products and processes, because adjustments in the statistical nomenclatures are only made from time to time. New products and processes are taken into account only if they have already achieved a significant economic importance. Often the impact of new solutions can, therefore, only be measured by their effect on the growth of larger product groups which are statistically covered.

A widely applied method of determining a country's position in the competition for new technologies relies on the use of indicators of R&D input (amount spent for R&D, number of active researchers). Existing R&D statistics are, however, not differentiated enough to allow a closer look into the positions in individual technologies. This is especially true for private R&D activities.

In this study, innovation activity will thus be measured by the number of inventions of a certain quality for which patents are applied. The indicator measures innovation activity by counting R&D results expected to pass the tests of patent offices for technical novelty and degree of innovativeness. Because patents secure an exclusive right for production and marketing, this indicator thus measures inventions that are expected to be economically relevant. A breakdown by country of origin or company of origin can then give an indication of the future position of competing industries. Data derived from patent documents are a widely used source because they allow statistical measurement of R&D output and its distribution by owner of the rights in an internationally comparable way.

For the analysis, ifo patent statistics were used. The information is drawn from patent documents published by the Vienna office of the European Patent Office. The ifo patent statistics provide, for each invention, the year of first application, the classification(s) of the invention by the patent offices according to the International Patent Classification (IPC), the countries for which a patent is claimed, the country of origin of the invention and the name of the company (or owner) applying for the patent. In the analysis below, inventions are only counted if the inventor or the owning company applies for a patent in at least two countries. This restriction is necessary to secure a similar "degree of innovativeness" and a similar expected economic importance of the invention. It also eliminates most of the distortions in international patent data which are due to differences in national patent systems. In particular, the inflationary effect of the Japanese patent system is suppressed: Japanese inventions are only taken into account if the applying companies expect the invention to pass US and/or European standards with respect to novelty and degree of technical change.

In Europe and Japan, inventions applied for patent are published 18 months after the date of application. The US patent office publishes them only after the patent is accepted. This implies that the most recent year for analysing invention activity is 1989, if the inventions are ordered according to the year of patent application.

EC POSITION IN ALL FIELDS OF TECHNOLOGY

Long-term trends and R&D output by country of origin

Measured by the number of inventions of supranational importance, Europe was the most important producer of new technologies in the past two decades. Taken together, the countries of the EC account for more innovations than either the USA or Japan (Figure 1). Although the invention activity of the EC has followed a rising trend in the long run, it is Japan which recorded the fastest growth of inventions.

In all countries/regions, invention activity is influenced by the business cycle. A rising business trend creates better opportunities for R&D and for bearing the costs of patent application. In a downswing, research activity has to be partly cut back due to financial constraints. Invention activity thus usually follows the business cycle, with a one year delay. The impact on EC invention activity of the upswings in Europe in the early seventies, in the second half of the seventies and in the second half of the eighties is visible in Figure 1. In the USA, Japan and the EFTA countries, the number of invention also shows a cyclical pattern.

Due to the stronger rise in invention activity in Japan and in the East Asian NICs, the EC has nevertheless lost shares in worldwide inventions during the last fifteen years (Table 1). The East Asian NICs started to secure their own competitive position in terms of the development of new technologies in the second half of the eighties. Whereas North America has fallen back in the race for new technologies, its loss in the share of worldwide inventions was not as pronounced as that of the EC during the eighties. Especially in the first half of the eighties, the "Reagan Boom" accounted for a better US-performance.

Within the EC, nearly half of the inventions originate in Germany. This is a far greater share than Germany's share of EC GDP (roughly one quarter) or than its share of industrial production in the EC. This confirms the pronounced specialisation of German industry on R&D or know how intensive industries. The United Kingdom and France rank next in the list of R&D output for which patent application is considered worthwhile, though at a considerable distance. Between these countries and Italy another big gap emerges.

Technological specialisation of EC industry

A breakdown of EC inventions by sector allows for an analysis of the technological specialisation of R&D activity in the European Community. The science-and-engineering-based industries shown in Table 2 cover more than 80% of all inventions worldwide. The table does not only show the EC position in the race for new or improved products within the EC internal market but also the EC position on the Japanese and US markets. In addition, the Japanese and the US performances on the EC market are shown. Two indicators are used. The specialisation indices compare the EC share of invention activity by sector with the EC share of inventions in all fields of technology. Values significantly above one hundred show strong points, values well below one hundred weak points for the EC in the race for innovation. The changes in the EC's share of innovation in the various world regions show if the EC's position has improved or not. Because the Japanese gains over time might be underestimated and losses exaggerated in the raw figures, the changes by sector have been standardised by relating them to the overall change in the corresponding shares in all inventions.

Measured by the share of EC-based inventions, Europe has a strong position in some areas of mechanical engineering such as agricultural machinery, machinery for food, processing and packaging, and woodworking machinery. Another strong point for the EC is the aerospace industry. The potential technological edge in subsectors of mechanical engineering is, however, unlikely result in pronounced job increases in the Community because some of the customers of these machinery producers belong to declining sectors. This is true for textiles and steel, and to a large extent for agri-food businesses.

In most industries with European technological edge, the technological position is strong on all markets of the Triad as indicated by the values of the specialisation index for the EC, the USA and Japan (Table 2). Only in agricultural machinery does the strong overall position reflect only a dominant position for the EC market. The lower propensity of the aerospace industry to apply for patents in Japan may reflect that the main competitors in this industry come from the USA. This is confirmed by the rate of concentration of US inventions in the aerospace for which the USA has applied for patent in the EC. In terms of the change over time, the European industries with a strong technological edge managed to improve their position in the most recent period. Measured by the adjusted change in the share of the inventions applied for patent for the different markets, this was often true for all three markets of the Triad.

In a second group of industries - extending from machine tools to electric power generation and transmission facilities - the EC still has a fairly strong technological position. These industries, however, have to cope with more intense competition from outside the Community. In motor vehicles, in gears and transmission equipment, in the steel industry and in technologies for the production and transmission of electricity, Japan is a powerful competitor in the race for innovations. Japanese, US and Scandinavian companies are in fact the main challengers to the EC companies in the field of engineering.

The next group consists of sectors with a below-average share of EC inventions. These industries have to fight either against a single dominant competitor like Japan (for instance in robotics and consumer electronics) or the USA (both in phar-

maceuticals and in medico-surgical equipment), or are confronted with an intense technological competition from both the USA and Japan (as in measuring and control instruments, office machines and EDP equipment). In fact, in electronic based industries, the EC has lost shares in all regions. Thus, in the telecommunication equipment sector, where deregulation and privatisation of telecom services have occurred worldwide, the technological competition from other regions has considerably increased.

Most ingenious companies

It is difficult to identify the most ingenious companies at the global level. The most important problem results from the different ways in which R&D and patenting are organised from company to company. In centralised organisations, all inventions realised in the different establishments and subsidiaries of the company worldwide are applied for patent at the company's headquarters. Other companies prefer to allow daughter companies to apply for patent. In order to secure comparability, it is therefore necessary to "consolidate" the invention activity of companies with a decentralised organisation of R&D or patent application. The consolidation was realised as far as relationships with other appliers for patents were recognisable, or where such information was known from other sources. A full comparability could, however, only be achieved at the level of combines.

The 15 most ingenious companies worldwide account for more than 500 inventions of supranational importance per year. As Figure 2 shows, six Japanese companies and six European companies rank among the current top 15, alongside only three American companies. The differences in the number of inventions that each company accounts for are, however, not very pronounced, such that the ranking can change over time. Companies active in the electronic and electrical engineering sectors occupy the first 9 ranks. Chemical companies follow, at a distance.

The list of the most ingenious European companies is also dominated by electronics/electrical engineering companies, and chemical companies. Bosch and Daimler Benz (including their subsidiaries in the electronic industry and aerospace) are the only outsiders representing the car industry. Among the top ten, many are of German origin. This is consistent with the high share of Germany (West) in all inventions of European origin (Table 1). A significant share of the inventions applied for patent by Philips, ABB and Alcatel also originates in Germany.

EC POSITION IN SELECTED FUTURE ORIENTED FIELDS OF TECHNOLOGY

Biotechnology

Definition of the R&D field

The sector of biotechnology, which includes genetic engineering, is a high-tech sector the development of which is just starting. At the same time it is a very controversial field, at least in some countries. The public presentation by mass media focused from the very beginning on special possibilities (sometimes impossibilities) of genetic engineering, allegedly aimed at creating monsters or chimeras, deadly micro-organisms or cloned humans. One of the consequences was and still is that in some countries almost no field tests have been performed (Germany, Denmark), whereas in other countries numerous tests have taken place (USA, Canada, Belgium, France, and the United Kingdom).

In fact, there is a small part of genetic engineering which is hazardous and requires high attention and precaution when used in biotechnic processes and applications. Most of biotechnic processes and genetic engineering are without any risks, however.

One can distinguish between classical biotechnology, comprising fermentation and preservation processes used in the production of beer, wine, cheese, bread, vinegar etc., and modern biotechnology, which is mainly characterised by the utilisation of genetic engineering. The sub-sectors are either products (micro-organism, cells, enzymes, proteins) or processes (fermentation, analyses, separation technics) or fields of application (pharmacy, agriculture, diagnosis, environmental protection, decontamination).

Compared to other high-tech fields like microelectronics, advanced materials, information and communication technology, the field of biotechnology has a limited radius of activities

and applications, though it can be considered to be a key technology in these applications as well.

Long-term trends and recent changes in the focus of worldwide R&D

There was a steady upward trend in innovations in this sector until the early eighties, with the USA and the EC (12) practically on the same level in terms of the number of patents applied for in at least two countries (Figure 3). In 1982, however, American inventors took off compared to the EC, reaching a more than fifty percent higher level in 1989. Japan distinctly trailed behind during the whole period of observation (1970-1989). Within the EC, Germany was in the lead (Figure 3), with the United Kingdom in second place, and France in third.

The development in the recent past followed the same pattern. Between 1986/87 and 1988/89, the USA expanded its invention activities significantly above average, increasing its leading position. The two fields of biotechnology and genetic engineering which were most dynamic, both in the USA and worldwide, were the "production" of micro-organisms and enzymes and micro-organism or enzyme based measuring and test methods.

Position of the EC as a location for R&D

The above developments brought about a change in countries' shares (Table 3). The general development in biotechnology was not to the advantage of the EC countries: the EC share of about 30% in 1988/89 was only slightly lower than in the previous period, but the gap between the USA and the EC increased from 10.8% to 16.2%. The importance of the EC among the five sub-sectors is remarkably balanced (between 26.6% and 31.3% share worldwide). In one sector, (analysis of substances by testing for chemical or physical properties), the EC was more dynamic than the USA.

The ranking of the EC members (Germany, the United Kingdom, and France) is also provided in Table 3. The German lead is significant in the "hardware" sectors, appliances and devices etc., analysis of substances etc., measuring and test methods, but not very distinct in the perhaps most important sector of micro-organisms and enzymes.

The breakdown in Table 3 does not allow a judgement to be made on the development by application fields. From other investigations we know that pharmaceuticals, medical diagnosis, cleaning and decontamination, and agriculture are sectors of remarkable size. Agriculture includes plant and pest control, genetically changed breeds of plants and animals, special fertilisers and special feed. The EC's importance is lower than average in the sectors of pharmaceuticals, medical diagnosis, mutations and genetic engineering, a little above average in the fields of plant control and feed. In the sectors cleaning and decontamination, the EC plays a leading role among the Triad thanks to Germany's efforts in these fields.

The other EC countries, the Netherlands, Italy, Belgium, etc. only have a limited importance in biotechnology research. Together, their share is a little over 5% of the world total and in some sectors it is significantly below. The other world countries (Switzerland, Sweden, Canada, Australia, etc.) together have a share of less than 10% (Table 4), below Germany's share. The minor importance of those other countries, however, does not mean that no important inventions have been made there.

Position of EC companies in the race for innovations

The analysis of patent applications also allows to rank enterprises (or institutes) according to the number of inventions. The patent applications in these rankings are registered with legal entities, which means for instance that Bayer AG, Germany, and Miles Inc., USA, are registered separately.

Among the fifty enterprises or institutes with the highest number of applications, 26 are from the USA (including Merck

& Co. Inc.), 15 from the EC, 7 from Japan, and 2 from Switzerland (Table 4).

The two lists in Table 4 show that firms which are producing pharmaceuticals or other chemicals are leading. The number ten in the EC ranking is an exception because the Gesellschaft für biotechnische Forschung is a research institute.

Advanced materials

Definition of the R&D field

R&D related to advanced materials covers a broad spectrum of high performance materials, some of them with sophisticated properties. These materials belong to a variety of sectors, like ceramics, metals, plastics, semiconductors, supraconductors, and composites. Examples are high-temperature resistant plastics, conducting plastics, high-temperature supraconducting ceramics, III-V semiconductors, special kinds of steel, carbon-fibre-reinforced carbon or plastic, aramide-fibre-reinforced plastic, metal-fibre- or ceramic-fibre-reinforced ceramic or aluminium, rapid solidified metals, aluminium, lithium, or titanium alloys.

The fields of application are varied. In a recent assessment, it was pointed out that almost all new technical fields require information and communication technologies or advanced materials or both (US Department of Commerce, Emerging Technologies, Washington 1992).

In the road vehicles, air- and space-craft sectors, light and at the same time physically very stable materials are required. Other properties might be necessary in addition, such as heat resistance, chemical resistance, electric conducting and non-conducting, magnetism. The same applies to material for all kinds of engines.

The electronic, optronic, and sensoric sectors need semiconductors, supra-conductors, special polymers with different properties, ceramics, special glass.

In the field of medical implants, ceramic materials, metal alloys, and polymeric material for diaphragms or constructive elements are used. In medical diagnosis and therapy, polymeric optical fibres and laser technique fibres have become state of the art; in imaging diagnosis techniques supra-conductors are necessary.

Long-term trends and recent changes in the focus of worldwide R&D

A striking feature in the long-term development of worldwide inventions was the rising trend for Japan from 1978 onward. In 1977, Japanese inventors were at the same level as Germany (West) measured by the number of patents applied for in at least two countries. In 1989 they had reached the level of the USA and the EC. The positive development of EC inventive activities derived mainly from German efforts, whereas France and the United Kingdom showed little movement.

Looking at recent changes, i.e. the years 1986 to 1989, the development was different. Comparing the two two-year periods 1986/87 and 1988/89, a worldwide increase by more than eleven percent was registered. Germany was far above average as was the EC, whereas the United Kingdom and Japan were distinctly below average (Table 5). These results are based on a selection of patent codes which is different from the one used for long-term series, for which no useful breakdown exists.

The search for very dynamic or heavily contracting sub-sectors (more detailed than the breakdown of Table 5) had the following result: in the sector of high-performance ceramics, patent applications for materials for prostheses or for coating them grew by 42% between 1986/87 and 1988/89. In the field of polymers, liquid crystal polymers (+19%) and optical elements (+ 24%) showed a remarkable increase. Among semiconductors, compounds of gallium, indium, or thallium (+ 51%) expanded strongly. The same applied to (composite) articles or shaped materials containing macromolecular substances (+ 19%) and the chemical after-treatment of carbon filaments (+ 18%). In the glass sector declines had to be registered, and the powder metallurgy sector showed increases and decreases as well. Finally in the crystalline field the production of polycrystalline material seems to be a promising sub-sector.

Position of the EC as a location for R&D

On average, the EC has a leading position world-wide as far as inventive activities in the field of advanced materials are concerned (Table 6). In detail, there are strong exemptions where Japan is in first place: carbon materials, semiconductors, metals, and powder metallurgy. Composites, fine ceramics, and glass are domains of the EC. The ranking shows that Japan does not play the leading role in fine ceramics, contrary to what as it is often stated in public.

Source: ifo Institut

In fact, Germany, number one among the EC countries in all sub-sectors, almost comes up to Japan in ceramics research. The United Kingdom has a relatively good position among the EC countries in the glass sector, whereas France is comparatively strong in glass and ceramics R&D.

Materials for prostheses had a particularly strong increase in the USA (+ 61%), less in the EC (+47%), and least in Japan (+30%). The liquid crystal polymer sector went up in EC countries by 41%, but went down in the USA by 4%. Compounds of gallium etc. increased especially in the USA (+130%) and Japan (+62%). Composites, an EC domain, showed a strong upswing in the EC (+38%), only minor increases in the USA (+10%), and Japan (+3%).

Position of EC companies in the race for innovations

Ifo Patent Statistics allow a ranking of enterprises (or institutes) showing their importance as inventors (more precisely, as applicants for patents) on the basis of the numbers of patents applied for.

Among the first fifty enterprises or institutes (according to the number of patent applications) 18 were from Japan, 17 from EC countries, 13 from the USA, and two from Switzerland.

The rankings demonstrate the dominance of producers from the chemical and electrical/electronic sectors in the R&D field of advanced materials. In addition to polymers, most of the raw material for fine ceramics, carbon material, or composites also come from chemical producers. The electric/electronic industry likewise is engaged in material R&D as part of their microelectronics, optronic, and sensoric development attempts.

Information and communication technologies

Definition of the R&D field

As indicated by the ranking of the most ingenious companies, one of the most important fields of current technical progress is the area of microelectronics and information and communication technologies (ICT). The area of ICT covers all technologies relevant for electronic information processing, information storage, retrieval and display as well as for communication via cable and cableless communication. All technologies necessary to change the media for information storage (i.e., electronic media to paper) are also summarised in this group of technologies. The core area of ICT products consists of semiconductors. Therefore, microelectronics technologies must also be considered. These technologies are located at the borderline between chemistry and engineering. In terms of the International Patent Classification, the information and communication technologies are summarised in Section G. Technologies relevant for semiconductors are classified in H01L and in C30B of the IPC.

Long-term trends and recent changes in the focus of worldwide R&D

Measured by the number of inventions with patent applications in at least two countries, the innovation activity has increased considerably both in ICT and in technologies for improving semiconductors during the last 20 years. Whereas inventions in ICT-oriented fields of technology accounted for 11% of all worldwide inventions in the early seventies, this ratio increased to 18% at the end of the eighties. The corresponding share for semiconductor technologies increased by 2 percentage points in the same period. Microelectronics and ICT are, therefore, one of major driving forces of worldwide innovations.

ICT oriented invention activity increased strongly in all parts of the Triad. Japan, however, developed these fields of technology far more intensively than Europe or the USA. The rise of Japanese industry to a leading-edge, high-tech industry was largely achieved by the application of microelectronics. In the race for new or improved products for electronic information processing, storage and communication, Japan has overtaken both the American and European industry, measured by the number of inventions of supranational importance. This was true both for the semiconductor-oriented technologies

Table 8: All fields of application of ICT
Distribution of R&D output by region, 1988/89

(%)

Japan	46.8
USA	29.8
EC	18.5
Other	4.9

Source: ifo Institut

and for ICT. A closer inspection shows that the ascent of Japan as a semiconductor innovator was achieved in the shadow of successes in the area of technologies for improving information and communication equipment. In the early seventies, consumer electronic equipment pulled chip-oriented invention activity. In the second half of the seventies, EDP equipment improvements took over as stimulus. As in all regions of the Triad, communication-oriented invention activities gained momentum, also in Japan, during the eighties.

In the area of office machinery and electronic data processing (EDP) equipment, R&D activity in the triad concentrated especially on the improvement of input/output operation in most recent years. Technologies for individual cableless telecommunication and complementary technologies like devices for suppression of noise and interference and error prevention were in the centre of interest among the technologies relevant for telecommunication equipment. The opening of (hardware) possibilities for individual uses of broadcast services was also a central research topic in the field of technology relevant for consumer electronics. Another important recent area is stereoscopic colour TV. In the other fields of application of microelectronics, the big themes of R&D centred around aircraft control and identification.

Position of the EC as a location for R&D

Measured by the distribution of inventions applied for patents in at least two countries, the technological position of the European Community on present and future markets for products based on ICT tends to be weak (Table 8). Less than one fifth of the inventions in the most recent years originate from EC countries, compared to one half or so of Japanese origin. The United States also has a higher share than the EC. In the technologies relevant for semiconductors, the EC position is even weaker than in the ICT equipment-oriented technologies. Taking into account that EC inventions are also counted if they are applied for patent only for two or more countries within Western Europe but not for third countries, the European position might even be over-estimated. Since the EC market has a similar dimension as the USA market, these inventions could be viewed as having a similar quality as the US inventions applied only domestically. Therefore, only inventions might be strictly comparable which are applied for patent in regions outside the home region (US inventions outside North America, Japanese inventions outside East Asia, EC inventions outside Western Europe).

By field of ICT applications, the EC position is weakest in office and data processing equipment (Table 9). In consumer electronics, the EC share is also still below average. The best EC position, relatively, is in telecommunications equipment. Measured by the number of worldwide inventions, however, the latter is at present technologically less important than the data processing technologies. As the next twenty years are viewed as the decades of integration of the islands of information processing and storage via communication networks, the importance of these communication technologies might increase considerably in the future. This would offer a chance for European ICT industry to improve its competitive position.

Within the EC, Germany is the biggest producer of improvements in semiconductor technologies and ICT. The specialisation index indicates, however, a far less strong position in these areas than in all fields of technology. French and British R&D activity is more oriented towards ICT technologies than German R&D. In fact, in France and the United Kingdom, a specialisation as a location for telecommunication-oriented R&D is emerging.

An inquiry into the reasons for the weak European technological position produced strong evidence for the inhibiting impact of the past fragmentation of European ICT markets. Fragmented markets imply higher risks of regaining the high R&D expenditures and, even more important, less competition between the suppliers. Competitive pressure is, however, a crucial factor for innovation activity of companies. Therefore,

an improvement of competitiveness of European industry on the ICT markets calls mainly for an abolition of inner-European barriers to market entry and for more competition. The completion of the internal EC market by 1993 is without doubt a step in the right direction.

Position of EC companies in the race for innovations

The ranking of companies shows that the weak European position as a location for R&D corresponds to a weak position of EC companies (Table 10). Unlike the case for all fields of technology, in the application of microelectronics there are far fewer EC companies present in the ranks of the most ingenious companies. As far as possible, the table compares again consolidated inventions by company.

The ranking of the most ingenious companies in semiconductor technologies differs from the ranking in the technologies relevant for ICT equipment. Most inventions in semiconductors originate from Toshiba and Mitsubishi Electric, followed by IBM and Siemens in the period 1988/89. The strong technological position of IBM in ICT equipment is owed to its still excellent position in electronic data processing equipment.

In this field of technology, Philips is the only EC firm which ranks among the top ten. Siemens (including Nixdorf) only ranks 13. In consumer electronics, although Japanese companies dominate technological improvements, the most ingenious single company is Philips. Thomson ranks fourth. In fact, European companies perform best in the area of telecommunication technologies. With Siemens, Alcatel and Philips, three European companies rank among the top five in this area of technology. Thomson, Bosch and Daimler Benz follow with ranks between 10 and 17.

The correspondence between the differences in technological position of the EC as a location for R&D by field of ICT and the differences in the ranking of EC companies by field of ICT indicate that the weak competitive position of European ICT industries reflects a lack of companies big enough to meet the challenges of the internationalised ICT markets. With the completion of the internal market, the ICT newcomers like Alcatel, Bosch, Daimler, Mannesmann should have a chance of growing into such a position. The inclusion of the EFTA countries could also bring companies like Nokia and Ericsson in a position to perform better in the race for new applications of microelectronics.

Technologies for environmental protection

Definition of the R&D field

Environmental problems arise both from the harmful production techniques of various industries and also from individual life-styles (e.g., heating, private transportation). In the past, measures adopted (laws, standards) for the protection of the environment primarily involved the employment of technologies to reduce emissions. Preventive environmental protection, i.e., the prevention of emissions by changing production techniques and the behaviour of all concerned has, however, now been recognised as a better way to address the problems.

In this report, the development of technologies relevant to environmental protection has been made on the basis of patent applications in three areas: waste management, waste water treatment and clean air measures. For the technological field "waste management", the IPC category "chemical means for combating harmful chemical agents; processes for making harmful chemical agents harmless" was included as well as inventions in the area of disposal of solid waste (dumping or destroying of waste or its transformation into something useful or harmless). Statistics in the area of "waste water treatment" include, for example, the biological or multistage treatment of waste water, sewage or sludge and recycling procedures such as the regeneration of pulp liquors in the production of cellulose or paper. "Clean air measures" include, among others, technologies to reduce air pollution. This includes inventions for flue gas desulphurisation (SO_2) as well as circulating fluidised bed combustion and the field of inventions for reducing NO_x emissions.

Because of the methodological approach, however, overlapping in fields of technology is not always excluded, such as in the case of waste removal by thermal procedures, since this also affects the area of "air". In the overall profile of environmental techniques, however, double counting has been avoided. Areas such as energy conservation and noise abatement, which could not be demarcated clearly enough on the basis of the IPC, were not taken into account.

Long-term trends and recent changes in the focus of worldwide R&D

The development in the number of patent applications in at least two countries in the area of environmental technology as a whole shows strong innovation efforts in the USA, West Germany and Japan at the beginning of the 1970s. The awareness of the necessity of implementing measures to protect the environment led, for example, already in 1967 in Japan to the "Basic Law for Environmental Pollution Control" (with a revision in 1970) and set clear framework conditions for technological solutions to the problem. Japan made most of its patent applications in 1975, a level which has subsequently not been reached. For the USA, a stagnation can be seen from 1971 to 1988, with a strong increase occurring in 1989.

West Germany made a major contribution to the rising trend for R&D efforts in the EC. The hotly debated environmental discussion with new laws for clean air and other measures

gave a boost to innovations. The number of market-relevant patent applications exceeded those of the USA in 1985. Thus, West Germany accounted for 30% of world patent applications for environmental technology and 62% of those in the EC (Tables 11 and 12).

A comparison of the two two-year periods 1986/87 with 1988/89 shows a slightly below-average growth rate for West Germany. Of note are increased technological activity in the United Kingdom (+22.6%) and France (+18.4%). Differentiated according to environmental areas, research in France was stepped up primarily in clean air measures (+58.2%), and in the United Kingdom in waste water treatment. The latter area has also been assigned greater importance in the USA, whereas inventions in Japan indicate intensified research in waste management.

But it must not be overlooked that - in terms of the total R&D output in the world for all areas of technology with patent applications - the number of patent applications for environmental technologies must be regarded as low and in addition has declined slightly. In 1980 the world share of patents for environmental technologies in total registered patents was still at 3.5% and since 1986 has stagnated at ca. 3.2%. The downward trend is even stronger in the USA and Japan, where the share of environmental patents in total patents in 1988/89 was 2.7% and 1.7% respectively, compared to 3.4% and 2.2% in 1980 (Table 13). These countries have evidently concentrated their marketing claims in other areas of technology. France and the United Kingdom also did not reach the shares they recorded in 1980. Only Germany showed an above-average specialisation, with a share that reached nearly 5.4% in the late eighties.

Position of the EC as a location for R&D

Table 12 shows for Germany a dominating share in innovation related to waste management with more than 38% of the world patents in this area in the world and nearly 70% of the EC patents. However, the development for Germany shows that research is now focusing on the problem of waste water treatment (+16.5%). It is not surprising that at the same time the number of patent applications in the area of clean air measures has declined since policies on preventing air pollution in Germany have brought out a major improvement by the reduction of emissions of dust (filters) and NO_x (catalyzers). In the process, many technical solutions have been patented and implemented.

In comparing technological competitiveness it is helpful to provide a normalised listing of patent applications, i.e. to equate the average activity in a field of technology for a country or region with 100. This comparison shows above-average values for the EC in environmental technologies which - as mentioned above - are attributed to the German contribution.

Although the problem of waste management is in urgent need of a solution, only 0.7% of all patent applications worldwide are in this area. Although the figures for the EC are above

average, countries such as France and the United Kingdom are clearly below. For the USA, applications show stagnation at a below-average level of activity. For Japan, despite an increase in patent applications of 23.4% for period II/I, the activity index at only 34 points is still extremely below average.

Position of EC companies in the race for innovations

The ranking in Table 14 indicates those firms which have made most patent applications worldwide for inventions in the area of environmental technology in 1988/89. Most of these firms, due to their size, are also strongly represented in sub-areas of technology.

In this list of the first ten, none are Japanese firms. The following Japanese companies ranked 18, 20 and 22 worldwide: Mitsubishi Heavy Ind. Ltd, Nippon Catalytic Chem. Ind. and Ebara Corp.

The ranking of sub-areas for 1988/89 at a minimum of 5 inventions (per firm) with patent applications in at least two countries is indicated in Table 15.

SUMMARY

Today's competitiveness in R&D output is tomorrow's competitiveness in turnover. One widely used method for measuring R&D output is the analysis of inventions applied for patent which allows a very differentiated breakdown of worldwide R&D activity on a comparable basis. The use of information from patent applications gives a more up-to-date picture than from granted patents.

This approach shows that the technological position of the EC is very strong in many R&D fields. In all fields of technology, the EC has a clear lead when inventions with supranational importance are considered. But there are sectors in which the USA (biotechnology) or Japan (microelectronics) are leading, or where a head-on competition can be registered (advanced materials). Generally, it can be said that the EC position is less strong in science-based fields, and stronger in engineering-based activities.

Within the EC, Germany, France, and the United Kingdom are the leading inventors. The analyses of some future-oriented fields of technology showed that in the R&D field of biotechnology, despite the leading position of the USA, nearly 30% of inventions come from EC countries, with Germany and the United Kingdom in first and second place. The sector of advanced materials is equally shared by the EC and Japan (over 30% each), with the USA somewhat behind. In the fields of microelectronics applications between 40% and 50% of inventions are from Japan, except in the telecommunication sector where Japan also is leading but closely followed by the EC and the USA. The relatively strong technological position of telecommunications offers Europe a chance to catch up in ICT applications because the importance of telecommunications will increase in the emerging era of networking the islands of information processing facilities and of individual communication. The fourth future-oriented field of technology, environmental protection technologies, is a domain of the EC, mainly of Germany.

A worldwide breakdown of invention activities by companies sees Toshiba and Siemens on top of the list, followed by Japanese, American, Dutch, and German companies. In both the world ranking and the EC ranking the dominance of the chemical and the electric/electronic industry is obvious.

In summary, although the EC position in the international race for inventions is satisfactory, strong efforts are nevertheless necessary to maintain or improve this position.

Cooperation between small enterprises within the EC

THE EMERGENCE OF COOPERATION

There are many considerations which together lend overwhelming support to the concept of cooperation among small enterprises. Cooperation enables small enterprises to overcome disadvantages arising from the small scale of operations (high fixed costs), a limited scope of production (exclusion from many lucrative markets), a low market power as buyers and as sellers (exploitation by strong suppliers and strong clients) and structural financial weakness (inability to adjust and to modernise). In fact, for small enterprises, cooperation is the means to match in several respects the advantages of large enterprises without a loss in independence.

Therefore, it is somewhat surprising that cooperation among small enterprises is the exception rather than the rule throughout the various industry and service branches. Only in the retail trade and, to some extent, in urban taxi services, is cooperation a frequent phenomenon.

Two fundamental reasons can explain why cooperation among small enterprises is not as universal as its general advantages might suggest:

- 1) While there are opportunities for beneficial cooperation across a wide range of economic activities, there is relatively little real need for it, i.e. the survival of the SME in the market does not normally depend on it.
- 2) Cooperation neither emerges automatically out of an opportunity nor is it gratuitous. To establish it constitutes an investment that costs. And it takes a tremendous effort to overcome the many "natural" obstacles which are rooted among others in the individualistic resistance against collective discipline. Often there is nobody who will take it upon himself to organise cooperation and is capable of doing so.

These two general observations make it plausible that cooperation between small businesses is the exception rather than the rule. But, in order to explain why in some countries small enterprises cooperate much more frequently than in others, we have to consider the following factors:

- opportunities and needs
- organisation
- attitudes
- legislation and policy.

Opportunities and needs

The importance of cooperation for small enterprises is closely linked to the wider issue of these enterprises' place in the modern industrial and service economy. Historically, cooperation between small enterprises was often linked to the defence of a whole way of life and a social order which had their roots in a pre-industrial mode of production.

Today, the battle against the impoverishing effects of industrialisation has been fought successfully on fronts other than SME cooperation. It has resulted in the economic emancipation of the working class. The status of a salaried employee conveys several privileges the independent entrepreneur does not have. Thus, from a normative point of view, the case for the defence of small enterprises at any price is much less convincing. And, in fact, in many areas SMEs have had to give way to larger enterprises, capable of organising production more efficiently and of innovating more systematically.

But there are many economic activities for which smaller enterprises are better suited than large ones. And, while it is true that large enterprises have not stopped invading former niches of small enterprises, it is also true that new niches arise continuously. In fact, large enterprises themselves constitute one of the most important markets for small suppliers of goods and services. The constitution of new large firms typically gives rise to new business opportunities for many small firms as well. Even within the same sector there are patterns of symbiosis between large and small firms.

For those SMEs whose place in the market is based on "natural" advantages linked to small size, cooperation is not vital, although it might be advantageous. For the others, the attempt to match via cooperation the advantages of their big competitors can easily resemble swimming against the current - a brave effort but ultimately in vain. At any given point in time, to start cooperation is really appealing for only three specific segments of SMEs:

- (a) Those which have just started to feel or which foresee in the not-too-distant future the pressure of large-scale competition. But, even for them, cooperation is normally just one strategic option. Another frequently more readily accessible one is the shift into different market segments. Still another and in many ways simpler one is to join the large-scale competitors through franchising arrangements.
- (b) Those who are confronted with new needs for which there is no adequate supply in the market yet, e.g. specialised data processing or specialised waste disposal facilities. Both type-a and type-b cooperation are facilitated by the homogeneity of the partners' businesses with regard to size, product and kind of clientele.
- (c) Those who are confronted with attractive market chances, which are foreclosed, however, to the individual SME and require extended supply facilities. This kind of cooperation presupposes complementarity among the partners (with regard to product profile and/or clientele) rather

than homogeneity. Mutual competition is to be avoided at any rate.

The extent to which these three conducive conditions are present differs from sector to sector. Obviously, it is time-bound, i.e. it changes in accordance with technological and regulatory developments favouring larger or smaller businesses. Particularly factors (a) and (b) point to specific moments in the development of an economic sector rather than to permanent characteristics. They refer to transitory opportunities, which must be seized in time. For several problems which SMEs face the cooperative solution is just one alternative. Once another solution is established the case for cooperation is rather weak. Such an alternative solution can be developed, for example, by the market in the form of attractive commercial supply. To set collective self-supply against it has always proved to be very difficult, even if this would offer additional advantages in the longer run.

Whether opportunities and needs for cooperation present themselves more or less frequently in a country obviously depends on its economic structure. In our sample of seven EC countries this factor singles out Italy as the country where SME cooperation should be expected to appear most frequently, because the market share of small businesses is generally highest there (as a consequence of a complex political blockade to the development of the corporate sector). At the other end of the scale we have Ireland and Britain. In Ireland, the scope for SME cooperation is rather limited, because the late industrialising open Irish economy has allowed only those small businesses which fit into typical SME market segments and thus are able to survive well on their own to develop. The very base for SME cooperation outside the primary sector always has been particularly narrow there. In Britain, the concentration of production has progressed further than elsewhere and has narrowed the scope for SME cooperation in the process, even though this trend has reversed somewhat over the last decade.

Organisation

In order to form a cooperative or another legal form of institutionalised cooperation (a "quasi-cooperative") somebody has to take the initiative and promote the idea among potential partners. Once a collective decision to cooperate has been taken, the common enterprise has to be set up, and the behaviour of the partners has to be coordinated. All that requires time and dedication. In addition, it requires either expertise or additional time and money to acquire.

The initiative can emerge out of the dynamics of an already existing and interacting group. But even if cooperation is desirable, it is normally a big step from general interest in an idea to its active implementation. Normally it requires a leader who pushes ahead on his/her own or who offers him/herself to the group as the agent to set up the cooperative venture. Again, persons who are (a) motivated enough to take on this leadership function and (b) endowed with sufficient competence, authority, time and maybe even money, are not readily available whenever there is an economic opportunity or need for cooperation.

Moreover, the leadership function does not only consist of agency services. In addition, it has to induce the led ones to conform with collective decisions and to abstain from disruptive behaviour which imperils the collective cause -particularly in the face of tempting offers by competing suppliers who try to keep their clientele from cooperating.

All these considerations point to the fact that a non-cooperative solution to a problem of economic coordination, be it a market solution based on demand and supply, be it an in-house solution based on power and authority, is in many respects easier than a cooperative one. It is more likely to succeed.

Altogether, the incidents where cooperative ventures during the past decades have been promoted and set up by individual leaders or have emerged out of a collective initiative are scattered. Examples for the prominent role of individual leadership are:

- DATEV, the German fiscal advisors' giant data processing cooperative, whose launching at a particularly conducive point in the development of the profession's market must be attributed largely to the initiative of one representative of a regional professional chamber;
- the French transport cooperative "la Flêche cavaillonaise", which is the product of one particular "founding father" and partner.

Most instances where individual initiative without organisational mandate was of decisive importance are found when the promoter perceives special opportunities for his own business. In this respect one can consider the promotion of a cooperative venture as an extension of private entrepreneurship. In the case of DATEV, however, there was also a clear preference for a collective solution to the problem at issue which implied a decision against private market solutions. In fact, it was the quick determined seizing of the opportunity on behalf of a cooperative solution which prevented private suppliers from occupying the emerging market. In all other countries the same field has been left to commercial suppliers. In France, for example, a large data-processing centre for tax advisors is being run by a group of big banks, a software house and others.

The emergence of a cooperative venture out of a collective initiative cannot always be neatly distinguished from the preceding pattern, since in the formation of a collective decision key individuals often play an important role. But there are instances where group dynamics clearly dominate the decision-making process. Among others, this was the case with:

- the cooperative of the German "alternative" insurance traders, whose group cohesion was reinforced by their explicit deviation from ordinary professional standards and their consequent separation from established institutions providing auxiliary services;
- the cooperative solution of tanners in Valdarno Inferiore (Italy) to the newly arising problem of having to recondition the water contaminated during the first phase of hide processing - a solution facilitated by continuous physical and social proximity and, of course, by the country's "cooperative culture";
- the French cooperation of leather product manufacturers IFCO, which arose out of a network of already existing informal contacts.

There are certainly more examples. The essential message here refers to their isolated and specific character. The alternative to the unsystematic emergence of cooperation out of highly specific and, by definition, exceptional circumstances is the systematic promotion by an institution explicitly dedicated to this task and funded for it. Such institutional promotion can be done by professional and business associations, by the cooperative movement, or by government bodies. However, our investigation has rendered only few examples where such organised promotion has had relatively good success. The following cases can be listed here.

Italy: The big Italian cooperative federations - on national, regional and provincial level - promote the formation of new cooperative ventures in varying legal forms: they look for eligible partners, they help with all the legal and administrative work connected with the founding process, and they offer advice and direct help in managerial and financial issues. In doing this the cooperative federations can draw upon substantial resources as regards manpower and finance, on favourable legislation and general political support, and on

long-standing "cooperative culture", which makes for a favourable disposition on the side of the SME. This way, they have created many hundreds of new cooperative ventures in the past years, a success all the more notable because of the already large stock of existing cooperatives and cooperative-like companies.

Catalonia: The Federation of Service Cooperatives of Catalonia has contributed decisively to the foundation of more than 100 new SME cooperatives in all kinds of economic sectors since 1987. It has taken the initiative to promote cooperation in the form of countless seminars, conferences, written exposes, and personal talks with representatives of small business, crafts, and independent professions. It has also assisted the actual founding processes with its legal and administrative expertise and with its manifold good connections. It seems that a good deal of this organisational achievement must be attributed to the personal involvement of the federation's long-time president, which underlines again the importance of the "leadership" factor even within established organisational settings. Like in Italy, the federation was helped in its promotional activity by a strong cooperative tradition in Catalonia and a favourable official attitude.

France: A similar case on a much smaller scale is the creation of 27 transport cooperatives by the French sectoral cooperative federation UNICOOPTRANS. Here, too, the personal role of the manager of UNICOOPTRANS has been of overwhelming importance.

The French Confederation of Crafts Cooperatives and Groupings (CGCGA) and its sectoral branch FNACB (construction) helped to create more than 350 new cooperatives of independent crafts businesses after 1983. Of decisive importance for this record was (a) the explicit statutory commitment of CGCGA to the creation of new cooperatives; (b) the cooperative law of 1983, which offered an especially well suited legal form to crafts cooperations and endowed it, on top, with fiscal privileges; (c) government funding for CGCGA's promotion campaigns. But again, the case of CGCGA also points to the difficulties of overcoming SMEs' resistance to cooperation: CGCGA members' turnover represents only 1% of the turnover of French crafts businesses.

Spain: The Spanish government Institute of Small and Medium-sized Industrial Enterprise (IMPI) has in the course of the past 10 years or so promoted more than 100 cooperative ventures among small businesses of many different sectors. Apart from general brokerage services, a decisive element for this success has been IMPI's participation with temporary risk capital in the newly established "companies of collective action", something which proved attractive to many businesses. However, the case of IMPI also highlights two important difficulties encountered by institutional promoters of cooperation: budget limits and distrust by SME of official agents.

United Kingdom: The National Cooperative Development Agency in the UK helped in the few years of its existence to create several dozen cooperative ventures among SMEs. This case highlights most clearly the importance of government funding. Cooperative expansion stopped in the UK as soon as NCDA funding was discontinued. Apart from the commitment of the NCDA promoters and the agency services they were able to offer to the new cooperative ventures, their success can be explained to some extent by the low level of cooperation they started from.

Other attempts at organised promotion of SME cooperation were considerably less successful. The difference between success and failure seems to be attributable mostly to differences in the human and financial resources available for promotion. None of the less successful agencies were predominantly or even exclusively devoted to the creation of new cooperative ventures. This was a relatively marginal task compared to several others. Another condition of promotional success is the access the promoting institution can establish with its target group, the small businessmen. In this regard it is of extremely high value that the cooperative cause has been adopted by the professional organisations. That this was not the case marked a serious limitation of most of the above listed campaigns, if compared, for instance, with the pervasive success of cooperativism in Italy, among several German crafts, and in retail trade.

Still, our findings lend overwhelming support to the notion that explicitly pursued and well-funded promotion is of supreme importance for the actual emergence of SME cooperation. All cases where we have a creation of new SME cooperatives or similar entities in large numbers can be attributed to this factor.

Attitudes

Systematic promotion seems to be the key to SME cooperation on a large scale. But the disposition of small businesses to respond positively to such promotion still differs from country to country. Besides, the question must be raised: what makes for systematic promotion? This directs the attention to the factor "attitudes".

To some extent this factor is sector-specific. A condition which seems to increase the disposition to cooperate - in spite of the notorious individualism of small independent business everywhere and throughout all branches - is a relatively high level of professional education and a certain professional tradition or "culture", as we find it, e.g. with crafts but not with newly independent lorry drivers. But there are also significant country-specific differences. We might refer to them as the "ideological environment". This factor has at least three dimensions:

- the prevalence of individualism versus an inclination to cooperate within the business world, and the society in general;
- historical experience and familiarity of the business world with institutionalised cooperation;
- the prevalence of economic pragmatism versus the prevalence of "Social Economy" ideals within the cooperative movement;
- government attitude towards SME cooperation.

A positive ideological environment can reflect the historical strength of cooperativism in a country or a region (prime example: Italy). It can also originate in a relatively recent social movement to which certain groups adhere. On the other hand, the association of cooperation or certain forms of it with a social movement and its ideology can become a negative factor, turning off those who are more oriented towards economic advantage than meta-economic values. With a note of caution, we can characterise the ideological environment in the various countries of our investigation as follows:

Belgium: Strong association of cooperativism with the ideals of a non-capitalist "Social Economy", which proves a handicap for the formation of SME cooperatives; slightly positive government attitude.

UK: The idea of SME cooperation is largely absent from the economic "culture"; moreover, strong association of cooperativism with the ideals of a non-capitalist alternative economic order, which reinforces business distrust, while the cooperative movement itself remains sceptical about SME cooperation; government attitude during the 1980s mostly hostile.

France: On the one hand, strong association of cooperativism with the ideals of a non-capitalist "Social Economy"; on the other hand, pragmatic outlook of those organisations which represent service cooperatives, tendencies which compensate each other to some extent; positive government attitude throughout most of the 80s.

Germany: Strong historical roots of cooperativism (also in East Germany), associated almost exclusively with the form of SME cooperatives but also with agriculture and crafts, which makes for a somewhat pre-industrial tint; main-stream cooperative ideology emphasising economic pragmatism with an explicit anti-Social-Economy accent; general acceptance of the idea of SME cooperation in forms other than cooperatives; neutral government attitude.

Ireland: Idea of SME cooperation outside the primary sector largely absent from the economic "culture"; neither positive nor negative ideological connotations; neutral till slightly positive government attitude.

Italy: Strong historical roots of cooperativism; pragmatic outlook of the cooperative movement; SME cooperation widely accepted part of the economic "culture"; strongly positive government attitude.

Spain: Strong association of the main-stream cooperative movement with the ideals of a non-capitalist "Social Economy" and with the form of worker cooperatives; therefore a certain neglect of SME cooperatives; at the same time pragmatic outlook oriented at economic success; wide-spread distrust among SMEs of any cooperation and in particular of government initiatives; strongly positive government attitude.

Relating the factor "attitudes" or "ideology" to the other explanatory factors, its highest importance seems to be its influence on systematic promotion. This can be seen clearest where a positive government attitude leads to the establishment and funding of a promotional agency. This has been the case in Spain and - paradoxically - for some time in anti-cooperative Britain. In Italy, but to some extent also in Spain and France, we have the case that the mobilisation of resources for the promotion of pragmatically oriented SME cooperation is ultimately rooted in the ideological vigour (and the economic and political strength) of the wider cooperative movement. In the context of such considerations it strikes the attention that the equally strong cooperative movement of Germany exhibits much less promotional zeal.

Legislation and policy

Favourable legislation and government policies have contributed to the emergence of new SME cooperatives in various ways. The most direct and important, of course, has been the funding of promotional efforts, which we found in Spain, France and - temporarily - in Britain.

Another aspect which apparently has mattered in the past is adequate legal provisions for cooperative enterprises. In France, there was a surge of such new enterprises in the wake of a law in 1983 which established the cooperative of craft shops as an own enterprise type with specific rights and obligations oriented at the needs and the limitations of such cooperations. However, it is not clear how much of that surge can be attributed to the newly established enterprise type, because the same political initiative which brought about the favourable legislation also provided for the subsidies to CGCGA which helped funding its large-scale promotion activities.

State regulations - endowed with legal sanctions or not - also affect the opportunities for advantageous cooperation. Tax privileges and other subsidies can add to the economic advantage to be gained through uniting certain business functions. Even though we find such privileges in France and Spain they are not of such a magnitude that they would by themselves define an economic advantage of cooperation as compared with non-cooperation. Most of all, they discriminate in favour of the legal form of a cooperative, compensating somewhat its inherent disadvantages. In part they also have the function of an investment subsidy, which facilitates the seizure of an economic opportunity.

Trade policy is another example which illustrates the effect of state regulations on SME cooperation. When former trade barriers are removed, the need for cooperation between hitherto protected SMEs can increase. It also opens up new market opportunities which are accessible for SMEs only if they cooperate. European integration and the fear of increasing competition derived from it seems to have induced some new cooperation in Spain, where this topic has been used as a stimulus by promoting agents.

Finally, regulation also restricts the scope for SME cooperation, as is the case in Italy and Belgium, where practitioners of certain liberal professions are prevented from it by law, or in Britain, where the government's competition policy keeps bus companies from cooperating for common business.

THE DEVELOPMENT OF EXISTING COOPERATIVE VENTURES

Once they have been set up, cooperatives and "quasi-cooperatives" of small businesses are susceptible to two types of forces, internal and external. Internally they are exposed to centrifugal as well as to centralising tendencies. The former are embodied in the member SMEs, whose primary preoccupation is their own economic success and who exhibit a latent tendency towards short-term considerations. Centralising tendencies are embodied in the managers of the cooperative enterprise, who are entrusted with the well-being of the group as a whole and insofar bound towards a longer-term perspective, but who are also interested in the success of the common enterprise as such, regardless of the members' preferences. Externally, changing market conditions pose challenges and present opportunities. Both the success of the cooperative enterprise and that of the member SMEs depend on the appropriate response. The ultimate sanction for response is disappearance from the market. But success has its price too. It might be profound transformation.

Concentrating on performance (rather than structure) as our primary criterion of cooperative development we should distinguish from the outset three main purposes of cooperation:

A) survival in the competition with larger companies (need, focusing on costs);

B) rationalisation for better economic results (option, focusing on costs);

C) fitness for extended business (option, focusing on the scope of production).

Cooperation for the purpose of survival

Such cooperation involves small businesses which do not operate in a niche market for which small size is appropriate, but in a market segment in which smallness has become a "natural" disadvantage. Through cooperation they try to defy the pressure of the market for structural change. The one trade where cooperation is most clearly dominated by the survival motive is retail trade. To a minor extent it applies to craft bakers, who are confronted with the competition of industrial bakers.

Here the main challenge for existing cooperatives and "quasi-cooperatives" has been and continues to be the increase in competitive pressure on the member SMEs. Initial ways of cooperation have again and again proved insufficient to match the ever-increasing advantages of large-scale competitors. This fundamental challenge is the background to various development patterns.

First, as far as success in achieving the basic purpose is concerned, cooperation has not been able to prevent the advance of concentration in retail trade. Everywhere a very large number of small retail shops have had to close down. However, cooperation can slow the process and build up a new defence line. For the overwhelming majority of their members, the retail cooperatives are today a necessary condition of survival as independent firms. However, it is mostly the larger ones

among SMEs which have the greatest chance of survival with the help of cooperation. Most of the still really small shops are unanimously said to be doomed, unless they are placed in a protected market niche (defined e.g. by a special location or a range of merchandise which is not subject to price competition).

Second, the necessity to match the increasing economies of scale reached by the large supermarket chains, department stores, etc., has profoundly affected the relationship between the cooperative enterprise and its members. For the latter this has meant an increasing loss of independence. The ongoing trend in cooperation ranges from the common purchase of merchandise to the common and more tightly coordinated and supervised marketing concepts and product range strategies, which in turn are the precondition for the achievement of ever higher scales in purchasing.

Third, also dictated by the need to reach ever-increasing economies of scale has been a centralisation process within the cooperative structure, that is, a shift of decision-making away from the individual cooperative to the cooperative central at national level. It has gone hand in hand with a move towards fewer and ever larger cooperative enterprises. The single national cooperative has become the dominant pattern in retail.

Four, the indispensable quest for larger scale has triggered initiatives by the cooperative organisations to actively expand business beyond the members' current capacities or needs. One way to do this has been the active search for new members. Another has been the creation of branch shops directly administered by the cooperative enterprise and thus separate from the members' business. With the German food retail cooperative REWE, for example, such directly administered branches have by now come to account for more than 40% of the group's overall turnover. Often the members of the cooperatives do not endorse these initiatives, which they consider as unrelated to their own interests or even as competing with them.

Five, the increasing importance of common marketing strategies, based on common product ranges, common brand names and a common image has reinforced selectivity with regard to the admittance of members to the cooperative group. Welcome are only relatively strong and well-managed enterprises for the success of the strategy depends on reliable and competent implementation throughout the group.

Finally, in order to reconcile the need for a certain homogeneity with the need for large scale and with the principle of solidarity, retail cooperatives have introduced separate strategies, sometimes associated with different names, for different types of member SMEs.

Altogether, cooperative ventures formed for the purpose of survival closely follow the dictates of the market. These dictates favour the inherent centralisation of the cooperatives' management. This doesn't leave much leeway for the quite visible centrifugal tendencies of independence-minded members and little room for ideologically inspired variations. Management incompetence carries the immediate threat of bankruptcy. There is no indication that support from outside, be it from the state or from the broader cooperative movement, has played a significant role.

Optional cooperation for the sake of better economic results

This category applies to small businesses which operate in more or less protected market segments, not contested by large competitors. Such businesses include craftsmen oriented towards local markets, practitioners of liberal professions, or taxi drivers. If they cooperate, they do it in order to rationalise their purchase of inputs and to achieve bargaining power vis-a-vis their suppliers. Depending on the market situation, the costs saved this way boost their profits or allow them to offer cheaper goods or services to their clients. But enterprises of this category also cooperate in order to supply each other with services and sometimes even goods which are not readily available in the market at the same quality and/or price. Mostly this refers to branch-specific consulting services on technical and economic issues. Such services are mostly offered by the central organisations of cooperatives whose principal function is common purchase. However, in some cases the collective self-supply of services is the central purpose of the cooperative enterprise. This is the case, for instance, with taxi drivers' cooperatives which run booking centres for their members or with the German fiscal accountants' data processing cooperative.

Since cooperation is not vital in this category there is no need to adjust it to the dictates of large-firm competition. The challenge cooperative enterprises face here is another one: it is they who have to compete with the commercial suppliers of their members in order to stay in business. It is a typical pattern in the relationship between the cooperative enterprise and its member SME that cooperation is put in jeopardy by the availability of attractive supply alternatives for the members paired with low commitment on the members' side to the cooperative cause. Sometimes this turns into a vicious circle: low commitment of members prevents the cooperative from achieving sufficient scales of operation and hence from being attractive in its offers.

In many cases where the market has come to question the necessity of cooperation the managers of the cooperative enterprise took on the challenge. They accepted that they cannot count on the unconditional loyalty of their member SMEs, but that they have to strive continuously for a competitive edge over alternative suppliers. The means to achieve it have been basically the same as with any other enterprise: continuous modernisation, rationalisation, centralisation where it mattered, emphasis on marketing, etc. Doing business with non-members in order to achieve more advantageous scales of operation has been part of it. This approach has secured for many cooperative enterprises the position of a preferred supplier with their member SMEs. However, it has also implied that the relationship between the two sides came to resemble more that of a market partnership: each partner has his own self-interest and one cooperates to the extent that these interests meet. The self-interest of the cooperative's management in commercial success superseded in a subtle way the original task of serving the member SMEs.

Things are different with some cooperative ventures that have emerged out of the need or the desire to fill a supply gap of the market. They could maintain something like a monopoly position, either because the market does not readily support more than one supplier (e.g. booking service for taxis) or because the advantage of the first one to occupy a certain market niche is difficult to match for a late-comer. The latter has been the case, for instance, with the German fiscal advisors' data processing cooperative DATEV. Where outside competition does not question the cooperation, the cooperative spirit, oriented towards the collective purpose of the common undertaking, tends to be stronger.

Cooperation for extended business

We find this type of cooperation in a large variety of manufacturing and service industries. Its essence is that the member enterprises pool their capacities in order to take on production tasks or offer service jobs which none of the partners would be able to do alone. This pooling of capacities can take various forms:

- It can consist simply of the quantitative adding up of several similar production capacities so that orders of a larger volume, e.g. the transport orders of a larger enterprise or a big industrial cleaning job, can be accepted. In this case the cooperative enterprise functions as a booking and co-

ordinating office for the individual jobs, which are carried out separately by the member SMEs.

- It can consist of the pooling of complementary specialisations so that the group as a whole can offer - under one single brand name - a greater variety of products (e.g. different types of leather, transport services to different locations, legal advice on different subject areas) than each member SME. The cooperative enterprise does the marketing, the production job goes to a single member SME according to the nature of the client's order.
- Several SMEs of different specialisations can join in the common, centrally coordinated production of a good or a service. For example, different craft enterprises can form a cooperative construction company. Or a number of firms of various branches produce shoes according to a common design.
- Several SMEs of the same branch can join in acquiring or renting equipment (including real estate) which extends their production possibilities but which would not make economic sense, or be feasible, for any one of them alone.
- SMEs can join in a common effort to market their individual products, reaching this way market segments which are beyond the reach of the single enterprise (examples: travel agency of bus owners, export communities).

For this type of cooperation membership is exclusive - with regard to the number of participating SMEs and with regard to their qualification. Like in retail cooperations with a common marketing concept, member SMEs must not compete with each other in the same product market or for the same clientele. Often this means only one enterprise per local or regional market.

SMEs who get together to coordinate their entrepreneurial core functions producing and selling have - almost by definition - a high initial commitment to their common undertaking. However, the dependency of this type of cooperation on permanent close coordination and discipline also makes it especially vulnerable. If only a few partners do not live up to their obligations within the common production and marketing concept, the whole cooperation can be put in danger. Over and over such cooperations have broken down, because the individual interests of some partners began to interfere with the group's common interest. Also the distribution of costs and benefits is often a more sensitive matter here than in cooperations restricted to common purchase.

Altogether, the high demands on commitment, discipline and coordination are reflected by the relative scarcity of this sort of cooperation and by an elevated level of difficulties, conflicts and fluctuations where it has been attempted. This seems to confirm the suspicion that coordination based on solidarity is more vulnerable than one which is based on the interplay of supply and demand or on authority.

COOPERATIVES AND OTHER FORMS OF SME COOPERATION

Much of the institutionalised long-term cooperation between small businesses in the EC takes place in forms other than cooperatives ("quasi-cooperatives", as we call them here). Whether the cooperative form or another form is chosen depends most of all on economic and practical convenience, but beyond that also on factors which belong to the sphere of ideology.

In Britain, the cooperative has never been legally instituted as a separate enterprise type. There, all de-facto cooperatives must adopt one of the existing legal forms, preferentially a joint-stock corporation. Elsewhere, cooperating SMEs have the choice. Many consider the cooperative enterprise form as less convenient because of:

- the relative slowness of decision-making and therefore a lower degree of flexibility vis-a-vis changing market conditions (because of the dispersion of responsibility);
- the lack of individual property rights in the capital of the cooperative enterprise, which reduces the flexibility with regard to enterprise structures, participations, etc., and makes the raising of finances difficult.

It seems that these inconveniences are more important the more the cooperation aims at the pooling of the member SMEs' capacities and the coordination of their activities, i.e. the more the entrepreneurial core functions of production and marketing are affected. Thus, cooperations of our type C are predominantly organised as joint-stock, limited-liability or other conventional forms of enterprises. But it is also in this field where we often find relatively loose, sometimes temporary forms of cooperation (e.g. in the construction trade). On the other hand, the classical cooperative form seems to be especially appropriate where the task is to supply a certain auxiliary service to a large number of small businesses. Where the development of originally service-centred cooperatives has led to an increasing emphasis on coordination, notably in retail trade, we observe the emergence of conventionally structured subsidiaries of the cooperatives.

A factor which touches upon convenience and ideology at the same time is custom and tradition. Several trades have developed their specific forms of cooperation aside from the cooperative movement. These forms are adjusted to their needs, but they are also important for their identity. Perhaps most noteworthy in this regard are the formalised partnerships of practitioners of liberal professions. From a functional point of view they constitute enterprise forms between a service cooperative (independence of the partners with certain common functions) and a workers cooperative (one identity towards the client; to some degree common products, done in division of labour under one roof; in part common profit). However, from an image point of view, they are considered as an altogether separate form of organising business.

Generally, there is a tendency among small businesses not to consider cooperatives as a serious option. They are associated in a vague, unfocused way with a lack of business orientation, with amateurism or some sort of romanticism, with outdated pre-industrial economic structures, sometimes with socialist tendencies. This generalised image is often propagated by professional advisors, banks, etc., who are not familiar with cooperatives and simply dismiss them in recommendations to their clients.

Italy is certainly the country where this tendency is weakest. There cooperatives are most firmly entrenched as part of the country's business culture. At the other end of the spectrum we have Britain, in whose economic culture the concept of the cooperative is most conspicuously absent. In Britain, like in Ireland, small business cooperation itself is underdeveloped. In other countries we certainly find a general disposition to consider "quasi-cooperative" forms first when it comes to cooperation.

But there is also the second component to the ideology factor: the ideological orientation of the cooperative movement itself. It can be localised between business-like pragmatism and anti-capitalist value orientation on the one side and between self-conscious assertiveness (reflected in active promotion) and silent accommodation on the other. It seems that a combination of pragmatism and assertiveness can provide for a counterweight to latent prejudices within the small business sector. This view is supported by the experience of Italy and to some extent of France, Germany and Catalonia. On the other hand, to some small businesses it is precisely the notion of the cooperative as an alternative way of organising economic activity, an alternative where individual profit is not the supreme criterion, which makes it attractive. This has been the case

for example, in Germany, with the consumer-oriented insurance traders and bicycle shops. But certainly, only a small minority of cooperating small enterprises can be drawn to the particular form of a cooperative.

CROSS-BORDER COOPERATION

Our investigation has rendered three basic findings on the extension of small business cooperatives or "quasi-cooperatives" across nation borders:

1) The majority of respondents in all investigated countries and economic branches do not consider cross-border cooperation that would go beyond individual partnerships among two or three enterprises as important for small business, not even with the completion of the Single European Market. According to this dominant view, the additional advantages of scale which could be gained through an extension of cooperation are not significant enough to outweigh the substantial difficulties such an extension would have to overcome. At any rate, cross-border cooperation is not considered as the most indicated response to increasing competition in the wake of the Single Market. This argument refers basically to cost-oriented cooperation (types A and B). As far as cooperation for extended business is concerned (type C), its importance is diminished by the fact that small enterprises are overwhelmingly oriented towards local and regional markets.

2) Notwithstanding the dominant disinterest, we encountered a sufficient number of respondents who actually do consider cooperative activities across national borders as important or desirable.

3) But those who are interested also find cross-border cooperation extremely difficult to bring about. In fact, the general impression is one of complete helplessness, which stifles any serious attempt. The difficulty is underlined by the fact that the investigation encountered less than a handful of cases of a successful extension of cooperative activities across national borders.

The desirability of cross-border cooperation

An extension of cooperative activities across national borders is considered as desirable or has actually proved to be advantageous for all three types of cooperation.

Cost-oriented cooperation among small retail shops for the sake of survival in the competition with large enterprises obtains a new dimension through the fact that these large enterprises themselves have started not only to internationalise their sales outlets but also to pool their purchases internationally. They do see additional rationalisation possibilities in even larger scales of operations than they have reached already. In part, they themselves cooperate internationally.

With optional cost-oriented cooperation as it characterises most of the European crafts cooperatives (type B), an extension across national borders can offer an opportunity for further rationalisation and/or strengthening. An example is offered by a Catalonian restaurant cooperative which has members along the French Mediterranean Coast. Here it is a matter of disregarding, if possible, the political boundaries to a sensible radius of cooperation and substituting them by economically more meaningful bounding criteria, for example, geographical distance or regions of structural similarity. In this category, internationalisation seems to make sense predominantly as an extension of cooperation to the adjacent region in the neighbour country. But we also see some signs that the geographical radius of meaningful cooperation simply becomes larger while political borders simply lose importance.

The increasing internationalisation of many economic activities itself also creates new needs for coordinating services, to which the market often does not respond for a long time. Here cooperation could fill the gap with collective self-supply. An example is the need for something like a bourse service which connects in a rational way the demand for and the supply of international road hauls. Road hauliers cooperatives could take it in their hands to set up such a system.

Extending SME business to new markets, which either arise or get in reach with the general advance of internationalisation and in particular the Single European Market is a relatively strong motive behind the interest in cross-border cooperation. The transport market provides again an example: By cooperating across national borders, small transport firms could gear up to offer international transport services for which any individual one of them would lack the capacity. Another example is the consulting market, where the national expertise of individual consultant firms can be and are being pooled in order to meet the increasingly internationally oriented demand of clients (not to speak of the better access to international funding).

But it is not only the opportunity of new markets which can make extended-business-oriented cross-border cooperation (type C) desirable. Sometimes suitable partners for an advantageous cooperation can be found more easily across national borders, for instance, because the obstacle of mutual competition is less pronounced. This possibility is most likely to be encountered in branches with relatively few national suppliers in a single country, like, for example, in leather production.

Finally, we have the motive to strengthen colleagues abroad, thus strengthening the own professional group in the increasingly important international (and particularly EC) arena and/or promoting the cause to which the own professional activity may be dedicated.

As the various examples show, the extension of cooperative activities across national borders can take different forms:

- Existing cooperatives in various countries run something like a second, third, or higher degree cooperative on an international level (Intersport, BAKO Europa). As a step beyond this, they could even merge into one cooperative.
- SMEs in two or more countries form a cooperative venture, for which the European Economic Interest Grouping (E.E.I.G.) has come to provide a convenient legal form.
- SMEs in one country join a cooperative or "quasi-cooperative" of another country (French members of a Spanish restaurant cooperative; Austrian, Scandinavian and Belgian members of a German watch retail cooperative).

Obstacles to cross-border cooperation

As shown above, it takes a big effort in terms of initiative, time and organisational skill to bring about cooperation among small businesses. This is the reason why we do not find much more of it. That the frequency of cooperation goes beyond that of sporadic incidents presupposes one of three things:

- cooperation is necessary for SME survival in the market;
- cooperation is promoted systematically by an agency which is dedicated to this task and endowed with sufficient resources;
- there is a social movement, which triggers an exceptional dynamic of collective behaviour.

Of course, all these restrictions are valid for cross-border cooperation as well. And they explain as such already a good deal of its rare occurrence. But the fundamental obstacles are enhanced by the fact that:

- (a) the pre-cooperation density of communication is normally much lower than within a country; businessmen simply do not meet so frequently and often they do not master the other language;
- (b) the conditions for doing business are often very different from one country to another; this applies to consumer habits,

market structures, regulations and the business culture in general.

Significantly, legal barriers to cooperation across national borders seem to play hardly any role at all. This would correspond to the experience of so many transnational corporations, who all have found ways to arrange themselves with the diversity of different national laws.

Consequences

It is to be expected that cooperative and "quasi-cooperative" activities are extended beyond national borders more frequently in the foreseeable future as several of the obstacles which were in its way so far are somewhat relaxed:

1) The increasing internationalisation of business in general forces some small businesses to follow suit if they want to survive in their markets (retail trade). The completion of the Single European Market reinforces this trend.

2) The increasing internationalisation, again reinforced by the Single Market, makes for many new business opportunities, which require cooperation if small enterprises want to make use of them.

3) European unification reduces the regulative differences between EC countries.

4) European unification contributes to a general levelling down of differences in business cultures and even consumer habits within the Community.

However, all these developments will not do away with the basic impediment: the need for agency services which are not available immediately. If cross-border cooperation is to increase significantly, this would require deliberate, sustained efforts of promotion which are backed with sufficient resources.

Sectoral prospects

THE MACROECONOMIC ENVIRONMENT

After an early promise of recovery in 1992, the world economy has lost momentum. Declining production figures, sharp falls in new orders, overcapacities in the manufacturing sector, rising unemployment and further losses in consumer confidence now characterise nearly all the major world economies.

The slow growth of EC domestic demand is caused by a fallback of consumer and business confidence. In addition, exports to the United States are at a standstill, due to the weak economic climate there and the loss of competitiveness of European exports due to the depreciation of the US-$ against most European currencies; the loss of markets in Eastern Europe contributes as well to the depressed mood in the Community.

The most crucial factor contributing to the slow growth of the EC economy is, however, the policy of high interest rates of the German Bundesbank, which is putting enormous deflationary pressures on the other European countries. In addition, the "convergence" gaps between EC economies have led to the breakdown of the fixed exchange rate system built into the Exchange Rate Mechanism (ERM) of the European Monetary System (EMS). The resulting exchange rates realignments on and about "Black September" have increased the uncertainties about the prospects for the European economies, as well as about the future of the Maastricht Agreement.

The combination of exchange rate turmoil, political uncertainties and poor economic indicators is leading all forecasting authorities to revise downwards their forecasts for 1993.

GDP growth in the EC as a whole is expected to reach 1.8% in 1993, compared to 1.0 percent in 1992. This is mainly a result of the nascent recovery in the United Kingdom, where GDP growth is now expected to be a little below 2% in 1993, up from a negative 0.9% in 1992. The increase in the overall GDP growth forecast for the UK appears to be principally a reflection of stronger projected growth in net exports. The outlook for production in the manufacturing sector, which is likely to benefit from increased competitiveness, has also improved.

Slow growth is also expected in Germany (1.4% in 1993), due to continued worries over public finances, the receding prospects for early significant cuts in interest rates and the deteriorating outlook for growth elsewhere in Europe. The increase of the VAT in January 1993 will cause the average inflation rate to remain high in 1993, which will induce the German Bundesbank to remain cautious regarding cuts in interest rates in the near future. Consequently, investment expenditure is expected to remain flat, also hampered by overcapacities in the manufacturing sector. Consumer expenditure is expected to remain weak, as disposable income is hit by expected contributions to health costs and by further indirect tax hikes (e.g. oil duties).

The French economy is expected to grow by 2.2% in 1993, compared to 2.1% in 1992, due to weak export growth; tighter fiscal policies in a number of countries and the devaluations in several of France's major export markets have done little to improve the outlook for export growth in 1993, which had been deteriorating in recent months.

Prospects for the Italian economy are not encouraging, in the face of high short-term interest rates and planned cuts in public spending and revenue increases totalling 93 trillion lire. These cuts in spending and revenue increases aim to hold budget deficit in 1993 down to 150 trillion lire, and are likely to dampen consumer expenditures. GDP growth is expected to reach 1.9% in 1993, compared to 1.5% in 1992.

In the medium term, it is expected that growth in all EC countries will recover, as reduced interest rates revive the economies. GDP growth for the EC as a whole is expected

Table 1: Macroeconomic prospects for the EC in the 1990s

(real annual % change)	1991	1992	1993	1994	1992-1996
Gross Domestic Product	1.1	1.0	1.8	2.7	2.4
Consumer spending	1.6	1.3	1.5	2.1	2.1
Gross fixed investment	0.1	0.1	1.8	4.2	3.5
Exports of goods	2.5	4.4	4.8	5.4	5.0
Imports of goods	5.2	4.8	4.1	5.0	4.7
Industrial production	-0.7	1.0	1.4	2.9	2.3
Consumer prices	4.5	4.0	4.1	4.2	3.9
Short-term interest rates (1)	7.8	6.5	6.0	6.0	6.2
Long-term interest rates (1)	8.4	7.8	7.7	7.7	7.8
Unemployment rates	9.0	9.6	10.2	10.5	10.2

(1) Nominal rates for OECD economies (period averages)

to reach average annual growth rates of 2.7-2.8% from 1994 on. The assumption is that efforts to achieve convergence, in line with the Maastricht agreement, will resume after the turbulence of 1992, creating a favourable climate of confidence and stability.

THE SECTORAL OUTLOOK

The economic environment for EC industry has experienced far reaching changes during the last decade. Preparation for the advent of the single market has triggered important structural changes. The gradual disappearance of trade barriers has given rise to increased efforts by companies to reach the critical size, and to enhance their market shares. Another consequence of the break-down of trade barriers and the prospects of a large, unified, European market was increased competition from non-EC countries, in particular from Japan, the NICs and the United States, but also from non-EC companies establishing production facilities in the EC (e.g. Japanese transplants in the UK). The movement towards easier access to the EC markets for non-EC producers can be expected to gather even more strength in the future, as technical harmonisation takes hold in all of the EC countries. Another important change is the potential opening of the East European markets. The end of the cold war may have temporarily caused a loss of markets, as the transformation of centrally planned economies into market economies is accompanied by huge financial problems; in the medium term, however, once these economies revive, new market opportunities will be created for EC producers.

Developing markets in Asia, the region in the world with most growth potential, will also give added stimulus to demand growth; competition from the NICs and Japanese producers in these markets is, however, expected to be very stiff, as the latter benefit from traditional links and cultural advantages in these part of the world.

Environmental concerns are likely to provide EC industries with fresh impetus for the development of new products, but will also require costly adjustments from some industries, which may result in increases in production costs and some losses in competitiveness.

Intermediate goods

Intermediate goods producing sectors chiefly deliver inputs to downstream industries, in particular to the construction industry and to the investment goods sector. In many cases, intermediate goods industries suffer chronically from overcapacity problems. This gives rise to ruinous price competition and low profitability, even in times of strong demand. Most companies working in this area are also confronted with environmental problems, as their production processes or the use of their products are linked with damages to the environment.

Non-energy mining and quarrying industry

This sector, which includes the production of iron ore, non-ferrous metal ores and industrial products, is expected to grow at roughly 1% per year in the short-term, 2% in the medium-term.

Within the EC, the most important subsector is the industrial minerals sector, which accounts for 90% of the industry's output. The major consuming industry is the construction industry, which absorbs about 45% of all EC mined materials. Competition from abroad in the field of industrial minerals is restricted by the costs of transportation, which ensures that local materials are predominantly used. In the field of non-ferrous metal ores, however, price competition from overseas threatens the situation of EC producers.

Ferrous metals

The sector of ferrous metals includes the production of iron and steel, the manufacture of steel tubes, and the drawing, cold rolling and cold folding of steel. By far the largest component within the sector is the iron and steel industry, which accounts for 74% of the sector's output. The industry is a supplier of inputs to investment goods industries as well as to the construction industry. Production increased considerably in 1988 and 1989, in line with increased demand from the investment goods sector. From 1990 on, however, production of ferrous metals flagged. Competition from the NICs increased, thanks to their lower production costs. Exports, on the other hand, were hurt by the loss of markets in Eastern Europe and by reduced demand from China. In general, the ferrous metals industry suffers from world-wide overcapacity problems, and from intense price competition in export markets. In the short-term, the outlook for the industry in the EC is not encouraging. Demand from the consuming industries is expected to remain low. In the medium-term, both production and consumption are expected to increase, as the recovery of the world economy boosts demand for the industry's products.

Non-metallic mineral products

Demand for non-metallic mineral products depends heavily on the activity of the construction sector, as nearly 70% of production is used in construction. The bulk of glass and ceramic products, however, is used in a variety of other sectors; the EC is the leading world exporter of the latter kind of goods, but the share of international trade in the industry is fairly limited, due to high transport costs, as well as non-tariff trade barriers. The outlook for the industry in the nineties is quite favourable and production is expected to grow by an average of 2% per year in the period from 1992 to 1996.

Chemicals (incl. pharmaceuticals)

The EC chemical industry experienced a strong expansion over the last two decades, among others as a consequence of the replacement of traditional materials (steel, wood, paper, glass etc.) by new materials derived from chemical processes. At the beginning of the present decade, however, demand for basic chemicals has been weakened by the cyclical slowdown of the European economies, and by slower export growth, as a consequence of the recession in the United States. Demand in other sub-sectors, such as the pharmaceuticals sector, continued to grow rapidly.

The prospects for the industry as a whole are not encouraging in the short-term. Production is expected to increase by a moderate 2.4% in 1993. This figures covers flat production in most subsectors, while the production of pharmaceuticals and cosmetics/perfumes continues to grow rapidly as a consequence of rising demand for personal care products and growing concerns for health. In line with faster economic growth in the medium-term, the production growth of basic chemicals is expected to resume also.

Increased concern over the quality of the environment entails both opportunities and new markets for the chemicals industry, but also imposes new burdens on the industry, through the need to reduce noxious emissions, as well as through restrictions imposed on the consumption and the disposal of the industry's final products.

Investment goods

The investment goods industries in the EC were hard hit during the last two years. Declining investment growth worldwide, as well as strong competition from Japan and the United States, have battered the sector, particularly those industries suffering from excessive fragmentation. In order to meet these challenges, the industry is undergoing major structural changes, as well as revising its strategies. Consolidation through mergers and acquisitions, as well as increased R&D expenditures, should help the industry to reinforce its market position in the next years.

Table 2: Sectoral prospects for the EC in the 1990s

(real annual % change)	1993	1992-1996
Intermediate goods		
Non energy mining and quarrying	1.0	2.0
Ferrous metals	1.0	1.3
Non-metallic mineral products	1.2	1.8
Chemicals	2.4	3.1

Wood processing	3.4	3.4
Pulp, paper, printing and publishing	3.5	4.2
Rubber products	1.0	1.9
Plastics processing	5.0	6.0

Source: Panorama of EC Industry

Mechanical engineering

The well known dependence of the mechanical engineering industry on cyclical fluctuations in investment activities is the main source of the sharp decline in production suffered during the last few years. Future prospects for the mechanical engineering industry, however, are quite good. The main factors for this improved outlook are: still ongoing microelectronisation of the machines, which will create demand for new machines (CAM, CIM); the modernisation drive brought about by the common EC market and the European Economic Area, and the opening of new markets in Eastern Europe. On the other hand, growing competition from abroad, particularly from the USA, Japan and the NICs, is likely to cause increased pressure for EC companies. Japan competes mainly in the area of high technology machines or components, while manufacturers from Taiwan and South Korea are making inroads with more basic products.

Electronic engineering

The electronic engineering industry in the EC has been faced with a number of challenges over the last few years. The most important ones are the reduction of product life cycles and the pressure on profit margins. As lead times for the development of new, more sophisticated, products for consumer and business markets becomes ever shorter, the life cycle of products has declined sharply. Fast productivity gains have also caused prices to decline rapidly. At the same time, competition from outside the Community has increased considerably, particularly from the United States and Japan, a consequence of slow demand growth on their home market. Competition from imports was also strengthened by the decline in the exchange rates of the USD and the Yen, which made companies from these countries more competitive in terms of prices. The answer of EC companies was to strengthen cooperation with other companies, particularly in the field of research and development (e.g. Siemens, IBM and Toshiba).

During the eighties, the EC electronics industry experienced high growth rates in both production and demand. In the last few years, however, general market conditions have worsened. The recession and the reduction of general income levels have hampered the development of the industry. Growth rates, however, remained positive and above those of the manufacturing sector in general. The only sector which has experienced a decline in production is the consumer electronics sub-sector. Future prospects for the industry are nevertheless quite good, as new product innovations are likely to stimulate demand. Examples for such innovations have been the notebooks, laptops, fax machines and camcorders. Structural changes in the field of home offices and the merger of computers and telecommunication are likely to give a new boost to demand. New demand can also be expected some time in the future from Eastern Europe.

To keep growing, however, the EC electronics industry needs to face up to competition from outside the Community through increased R&D efforts, and through additional mergers and acquisitions, in order to both strengthen their market position and gather the huge resources necessary to finance these same R&D expenditures.

Transport equipment

The transportation equipment industry as a whole experienced moderate growth in 1991, after a stagnant 1990. Considering the subsectors of the industry, output of the motor vehicles and the motor vehicle parts and accessories industry declined by more than 2.5%, due to weak demand at home and in export markets. In contrast, the aerospace industry has helped to counter the situation.

In general, production growth in the transport equipment sector is expected to average 2.6% per year up to 1996.

The motor vehicles industry, however, has to be aware of the important challenges to be faced during the nineties. Competition from Japanese companies, including transplants, will force companies to increase their production efficiency (lean production), if they are to maintain their market share. To profit from economies of scale, a strong movement towards international cooperation has been observed over the last years. This process can be expected to go on, not only between EC manufacturers, but also between US and Japanese manufacturers.

Another important challenge of the nineties will be the protection of the environment. Heavy energy users, one of which being the transport sector, are likely to be under attack over the course of this decade. This could lead to a modal shift in transport services the sector (e.g. from cars to rail).

Instrument engineering

The instrument engineering industry is an extremely diverse sector, with demand stemming both from industry and from households. In general, demand for products of the industry has increased in the eighties as a consequence of the healthy economic climate, with high spending in consumption and investment, but also as a consequence of the development of new technology, increasingly combined with microelectronics.

In line with the economic downturn in the last few years, production growth as well as consumption growth have declined markedly. Competition from outside the EC has increased considerably during these last years and the trend is still ongoing. The strategies of EC companies have to be to reduce costs and to increase production efficiency, as well as to increase R&D efforts. One important problem in this context, however, is the small to medium sized structure of the companies. Thus, restructuring is one of the main efforts which have to be undertaken.

The outlook for the industry is better in the medium-term than in the short-term. Production is expected to grow at an annual average rate of 3.1% during 1992 to 1996. Environmental concerns, the automation of industrial processes, and the development of new products are the main driving forces.

Consumer goods

Demand for consumer goods industries depends largely on the development of consumer expenditure. A fast changing fashion climate, combined with strong competition from

abroad, has forced the industry to undertake a remarkable concentration processes during the last years.

Food, drink and tobacco

Demand for food products is increasing moderately, even though population growth in the EC is close to zero. The share of food consumption in total expenditures has declined to about 20% in most countries. What little growth there is mainly reflects shifts in demand from fresh and/or artisanal products to easy-to-make products with a higher service content, which keep longer then fresh ones.

The EC food and drink market structure has also undergone a major concentration during these last years. This is not only in order to profit from economies of scale, but also in order to maintain and strengthen market position against competitors. Growth expectations in the EC for the next few years are better than in the recent past for both production and consumption. A continuation of the movement towards processed products, in particular towards high service content products, and faster population growth through immigration rather than through changes in birth rates, are the main factor underlying this improved outlook for growth.

Textiles, clothing and footwear

The growth of demand for textile, clothing and footwear, as measured by apparent consumption, has been significantly faster than production growth in the period 1982 to 1991. The gap is filled mainly by imports from East Asian countries who benefit from significant cost advantages, particularly in the production of mass-produced items. In the field of high quality products, on the other hand, EC producers are more competitive, and price elasticity there is lower. Efforts of EC companies to reduce costs have led to a shift from labour intensive production to more capital intensive production, with automation processes and highly efficient production systems (JIT). EC producers have also increased the speed at which they respond to changes in fashion and trends.

The outlook for the industry over the next few years is quite good. Production growth is expected to reach roughly 2% in 1992 to 1996. Consumption growth will remain higher, at 3.4% for the same period.

Competition from non-EC countries is expected to become even stiffer, as trade liberalisation in the context of the GATT negotiations are likely to phase out the Multi-Fibre Agreement (MFA) and the Lomé Convention. Liberalisation efforts, on the other hand, will also increase export possibilities in markets currently protected, such as the Japanese market. The ability of EC producers to respond quickly to market changes is an important asset. In the long-term, an important potential market is that of the East European countries, but EC producers will face substantial competition there from low-cost producers.

Wood processing

The woodworking industry has experienced a less favourable year in 1991, as its most important end-markets, the construction sector and the furniture industry, experienced only moderate growth, a consequence of slow income growth and high interest rates. Trade flows between Member States are more important than extra-EC trade, due to the importance of transport costs and technical barriers. The deficit in the EC trade balance is explained mainly by imports of tropical hardwood, plywood and hardboard from Asia, South America and Brazil, but also by imports from countries of Central and Eastern Europe at extremely low prices.

EC production is expected to grow at an annual rate of 3.4% in the years 1992 to 1996. Environmental regulations and the imposition of technical barriers to trade between Member States, however, may increase costs for the industry. Production processes need to be rationalised to improve production efficiency. In addition, European standardisation may lead to increased extra-EC imports.

Pulp, paper, printing and publishing

This sector, which includes activities such as the production of pulp, paper and board, the conversion of paper and board, as well as printing and publishing, is currently plagued by overcapacity problems, a consequence of large investments by the industry in the eighties. Consequently, prices have been put under downward pressure. Competition stems mainly from the EFTA countries, i.e. from Scandinavian competitors, and has caused the industry's concentration to increase. The outlook for the industry is quite good, as renewed economic growth is expected to spur demand in 1993.

One of the most important challenges for the industry in the coming decade will be its response to new EC and national environmental regulations, as some of them, like EC packaging legislation, could fundamentally alter the market for pulp and paper products. In printing and publishing, signs of maturity are obvious. New electronic media are not expected to replace, but rather to complement written media.

Rubber products and processing of plastics

The outlook for the rubber products and plastic processing industry differs considerably; while the rubber products sector is expected to grow at roughly 2% per year in the period 1992 to 1996, the outlook for the plastic processing industry is much more optimistic, at about 6% per year over the same period.

The explanation is the heavy dependence of the rubber industry on the transport equipment industry, mainly in the form of tyres, which account for roughly 60% of demand for rubber products in the EC. Taking tyres, tubes, and other products together, the automotive sector covers about 70% of the rubber products market. Given the weakness of the automotive industry in the short term, this explains the slower growth of the rubber industry. In the medium term, however, growing traffic, as a consequence of increasing intra-EC trade, will spur demand for tyres too. The optimistic outlook for the plastic processing industry is based on the fact that there exists extensive and diversified demand for plastic goods; consequently, the ability to compensate for slow demand growth in any single demand sector is much higher than in rubber products.

An important issue for the industry is the problem of waste. Both plastic and rubber products are a durable component in the waste stream. Tyres are used again by retreading, but this solves the problem only partly, since, in the end, every tyre ends as disposal waste. Chemical recycling is to expensive and generates air pollution.

Construction

The construction sector has been characterised by declining trends in nearly all EC countries these last years. Germany and Portugal are the only exceptions, thanks to a great backlog of demand in Portugal, and to the boost of reunification in Germany. Public expenditure for infrastructure work has been declining as a result of efforts to reduce public debt; this has affected mostly the areas of civil engineering and public sector building. High interest rates have also affected the sector of private commercial buildings. In the medium-term, the construction sector is expected to increase its activity, as the general economic climate improves and interest rates come down. This will affect the building of new homes, as well as modernisation and reparation activities of existing buildings. The subsector of civil engineering will benefit from investment in the protection of the environment, in revamping existing infrastructure facilities and in the area of trans-European networks. Germany will experience a particularly dynamic development, as the expansion and reconstruction of the public infrastructure in the eastern part of the country

will develop. Competition between EC firms is expected to increase, as the common market will provide the possibility for EC firms to compete on bids for works anywhere in the Community.

SERVICES

The services sector experienced high growth in the last decade. Even though these growth rates were well above those of the manufacturing sector, even higher growth had been previously expected. Liberalisation efforts in the EC and the advent of modern means of communication technology are likely to create new opportunities for the sector, but also to increase competition.

Tourism

The tourism industry experienced rapid growth during the last years, for the following reasons:

- a general rise in private income levels,
- a substantial increase in the availability of free time for vacationing.

These two factors contributed to the multiplication of second holidays and short-breaks, as well as to a greater incidence of holiday taking.

Another important factor was the increase in business related travel, which is probably the fastest growing segment of the travel market.

In 1991, the previously rapid growth of the tourism industry in Europe slowed substantially, as a result of a variety of factors, including the Gulf war, unrest in the Balkans and the recession in some of the major originator countries which affected mostly the lucrative long-haul market.

The outlook for the tourism industry in the nineties is quite good. In line with the economic recovery, international tourism expenditure will increase. Increases in short-break holidays will lead not only to increased tourism expenditure but also to a better utilisation of capacity. New tourists will come from Asia's NICs and from Eastern Europe. Most important is the product innovation, i.e. new programmes, responding to changes in demographics, social patterns and tastes which stimulate travel to less developed regions and encourages better off-season utilisation of facilities.

Transport and communications

The transport and communication sector is engaged in the conveyance of goods, passengers and information. As this industry is a necessary complement to economic activity and interaction, European integration will spur demand for this kind of products. Competition between EC Member States, however, is expected to increase, as common policies for transport and communication are introduced. This forces potential competitors to invest heavily in modern equipment.

Demand for transport and communication is also expected to be spurred by the opening of the Eastern European economies. This type of demand, however, is likely to develop only in the medium term.

Finance and insurance

The financial sector experienced a complete overhaul during the last decade. The traditional separation between activities - kept strictly partitioned by official regulations - has been progressively removed, a result of the trend toward deregulation, globalisation and the removal of barriers between services. The distinction between commercial banks, investment banks and brokerage houses has become more and more negligible. In addition, links between the banking and insurance sector have grown. The deregulation of the industry has led to an explosion of market activity and to a proliferation of new products. As a consequence, competition in terms of products has increased, particularly regarding household savings, with the advent of larger numbers of players among credit institutions, insurance companies and cooperative investment organisations. New technologies, based particularly on computers, have become a more and more indispensable factor. Consequently, the financial sector is now faced with major investments for retraining the workforce.

The outlook for the industry in the EC is quite good, but increased competition will endanger the profitability of companies. Continuing increases in efficiency and productivity are a must, as well as new product development to ensure survival in the market. The impact of the common market will probably not be too important, as financial services, savings and insurance are already operating globally, at least in major firms.

Electronic information services

The supply of electronic information covers a wide range of services: financial data, economic data, business data, professional data, industry specific data, and information newspapers, news, services, magazines, etc..

Despite the fact that growth in this sector did not fulfil expectations completely, this sector's growth rate has remained significantly higher than that of the economy in general. The crucial issues in this context are the cost of electronic information and the shortage in end-user training.

Prospects for the information services sector are quite good, as the infrastructure for these services (micro-computers and modems, videotex, telephone lines and fax) becomes more and more user-friendly, improving the ability of users to work with these services.

Commercial distribution

THE IMPORTANCE OF COMMERCIAL DISTRIBUTION

Commercial distribution is generally a misunderstood and undervalued sector of the economy. The simple fact, however, is that commercial distribution - the companies, processes and activities involved - affects us all in one way or another. As individuals we all shop and expect goods and services to be available when we require them. Similarly, for manufacturing, companies commercial distribution provides the means of access to end-users whether consumer or industrial purchasers. An understanding of commercial distribution, its functions, activities and behaviour is therefore essential not just to those involved in the sector itself but for those manufacturers who must use the sector to reach their final consumers, and those politicians determining employment policy.

The problem of recognition faced by the sector is partly due to differences in the perception of what constitutes 'commercial distribution' and in particular the scope of its activities. To some commercial distribution is simply a business process or function, whilst others identify it as a distinct sector of the economy in its own right. These perceptual problems are compounded by a lack of clarity in statistical data collection within the Community. This serves to reinforce the confusion over what commercial distribution involves. Data collection is commonly based upon a number of factors ranging from type of product involved; company size or form; establishment or selling technique; or the activities performed. Definitions also vary from country to country, further compounding the problems of comparability, and the construction of a uniform definition of the sector.

Despite the problems associated with statistical sources and definitions, estimates of the contribution of those companies involved in commercial distribution to the European economy can be derived. Estimates suggest that commercial distribution within the Community involves at least 4 million businesses, with 18.4 million people generating a turnover in excess of 1300 billion ECU (excluding VAT). The contribution to individual national economies varies from market to market, but averages 13% of GDP, and companies involved in the sector are now amongst the largest enterprises in many countries.

THE NATURE AND ROLE OF DISTRIBUTION CHANNELS

In simple terms commercial distribution involves the activities in the distribution channel by which goods and services move from the supplier to the end customer. Understanding the distribution channel and the processes that take place within it, requires the consideration of a number of dimensions which provide for complexity:

- channel members
- channel activities
- channel flows

Channel members have been traditionnally categorised as primary organisations or facilitating organisations. Primary organisations - such as suppliers of goods and services, wholesalers and retailers - usually take legal title to products and services as they flow through the channel. Facilitating organisations - agents and brokers, transporters, warehousemen, market researchers, advertising agencies, insurers and financial agents - provide special services to support the flow of goods and services.

Channel activities have traditionally included the sourcing and purchasing of product and services; storage, assembly, packaging; bulk-breaking, sorting and picking; physical distribution; and marketing and sales promotion.

As far as channel flows are concerned, the distribution process involves a number of flows - of products and service, information, finance and risk - which pass from organisation to organisation within the distribution channel.

The nature of the products and services themselves, plus consumer demand for products and services, influence these dimensions and contribute to differences in the size, type and structure, and behaviour of distribution channels.

The activities performed within distribution channels are commonly perceived as adding value (or destroying value if poorly performed) to the product or service concerned. Increasingly, owing to the information now available from new technology, channels are being driven or initiated by consumers through their choices and expectations of products, outlets, services and their time requirements. The activities undertaken to meet these requirements inevitably incur a cost and this, plus the changing demands of consumers, increasingly focuses attention upon distribution channel management as essential for most businesses.

As distribution channels involve a number of different organisations each with different business goals and performing a variety of tasks, relationships within the distribution channel become crucial to its efficient functioning and performance. Relationships are affected by:

- power or dependency, which determines the relative importance and roles of channel members;
- market structures and the nature of market competition, which determines the nature of tasks required and the relative importance of these tasks.

Commonly a 'leader' evolves in a channel to manage or control the process and activities, although the presence of a leader does not mean that benefits are equally distributed amongst channel members. Government intervention may take place to manipulate these factors if it is felt that one particular organisation is misusing power within the channel.

DEVELOPMENTS IN DISTRIBUTION CHANNELS

Distribution channels take many forms and have evolved over time. In conventional channels relationships are essentially determined by power, particularly coercive power (the belief that a more 'powerful' organisation can punish, or fail to reward, a less powerful organisation). Channel members are loosely aligned and their efforts and interests are closely linked to the 'next' member of the channel, for example manufacturers deal only with wholesalers and wholesalers deal only with retailers. Increasingly these conventional channels are regarded as inefficient, as the alignment and nature of relationships usually ensures that negotiations at each level in the channel are conflict driven with each channel member seeking to preserve his own position. This form of distribution channel almost inevitably leads to a duplication of functions and activities, and only allows limited access to others in the channel. Essentially roles are pre-determined and relatively inflexible.

Increasingly in Europe and elsewhere, channels are now being regarded more as integrated vertical marketing systems. In this type of distribution channel, organisations are vertically aligned, with the whole distribution channel managed as a single system. The view is that these forms of channel are more efficient as conflict is reduced, synergies arise, and every channel member works together for the total benefit of the channel, rather than for his own individual position. In many markets, especially food, the impetus for such vertical marketing systems has come from retailers. In in other product markets, such as clothing and electrical goods, manufacturers have taken a firm lead in developing this approach to channel management.

The move to vertical marketing systems has arisen as the more progressive channel members have recognised that the value added by channel activities does not only arise from the transformation of raw materials to finished product or the physical movement of goods and services, but from more intangible sources of value associated with a wider range of marketing activities. Historically, manufacturing has been the major contributor to the total added value of a product. The standardisation and mass production of many products, coupled with low cost capacity from countries outside the Community, has meant that the overall share of manufacturing to total added value has decreased in the EC. Increasing customer sophistication has made marketing a more important contributor of value added. The marketing value added component is derived from an improved understanding and recognition of consumer needs and desires, from an ability to design or enhance products and services to satisfy these needs and desires, and from the need to reduce the risk associated with distribution and retailing of the product. It is the commercial distribution sector which provides this 'new' added value for the end customer. The development of powerful brands within the commercial distribution sector is just one reflection of the importance of these marketing related activities.

ISSUES FOR COMMERCIAL DISTRIBUTION IN THE 1990S

Whilst these developments in commercial distribution and the distribution channel are uniformly observed, the pace at which they have occurred within Europe varies. In crude terms the evolution of the vertical marketing system approach to commercial distribution is more common in northern Europe than southern Europe, where traditional channels are still prevalent. Within these markets, however, many examples of vertical marketing systems can be found, just as examples of traditional channels persist in some product and service markets in the north.

Whilst national differences in the structure of commercial distribution persist in the Community and elsewhere, the internationalisation of activities and firms involved in the sector is undoubtedly increasing. The sourcing of products from foreign markets is common, both inside and outside the Community. The mutual recognition of national product standards in 1993, combined with the removal of border controls will provide a further impetus to this activity. As a number of major manufacturers have intensified their attempts to develop pan-European products and brands, pan-European buying groups of retailers have been formed in recent years. More commonly, channel members themselves have developed a presence beyond national boundaries. Retailers, wholesalers and transportation companies have internationalised their activities - examples of which are the French hypermarket chains in Spain, the pan-European activities of Metro/Makro, Christian Salvesen and NFC. These trends are likely to continue, and are not the preserve of the largest companies. Implementation strategies involving joint ventures, franchising and other forms of contractual coordination, plus the highly specialised nature of some commercial activities, allow smaller companies to pursue similar ventures.

On the broad theme of internationalisation, the recent events in Eastern Europe provide a variety of opportunities and raise issues for those involved in all aspects of commercial distribution. At a very simple level these markets are now open to Western providers of distribution services and a number of retailers and wholesalers have already moved into these states via joint ventures and acquisitions. In financial terms, most of this activity must be regarded as long term investment given the problems of adjustment to market-driven economic systems. A more fundamental issue in the East, before one contemplates the likely evolution of distribution channels and vertical marketing systems, is the development of an infrastructure to support the distribution process. Logistical issues in particular must be addressed. Transport infrastructures and storage facilities are inadequate and there is considerable scope for Western European companies to play a leading role in technology transfer. The development of such basic infrastructure is essential to the functioning of any form of market economy.

The benefits of vertical marketing systems have raised the awareness levels of the crucial importance of supply chain management in most businesses. The role of technology in providing and changing the available information in the distribution channel has been fundamental to the realignment of channel members, activities and relationships. A clarification of channel activity has taken place. For example, the identification of product movement in the channel has allowed for further efficiencies in how the channel performs functions and provided the scope to add more value via channel activities. Many of the mundane, regular procedures between channel members have been automated via electronic data interchange (EDI) technology, reducing the scope for human error, the costs of paperwork and speeding up the processes involved. Improved information systems have allowed channel leaders to view the whole channel as a single entity, and the role and importance of selected activities in adding value to products or services has also become clearer. This has led to a change in the activities performed by individual channel members. Often specialist activity suppliers such as brokers, specialist transportation companies or distribution centre managers have been contracted to perform activities previously undertaken by more generalist channel members. One tendency has been for formal, ownership based, vertical integration to give way to contractual forms of vertical integration.

Technology has also generated new information and allowed new forms of data analysis. Also it has allowed the ownership of information to change hands. For example, the consumer data now generated at the point of sale for consumer goods provides retailers with more specific data on consumer demands and preferences, and this information has allowed them to become channel leaders. Viewing the channel as an integrated marketing system has meant that this information has

been used to lead innovation in the channel. In many product markets, innovation and new product development are stimulated 'down stream' by retailers, who increasingly discuss product specifications with suppliers and others involved in the channel. Products and services are now developed to fulfil market demands, rather than markets being sought for existing products and services.

The benefits of managing the distribution channel as a vertical marketing system have allowed some channel members to develop very strong positions in relation to horizontal competitors (other retailers or wholesalers for example). For smaller or less powerful organisations this development has created a real need to consider some form of association to build the scale and combined competencies which the larger dominant organisations have developed. Again technology can play an important role in initiating and managing such associations. However, this raises issues concerning the adoption of information technology by small and medium sized companies. The costs of technology, plus human resource issues such as competencies and training, provide barriers which must be overcome. Alternatively these businesses may establish a unique form of added value which allows them to be differentiated from these market leaders, so that in effect they do not directly complete. Such dominant positions may also be perceived as providing a competitive threat to other members in the distribution channel, particularly if their position and power is used in a traditional, more coercive, way in the channel.

CONCLUSION

In summary, the importance of the commercial distribution sector to the European economy and employment should not be underestimated. Commercial distribution and the activities performed in the distribution channel are crucial to the success of any business. As a sector made up of a number of different organisations and requiring a range of skilled activities, the world of commercial distribution is complex and frequently changing. Undoubtedly, throughout Europe, approaches to the distribution channel are changing, with a move away from a traditional conflict based approach to one regarding the channel as an integrated entity and as a single vertical marketing system.

The role of technology in allowing these changes is important, and provided that such technology is available to all, the benefits of the vertical marketing channel approach are available to both large and small. As the single market comes into being, four broad trends would appear to be evident within the commercial distribution sector. First, a growing internationalisation of the activities and companies involved; second, the potential to play a leading role in developing distribution infrastructures in Eastern Europe; third, the increasing recognition of the importance of supply chain management and the changing role of members as distribution channels are managed as vertical marketing systems; fourth, the issues of horizontal and vertical competition as individual organisations reap the benefits of these changes.

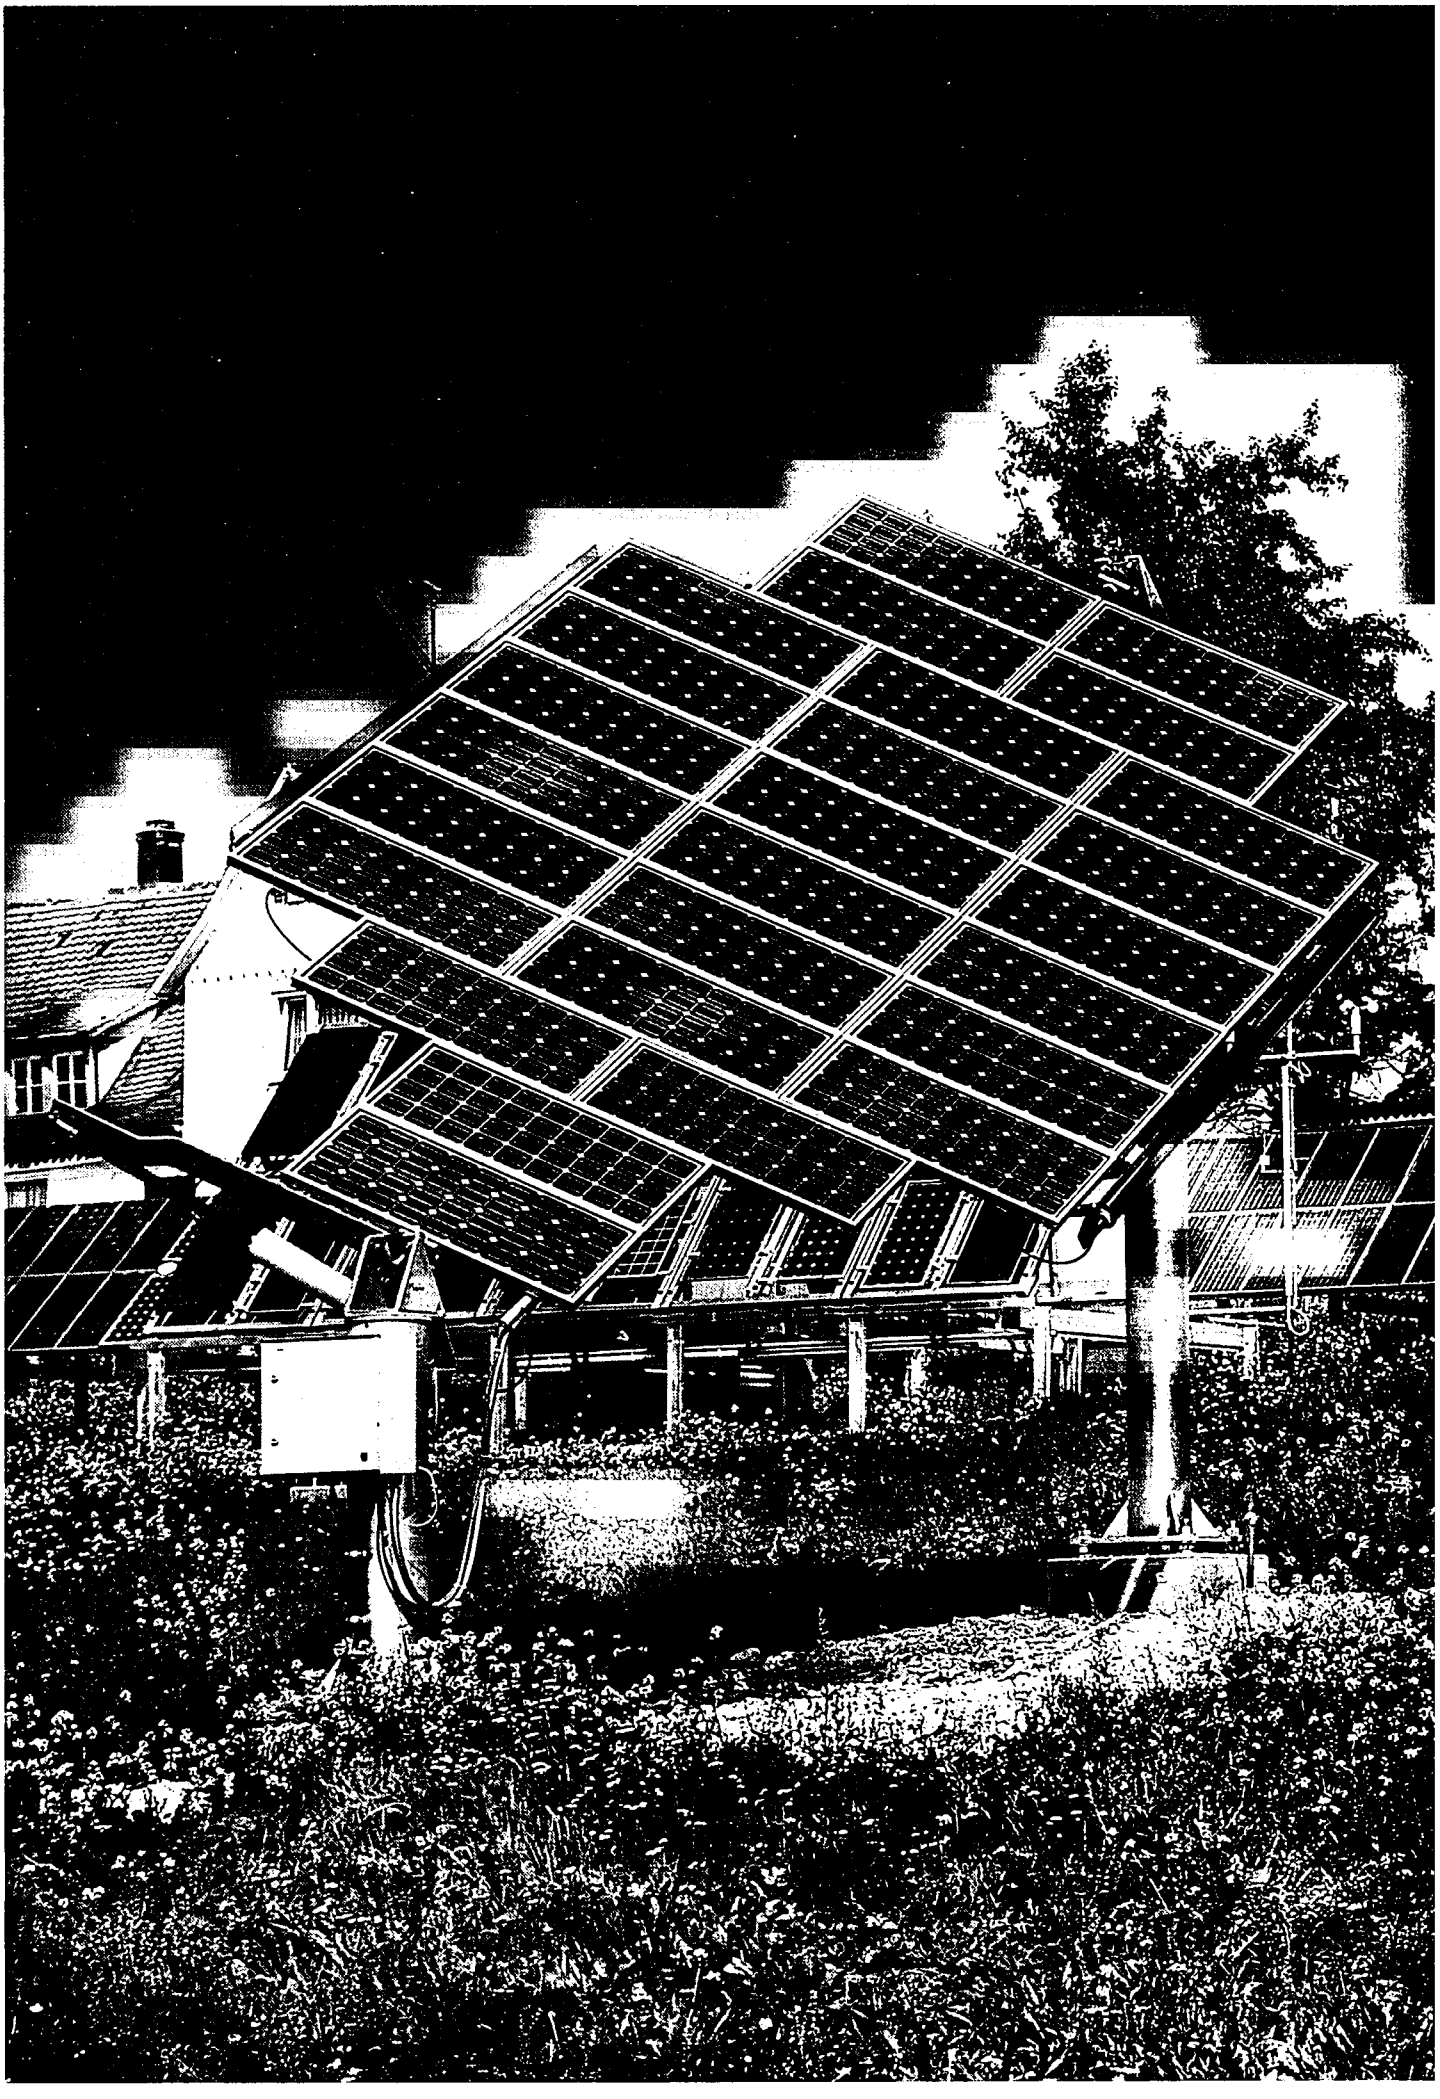
Reviews and Forecasts: Industrial Sectors



Energy
NACE 11, 12, 13, 14, 15, 16

In 1991, primary energy consumption in the EC was about 1 200 million toe, which corresponds to about 15% of total world consumption. At the same time, the EC contributes to about 8% of total world primary energy production. EC primary energy production is dominated by the United Kingdom which accounts for around 36% of the total. Consequently, the EC is a net importer of energy; in 1991 net imports amounted to 617 million toe.
The primary energy mix is dominated by oil, which accounts for about 45% of primary energy demand. Natural gas consumption is increasing fast. In the second half of the 1990s, it will become the second largest share in the fuel mix, replacing coal.

INDUSTRY PROFILE

Description of the sector

The energy industry is composed of the following subsectors: extraction and briqueting of solid fuels (NACE 11); coke ovens (NACE 12); extraction of petroleum and natural gas (NACE 13); oil refining (NACE 14); the nuclear industry (NACE 15); production and distribution of electricity, gas, steam and hot water (NACE 16).

In addition, a description of the renewable energy industry is given in this chapter (not defined by NACE). The inclusion of this industry, though it has a relatively tiny impact on energy supply, reflects the growing appreciation of the contribution that renewable energy can make to reducing carbon dioxide and other atmospheric emissions.

Although different forms of energy are physically very different (gasoline, coal, electricity etc.) they can be accounted for jointly. Their gross calorific value (the amount of heat that can be obtained from each form of energy) makes consolidation possible and all the energy forms can be converted into a common unit. The tonne of oil equivalent (toe) is most commonly used for this purpose.

Capability of substitution amongst forms of energy corresponds to this idea of energy compatibility. For example, heat production in an industrial boiler can be served by coal, oil products, natural gas or electricity. In such a case, one can talk in terms of: final energy consumption, which merely consists of the energy used by end consumers; and primary energy consumption, which takes account of losses along the whole energy chain (production, conversion, transport and distribution) as well as the consumption by concerns within the energy industry itself.

Energy intensity corresponds to the amount of energy consumed per unit of gross domestic product (GDP). Energy intensities vary from country to country depending on the economic background, national energy policies and sectoral and industrial structures.

Main indicators

Between 1985 and 1991, GDP has increased by 19.3%; an average annual increase of 2.8%. Over this period, gross inland consumption increased by 16.8%; an average annual increase of 2.6%. Primary production increased only 5.4% which has resulted in an increase in net imports of 35% between 1985 and 1991, principally from imports of oil and coal.

In the period 1973 to 1985 energy intensity decreased by more than 20%. The EC objective was to reduce energy intensity by a further 20% by 1995. In 1990, the energy intensity of the EC was 7% below the 1985 level, considerably less than half way towards the target. This is partly due to the fall in oil prices in 1985/6, however energy intensity had already begun to flatten out as consumers learnt to live with higher energy prices.

International comparison

The EC is a relatively large consumer of energy. Primary energy consumption in the EC in 1990 was around 1 200 million toe (see Table 7); over 14% of total world primary energy consumption. The USA, the largest energy consumer in the world, accounts for over 24% of total world primary energy consumption. The only country, other than the USA, to consume more energy than the EC is the former USSR with nearly 17% of total world consumption.

In demographic terms, the EC consumes roughly 3.5 toe per head of the population. This corresponds to that of Japan,

Source: Eurostat

where energy consumption is little over 5% of world consumption. The USA has the highest ratio at 7.9 toe per capita, the former USSR consumes around 4.7 toe per capita.

The oil dependency ratio of the EC in primary terms fell to 44.6% in 1990. In Japan, 56.2% of primary energy consumption is derived from oil. The proportion of oil consumed in the USA is slightly less than the EC at 39.5%.

Natural gas, currently undergoing rapid expansion in the EC, still occupies a relatively low proportion of EC primary energy consumption in an international perspective. Compared with the EC's 18.3%, natural gas consumption in the USA is 24.9%. The USSR, home to the largest proven gas reserves in the world, consumes a massive 42.2% of total primary energy consumption as natural gas. In Japan, natural gas takes a 10.3% share in primary energy consumption.

In the EC, coal consumption occupies a 20.5% share in the fuel mix in terms of primary energy. The former USSR consumes a similar percentage. The USA, however, has a coal share in primary energy consumption of 24.2%; reflecting the greater emphasis of coal in the power generating sector. Japan is less coal intensive, with coal accounting for 17.2% of total energy consumption. China, on the other hand, is extremely dependent on coal. Coal contributes a huge 76.7% to primary energy consumption, though inefficiency in combustion processes is a major factor contributing to this.

Hydroelectric power in the EC takes a relatively low share in the fuel mix. At 3.4% of total primary energy consumption, hydro electric power has lower share than the USA (3.6%), the former USSR (4.2%) and Japan (4.8%). The principal reason for this is tight environmental regulations which have curtailed many ambitious projects. These factors are being applied worldwide and suitable sites are becoming scarce.

The EC contributes 7.7% to total world primary energy production. The country contributing the largest share of production is the former USSR with 22.2%. The USA follows close behind with 19.4%. EC primary energy production is dominated by the United Kingdom which accounts for around 36% of the total.

In global terms, the EC is not a significant energy producer and has been in decline since 1987. It is, however, a significant consumer. This results in the EC being 50% dependent on imports for its energy supplies, 7% more than in 1985. Oil production, 78% of which comes from the United Kingdom, is modest in an international context. EC oil production is 27% that of the USA and only 4% of total world oil production.

The EC is a rather more significant producer of natural gas with over 7% of total world natural gas production (73% of which comes from the Netherlands and the United Kingdom). The former USSR is the world's largest producer of natural gas: Soviet natural gas production in 1989 came to over 5 times that of the EC.

Coal production in the EC (45% of which came from the former West Germany and the United Kingdom in 1989) was around 160 million toe: less than a third of the output of the world's largest coal producer, the USA (closely followed by China).

Primary electricity production in the EC accounts for 17% of the world total. The USA accounts for over 20% of world primary electricity production. This is 4.9% of total US energy production. Japan on the other hand, with very small indigenous reserves of fossil fuels, has 73.5% of its total energy production as primary electricity.

Foreign trade

The European Community shows a deficit in the energy trade balance. Net imports were 617 million toe in 1991, i.e. 51% of gross internal consumption which is 7% more than the share in 1985.

EC energy imports have increased since 1988. In the latter part of the 1980s this was due to a slight increase in energy prices and a renewed start up of economic activity. The Gulf War increased crude oil imports for EC refineries working close to capacity. This in turn led to an increase in exports

of refined products which explain the upturn in exports which took place in 1990.

In 1991, around 38% of extra-EC crude oil imports came from the Near or Middle East. Since the Gulf War in 1990 when crude oil imports from Iraq and Kuwait ceased, Saudi Arabia has increase production to cover the difference. This meant that Saudi Arabia's share in extra-EC imports from OPEC countries has risen from 19.7% in 1989 to 31.8% in 1991. Overall, since the end of 1987, extra-EC crude oil imports from OPEC countries have been increasing by 3% per year. The percentage of extra-EC imports coming from the former USSR and eastern Europe has fallen by 4.2% between 1989 and 1991.

MARKET FORCES

Demand

Energy demand by sector

Conservation and structural changes in the 1970s had a great impact on the industrial sector, particularly in energy intensive industries. Industrial energy consumption (including non-energy use) declined 21% between 1973 and 1985. In the residential and commercial sector, despite improvements in the efficiency in end use equipment and in the use of insulation, by 1986 energy consumption in this sector had increased almost 10% on 1973 levels. Since then energy consumption has declined in the residential and commercial sector and in 1989 consumption was down to almost 1983 levels. In 1990, consumption increased slightly, though it remained at roughly the same share of final energy consumption. Energy use in the transport sector increased 24% between 1980 and 1988, an average annual increase of 2.7%, despite improvements in vehicle fuel efficiency. Since then, energy consumption in the transport sector has increased at a rate 1.5% above this, reflecting large increases in the vehicle parc.

As a result of these trends, the share of industry in EC final energy consumption declined from 32% in 1980 to 28% in 1988. Since then the share has remained fairly stable. The transport sector share in final energy consumption overtook industry, absorbing almost 29% in 1990. Over the decade, the transport sector has increased its share by 6.5%. The residential and commercial sector remains the largest with its 34% share.

Energy demand by fuel type

Oil is still the dominant fuel type in the EC, whose major part of demand comes from the transport sector. The share of oil in gross inland energy consumption has declined only slightly since 1985, at a little under 45% in 1990. The main shift away from oil took place in the early 1980s when the share of oil declined almost 9% between 1980 and 1985. The share of oil in the industrial energy mix has been declining more rapidly than that of the residential and commercial sector. In 1990, oil shares in primary energy consumption for these sectors were 34% and 33% respectively and the transport sector nearly completely dependant on oil.

The contribution of natural gas in gross inland consumption has been increasing slowly. Over the last decade it increased its share in the primary fuel mix by 2%, with almost 19% in 1990. The share of electricity has increased greatly over the decade from just over 6% in 1980 to 15.5% in 1990. The

Source: DABLE

growing role of electricity in meeting end-use energy requirements has been accompanied by an increasing penetration of nuclear power in the early 1980s, tailing off in the latter half of the decade. Nuclear energy and hydropower accounted for around 44% of electricity generation in 1990.

In the industrial sector, fuel consumption in the 1980s has been categorised by a marked increase in the share of natural gas. This has been accompanied by the decline in the use of oil products. Residual fuel oil consumption has declined by almost a third over the last decade. In 1980, the share of petroleum products and natural gas in industrial final energy consumption were 37% and 21% respectively. By 1985, the shares had evened up to roughly 24% each. In 1990, natural gas had gained the larger share with 30%, leaving oil products with just over 19%. Consumption of solid fuels has increased only slightly over the decade with a share of 18% in 1990. Electricity consumption has seen a high rate of growth, an average annual rate of increase over the decade of 1.8% (0.5% per year below the average annual growth of GDP).

Supply and competition

EC primary energy production has increased at a lower rate than consumption which has resulted in greater net imports. Production increased by just over 5% between 1985 and 1991 to reach a total of 621 million toe.

The EC coal industry, facing foreign competition with far lower costs, and tough environmental legislation increasing its own costs, has been in steady decline in recent years. Between 1985 and 1991, hard coal production declined by 12.6%. Solid fuels as a whole increased slightly, but that is due to the inclusion of the new Bundesländer in the statistics, pushing up lignite production which had declined by over 4% to 1990.

Oil production, principally from the UK North Sea oil fields, declined by 22.5% between 1985 and 1990. This meant that the share of oil in total primary energy production declined from 26% in 1985 to 19% in 1991. Natural gas production, principally from the United Kingdom and the Netherlands, has increased 13% over the same period. This has resulted in its share in primary energy production increasing slightly to 23% in 1991.

Primary electricity production, mainly due to the bringing on line of nuclear power stations, increased its share in primary production from 24% in 1985 to 28% in 1991.

INDUSTRY STRUCTURE

The EC energy industry is characterised by the existence of large companies, many of them being either de jure or de facto monopolies, especially in the electricity and gas distribution industries. Some have an international dimension (the major oil companies), while others are national, often state owned or with a large participation by the state.

REGIONAL DISTRIBUTION

In the EC as a whole, energy intensity has declined by 7% over the 1985-1990 period. Examination of the regional contributions to this reduction in energy intensity reveals marked differences between member states. Leading the way in energy intensity reductions are, the former West Germany, Denmark and the United Kingdom. In the Mediterranean countries, where there are less opportunities for efficiency gains in space heating (such as through improved insulation), energy efficiency gains have been less marked and intensities have, in some cases (Greece and Portugal), increased. What is apparent in all countries where improvements in energy intensity have been made, is the recent slowdown in the rate of decline.

Regional differences in the consumption of oil and solid fuels are apparent. The countries who are over 50% dependant on oil are: Greece, Spain, Italy, and Portugal. The countries least dependant on oil are the United Kingdom, the Netherlands, France, former West Germany and Belgium. These regional disparities in oil dependence are due to a number of factors: reliance on oil fired electricity generation, the size and age of the vehicle parc, the penetration of oil used for space and other heating requirements, and the associated efficiency. Industry has tended to switch away from heavy fuel oil for its heating requirements over the past decade, so that this factor is becoming less significant.

Regional differences in the consumption of solid fuels can almost exclusively be explained by the share of solid fuels in the power generation sector. As a result of this, Denmark, Greece, Ireland, Germany (including the new Bundesländer) and the United Kingdom, all have a significantly higher share of solid fuels in the fuel mix than the EC average. France, noticeably, has a very low coal dependence due to the small share of coal fired electricity generation in its nuclear dominated power sector. Italy, though it has no nuclear generation, relies more on natural gas and oil for power generation than solid fuels.

ENVIRONMENT

The issue of global warming has been in the forefront in the public debate and in the environmental activities of the Communities. As a first step in the preparation for the Rio de Janeiro conference on Global Warming the joint energy and environment Council decided in October 1990 to stabilise the Community's CO2 emissions in the year 2000 at the 1990 level. No specific measures for achieving this target were adopted by the Council.

Following this, the Commission outlined in October 1991 an EC strategy to limit CO2 emissions and to improve energy efficiency. The Commission considers, that a CO2 policy is needed and that such a policy would work out more efficiently if adopted on the EC level than adopted on the national level. A coordinated carbon tax policy is seen as been critical in order to avoid distortions in the internal market for energy as well as for trade within the Community. The Commission outlines three sets of measures to control CO2 emissions: first, specific measures, including R&D programmes, sector measures and other types of regulatory and voluntary measures; second, fiscal measures; and third, complementary national programmes.

The fiscal measures suggested by the Commission is a tax on energy use corresponding to $10/bbl. The carbon tax element of the total tax should not exceed 50%. The Commission was invited by the Council to present formal tax proposal. In this proposal (submitted to the Council in May 1992) the Commission foresees that the new energy and carbon taxes will be national taxes levied on the top of already existing energy taxes. The new tax policy should only be implemented if other members of the OECD adopt similar taxes or other measures having similar effects, following the principle of "conditionality". The proposal from the Commission foresees that energy intensive industries may obtain tax refunds, if they are confronted with serious difficulties because of competition from non-OECD countries not having imposed carbon taxes or equivalent measures.

REGULATIONS

In order to promote an integrated internal energy market, the Commission is pursuing two lines of action. On the one hand, the Commission is enforcing the existing Community legislation and treaty obligations and in particular the free trade

provisions of the EEC treaty as well as competition and state aid provisions.

The other strategy, which involves regulatory changes and new Community legislation, started being seriously envisaged in the June 1987 Council, when energy ministers asked the Commission to identify the remaining obstacles to the functioning of the internal market for energy and to make proposals for their progressive elimination before the end of 1992. The subsequent Commission report (COM(88)238) was followed by a first set of proposals which have been adopted by the Council and constitute what is referred to as Phase 1 of the creation of an internal market for energy. The measures concern only gas and electricity: June 1990: directive on price transparency for gas and electricity; October 1990: directive on transit of electricity; May 1991: directive on transit of natural gas.

The directive on price transparency provides for collection of information on electricity and natural gas prices for final consumers across the Member States. It is first of all a statistical instrument, which allows comparisons of price levels. The two transit directives give access to the electricity and natural gas transmission grids for transport across a Member State on certain conditions.

Early 1992, the Commission made another series of proposals for Phase 2 of the energy internal market. These proposals have not yet been adopted by the Council. They include three set of measures:

- the liberalisation of electricity generation and the freedom to construct transmission lines for both gas and electricity;
- the unbundling of production, transmission and distribution activities for vertically integrated gas and electricity companies. Unbundling is an accounting concept and does not require changes in the ownership structure;
- the introduction of limited third party access to the gas and electricity networks. Eligible customers will be industrial companies whose annual electricity or natural gas consumption exceeds a specified threshold (100 GWh for electricity and 25 million of m3 for gas). Distribution companies with a market share above a threshold (3% in the case of electricity and 1% in the case of gas) will also have third party access to transmission grids.

RESEARCH AND DEVELOPMENT

The historical improvement of energy efficiency in industry is characterised by several phases that are listed below.

Firstly, changes in the structure, technology and management of energy saving measures. Implementation took place with the advent of higher energy costs in the 1970s. These measures did not require large capital investments and can be termed a stage of rationalisation.

Secondly, investments instigated by improvements in energy performance through design changes. These were made by the energy intensive industries, mainly because market prospects in the 1980s, which were mediocre at the turn of the decade did not encourage them to make investments in capacity increases. Industry consolidated and centred on inward investment with a view to reducing costs.

Thirdly, investments in which improvements in energy efficiency come as one consideration in the decision making process; coupled with capacity increase, product quality improvements and the reduction of other operating costs.

Since the first of the oil crises in 1973, energy efficiency has been one of the principal elements of the EC's energy policy. The Community's commitment to energy efficiency has been evident in the many measures aimed at improving the rational use of energy adopted by energy ministers since 1974. Most notable examples are the Joule and Thermie programmes, still in existence. The effects of these policies, indicated by the decline in energy intensity, have been waning partly as a result of lower crude oil prices. The SAVE (Specific Actions on Vigorous Energy Efficiency) programme will soon be introduced to reignite enthusiasm in energy efficiency.

SAVE will consist of three elements:

- Legal and administrative measures aimed at creating a more positive environment for energy saving. The legal aspects take the form of a single directive encompassing those measures without bearing on the internal energy market. A large measure of freedom will be left for Member States to implement the directive with developments being monitored by the commission, as under the principles of subsidiarity.
- A support programme to assist in expanding or creating an energy saving infrastructure so as to best utilise member states' reserves of technical expertise.
- A network designed to disseminate information and coordinate activities on a community level concerning energy efficiency activities.

The Thermie programme, designed to promote new and innovative energy technology, was approved by the Council of Ministers in 1990 to run for 5 years with an estimated total budget of 700 million ECU. Thermie operates in four areas: the rational use of energy in industry, buildings, transport and the energy industry; renewable energy sources (solar, biomass, waste and wind); solid fuels (combustion and waste); and hydrocarbons (safety and environmental protection, exploration and production).

The EC has recently called for projects for the 1993 round of Thermie funding which will place particular emphasis on energy technologies having a benefit on the environment, especially those reducing emissions of CO_2.

OUTLOOK

In the EC as a whole, gross inland consumption will grow at a rate increasingly below that of GDP as a result of energy efficiency improvements. Total gross inland consumption will increase 19% between 1990 and 2005 on this basis. Energy intensity would decrease 20% on 1985 levels by 2005 on these predictions, though increased effort in conservation on a Member State level and the implementation of the SAVE programme may speed up this decline.

The future primary energy mix will be characterised by the continued dominance of oil, with its share remaining over 40% in 2005. This is predominantly as a result of increasing fuel demand from the transport sector. Moderate oil prices in the short term reduce the incentive for fuel switching away from oil. Demand for oil will be particularly strong in the lower income Member States as stronger economic growth feeds through into energy demand.

Natural gas consumption increases at the fastest rate of all fuels, at over 1.5% above the rate of growth of GDP in the short term to 1% above in the start of the next century. This results in natural gas occupying the second largest share in the fuel mix, replacing coal, in the second half of the 1990s. In 2005, natural gas will have a share of over 24%, 7% more than in 1990. This rapid increase reflects the growing attractiveness of this fuel in terms of environmental and economic considerations. Nuclear power units are coming on stream in France and the United Kingdom, leading to an expected increase in nuclear electricity production. Renewable energies are expected to triple their share though their contribution in absolute terms will remain modest.

In the light of increasing demand, prospects for Community energy production are less favourable. Production costs are

Table 9: Energy
Expected annual gross consumption growth rates (1)

relatively expensive compared to other regions of the world, especially with regard to hard coal. As a result, hard coal production levels will decline appreciably to a level which will be primarily determined by the availability of state aid and other policy measures. Oil and gas production from many existing fields may be depleted in 10 to 15 years time, but production from new fields should largely offset these losses. Consumption will still outpace production, however, and imports will increase as a result. Import dependency in 2005 is likely to increase by around 10% of 1990 levels.

In the industrial sector, final energy consumption is forecast to increase at an average annual growth rate of 0.4%. This is 0.8% per year below the annual growth rate of total final energy consumption in the EC. As a result of this, by 2005, the industrial share is reduced by 4%.

In the long term growth in industrial energy demand is forecast to virtually stagnate. This is as a result of structural changes within the sector as well as due to further efficiency gains: The industrial base is shifting away from the energy intensive industries towards less intensive industries such as electronics. Energy efficiency measures will occur both through price stimulated behavioural changes as well as through policy measures taken at a national and community level.

Written by: DRI Europe

Solid fuels
NACE 11

Solid fuels accounted for 22.5% of gross EC inland energy consumption and 29.7% of EC primary energy production in 1991. Back in 1980, the share held by solid fuels of primary energy production was about 40%. The decline since then has been wholly attributable to hard coal, while the contribution of lignite has been stable until 1991, when the addition of former Eastern Germany caused lignite output to increase by more than 90% and lead to an increase in total solid fuels output. Nevertheless, in terms of contribution to total EC thermal energy, lignite produces just about 39% of that produced by hard coal.

INDUSTRY PROFILE

Description of the sector

NACE 11 covers not only hard coal (NACE 111) but also brown coal or lignite (NACE 112). Solid fuels or "coals" are usually classified according to their rank in terms of their degree of maturity. This ranges from peat, the lowest rank, to lignite, bituminous coal and finally anthracite, the highest rank. Although reference will be made to the total contribution of solid fuels to the EC energy balance, the emphasis in the following pages will be on hard coal.

Main indicators

In 1991 indigenous production of hard coal satisfied 59.3% of EC hard coal consumption, well down from 80.5% a decade earlier. In 1991, about 260 000 people were employed in hard coal production in the EC, that is 57% less than in 1980.

Recent trends

Total EC output amounted to 193.4 million tonnes in 1991, 25.7% lower than the 260.3 million tonnes produced in 1980. The three largest coal-producing countries, the United Kingdom, Germany and Spain, together accounted for 93.4% of total output. Over the 1980s, capacity reductions left production declining in all of these countries except Spain.

International comparison

EC hard coal output has fallen faster than EC hard coal consumption, creating an ever growing need for extra-EC imports.

The EC ranks with Japan as one of the two foremost importers of hard coal. The drastic reduction in European production since the 1960s was due to competition from imported coal and, to a lesser extent, to competitive pressure from cheap hydrocarbons since 1986. Indeed, because of unfavourable geological conditions, which amongst other effects means that European coal is mostly produced from deep underground mines rather then open-cast mines, European coal is expensive to produce and, over the years, its competitive position has grown ever weaker. Less than 10% of European coal is extracted from surface mines, compared to 50% in Australia, 60% in the USA and 85% in Canada. German production costs are particularly high with hard coal deposits at an average depth of 900 m.

High production costs affect the competitive position of European coal against imports from abroad. This was exacerbated by the depreciation of the dollar compared to EC currencies in the late 1980s which rendered imported coal even cheaper in EC currencies.

The financial losses due to growing competition from imported coal and other sources of energy have forced the European coal industry to rationalise, closing the most uneconomic mines, reducing the work force and increasing productivity. The number of underground mines in the EC fell from 479 in 1980 to 265 in 1991.

Foreign trade

In 1991, indigenous coal production accounted for 59.3% of gross coal consumption in 1991, with the remainder being covered by imports and stocks. Over the 1980s, intra-EC trade, fell sharply from 17.0 to 9.0 million tonnes, mainly due to the deterioration in the price competitiveness of EC coal versus coal originating from third countries.

Although complete freedom in the movement of coal between Member States is ensured by the ECSC Treaty provisions, trade policy measures in some countries remain an obstacle to free circulation. These include vertical agreements between national coal producers and consumers, which the Commission is currently examining within the context of the Single Market.

The USA supplies the greatest volume of foreign imports to the EC, providing 50.9 million tonnes, 38.8% of total extra-EC imports in 1991. Imports from South Africa and Australia accounted for 19.4% and 15.1% respectively. The remaining 26.7% was made up by largely of imports from Columbia, Poland, the USSR, Canada and China.

MARKET FORCES

Demand

By far the greatest consumer of solid fuels is thermal power generation which, in 1991, accounted respectively for 62% (hard coal) and for 68% (lignite) of consumption. The second largest market for solid fuels is for the production of coke (90% of which is used by the steel industry) in coking plants. The third largest market is the industrial sector.

During the period 1980-1991, hard coal consumption by power stations increased in the EC of about 11% On the contrary, coking plants reduced their hard coal consumption of about 30% during the same period. In addition to declining steel production, development of electric arc furnace (EAF) based steelworks and technological improvements contributed to the reduction in coke consumption, and therefore in coal consumption in coke manufacturing. EAF based steelworks took a noticeable share of the European market of low-grade long products, recycling significant quantities of scrap. Estimates by the European Coal and Steel Community (ECSC) suggest that a third of the European gross steel production will come out from EAF based steelworks in 1992. This production method does not require coke. Technological improvements aimed at reducing production costs resulted in particular in a reduction in specific coke consumption per tonne of pig iron production in blast furnaces. The major technical change has been the wider use of pulverised coal injection (PCI) in blast furnaces, thereby reducing specific coke consumption: as a result of the PCI technology, there has been a partial substitution of coke by coal in the production of steel. The full potential for use of PCI in Europe has not yet been realised and there is, therefore, scope for further reduction in coke consumption.

The large share of total coal demand accounted for by the power generating sector ensures that this sector will play a critical role in the future of hard coal consumption. Coal's share in the power generation fuel mix is expected to gain between three and four percentage points, largely to make-up for output lost as heavy fuel oil falls increasingly out of favour and as nuclear construction programmes slow down.

The use of hard coal in the industrial sector (which excludes power stations and coking plants) increased steadily over the 1980s from 17.0 to 29.1 million tonnes. The industrial sector includes a many small and medium-sized consumers from various industries, such as cement, chemicals, food, engineering, and with varying energy requirements (for example motive power, high-temperature heat, low-temperature heat). Following the second oil crisis, which demonstrated the need of the EC to reduce its dependence on imported oil and gas as well as to diversify energy sources, there was an upturn in industrial coal consumption. To some extent, this upturn was prompted in by government incentives that were offered to companies to encourage them to switch from oil and gas to coal and also by programmes offered by European coal producers to encourage conversion to coal.

Nonetheless, growth in coal use by the industrial sector was relatively slow and limited to a few countries. An exception was the cement industry, where coal maintains a clear-cut price advantage over other energy sources even without government incentives. Given that coal installations carry a higher capital cost than oil or gas installations, industry will switch from oil and gas to coal only if it expects that the differential of the fuel prices will become sufficiently large. This criteria is reflected in the observation that since the oil price collapse of 1986, conversion from oil and gas to coal has virtually disappeared.

The remaining sector in which significant quantities of hard coal are consumed is the domestic sector which includes households, services and administrative bodies. Solid fuel consumed in this sector is used almost exclusively for space heating, and its consumption is decreasing. Throughout the EC, environmental concern is expected to leave solid fuels losing ground to natural gas. Having accounted for about 6% of the domestic sector fuel mix in 1990, solid fuels should account for only 4% in the year 2000.

As for lignite, because of its low calorific value, transport over long distances is uneconomic. Thus most lignite is mined and consumed on-site or nearby in power stations or briqueting plants. Between 85 and 90% of total lignite was burnt in power stations over the 1980s, whilst the remainder was used to manufacture briquettes and for the preparation of pulverised lignite for use in the industrial market.

Supply and competition

Coal is the most abundant fossil fuel in the world and in the EC. EC proven hard coal reserves are estimated to have stood at 33 billion tonnes at the end of 1989. At current rates of production, this means that hard coal reserves would last about 170 years.

At the end of 1989, EC reserves of sub-bituminous coal and lignite are believed to have stood at about 60 billion tonnes. Some 90% of these reserves were in Germany. The EC has 14% of world reserves of sub-bituminous coal and lignite. Most lignite mined in the EC is extracted by surface or "open cast" methods, which allow higher productivity than underground mining and yield a fuel that is competitive with other fuels used for electricity generation.

Although the EC is reasonably well-endowed with coal, the majority of remaining reserves are deep deposits that require working at very great depths, sometimes in excess of 1 000 metres with heavy-duty, sophisticated equipment, both for technical and safety reasons. This has led to high production costs and has undermined the financial situation of the coal production industry.

Production process

Over the 1980s mine closures and general restructuring saw the number of workers employed in the extraction of hard coal to be reduced by more than half. Much of the decrease is accounted for the work force of British Coal which fell from 293 900 in 1980 to about 58 100 in 1991 (of which 44 600 are colliery employees). The same trend exists in the other producing countries: the ultimate example is provided by Belgium, where coal mining is due to cease at the end of 1992.

Generally, the marginally least productive mine is the mine that is closed. This has lead to a significant increase in productivity in the EC coal mining industry. During the 1985-1991 period, productivity increased substantially, posting a 52% in output per man-hour underground in the EC. Capital expenditure over the past decade has concentrated on developing and implementing the use of new coal mining technology, increasing the share of production held by surface mines, the exploitation of additional reserves, and the closing of uneconomic pits.

Research and development

Although several programmes on health and safety in mines have been successfully undertaken, the emphasis in this report is mainly on technical research in the two key areas of mining technology and product upgrading.

Research in mining technology is concerned with improvement of roadway support techniques (particularly in light of ever greater working depths), monitoring of ventilation, automatic steering of mining machines, and more efficient and safer transport systems for both personnel and materials. Research is also being made into remote control, data processing and modern communication systems, to examine whether and how they can contribute to increased safety, improved working conditions and more efficient mining operations.

Research into product upgrading concerns efficiency and environmental considerations of coal preparation, handling and coking. Both fundamental and applied research is being carried out by mining institutes, universities and laboratories, often on a jointly at an international level basis, and with ECSC financial support amounting to some 60% of total costs.

After the first oil crisis, in 1974, interest grew in the conversion of hard coal and lignite into other materials as a way of reducing dependence on imported hydrocarbons. As a result, several pilot and demonstration programmes were launched by the EC into:

- gasification and liquefaction of solid fuels (including underground gasification);
- substitution of hydrocarbons by solid fuels with fluidised bed combustion, coal-liquid mixtures and combined cycles as key areas of research;
- utilisation of solid fuels within the framework of the EC "JOULE" R&D programme into non-nuclear energy and rational use of energy (1989-92);
- energy production from fossil fuels based on advanced technologies, notably combined cycles, within the recent "Framework programme" (1990-94);
- new and improved clean combustion methods for solid fuels, underground coal gasification and use, treatment or enhancement of wastes arising as a result of the use of solid fuels, within the new demonstration "Thermie" Programme (European Technologies for Energy Management) which was proposed by the Commission to run from 1990-94 and has since been adopted.

INDUSTRY STRUCTURE

Companies

In Belgium, the only mining company, Kempense Steenkolenmijnen, is a public company in which the state has a majority holding. The central fuel buying agency for the Belgian electric utilities is the Pool des Calories.

Most coal imported by Denmark is consumed by the two Danish power companies, Elsam and Elkraft, which buy coal directly on international markets.

The bulk of French coal production is the responsibility of the nationalised company, Charbonnages de France (CdF). A few small mines are operated by Electricité de France or are privately held. The Technical Association for Coal Imports (ATIC) holds a monopoly over coal imports.

Ruhrkohle, the major shareholder in which is VEBA, is the largest of Germany's coal producers controlling the coal activities of the companies EBV, Sophia Jacoba and Auguste Victoria. The second largest company, Saarbegwerke, is owned 74% by the Federal state and 26% by the German Land of Saarland. The other (small) companies are completely privately owned.

The major producer of lignite in Greece is the publicly-owned Public Power Corporation (PPC). Additionally, there are some small privately-owned mine in northern Greece. Greek lignite is burned almost exclusively in PPC's power plants.

In Ireland, coal mined by the privately-held company Arigna Coelieris is burned in a 15 MW power station that is owned by the Electricity Supply Board.

Italy's modest lignite output is found in Tuscany and Umbria. There is also sub-bituminous coal production in Sardinia. Coal imports are the responsibility of ENEL, ENI and Finsider, the steel company.

Coal is produced in Portugal at only one mine. Most of this coal is burned in a power plant belonging to the state-owned power company, EDP.

Coal in Spain is produced by a plethora of companies, more than 200 in total. The leading company, Hunosa, is publicly owned whilst most of the rest are held privately. Sales of coal to power stations are made under the auspices of a contract between Carbunion, the association of coal producing companies, and UNESA, the association of electricity utilities.

Finally, in the United Kingdom the National Coal Board was renamed British Coal as part of the British government's preparations to privatise the coal industry. Most underground mines are owned and operated by British Coal. Open-cast mining is undertaken by private operators, mostly under contract to British coal.

Strategies

The strategies of companies in the EC solid fuels sector are largely shaped by the foreseen decline in EC output, caused by the EC drive for increased competitiveness within the context of the EC state aid policy. Producing companies that wish to continue to exist in the long term have to diversify and rationalise. British Coal, which the British government hopes has enough future to make its privatisation possible, continues to close pits and reduce staff. As a result of the recent Coal Round Table, German producers such as Ruhrkohle will have to make more job cuts and close pits. Charbonnages de France, which faces similar cuts, is liable by law for the livelihood of its mining employees, and thus is investing in developing alternative employment for them. The Spanish coal industry has accepted to implement a restructuring plan which will result in the closure of the uneconomic underground pits and hence in a further reduction of the underground workforce.

In order to cope with the employment effects of the restructuring process and in order to reinforce the reconversion process in the mining regions affected by pit closures, the European Commission established the Community initiative "RECHAR", which is additional to the other Community financial instruments.

REGIONAL DISTRIBUTION

Hard coal is currently mined in significant quantities in four EC members, Germany, Spain France and the United Kingdom. Small quantities are also produced in Portugal and Ireland.

Lignite is mined in the following six EC countries: Germany (280 million tonnes),Greece (50 million tonnes), Spain (15 million tonnes), Ireland (6 million tonnes), Italy (1.6 million tonnes) and France (0.3 million tonnes). The three biggest producers accounted for over 97% of total output in 1991. The greatest change was in Germany, where the addition of eastern German output to total figures for Germany from the start of 1991, lifted output by 160%. This increase was the cause of an increase in EC output of 94% from 1990 to 1991 to 353.0 million tonnes. This increase represents a dramatic change compared to the entire previous decade during which total EC output was fairly stable at between 180 and 190 million tonnes/year.

ENVIRONMENT

As with any fossil-fuel, the production, transformation and use of solid fuels have an impact on the environment. Hard coal and lignite are used mainly for power and heat generation, processes which attract environmental protection measures. In particular, major efforts have been undertaken since the mid-1970s to reduce particulate, SO_2, and NOx emissions from coal- and lignite-burning power plants, albeit at the expense of conversion efficiency and the relative cost of coal-generated electricity. As a result of the installation of flue gas desulphurisation (FDG) and NOx removal units, drastic reductions in the emissions of pollutants have already been achieved. Further improvements are expected over the balance of this decade with the development of a large number of pilot plants that employ advanced methods of clean coal utilisation.

Compared to other fossil fuels, solid fuels emit the highest amount of CO_2 per unit of energy. In order to ensure that the greenhouse gas emissions from coal use are minimised, it is important that, wherever possible, the efficiency of coal utilisation continues to improve. So far, this century, the efficiency of coal-fired power generation has doubled due to technological improvements. Further efficiency gains are expected as combined cycle systems are developed and widely deployed. CO_2 emissions from such plants are as much as 20% lower than from conventional plants. Furthermore, the emplacement of combined heat and power (CHP) plants offers potential CO_2 emissions reductions of more than over 50%.

REGULATIONS

The Treaty establishing the European Coal and Steel Community (ECSC) stipulates under Article 4(c) that national financial support to the coal industry is prohibited. Decision 2064/86 is the latest in a long series of decisions by which state aid is allowed under strict conditions, to be granted to the coal industry. this decision expires on 31 December 1993.

The Treaty also stipulates under Article 55 that the High Authority shall promote technical and economic research relating to the production and increased use of coal and to occupational safety in the coal industry. From 1959 onwards, the ECSC High Authority, and subsequently the European Commission, granted financial aid to that end.

The Treaty establishing the ECSC will expire in June 2002. The European institutions have started discussions on the fu-

ture of the provisions of this Treaty, and their phasing-in to the EC Treaty.

OUTLOOK

Solid fuels face a declining share in both the domestic and industrial sectors, although, as oil and gas prices are expected to rise more quickly than coal prices, the competitive position of coal should improve. Other cleaner fuels are favoured for space heating, whilst the use of coal in industry is linked closely to the fortunes of the iron and steel industry. Coal does, however, have a future in power generation where its share of the fuel mix should rise into the next century, although lignite consumption in power generation is forecast to drop mainly in Eastern Germany for environmental reasons.

Competition from third countries and the general effort to lessen national subsidies means that, by the year 2000, 71% of consumption is forecast to be serviced by imports compared with about 40% in 1991. Meanwhile, coal production should fall between 65 and 75% by the year 2000. Although indigenous production avoids the risk of exchange rate movements and plays an important role in terms of security of supply, it is not competitive at present price levels on the world energy markets. This has become increasingly apparent over recent years. Indeed, the only countries that have significant coal industries now are those that protected them in the past.

Consequently, major developments are expected in the British, Spanish and German coal markets. British Coal faces a hard battle to maintain its contracts with the power generation industry in the United Kingdom which are due for renewal next year. In Germany, cuts in the subsidies to both steam coal and coking coal are being negotiated, which can be expected to lead to cuts in production. Meanwhile, in Spain, a major restructuring of the industry is in progress, along with some improvement of import facilities.

Exploration and production of crude oil and natural gas
NACE 13

Total production of hydrocarbons in the EC stood at 254.9 million tonnes of oil equivalent in 1991. The United Kingdom and the Netherlands are the two leading hydrocarbon producers within the EC accounting for 52% and 26% of output respectively in 1991. The EC depends on imports for about two thirds (in volume) of its total hydrocarbons consumption.

INDUSTRY PROFILE

Description of the sector

NACE 13 comprises three main activities:

- the exploration of both crude oil and natural gas;
- the production of liquid hydrocarbons (i.e. crude oil), condensates and other liquids resulting from gas processing operations;
- the production of natural gas.

Main indicators

Crude oil production in the EC has been declining. In 1991, total output stood at 111.1 million tonnes, 4.1% down on 1990's level of 115.8 million tonnes. Total world production of crude oil was 3 151 million tonnes in 1990, 1.4% higher than in 1989. Output grew in spite of the Gulf crisis as other producers quickly moved to replace lost Kuwaiti and Iraqi output. Of this, the EC's contribution of 115.5 million tonnes represented 3.7% of total world output. Provisional data for 1991 point to a decrease in world output by 1.1% to 3 116 million tonnes. EC output is estimated to have fallen 2.6% in 1991 to 112.5 million tonnes, which left it producing 3.6% of total world output. Total proven world oil reserves have been declining since 1989. They are estimated to have stood at 133.9 billion tonnes at the start of 1992, compared to 135.0 billion tonnes a year earlier and 135.3 billion tonnes in 1990. The EC share of total proven world reserves, at the start of 1992, was 847.1 million tonnes, or 0.6% of the world total. At current rates of production and assuming that no further reserves are found, EC indigenous supplies would be exhausted within eight years.

As for natural gas, from 1990 to 1991, natural gas output in the EC rose 10.9% to 143.8 million toe (tonnes of oil equivalent). Total proven world gas reserves rose 3.8% to 124.1 trillion m^3 (124.1 billion toe) at the start of 1992. At the start of 1992, EC gas reserves accounted for just 2.7% of the world total.

Recent trends

The EC produces only 22% of the oil and about 60% of the natural gas it consumes, being therefore quite dependent on imports for its energy consumption.

During the 1980s, world consumption of natural gas increased by 34%, while during the same period EC consumption has only increased by 12%.

The 1986 oil price collapse led to cutbacks which saw employment in the sector contract by 30% to 35%. In 1989, overall employment within the sector was estimated at 95 000 people. During 1990 and 1991, employment in the sector rose but has since fallen back under the weight of economic slowdowns.

Foreign trade

Extra-EC imports of crude oil stood at a level of 479.9 million tonnes in 1991. In 1990, the crisis in the Gulf reduced imports from the Middle East: while in 1989, 10.9% of imports were from Iraq and Kuwait, in 1990 only 7.6% were from those two countries due to the cessation of Kuwaiti and Iraqi exports following the Iraqi invasion of Kuwait. Over 1991, imports from Kuwait began to recover, but, for the year, totalled just 8.0% of 1990's level. Prior to the conflict in the Gulf, the EC member with greatest reliance on Kuwaiti imports was the Netherlands, which accounted for 48% of EC imports from Kuwait in 1990.

Natural gas imports to the EC totalled 99.3 million toe in 1991. The greatest proportion of imports, 45%, were from the former Soviet Union, followed by Algeria and Norway with 29% and 26% respectively. Despite the upheaval in the former Soviet Union their share of total EC imports grew by 1% from 1990 to 1991. Germany accounted for the greatest proportion of gas imports into the EC in 1991, taking 30.0%, Italy and France were placed second and third, accounting for 25.8% and 24.4% respectively.

Intra-EC trade in the form of imports of gas from the Netherlands increased by 6% from 1989 to 1990 to 1.2 million TJ (terajoule); fully 55% of Dutch exports were to Germany. Germany also accounted for all of the 17.2 thousand TJ worth of Danish intra-EC exports.

MARKET FORCES

Demand

Crude oil and natural gas are used to generate power and/or heat, and are widely used in everyday's life by all industries, households and final consumers. The demand for crude oil and natural gas is characterised by a low price and income elasticity, given their nature of basic input for all industrial activities and for heating purposes. The more recent years have been characterised by the emergence of a substitution process favouring natural gas against crude oil, mainly because of environmental considerations.

Supply and competition

Nearly 90% of EC production originates from fields on the British continental shelf. The high expense of exploiting offshore fields is the main reason why the production cost of EC oil is higher than areas with onshore resources. In 1990, the average cost of producing a barrel of oil from the United Kingdom North Sea was USD 18 per barrel. This figure includes the costs of exploration, development, and operation over expected field lifetimes, and assumes a 10% real rate of return before taxes and royalties.

In 1990, the total number of wells drilled in the EC rose by more than 21% to 715, which represented just 1.2% of the world total of 58 900 wells drilled. In 1991, 236 exploration wells were drilled in the North Sea, 83 of which were appraisal wells.

Production process

The exploration and exploitation of oil and gas requires a highly skilled and experienced work force. The fact that much exploration in the EC takes place offshore only heightens these requirements. By the same token, the EC is in a position to export highly trained and skilled labour in this sector.

R&D activity in the industry has traditionally been significantly high. The nature of R&D programmes reflect the significant proportion of offshore operations undertaken in the upstream oil and gas sector. The high price of crude oil which was maintained during the first half of the 1980s, encouraged research into enhanced recovery methods as well as into improving the tools and operating efficiency of exploration and production, with a view to reducing costs. Most of these pro-

grammes produced excellent results and generated significant growth in terms of services and equipment installation within the EC. However, the 1986 crude price fall hampered much of this research as players in the industry re-evaluated their priorities. Even so, the depth of water and the sometimes harsh operational environment in the North Sea have forced EC companies involved in oil exploration and exploitation in the areas to acquired wealth of experience of offshore operations. Much of this expertise is unparalleled elsewhere in the world.

Since the late 1980s, the increased emphasis on development of smaller fields and deeper fields has led to further technological developments many of which streamline or increase the efficiency of exploitation. Some of the important technological advances made in the North Sea include: improved and streamlined platform designs; development of sophisticated floating production systems; improved platform safety systems such as interlocking fireproofing panels, multimedia on-platform safety monitoring systems, and offshore escape systems; the development of dynamically positioned drilling vessels, capable of operating at depths of 2 000 m; the completion of the first commercial horizontal drilling operation; the development of deep-diving techniques and submarine vessels for underwater activities; the development of sophisticated pigs such as high friction reversible safety pigs; better geophysical data acquisition systems such as real-time processing of short offset 3D data.

INDUSTRY STRUCTURE

Companies

Over the 1980s, the participation of governments in the upstream oil and gas sector steadily decreased. This was largely a reflection of the political agenda of the government of the United Kingdom, the largest EC hydrocarbon producer which allowed the 1981 privatisation of the British National Oil Company (BNOC). Competition to obtain exploration licences grew over the 1980s, with increasingly smaller areas are being allocated to a growing number of companies, many of which were including small independent operators. Nonetheless, the majors did not relinquish their dominant position in exploration and production: this was not entirely due to their own efforts but was also in part due to the damage wrought on many small players by the 1986 price collapse which lead to a concentration of exploration and operating licences particularly in the North Sea. The largest operators in the EC include Shell, Exxon and BP, all three of which are very active in the North Sea (with Shell and Esso involved in many joint ventures on a 50/50 basis), NAM in the Netherlands, BEB in Germany, as well as national oil companies such as ELF, DSM, AGIP and Repsol, which are involved in operations both domestically and elsewhere in the EC.

REGIONAL DISTRIBUTION

The production of crude oil and natural gas is extremely polarised in the EC. The United Kingdom dominates EC crude oil output, accounting in 1991 for some 80% of total EC oil production. As far as natural gas is concerned, the Netherlands alone accounted for 43% of total EC gas production, followed by the United Kingdom with 31%.

ENVIRONMENT

Tight regulations are applied to all offshore operations in the EC, including regulations regarding oil spills, and oil mud and cuttings discharges. Work is also being pursued to define rules and standards for the abandonment of disused offshore installations and structures.

Safety regulations are also very strict, following several accidents which occurred in the North Sea at the end of the 1980s.

REGULATIONS

The process towards the achievement of the Single European market has highlighted some few obstacles to the free movement of goods and services in the EC. Most of barriers to trade which have been addressed by the Commission were various regulations which favoured State companies (i.e. compulsory government participation, reserved areas, local landing obligation) and obligations for local procurement of goods and services. On 11 May 1992, the Commission adopted a proposal for a Council Directive on the conditions for granting and using exploration and production licences.

OUTLOOK

EC crude oil production is expected to remain fairly flat until the middle of the decade as enhanced recovery techniques are applied and small fields are brought on line in the North Sea sector. Later in the decade and into the next century, crude oil production in the EC is forecast to decline steadily. This fall will represent for the most part a drop in United Kingdom output which, by the year 2000, should have slipped back to an annual 87 million tonnes from 95 million tonnes in 1995. Although higher prices should lead to an upturn in exploration activity over the next few years, new finds are considered most unlikely to arrest the long term declining trend in United Kingdom oil output.

The outlook for natural gas is rosier. By the year 2000, Dutch output is expected to have risen 15% from 1991 to 71 million toe, whilst United Kingdom output is expected to stay steady. During the decade after 2000, Dutch output is expected to rise a further 9% but United Kingdom output should start to decline.

Declining indigenous crude oil production is expected to lead to an increased reliance in the EC on natural gas and imports of foreign crude oil. A further complication is the expected drift in EC demand towards lighter, low sulphur products. In addition to prompting more upgrading capacity, this should also lead to a shift towards importing ever lighter and sweeter crudes.

Nuclear fuels
NACE 15

The EC's annual nuclear fuel requirement is about 14 000 tonnes of natural uranium (tU), a figure which is expected to edge slightly higher over the next decade, despite a larger increase in the electro-nuclear capacity. The fact that total requirements are expected to increase at a slower rate than nuclear capacities reflects the employment of better fuel management, the use of plutonium recycling and the recycling of reprocessed uranium.
The EC itself has an annual uranium production of about 3 250 tU, with uranium produced by five Member States: France, Spain, Portugal, Germany and Belgium. France is by far the leading EC producer, with annual production of 2 850 tU in 1990, representing 88% of the total EC output. The EC's requirement for conversion is about the same as its need for natural uranium, with current requirement levels represent 67% of the EC's capacity. The EC energy objectives for 1995 take into account the importance of the nuclear industry to the EC's energy supplies and emphasises the need to ensure that all aspects of planning, construction and the operation of nuclear installations meet optimum safety standards.

INDUSTRY PROFILE

Description of the sector

NACE 15 covers all activities relating to the different stages of the nuclear fuel cycle, i.e. from ore extraction (NACE 151) to fuel element production and processing (NACE 152), according to the following sequence:

- Extraction of uranium and thorium ores;
- Chemical concentration of uranium and thorium ores;
- Refining of uranium and thorium;
- Enrichment of uranium in isotope 235;
- Production of plutonium and uranium 233 through spent fuel reprocessing;
- Preparation of nuclear fuels and fabrication of fuel elements.

MARKET FORCES

Supply and competition

Uranium production

The EC itself has an annual uranium production of about 3 250 tU, with the remainder of its requirements being imported. By-and-large electricity producing companies tend to diversify their sources of supply in order to guard against unexpected interruptions in supply. They have also built-up stockpiles which can vary from two to four years' worth of consumption. According to the latest data from the International Atomic Energy Agency (IAEA), in 1989 the EC paid about 69 ECU per kgU for uranium supplied on long term contracts, down 0.75 ECU per kgU from 1988 level. At 1989 prices, the value of uranium imported into the EC is about 745 million ECU. Within the EC, uranium is produced by five Member States: France, Spain, Portugal, Germany and Belgium.

In France there are four uranium production locations, the details of which are shown in Table 1. Two other sites at Vendée and Lozère were closed in 1989 and 1990 respectively. The remaining sites extract uranium ore from thirty or so mines. France is by far the leading EC producer, with annual production of 2 850 tU in 1990, representing 93% of its production capacity and 88% of the total EC output. It is estimated that the uranium resources that have already been discovered in France, with recoverable costs of up to 72 ECU per kgU, could still maintain production at their present rate for a period of 15 to 20 years. Currently, there are no projects aimed at increasing annual production, with the OECD's Nuclear Energy Agency, projecting a decline in output to around 1 350 tU in the first decade of the 21st century.

In 1990, Spain's annual production was about 215 tU. Almost all this uranium (90%) was produced in the Sealices el Chico mine works at Ciudad Rodrigo from ore extracted from the uranium deposits at Fe. The surplus was produced by the small Haba experimental mine situated at Don Benito (which has an annual output capacity of around 30 tU). The government organisation, Empresa Nacional de Uranio SA (ENUSA), owns and manages the uranium production centres. Deposits have been discovered in Spain, which, at a recovery cost of up to 72 ECU per kgU, amount to a total of 27 000 tU. There are plans to increase the production from Spain's current facilities to about 850 tU per annum by the second half of this decade.

In 1990, uranium production in Portugal was around 110 tU. This uranium was mined from Urgeiria and consists of ore extracted from several deposits in the Upper Beira region. Work has started on a new production centre at Nisa in the Upper Alentejo region, which will process ore from several deposits in the region. Responsibility for uranium production in Portugal lies with the public organisation Empresa Nacional de Uranio (ENU). In Portugal, discovered uranium resources, which can be recovered at a cost of 72 ECU per kgU or less, are sufficient to maintain output at about 370 tU per annum for at least the next twenty years. As Portugal does not have a nuclear power programme of its own it exports its uranium, some of which goés to other Member States. Portugal's uranium output is projected to increase over the course of the next decade, rising to around 150 tU as the new sites start to come on line.

About 30 tU were produced in Germany in 1990, from the underground mine at Ellweiler and from Menzenschwand and Grobschlopen, which are both open cast. Production capacity at Ellweiler is about 125 tU per annum, but limited ore supplies means that capacity is under utilised. There are no plans to increase uranium production in Germany, despite the fact that Grobschlopen deposits could supply a processing facility with 250 tU per annum of uranium ore. The discovered resources, with a recovery cost of up to 72 ECU per kgU, are about 2 500 tU, but the Nuclear Energy Agency believes that German production will be wound down over the next decade and stopped after the year 2000. In former East Germany, there is an estimated 100-500 tU reserves. Production was centred on the Erzgeberge, which straddle the border with Czechoslovakia in the south-eastern part of East Germany. Production was undertaken by SDAG Wismut Uranium Combine, which was reportedly once the third largest uranium producer in the world. All output went to the Soviet Union under an agreement dating back to the immediate post-war period, where the uranium was enriched and made into fuel. Since the beginning of 1991, SDAG has practically stopped mining, with the companies only output coming from slag.

Finally, about 40 tU per annum are produced in Belgium from imported phosphates. Belgium has no known uranium resources and is expected to maintain current rates of production over the foreseeable future.

Conversion of uranium

The EC's requirement for conversion is about the same as its need for natural uranium, which is about 14 000 tonnes per annum, a figure that is anticipated to increase by around 1% per annum over the course of the 1990s. Current requirement levels represent 67% of the EC's capacity, which is also characteristic of the world situation, where total require-

ments amount to less than 60% of total conversion capacity. However, despite strong competition, BNFL (UK) and Comurhex (F) have been able to obtain a significant proportion of the non-EC European countries' markets and have thus been able to ensure adequate utilisation of their facilities. The EC's conversion capacity is expected to increase to around 24 000 tU by the second half of the 1990s, due almost exclusively to expansion in the United Kingdom.

The average conversion cost is about 6.5 ECU per kgU and the turnover in the EC market is about 90 million ECU. The EC attaches more and more importance to the idea of converting reprocessed uranium. In France, Comurhex and Cogema have linked together to form the Urep marketing company with the aim of offering a range of services in this field; meanwhile, in the United Kingdom, BNFL has begun converting reprocessed uranium, recovered from Magnox fuel, at its existing installations.

Uranium enrichment

Uranium enrichment is an important stage, both because it requires advanced technology with a high level of specialised knowledge and because this operation accounts for about 27% of the total cost of the fuel cycle. Production in the EC is in the hands of two multinational groups, Eurodif and Urenco.

France joined forces with Belgium, Italy Spain and Iran in forming Eurodif and in deciding to construct a large enrichment plant at Tricastin (F) using a gaseous diffusion process. The decision to go for a large, high capacity plant was taken in order to obtain the maximum benefit from economies of scale, which are considerable in the case of the gaseous diffusion technique. This choice was also influenced by the optimistic climate towards nuclear energy which reigned after the first oil crisis in 1973.

The Tricastin plant, which began service in 1979, is one of the biggest in the world, with an annual capacity of 10,8 million separative work units (SWU, which is a measure of a plants enrichment potential). A pressurised water reactor (PWR) with a capacity of 1 GW, has an annual requirement of about 25 tonnes of enriched uranium (i.e. uranium containing approximately 3% U_{235}), which in turn requires about 150 tonnes of natural uranium and 95 000 SWUs. Products from the Tricastin plant presently satisfy about 40% of the world's requirements. After the plant reached full production capacity in 1982, it had to trim its rate of output to accommodate a reduction in demand.

Urenco Ltd (UK) was formed on the basis of an equal equity split between Uranit GmbH (D), British Nuclear Fuels Plc (UK) and Ultracentrifuge Nederland (NL). The company was established to develop and apply, on an industrial scale, the technique of enrichment by means of ultra-centrifugation. Urenco coordinates the groups production and marketing, whilst a related company, Centec, coordinates research and development programmes and the exchange of technical information amongst its parent companies.

The present output of the Urenco group of plants is around 2.5 million SWU per annum, although a number of projects are currently being undertaken to increase this output to 4.5 million SWU by the end of the decade. The centrifugation technique does not require the construction of large plants, consequently output can be increased by adding modules as and when necessary. The new units can be built relatively quickly, enabling investment to be planned in relation to contracts obtained, ensuring a high level of plant utilisation.

Production of the fuel elements

Within the EC, fuel production tends to occur on a national basis. Only the Netherlands has to import all its final fuel as it has no production facilities of its own. Of the other countries, Germany is the only one where production capacity is less than its fuel requirements. For the EC as a whole, fuel requirements in 1990 represented 56% of the EC's production capacity, with the United Kingdom having the largest amount of over-capacity (55%).

The largest producers within the EC are Siemens (D), which is capable of producing 400 tU of fuel per year; ANF (previously owned by Exxon) with 400 tU, Agip (I), with 200 tU; ENUSA (E), with 250 tU; BNFL (UK) owns a factory producing fuel for light water reactors (LWR), which has an output of 200 tU; finally FBFC factories (F/B) have an overall output of 1 550 tU in 1991.

The average cost of producing fuel elements is about 230 ECU per kg, which makes that the EC market turnover was about 680 million ECU in 1991. Because of the development of plutonium reprocessing and recycling, the production of plutonium fuel elements is becoming increasingly important. Special plants created in Germany, France and the United Kingdom deploy a total annual output of about 100 tU of mixed oxides.

Storage and reprocessing of discharged fuels

The majority of EC countries (France, United Kingdom, Germany, Belgium, Italy and the Netherlands) have adopted fuel reprocessing after an interim period of storing the spent fuel on the power station site, either in special dry storage facilities or in under-water storage tanks. Spain and a number of countries outside the EC have opted for a longer period of fuel storage (from 20 to 50 years), while it awaits either reprocessing or disposal in deep-lying geological formations. Only France and the United Kingdom have any reprocessing facilities at the moment, a situation that seems unlikely to change in the medium-term.

Fuel reprocessing and waste management represent a considerable proportion of the fuel cost, almost 20% if account is taken of the recovered fissile material value, and 30% if this is not taken into account.

Present experience in the field of reprocessing mainly stems from metallic fuels reprocessing from gas cooled reactors powered by natural uranium. This reactor type was initially adopted by France and the United Kingdom, but no stations of this type are being built at present. To date, more than 40 000 tonnes of uranium from spent fuel of this type have been processed, whilst uranium oxide fuel, reprocessed from LWR and AGR reactors, amounts to around 3 000 tU. Of this latter figure, 2 500 tonnes have been processed at the UP2-400 plant at La Hague in France, the only commercial plant at present in service. This plant's annual output was 400 tonnes in 1989, but a decision to enlarge the site, with the construction of UP3, has added a further 800 tU. Over the next few years there are plans for the UP2 plant's output to be increased to 800 tonnes per annum.

In the United Kingdom, BNFL is building Thorp at Sellafield which will be capable of reprocessing 600 tonnes of irradiated fuel per year and is due to come on line in the mid-1990s. Its output is aimed at covering national requirements as well serving other EC and non-EC countries, the latter including Japan, Switzerland and Sweden.

Meanwhile, Germany has abandoned its plans to build a nuclear reprocessing plant at Wackersdorf and instead has decided to step up its cooperation with France in the joint processing of spent uranium fuel. At the same time, Germany has also signed a reprocessing agreement with BNFL to have fuel reprocessed at Sellafield and closed its only reprocessing plant in 1990.

Production process

To a far greater extent than other energy sources, nuclear energy has to be backed up by a complex combination of industrial activities. These include mining natural uranium, the preparation of nuclear fuel and the construction of sophisticated power stations. These characteristics are reflected in the structure of electricity costs. Only 17% of total costs is expended on fuel: 7% on natural uranium and 10% on the various processing stages of the nuclear cycle. However, 70% of the total cost arises from amortisation of the investment in the power stations, with the remainder (13%) accounted for by the stations operating costs.

The conversion process produces an uranium compound (uranium-hexaflouride) which lends itself to subsequent processing (enrichment and fabrication) and which possesses the required chemical purity. Conversion represents a small part in the total cost of the fuel, about 3%. At present, two companies carry out conversion operations in the EC: BNFL in the United Kingdom and Comurhex in France. Outside the EC, Canada and the United States also have conversion facilities. The EC's conversion capacities are shown in Table 2.

Enrichment is the process in the fuel cycle whereby the fissile isotope content of the uranium is increased. This stage is necessary in the case of fuel destined for light water reactors (either pressurised or boiling) and for advanced gas cooled

Source: NEA

reactors. These types of reactors using enriched uranium, represent over 90% of the installed nuclear capacity within the EC.

Fabrication of the fuel elements comprises the operations during which uranium fluoride, enriched or otherwise, is used to produce the final fuel elements to be introduced into the reactors. This stage represents about 11% of the total fuel cost.

Reprocessing is a complex operation performed on spent fuel discharged from nuclear power stations. This fuel is a mixture of reusable products (unconsummated uranium and plutonium created during the fuel irradiation in the power station's reactor) and fission products which are highly radioactive and are akin to the ashes from using fissile material. The reprocessing operation enables the various products to be separated. In the medium term, by recycling material recovered from thermal nuclear power stations in the reprocessing process, the amount of natural uranium needed by a nuclear power station is reduced. In the long term, there is the possibility that fast breeder reactors will almost totally eliminate the need for additional natural uranium within the confines of the existing industry structure.

ENVIRONMENT

Environmental considerations of the nuclear fuel cycle stem from the discharges of radioactive effluent from nuclear installations. In the attempt to limit these discharges, waste material has been concentrated into solid and solidified forms, which have the characteristics of concentrating radioactive matter and reducing the rate of decay of its radiological toxicity.

There are three main categories of waste:

- Low-level waste, which forms the vast bulk of waste material, amounting to several million cubic metres. The material is either held in surface or near surface installations where the composition of the waste is controlled over a maximum period of 300 years. Alternatively, the waste is stored in underground installations, where the need for verification and measurement of the waste is considered to be limited. Prior to 1982, some of the low-level waste was dumped in special containers at sea. However, following the adoption of the Convention on the Prevention of Marine Pollution from the Dumping of Waste and Other Matters the practice was curtailed.
- Intermediate waste, which can be divided into: a) material that has been contaminated by radionucides, which have a long half life but produce little heat because of their moderate concentration of radioactive elements; and b) material containing and emitters only but of intermediate level of radioactivity having an insignificant heat production.
- Highly active waste, i.e. irradiated fuel discharged from the nuclear reactor and highly active vitrified waste produced after reprocessing of the fuel.

Waste from the latter two categories has a very high radioactive toxicity, which can persist over thousands of years. Given the length of time that containment of such material will require, disposal systems have to be passive, with the long-term safety not dependent on human control or surveillance. Currently, investigations are being concentrated on the burial of the waste in deep stable geological formations, which offer adequate isolation capabilities. On-land sites are the only ones currently under investigation, although research is also being carried out into the possibility of burial in sub-seabed formations.

EURATOM

Another area of concern within the nuclear fuels cycle is to ensure that material is not being diverted for the development of nuclear weapons. Within Europe, the Euratom nuclear safeguards system was established in 1957, with its general objectives defined as ensuring that "nuclear material have not been diverted to purposes other than those for which they were intended".

The Euratom safeguards system is founded in European law, with strong sanctions for infringements. It applies to all civil nuclear materials from the moment they are mined on Community territory or are imported into the EC. Aside from ensuring that the material is not being diverted from peaceful uses, Euratom also checks to see that declarations of specific use are correct and that the suppliers obligations are being respected.

Because the nuclear installations are designed with security and health concerns in mind, the nuclear material is becoming increasingly inaccessible. As a result, Euratom is having to develop advanced measuring instruments and sophisticated computer surveillance systems, which record and react to events that may be of interest to the inspectors.

OUTLOOK

The EC's annual nuclear fuel requirement is expected to edge slightly higher over the next decade, from its current level of 14 000 tU. Uranium production is forecast to fall to around 2 400 tU by the turn of the century, a decline of 26% on 1990s level. Whilst Spanish and Portuguese output are anticipated to increase, a drop in French production of 43% is expected to be responsible for the overall decline.

At the same time, the EC's conversion requirement is anticipated to increase by around 1% per annum over the course of the 1990s and enrichment services should expand from 8.9 million SWU in 1991 to 9.9 million SWU in 1995 and on to over 10 million SWU in the next century. The EC's total fuel requirements is expected to peak in the mid-1990s and then to fall below 2 500 tonnes between the years 2000 and 2010. This should coincide with greater decline in fuel production capacities, such that overall utilisation rates increase towards 80%. Meanwhile, current expansion plans for reprocessing facilities are set to raise capacity to over 4 000 tonnes in the EC by the turn of the century.

It is forecast that the EC's requirements for enrichment services will increase gradually from 8.9 million SWU in 1991 to 9.9 million SWU in 1995 and to over 10 million SWU in the next century. Despite natural uranium requirements increasing only very slightly over the next decade, there should be a greater increase in enrichment requirements. In practice, technical progress on better utilisation of uranium in the reactors does not reduce the need for enrichment services as much as it reduces the need for natural uranium. In addition, recycling reprocessed uranium has no appreciable reduction on enrichment requirements.

A total output of over 200 tonnes of mixed oxides fuel will gradually become necessary during the 1990s in order to satisfy the requirements of the plutonium thermal recycling programmes. Increased output is expected to come from France and the United Kingdom over the next couple of decades, while total fuel requirements are forecast to peak in the mid-1990s, falling below 2 500 tonnes between the years 2000 and 2010. At the same time, production capacities are projected to fall to below 3 100 tonnes and as a result, the utilisation rates should move up towards 80% by the year 2010.

Current expansion plans for reprocessing facilities are set to raise capacity to over 4 000 tonnes by the turn of the century. This should leave about 60% of capacity to deal with the current year's spent fuel and 40% to get through the backlog of material that has been in storage. Taking account of quantities to be reprocessed from countries outside the EC, it is estimated that interim storage requirements could be about 20 000 tU from 1995 to 2000. The necessary storage capacity to cover these requirements is already in place.

The industry is represented at the EC level by: Forum atomique européen (FORATOM). Address: 22 Buckingham Gate, London SW1E 6LB, United Kingdom; tel: (44 71) 828 0116; fax: (44 71) 828 0110.

Refining and distribution of oil products
NACE 14

After spending much of the 1980s concerned about overcapacity, the EC refinery sector is now looking to reverse that trend, while at the same time expanding its upgrading capacity. EC oil demand having fallen over the first half of the 1980s, has since stabilised around 480 million tonnes per year. The displacement of oil has occurred in the industrial, domestic and power generating sectors, whereas road transport remains completely dependent on oil. Unleaded gasoline is now available in all European countries. Its share of the total EC gasoline market has increased from 10% in 1987 to an estimated 41% in 1991.

The number of automotive retail outlets has declined fast. In 1990, there were 127 000 outlets in the EC, which means one quarter less than in 1980. Although competition is stiff, the integrated oil companies, especially the major companies, are regaining ground in retailing because excess refining capacities have disappeared in some countries. Access to supplies is essential for maintaining and expanding a market position in retailing.

INDUSTRY PROFILE

Description of the sector

NACE 14 includes the activities of petroleum refining and the processing of petroleum derivatives, with the exception of petrochemicals. The main products of this activity are refinery gas, liquefied petroleum gas (LPG), aviation fuels, motor gasoline, light distillates, kerosene, diesel and residual fuel oils.

Strictly speaking, units engaged in distribution of oil products and transportation of crude oil are not included in this definition, but given the close relation between the two activities, they are also dealt with in this monograph.

Main indicators

Just over one fifth of crude oil supplies to the EC come from within the EC itself, and of that over 90% is from the North Sea. The remaining supplies are imported from third countries, the level of which continued to increase in 1990, rising by 4.6% over the previous year's level. A marginal increase in the EC crude oil and condensate production was achieved as a result of increases in Denmark, the Netherlands, Italy and the United Kingdom, which were sufficient to offset losses elsewhere. The United Kingdom's level of output rose slightly in 1990 from the previous year's level, increasing by 340 000 tonnes. This increase would have been greater but for the fact of maintenance work that was carried out on a number of the fields during the course of the year.

(1) Includes Intra-EC trade
Source: Eurostat

There was an increase in the EC imports of crude and feedstock, rising by 20.2 million tonnes to 451.5 million tonnes in 1990 from 1989. This reflected the growth in refinery runs in 1990. Total exports from EC countries increased in 1990 from 1989, by 6.7 million tonnes to 66.7 million tonnes. The increase was primarily due to an additional 5.3 million tonnes of exports from the United Kingdom. Of the total volume of exports, 46% was to Member States, while exports to third countries rose by 2.4 million tonnes to 27.3 million tonnes.

Finally, in 1990 the upgrade capacity for the whole of the EC increased by 8.1%, to represent 31.3% of the primary distillation capacity and is believed to have risen to just over 32% in 1991.

Recent trends

Refining

The reduction of the total primary distillation capacity in the EC over the past decade continued in 1990. The total EC capacity fell 9 million tonnes/year to a total capacity of 572 million tonnes/year. The entire reduction was concentrated in the Netherlands, where primary distillation capacity fell 13%. This was the result of the joint venture between BP and Texaco, which involved the combining of the 21.6 million tonnes/year BP refinery at Rotterdam, with the 10.2 million tonnes/year Texaco refinery at Pernis. Rationalisation of the two facilities left a total primary distillation capacity of 22.7 million tonnes/year under the control of the new company called the Netherlands Refining Company.

A couple of further capacity reductions are believed to have occurred in 1991 in Germany and the United Kingdom, though these are expected to be more than offset by increase in capacity in Greece, Italy and the Netherlands. The net increase to the EC primary distillation total is believed to be just under 500 000 tonnes/year in 1991.

Fuel retailing

The 1980s have been characterised by a marked decrease in the number of petrol retail outlets (down 26% during the period 1980-1990). Rationalisation of the retail network did not occur uniformly across countries; the most drastic reductions in number of outlets took place in the Netherlands (-36%), France (-35%) and Germany (-29%), whereas the networks have expanded in number in Greece (+16%) and Spain (+17%). The rationalisation process has increased the competitiveness of those outlets that remain, in part because of increased throughputs. There are still considerable variations in average monthly throughputs across countries; the highest are to be found in Spain, because of the small number of outlets, whereas the average throughputs are approximately five times smaller in Italy, Ireland and Greece, where the rationalisation process has been slower.

Of all the EC countries, Italy has the largest number of service stations (31 000 or 24.5% of the EC total) for only 15% of the EC automotive fuel consumption. Germany has only 14% of EC retail outlets, compared to a level of automotive fuel consumption equal to 23% of the EC total. Spain consumes 9% of the EC transport fuels, but has only 4% of the retail outlets.

Foreign trade

In 1990, imports of refined products into EC countries rose by 6.1 million tonnes. Extra-EC imports accounted for 53% of total imports into the EC. OPEC remained the major supplier of crude and feedstock supplies outside the EC. Provisional

data for 1991 suggests that its share of extra-EC imports has edged up to almost 63%. Other major sources of suppliers were the former Soviet Union, which accounted for 11% of extra-EC imports in 1990, and Norway, whose share was also 11%. Within the OPEC group of countries, there was a dramatic reduction in imports from Kuwait, down over 5.8 million tonnes, and from Iraq, down 9.3 million tonnes. However, these declines were more than offset by increases from Libya (up 9.0 million tonnes), Iran (up 7.5 million tonnes) and Saudi Arabia (up 3.2 million tonnes). Imports of oil products from the USA have shown the greatest increases over the past few years, rising from 6.9 million tonnes in 1989 to 7.7 million tonnes in 1990 and an estimated 11.1 million tonnes in 1991. The share of total imports into EC countries accounted for by the US has risen from 4.1% in 1989 to 6.2% in 1991. Much of this increase has been associated with the growth of imports of gas oil, particularly in 1991.

In terms of the regional spread of imports into the EC, there has been virtually no change in the volume of material imported from the Middle East, while that from the African continent has increased markedly. Supplies from Africa accounted for 32% of extra-EC imports in 1990, compared to 29% in 1989. The Middle East's share has fall to 39% in 1990, from 41% in 1989.

Among the EC countries, the trade balance varies widely in terms of volume. In 1990, the United Kingdom was the only country to show a surplus, having exported 55.6 million tonnes against imports of 52.7 million tonnes. Most of the other countries have a broad deficit, with the notable exception of Denmark where exports of crude and feedstock amounted to 60% of total imports.

MARKET FORCES

Demand

Table 5 shows product consumption for each of the EC countries in 1990. These figures concern only inland deliveries, excluding bunkers and refineries' own consumption. EC oil demand fell by 21% between 1973 and 1985, increased slightly between 1985 and 1988 and has since then stabilised around 480 million tonnes per year. Oil has lost market share to the benefit of solid fuels, natural gas and nuclear power, with the share of oil in total primary energy demand declining from 60% to 44% over the period 1973 to 1989.

The displacement of oil has occurred in the industrial, domestic and power generating sectors whereas road transport remains completely dependent on oil: as a result, 53% of the oil is now consumed in the transport sector, compared to 30% in 1973. These developments in energy and oil use have had a dramatic effect on the structure of oil demand, which has become lighter. The share of heavy fuel oil in inland oil demand has declined from 31% in the mid 1970s, to 29% in 1980 and 16% in 1989, while that of light products (LPG, naphtha and gasoline) has increased from 25% in the mid 1970s to 26% in 1980 and 35% in 1989.

Consumption of middle distillates declined in the second half of the 1970s, but has remained virtually stable throughout the 1980s. The share of middle distillates in inland oil demand has changed less than for the other oil products, but has increased slightly since the mid 1980s to reach 40% in 1989, compared to 36% in the mid-1970s. The increase in the share of middle distillates is due to strong demand for jet fuel and automotive diesel, whereas consumption of heating oil has declined rapidly.

Supply and competition

Prices of crude oil and oil products displayed considerable volatility over the past few years. At the start of 1990, oil product prices were relatively depressed, as demand was relatively weak. The events of August 1990, with the dramatic increase in crude oil prices, were also reflected in the oil product markets, where prices increased sharply. As markets moved closer to the winter heating season, concern was expressed over the supplies of distillate. At the same time, there was concern that imports from the former Soviet Union would be reduced as more product was expected to be consumed in the USSR, leaving less for export.

The confluence of these factors caused distillate prices to rise rapidly at the end of 1990 and into the start of 1991. This price movement was in the opposite direction to that of crude oil prices. This anticipated tightness of the distillate markets, and to some extent the heavy fuel oil markets, ensured that relative to crude oil, product prices rose in January and February, though their actual levels did show a decline. Over the second quarter of 1991, product markets moved towards their seasonal low point, burdened somewhat by relatively high stock levels. Winter demand had not been as strong as anticipated, and imports of distillate from the Soviet Union had not dried up as some traders had feared. Product prices fell both against crude oil prices and in absolute terms over the second quarter.

The economic recession on both sides of the Atlantic meant that demand remained weak over the remainder of 1991 and product prices fell to the start of the third quarter. Prices then rose on the seasonal upturn in demand over the third quarter, as well as from market expectation that economic recovery would add to relatively strong winter demand. Both these latter factors proved to have been overstated by the markets, with the result that oil product prices generally fell from November 1991 to the beginning of 1992.

Gross refinery margins, calculated as a function of quotation of products on the Rotterdam spot market and the spot price of crude oil, witnessed some large swings during the course of 1990 and 1991. Relatively low crude oil prices and high product prices, over the first half of 1990, led to a situation where upgrade and simple refineries were covering their variable costs, and complex refineries were more or less at break even with their total costs. However, the invasion of Kuwait by Iraq, led to a sharp increase in crude oil prices which far outpaced product price movements, with the result that refinery margins moved into the red.

Over the course of the winter of 1990/91, product prices surged ahead of crude prices, causing a sharp reversal in the margins, which rapid moved back into the black on to a peak in February 1991, at levels well in excess of the total cost of refining. Since that peak, margins have again fallen to the point where

simple refineries spent the last three quarters of 1991 oscillating around the zero mark. Complex refineries have tended to do better, remaining above zero and the variable cost line, but remaining below the level to meet total costs. This situation is encouraging the move towards more complex units. However, the current situation is still not favourable for an expansion of the refinery sector's total primary distillation capacity. The fact that the rationalisation process has been reversed over the past couple of years does not therefore reflect prevailing market conditions, but rather the medium to long-term outlook.

Consumer prices vary widely across Member States. The major determinant in the differences in consumer prices across the EC is the level of taxes applied to oil products. At the Ecofin Council meeting of 19 October 1992, the directive concerning the harmonisation of excise taxes was adopted. The following minima have been agreed and should be put in application as of 1 January 1993: leaded gasoline 337 ECU/thousand litres; unleaded gasoline 287 ECU/thousand litres; automotive diesel 245 ECU/thousand litres; heavy fuel oil 13 ECU/thousand kilos; and heating oil, 18 ECU/thousand litres. The Member States which, as of the first of January 1991, did not apply an excise tax on heating oil, are authorised to continue to apply a rate of zero on the condition that they pay a control tax of 5 ECU per thousand litres as of 1 January 1993. The minimum rate for LPG and methane used as transport fuel is fixed at 100 ECU per tonne and that on transport kerosene is fixed at 245 ECU per 1000 litres.

Only Luxembourg has a lower rate than the advised minimum on premium leaded gasoline. Two countries (Luxembourg and the Netherlands) have a lower excise tax for automotive diesel fuel. Concerning heavy fuel, Belgium applies a zero rate of tax. For the period from 1 January 1993 to 31 December 1994, Luxembourg can apply a minimum rate of excise of 292 ECU per 1000 litres for super leaded gasoline, 242 ECU per 1000 litres for unleaded gasoline and 195 ECU per 1000 litres for automotive diesel fuel. Greece will benefit from the same treatment for automotive diesel fuel. Because only minima have been set, the final agreement will have only a small effect on consumer prices of oil products in Member States, and therefore on the level and structure of oil consumption.

As regards value added taxes (VAT) harmonisation for the oil products, a transitional agreement has been formulated. Following the adoption of the proposal for directive on the harmonisation of value added tax (VAT) rates at the Ecofin Council meeting of 19 October 1992, petroleum products were submitted to the normal rate, that is, a minimum tax of 15%. Nevertheless, Member States which applied a lower rate on petroleum products as of 1 January 1991 are authorised to apply a minimum rate of 12% from 1 January 1993, to 31 December 1996. The United Kingdom which applies a zero rate on diesel oil for heating can maintain this rate until 31 December 1996.

Production process

Within the EC, each Member State has widely differing production structures. Germany, France and the United Kingdom are characterised by their low proportion of heavy fuel oil and by a relatively high proportion of gasoline output. At the other extreme, Greece, Portugal and Ireland have a refinery sector that is characterised by a high proportion of heavy

fuel oil production and relatively low light-end output. Over the past few years the move towards increased upgrade capacity and product quality improvement has continued to shift the structure of refinery production away from heavy oil products in favour of the light ones.

Any assessment of the utilisation rates of primary distillation capacity poses a statistical problem due to the increase in the share of feedstocks in refinery throughputs. Some of these semi-finished products are redistilled while others go directly into secondary plants, the problem being that the division between the two categories is not recorded in a number of EC countries. This is why in its communication (Com (88) 491) to the Council on the oil market and the refining industry in the EC, the Commission presented a range consisting of a "maximum" (the relation of total input for transformation in the refineries to distillation capacity) and a "minimum" (calculated solely on processed crude oil).

The variations between these two points differs from country to country and from year to year, as refiners switch from crude oil to semi-finished products depending on their relative prices. These variations are related to the prevailing economic, seasonal and climatic conditions in each country, as well as turnarounds and the opportunities for exports of key products such as gasoline to the United States. European refineries went into turnarounds early in 1990, causing utilisation rates to fall to around 74% in February and March, before climbing to a summer peak. In 1991, turnarounds occurred later in the year, with the utilisation rate dropping to a low of 77% in April and May, before again moving to a summer peak. Overall, 1991 witnessed smaller variations in the monthly utilisation rate, as refineries responded to higher levels of demand and postponed their turnarounds until the start of 1992.

INDUSTRY STRUCTURE

Companies

Refining

After spending much of the 1980s concerned about the over-capacity in the refinery sector, Europe's refinery sector is now expanding its upgrading capacity. The Mobil refinery at Wilhelmshaven (D) has been bought back into operation. The refinery was acquired by Beta Refining & Marketing, a company jointly owned by the trading company Bulk Oil and the French trading firm Dreyfus.

The Schewdt refinery, the largest refinery in eastern Germany, was bought in 1991 by a consortium of Veba (37.5%), DEA (37.5%) and Agip/Elf/Total (25%). The Leuna and Zeitz refinery, were packaged with Minol and sold to a consortium of Elf Aquitaine, Thyssen and SB Kauf. Part of the deal requires that the new owners of the refinery provide the Leuna chemical plant with competitively priced feedstock and a pipeline link to the Baltic.

Prior to this, in the Netherlands, a new joint-venture company between BP (65%) and Texaco (35%) was created in November 1989 to link up BP's Europoort refinery with Texaco's Pernis refinery. Texaco allows BP to use it catalytic reforming process to boost octane levels, while BP lets Texaco use its catalytic cracker to produce more light-ends.

The process of change in state monopolies has continued over the past few years. In Greece the refinery sector remains in the hands of the state, but a three phase plan has been developed to liberalise the markets, including a in the first stage the removal of counter cyclical tax and the lifting of controls on refinery base prices. The second phase will remove all remaining prices and margins regulations and the third phase will allow for the importation of oil products.

In Spain, the refinery and product distribution sectors are being liberalised, with Campsa being split up amongst the refineries that own the company. In late 1992, a new law was being discussed which would permit this opening of the market. At the same time, the number of operators in the parallel system has increased, despite the continued restrictions imposed by the government's quotas. All the product prices have been liberalised, although gasoline, gas oils and heavy fuel oil prices must remain below a state set maximum price which is reassessed every fifteen days.

In France, a reform bill was being discussed in late 1992 that would lift some of the restrictions relating to crude oil imports and change the system of securing stock reserves.

In Portugal, the oil product markets were liberalised at the start of 1991, including the system of market quotas. This has put Portugal's three refineries under pressure to modernise and expand their upgrade capacity to enable them to compete with imports. As part of the process, the Cabo Ruivo refinery no longer distils crude oil, but is being reconfigured to form a blending plant and distribution centre.

Fuel retailing

The major companies continue to have a dominant position, even during years of recession, as they have continued to invest large amounts to protect their market share. They now flag nearly 30% of the EC retail outlets. Shell (NL/UK) has the dominant market share, closely followed by BP (UK). Some of the traditionally national oil companies have now spread their presence throughout Europe: Total is present in eight countries for a market share of 4.4%. A newcomer to the European downstream business is Kuwait Oil, which introduced the Q8 brand in 1986 and now owns 4.5% of the EC retail outlets. Kuwait Oil is now the largest retailer in Denmark and is a major presence in Italy, the United Kingdom, Belgium and the Netherlands. Although competition is stiff, the integrated oil companies, especially the major ones, are regaining ground in retailing because excess refining capacities have disappeared in some countries. Access to supplies is essential for maintaining and expanding a market position in retailing.

Overall, in the countries where regulations permit, supermarkets have an important market share, but nowhere it is as large as in France where 33% of automotive fuels are sold by supermarkets (the market share is as high as 39% for gasoline alone). In the United Kingdom, their market share is 12% but is expected to increase to 20% by the mid 1990s. The other two countries where hypermarkets have a substantial market share are Belgium and Germany, where it is 10%, though this share is not expected to increase much more in the near future. During 1990, some supermarkets have sold their service stations to oil companies: this is the case of Casino (F) which sold to Shell and Agip (I).

In parallel with these developments, there has been a trend toward concentration. During 1990, Elf (F) was the most aggressive acquirer, with acquisitions in Spain and the United Kingdom. Shell, Agip and Norsk Hydro (N) also made acquisitions in the EC retail business.

ENVIRONMENT

An EC directive formulated in 1985 required that unleaded gasoline be marketed in all Member States from 1 October 1989. This date coincided with the date at which all large cars produced (2 litres) were to be equipped with catalytic converters. Unleaded gasoline is now widely available in all European countries. Moreover, all cars produced after 1 October 1990, whether they are equipped with catalytic converters or not, must be able to run on unleaded gasoline (Eurograde 95 RON). Although there have been some derogations for old-type engines, 90% of cars produced can run on Eurograde.

Amendments to the directive permit Member States to ban leaded regular grades, which Germany and Luxembourg have done, while Belgium is in the process of implementing a ban. The directive encourages Member States to introduce tax incentives in favour of unleaded gasoline in order to accelerate its penetration, which all countries have done. In addition, in order to allow a larger proportion of the existing car park to run on unleaded gasoline, most oil companies have introduced an unleaded fuel with a higher octane level, Super-premium unleaded (98 RON). Super-premium is marketed in most countries, with the exception of Greece, Portugal, Spain and Italy.

The introduction of tax incentives and of high octane grades of unleaded gasoline have led to a rapid penetration of unleaded in the gasoline market: its share increased from less than 10% in 1987 to an estimated 41% in 1991. Concurrently, sales of leaded regular have nearly disappeared in several countries even if they are not banned (United Kingdom, Denmark, Netherlands). Nevertheless, the rate of penetration of unleaded varies widely across countries, because of different tax incentives, government policies and the structure of the car park. The penetration is as high as 80% in Germany and still very small in Spain and Greece; it is accelerating in United Kingdom, Belgium and France.

From the beginning of 1993, all new gasoline-powered cars registered in the EC will have to be fitted with three-way catalytic converters, in order to meet exhaust emissions standards. This presages in favour of the universal use of unleaded gasoline, although the point at which this occurs will depend on the rate at which owners of pre-1993 cars opt for unleaded fuel and the rate at which old cars, able to use only leaded fuel, are scrapped. The effect will be relatively small in Germany, Denmark and the Netherlands, where the purchase of catalyst-equipped cars has been favoured for some time by tax incentives. However, in other countries, the new emission rules will give a significant push to sales of unleaded gasoline.

REGULATIONS

EC legislation relating to fuel quality addresses the content of lead, benzene and oxygenates of gasoline and the sulphur content of diesel and other gas oils (national standards specify other fuel properties). The European Standard Organisation (CEN) has developed European specifications for unleaded gasoline (EN228). CEN is working on specifications for automotive diesel and LPG, as well as on more comprehensive gasoline specifications.

- Lead content of gasoline: the maximum authorised lead level in leaded gasoline is 0.4g/litre, but EC countries are encouraged to use a maximum limit of 0.15 g/litre. All EC countries, except Portugal, have now adopted this lower limit.
- Benzene: the maximum benzene content of gasoline is set at 5% for both leaded and unleaded grades.
- Oxygenates: a directive requires that Member States permit fuel blends containing oxygenates and specifies the maximum content. If this maximum is exceeded, then the pumps must be clearly labelled. Most countries restrict limits below the maximum, with only four countries (Belgium, Denmark, Ireland, Luxembourg) permitting levels equal to, or exceeding, this level .

- EN228: CEN EN228 specifies the octane quality of Euro-grade unleaded (95 RON/85 MON), the benzene content (5% vol. max.) and the lead content (0.013g/litre). The sulphur content is currently set at 0.1% weight maximum, but will be reduced to 0.05% by 1995. Volatility and density specifications have also been agreed.
- Sulphur in gas oil: a 1987 directive specifies a maximum level of sulphur in gas oil of 0.3% weight, except for gas oil used in shipping for further processing; the directive allows Member States to reduce the sulphur content to 0.2% if necessary for environment or health reasons. Five EC countries have already reduced the sulphur content to 0.2%. A draft directive submitted in June 1991 calls for a reduction in the sulphur content of all gas oils to 0.2% by 1 October 1994. A further reduction is to be implemented by 1 October 1996 for the sulphur content of automotive diesel (to 0.05% by weight), as this is required to meet the exhaust emissions limits for diesel engines. The Council asked the Commission to propose a further reduction of the sulphur content of gas oil for industry, space heating and bunkers, and sulphur limits for aircraft kerosene. The amended draft directive also requires that the distributed automotive diesel of 0.05% sulphur be gradually available by 1 October 1995. The directive is in the process of being approved.

CONTROL OF RESERVE STOCKS

The reserve stocks consist of quantities of oil products which can be called upon at any time by a country to bridge a temporary shortage situation or difficulties in the sourcing of hydrocarbons. Directive 68/414 required the creation and maintenance of reserve stocks at EC level representing initially 65 days; this was then increased from 1 January 1975 to 90 days' consumption for three categories of product: petrol, jet propulsion fuel and diesel, and heating and heavy fuel oils. Since the directive merely imposed the obligation to achieve an end result, the EC members have over the years established systems quite different from one another and which can be divided into two categories depending on the existence or otherwise of a centralised stockpiling authority.

EC countries with a central reserves administration

Four countries have a central reserves administration: Denmark, Germany, France and the Netherlands.

Denmark has had legislation governing reserve stocks for over 30 years now; the reserves are administered by the Foreningen Danske Olieberedskabslager (FDO), a non-profit making foundation established in 1959 with voluntary membership. The FDO is financed by contributions from its members. The 1959 legislation related chiefly to fuels and was amended when Denmark joined the EC by the law of the 24 May 1972 which widened the stockpiling commitment to the three product categories specified in the EC directive. Currently, Denmark has 120 days' reserves of stocks.

In Germany, the lion's share of the stockpiling requirement of 80 days' consumption is administered by the Erdölbevorratungsverband (EBV), a national body with public corporation status financed by means of a special tax. Up to 90% of the reserves stocked by the EBV are its own property. The refineries themselves ensure an additional 15 days on their own initiative. In addition, the federal government has amassed stocks of crude oil equivalent to 30 days' supply.

France long ago established legislation requiring the stockpiling of oil reserves (the commitments to create and maintain safety reserves can be traced back to the law of the 10 January 1925). More recently (1988) France established a central reserve administration, the Société Anonyme de Gestion des Stocks de Sécurité (SAGESS). This is a private limited company with a special fiscal and legal status. Its shareholders must be all those companies (refiners and independents) who hold a special licence to import and market oil products; its operating costs are defrayed by the contributions paid by the shareholders. SAGESS is responsible for half the total legal stockpiling requirements, i.e. 45 days, twelve of which it actually owns and the balance being covered by allocations; the remaining 45 days are the responsibility of special licensees.

In the Netherlands the collective administration of stocks is entrusted since 1986 to the Central Organ Vorraadsvorming Ardolie-produkten (COVA), a public body which maintains 70 days of reserves of the light and medium distillation fractions. COVA is financed out of a levy on oil products additional to excise tax. The refineries are required to maintain a 50 day stockpile and sixteen and two-thirds days are maintained by the independents. The stockpiling of heavy fuel oils has been administered since the 1 January 1987 by the Union of electricity generators (SEP).

EC countries with no central reserves administration

In Belgium compulsory stockpiling represents one quarter of domestic supplies made during the previous calendar year; the responsibility is assumed by refineries and importers who are both required to maintain 90 days.

In Greece the distributors are principally required to maintain 90 days' reserve stocks, however this obligation may be assumed by the local refineries which supply the distributors. Distributors only commit themselves to the products which they actually import.

In Spain the requirement to hold 90 days of oil reserves is spread evenly between the refinery companies and Campsa, a distribution company created by state monopoly.

In Ireland stockpiling is ensured by importers by means of coverage contracts signed with the state refinery company located at Whitegate.

In Italy the compulsory 90 day reserves are administered by various different bodies: the refiners, importers, ENEL the national electricity generating company as well as the government itself whose strategic stocks are handled by ENI.

The Portuguese oil reserves are administered by import licence holders (refineries, importer-distributors) and represent 120 days of consumption although part of these may be provided by the state corporation Petrogal.

The target of 90 days of oil reserves is cut by 15% in the United Kingdom, owing to its status as an oil producer. Two groups of operators are required to maintain reserves: first the refineries (76.5 days); second, importers, distributors and consumers importing more than 50 000 tonnes per annum for their own account are required to maintain 66 days reserves.

OUTLOOK

In the wake of the dramatic changes that have occurred within the oil sector over the past few years and reflecting the uncertainty over future developments, oil prices are forecast to remain subject to a high degree of volatility over the short-term. Excess supplies and weak demand are expected to lead to relatively low crude and product prices in the near future, although in the longer term real oil prices are forecast to increase towards their 1990 peak by the middle of the decade.

The structure of oil product demand is expected to shift in favour of middle distillates. The previous move to lighter products is now almost stabilised, while the trend away from heavy-end products is set to continue. By 1995, the share of unleaded gasoline in the EC is expected to exceed 75%. Although there will continue to be wide variations from country to country in the market share, the difference between countries is expected to be far less than in 1990. Overall though, the

share of oil in EC primary energy demand is forecast to decline further over the next decade, giving way to natural gas.

The refinery sector is expected to see a very modest expansion of primary distillation capacity. However, the upgrade capacity within the EC is expected to increase at a faster rate, reflecting the move towards higher quality products and the shift in oil product demand away from the heavy-end. The retailing market is expected to move into a more sophisticated and increased product specification era, with the emphasis on product quality and performance, as well as on brand differentiation. The trend towards diversification, automation and increased size of sites is also expected to continue.

Written by: DRI Europe
The industry is represented at the EC level by: Comité Professionnel du Petrole (CPDP). Address: B.P. 282, F-92505 Rueil-Malmaison Cedex; tel: (33 1) 47 08 94 84; fax: (33 1) 47 08 10 57.

Electricity generation and distribution

NACE 161

Electricity consumption in the EC grew by 30% in the 1980-1990 period, while the electricity intensity of GDP has been generally stable from the second half of the 1980s.
Nuclear contribution to the electricity sector has risen considerably over the past two decades, but generating capacity is expected to peak in the latter part of the 1990s and then decline at the start of the 21st century. Electricity production from renewable sources remains very isolated, limited by high investment costs and increasing concerns over siting. Constraints on these primary energy sources will mean that increases in demand over the next decade or so will have to be met by increases in conventional thermal capacity.
On the distribution side of the industry, the Commission is pursuing its plans to develop an internal electricity market, with the proposal for a further two stages to be added to the directives on transit and price transparency. The new proposals include the introduction of third party access on a limited scale.

INDUSTRY PROFILE

Description of the sector

NACE 161 includes generation of electric power destined for public use from thermal energy (161.1), hydro-electric energy (161.2) and nuclear energy (161.3), distribution of electricity (161.4) and generation of electricity for its own consumption (161.5 to 161.7).

Main indicators

Three countries account for two thirds of the total EC electricity production: Germany (27%), France (23%) and the United Kingdom (16%). If we add Italy (11.5%) and Spain (8%) to the other three, then their combined electricity production accounts for over 85% of the total. Over the course of the 1980s, France has dramatically increased its share of total EC electricity production, up from just over 18% in 1980. This increase reflects the French policy aimed at reducing its dependence on imported oil and promoting increased electricity use in conjunction with the development of nuclear power plants. The other countries where there has been a noticeable increase in electricity production over the course of the 1980s, have been Greece and Portugal.

Electricity consumption increased by 30% from 1980 to 1990, an average yearly growth rate of 2.5%, which represents a slow down compared with the correspondent rate of 3.7% from 1970 to 1980. However, the rate of growth of consumption has been greater over the second half of the 1980s than over the first half, and in recent years has grown at a faster rate than in the 1970s.

Recent trends

The electricity intensity of GDP, having increased between 1970 and 1985, has been relatively stable over the second half of the 1980s, although across countries the trend has varied widely.

Several factors explain why electricity intensity in the EC stopped increasing after 1986:

- the oil price collapse and the general decline in fossil fuel prices, while electricity prices remained much more stable, which resulted in electricity becoming less competitive;
- the saturation effects in some applications and some countries. This is most evident in the northern EC Member States, while there is scope left for increased penetration of electrical appliances in the Mediterranean area;
- the development of more efficient appliances and processes in general.

Most of these factors will continue to have an impact on electricity consumption in the future, though the catch-up effect of increased electrical appliance utilisation in southern Europe, coupled with some fuel switching to electricity in the industrial sector, should ensure that electricity intensity remains stable over the next few years. However, saturation effects will progressively become more widespread, with the result that the electricity intensity of GDP should start to decline over the second half of the 1990s.

Electricity has increased its penetration of total energy consumption, rising from 14.7% in 1980 to 18.2% in 1990. Electricity's share of final energy consumption varies substantially across countries, reflecting the structure of industry, the level of automation in industry, the use of electricity for space heating and the level of appliance ownership in the domestic sector, amongst other factors.

Within the EC, Spain and France have the highest level of electricity penetration, while Luxembourg, the Netherlands and Ireland have the lowest. In France, there is a high level of electricity for space heating, whilst in Luxembourg, the low share of electricity reflects the dominance of coal use in the important iron and steel sector.

Foreign trade

Electricity trade between EC and non-EC countries remains very low, while the supply of electricity between Member States has noticeably increased over the past fifteen years. In 1990, the trade in electricity by the Member States increased to 215.5 TWh, compared to 200.5 TWh in 1989 and 58 TWh in 1973. The amount of electricity traded has risen faster than the rate of increase of consumption, such that in 1990 it accounted for 12% of gross inland consumption, up 2% from 1987.

France is the major net exporter of electricity within the EC; Belgium, Denmark and Spain have also recorded small net exports in 1990. France's net exports amount to about 12% of the country's gross inland consumption, a situation that resulted from the development of excess nuclear power capacity in France. The major export markets for France are the United Kingdom, Italy, Germany and Switzerland.

MARKET FORCES

Supply and competition

Electricity production from renewable sources remains very isolated, despite efforts at the EC and national government level to promote and subsidise their development. So far only geothermal and wind power have made inroads into the energy sector, though across the EC there are wide variations in the use of renewable sources. Of these two energy forms, Denmark has the highest share of wind power, 1% of total generation, while Italy has the highest EC level of geothermal power, 1.5% of total generation. The principal limitations to the development of renewable sources are given by high investment costs, though siting is becoming an increasing concern in a number of countries.

No new orders for construction of nuclear power plants have been placed in Europe from 1987 onwards. The completion of capacity currently under construction and firmly committed capacity will lead to a peak in nuclear generation capacity and production in Western Europe in the late 1990s. At the same time, no new plants are expected to be commissioned in the late 1990s. Orders for new plants in France and the

United Kingdom after the year 2000 will not be sufficient to offset the steady decline in generation capacity (though life-extension programmes are expected to draw out operating spans by as much as 40 years for most reactors).

The slowly declining shares of nuclear and hydro/geothermal power over the next decade will allow the share of conventional thermal power to expand. Consequently, the major capacity development questions facing the Western European electricity supply industry surround the refurbishing, replacement, and expansion of conventional thermal power generation capacity. In 1990, the conventional thermal generation fuel mix in the EC was split roughly 65% solid fuels, 18% oil products and 13% natural gas, with 4% to other thermal sources. Fossil fuel use in conventional thermal power plants continues to dominate the energy input mix within the power generating sector. Nevertheless, their share has declined substantially over the past two decades, from 83% in 1973 to 67% in 1991. By-and-large it has been the increase in nuclear power generation that has caused the decline in fossil fuel's share of the total energy input into the sector. Nuclear's share has risen from 5.4% in 1973 to 33.2% for the EC as a whole in 1991.

In the meantime, hydro-electric power, having maintained a relatively stable share of the total energy input over the 1970s and first half of the 1980s, has seen its share edge lower. As electricity production increases over the next decade, it is expected that hydro-electric's share of the total will fall further. The scope for additional hydro-electric development is limited for a variety of political, economic, and environmental reasons, with the result that the remaining exploitable hydro resources will see limited development throughout most of the EC. Significant developments are only expected to occur in the Mediterranean area.

Environmental arguments against the continued development of solid fuel-fired generation capacity can be met by installing pollution abatement equipment. Italy is an example, where new capacity, planned and under construction by ENEL, is split between 26% combined-cycle plants, fuelled by natural gas or gasified coal, and 74% multi-fuel plants capable of burning oil, gas, or coal and equipped with flue gas desulphurisation (FGD), de-NOx and third generation electrostatic precipitators: whatever fuel is burned, the emission levels are within the limits set by the Italian government. The heavy investment in emission abatement equipment and fuel flexibility reflects the importance to the power generating utilities of continued use of coal-fired power plants, which in turn reflects the expectation that coal will retain a relatively low and stable price profile.

The use of natural gas in combined cycle generation offers higher thermal efficiency than "conventional" generation. However, improvements in the efficiency of coal can also be achieved using Integrated Gasification Combined Cycle (IGCC) generation. There are four main reasons why a shift towards natural gas can be expected in the power generation fuel mix:

- Environmental advantages: growing concern about the environmental impact of energy consumption helps to sustain interest in natural gas, which is less polluting than most of the other fossil fuels.
- Price: although marginal costs (fuel and operating costs) are higher than those of coal, the total cost, including capital costs, per MWh of output are less.
- Co-generation: growth in the application of combined heat and power is creating many new market openings for natural gas consumption in industry. The countries showing the largest growth potential for gas-fired co-generation are Denmark, Italy and the United Kingdom.
- Changes in industry structure: the European electricity generation industry is undergoing some degree of change. There is a trend, most noticeable in the United Kingdom, to encourage the generation of electricity from many different sources and new entrants are encouraged into the industry. It will not be unusual for new entrants to enter the industry on a small scale - perhaps supplying to a small group of local industrial customers or to one distribution company. Generators such as these will be encouraged to use natural gas. Gas-fired generation is possible from relatively small units without a great loss in economies of scale.

To achieve a more open internal market in the field of electricity, the Commission has identified a certain number of potential obstacles which must be eliminated. Amongst these, a lack of harmonisation of kWh prices between EC members is one key problem. Prices are strongly influenced by certain elements that the electricity generating companies do not control, such as national and regional policy in the field of energy, the environment and taxation. Within the EC these various policies can be strongly linked and sometimes contradictory.

Another major consequence of the establishment of the internal energy market is the opening up of tenders for the supply of equipment ordered by the public electricity companies. These companies must open up their bid procedures in order to treat, on an equal footing, all EC suppliers. These measures have contributed to the acceleration in the concentration/restructuring of the European electro-mechanical industry.

Production process

The nature of electricity production requires that it must be transmitted to the point of use within areas, regions and Member States. This imposes technical requirements for the operational management of electricity transmission to reduce the inevitable power losses to a practical minimum in the interests of economy and energy efficiency. Electrical interconnections across national frontiers have developed over many years as a logical extension of local, regional and national interconnections and have been driven by the economic and technical advantages which a more profitable use of generating facilities provides.

In the EC, this trend has resulted in one of the most closely integrated high-voltage international networks in the world, although Ireland and Greece are still not directly interconnected with any other Member State. In the case of Greece, the EC is currently studying a plan to connect it to Italy as a means of providing Greece with greater security of supply. Greece is currently importing electricity from Albania, Yugoslavia and Bulgaria.

International exchanges are managed, without executive powers, by a cooperative organisation of electricity authorities. These are UCPTE (Austria, Belgium, France, Germany, Italy, Luxembourg, the Netherlands, Switzerland, Greece, Portugal, Spain and Yugoslavia), UFPTES (France and the Iberian group of islands), SUDEL (Austria, Italy, Yugoslavia) and NORDEL (Denmark, Norway, Sweden, Finland and Iceland).

UCPTE announced in March 1990 the creation of a computerised exchange, grouping surplus capacity and electricity needs of member organisations. This system enables the daily management of exchanges instead of the previous weekly sessions.

The electric utilities enter into commercial arrangements for the exchange of electrical energy, with the transfer arrangements falling under three main types: hour-by-hour exchanges on a cost basis, including back-up in the event of grid difficulties; contracts (usually short-term) for net transfers; permanent arrangements for the transfer of energy from joint-owned production plants in a neighbouring country. Furthermore, it should be noted that all the elements of the international interconnection system are owned by the monopolies and transfer arrangements are cooperative and not mandatory. These interconnections do not, by any definition, constitute a common carrier system.

INDUSTRY STRUCTURE

Companies

The electricity supply industry (generation, transmission and distribution) in the EC is characterised by the existence of national monopolies which are either de jure monopolies or de facto monopolies (such as the contracts signed between municipalities in Germany). The supply of electricity involves numerous activities from fuel input and energy generation to transmission, transmission network maintenance and local distribution.

The electricity supply sector in the Member States can be divided into three major categories: integrated State-owned; decentralised mixed ownership; mixed ownership, State-dominated. France has the highest level of vertical and horizontal integration, whilst at the other extreme Germany and the Netherlands have the most decentralised structures.

In Belgium, the three private generators (Ebes, Intercom, Unerg) have grouped together since July 1990 to create a new entity, Electrabel. This grouping is the result of sector rationalisation process under way since the 1950s and will enable them to better confront foreign competition. The municipalities are responsible for the distribution of electricity destined for lighting and domestic use, as well as to industrial users who consume less than 1000 kW.

In Denmark, the electricity generation is in the hands of twelve companies, most of which directly or indirectly owned by municipalities. The public electricity generation companies are grouped into two associations, ELSAM and Elkraft, which are responsible for coordination and planning of generation and transmission capacities, as well as the daily operational coordination of fuel purchases for power stations. Electricity distribution is provided by 111 companies, five of which are generating companies, 54 are municipal companies and 52 are cooperatives or foundations.

In France, the monopoly for electricity generation, transport and distribution was given to Electricité de France (EdF) in 1946. EdF covers 88% of installed capacity and 96% of electricity distribution.

In Germany, the electricity supply industry is highly decentralised, with some 960 individual public electricity companies. However, the sector is tightly controlled by several federal and regional organisations which are responsible for coordination and regulation. Nine large public companies (two of which are nationalised) own and operate the majority of gen-

eration capacity, including all the nuclear power stations and almost the entire national high-voltage grid.

East Germany will be shortly interconnected with the UCPTE networks. Prior to unification, East Germany was connected to the Mir grid, which primarily received power from the Soviet Union for base load supply rather than peak exchange as in the case of the UCPTE grid.

In Greece, the Public Power Corporation holds the monopoly for generation, transmission and distribution. The situation in Ireland is the same with the Electricity Supply Board.

In Italy, Ente Nazionale per l'Energia Elettrica (ENEL) is a state company responsible for electricity generation, imports, exports, transmission and distribution throughout the country. The only exceptions to ENEL's monopoly are the following: municipal companies in existence before 1962; generating organisations which consume more than 70% of their own production; production by combined heat and power plants of less than 3MW; generation from renewable resources. A recent electricity law in Italy provides for pre-privatisation changes in the structure of ENEL.

In the Netherlands, electricity generation transmission and distribution is in the hands of municipal and provincial companies. After the sector re-organisation in 1987, there are now seven provincial companies and one municipal company responsible for electricity generation and transmission. They are grouped within the electricity generators cooperative (SEP), which is responsible for capacity planning and inter-provincial and international electricity exchange coordination. Sixty seven municipal companies distribute electricity and are grouped within VEEN.

In Portugal, Electricidade de Portugal (EdP) has the quasi-monopoly for generation and transmission. Independent generation and transmission is permissible in those areas not covered by the EdP distribution grid. A recent electricity law in Portugal provides for a new structure (removing generation monopoly) for EdP.

In Spain, the electricity industry is composed of a large number of public companies, 21 of which are grouped under Unidad Electrica (UNESA), which is responsible for co-ordinating generation and transmission activities. The electricity grid was nationalised in 1984 and is operated by REDSA.

The United Kingdom undertook a privatisation programme in 1990 and 1991, with the sale of the twelve Area Boards, the CEGB and the Northern Irish and Scottish generating and distribution companies. From these sales seven new generating entities have emerged: National Power, PowerGen, Scottish Power, Scotland Hydro-Electric, Scottish Nuclear, the Northern Ireland Power Generation Company and the state-owned Nuclear Electric. The latter is responsible for all non-military nuclear power stations and has remained in public ownership. The transmission grid is jointly owned by the Regional Electricity Companies, but its operations remain independent.

ENVIRONMENT

The directive (no. 88/609) on emissions control from large combustion plants (those with a rated thermal input equal to or greater than 50 MW) was adopted by the Council in November 1988, after four years of lively debate. The directive comprises two parts and is based on the use of best available technology at a reasonable cost. Applying this technical constraint helps to ensure the evolution of new and better technologies aimed at pollution abatement.

The first part of the directive applies to new combustion plants, built after 1st January 1990 and whose rated thermal input is greater than 100 MWh (coal) or 50 MWh (oil and natural gas). Under the directive, all new large combustion plants are subject to a licensing procedure to ensure that the plant meets specified emission standards for SO_2, NOx and particulate. The second part applies to existing stationary combustion sources (those for which authorisation was given prior to 1st July 1987), and specifies target values for reduction of emissions based on the 1980 level. Compared to 1980, SO_2 emissions must be reduced by 60% by the year 2003, and NOx emissions by 30% by 1998, the former in three stages, the latter in two phases. Plants authorised prior to 1987 and built before 1990 must either conform to the new plant standards or be taken into account in the global ceiling value.

Although new plant emissions standards have been uniformly established, global targets still vary from country to country. In addition, exceptions have been included at the request of specific countries, as well as a number of caveats that allow for the relaxation of targets and or target dates "If a substantial and unexpected change in energy demand or in the availability of certain generating installations creates serious technical difficulties for the implementation by a Member State of its programme [of SO_2 and NOx abatement]."

The emission limits for large combustion plants favour the penetration of natural gas in the power generating sector. The limits imposed on NOx emissions in new plants can be met without the need for expensive NOx emission abatement equip-

ment, though the SO_2 emission limits are relatively restrictive as regards the use of coal.

The current discussions on the proposed CO_2/energy tax focus on the stage of the electricity production process where the CO_2 tax is levied, i.e. on the input fuels (coal, nuclear, oil...) or on the output (electricity itself). The main problem of an input tax is that conversion losses would be taxed too.

REGULATIONS

The development of electricity exchange within the EC has received considerable attention from the European Commission, with the Council adopting a number of directives which constitute a first step towards the completion of the internal market in electricity.

The transit directive (no. 90/313/30), approved by the Council on 30th October 1990, provides that "each high voltage transmission utility shall facilitate power exchanges between other utilities through its grid, provided that transmission reliability is not affected." Meanwhile, the price transparency directive (no. 90/185/16), approved by the Council in June 1990, provides that "electricity and gas utilities shall supply to the Statistical Office the rates they charge to all categories of customers on the understanding that published aggregate figures will respect confidentiality."

The Commission has also presented plans for the further development of an internal energy market within the EC, involving two stages in addition to the two directives cited above. The second stage is based on three elements:

- The creation of a transparent and non-discriminatory system for granting licences for the production of electricity and the building of electricity lines. The aim of this proposal is to "open up investment in production and transport to independent operators, and in particular to large industrial users."
- The creation of transparency of operations by the separation of the management and accounting of production, transmission and distribution operations in vertically integrated undertakings.
- The introduction, on a limited basis, of third party access (TPA). The transmission and distribution companies will be obliged to "offer access to their network to certain eligible entities at reasonable rates, within the limits of available transmission and distribution capacity." Those eligible will include large industrial users and distribution companies.

The Commission also wishes to see subsidiarity play a substantial role during the second phase. This involves Member States retaining their regulatory powers for all end-users not eligible for TPA, as well as determining the extent and nature of distribution companies' rights and their public service obligations. Member States will also be free to establish the criteria used for granting licences to build power stations and transmission and distribution lines. The Commission would like to see this second stage entered into force on 1st January 1993. The third stage will be defined in detail in the light of the experience acquired during the second stage and will be entered into force on 1st January 1996.

OUTLOOK

The principal concerns in the outlook for power generation surround the evolution of the fuel mix for conventional thermal power generation. Development of hydro power, renewable sources, and nuclear power will remain constrained over the next decade. As a result increases in demand will have to be met by increases in conventional thermal capacity.

Within this context their is considerable scope for natural gas use for power generation in Europe. It is, however, only in few EC countries where the use of gas in power generation will increase substantially. Italy, Belgium, Denmark and the United Kingdom are all in the process of changing the fuel mix in favour of gas. Such a move is also planned in Greece and Portugal, but in these countries the future of gas is much more speculative and uncertain. Natural gas fired power generation could almost double its share of the power generation fuel mix in the EC by the year 2010, from its 1990 level, almost tripling the volume of gas consumed in this use.

By the year 2000, the demand for natural gas fired power generation will increase to the detriment of oil-fired power. Nevertheless, solid fuels will continue to dominate the conventional thermal power generation fuel mix.

Written by: DRI Europe
The industry is represented at the EC level by: Union internationale des producteurs et distributeurs d'énergie électrique (UNIPEDE). Address: 28, rue Jacques Ibert, F-75858 Paris Cedex 17; tel: (33 1) 40 42 37 08; fax: (33 1) 40 42 60 52.

Transmission and distribution of natural gas

NACE 162

In 1990, EC natural gas production rose by 4.6% over the previous year, and accounted for 62.4% of gross consumption. The United Kingdom and the Netherlands both increased their output in 1990 compared to 1989: these two countries account for 74% of the EC total natural gas production. The Soviet Union was the major supplier of natural gas to the EC, followed by Norway and Algeria.

Growing concern about the environmental impact of energy consumption has helped to sustain interest in natural gas. It contains relatively low levels of sulphur and by-and-large emits less NOx per unit of energy than other fossil fuels, it also produces less CO_2 per unit of energy burnt than any other fossil fuel. As a result, natural gas is expected to become increasingly important within the energy fuel mix.

INDUSTRY PROFILE

Description of the sector

Natural gas is normally burned as a fuel for space heating and hot water production, as well as being used in power stations to generate electricity and used as a feed stock in the chemical industry. The natural gas industry embraces a range of activities, of which the three principal ones are exploration/production, transmission and distribution. Some companies carry out all three activities, although exploration and production are generally considered to be outside the gas sector, since it is mainly carried out by major oil companies. The industry applies the term transmission to:

- the purchase of gas from producers or from other transmission companies;
- the transportation and storage of natural gas;
- the sale of gas to other transmission companies, to industrial consumers and power stations and to local distribution companies.

The distribution activity is concerned with the supply of natural gas by a local network to domestic and non-domestic consumers linked to its network.

Main indicators

In 1990, EC natural gas production rose by 4.6% over the previous year, to 6026.7 TJ (terajoule). As a proportion of gross EC consumption, production edged higher to 62.4% in 1990, though it remains below the levels seen in 1985, when production represented 68.8% of gross consumption. The two largest producers within the EC, the United Kingdom and the Netherlands, both increased their output in 1990 compared to 1989, with production rising 14% and 0.8% respectively.

Gross consumption in 1990 increased by 3.1% from 1989s level to 9660.2 TJ. Consumption increased in virtually all the EC countries in 1990, with the only exception of the Netherlands, where it fell 0.7%, and of Portugal which consumes no natural gas. Germany and the United Kingdom consumed the largest amount of natural gas of all the EC countries in 1990, with both representing 22.9% of the EC total, followed by Italy (18.8% in 1990), the Netherlands (14.9%) and France (12.1%). Spanish consumption only accounted for 2.5% of the EC total in 1990, although it has risen at the rate of 22.7% per annum from 1.4% of the EC total in 1987. This expansion rates reflects the creation of a market in a very underdeveloped sector, with industry accounting for 75% of natural gas demand.

Recent trends

The average rate of increase in consumption was 2.4% per annum over the second half of the 1980s, which represents a slowdown if compared to an yearly growth rate of 4.8% between 1982 and 1985. The slowdown in natural gas consumption reflects the decline in the domestic sector's demand for natural gas over the second half of the 1980s, although 1990 itself saw an increase in consumption of 3.9% in the residential and commercial sector's consumption. Demand in the industrial sector has shown strong growth over the 1980s, and rose by 3% per annum between 1987 and 1990. Nevertheless, the greatest increase in consumption in recent years has occurred in the power generating sector, where consumption rose by 5.6% per annum between 1987 and 1990.

Foreign trade

Imports from outside of the EC rose by 2.8% in 1990 to 3843.6 TJ, representing nearly 40% of the gross EC consumption. The Soviet Union was the major supplier of natural gas to the EC, accounting for 44% of the total EC imports from outside the EC. This represents an increase from 1989, when Soviet supplies accounted for less than 40% of the total and it also representing a 14% increase over the previous year. Imports of natural gas into the EC in 1990 were divided between Germany (45%), Italy (32%) and France (23%).

It is estimated that the existing production and transmission infrastructure will permit the former Soviet Union, without much incremental cost, to increase its exports to western Europe by around an additional 20 million toe (tonnes of oil equivalent). Given the size of the Russian gas reserves and provided the appropriate political and economic conditions prevail, substantially greater supplies into the EC could be envisaged.

The other major sources of natural gas supplies from outside the EC are Norway (27% of the total in 1990) and Algeria (28% of the total in 1990).

Norwegian natural gas deliveries into the EC will take on a new dimension when the development of the Troll-Sleipner project and the corresponding infrastructure are completed

in the mid-1990s. The Norwegian authorities have also agreed on the construction of a new pipeline linking the Norwegian North Sea to Emden in Germany, which is due to come on stream in the second half of 1995. By the year 2000, Norwegian natural gas exports are likely to be at a level of around 50 million toe, most of it heading into the current EC countries.

Algerian natural gas imports into the EC in 1990 were divided between Italy (38%), France (35%), Spain (12%) and Belgium (15%). Algerian gas is either transported by pipeline via Tunisia and into the Italian grid or is exported as liquefied natural gas via Arzew and Skikda to terminals in Belgium, France and Spain. Within few years Greece will also receive Algerian natural gas in this manner.

MARKET FORCES

Demand

There is an important market for gas in industrial co-generation. This market accounts for about 10% of western European power generation. growth in the application of combined heat and power is creating many new market openings for natural gas consumption in the industry. the countries showing the largest growth potential for gas-fired co-generation are Denmark, Italy and the United Kingdom.

In Denmark, the government has made a commitment to expand gas-fired combined heat and power applications. In Italy, the lack of power generation capacity and the constraining site approval regulations for public power plants have made new industrial co-generation more attractive as it is the easiest capacity to expand.

Under the 1983 Electricity Act, co-generators in the United Kingdom could sell surplus power to the Central Electricity Generating Board. This was not a great success, at least until the advent of electricity privatisation, which allowed large consumers to purchase from any one of the twelve area boards or the two conventional generators. This prompted consumers to carefully consider co-generation, because they no longer faced one buyer for their surplus power and could seek the buyer offering the best price.

Co-generators do not necessarily need to use a gas-fired system. Nevertheless, the total cost is less than that of a coal or oil-fired equivalent , although marginal cost comparisons are not so favourable.

Supply and competition

In many countries the price of gas is linked to that of competing oil products. Some countries index gas prices to the prices of light heating oil as well as heavy fuel oil, reflecting the fact that gas competes in the space heating market in addition to the power generation market. An alternative method is to link gas prices to those of coal.

Third party access could result in natural gas prices falling as increased competition leads to the removal of monopoly rent and penalises inefficiency. However, the increased risks associated with the loss of monopoly power by the natural gas companies, will lead to the gas company's requiring higher returns to cover those risks. The resulting effect on prices depends upon the relative effects of encouraging new entrants into the national markets and what impact that will have on actual levels of competition, against the risk adversity of gas companies. The effects need not be uniform across all countries.

Production process

The physical infrastructure of the gas industry consists of pipelines and of other equipment needed to regulate the passage of gas through the pipelines (notably compressors) as well as for storage and gas treatment. Investment in 1988 was ECU 4.77 billion, an increase of 6% from 1987, and involved an increase in both transmission (+9.67%) and distribution (+5.6%). From 1982 to 1988, transmission investment declined by about 22%, but investment in distribution activities has increased by 56%, resulting in an overall increase of 24%.

This pattern reflects the maturity of the transmission grid in the majority of Member States, and the continuing expansion of the distribution lines to supply new end-users.

There are plans for a sub-sea pipeline, which will link the republic of Ireland to the United Kingdom. In Portugal, which as yet has no natural gas supply, planning continues for a proposed LGN terminal to the south of Lisbon, from which it is planned to construct pipelines running north to Lisbon and other principal cities. Spain and Algeria have agreed to a new link between Algeria and Europe through Morocco, with a further extension into France currently being considered. It has been decided to upgrade the existing link between Algeria and Italy. The gas infrastructure needs of eastern Europe is expected to result in more integration with the West.

INDUSTRY STRUCTURE

Companies

The organisation and structure of the gas industry varies from country to country. In some Member States one company covers the whole gas chain, while in others there may be a number of companies involved in the production, transmission and distribution of natural gas. Additionally, some companies are owned by public authority, while in others ownership is mainly in the private sector.

The United Kingdom, France and Ireland all have a vertically integrated gas industry, a structure that Greece is also planning to develop. The French (GdF), Irish (BGÉ) and Greek (DEPA) companies are 100% owned by the State, while in the United Kingdom, British Gas was privatised in 1986.

However, in the United Kingdom a process designed to change the structure of the industry is well underway. British Gas has agreed to halve its share of the industrial gas market by 1994 and by a further 10% in 1995, by making available gas to competitor companies in the retail distribution sector. At the same time, British Gas is to create a separate subsidiary to run its pipeline and storage systems, which will also serve its competitors on an equal basis.

In Belgium, Luxembourg, Denmark, Italy, the Netherlands and Spain, a two-tiered structure has developed. There is a national transmission company and local governments tend to own the companies that distribute gas. In Italy and Spain, the transmission company is state owned, with their respective transmission companies, SNAM and ENAGAS, subsidiaries of government controlled companies. Other companies, such as DISTRIGAZ of Belgium, SOTEG of Luxembourg and Gasunie of the Netherlands, are a mixture of state and private ownership, with the state holding 50% of the company.

Two companies, notably those with some public sector involvement, have exclusive national concessions for the purchase and/or transport and storage of gas. In Italy this is limited geographically, with SNAM having the exclusive rights in major parts of the country.

There are exceptions to this model within the two-tier structure, the most notable of which is in Germany, where there are six companies importing gas, 18 transmitting it over long distances, as well as over 500 regional transmission companies operating local concessions.

Overall, these various structures have differing consequences for the gas transmission market structure, with some companies having monopolist or virtual monopoly positions. In Italy, SNAM has about 98% of the domestic market, while in Germany, Ruhrgas, the largest of the transmission companies, has about 75% of the market.

REGIONAL DISTRIBUTION

In 1990, two countries accounted for 74% of the EC total natural gas production, respectively 32% for the United Kingdom and 42% for the Netherlands. Of the other EC countries, Italy, Germany, France and Denmark accounted for 23% of the total EC production in 1990. Greece, Spain and Ireland all produce natural gas, though their combined output fell 4% in 1990. Portugal and Luxembourg have no natural gas production.

ENVIRONMENT

Natural gas contains virtually no sulphur at all and by-and-large it emits less NOx per unit of energy than other fossil fuels. It can also make a contribution towards reducing the risk of adverse effects of global warming, as natural gas combustion produces less CO_2 per unit of energy burnt than for the other fossil fuels.

Growing concern about the environmental impact of energy consumption has helped to sustain interest in natural gas. In late 1988, the EC directive concerning emissions from large combustion installations was adopted, which imposes environmental abatement measures on new power plants. Increasingly stringent emission limits for SO_2 and NOx favour the use of natural gas which, in most cases, does not require the heavy investments in emission abatement equipment that are associated with use of solid fuels and "normal" (i.e. high sulphur) heavy fuel oil.

The years 1989 and 1990 were marked world-wide by increasing concerns about the environment in general, and the greenhouse effect in particular. As a consequence, several countries (i.e. the Netherlands, Denmark, Italy and Belgium) have adjusted their generation capacity plans in order to incorporate an increased share of combined-cycle, gas-fired base and mid load power.

Methane, which contributes to the greenhouse effect if it is leaked or vented, contributed around 15% to the "radiative forcing" added to the atmosphere in the 1980s, based on the estimate that one molecule of methane has about 3.7 times the global "climate forcing" effect of one molecule of CO_2. However, emissions of methane from the natural gas chain currently contribute not more than 1 to 2% of the overall effect.

REGULATIONS

With the creation of the Single Market scheduled for the end of 1992, the European Commission has turned its attention to the ways in which a single energy market can be created. There are a number of elements to the Commission's approach within the gas sector, which can be seen as an evolution towards third party access (TPA) legislation. Firstly, in some countries the electricity or gas carrier is defined by statute. The Commission took action to remove the discriminatory aspects of these statutory monopolies in 1991 under article 37 of the Treaty of Rome, which requires that state monopolies should create no commercial discrimination. Secondly, the Commission is taking further action in the form of draft directives concerning two aspects. Two directives are aimed at providing

third party access in gas and electricity markets, which find their legal basis in Article 90 of the Treaty of Rome. Other two directives seek to create a level playing field for both the gas and electricity industries, based upon Article 100A of the Treaty of Rome.

The directives based upon Article 100A have severe ramifications for some Member States. They seek to remove the influence of national governments in setting and approving tariffs other than for certain social welfare and rural supply protection cases. The directives also seek to separate the transmission and distribution functions of utilities and require them to produce transparent accounts.

The draft proposals put forward by the Commission under Article 90 concerning TPA are broadly as follows:

- the removal of "special and exclusive" rights awarded that cover the "conversion, liquefaction or storage of natural gas". Furthermore, exclusive rights on the creation of new transmission, distribution and storage infrastructure are also to be removed. Member States, however, retain the authority to refuse to authorise pipelines should the existing transmission and distribution arrangements be deemed adequate;
- should special or exclusive rights be granted, then third party access must also be granted - thus negating the exclusivity. This access should be grounded on principles that are "public, objective and non-discriminatory". However, access to interconnected grids can be restricted by Member States to those consumers who consume in excess of 1 mcm/year of natural gas;
- provisions are made for "essential requirements" such as "reliability, security [and] technical integrity". These provisions allow the compliance of Member States to the directive to be adjusted in the light of these factors, although it is the duty of Member States to ensure that private undertakings "shall be required to comply with only the minimum formalities which are indispensable in order to ensure that the essential requirements are met";
- Member States are obliged to ensure that conditions of licensing and the definition of "minimum formalities" are carried out by a body that is independent of the bodies administering the grids and of the bodies competing in either the gas or electricity markets;
- Commission approval is required for a member state to grant aid to participants in these markets;
- Member States are empowered to take action when there is a serious threat to their energy supply although they must first inform the Commission.

Eurogas, the European Union of the Natural Gas Industry, does not endorse the analysis of consequences of TPA. In short, it is the view of Eurogas that TPA is likely to create significant potential disadvantages for the Community in terms

of reduced supply security, potentially increased cost of supply and conflicting economic signals.

OUTLOOK

The share of natural gas in Western Europe's energy mix is expected to increase steadily throughout the next two decades. Natural gas for industrial and residential use will make significant inroads in some as yet undeveloped markets such as Portugal, Spain, Greece and Ireland. The principal area of demand growth is expected to be in power generation.

There are various other factors which are anticipated to continue to influence the use of natural gas, including: environmental concerns and their consequences for the pattern of fossil fuel use; security of supply; developments in other fuel markets, notably the trends in oil availability and prices, as well as the role of nuclear electricity generation within the EC; the exploitation of new sources (e.g. Nigeria, Northern Norway, etc.); the competitive position of natural gas in the different end-markets; the impact on the gas sector of the Commission's moves towards an integrated energy market; the long-term effects on the supply and demand patterns of natural gas, given the anticipated growth in European demand underpinned by the need for cleaner forms of energy.

Written by: DRI Europe
The industry is represented at the EC level by: European Union of the Natural Gas Industry (Eurogas). Address: Avenue Palmerston 4, B-1040 Brussels; tel: (32 2) 237 1111; fax: (32 2) 230 6291.

Renewable energy

In 1991, renewable energy contributed around 4% to gross inland energy consumption in the EC. Of this percentage, the majority of the share comes from large scale hydro-electricity production (31%) and from the combustion of biomass in one form or another (60%). Of the remaining 9% are a variety of renewable technologies in varying stages of development, bordering on commercial viability. Through national and EC funded R,D&D programmes, this share is expected to increase to 23% of total primary renewable energy production by the year 2005.

Funding for renewable energy, though low compared to other energy research programmes, has increased substantially in past years. All the signs suggest that this trend will accelerate, driven predominantly by environmental considerations. At EC level, of the major programmes, the Joule programme has finished but its work is being continued as part of the Non-Nuclear Energies programme; funding will continue through the Thermie and Valoren programmes, and begin through the Altener programme as part of the policy to stabilise carbon dioxide emissions by the year 2000.

INDUSTRY PROFILE

Description of the sector

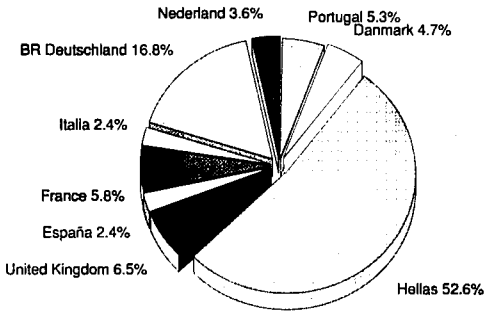
The main renewable energy technologies are the following:

- Geothermal energy, which is used in two ways, either for electricity generation or direct use of heat. The temperature of the extracted fluids, rising from the earth, determines the use to which it is put;
- Tidal power, which extracts energy from the tides using the same principles as hydropower facilities but capturing the tidal ebbs and flows rather than the flow of a river to generate electricity;
- Small hydro-electricity generation, which is basically the same as conventional hydro electricity, though at a smaller scale;
- Biomass, i.e. all the matter that can be derived directly or indirectly from plant photosynthesis. "Indirectly" refers to the products available via animal husbandry and the food industry. Feedstocks for the technologies include wood resources, agricultural wastes, residues and surpluses and energy crops.
- Wind power generation, which uses wind turbines;
- Active solar generation, usually consisting of one or more collectors, an energy transport system to move the heat to the point of use, an electronic control system, and an energy storage system;
- Photovoltaic systems, which convert solar radiation into DC (direct current) electricity without moving parts or thermal energy sources.

MARKET FORCES

The situation in 1989, by Member State, for each of the renewable energy technologies is shown in Table 1. Before discussing each technology, the following salient points can be noted. Greece has the largest installed capacity of solar collectors. In France, Spain and Portugal, where the climate is particularly favourable, active solar technology also makes a contribution. The Danish have by far the largest amount of wind power installed. Italy, France and Spain generate the majority of small hydro generated electricity in the EC. Italy has the largest geothermal energy industry, a large proportion

Figure 1: Renewable energy
Active solar collectors' market in the EC, 1990



Source: Eurostat

of which (520 MW) used for electricity generation. Portugal and France have a significantly high biomass consumption due to much direct combustion of wood. Denmark, however, uses a high proportion of agricultural waste, mainly crop residues like straw.

Geothermal energy

From a world perspective, the production of electricity from geothermal sources has seen a increase in the rate of growth over the past decade. Between 1980 and 1990 the production increased by 50% from 3 900 MWh (megawatt/hour) to 5 850 MWh. In the EC by far the greatest amount of electricity was generated in Italy (545 MW in 1991) where over 50 geothermal units are in operation. Other countries include France (4.2 MW in Guadeloupe), Portugal (3 MW in the Azores), Greece (2 MW on Milos). Germany has a 10 MW plant at Neubrandenburg. The capacity of this plant is to be doubled in the near future and a second 50 MW plant is being considered at Schwerin. Further developments are centred in Italy where a 60 MW plant opened at the end of last year in Tuscany making it the largest in the world. Plans for three more plants of this size are being considered in line with governments policy to increase the share of geothermal derived electricity to 3% of total national energy production.

In addition to geothermal energy for electricity production, hot water from deep in the ground may be used for space heating on a smaller scale. World-wide, the consumption of geothermal energy for heating was around 2 million toe (tonnes of oil equivalent), predominantly in Japan, China, Iceland and Hungary. In the EC it is estimated that in terms of primary energy, it represented 370 000 toe in 1990. The regional distribution is the same as that for geothermal electricity production, yet it differs in that it is used extensively in urban areas. In 1990 the equivalent energy saving by using this source of energy, was 170 000 toe in France and 200 000 toe in Italy. Other countries with geothermal potential for heating include Spain, Portugal, Greece and Germany. In former East Germany much use was made of geothermal energy for district heating and in the west, a new geothermal project in Bavaria hopes to save around 2.5 million litres of heating oil a year.

Tidal power

The largest tidal power station in the world is at La Rance, in France. Conceived as a prototype for other, possibly larger, tidal plants along the Brittany coast, it has been operating since 1968, with an installed capacity of 240 MW_e (megawatt of electricity).Predominantly due to concern over the environmental impact of tidal barrages, no further sites have been developed despite their considerable potential. The best sites are to be found along the west coast of Portugal, France, Ireland and the United Kingdom. In the United Kingdom, where the tidal potential is approximately 54 TWh/year (terawatt/hours per year), the government has been heavily investing on tidal energy research and feasibility studies since 1979. Two studies are well established: the largest, a barrage across the Severn Estuary could generate around 17 TWh_e (terawatt/hours of electricity), equivalent to about 2.5 large (1 000 MW) power stations, while the other project proposed is across the Mersey which could generate 0.5 TWh_e. The environmental impact of all these projects is the major factor preventing their implementation.

Small hydro-electricity generation

In the EC the total installed hydroelectric capacity is about 80 GW (gigawatt). Small hydroelectric plants (less than 10 MW) contributed 5 GW to this or just over 6%. However, there is a marked trend towards small scale applications of hydropower which have a far smaller impact on the environment than their larger counterparts. The reason for this shift is mainly due to the limited availability of new large scale sites. It is estimated that the percentage of sites economically exploitable already used is 95% for large hydro but only 20% for small hydro-electricity. France, Italy and Spain have by far the largest small hydro potential. It has been estimated by other sources that the total EC exploitable potential for small hydro-electricity is around 4-5 GW.

Biomass

The theoretical potential for biomass in the EC is very large at around 100-120 million toe. Within the EC, wood, straw and municipal solid waste are the most commonly used biomass fuels. The primary energy derived from these sources amounted to almost 22 million toe in 1989.

The great proportion of this total is given by wood. The EC currently consumes around 20 million toe of wood energy. France is by far the largest consumer of wood taking 45% of the EC total due to the large proportion of wood burning stoves used in rural areas.

The biggest consumer of straw for energy is Denmark. Here there are over 12 000 straw-burning stoves on farms and over 30 district heating schemes using straw. Its importance is shown when one considers that it provides 1.5% of Denmark's primary energy needs. Biomass globally provides 5.8% of Denmark's primary energy requirements and the government intends to increase this to 9% by the year 2000.

The most widely used method of recovering energy from municipal solid waste (MSW) is by incineration; the other major source is landfill gas which is expanding fast. In the EC around 550 schemes were operating in 1988, 174 with heat recovery of which more than 80% are in France, Germany and Denmark. Disposal of MSW to landfill is widely practised in many Member States. The United Kingdom is notable in that 90% of MSW is disposed of to landfill. Typical schemes generate between 1 to 5 MW and may be used to generate electricity or used directly as fuel in industry.

Biogas is a gas, mostly methane, produced from the anaerobic digestion of organic residues. Agricultural waste, sewage and a variety of liquid industrial effluents can be treated anaerobically. The technology is widespread at sewage works and it is expected to be used increasingly in treating food industry waste and slurry from intensive livestock farming. Member States currently using biogas to any extent are Italy and the United Kingdom and also Denmark and the Netherlands, due to their livestock farming industry. The world's first biogas plant was finished in July 1991 in Denmark and is planned to generate 3 million m3 of methane.

Other than wood, energy crops do not contribute significantly to energy produced from biomass. The development of energy crops is closely tied up with the Common Agricultural Policy (CAP) and it is not clear what the result will be. Wood could be sustainably harvested or copiced (i.e. outer branches of a tree are stripped away without causing it any terminal damage) on land set aside for non food production. If 15 million hectares of farmland is in surplus by the end of the century, and if it was all turned over to fuel wood crops then it is estimated that 120-150 million tonnes of wood with an energy content of 55 to 65 million toe might be produced.

Biofuels may also be produced from energy crops by the processes described. The Netherlands are investigating using feedstocks such as elephant grass, poplar wood or straw for gasification for use in electricity generation plants. In Denmark, Copenhagen's bus company is planning to run 5 buses on diesel from rapeseed oil. The Italian chemical manufacturer Novamont is starting work on a refinery to produce biodiesel from feedstocks of rapeseed and soya. It will have a capacity of 60 000 tonnes/year and a second such plant is planned for 1993.

Wind power

Denmark is the largest generator of electricity from wind energy in the EC. The industry has expanded considerably so that in 1991, the total installed capacity in the EC was 509 MW of which Denmark accounted for 70%, the Netherlands and Germany both for 11%. By way of comparison, it is estimated that the installed capacity in the USA is 1 500 MW consisting of around 15 000 turbines. The important point to note is that Denmark has one of the smallest wind power capacities, and yet has by far the largest installed capacity. This is mainly due to subsidies given by the Danish government during the late 1970s and early 1980s and the opportunity of a large export market in California. The recent government ban in Denmark on turbines at single sites should not significantly harm the Danish wind industry as the market is largely for exports. The United Kingdom on the other hand has the largest potential but relatively few turbines installed.

Recent developments have been the starting of work on a 10 MW wind farm in the Canaries Islands, designed to provide for 10% of the islands' electricity needs; it consists of 45 turbines and will be used to run a water desalination plant. In Spain, a 10 MW plant is also planned by Endesa, the state electricity company, and Ecotecnica, a Spanish turbine manufacturer. In Greece, a series of wind projects have been approved for use on the Aegean islands.

Technical difficulties have meant that off shore farms are less commercially developed. In Denmark, however, the electric utility Elkraft brought on-line the world's first off-shore wind farm consisting of eleven 450 kW (kilowatt) turbines. A second 5 MW farm is planned by the other electric utility, Elsam consisting of ten 500 kW turbines.

Active solar collectors

By far the largest user of active solar collectors is Greece. In 1989, the total installed solar collector surface area was around 1 300 thousand m2. It is estimated that this contributes around 67 thousands toe to primary energy production. In Greece, hot water from active solar collectors contributes 4.5% to the total hot water needs. In the other Member States, this fraction is considerably less due to less favourable climatic conditions and a smaller area of collectors installed.

Today, solar collector sales in Greece represent over half the total sales in the EC. Solar collector production in Greece, however is solely for the home market, which is very large. At EC level, imports from outside Europe are decreasing: they amount to about 2 500 solar water heaters and about 1 000 additional collectors each year.

Photovoltaic systems

The decrease in cost accompanied by the increase in efficiency of photovoltaic (PV) cells has enabled a rapid growth in the world photovoltaic market. Since 1978, when a mere 1 MW was installed, it has increased to reach around 56 MW in 1991. This growth has been primarily for isolated sites. However, it is now becoming feasible to use PV for power generation in a centralised manner. In April 1992, in Switzerland, Europe's largest and most modern PV power station came on line with a capacity of 500 kW. In Spain, Germany's RWE and Union Electric Fenosa are to build a PV power station of twice this capacity (1 MW) near Toledo, to be completed in 1993. Currently the demand in Europe exceeds the production capacity.

Production process

Geothermal energy

Electricity generation is the most attractive use due to the low distribution costs. At temperatures below 150° C the most common application is for direct heat. This has advantages in terms of its simplicity, efficiency, adaptability and is relatively cheap. The hot water cannot economically be transported a distance greater than about 1 km so the site location is limited by the end use location. Other methods such as magma, geopressured and hot dry rock technologies have been investigated though none are near to commercial viability.

Tidal power

The simplest systems generate power by capturing water at high tide and running the head of water through turbines. More complicated systems impede the flow of water in both directions. The turbine best suited for the low head characteristics is the bulb-type turbine and units are manufactured with runner diameters of 7.5 metres and capacities of 60 MWe.

Small hydro-electricity generation

Countries and institutions define what is small differently. An upper limit for small hydro is 10 MW, while they may have capacities as low as a few hundred kW. The technology differs in that turbines are specifically designed for low head conditions and the control equipment differs in its complexity.

Biomass

The resource base is huge and is said to be in the order of 100-120 million toe. On a global scale, the majority of the population relies on biomass as its primary source of fuel. In the industrialised world, where energy production is more centralised, biomass energy conversion is perhaps the most technically, economically and socially complex renewable energy option. Old, well developed technologies co-exist with completely new, advanced techniques for converting biomass to useful energy. The end uses to which biomass energy source can contribute are liquid fuels, heating and electricity generation.

Liquid fuels may be produced by various methods, three are mentioned here. First, "bio-diesel" consisting of complex natural esters from the esterification of oils extracted from plants such as rapeseed, linseed and the sunflower. Second, the hydrolysis and subsequent fermentation of plants with a high energy value can produce methanol or ethanol which can be used as fuels in vehicles with engine modifications. Lastly,

liquefaction is a variant of the pyrolysis technique where a diesel or gasoline fuel may be produced by one of two methods. An indirect method gasifies the biomass and is followed by the catalytic conversion of the product to a liquid fuel. Direct liquefaction misses out the gasification step using lower temperatures to produce partially deoxygenated, complex oils which are then upgraded.

Electricity generation and heating requirements can be met by direct combustion or gasification of wood, straw or other dry biomass. Household waste may be incinerated or the landfill gas used to provide heat. Agricultural waste such as slurry from animal husbandry may be used in the anaerobic digestion process to produce biogas, a high grade gas consisting mostly of methane. In addition, any organic material may be gasified (or liquefied) by its thermal decomposition in the absence of oxygen by pyrolysis.

Wind power

Wind power in Europe in its present form can be said to have begun in the mid 1970s in the wake of the oil crisis. Over this time there has been considerable improvement in the design of turbines so that the efficiency, measured in energy in kWh per swept area per year, doubled between the beginning and the end of the 1980s. Modern wind turbines can be of two configurations: a horizontal or vertical axis. The horizontal axis machines, however are the most common units manufactured. The average size of wind turbines installed in the EC has increased steadily and the trend is still continuing as can be seen in Figure 3. There is no consensus as to the optimum size for machines, though R,D&D work is currently centring on 300 kW machines with rotor diameters of 25 metres. Along with improved technology comes increased reliability. A study of the top performing wind farms in California showed an increase in the availability electricity generated from 60% to around 95% over the 1980's. As for the plant cost for a wind farm, based on Danish experience, for turbines in the range 100-300 kW the average cost per swept area is 280 ECU/m2. The costs vary from country to country and from site to site: depending on the terrain and other factors the total costs per swept area may vary between 400 and 600 ECU/m2.

In addition to onshore wind sites, a very great potential exists for turbines sited off-shore. There are particular problems associated with this, however, such as difficulties of operation in a saline environment, achieving designs rigorous enough to stand up to storms, and the difficulties of access for maintenance. Off-shore sited turbines tend to be larger than their land based counterparts and environmental constraints hindering turbines on land are more relaxed for off-shore sites.

Active solar collectors

Beside operating in temperature ranges that satisfy building energy needs, active solar technology can supply heat for industrial processes at moderate temperatures. The essential component in system is the collector and several designs are available: flat plate collectors (glazed or unglazed), evacuated tube collectors and air collectors.

Unglazed solar water heaters are used in outdoor applications, predominantly for heating swimming pools. Glazed solar water heaters form the bulk of the market, representing approximately 90% of total installed collector surface area. Evacuated tube collectors form a small but growing part of the market, particularly in northern Europe. In value terms they account approximately for 10% of total EC sales. Air collectors are generally built into the building structure to produce warm air directly or in connection with a heat pump for space heating. The most important and widely used application is for drying hay, particularly used in Sweden where an estimated 200 thousand m2 have been installed.

Photovoltaic systems

The basic element is the photovoltaic (PV) or solar cell. This comprises of semiconductor materials which have both negative and positive charge carriers. When photons from ultraviolet, visible and near infra-red light are incident on the cell, electrons in the semiconductor are freed, and an electric current is generated. Cells are built into modules of size of around 1 m2 and may generate in the region of 100 W_p (peak watts). Efficiency has been increased by around 50% over the past decade The different technologies used are the following:

First, single crystal silicon is a well established technology, with cells that tend to be stable and relatively efficient. The cost of manufacturing, though decreasing, is relatively high. Second, polycrystalline silicon ingots with grain sizes of several millimetres can be produced by a casting process less expensive than single crystalline process. Larger areas are needed for the same power, and module efficiency is slightly lower. Polycrystalline silicon ribbons may be manufactured using edge defined film fed growth and dendritic web processes. The manufacturing process is complex though it has high potential for high speed production. Third, thin film technology is an area of intense research effort. Films are deposited directly onto substrates by technologies such as glow dis-

charge, chemical vapour and electro-chemical deposition. Semiconductor materials being investigated include amorphous silicon, copper indium diselenide, gallium arsenide, and cadmium telluride.

ENVIRONMENT

In the mid 1970s, interest in renewable energy was born as a result of high crude oil prices after the first oil crisis. Nowadays the interest is inspired more on the environmental benefits that renewables offer, particularly with respect to their use in reducing carbon dioxide emissions.

With the exception of biomass, renewable energies are almost free of pollution. This stands them out very clearly from conventional methods of energy production where increasing concerns over pollution from the energy sector is forcing very large investments in emission control equipment. This is not to say that renewable energy has a negligible environmental impact. Ironically the growth of the renewable energy industry is driven on the one hand by world scale environmental factors such as the threat of global warming, while being constrained by environmental factors on a local or regional level, such as the visual impact of wind turbines and the environmental impacts of hydro schemes.

The main environmental factors promoting the industry are the following:

- Biomass releases carbon dioxide when burnt to produce energy. However, during its growth, carbon dioxide is sequestered from the atmosphere. If the biomass use is accompanied by afforestation then the net carbon dioxide emissions may be zero or even negative.
- With the exception of biomass, energy produced from renewable sources does not produce sulphur dioxide, sulphur trioxide or nitrous oxide, the principal components of acid rain.

The environmental impacts of renewable energy technologies, though less than that of conventional energy sources, are significant as they affect implementation:

- Tidal power has an enormous impact on the environment. This is the single major factor constraining its development. Most of the potential impacts arise from three main causes: changes in water levels, flow patterns and velocities; sediment movement and the physical presence of the barrage. The most serious effects are felt in navigation and for port facilities, water quality will be affected and the impact on wildlife, particularly birds and fish, is particularly acute.
- The environmental impact of wind power is essentially on the human rather than the natural environment. Visual impact is the key factor, especially since the best sites are often the most beautiful with the least signs of human interference. Noise levels are another factor. Telecommunications may be affected though this is a localised problem. The impact of large scale implementation of wind turbines on birdlife and bird migration is relatively unresearched.
- Active solar collectors and photovoltaics have a visual impact since their use is predominantly in a widely dispersed fashion and because they must, for maximum efficiency, be placed in prominent positions.

EC AND MEMBER STATE SUPPORT

Over the last decade several countries have successfully encouraged the development of domestic renewable energy industries. At EC level, several initiatives are underway. The more interesting policies in Member States are:

In Denmark, subsidies for installing wind turbines were phased out in 1989 and replaced by tax credits. Shareholders obtain income from the electricity sold tax-free below a set limit. State aid also encourages the use of straw as fuel, biogas plant and certain solar projects.

In France special grants have been used to cover the exploration risks of geothermal development. In the area of biofuels the French government also gives grants derived from the tax on petroleum products.

In Germany a new law (Einspeiseverguetungsgesetz, 1991) has helped wind and photovoltaic energy by forcing the electricity utilities to pay for electricity generated by these methods at a premium rate of 90% of the price paid by end consumers. Subsidies encouraging the installation of wind power are also available. For electricity produced by small hydro-electric generation, biogas and agricultural and forest waste the rate they are paid is fixed between 65-75% of the electricity sale price.

In Greece, the government has made particular commitments to the promotion of wind and geothermal installations. Financial incentives take the form of subsidies in the region of 40-55% of the total investment.

In Portugal, the EC Valoren project and a national programme to promote renewable energy (SIURE) have benefited around 100 projects such as small hydro-electric generation, active solar collectors, photovoltaics, geothermal energy, wind power, the use of wood residues and the production of biogas. The relaxation of the authorisation procedure for the production of electricity from small installations has particularly benefited small hydro, biomass and biogas. In addition to EC funding, 10 million ECU have been invested in projects in the areas of active solar collectors, photovoltaics, biomass and biogas

In Italy, funding is available covering 30% of the capital costs for renewable energy projects. For demonstration projects 50% funding is available and for the installation of photovoltaic equipment in buildings, 80% subsidies are available. Efforts to remove barriers to the incorporation of electricity from small generators has resulted in very favourable tariffs for wind, photovoltaics and geothermal energy in particular.

In the Netherlands, wind power installation is subsidised on the basis of the swept area and in the area of R,D&D, funding for 50% of the costs are made available. General subsidies go to solar, biomass and geothermal projects of up to 40% of costs.

In the United Kingdom's privatised electricity sector, regional electricity companies (REC's) are obliged to purchase a portion of their electricity from non-fossil sources under the Non-fossil Fuel Obligation (NFFO). This obligation also forces the REC's to purchase the electricity at premium prices organised in bands. Different renewable technologies are associated to different price bands according to their commercial status. Other than energy from waste, wind and small hydro-electric generation projects are currently being supported under the scheme.

The European Commission has several programmes running which support renewable energy. The major ones are:

The Altener programme has been deigned by DG XVII (Energy) to promote greater penetration of renewable energy. It is destined to run to 1993 currently with commitments of 1.2 million ECU. It may continue through to 1997 with additional funds.

A non-nuclear energies programme has taken over from the Joule programme which had run from 1989 under the Community's Framework Programme on research and technological development. The renewable energy systems covered are: wind energy, photovoltaics, biomass and geothermal energy.

Thermie is the DG XVII R,D&D programme designed to promote, among other objectives, the greater use of new and renewable energy sources. Renewable energy takes its share

Table 6: Renewable energy
Primary energy production in the EC, 1991-2005

(ktoe)	Photo-voltaics	Active solar	Wind	Hydroplants <10MW	Hydroplants >10MW	Biomass (total)	Geo-thermal	Total	Contribution to gross inland consumption (%)
1991	N/S	200	100	1 300	13 300	25 400	2 300	42 600	3.7
2005	100	1 200	1 700	2 600	17 100	66 600	3 000	108 700	7.8

Source: Altener report, DG XVII, 1992

of the funds along with R,D&D into the rational use of energy, hydrocarbons and solid fuels. The programme is designed to run from 1990-1994 with an estimated 700 million ECU of funds.

Valoren is a Community programme relating to the development of certain less favoured regions of the Community by the encouragement of their indigenous energy potential. DG VIII (Development) offers 50% subsidies for wind farms in selected countries, such as Ireland.

The Reward programme of DG XII (Science and Technology) is a two year programme, due to end in 1992, for research and development into the recycling of waste and is a continuation of a programme started in 1986.

OUTLOOK

Strong growth in the renewable energy industry is predicted into the next century. Some technologies will see faster growth than others and this will depend on the type and effectiveness of policies easing their market penetration rather than any technological development, though this will take place. Photovoltaics, however, are less commercially viable than the other renewable energies discussed. A decrease in the module cost per kW is a prerequisite before photovoltaic technology can compete seriously in the electricity generation industry.

The shares of each renewable energy technology in 1991 and 2005, according to the objectives of the Altener programme, are given in Table 6. Biomass is the area where strongest growth could occur; other renewable energy technologies, notably wind and geothermal energy, will also grow considerably. The share of large hydro-electric generation, though remaining large, will see relatively slow growth due to the lack of suitable sites remaining.

For electricity generation, biomass, predominantly wood, agricultural residues like straw, and waste will be increasingly used. Direct combustion will be the main method though gasification will see the largest growth. Wind energy will see strong growth though it is dependent on political factors to enable its widespread development. The introduction of the single energy market will greatly benefit wind power in the long term through trade. In the generation of electricity from geothermal sources, only Italy and Greece have high temperature geothermal resources. Italy is likely to see the largest growth in this area in the short term. Small hydro-electricity generation will experience higher growth than its larger counterpart. Photovoltaics, though a small component, will see growth in applications for remote locations. In the long term PV will see higher growth through grid connection, from either centralised or decentralised generation sites.

For heating applications, biomass will again play the major part, gasification technology showing the largest growth. Geothermal energy for heating will experience growth in all Member States where resources are available. The future prospects for the active solar collectors market depends to a large extent on the effectiveness of national and EC energy plans. Denmark and the Netherlands will see large growth due to government commitments to reducing carbon dioxide emissions; similar conditions should favour the industry in Germany. Italy has recently included the development of active solar energy into its national energy plan, ambitious targets have been made and these should promote strong growth. Spain has considerable potential, a government commitment combined with public education campaigns could result in active solar being widely implemented. In Greece, the market, though large, is not near to saturation and is likely to continue increasing steadily.

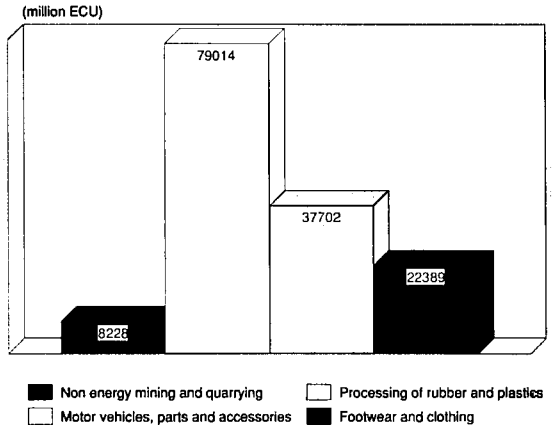
The future for biofuels, formed from energy crops such as rapeseed or sunflowers, depends very much on future agricultural policy in the EC. Economic factors are extremely complicated making predictions difficult. Given the very large potential, the relatively high value of liquid fuels and the environmental benefits (weighed against the costs) of using biofuels, the use of biofuels is likely to increase.

Written by: DRI Europe

Non energy mining and quarrying
NACE 21, 23

The non energy mining and quarrying industry is a mature and relatively stable industry of minor significance in the production of metallic ores, but of world status in industrial minerals, in particular construction raw materials. The limited resources of high grade and tonnage non-ferrous ores make this sector dependent upon imports to satisfy metal industry demand. The industrial minerals sector is capable of meeting net demand.
The non-ferrous metals mining sector is dependent upon international supply conditions, which largely determine prices, as well as certain industry activity levels which establish demand. The industrial minerals sector is affected by international competition to a lesser extent, but its profitability is directly related to industrial activity, in particular in the construction industry.
EC consumption of mined products is slightly higher than that of the USA, although production is lower. EC companies are major participants in mining activities overseas.

Figure 1: Non energy mining and quarrying Value added in comparison with other industrial sectors, 1990



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The non energy mining and quarrying sector can be divided into two main categories: the extraction and preparation of iron ore and non-ferrous metal ores (NACE 21); and the extraction of minerals other than metal ores, such as construction raw materials, sands and clays, salt, stone, potash and phosphate, other industrial minerals and peat (NACE 23).

Main indicators

Approximately three thousand mines and quarries of various sizes are operated within the EC, producing mined products of about thirty commodities. Industrial minerals account for 90% of production in terms of both value and volume.

The EC is a major world producer of building materials, sands and clays which alone account for 75% of total mine production. More than 10% of world production of ten other minerals is also achieved. The EC is also a minor producer of non-ferrous metal ores and concentrates and has a small output of iron ore. In total the EC produces between 10 and 20% of its raw material needs in the metallic and industrial minerals sectors, and almost 100% in the construction materials sector.

Production figures in current terms reflect the improved economic trading conditions enjoyed in the early/middle and at the end of the decade. A downward trend in the numbers of people employed in the industry is also noticeable as a result of improvements in mechanisation.

Germany is the most significant producer in the EC in terms of both volume and value, and this position will strengthen as production figures from the former Eastern Germany are added in the future. Five countries, Germany, France, the United Kingdom, Italy and Spain together account for 83% of EC mine production by value.

Recent trends

Although each of the commodities mined in the EC has unique aspects which affect its price and demand, the overall figures are heavily influenced by the industrial minerals and in particularly by the bulk construction raw materials whose prices are relatively constant in real terms. Thus changes in output and consumption mirror industrial activity, especially in the construction sector.

A small decline in overall production occurred during the 1980s. Modest increases for most commodities are forecast from 1993.

International comparison

EC consumption remains ahead of US consumption, but higher US production, particularly of non-ferrous metals, continues to allow the USA to enjoy a net neutral trade balance for all mined products. The EC is a significantly larger producer of construction raw materials. The increases in production in the USA arise from significant increases in the non-ferrous metals and construction raw materials sectors. The Japanese non energy mining and quarrying sector is not very significant: In 1990, Japanese production was about one quarter of that of the EC, and overall consumption approximately half.

Foreign trade

EFTA countries continue to be the main destination for exports, with the balance being fairly evenly distributed between the industrialised and third world countries. The major contributors to exports are construction raw materials (40%), non-ferrous metals (25%), other industrial minerals (20%) and potash (15%). Exports from the EC represent less than 10% of production and follow production trends. Imports similarly follow consumption trends and have remained relatively constant at around 35% of consumption levels.

Overall import requirements have remained relatively constant over the 1986-91 period. Third world countries, particularly those in South America and Africa, provide the largest contribution to imports. North America and Australia are also major suppliers. The largest import requirements are for non-ferrous metals (38%) and iron ore (34%).

MARKET FORCES

Demand

Approximately 25% of overall consumption is of ferrous and non-ferrous metal concentrates which are the raw materials for iron and steel making or metal smelting. Iron ore production is very limited (less than 1% of world production) and is mostly derived from remnant orefields in proximity of steelworks. Demand for non-ferrous metal ores reflects final finished metal demand, the major consuming industries being electrical (copper), construction (zinc and aluminium), transport (lead and aluminium) and containers (aluminium). Other significant industry users are machinery and chemicals. Prices and production levels for non-ferrous metal ores follow the general trends of these industries, although they are also influenced by supply and, more recently, environmental factors. Substitution threats to metals produced in the EC are not significant.

The major consuming industry for industrial mineral products is construction which receives 45% of all EC mined materials. As these minerals are the fundamental ingredient of roads and buildings, their demand is totally related to the level of construction activity.

The position is more complex for other industrial minerals where the primary consumers, such as the glass industry, are subject to different forces and relationships. As a result the demand, in this instance for silica sand and limestone, is subject to diverse glass industry markets such as transport (windows) and containers (bottles). The container industry is also a good example of intense competition between raw materials, in this case glass, aluminium and plastic. Other industrial minerals enjoy a wide spread of applications and thus overall have some protection against the poor performance of one industrial sector. Their demand, in consequence, reflects general industrial and consumer demand.

Supply and competition

As indicated, the small production of iron ore in the EC has a local convenience factor and is not typical of international supply which is dominated by large, high grade, low cost producers overseas. This competitive situation applies to non-ferrous metals which are under significant threat from overseas operations, with supply a dominant factor in setting price levels. The EC has a small number of world-class mines which are able to compete effectively in currently general over-supply situations, based on the size and quality of the deposits.

For industrial minerals the relatively low cost of the bulk materials and the costs of transportation ensure that local materials will be used in normal circumstances, and this provides the EC industrial minerals sector, with its generally adequate resources, with resilience in the case of international over-supply. The same factors restrict export potential, except where special conditions apply.

For the major mining area of construction raw materials there is a large degree of co-ownership of mining and consuming companies which secures mine output. Price levels are often not disclosed as a result. There is no supply of phosphates within the EC, but potash operations are threatened by potential oversupply from overseas, in particular from Canada and Israel, as previous protectionist policies are dismantled, in part due to the Single Market. Overcapacity exists in the EC salt mining industry, primarily due to lower utilisation of road salt but low price levels safeguard EC markets. Involuntary sulphur production from other industries ensures adequate supplies of sulphur, mainly as sulphuric acid. There are no EC supplies of certain important industrial minerals, most notably borates, and competition from countries such as Morocco (barite) and China (magnesia and fluorspar) is placing considerable pressure on other EC industrial mineral operations.

Production process

Mining operations vary widely from large "superquarries" for bulk stone products to smaller, sophisticated plants for products such as magnesite. Major underground operations also exist for base metals and potash, and most of the sulphur produced is as a by-product from other industries. Skilled labour availability in the EC is good, as are labour relations in comparison to North America and Australia. Most types

of mining have improved by the use of modern equipment rather than changes in technology, although improved mineral processing techniques in certain areas, in particular for white filler minerals such as kaolin, calcium carbonate, and talc, have allowed new product grades to be developed.

The productivity of the industry has increased over the last decade principally due to advanced equipment. Peaks have occurred coincident with economic upturns and higher commodity prices.

INDUSTRY STRUCTURE

Companies

There are approximately 50 companies, virtually all European owned mostly, but not always by the private sector, who have major interests in EC mining and quarrying. Medium to large sized operations are estimated to number around 150, with a substantially larger number of small operations. In addition to their European operations, EC mining companies also have significant overseas interests and control more than 20% of world production of several commodities including bauxite, lead, zinc, china clay, beach sands and borates.

Strategies

Companies involved with non-ferrous metals mining have as their prime objective the discovery of high quality deposits which can be developed to international competitiveness. Currently, the primary EC exploration target is the Iberian peninsula, where bore metals (Cu, Zn, Pb) are the main target.

For construction raw materials companies, strategic objectives include extending and strengthening linkages with downstream activities and expansion by acquisition. EC companies have increased their ownership of overseas companies in this sector, in particular in the USA. Company strategies in the phosphate industry have concentrated on product development and for potash and other industrial minerals, cost reduction and productivity increases are a priority. To date only minor investments have been made in the former Eastern Bloc, but the evolving policies of several countries, including Russia, strengthen the medium-term prospects of increased participation in this area.

Investment figures for a number of industrial minerals are not available but it is estimated that capital investment for the total mining industry in 1990 was in the order of 1 750 million ECU.

REGIONAL DISTRIBUTION

Spain, Portugal and Greece are the most important countries for non-ferrous metals production. Spain and France are the only producers of iron ore. Aggregates and cement are produced throughout all EC countries, with ornamental stone concentrated in Italy and Spain. Silica sand production is also fairly evenly distributed, with purer deposits in Belgium, Germany and France. The United Kingdom is the major producer of kaolin. Potash operations are mainly in Germany, France, Spain and the United Kingdom, and other industrial minerals are dispersed throughout the EC.

ENVIRONMENT

Environmental legislation, as applied to mining operations, is continuously tightening and is a significant factor in the industry. The major hazard for non-ferrous metals is acid mine drainage derived from oxidation of exposed sulphide minerals. For potash the problems are the salt produced during processing and the consequences of excess fertiliser usage. All commodities are now subject to legislation on dust and noise emissions, and in particular to waste dumping limits and aftercare of sites.

Other consequences of increased environmental awareness are the increasing amounts of sulphur products arising from the prevention of sulphur emissions. Some sulphur is stabilised as chemical gypsum which will reduce the demand for natural gypsum. The mining of peat is also under attack due to its occurrence in low-lying areas with the consequent risk of land loss by flooding. It is notable that large quantities of industrial minerals are used for environmental clean-up and as filter media and absorbents.

REGULATIONS

The main regulations which affect non-energy mining and quarrying are environmental and are summarised in Table 7. Single market regulations have been notable for the removal of market restrictions within the EC industrial minerals industry.

OUTLOOK

The EC will remain a minor domestic producer of non-ferrous metal ores and concentrates and will continue to be heavily dependent on imports for the metal manufacturing industry. The EC will also continue to be a major producer of construction raw materials, and EC companies will continue to be major international participants in overseas production of non-ferrous metals and industrial minerals. The EC potash industry is expected to undergo restructuring to meet low growth forecasts. In general terms the entire mining sector provides the raw materials for all subsequent industries and its prosperity will be directly related to overall industrial economics, in particular the building industry which accounts for the highest percentage of mined products.

Individual risks and opportunities apply to each of the commodities mined. The major risks applying to all materials are associated with general recession, with extra production costs being incurred by the need for higher standards of environmental compliance. Opportunities are conversely associated with general industrial prosperity with the possibilities of further mineral deposits being developed in southern areas of the EC and in Ireland.

Written by: B.M. Coope & Partners
The industry is represented at the EC level by: International Association of European Mining Industries (EUROMINES). Address: Avenue de Broqueville, 12, B-1150 Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Iron ore
NACE 211

The EC is a minor producer of iron ore, providing only 3% of the Community's requirements. Virtually all of the mined ore, which is of low grade, is utilised within the EC for the production of iron and steel. Iron ore mining in the EC is expected to continue to reduce gradually in competition with larger, higher quality and cheaper to mine deposits overseas.

INDUSTRY PROFILE

Description of the sector

NACE 211 covers the extraction and the preparation of iron ore. The industry mines iron oxide ores, normally with little further processing, as feedstock to the iron and steel industry. The preparation activity consists of three different phases: crushing, sintering and concentrating.

Main indicators

Production within the EC has declined, with 1990 output in tonnage terms around 50% of 1985 levels. The EC remains heavily dependent upon imported iron ore. Apart from a small, specialist usage for pigments, virtually all the mined ore is used in the manufacture of iron and steel. Only France and Spain are major producers, with nominal production only in Germany and the United Kingdom. Production in France and Spain is of non-agglomerated ore only, the French production being of low grade and consumed exclusively by a nearby related steelworks in Belgium.

Recent trends

Consumption within the EC has remained relatively constant at around 170 million tonnes of ore per year (compared with production in 1990 of only 12 million tonnes). Ore prices in current values have remained consistent, but have fallen substantially in real terms. Because of its poor quality, the unit value of the iron ore mined in the EC is significantly lower (by over 50%) than normally traded ore. Exports of iron ore are insignificant compared with imports which supply most of consumption requirements.

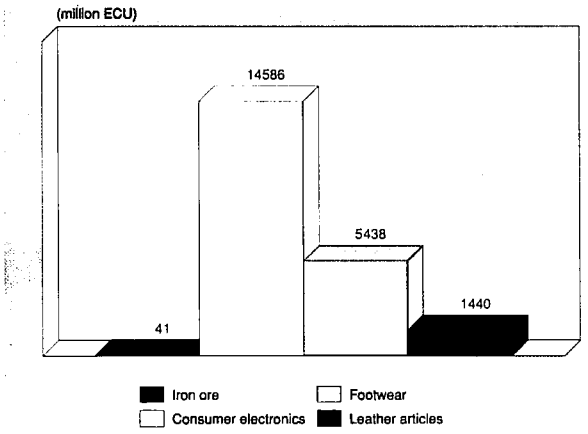
International comparison

Comparison with Japan shows similar dependency on imports, but with consumption in the EC remaining stagnant relative to the two other countries. Japan has discontinued iron ore mining, but USA operations have increased over the period. In tonnage terms the USA has produced at relatively constant levels, around 50 million tonnes per year, since 1984. EC production has fallen from 30 million tonnes per year to 12 million tonnes since 1982. Total world production is approximately one billion tonnes.

Foreign trade

The trade balance has remained fairly constant at current values during the 1982-1991 period. The level of exports is insignificant and is dominated by minor trade to Eastern European countries. Brazil remains the major exporter of iron ore to the EC. Together with other South American countries imports from this region are approaching 50%, the balance being fairly evenly distributed between EFTA, Canada, Africa and Australia. Intra-EC and extra-EC exports are at such low levels that the trends shown are insignificant, but the reduction in production is clearly demonstrated. The ratio of imports to consumption has shown a small upward trend, reflecting in part the fall in production.

Figure 1: Iron ore
Value added in comparison with other Industries



Source: Eurostat, B.M. Coope & Partners

MARKET FORCES

Demand

Virtually all EC iron ore production is consumed by neighbouring EC steel makers. The demand for iron ore is responsive to market factors and specific industries which consume steel. The recessionary decline in the automotive industry, for instance, reduced steel demand by more than 10% in this area between 1990 and 1991. Similar reductions were experienced in construction and machinery.

EC production of iron ore is very small in world terms, (less than 1% of world production), and with the remaining production coming from low-cost mines, it is relatively insensitive to market factors, being viable only because of local convenience. Virtually every major steel producer in Western Europe has shown a significant fall in output in 1991.

Supply and competition

The prolonged steel boom came to an end in 1989, with 1990 showing negative growth of just under 2% and 1991 nearly 5%. Although iron ore prices have remained firm for special reasons associated with stock positions and individual supplier nation disruptions, the iron ore market must inevitably follow

Source: Eurostat

steel demand which has been affected by recession since 1989 in the major consuming industries.

Internal competition within the EC is limited to France and Spain, with France producing at more than twice the Spanish level, and in both cases declining. Foreign competition and lack of adequate reserves will continue to leave the EC as a minor producer only. Overseas competitors do enjoy some advantages over EC mines, but the overriding influence is the low grade and limited nature of reserves in the EC. No figures exist to establish a profitability index, but production levels within the EC and prices in real terms have declined.

Production process

There have been no significant impacts upon mining operations which have been modernised without major innovation. Employment levels have fallen over the period to reflect reduced production and productivity increases. The unit labour cost has also risen. The specifications for iron ore have remained fairly constant but with some pressure for higher grade material.

INDUSTRY STRUCTURE

Companies

The iron ore mining industry in the EC is very small, with only a handful of operations. The largest operations are in the French region of Lorraine at Mairy and L'Orne (Lormines) and Terres Rouges (ARBED). Iron ore mining in the EC is a small industry with relatively low investment. The mining companies concerned are medium-sized private enterprises whose aims are limited to profitable development of deposits in their geographical region.

ENVIRONMENT

Environmental concerns in iron ore mining are significantly less than for non-ferrous metals mining because of the absence of sulphur in the ores and the small scale of the activities. Factors are the discoloration of rivers and despoliation of the countryside. Good husbandry by the operators and the long tradition of mining in the areas concerned has ensured there are no major problems.

OUTLOOK

EC production is likely to remain at a low level with consumption steady and proportional to steel demand. Export levels will continue to be nominal. Iron ore mining will be adversely affected by increasing environmental compliance costs and during periods of low demand. Increased output will be encouraged by high steel demand.

Non-ferrous metal ores
NACE 212

The EC retains a small but significant non-ferrous metals mining industry which provides around 15% of the EC's raw material requirements for metal production. Non-ferrous metals in the EC is a mature industry subject mainly to international influences. Little change to the established pattern is expected during the 1990s.

INDUSTRY PROFILE

Description of the sector

NACE 212 covers the extraction and preparation of non-ferrous metal ores. A number of underground and open-pit non-ferrous mining operations are located within the EC. Mined ores are processed to concentrates which form the feedstocks for metal smelting and refining activities covered in Chapter 4. The major metals mined in the EC are zinc, copper, aluminium and lead, with smaller amounts of nickel, tin and tungsten. The extraction and preparation of uranium and thorium ores are not included.

Main indicators

Copper concentrate production has increased substantially since 1989 with the coming on stream of the Neves Corvo mine in Portugal. Revenues from copper and zinc production in the EC are now approximately equal and together with bauxite account for over 80% of non-ferrous metal turnover. All the metals mined in the EC have been affected by the recession since 1989, but copper has performed with more resilience, dropping in value around 20% between 1989 and 1991 compared with more than 20% for other base metals. By virtue of the world-class copper deposit at Neves Corvo, now in full production, Portugal has become the leading EC producer of non-ferrous metal concentrates. Portugal, together with Spain (zinc) and Greece (bauxite) accounts for over two-thirds of EC production.

Recent trends

Overall production levels have remained relatively constant, with increased production in copper compensating for reduced zinc and lead output since 1989. The fall in value of production since that time reflects the decline in international metal prices. Estimated figures for 1991 and 1992 indicate that with copper performing better than other base metals and zinc production declining, production revenues from these metals will become similar. Trade figures reflect strongly metal prices which reached a peak in 1989. Employment figures, however, continue to reduce as a result of productivity improvements.

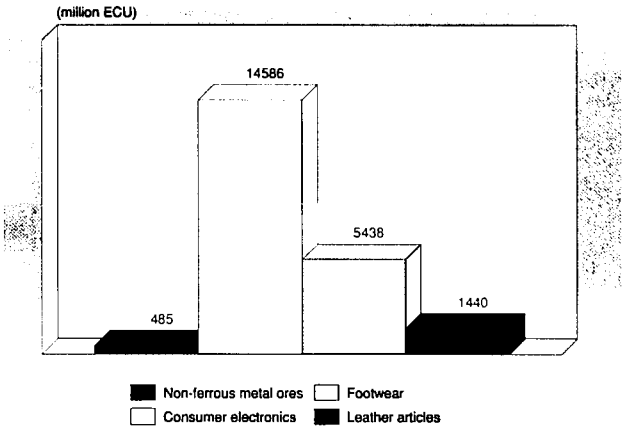
International comparison

EC and Japanese trends have remained roughly in parallel except that the small Japanese production base has further reduced. The trend in the USA to produce more concentrates is notable. USA figures in current dollar terms are closer for both years, the difference in part reflecting changes in parity of the US dollar with the ECU.

Foreign trade

The EC remains dependent upon imports, with a very small value exported. Exports are dominated by zinc and lead concentrate shipments to EFTA countries and copper shipments to Japan. There has been no significant change in the East-West movements for base metal concentrates to date. The dependence of the EC upon a wide geographical spread is illustrated in Figure 5. The largest individual volumes are from Africa, (aluminium), Canada and South America (zinc). The consistency of the non-ferrous metals mining industry is highlighted by the relatively constant ratio of imports to consumption shown in Figure 6.

Figure 1: Non-ferrous metal ores
Value added in comparison with other industries, 1990



Source: Eurostat, WBMS

MARKET FORCES

Demand

None of the concentrates mined and processed are products in their own right, and all proceed for added-value processing to metals. Within the EC the largest consumers are the lead and zinc smelters, followed by steel making and copper smelting. Very few of the EC non-ferrous metal mining operations are vertically integrated on site, although some of the consumers have ownership interests in the mining operations.

Final metal products are influenced by the international economic situation, and the decline in consumer spending since 1989 has been partly responsible for reduced prices and demand. With prevailing recessionary influences, base metal prices are showing no signs of improvement. Unlike many other industries, other factors are also significant in affecting the market, most notably supply continuity, East-West trade and, more recently, environmental considerations.

The overall situation may be summarised as steady demand with potentially more than adequate supply, resulting in pressure on prices unless demand is disrupted. Reductions in mine production in Eastern Europe and environmental pressures may provide sufficient influence to moderate supply to improve prices when general consumer demand improves. The non-ferrous metals markets are mature, and little affected by substitution or innovation.

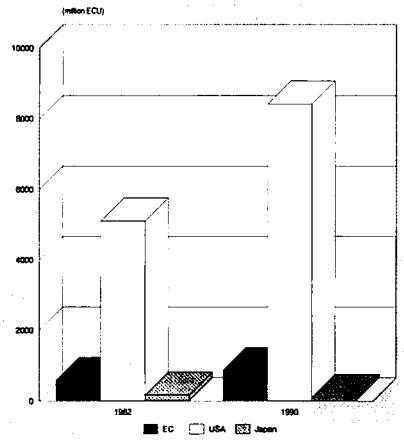
Supply and competition

The EC is a small but significant producer of lead, zinc, copper and aluminium concentrates, producing a small part of the material for EC requirements and operating in a strongly competitive international supply situation with no control over prices charged.

The strong supply position provides smelters with a strong negotiating position on prices, and they in turn are being pressed by fabricators and metal consumers. Internal EC competition is not a factor in market competition in mining, which is dominated by overseas metal mines. Factors which strengthen the competitiveness of overseas, third-world producers include lower labour costs, higher grade and larger ore deposits and lower environmental compliance costs. EC operations (in common with those in North America) enjoy better technology and productivity, and where ore deposits are of high quality (e.g. Neves Corvo), EC operations are highly competitive.

The maintaining of a higher level of revenues than may be expected after the 1989 boom reflects the increasing value of copper production, which increased nearly tenfold between 1987 and 1991. Copper has suffered less than other major non-ferrous metals over this period in terms of prices.

Figure 4: Non-ferrous metal ores
International comparison of production at current prices



Source: Bumines, Eurostat

Production process

There are no particular external factors affecting the mining of non-ferrous metals in the EC, which possesses appropriate levels of energy, labour and technology. Operations under threat are affected by international metal price considerations and the quality of deposits being mined. No radical changes in mining methods have been introduced, although modern equipment has allowed productivity to increase.

INDUSTRY STRUCTURE

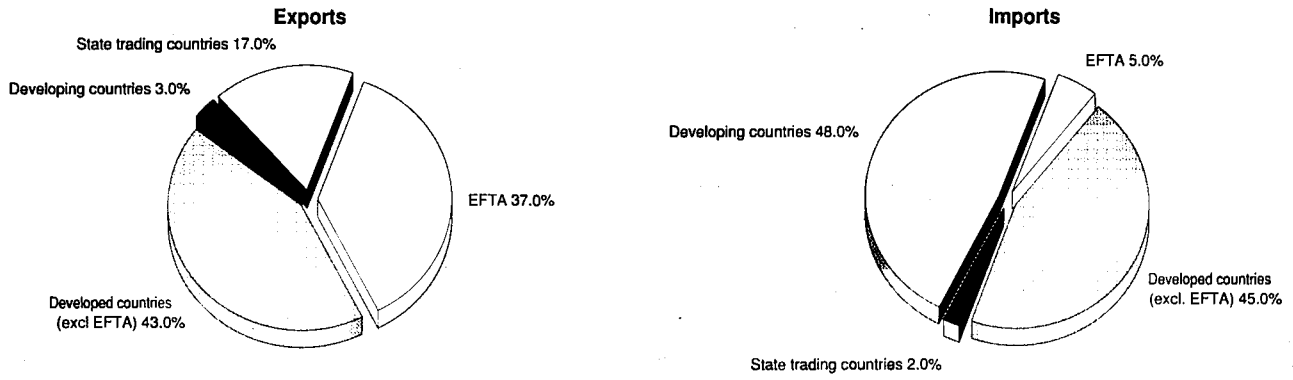
Companies

The largest mines are Neves Corvo (Portugal, copper) and Navan (Ireland, lead/zinc). European ownership of EC non-ferrous metal mining companies is virtually 100%. The major European companies also have a significant share of world mine production, in 1989 being bauxite (25%), copper (11%), nickel (20%), lead (20%) and zinc (20%). EC companies overall are responsible for approximately 10% of world mine production, the largest companies being RTZ (UK) and Metallgesellschaft (D).

Strategies

Many mining companies are also involved in final metal production and their strategies are best considered in a combined context. On the mining side the policies of the major EC companies can be simply defined as locating and developing high quality ore deposits, for which the priority is regional geology above all. Within the EC the Iberian peninsular represents the best geological target, although there is considerable activity in Ireland also. Exploration is intensive in this area, although several other regions of the world, notably Chile, have a greater focus. The finding of Neves Corvo has

Figure 5: Non-ferrous metal ores
Destination of EC exports and origin of EC imports, 1990



Source: Eurostat

strengthened enthusiasm for finding other major deposits, but they are likely to be deep and difficult to locate.

EC mining companies are taking preliminary interests in opportunities in Eastern Europe as well as the former Soviet Union, but it is too early to say whether they will be developed on a major scale. The single European market is not a factor in mining company strategy. Investment within the EC is in proportion to the level of mining operations. The last major investment was approximately 400 million ECU in 1988/89 for the Neves Corvo mine.

As for M&A activity, RTZ extended its pre-eminence as Europe's largest mining company with the acquisition of the mineral division of BP in 1986.

REGIONAL DISTRIBUTION

The most significant mining regions of the EC are Spain and Ireland for lead and zinc and Portugal for copper. Germany and Italy are also significant for lead and zinc, with Greece for bauxite and nickel and Portugal also for tin. Lead and zinc production from Denmark (Greenland) is discontinuing in 1991.

ENVIRONMENT

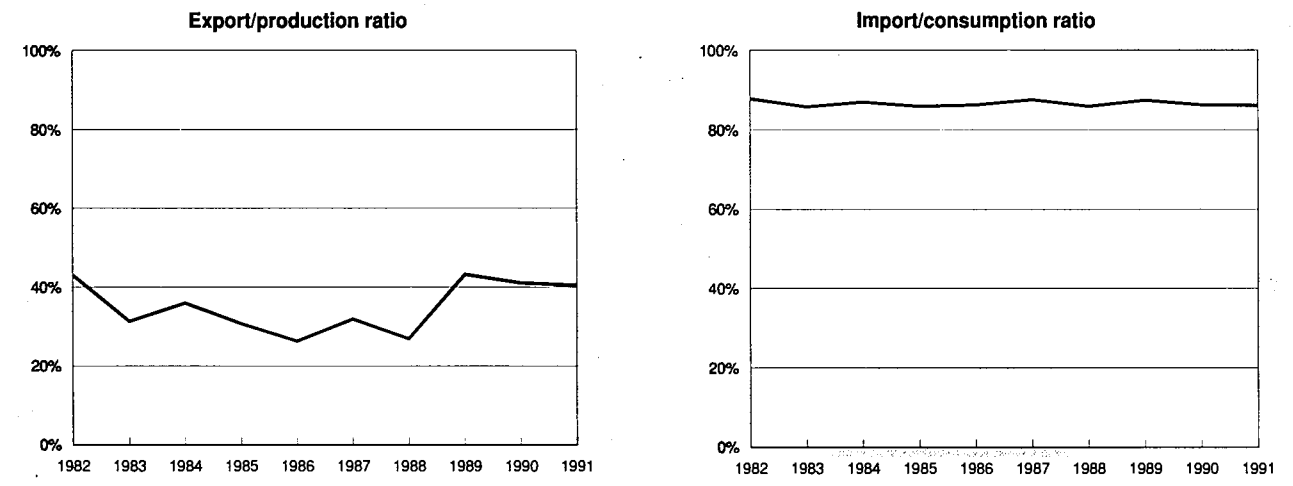
Mining hazards are principally water-related, in particular acid mine and rock drainage. To date within the EC there has been no major conflict between mining and environmental interests, but EC legislation is becoming more stringent and companies are being urged to comply. One example which highlights the water problem has occurred in the United Kingdom following closure of the tin mines. Acidic mine water has entered water courses and there is no longer a mine operator to take responsibility for the problem. This situation will be avoided under forthcoming legislation.

OUTLOOK

The EC is expected to remain a minor producer of ores and concentrates with dependence upon imports, mainly from outside Europe, for subsequent metals production. This picture is unlikely to change over the decade.

Internationally in neutral economic conditions continuing modest increases in metal consumption are expected, with metal prices rising from their historically low positions in

Figure 6: Non-ferrous metal ores
Trade intensities



Source: Eurostat

1991. For mining operations, however, the supply situation will remain competitive with only low-cost mines remaining viable. This will result in the closure of some higher cost lead/zinc mines in the EC, but will not affect the larger, modern mines responsible for most of EC output.

At the same time, output will continue to be affected by recessionary influences and mines will have to absorb higher environmental costs. A long-term risk would occur if large tonnages are exported from the former Eastern Bloc, although this should not affect the large EC mines.

The mining industry will be boosted by shortages of supply and increased from whatever causes, but a major increase in EC output can only arise from the discovery of new deposits. Large new projects are under investigation in Ireland (Lisheen), France (Chessy) and the United Kingdom (Parys Mountain). Other prospects exist in Greece, Ireland, Spain and Portugal.

Stone
NACE 245

The European stone industry is the oldest and today still an important section of the world's non-energy mining industry. Europe produces, transforms, trades and consumes all kinds of stone materials including marble, granite and travertine. These products are destined for various uses although the largest consumer is the building industry, particularly the upper end of the industry, where there is strong competition from alternative materials such as ceramics and glass which have greater investment capacities for research, development and marketing.

INDUSTRY PROFILE

Description of the sector

The ornamental stone industry is divided into two main sections: the excavation of raw materials and their subsequent transformation into the various finished products. The processed materials are mainly calcareous (marble, travertine, etc.) or siliceous (granite, serizzo, beola, etc.) and their relative uses differ to some extent. Granites are principally employed for exteriors or wherever greater resistance is required to stand wear and tear and atmospheric pollution. Marbles are principally destined for interiors or where there is greater protection from external elements.

Main indicators

In the 1980s the industry experienced a real boom. From 1981 to 1991, world quarry production rates rose from around 20 to over 30 million metric tonnes and this was accompanied by an equally significant increase in the number of producer countries. At present only nine countries exceed an annual production of one million metric tonnes and six of these belong to the EC (see Table 1). Up until 1991 the EC ornamental stone industry accounted for over 50% of world production and around the same percentage of global international exchange in terms of volume. The products exchanged within and outside the EC include rough blocks and a wide variety of finished articles.

Recent trends

Present production figures amount to an average of around 30 million metric tonnes per year with a recent, constant upward trend mainly due to the entry of new producer countries into the world market. Since the early 1980s at least ten new producers of some significance have emerged and become self-sufficient, a phenomenon which has also led to an increase in machine production for the quarrying, sawing and processing of stone. Recently, this off-shoot of the stone industry has been flourishing and is mainly based in EC countries like Italy, Germany and France. The EC Mediterranean countries form the heart of the sector at both a European and a world level even though other areas in the world are now also developing. In 1991 the largest producer of blocks for ornamental use was Italy which has always held the leading position in the market, followed in the EC by Spain, Greece, Portugal and France.

International comparison

Since 1985 Japan has been a significant importer mainly of granites which are primarily destined for funeral art. Japan buys lower range semi-processed or finished articles from Taiwan and South Korea, and stone for complex work which requires the use of sophisticated production techniques and a wide range of different products from Italy. The same applies to the USA even though it has good national production rates. But since 1988 the USA has witnessed a gradual reduction

in demand for finished products, especially in granite, due to the slump in the non-residential buildings market. Compared with the other building activities in North America, the European stone industry has felt the decline less than ceramics and other competitors. Moreover, the US market, like the Far Eastern market, generally remains a privileged market as regards the average unit value of the product it absorbs.

In South East Asia there is a tendency towards self-sufficiency which is likely to continue over the next few years. The great buying power of the Japanese market, the extensive building activities in some of the newly industrialised countries, the availability of low-cost labour, the proximity of areas with high raw material production rates such as India, South Africa and more recently China, all create a shorter distribution chain for products which excludes all competitors, but a few privileged niches in the market. The EC industry occupies a strong position as far as the latter are concerned.

Foreign trade

Trade in volume mainly involves raw and semi-finished materials. In 1991, the leading importer was Italy, closely followed by Japan which has only recently attained this position. Important exporters apart from Italy include Spain, Greece, and South Korea. South Korea is the only country to have recently (1988-1989) penetrated the market as a producer, transformer and consumer. EC exports mainly consist of finished products which are principally destined for the building industry.

Until 1982-1983, there was also a strong demand from the Middle East countries. Subsequently, external factors led to an abrupt decline in demand to a mere 35% of its most memorable peak. The effects of the international crisis in the Persian Gulf are mostly responsible for the 1990-1991 figures, although some improvements appeared in 1992. Nevertheless, the most important market is still the EC itself, first and foremost in Italy and Germany, followed by Spain and France.

MARKET FORCES

Demand

The demand for stone materials is widespread. It ranges from the large importers of blocks which amount to only a few dozen firms throughout the world, concentrated in Italy and Germany, to the large North American building firms and developers and the final consumers for all the other sections of the market.

The greatest problems for the sector arise from the extreme fragmentation of the consumer market together with the very limited average size of companies. Moreover, the lack of capital to invest in research, development, promotion and marketing makes it difficult to exploit this dispersed consumer market which is often regional and not even national.

On the other hand, the factors which sustain demand are above all the intrinsic factors regarding the products themselves such as their reputation, response to technical problems, aesthetic variety and image.

Quarrying technology is relatively simple and therefore problems mainly arise from the lack of infrastructures. Countries capable of offering technologically advanced finished articles at competitive prices are however very few. With the exception of Italy and to a lesser extent Spain and the other EC countries, all remaining significant stone consumers are far from being self-sufficient even within their own home markets.

Supply and competition

The traditional usage, the extensive and intensive production, the ability to transform raw materials, a building industry very much oriented towards maintenance and restoration, all favour the use of stone. It is often considered a material which adds prestige to buildings where it is used, be they residential or non-residential. The difficulties of a sector which is not in a position to invest sufficient capital in promotional and marketing activities may affect its development over the next few years. Sections of the market which are in a position to expand despite the recession which is now threatening certain countries are still confronted with the deep penetration of the market by their competitors such as glass and ceramics. Indeed, the general increase in the competitiveness of all markets has already adversely affected the price trends in 1991, which had to decrease in real value to retain a hold in the major markets.

Production process

The development in processing technology has widened the field for the use of stones, especially in the building and furnishing industries, and this development has been accompanied by improvements in stone laying and maintenance techniques. The new uses have emerged mainly thanks to the techniques for obtaining minimal thicknesses and applying them. This has enabled stone products to penetrate the avant-garde markets such as the removable floorings market for

electronic processing centres and the light vertical claddings market. Marbles and granites can therefore be used inside lifts, in ships, on skyscraper facades in areas subject to typhoons and in other situations which would otherwise be inconceivable for traditional methods. Alongside these avant-garde uses, there are of course the more traditional, well-established areas of usage, such as funeral art, furnishings, monuments, decorative architecture, where production processes have also undergone a radical technological transformation. For some of the traditional uses, the processing of stone is part of production in other industrial sectors. Particularly in the case of furniture production, marble and granite cutting and polishing workshops for vanity tops, kitchen table tops and bathroom furniture coverings work as an integral part of the production line of finished furniture. However, the most interesting market as regards the quantity of material sold and the value added absorbed is still the building industry.

INDUSTRY STRUCTURE

Companies

The average size of companies in the sector is generally very limited. In Italy, for example, the average company has no more than 10 employees, although there are various companies which have joined forces to develop market strategy and pool resources. Recent and reliable statistics are not available for all the EC countries but it is estimated that there are now around 500 000 employees overall, at least half of whom work in the quarries. There have been great changes in the production methods, speed and costs in recent times due to the mass introduction of diamonds in the quarrying and processing of marble at the beginning of the 1980s. The greatest concentration of productive firms is in Italy, where stone materials are available in nearly all its regions but mainly in Tuscany, in Carrara and the surrounding area, Sardinia, Sicily, Puglia, Lazio, Lombardy, Piedmont and Veneto. It is calculated that in all there are over 70 000 quarry workers, in addition to those working in industries connected to quarrying, transformation and commerce. The same situation can be seen in Spain and to a lesser extent in France, Greece and Portugal, whereas in Germany the transformation industry prevails.

Strategies

A problem which affects almost all EC countries is the ageing labour force. The turnover of the generations of workers is very slow indeed and this is a problem which may become very serious in the future for a sector which often requires a long period of complete professional training. The biggest question mark in the sector remains the economic and commercial prospects. The sector is inevitably dependent on the building industry, especially its upper end (residential, non-residential, urban landscape, restoration of old town centres, renovation in general). The tendency towards self-sufficiency of certain foreign markets could reduce the overall market of the European stone industry and limit it more and more to the market within the EC itself. As far as stone companies are concerned, this could lead to even more problems for smaller companies which would be forced to specialise still further or opt for subcontracting, leaving the larger companies to deal with the more complicated contracts and the more distant markets. The major companies are already directly present on distant markets, have local associates and coordinate complex projects.

ENVIRONMENT

Important environmental issues involve the stone industry in both its productive divisions, that is, quarries and workshops. There are serious problems as regards the respect for and restoration of the structure of the mountains where quarrying activities are carried out. Various countries and regions do actually impose a programme of temporary management of the quarry dumps and at least partial reconstruction of the natural habitat to be included in the quarrying plans. This is not always feasible and sometimes leads to the interruption of activities due to the impossibility to comply with regulations in force.

Respect for the environment must continue after the quarrying process. This requires compliance with the regulations regarding interior working environments (microclimates inside the workshops, noise levels, dust, mud, complete safety) and mutual respect between workers and inhabitants. Thus, the management of refluent slurry, the protection against noise, the protection of water courses from polluted waste, overloaded roadways, are problems which concern technical re-

Table 5: Stone

searchers, machine manufacturers and environmentalists alike. Technical researchers are in fact working to find the best solutions (for example, the reutilisation of marble rubble) while manufacturers are trying to produce machines with lower noise levels and less dust production (sound-proof machines, purified plants at the design stage, etc.) and environmentalists are involved in imposing respect for the environment and the regulations in force.

REGULATIONS

The EC's stone industry is subject to the regulations which in general cover building material products. Today, it has to face two major restraints: as regards production, the respect of the environmental and workers' safety regulations both inside and outside the quarry and the workshops; as regards usage, the respect of special safety regulations regarding anchorage systems for vertical cladding and the development of a joint set of regulations for the EC with respect to certain production methods. There are various technical committees within the Normalisation European Committee (NEC), which have an internal sub-commission which deals with processed stones. Among these, we can name:

- TC 125, which deals with masonry, and plans to set up a sub-commission for natural stone masonry;
- TC 128, which deals with building coverings, etc., and has a work group for slates as covering;
- TC 178, which deals with roadways and curbs, and has a sub-committee for natural stones;
- TC 246, which deals with floorings in general in natural stone, interiors, stairs, terraces, balconies, etc., and exterior facings. It is already organised into three subgroups, one for terminology and classification, one for test methods and the most important one, for the prerequisites and limits for specific products. In view of '93, stone products must be ready with the necessary prerequisites so as to be able to circulate freely within the EC and withstand competition from similar materials.

OUTLOOK

Although the world's stone sector is in constant but modest overall expansion, the European sector's future is more closely linked to the general tendencies of the European economies and their building activities. The achievement of the Single Market will not affect the firms already operating outside their own region. At worst they will have to conform to the standardised regulations and the consequent quality certification prerequisites. Trade relations with distant markets will be more difficult as the latter are forming autonomous productive systems to face European firms. It will be more complicated for individual firms, especially smaller ones, to gain a place on such markets without having privileged partnerships with local firms and the necessary support in the form of assistance, services and credit facilities.

On the other hand, the opening of new quarrying activities in developing countries and the consequent increase in familiarity with using natural stones since the late 1980s, is gradually creating better prospects for new markets. Whether or not the European stone market will be able to continue to expand in the 1990s depends on how effectively it equips itself to face these new realities.

Construction raw materials, sands and clays

NACE 231

The EC is one of the world's major producing and consuming regions for construction raw materials, sands, and clays. In the construction raw materials sector the EC is self-sufficient for virtually all mainstream products and external trade tends to be in material chosen on aesthetic grounds. The economic performance of this industry is tied directly to the level of building and construction activity in the EC, which has been stagnating in recent years.

The EC's industrial sands and clays industries can justifiably be considered as world leaders in both the size of production and influence in world markets. The EC is also theoretically self-sufficient in these materials although external trade is prominent among the more specialised grades. The economic performance of this sector is closely related to overall manufacturing activity in the EC and in particular by such industries as glass and ceramics, metallurgy, paper, paints, plastics, etc.

INDUSTRY PROFILE

Description of the sector

The mainstream products covered by NACE 231 include: crushed stone for construction and road aggregate; sand and gravel for construction and road aggregate; limestone and chalk for cement and lime; gypsum for plaster and cement; common clays for bricks, tiles and pipes; dimension stone (including marble and granite). For more information about this last, please refer to the previous chapter on stone.

Construction aggregates are the bulk raw materials used in the building or roads, railways, and buildings. They are produced throughout the EC and a typical operation will consist of a sand and gravel pit or a hard rock quarry producing crushed and graded limestone or granite.

Limestone and chalk are the main raw materials used in cement and lime manufacture and quarries for these end-uses are invariably captively owned by large cement (or lime) manufacturing groups. In a similar way common clays for the production of bricks, tiles, and pipes are also owned by the manufacturers of these products.

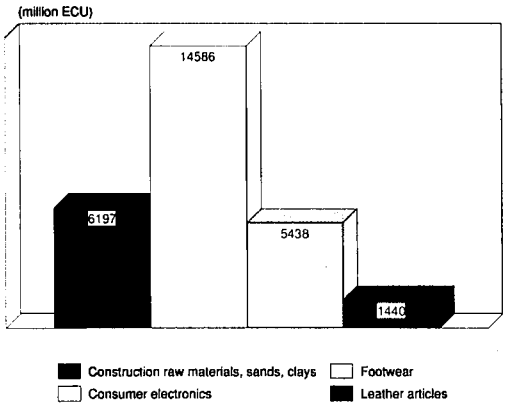
Main indicators

Production levels increased gradually throughout the 1980s but fell away during 1990 and 1991. This reflects not only the strong performance of the construction industry in the late 1980s but also the more recent downturn in construction activity. EC production volumes remained fairly constant during the 1980s compared to strong growth in the USA.

Since production of the major product lines are universal it is not surprising that value added data are in line with overall economic activity. Thus Germany displays the largest value followed by France, the United Kingdom, and Italy.

Prices for most of the bulk construction raw materials tend to be more or less constant in real terms and thus value growth for both production and consumption tends to reflect volume growth. Likewise the higher levels of extra-EC exports in recent years reflect higher volume sales of products such as gypsum, dimension stone granite, and carbonate fillers.

Figure 1: Construction raw materials, sands and clays Value added in comparison with other industries, 1990



Source: Eurostat, B.M. Coope & Partners

Foreign trade

The EC is highly active in both the importing and exporting of these materials but in recent years has become a net importer. This is primarily due to a surge in the imports of dimension stone granite from countries such as Norway, South Africa, Brazil, and India. It should also be noted that most of this product is imported in raw form for processing by the EC's domestic stone processing industry (particularly in Italy).

The large increase in intra-EC trade sustained throughout the 1982-1991 period is primarily a function of rising volumes across a range of products including kaolin, bentonite and other special clays, sand and gravel, crushed stone, marble, and granite.

Exports are dominated by shipments to EFTA countries, particularly of paper grade kaolin to Finland and Sweden and construction aggregates to Switzerland. Highlights in export trade to non-EFTA countries are the shipments of dimension stone marble and granite to Japan and the USA. In 1985 Saudi Arabia was also a major destination for the latter products.

As far as sources of 1990 imports are concerned, the EFTA countries accounted for about one third of total and the main

highlights were dimension stone granite from Sweden, Finland, and Norway. Other important countries were represented by the USA (mainly kaolin and bentonite) and South Africa (mainly granite and andalusite).

MARKET FORCES

Demand

The construction industry is clearly the dominant factor in any discussion of markets for this group of raw materials. As the fundamental ingredients involved in the construction of roads and buildings demand for the major product lines are directly dependent on overall construction activity.

One notable trend which has been hinted at in earlier sections concerns the increasing use of natural stone (as represented by dimension stone granite and marble) for the exterior and interior surfaces of buildings. Traditional clay facing bricks also experienced strong demand during the 1980s for much the same aesthetic reason.

A more complex picture is in evidence with regard to markets for industrial sands and clays and the industrial grades of limestone and chalk. Major consuming industries for these products are glass and ceramics, metallurgical industries, and fillers and coatings (in the paper, paints, plastics, rubber, sealants and adhesives industries). Silica sand and limestone are both essential ingredients of glass. In the fillers and coatings category it is worth noting the fierce rivalry between two mineral products of this sub-group, namely kaolin and calcium carbonate (prepared from white limestone, marble, or chalk). Demand for both products was strong during the 1980s but calcium carbonate has been replacing kaolin in many paper products, partly as a result of a technological change in the paper making process (from acid to neutral of alkaline sizing).

Supply and competition

The EC is a major world producer and is theoretically self-sufficient for virtually all the minerals and rocks in this group. Thus prices tend to be an intra-EC affair based on contracts negotiated between producer and consumer. Indeed because of the high degree of captive ownership in the construction minerals area many prices tend to be an intra-company affair.

Transportation is major consideration in bulk raw material markets and thus producers often operate their own trucks and sell on a delivered basis and in many cases sell semi-finished or finished products such as ready-mixed concrete, coated roadstone, and plasterboard. Sales of these value-added products plus the strong element of service offered to the customer often combine to give attractive operative margins for companies operating in the sectors.

Transportation is also the factor which normally rules out foreign competition in bulk construction raw materials on cost grounds. The exceptions to this rule cover situations where non-EC countries are neighbours (e.g. Norwegian and Swedish stone shipped to Denmark and Germany), where "superquarries" have been set up to export stone in low-cost bulk carriers (e.g. Glen Sanda in Scotland), and where high value items are preferred on aesthetic grounds (e.g. dimension stone granite from South Africa, Brazil, and India). In the latter case it should be noted that the EC stone processing industry adds major value to the material before sale and is actively engaged in extra-EC exports of the cut and polished versions of the products.

Meanwhile in the industrial clays, sands, and carbonates sub-group the chief foreign competition arises in the kaolin and special clays area. Paper-coating grades of kaolin satisfy many

of the requirements of a "strategic mineral" as a result of the scarcity of deposits and their economic importance to a major industry. Large scale world production is limited to south-west England in the United Kingdom, Georgia in the USA, and Amazonia in Brazil. Although the United Kingdom is the principal source for the EC and EFTA countries overall demand is supplemented by significant tonnages imported from the USA and Brazil. The paper industry is highly cyclical and kaolin prices tend to offer high margins at the top end and low margins at the bottom end of the cycle. Market shares do not alter markedly during different stages of the cycle, suggesting that producers from the three areas are more or less balanced in competitive terms within the European arena.

The USA is also a major supplier of bentonite and other smectite clays to EC markets. Some of the products have a technical edge over EC products (for instance, the US sodium bentonites have superior properties over the calcium bentonites of European origin) but this particular field is marked by its diversity (in both range of products and range of end uses) and EC producers continue to satisfy the bulk of demand.

Production process

As discussed earlier, construction raw materials extraction is often in the hands of large construction groups whose activities may range from cement and plaster products manufacture to civil engineering. The quarrying divisions of such groups tend to be large scale, highly mechanised operations with quality control well in evidence to cover what is in essence a crushing and grading exercise. In the aggregates sector these operations co-exist alongside smaller, less sophisticated operations which nevertheless have an important role to play in highly localised markets.

In the industrial clays, sands, and carbonates sector the mineral processing requirement is much greater and may involve a variety of beneficiation techniques as well as fine particle processing and surface modification. Recent advances in processing technology (using techniques such as high intensity magnetic separation, acid treatment, high temperature processing, jet milling, air separation, coating and agglomeration) have improved product quality, expanded raw material reserves, and led to the development of entirely new product grades.

INDUSTRY STRUCTURE

Companies

Certainly some of the largest enterprises operating in construction raw materials sector are the major cement, brick, and aggregates groups such as Lafarge Coppee and Ciments Francais of France; RMC, Redland/Steetley, Tarmac, Tilcon

(BTR), Blue Circle, Hanson, and Evered Bardon of the United Kingdom; Heidelberger Zement, Dyckerhoff, and Basalt AG of Germany; Holderbank of Switzerland; Italcementi of Italy; CBR of Belgium; and CRH of Ireland - all of which measure their employees in thousands or tens of thousands.

Other major enterprises extracting limestone include the lime specialists such as Lhoist, Carmeuse, Rheinische Kalkstein-Werke (Wulfrath), and Buxton Lime (Minorco) and the carbonates producing Omya group (Pluess-Staufer). In the gypsum and plaster sector the major enterprises are BPB Industries (UK), Lafarge Coppee (F), and Gebr. Knauf (D). Major players in the industrial sands industry are Sibelco (B), Quarzwerke (D), Hepworth (UK), and their subsidiaries in other EC countries. In the kaolin and ceramic clays sector major enterprises include English China Clays and Watts Blake Bearne (UK), Amberger Kaolinwerke (D), and AGS and Imetal (F). Major enterprises in the bentonite and special clays sector are Sud Chemie (D), Laporte (UK), Tolsa (E), and Eliopoulos (GR).

In each of the sub-sectors in which they operate, the above named enterprises represent over 60% of total EC turnover. All these companies are either European or international in character. Most of the large cement and aggregate groups maintain major international interests, particularly in North America. This is also true of the major industrial sands and clays enterprises: Sibelco, English China Clays, WBB, and Sud-Chemie.

Strategies

In the construction raw materials sector, market strategies of the larger enterprises are bound up in their downstream activities. Nevertheless there has been a marked consolidation of the industry in the EC itself as major groups have continued to increase reserves of raw material and influence in downstream products by acquisition.

The EC and North America tended to be main areas of focus for acquisitions in the cement and aggregates sectors during the 1980s. More recently the shift of focus towards Eastern Europe has been much in evidence although the 1992 take-over of Steetley by Redland demonstrates that intra-EC consolidation will continue. No major moves have yet been made in the CIS and this is unlikely to happen until greater stability rules.

US acquisitions have also been made by major EC operators in the industrial sands and clays sector. Sibelco of Belgium acquired the USA's largest silica sand producer, Unimin, in the mid-1980s and incidentally the second largest producer there, US Silica, is now owned by RTZ (UK). In 1990/91 English China Clays (UK) acquired the USA's largest kaolin producer, Georgia Kaolin Co, to add to its existing operations in the USA. Watts Blake Bearne (UK) acquired United Clays in 1989 and Laporte (UK) acquired Southern Clay Products and Waverley Mineral Products.

In the aggregates sector the acquisition of quarries (or sand gravel pits) is a prime motive - i.e. the best way to increase aggregate reserves (with planning permission) and to maximise involvement in major construction activity is to acquire existing operations and invest to expand or modernise as required.

In the cement sector the prime motive is in acquiring the cement producing unit and the limestone reserves a secondary consideration. The European cement industry has suffered from overcapacity in the past and thus many mergers and acquisitions were part of the rationalisation process. However, more recent acquisitions by the big international groups have been aimed at increasing influence in non-traditional regions - e.g. the USA, Iberia, Eastern Europe, Turkey, etc. Intra-EC investments have often involved new technologies to cut production (and particularly energy) costs.

Meanwhile investment by the industrial sands and clays sector in recent years would appear to be directed at product development and process improvements rather than to exploration or expansion.

REGIONAL DISTRIBUTION

Aggregates and cement are produced throughout the EC with all 12 countries recording production. With regard to aggregates, sand and gravel is more prevalent in low-lying regions and crushed stone more common in highland areas. Dimension stone workings tend to be highly concentrated, for instance in the Carrara marble district of Italy and the Pontevedra/Badajoz granite district of Spain. Gypsum is not nearly so widespread as limestone but large deposits exist in Germany, France, Spain, and the United Kingdom and mining (both open cast and underground) and processing (including plaster and plasterboard) tend to be carried out at single sites. Silica sand is fairly widespread although the naturally pure deposits suitable for glass sand are located in Belgium and in the north of Germany and France. Sand deposits elsewhere usually require intensive beneficiation to achieve acceptable levels of purity.

The Cornwall and Devon region of England accounts for about two-thirds of total EC kaolin output. Other significant centres include Bavaria in Germany and Brittany in France. The main ball and ceramic clay producing districts in the EC are Westerwald in Germany, Charente in France, and Devon in the United Kingdom. The main bentonite centres are Bavaria in Germany, Milos island in Greece, Sardinia in Italy, and South-East England whilst the region around Madrid is the sepiolite capital of the world.

ENVIRONMENT

Most of the minerals and rocks in this group are mined by open cast methods and operations therefore consist of a quarry (or sand and gravel pit) with associated processing plant. Many such operations are thus highly visible and subject to the so-called NIMBY factor (Not In My Back Yard).

The modern quarrying industry has an excellent record for dealing with potential problems such as dust emissions and noise pollution during the life of an operation and for restoration of the land once the extractive process has finished.

Many of the products of these industries are used in environmental processes (e.g. limestone and lime in water and air treatment, silica sands for water filtration, absorbent clays for oil spills, etc.). Paradoxically many limestone and lime-based processes to remove sulphur from gases or waste streams yield chemical gypsum as by-product. The use of this by-product gypsum will reduce demand for natural gypsum.

OUTLOOK

The EC will continue to be a major centre for the production of construction raw materials, sands, and clays. EC enterprises operating in this sector will continue to be major players on

Table 6: Construction raw materials, sands and clays

the world scene. Future development of EC production and consumption will be closely tied to the overall level of building activity.

With regard to future demand, construction raw material markets will remain an predominantly intra-EC affair with any resurgence governed by overall EC building activity. Some influence from the expected building boom in Eastern Europe will be apparent although the EC's exported products are more likely to be finance, management expertise, and technology rather than physical volumes of bulk construction minerals.

The latter comment can also be applied to the field of industrial clays, sands, and carbonates although there will undoubtedly be increased levels of inter-trade between the EC and former CMEA countries - initially with eastward trade prompted by quality requirements and westward trade more a function of price.

Potassium salts and natural phosphates
NACE 232

The EC is a major producer, consumer, and exporter of potassium salts (generally referred to under the commercial title, potash). It does not, however, produce any natural phosphates and is thus a major importer of phosphate rock. These two products are used primarily in the manufacture of chemical fertilisers, an activity in which the EC features strongly as a major producing region. The economic performance of this industry is closely tied to levels of agricultural output.

INDUSTRY PROFILE

Description of the sector

The EC potash industry mines potash ores from underground workings and at associated plants at the surface processes the ore into saleable products. The principal techniques used for producing rock potash include flotation, electrostatic separation, and evaporation and crystallisation for special grades. The main commercial product is potassium chloride, also known as muriate of potash, although the EC producers also prepare grades of potassium sulphate and mixed salts containing potassium and magnesium.

Potash in this form can be applied directly to the soil but is normally sold to fertiliser manufacturers for blending with phosphate and nitrogen compounds into mixed (NPK) fertilisers. Purer grades of potassium chloride are used to produce potassium hydroxide, and industrial chemical used in soaps and detergents, glass and ceramics, chemical dyes and drugs.

Potash statistics are often presented in terms of K_2O content. For instance, potassium chloride has a theoretical K_2O content of 63.2% and is commonly sold on a minimum 60% K_2O basis.

Potash ores are commonly associated with rock salt (the sodium chloride ore, halite) and thus potash producers tend to produce salt as a by-product or co-product.

Main indicators

As shown in Figure 2, potash is produced in five EC countries, with Germany and France accounting together for more than 70% of total production. During the 1982-1991 period both production and consumption of potash rose to a peak in 1985, since which time production has declined by 24% and consumption by 38%. The declines reflect both falling tonnages and prices. Employment in the sector was also badly affected by this poor performance, declining of about 7 000 units in the 1982-1992 period.

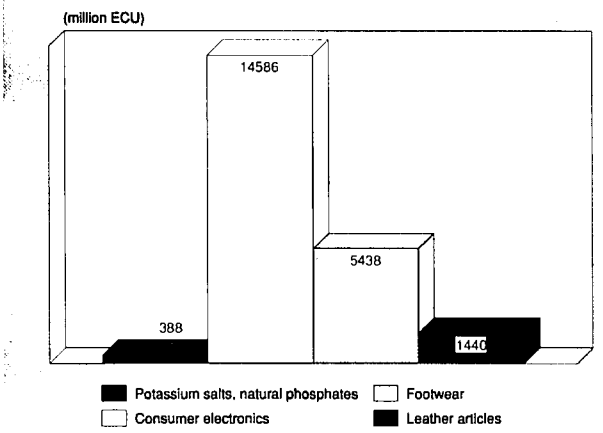
International comparison

The USA is a major producer of both phosphate rock and potash although the bulk of its potash requirements are actually met by imports from its northern neighbour, Canada. Combined production and consumption showed a small increase in tonnage during the period under review but in real value terms showed a similar decline to the EC. Japan does not produce either product and consumption, particularly of phosphates, declined markedly during the 1982-1990 period.

Foreign trade

The EC is active in both import and export trade in potash. Imports during the 1982-1991 period were primarily from Israel, the former Soviet Union, former East Germany, and Canada. Exports were primarily to India, China, Brazil, Japan,

Figure 1: Potassium salts and natural phosphates Value added in comparison with other industries, 1990



Source: Eurostat

and Algeria. With no production of its own, the EC is a major importing region for phosphate rock and the main sources are Morocco (about 40% of total) followed by the USA, Israel, Togo, and South Africa.

The patterns of trade have remained more or less the same throughout the period under review although the total (particularly for phosphate rock) has fallen. It should be noted that some source countries increasingly ship phosphoric acid rather than phosphate rock to the EC countries.

Production and exports (both intra- and extra-EC) both increased in the early part of the 1980s but after 1985 production declined, extra-EC exports fell and partially recovered, and intra-EC exports remained stable. Both extra-EC imports and EC consumption declined during the 1982-91 period.

MARKET FORCES

Demand

The fertiliser industry is clearly the dominant factor in any discussion of markets for potash and phosphate rock. This industry is itself highly dependent on demand from EC agriculture and is thus subject to political factors and environ-

mental issues as well as the vagaries of agricultural production and practices.

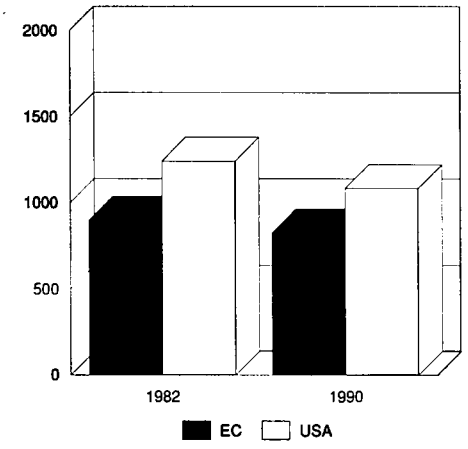
Both potassium and phosphorus are essential to plant growth and neither can be substituted. If levels of usage are cut in one year it normally means that correspondingly higher levels are required in subsequent years to maintain agricultural production levels.

Demand should continue to grow in Third World countries that are eager to boost agricultural yields but their ability to pay may be governed by aid programmes.

Supply and competition

In world terms both the potash and phosphate rock industries have tended towards oversupply in recent years as demand has fallen, particularly in the developed world. Potash prices have been subjected to greater downward pressure because of the much higher overcapacity existing in countries such as Canada and the former Soviet Union (the world's two largest producers) and because of lower prices being offered from the former Eastern Bloc and from low-cost brine-based producers.

Figure 4: Potassium salts and natural phosphates
International comparison of production at current prices



Source: Bumines, Eurostat, B.M. Coope & Partners

The EC potash industry will face competition from foreign suppliers with lower labour costs (e.g. the former Soviet Union), high productivity (e.g. Canada with its economies of scale), and more accessible raw materials (e.g. the brine deposits of the Dead Sea exploited by Israel and Jordan).

Production process

EC potash production involves underground mining, which is still fairly labour intensive despite the use of continuous mining machines and ancillary equipment. Processing plants are based on modern versions of long-established technologies but improvements in productivity have been achieved through increasing recoveries, etc.

INDUSTRY STRUCTURE

Companies

Today the EC potash industry consists of five large enterprises, one each in the five countries recording production. The most recent corporate change has been the grouping of the three Spanish operations under the collective ownership of the state owned INI.

The principal enterprises, with the approximate numbers of employees and shares of overall turnover are: Kali und Salz (D) with 5 000 employees and 46% of total turnover; MDPA (F) 3 000 and 27%; INI (E) 2 000 and 14%; Cleveland Potash (UK) 880 and 11%; Italkali (I) 660 and 2%.

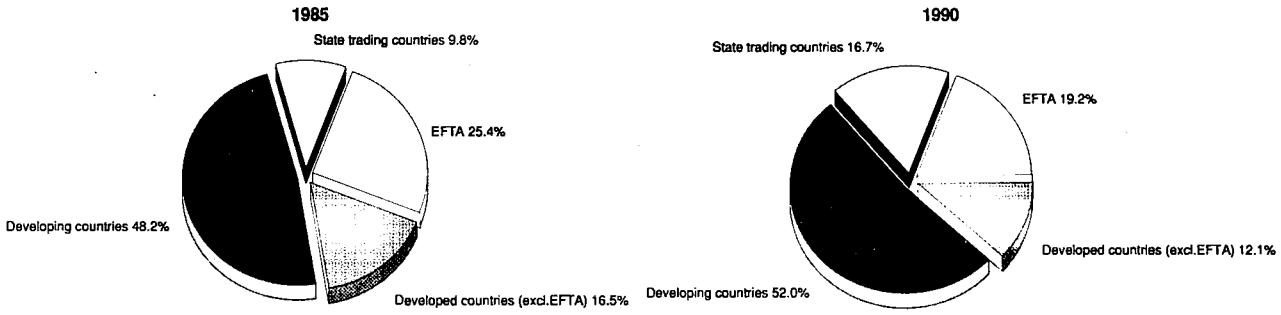
Government involvement in the industry is well in evidence in France, Spain, and Italy. Meanwhile Kali und Salz is predominantly owned by the German chemical company, BASF, and Cleveland Potash is owned by Anglo-American Corp. of South Africa.

It should also be noted that the former East Germany is a major producer of potash and in former days operated at the 3.5 million tonnes K_2O level. Since the reunification of Germany the industry has been reorganised under the banner of Mitteldeutsche Kali. Some of the uneconomic and most heavily polluting operations have been closed and the leaner and fitter organisation remaining has a capacity closer to 1.8m tonnes K_2O per year.

Strategies

Within the EC, the French and German producers still exercise strong influence over the marketing of potash in continental

Figure 5: Potassium salts and natural phosphates
Destination of EC exports



Source: Eurostat

Europe. The two enterprises also have a joint venture based in Vienna to conduct extra-EC sales and another in Canada which owns the New Brunswick potash producer, Potacan. It should be noted that the French MDPA has a schedule in which current production levels will be maintained until the late 1990s before a progressive reduction will result in closure in 2004 as reserves are depleted.

Investment in the industry during the 1980-1991 period has tended to be aimed at product development (e.g. adding granulating plant to produce granulated grades of potash) or process improvement. The last totally new operation to be built in Europe was the Cleveland Potash operation in the United Kingdom which entered production in the mid-1970s.

REGIONAL DISTRIBUTION

The EC's main producing centres are around Hanover and to the west of Halle in Germany; Alsace in France; to the north of Barcelona and near Pamplona in Spain; north-east England in the United Kingdom; and in Sicily in Italy.

ENVIRONMENT

The principal environmental issue for the EC potash industry concerns the salt that is produced during the processing of potash ores. Although some is processed into a commercial product the scale of production often means that vast tonnages of waste salt are generated. In the past this waste has been discharged into rivers such as the Rhine (and the Werra in former East Germany) but legislation has forced producers to adopt alternative means of disposal, to increase production of saleable salt, or to close down the main offending operations.

Fertiliser usage has also become a major environmental issue in recent years because of the damaging effects of phosphorus and nitrogen in water courses. Thus although potassium is not regarded as a direct problem it is affected by the cutback in mixed fertiliser application.

OUTLOOK

The EC potash industry is likely to undergo an orderly wind-down over the next decade, particularly in France, Spain, and Italy. Production in Germany and the United Kingdom will probably be maintained at current levels. Those companies wishing to continue or expand production will tend to seek participation in foreign ventures.

Future EC consumption of potash and phosphates is likely to show only modest growth. The further requirement for extra-EC imports of potash (to meet the above shortfall) should

Crystallised salt
NACE 233

EC production of crystallised salt reached 20.4 million tonnes in 1991. Consumption amounted to 19.9 million tonnes. Over-capacity and diversity are the main features of the salt sector: demand fluctuates with climatic and economic conditions. In the recent past, three successive mild winters have led to a dramatic reduction in the sales of road salt. Deliveries collapsed from 6.4 million tonnes in 1985 to 1.4 million tonnes in 1989. There is also some industry concern that the demand for chlorine which is the main outlet for salt may again decline.

INDUSTRY PROFILE

Description of the sector

Salt production basically involves solar evaporation (sea salt), dry mining (rock salt) and solution mining (vacuum salt, salt in brine). In the monograph, salt in brine will be excluded unless otherwise specified.

Main indicators

Output of crystallised salt contracted in recent years from 23.8 million tonnes in 1986 to 19.3 million tonnes in 1990. It recovered in 1991 to 20.4 million tonnes. Salt consumption within the EC is now back to the 1986-1987 level of 20 million tonnes, after falling to a low of about 17 million tonnes.

The breakdown of production by main product line shows that in 1991 rock salt accounted for 43% of total crystallised salt production, followed by vacuum salt with 39% and solar salt with 18% respectively. During the period 1988 to 1990 production of rock salt had decreased sharply (by nearly 25% in 1988 alone), thus making vacuum salt the main product line of the EC salt industry.

International comparison

Salt consumption is higher in the USA than in the EC. In 1991, US overall salt consumption stood at 23.8 million tonnes compared to 19.9 million tonnes in the EC. The proportion increases if per capita consumption is considered. In fact, in 1991 overall per capita consumption of salt in the USA reached 95.2 kilos, compared with 62.2 kilos in the EC. However, consumption patterns vary according to the end use of salt. For example, per capita consumption of food grade salt is higher in the EC than in the USA (7.2 kilos against 4.4 kilos respectively). On the other side, US road salt consumption is twice the size of that of the EC (9.7 million tonnes compared to 5 million tonnes respectively).

Foreign trade

In 1989, extra-EC imports amounted to 0.5 million tonnes and extra-EC exports reached 1.3 million tonnes. Intra-EC trade was 3.2 million tonnes, equivalent to 71% of total exports and 94% of total imports. Both the exports to imports ratio and the trade balance steadily decreased during the 1982-1990 period, and showed some signs of recovery in 1991.

Trade in salt is relatively unimportant, accounting for 10% or less of total production on average. The EFTA countries represent the main destination of extra-EC exports, while on the import side developing countries supply nearly three quarters of total extra-EC imports.

MARKET FORCES

Demand

Successive mild winters have had an adverse effect on the requirements for road salt. This is reflected in the reduced output of rock salt which is mainly used as a de-icing agent (except in Germany). Rock salt is not alone in being exposed to the climate changes: solar salt too is also dependent upon climate variations. Heavy rains in summer may have a detrimental impact on solar evaporation.

Demand for salt in other outlets has essentially remained static although the chemical industry has registered sustained growth during the 1988-90 period. Salt sales have been fuelled by the water treatment processes, which are expanding. The recent buoyancy in chloralkalis has changed to some sluggishness.

Other clients of the salt industry include the dyestuffs and the soap manufacturing industries. Pure salt is added to some explosives as a flame retardant. Leather tanning used special grain size of salt for the preparation of skins. High purity salt is utilised in the production of pharmaceuticals.

Supply and competition

The EC market for crystallised salt is shown in Figure 2. Certain quantities mentioned under the "food grade salt" heading relate to other outlets. The importance of the "miscellaneous industries" heading illustrates the difficulty of allocating certain tonnages under the right heading.

In 1991, sales of food grade salt amounted to some 2.3 millions tonnes. Salt sales to the food industries and to the households do not relate solely to the dietary use of this type of salt. Although sales of food grade salt reach about 20 grams daily per capita, the actual dietary salt intake is only around six to seven grams. According to INTERSALT and other studies, median salt intake is far lower than anticipated.

For miscellaneous industries, which includes agriculture, water softening and other outlets, salt sales amounted to 3.2 million tonnes. In agriculture, salt is used in cattle feed, to preserve green fodder and to improve soil deficiency in sodium (fertiliser for sugar beet in the United Kingdom). One of the increasing outlets for salt is the regeneration of ion exchange resins used in water softening. In the United States the sales of special salt for water conditioning increased by 12% over five years. In the EC the situation remains contrasted and varies from one Member State to another.

Sales of crystallised salt to the chemical industry amounted to 9.4 million tonnes in 1991. The production of chlorine

decreased by 5%. In Europe as a whole there is a structural surplus of chlorine. The production levels have fallen in most of the Member States. The requirements are also estimated to have dropped by 5%. This slump is accredited to weaker demand from both the paper and pulp and the aluminium industries. Three technologies are used at present to manufacture chloralkalis by electrolysis. The breakdown of the technologies in 1991 was as follows: mercury (crystallised salt), 68%; diaphragm (salt in brine), 5%; membrane (crystallised salt), 7%.

The requirements for road salt to clear ice and snow from roads depend on weather conditions. In 1991, demand amounted to 5 million tonnes. The substantial contribution of winter maintenance to traffic safety and transport economics depends not only on the level of service but also on the improvements of salt spreading. Many countries extensively use wet salt for preventive treatment. Apart from the reduction in spreading quantities, direct environmental improvements are also achieved. But winter maintenance with curtailed salt spreading, including the so-called white networks, increases the risk of accidents significantly.

INDUSTRY STRUCTURE

Companies

The structure of the EC salt industry is characterised by a high degree of concentration. The most powerful operators are chemical companies which have departments specialised in salt production for their activity. Among the largest companies are Akzo (NL), the world's largest salt producer, Solvay (B), ICI (UK) and Kali und Salz (D), which belongs to the BASF group. Elsewhere one finds a number of private companies such as the Compagnie des Salins du Midi (F) and British Salt (UK), or semi-public companies, particularly in Greece and Italy. For soda ash, the main supplier is Solvay with production facilities in seven countries. Brunner Mond & Co. is the second largest manufacturer in Europe. The company was formed in 1991 following the sale of ICI Soda Ash Products to a group of investors led by Penrice Ltd.

Strategies

ICI has sold its salt facilities: the Winsford mine with a capacity of 1.8 million tonnes and the Weston Point operation with a 1.0 million tonnes capacity. The new owner, a US based group of investors, is now operating both of them under the name of Salt Union Ltd. ICI said that supplies of brine, essential for its own chlorine production, will continue.

Solvay has recently increased its annual production capacity of soda ash by 540 000 tonnes with the return of its Bernburg plant.

Kali und Salz, BASF's potash and rock salt subsidiary, decided in the beginning of 1991 to shut down part of its operations and reduce its services. All rock salt production is to be concentrated at the mine at Braunschweig-Luneburg.

Finally, in 1991, the company Asensio Madrid SA (E) started vacuum salt production in a plant with an initial capacity of 30 000 tonnes per year.

ENVIRONMENT

In selecting different studies irrespective of their scientific standards, to obtain "a quantitative estimate of the effect of sodium intake on blood pressure" researchers are still emphasising the importance of sodium restriction in the population at large and recommending both low sodium food and low sodium diet. However, recent data indicate that a life-long restriction of salt is dangerous for the general population. Moreover, salt is used in several Member States as a carrier of iodine and/or fluoride. In that case, sodium restrictions might have a detrimental impact on preventive steps recommended by the World Health Organisation (WHO) and supported by national authorities.

OUTLOOK

It is very difficult to predict the future of the salt industry. Almost 50% of crystallised salt is used in the chemical industry. Therefore, the salt industry is highly dependent on developments in the chemical industry. Furthermore, many clients of the chemical industry, such as the paper industry and water treatment plants, are expected to decrease their use of chloralkalis in the coming years.

The second largest use of crystallised salt is as road salt. Variations in the severity of winter weather conditions from year to year have unforeseeable effects on demand for road salt. The continuing decline in consumption of food grade salt is a source of concern for salt producers.

The industry is represented at the EC level by: European Committee for the Study of Salt / Comité Européen d'Etude du Sel (CEES). Address: Rue Daru 17, F-75008 Paris; tel: (33 1) 47 66 52 90; fax: (33 1) 47 66 52 66.

Other minerals and peat

NACE 239

The EC is a major world producer of industrial minerals. Amongst the remaining industrial minerals grouped in NACE 239 the EC can claim to produce more than 25% of the world's diatomite, dolomite, feldspar, perlite and pumice and more than 10% of the world's barite, fluorspar, magnesite, sulphur and talc. The EC is also an important producer of peat, a fuel mineral with important agricultural applications. EC producers account for more than half the peat produced outside the former Soviet Union.

INDUSTRY PROFILE

Description of the sector

The industrial minerals included in NACE 239 include multi-purpose bulk products such as dolomite (used in construction, agriculture, metallurgy, chemicals, glass, ceramics, and as industrial fillers); single-purpose bulk items such as sulphur (used to produce sulphuric acid); and low volume, high value items such as graphite (used in refractories, lubricants, electronics, brake linings, carbon brushes, etc.).

The full list of EC-produced items would cover asbestos, barite, celestite, diatomite, dolomite, feldspar, fluorspar, graphite, iron oxide pigments, magnesite and other magnesium compounds (e.g. magnesium chloride brines and natural magnesium sulphate), mica, olivine (and dunite), perlite, pumice and pozzolana, sulphur (including pyrites and by-product sources), and talc.

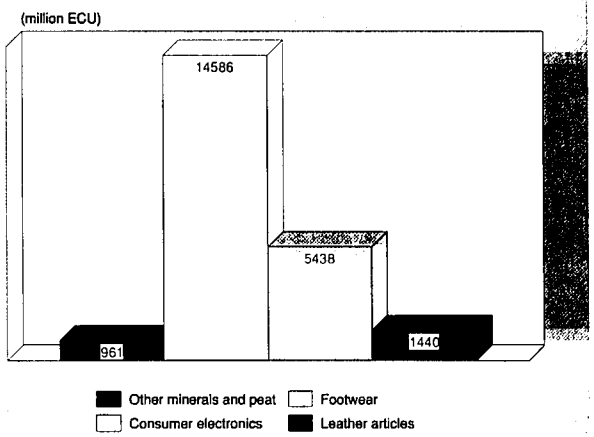
A number of the operations producing these minerals are controlled by consuming companies, for instance, refractory manufacturers (magnesite and dolomite), chemical manufacturers (fluorspar and barite), oil and gas companies (by-product sulphur), and glass producers (feldspar and dolomite). Others are controlled by specialist industrial minerals companies whose interests would also include related products in NACE 231 and NACE 232. Some major metals and metallic ore producers also have interests in some of these operations.

Main indicators

Consumption peaked in 1989 and the subsequent decline reflects the current industrial recession. In contrast production values peaked in 1985 but the picture was distorted by the high prices of sulphur prevailing during the mid-1980s. Germany, France, and the United Kingdom are the leading producers in this group followed by Italy, Spain, Ireland (almost solely on account of its peat production), and Greece (where magnesite, perlite, and pumice are prominent).

In value terms sulphur, dolomite, and peat are the major items in this group (accounting respectively for 25%, 26% and 12% of total production). The special position of magnesia and magnesium compounds should also be mentioned. Within the EC magnesia is obtained from natural magnesite in Greece and Spain; from sea water in the United Kingdom, Ireland, and Italy; from solution mining of magnesium-rich salts in the Netherlands; and as by-product of solar salt production in France. Magnesium sulphate and magnesium chloride are also extracted as a by-product of potash mining in Germany. However, since the greater proportion of this production is derived by chemical process it does not meet the strict definition of NACE 239 and thus only magnesite-based magnesia is included in production figures for this section (although for foreign trade it should be noted that figures do not differentiate between magnesia of natural or synthetic origin).

Figure 1: Other minerals and peat
Value added in comparison with other industries, 1990



Source: Eurostat, B.M. Coope & Partners

International comparison

Declining production values for the USA and Japan since 1985 are also partly attributable to the sulphur price factor although in the case of Japan the falling price of iodine was an extra factor in the scale of its decline. Production of products such as asbestos and barite fell in all three regions throughout the 1982-1991 period. It should also be noted that apparently stable prices for many industrial minerals represented a price fall in real terms which often masked volume growth during the 1985-1990 period.

Foreign trade

The EC is an active exporter of magnesia and magnesium compounds, sulphur, and peat. As Table 3 shows, however, the EC is very much a net importer with the major imported items being magnesia and magnesium compounds, sulphur, asbestos, and borates but with products such as talc, graphite, feldspar, fluorspar, peat, barite, and vermiculite also prominent. The negative trade balance has decreased significantly since 1985 and at the same time the levels of intra-EC trade have grown to account for 50% of total imports.

EFTA countries and developing countries feature prominently as destinations for exports. Highlights include exports of sulphur from France to north and west Africa; exports of magnesia and other magnesium compounds not only to EFTA countries such as Austria and Sweden but also to distant destinations such as the USA, South Africa, and the Far East; and exports of peat from Germany to Switzerland and Austria.

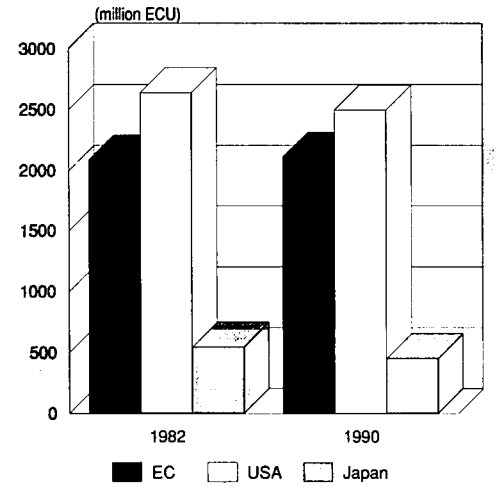
The developed countries (with the exception of EFTA) are prominent among the sources of imports of minerals in this group and together with the former Eastern Bloc countries account for 70% of total extra-EC imports. Highlights include imports of borates from Turkey; asbestos and sulphur from Canada; diatomite and sulphur from the USA; sulphur from Poland; magnesia, talc, and graphite from China; talc from Finland and Austria; and feldspar from Norway.

MARKET FORCES

Demand

The minerals in this group are consumed by a wide range of industries amongst which chemicals, construction, and glass and ceramics are prominent. Demand depends very much on general income developments since not only are the products consumed across the whole range of manufacturing industry but also in the construction, agricultural, and energy sectors.

Figure 4: Other minerals and peat
International comparison of production at current prices



Source: Bumines, Eurostat, B.M. Coope & Partners

Since sulphur is the dominant industrial mineral in terms of production and consumption value it is worth considering in detail. At first sight it is virtually a single use raw material with over 90% being used by the chemical industry for the production of sulphuric acid, the cheapest and most versatile industrial acid. Although the range of applications for sulphuric acid is virtually endless it is nevertheless the case that 60% is actually consumed by the fertiliser industry. Thus demand for sulphur itself is highly dependent on fertiliser manufacturing activity and ultimately influenced by agricultural performance and practice. The volatility of sulphur prices appears to have little effect on demand which in volume terms has remained surprisingly stable in the EC during the 1982-1991 period. This is primarily due to the fact there is no real substitute for sulphur or sulphuric acid.

Another mineral in this group which deserves individual attention is peat and this because it is arguably a fuel mineral rather than an industrial mineral. Over 70% of EC peat consumption is for application as a combustible fuel for which markets tend to be local and on a large scale tend to be bound up in long term arrangements between producers and power generating companies. The other 30% is used primarily in horticultural applications where it vies with other organic materials such as straw and compost as well as certain industrial minerals such as absorbent clays and perlite.

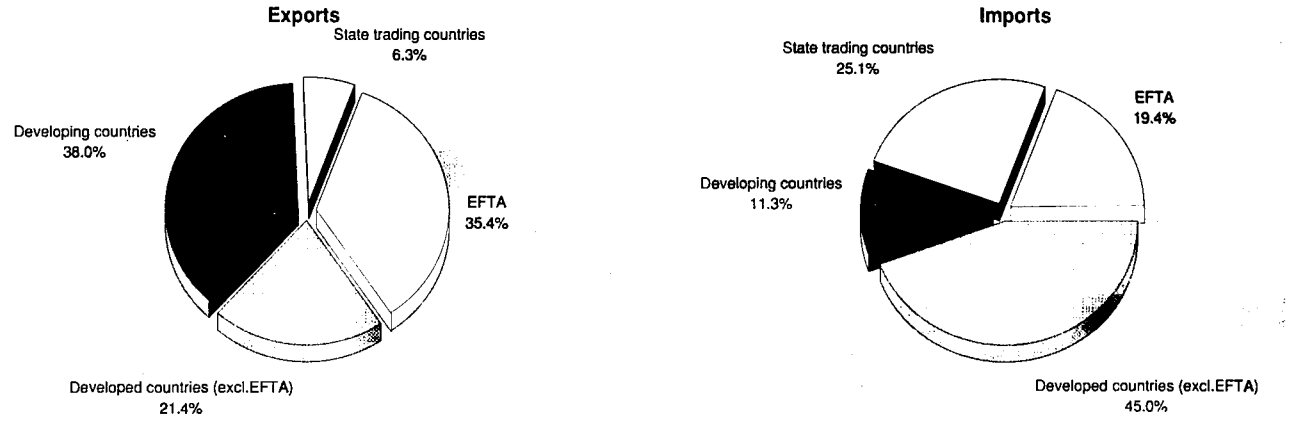
Barite is used primarily as a weighting agent in oil well drilling muds and demand is thus heavily influenced by oil industry drilling activity, particularly in the North Sea.

Diatomite's use as a filtration agent in foods, beverages, pharmaceuticals, water treatment, complements its other use in the construction industry.

The refractory raw materials, magnesia and dolomite, have been affected by the trend to use high performance materials with longer lives. For magnesia this actually means that total volume consumption in refractories is decreasing (and has been for several decades) but volume consumption of high quality grades (of higher value) has been increasing.

Finally, the demand for minerals such as asbestos and fluorspar (the raw material for CFC production) have been affected adversely by environmental legislation.

Figure 5: Other minerals and peat
Destination of EC exports and origin of EC imports, 1990



Source: Eurostat

Supply and competition

It has been noted earlier that even for the major export items in this group, the EC still tends to be a net importer. This can be attributed to the practice of upgrading imported raw products (a portion of which may be re-exported) or to geographical factors (e.g. Italy supplies Switzerland but Sweden supplies Denmark). However, it is also due to the multiplicity of grades available and the suitability of certain grades for specific end-uses.

With regard to sulphur supply, the aspect of involuntary production demands attention, not least because it is the primary cause of the sulphur price volatility noted previously. Apart from pyrites, all sulphur produced in the EC is a by-product of other processes, either of extractive processes (of sulphur-rich oil and gas) or of industrial processes (such as the smelting of metallic sulphide ores or from the burning of high-sulphur coals in power generating plants). The recovery of sulphur dioxide gas (as sulphuric acid) from stack gases is a legislative requirement to combat acid rainfall. This domestic recovered sulphur supply now accounts for the bulk of the EC requirements and extra-EC imports tend to consist of elemental sulphur from natural sources.

With regard to supply of the more mainstream industrial minerals a number of different conditions exist: the EC is totally lacking in certain resources (e.g. borates and vermiculite) for which all requirements are imported; the EC possesses resources limited by both quality and quantity of minerals such as asbestos and graphite and thus the bulk of the requirement (including special grades) are imported; for some minerals, the EC possesses adequate resources and is theoretically self-sufficient but foreign sources are preferred by some consumers on grounds of cost or quality. For example Moroccan barite is significantly more cost-competitive than domestic produced due to lower labour costs. For quality a straightforward example would cover the supply of certain grades of talc for cosmetic, ceramic, and paper processing applications from Australia, the USA, and China.

Low labour costs in China are well-recognised and for magnesite large, accessible deposits do lead to low operating costs. However, pricing policies which do not appear to take full account of fuel and transportation costs are of clear concern to EC producers.

Production process

The type of production process for industrial minerals varies widely. At one end of the spectrum is the large quarrying operation with associated crushing and sizing/grading plant serving large volume, low value markets such as construction (e.g. certain dolomite, pumice, and pozzolana operations). At the other end of the spectrum may be a magnesite operation employing a range of sophisticated processing techniques: laser sorting, high intensity magnetic separation, heavy media, flotation, and high temperature calcination and sintering. Elements of the processing of diatomite, talc, and graphite also qualify for the sophisticated label.

INDUSTRY STRUCTURE

Companies

The top enterprises (with more than 500 employees) involved in this sector include two energy companies producing sulphur from sour gas, Elf-Aquitaine (F) and BEB (D); three dolomite producing groups, Redland/Steetley (UK), the Lhoist group (B), and Dolomitwerke Wulfrath (D); one magnesite/magnesia producer, Grecian Magnesite (GR); the Irish state-owned peat producer, Bord na Mona (IRL); and the two major metal mining groups, RTZ (UK) for its talc interests, administered through Talc de Luzenac and Metallgesellschaft (D) for its fluorspar, barite, and pyrites interests administered through Sachtleben.

Apart from the largest ones, there are other important enterprises, which tend to have their principal producing operations in one country but the market outlook is very much European or international in scope. Many of the them have their origins in family-owned companies and connections are still strong. The large international metals and energy groups have been drawn into the sulphur (or sulphuric acid) production and fluorspar and barite have also attracted metals groups.

Government involvement in this group tends to be the exception rather than the rule but major exceptions are the French state-owned Elf-Aquitaine and the Irish state-owned Bord na Mona.

Strategies

No single coherent strategy can be described for industrial minerals other than to point out that as a result of the 1979-1983 industrial recession, EC industrial minerals producers became much more cost-conscious and all sought to improve productivity in the more competitive environment of the 1980s. Thus efforts to reduce labour costs and energy costs were combined with engineering endeavour to improve recoveries and product quality.

New mining projects included barite in Scotland (MI and Minworth); feldspar in Italy (Sassifo), Spain (Rio Piron), and

Greece (Porcel and Mevior); and natural sodium sulphate in Spain (Minersa and Santa Marta).

Corporate changes in the dolomite sector were noted through the acquisitions of Carmeuse in Spain to set up Calcinor and the more recent take-over of Steetley by Redland in the United Kingdom although in both cases dolomite was secondary to the main purpose.

An acquisition more directly relevant to this group of minerals was the 1988 take-over of Talc de Luzenac of France by RTZ. Talc de Luzenac is the major talc producer in Europe with production facilities in France, Italy, Spain, Austria, and Canada.

A current example of the strategy of diversification into downstream products concerns the Greek magnesite producer, Grecian Magnesite, which is constructing a plant to manufacture magnesia-based monolithic refractories.

REGIONAL DISTRIBUTION

Not surprisingly geology is the prime factor in deciding the location of most of the operations in this group, except for the by-product sources of sulphur which are governed by the location of smelters and petrochemical plants. Dolomite is the most abundant mineral in the group and production occurs in most EC countries apart from Denmark and the Netherlands, although its should be noted that special grades (e.g. high whiteness or refractory grades) are limited to only a few locations. Large deposits of pumice and pozzolana occur in the volcanic regions of Germany, Italy, Greece, and Spain and a large number of operations are active. Peat occurrences are also widespread, although by far the largest concentration of EC production is in Ireland. Feldspar is another common mineral with a number of operations spread throughout the EC.

ENVIRONMENT

The main ecological issues concerned with the quarrying of the bulk products in this group are shared with the products of NACE 231. Once again it should be noted that the modern quarrying industry has an excellent record for dealing with potential problems such as noise and dust and has developed land rehabilitation techniques to a considerable degree. Most major problems arise over "visual pollution", particularly if a quarry is close to urbanisation or in an area of outstanding natural beauty.

Two of the minerals in this group have been in decline because of ecological issues. The health hazard problems of asbestos are well documented and although safer methods of handling asbestos are now in evidence, usage will continue to fall. A number of industrial minerals, such as wollastonite and mica (as well as minerals used in glass and mineral fibres), are substituting asbestos.

As the principal raw material for the manufacture of CFCs (chlorofluorocarbons), fluorspar has been subject to declining consumption as result of efforts to stem ozone depletion. In the long term this industry may well recover if hydrofluorocarbons (also based on fluorspar as starting raw material) are accepted as more benign alternatives.

Several minerals in this group are benefiting from "eco-markets", such as dolomite and magnesia for water and sludge treatment. Insulating minerals such as diatomite, perlite, vermiculite, and magnesia also benefit from energy conservation and fireproofing legislation.

Lastly it should be mentioned that EC production of sulphur is largely based on the recovery of sulphur dioxide which would otherwise be released to the atmosphere. Although sulphur recovery plants can often be justified on commercial grounds alone, the importance attached to preventing sulphur emissions from all sorts of industrial processes will ensure that recovery is maximised.

OUTLOOK

The EC will continue to be a major consuming centre for the minerals in this group. The presence of domestic resources can give both commercial and technical advantages to downstream industries (and are often the "raison d'être" for such industries in the first place). The EC will continue to require imports of some products from outside the region on the grounds that EC supplies are limited either by quantity or quality or both.

For some imported minerals prices and costs became an issue of contention during the 1980s which seems set to continue well into the 1990s, particularly if well-run EC operations are being harmed by unfair competition.

Ferrous metals
NACE 221, 222, 223

Since 1990, EC production of ferrous metals has been declining. During 1988 and 1989, however, production in real terms rose by 8% per year on average. This revival took place after a period of crisis dating back to the 1970s which was caused by both low growth in the main customer sectors and the emergence of new producing countries. The 1980s were characterised by a steady process of rationalisation and reduction of capacity, which began at the end of the 1970s and caused major cutbacks in employment. This restructuring made sizeable productivity gains possible, and allowed most EC firms to return to profitability.

INDUSTRY PROFILE

Description of the sector

The production and preliminary transformation of ferrous metals covers both the steel industry as defined by the ECSC Treaty and the preliminary processing of ferrous metals. According to the NACE classification, it includes the following branches: iron and steel, as defined in the ECSC Treaty (NACE 221); the manufacture of steel tubes (NACE 222); drawing, cold rolling and cold folding of steel (NACE 223).

Iron and steel is by far the largest component of the sector. It accounts for 74% of total ferrous metal production. Both the manufacture of steel tubes and the industry of drawing, cold rolling and cold folding accounts for only 13% of ferrous metals production.

Main indicators

In 1988 and 1989, the ferrous metals industry in the EC had achieved record levels of production and consumption. With the economic slowdown in most of the consuming sectors that began in 1990 and intensified in 1991, however, the ferrous metals industry experienced significant declines. Apparent consumption (in terms of constant prices) decreased by 2.4% in 1990 and by 2.9% in 1991. Production fell even more, causing a sharp decline in trade balance. For 1992, a further decrease must be expected for the EC ferrous metals industry.

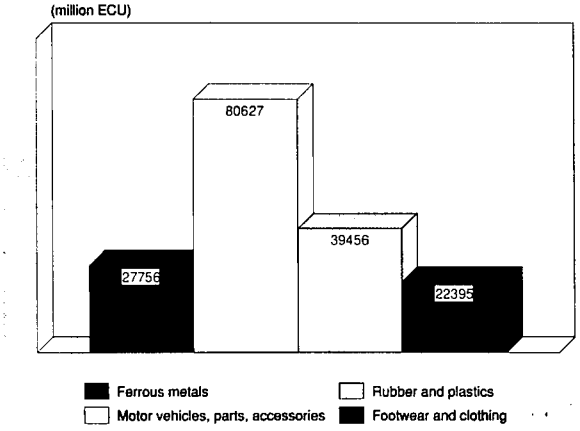
Figure 2 shows a breakdown of value added by Member States. Four countries (Germany, Italy, France and the United Kingdom) account for more than three-quarters of total value added in the EC.

Recent trends

Growth in the ferrous metals industry has clearly lagged behind development in the manufacturing industry as a whole (see Figure 3). While the overall manufacturing industry is characterised by a strong growth of production and consumption, stagnation has occurred in the ferrous metals sector. The most remarkable development, however, is the rapid deterioration of extra-EC exports of the ferrous metals industry since the mid 1980s, which had a negative impact on the production level. The strong and continuous decline in employment over the whole period 1982 to 1991 is the result of great rationalisation efforts and of restructuring measures introduced in the early 1980s, especially in the iron and steel industry.

Table 2 shows a breakdown of consumption, production and extra-EC exports by major industries of the ferrous metals sector. Iron and steel is by far the largest component, accounting for more than 70% of production and consumption, and for almost 60% of exports to non-EC countries.

Figure 1: Ferrous metals
Value added in comparison with other industrial sectors, 1991



Source: Eurostat

International comparison

International comparisons are difficult due to lack of data on ferrous metals production. Taking crude steel as an indicator, it can be seen from Figure 4 that the EC is the largest producer in the world, followed by Japan and the USA. The EC and Japan also are the most important exporters. While the EC has maintained its export level in the period 1982 to 1990, Japan experienced a considerable decrease in exports. In the USA (in contrast to the EC), steel consumption is significantly higher than steel production. A lack of competitiveness in the USA has led to growing imports.

The development of production is shown in Figure 5. Regarding the relatively strong growth in the USA it must be taken into account, however, that the USA suffered a downturn in production of nearly 40% in 1982.

Foreign trade

Ferrous metals account for about 4% of total EC exports of goods and 2% of imports. The trade balance of the sector shows a large surplus.

As can be seen in Table 4, the ferrous metals industry achieved its best results in trade with third countries in 1985. The export surplus amounted to nearly 15 billion ECU. Since then, however, trends in foreign trade have turned noticeably against the EC. While extra-EC imports continued to increase strongly (with the exception of 1991), extra-EC exports suffered sharp declines. This led to decreasing export surpluses and a declining export-import ratio.

Figure 6 shows significant changes in the destination of EC exports between 1986 and 1991. For the EFTA countries, the major export market, and for the OPEC countries the export shares have increased, whereas the US market has lost importance. Japan's share in EC exports of ferrous metals is of no significance.

The EFTA countries play a major role as suppliers of the EC market with ferrous metals. Almost 60% of total EC imports originate from these countries. The share of imports from the USA as well as from Japan has increased but accounts for only 5% of extra-EC imports. Among the countries included in the rest of world, the East European countries in particular have gained importance in recent years.

Intra-EC trade has increased strongly in the period 1982 to 1991, owing to the long existence of an integrated European market in the field of ferrous metals. At the same time, however, the penetration rate of foreign competitors supplying the internal market increased steadily from 6.8% in 1982 to 8.8% in 1991.

MARKET FORCES

Demand

The ferrous metals sector is a major supplier of intermediate goods, especially to the following industries: the metal products industry, mechanical engineering, electrical machinery, the transport equipment sector and the construction sector.

According to the improvement in the activity level of ferrous metals, consuming industries consumption of ferrous metals increased strongly in 1988 and 1989. In addition, strong stockpiling on the part of producers, traders, and consumers had a positive impact on domestic demand.

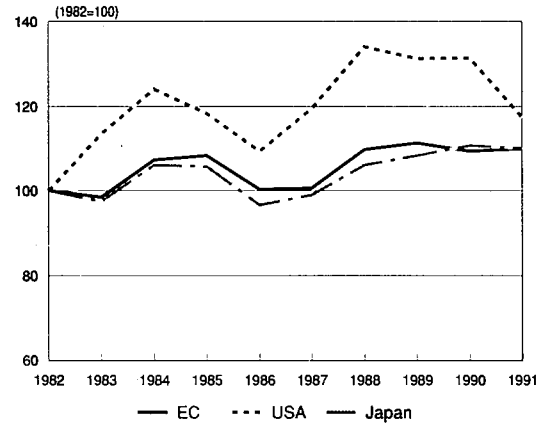
Figure 5: Ferrous metals
International comparison of production growth at constant prices



Source: Eurostat

The recovery in the ferrous metals industry took place after a long period of crisis. From 1982 to 1987, production within the EC (measured in terms of constant prices) decreased at a yearly average of 1.8%. The origins of this crisis, however, go back to the 1970s and the first oil embargo. Most of the ferrous metal consuming sectors went through difficult times in the course of the second half of the 1970s and in the first half of the 1980s, reducing their consumption of intermediate products.

Nonetheless, other factors also contributed to the downturn in the ferrous metals industry. These include the emergence of substitute products, such as plastics, and the emergence of new competitors, particularly in the newly industrialised countries. These countries (which profit from low production costs) experienced a substantial increase in production level. A growing number of newly industrialised countries were able to cover not only their own needs, but to compete successfully on the world market. With the reduced demand of traditional export markets in Eastern Europe and China, this led to a severe downturn in extra-EC exports. The export rate of the EC ferrous metals industry (measured in real terms) fell from 22.7% in 1985 to 16.7% in 1991.

Supply and competition

The ferrous metals industry in the EC (while permanently cutting back work force and technical capacity) suffers from worldwide overcapacities. The effects on price setting margins are considerable, especially in export markets and for products with a low share of value added. Given the ample possibilities of worldwide supply, customers are accustomed to exercising strong price pressure on the producers.

Internal competition within the EC is strong, which is reflected in a high intra-EC trade. In 1982, intra-EC trade of ferrous metals amounted to 14.5 billion ECU or 22.4% of EC consumption. In 1991, intra-EC imports increased to 25.4 billion ECU or 30.8% of consumption.

The EC ferrous metals industry has a strong competitive position against non-EC countries, particularly because of their technological advantages. Unfavourable, however, is the competitiveness of European suppliers with regard to cost. Newly industrialised nations offering production cost benefits compared with EC suppliers, emerged as new suppliers on the European market. The import pressure from East European countries also toughened, especially given that their selling prices do not reflect true production costs. The share of foreign competition in the internal market has increased from 6.8% in 1982 to 8.8% in 1991.

Production process

In terms of technology, the EC ferrous metals industry is one of the most advanced in the world. Research and development constantly assure high quality in steel production and rolling processes. Drastic restructuring measures (especially in the iron and steel industry) have led to significant labour reductions. In the period from 1982 to 1991, the number of employees in the ferrous metals sector dropped by 40%, a rate of 5.4% per year.

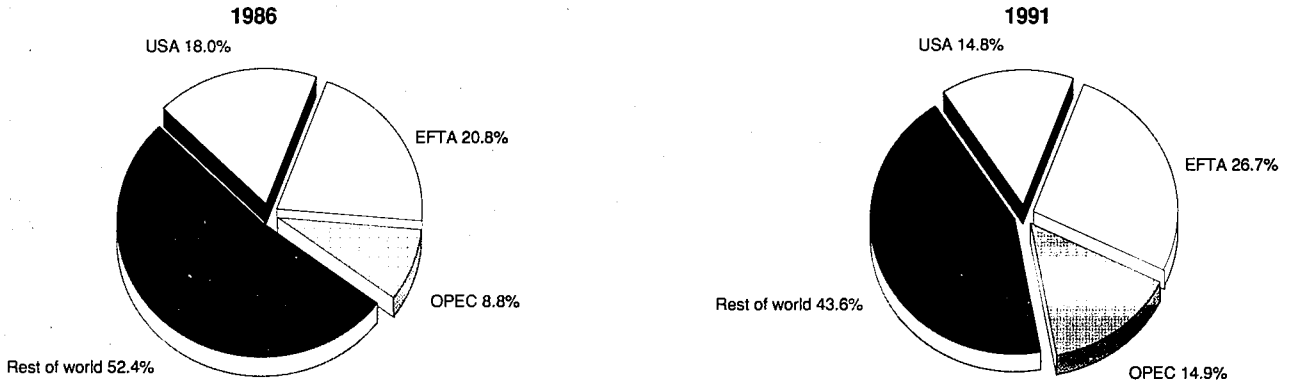
The necessary modernisation of the EC industry was undertaken fairly late, having only begun at the end of the 1970s. This explains why the return to profitability did not begin until the second half of the 1980s.

INDUSTRY STRUCTURE

Companies

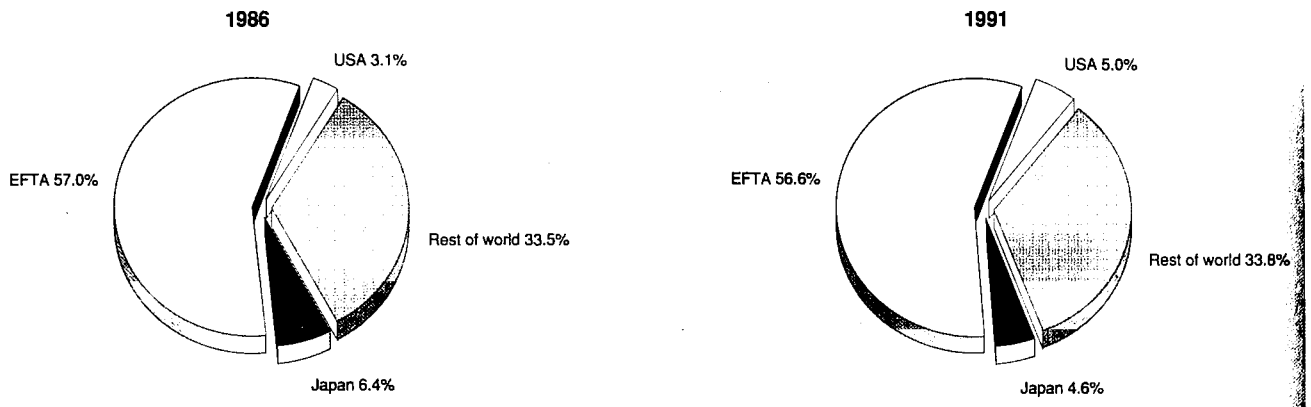
With regard to concentration of the ferrous metals industry, one has to distinguish between the iron and steel industry and the steel tube sector on one hand, and the drawing, cold

Figure 6: Ferrous metals
Destination of EC exports



Source: Eurostat

Figure 7: Ferrous metals
Origin of EC imports



Source: Eurostat

rolling and cold folding industry on the other hand. Both the iron and steel industry and the steel tube sector are characterised by large companies and a high degree of concentration. Drawing, cold rolling and cold folding mills, in contrast, are mostly medium-sized enterprises with low concentration. Moreover, steel tube manufacturers are often linked to steel producers, and a considerable part of output of the drawing and cold rolling mills is manufactured by the subsidiaries of the major steel groups.

Strategies

The modernisation and restructuring of the ferrous metals industry is reflected (especially in the iron and steel sector) in a number of mergers, acquisitions and joint-ventures. For example, the merger between Usinor and Sacilor in France, the creation of Ilva in Italy and the takeover of Hoesch by Krupp in Germany.

In contrast to the major companies in the steel industry and the steel tube sector, mergers, acquisitions and joint-ventures form a less suitable strategy to strengthen the competitiveness for the medium-sized firms of the drawing and cold rolling sector. These firms tend to emphasise rationalisation and specialisation.

Finally, it should be noted that product diversification is taking place. Companies are reducing their supply of ordinary, mass-produced steel products in favour of more sophisticated products. For example, the development of high-yield point sheet steels and coated sheets, (for the car industry in particular) have enabled the steel industry to increase unit prices and value added. Furthermore, special alloyed and non-alloyed steels are becoming increasingly important.

The great efforts EC ferrous metals industry is undertaking to rationalise and modernise their facilities in view of the Single Market, however, are not visible in the development of home investment, due to a lack of current data.

REGIONAL DISTRIBUTION

The distribution of ferrous metals production among Member States does not closely reflect the ranking in terms of GNP. The ranking of the four main producers of ferrous metals, (from which almost 80% of the production originates) is as follows: Germany ranks at the top, followed by Italy, the United Kingdom and France.

(1) 1990
Source: DABLE

The development of ferrous metals production was similar in most EC countries over the course of the 1980s and the share of each Member State in total production changed very little over this period. There are, however, some exceptions. The share of France decreased significantly, whereas that of Belgium and Luxembourg increased. Italy took second place from France during the 1980s.

ENVIRONMENT

Costs arising from environmental protection are considerable, especially for the iron and steel industry. They are, to a large extent, due to costs incurred by the treatment of smoke emissions from raw material production units and by reheating furnaces, treatment of waste water from the pickling installations and noise control in the production units.

In light of the high costs and the fact that the requirements and enforcement of environmental protection is not equally strict in all countries, a harmonisation of environmental protection legislation in Europe is absolutely essential for avoiding distortion of competition. European steel producers therefore continue to work with the European Commission in the framework of the Environmental Protection Research Programme (established under Article 55 of the Treaty of Paris).

REGULATIONS

With the signing of the treaty establishing the European Community for Coal and Steel in 1951, the founding states obligated themselves to subordinate their respective national steel policies the decisions of the ECSC institutions. The institutions of the ECSC are authorised powers which were used particularly during the years of the steel crisis between 1980 and 1988. Such powers include: introducing quotas limiting production and deliveries on the internal market; fixing steel prices; limiting imports with non-ECSC countries; and directing investments.

Government subsidies are strictly prohibited by the ECSC Treaty. Nevertheless, the EC Commission tolerated the granting of subsidies by the Member States for a long time. Moreover, in 1980 the EC Commission even restricted the prohibition of subsidies established in the EC Treaty by stating in the so-called Aid Code that this prohibition is not meant for subsidies with which a common steel policy is pursued and aims of the ECSC Treaty are supported. Therefore, in the course of the restructuring of the EC steel industry many subsidies were allowed. The Aid Code of 1980 was to expire at the end of 1985. However, it has been prolonged several times following a clearly restricted guidelines. Since the beginning of 1986, government subsidies for the steel industry may only be granted to foster research and development, to safeguard the environment and to meet the social costs incurred by total plant closures.

In summary, regulations for the steel market and the steel policy of the EC in future are expected to be more oriented towards liberalisation. Instead of direct interventions, supporting measures and measures for monitoring the competition will be emphasised.

OUTLOOK

At the end of 1989, ferrous metals producers were confronted with weakening demand, which intensified in 1990 and 1991. A slow-down in production growth of consuming industries was the main reason for the decline in EC consumption. In addition, EC exports to non-EC countries fell considerably in 1990, due to a strong reduction of demand from the USSR and China. The slight recovery of extra-EC exports in 1991 was caused primarily by exceptional deliveries of steel tubes to Norway. According to these trends in domestic and foreign demand, EC production of ferrous metals dropped by 4.1% in 1990 and 1.6% in 1991.

Production levels in most of the consuming industries will remain low, especially in the car industry, mechanical engineering and the building sector. Under these circumstances, a further drop of consumption in the Single Market of about 1% must be anticipated. EC exports are expected to fall considerably, owing to a reaction in the steel tube sector. Production of ferrous metals is likely to decrease. As far as the mid-term prospects for the development of EC ferrous metals industry are concerned, they are more favourable than in the past. The reason for this positive assessment is attributed especially to expected EC economic growth of 3% annually for the period 1992 to 1996.

Iron and steel
NACE 221

After achieving record levels in steel production and consumption in 1988 and 1989, the EC steel market has performed less spectacularly since 1990. In most Member States, with the exception of Germany, a reduction of steel consumption and production set in during the course of 1990 intensified in 1991. This was primarily caused by weaker production activity in the steel-using industries.
In the years between 1974 and 1987, steel industries in the industrial countries suffered serious set-backs owing to reduced production in steel-using industries, a decrease in the quantity of steel required to produce given products, and increased competition from newly industrialised countries.
A major restructuring effort was undertaken in the EC during the 1980s which led to large capacity cuts and important productivity gains, which have allowed European companies to take advantage of a favourable economic climate since 1988.

INDUSTRY PROFILE

Description of the sector

The steel industry encompasses steel production from raw material processing to the production of finished and final rolled steel products. Steel and coal were the subject to the ECSC Treaty in 1952, one of the first European industry agreements. The special provisions governing theses two products remained in force after the two administrative bodies of the Community were merged.

The steel industry as defined by the EC covers the following operations:

- coke manufacture (except if coke is purchased from the coal industry or independent coking plants);
- ore preparation, especially in the manufacture of sinter and pellets
- pig-iron production in blast furnaces;
- steel production from pig iron in converters;
- steel production from scrap in electric furnaces;
- continuous casting and/or hot rolling of semi-finished products;
- hot rolling of long and flat products;
- cold rolling of flat products;
- metallic and organic coatings.

The finished and final products of the steel industry, including ordinary, special and alloyed steels, can be divided into hot-rolled and cold-rolled products.

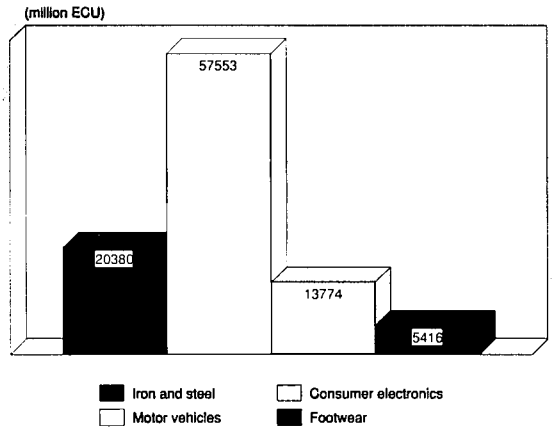
Hot-rolled

- flat products: coils, rolled strip or strip cut from coils, heavy or medium plate, rolled or cut from coils;
- long products: heavy sections, light sections, including reinforced concrete rounds, wire rod.

Cold-rolled

- thin sheet steels and coated sheet steels (tin plate, galvanised, electro-galvanised, lead-covered, aluminium-coated, plastic-coated, pre-painted, etc.).

Figure 1: Iron and steel
Value added in comparison with other industries, 1991



Source: Eurostat

Main indicators

The steel boom of 1988 and 1989 (set off by overall economic growth) led to record levels in steel production and consumption in the EC. With the economic slowdown that began in 1990 and intensified in 1991, especially in the steel-using industries, significant reductions in production and consumption were recorded by the EC steel market. The rise in production and consumption shown in Table 1 for 1991 is solely attributable to the inclusion of the former GDR. Without this regional effect, EC production for 1991 would have been 3.4 million tonnes lower and steel consumption 2.6 million tonnes lower. For 1992, a further weakening is expected in the EC steel market.

Table 2 shows a breakdown of steel production according to the most important product categories. The proliferation of new production techniques since the 1970s (such as continuous coating and electric arc furnaces has greatly improved productivity in certain steel production processes.

Figure 2 indicates the distribution of total EC steel production among the Member States. Four countries, Germany, Italy, France and the United Kingdom, account for nearly three-quarters of production.

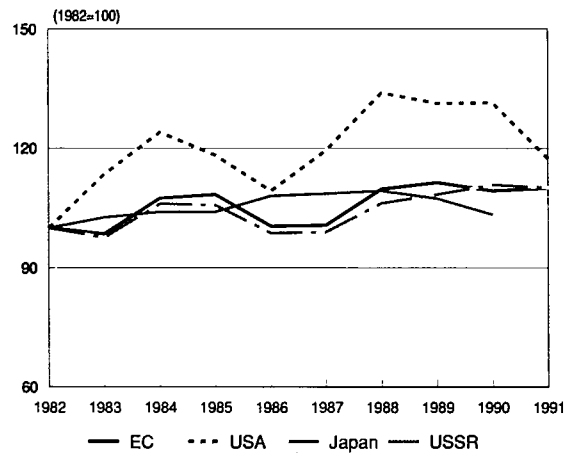
Recent trends

In all industrialised countries, growth in the steel industry is dependent upon growth in the economy as a whole, and particularly in those manufacturing industries which are high consumers of steel products. Despite the strong recovery in 1988 and 1989, steel production and consumption at the beginning of the 1990s was only slightly above the level of 1982. The strong and continuous decline in employment over the entire period under observation is a result of the restructuring measures introduced in the early 1980s.

International comparison

The EC is the largest steel producer in the western world, followed by Japan and the USA. In the EC and Japan, steel production far exceeds domestic steel consumption, reflecting the EC's role as the most important steel exporter. While the EC has maintained its export level in the period 1982-90, Japan, however, experienced a considerable decrease in steel exports. In the USA, by contrast, steel consumption is significantly higher than steel production. A lack of competitiveness in the USA has led to growing steel imports.

Figure 4: Iron and steel
International comparison of main indicators in volume



Source: Eurostat, IISI

The development of steel production over time is shown in Figure 5. The USA, it seems, has had the strongest growth in production compared with the EC and Japan. However, it should be kept in mind that the USA suffered a downturn in production of nearly 40% in 1982.

Foreign trade

EC steel exports to non-EC countries are indicated in Table 4. After a peak in 1985, extra-EC exports have decreased. This reduction actually continued during the peak production years 1988 and 1989 as EC steel production was primarily required to service the exceptionally high demand in domestic markets. In contrast to exports, extra-EC imports show a clearly growing trend, which has led to reducing foreign trade surpluses and a declining export-import ratio.

The USA and the EFTA countries are the most important export markets for the EC, receiving about half of extra-EC exports. Exports to Eastern Europe have decreased considerably as a result of the recent political and economic changes in these countries.

The main suppliers of steel to the EC are the EFTA countries with an import share of nearly 40%. Approximately 25% of extra-EC imports are from Eastern Europe, whereas Japan exports relatively low quantities to the EC.

Although extra-EC exports have declined since the mid-1980s, the importance of intra-EC trade between the Member States has increased. This development is attributable to the long existence of an integrated European steel market.

The market share for foreign competitors in the internal EC market fluctuates from 1982 to 1991 between 8.3% and 10.2%. The development of the import share from 1982 to 1985, however, is not fully comparable with the years thereafter due to Spain and Portugal having joined the EC.

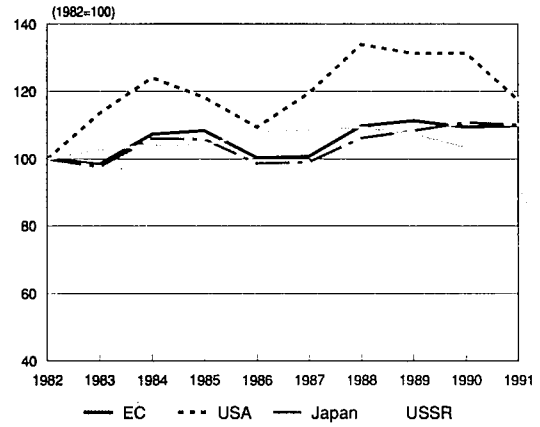
MARKET FORCES

Demand

The apparent consumption of ECSC steel in the EC for 1991 was 126 million tonnes (approximately 17% of world consumption) in crude steel equivalent.

Primary processing industries account for approximately 35% of the ECSC steel used in the EC, the most important of which were the steel tube sector (14%), wire and bright drawing (9%) and cold-rolling and cold-forming (6%). In terms of

Figure 5: Iron and steel
International comparison of production growth in volume



Source: Eurostat, IISI

final internal demand the most important consumers are building and civil engineering (15%), vehicles (11%), metal goods (10%), mechanical engineering (7%), and structural steel work (6%).

There are a number of factors that caused a drop in the share of steel consumption of the EC (and of industrial countries in general) in world steel production since the mid-1970s. These factors were:

- a reduction in the tonnage consumed due to weak overall economic growth and especially to production cuts carried out in a number of steel-using industries;
- a continuing reduction of specific steel consumption, i.e. a decrease in the quantity of steel required to produce a given product. This drop in specific steel consumption can be attributed to major improvements in the quality, properties and performance of steel products themselves as well as to the substitution of steel by other materials (plastics, aluminium).

In contrast to western industrial countries, steel consumption in the newly industrialised and developing countries (as well as in the controlled economies of Eastern Europe) experienced strong increases in the past. Their share of world steel consumption increased from 40% in the mid-1970s to 55% in 1987.

Since 1988, the trend of industrialised countries towards a declining share of steel consumption has stopped. The sharp increase in domestic demand in most western industrial countries had led to a strong increase of steel consumption in the period for 1987 to 1990, especially in the EC (+22%) and Japan (+31%). At the same time, East European countries and the former Soviet Union experienced sharp contractions in steel consumption (10%) as a result of the radical political and economic changes taking place.

The general slowdown in the economic growth of most industrial countries in 1991 caused a drop in world steel production and consumption by 4.4%. In the EC steel consumption (excluding former East Germany) fell by 2%. This reduction was attributed particularly to the fall in demand from the motor-vehicle and construction industry.

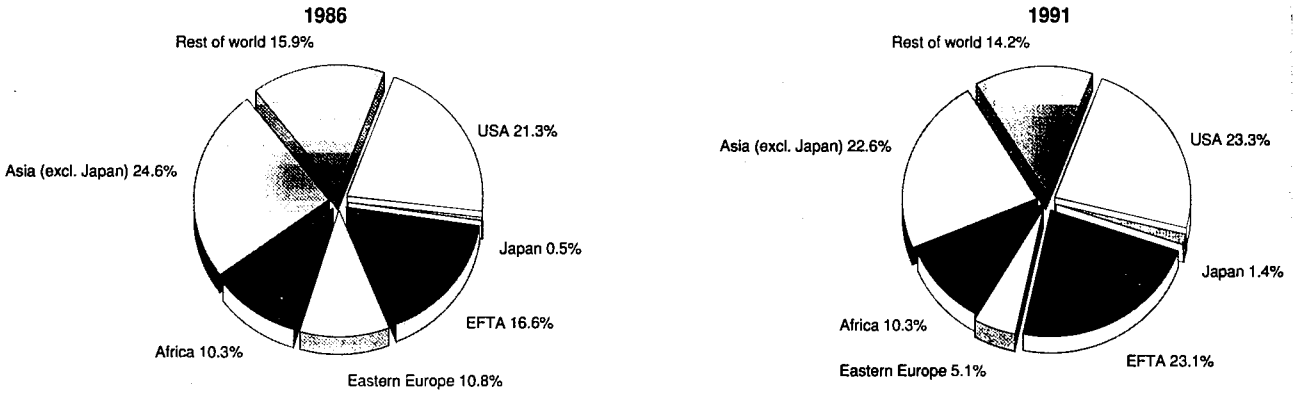
Supply and competition

In response to the reduction in consumption induced by the structural and economic factors listed above, a massive restructuring effort took place in the EC during the 1980s. This was aided between 1980 and 1986 in part by assistance from national governments under the terms of the State Aid Code approved by the Council and the market controls regulated by Article 58 of the ECSC Treaty. The controls expired on June 30, 1988. As far as crude steel is concerned, this resulted in a 40 million tonnes reduction in production capacity, which represents a 19% cut in capacity. Furthermore, by the end of 1988, 34 million tonnes (18%) of hot rolling capacity in the EC 12 had been terminated.

At the same time, however, a substantial increase in production took place in the newly industrialised countries, which profited from low production costs (cheap labour, cheap energy, indigenous raw material supply) as well as from developments in steel production technology (mini-mills). A growing number of these countries did not only cover their own needs, but were competing successfully with the traditional exporting countries. This led to a reduction in EC producers' share of the international market and prevented them from compensating reducing domestic demand by increasing exports.

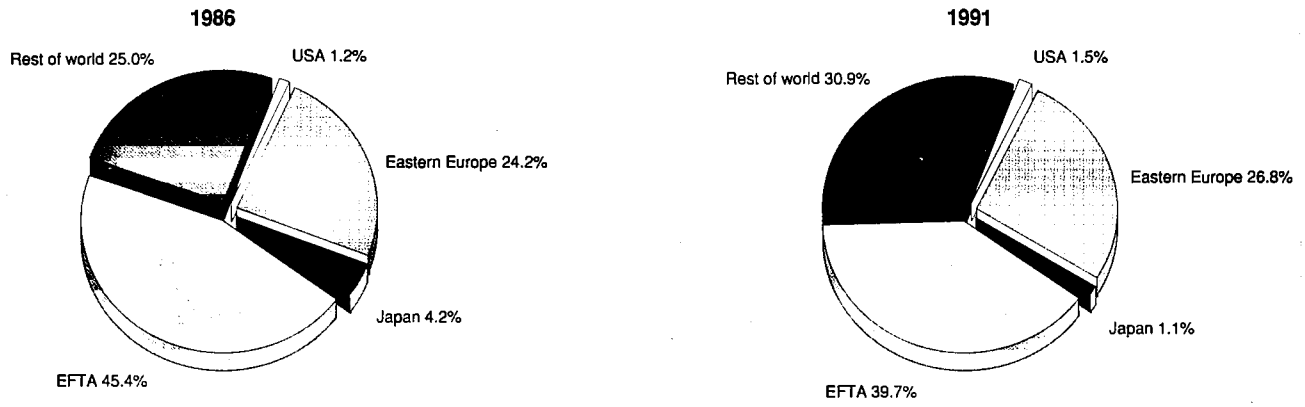
In addition, the newly industrialised countries broke into EC markets where large quantities of steel are often dumped at

Figure 6: Iron and steel
Destination of EC exports (1)



(1) ECSC steel products
Source: Eurostat

Figure 7: Iron and steel
Origin of EC imports



Source: Eurostat

prices that bear no relation to production costs. Practices of this sort led to a sudden jump in imports from non-EC countries, which rose from 5% to 11% of apparent consumption between 1975 and 1977. The buoyant climate on the international market of 1974, (caused by a steel shortage), and the relative openness of the EC market prepared the way for this increase. The subsequent downturn in the economic situation confirmed the presence of price dumping. Since 1978, however, imports have stabilised at around 10% of apparent consumption.

The effect of the restructuring undertaken since 1980 led not only to a progressive reduction of production capacity in the European steel industry, but also strengthened the financial results and the competitiveness of EC steel companies.

The EC steel industry has a strong competitive position in foreign trade. More than 20% of world steel exports in 1990 stemmed from EC countries. In contrast to Japan, whose share decreased from more than 25% in 1982 to only 14% in 1990, the EC has been able to hold its position.

Even stronger than their competitive position in foreign trade is the technological competitive advantage of the European steel producers. This is indicated by the international share of inventions. On the basis of applications for patents (in at least two countries) the EC steel industry is in first place in world-wide ranking. More than 40% of the innovations in steel industry came from EC countries in the period 1983 to 1989, compared with a share of 26% from Japan and 18% from the USA.

Much more unfavourable, however, is the competitiveness of the European steel suppliers with regard to costs. Former West Germany, which has the highest labour costs per hour worked in the EC, was only exceeded in recent years by the USA. In a better position are the United Kingdom and France. In 1989, labour costs per hour worked in the United Kingdom were about 30% and in France about 15% below the level of German producers.

Production process

Major technological advances in production techniques accompanied the termination of production capacity, thereby enabling the remaining installations to operate with greatly reduced costs and enhanced efficiency. The proliferation of continuous-casting plants, (whereby one step in the production process is eliminated and the requirements for crude steel consequently lowered) is one example of this. The share of the continuous casting method in crude steel production rose from 35% in the EC 10 in 1980 to 90% in 1991. In some countries (and in some companies) it reached 100%.

Workforce reductions have also taken place, due principally to plant closures and lower production in those plants which remained open. In the period from 1980 to 1990 the number of employees in the steel industry of EC 9 dropped by 43%, a rate of 5.5% per year. Productivity (measured as value added at constant prices per person employed) has risen constantly since the beginning of the 1980s. Over the whole period from 1982 to 1991 productivity improved by an average growth rate of 8.7% per year. Discarding inefficient production methods, investment in rationalisation programmes and constant technical research have achieved these productivity gains. They were necessary for the EC steel industry to compensate increasing production costs. Total costs per person employed in current prices have increased from 1982 to 1991 by 7.6% per year. Increases in unit labour costs have been somewhat lower.

INDUSTRY STRUCTURE

Companies

Steel producers can be classified above all according to their manufacturing methods.

The first category is made up of integrated companies which account for 70% of production. These companies produce pig iron in their blast furnaces and convert it in oxygen-based steel works, using a certain tonnage of scrap to maintain the temperature of the molten steel. Companies using this method are usually geared to the production of flat products, including subsequent cold rolling into thin sheet steel (which may be coated), and the production of heavy sections and wire rod. Integrated mills often have large-scale production capacity ranging from 2 to 10 million tonnes of finished products. Although cost reductions occur from economies of scale, integrated mills allow little production flexibility.

The second category is made up of small companies with more specialised types of production. These so-called mini-mills comprise enterprises whose sole operation is electric steel works, continuous casting plant, and rolling mill. Mini-mills play a considerable role in the management of industrial waste by converting scrap into quality steel products. These products include reinforcing bars, reinforcing mesh and small and medium-sized sections for the construction industry, as well as merchant bars and wire rods used particularly in the automobile industry.

Mini-mills have much smaller capacity than integrated companies. Their annual capacity ranges from 150 000 to 1 200 000 tonnes. The success of mini-mills, even in the past years of crisis in the steel sector, is explained by their flexibility and greater freedom to adapt production to market demand. In certain Member States, mini-mills account for a substantial amount of overall steel production. In Italy, for example, mini-mills account for 55% of steel production. Another example is Spain where 42% of all steel is processed by mini-mills.

The iron and steel industry is an industry with a high degree of concentration. In 1990, almost half of EC crude steel production was produced by only five steel companies. In descending order of output they were: Usinor-Sacilor (F), British Steel (UK), Ilva (I), Thyssen Stahl (D) and Hoogovens (NL). In addition, the top fifteen companies accounted for 73% of EC crude steel production.

A number of mergers and acquisitions have taken place in the course of modernisation and restructuring of the EC steel industry. For example, the merger between Usinor and Sacilor in France, the creation of Ilva in Italy and the rationalisation agreement between Krupp and Mannesmann in Germany. The most recent example is the takeover of Hoesch by Krupp.

It should be kept in mind, however, with the exception of Usinor-Sacilor, British Steel, Ilva and Thyssen, most of the European steel producers are only medium size in comparison to other international steel firms.

Strategies

In 1952, the ECSC Treaty created for coal and steel the necessary conditions for the "Single Market", which after 1992 should extend to all other industrial sectors. Consequently the formation of the Single Market is already a reality for the EC steel industry. Such a situation can only be considered as a new opportunity for reinforcing open competition and the complete freedom of intra-EC exchanges.

The 1992 project should provide a windfall for the industry in other ways, with a "very considerable" effect on energy costs, and a possible reduction in financing costs of 10% at least.

A side effect of the 1992 deadline is a new dynamism on the part of steel companies. Companies are starting to protect themselves against future downturns and strong competition from outside. Such measures include: paying more attention to customer service and commercial investment; diversifying into areas other than steel; take-overs and mergers; specialising in high-quality products; and more integrated production techniques.

The great efforts EC steel producers are undertaking to rationalise and modernise their facilities partly in view of the Single Market have become evident in the strong growth of investment in recent years.

REGIONAL DISTRIBUTION

There are steel plants throughout the EC, with varying levels of production capacity. A number of them were built inland, usually near the coal or iron-ore fields from which they used to draw their supplies, or near steel consumers. Those built more recently are on the coast, where they have easy access to imported raw materials, without the cost of land transport. They are also better placed to capture international markets.

The importance of the steel industry in the economy of member states varies largely. For example, in Luxembourg the share of steel production in total industry exceeds 40%. By contrast, the contribution of steel to total manufacturing production only accounts for about 1% in Denmark, Ireland and Portugal.

With regard to mini-mills, the highest concentrations of such mills can be found in northern Italy and Spain.

ENVIRONMENT

The steel industry is fully conscious of its responsibility with regard to environmental protection. Long before the protection of the environment had been placed on the political agenda, the steel industry intensively developed and generated techniques to reduce environmental pollution. These measures include the low-pollution manufacture of steel products, steel recycling and the utilisation of waste material.

The restructuring of the industry in the 1980s has resulted in the closure of many older installations and their replacement by modern plants, fully equipped with a whole range of pollution-control equipment. These new plants are which incorporate the best available anti-pollution technology in this field.

The steel industry's dust emissions have been considerably lowered. Emissions of carbon dioxide (CO_2) have also been strongly reduced by energy optimisation of process technology and an overall reduction in energy inputs. The increasing use of electric arc furnaces (EAF) across Europe is a leading example of such new processes.

In recent years the EC steel sector consumed about 60 million tonnes of steel scrap, the bulk of which was collected from discarded used steel-containing products. This recycling of scrap, which represents about 45% of total steel production, is one of the highest rates for any industry.

Environmental protection places considerable financial burdens on the iron and steel companies. In light of the high costs and the fact that the requirements and enforcement of environmental protection is not equally strict in all countries, a harmonisation of environmental protection legislation in Europe is absolutely essential for avoiding distortion of competition. European steel producers continue to work with the European Commission in the framework of the Environmental Protection Research Programme established under Article 55 of the Treaty of Paris.

REGULATIONS

For more than forty years, the European steel industry has been regulated by the European Coal and Steel Community (ECSC). The ECSC was originally established in 1952 to regulate pricing, transport, tariffs, etc. for coal, iron ore and scrap iron among the Member States.

As mentioned above in the section pertaining to the environment, European steel producers are working with the European Commission in order to harmonise environmental protection legislation in Europe.

OUTLOOK

A strong decrease of consumer stocks, induced by a weakening of production growth in steel consuming industries, was the main reason for the decline in demand of the internal EC steel market in 1990. In 1991, the downturn in production of steel consuming industries has strengthened; while the output of construction industry stagnated, the production of mechanical engineering and of motor vehicles actually declined. Apparent consumption in the EC (excluding former East Germany) decreased by 1.8% and crude steel production dropped to 134.2 million tonnes, a decrease of 2% in comparison with 1990.

Overall economic growth in the EC will remain weak and a reduction of steel stocks on the part of merchants and producers will have a negative impact on domestic demand. As a result, apparent consumption is likely to stagnate. Furthermore, there is no foreseeable improvement in exports or imports, as the EC has become an area with strong currencies and demand from some traditional export markets (USA, USSR, China) is shrinking while at the same time many more suppliers are appearing on the world market.

As far as the mid-term prospects for the development of EC steel industry are concerned, it can be said that they are more favourable than they were a few years ago. This growth should allow the continuing trend of reduced steel consumption over the past 15 years to be replaced by a positive development. Accordingly, the decline in specific steel consumption in the past few years seems to have slowed down considerably. New or improved steel qualities have evidently improved the market position of steel in competition with other materials. In addition, there has been better marketing on the part of the steel industry by offering their customers more specific solutions to compensate their needs. Apparent consumption of ECSC products (expressed in crude steel equivalents) therefore, is expected to have a growth potential of the order of 1% per annum in the period until 1996.

On the other hand, net import demand in the NICs and developing countries, and also in Eastern Europe, has declined drastically. The net exports of the two major exporters, (i.e. Japan and the EC) fell from about 70 million tonnes (crude steel equivalent) in 1974 to 22 million tonnes in 1990. As no change can be expected in this development for the medium term and since competition is expected to intensify, net EC steel exports for 1996 are expected to be only 10 million tonnes (crude steel equivalent).

Table 7: Iron and steel
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	1.0	1.0
Production	1.8	1.2
Extra-EC exports	2.3	1.9

Source: Ifo institute

These forecasts are well in line with those published by the European Commission in their publication "General Objective Steel - 1995". According to these forecasts, crude steel production in the EC will be about 138 to 143 million tonnes in 1995.

Given the developments in the second half of 1990 and in 1991, it seems unlikely that the favourable scenarios underlying these forecast (in particular for the oil price and exchange rates) will be met. Therefore, the lower forecasts for production are likely to be the more realistic.

Steel tubes
NACE 222

The steel tube industry has faced a severe volume and financial downturn since the mid-1980s due to worldwide overcapacity. Seamless tubes and welded tubes with an outside diameter of over 406.4 mm in particular were deeply influenced by the oil crisis, by the quotas imposed by the USA on its competitors to limit imports, and more recently by the low exchange rate of the dollar and by the lack of orders from the former USSR and from China, all of which have impaired the competitive position of EC manufacturers.
The EC has maintained its leading position in the world market, ahead of the USA and Japan, due to continuous productivity gains achieved over the last few years brought about by restructuring. Nevertheless, foreign trade has been steadily deteriorating.
Despite its improved competitiveness, the EC steel tube industry is under rising pressure from massive volumes of low-priced imports from Central and Eastern Europe which will force EC producers to further reduce their output.

INDUSTRY PROFILE

Description of the sector

The activity of NACE 222 includes the manufacture of steel tube fittings and compressed gas cylinders in addition to the manufacture of steel tubes. This monograph, which covers only steel tubes manufacture, is based on figures produced by surveys conducted by the professional organisations located in the EC Member States.

Steel tubes covers three product categories which differ considerably in their manufacturing procedures, raw materials, and investment requirements. These categories are classified in the following subheadings of Chapter 73 of the Harmonised Commodity Description and Coding System:

- No 73.04: seamless steel tubes;
- No 73.05: welded steel tubes of circular cross-section over 406.4 mm in outside diameter;
- No 73.06: welded steel tubes of circular cross-section up to and including (uti) 406.4 mm in outside diameter and welded steel tubes of non-circular cross-section of any perimeter.

Energy markets, e.g. oil, gas, nuclear, steam generation industries, as well as the car industry, machines, structural steel, mechanical service and construetion industries, are some of the main users of steel tubes. The developments in each of the product areas in steel tubes manufacturing thus vary according to their different end markets.

Main indicators

In 1991, apparent consumption of steel tubes in the EC decreased 7% against 1990 while production increased 1.8% generated by a strong performance in exports. Extra-EC exports increased by 30.6% because of an exceptional shipment of 934 509 tonnes of welded tubes (over 406.4 mm in outside diameter) to Norway. As a result, the trade balance improved by 54% in 1991 although with strong import pressure, EC producers' share of the domestic market decreased by 8.2%. Employment in the steel tubes industry declined by 1 800. The situation for 1991 by category is shown in Table 2.

Recent trends

Table 1 shows a marked decrease in production and exports of steel tubes which resulted - among other effects - in a loss of employment of 30 625 (30%) people between 1984 and 1991. Although apparent consumption increased steadily over the past decade (with the exception of 1991), it has mostly been to the advantage of third country competitors. The share of imports from third countries in EC consumption, measured in terms of tonnes, increased strongly from 9.3% in 1984 to 14.5% in 1991.

Growth in the steel tube sector has clearly lagged behind the developments in the manufacturing industry as a whole. Over the last ten years, the manufacturing industry has been characterised by strong growth in production and consumption and a stagnation in extra-EC exports and employment. In contrast, all indicators for the steel tube sector, with the exception of consumption, show a sharp decline.

International comparison

EC production of steel tubes in 1991 corresponded to 18.9% of world production against 20.6% in 1984. In the world ranking, the EC is ahead of Japan and the USA. The former Soviet Union has also been at the top of the list for the past several years. Particularly in Japan, but also in the EC, steel tube production easily exceeds consumption which refleets their role as the most important steel tube exporters.

While the EC, the USA and Japan suffered setbacks in terms of their shares of world production in the 1980s, the newly industrialised countries (NICs) and the developing countries (DCs) were the winners. Some of these countries have continued to expand their production capacity, often supported by heavy public subsidies. This group of countries includes Turkey, Mexico, Venezuela, Brazil, Argentina, Taiwan, the Republic of Korea and Thailand.

Foreign trade

A look at Table 4 shows the serious deterioration in external trade. Extra-EC exports of steel tubes have decreased continuously since 1984, with the exception of 1991 for the reason mentioned above concerning Norway. On the other hand, extra-EC imports increased steadily, leading to a declining trade balance and a declining export-import ratio.

Figure 5 shows big changes in the destination of EC exports between 1986 and 1991. Exports towards EFTA and OPEC countries doubled during this period. As for the former Soviet Union, the major export market in the past, the lack of hard currency has reduced its share of EC exports to less than one quarter of that of 1986.

The EFTA countries are dominant suppliers to the EC steel tube market. However, Figure 6 shows a decrease in the share

of EC imports held by EFTA and Japan while for the countries of Central and Eastern Europe, the share has more than doubled between 1986 and 1991.

As a result of the slowdown of exports and the increase of imports (measured in constant prices), turnover has declined since 1984 although there was a slight improvement in 1989.

MARKET FORCES

Demand

The most important steel tube consuming sectors are: oil and gas exploration and extraction, transport of oil and gas by pipelines, nuclear and other steam generation industries, mechanical engineering, the automotive industry, structural steel work, the building industry and other metal processing industries.

Due to developments in these sectors, apparent consumption of steel tubes in the European Community amounted to 9.8 million tonnes in 1991. Compared to 1984 this was an increase of 20.5% or 2.7% annually on average.

In view of this positive development in the domestic market it must be kept in mind, however, that the EC steel tube industry is highly export-oriented. In 1984 48.6% of EC steel tube production was exported to third countries. The decrease in this share to 33.0% in 1991 shows a serious change in the sales opportunities of the industry. If the exceptional delivery of 1 million tonnes to Norway is not taken into account in 1991, the ratio of exports to production would fall to 25.6%. The main reason for the reduction in extra-EC exports is the steeply diminished volume of orders from the CIS and from China.

Supply and competition

The EC steel tube industry, while continuously cutting back its work force and production capacity, still suffers from worldwide over capacity. The effects on financial margins are considerable especially in export markets and for ordinary categories of steel tubes. Given the range of possibilities for supply worldwide and coupled with rising imports into the EC, customers are in a strong position to dictate prices to producers.

Source: Eurostat

Internal competition within the EC is high and has strengthened in the recent past. In 1984, intra-EC trade amounted to 2.474 million tonnes or 30.4% of the consumption of steel tubes, whereas in 1991 imports were 4.149 million tonnes or 42.3% of consumption. In value, intra-EC imports totalled 1 763.2 million ECU or 31.5% of consumption. By 1991 this figure had increased to 3 115.5 million ECU or 42.9% of consumption. This development is an indication of the fact that there are very few trade barriers remaining in the steel tube sector today. The impact of the single market, therefore, is expected to be low.

EC competitiveness with respect to third countries, however, is threatened when imported steel tubes are subsidised in their production and/or are produced under non-market-economy conditions.

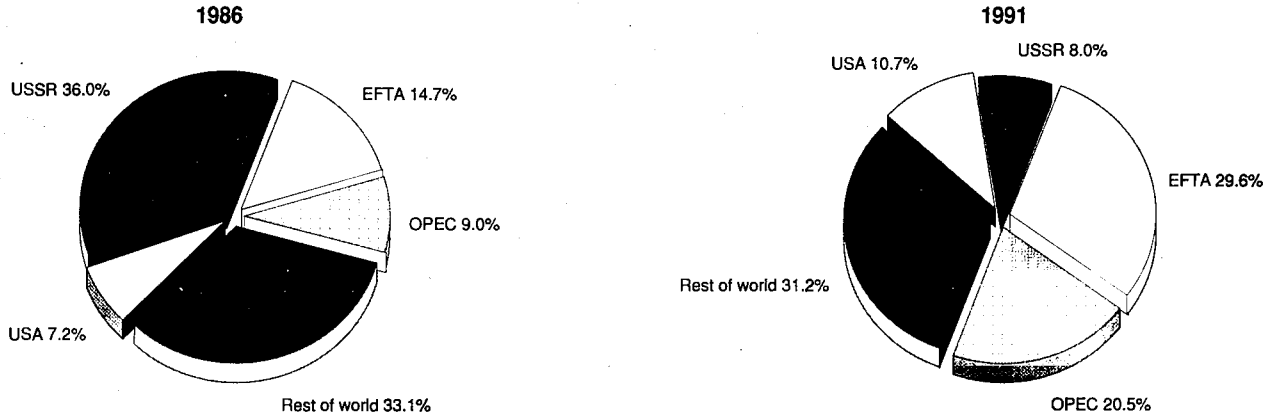
This is in fact the case with most of the imports streaming in from the Central and East European countries, especially from the second half of 1991. Their "costs" are not real ones and thus are often not reflected in pricing. For example, raw materials are often purchased in exchange for other materials and electric power, as well as water supply, are heavily subsidised.

Given such circumstances, these imports flood the EC market with price differences of 30 to 50% of the EC price level. The consequences are plant closures: two production lines for seamless tubes in the UK were closed in 1991 and several modern operations with very high productivity were closed in 1992, including one well-known continuous mill in Germany. In contrast, old and uneconomic mills in Central and East European countries have been trying to run at full capacity, mainly to generate exports directed to the EC. These imports are shown in Table 5. The trend will be marked by a further sharp increase in the future.

Production process

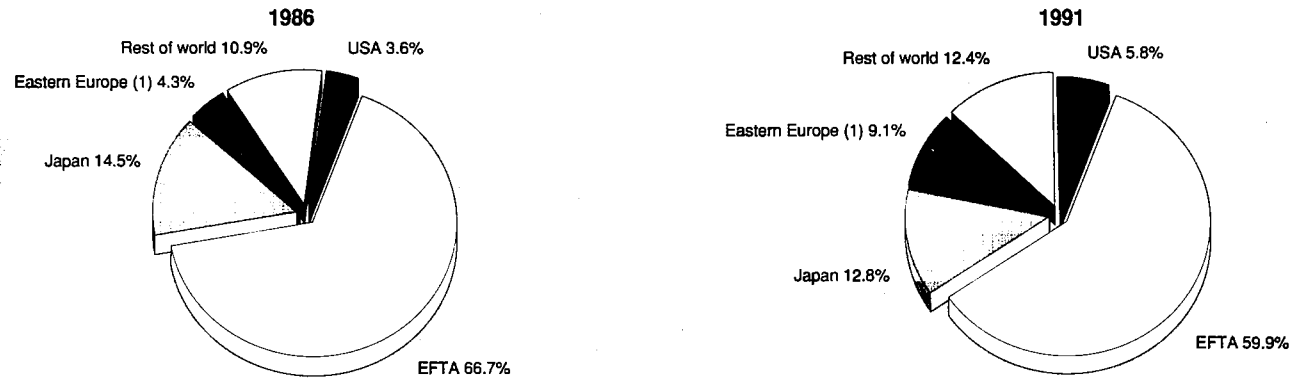
Technically speaking, the EC steel tube industry is a very strong performer. Continued investment in research and development assure high quality in steel production and rolling processes. On-going rationalisation efforts in production and labour have kept the costs at a competitive level. In the period

Figure 5: Steel tubes
Destination of EC exports



Source: Eurostat

Figure 6: Steel tubes
Origin of EC imports



(1) Bulgaria, Czechhoslovakia, Hungary, Poland, Romania
Source: Eurostat

from 1984 to 1991, the number of employees in the steel tube industry dropped by 31%, a rate of 5.1% per year. Productivity (measured in terms of tonnes per person employed) increased by 3.3% per year over the same time period.

One important fact has to be emphasised: in many groups of seamless and welded tubes different categories are produced on the same mill, i.e. tubes of ordinary grade as well as tubes of highly sophisticated quality. This means that the installations need to be filled with a substantial base load of commodity products as well as high grades to obtain a cost level which is competitive in the world market.

INDUSTRY STRUCTURE

Companies

The steel tube industry is a primary steel processing industry with a highly concentrated structure: four countries, Germany, Italy, France and the United Kingdom, account together for more than three-quarters of total production. In some countries, a single company can account for 50% or more of national output. In addition to the major steel tube manufacturers, who are usually linked to the large steel producers, there is a relatively large number of medium-sized and small firms. Among these companies there are some manufacturers, often small in tonnage terms, operating in small, highly value-added markets, specialised in the manufacturing of special dimension tubes and grades according to customers specifications.

At the end of 1991 there were 306 production units in the EC belonging to an estimated 250 enterprises, 72 of which were specialised in cold drawing of seamless or welded tubes.

Strategies

No significant investment has taken place in recent years owing to the reductions in capacity imposed by difficulties on the market since 1985. Contrary to the beginning of the 1980s where some investment was directed towards expanding capacity, current investments relate to improvements in productivity and quality (mainly in small diameters).

In the past, specialisation and concentration in tube manufacturing was a general trend in all tube producing companies and countries. To strengthen the competitiveness of the industry, consideration is now being given to cross-border cooperation followed by capacity reductions.

ENVIRONMENT

Costs arising from environmental protection are considerable. They are to a large extent due to costs incurred by the treatment of emissions from raw material production units and reheating furnaces, treatment of waste water from the pickling installations and noise control in the production units. These costs can amount to as much as 50 ECU per tonne, or 1% of the turnover of some EC firms.

REGULATIONS

Trade regulations are a key source of concern for the EC steel tubes producers. Trade barriers in the USA hamper the penetration of EC exports. These barriers might be subject to revision in the framework of the Uruguay Round trade negotiations.

The harmonisation of EC standards in the sector is well advanced: internal barriers are very low and do not impede the free circulation of goods among the Member States.

OUTLOOK

In 1991, apparent consumption of steel tubes in the EC decreased of 7% due to the slowdown of overall economic growth as well as a reduction of stocks on the part of both distributors and users. In contrast to consumption, EC production registered an increase of 1.8%.

Taking this fact into account, extra-EC exports in 1992 will probably drop again by nearly 16%. As apparent consumption is likely to stagnate due to weak overall economic growth and a further reduction in stocks, EC production is expected to decrease by around 10%. A recovery of the steel tube industry cannot be expected before 1994, brought on by stronger overall economic growth and a stabilisation of exports.

In the medium term, the development of the EC steel tube industry will be characterised by a number of risks and opportunities.

The main risks are a further increase of imports from the Central and East European countries which could lead to further plant closures. Continued weak demand in the US market and an increase of the export activities of subsidised mills in third countries will also dampen demand for EC steel tube manufacturers. CIS imports will not improve for some years.

On the other hand, three main opportunities might be seized by the industry. First, in the medium to long term, the economic recovery in the CIS and in Central and East Europe. Second, free access to the US market under GATT conditions, and third, an improvement in the world economic situation with a related increase in the demand from the energy industry.

First processing of steel

NACE 223

After substantial growth in 1988 and 1989, production of first processed steel fell in 1990. This was primarily due to the economic downturn experienced by their customers, particularly those in the building sector, the automobile industry and in mechanical engineering.
In the past, developments in the drawing and cold rolling mills were marked by decidedly weak growth rates due to slack demand at home and an ongoing deterioration of foreign trade. New suppliers from emergent industrial nations and competition from Eastern Europe made incisive inroads into the markets of the European Community as EC exports to non-EC countries receded simultaneously. One consequence of this unfavourable trend (and of intensified rationalisation measures) was a drastic drop in employment.

INDUSTRY PROFILE

Description of the sector

First processing of steel usually includes forging and the steel tube industry, which are considered separately in this publication. According to the NACE/NIPRO classification, NACE 223 encompasses the following activities:

- Cold drawing of steel;
- Cold rolling of hoop and strip;
- Cold forming of angles, shapes and sections from flat rolled steel products;
- Steel-wire drawing and the manufacture of finished wire products.

Cold drawing includes the production of cold machined steel bar stock. The transformation of hot-rolled steel bar into so-called bright steel is achieved primarily by two methods: drawing or reducing the material thickness by turning, scalping or grinding the steel bar.

Cold-rolled strip steel (cold strip) is produced in rolling mills (outside the ECSC Treaty). This is done by secondary rolling out of hot-rolled strip stock in a type of mill termed a strip mill. Cold-rolled strip steel can also be produced in rolls by splitting cold-rolled plate lengthwise. The resulting product, classified as split strip also falls within the cold rolling mill sector according to the NACE definition. In 1991, total production of cold rolled strip steel in the EC reached about 1.5 million tonnes.

Cold forming of steel includes two types of activity: press folding; and continuous forming by rolling machines. The first way of processing is used to produce small quantities of simple forms, while the second process allows the production of large quantities of complex forms. Within the continuous forming by rolling machines activity, one can distinguish two main production areas: long formed products (multi-purpose products and more specific products such as sheet steel piling) and large formed products for the building sector (corrugated and sectioned sheets). The production of cold formed products in the EC has been estimated at about 2.5 million tonnes in 1991.

Wire drawing is a process in which the initial stock is stretched cold in drawing machines until it assumes the shape of wire. The resulting cold drawn wire can then either be used directly or be processed to make finished wire products. Important finished wire products include: welded reinforcement mesh, pins and nails, barbed wire, cables etc. Cold drawing is the largest branch of the sector of first processing of steel. Production of drawn wire in the EC amounts to about 3.5 million tonnes, while consumption reaches about 4 million tonnes. If we also consider the production of by-products of drawn wire, the production of the sector is estimated at about 7 million tonnes, while consumption nears 8 million tonnes.

Main indicators

After several years of negative production growth, the drawing, cold rolling and cold forming mills in the EC were able to record healthy growth rates in 1988 and 1989. With the slowdown of production in consuming industries that began in 1990 and intensified in 1991, however, consumption of drawn, cold-rolled and cold-folded products again decreased slightly. Production fell even more significantly due to a remarkable decline in the trade balance.

Table 2 shows a breakdown of consumption, production and extra-EC exports by major product categories. The drawing, cold rolling and cold folding sector is especially important in Germany, Italy, the United Kingdom and France. This is indicated in Figure 2, which provides a breakdown of value added by Member State.

Recent trends

As in the steel industry, growth in the sector of first processing of steel has clearly lagged behind development in the manufacturing industry as a whole. The strong deterioration of extra-EC exports had a negative impact on production level. The recent decline in consumption and production will continue in 1992 and 1993. The long-term development of employment is the result of great rationalisation efforts. In 1989, the downward trend in employment was halted for the first time during the 1980s.

International comparison

As can be seen in Table 4, the drawing, cold rolling and cold forming mills achieved their best results in trade with non-EC countries in 1985. The export surplus amounted to nearly 1.7 billion ECU. Since then, however, trends in foreign trade have turned noticeably against the EC. While extra-EC imports continued to increase strongly, extra-EC exports suffered a sharp decline, leading to decreasing export surpluses and a declining export-import ratio.

Of all the recipients of EC exports, the EFTA countries play a major role, receiving more than a third of extra-EC exports. Other important export markets are the USA and the OPEC countries; whereas Japan's share is of no significance.

The EFTA countries are even more dominant as suppliers of the EC market with drawn and cold-rolled products. About two-thirds of extra-EC imports originate from EFTA. While the import share from the EFTA countries is decreasing, however, countries such as the USA, Japan and especially the East European countries are gaining importance.

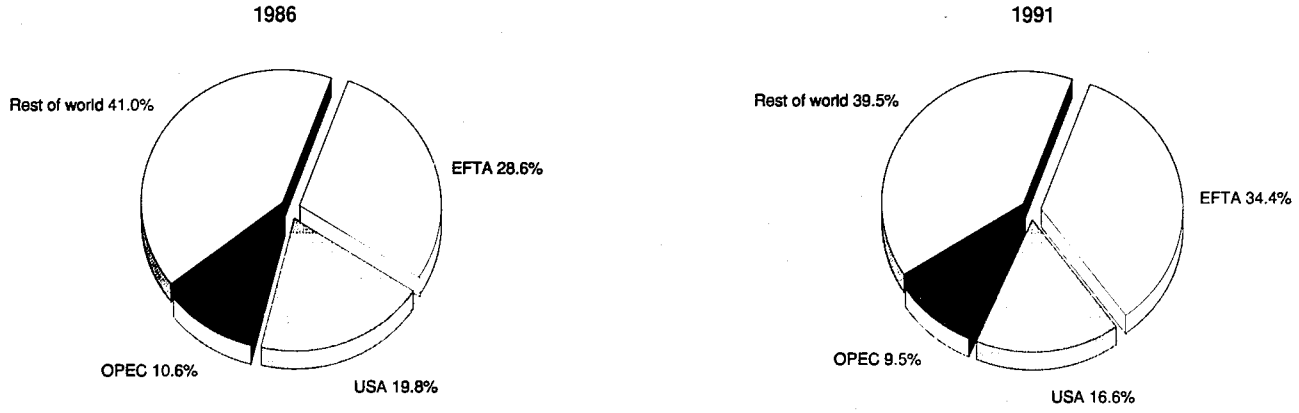
Intra-EC trade has increased strongly in the past. Given the even stronger growth of extra-EC imports, however, the importance of intra-EC trade for the supply of the EC market has decreased. Simultaneously, the penetration rate of foreign competitors supplying the internal market increased steadily from around 6% at the beginning of the 1980s to about 10% in recent years.

MARKET FORCES

Demand

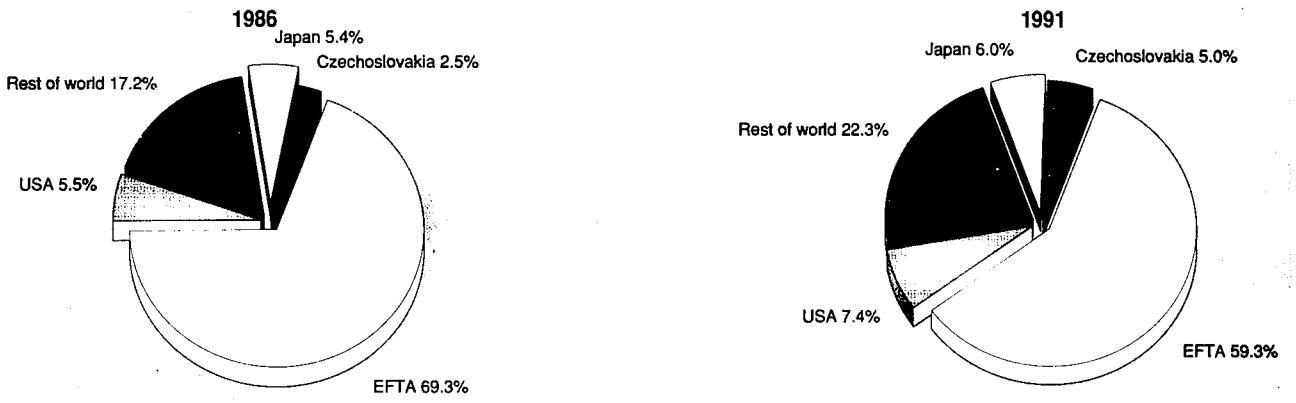
The apparent consumption of products of the first processing of steel industry in the EC (in 1985 prices) amounted in 1991

Figure 4: First processing of steel
Destination of EC exports



Source: Eurostat

Figure 5: First processing of steel
Origin of EC imports



Source: Eurostat

to 10 900 million ECU. Compared to 1982 this was an overall increase of 11.4% or of 1.2% per year on average.

A more positive development in consumption was prevented by two factors. To begin, the unfavourable development in production occurred in the most important user industries, above all the automobile and construction industries. The mechanical and electrical engineering industries are also major consumers of drawn, cold-rolled and cold-formed products. Most of these industries experienced significant losses in production, especially in the first half of the 1980s. For many areas, it was not until 1988 that the production level of the early 1980s was reached. The consumption of products from drawing and cold rolling mills consequently showed a declining trend through 1987, with a strong recovery not coming until 1988.

Secondly, the products from drawing and cold rolling mills were exposed to competition from other substitute materials. Wire and cold-rolled strip steel were forced to compete with plastic and aluminium to a certain extent. Bright steel and cold-rolled sections in particular were under threat from products of the steel industry. The enhanced properties and closer tolerances of steel products enabled some processors to substitute steel bar and hot-rolled sections for bright steel and cold-rolled sections respectively (i.e. to opt for a cheaper initial material).

Compensation for weak internal demand in the EC market was not to be found in foreign markets. The export of drawing and cold rolling mills to non-EC countries (measured in real terms) merely increased by 2.5 % between 1982 and 1991. The export quota fell from 21.8% in 1985 to 17.1% in 1991 as a result of the worldwide slump in demand coupled with intensified competition. Nevertheless, all major producer countries of the EC still manage to show a surplus in foreign trade with non-EC countries.

Supply and competition

As a typical supplier industry with a small to medium sized business structure, the drawing and cold rolling mills have little market power. On the demand side, they are confronted with some very strong major customers, such as the automotive industry, which creates fierce competition. Due to the homogeneity of the product, the drawing and cold rolling mills also have little chance of retreating from price competition to milder quality competition. In these circumstances, the

Source: Eurostat

chances for drawing and cold rolling mills lie above all in closely cooperating with their clients. This cooperation can extend to joint development of constructive elements. New corporate strategies of the clients (like just-in-time deliveries) favour EC firms in the Single Market since physical proximity is an advantage vis-à-vis competitors from non-EC countries. On the other hand, the drawing and cold rolling mills in the EC, as all supplier industries, are subject to increasing competition because of the tendency of the client industries to industrialise their purchases.

The share of foreign competitors in the internal market has increased rapidly since the mid-1980s. Young industrial nations such as South Korea and Taiwan (offering production cost benefits over European suppliers) emerged as new suppliers on the European market. The import pressure from East European countries also toughened, especially given that their selling prices rarely reflect their true manufacturing costs. Another unfavourable factor affecting the drawing and cold rolling industries in the past has been the fact that steel producers have shifted their export activities to products of the drawing and cold rolling mills in an effort to circumvent obstacles implemented to protect the ECSC steel industry during a crisis.

Production process

The drawing and cold rolling mills are the largest industrial consumers of rolled steel products. Expenses for intermediate materials from the iron and steel industry therefore are much more significant than in other industries. The independent drawing and cold rolling mills are unusually dependent on the prices and conditions of one supplier having great market power. Apart from cyclical fluctuations, the prices of the drawing and cold rolling mills thus tend to follow the cost prices of steel in the long run.

Since the drawing and cold rolling mills have no influence on the price formation of the steel industry, investments by drawing and cold rolling mills in the past have tended to concentrate on rationalisation with the main aim of saving labour costs. In 1991, the sector still employed 107 000 people, 22 500 (17%) fewer than in 1982. Labour saving measures caused productivity to strengthen from 1982 to 1991 by an average of 3.2 % per annum as gauged by value added per person employed at constant prices.

INDUSTRY STRUCTURE

Companies

The drawing and cold rolling steel industries are typical of most supplier industries in that they consist mostly of medium sized enterprises. Most firms are independent private businesses but a considerable part of output (whose percentage varies among the Member States) is also manufactured by the subsidiaries of the major steel groups.

A breakdown of drawing and cold rolling mills by size of enterprises is provided in Table 6, based on data from Germany, France, Italy and the United Kingdom. It shows the domination of small and medium sized enterprises in terms of the number of enterprises. However, only 4% of the enterprises account for 30 % of turnover.

Strategies

In contrast to the major firms in the steel industry and the steel tube sector, mergers, acquisitions, alliances and cooperation form a less suitable strategy for the medium sized drawing and cold rolling mills. The emphasis will continue to be placed on investments in rationalisation to achieve productivity gains. In addition, the trend towards specialisation will intensify. This applies also with regard to the completion of the Single Market.

The introduction of the Single Market will have only relatively minor effects on the drawing and cold rolling mill sector, given that trade among the various member countries is virtually unimpeded at present.

Products of the drawing and cold rolling mill industry are exchanged every year within the EC at a value of approximately 4 billion ECU. Due to comparable production techniques in all Member States, the quality of these products is relatively consistent.

REGIONAL DISTRIBUTION

Germany is the largest producer within the EC with around one-third of production and employees, followed in descending order of importance by the United Kingdom, Italy, Spain, France and Belgium. Together these five countries constitute

Source: Eurostat

some 90 % of total EC production of products from drawing and cold rolling mills.

The relative shares in production of individual countries have changed little over the past ten years. Germany and Belgium have achieved minor percentage gains while the United Kingdom and France have seen their output diminish. The same two countries have also sustained the largest reductions in employment as a consequence.

OUTLOOK

The decline in the market for drawn and cold-rolled products in the EC, which began in 1990 and intensified in 1991, was caused both by weakening domestic demand and a worsening export situation. Production cut-backs in the most important customer industries, especially in mechanical engineering, and the automobile and construction industries, led to a 3% decline in real apparent consumption in the EC market. At the same time, extra-EC exports fell by 10% as a result of the poor world economic situation and loss of business due to the economic upheavals in Eastern Europe.

In light of increasing competition and the persisting economic difficulties in Eastern Europe it is expected that extra-EC exports will remain at current levels.

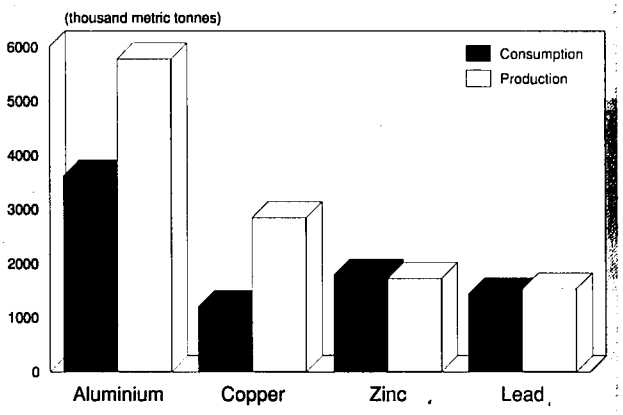
Non-ferrous metals
NACE 224

The EC non-ferrous metals industry had an annual turnover of about 30 billion ECU, and employed just under 300 000 people at some 3 000 industrial units in 1991. Having very few mining resources at its disposal, the EC is responsible for less than 5% of the mining production of the market-economy countries for aluminium, copper, zinc and lead. Nevertheless, in refined metal production it is of leading importance in the Western world, with refinement of the four major non-ferrous metals (Al, Cu, Zn and Pb) representing 24% of the world total. EC consumption of these same metals is even higher, representing 35% of world demand. The EC non-ferrous metals industry is a net importer of raw materials: ores, concentrates and other raw materials for refining, and unwrought metals for processing. It is also highly dependent on secondary materials (scrap and residue), which constitute the only "domestic" resource of major size in the EC. In purchasing the raw materials which are necessary for its supplies, and, to a lesser extent, in selling its products outside the EC borders, the EC non-ferrous metals industry is very much present on the international market, and is subject to its price fluctuations.

Figure 1: Refined metal
EC production and consumption, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The EC non-ferrous metals industry is widely diversified in terms of metals which are produced or processed, and which include the major non-ferrous metals aluminium (Al), copper (Cu), zinc (Zn) or lead (Pb); precious metals such as gold (Au), silver (Ag) or the platinum metals (platinum, palladium, rhodium); and alloy metals and other minor non-ferrous metals (molybdenum, vanadium, tungsten, manganese, cobalt, germanium, cadmium, etc.). In view of the fact that the EC is relatively poor in mining resources, its industry is largely dependent on primary raw materials imports, and also finds a significant proportion of its supplies in secondary materials (waste and residue). It is consequently geared to primary and secondary smelter metallurgy and to processing.

The most important consumer markets for the EC non-ferrous metals industry are within the EC itself, but outlets have also been found beyond EC borders. The industry is therefore involved in the international non-ferrous metals market, not only as a purchaser of raw materials, but also as a vendor of metals and processed or special products. In both these respects, it is extremely sensitive to the world balance of markets and to their cyclic developments, which are often irregular. The EC non-ferrous metals industry operates in a highly competitive field, and is supported by long years of technological experience, which has made it the world leader in various segments of its activities.

MARKET FORCES

Demand and supply

In terms of volume produced, aluminium, copper, zinc and lead are the dominant metals of the EC non-ferrous metals industry.

In the aluminium sector, EC production is about 4 million tonnes of metal per year, which is equivalent to almost 70% of EC demand. This represents only 17% of world production, however. The aluminium industry is facing two serious problems:

Table 1: Non-ferrous metals

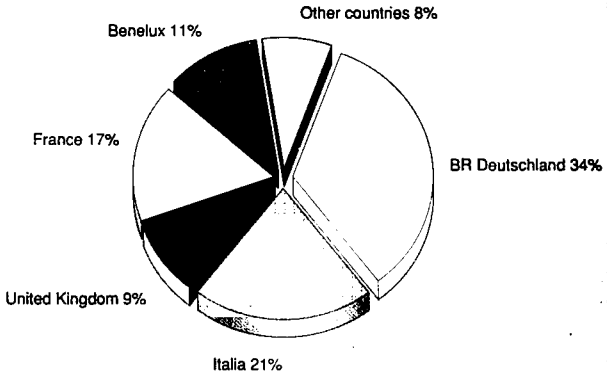
Figure 3: Copper semis
Breakdown of production by Member State, 1991



Source: WBMS

- the recent massive increase in exports of metal from the CIS;
- the ongoing problem of the tendency to move production units to geographic zones in which energy (an important cost component) is both abundant and inexpensive.

The EC zinc industry produces about 1.7 million tonnes of metal per year, 30%-35% of which come from the processing of ores and concentrates extracted in the EC - an exceptional ratio in EC non-ferrous metals. The industry's major problem is unquestionably how to manage the long cycles which affect its market, with a certain degree of inertia in the adjustment of supply to demand.

In the copper sector, the EC produces about 1.2 million tonnes of metal each year. As the EC is the largest consumer market in the world, this production volume equals somewhat less than 45% of its requirements. In order to lessen its dependence on imported cupreous materials, the EC industry has considerably developed recycling technologies, and is therefore able to obtain a significant amount of its supplies in the form of waste and residue within the EC itself.

Producing about 1.4 million tonnes of metal per year (one quarter of world production), the EC lead industry is able for the most part to satisfy the requirements of its market. The industry is experiencing problems due to inherent properties of the metal, the use of which, particularly in "diffuse" applications, is tending to decrease due to constraints connected with the environment. With this in view, the car battery sector is the only client industry capable of offsetting the losses of consumption in the other sectors, and increased recycling will further boost the share of secondary lead in the industry's supplies (more than 50%).

INDUSTRY STRUCTURE

Companies

The EC non-ferrous metals industry comprises about 3000 companies, most of which are active in the processing sector. The upstream sectors of primary and secondary smelter metallurgy are more concentrated.

Of the four basic non-ferrous metals - aluminium, zinc, copper and lead - the activities of the primary aluminium industry are most strongly integrated.

Germany produces 29% of the refined metal output of the EC, compared to 14% each for France and Italy (the next highest producers). Spain and the United Kingdom follow closely, while Belgium and the Netherlands trail behind.

RECYCLING

Recycling is an important aspect of the EC non-ferrous metals industry. "Secondary" materials or recyclable waste constitute an essential input for many of its metallurgical and processing concerns. Some of the latter's supplies depend entirely on access to secondary materials, although, for the most part, recourse to secondary materials goes together with raw materials supplies, for both economic and technical reasons.

The EC non-ferrous metals industry has much experience in the processing of secondary materials - especially in view of the scarcity of European mining reserves. Recycling has therefore traditionally enabled the industry to reduce its dependence on raw materials imports by making use of the "surface" resources generated by the consumption of goods ("old" waste) and by the industry itself (new or industrial waste). Considerable investments are devoted to recycling, in terms of research, equipment and human resources, to such an extent that recycling is at the root of more than 50% of total EC production of the four major non-ferrous metals (aluminium,

copper, zinc and lead), and accounts for more than 35% of their consumption in the EC.

More than ever, environmental concerns are impelling the EC non-ferrous metals industry to keep abreast of innovation in the recycling sector. The processing and upgrading of waste are contributing to the protection of the environment, reducing dependence on non-renewable natural resources, and allowing considerable energy savings in the extraction and implementation of metals (from 60% for copper to 90% for aluminium).

ENVIRONMENT

EC environmental policy emphasises integrated pollution control. Many of the issues related to the protection of the environment are of direct relevance to the non-ferrous metals industry.

The draft directives currently being drawn up in the field of industrial pollution are based on the concept of "Best Available Technologies". This approach increases the need to analyse the whole life-cycle of a product, managing the specific risks accordingly at each individual stage. Legislation on hazardous products is developing in such a way as to take into account the conditions of exposure over and above the intrinsic properties of products, which is a positive trend when it comes to assessing the impact of heavy metals.

Waste management also raises difficult questions of direct relevance to the non-ferrous metals industry. This is the case, for instance, of the proposals to limit the free movement of waste at an international level. Waste metals are used as

Source: Metallgesellschaft, European Aluminium Association

inputs by the sector. A competitive recycling industry and considerable energy-saving potential could be affected by limits on this trade.

Additional measures are under discussion concerning waste incineration and landfills. This is another area which could entail a large number of adjustments for the industry. Finally, the new directive on packaging waste will also have implications for the non-ferrous metals industry.

OUTLOOK

During the 1990's, the industry will have to face two major problems. The first is the opening-up of the economies of Central and Eastern Europe, which is giving rise to serious imbalances on the non-ferrous metals markets in so far as the products of these countries are more - and sometimes substantially - geared to the Western markets which provide currency, rather than to the domestic markets which still do not consume enough quantities.

In addition, the ratification of the Basel Convention for international movements of waste is complicating access to secondary materials (scrap and residue), which are an important supply source for the EC non-ferrous metals industry.

Written by: Eurométaux
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville, 12, B-1150, Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Aluminium
NACE 224

Growth rates for production and consumption of primary aluminium fell in 1991. However, high growth potential still exists in certain sectors such as packaging or car-making and should help to further the growth of the aluminium industry within the EC.
A substantial rise in imports from Eastern Europe resulted in a supply surplus and a 20% drop in prices in the EC. Imports from Eastern Europe should drop off in the next few years, but they will still be high compared to 1980 levels.

INDUSTRY PROFILE

Description of the sector

The aluminium industry in the EC covers mining production (bauxite), the production of alumina (an aluminium oxide) and primary and secondary smelter aluminium (recovered from waste and scrap materials), as well as the production of semi-finished products (alloys, bars, profiles, wire, sheet metal, foil, tubes and pipes).

The aluminium industry is the largest of the non-ferrous metal industries, and is the youngest as well in that aluminium smelting only began about a century ago. Lightness, longevity, resistance to corrosion, electrical and thermal conductivity and reflectivity make aluminium a popular choice in many sectors of the economy. Its aesthetic qualities, alloy possibilities and easy recyclability, all add to this appeal.

Main indicators and recent trends

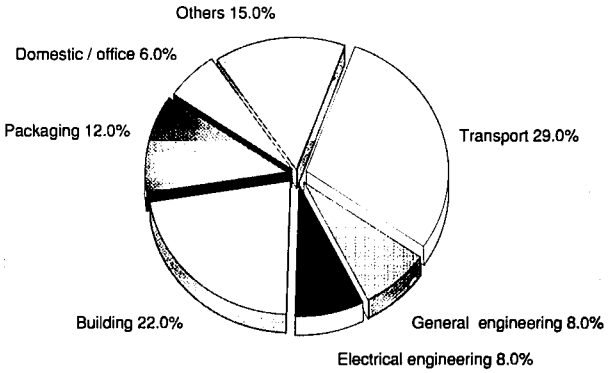
In 1991, the EC aluminium industry directly employed 200 000 people. Turnover amounted to approximately 20 billion ECU. Total aluminium consumption in the EC increased by slightly more than 2% in 1990. Consumption of primary aluminium in the EC countries increased by 2.5% compared with 1990. The production statistics of secondary aluminium indicate a further increase of the use of recycled aluminium by approximately 2% for the year 1990 compared with 1989. Secondary smelting operations produce half of total aluminium production.

International comparison

The largest producer of primary aluminium in the western world is the United States, with the EC in second place. Russia is probably the world's second largest producer overall, with a production capacity of 3 440 kt.

The EC market has become one of the most important markets worldwide. In 1991, the EC produced 2% of the western world production of bauxite (2 143 kt), 15% of the alumina (5 200 kt), 15% of the primary aluminium (2 260 kt), and 27% of the secondary aluminium (1 477 kt). In 1990, the EC was responsible for 32% of western world production of rolled and drawn products, wire, cable and castings (5 400 kt).

Figure 1: Aluminium
Total EC aluminium consumption by end use



Source: European Aluminium Association

The aluminium requirements of the EC are mainly covered by local production. Due to the dynamic growth of consumption, however, coupled with the slow growth of capacities, EC production now covers only about 60% of EC demand. The remaining unwrought metal requirements of the EC are covered by imports, especially from the EFTA countries (in particular Norway) and Africa.

Foreign trade

Intra-EC trade is highly developed, both for the unwrought metal and for semi-finished products or "semis". Overall, the EC is a net exporter of semis; however, this trade is highly dependent on monetary phenomena: trade with the USA is very much influenced by the development of the USD/ECU exchange rate.

INDUSTRY STRUCTURE

Companies

In the primary aluminium sector, which comprised 28 plants in the EC at the beginning of 1991, the major producer companies in the EC are: Pechiney (based in France), VAW (based in Germany), Inespal (based in Spain), Alusuisse (based in Switzerland), Alumix (based in Italy), Hoogovens (based in the Netherlands), and Alcan (based in Canada). Some of these companies have branches throughout the world (Alcan, VAW, Alusuisse, Pechiney).

Industry structures of the different processing sectors vary widely. The rolling sector is highly integrated. There are 40 EC sites which engage in rolling activity, many of which also work in the primary aluminium sector. The structure of the extrusion industry is more diffused, with 170 production sites, and is much less integrated.

MARKET FORCES

Demand

Researchers and engineers have been constantly improving material qualities; they have developed new alloys and production processes to open up new areas of application for aluminium.

The transport sector is by far the biggest customer of the aluminium industry, and uses 29% of aluminium production. As a light weight, durable material, aluminium is a very popular input in the motor vehicle, railway rolling stock and shipbuilding sectors. Cylinder heads, motor units, car body parts and complete frame constructions are manufactured from aluminium. The lighter weight of vehicles built with aluminium allows greater energy savings, which is attractive both economically and environmentally.

In the building sector, the second biggest purchaser market for aluminium products, is also a popular building material because of its durability and resistance to rust. It is used particularly for windows, doors and facades. This sector is a welcome raw material source for the secondary aluminium industry.

In Europe, around 12% of aluminium supplies are used for aluminium packaging applications. The protection of foodstuffs and of pharmaceuticals and cosmetics constitutes a continual demand. The recyclability of aluminium packaging materials makes aluminium particularly attractive at a time when concern about overfilled landfills is growing.

Supply and competition

The world aluminium market deteriorated considerably in 1991 following three years of a more-or-less perfect balance between supply and demand.

World consumption of primary aluminium firmly resisted a mediocre economic situation, recording an increase of 1.1% in 1991. However, this is a decrease in the growth rate compared to the preceding years.

Unwrought metal supplies rose considerably in 1991. Western world production increased due to the implementation of new capacity facilities which were planned in 1988 and 1989, after a seven year period during which world capacity stagnated.

Imports from the former USSR strongly increased after 1990. Unable to make use of traditional local outlets, East European producers diverted their products to the west European markets. Annual volume of exports from Eastern Europe rose from between 200 000 and 250 000 tonnes during the 1980s, to almost one million tonnes in 1991. This dramatic and unforseeable shock threw the market considerably off balance. The surplus resulted in a substantial increase in stocks.

West European producers were particularly affected by the market deterioration. Three-quarters of the Eastern European production exports is estimated to have been directed to the EC, resulting in extreme pressure on the European market. One result was a drop in price levels of more than 20%. In response, European producers took measures to adjust their production. Four factories were shut down in 1991. Furthermore, producers continued with the rationalisation efforts which they had started up several years previously.

All these movements testify to the extent of the restructuring process by means of which the industry intends to maintain its competitiveness.

ENVIRONMENT

Aluminium has properties which make it increasingly competitive in an ecology-conscious world. As previously men-

Table 4: Aluminium semis Exports and imports, 1991 (1)

tioned, its light weight is particularly effective in increasing energy savings in transportation sectors. However, the high recyclability of aluminium is an especially important competitive advantage, particularly in packaging, but in other sectors as well. Currently, 33% of total EC aluminium consumption is supplied from scrap recovery. The proportion recycled, however, varies widely among Member States. Aluminium products for packaging will be affected by the planned "EC Directive on Packaging and Packaging Waste" which is aimed at reducing the amount of waste, and which sets certain targets for recycling used packaging materials. In cooperation with other industries which are affected by this legislation, the aluminium industry is prepared to play a leading role in minimising the impact of packaging on the environment, and is working together with the public authorities with a view to reducing the quantity of packaging waste going to landfill. At the same time, the industry would like to emphasise the contribution made by packaging to product protection, the safe transportation and distribution of goods, and consumer information, etc.

Aluminium as a mineral is available in almost unlimited quantities - 7% of the earth's crust is aluminium. In order to produce aluminium, the raw material bauxite has to be extracted in the same way as other ores, which can have negative effects on ecological systems. Reclamation of the land mined is a top priority for the industry, and experiments and continuous efforts have yielded positive results in this area.

The reduction process for producing the metal consumes electricity, and gives rise to emissions. The aluminium industry worldwide reduced its electricity consumption from 17 KWh per kg produced in 1980 to less than 16 KWh at the beginning of the 1990s. Major emissions were reduced by a factor of four or more during the same period.

OUTLOOK

In the early to mid-1990s, a drop in the export rate of Eastern Europe is expected. However, the level will still be high compared to the 1980s.

Consumption is expected to grow at about 3% per year, in conjunction with a recovery in the economy worldwide. The opening of a new electrolysis plant in France at the end of 1991 should increase demand in the near future.

The packaging industry in particular offers opportunities to the aluminium industry for the near future. Although the USA market has already been significantly penetrated, there is still room for growth. Europe and Japan also have considerable potential in this sector.

Transport will also be a challenging area. The potential of aluminium in the automobile field is well known, and may lead to significant additional growth in consumption during the latter half of the 1990's. The aluminium industry therefore sees the highest growth potential for its materials in the transport sector.

Written by: Eurométaux
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville, 12, B-1150, Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Copper
NACE 224

The EC possesses few copper mining resources, but its copper metallurgical activities are highly significant. Refining and semis manufacturing capabilities in the EC have developed using imported primary raw materials and domestic (as well as imported) scrap, in line with the requirements of its large consumption. EC copper demand follows the slow growth pattern of a mature market. Recycling is brought to a high level as, in many of its applications, copper can be reprocessed without loss of quality.

INDUSTRY PROFILE

Description of the sector

The copper industry in the EC is characterised by poor upstream and good downstream integration: copper mining is negligible in comparison with refining and fabricating capabilities.

Since the start-up of mining at Neves Corvo in 1989, Portugal has become the only EC country with a sizeable copper mine production (165 000 mt Cu in 1991). Spain also records a copper mine output figure, but on a more modest scale, although activities go back many years. At present, with about 175 000 mt of copper extracted from domestic ores in 1991, the EC accounts for no more than 2% of total Western World copper mine output. The core of the EC copper industry in fact, is in refining and semi-manufacturing.

Refined copper production in the EC slightly annually exceeds 1.2 million tonnes. The largest facilities are located in Germany, Belgium and Spain. Refinery output arises from electrolytic processes, in the form of cathodes, which are generally melted and cast on the premises into "refinery shapes", i.e. billets, cakes and wire-rods, principally. About 60% of the feed supplies to the EC copper refineries are purchased on the international market in the form of copper blister, anodes or scrap. The remaining 40% come from the refiners' smelting operations, whose feed consists of domestic and imported copper ore concentrates and, to a lesser extent, copper-bearing residues or scrap.

Refineries' products are the major basic material for the copper semis manufacturers. The EC copper semis output exceeded 4.2 million tonnes in 1991. Germany, Italy and France accounted for about 70% of EC output in this industry segment, with the Benelux countries, the United Kingdom and Spain making up most of the balance. The range of products supplied by the semis manufacturers is very wide. They consist primarily of rods, profiles, wires, sheets, strips, tubes, etc. which the end-users integrate in the manufacture of their own products, with applications in such varied sectors as the electrical industry, the automobile industry, construction, machinery, shipbuilding, the aviation industry, the precision instrument and optics industry, the watch and clock industry, etc. With an output of three and half times that of EC refinery output, the EC copper semis manufacturers must turn to the international market to secure adequate volumes of feed supplies, together with the required alloying metals (zinc, tin and nickel for the most part). The EC semis production is in excess of demand, and the EC copper semis manufacturing industry is a net exporter by about half a million tonnes per year.

International comparison

The EC market absorbs nearly one third of the Western World's 8.8 million tonnes demand for refined copper. It is the largest copper consuming area in the Western World, ahead of both North America and Japan, with 2.8 million tonnes of copper consumed in 1991 as opposed to 2.3 million in North America and 1.6 million in Japan. Germany, France, Italy, Belgium and the United Kingdom are each among the top ten consumers in the Western World, together with the United States, Japan, South Korea, Taiwan and Canada.

In terms of production, the EC refiners account for about 15% of the Western World output. The 1.2 million tonnes produced per year is slightly ahead of Japanese production of around 1 million tonnes, but behind North American production, of 2.5 million tonnes. In the coming years, however, EC production will most probably lose its second place ranking to Chile, whose production exceeded the 1.2 million tonne mark in 1990.

For copper semis production, the EC countries hold by far the most dominant position worldwide, accounting for 39% of the Western World's 10.8 million tonnes output in 1991, the United States and Japan each contributing 23%.

MARKET FORCES

Demand

Though lacking copper primary resources, the EC has a strong copper industry, being the largest copper consumer market in the Western World. Demand for copper mainly arises from the electrical and electronic industries, which absorb about 50% of total EC consumption. These industries use copper primarily as a conductor material to carry electricity, in the form of wires, profiles and rods made of unalloyed copper. The construction sector is the second largest client: its requirements account for approximately 25% of total EC copper demand. A wide variety of semi-finished products of both unalloyed or alloyed copper, is used in plumbing, wiring, roofing, decoration, etc. The remaining 25% of demand arises mostly from industrial machinery and equipment, transportation equipment, consumer and general products.

Copper applications are fairly well-developed and the growth pattern of copper consumption closely follows the ups and downs of industrial activity at large. Copper demand on the EC market as a whole is growing slightly, as in most industrialised areas in the world. Trends differ from country to country, however. The economic revival in the former East Germany is expected to induce higher than average copper demand in the years to come.

Supply and competition

EC copper refining activity has been able to grow primarily by securing raw materials on the international market and making use of the domestic "surface mine" consisting of copper scrap and residue generated by consumers and production facilities. Access to feed supplies has become increasingly difficult over the past few years, however, as copper mining countries have developed their own refining facilities near their mines, thereby reducing raw materials availability on the international market. Furthermore, competition by rapidly

Source: WBMS

industrialising countries for copper raw materials has increased as these countries develop domestic refined output capabilities to satisfy the requirements of their consumer markets. The difficulty of access to feed supplies is inhibiting any significant expansion of EC copper refineries' capacities and no major projects in this field are due to reach completion in the short or medium term. The structural shortage of EC refined copper output versus the manufacturing industry's needs is therefore expected to continue.

EC copper semis output, on the other hand, is large enough to adequately supply the EC consumer market towards which it is primarily geared. Excess capacity should enable consumption growth to continue, while net export flows are maintained.

The London Metal Exchange (LME) quotations for copper cathodes generally govern the pricing on copper transactions made by the industry. The evolution of the LME copper price generally reflects the market balance at world level.

INDUSTRY STRUCTURE

Companies

There are ten major refineries in the EC, and it is estimated that the copper refining industry employed around 10 000 people in 1991.

Two companies have facilities of over 250.000 tonnes refined copper per year capacity: Union Minière (Belgium) and Norddeutsche Affinerie (Germany). Two others, Hüttenwerke Kayser (Germany) and Rio Tinto Minera (Spain), produce more than 100 000 tonnes per year each. Production capacity at the other facilities, in Spain, Italy, the United Kingdom, France and Belgium, ranges between 35 000 and 100 000 tonnes of copper per annum.

Downstream integration into smelting operations is minor, except in the case of Rio Tinto Minera in Spain and Nuova Samim in Italy. All the other refiners, except Metallo-Chimique in Belgium, have a deficit in copper smelting ca-

pacity. In the case of Metallo-Chimique, the opposite is true: its smelting capacity significantly exceeds its refining capacity.

There is much less concentration in the copper semis manufacturing industry, where about 100 companies are involved throughout the EC, employing some 75 000 people. Altogether, these enterprises have a production capacity which is not fully used at present. Activity is developed where demand develops, causing widespread presence throughout the EC. The EC copper semis manufacturers turn to the international market not only to fulfil their feed supplies requirements but also to sell their surplus output, as their production is in excess of EC consumption.

ENVIRONMENT

Recycling constitutes an important component of the raw material supplies of the copper refining and manufacturing facilities. Copper can be recovered from many of its applications

and returned to the production process without loss of quality in recycling. Having extremely limited access to domestic primary sources of copper, the EC industry has traditionally given much attention to so-called "surface mines", relying to a large extent on scrap feed to reduce the large deficit of its copper raw materials trade balance. Altogether, "secondary raw materials" account for about 40% of copper use. More than 40% of EC refined copper production arises from copper scrap recycling, and nearly 20% of copper semis output results from the direct use of scrap. In some cases, such as brass rods, for example, semis use 100% recycled copper.

The EC copper industry has developed advanced technologies and made considerable investments so as to be able to process a wide range of copper scrap, including complex, low-grade residues, and to comply at the same time with increasingly stringent environmental constraints.

Zinc
NACE 224

EC production of refined zinc reached a record level of 1 766 thousand tonnes in 1991, a 33% share of the world total of 5 372 thousand tonnes. The closure of exhausted mines and the lack of new deposits, however, reduced EC production of zinc concentrates, at 602 thousand tonnes, to its lowest level since 1982.

INDUSTRY PROFILE

Description of the sector

Zinc production can broken down into four steps: extraction of ore, processing of ore into zinc concentrates, refining of "primary" zinc, and refining of "secondary" zinc. The best known zinc ores are zinc blende (zinc sulphide - ZnS), smithsonite (zinc carbonate - ZnCo3) and calamine (a mixture of smithsonite and zinc silicate - ZnSiO4). Blende is often found mixed with galena (lead sulphide - PbS2). Mine activity is measured according to zinc concentrates, because zinc ores contain elements and minerals other than zinc itself. Zinc concentrate is the actual amount of zinc in the ore.

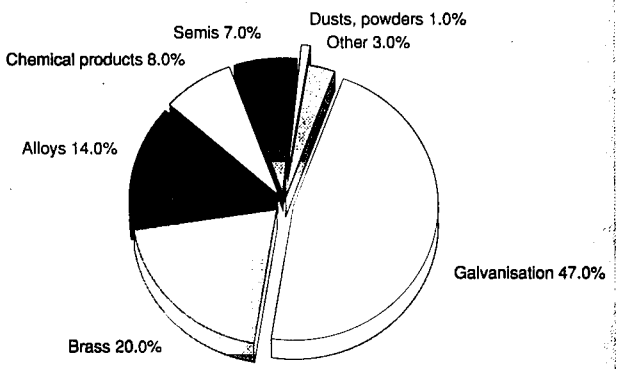
Refined zinc can be divided into two categories according to the source of the zinc inputs. Primary zinc is obtained by means of refining zinc concentrate. Secondary zinc comes from waste and similar materials, primarily from galvanising residue, which is reused after refining. It is possible to reuse some direct waste without refining. Secondary production represents a low percentage of world zinc production (4% in 1986).

The highest quality of zinc (SHG - Special High Grade) is 99.995 % pure, while the poorest quality is about 98% pure. There are four or five classifications between these two.

Zinc and its alloys are marketed in various forms:

- ingots, with various degrees of purity;
- extruded products, such as rods, bars and wire;
- rolled products (sheet and strip);
- pressure-castings;
- powders and dusts;
- chemical products, such as oxides.

Figure 1: Zinc
Breakdown of production by end product, 1990



Source: Eurométaux

Main indicators

In 1991, EC production of zinc concentrates (mine production) measured in tonnes dipped to its lowest level since 1982. Production of refined zinc, however, increased to a record level. Consumption of refined zinc also rose, as did imports. EC exports of refined zinc decreased, reflecting increased competition from foreign competitors.

International comparison

The most important world producers of zinc concentrates are Canada, Australia, Peru, the EC, and the USA. The EC share of the world total was about 11% in 1991, and covered around 34% of EC primary refiners' requirements This is a decline compared to the EC world volume share of 13% at the beginning of the 1980s, which covered 44% of the EC metal producers' requirements at that time. EC and Canadian mine production declined in 1991, while the production of the USA, Peru, and Australia all rose. European mine production was affected by the closure of exhausted mines and lack of new

deposits being mined (although Ireland and the United Kingdom contain mines which could be put into operation in the near future).

World zinc metal production reached a record volume of 5 372 000 tonnes in 1991. The major contributors were the EC, Japan, Canada the USA and Australia. EC production reached a record level of 1 777 000 tonnes, representing 33% of the world total. Production rose significantly in all the primary producing countries except the US, which experienced a small decline.

MARKET FORCES

Demand

World zinc metal consumption reached a record level of 5 359 000 tonnes in 1991. The EC, which is the primary world consumer, consumed a record 1 754 000 tonnes. The USA, another major consumer, saw its tonnage drop by 9% (90 kt). East Asian consumption increased to 1 729 kt, an increase of 7%, Japan alone consuming 844 000 tonnes.

The protection of steel from corrosion is the major use of refined zinc. Galvanisation alone absorbs 50% of the tonnage consumed annually in the Western world.

Supply and competition

Zinc prices remained very low throughout 1991, at an average of 1.116 USD. The average for the period of 1964-1991 was 1.358 USD (in 1991 dollars), while the average for 1982-1991 was just under 1.263 USD.

The EC has been a net importer of zinc ores since 1984. EC production of concentrates covers only 34% of the requirements of the processing plants. The trade balance decreased even further in 1990 and 1991.

(1) World imports
(2) 1991 includes the former East Germany
Source: International Lead and Zinc Study Group

EC exports of refined zinc dropped in 1991 compared to 1990, to the benefit of Canada and Australia. EC imports rose, resulting in a net deficit in trade in tonnes for the first time in the period of 1982-1991.

INDUSTRY STRUCTURE

The EC mining industry is primarily concentrated in Spain and Ireland. Production is concentrated in the hands of six large producers which include Asturiana de Zinc (Spain), Budelco (the Netherlands), Union Minière (France, Belgium), Ruhr-Zink (Germany).

In Europe, Union Minière closed its Overpelt plant in 1992. Nuova Samim announced the closure of its Crotone plant (with a 100kt capacity) in 1992 for renovation work and resumption of activity in 1995. Pasminco has announced its intention of selling off its zinc interests in Europe (Avonmouth, Budel (50%), ISC Alloys).

While EC production is decreasing, with plant closures underway or programmed, new plants and extensions are planned in other parts of the world, chiefly in Japan, Thailand, India and Iran.

ENVIRONMENT

Recycling plays an important role in the zinc industry. The share of recycling in zinc consumption is estimated at 32% in Europe. For the most part, waste is returned directly to the production circuit, with a small amount undergoing refining operations. This is secondary zinc production.

Production facilities currently meet current emission limits for air and water. Solid water, such as gypsum from waste water neutralisation and iron-containing residues from hydrometallurgy, is disposed of in controlled landfills. R&D efforts try to limit the volume of these residues as no viable alternative to them exist.

OUTLOOK

Very slow growth in demand is expected in the EC countries over the next several years. The major growth zones, both for supply and demand, are expected to be:

- Asia, especially East Asia, with the exception of Japan;
- the traditional consumer zones (North America, Europe) where growth in consumption will continue to be steady, although slow;

Lead
NACE 224

The EC possesses few lead-mining resources, but its lead metallurgical activities are powerful and competitive. EC consumption and production have experienced only small growth, resulting in decreases in the EC's share in world markets. Secondary smelting is an increasingly important source of lead, particularly as environmental regulations become tighter. Considerable restructuring has been taking place in the lead-refining industry and in its primary client industry, batteries. The restructuring will require new relationships between suppliers and consumers.

INDUSTRY PROFILE

Description of the sector

Lead is the most abundant heavy metal in the earth's crust. It is normally found in mixed ores with zinc and small amounts of silver and copper. Lead's softness, low melting point, chemical reactivity and resistance to corrosion give it great functional value, both in its pure form and in alloys or compounds.

Mine production of lead has decreased slightly, due to the importance of recycling. Refined lead is derived from two sources: primary material in the form of mined lead ore, and secondary material in the form of scrap and recycled products. Primary production requires the smelting of lead bearing ores to produce refined lead bullion. Secondary production may also require refining facilities if the recycled products contain unwanted compounds. With the impact of environmental and governmental regulations concerning the recycling of lead-bearing scrap, the secondary refining industry now supplies more than 50% of the lead consumed in the western world. This proportion will increase as the world car population increases, because lead acid accumulators in cars are the main source of scrap for secondary refining.

Primary refining is very much linked to the economics of mining lead-zinc ore bodies. The bulk of mine production of lead comes predominantly from works in which zinc and silver (to a lesser extent) are the principal profit makers; less than a third comes from the actual lead ore mining works in which lead is the principal commodity.

The most important consumer of lead is the battery industry. Other uses for lead include petrol additives (tetraethyl lead), paint, shot, glass, ceramics and plastics.

Main indicators and recent trends

Worldwide consumption of lead rose dramatically in 1980. Since 1982 in the EEC member states, consumption has risen by some 13% to 14% at an average annual rate of 1.5%. The EC is not a major mining region - only 167 000 tonnes of lead were mined in the EC in 1990, according to Eurometaux. Metal production, however, is much higher and amounted to 1 389 000 tonnes in 1990, of which 53% was from secondary (recycled) sources. Primary production has been declining steadily. Industry is responding effectively to potential ecological problems by recovering ever-increasing amounts of lead.

MARKET FORCES

Demand

Consumption of lead generally follows general economic activity, falling during periods of recession and increasing during periods of high economic activity.

Regional trends in consumption are variable. For example the share of the EC relative to world consumption has fallen in recent years. In the USA as well, consumption in 1983 was below the 1970 level. In contrast, most other areas of the world have increased consumption in recent years. Apart from the major influence of business cycles, consumption trends are largely driven by regulatory control on lead products (e.g. gasoline additives) and the cost and availability of substitutes.

Demand from the battery industry will continue to underpin consumption, largely as a result of rising demand for lead acid batteries for the automobile industry. Between 1979 and 1989 lead consumption by the battery industry increased by almost 40%, at an average annual rate of 3.4%. The vast majority of storage batteries are employed in starting, lighting and ignition (SLI) applications in motor vehicles. Demand for such batteries depends upon the number of vehicles built and, more importantly, upon the number of batteries required to replace exhausted units. Demand has also increased for other forms of batteries, such as those used in load levelling/peak sharing applications, as well as electric-powered vehicles and standby power uses.

A combination of environmental pressures and competition from other metals and materials has resulted in a stagnation or decline of lead demand in most of its other end-uses.

Consumption rose only marginally in rolled and extruded products, pigments and other compounds and shot, and these sectors contributed little to overall growth. In applications such as cable sheathing, alloys and gasoline additives, consumption has declined markedly: between 1979 and 1989 consumption in these three sectors fell by 50%. By 1989, they accounted for only 10.6% of the total consumption, compared with 23.2% in 1979.

In the case of cable sheathing and alloys, lead has suffered from a combination of substitution by other materials and the introduction of new technology which has rendered the metal obsolete. Increasing awareness about the impact of noxious emissions on the environment is the main reason for the slump in lead consumption in gasoline additives. Over the period from 1979 to 1989, consumption of lead by this end-use fell by two thirds, and it only remains of any significance in the United Kingdom.

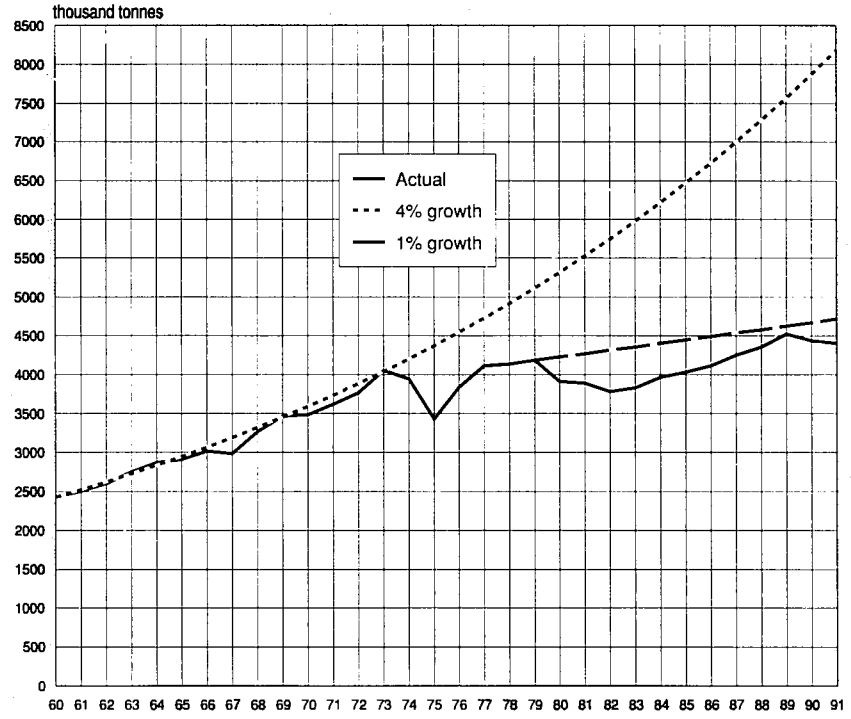
Consumption in Western world (1)



(1) Western world only; does not include CIS, People's Republic of China or Eastern Europe
Source: Eurostat

The market for lead and lead products is international in scope. Regional consumers such as the EC are significant importers of lead ore and bullion. Generally accepted daily prices for lead are set on the London Metal Exchange, for both physical commodities and financial futures and options. Differentials can exist but may not stimulate exchange due to the expense and time of international shipping, tariffs and other trading expenses. For example, the US trade in lead takes place primarily with Canada and Mexico, due to transport expenses. Regionally, Europe is the largest importer of both lead ore and refined metal. North America (US and Canada) and Australia export large quantities of ore and refined metal.

Recently, with the breakdown of socialist economies in Eastern Europe, large volumes of refined and partly refined lead have been exported by the CIS, particularly into European countries.

Supply and competition

Primary refined lead is strategically supplied by many multinationals to parts of the world where the net return is often lower than the intrinsic lead value contained. This tends to be the policy on a proportion of production after having satisfied indigenous markets. However, secondary refined lead is predominantly supplied in the country where the scrap arisings occur and refining is carried out.

With the growing importance of secondary refining from an environmental standpoint the major companies in Europe have a vested interest to be active in both primary and secondary refining. These companies are best placed to finance the investment that will be required to conform with increasing environmental legislation.

INDUSTRY STRUCTURE

Companies

Within western Europe there are ten primary smelter/refiners, ranging in size from production of 75 000 tonnes per year to 200,000 tonnes per year. In addition, there are approximately thirty secondary smelter/refiners in western Europe producing from 5,000 to 65,000 tonnes per year.

The primary refineries are mostly multinational, and are spread throughout UK, Sweden, France, Germany, Belgium, Spain, Austria, Yugoslavia and Italy. All plants with the exception of Britannia Refined Metals (UK), smelt lead and or lead/zinc concentrates before refining lead bullion. Britannia Refined Metals refines only crude lead bullion imported from its parent company MIM in Australia.

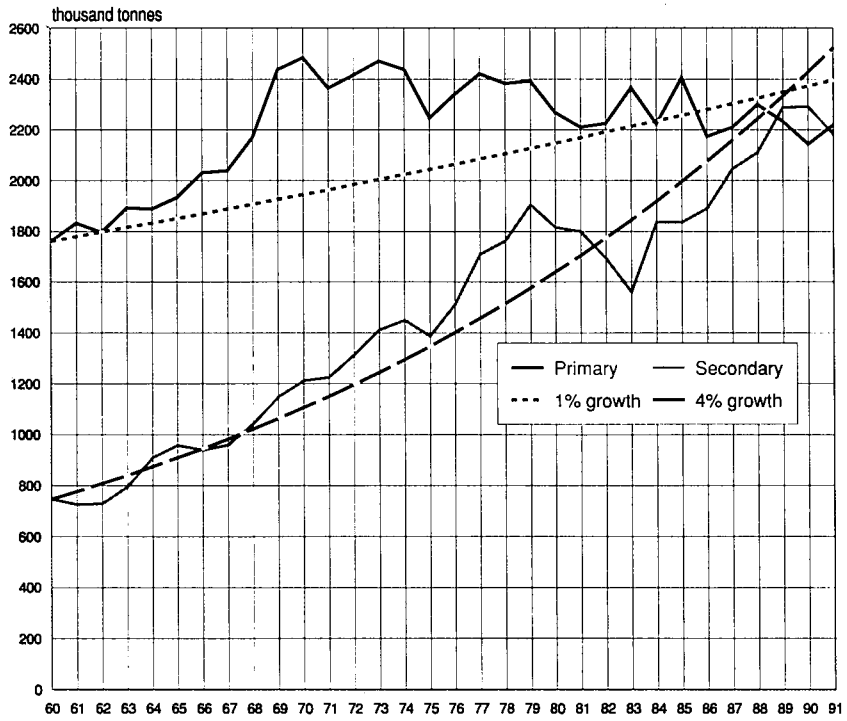
The secondary industry is characterised by a large number of smaller refineries, many of which are independent and which recycle and refine scrap generated in their local area. The number of these refineries is decreasing as the larger multinational companies, and the major battery manufacturing groups as well, acquire or set up new operations.

The largest primary smelters/refineries in western Europe include Britannia Refined Metals Ltd., Metaleurop SA (France), Metaleurop GmbH (Germany), Metallgesellschaft AG (Germany), Union Minières's Business Unit Hoboken (Belgium), Boliden Mineral AB (Sweden), Nuova Samim Spa (Italy) and Sdad Penarroya - España SA (Spain). With the exception of Union Minières's Business Unit Hoboken, all of these primary refiners are involved in secondary recycling / refining as well. Other companies include: STCM (France), CEAC (a battery producer) (France), Varta Batterie AG (Germany), Fonderie-et-Manufacture des Metaux (owned by Metaleurop) (Belgium), and H J Enthoven (part of Billiton) (UK).

Strategies

Within the overall lead refining industry and the major industry market of batteries which the industry supplies, there has within the last three years been considerable restructuring. So far this has mainly been apparent within the battery industry, with the formation in Europe of five major battery groups. These groups have become very powerful in their bargaining

Figure 2: Refined lead
Producton in Western world (1)



(1) Western world only; does not include CIS, People's Republic of China or Eastern Europe
Source: Eurostat

capabilities and some are competing with the lead refiners by building recycling/refining operations. This enables larger battery companies to process their own scrap and also operate collection schemes for waste batteries returned through their distributor networks.

For the future, secondary refiners will have to work more closely with the major battery companies, in order to maximise the recycling rate of battery scrap and to comply with governmental legislation. Government-approved collection schemes will be set up where refiners and battery customers will work closely together. Such schemes should be equivalent throughout the EC to allow fair competition on supply of lead and lead alloys between EC Member States and other European countries with similar schemes.

Environmental legislation will also require investment to reduce lead in air emissions. In recent years several new technologies - some still at the development stage - have been introduced which offer more efficient, environmentally acceptable methods of smelting lead concentrates. A major reason why the new technologies should gain ground is their ability, in most cases, to handle secondary material as feed. There are several advantages to an integrated smelting/refining complex:

- economies of scale;
- synergy of the smelting and refining processes;
- concentration of lead production in fewer areas, and closure of environmentally unacceptable plants;
- lower environmental lead levels.

It seems certain that the new pyrometallurgical technologies will further increase their share of total lead smelting capacities over the next decade at the expense of the conventional blast furnace. Ultimately, looking further ahead, there will probably be a place for the hydrometallurgical routes, although they may make inroads sooner in the treatment of battery paste. Undoubtedly, operational refining sites will decrease in Europe, and consolidation and rationalisation will occur as companies consider the investment required and returns available.

ENVIRONMENT

As lead is a toxic metal, there are concerns about losses of the metal to the environment. Most control measures are concerned principally with human exposure (humans are most affected by lead exposure) although there are certain instances in which animals can be exposed to environmental lead. The metal has relatively little impact on ecosystems. There has been much debate about the levels of lead which cause harm; general policy is normally to restrict emissions to the lowest practicable levels given the state of technology, and recycling is normally conducted whenever appropriate and economic.

The major uses of lead are increasingly recyclable. Batteries, representing 49% of lead consumption in Europe in 1990, are recycled with an efficiency greater than 90%. Indications are that the situation should become even better in the future. Among the other uses, tetraethyl lead (petrol additives), paint and shot have declined dramatically or disappeared completely over recent years. This has been partly as a result of environmental legislation (e.g. tetraethyl lead), partly as a result of voluntary reductions by industry (e.g. lead shot for fishing weights) and partly as a result of natural substitution (e.g. paint). Of the other non-recoverable uses, most lead is used in products from which it cannot be easily extracted such as glass, ceramics, plastics, so even in these cases there is minimal opportunity for ecological impact. The net result is that the uses of lead which can affect the environment are steadily disappearing.

During the production and processing of lead there are inevitably opportunities for emissions. These are kept to a minimum through the use of control technologies and legal limits

on the amounts which are allowed to escape. Airborne emissions are controlled through efficient filtration systems and by the employment of design and management systems to prevent uncontrolled losses to the environment. Aqueous effluents are treated before discharge to ensure compliance with limits imposed by water authorities. In addition, ambient levels of lead in the air outside plants and in receiving waters are limited to ensure suitable protection. Finally, solid wastes may not be disposed of indiscriminately. Depending on the lead content of a waste or the ease with which it dissolves into the environment, wastes are designated as safe or hazardous and disposed of in landfills designed to contain the lead.

REGULATIONS

Regulations affecting lead fall into three main categories: occupational exposure, emissions from plants, and controls on products.

Occupational exposure is addressed under EC Directive 82/605/EEC of July 28, 1992 on the protection of workers from risks related to exposure to metallic lead and its ionic compounds at work. This directive sets allowances on the level of lead in air in the workplace and on certain biological indicators which reflect the level of exposure of individual workers. The limits are supported by rules on the protection of the workforce through the use of measures such as protective clothing, respirators, washing facilities and through rules on eating, drinking, smoking, etc.

Emissions from leadworks are normally controlled by means of national regulations relating to air or water. There are no universal European limits in these areas. However, lead in the general atmosphere is limited under Directive 82/844/EEC of December 3, 1982 which sets a limit for levels of lead in air throughout the EC. Levels of lead in water are also controlled in a number of directives relating to different types and purposes of the water, e.g. water intended for human consumption, water for bathing, fishing waters, etc.

In the area of products, regulations apply to a number of non-recoverable uses of lead. The use of lead in petrol, for instance, is controlled under Council Directive 85/210/EEC of March 20,1985. Several Member States have their own regulations which impose tighter limits or which require the availability of unleaded petrol for vehicles introduced on to the market after a certain date. Another area in which legislation is applied is the use of lead in paints, which has been restricted under various pieces of national legislation for many years. Recently, lead carbonates and lead sulphates have been controlled also under EC Directive 89/667/EEC of December 21, 1989. This directive prohibits the sale or use of lead pigmented paints for use in domestic buildings.

OUTLOOK

The balance of primary output versus secondary output and the cost of conforming to environmental legislation will determine companies strategies for the future. The lead price will obviously also be a dominant factor, but this has been affected recently by the large exports of lead from the CIS. Thus, the Eastern European countries are going to play a large part in the coming years in determining the direction of the industry.

Secondary refined lead will grow in importance in the medium and long-term, and it is predicted that by the end of the century it will represent almost 60% of the supplies to the market.

The battery sector will remain the primary use of lead, and will increase its importance as a consumer. By the end of the century, it is expected that the battery sector will absorb almost 70% of all lead consumed.

Written by: Eurométaux
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville, 12, B-1150, Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

Nickel
NACE 224

In the EC, nickel is mined only in New Caledonia and Greece. Since 1976, the EC has dropped from the second largest producer of nickel products in the western world, to the third largest. The industry is concentrated, with the top four companies producing between 60% and 67% of western world output. Three companies have operations in the EC, while a fourth has production facilities in Norway. Nickel consumption is expected to grow as demand increases from NICs and Eastern Europe

INDUSTRY PROFILE

Description of the sector

The nickel industry transforms raw materials, either nickel ore (from Le Nickel-SLN and Larco mining operations located in New Caledonia and Greece, respectively) or semi-finished products, into nickel products directly used in the nickel consuming industries.

Products include:

- Ferronickel: produced by Le Nickel-SLN (New Caledonia) and Larco (Greece), used as a charge product in the fabrication of stainless steels;
- Metal: produced by Inco Europe (UK) and Eramet (France) in the form of cathodes used as an alloying element in various applications (such as the superalloy industry);
- Salts: produced by Inco Europe (UK) and Eramet (France), used mainly in the catalyst and electroplating industries.

All these products are raw materials supplied to customers which themselves produce raw materials to be further used in a wide spectrum of industries.

As reliable statistics are not yet available in most of the former Eastern bloc countries, figures refer to "western world" in most cases. This includes the former East Germany and Yugoslavia, but excludes former USSR, Cuba, China and other former COMECON countries.

Main indicators and recent trends

Since the mid-1970s, nickel consumption in the EC increased at an average annual rate of 2.7%. A record level of 239 000 metric tons was reached in 1990, but consumption fell by 9% in 1991 and is expected to continue to decrease throughout the early 1990's.

The metallurgical production of the EC also grew steadily during the 1980's, but stagnated after 1988, at an average level of 87 000 metric tons. The EC covers only 40% of intra-EC client industry needs. Mine production of nickel has expanded very quickly over the past ten years, especially in New Caledonia. The number of employees in the EC nickel industry decreased by one third between 1982 and 1991, although mine production is now 50% higher and metallurgical production 10% higher than at the beginning of the 1980's.

International comparison

Among the top four companies producing nickel in the world, one is located in the EC (Eramet), another owns a factory in the EC (INCO in the UK) and a third has production facilities in Europe (Falconbridge in Norway).

Table 3 shows the estimated share of the EC in world production of refined nickel (including former COMECON countries as well as Cuba and China). Considering now what used to be called the Western World, the share of the EC diminished considerably during the past 15 years (see Figure 2). The Canadian share decreased even more during the same period of time.

In 1991, western world consumption reached 669 000 metric tonnes, with the EC representing 33% of the total. This share of one third has been relatively stable since the 1970s. Asia, however, increased its share of consumption from 24% in the mid-1970s to 36% in 1991, primarily at the expense of the US, whose consumption decreased from 31% of nickel consumption in 1976 to 19% in the late 1980s.

MARKET FORCES

Demand

Nickel consumption in the western world grew at an annual rate of 2.2% between 1976 and 1991. EC consumption increased by 2.7% per year during this period, while Japanese consumption rose by 3.5% per year, and consumption in the US decreased by 1.8% per year. East Asia as a whole was the fastest developing area during this period of time with an average annual growth rate of 5.4% as new nickel-consuming industries were being installed, especially in Korea and Taiwan.

Among the various nickel uses, stainless steel plays the leading role. Nickel consumption in stainless steel, which represents more than 60% of total nickel consumption (65% in the EC), grew 4.5% between 1976 and 1991, while nickel consumption in the non-ferrous industry declined 0.2%. The two primary reasons for this rapid evolution of nickel demand in stainless steel are that production of nickel-bearing stainless steel (austenitic) rose at a higher rate than that of stainless steel with no nickel (ferritic) and that due to the improvement of the yield in stainless steel production, the rate of growth of primary nickel (4.5%) was higher than that of secondary nickel (2.6%).

Production of nickel-bearing stainless steel is influenced both by the overall production of capital goods (which represents more than 60% of nickel consumption) and by the intensity of use of nickel-bearing (austenitic) stainless steels in the capital and consumer goods sectors.

Over the past 15 years, the use of austenitic steel has increased at a higher rate than industrial production in the OECD countries. This increased use is mainly due to the technical qualities

of austenitic steel, which, for many applications, has no acceptable substitute.

Recent developments in export markets show an extremely strong growth of nickel consumption in East Asia. Korea and Taiwan were the first to experience rapid growth, followed by China. The Eastern European countries might constitute the next boom area, but it is too early to be certain.

Supply and competition

Until 1970, about a dozen firms engaged in nickel production, and increases in output were the result of extending and modernising existing installations. At that time, all producers were working at near-capacity level.

At the end of the 1960's, difficulties in nickel supplies led to a boom in investments by new producers; production, however, did not start until the mid-1970's. Most of these projects were located in NICs where large nickel deposits were found. Canada and New Caledonia, which were responsible for around 75% of the western world production in the early 1970's, provided only about 45% in the early 1980's.

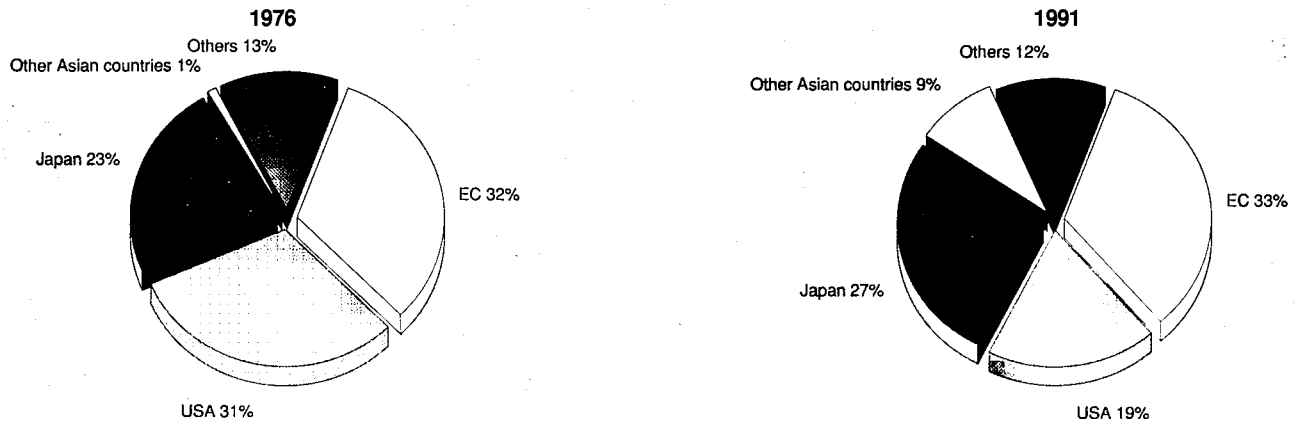
Maximum capacity was reached at the beginning of the 1980's, but because of low demand, and subsequently very low nickel prices, producers had to significantly reduce their levels of activity after 1975, bringing about a decrease in the rate of use of production capacity. Several facilities closed after 1984, due to production costs which were too high to enable firms to survive the depressed period of the first half of the 1980's. Real capacity also decreased due to lack of maintenance in most of the plants still in use.

Considerable progress in increasing productivity has been achieved since the 1980s, including a significant reduction in energy consumption. This enabled some firms to reduce production costs and overcome economic slowdowns which affect the production of capital and consumer goods, and therefore the nickel industry. Many firms still suffered heavy losses, however.

Production costs decreased in constant terms, and the average break-even price for low-cost producers, which was over 6.5 USD per kg at the end of the 1970's, decreased to a level of between 4.5 USD and 5.5 USD per kg by the mid-1980s. The most competitive producers remained the sulphide producers in Canada and Australia which were less affected by the high price of oil at that time.

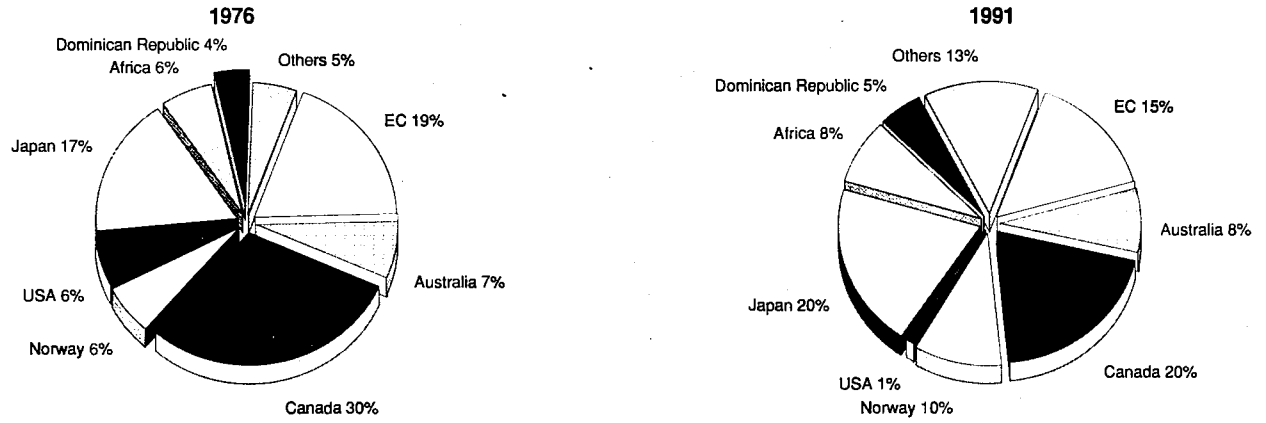
After 1985, production costs increased significantly. Producers treating sulphide ore (e.g. INCO) faced increases in wages and social benefits for their workers and lower ore content

Figure 1: Nickel
Western world nickel consumption by area



Source: MARKETING ERAMET

Figure 2: Nickel
Western world nickel production by area



Source: MARKETING ERAMET

in their mines due to the lack of renewal in mining development.

Producers processing oxidised ore , including the EC firms Larco and Le Nickel-SLN, also suffered an increase in costs, but to a lower extent. The decrease in the price of oil and the depreciation of some currencies in Indonesia, Colombia and the Dominican Republic helped these producers to reduce the gap with the sulphide producers and in some cases to take the lead in terms of costs. The break-even price of the low-cost producers was estimated at the beginning of the 1990s at 6.5 to 7.5 USD per kg, while the average for the whole industry was between 7.5 and 9 USD per kg.

As production capacity was increasing in the western world, noticeable growth in net imports from COMECON countries was also occurring, particularly from Russia, which became a very important supplier to the West and especially to the EC. As a consequence, the share of net imports from COMECON countries rose from less than 11% of EC consumption during the 1981 to 1986 period to 19% during 1987 to 1991.

The future trend of deliveries from CIS and Cuba will have a vital influence on the supply/demand balance over the coming years.

INDUSTRY STRUCTURE

Companies

Inco Europe Ltd is a subsidiary of Inco Ltd, a private Canadian Company. Inco's first factory began production in 1902 and was owned at that time by Mond Nickel Co. Inco Europe transforms its matte (an intermediary product supplied by its mother company) into pure nickel and nickel salts. Inco Europe Ltd markets its production throughout the world, although Europe is the preferred market because of its proximity. US firms are usually supplied by Inco Canada.

Eramet is a subsidiary of ERAP, which is the holding company of the state-owned company Elf-Aquitaine. ERAP owns 70% of Eramet. Other shareholders are Elf-Aquitaine (15 %) and Imetal (15 %). Eramet is the mother company of Le Nickel-SLN in New Caledonia. Its factory situated in Le Havre-Sandouville was built in 1978 to replace the former factory in Le Havre founded in 1888. Matte, which is shipped from its subsidiary in New Caledonia is processed into pure nickel and salts. Eramet's sales are world-wide: Eramet markets the ferronickel production of Le Nickel-SLN as well as the production from the factory in Le Havre. With the production from Le Nickel-SLN, Eramet produces ferronickel as well as nickel salts and metal cathodes.

Larco, a Greek company founded in 1963, extracts ore which is transformed into ferronickel. Larco is currently a state-owned company, but the government wishes to privatise it. Larco mainly sells in Europe. All production is exported, due to the small demand in the Greek domestic market.

Strategies

Growing steadily, nickel demand requires a corresponding sustained increase in nickel supply. To allow such a development, certain actions have to be taken by the nickel producers. Investment in additional capacity at the lowest possible production costs must increase, especially through extensions and improvements in productivity of existing mining and

smelting capacities rather than opening and building new mines and production facilities.

Apart from economic considerations, long-term security of supply can best be provided by giving priority to investments in integrated operations. Integrated nickel producers are not dependant on an external supply of nickel ore, and also have their own refining facilities. They are therefore less dependant on cyclical market developments and are better able to withstand periods of recession.

Nickel producers must keep abreast of market developments; close cooperation between nickel producers and consumers is necessary for both industries.

REGIONAL DISTRIBUTION

The nickel market is a worldwide market and, to a large extent, nickel mining areas do not correspond to nickel consuming areas. Major nickel consuming countries are net nickel importers, either in the form of nickel ore and intermediate products or of finished products.

Nickel consumption in the EC represents approximately one-third of western world consumption but the production of refined nickel of the three EC companies accounts for only 10% of world production.

Germany is by far the main market in the EC (see Figure 3), representing 36% of total EC consumption, but has no domestic production. France is the second market, with a share of around 17% of total EC consumption. Other consuming Member States are the UK and Italy (around 14%), Belgium (9%) and Spain (8%). The remaining EC countries are not substantial consumers of nickel.

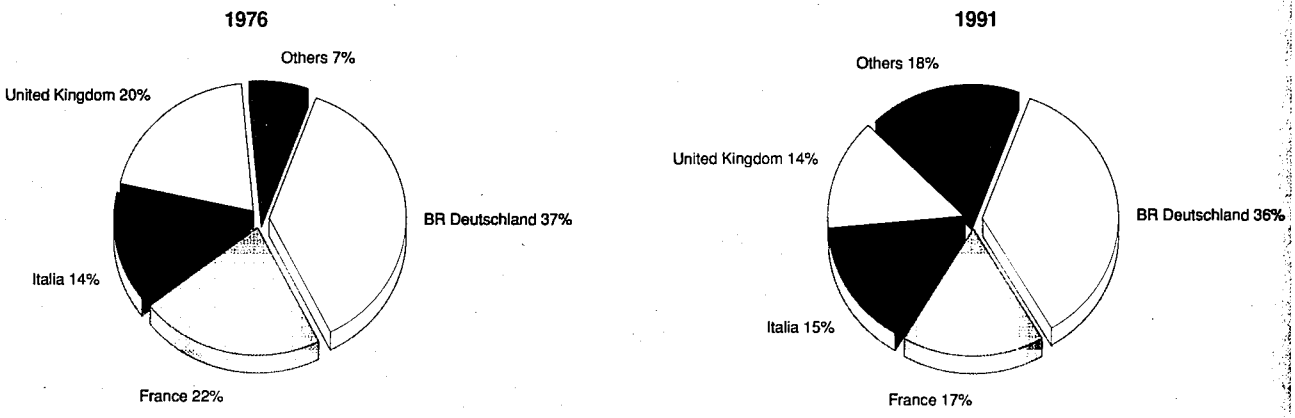
Since the mid-1970s, nickel consumption in the EC has grown by an average 2.7% per year although growth rates vary widely among Member States. Belgium (with a 16% increase per year.) and Spain (with a 6.2% increase per year) experienced the highest expansion in consumption, while consumption in France increased only 1.2% per year and in the UK by 0.4% per year.

ENVIRONMENT

Although nickel itself does not create environmental problems, some nickel compounds have ecotoxic (dangerous to the environment) and/or toxic (dangerous to humans) properties.

Most of the nickel producer and user industries have already reduced their emissions to an environmentally acceptable level. At the EC level, atmospheric emissions have been controlled and reduced through the installation of efficient filter systems.

Figure 3: Nickel
EC apparent consumption



Source: MARKETING ERAMET

Liquid effluents have been under control for many years now, and their levels comply with regulatory limit values.

Solid waste containing water-soluble compounds such as nickel-bearing metallic hydroxides is still a concern. In most cases, however, it is disposed of in controlled landfills. Nickel-bearing recyclables (stainless steel and alloy scrap, spent catalysts, etc.) are not an area of concern related to the nickel content.

REGULATIONS

In spite of minimum specific risks for the general environment, nickel and some of its compounds are facing increasing regulatory pressure at EC level.

Skin-contact allergy is a clearly established risk linked to direct and prolonged exposure to nickel in some common products. The European nickel producers support the efforts of the EC Commission to establish rules for the protection of the fraction of the population at risk.

Nickel is suspected of inducing respiratory cancer in workers in certain nickel refining processes. In addition, the classification of some nickel compounds as human carcinogens (Directive 67/548) will have a severe impact on industry and will require protective measures for workers exposed to these substances (Directive 90/548). This classification has been contested by the industry.

The nickel industry is also concerned by controls which will be applied to trans-frontier shipments of "wastes" in accordance with the Basel Convention and therefore strongly supports the approach adopted by the OECD for "wastes destined for recovery operations". In addition, it also urges the EC Authorities to model their new "Shipments of Wastes" regulation on this OECD approach.

OUTLOOK

Nickel consumption should continue to grow at a relatively sustained rate in the medium and long term, although it will fluctuate greatly in the short term due to cyclical variations in general economic activity.

The following factors could result in continued development of nickel consumption:

- growth of nickel consumption in industrialised countries in connection with the development of new applications, most of them linked with the protection of the environment: Clean Air Act in the USA, Earth Summit of Rio de Janeiro;
- a boom in demand for nickel in newly industrialised countries, especially East Asian NICs, and in some Latin America countries due to the construction of new plants and the need for durable goods;
- the reconstruction and reshaping of a civil industry in the former COMECON countries.

Production areas which show the greatest growth potential for the 1990s are located in the countries with the largest and richest mines, especially New Caledonia, Australia and Indonesia.

For the moment, some of the data for the nickel market are estimates. The recent creation of the "Groupe d'Etudes international sur le nickel" should improve the availability of information thanks to greater cooperation of the participating governments.

Precious metals
NACE 224

The EC has the largest refining/fabricating capacity for precious metals in the world, even though its mineral resources of such metals are limited. Recovery of raw materials from scrap and industrial residues is an ever-increasingly important source of precious metals for the EC refiners and fabricators. Platinum consumption in particular will be affected by environmental regulations requiring the use of auto catalysts containing platinum group metals, which can be recovered from the auto catalyst during recycling.

INDUSTRY PROFILE

Description of the sector

Precious metals include such well-known metals as gold, silver, and platinum group metals: platinum, palladium, rhodium, iridium, ruthenium and osmium.

Precious metal activities can be grouped under five headings:

- mining;
- refining;
- trading: on a commodity basis;
- fabricating: processing, alloying, and converting the metals into wrought semi-manufactured goods, industrial components, chemical compounds, etc.;
- manufacturing: producing items for sale at retail level, i.e. jewellery, silverware.

Main indicators

Mine production

The twelve countries of the EC now possess within their borders relatively insignificant mineral sources of gold and silver and practically none for the platinum group metals. What primary precious metals are actually extracted from EC ores are mainly by-products of copper or lead and zinc mining. Spain, Greece, Italy, France and Ireland do post a figure on the list of the world silver mine producers, though their joint output is only 4% to 5% of the Western World total, i.e. 542 tonnes in 1991. Of EC Member States, only Spain, France and Portugal (to a minor extent) appear on the world producers list for gold, with less than 1% combined of the Western World output, i.e. approximately 12 tonnes altogether in 1991.

Precious metal specialist mining operations are directly affected by precious metals prices and market economics. In this respect, persistent low prices and growing environmental constraints over the last years have weakened profitability and led to closures, as was the case during 1991 for Mines de Salsigne in France. By-product precious metals output is less sensitive to precious metals prices as such: base non-ferrous metals activity trends are the leading factors in this case.

Scrap recovery

Though poor in precious mineral sources, the EC can rely on to a great extent its "above ground" precious metals sources, i.e. scrap and industrial residues. Scrap and residues make up a significant proportion of the raw material supplies of all the EC precious metals refiners and fabricators. A number of EC companies are involved in collection, sorting, pre-processing and trading of the scrap and residues. The intrinsic value of the precious metals contained in scrap or residues (such as discarded electronic circuit boards and devices, spent catalytic converters, spent plating baths, spent photographic solutions and effluents, spent films and X-ray plates) justifies the cost of recovery and recycling.

Environmental issues and concerns encourage recycling as a source of precious metals. Environmental regulations are imposing increasingly stringent limits on the tolerable metal content in discarded products, increasing the incentive to recover and recycle them. These regulations also have an effect on the production and usage of some new goods; for instance platinum-(or, rhodium-) containing auto catalyst converters, which are a significant source of secondary platinum.

Refining and fabricating

Precious metal refining occurs either at non-ferrous base metals refineries or at precious metals specialist fabricating operations. Total EC precious metals refining/fabricating capacity is the largest in the world. Refinery output arises from the treatment of copper or lead concentrates and blister copper, most of which is imported, as well as from the processing of precious metal scrap and residues, both domestic and imported. The resulting production is essentially in the form of metal which is sold on the international market. Belgium and Germany are the leaders in this segment of activity, in which all EC copper and lead refineries are involved. The number of products offered by the refineries is fairly limited, i.e. high grade intermediates such as "doré" or straight high-purity metal in the form of ingots, granules or powders.

Source: Degussa

Fabricating output arises from the treatment of high grade precious metal intermediate products, either metal as such, or scrap and residues. Intermediate products can be domestic or imported. Germany, the United Kingdom and France are the leaders in this sector. The range of products supplied by fabricators is extremely diversified owing to the many end-use requirements of the electrical and electronic industries, jewellery and precious wares manufacturing, the photographic industry, the catalyst industry, etc.

Trade

The EC precious metals industry is a net importer of precious metal-bearing raw materials, both primary (of mineral origin) and secondary (scrap and residues) and of unwrought silver, gold and platinum. EC products are traded in various international markets: the high value of the metal production allows long distance movements, and exchange flows develop according to world market conditions. As regards fabricated products, the EC industry presence worldwide is ensured by the international sales networks of its enterprises and by the setting-up of production units abroad to supply local consumer markets.

MARKET FORCES

Demand

Industrial demand absorbs the major share of precious metals production, though gold and silver still play a role in coinage (mostly commemorative coinage) and gold remains the investment metal worldwide. Major outlets vary among precious metals: jewellery in the case of gold, photographic products for silver, automotive catalysts and jewellery for platinum and electronics for palladium. Consumption trends are closely linked to the outlook of the industrial consumer sectors. In this respect, automotive catalysts are certainly the most promising sector, considering the ongoing generalisation of the use of catalytic converters in the automobiles.

Gold, silver and platinum are able to rely on the jewellery sector as a constant source of demand. This is not the case for palladium, future demand for which relies on the further growth of a small number of specific industrial applications. Palladium demand is stagnant at present.

Owing to their uses, all precious metals but gold are consumed mainly in the industrialised areas - Europe, Japan and North America. These three geographical zones account for at least 95% of Western World consumption of silver, platinum and palladium, and for slightly more than 55% of gold consumption.

Gold

The EC accounts for just over 25% of total world demand for gold. In 1991, EC utilisation of gold increased by 4.6%, a small increase compared to the preceding years. Demand in Italy traditionally dominates EC demand: the Italian jewellery industry used 415 metric tonnes of fine gold in 1991, which was 72% of the total EC usage for jewellery, estimated at 575.5 metric tonnes. A considerable part of Italian jewellery production is exported to North America, the Middle East and to other EC Member States such as Germany and the United Kingdom, although Italy itself remains by far the largest jewellery market in the EC. Although demand for gold jewellery continued to rise in Germany and Italy in 1991, it remained static or fell in other EC countries, such as the United Kingdom, where there was considerable destocking by the retail trade.

There was little change in the demand for gold for other uses in 1991. Demand in the electronics industry dropped slightly but there was a small increase in demand for decorative applications. The use of gold in dentistry rose in Germany to 11.6 metric tonnes, an increase of over 20%, partly due to

the temporary introduction of subsidised dental treatment for the residents of the former East Germany.

Silver

Industrial demand for silver in the EC now represents about 40% of the world total. The principal consumer sector in Europe is the photographic industry, where overall demand has remained steady in recent years. In 1991, however, some EC countries (such as Germany and Italy) experienced strong signs of a considerable increase in demand for silver in the form of jewellery, cutlery and silverware as the lower price of silver made such items popular purchases. On the other hand, utilisation of silver in the electrical engineering and electronics industries is tending to decline.

Platinum

In 1991, the EC accounted for approximately 18% of the world demand for platinum. Consumption of platinum in the EC is on a significant upward trend, primarily because of its use in auto catalysts for the car industry. By 1 January 1993, the EC directive on vehicle exhaust emissions will require all new petrol-engine cars to be fitted with auto catalysts containing platinum group metals. Many car manufacturers anticipated this date and began to offer cars fitted with catalysts in earlier years. In some countries, such as Germany or Belgium, the purchase of such cars was encouraged by the government through tax rebates.

While industrial and investment demand has tended to fluctuate from year to year, consumption of platinum in the European jewellery trade has generally been increasing, as more modestly priced platinum items have become available. Retail sales in Germany rose by 13% in volume in 1991. Demand for platinum in jewellery is especially high in Japan. In 1991, 39 tonnes of platinum were used by the Japanese jewellery manufacturers, compared with 107 tonnes of gold, whereas in the EC jewellery trade the ratio was 2 tonnes of platinum to 575 tonnes of gold.

Palladium

EC demand for palladium represents about 16% of Western World consumption. The use of dental alloys surged in 1991, primarily because of an increase in demand in Germany following reunification. There was also an increase in demand in the EC electronics industry as new ceramic capacitor production facilities began operations in Germany and the United Kingdom. The volume of palladium used in auto catalysts did not increase between 1987 and 1991, and its use in jewellery also stagnated between 1988 and 1991, according to Eurostat figures.

Supply and competition

Precious metal supplies come from the treatment of actual precious metal ores, from the recovery of precious metals contained in non-ferrous metal ores (copper, lead-zinc or nickel ores), or from the recycling of precious metal scrap and residues. The proportion of by-products to genuine output is the highest in the case of silver: between two-thirds and three-quarters of primary silver is extracted as a by-product In contrast, genuine output is dominant in the case of gold and platinum group metals. Output volumes arising from recycling are still significant, however, meeting 15% to 20% of industrial demand for platinum and gold, and at least 25% for palladium and silver.

For mine output, South Africa holds a leading position in gold and platinum, while Mexico is the leader in silver and the CIS in palladium. As mine activity and development in both the precious metal and base non-ferrous fields were fairly well sustained in the late 1980s, it is likely that currently-developed supply sources will adequately support precious metals production requirements in the short to medium term. Disturbing factors might arise, however, as a result of internal political developments in South Africa and the CIS These factors could alter the supply pattern of gold and platinum group metals.

In other respects, a prolonged price weakness would primarily affect genuine gold and silver mining concerns, eventually endangering their viability.

INDUSTRY STRUCTURE

Though few in number, the EC precious metals refiners and fabricators are world leaders in the refining, recycling, fabrication and trading of precious metals. Union Minière (B) and Norddeutsche Affinerie (D) top the EC refiners list, while prominent names on the specialist fabricators list are Degussa, Heraeus and Doduco in Germany, Comptoir Lyon Alemand in France, Johnson Matthey in the United Kingdom, and the European outfit of the US company Engelhard.

The total installed refining and fabricating capacity of the EC precious metals industry is the largest in the world and its enterprises rely strongly on imported raw materials in order to fully meet their requirements.

The EC precious metals concerns are of international stature. They are a high performance industry with a strong focus on R&D. In many activity segments, EC firms implement state-of-the-art technology ahead of US and Japanese competitors.

Prices

Precious metals are internationally traded and their prices are quoted on various world commodity Exchanges such as New York, London and Tokyo. Because of their traditional image as "monetary" and "investment" metals, gold and silver prices previously were highly sensitive to the world political climate. However, this aspect of price behaviour has faded somewhat lately, especially for silver.

In the case of silver, oversupply put quotations under considerable pressure in recent years, and the downward trend of prices was only occasionally interrupted by short-lived speculative activity. Platinum and palladium prices are developing much more in line with the physical balance or imbalance between supply and demand, without any other considerations. Both platinum and palladium prices have been showing a downward trend, however, since the late 1980s. Production grew more rapidly than demand in the case of platinum while demand dropped in most applications for palladium.

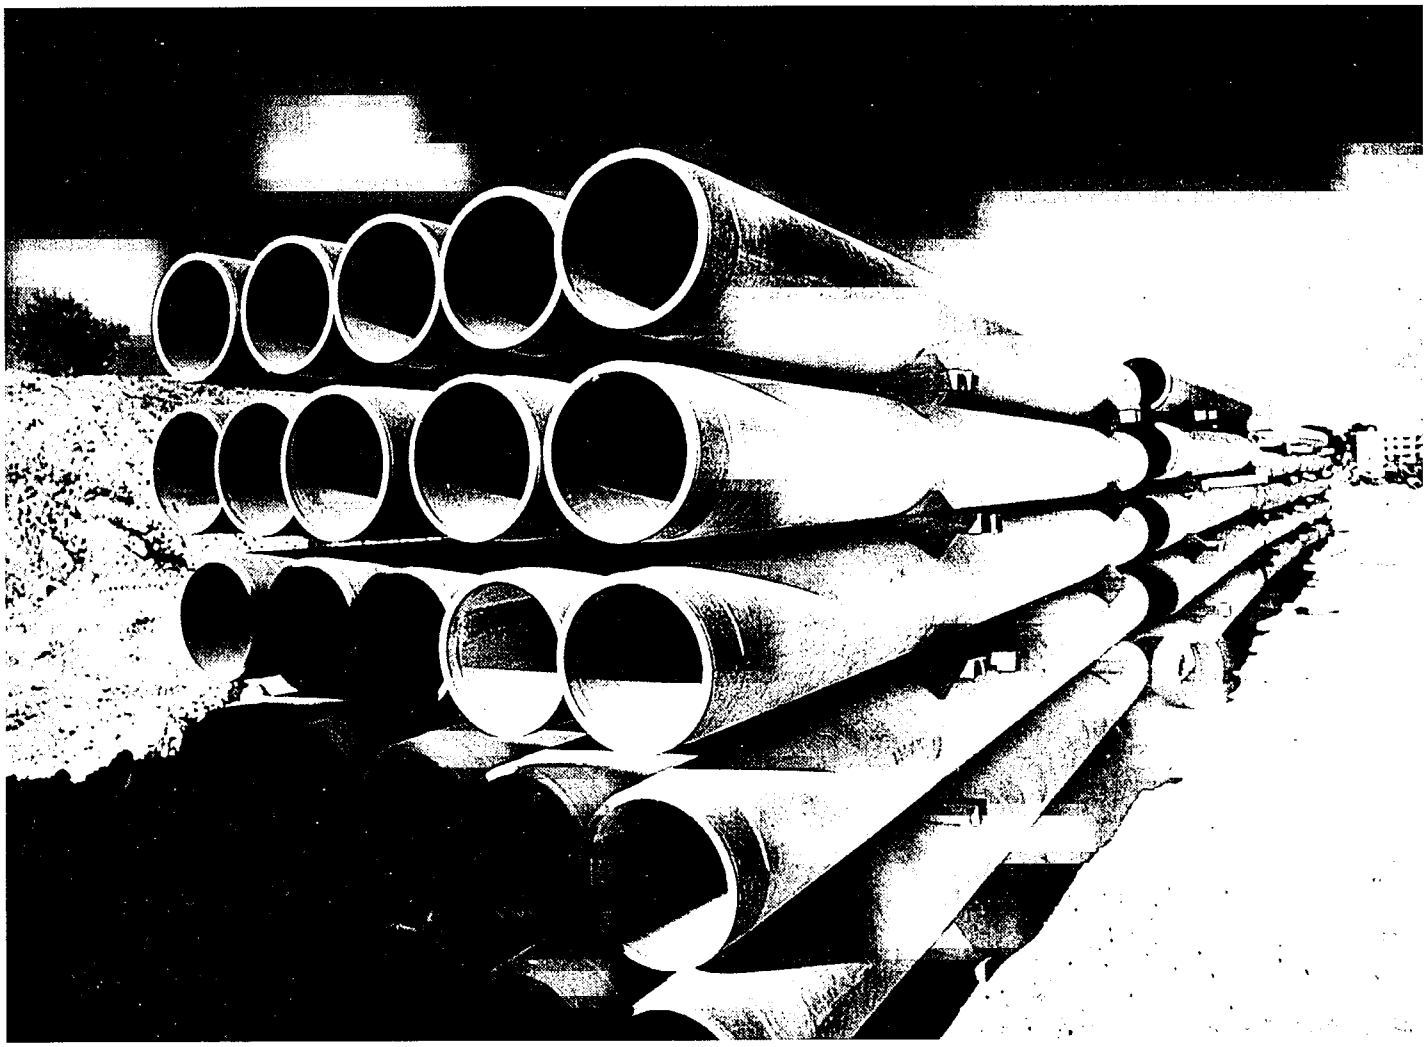
The industry is represented at the EC level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville, 12, B-1150, Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.



Non-metallic minerals
NACE 24

Fluctuations in the activity of this industry are primarily linked to those in the construction sector. During the crisis in the construction sector in the first half of the 1980s, real growth in the non-metallic minerals industry stagnated. After strong growth from 1987 to 1990 in line with an improvement in overall EC construction activity, the industry growth was poor in 1991. In recent years, the sector has undertaken major efforts towards rationalisation and increased productivity. The manufacture of non-metallic minerals causes a fair amount of pollution and is energy intensive. The industry's profitability will therefore also depend on the future pattern of energy prices and any tightening of EC policy on environmental matters.

Figure 1: Non-metallic minerals

INDUSTRY PROFILE

Description of the sector

Non-metallic minerals fall into NACE categories 241 to 248. In addition to this overview, sub-chapters appear for: clay products (NACE 241); cement, lime and plaster (NACE 242); concrete (NACE 243); glass (NACE 247); and ceramic goods (NACE 248). The working of stone (NACE 245) is discussed in Chapter 2 of the Panorama.

Clay products (bricks and rooftiles), cement and concrete are almost exclusively consumed by the construction industry. Also an important part of glass production (some 80% of flat glass production and a part of glass fibre fabrication), and of the ceramics industry (ceramic tiles and sanitary ware) is destined for construction purposes. The bulk of glass and ceramic products, however, are used in a wide variety of other sectors, such as iron and steel, non-ferrous metals, chemicals, motor vehicles, electronics, food and pharmaceuticals.

Main indicators

In 1991, the non-metallic minerals sector produced goods worth 90.6 billion ECU and employed 944 000 people. Following the upturn in 1987, the non-metallic minerals sector continued to grow from 1988 to 1989, slowing in 1990. Production declined, in real terms, in 1991 (-1.6%). Extra-EC exports declined in 1990 and 1991, with the trade balance remaining positive. While employment rose from 1988 to 1990, it resumed its downward trend in 1991.

The most important subsector of the non-metallic minerals industry is the concrete subsector, with a production of about 27 billion ECU, representing almost 30% of its output. The glass sector follows with some 25%. The cement and the ceramics sectors occupy the third and fourth place each with some 18% of non-metallic minerals output.

Germany is the largest producer of non-metallic minerals in the EC, accounting for 27% of total value added in 1991, followed by Italy (20%) and France (16%).

Recent trends

The crisis in the first half of the 1980s in the construction sector did not pass unnoticed in the non-metallic minerals sector, of which about two-thirds of its production is destined for the construction industry. Real annual production growth stagnated between 1982 and 1985. The upswing experienced in the sector in the period 1987-1989 was mainly due to the recovery in the construction sector. Consumption in real terms surged faster than production, with the difference made up by increasing imports.

EC production increased by 5.3% on average annually over the period 1982-1991. Intra-EC trade and extra-EC exports of non-metallic minerals remained stable during that period. The penetration rate of extra-EC imports in EC consumption increased, though remains small (4.1% in 1991). Important subsectors of the non-metallic minerals sector (bricks and tiles, cement and concrete) are materials which are too heavy in relation to their value to be transported economically over large distances and as a consequence trade remains limited.

International comparison

The EC is the world's leading producer of non-metallic minerals. Its production is twice the size of that of the USA and nearly 60% higher than that of Japan. The most remarkable growth during the 1982-1991 period took place in Japan, which has nearly doubled its production of non-metallic minerals, while the non-metallic minerals industry in the USA stagnated by comparison.

Source: Eurostat

In the 1988-1991 period, production growth slumped worldwide. Particularly in the EC, annual growth rates declined from about 9% in 1988 to -1.6% in 1991.

Foreign trade

Extra-EC exports decreased in volume terms over the period 1982-91. Rising imports over the period thus generated a deterioration in the trade balance. The export/import ratio steadily fell from 3.71 in 1982 to 1.97 in 1991. The hefty decrease in extra-EC exports of cement over the period 1982-86 and the surge in cement imports during the period 1988-91, causing a dramatic fall in the export/import ratio for cement (from 47.1 in 1982 to as low as 1.2 in 1991), to a large extent explain this evolution. Intra-EC trade expanded in line with extra-EC imports, so that intra-EC imports almost maintained their share of total imports over the period.

The EFTA countries became a relatively more important export market over the period 1986 to 1991, at the expense of the USA. The EFTA countries also remain the most important source of EC imports, although its share of total EC imports has declined since 1986.

MARKET FORCES

Demand

Roughly two thirds of the industry's production is absorbed by the construction sector. The main reason for fluctuations in the major part of the sector's sales, therefore, lies in the fluctuations affecting the construction market. During the first half of the 1980s, the combination of high interest rates and low real income led to a drop in demand for the construction sector, on the part of both households and firms. From 1986 onwards, the recovery in capacity investment helped to boost the growth of non-residential construction. Demand for residential construction, on the other hand, did not really recover until 1988.

Only part of the production of the glass and ceramic subsectors is used in the construction sector, and the most important share finds a widespread application as intermediary products in several industrial sectors, or as a final product destined to households. Sales of particular product lines will then depend on the main client in question (e.g. sales of refractory products are to a large extent determined by the activity in the iron and steel industry).

Figure 4: Non-metallic minerals

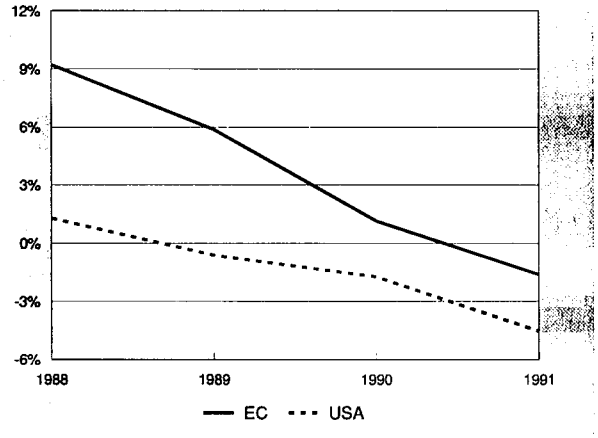
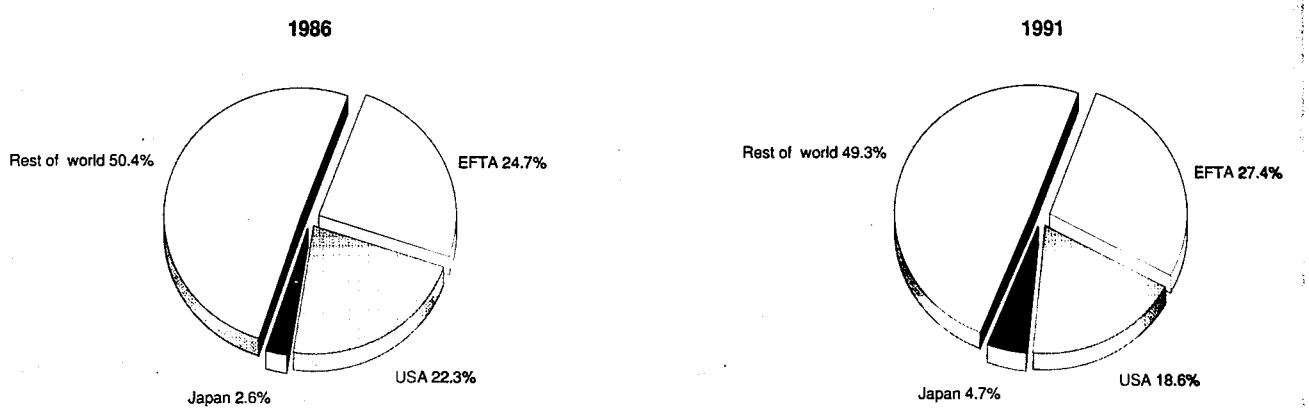
Source: Eurostat, Census of Manufacturers

Figure 5: Non-metallic minerals
International comparison of production growth at constant prices



Source: Eurostat

Figure 6: Non-metallic minerals
Destination of EC exports



Source: Eurostat

Supply and competition

The sector's production is mainly composed of intermediary goods which account for roughly 95% of its value. Most of these intermediary goods are absorbed by the construction sector, while the rest is mainly used by the industry itself (for example, purchases of cement by the concrete industry).

Even though the industry remains predominantly locally organised, due to the important transport costs, it is affected by a number of trade barriers such as standards, certification, etc. The removal of these barriers would allow the industry to lower its production costs.

Production process

The crisis in the construction industry in the early 1980s resulted in large-scale cuts in staff in most of the subsectors of non-metallic minerals. The trend was not reversed after 1986, and the employment level for the whole industry remained stable. Reductions in the workforce between 1982 and 1991 were the result of major rationalisation programmes based on the closure of unproductive units or greater reliance on automation, e.g. in the cement industry, where such efforts brought about an increase in productivity of 59% between 1982 and 1991, measured in terms of value added per person employed.

INDUSTRY STRUCTURE

Companies

With the exception of a few segments of the industry such as cement and flat glass production, the non-metallic minerals sector tends to be relatively dispersed, dominated by local monopolies, serving fairly small regions. The five leading firms in the non-metallic minerals industry barely account for 22% of total production. This compares to figures as high as 42% for the chemicals sector, or the motor vehicles industry where the top five producers account for 66% of total production. The low level of concentration in the non-metallic minerals sector is mainly due to the weight of the material in the construction materials part of the industry, which makes transport a costly matter.

Another reason for the lack of concentration is the absence of economics of scale in largest part of the industry. The cement business is an exception, a field which is increasingly becoming internationalised.

Source: Eurostat

Strategies

The industry will probably become more concentrated with the creation of the EC Internal Market, in response to a higher level of concentration on the part of its main client sector, the construction industry, that will itself be influenced by the deregulation of public contracts.

REGIONAL DISTRIBUTION

All Member States produce non-metallic mineral products. Production is by far the most developed in Germany, followed by Italy, France and the United Kingdom. As far as construction materials is concerned, measured as a share of GNP, the countries in the south of the EC (Italy, Spain, Portugal and Greece) tend to specialise the most in construction materials.

ENVIRONMENT

As a major user of furnaces, the non-metallic minerals sector gives rise to gaseous emissions, mainly nitrogen oxides (NO_x), sulphur dioxide (SO_2) (which causes acid rain) or carbon monoxide (CO). Discharges of dust also pose a common problem, particular as regards the manufacture of cement or terracotta. Efforts to reduce the atmospheric pollution caused by the sector cost companies large amounts of money. By way of an example, de-dusting equipment can account for up to 15% of the value of investments in the cement industry.

The high consumption of energy and of fossil fuels in particular, is also posing an increasingly serious problem in terms of carbon dioxide emissions (CO_2) that contribute to the greenhouse effect. Although major energy savings could still be achieved by modifying or replacing production facilities, a pro-environmentalist EC policy involving the introduction of a tax on carbon emissions or on energy in order to encourage firms to switch to less harmful sources of energy and a reduction in consumption in absolute terms, would lead to a marked increase in the sector's production costs, with unavoidable repercussions on prices. Energy accounts for around 30% of the inputs used in the manufacture of cement, chalk, and plaster and 10% of the inputs for concrete.

Table 6: Non-metallic minerals
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	1.5	2.1
Production	1.2	1.8
Extra-EC exports	0.6	0.8

Source: DRI Europe

Raw materials supply for the non-metallic minerals sector could be seriously hampered in the future. Because of environmental reasons, mining companies are facing increasing difficulties to obtain licenses to open new sites or even to extend existing sites which will reduce the availability of the raw materials for the non-metallic minerals sector in addition to increasing prices.

REGULATIONS

The coming into effect of the Building Products Directive in the framework of the European Single Market marks the onset of the design of a whole range of technical specifications for building products on a European level. This directive will increase competition on a European level.

OUTLOOK

Demand for non-metallic minerals is expected to grow steadily in the 1990s, thanks to the favourable outlook for the construction sector. On average, an annual growth rate of about 2.1% can be expected. Production will follow closely, as the possibilities for trade are limited in the largest part of the industry. Export growth will be slow as capacity will rather be directed towards serving demand in the domestic construction sector.

Written by: DRI Europe

Clay products
NACE 241

Due to local building traditions, types of bricks and rooftiles tend to vary according to country. The largest EC producers are Germany, Italy and the United Kingdom, each with value added well above 700 million ECU. Growth of the industry will be slow, as bricks and tiles face increasing competition from alternative production materials. Despite considerable rationalisation measures during the 1980s, employment will continue to decrease.

INDUSTRY PROFILE

Description of the sector

Bricks and rooftiles have formed part of the historic and cultural heritage of almost every country in the world. Local traditions have influenced standards and national building regulations (e.g. concerning brick size or construction method). In countries such as France and Germany, noticeable differences exist even between regions. In general, there are two categories of clay construction products: bricks and rooftiles.

Bricks

Brick is a construction material made from pre-formed clay which are baked in large ovens. Various brick styles are classified on the basis of national standards, but the following classification applies to all European categories:

- solid bricks contain no perforations, or at least do not have perforations exceeding a certain fixed percentage (15% to 25% of total brick volume, according to the country);
- perforated bricks contain a large number of small (generally vertical) perforations;
- hollow bricks contain large perforations which are generally horizontal (normally more than 50% of gross volume).

The type of brick used varies between countries. In Ireland, the Netherlands and the United Kingdom, solid brick is the most widely used; in Belgium and Denmark both solid brick and perforated brick are common whereas in France, Spain, Portugal and Greece, hollow and solid bricks are mainly used.

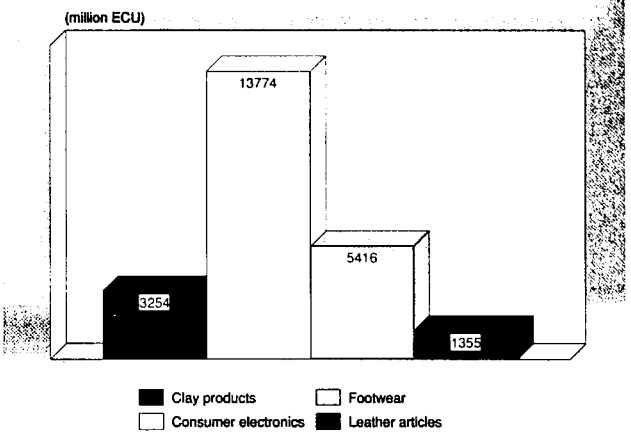
In northern Europe, facing bricks are used in cavity walls, which consists of an outer leaf (facing bricks) and an inner leaf that can be made of solid or perforated brick or of other materials. In southern Europe, the majority of buildings have hollow brick walls, which are rendered (e.g. covered with plaster). In certain areas it is customary to cover parts of the facade with facing bricks (e.g. Toulouse, Barcelona, Venice).

Rooftiles

Rooftiles have a special shape which facilitates roof covering. The production method is the same as for bricks. The clay is kneaded until the desired shape is obtained and the rooftile is then oven-baked. Rooftiles vary with each manufacturer and therefore are not interchangeable. Generally it is possible to distinguish between the Mediterranean type (the roofs with a slight slope) and the northern European type (for roofs with a steep slope).

The brick and rooftile industry's main markets are houses, multi storey buildings, and pavements. The rooftile industry covers maintenance, repair and transformation of existing buildings.

Figure 1: Clay products
Value added in comparison to other industries, 1991



Source: Eurostat

Main indicators

Following a crisis period during the first half of the 1980s, production of clay products in current prices again rose from 1987 onwards. The rising trend in recent production figures continued throughout 1991, when production amounted to 6.4 billion ECU. Extra-EC exports are small and have not shown important variations in recent years. The trade balance remained positive throughout 1991. Employment since 1982 has decreased in the sector, apart from a 4% increase in 1989. In 1991, employment stood at 71% of the level recorded in 1982.

Recent trends

Apparent consumption and production reached their lowest level in 1986 and recovered between 1986 and 1989, maintaining a flat level ever since. In 1991, employment hit record low levels. Table 2 also clearly illustrates the turning point in the middle of the 1980s, showing negative production and consumption growth in the first half, followed by a highly positive growth rate afterwards.

International comparison

Japan and the USA lag far behind the EC in brick and tile production, due to the predominance of other construction

materials such as wood, concrete and plastics. In the USA, production has been shrinking in recent years, as competing construction materials are increasingly preferred.

Foreign trade

Extra-EC trade in the clay sector is extremely small. Exports represented less than 3.5% of EC production in 1991 while imports were negligible (0.4% of apparent consumption). The EC trade balance for clay products traditionally records high surpluses. Intra-EC trade in clay products is also quite limited, accounting for only 7% of EC production in 1991.

The share of the main destinations for EC exports of clay products remained fairly stable over the period from 1986 to 1991. The EFTA countries are the largest single trading block receiving most of the EC's exports (31.8%), followed by the OPEC countries.

The EFTA countries also account for the largest share of extra-EC imports, attaining about half of total imports. Other important import sources for the EC are Turkey, Czechoslovakia and Brazil, each accounting for approximately 9% of EC imports.

MARKET FORCES

Demand

Following the Second World War, housing construction in most European countries experienced a long period of intense activity, followed by a considerable decline. The decline did not affect all countries at the same time, but generally occurred between 1980 and 1985. An increase in interest rates on mortgages, budgetary deficits and increased employment uncertainty brought about a decline in building activity that in turn created a fall in the demand for clay products.

Bricks

With regard to brick, fluctuations in demand are somewhat smoother than fluctuations in the activity of the housing sector. When the housing sector experiences a sharp upturn, brick manufacturing does not always follow because competing construction materials find an opportunity to increase their market share. In periods of downturn, traditional brick construction is more resilient than competing techniques and brick's relative market share increases.

Figure 4: Clay products

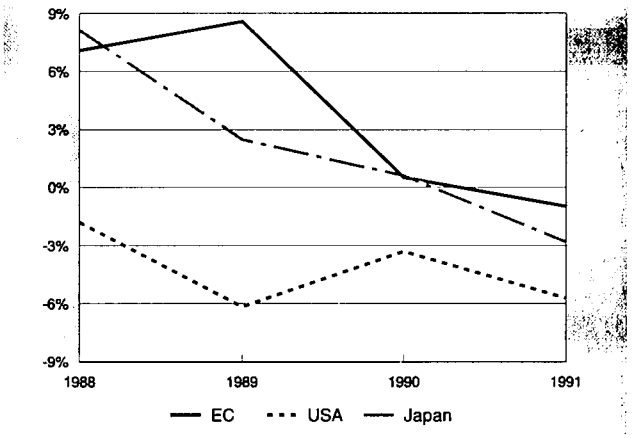
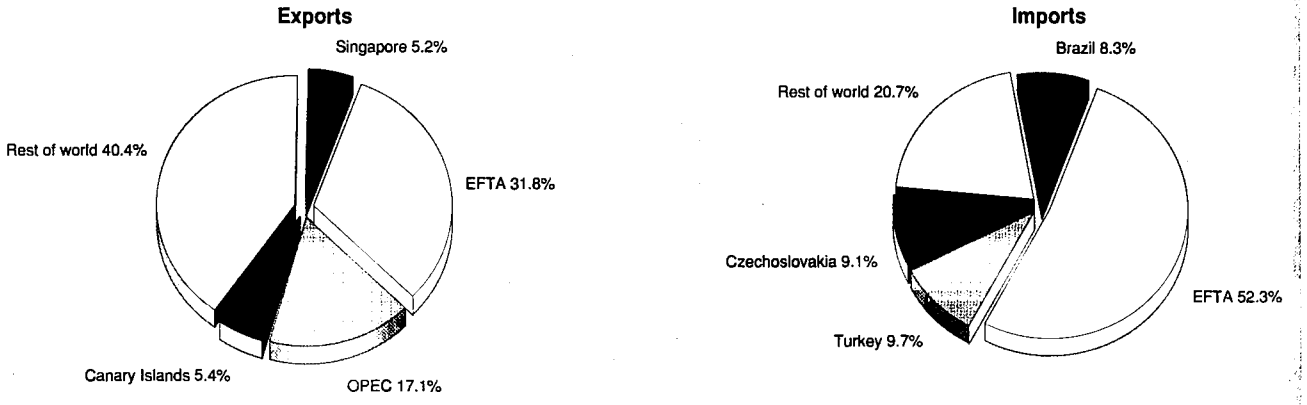
Source: Eurostat

Figure 5: Clay products
International comparison of production growth at constant prices



Source: Eurostat

Figure 6: Clay products
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

The situation of brick production varies from country to country: while some Member States (Italy and Belgium) managed to return to the 1980 production level, others (Germany, France and Denmark) are still far from that level. However, no Member State has managed to exceed the pre-crisis level.

Rooftiles

Following the Second World War, with the advent of concrete rooftiles and the diminishing demand for sloped roofs, clay tiles were abandoned everywhere, but in the last fifteen years, however, a rebound of demand has occurred. During the 1960s and 1970s, priority was given to new construction. Since 1980, the emphasis has been on renovating existing buildings. While masonry remains intact, roofs of traditionally designed houses often must be renovated.

The upturn after the crisis in the construction sector was more quickly felt in the rooftiles subsector than in bricks, and several countries (Germany, the United Kingdom and Denmark) are now even experiencing production levels that are far higher than those of the beginning of the 1980s. Over the period 1980-1985, the rooftile sector and the existing building renovation sector experienced reasonable activity levels and even modest growth in certain countries.

Supply and competition

Given that extra-EC trade is very limited in this sector, pressure from outside competition is not a major issue. Intra-EC trade is also very limited, and competition remains on a regional or even local scale, whereby most brickyards sell their products within a maximum radius of 70 kilometres around the factory. If trade occurs, it seldom crosses more than one boundary. Some small countries, nevertheless, export a sizeable percentage of their domestic production across borders, as they are not too far from their clients. In the Netherlands, exports represent up to 20% of national production and, in Belgium, they account for up to 10%.

A number of factors explain the regional character of the industry: firstly, the weight of the material makes long-distance transport relatively unprofitable; secondly, national standards and regulations form a barrier for increased trade. As national regulations generally arise from local building traditions, the opportunity to eliminate these trade barriers via EC-level harmonisation is limited. The problems of product liability that are due to the fragile nature of the product act as a hindrance to the international rooftile trade.

Production process

In older brickyards and rooftile factories, labour costs make up the largest share of production costs; in the more modern ones, it is energy and capital depreciation. Energy costs can account for as much as 25% of the total cost, making the brick industry sensitive to changes in relative energy prices. Many brickyards regularly change their fuel type (coal, fuel oil, natural gas, LPG) as prices change. However, clients tend to be very conservative and do not easily accept slight modifications caused by changes in production methods.

The number of people employed in the brick and rooftile industry has dropped over the years, owing to the closure of many old factories that employed a large number of manual workers and to the modernisation of existing firms, which now require a smaller labour input. Between 1982 and 1991, the number of people employed in the sector fell from 117 300 to 84 600. Except for Greece which registered an average annual rise of 1.5%, all EC countries experienced a sharp decrease in manpower. The countries most affected by this reduction were France (-8.6% per year between 1980 and 1988), the Netherlands (-8.3%), Italy (-8.2%) and Belgium (-7.9%). The largest employers in the EC for this sector are the United Kingdom, (16 000 people in 1988), Germany (15 500), Italy (14 500) and Spain (13 300).

Due to increased mechanisation, the clay product industry's productivity has continued to rise. For instance, average annual production expressed in m^3 per worker in the Belgian brick industry increased from $150m^3$ in 1950 to as much as $993m^3$ in 1989. Table 4 shows the marked rise in labour productivity, with the sharpest increases following the end of the crisis in the clay products sector (1985 to 1988).

INDUSTRY STRUCTURE

Companies

The typical brickyard in the EC is a family-owned firm with 10 to 50 employees, depending on the degree of technology. In most countries, there are companies which own a number of brickyards more or less concentrated in a particular region. The oldest factories mostly have a seasonal activity with employees unemployed during the winter. Even in countries where the brick industry is strongly automated (mainly northern Europe), there are still older, more traditional brickyards that have survived by specialising in the manufacture of handcrafted products, which sometimes proves to be a very profitable activity.

Table 5: Clay products
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	0.6	0.9
Production	0.5	0.8
Extra-EC exports	-0.3	-0.1

Source: DRI Europe

The modernisation of these companies has resulted in a continued trend towards concentration: in all countries, the number of brickyards has fallen considerably, dropping from 2438 to 1809 companies from 1982 to 1990. Since 1988, some companies have begun to expand beyond national borders and establish themselves as multinationals.

OUTLOOK

Following the trend in recent years, consumption and production of bricks and rooftiles are expected to grow slowly. Growth will be lower than for the non-metallic minerals in general, due to pressure from competing construction materials. The renovation of older buildings should provide some opportunities.

Cement
NACE 242

The slowdown of economic growth in the EC since 1990 has resulted in decreasing production volumes for the cement industry in 1991. The trends in production and consumption, however, show marked differences between EC countries. Despite diminishing growth for the sector, imports have continued to increase. The prospects for the industry are mediocre, except perhaps for Germany.

INDUSTRY PROFILE

Description of the sector

The activity of the cement industry is closely linked to the general economic situation. Cement is an important basic material for buildings and civil engineering works, representing major public and private investment.

Cement production consists of two essential phases, the manufacture of semi-finished and finished products.

The manufacture of a semi-finished product, so-called "clinker" is obtained from the calcination in a high-temperature kiln (1 450°C) of raw materials (clay, limestone, etc.) previously prepared in paste or powder form depending on the production process used (wet or dry).

Cement as a finished product is manufactured by the homogeneous mixture of the ground clinker and calcium sulphate, with or without (depending on the type of cement), one or more additional components: slag, fly ash, pozzolana, filler, etc.

Main indicators

Production in EC countries in 1989 amounted to 171 million tonnes (i.e. less than 15% of the world production) compared to 21% in 1980. Production expressed in volume terms show the recession in the industry in 1991.

Italy is the largest cement producer and consumer in the EC producing 40.8 million tonnes and consuming 43 million tonnes. Germany and Spain occupy second and third places, closely followed by France.

Recent trends

After experiencing a high rate of economic growth in Western Europe from 1987 to 1989, economic activity slowed sharply in the second half of 1990 and growth virtually ceased in the first half of 1991. Consequently, 1991 marked a heavy downturn in consumption for a number of EC countries as consumption for the EC as a whole decreased by 2.7% in 1991 compared to 1990.

The trends across countries, however, vary considerably. The best performances in 1991 were recorded by Luxembourg and Portugal, with the strong performance in Portugal linked to heavy investment in the public sector and by a rising housing sector. UK consumption decreased by about 18%, Denmark and Ireland by 8%, France, Netherlands and Germany (in spite of public sector investment following reunification), 4% to 5%. No growth, or relatively weak growth, was registered in Belgium, Italy, Spain and Greece.

International comparison

World cement production was estimated at 1 153 million tonnes in 1991. The 10 major cement producing countries, in order of importance, were: China (220 million tonnes), the former Soviet Union (131 million tonnes), Japan (92.4 million tonnes), the USA (65.1 million tonnes), India (50 million tonnes), Italy (40.8 million tonnes), South Korea (38.8 million tonnes), Germany (31.1 million tonnes), Spain (28 million tonnes), Turkey (27.4 million tonnes) and Brazil (27.3 million tonnes).

For the first time ever, world production of cement (excluding China) showed a slight decrease during 1991. Overall market growth (including China) is flat, confirming the downturn initiated in 1990. After a period of sustained growth, the United States, the Western European countries and Eastern Europe alike experienced lower production and consumption, varying from a level of 2.5% in Western Europe up to 10% or more in the USA and Eastern Europe.

The geographical distribution of trade in cement is largely influenced by the nature of the product: its modest price per unit and considerable weight makes it vulnerable to the effects of transport costs, especially road transport. As a result, cement is delivered most often to the markets that are closest to the place of production.

It also explains why world trade in cement currently accounts for less than 6% of production. Moreover, it is marked by a very pronounced geographical polarisation. In 1991, 45% of imports were recorded in only seven countries: the USA, South Korea, Thailand, Germany, Spain, Italy and Hong Kong. Four countries accounted for 40% of the world's exports: China, Greece, Japan and Turkey.

Foreign trade

In spite of the general downward trend in consumption, imports by EC countries continued to grow in 1991, increasing by approximately 12%. This volume represents more than 10% of production and consumption.

The largest increase in trade was reported in Germany where imports doubled. Import growth also continued in Spain and Italy during 1991, reaching 11.6% and 7% respectively of domestic consumption.

The EC's main exporter was Greece, retaining the same level as the previous year with 43% of production.

China again increased its exports by approximately 30% and export volume amounted to 10.5 million tonnes; record exports were made by Spain and Japan with 13 million and 14 million tonnes respectively in 1983. The main recipients of Chinese cement are Korea and Thailand whose total imports reach 12 million tonnes and Japan with imports of 1.8 million tonnes.

Trade to the USA continued to drop in 1991, to 7.9 million tonnes, or nearly half the amount of 1990. A decrease in imported cement from Mexico to the USA was a result of the weak US economy and the application of the ITC's (International Trade Commission) anti-dumping penalties.

MARKET FORCES

Demand

Cement consumption is linked directly to activity in the building sector and, more accurately, to investments made in residential and non-residential buildings, as well as in civil engineering works. From 1986 onwards, European countries began once again to increase their investment in building and the cement industry quickly recovered from the crisis, to reach consumption levels in 1989 that matched 1980 consumption. Following the weakness of the construction sector in 1991, demand for the industry grew at a slow pace.

Supply and competition

EC capacity is currently more than enough to cover internal demand. Nevertheless, there is continued exposure to cement imports from Eastern Europe and developing countries at artificially low prices (dumping conditions, where only variable expenses are taken into consideration), or at prices imposed by the authorities in the countries in question.

The legal resources for defence against concentrated dumping at the borders are normally inadequate. Whereas overall economic harm to the EC might appear limited, the same does not hold at regional level.

Production process

The cement industry is a capital-intensive sector: it processes large quantities of low-value raw materials in very expensive facilities, to manufacture a product with a low unit price.

Table 3: Cement
International comparison of production in volume

(thousand tonnes)	1988	1991

Asia	477 800	515 800
Oceania	7 550	6 900

Source: Cembureau

Cement production requires large quantities of energy. The average energy consumption per tonne of clinker produced in the EC today amounts to less than 900kcal/kg. This value may vary widely from country to country (from 800 to 1400kcal), depending on the production method applied. Energy consumption in relation to cement manufacture also depends on the policy pursued by the different national industries as regards investment and the development of composite cements.

The second oil crisis confirmed the usefulness of the conversion of energy supplies undertaken since 1973. The industry has since continued its efforts in two directions:

- search for cheaper fuels (diversification of fuels thanks to the versatility of equipment and use of wastes as secondary fuels);
- a rational use of energy (new manufacturing processes, development of composite cements, heat recovery, etc.).

However the cost of energy (including consumption of electricity for grinding the clinker) is very important and can vary from about 25% to 35-40% of the total production cost of cement.

INDUSTRY STRUCTURE

There are no generally accepted criteria for ranking cement companies or groups, as both turnover and capacity can be defined in different ways. Published turnover in consolidated accounts may include non-cement activities, and the existence of trading affiliates can lead to different quantities of cement being produced and handled by a company. The calculation of capacity control in part-owned companies is treated differently.

Taking into account the above, several cement producing groups considered to be the largest operating companies in the world are, in alphabetical order, CEMEX (Mexico), Holderbank (Switzerland), the newly merged Italcementi (Italy)/Ciments Français (France), and Lafarge Coppée (France).

Restructuring and market positioning of the leading companies is expected to continue. Several joint ventures have been set up, particularly with Eastern Europe.

ENVIRONMENT

As public concern for the environment steadily increases, so does the activity of the EC Commission and Parliament in tackling environmental issues. EC regulatory activity is also extensive in other issues directly related to the European cement industry, such as emission control, waste classification, incineration of hazardous waste, integrated pollution control, environmental auditing and liability for damages to the environment.

The cement industry has therefore devoted much effort to environmental issues, particularly in the completion of the

European cement industry's document "Approach to the Environment". This document tackles the environmental impacts associated with the manufacture and distribution of cement.

REGULATIONS

A European pre-standard for common cements has recently been adopted by the European Committee for Standardisation (CEN). The pre-standard details composition, specifications and conformity criteria for the traditional common cements used in Europe. Cements conforming to the requirements of the pre-standard are termed "CEM" cements. The pre-standard is presently being introduced in the EC and EFTA countries.

The pre-standard will have a life of three to five years and will operate with existing national standards. During this time, further work will be carried out and the changes required prior to the adoption of a full European standard will be identified and clarified.

OUTLOOK

The overall growth in the market is expected to slacken considerably. A possible exception will be Germany, stimulated by the developments in the Eastern Länder.

Precast concrete
NACE 243.2

After a general status quo in 1991, the sector exhibited signs of a recovery in 1992 in some countries, closely following developments in the construction sector, which is virtually its only client. Steady growth can be expected for the sector in the medium term. Though the industry is mainly made up of small to medium-sized companies, some merger and acquisition activity has been taking place in anticipation of the Single Market. Stricter EC legislation on emission norms regarding air and water will also have its influence on the precast concrete industry. The limited expansion possibilities for mining and quarrying might also pose supply problems for the industry.

INDUSTRY PROFILE

Description of the sector

The precast concrete industry is the collective name given to all enterprises that manufacture precast concrete products at specially equipped plants (at a permanent location) which operate independent of weather conditions. The products are delivered to the construction sector ready to be put in place in building and road construction projects, civil engineering works, etc.

Concrete is made from a mixture of sand, water, cement, gravel or other aggregates, and other possible additions. The concrete industry as an industrial sector is situated between the sector covering the suppliers (i.e. cement manufacturers and quarries which supply sand, gravel, and stone) on the one hand and the customers (i.e. the construction sector) on the other.

The precast concrete industry embraces a wide range of products:

- products for road construction (paving flags, stones and blocks, kerbs, safety and sound barriers, sewerage and drainage pipes and accessories, etc.);
- elements for building construction (masonry units, cladding elements in architectural concrete, floor elements, beams and columns, wall elements for industrial, commercial and agricultural buildings, etc.);
- elements for civil engineering works (bridge girders, tunnel elements, etc.);
- units for various other purposes such as flood protection, urban and garden landscaping, lighting poles, and agricultural installations.

Furthermore, the following general characteristics of the precast concrete industry can be highlighted:

- relatively low value-added content of certain mass-produced precast concrete units;
- strong dependence upon the efficiency of the business, (i.e. the degree of mechanisation of the production process and the effectiveness of management);
- a predominance of small to medium-sized businesses (often family-owned enterprises).

Main indicators

Table 2 shows that, for the EC countries (for which data are available) production at current prices has grown considerably over the last three years. In 1991, growth was not pronounced in almost all Member States, except Germany where continued growth was noted, and the UK where a strong downturn persisted.

Even though there is not complete information on EC employment in the precast concrete industry, a reasonable estimate is around 180 000 people. The number of employees is spread over nearly 5000 precast concrete plants, of which approximately 600 employ more than 50 people.

Recent trends

In the industrialised countries, the activity of the precast concrete industry depends largely on the overall economic climate and on activity in the construction sector in particular (99% of the precast concrete production goes to the construction sector), though trend differences can be observed between residential building, non-residential building and road construction (the latter absorbs roughly 30% of the precast concrete production).

The economic crisis caused a 30% to 40% drop in precast concrete production in the EC with an almost equal fall in employment from the mid-1970s to 1984. With the economic revival, production has increased, with figures varying depending upon the country considered.

An important indicator of the precast concrete industry's real strength is the percentage of the precast concrete industry in the total national cement consumption, because it illustrates the actual penetration of the precast concrete products on the construction market. It shows a rather positive trend in most countries, especially in those countries where the industry has successfully commercialised its precast concrete solutions. Indeed, by producing certain construction materials at a fixed plant instead of at the building site, construction costs may be significantly reduced.

Foreign trade

Generally, precast concrete products are heavy and bulky in relation to value. The average value of one metric tonne of precast concrete products is approximately 100 ECU (but for

some standardised non-reinforced products manufactured on a large scale, this value can be as low as 35 ECU). Consequently, long-distance transportation of precast concrete products is unusual and trade is mostly limited to a single border crossing. A typical exception is, however, the technologically highly-advanced precast concrete products such as sophisticated cladding elements in architectural concrete.

MARKET FORCES

Demand

The activity in the precast concrete industry strongly depends on the activity in the construction sector, which in turn is greatly dependent on the overall economic climate. As a consequence, periods of high activity peaks in the concrete industry are succeeded by low-activity periods leading to costly overcapacity.

A further factor causing variations in activity levels is the financial situation of the public authorities. Approximately one-third of construction activity covers public works (involving road construction and civil engineering works, etc.), a field soon afflicted by cuts when the public authorities experience financial difficulties.

Supply and competition

The concrete industry faces competition from traditional construction procedures with an intensity varying from country to country and closely related to the marketing skills of the local concrete industry.

There is indeed a wide range of substitution products offered, ranging from classical materials such as clay brick and timber, to newer materials such as PVC.

Production process

Since non-reinforced concrete began replacing natural stone, timber and cast iron in many applications, the precast concrete industry became highly mechanised. The rapid technological development of reinforced and pre-stressed concrete led to the breakthrough of various plant-manufactured structural elements for building construction projects and civil engineering works.

Lightweight concrete was first applied in the precast concrete industry for the manufacture of masonry units, wall and floor elements.

The construction boom in the 1960s and early 1970s, as well as the increase in building costs over that same period led to a further industrialisation of the precast concrete industry. Profits were reinvested in both plants and modern machinery such as semi- and fully-automated batching and manufacturing equipment. Handling, packaging and transporting techniques were equally revolutionised.

To date, the following particular technological aspects of the precast concrete manufacturing may be pointed out :

- the manufacture at a plant with a permanent location in controlled conditions;
- the use of a proper scientific concrete technology such as the use of 0-slump concrete, hot concrete and pretensioning techniques, particularly in moulding and compacting techniques and accelerated hardening techniques;
- advanced quality control which goes beyond the checking of the fresh concrete; quality control in the precast concrete industry includes the control of dimensional accuracy, of the properties of the hardened concrete, the position of reinforcements, all of which is done before the product is incorporated into construction;
- an advanced automation of manufacturing methods, not to mention an increasing level of industrialisation and standardisation.

Skilled manual workers constitute about 25% of employment in the precast concrete industry. These workers are involved in special production procedures such as reinforcement steel bending and netting, and the finishing of architectural concrete (e.g. polishing).

In several Western European countries the limited number of labourers in this field are in particularly high demand as younger school graduates do not appear to be strongly attracted towards this occupation. To cope with this problem, the industry has set up specific programs ranging from training courses for young adults and/or unemployed people, the publication of manuals, and campaigns designed to improve both the image of the industry and the attractiveness of jobs in precasting. For instance, in recent years the industry in Germany has regularly organised a national promotion day, offering younger people the opportunity to visit precast concrete plants.

INDUSTRY STRUCTURE

Companies

As already mentioned, the precast concrete industry is predominantly composed of small to medium-sized enterprises, that are generally family-owned businesses.

Strategies

In recent years, there has been some degree of concentration in the industry, because either one or more small businesses were bought up by major industrial groups (often a large building company, a cement factory or an aggregates supplier), or because various smaller concrete businesses have merged. The trend toward increased concentration varies in nature and intensity from country to country, and is to some extent due to anticipated market changes in view of the Single Market, either by allowing large construction companies to control supplies in the foreign market they will enter, or by creating concrete companies large enough to deal with the large construction companies on a recently internationalised market.

Besides entering into mergers and acquisitions, the industry also aims at further increasing productivity (estimated to have

risen by roughly 35% over the last fifteen years) and improving quality. First of all, the precast concrete industry has raised fixed investment by about 40% from 1985 to 1990. These investments, reflecting significant efforts toward innovation in the sector in recent years, involved not only replacement of older equipment and installations but also an increase in capacity, thus enhancing the competitiveness of plants in their region.

Secondly, precasters have become increasingly aware of the market advantages of guaranteeing the adequate durability of products (durability implying here both soundness and long-term appearance) and improved design.

Basically, most "new" products in the precast concrete industry are an evolution of existing elements. Nevertheless, the industry has developed (and is successfully marketing) valuable solutions in fields relative to, for instance, environmental problems such as sound barrier walls to protect residents living near highways or railways from noise hindrance.

Technological evolution constitutes a further influential factor. Indeed, the technical realisation of new types of beams or girders with, for instance, larger spans, would automatically create a higher demand for these structural elements.

REGIONAL DISTRIBUTION

The precast concrete industry is particularly important in Germany, relatively important in the Netherlands and Belgium, and to some extent, in France. In some countries, there is a higher concentration of the precast concrete industry in certain regions (e.g. the South West of the UK).

Geographical factors also played an influential role in the precast concrete industry. The more densely populated a region, the more important and developed the precast concrete industry tends to be. These regions have a higher demand for building, water and road construction and since precast concrete products are heavy, and costly to transport, production takes place near the centre of demand. An example of this is the triangle of dense population in Belgium, the Netherlands and Germany, in contrast to more sparsely populated regions in central France and Spain.

Climatic conditions also play an important role. In general, the further north a country is situated, the more developed its precast concrete industry. Traditional building activity in northern countries often has to be suspended during the winter due to bad weather conditions, while precast concrete products allow uninterrupted building activity.

Traditional use of certain construction materials has influenced the degree of development and strength of the precast concrete industry in the various Member States. In the Netherlands, for example, a boom began for precast concrete pavers when traditional clay pavers started to become too expensive. This secured the Dutch paving industry a strong position which allowed large-scale production at a favourable cost. Another result of this situation was that transportation beyond The Netherlands' borders became possible. By contrast, the British precast concrete flooring industry has encountered great difficulty in breaking into the traditional timber floor market for low-rise housing. The unequal development of the precast concrete industry in individual EC countries is illustrated in Table 3, which shows the share of the precast concrete industry in total national cement consumption for each Member State.

ENVIRONMENT

EC legislation on pollution control will also have its influence on the precast concrete industry. The German legislation concerning environmental protection aims particularly at reducing emissions from the raw materials and manufacturing industries. Hence, considerable know-how and capital investments in environmental protection are required of these industries. By means of modern techniques (such as waste water treatment installations), the pollution of air, water and soil may be controlled notwithstanding a growing production; modern techniques will thus help dissociate industrial production and economic growth more and more from environmental exploitation.

Increased restrictions on gravel extraction, anticipated in a number of Member States, could affect the concrete industry by rendering raw material supplies more difficult on the longer term. Raw material shortages might arise in some countries. In addition, the quarries supplying the precast concrete industry with sand and aggregates are either forbidden to extend further, or threatened with closure. Since about 80% of concrete is made up of sand and aggregates (1 m3 concrete requires two tonnes of these raw materials), this may cause serious short-term problems, not only for the concrete industry but also for the construction industry as a whole.

Consequently, certain research programmes are being conducted with the aim of recycling concrete debris, crushed concrete and waste concrete as raw materials. Due to requirements for high quality inputs, however, the precast concrete industry has only limited opportunities for using such recycled materials. Moreover, high-quality aggregates are also a prerequisite to meeting the stringent performances demanded as a rule of concrete products. Furthermore, they play an important role in one of the major advantages of precast concrete (i.e. smaller dimensions of the components which would reduce their weight, improving transportation costs).

In the precast concrete industry, a noise problem may occur as increasing urbanisation encroaches upon precast concrete plants. However, the industry has already recorded some success in reducing noise levels.

REGULATIONS

The advent of the Single Market and the coming into effect of the Building Products Directive (BPD) has emphasised the urgency for work on harmonisation, standardisation and certification.

Products meeting a European technical specification elaborated under an EC Commission mandate may carry the EC mark attesting their conformity with the given European technical specification. Such a European technical specification can either be a harmonised EN standard elaborated by CEN (European Committee for Standardisation) or, if no EN exists, a European Technical Approval (ETA) elaborated by EOTA (European Organisation for Technical Approvals).

Adoption of such common standards and quality certification systems at Community level is essential for the precast concrete industry. The precast concrete industry has a preference for the most stringent level of attestation of conformity, involving product certification by an approved certification body. Such certification would help to maintain client confidence in the high quality of the products, improve the quality image of the concrete products, and reduce the chances of having regulatory attestation exist next to some kind of voluntary certification system.

OUTLOOK

In general, 1992 is expected to show recovery in certain countries from the overall status quo in the industry in 1991. Steady growth perspectives can be foreseen for the medium term. The forecast is the result of steady growth in France and Italy, high growth in Germany (where the domestic market is buoyant) and negative growth in 1992 for the UK, where the construction sector is in deep recession (which will only be followed by slow positive growth). Exports - concentrated mainly, if not exclusively, on neighbouring countries - are expected to increase following the increasing trend in international trade, yet somewhat slower in the medium term, as with the expected growth in the construction industry domestic producers will concentrate somewhat more upon domestic demand.

Glass
NACE 247

With a steady annual growth rate over the last few years, the glass industry has shown its ability to weather the downturn in the economy; despite the fact that two of its largest customers, the motor vehicle and construction industries, have experienced significant reductions in output.
Still maintaining its position as the world's largest producer of glass, the EC does not face intense competition from a rapidly growing Japanese industry as relatively high transport costs inhibit long distance trade. As a result, the EC's largest trading partners will remain Eastern Europe and the EFTA countries.
Emerging technologies for glass production and a growing emphasis on recycling are expected to sharply lower glass production costs, particularly by lowering the energy inputs needed.

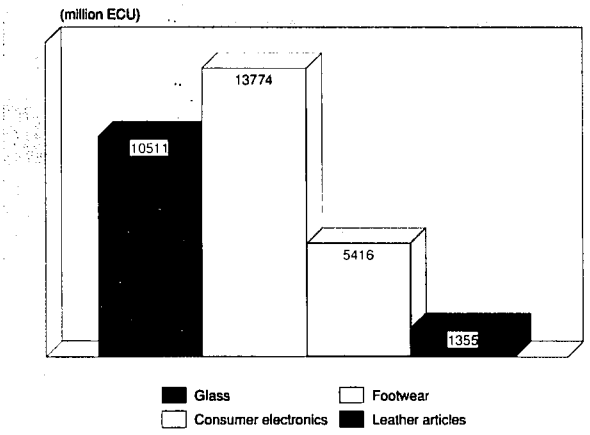
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The glass industry corresponds to NACE 247 and includes four main segments. Container glass (also known as hollow glass) accounts for two-thirds of this industry. Flat glass, which is primarily used in the construction and transport equipment sectors, represents about 22% of this industry. Glass tableware accounts for another 4% of the glass industry. The remaining 8% is divided between glass fibre, special glass (high technology products), and glass products not mentioned in above.

Main indicators and recent trends

The EC glass industry produced 22.6 million tonnes of glass in 1991, with a turnover of about 23 billion ECU. 247 700 persons are employed by the glass industry. Production per employee was 91 tonnes in 1991.

During the recession of the early eighties, the EC glass industry was hit by a lowering of demand. Production fell in 1981, and did not return to its 1980 level until 1986. In 1987 and 1988, strong demand boosted production by about 7.5% per annum.

In 1989 and 1990, demand slowed, but nevertheless maintained a steady annual growth rate of 4.5%. Production followed demand and grew by 4.7% in 1989. In 1990, extra-EC export demand fell and the trade balance with the rest of the world decreased from 1 140 million ECU to 991 million ECU. As a consequence, production grew more slowly than consumption in the EC, at 3.7%

In 1991, the recession hit the glass industry and its main market: (packaging, construction, and motor vehicles) as production fell by 0.3%.

International comparison

The EC is the world's largest glass producer. In 1991, the EC glass industry produced 22.6 billion ECUs worth of glass products. Japan and US production is only about two-thirds of EC production. The Japanese glass industry, however, was the fastest growing. While European glass producers doubled their production (measured in ECU) between 1980 and 1991, Japanese producers increased production almost fourfold.

Foreign trade

Long distance shipments of glass products are hampered by their low value/weight ratio. Transport cost is high compared to the value of the product. As a result, in 1991, intra-EC trade accounted for only a quarter of production, and only 11% of production was exported outside the EC.

The EC remains a net exporter of glass products, although its trade surplus is slowly deteriorating. It reached a peak of 1.4 billion ECU in 1985, but was only at 0.8 billion ECU in 1991. This development occurred in parallel with a deterioration of the terms of trade, which increased from 100 in 1985 to 103.2 in 1991.

About half of all extra-EC imports originate from East European countries. During the 1980's, these countries developed their cheap, low-quality glass exports to the EC in order to obtain hard currencies. This trend has continued with the opening of the East European economies. In parallel, western companies have started to expand in these countries, either by joint ventures or by acquiring local producers. Producers located in Eastern Europe will thus rapidly acquire the technology needed to upgrade their exports to the EC.

In the glass industry, the main trading partners of the EC are the EFTA countries: 31% of all imports that enter the EC have their origin in these countries, and 30% of extra-EC exports are sold in EFTA countries. Other important trading partners are the East European countries. Czechoslovakia alone accounts for 9.4% of total EC imports. Given the high

transport costs of glass products, the proximity to the EC of these countries (most of them share a common border with a Member State) explains their large share of glass imports into the EC.

MARKET FORCES

Demand

Glass products are mostly used as intermediary inputs by other industries: this represents more than 80% of glass sales. Private consumption accounts for 10% to 15% of glass sales. Glass is mainly used for packaging (hollow glass). The food industry accounts for about 25% of glass sales. Other important glass users are the construction sector (15% of sales) and the car industry (6% of sales), which mainly use flat products.

Supply and competition

During the 1980's, the introduction of the float glass process revolutionised production methods and triggered a wave of capacity expansion, all of which led to surplus production. Such overcapacity has coincided with a strong downturn in demand from the glass industry's largest consumers, the motor vehicles industry and the construction industry.

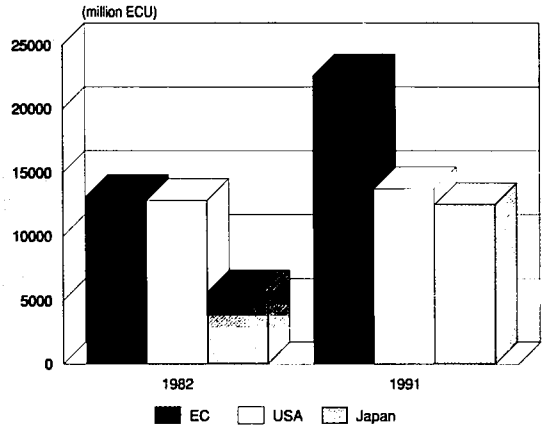
These factors in turn led to extensive restructuring of the EC industry and major job cuts, sometimes by as much as 50%. At present, investment represents over 7% of the value of production, a sign of the industry's efforts to expand and modernise its facilities. Large sums of money have also been invested in research, technology being a key factor in competitiveness.

The only major competitive threat is from East European countries which are able to produce glass (of a lower quality in general) at a lower cost. The privatisation of firms in Eastern Europe presents an opportunity for EC producers to acquire cheaper sources of glass.

Production process

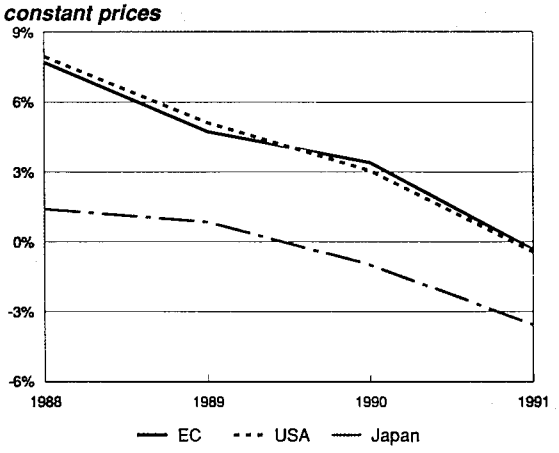
Technology in the glass industry has considerably improved in the past few years, and there is still considerable potential for improvements.

Figure 4: Glass
International comparison of production at current prices



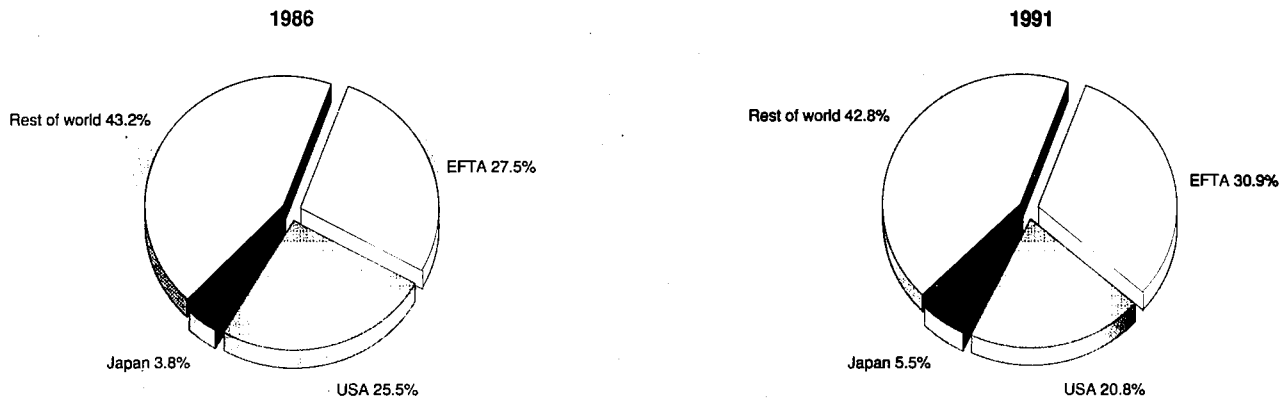
Source: Eurostat, Census of Manufacturers

Figure 5: Glass
International comparison of production growth at constant prices



Source: Eurostat

Figure 6: Glass
Destination of EC exports



Source: Eurostat

The energy efficiency of furnaces are constantly increasing, Furnaces currently use a vitrifiable mixture with more than 50% cullet (recycled material). Some glass furnaces for green glass even produce glass of very high quality with 100% cullet mixtures. The improvements in technology are such that a machine that used to produce 70 000 bottles per day in 1976 can now produce almost 300 000 bottles per day.

The average weight of a bottle is decreasing over the years thanks to improvements in the quality of glass. For example, the weight of a bottle of beer was reduced by 33% in a few years.

In the flat glass sector, the float glass process introduced during the eighties has allowed major efficiency and quality gains.

INDUSTRY STRUCTURE

Companies

Glass production by means of modern processes (flat or container glass) requires large-scale investment and considerable financial resources. This sector therefore tends to be concentrated. This tendency became more marked during the 1980s, when a major restructuring of the industry was performed (the modernisation to float glass production).

The major groups in the flat glass industry are St-Gobain in France, Pilkington in the UK, Glaverbel in Belgium (controlled by Asahi Glass of Japan). Two top North American producers are also active in Europe, PPG and Guardian.

In the container glass industry, the major producers were, in 1989-1990: A.V.I.R. (Italy), Gerresheimer Glas (Germany), Hermann Heye (Germany), Nienburger Glas (Germany), Oberland Glas (Germany), PLM Group (Germany, United Kingdom, Netherlands), Rockware Glas (United Kingdom), Saint-Gobain Emballage (France), United Glass (United Kingdom), Verenigde Glasfabrieken (Netherlands), Verreries Souchon Neuvesel (France), Vetri (Italy), and Vicasa (Spain).

Strategies

During the 1980s, the introduction of the float glass production processes revolutionised flat glass production. Huge investments were launched to achieve the modernisation of the European flat glass industry. However, this led to a excess of capacity of production when demand was low in the early 1980s.

These factors led to an extensive restructuring of the EC glass industry and to major job cuts. Hitting a low point in 1986, employment was 11.6% below the 1982 figure. Since then, it has recovered slightly. In 1991, the glass industry had a

Source: Eurostat

workforce of 247 700 in the EC, a 5.6% improvement over 1986.

ENVIRONMENT

Glass containers can be easily recycled. In 1991, about 30% of total container glass consumption was recycled. No other packaging material has such a high rate of recycling. This gives glass packaging a competitive advantage over other materials.

This is also important in terms of energy, particularly at a time when the EC is talking of increasing energy taxes. Each ton of recycled glass saves approximately 1.2 tonnes of raw materials and 100 kg of oil. The glass industry is an energy intensive one. About 15% of all costs (raw material inputs and labour) are for energy purchases.

REGULATIONS

Several European directives play an important role in the regulatory environment of the glass industry.

For flat glass, Directive 22/92 (Safety glazing and glazing methods on motor vehicles and trailers), sets norms for safety glasses on vehicles. Directive 89/106/EEC (Council Directive of 21 December 1988 on the approximation of laws, regulations and administrative provisions of the Member States relating to construction products) sets norms for construction materials, including window glass.

In the hollow glass industry, several directives are under study. They will deal with recycling and the rate of recycling of packaging materials. Another directive in preparation will set technical norms.

OUTLOOK

The outlook for the glass industry depends mainly on its European domestic market, as international trade is limited in this sector.

In the flat glass industry, demand from the motor vehicle industry and the construction sector is not expected to grow rapidly. It will, however, recover from the downturn experienced in 1991. In the container glass industry, demand is steadily growing, as it linked to consumer products which have non-cyclical demand (food, etc.).

Other sectors have a smaller impact on the outlook, as they have a smaller share of this sector. Glass fibres and special products should, however, see their demand grow more rapidly than the rest of the sector.

Table 8: Glass
Expected real annual growth rates

(%)	1992-93	1992-95
Apparent consumption	3.3	3.8
Production	2.7	3.2
Extra-EC exports	1.0	1.0

Source: DRI Europe

As a result, production of glass is expected to grow by 2.5% per year on average between 1992 and 1995. In 1992, production will grow more slowly as the economy progressively recovers from the 1991 slowdown. In the medium run, production will grow at about 3.5% per year.

The industry is represented at the EC level by: Comité permanent des industries du verre de la CE (CPIV). Address: Avenue Louise 89, B-1050 Brussels; tel: (32 2) 538 4446; fax: (32 2) 537 8469.

Ceramic goods
NACE 248

The ceramics industry, including the production of construction materials such as tiles and sanitary ware, tableware and ornamental ware, and special ceramics for industrial use, experienced steady growth from 1984 to 1990. 1991 was marked by a standstill in EC production of ceramic goods, and by a sharp increase in import penetration.
The prospects the sector are weak. The market for tableware and ornamental ware will continue to be unfavourable and although the market for ceramic tiles and sanitary ware has stabilised, no real improvement is expected in the short-term.

INDUSTRY PROFILE

Description of the sector

Ceramic products are classified under NACE 248, which includes a number of heterogeneous industries. This chapter will focus on the following main subsectors: tiles for floors and walls (248.3); sanitary ware (248.5); tableware and ornamental ware (248.6, 248.7); industrial ceramics (248.8); refractory products (248.1). Although bricks and roofing tiles are a type of ceramic good, they are classified separately in NACE 241.

In its broadest sense, the ceramic industry encompasses any industry which manufactures products based primarily on clay minerals which, after forming and drying, are subjected to high-temperature firing. Classified according to use, the main products are: materials for construction (tiles, sanitary ware, bricks and roofing tiles); tableware and household goods (tableware, household articles and ornamental ware); products for electrical, electronic, mechanical and other uses (insulators and electrical insulating parts, products for chemical use, specialised and advanced technical ceramics); refractories and heat-resistant products; products for drainage and channelling (stoneware pipes).

Main indicators

In 1991 all the main indicators for ceramic goods showed a standstill, compared to 1990. This slowdown was mainly due to the weak growth of the building sector, which is the main client of the ceramic goods industry. Ceramic tiles, tableware and ornamental ware are the most important product lines in the sector.

Recent trends

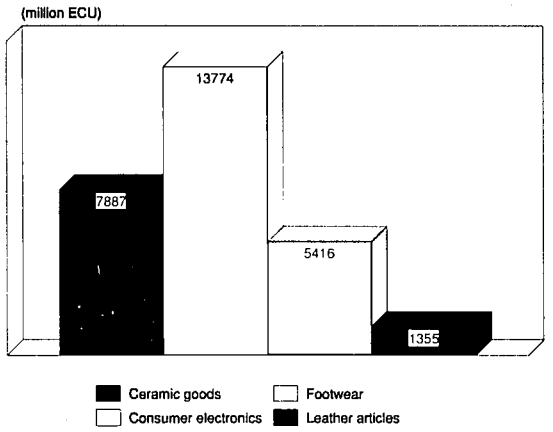
After a period marked by stagnation, which affected in particular those sectors dependant on the construction industry (tiles, sanitary ware), sales picked up from 1984 and continued to grow steadily until 1990. 1991 saw a decrease of real production. Average real annual production growth from 1985 to 1991 was weak (2.2%), while the correspondent figure for consumption was 3.2%. The faster development of consumption was accounted for both by growing extra-EC imports and by an EC industry that was primarily concentrating on its domestic market. The decrease of extra-EC exports in real prices was 0.6% on average annually for the period 1985 to 1991, while imports increased by 7.3%.

The number of people employed by the industry remained almost stable since 1986, yet reached its lowest level for the last decade in 1991, with 250 600 people employed.

International comparison

The EC is the world's largest ceramics producer. Over the last decade, Japan recorded a spectacular production growth. The international comparison differs according to product line.

Figure 1: Ceramic goods
Value added in comparison with other industries, 1991



Source: Eurostat

Japan is the world's leading producer of tableware and ornamental ware, followed by China, South-Korea, Central and Eastern Europe. In the tiles market, a rapid growth in production capacity is taking place in South-East Asia and in the East European countries, while Brazil claims to be the second world's largest producer.

Foreign trade

The external balance of trade in the EC was positive throughout the 1980s and after a record year in 1989, declined by 1991 to 2.04 billion ECU. While extra-EC exports stagnated in 1991, extra-EC imports surged, resulting in a sudden drop of the export/import ratio, which had so far remained stable.

EC exports of ceramic goods are mostly destined to the EFTA countries (22.6% in 1991), closely followed by the USA (19.6%). Exports to the OPEC countries are not negligible. Imports increasingly originate from China (15.8% in 1991 compared to 3.5% in 1986), while the share of the EFTA countries remained the highest (22.1%).

Extra-EC exports as a share of production remained particularly stable between 1982 and 1991, at 19.1% in 1982, increasing to 20% in 1991. The share of extra-EC imports in

EC consumption increased from 6.6% to 7.1% between 1982 and 1990, and sharply increased to 8.4% in 1991.

MARKET FORCES

Demand

The products of the ceramics industry find their uses in a large number of different sectors and applications.

Ceramic tiles are used in both private, public and industrial structures and buildings. Demand for the tile industry is largely dependent upon the activity in the construction sector. The renovation of older buildings is still providing market opportunities for the sector, even if the general situation in the building sector is not too bright at present.

The tableware and ornamental ware subsector encompasses a broad range of equipment and decorative articles for households, hotels and public institutions. The subsector was better able to resist the economic depression of the crisis years than many other subsectors of the ceramics industry. The excellent market penetration of extra-EC exports during the 1980s was due to a large extent to the exporting of products in the top-quality range.

The demand for the ceramic sanitary ware industry, which produces for both private and public use (hospitals, hotels, etc.), is to a large extent determined by the construction sector. Besides the general situation in the building sector, the changing lifestyle whereby increasing importance is attached to bathrooms is an important factor for the sanitary ware subsector.

The products of the industrial ceramics subsector are used for electricity distribution networks (ceramic insulators), electronics, motor vehicles, telecommunications and mechanical construction (advanced ceramics). The cut-backs, especially in the nuclear energy field, of planned extensions to the electrical distribution networks led to a considerable reduction in the EC insulator industry's activity. The market for advanced ceramics, on the contrary, covers a growing number of applications, with an estimated 75% of activity in the electronics sector in 1989.

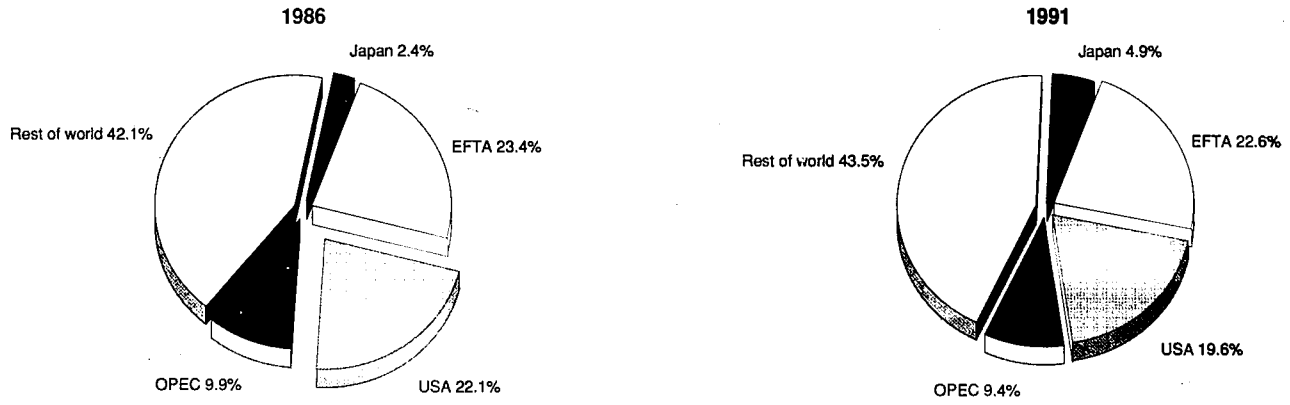
Figure 6: Ceramic goods
Destination of EC exports



Source: Eurostat

Refractory products which can withstand high temperatures and hot or cold physical or chemical action, are mainly consumed by the steel, ceramics, non-metallic minerals, chemicals, petrochemicals, non-ferrous metals, and energy sectors. The technological advances in the iron and steel industry (i.e. the increased use of the continuous casting process, which uses less refractory bricks) will bring about a gradual reduction in the amount of refractory products consumed.

Supply and competition

To improve their competitiveness, EC enterprises have in recent years shifted towards increased specialisation in the high value-added product range and in highly technical products, which require greater research and development resources. EC enterprises progressively gave up the lower end of the market to external competition. On the whole, imports from third countries increased sharply in 1991, with an average penetration rate of 8.3%..

The EC is the world leader in the subsector of ceramic tiles, and has gained new export markets in recent years. Although imports from Brazil, Asia and Eastern Europe have increased, the export/import ratio for tiles remains very high (about 9.5 in 1989).

The tableware and ornamental ware subsectors have been subject to growing competition from non-EC manufacturers since 1986. On the other hand, exports of tableware and ornamental ware strongly increased during the 1980s, with excellent market penetration of top-of-the-range products, particularly in the USA. Competition of alternative products such as glass and plastics continues to be limited to specific outlets.

In the sanitary ware subsector, competition from substitute materials (plastics, stainless steel) has hindered the further development of the market share of the ceramic products. Also, external trade has declined because EC producers have concentrated on the internal market, responding to competition by developing top-of-the-range products, while developing countries are acquiring competitive industrial units and developing an export-oriented policy.

The ceramic insulators sector suffers from the development of capacity in other countries such as Japan which is presently the world leader in production. The industry also faces growing competition from substitute materials (toughened glass, composites and synthetic materials). The advanced industrial ceramics sector on the other hand is a rapidly growing industry, where an increasing number of new enterprises is entering the market and where existing producers are stepping up their capacity.

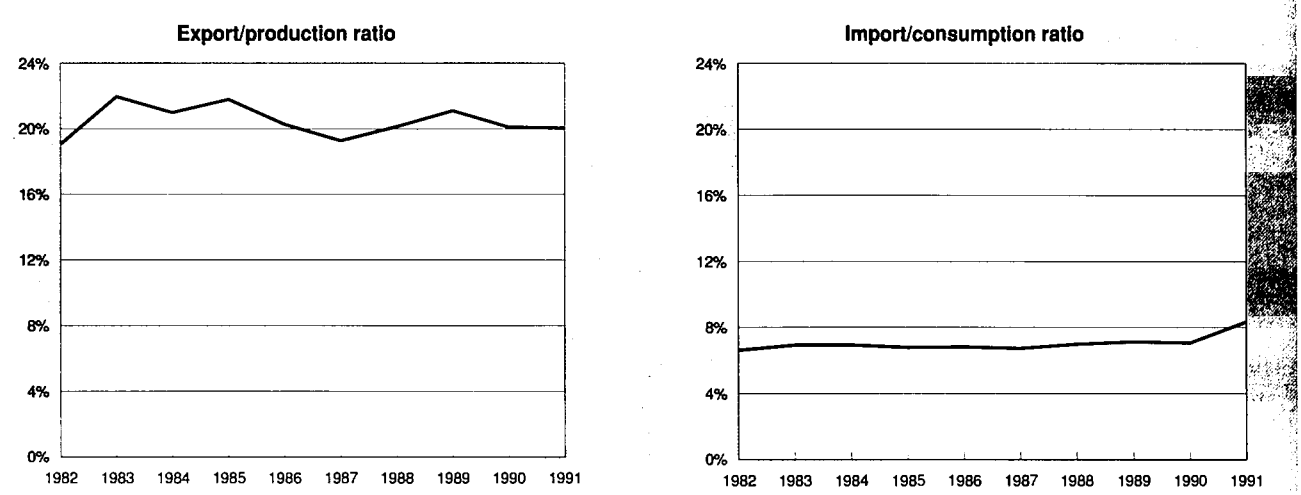
Figure 8: Ceramic goods
Trade intensities



Source: Eurostat

Production process

The industry consists of a wide range of activities, which are carried out by firms of all sizes. Consequently, productivity levels vary considerably across subsectors. Technologically advanced firms co-exist with traditional labour-intensive enterprises.

Overall, the ceramic industry is highly labour-intensive, with labour costs accounting for 35% to 60% of production costs, depending on the subsector concerned. Labour productivity increased slower than unit labour costs over the period 1982 to 1991, yet total unit costs have increased even faster than labour costs.

In both the tiles and sanitary ware subsectors, standardisation, the introduction of new technologies and of automated lines have modernised production and increased competitiveness in recent years. In the tableware and ornamental ware sector, mechanisation been implemented for certain steps of the production process.

INDUSTRY STRUCTURE

Companies

The ceramic industry is composed of a large number of small and medium-sized companies, particularly in the tableware and ornamental ware subsector. Technological change and the depressed economic situation during the last decade brought about a reduction of the number of enterprises and employment. While in 1982 the EC industry comprised some 2 800 companies in 1980 with about 320 000 employees, it is estimated that 1989 there were approximately 2 300 companies employing about 254 600 people.

A few enterprises operating at the EC level are:

- Sanitary ware: Ideal Standard (F) and Sphinx (NL);
- Bricks: Redland (UK);
- Refractories: Didier-Werke (D) and Hepworth (UK);
- Technical ceramics: Morgan (UK), Atochem (F) and Hoechst Ceramtec (D);
- Tableware: Villeroy & Boch (D), Royal Doulton (UK) and Hutschenreuther (D);
- Ornamental ware: Royal Doulton (UK);
- Wall/floor tiles: Villeroy & Boch (D), Riwal Ceramiche (I), Marazzi Ceramiche (I), Sphinx (NL) and Fabresa (E).

Strategies

Thanks to intense research and development activity and considerable investment during the last two decades, the ceramics industry has achieved a high degree of modernisation. New user requirements have led to new higher performance compositions being produced with new technologies.

Community tile products have achieved a worldwide reputation thanks to large investment in research and development and to their intrinsic quality and design.

Mechanisation of some steps in the production process of tableware and ornamental ware has led to considerable improvements in product quality, and at the same time has resulted in an increased concentration in the sector. Companies in the tableware and ornamental ware subsector, however, remain mostly small and medium-sized.

In the sanitary ware subsector, small and medium-sized firms have practically disappeared, having been taken over by large EC or non-EC companies. The trend towards concentration and internationalisation is expected to continue in the years ahead. Over the past few years, several leading companies have set up plants in countries with cheaper labour (Portugal, Spain and North Africa). All of the major firms are seeking to establish themselves in a wide range of product lines and markets, so as to offer wholesalers a extensive choice of products in keeping with the colour schemes for ceramic tiles or bathroom and kitchen furniture.

The EC ceramic insulator industry has declined and undergone sweeping restructuring since the early 1980s. Contrary to the insulator industry, the number of companies in the sector of advanced ceramics has grown at a pace matching the increasing number of highly technical applications. The tendency towards horizontal and vertical concentration continues at the EC level, particularly by the inclusion in large industrial groups of both producers and users of ceramic materials and products.

Regarding refractory products, rationalisation has pushed smaller companies out of the market and has lead to greater concentration.

REGIONAL DISTRIBUTION

Ceramic enterprises are scattered throughout the EC with strong regional concentrations for some products, particularly tiles, tableware and ornamental ware.

Though present throughout the EC, the tile industry (about 910 companies in 1989), is regionally concentrated in the Italian region of Sassuolo in the provinces of Modena and Reggio Emilia, where about 55% of EC production is located, and in the Spanish region of Onda (Castellon), which accounts for 27% of total EC production.

EC production of tableware and ornamental ware is dominated by two countries, Germany and Italy with 29% and 27% of EC production, respectively.

ENVIRONMENT

The ceramics industry is an energy intensive sector and, compared to the other sectors of the non-metallic minerals, relatively open to foreign competition. The application of an EC-wide tax on energy inputs for environmental reasons could have an important impact on the industry.

OUTLOOK

Modest growth rates are expected in the short and medium term. Demand for tableware and ornamental ware is stagnating and no improvement is expected in the short term. Sales of ceramic tiles will improve slightly due to renovation activity in the building sector. The economic development in the Länder of former East Germany will increase sales in this product line, although more pronounced on the medium term. The sanitary ware sector in particular will benefit from the same factors. On the whole, the industry is expected to grow at 1.2% annually in 1992 and 1993 with stronger growth anticipated thereafter.

Chemicals

NACE 25

The EC is the world leader in chemical sales, well ahead of its main competitors, the USA and Japan. After several years of solid growth, depressed prices and overcapacity characterised the performance of the industry in 1990 and 1991, against the background of a sluggish world economy. Current overcapacity (not only in Western Europe, but also in East Asia and elsewhere) will continue to depress profits for the next few years. Major opportunities exist for acquisitions and for the creation of strategic alliances.

INDUSTRY PROFILE

Description of the sector

The chemical industry is an industrial branch of very heterogeneous character in which the main activities consist of chemically transforming materials into diverse substances, giving them new physical and chemical properties. For these activities, the chemical industry employs raw materials from the petroleum, mining and extractive industries such as oil, minerals, metals, but also certain agricultural products. The main activities of the chemical industry correspond to the following product groups: basic chemical products; fertilisers and nitrogen compounds; plastic in primary form and synthetic rubber; pesticides and other agrochemical products; paints, varnishes, and other similar coating products; pharmaceutical and medical products; soaps and detergents, cleaning and polishing preparations, perfumes, toilet preparations; and man-made fibres.

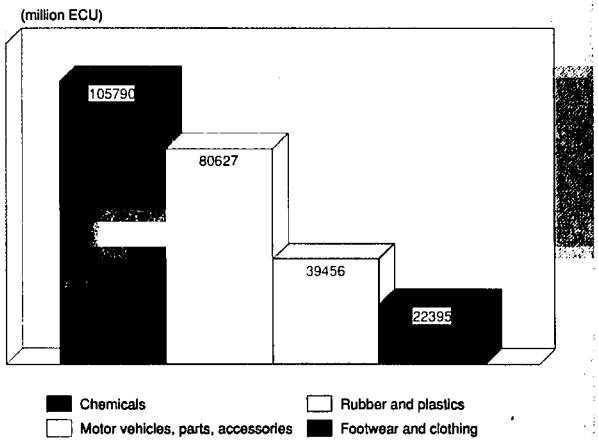
The industry comprises two upstream branches constituting basic chemicals (basic inorganic chemicals and basic organic or petrochemicals) and a series of downstream branches such as pharmaceutical products, agrochemicals, detergents, etc. The upstream sectors' outlets are almost exclusively the downstream sectors, which themselves supply either other industries (agriculture for agrochemicals, the plastics transformation industry for plastics in primary form), or the end-user (soaps and detergents, for example). Figure 9 gives a schematic overview of the chemical industry's production process.

Main indicators

Compared to the foregoing years, growth in all the main indicators in current prices was marginal in 1990 and 1991. 1991 was a particularly tough year, since the economic slowdown in many industrialised countries was compounded by the business distortions resulting from the Gulf crisis. With the key North American export market depressed, sales and profits in Europe were weak. Only pharmaceuticals lived up to its recession-proof reputation with a continuing strong performance: pharmaceutical companies net earnings and profits increased by 20% or more during 1991.

British, Italian and French companies were the first in Europe to resort to severe job cuts worldwide. The German economy only came to a standstill during 1992, much later than other EC economies, as until then, German companies were able to profit from increasing domestic demand. The German "big three" (BASF, Bayer, Hoechst) all started, though to a lesser extent, to shed labour in the latter half of 1991 and during 1992, in response to the weakness in their domestic and export markets.

Figure 1: Chemicals
Value added in comparison with other industrial sectors, 1991



Source: Eurostat

Recent trends

After a rapid expansion over the 1960s and 1970s, the first half of the 1980s was rather grim, with stagnant production and overcapacity which led to a drastic restructuring of the industry. The restructuring, accompanied by huge redundancies and cutbacks in capacity, enabled the chemical sector to start off from a much stronger base when the economic environment improved from 1983 onwards. The years from 1986 to 1989 were associated with high profits and strong expansion.

Prospects changed in 1990 with the economic slowdown in Europe and North America. Demand from the main clients weakened. The fall of the dollar and the yen led to losses in competitiveness on foreign markets. Imports grew, but exports stagnated. High energy costs also contributed to squeeze margins. With the exception of the pharmaceutical industry, profits started weakening in the first half of 1990. Since then, significant losses have been reported by many of the EC companies, as well as by their EFTA and American competitors.

International comparison

US production in 1991 stood at 85% of EC production, and Japanese production amounted to almost half of EC production.

US companies suffered declining sales and profits during 1991, with 60% of the companies showing sales and net profits lower than in 1990. On a weighted average basis, sales were down 2.4% and profits 13.5%, compared to 1990. Just as in Europe, the core of the problem was the overcapacity and the consequent falling prices of commodity chemicals, along with the specialties experiencing sliding demand, linked to the recession.

The development of the US chemical industry differs slightly from that of the EC. American companies have experienced high growth rates during the second half of the 1980s, not only thanks to an increase in domestic demand, but also due to increased exports. Thanks to the weak dollar, American competitiveness in basic chemicals was noticeably improved between 1985 and 1989. Consequently, American companies did not experience the same incentives as their EC counterparts to develop downstream in sectors less sensitive to exchange rate movements. One other reason why such diversification was not forthcoming in the USA, was the presence of important oil resources, one of the primary raw materials of basic chemicals.

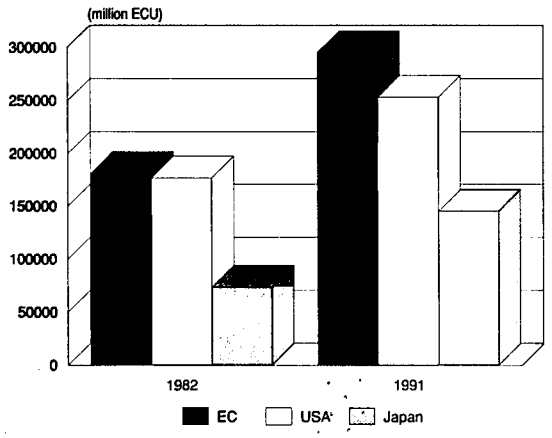
Markets for chemical products have developed fast, particularly in East Asia, but also in Brazil and the Middle East. Although the opportunities for the EC chemical industry are clear, new producers have appeared in these regions. The major share of world production, however, by far remains in the hands of European and American groups.

Foreign trade

The EC is the world's leading exporter of chemical products, with exports more than twice the size of those of North America. In 1991, EC companies exported more than 16% of their production outside of the EC. Traditionally, the EC has a trade balance surplus (along with the EFTA countries). The surplus, however, has been deteriorating since 1986, following the fall in the US dollar.

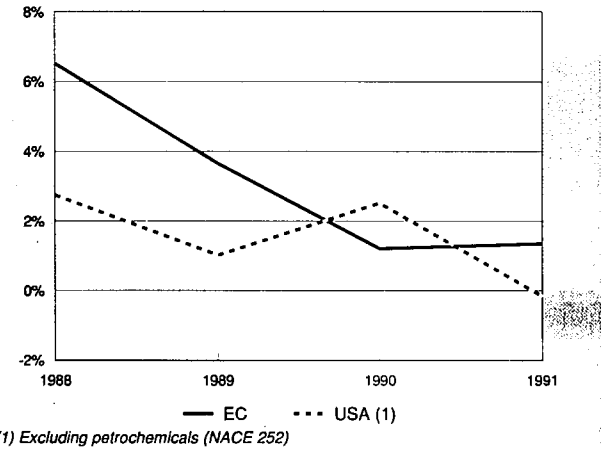
Overall, EC exports are specialised in refined chemicals, while imports are in basic chemicals. To a certain extent, the EC imports basic chemicals in order to export refined chemicals.

Figure 4: Chemicals
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers, US Chemical Industry Associations

Figure 5: Chemicals
International comparison of production growth at current prices



(1) Excluding petrochemicals (NACE 252)
Source: Eurostat, Census of Manufacturers, US Chemical Industry Associations

Competitive discipline created by imports is therefore higher for basic chemicals than for refined chemicals.

The main destination for EC chemicals exports are the EFTA countries, the USA, the developing countries, and to a lesser extent the Pacific region, including Japan, Australia and New Zealand. Compared to the average EC trend, it appears that Germany and Denmark are more oriented towards Western Europe. The United Kingdom and Ireland export more towards North America, while the proportion of exports towards developing countries is higher in France, Spain and Portugal than in the other EC countries.

MARKET FORCES

Demand

About 70% of chemical product demand stems from industry in the form of intermediate consumption. The principal client sectors of the chemical industry are the plastics transformation industry, the textiles industry, agriculture, and the chemical industry itself, which represents more than 30% of its own demand. This considerable self-consumption is explained by the high degree of industrial vertical integration in which the downstream elements, refined chemicals or specialty chemicals, are the almost exclusive outlets for components situated upstream, i.e. the basic chemicals.

The strong expansion of the chemicals sector over the last two decades can be explained in part by factors such as innovation and the replacement of traditional materials such as steel, wood, paper and glass by new materials derived from chemical processes. This substitution factor has enabled the chemical industry to experience premium growth rates, at a level much higher than the average manufacturing growth rates (10% compared to 2% over the period 1970-90). More recently, the contribution of this factor in the growth rate of the chemical industry has diminished, marking the industry's progressive evolution towards maturity.

In 1991, weakening demand accompanied by the cyclical slowdown in the European economies led to a decline in bulk chemicals' production. Similarly, the recession in North America hampered further export growth. Some industry analysts believe that the recession can be traced back to as far as 1988 when growth in the chemical industry outstripped both GDP at 2.3% and other manufacturing industry at 1.8% (average industry growth over 1980-90 was 3.4%). In 1988 the difference was much larger, with second-half production almost 7% higher than the preceding year's, while GDP was up near 3% from the second half of 1987. The result of the explosive growth was the build-up of large stocks in the chemicals chain. Sizeable destocking occurred during the first half of 1990, and then again in the first half of 1991.

Demand in other sub-sectors of the chemical industry continues to be high, such as in pharmaceuticals and in some of the specialty chemicals, which showed steady production growth.

Many EC producers that have established operations within the USA, in response to the unfavourable exchange rates during the 1980s, have now pinned their hopes on the recovery of demand on this market, as the two engines of growth for the USA industry - the automotive and construction industries - have shown signs of encouragement early in 1992. Yet industries' expectations remain cautious because consumer lead recovery is doubtful, with consumer spending not rising despite lower interest rates. Another reason for the lack of optimism, despite early signs of recovery of the US economy, is the presence of sizeable overcapacity in the basic chemicals and polymers sectors.

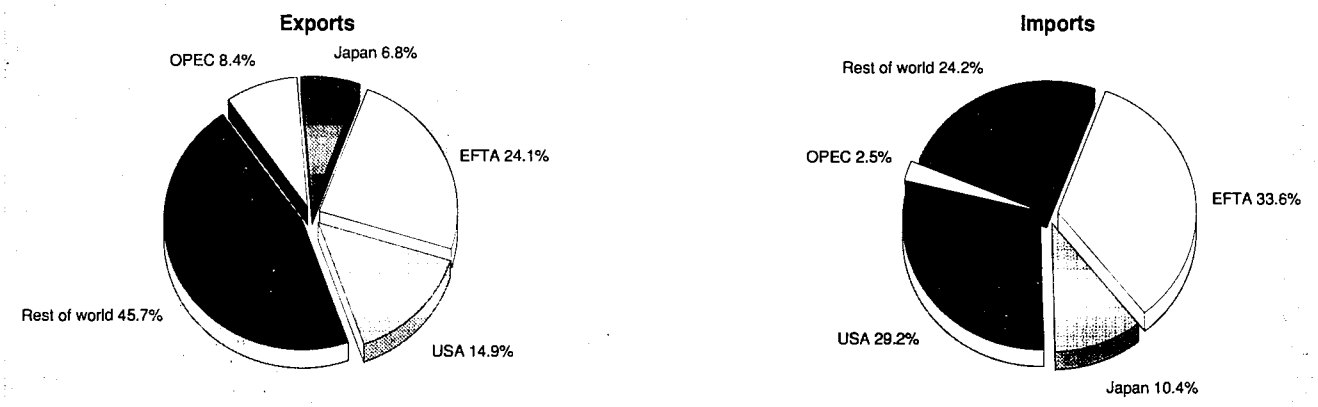
Another important factor in the creation of demand is the continuous effort towards product innovation. EC companies spent around 4.8% of their turnover on R&D in 1990. In specific sectors of the pharmaceutical and agrochemical industry, this percentage can amount to more than the double of that figure. The most innovative fields of R&D include bio-technology and new materials (advanced composite materials, polymers, plastics and ceramics). As a general tendency, R&D efforts are more and more focusing on transformations of existing products rather than on true discoveries.

Supply and competition

The future of both bulk and specialty chemicals is clouded by mounting competition. These sectors will increasingly have to focus on higher value-added and more specialised market segments in order to maintain margins. The pharmaceutical industry will continue to benefit from rising standards of living and growing concerns for health.

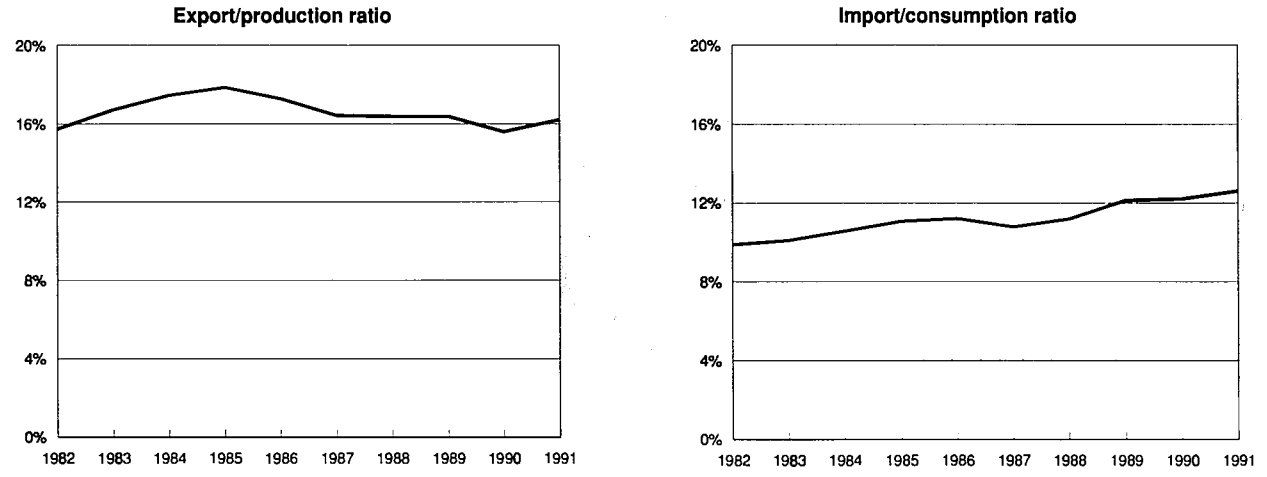
In basic chemicals, a remarkable part of demand is directed to foreign markets. Export intensities amount to 50% in Germany and the United Kingdom, and around 60% in France. Export markets were hit by the fall of the dollar that increased US competitiveness on markets with low or no product differentiation and high competition. The squeeze in profit margins was emphasised by the upward pressure on oil prices during the Gulf War, although these came down shortly afterwards. Also pharmaceuticals have been losing market share

Figure 6: Chemicals
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

Figure 7: Chemicals
Trade intensities



Source: Eurostat

on export markets since 1987. In terms of competitiveness, the specialty chemicals sector is in better shape than the basic chemicals sector. Profit margins, however, shrank in 1991, as a result of growing input and unit labour costs.

Oil and other raw material prices are expected to rise at most only moderately, yet chemical producer's prices are expected to be weak in some sectors and in some countries, leading to unsatisfactory margins.

Production process

The EC chemical industry employs almost 1.8 million people, i.e. about 7% of the EC's manufacturing industry employment. The majority of employees in the sector has a high level of qualification and training. Since 1974, the sector has had a diminishing labour force, but the upturn in production levels since 1984 has led to a stable employment number. Productivity shows only an average annual growth rate of 3.5%, while in the past this rate was usually above 5%. This phenomenon probably relates to the maturing of the industry and its greater portion of higher value-added production, characterised by lower production volumes.

The greatest proportion of investment expenditure is at present directed towards productivity improvement, new product introduction, improvement of production processes and environment. In contrast to investment level growth in nominal terms of about 10% over the 1985-89 period, investments have declined in 1991. The level of improvement expected by CEFIC is not enough to halt the decline in investments in 1992.

The sector is also a big energy user. The energy use is rather concentrated in the upstream basic chemicals sub-sector. The biggest energy user is the petrochemical sector, with electricity and hydrocarbon consumption, including the use as raw material, of 35% to 40% of production costs. Other sectors with high energy contents are plastics (20% to 25%), inorganic chemicals and fertilisers (each about 15%). The refined chemicals sector is a relatively small energy consumer, but since the basic industry is its main supplier, it is bound to be affected indirectly by energy price rises. Profitability of basic chemicals is more vulnerable to oil price increases than that of specialty chemicals, since the first one can only with more difficulty pass price rises to consumers, being subject to relatively harsher competition.

INDUSTRY STRUCTURE

Companies

Seven of the world's top ten chemical companies are EC based. With about 46 000 enterprises (including small enterprises, with less than 20 employees) in 1988, the chemical industry remains a concentrated sector, with 5.3% of the enterprises representing 83.4% of turnover. The top ten leading EC companies represented 48.6% of total turnover of the industry in 1990, with the top 5 companies taking 32.6% of turnover.

Strategies

During the 1980s, larger companies were moving into specialty chemicals in order to improve margins and profitability. Merger and acquisition (M&A) activity leading up to the Single Market has been intense, concentrating almost exclusively on downstream chemicals (plastic containers and film, specialty chemicals, pharmaceuticals, cosmetics, fertilisers) with the objective

Table 5: Chemicals
Breakdown by size of enterprise, 1988 (1)

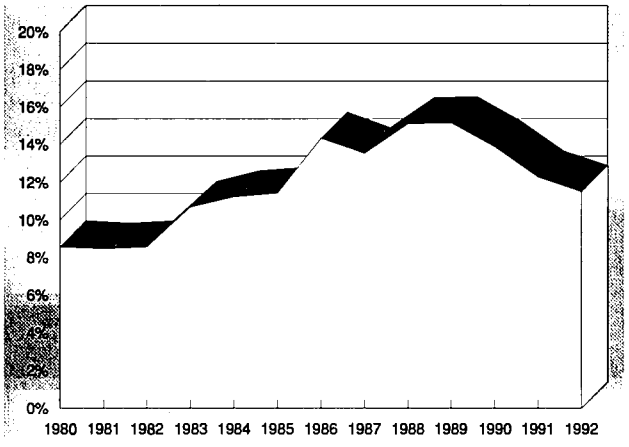
of strengthening and expanding market share. Also, the fall in the dollar exchange rate has encouraged EC companies to undertake major investments in the USA during the second half of the eighties.

In 1990, M&A activity subsided as a result of the uncertainty caused by the Gulf War, the fall in profit margins and the higher interest rates that made funding more expensive. Also 1991, which was influenced by cost reductions and rationalisations, was a quiet year for M&A activity. Fewer big deals were signed than for instance in 1989, for the same number of transactions. A lot of businesses were for sale, however, because chemicals groups considered refocusing their activity upon their core businesses, and selling off of long established acquired businesses that never or no longer fulfilled their promise in terms of profitability. These companies were facing the problem of insufficient buyer interest.

In terms of sectors, pharmaceuticals and specialty chemicals led the M&A scene in 1991. Geographical patterns in M&A still show a preference for Western Europe in terms of chemical acquisitions, which represented 57% of the total in 1991. Transactions in Eastern Europe increased slightly in number to 3% of the total in 1991, and still focus interest from Western countries thanks to the ongoing privatisation process. With a view to investments in Eastern and central Europe especially, which at first sight look like bargain opportunities, companies have realised that successful acquisitions must be based on true economic value, pointing to the importance of starting to take into account environmental expenditures required by national governments.

Figure 8: Chemicals
Pre-tax profits (1) to turnover of the industry (2)



(1) Profitability is measured by the % share of the industry's operating surplus divided by the value of production
(2) For BR Deutschland, France, Italia and United Kingdom only
Source: DRI Europe

REGIONAL DISTRIBUTION

Proportionally to GDP, Spain, Belgium, Luxembourg, the Netherlands and Ireland have chemical industries bigger than that of other EC countries. With regard to product segmentation, the German, Dutch and French industries are more oriented towards basic chemicals and plastic materials, while the United Kingdom and Italy have a greater share of pharmaceutical and a few other every day consumer products.

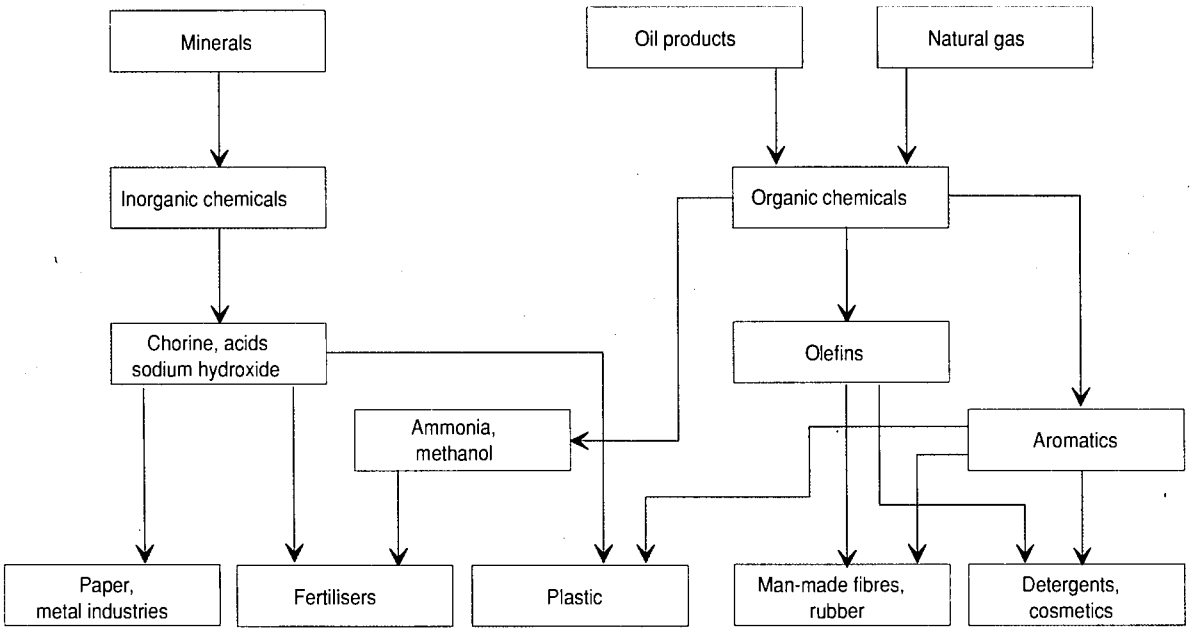
Figure 2 shows that Germany is by far the largest EC producer in terms of value added, representing one third of EC value added. France takes the second place, followed in that order by the United Kingdom and Italy.

ENVIRONMENT

Environmental problems are particularly noteworthy in the case of the chemical industry. Environmental costs represent some 3.5% of turnover for major European chemical companies, and 15% of new investments. This latter percentage will increase to 20% or more in the decade to come.

The problems raised by the chemical industry with regard to the environment can be separated into the pollution caused during the production process, and the downstream pollution occurring during consumption and disposal of the industry's final products. In the first area the industry is emitting harmful substances into water bodies and into the air, for example NOx and SO2, causing acid rain. The industry is also confronted with the scarcity of tipping sites to deposit solid waste. With respect to global environmental pollution, as a big energy user, the industry is a big emitter of CO2, one of the gases contributing to the greenhouse effect. The industry has solidly opposed a tax on energy use or on the carbon contents of the fuels used, proposed by the EC Commission as a means to achieve stabilisation of CO2 emissions at the turn of the century. Industry resistance has shifted to acceptance that a tax might be necessary, but under the condition that it should be implemented internationally. In the area of the environmental auditing of industrial installations, the industry has largely accepted the core principles of an EC Commission

Figure 9: Chemicals
Production process



Source: Eurostat

proposal on eco-audit, according to which industry would voluntarily allow such audits, checked by accredited auditors.

Pollution linked to the use of chemical products can happen either at the time of actual use or at the time of disposal of solid waste. In the first case, examples relate to the use of solvents in paints and adhesives, and to the contamination of water tables by nitrates in fertilisers. In the area of solid waste disposal, the industry is faced with the successful implementation of plastics recycling infrastructure within 10 years, according to the EC proposal on packaging waste. This will stretch the plastics industry, as the recycling of plastics is generally less advanced than that of other materials used for packaging, such as paper and board, glass or aluminium.

REGULATIONS

The main legislative measures by which the chemical industry hopes for rapid progress on the road to harmonisation cover the following areas: standards, bio-technology, environment, energy, indirect taxation, fewer administrative constraints, transport de-regulation, R&D, competition, and trade policies.

Concerning trade regulations, in the framework of the Uruguay round of the GATT negotiations, much work was devoted to the tariff negotiations. CEFIC, in a joint initiative with its US and Canadian counterparts, advocates the harmonisation of chemical trade tariffs at 5.5 or 6.5% and the allowance of up to 15 years to bring existing tariffs down to this level. Other trade issues include export controls in extra and intra Community trade, the treatment of anti-dumping complaints, and the generalised system of preferences.

Internal market issues include the support of CEFIC for the EC Commission DG XXI proposal on indirect taxation in order to arrive at a truly harmonised system throughout Member States, minimising bureaucracy.

OUTLOOK

Prospects for 1992, although perhaps showing some improvement over 1991, are not too bright: a low increase in production is expected together with limited growth in the world economy. Signs that the US economy will pick up remain mixed. High real interest rates are a constraint in western Europe, where both consumer and industrial confidence remain weak. Demand could start to revive in 1993 as interest rates are reduced and confidence is regained, leading to a pick-up in consumer spending. Any small increase in output will be driven by advances in pharmaceuticals and in cosmetics/perfumes activities. Production is likely to be flat in other areas, and continues to decline further in fertilisers. Prospects in the medium term are somewhat brighter, based upon a revival of world economic activity.

Basic industrial chemicals
NACE 251, 252, 253

The basic chemicals sector has recently been suffering from weakening demand and stiff competition from both North America and the newly industrialised countries. During the second half of the 1980s, export markets for basic chemicals were hit as the fall of the US dollar increased the competitiveness of North American producers. This squeezed profit margins, which was later emphasised by the upward pressure on oil prices during the Gulf war.

INDUSTRY PROFILE

Description of the sector

The basic industrial chemicals sector includes units exclusively or primarily engaged in the manufacture of inorganic chemicals (including fertilisers), electrochemical products, organic chemicals (including those obtained from petroleum and coal), synthetic rubber and plastics materials, mineral pigments and organic dyestuffs, isotopes etc., and in the distillation of tar and benzole. In this classification are considered not only the units producing such basic chemicals but also those units which both produce them and process them into finished products.

The data presented in this monograph correspond to the three NACE classes 251, (the manufacture of basic industrial chemicals and further processing of these products), 252 (the manufacture of chemicals obtained from petroleum and coal) and 253 (the manufacture of other basic industrial chemicals). Given the high degree of vertical integration of the chemical industry, it is difficult to provide separate data for each subcategory.

Given the relative importance of the petrochemical sector (it accounts for more than the half of the basic industrial chemicals turnover), a specific monograph based on data provided by the relevant association follows.

Finally, in this monograph particular attention is given to the plastics manufacturing sector, which accounts alone for about a quarter of total basic industrial chemicals employment.

Main indicators

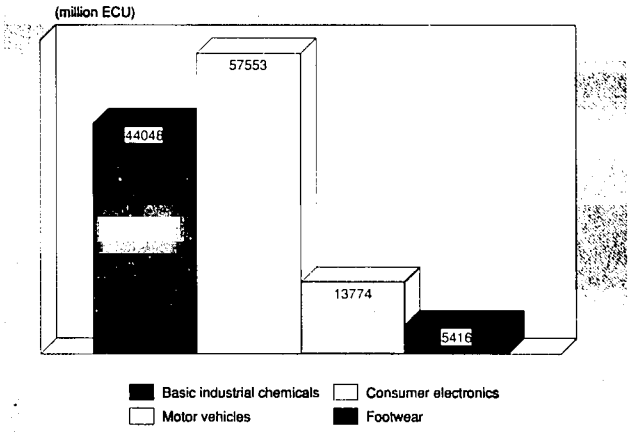
After steady growth in the first half of the 1980s, all the main indicators were affected by a sharp decline in 1986. Due to the fall in crude oil price and a weakening of the exchange rate of the US dollar, production and consumption decreased by about 4.2% and 2.5% in volume terms respectively. The continuing slowdown of the European economies in 1990 and 1991, as well as the recession in the USA and Canada, depressed demand of basic chemicals. During the 1990-1991 period, production in volume terms decreased of 3.2% and consumption of 1.4%.

The reduction in basic chemicals employment, which started in the early 1980s is still going on. During the 1982-1991 period employment in the sector decreased of about 45 000 units.

International comparison

The EC is the world's largest basic chemicals producer although it is by a narrow margin. In 1991, EC production was about 2% higher than that of the USA, a margin that has more or less remained steady throughout the 1980s. Japan ranks third in the world basic chemicals market, but its production is half the size than the EC and US ones. The importance of the newly industrialised countries (NICs) is steadily growing, and their competition is affecting the position of the EC industry on the world market.

Figure 1: Basic industrial chemicals
Value added in comparison with other industries, 1991



Source: Eurostat

In the period 1988-1991, production growth slowed in the EC, the USA and in Japan. Among the three main producers, the EC basic chemicals industry was the most badly affected, due to weakening demand at home. The US industry was also hit by the recession, while Japan was able to maintain a positive, although decelerating, growth rate in production.

Foreign trade

The EC trade balance in the basic chemicals sector steadily decreased during the 1980s because of rising imports and weak exports; in the period 1982-1991, extra-EC imports doubled, whereas extra-EC exports increased by about 55%. Moreover, all of these gains in export markets were made in the period 1982-1985, after which time exports have stagnated. The export/production ratio slightly decreased from 1985 to 1991, while during the same period the import/consumption ratio increased by 28%.

Export markets for the EC basic chemicals industry are well spread. The EFTA countries and the USA together account for about 42% of total extra-EC exports, and Japan for 7% only, while the remaining 51% is scattered around the rest of the world. As for extra-EC imports, they are more concentrated: about 57% of them comes from the EFTA countries and the USA and 8% from Japan.

MARKET FORCES

Demand

Industry demand represents about two thirds of basic chemicals sales, and more than 45% of this intermediate demand come from the speciality chemicals sector. Indeed, basic chemical products are mainly used as inputs in other chemical processes. The basic chemicals sector itself accounts for another 13% of its own sales, and the rubber and plastics sector for about 11%.

Plastics

The wide range of these properties and the tailoring of these properties for specific applications have led to a vast and diversified demand for plastic materials. The main outlets are to be found in the following industries: packaging, construction and civil engineering, transport equipment, household equipment, electronics, textiles, agriculture, health and medical applications, paper and wood, photography and armaments.

The sustained growth in demand for plastics is attributable to the improvement of the economic environment, and particularly to the favourable conditions prevailing in the end-user sectors such as the automobile and construction industries. Plastic materials usage to replace other materials in industrial and household goods production remains an important growth factor, although it is no longer the major one: often, plastic materials replace traditional ones such as glass or steel, as they are lighter and energy-saving.

Supply and competition

The European basic chemicals industry has a strong technological base, and it compares favourably with the US and Japanese industry from the point of view of research and development. This represents an important strategic condition for a modern industry which depends on the use of more and more sophisticated materials and technologies.

Plastics

Plastics manufacturers produce polymers and synthetic resins mixed with additives to form plastic materials. The main thermoplastic products are: low density polyethylene (LDPE), high density polyethylene (HDPE), polypropylene (PP), polystyrene (PS) and polyvinyl chloride (PVC). Thermoplastics represent about two thirds of total plastics production in Western Europe. By way of comparison, European production of these plastic materials is equivalent in volume terms to that of the USA and more than double that of Japanese production.

Plastic material manufacturers are not only raw materials manufacturers: they also help the entire plastic products sector by contributing to the technical and commercial development of plastics applications. Mass market plastics, which represent more than two thirds of total plastics production, have played a vital role in the plastics industry since the Second World War. However, they have been hit by sharp oil price rises and by the economic downturn during the period from 1975 to 1983, which led to production overcapacity. The mass market plastics industry has actively rationalised and restructured over the past years, notably between 1982 and 1984, adjusting production capacities and obtaining cost reductions. The more recent years have brought an upturn in demand and profits, but 1990 and 1991 have again seen problems.

Production process

Petroleum products and first oil derivatives are used both as raw materials and as an energy source by the basic chemical sector. Fuel and power products represent the major input costs for the basic chemical industry. Therefore, profits in the industry depend to a large extent on oil prices. Figure 8 shows the slump in profits which followed the Gulf crisis.

High capital investments in machinery and technology are essential in this industry and represent, along with the availability of raw materials, a significant entry barrier. High competition, low product differentiation and heavy environmental constraints also increase the difficulties of the basic chemicals activity.

Any further increase in capacity will probably be cautious, taking account of the experience of the last decade; investment plans are mainly directed towards new processes and product development, as well as towards productivity improvements in order to maintain the industry's competitiveness. Finally, factors determining investment seem to be linked more and more to the environment, notably in areas such as waste management, and public acceptance of chemical products and chemical industry activities.

INDUSTRY STRUCTURE

Companies

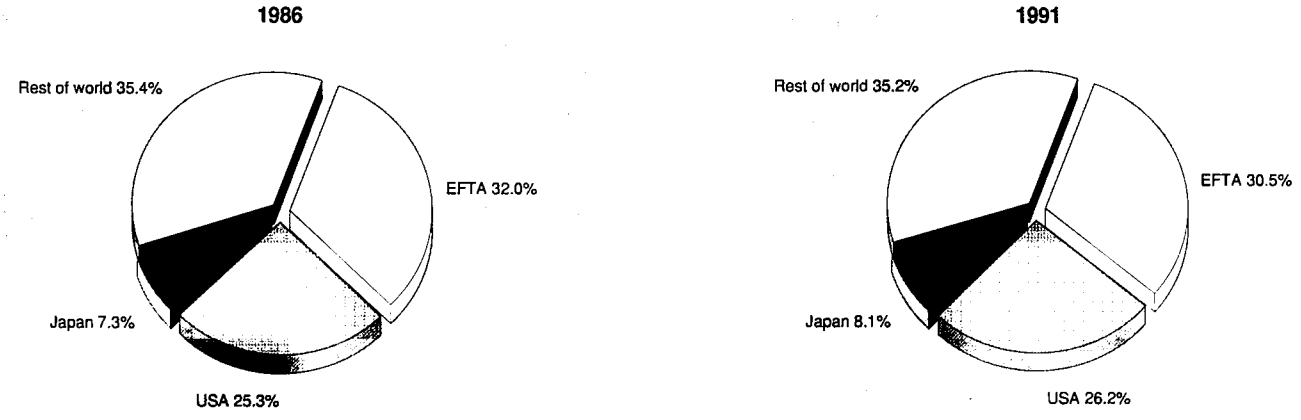
Concentration is clearly higher in the basic chemicals sector, the exclusive domain of large companies, as opposed to refined chemicals. For example, in Germany, six producers share 80% of inorganic chemical production. Competition is however much more intense than might be believed from the strong concentration. The industry experiences a high potential for competition among the present producers on the market and the threat of the arrival of new competitors (e.g. from the oil-producing countries and South-East Asia).

Among the leading EC producers in the field of basic chemicals are six firms: BASF, Hoechst and Bayer (D), ICI (UK), Rhône Poulenc (F) and Enichem (I). Other main European basic chemicals companies are the Swiss Ciba-Geigy, Sandoz and Roche, the Finnish Neste, the Swedish Dyno Industrier and the Norwegian Norsk Hydro.

Strategies

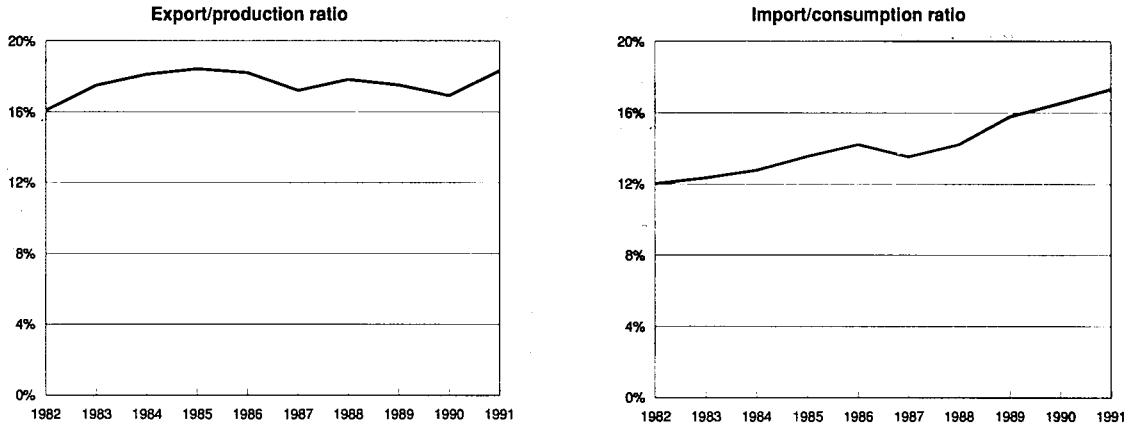
During the 1960s and up to the middle of the 1970s, the basic chemicals groups strategy aimed at increasing output and capacity. The 1970s economic crisis highlighted the need to restructure the industry. Company strategies were consequently modified along three main lines: first, product ra-

Figure 6: Basic industrial chemicals
Origin of EC imports



Source: Eurostat

Figure 7: Basic industrial chemicals
Trade intensities



Source: Eurostat

tionalisation, which led to major redundancies; second, increasing installation size, in order to benefit from economies of scale; third, merger and acquisition (M&A) activity in Europe and the establishment of joint-ventures in the rapidly growing Asian markets.

In 1991, the main M&A operations were the following: Hoechst (D) acquired Colorplast (D), a manufacturer of pigments for colouring plastics; LVM (NL) acquired Cousin Tessier (F), which operates in plastic and thermoplastic rubber compounds; Metallgesellschaft (D) acquired Dynamit Nobel (D), a plastic manufacturer.

On the joint ventures side, in 1991 Courtaulds (UK) and Formosa Plastics (Taiwan) agreed on a polypropylene packaging film technology and marketing deal; Hoechst (D) and Mitsubishi Kasei (J), started common manufacture and sale in Germany of polyethylene terephtalate (PET) film for magnetic tape applications; finally, Repsol Quimica (E) and the Algerian Enip established a joint-venture for the construction of a HDPE plant at Skikda, Algeria.

ENVIRONMENT

Environmental problems are of particular importance to the basic chemicals industry. The industry itself is well aware of the pollution problems of which it is directly or indirectly responsible and has already undertaken important efforts, often ahead of legislation. For the moment, the investment expenditure aimed at fighting various forms of pollution linked to production processes represents up to 10% of the sector's total investment. It is expected that this percentage will double during this decade.

As far as plastics are concerned, the main environmental issues are the consequences of plastic contact in the case of medical or food applications, plastic safety with regard to fire and the ecological consequences of plastic usage. The recycling of used plastics is being developed, although this process still remains relatively expensive when the extra cost of waste sorting and the plastic recycling itself is taken into account.

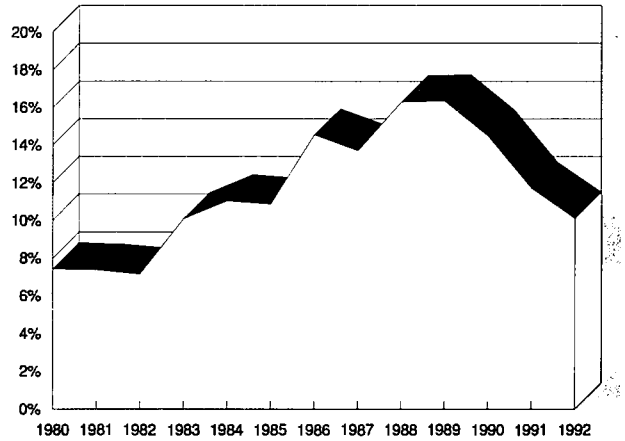
Finally, battles continue to be fought over proposed EC legislation concerning the movement of toxic waste inside and outside Member States. The Environmental Council which took place in May 1992 again failed to reach a consensus. The aim is for EC Member States to ratify the international Basle Convention on the control of cross-border movements of hazardous wastes and their disposal, which has five broad goals:

- to minimise the generation of hazardous waste;
- to keep cross-border movements of hazardous waste to a minimum;
- to achieve national self-sufficiency in disposal;
- to ensure the informed consent of the receiving country before shipping hazardous waste;
- to end trade of hazardous waste with countries which have not agreed to the Convention.

REGULATIONS

Trade regulations are of vital importance to the basic chemicals industry given its dependence on foreign trade as a source of income. Recent years have seen the active participation of the EC basic chemicals industry in all GATT trade negotiations. The main issues under current debate are the following: improved market access for EC firms which might

Figure 8: Basic industrial chemicals
Pre-tax profits to turnover



(1) Profitability is measured by the % share of the industry's operating surplus divided by the value of production
(2) For BR Deutschland, France, Italia and United Kingdom only
Source: DRI Europe

be obtained with the harmonisation of chemical tariffs; stronger intellectual property protection through GATT; and prohibition of the most trade distorting practices. However, an important focus of the negotiations has been devoted to tariffs. A joint framework agreement for tariff harmonisation in the Uruguay Round has been reached, which provides for tariff harmonisation at 5.5% or 6.5% and allows up to 15 years to bring tariffs down to the harmonised level.

OUTLOOK

The future of the basic chemicals industry is clouded by rising competition from producers in other parts of the world, particularly in developing countries. EC companies will continue focusing on higher value-added activities, progressively abandoning the less specialised market segments. A renewal of the sector with rapid growth rates is not likely in the near future.

Petrochemicals
NACE 252

The petrochemical industry represents more than one half of the basic chemical sector and a quarter of the total chemical industry turnover.
The sector is suffering from reduced profitability after the buoyant growth experienced during the 1987-1989 period. Although the industry is facing depressed demand and is threatened by global overcapacity, petrochemical companies are pursuing their modernisation efforts.

INDUSTRY PROFILE

Description of the sector

Petrochemicals is defined as the industry which uses raw materials derived from oil or natural gas to manufacture the following products:

- primary petrochemicals: unsaturates (i.e. ethylene, propylene, butylene, butadiene, acetylene), aromatics (i.e. benzene, toluene, xylenes, naphtalene), methanol, ammonia, carbon black;
- petrochemical intermediates: ethylene, vinyl chloride, acrylonitrile, cyclohexane, ethyl benzene, styrene, phenol, etc.;
- petrochemical products: plastics, synthetic fibres, solvents, surface active agents, additives, synthetic rubber, fertilisers and agricultural chemicals.

The last category is not dealt with in this monograph, but its elements are the subject of separate monographs in this and other sectoral chapters. The lack of a common data base for petrochemical products is the main reason for the absence of complete statistical data.

Main indicators

In terms of basic and intermediate products, the petrochemical sector accounts for approximately one quarter of the total value added of the chemicals industry, that is 26 billion ECU in 1991. Total employment in the basic chemical sector (e.g. including NACE 251 and 253) reached the level of 633 000 units in 1991, with a decrease of nearly 20% from 1980.

An analysis of the primary petrochemical products shows weak growth for the main products. It is estimated that in 1991 ethylene production in the EC rose 2%, reaching 13.1 million tonnes, while consumption attained a level of 13.2 million tonnes. As for propylene, its production, which is largely dictated by ethylene demand, increased by 4.6%, reaching 8.4 million tonnes, while consumption reached 8.6 million tonnes.

Recent trends

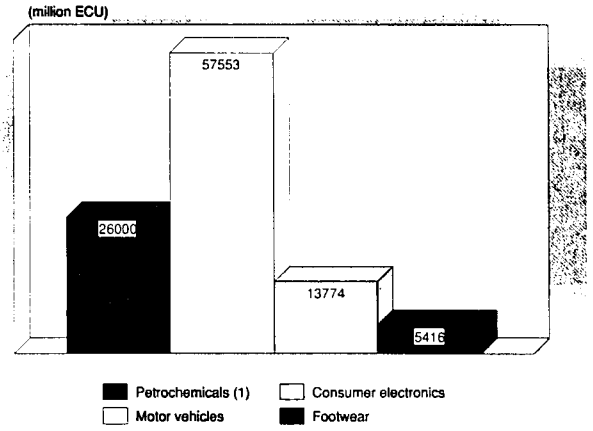
Within the EC, the supply and demand of primary petrochemical products was reasonably well balanced during the 1983-1990 period.

Both extra-EC exports and imports have grown steadily from 1982 to 1991, while the trade balance has decreased from 1988 onwards.

International comparison

The EC is a major player in the world market for primary petrochemicals, being the largest producer of butadiene and benzene and the runner-up, after the USA, for ethylene and propylene. EC production, in volume terms, is about double that of Japan. New producers have recently emerged on the world scene, particularly in Southeast Asia (e.g. Korea), Brazil and the Middle East.

Figure 1: Petrochemicals
Value added in comparison with other industries, 1991



(1) DRI Europe estimate
Source: Eurostat

Foreign trade

The EC's trade balance with the rest of the world is positive (about 2 000 million ECU in 1991), although it has been sharply decreasing from 1988 due to a strong rise in extra-EC imports. The exports/imports ratio has also fallen from its peak of 1.73 in 1983 to 1.14 in 1991.

The breakdown for Member States shows the predominance of Germany, which is both the major exporting and importing country in the EC, accounting for 41% of extra-EC exports and 23% of extra-EC imports. In this respect, other relevant countries within the EC are the Netherlands, whose figures are respectively 12% and 13%, the United Kingdom (11% and 13%), France (11% and 13%), Italy (10% and 14%) and Belgium (6% and 12%).

The EFTA countries and the USA are the main end markets for extra-EC exports as well as the main source of EC imports: in fact, together they make up for 43% of total extra-EC exports and 60% of extra-EC imports. The developing countries also represent an important market for the EC, accounting for nearly 20% of total EC exports.

MARKET FORCES

Demand

The different products of the petrochemical industry are used in a variety of downstream industries such as construction, electrical industry, packaging, transport, metal working mining, agriculture, rubber and petroleum refining.

The demand for primary and intermediate petrochemicals depends on several factors. First, the economic environment and the growth in end markets; second, inter-product competition (e.g. between different sorts of plastics or between plastics and other materials like steel); third, the emergence of new products; finally, the influence of environmental restrictions.

Product innovation plays a fundamental role in the petrochemical industry. The development of new fuels, such as unleaded fuel, is opening up new perspectives for the industry, particularly for the valorisation of aromatics. For example, several companies are heavily investing in products based on methane, such as the MTBE, an additive used for the production of unleaded fuel.

Supply and competition

The petrochemical sector is currently threatened with the prospect of severe overcapacity. In fact, during the period 1987-1991, the industry invested heavily in plant modernisation and the development of new technologies, thus greatly increasing its overall competitive position. Today, however, the slowdown of economic growth in the industrialised countries, and the competition of new plants in some developing countries have put the need for this EC capacity in doubt.

During the 1980s, expansion in capacity outside the traditional EC, US and Japanese producers progressively reduced the EC's position as a net exporter of olefin derivatives. The overcapacity problem that has developed in the EC has equally arisen in all the main regions the world, which thus suffers a global overcapacity problem which will take several years to resolve.

An interesting feature of the innovation of the petrochemical industry is given by the growing presence of the oil refining industry in the production of intermediate petrochemical products, which is mainly due to the process by which fuels are reformulated. The progress of the unleaded fuel and of the reformulated fuels implies the rejection of some components, such as benzene, which can therefore be found in larger quantities on the market.

Production process

The petrochemical sector is a heavy consumer of oil products: energy-producing materials account for most of the production cost of a cracker. The major input for the production of intermediate petrochemicals is naphtha, a product of oil refining, which accounts alone for about 65% of total petrochemical production in Europe.

The cost of raw materials used by the industry remains at rather elevated levels, notwithstanding the decrease in the price of oil that took place after the Gulf war. Cracker operators depend largely on OPEC decisions for the price of naphtha. The price of naphtha, which follows the price of oil, reached a level of 156 ECU per tonne in May 1992, a price which is substantially higher than the 115 ECU of July 1990. Moreover, since oil prices are fixed in USD, variations in the USA currency deeply affect the activity of the industry. In the 1990-1991 period, for example, the relative weakness of the dollar has given an important comparative advantage to USA producers vis-à-vis their European competitors. However, it must be recognised that negative effects from the variations in the exchange rate of the USD have been offset for the EC petrochemicals industry since 1983, by causing a fall in supply costs, a fall in the dollar-quoted borrowings, and producing positive side-effects on sales prices.

In the longer term, more fundamental feedstock problems than the tightness of naphtha supply might arise. There is no alternative feedstock that appears capable of cost-effectively replacing naphtha over a long period of time, despite the fact that naphtha will probably become more and more scarce and expensive. Recently, major European petrochemical companies are seeking to take advantage of rapid growth and a stable profit performance in the industrial gases market, by setting up pipelines which transport gases to feed petrochemical sites. While liquefied petroleum gas (LPG) can and will be an attractive alternative to naphtha from time to time, LPG prices tend to be volatile and very expensive for extended periods. Therefore the addition of LPG cracking flexibility is attractive only close to indigenous sources of supply, where it can be selectively used during periods of intense price competition.

Another relevant cost factor in the petrochemical industry is given by R&D activity, which is estimated to reach a level of 1.6 billion ECU each year, i.e. around 4% of total turnover. This compares with the average 2% of GNP devoted to research by all European industries and governments.

INDUSTRY STRUCTURE

Companies

Activity in the petrochemical field is performed by large-scale European and international groups, which have undergone extensive restructuring following the oil crises and the slowdowns in the economic growth which characterised the end of the 1970s and the beginning of the 1980s. The restructuring has prompted a reduction in the number of producers and sites as well as a shift in emphasis with regard to certain products. For example, in 1991, there were only 19 producers of ethylene in the EC, compared with 25 in 1985.

Among the five leading EC chemicals firms, four of them are involved in the production of basic and intermediate petrochemicals, excluding Rhône Poulenc (F), which has intentionally withdrawn from the field of basic chemicals. Nevertheless, the proportion of activities involving basic chemicals varies among the remaining four: Hoechst (D) can ascribe a share of 12% of its turnover to petrochemicals, Bayer (D) 14%, BASF (D) 20% and ICI (UK) 19%. Among the ten non-EC leaders, Dow Chemical (USA) and Exxon (USA) are firmly installed in the European petrochemical sector.

The petrochemical sector is closely related to the oil refining industry for its supply of raw materials. This has engendered the development of petrochemical activities on its own from the refining industry, as part of a strategy of downstream integration. It is worthwhile to note that among the top 15 chemicals groups at the world level, four of them are petrochemical subsidiaries of larger oil companies: Shell Chemical (NL/UK), Enichem (I), Elf Atochem (F) and Exxon Chemical (USA). As for the remaining 11 companies, petrochemicals account for only a small part of their activity.

The industry is not however exclusively dominated by large firms. There are about 10 000 chemical and petrochemical companies in Western Europe, generating an annual turnover of around 160 billion ECU. They employ two million people and form the third largest European industry.

Strategies

The response of petrochemical firms to the challenges they confront in the market is threefold: to improve the production process and optimise costs; increase specialisation in some particular product areas; and implement a dynamic strategy of joint ventures and alliances.

Apart from the traditional elaboration of new products, R&D activity in the industry is principally aimed at developing processes that can increase the flexibility of petrochemical sites in order to better answer to the fluctuations of feedstock of raw materials and of demand.

In the years to come, growth rates in petrochemicals will vary significantly according to the different products. Firms are pursuing a strategy of specialisation, trying to better respond to the exact needs of customers. Producers are concentrating commercialisation efforts on some specific end markets, such as the car industry, glues and adhesives, fuel additives, etc.

The third main strategy pursued by firms of the sector is to build up joint ventures and strategic alliances. In 1991, EC firms frequently used the instrument of joint venture to open up markets abroad. Within the EC, in 1991 the main operation has been the joint venture between Repsol Quimica (E) and Atochem to start common polystyrene production in Spain. Other examples are the joint venture between Enichem, Atochem and the Qatar General Petrochem Corporation for the expansion of ethylene and polyethylene production at Umm Said and the venture between Enichem, the Algerian Sonatrach and Total (F) for the construction of an Algerian MTBE plant. China has also been the favoured target for Total, Shell and Tecnimont (I) for several joint ventures with the Chinese authorities to build refineries and petrochemical plants.

As for alliances, the driving force behind this choice is the heavy investment expenditures that nowadays are often too costly to be undertaken by a single company. BP's (UK) associating with Atochem to commonly exploit a cracker in Lavéra (F), Exxon and Shell alliance in Gravenchon (F) and Fina (B) and Neste (SF) in Antwerp (B) are examples of such strategies.

ENVIRONMENT

Pollution by the petrochemical industry has greatly diminished over the last two decades because of four main factors. First, the closure of plants whose environmental performance was not satisfactory and their replacement with units using clean technologies; second, modifications to the production process to make it less polluting; third, the set-up of effluent processing plants downstream of the polluting units; fourth, the Responsible Care programme aimed at progressive improvement in environmental performance.

Another main concern for the industry is represented by VOCs (Volatile Organic Compounds). Fuels and natural gas evaporate quickly, thereby polluting the atmosphere and damaging workers' health. These problems must be resolved by equipping loading/unloading/storage plants with steam recovery systems.

OUTLOOK

The factor that will influence the petrochemicals industry in the near future is most certainly overcapacity, not only in the EC but globally.

The dangerous situation of overcapacity will be alleviated by the following remedies: first, an improvement in the European cost structure; second, a reduction in the number and ownership of crackers; third, the rise of flexible crackers able to receive propane and butane. Without significant further restructuring of the industry, this problem is unlikely to be solved until the late 1990s.

(%)	1992-93	1992-96
Apparent consumption	2.0	1.9
Production	1.2	1.2
Extra-EC exports	3.3	3.1

Source: DRI Europe

Another influence will be that investment in environmental protection is steadily increasing, and is expected to rise by about 15% between 1991 and 1994. Legislative requirements, such as the Integrated Pollution Control in the United Kingdom or the Clean Air Act in the USA, are the main driving force behind this increase.

Finally, a third important factor are feedstock problems. The long-term solution to raw material shortfalls lies in having a broad diversity of feedstocks, which will also offer cost advantages.

Written by: DRI Europe
The industry is represented at the EC level by: Association of Petrochemicals Producers in Europe (APPE). Address: Avenue Van Nieuwenhuyse, Bte 1, B-1160 Brussels; tel: (32 2) 676 7229; fax: (32 2) 676 7230.

Paints, varnishes and printing inks
NACE 255

The EC is the world's second biggest producer of paints, varnishes and inks after the USA and well ahead of Japan. Germany alone accounts for about one third of total EC production in volume which totalled about 5 million tonnes in 1991 and was valued at 15.8 billion ECU.
Given the structure of the industry (paints and varnishes is highly concentrated) and the importance of service linked to sales (repair work, rapid supply to the ink industry), export levels are relatively low.

INDUSTRY PROFILE

Description of the sector

NACE 255 includes paints, paint fillers, varnishes and printing inks. The sector encompasses a full range of products with various applications, of which four main categories are:

- architectural coatings, including exterior and interior house paint, primers, finishing coats, pore fillers, varnish and dyes;
- coatings used for a whole series of industrial products and consumer products (e.g. wood or metal furnishing, automotive industry, aircraft industry, machinery and equipment, domestic appliances, electrical insulation, film, paper and foil, toys and sporting goods);
- special coatings designed for specific applications or for use in special conditions, including products for the repainting of cars and machines, high-performance maintenance, road markings, bridge maintenance and metallic coatings;
- printing inks used for a series of printing processes (e.g. letter pressing, offset/litho, gravure, flexography, screen printing, etc.)

The statistics provided in this monograph do not take into account Greece, Ireland and Luxembourg, for which no reliable data exist.

Main indicators

Paints and varnishes account for nearly 90% of production in measured in volume and 85% of production in value of the paints, varnishes and printing inks sector.

In 1991, production of paints and varnishes reached approximately 4.4 million tonnes or 13.4 billion ECU. Germany accounted for nearly 27% of production in volume, followed by the United Kingdom (17%), Italy (16%) and France (15%). Extra-EC exports continued to rise, reaching a value of 1 800 million ECU, as did the trade balance, which showed a surplus of about 1 250 million ECU.

As for printing inks, production totalled about 2.4 billion ECU in 1991, that is nearly 590 thousand tonnes. Germany again dominates the sector in the EC, accounting for more than 40% of production in volume and one third of the total EC workforce, which stands at a level of about 14 000 workers.

Recent trends

Production of paints, varnishes and inks grew at an average yearly rate of 4.2% during the period 1982-91, thus outpacing consumption which rose 3.9% per year.

Extra-EC imports rose at a yearly rate of 6% during the same period, while export growth has been sluggish, particularly in the years from 1985 to 1991. Employment in the sector has recently started to recover after falling to its lowest level in 1988.

International comparison

The USA is the world market leader in paints, varnishes and inks although its production has been decreasing in recent years. In fact, a comparison of production measured in constant prices shows that in 1991, US production actually decreased by about 5%, while EC and Japanese production increased by 19.4% and 14.3% respectively. Nevertheless, the USA held onto its position as the world's largest manufacturer of paints, varnishes and printing inks with production of nearly 14.5 billion ECU, that is 8% more than the EC and nearly the double that of Japan.

Foreign trade

In general, paints, varnishes and inks are not highly traded. However, this depends very much on the application of the product: while common house paint is sold within a few hundred kilometres of the factory, special aeroplane coatings are internationally traded. The same applies for specialised printing inks. In all the countries with large production capacities, firms chiefly serve their domestic markets. Consequently, because of their proximity, EFTA countries are the main trading partners for the EC, accounting for about one third of total extra-EC exports and 60% of extra-EC imports.

MARKET FORCES

Demand

Although they are grouped in one common NACE category, paints and varnishes have different characteristics than printing inks.

Paints and coatings are widely used in manufacturing industries such as motor vehicles, building and construction, metal products, steelworks, wood, electric appliances, and marine equipment. As for printing inks, they are used to produce newspapers, books, advertising material, packaging and wall coverings.

Paints and coatings are quite vulnerable to developments in the demand for the products of the industry's main industrial clients. This is particularly true with regard to construction, marine equipment and car manufacturing. An exception to this general rule is given by the vehicle refinishing market: when fewer cars are produced or sold, consumers hold onto old models and refurbish them. Production of printing ink is generally less affected by fluctuations in the level of industrial

activity and the demand for durables and investment than in the paints and varnish sector.

Some clear trends in buyers' preferences have emerged in the recent past. Wood care products are taking an increasing share of the decorative coating market, at the expense of paints. Powder coating is estimated to be the fastest growing paint market in the world, with volume increases averaging about 15% a year during the 1980s; powders contain no solvent and therefore there are less emission problems. Finally, high demand for high solid paints (i.e. products with a high concentration of pigments), has produced a corresponding reduction in the use of non-aqueous solvents.

Supply and competition

Client industries require quite a long period of time before they accept new coatings. In the automotive industry, for example, where the importance of consumer tastes and the need for high quality products, to satisfy requirements of resistance and functionality are particularly important, it is normal to wait at least one year for acceptance, followed by up to two years of trials. The demanding requirements of the client explain why the paints and varnishes industry is spending large amounts of money on R&D activity and advanced technologies.

The market power of the industry's major industrial customers is strong. An extreme example is provided by the EC market of coil coating, (i.e. a decorative or protective coating on freshly produced metal before the main manufacturing step or construction process), which is dominated by major metal producers such as British Steel.

Production process

During the 1980s, the paint and varnish industry developed new products and adopted new applications driven by rationalisation in its client industries and environmental problems. "High solid" paint and powder fillers (which reduce the losses caused by overspray and allows recycling) are just two noteworthy examples.

In the recent past, production in the EC has been hampered by a technical shortage of raw materials. The recent shortage and sharp rise in the price of titanium dioxide, which peaked at 2.56 ECU/kg in late 1989, has been followed by a situation of overcapacity that has caused prices to decrease to a level

of 1.75 ECU/kg in 1992. This substance is at present the most widely used pigment, not only in white paint, but also in the lightening of most other shades.

Companies are also increasingly suffering from a lack of experienced technical staff, resulting from a mounting degree of complexity in the production process and the fall in the number of training facilities.

INDUSTRY STRUCTURE

Companies

All Member States have paint production plants, although a considerable number of these are to be found in the major EC countries. In 1989, the ten biggest paint and varnish companies held about one third of the world market.

Within the EC market, the leaders are ICI (UK) which is also the world's leading producer, BASF (D), Herberts (D, a Hoechst group company), Akzo (NL) and Courtaulds (UK). Another major European player is Nobel Industries (S).

Apart from major companies, there is still a large number of small and medium-size companies which survive through specialisation and a high quality of service.

Unlike the paint and varnish sector, there is only a limited number of multinational firms in the printing ink industry. In general, production units in southern EC countries are considerably smaller (and often family-run) than in the northern Member States.

Strategies

On the world market, there are four true world players: ICI (UK), PPG (USA), BASF (D), and Courtaulds (UK), while other major companies such as Akzo (NL) and particularly Sherwin-Williams (USA) operate mostly at home.

The sector has been characterised by an increasing number of acquisitions, which reflect the need to reach an adequate size to confront the concentration of distribution networks. The most important acquisitions in 1991 were Akzo's acquisition of MacPhersons' (UK) decorative business and Herberts' acquisition of Becker Powders (UK). However, paint and varnish companies are also frequently using joint ventures in order to gain access to new markets. In 1991, for example, Courtaulds and PPG set up a joint venture for aerospace and defence coating businesses in the United Kingdom and Italy, BASF and Nippon (J) did the same in the automotive coating business and ICI and Ferro (USA) followed suit in powder coatings.

ENVIRONMENT

The main environmental issue affecting the sector is the emissions of volatile organic solvents which are used extensively in paints. Legislation in this area varies widely across the EC. German legislation calls for limits of 150 mg/cubic metre of carbon derived from organic vapours leaving the factory, while in the United Kingdom the limit is set at 50 mg/cubic metre. Although water-based paints are an alternative, they are more expensive and less durable than solvent-based varieties.

The industry is currently devoting a considerable share of its R&D expenditure to solve this problem and has already put forward some successful waterborne coatings. Another environmental concern is titanium dioxide, or white oxide. Paints, lacquer and inks represent around 60% of titanium dioxide consumption in the EC; in its natural state, it damages neither health nor the environment, but its refining is polluting.

As for printing inks, the use of non-aqueous solvents may pose problems similar to those encountered by the paint and varnish industry, even if the more limited number of professional users means that emissions can be controlled more effectively.

REGULATIONS

The EC Commission has put forward several directives on environmental pollution which concern the paint and varnish sector, all of them concerning titanium dioxide. As for solvents, they are not yet the subject of an EC directive.

In 1978, a Commission directive (78/176/EEC) was adopted with the aims of reducing pollution caused by waste and encouraging recycling. A second directive was adopted in 1982 (82/883/EEC) to ensure extensive prevention and to define procedures to control and monitor waste emissions into the environment, including the sea. Finally, in 1983 the Commission submitted a draft directive to harmonise programmes to reduce pollution caused by titanium dioxide using industries; however, in the absence of any consensus, the directive has not yet been adopted.

OUTLOOK

Although the paints, varnishes and inks industry is not recession-proof, it is certainly recession-resistant: the steady need of these products by industrial users and by private consumers (professionals or households) means that there are always returns in good and bad times. At the moment, the main concern for the sector are the environmental protection regulations and the reliance of some raw materials upon the price of crude oil: both these elements can disrupt any increase in volume. Taking into account these factors, the growth rate for production in the paints, varnishes and inks sector as a whole is expected to reach around 3.1% per year in the period 1992-96.

Other specialty chemicals

NACE 256.1-256.7

Specialty chemicals are sold on a large number of small or niche markets, for a wide range of applications. Higher value-added, larger profit margins and growth characterise the sector, if compared to the basic chemicals. Competition is not only on price, but foremost on the ability to effectively render service to the client industries, through improving their production processes or products. Environmental concerns form another major drive for innovation in the sector. Partly because of this, the present performance and the prospects of the industry are less bleak than for many other parts of the chemical sector.

INDUSTRY PROFILE

Description of the sector

The manufacture of other specialty chemicals includes a number of products mainly destined for industrial purposes which are described below.

The manufacture of compressed gases (NACE 256.1) includes air gases, acetylene, propane, and carbon dioxide, as well as gas mixtures and various specialty gases (such as argon and other rare gases) that are supplied in smaller quantities in steel cylinders to customers primarily in the engineering industry. Applications in the medical sector include the supply of liquid nitrogen for the conservation of blood, cell cultures, bone marrow and organ transplants. It does not include the delivery of large volumes of primarily the air gases oxygen and nitrogen supplied by pipeline to the steel, chemical and glass industries, nor the gases in liquid form in medium quantities delivered to customers in road tankers.

The manufacture of glues and gelatine (NACE 256.2) includes gelatine, peptone, modified starches and glues. Glues can be subdivided in two types, liquid and solid glues. Liquid glues consist of a glue-based material liquefied with a solvent, which evaporates after gluing. Solid glues have to be activated by water, solvent or air before they can be used.

The chemical treatment of oil and fats (NACE 256.3) includes the processing of animal and vegetable fats and waxes into a wide range of applications. Their use as culture media and tabletting aids in pharmaceuticals, in cosmetics, as emulsifiers in food, as wire insulation in electronics, and for the removal of printing ink in paper recycling are just a few examples to demonstrate the variety of the application range. Other client sectors include animal feed, industrial lubricants, leather, mining, paints and coating, plastics and rubber production.

The manufacture of essential oils and of natural and artificial flavouring and perfume materials (NACE 256.4) includes essential oils such as lemon, orange and lime oils, geranium, jasmine, lavender and peppermint oils; flavourings, anti-oxidants, colourings, emulsifiers and stabilisers, and enzymes, all to be used as food additives.

The manufacture of explosives, pyrotechnic articles and matches (NACE 256.5) includes propellant powders, detonators, fuses, matches, flares and liquid gas fuels.

The manufacture of auxiliary products for the treatment of leather and textiles and the manufacture of tanning agents (NACE 256.6) includes surface agents (not soaps), lubricants, leather and skin treatments.

The manufacture of miscellaneous chemical products for industrial purposes (NACE 256.7) concerns the production of active carbons and activated earths: abrasive compounds, auxiliary products for use in mechanical engineering and metallurgy, natural resins and their derivatives, etc.

This chapter includes a wide variety of heterogeneous products, for application in a tremendous number of industrial and household uses. These chemical products differ considerably from other chemical products, in the way they are produced and marketed: production is often on a small scale, and more and more according to the specifications of one particular client; which is why specialty chemicals is a very service oriented sector and intricate understanding of the clients' products or production process is a prerequisite for successful marketing of the specialty products. R&D is not so much oriented towards new discoveries, rather towards the application of existing substances in new applications. Specialty chemicals are also characterised by profit margins which are often markedly higher than in the commodity chemicals business.

Main indicators

A general overview of the main indicators for the group of industries included in this chapter is not available. As a general remark, it can be observed that some specialty sales have inevitably felt the repercussions during recent years of the recession in their clients' business. On the other hand, many companies active in specialty chemicals have managed to boost sales in some segments, sometimes offsetting sales volume reductions that they underwent on larger volume markets.

International comparison

Specialty chemicals, with their relatively high value-added and high margins, seem to have attracted the Japanese producers into the market, until recently rather absent in the chemicals field. In the flavour industry, for example, the most significant recent growth has been in the Japanese industry

that is expanding into the international market as a global player.

Foreign trade

Extra-EC exports of specialty chemicals increased annually by 6% over the period 1982-91. Imports into the EC even rose faster, at 8.1%, in current terms, which was almost as fast as the increase in internal trade, which rose by 8.6% annually over the same period. The evolution of trade figures for the different countries do not show striking deviations from the general EC trend, although Germany experienced slightly higher than average import growth. Most of the exports of specialty chemicals are destined to the rest of the world and to the EFTA countries, whereas imports mostly originate from the USA and EFTA.

MARKET FORCES

Demand

Compressed gases

Though the weak economic growth in 1991 affected demand for industrial gases in general (including large volumes not part of this NACE) on the EC market, some specialty uses have fared better. Hoechst was able to profit from the favourable economic situation in Germany, which is the largest industrial gas market in Europe. The German company managed in 1991 to increase the quantities of oxygen and nitrogen sold for applications in the chemical industry, the electrical engineering sector, the food industry and environmental protection. This more than compensated for decreased volume sold in the steel sector.

Glues and adhesives

The industry sells to clients in four main customer groups: the construction industry, the furniture industry, the paper and packaging industry, and miscellaneous, which includes the automotive, electronic, shoe and cigarette industries. The manufacture of glues for office and household uses is included in NACE 259 (see the chapter on other chemical products). The sector experienced strong sales growth up to 1989, generated by the favourable economic situation worldwide. Other factors influencing the sales of glues are the development of new products, such as highly specialised metal and plastic glues, sold on niche markets where they replace common methods of connecting like nailing, screwing and welding. The application of glues in these sectors does not merely constitute a substitute material, but often becomes the starting point of technical innovation in the client sector; for instance, since gluing allows the usage of lighter and thinner materials, the construction of cars and aeroplanes with lighter materials becomes a possibility. Such increasingly targeted markets, in which customer needs are well understood, offer large sales potential and good growth prospects, even in periods of economic weakness.

Source: Eurostat

Chemical treatment of oils and fats

According to APAG, worldwide consumption of basic oleochemicals (fatty acids, fatty alcohols, glycerine) is estimated to be over 3.5 million tons. More than one third of this is produced in Western Europe. Basic oleochemicals are only an intermediate step in the total oleochemicals industry, a provider of jobs for over 10 000 people in Western Europe alone.

The diversity of markets for the oleochemicals is an important factor in the stability of the industry. The chemical possibilities of renewable oils and fats are rapidly being more and more exploited to take advantage of their ecologically safe properties. One example of current development includes ecologically safe lubricating and hydraulic oils (natural fatty acid esters which will replace non-biological base oils in important applications such as in agricultural machinery, forestry saws, outboard motors, etc.).

A great deal of research is going on to produce new ecologically acceptable surfactants for the detergents industry, such as new non-ionics, combining oleochemicals with other natural molecules. In this way markets are created for oleochemicals through technological advances and sometimes through surfactant substitution. Given the environmental pressure on several varieties of surfactants, specifically related to the toxicology and biodegradability of the product, there is a growing trend to use more natural feedstocks based on plant derivatives rather than petrochemicals. Such products are believed to be less environmentally damaging and are said to lead to milder consumer products for the domestic and personal care sectors.

In 1990, for Europe, the market for specialty surfactants was estimated at 840 million ECU, out of a total surfactant market of 1.82 billion ECU. Although growth in the overall surfactant market is steady, generally matching that of GDP of 1% to 2% per year, speciality surfactants average growth rates of 6% per year on average, with some sectors registering growth of up to 10% per year. Of the total surfactant demand in Western Europe, about one third (500 000 tons) goes into industrial applications, many of which can be classified as specialty. End-use sectors include textiles, polymers, petroleum additives, metal working fluids, agrochemicals and food.

Essential oils, flavouring and perfume materials

Company results show growing demand in this area, deviating from the weaker results of the commodity chemicals divisions in 1990 and 1991. Since the 1960s, the sociological revolution in the kitchen for convenience and speed has driven food flavourings industry growth. In 1990, the worldwide flavour market was valued at some 2.4 billion ECU. Demand, and the industry itself, is fragmented, taking into account the large variety of flavour profiles and their parameters for technologically efficient application (standardisation, purity, ease of handling, life time, etc.).

Auxiliary products for the treatment of leather and textiles

Dyes for the textiles industry have recently faced decreasing sales; sales of colourings to other industries show a mixed and sometimes more positive picture (printing inks, paints, plastics, etc.). The business in chrome chemicals, especially tanning agents for leather, is suffering from intense competition.

Supply and competition

The characteristics of the specialty market are the high functionality and specification of the product and lower volumes. On the whole, the specialty end of the market is not feeling the same degree of competitive pressure as the commodity end of the business. Product costs and sales prices are typically higher in specialty chemical business, as are value-added and margins. Purchases of specialty chemicals are often based on performance rather than on price. Technical development, especially product quality and consistency, is becoming one of the leading factors influencing competition on the market at present.

Specialty chemicals are manufactured according to precise specifications related to their final use. The products are constantly evolving to follow innovation in the client industries' products and processes. Detailed knowledge of the client's business, anticipation of the development of his market segment, and fast reaction to his needs are the clues to successful marketing in the specialties segment. For instance, the development by specialty chemical manufacturers of new stabilisers, that substantially increased the fluidity of plastics, have enabled plastics manufacturers to increase their production rhythm. In the same way, the formulation of liquid ultraviolet absorbers has enabled paint manufacturers to simplify production and to reduce costs.

Innovation in the specialty chemicals industry is characterised by minor transformations to existing products rather than by new inventions or breakthroughs. Another important driving force of innovation in the specialty chemical industry, is the urge towards the controlling of the toxic characteristics of the products, with clients increasingly eager to create a green image for their products.

When the product cycle reaches maturity, even the most performant additives eventually see their prices drop on the market. This may open new markets for the product. This has happened for the ultraviolet stabilisers, that, originally developed for the plastics industry, have now diversified into the rubber industry.

INDUSTRY STRUCTURE

Companies

Both fully integrated, large companies as well as small niche players are present on the specialty chemicals markets. By means of example, some of the larger companies present include ICI (UK) and Henkel (D) (specialty surfactants), Rhône-Poulenc (F) (flavourings), Atochem (F) (polymers for leather and textiles), Elf Aquitaine (F) (elastomers), Bayer (D) (dyes, pigments, optical brighteners), Hoechst (D) (food additives, pigments, industrial gases), and Tessenderlo Chemie (B) (food additives, gelatine).

Strategies

Marketing strategies differ across companies. Some companies follow a product-based approach whereby they try to use their chemical expertise to sell the product in an as wide range of end-products as possible. Another strategy is to focus on end markets, such as agrochemicals or textiles, rather than on products. This has the advantage of a closer rapport with the client industry, which is important given the service orientation of much of the specialties business.

Product innovation strategies are directed towards minor transformations of existing products, rather than on true discoveries. The research is often oriented in the direction of a better controlling of the toxic consequences of the products and their adaptation to automated production processes. To remain profitable, the companies have to decline/reject the possible development of a lot of products and extend the possible application range of those they do develop.

ENVIRONMENT

In the industry of specialty chemicals, environmental protection constitutes one of the foremost lines of action to steer research and development of new products. Minimising toxicity has become a criteria for innovation that is as important as efficiency. The industry is bound to follow and even anticipate EC and national environmental regulations that are ever becoming stricter under pressure of the public opinion.

A lot of products containing solvents (e.g. adhesives, paint) have already been abandoned, and pigments based on heavy metals are undergoing the same fate. The strict legislation in these areas has become a real stimulus for researchers to find substitutes/alternatives for lead, cadmium and molybdenum. The same holds for additives for paint, varnish and plastics. The use of plant-based surface agents instead of petrochemicals is another example of the use of a renewable raw materials leading to a less toxic end product.

REGULATIONS

Developments on regulatory matters at the EC level concerning the industry included work on the control of movements of waste (e.g. the transport of spent carbon for activated carbon producers), the harmonisation of food additive regulation developed by the EC Commission (flavourings, gases for use in the food industry), and the EC directive on plastic materials which come into contact with foodstuffs (fatty acids). The explosives industry has advised the EC Commission on a harmonised base for approval by the EC Commission for release on the market of explosives for civil use, including an effective system of transborder control after abolition of current border controls. Legislation affecting the industrial gases subsector includes the pressure equipment directive (industrial gases), the standardisation of gas cylinders by the technical committee CEN TC 23 (industrial gases), and the drafting of guidelines by EIGA to comply with EC classification and labelling directives.

OUTLOOK

Specialty chemicals face a bright future. The industry is expected to realise high growth and profit margins, rather comparable to the pharmaceuticals industry, and unlike the commodity chemicals. One factor at play in the success of the industry is the general tendency towards more technologically oriented products which is believed to be maintained in the future. Public demand for more environmentally friendly products is a second factor that tends to favour specialty production growth. Lastly, the industry has not fully exploited the excellent possibilities in product development, which is a major factor in the expansion of existing markets and in the development of new markets.

Agrochemicals
NACE 256.8

The EC is the world leading producer of agrochemicals for crop protection. The EC also maintains a favourable balance in world agrochemical trade, with exports almost twice imports. Growth is forecast in the European crop protection market, driven in particular by a continuing increase in demand from the developing nations.
The prospects are rather different in the field of fertilizers where the EC is confronted by stiff competition from East European and North African countries. The depressed market, along with the crisis of overcapacity continue to affect the performance of the European fertilizer industry. It is committed to further restructuring in order to improve profitability.

INDUSTRY PROFILE

Description of the sector

According to NACE 256.8, the agrochemical industry can be defined as the manufacture of chemical products for agricultural purposes. There are two major branches within agrochemicals: fertilizers and chemical products for crop protection.

The fertilizer industry produces and markets both single nutrient fertilizers (comprising either nitrogen, potash, and phosphate processed from imported mineral rock) and various compound fertilizers (containing mixtures of nitrogen, potash and phosphate).

Chemicals designated for crop protection include pesticides, fungicides, herbicides, and plant growth regulators, and many new biotechnological products used to protect plants against disease and pests, currently under development.

Main indicators

Crop protection

The EC is the largest producer of agrochemicals designated for crop protection, with France constituting the major EC market and the third biggest market in the world, after the United States and Japan. In 1990, the West European plant protection market was estimated at around 7 916 million USD, that is 30% of the world market. In comparison, the US market accounts for 7 050 million USD.

Fertilizers

The market for fertilizers has been particularly depressed over the last several years, suffering from problems of overcapacity combined with weak demand. Consumption of fertilizer has been static or declining in the EC throughout the 1980s. Since 1986, consumption has been on a slow downwards path taking it below 10 million tonnes per year. 1992 is likely to see an acceleration of this decline as farmers use less in response to CAP reforms. The fertilizers industry is also suffering from an increasing trade deficit. Extra-EC imports which have grown steadily throughout the eighties, reached 1.26 billion ECU in 1991 and are about two and a half times the level of extra-EC exports. As a result, since 1988, production of fertilizers has fallen steadily in the EC, both in real terms and in current prices, and the decline has been sharper than for consumption. Nitrogen production peaked in 1984 with output of 10 million tonnes. In 1990 output was well below 9 million tonnes. Nitrogen production is the largest of the three main fertilizers, followed by potash and phosphate with respectively 4.8 million tonnes and 3.2 million tonnes output in 1990.

International comparison

Crop protection

The EC is the leader in the market of agrochemicals for crop protection. France, Italy, the United Kingdom, Spain, West Germany, Denmark and the Netherlands constitute the major markets in the Community. In terms of real growth, EC countries accounted for five of the top six agrochemical markets in 1990. Overall, the EC is the world's largest market for agrochemicals, with about 30% of the total, with the USA in second place with nearly 24% of the world market. Assuming that volumes and prices in the world market remain more or less stable and proportional to crop acreage, the EC should continue to be the world leader in the crop protection market in the 1990s.

Fertilizers

The European fertilizer industry accounts for 12% of world fertilizer production and is the fourth largest world producer after the former Soviet Union, the USA and China.

Foreign trade

Crop protection

The EC is a net exporter of crop protection products, and the European trade surplus kept on increasing until 1985. Since that peak, the EC has been losing market shares abroad, causing the trade surplus to decline. Extra-EC exports are indeed growing only slightly (by less than 4% in 1991, compared to much higher growth in the early eighties). Import growth has been consistently stronger than export growth throughout the 1980s.

While in 1986, the USSR was the EC's most important export market, this region's share of total EC exports had almost halved to 11% by 1991. The OPEC and EFTA countries are now at the top of the list of EC export markets. The "rest of the world", however, remains the biggest destination of EC exports.

Concerning imports, the most important competitors for EC agrochemical firms are the EFTA countries (with more than 50% of total extra-EC imports), followed by the USA.

The share of intra-EC imports in the total remains important (over 75%) although slightly lower than its peak recorded in 1986.

Fertilizers

The scheme is rather different in the field of fertilizers. A trade deficit has been existing since the early 1980s but it has widened in the past few years, reaching 790 million ECU in 1991. The worsening trade balance is due both to rising imports and falling exports. In 1991, extra-EC imports exceeded 18% of demand while the share of extra-EC exports in production fell to 7%. Both trends look set to continue with particular pressure on the import side as the EC producers have to compete with CIS producers that benefit from considerably lower gas prices.

MARKET FORCES

Demand

Demand for agrochemicals is directly linked to the dynamism of the agriculture sector, which represents almost its only end-market. Demand will thus benefit from any implementation of new techniques in the farm industry, which are aimed at improving the acreage yield. Economic and regulatory factors represent other important parameters influencing demand for agrochemicals. Indeed, demand will be constrained by measures exerted on the farm industry, like the removal of Monetary Compensatory Amounts (MCA) or the reform of the Common Agricultural Policy, which have direct effects on the volume of agricultural production. Economic factors

such as labour costs in the farm industry may contribute to a varying picture of demand across countries: for example, herbicides, which are the largest product group and also the most rapidly growing market segment in Europe, are particularly useful (and largely used) in developed countries where labour is expensive. Indirectly, population growth constitutes a major factor influencing demand for agrochemicals, which provide a certain guarantee to maintain sufficient food resources for the growing world population. Climatic conditions have also a significant effect on demand for agrochemicals. Indeed, insecticides for example are more used in southern EC Member States such as Spain and Greece than in the northern countries (especially orchards). On the contrary, fungicides which are used to control fungal diseases mainly in high value crops, are increasingly used in the northern Europe experiencing high rainfall and a cool climate.

Supply and competition

Crop protection

Competition between companies is particularly tough in the crop protection industry. The EC manufacturers hold a strong advance in terms of research and development, thanks to important investments in this activity. Numerous take-overs occurred over the recent years, through acquisitions and mergers, with plant biotechnologies as main targets.

Fertilizers

The fertilizer industry is very sensitive to the vagaries of world supply and demand and to global competition. Competition is mainly coming from developing countries, which enjoy large resources of natural gas and natural phosphates. Eastern countries have also been important competitors as they are looking for foreign exchange earnings through the marketing of fertilizers. As the sector is not high-technology intensive, the EC does not have any particular competitive advantage in the field of fertilizers and is hardly hit by these countries' competition.

Profitability has been very low for EC manufacturers since 1980. Massive restructuring and downsizing has already taken place. Employment in the EC stood at 110 000 in 1983. By 1991 this had been reduced to 40 000, a fall of almost two third. EC production capacities have fallen since 1980; very sharply for mixtures of nitrates and phosphates, much less so for ammonium nitrate. On the other hand, capacity has increased in the rest of the world although ammonium nitrates has seen much less growth. The EC has retained its share of the world capacity for the latter product but seen a large decline for urea, sulfate of ammonia and compound fertilizers.

Production processes

Crop protection

The main feature which characterises recent trends in the crop protection industry is the increasing share of research and development in total sales. On average, the top twenty companies committed 9.7% of total sales to R&D in 1990. Biotechnology has emerged as a key area of research. The main thrust of this research is in the area of plant genetics and the development of biopesticides. Genetic engineering techniques have made traditional plant breeding far more efficient and sophisticated. New plant varieties are being developed with features such as: resistance to pests and disease; resistance to herbicides; resistance to frost or drought; and improved product quality.

Research in biotechnologies will not noticeably reduce total agrochemicals sales, but will cause modifications to the type of products and to the competitiveness of those involved. The products distributed will be safer for the environment and give stronger pest control, whilst the first results of biotechnology research should appear on the European market early this decade.

Fertilizers

Fertilizer plants are often large, integrated operations that process raw materials into inputs for other industrial sectors. These inputs include ammonia, nitric acid, urea, ammonium nitrate, sulphuric acid and phosphoric acid.

The industry is highly dependant on its supplies of raw materials, hydrocarbons (particularly natural gas) and natural phosphates. The sector manufactures heavy and low value added products, for which the production process is quite simple. Fixed costs are an important element of the cost structure as the industry is highly capital intensive. On average, they account for about two-thirds of total costs.

In terms of research, the fertilizer industry is looking at methods of fertilizer application that ensure usage is more efficient and environmentally friendly.

INDUSTRY STRUCTURE

Companies

Crop protection

Taking into account the research and development capacity and the production levels or distribution network, the number of companies of importance in the agrochemical industry was estimated to about 40 world-wide in 1985. The majority of agrochemical manufacturers are located either in the USA, Japan or Western Europe. Nearly all these firms are multinational chemical companies whose agrochemical segments represent a relatively small part of the total sales of the group to which they belong.

Ciba-Geigy (CH) is considered as the leading producer of herbicides with an estimated world market share of 13%. Monsanto (USA) is the second largest herbicides producer, with 8%, followed by Bayer (D) and BASF (D) with 7% each. In the field of insecticides, Bayer and Rhône-Poulenc (F) are the leaders, followed by FMC and Hoechst (D). In fungicides, the main companies are Bayer (18% of the world market), Ciba-Geigy, Rhône-Poulenc, Du Pont (USA), BASF and Sandoz (CH).

Fertilizers

The fertilizer industry is also concentrated. Between 1980 and 1991, the wave of mergers and acquisitions has lead to the industry seeing seven companies responsible for more than 80% of production. These seven are: Norsk Hydro (Norway), Kemira Oy (Finland), BASF (D), Grande Paroisse (F), Enimont (I), DSM (NL) and FESA (E). Norsk Hydro and Kemira Oy have the largest capacities in the EC.

Strategies

As farmers demand more and more environment-friendly chemicals to treat their crops, agrochemical industrials are committed to ensure they meet new higher regulations. As this constraint is particularly costly in terms of R&D, not all of the industrials are keen at investing in this field. As a result, restructuring is most likely to take place, mainly in the form of joint-ventures, at least for the largest groups. Restructuring has, actually, already begun, like Schering which tried (but finally failed) to set up a venture with Sandoz; other significant groups are looking at the possibility of building up niches either in particular product area or geographical.

The EC fertilizer industry is committed to a huge restructuring and rationalisation process both within national borders and at EC level. Sales networks have been developed in all countries. Plants have been shut down and production concentrated at the most favourable locations in terms of supply and outlets. Investments have been made in order to improve efficiency and productivity (especially to optimise the use of energy) to produce the best fertilizers and market them in the best way.

REGIONAL DISTRIBUTION

The EC represents about 31% of the total agrochemical market value. France, Italy, the United Kingdom, Spain and Germany are the largest producers in the EC, and are also the largest consumers of plant protection chemicals, using about 95% of the herbicides, 97% of the fungicides and 77% of total pesticides consumed in Europe.

France, together with the US and Japan, is one of three countries representing half the world herbicides market, and accounted for 10% of the world herbicides sales in 1990. Today, the largest EC market is herbicides, except in of Italy, where fungicides sales exceeded herbicides in 1990.

ENVIRONMENT

Whilst respecting environmental needs, the industry must also balance its role of crop protection and the maintenance of reliable food supplies. Advances in the agrochemical industry are critical in order to limit the risk of agricultural disasters but also to limit the already important losses recorded in potential food production world-wide, due to pests diseases and weeds (about 30% of the total). The big challenge facing the industry now is thus to find an adequate balance between the respect of green policies and the production needs of modern agriculture. Major resources are invested by the industry each year in this objective. As a matter of fact, for every new product tested, only one in 15 000-20 000 is marketed.

The chemical origin of fertilizers, along with the fact that they are spread on the majority of cultivated land also raises questions as to their effects on the environment and the food chain. If spread in the right amount and at the right time, the fertilizers cover the plant's nutritive needs and are absorbed nearly completely. The presence of nitrates in water and of cadmium in the soil are matters of particular care and although their levels currently recorded do not constitute a health hazard, the fertilizer industry is committed to preventing their increase and, if possible, to reduce them.

REGULATIONS

The most important concern facing the agrochemical industry is the recently signed Common Agricultural Policy reform. The core of the reform is a shift away from price support mechanisms, in favour of direct compensatory payments to farmers. This measure, which covers about 75% of total farm production under CAP regulation, entail full compensation of farmers for reduction in prices. To further limit supply, it will be accompanied by a compulsory land set-aside scheme for cereals, oilseeds and protein crops. Indeed, invoking the fact that compensatory payments could give less incentive to raise production than high output prices, reform of the CAP could cut agrochemical sales by about 20%, according to industry sources. Nevertheless, Agra Europe, an independent agency, is casting some doubts on this conclusion. According to Agra Europe, the reform is unlikely to bring about steep falls in EC production of cereals, and thus to have such a dramatic effect on agrochemical sales.

Anyway, this reform, along with the establishment of the single European market is going to increase competition in the ag-

rochemical field. As a result, the number of participants is likely to decrease. Also, it is hoped that some cost gains can be achieved by the industry through regulatory harmonisation and efficiencies to offset the expected lowering of prices foreseen in some Member States.

The EC's agrochemicals registration directive, adopted by the Council in July 1991 (another directive set up in the view of the single European market), is expected to bring about significant changes in the regulatory control of crop protection products. This measure is aiming at harmonising approval procedures across Europe, setting a European system for active ingredient registration and encouraging mutual recognition of national product approvals by the remaining Member States. So far, the diversity of national product registration requirements have represented important costs for the industry when launching new products.

OUTLOOK

Lower growth of agrochemicals is expected in the European countries, as a result of the CAP reform. Competition between companies will continue to increase, all the more so as R&D costs are becoming increasingly important. Further concentration will occur through mergers and acquisitions, principally in the field of biotechnologies.

The European fertilizer players will have to cut capacities further in order to improve their profitability. Further changes in the ownership structure are to be expected also, with more consolidation.

Soaps and detergents, perfumes and toiletries
NACE 258

The combined sector of soaps and detergents, and perfumes and toiletries was characterised by steady growth during the 1980s. From 1989 onwards there has been an acceleration in real output growth of the sector due to the introduction of some innovative products (e.g. liquid laundry detergents, enhanced skin care products). The consumption of the industry's products is closely linked to the standard of living, but also to individual tastes and fashion, hence the relative importance of marketing and R&D activity.

INDUSTRY PROFILE

Description of the sector

NACE 258 is divided into two product categories:

- the manufacture of soap and synthetic detergents (NACE 258.1) which covers toilet, household and industrial soaps and washing products, surface cleaners and washing powders; and,
- the manufacture of perfumes and toilet preparations (NACE 258.2) which covers hair products, beauty products, toiletries for men and women and alcohol-based products.

Although being grouped in a common NACE, the two subsectors differ substantially in terms of industry structure and recent trends and will therefore be considered separately when possible.

Main indicators

Production in the soaps and detergents sector is dominated by laundry and surface cleaning products which together account for nearly 90% of NACE 258.1. Among surface and scouring products, liquid products and laundry washing powders together represent more than 90% of total production. The five main EC countries (respectively, by share of production, Germany, the United Kingdom, Spain, France and Italy) account together for more than three quarters of total production of soaps and detergents.

The breakdown by country reveals that Germany, France and Italy (in this order) are the largest producers of perfumes and toiletries, together accounting for two thirds of total ex-factory sales. The breakdown by product line shows that beauty and care products account for nearly 30% of ex-factory sales, followed by hair products (about 25%) and toiletries (around 20%).

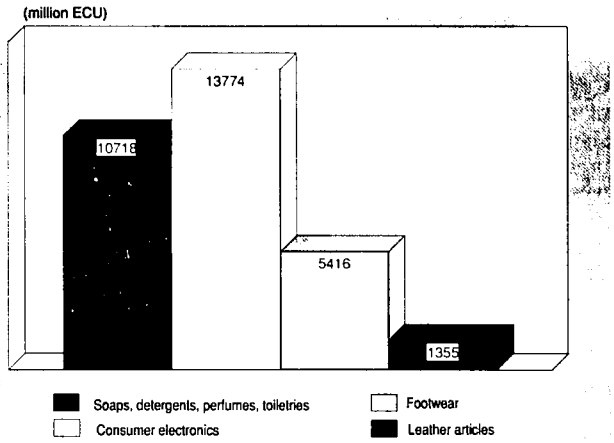
Recent trends

During the 1980s, the combined sector of soaps and detergents, perfumes and toiletries performed well: all the main indicators increased steadily, with the exception of employment. The workforce dipped to its lowest level in 1986 although it has since recovered such that by 1991, employment was 13 000 people more than in 1986, an overall increase of 6.3%.

International comparison

The EC is the world's largest producer of soaps and detergents, perfumes and toiletries. In 1991, EC production was some 40% higher than that of the USA and nearly four time the size than that of Japan. Figure 5 shows that, during the 1988-1991 period, EC production grew at fairly strong rates of growth of more than 4% per year in volume, while production growth in both the USA and Japan was more variable.

Figure 1: Soaps and detergents, perfumes and toiletries Value added in comparison with other industries, 1991



Source: Eurostat

Foreign trade

The EC industry has widespread export markets for soaps, detergents, perfumes and toiletries. Among the most important export markets are the developing countries (which absorbed about 40% of total extra-EC exports in 1991) and the EFTA countries (about 30% in the same reference year). As for extra-EC imports, the EC's main external suppliers in 1991 were again the EFTA countries (nearly 50% of total imports) and the USA (about 30%).

In the soaps and detergents segment, the level of foreign trade is relatively unimportant, although the exports/imports ratio is positive (about 4.9): in 1991 for a total export value of 978 million ECU, the EC imported soaps and detergents to the value of 199 million ECU. Intra-EC trade grew sharply in 1991 compared to 1990, reaching a level of 1 529 million ECU, an increase of 12.5% over the previous year.

The internal structure of trade has remained unchanged in the last two decades: the EC mainly exports washing, surface cleaning and scouring products and toilet articles, but very few domestic and industrial cleaning products. With regard to imports, washing, surface cleaning and scouring products account for about 60% of the total.

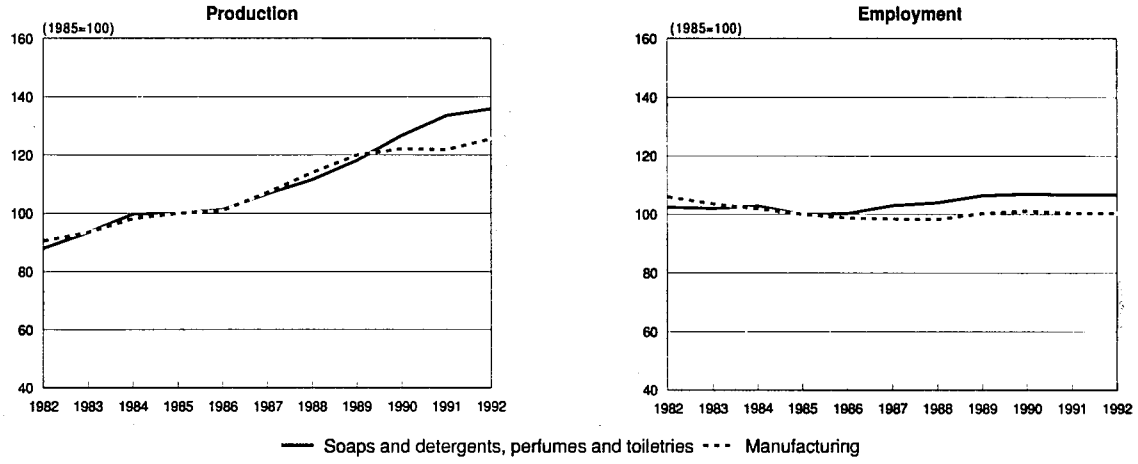
Figure 3: Soaps and detergents, perfumes and toiletries
Production and employment indices compared to EC manufacturing



Source: Eurostat

By contrast, the perfumes and toiletries segment is more export-oriented, and in 1991 it accounted alone for nearly 75% of the sector's total extra-EC exports. Although its export/import ratio is the same as the soaps and detergents segment (4.9 in 1991), extra-EC exports totalled around 2 600 million ECU in 1991, while extra-EC imports reached 540 million ECU.

Overall, the combined sector of soaps, detergents, perfumes and toiletries is much more export intensive than import intensive; close to 10% of EC production is exported, a share that has remained fairly steady throughout the 1980s while the share of imports in consumption is less than 3%.

MARKET FORCES

Demand

The great majority of soaps, detergents, perfumes and toilet products is sold to households and individual consumers, although for the soap and detergent industry hotels, restaurants and institutional outlets are also important end markets. For both subsectors, marketing and sales promotion play an important role in defining consumer needs and account for a substantial part of total investment.

Soaps and detergents

Soap and detergent consumption is closely linked to the standard of living, but is also influenced by the introduction of new products. During the last few years emphasis on energy conservation combined with the need to take great care of delicate materials has produced a marked trend towards washing laundry at lower temperatures. The introduction of products operating at lower temperatures has reinforced this evolution in demand; liquid detergents in particular, which are easy to use, provide such an example. On average, they represent 18% (by value) of the EC market of detergents.

In addition to changes in consumer tastes over time, EC manufacturers must deal with wide differences in habits depending on the country in which they are selling. History and climate conditions can considerably influence consumer needs and demand.

Source: Eurostat

Perfumes and toiletries

The sector of perfumes and toiletries is characterised by a strong link between individual product consumption trends and living standards. Fashion and advertising also have a considerable influence on sales. The main consumer trends which became apparent during the 1980s led to greater product diversification. For example, the promotion of a more natural look for women, together with the introduction of products such as gels and fixing mousses, explains in part the increased popularity of these products. The initial changes in product patterns in the hair care market influenced the make-up market during recent years.

Supply and competition

Apart from inter-industry competition, which is common to both subsectors in the EC, external competition is of a different nature: in the soaps and detergents sector it comes from distributors, while in the perfumes and toiletries industry the threat comes from foreign competitors.

Soaps and detergents

The EC soap and detergent industry operates in a very competitive environment but benefits from considerable potential in developing countries. While the supply of raw materials is widespread, the finished product is dominated by a few northern multinational companies. Within the EC, there is a relatively mature market in the northern Member States, while a sharp growth in the use of cleaning products is taking place in the southern countries.

Over the last twenty years the emergence of hypermarkets has considerably modified the distribution system of the industry. Manufacturers in the soaps and detergents sector have now to face more powerful buying groups. Furthermore, over the last few years, distributors have launched their own products (own label brands) onto the market, thus heightening existing competition.

Perfumes and toiletries

During the last few years, the growth in products for men has risen sharply, with as yet no indication of any decline. Although such growth is mainly the result of the attracting of a group of new consumers, the successful promotion of product "loyalty" has stabilised sales. Fashion dictates the trend in new products, demand for which is generated by the general concern for improved grooming and care. Marketing, which focuses more and more on skin hygiene and the protection of the environment, is also responsible for these developments.

The industry has been affected by foreign competition, with products manufactured by Japanese companies (e.g. Shisheido) becoming increasingly available on the EC market. The Japanese firm has recently set up a cosmetics factory in the Loire Valley, which reflects the internationalisation of the perfumes and toiletries industry.

Production process

Within both sectors, research and development and marketing represent an important part of the operating process, given the importance of anticipating future demand on the part of the consumers.

Soaps and detergents

In this very competitive environment, considerable funds are allocated to R&D activity. On average, a company dedicates 2.5% of turnover to R&D. This investment provides a better understanding of future demand, encourages the development of new products and the improvement of existing products to respond to, among other issues, environmental problems. In the production process, the use of enzymes in laundry washing powders is increasing as the effectiveness of these biological powders on stains, blood and eggs, for example, is widely recognised. The appearance of liquid formulas, particularly effective at low temperatures, also consists a recent evolution. Innovation is driving the industry forward with increased concentration of liquids and powders and the introduction of "fat busting" enzymes.

Perfumes and toiletries

Irrespective of age, European consumers are becoming increasingly aware of their appearance, personal hygiene and health. Campaigns launched to combat skin cancer, for example, have resulted in a greater use of sun creams. Following a clear consumer trend, an ever growing range of natural products is now available. Bath, shower and hair mousses and gels have replaced the more conventional products, as have skin products, especially those designed to reduce signs of ageing.

NDUSTRY STRUCTURE

Companies

Both subsectors are characterised by the presence of major multinational companies, which are often active both in the soaps/detergents and the perfumes/toiletries segments. Another common characteristic is the strong interest shown by companies for the east European market.

Soaps and detergents

In Europe, the soaps and detergents sector accounts for about a thousand manufacturing and distribution companies, which vary from those who only supply the local market to large international companies who serve the world market. The European and American multinational companies possess a large number of production units within the Community.

The world market for cleaning products is dominated by five major multinational groups, of which three are EC-based: Unilever (NL/UK), Henkel (D), Benckiser (D), Colgate Palmolive (USA) and Procter & Gamble (USA). At present many of these companies are intensifying their efforts to penetrate other markets, notably by buying out or buying shares in companies often placed downstream of their production process. In 1991, the main M&A operations in the industry were Benckiser's acquisitions in the USA of Quintessence Holdings, and of the Germaine Montell and Lancaster cosmetic product lines from Revlon.

Heavy investment is being made by the major manufacturers in Eastern Europe: in 1991, Henkel established joint ventures in Czechoslovakia and in the former Soviet Union, Procter & Gamble was active in Poland, Hungary and Czechoslovakia and Unilever acquired Pollena Bydgoszcz, a Polish detergent manufacturer.

Perfumes and toiletries

The following five firms dominate the world market: L'Oréal (F), Unilever (NL/UK), Shisheido (J), Avon (USA) and Procter & Gamble (USA). Among the other important EC firms are Wella (D), LVMH (F), Schwarzkopf (D) and Sanofi (F). Although the major groups grew in strength over the past few years, smaller companies have also begun to appear on the market, particularly at the national level, operating in niche markets.

The sector has been characterised by some major acquisitions in the period 1988-1990 (e.g. LVMH and L'Oréal took control of Lanvin, Unilever bought out Fabergé/Elizabeth Arden). In 1991, the main M&A operations were undertaken by L'Oréal, which acquired Dralle, a German hair care firm and by Sanofi, which acquired the French Quest International France, Unilever's essential oils subsidiary. The major multinationals operated on the east European market as well: for example, Procter & Gamble established joint ventures in Poland and Hungary in the field of hair and personal care products.

ENVIRONMENT

Soaps and detergents

The use of soaps and detergents has at times been associated with water eutrophication, i.e. a decrease in oxygen which engenders an abnormally high level of aquatic vegetation. Water eutrophication continues to be a cause of public concern. It is however generally appreciated that detergent ingredients form only a minor fraction of this form of pollution, which mainly originates in industrial, agricultural and human waste. The view on phosphates has moved significantly and this well researched ingredient is now preferred by a number of respected authorities.

Plastic packaging of detergents is another environmental issue characterising the industry. For this reason, recycled paper and cardboard usage is increasing. Similarly, several companies now use a minimum of 25% recycled plastic in detergent bottles and are actually supporting collection and recycling schemes for plastic.

Perfumes and toiletries

In the last few years, environmental problems have become an important issue both for producers and consumers. All manufacturers within the sector are investigating ways of reducing the effects of their products on the environment. At present, attention is being focused on two specific possibilities: the biodegradable properties of toiletries and cosmetics, and the incorporation of preservatives in their manufacture.

Problems relating to aerosols which contain ozone layer damaging CFC (chlorofluorocarbons), particularly deodorants and hair fixing products, are currently being solved by replacing CFCs with environment-friendly components.

Finally, there is a great industry concern about the current debate on animal testing. The harmlessness of perfumes and toiletries needs to be tested before they are sold to consumers, and so far the only legal way of doing so is animal testing. The perfumes and toiletries industry refuses a prohibition of such practices until new testing methods are introduced, and at the same time supports R&D efforts to discover alternative methods.

OUTLOOK

In the medium to long term, growth in the soap and detergent sector depends to a great extent on consumer behaviour and the development of other sectors such as textiles and household equipment. At the same time, protection of the environment and product safety will play an ever increasing role in industrial development. Expansion in sales volumes may be expected with the growing economic prosperity of former Eastern bloc countries, where heavy investment is being made by the major manufacturers. Finally, within the EC, there still remains a considerable growth potential, notably in the Southern countries.

Table 5: Soaps and detergents, perfumes and toiletries
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	3.3	3.3
Production	3.3	3.2
Extra-EC exports	5.1	4.2

Source: DRI Europe

As for perfumes and toiletries, the prospects for growth vary in accordance with the wide range of products within this industry. Market saturation is likely to slow the sharp growth in hair care products that took place in the EC market during recent years. On the other hand, growth in beauty and skin care products is set to continue, as well as for men's toiletries.

Pharmaceuticals
NACE 257

The EC is the world leader in terms of pharmaceuticals production and exports. Total EC output amounted to 60 billion ECU in 1991, of which non-prescription pharmaceuticals accounted for a share of 20%. The sector is also characterised by a constant trade surplus, as well as by a rapid growth of intra-EC trade.
R&D accounts for a large part of investments in the pharmaceutical sector, and its R&D/turnover ratio is one of the highest in the EC industry. The pharmaceutical industry is adapting itself to meet the new challenges presented by new technological developments (biotechnology), politics (upheaval in Eastern Europe), economics (emergence of new competitors) and demography (ageing population).

INDUSTRY PROFILE

Description of the sector

Within the EC, medicinal products are defined according to Article 1 of Council Directive 65/65/EEC (see Official Journal L 22. of 9.2.65 for more details):

- Proprietary medicinal products: Any ready prepared medicinal product placed on the market under a special name and in a special pack;
- Medicinal product: any substance presented for treating or preventing disease in human beings or animals;
- Substance: any matter irrespective of origin (i.e. human, animal, vegetable, chemical).

Medicinal products can be divided into two main groups according to the selling pattern: the first is prescription pharmaceuticals, which need to be prescribed by a medical doctor to be purchased; the second is over the counter (OTC) pharmaceuticals, which can either be prescribed by doctors or bought by the consumer without a prescription, or bought spontaneously by the consumer (the true self-medication market).

It is not easy to translate the concept of medicinal products into economic terms; until recently, each Member State had its own classification. To avoid confusion, the sector has adopted a grouping of data based on the Standard International Trade Classification (SITC), heading 54 of the OECD, i.e. the entire "medicines" section, as well as the sections covering specific active substances.

The key figures are based on this definition. Missing data have been completed, wherever possible, with Eurostat data drawn from a NACE 257 base. The data reported are approximate and therefore should be considered as trend indicators, providing an acceptable basis for comparison.

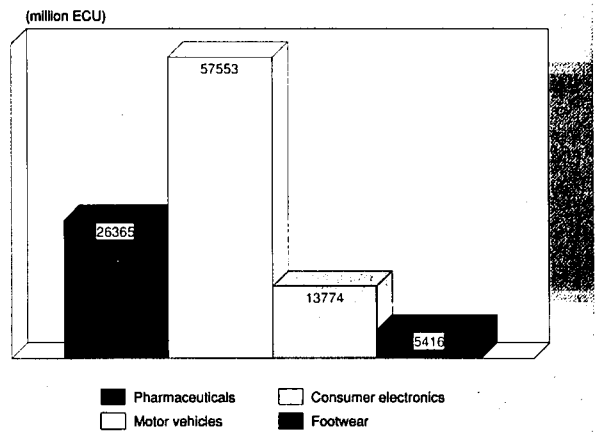
Main indicators

The production of pharmaceuticals in the EC grew by 9.9% in 1991, with all Member States enjoying an increase. Most notable were the rises registered in Germany (14.9%), Italy (9.3%) and France (7%): these three countries together account for two thirds of total EC production.

Total EC consumption of pharmaceuticals increased by 10% in 1991; this strong performance was common to all Member States, with the exception of Belgium and the Netherlands.

During the same period, employment increased by 2.3% in the EC as a whole. All Member States have recorded growing or stable employment figures except the United Kingdom (-5.8%) and Portugal (-2.2%).

Figure 1: Pharmaceuticals
Value added in comparison with other industries, 1991



Source: Eurostat

As far as extra-EC trade is concerned, exports grew during 1991 in all Member States except Portugal (-15.6%) and France (unchanged). Extra-EC imports grew all over the EC, with the most noticeable increases in Germany (29.3%), Spain (25.8%) and France (25.3%).

Recent trends

Production and consumption in the pharmaceutical sector increased rapidly during the 1980s, both at a rate of more than 6% per year. As for trade, growth in extra-EC exports has been quite weak, particularly in the period 1985-1991, while growth in extra-EC imports has been more stable. Altogether, the pharmaceutical sector has been characterised by higher rates of growth than those of overall manufacturing activity in the EC during the period 1982-1991.

International comparison

In the world pharmaceutical market, the EC is the leading producer. In 1991, the value of production was about one third higher than that of the USA, and more than the double that of Japan. Moreover, during the period 1987-1991, the EC recorded an increase in production of 36.1% (measured in constant prices) compared with a rate of 15.9% in the USA and 29.5% in Japan.

The Japanese pharmaceutical industry has long been focused on the domestic market, an attitude encouraged by the national health insurance system which has provided the entire population with access to low-cost health care. This has prompted patients to see their physicians frequently, resulting in growing demand for medicinal products and steady expansion for the pharmaceutical industry. The government is now trying to control spending on the national health system and has reduced its official drug reimbursement prices. This policy is progressively reducing profits on any drug. As a reaction to slumping domestic product prices, the Japanese industry is developing new markets in the USA and Europe and acquiring foreign firms. Nevertheless, when it comes to medical research, Japanese manufacturers remain far behind their counterparts in the USA and Europe. Well aware of this problem, Japanese companies are investing heavily in R&D in a bid to catch up with their foreign competitors.

Foreign trade

The EC as a whole is a net exporter of pharmaceuticals in the world market. Nevertheless, Greece, Portugal and Italy are net importers of pharmaceuticals; the small size of national industries in Greece and Portugal helps explain the importance of imports to these economies. The negative trade balance of Italy dates back to the early 1980s. Due to a strong growth in internal demand in Italy, imports grew by 12% per year during the 1989-1991 period compared to an increase of 10% in production and of 5% in exports.

The export/import ratio of the industry has declined steadily during the period 1982-1991, going from a value of 2.8 in 1982 to 1.9 in 1991. These figures indicate that, although the European pharmaceutical industry remains the world leader, it has been losing ground on foreign markets.

Extra-EC imports come overwhelmingly from western industrialised countries, with the USA and EFTA countries accounting together for 85% of total imports in 1991. On the contrary, export markets for the EC pharmaceutical industry are more dispersed. Developing countries, together with the category "others" (e.g. mainly Middle East and South and Central America), account for more than half of extra-EC exports.

As far as intra-EC trade is concerned, figures measured in constant 1985 prices show that it has nearly doubled in size,

Figure 4: Pharmaceuticals

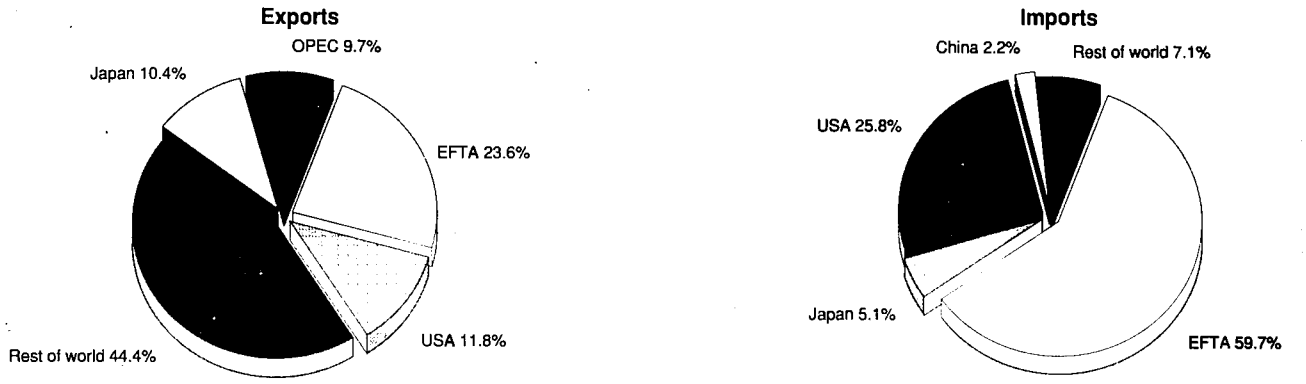
Figure 6: Pharmaceuticals
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

rising from 3 511 million ECU in 1982 to 6 337 million ECU in 1991.

The trends in demand and production, and structural changes that are taking place in the prescription and non-prescription pharmaceuticals markets are analysed separately after the next sections.

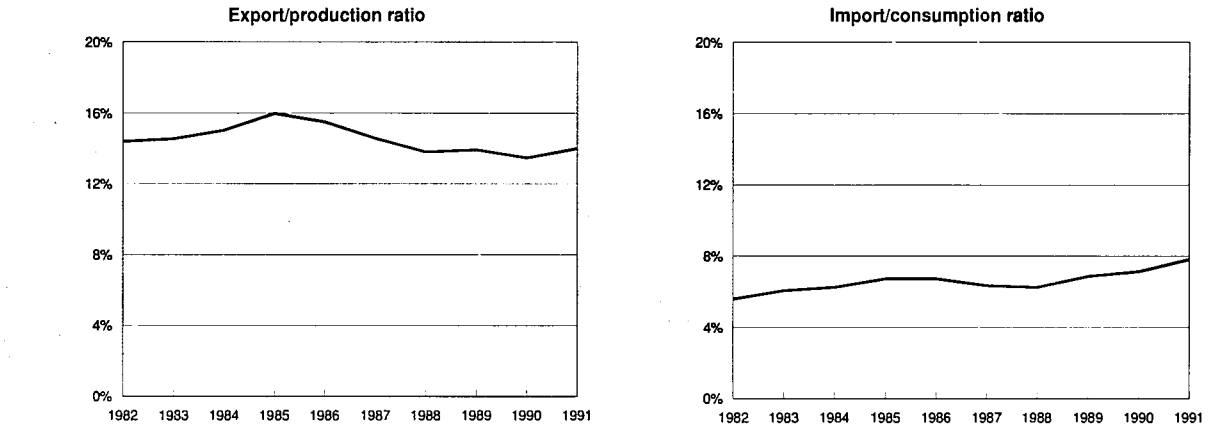
REGULATIONS

The legislative framework for pharmaceutical products was definitively changed with the adoption, in March 1992, of four directives related to pharmaceutical advertising (92/28/CEE), to the classification of the supply of medicinal products (92/26/CEE), to pharmaceutical label/leaflets (92/27/CEE) and to the wholesale distribution of pharmaceuticals (92/25/CEE). The Council Directive 92/26 defines a set of criteria that allow to classify a given product as a prescription or non-prescription pharmaceutical, whereas the other three directives apply to both prescription and non-prescription pharmaceuticals. The four directives, which will come into force on 1 January 1993, guarantee that all manufacturers will be able to operate under the same conditions in the whole Community.

The criteria for the registration of pharmaceutical products are identical in all Member States, but the registration procedures are not always the same. The application of the registration process to each product in each country constitutes a waste of time and is the main legislative barrier to the free circulation of products since manufacturers have to obtain a separate marketing authorisation for each country.

Manufacturers have the possibility of coordinating national registration decisions under the "multi-state" procedure improved by Council Directive 83/570/EEC. This procedure has, however, not been utilised to its full potential. The Commission has made a proposal for a future marketing authorisation system for medicinal products, which is still under discussion. This system would include the establishment of a European Agency for the Evaluation of Medicinal Products and of a centralised Community procedure for new and high-technology products and for products issued from biotechnological processes; the creation of a new decentralised Community procedure based on the principle of mutual recognition, with important safeguards to ensure that there is no dilution of the strict standards of quality, safety and efficacy; and the maintenance of national marketing authorisations for products of local importance.

Figure 7: Pharmaceuticals
Trade intensities



Source: Eurostat

In 1992, a survey was carried out at the request of the Commission's Directorate General for the Internal Market and Industrial Affairs (DG III) about the efficiency of the current marketing authorisation system. This survey has once again demonstrated that the periods of time within which the authorities must process an application for a marketing authorisation (maximum 210 days, according to directives 65/65/EEC and 81/851/EEC) are in practice respected by only a few Member States. It is hoped that the adoption of the future marketing authorisation system will bring some improvement to this unsound situation.

Finally, a regulation establishing the Supplementary Protection Certificate (SPC) was adopted in June 1992 which will come into force on the 1st January 1993. This measure applies to all products subject to an authorisation in any Member State, i.e. both to prescription and non-prescription pharmaceuticals. The main aim of the SPC is to compensate for the period of effective patent protection lost while a medicinal product undergoes research and development (it takes over 10 years from the time a patent is applied until a marketing authorisation is granted, leaving only a short exclusivity period to the innovator to recoup its investment in R&D before imitations appear on the market). The SPC itself may not under any circumstances exceed five years.

ENVIRONMENT

The current discussions on the reduction of packaging and packaging waste can not be separated from the need to provide the consumer with comprehensive information and the need to protect the product.

Since the product information is contained either on the label or in the patient leaflet, it is essential that product and packaging are kept together until the final disposal of the product. Any measures in the area of packaging recycling or packaging waste reduction must therefore be balanced against these two requirements.

As far as the debate on the reduction of the use of ozone-depleting substances is concerned, account must be taken of the benefit to the consumer of certain medical products containing ozone-depleting substances as a means of delivery of the product.

Prescription pharmaceuticals

MARKET FORCES

Demand

Pharmaceuticals are bought mostly via a doctor's prescription, although a distinction has to be drawn between prescription pharmaceuticals and OTC products: prescription pharmaceuticals can be sold only in pharmacies, while OTC products may be sold in some countries in pharmacies only, in others in drugstores and sometimes even in food stores. Apart from consumers, other categories of purchasers are medical doctors, hospitals, and other institutions operating in the health care system.

The demand for pharmaceutical products has recently been greatly influenced by two main factors. First, the ageing of the population, which partly originates in improved medical care and products, is slowly changing the pattern of production to adapt to the growth of importance of the elderly as a share of the total population. Second, the opening up of Eastern Europe has created new market opportunities for the EC industry. Production traditionally oriented towards less sophisticated medicines combined with severe distribution problems have led to a situation in which there is urgent need for a reliable supply of advanced medicinal products.

Supply and competition

Production is very diversified as it meets specific and very diverse demand. It varies in its degree of integration (from the synthesis of basic chemicals to the preparation of finished products) as well as in the type of dosage formulation produced (tablets, pills, injectable ampoules, or capsules).

Production must meet the demand for both widely prescribed medicines for the treatment of common illnesses, as well as for medicinal products to treat certain rare conditions. In both cases the legislative framework is the same; production standards are very strict and high quality is essential.

Domestically, the EC pharmaceutical industry faces problems of various regulatory environments, pricing policy and patent laws which differ from country to country in the EC. Internationally, it faces strong competition from the United States and Japan.

Production process

Medicinal products depend heavily on research for progress. Research and development (R&D) accounts for a huge part of investments in the industry. EC pharmaceutical companies invest nearly 5 billion ECU a year in R&D, which répresents about 15% of this turnover, and is among the highest R&D/turnover ratios in industry. Depending on the size of the national industries, investment varies between 3% and 24% of turnover. As a result of this investment, six EC companies are among the ten biggest R&D investors world-wide. Research costs are rising and there is the need to invest simultaneously in new fields such as biotechnology.

Another problem area is the long development time of a product. It takes over ten years from the time a patent is applied for until marketing authorisation is obtained. This process uses up more than half the patent protection granted to the innovator. A special regulation establishing a Supplementary Protection Certificate (SPC) was thus adopted (see the section on Regulations) to give EC manufacturers an extension of the patent-protection period, similarly to what has been the case in Japan and in the US.

INDUSTRY STRUCTURE

Companies

Three EC companies are among the ten world-wide pharmaceutical leaders: Glaxo (UK), Hoechst (D) and Bayer (D). SmithKline-Beecham, which is the result of the merger of Beecham (UK) and SmithKline Beckman (USA), can be added to this group. Of the remaining six, two are Swiss and four USA-based companies. Within Western Europe, the leading companies are from the United Kingdom (Glaxo, Wellcome, ICI, Beecham), Germany (Hoechst, Bayer) and France (Rhône Poulenc).

Strong competition exists both in Europe and world-wide and no single company has a dominant position: the ten largest companies represent only 25% of the world market.

Strategies

In order to face new challenges in terms of R&D costs, increasing competition and market diversity, new groupings of major companies have emerged through mergers and acquisitions. The trend was initiated with the merger of SmithKline Beckman (USA) and Beecham (UK), giving SmithKline-Beecham, Bristol Myers (USA) and Squibb (USA) giving Bristol Myers-Squibb and the acquisition of Rorer (USA) by Rhône Poulenc (F). In 1991, the major acquisition operation was pursued by SmithKline-Beecham which acquired Sächsisches SerumWerke, an East German manufacturer of vaccines and the largest producer of influenza vaccine in Germany. As for the Japanese M&A activity, in 1991 Yamanouchi (J) acquired the pharmaceutical division of Royal Gist-Brocades (NL).

Source: Institute for Medicinal Statistics

The European Single Market has also had an impact on pharmaceutical wholesalers. While this segment is quite concentrated in the northern European countries, there is still some scope for further M&A activity in the southern European countries. Thus, Alliance Santé (F), formed with the merger of French ERPI and the Italian Alleanza Farmaceutica, is set to merge with Cofares (E), the largest Spanish company in this sector.

OUTLOOK

The last years have been particularly euphoric for the pharmaceutical industry, thanks to rapid economic expansion and the consumer boom in the late 1980s and the German reunification. The pharmaceutical sector will remain among the fastest growing sectors over the 1990s; however, production growth is expected to return to its rates of the early 1980s, that is, about 4.5% per year. Exports and imports will grow at rates of about 5% per year, thus significantly lower than in the recent past.

Non-prescription pharmaceuticals

MARKET FORCES

Demand

OTC products can be purchased directly by the consumer without being prescribed by a doctor. The products are generally used preventively and for benign disorders. OTC purchasing is a well established practice which brings the following advantages: it reduces the financial burden on the state health care system; it reduces the doctor's workload in taking care of health problems which do not require medical treatment; it promotes personal responsibility on issues which affect a person's own health.

There is a certain degree of confusion in the determination of market size for OTC products. The rules governing these products' classification, reimbursement and sales outlets, vary considerably from country to country. The same product is sometimes supplied only on medical prescription in one country and over the counter in another. There are also several products which may be sold without a prescription but are nevertheless reimbursed or partially reimbursed if prescribed by a doctor.

The Institute for Medicinal Statistics has estimated that the total market for non-prescription medicines in 1991 was about 15 billion ECU, while the size of the self-medication market reached 8.6 billion ECU, i.e. 57.2% of the total OTC market. The latter is dominated by cough and cold products and analgesics, and grew at an average rate of 8.2% since 1987. This compares with an average growth of the total market for non-prescription pharmaceuticals of 7.5% in the years 1987-91.

The importance of the non-prescription potential and the self-medication turnover varies greatly from country to country. The practice of self-medication is well established in the northern Member States including France, while it is quite underdeveloped in the southern Member States. Until recently, OTC products were, at least officially, an unknown phenomenon in Greece.

INDUSTRY STRUCTURE

Companies

OTC products are manufactured both by large companies, which in general also manufacture prescription-only medicines, and by smaller more specialised enterprises. Until recently, the majority of companies in the sector were national companies supplying their respective domestic markets because of differences in Member States' legal requirements and consumer habits. This explains why the market is still fragmented and that there are only very few "Euro-brands" (i.e. OTC products sold under the same name all over Europe).

Table 6: Self-medication products
Turnover of the principal products at public price level, 1991

(million ECU)	B	D	E	F	I	NL	P	UK
Cough and cold remedies	68.7	439.8	92.2	510.8	211.8	31.3	8.8	219.7
Analgesics	68.4	488.1	135.3	359.5	169.2	30.8	5.2	212.6
Digestives and intestinal remedies	64.2	341.8	72.4	375.2	240.4	19.8	6.8	131.2
Skin treatment	29.2	257.4	89.9	352.7	114.6	18.3	8.7	139.8
Vitamins and mineral supplements	39.6	300.3	59.1	236.3	145.2	24.2	2.6	91.3

Source: Institute for Medicinal Statistics

The top three companies are Sanofi/Sterling Health (F/USA), with a share of 5.4% of OTC world market, Rhône-Poulenc Rorer (F/USA) with a share of 3.6% and Bayer (D) with a share of 3.4%.

Strategies

With a view to obtaining the necessary critical mass to operate effectively in the Single Market and on exports markets, the OTC products industry has also been affected by a certain number of M&A operations. In fact, among the first six companies world-wide, five of them acquired their position as a result of mergers and acquisitions at the end of the 1980s. The most important mergers have been the one between Sanofi (F) and Sterling (USA) in 1990, and the acquisition of Rorer (USA) by Rhône Poulenc (F) in 1990. Nowadays, international companies are responsible for almost 60% of total turnover of the OTC industry.

Table 7: Pharmaceuticals

(%)	1992-93	1992-96
Apparent consumption	4.5	4.1
Production	4.6	4.1
Extra-EC exports	5.0	4.6

Source: DRI Europe

OUTLOOK

The demand for OTC products is likely to go on growing apace in the following years. This is confirmed by the fact that many pharmaceutical companies are developing their OTC segments.

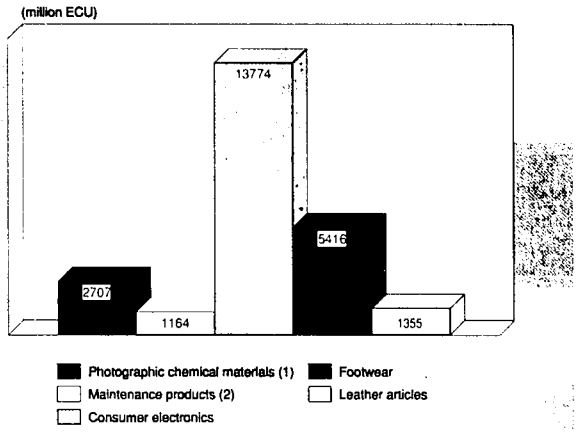
Other chemicals
NACE 259

Other chemicals include the manufacture of a number of chemical products for non-industrial use, of which photographic chemical materials and household and industrial maintenance products are the most important. Demand for photographic chemical products has been strong in recent years and prospects for the future remain good. Producers have made efforts to improve the quality of existing products and to bring out new ones. Although the demand for household and industrial maintenance products has seen some consolidation during recent years, its sales are not as vulnerable to the economic downturn as those of basic chemicals. The market has become more consumer oriented, where competitive factors such as new product development, ease of use of products and product distribution reign.

Figure 1: Photographic chemicals and maintenance products
Value added in comparison with other industries, 1991



(1) NACE 259.1
(2) NACE 259.2
Source: Eurostat

INDUSTRY PROFILE

Description of the sector

NACE 259 includes the manufacture of a number of chemical products, chiefly for household and office use:

- photographic chemical materials, including photographic film and paper, and auxiliary products (NACE 259.1);
- polishes for household use, including (shoe, furniture and floor care products, metal polishes, car polishes, etc. (NACE 259.2);
- chemical products for office use, including pencils, writing inks, office glues, stencils and carbon paper (NACE 259.3);
- other chemical products not intended for industrial use (NACE 259.4).

The analysis which follows focuses primarily on the two most important subsectors among the "other chemicals" sector: photographic chemicals (NACE 259.2) and household and industrial maintenance products (NACE 259.2 and 259.4) of which the most important product types are cleaning products, disinfectants, polishes and deodorisers.

Main indicators and recent trends

Photographic chemicals

Photographic chemicals production is more than twice that of maintenance products. Photographic chemical products have shown strong growth over the 1989-90 period. Growth was flat in 1991. Compared to maintenance products, the industry is much less labour intensive, employing close to 40 000 people in 1991. Since 1992, however, the sector's workforce has shrunk by 8 000 people.

Maintenance products

The rise in demand for maintenance products over the last decade was not entirely paralleled with a comparative rise in production; instead, imports have increased their share of EC consumption. Over the last decade, imports were booming at around 10% in real terms on average per year, while exports stagnated during the second half of the eighties (Table 3). Employment in the industry has been almost constant over the last decade.

Foreign trade

Globally, over the entire product range within the other chemicals grouping, the EC is a net importer. The export/import ratio decreased over the second half of the eighties. The EC maintenance products industry, however, is a net exporter, although the industry's export/import ratio has gradually decreased from 5.7 in 1984 to 3.3 in 1991.

More than half of the exports of other chemicals are directed towards the EFTA and the USA. Imports are dominated by Japan, accounting for one third of EC imports.

Intra-EC trade is on the increase. Between 1982 and 1991, the total value of other chemical products traded within the EC more than doubled, in current prices.

MARKET FORCES

Demand

Photographic chemicals

Swift demand increases for photographic chemicals are linked to factors such as increased household income and more time

available for leisure activities and travel. This development has been paralleled, during the eighties, by the appearance on the market of cameras suitable to everyone's needs: increased sophistication of cameras on the higher end of the market was complemented by the introduction of easy-to-use automatic cameras, and even of throw-away cameras.

Maintenance products

The long term development of the demand for maintenance products is linked to a number of demographic factors. The ageing of the population brings with it the need for more intensive use of space and thus more frequent maintenance. The number of households is increasing, with more smaller (e.g. single person) households, pushing up demand. The increasing number of women working outside the home has changed the nature of demand: more practical products are demanded, designed to help save time. Consumption of maintenance products also varies regionally, from one Member State to the other, according to climate and local customs.

Supply and competition

Photographic chemicals

In the photographic chemicals industry, producers have brought new products on the market, including special purpose films or films with slightly different colour effects.

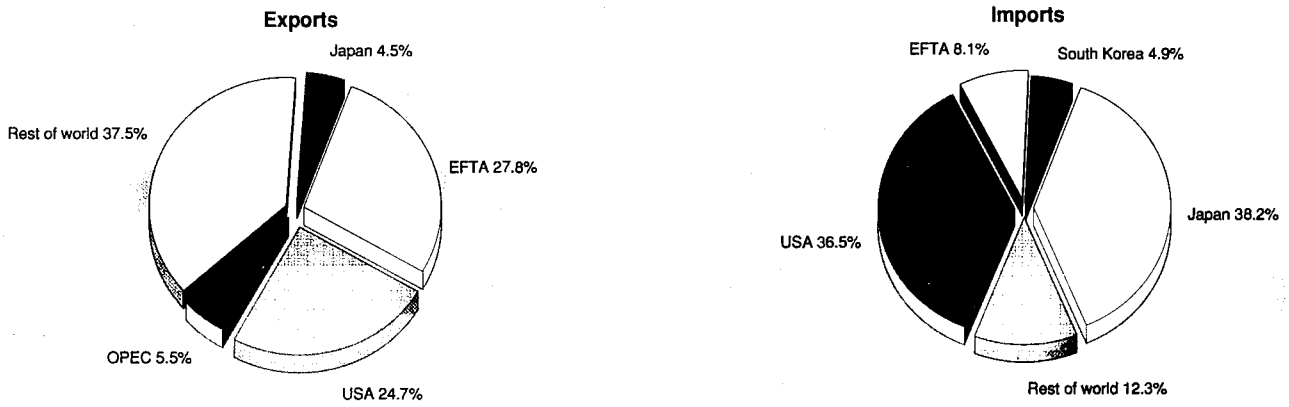
Maintenance products

Competition on the market for maintenance products is not only on the quality of the products, but more and more also on ease of use, which is linked to packaging and preparation of the product (e.g. ready to use products rather than products that still need to be diluted with water). Research and development in the sector is often geared towards exactly these aspects of product marketing.

Production process

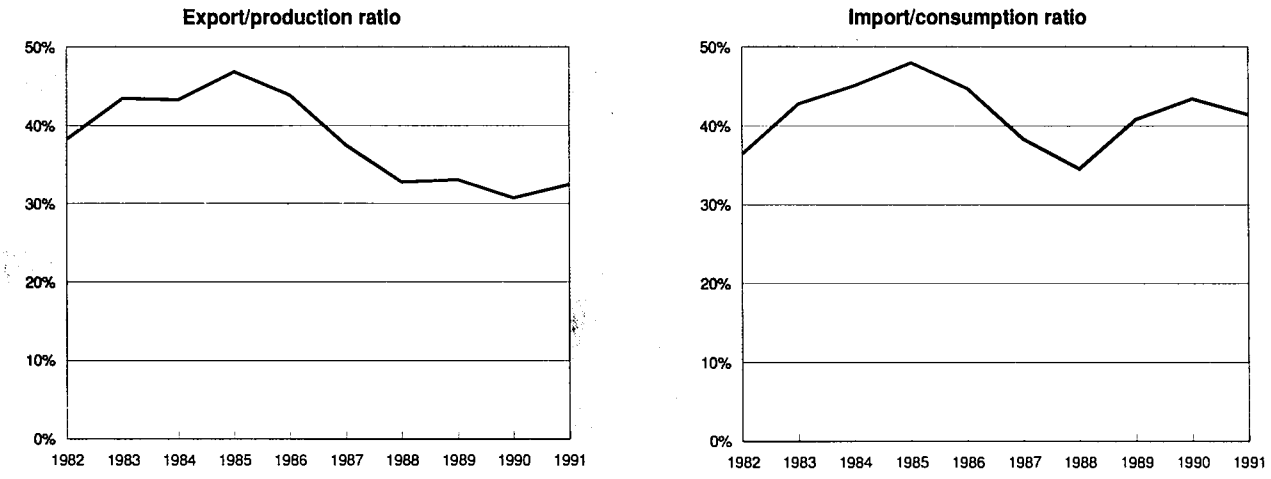
Investment in the other chemicals subsectors is geared towards product development. Rapid changes in consumer tastes and in government regulations mean that constant efforts are

Figure 3: Other chemicals
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

Figure 4: Maintenance products
Trade intensities



Source: Eurostat

needed in R&D in order to maintain market shares. Packaging and production processes are constantly being improved and altered. In the maintenance products subsector, consumer safety and environmental considerations are determining factors when it comes to product development. Packaging and labelling must ensure that the product is both easy and safe to use.

Photographic chemicals

In the photographic chemicals subsector, increasing automation of production processes has lead to production increases over the last decade, despite shrinking employment. The number of people employed was diminished by 16%, to an estimated 40 100 in 1991.

Maintenance products

Employment in the maintenance products subsector has been stable over the last decade, at around 32 000 people. Productivity increases enabled the industry to fuel increasing demand.

INDUSTRY STRUCTURE

Companies and strategies

Companies in the industry include large multinational companies besides smaller companies serving national or regional markets. These companies are often not only active in the chemical consumer products sector, but in other consumer product sectors as well. Statistics are therefore difficult to obtain.

In 1990 the number of companies active in the maintenance products sector was estimated at 560 within the EC, including the former Eastern Germany.

ENVIRONMENT

Photographic chemicals

Environmental issues concerning the EC photographic chemical industry include the discharge of silver thiosulphate in photographic waste into water bodies, in connection with the EC Directive on pollution caused by dangerous substances into the aqueous environment, and the classification, packaging and labelling of photographic processing chemicals in accordance to the EC Directives on dangerous preparations and dangerous substances.

Maintenance products

In the maintenance products subsector, major efforts have been made to develop new types of propellant for aerosols and containers that do not involve the use of pressure. Better labelling, in accordance with EC regulations, should assure consumer safety.

OUTLOOK

Photographic chemicals

The photographic chemicals industry has seen slow growth in 1991, but the sector is expected to return to higher growth rates, linked to overall improvement in the EC economy and increased consumer confidence.

Maintenance products

The market for maintenance products is expected to be stable, with growth rates slightly below that of GNP. It is unlikely that the use of maintenance products would be reduced, given their strong integration into many aspects of daily life, and, therefore, the sector's relative insulation from the vagaries of the economy. The opportunities for growth are somewhat higher in the southern Member States, where the use of maintenance products is less developed.

Man-made fibres
NACE 26

The manufacture of man-made fibres in the EC is confronted with intense competition particularly from developing and industrialised countries. The European industry is thus turning its attention to higher value added products, while pursuing an investment policy aimed at rationalisation and research and development.
The crisis in the textiles industry, along with the economic gloom which has characterised recent years, brought about a marked slowdown in the growth of demand in 1991. The European industry will grow at a slow pace in 1992, and will record a low level of growth in the first half of the 1990s.

INDUSTRY PROFILE

Description of the sector

The chemical fibres (or man-made fibres) industry covers three different types of fibres: synthetic fibres, cellulosic fibres, and mineral fibres.

Chemical fibres mainly consist of synthetic fibres which accounted for 84% of world chemical fibre production in 1991. The main synthetic fibres are polyester, polyamide (nylon), acrylic and polypropylene fibres. Cellulose-based fibres include acetates, rayon, rayon staple fibre and viscose. These artificial fibres, which are derived from natural sources such as cellulose, account for the remaining 16% of world chemical fibres production. Although mineral fibres are also part of the chemical fibre sector, they are excluded from the statistics presented in this chapter.

All of these fibres are divided up into sub-categories according to their physical form. Filament is a continuous polymer which is remilled in its molten state via a fine strainer and then solidified by cooling. It is then spun in a variety of ways, depending on how it is to be sold. It can also be cut up into short fibres for use in the manufacture of fabric using traditional machines designed for natural fibres. These short fibres often have very similar characteristics to those of natural fibres.

The preponderance of synthetic fibres over cellulosic products is becoming more and more pronounced. Among synthetic fibres, short fibres represent the bulk of EC production, with more than 50% of the total. Synthetic filaments also comprise an important share of EC production. Alternatively, cellulosic fibres, which represented about 22% of total chemical fibres in 1980, now represent a mere 16%.

Main indicators

Since 1980, EC production of man-made fibres has grown at an average annual rate of 1.6%. In 1990, production in volume grew 2.6% in the EC, after a strong 4% gain recorded in 1989. This production performance was driven by strong home demand which was influenced by demographic factors and increased earnings and which produced a 4.6% increase in consumption in 1990. This output growth is significant when compared to world production which grew only 1% in 1990.

The downturn in the textiles and automotive industries in 1991, however, led to a sharp decline in the production of man-made fibres in Western Europe. Production fell 6% in 1991 from 1990, the decrease being particularly strong for cellulose fibres and polyamide.

Extra-EC exports collapsed in 1989 and 1990 before stabilising in 1991. The trade deficit, which appeared in 1988, improved in 1991.

In 1991, the EC man-made fibres industry employed 77 400 workers, an apparent 7.7% increase from 1990. This is, however, due to the inclusion of eastern Germany in the 1991 statistics. The general trend in employment continues to be downward; as figures for all of the other EC man-made fibres industries showed further shrinkages in their staff in 1991.

Recent trends

The EC chemical fibres industry has undergone extensive restructuring since the late 1970s. The low rate of increase in European textile consumption during the 1970s (following the first oil crisis) contributed to this structural change. Among the other motives for this restructuring were the growing deficit on the EC's textile and clothing trade balance and the development of chemical fibre production capabilities in the rest of the world, not to mention the numerous investments made by EC firms in other parts of the world.

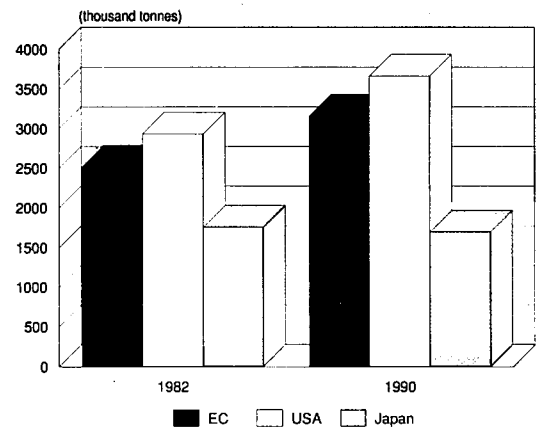
International comparison of production volume



Source: Eurostat

In fact, two waves of production capacity reduction have occurred since 1978. Between 1978 and 1985, over 900 000 tonnes or one-third of the total European capacity, was cut. Another prominent development has been technological changes which reduced manpower requirements. As a result, employment levels in the chemicals fibres sector collapsed, recording a 38% cut from 1980, a decline accompanied by a significant upgrade of apparent labour productivity.

International comparison

Compared to 1977, the EC man-made fibres industry has been losing ground in the production of all kinds of fibres. This is particularly the case in the field of synthetic filaments, where the EC represented less than 14.0% of world production in 1991, down from 20.6% in 1977.

The Japanese man-made fibres industry represents only 9% of world production, while the USA remains the world's leading producer with about 19% of world output, although its position is weakening. Production of the newly industrialised countries (NICs) accounts for an increasing share of world output, displacing the former pre-eminence of both the USA and some EC Member States.

Indeed, the newly industrialised countries are becoming crucial actors in the man-made fibres industry: the most dynamic countries are South-East Asia, among which are Taiwan, South Korea and China. For example, while the East Asian countries represented only 22% of world production of polyester in 1980, this share jumped to 45% in 1989 and could rise to 60% of world production of polyester by 1999. Overall, the South-East Asian industry produces five times as much as it did during the 1970s, and three times as much as the industrialised countries.

In 1991, Japan's production of man-made fibres stagnated while the USA recorded a marginal increase (+1.6%) in production in spite of its weak economy. Production in the newly industrialised countries continues to rise strongly, although at lower rates than those recorded in recent years.

Foreign trade

The EC has a strong rate of import penetration, while the share of its exports in production remains weak. The EC trade balance on man-made fibres has declined steadily since 1983, falling into deficit in 1988 when imports jumped 18% and exports fell 3.7%.

In 1990 and 1991, extra-EC imports decreased slightly (-1% and -6%, respectively), while export performance actually improved in 1991 (+1.9%) compared to the collapse recorded in 1990. Declining demand, along with increasing supply coming from other regions of the world, put pressure on prices as the weakness of the dollar negatively affected extra-EC exports.

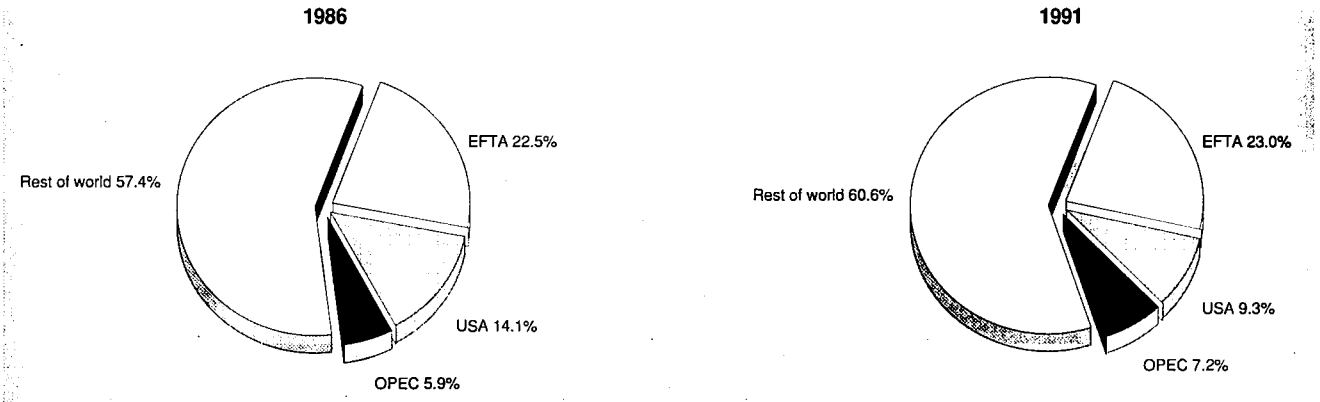
Turning to developments within the Member States, Germany is by far the largest exporter of man-made fibres, accounting for 41% of EC exports. Germany is both the largest producer and the leading importer within the EC, with 18% of total imports, followed by Italy and the United Kingdom. Only Germany and Ireland recorded trade surpluses for the EC in 1991.

The USA is the EC's foremost national trading partner. Although imports from the USA increased between 1986 and 1991, EC man-made fibres exports lost ground in the US market.

Eastern Europe has been an important EC export market. Until 1990, this region had been more important in terms of exports (with about 25% of total extra-EC exports in 1986) than the EFTA countries. Since 1990, however, EC exports to Eastern Europe have fallen drastically.

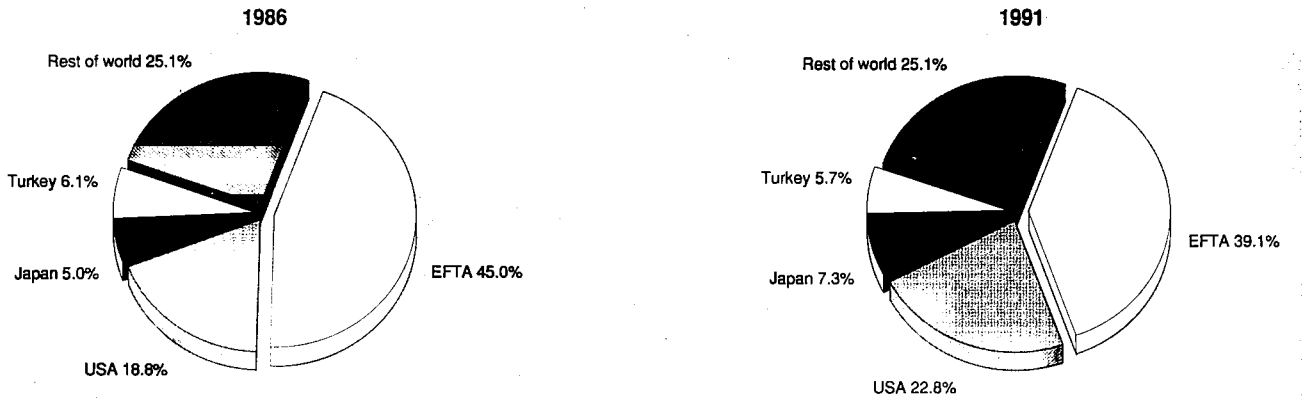
Although EC manufacturers export less than 15% of their production on average to non-EC markets, extra-EC imports

Figure 3: Man-made fibres
Destination of EC exports



Source: Eurostat

Figure 4: Man-made fibres
Origin of EC imports



Source: Eurostat

are gaining an increasing share of consumption in Europe, a share which rose to more than 40% in 1991.

On the other hand, extra-EC imports are mainly coming from EFTA countries, followed by the USA. Imports from developing countries are becoming more and more important and have risen five fold (in current terms) between 1980 and 1991.

Intra-EC trade represents about 71% of total EC imports, which illustrates the high degree of trade between the Member States. Intra-EC trade has however been slowing in the recent past.

MARKET FORCES

Demand

Chemical fibres represent an important share (approximately 65%) of total fibres consumption in the EC. The main end-market for these fibres is the clothing industry, with 42% of total consumption, while fabric for interior furnishings represent another 36% and industrial applications 22%. As consumers account for an important share of demand, overall economic activity and personal disposable income are overriding factors in the dynamics of the man-made fibres. The situation downstream also has a significant influence on the man-made fibres industry. Since 1986, the large increase in imports of textile and clothing products (which has more than doubled in the last 6 years) has hampered the activity of the textile processing industry, thereby reducing EC market shares for textile products.

Looking at consumption of man-made fibres compared to textiles and clothing demand, similar trends emerge. The growth recorded throughout the 1980s in the textiles sector mirrored the overall increasing trend in the consumption of man-made fibres. The relative downturn registered since 1990 in the textiles industry is also noticeable in the fibres sector as consumption growth has decreased during the same period. The reduction of the European market for man-made fibres has indeed been driven by the disappearance of several of its European clients which have shifted operations to developing countries.

The upturn recorded in European consumption throughout the 1980s has also been a positive factor for the man-made fibres industry. Demand for these products has been driven not only by demographic factors, but also by increased earnings which directly influence the main markets for man-made fibres.

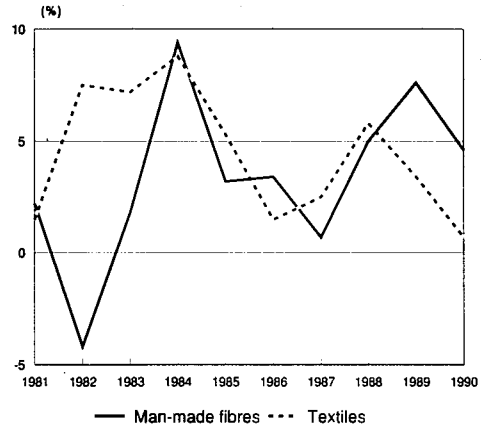
Consumption growth of man-made fibres versus textiles in the EC



Source: Eurostat

Supply and competition

In the few countries for which statistical information is available, the EC industry's competitiveness is jeopardised by stagnating productivity growth. Despite the continuing fall of employment levels, unit labour costs have continued to increase in all the Member States, driving down the industry's competitiveness.

Since 1990, exchange rates have also been a factor in the industry's declining performance in Europe. The weak US dollar continues to benefit US exports to the EC, which remains an open market. In contrast, not only have European producers suffered from the dollar weakness, but production for external markets is often lost when a local producer is established.

The resulting decline in output and the under-utilisation of production capacities has led to a significant fall in EC industry earnings.

Production process

Enhancements in the technology of yarn and fabric formation have been a major factor of the increasing dominance of synthetic fibres over natural fibres. Some processes, such as tufting for carpet manufacture, were initially made possible by developments in synthetic fibres technology. Given their particular suitability for a variety of end-uses, man-made fibres, and in particular synthetic fibres, have been able to capture a significant part of the fibres market.

The production process is increasingly capital intensive, following the need for higher technology products. This feature is the main factor that drives up labour unit costs in the sector, as the industry requires a highly skilled workforce.

INDUSTRY STRUCTURE

Companies

The man-made fibres industry is dominated by a small number of big companies. Companies are specialised in particular fibres, concentrating on speciality fibres in order to avoid competition from developing countries.

With a production capacity of 1.1 million tonnes, Hoechst AG (D) is the world's largest producer of polyester. Its turnover in chemical fibres amounted to 7161 million DM in 1991. Akzo Fibres and Polymer Division (NL) is the second largest EC producer of chemical fibres, followed by Rhône Poulenc Fibres, SA (F). ICI Fibres Ltd (UK) has been the leading European producer of polyamide (nylon).

Among the other main actors in the sector are Courtaulds Fibres Limited (UK), followed by Enimont SpA (I), SNIA Fibre SpA (I), and Bayer AG (D).

The main foreign producers, such as the American Du Pont de Nemours (the world's leading producer of nylon) or the Japanese Asashi, also have production facilities in Europe.

Strategies

The major firms in the man-made fibres industry operate with a very global perspective. Not only do non-EC companies have activities in Europe, but EC companies are present throughout the world. A good example is Hoechst which has a tyre cord capacity of 110 000 tonnes in North America. Meanwhile, the company is also present in the Far East and in China. In terms of sales, Hoechst obtains about 85% of its turnover from outside Germany.

Over the past 15 years, EC producers of man-made fibres have focused research on high value added specialities, such as technical yarn and carbon fibres. The bulk of research and practical applications is directed to high-tech fibres intended for the car, space and defence industries. Technical applications are increasing their share of the European man-made fibres market, while the clothing market is constantly shrinking in Europe. Today, technical applications represent more than 20% of EC consumption, from 11% in 1980. By contrast, production of low-technology fibres has gradually shifted from the developed world to the newly industrialised countries.

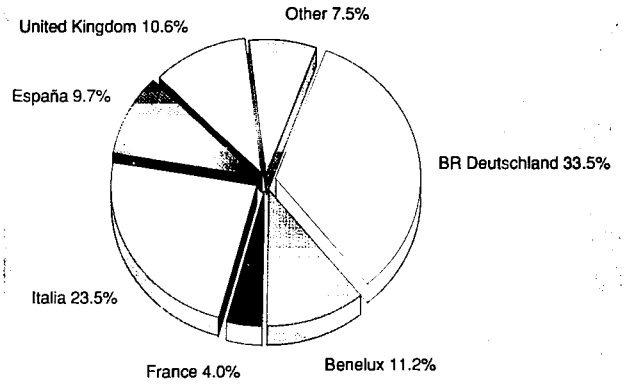
REGIONAL DISTRIBUTION

Among the EC member states, the largest producer of man-made fibres is Germany (34% of EC production in 1991), followed by Italy (24%). Benelux and the United Kingdom are also important producers, each accounting for 11% of EC man-made fibres production.

REGULATIONS

The European Commission has recently taken a decision on the code limiting state subsidies for the synthetic fibres industry. The code's previous extension expired in July 1992, and the decision made by the EC will extend it to the end of 1992. Given that the market for man-made fibres is presently suffering from oversupply, the code's discouragement of increasing production capacity is welcome by the industry.

Figure 7: Man-made fibres
EC production in volume, 1991



Source: Eurostat

OUTLOOK

The EC man-made fibres industry is expected to perform slightly better in the near future. The bulk of the growth will be accounted for by synthetic fibres, especially polyester. Demand for cellulosic fibres will show marginal growth.

Table 5: Man-made fibres
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	2.2	3.2
Production	2.7	2.4
Extra-EC exports	1.5	1.0

Source: DRI Europe

Demand from the industry's main clients is expected to improve. The textiles industry will witness a slight increase in production while import growth will lose momentum. The automotive industry is also expected to improve in 1992, thus contributing to a stronger production performance in the man-made fibres industry.

Metal products
NACE 31

The EC metal products industry is the largest in the world, producing 36% more than the USA and 67% more than Japan in 1991. Metal products experienced rapid growth in the mid to late 1980s following downturns caused by the industrial crisis in the earlier part of the decade. The industry's products serve mainly as intermediate commodities for other industries such as motor vehicles and construction. Despite recessionary slowdowns in these industries, metal products suffered only a minor slowdown in growth in 1991. Production and consumption are expected to virtually stagnate in real terms in 1992 and the prospects for the first half of 1993 are not brighter.
Although comprised of many small firms, the metal products industry is actually one of the largest employers in the EC, with a workforce of over 2.1 million.
Recent efforts to diversify product lines in recent years have helped the metal products industry become less dependent on the heavy industrial markets they traditionally supply.

INDUSTRY PROFILE

Description of the sector

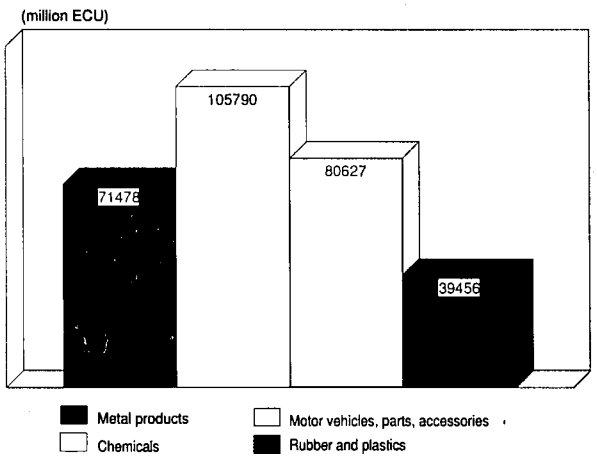
The metal products industry as defined by NACE 31 includes the following sectors:

- Foundries (NACE 311), includes iron and steel foundries which produce cast iron, ductile cast iron, etc., and non-ferrous foundries which produce copper cast, aluminium cast, etc.;
- Forging (NACE 312), includes transforming semi-finished metal into forged metal products through the use of a die;
- Secondary transformation of metals (NACE 313), involves the production of articles such as lathes, nuts, bolts, springs (excluding furniture and watch springs) and chains (excluding articulated link chains). The sector also includes such processes as galvanising, anodising and enamelling of metals and general mechanical engineering on a sub-contract basis;
- Structural metal products (NACE 314), includes the production of metal bridges, frames, doors, windows, railway tracks, etc.;
- Boilers and metal containers (NACE 315), includes the manufacture of various boilers, fittings, water tanks, and pipework, etc.;
- Tools (NACE 316), includes hand tools, tools for joinery, fixing tools for construction and metal saws, cutlery, metal packaging;
- Other metal workshops (NACE 319).

Main indicators

The EC remains the world's largest producer of metal products. Of the Member States, Germany is by far the largest manufacturer with value added output of nearly 29 million ECU in 1991. France is also a major producer with about 13 million ECU; the contributions by Italy and the United Kingdom reach 8.7 and 8.5 million ECU, respectively. These four Member States accounted for 83.5% of value added within the EC in 1991. Italy in particular has shown considerable improvement over the past decade, surpassing value added from the United Kingdom for the first time.

Figure 1: Metal products
Value added in comparison with other industrial sectors, 1991



Source: Eurostat

Of the sectors of the industry listed above, hand tools is the largest with an output of 70.4 billion ECU, followed by secondary transformation of metals with 24.7 billion ECU of output.

Recent trends

The metal products industry in 1991 continued to grow in terms of production and apparent consumption, albeit at a slower rate than in 1989 and 1990. Given that most of the industry's products are basically intermediate commodities for other industries, (products for final consumption account for only 10% of output), demand is heavily dependent upon the industry's main markets (mechanical and electrical engineering, transportation equipment and construction). Recessionary conditions in these downstream markets have reversed the booming demand which characterised the industry at the end of the 1980s. While production and consumption growth have remained positive, employment growth has halted and the trade balance diminished.

In real terms, production in 1991 did drop slightly; however, it remained above its 1989 level. Since 1988, production of

Source: Eurostat

metal products has outpaced growth experienced in EC manufacturing as a whole. Regarding real growth in the industry, production and consumption experienced sluggish growth between 1982 and 1985. After 1985, however, real growth rates more than tripled, resulting in healthy growth figures for the entire period 1982 to 1991. Given the high demand by booming transportation and construction industries for metal products, it is not surprising to find a rapid growth in imports between 1985 and 1991.

International comparison

Apart from being the world's largest producer of metal products, the EC has been able to maintain better growth rates than its closest competitors, the USA and Japan. In recent years, however, competition from East Asian countries such as Hong Kong, Singapore, and South Korea in sectors such as hand tools have been intensifying.

Foreign trade

Although the metal products industry is a net exporter, external trade accounts for only 7.8% total production. Of the percentage that is exported, however, over 35% was exported to the EFTA countries in 1991, an improvement of 6% from 1986. While exports to the EFTA countries rose, the EFTA share of EC imports actually dropped as competition from Taiwan and other relatively small trading partners gained market share.

MARKET FORCES

Demand

Almost all sectors of the metal products industry are linked to very cyclical downstream industries (i.e. mechanical engineering, motor vehicles and construction). For example, the motor vehicle industry consumes more than 70% of all aluminium based castings (foundries sector), and as much as 45% of all ferrous metal castings The recent recession in these industries has had a negative effect on metal products, particularly in the United Kingdom. In Germany, demand for metal products had been given an added boost after reunification. Although this extra demand has abated, German productivity in particular has improved enough to increase its price competitiveness in foreign markets.

Supply and competition

Companies tend to supply national markets as a large share of firms are simply too small to service customers throughout the Single Market. Production is particularly specialised in Germany, while Spain, the Netherlands and Belgium are also noted for serving very specific markets.

Production process

Since the early 1980s productivity has been increased through greater automation of production processes. Apart form the introduction of robotics, the industry is utilising innovations such as Computer Numerical Control (CNC), Computer Aided Design (CAD) and Flexible Manufacturing Systems. As a result, the need for skilled labour in these sectors is increasing. Although firms are striving for greater mechanisation of production, most sectors of the metal products industry remain labour intensive. For example, in the forging industry, personnel costs range between 40% to 50%. Most of the remaining costs are allocated to metal inputs and energy costs.

INDUSTRY STRUCTURE

Companies

The metal products industry is characterised by relatively low industry concentration. About 98% of all enterprises employ less than 100 people. These small firms account for 56% of employment in the sector and almost 35% of turnover. As most firms do not serve final consumer markets, they tend not to have brand names recognised by the general public.

Strategies

In certain sectors, the need to lessen the dependence on heavy industry has encouraged firms to diversify their operations. Many firms are not only seeking new outlets for products but are reconsidering the composition of their key activities.

REGIONAL DISTRIBUTION

For most of the sectors, the high weight/value ratio prohibits long-distance transport of goods. In order to remain profitable, many firms locate near their clients. Given that Germany in particular has a number of relatively large regions of heavy industry, it follows that large number of firms in the metal products industry are in close proximity to such clients. For example, German companies account for 51% of EC forging, and 80% of all German forging companies are concentrated in North Rhine-Westphalia.

ENVIRONMENT

Each of the sectors in the metal products industry has a unique environmental concern. To summarise these issues, a short description of environmental problems concerning individual sectors is in order.

Foundries are very active in recycling materials used during the production process. This sector is also focused on the subject of clean air, and often makes large investments in order to comply with strict regulations.

The forging industry is mainly concerned with reducing noise pollution resulting from the use of forging hammers. Furthermore, energy conservation has been emphasised with efforts to use more efficient electro-hydraulic systems to power forging hammers and to utilise waste heat from the forging process.

The electroplating industry (secondary transformation of metals) is particularly concerned with reducing the metal content of the effluent through the introduction of new production processes.

Apart from environmental issues related to production, the boilers and metal containers sector is concerned with the corrosion of tanks containing chemicals and oil products during underground storage.

The light metal packaging industry is presently exploring new programmes which will ameliorate the environmental impact of its products, mainly through the promotion of consumer recycling.

REGULATIONS

At present, directives pertaining to the metal products industry are primarily related to safety standards. One of the more notable examples is a study taking place which would make ISO 9000 standards compulsory not only for EC manufacturers, but also for importers.

One of the major issues confronting the metal products industry is the harmonisation of EC standards. The present difficulty for manufacturers is deciding what standard of production processes will be used in the near future (i.e. existing national standards or a future unspecified EC standard). The unpredictability associated with this situation is an obstacle in making future investment decisions.

The general upgrading of environmental requirements in the EC will have a particular impact on foundries, which might suffer a loss in competitiveness vis-à-vis third countries producers.

OUTLOOK

Due to the present recession in the major markets of the metal products industry a fall in real terms is forecasted for 1993. In the medium term the outlook is not so discouraging.

Table 8: Metal products

Improvements in the mechanical engineering, motor vehicles and construction markets are necessary for strong growth in the metal products industry. It should be noted, however, that efforts to lessen dependence on heavy industry in recent years has helped reduce the degree of cyclical downturns of demand intermediate commodities traditionally supplied by this industry. Furthermore, innovations in production processes are also allowing sectors to become more profitable not only by reducing material waste but also by producing products with a higher grade of value added.

Written by: DRI Europe
The industry is represented at the EC level by: Organisme de Liaison des Industries Métalliques Européennes (ORGALIME). Address: Rue de Stassart 99, B-1050 Brussels; tel: (32 2) 511 3484; fax: (32 2) 510 2301.

Foundries
NACE 311.1, 311.2

The EC is one of the largest casting producers in the world, with about 20 billion ECU in production per year.
Most castings serve as components in the motor vehicle and mechanical engineering industries. Foundries are usually small or medium sized enterprises, but are often part of a larger enterprise, producing castings for 'in house' use. Customers are typically large companies.
Employment in the EC as a whole fell between 1982 and 1991, but productivity increased. Although external trade is not a significant part of production, imports have been rising. The trade balance is, however, still positive.

INDUSTRY PROFILE

Description of the sector

Foundries are industrial plants which produce castings, which are primarily used as semi-finished products for other industries. To make a casting, liquid metals are cast in a mould to solidify; different techniques are available to produce castings of various sizes and shapes. Foundries can be classified by the different type of casting, but in the NACE are grouped according to the metal used in the casting:

- iron and steel foundries (NACE 311.1) which produce cast iron, ductile cast iron, malleable cast iron and steel cast;
- non-ferrous foundries (NACE 311.2) which produce copper cast, aluminium cast, zinc cast, etc.

Many alloys exist for each metal mentioned, some of which are standardised, but others of which vary according to the requirements of the casting demanded. Foundries often offer around 200 different qualities or alloys.

Statistics on external trade in castings are not complete. Many castings, including those used as components in car manufacturing, are not recorded separately, but are included in the "miscellaneous goods" category.

Main indicators

Production and apparent consumption have both risen steadily since 1982. Employment has decreased nearly 20% overall since 1982, however, resulting in increased productivity. Exports were variable between 1982 and 1991, and the trade balance, though still positive, shrunk about 5.5% annually over that time.

More than 80% of all castings in volume produced in the EC are still ferrous metal castings, but the proportion is declining. In the last ten years, the share of non-ferrous metal castings increased from 12% to about 16%, and in value the proportion is much higher. The proportions vary widely throughout the EC: in Germany and France, the share of non-ferrous metals is 34%, and in Spain about 40%.

The largest European producer of castings is Germany with 37% of total value added in the EC, followed by France with 22%. The five largest producers, Germany, France Italy, the United Kingdom and Spain, are responsible for about 95% of EC production.

Personnel costs in foundries can reach 50% of total production costs. Therefore, the value added in relation to the production value is relatively high.

Recent trends

Production at constant prices for the foundry industry has risen steadily since 1982, but at a much slower rate than that of manufacturing in general. Employment, however, decreased almost 20% between 1982 and 1991, compared to a 5% drop in employment in manufacturing.

Although both production and apparent consumption grew between 1982 and 1991, most of the growth was in the second half of the decade. Imports also had a higher growth rate between 1985 and 1991 than between 1982 and 1985. Exports, which decreased sharply in the first half of the 1980s, recovered somewhat after 1985, although they continued to decline.

International comparison

Following to the break-up of the USSR, the EC has become the largest producer of castings, followed by the USA. China and Japan are also large world producers.

About 20% of all castings in volume produced in the world are fabricated in the EC, but the EC share in value is higher. The EC has been shifting to lighter, thin walled castings and light alloys with higher value by weight.

The EC, the USA and Japan all have very similar product lines. Their shares of non-ferrous metals castings achieve between 13% and 15% of their total production. The foundry industries in all three respond to the same economic factors, so shifts in production are similar as well.

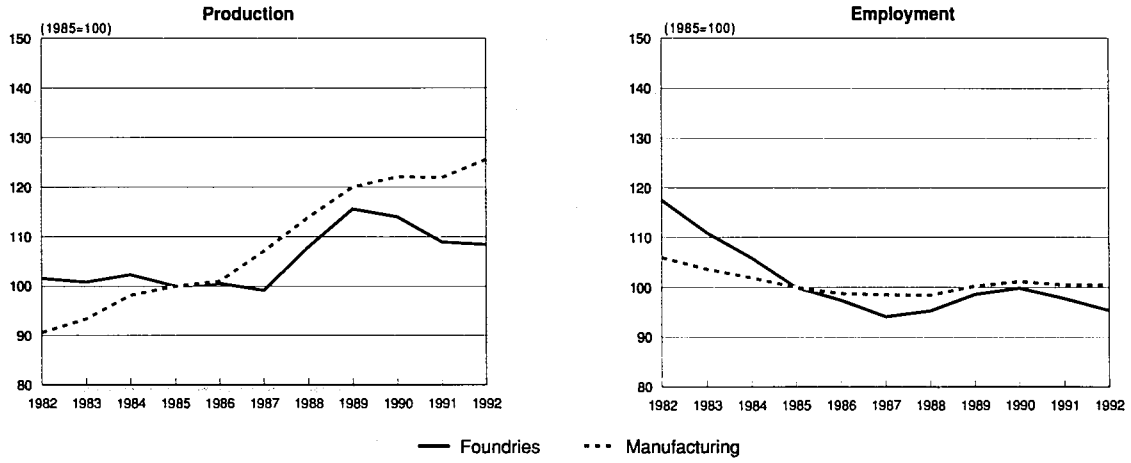
Figure 3: Foundries
Production and employment indices compared to EC manufacturing



Source: Eurostat

There is a large difference in labour productivity, however, expressed as production value per person employed. Productivity in the Japanese industry is almost twice as high as in the EC, and productivity rates in the US are 20% higher than in the EC.

Foreign trade

Historically, foundries were built near collieries and/or smelting works. Today, they are more customer-oriented. Products must correspond to individual requirements, and permanent contact with the customer is necessary. Also, due to the weight and size of the castings, transportation costs are high compared to value of the products. For these two reasons, external trade is of minor importance in the foundry industry compared to other industries. The most important trade partners are neighbouring countries. Therefore, intra-EC trade is much greater than extra-EC trade, and the EFTA countries are by far the primary extra-EC trade partners. Trade over large distances is usually confined to components, spare parts for plants and special products with a high value such as finished high grade steel castings.

MARKET FORCES

Demand

The largest consumer of foundry products is the car industry. More than 70% of all aluminium-based (Al-based) castings are installed in cars. The proportion of ferrous metals castings delivered to the automotive industry is lower than for Al-based castings, but is still significant at about 30%, and is as high as 45% in Germany.

Another important client of the foundry industry is the mechanical engineering industry which consumed up to 30% (in Germany) of all grey iron and nodular iron castings in 1991. During boom years, this percentage can rise much higher, due to increased investment in machines.

Pressure pipes and fittings are the most important end-product of the foundry industry. Their share in production is the highest in France at 31%. However, the value of these products is relatively low.

The foundry industry is a mature, rather than a rapidly growing, industry. The yearly production in tons was stable between

1982 and 1991. Growth occurred only in value, caused by the shift to lighter, thin walled and core intensive complex constructions and lighter alloys, especially aluminium-based alloys.

Casting as a master pattern process is in direct competition with sintering, but also with methods of metal forming such as forging, rolling, pressing, drawing and deep drawing. Joining techniques, such as welding, gluing, riveting, and screwing, also offer substitutes for casting.

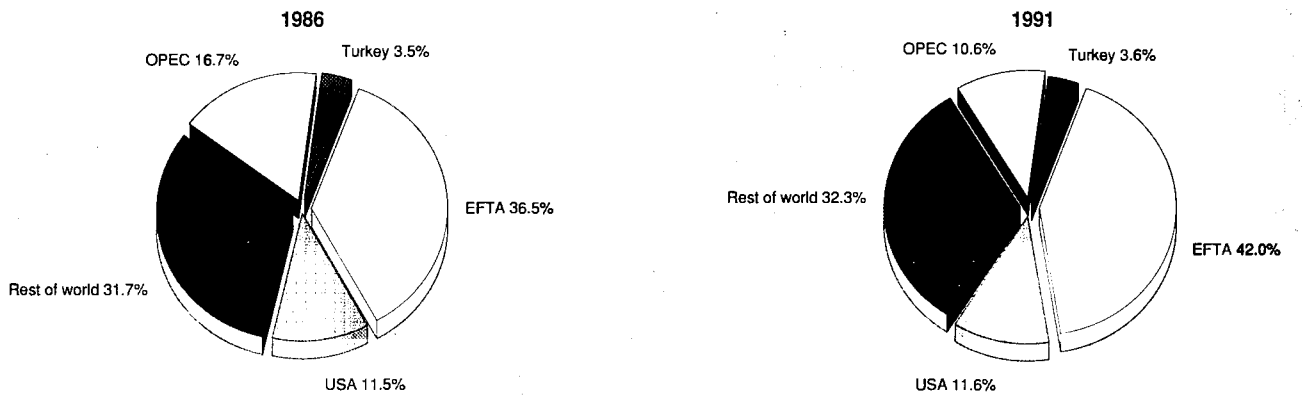
In recent years, however, the competition between various materials has been of greater importance. The importance of certain plastic products in the production of cars, pipes and fittings has increased rapidly. Heavy products, such as ingot moulds, are substituted with complex light components in the automotive industry as well. It appears that this substitution process is slowing down. Generally, reasons for substitution are weight, wear-, heat- or acid- resistance, behaviour in ageing, price, or the possibility of recycling. In the future, mineral products such as ceramics, or composite materials such as fibre could become important substitutes.

Since castings are mainly intermediate products, foundries are highly sensitive to changes in economic conditions in those sectors which use castings as an input, particularly the motor vehicle industry and mechanical engineering sector. This explains the industry's relatively poor performance in the early 1980s, and the profitability improvements recorded in more recent years.

Supply and competition

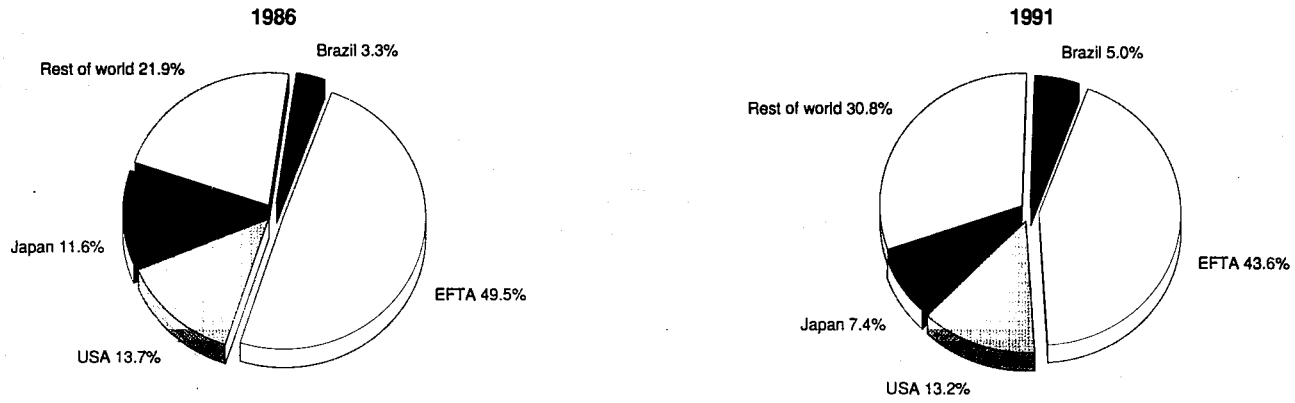
Although the intensity of use of castings has decreased in the major client industries, the booms in car and machine production in the late 1980s were strong enough to result in a slight growth in volume. However, when comparing actual volumes of production with that of 1980 or even 1970, a decline is obvious. Furnace-, moulding- or fettling capacities are therefore more than sufficient to satisfy demand, although there is difficulty finding sufficient skilled labour. Because of the excess capacity and large number of foundries and the strong market power of the industry's major customers, foundries do not have much power to set prices, and profit margins are low.

Figure 6: Foundries
Destination of EC exports



Source: Eurostat

Figure 7: Foundries
Origin of EC imports



Source: Eurostat

The direct effects of the Single European Market on foundries are likely to be small, since the simplification of border formalities and the elimination of delays at borders will have little impact on international trade with castings. Changes in other sectors, however, will probably have significant spill-over effects, such as the liberalisation of public procurement, which will have important implications for such products as pressure pipes or castings for sewer systems. Furthermore, changes in the transport and insurance sector will make it possible to sell castings in more distant markets. Since the demand for castings itself is not expected to increase rapidly in the EC, however, this will also mean enhanced competition among EC firms. The foundries in low labour cost areas, as well as those having the lowest production costs with reference to environmental legislation, will enjoy a competitive advantage. Both factors vary widely across Member States.

Production process

Casting production is still a labour intensive industry. Even when the production process is extremely mechanised, the proportion of personnel costs in total cost reaches 40%. In hand-moulding and single-piece work, the share of labour costs achieves 50% or more in some cases. Much effort has therefore gone into increasing productivity in order to decrease labour costs.

Metal inputs are also an important cost to the industry. Its share of total production costs varies widely, between 15% and 25%, depending on the input materials (scrap, pig iron, alloys, high purity metals) and the current prices. While the input materials depend on the required end-product, prices are subject to market forces. Capital costs such as depreciation and interest costs, depend on the technology used. They are higher in a fully automated foundry and lower in hand moulding and single-piece work.

Energy costs are significant as well. Depending on the furnace installed, either coke or electricity is the primary source of energy; coke for a cupola and electricity for an electric induction or an arc furnace. Because of increasing quality requirements and the shift to nodular iron or light alloys castings the share of foundries using electricity is increasing compared those using coke.

INDUSTRY STRUCTURE

Companies

Foundries are generally small or medium-sized companies. More than half employ fewer than 50 employees, and many are family concerns. Those that are not are often vertically integrated into part of a bigger enterprise, producing castings for use "in-house". Foundries have not found it necessary to develop a more concentrated industrial structure. Investments in rationalisation were meant only to increase labour productivity.

Advanced technology, however, allowed the development of a number of large firms in the sector. The development of automatic moulding machines made large series production possible. Since this type of production requires two to three work shifts to be efficient, certain firms grew to 1000 or more employees. Such foundries specialise primarily in producing large series, especially castings designated for cars.

The average size of production units is distinctly higher in the case of ferrous foundries compared to non-ferrous. Those foundries which specialise in the production of Al-based cast-

ings for the use in autos are exceptions, and are often as large as the corresponding ferrous foundries.

Strategies

The foundry industry is constantly looking for innovation in both production and material technology. New alloys are always being sought to correspond with specific client needs. In particular, new compounds are developed which are more resistant to wear, heat, rust, and acid.

Castings are both becoming smaller and lighter, and bigger and heavier, depending on the use to which they will be put. In many cases, dimensional tolerances are becoming narrower as well. The different demands on the foundries, often pulling in opposite directions, are resulting an increased heterogeneity of foundries.

A single strategy for foundries is therefore not viable. Problems for all foundries are labour costs and environmental legislation, resulting in higher costs. The first objectives of investment are modernisation, to increase labour productivity and reduce emissions. Spanish and French foundries have so far had the greatest success in increasing labour productivity.

Mergers and acquisitions also occur in the foundry industry, but usually the production units remain unchanged, as a profit centre of the new owner. There are two primary reasons for M&A activity:

- to produce castings for in-house use, resulting in increased independence for the client industry;
- to produce a wide variety of goods, both light alloy and high grade steel for example. This would allow a foundry either to fulfil all demand for a few specific customers with diverse needs, or to fulfil demand for a number of firms in an area.

REGIONAL DISTRIBUTION

As previously mentioned, foundries which traditionally were built near supplies of raw materials are now built close to clients, although many foundries are still located near collieries and coal mines. As a result, modern and efficient foundries now tend to locate in those regions of Europe where high-capacity car production plants, or productive mechanical engineering companies are found.

ENVIRONMENT

Recycling has always been extremely important for foundries, as a large portion of materials used can be recycled in the production process: metals can be smelted again, and the sand used in moulding or the core shop can be reconditioned. Furthermore, used castings are recycled to the production process.

Nevertheless, it is impossible to avoid waste completely. Certain residues, such as thermally worn moulding sands, always occur, although foundries do look for ways to reduce these residues further.

The prime concern of foundries in their environmental production work at present is clean air, particularly to eliminate dust. Strict conditions laid down by in regulations must be complied with, and high investments are necessary in some cases.

Since not all foundries have the financial capacity to undertake such investments, some of them will have to stop production after the transition period. Profitability for those that remain will decrease as well, due to increased costs. Currently, environmental legislation varies form country to country, resulting in loss of competitiveness for foundries in environmentally-conscious countries, so the EC will need to harmonise environmental legislation.

REGULATIONS

There are no EC-wide regulations specific to foundries. Among the regulations which will affect the industry are:

- regulations affecting the protection of the environment;
- regulations regarding additional costs to wages and salaries (social security taxes);
- regulations affecting tax rates, especially local business taxes, general property taxes, corporation taxes;
- regulations regarding prices for energy, public levies to deposit waste, wages and salaries;

OUTLOOK

Favourably influenced by cyclical factors, the tonnage of foundries increased by 12% in the late 1980s. The early 1990s saw a reduction of 7%. In the mid-1990s, decreases in growth are expected due to reductions in the outputs of the car and the mechanical engineering industries. Imports from non-EC countries are expected to increase as well.

To limit the effects of these factors, different strategies are possible:

- foundries could develop higher quality products, for instance by using sophisticated alloys;

Table 11: Foundries
Expected real annual growth rates

- foundries could offer additional services, through a higher grade of value added, for instance by finishing operations;
- foundries can adopt modern techniques on a large scale for developing complex cast constructions, such as axle trees, which were impossible to cast only a few years ago;
- foundries could find new end-markets, for instance by producing lamp-posts, castings for sanitary facilities or bells.

Although the trade balance has been weakening, the international position of EC foundries is not bad at present. However, since many steps of the operations are highly labour-intensive, particularly in pattern making, the fettling shops and the finishing process, further rationalisation is necessary. CAD/CAM systems for patternmaking and/or the fettling shops, as well as CNC machines for finishing operations could be a solution. Speeding up the delivery process, avoiding factory rejects, supplying castings 'just-in-time' and producing high quality products are important ways of improving the world wide competitiveness of EC foundry products.

Written by: Deutscher Giessereiverband (DGV)
The industry is represented by at the EC level by: Comité des Associations Européennes de Fonderie (CAEF). Address: Rue de Bassano 2, F-75783, Paris Cedex 16; tel: (33 1) 472 35 550; fax: (33 1) 472 04 415.

Forging
NACE 312.1

With an output of 3.3 million tonnes in 1990, the EC forging industry is ahead of both the United States and Japan in terms of size.
The forging industry supplies high-tech areas, such as the aviation industry, railways and the automobile industry. Other important end markets are agricultural and construction machinery, industrial trucks.
A slowdown in production in the industry at the end of the 1980s stemmed from the weakening economic climate in Europe combined with market saturation. This slowdown in forging activity is expected to continue throughout the first half of the 1990s.

INDUSTRY PROFILE

Description of the sector

Forging consists of taking a piece of semi-finished metal (a "slug"), heating it until it becomes malleable and then forming it into a die, the two halves of which are brought together rapidly in forging hammers or presses. Forged metal products are used when great forces have to be transmitted and where particular emphasis is placed on safety and reliability, for example in engines, aircraft turbines, steering and axle systems of motor vehicles. Forgings are primarily semi-finished products, usually requiring further processing at least in certain areas, e.g. heat treatment, surface treatment or machining. They are used in other industries such as the aviation, railway rolling stock, and automobile industries. In some cases, however, items can be produced ready for use.

Forgings are produced with or without heating the blank, which in most cases is a length of rectangular or round bar or a shaped piece of thick sheet metal, using specialised forming tools. Hammer forgings are produced with simple flat or round tools with a machining allowance of several millimetres. In other product groups, such as drop forgings, flanges and extrusions, more specialised and technologically advanced tools are used for a more specifically shaped product. In many cases, ready-to-use working surfaces and products can be produced by a combination of production methods.

A wide variety of steel materials and non-ferrous metals (Al, Mg, Cu, Ms, Ni-alloys, etc.) can be transformed by forging. The different malleability of the various materials determines the nature of the production methods and also limits the shape and accuracy which can be achieved.

The properties and characteristics of the products, in regards to strength, structure, machinability, etc., are governed both by the processing itself (heat treatment by forge, work-hardening, etc.) and by subsequent operations (annealing, temper-hardening, strength radiation, etc.).

The forging industry is capable of producing high-quality products, offering considerable advantages for the customer, particularly according to criteria of weight, security against fracture, service life and consistent quality.

Main indicators and recent trends

In 1990, the forging industry in the EC produced 1.834 million tonnes of drop forgings from steel. If drop forges of the automobile and other industries are included (0.523 million tonnes), the greatest part of forge output (approximately 71%) was attributable to the drop forge product group.

Production of forged steel products (NACE 312.11) measured in volume terms declined over the period 1982 and 1986, brought about by the weakness in demand in EC market. As the European investment climate improved in the second half of the eighties so did demand for steel forged products and consumption and production started to recover in 1987. The trade balance has increased since the beginning of the eighties although in 1991, it was down from its peak in 1985.

The trend towards increased output observed in various countries starting in the mid-1980s reversed after 1990. The downturn was caused primarily by weaknesses in engineering, mining and agricultural machinery, and the declining demand for motor vehicles.

MARKET FORCES

Demand, supply and competition

In 1990, with an output of around 3.3 million tonnes and sales of roughly 6.6 billion ECU, the European forging industry occupied the top spot among western countries, ahead of Japan and the USA.

The motor-vehicle industry is by far the most important customer for forges, and uses about 50% of total forge production. Other important clients include different engineering industries

such as agricultural machinery, construction machinery, industrial trucks, static machinery and engine construction.

The majority of firms in the forging industry are component suppliers. Both standard products such as shafts, clamping systems for the construction industry, etc., and products designed to a customer's specifications are sold on the open market. Hammer forges are often large firms, such as steelworks. The drop forging and extrusion companies are predominantly medium-sized. In cases of recurrent large production runs, some automobile and bearing manufacturers produce individual items in their own production shops, but this is not done frequently.

INDUSTRY STRUCTURE

Companies and regional distribution

The drop-forging industry is comprised principally of medium-sized firms, although concentration and cooperation activities have spread beyond national borders. In recent years, output has developed in various areas in different Member

Figure 3: Forging (1)
Production by country

(2) Data for Italy are estimates
Source: Euroforge

States. There are some 140 drop-forging companies in existence in Germany, accounting for roughly 51% of EC production. Germany thus occupies a leading position in the western world. 80% of German companies are located in North Rhine-Westphalia and 12% in Baden-Württemberg. Information on forges in the former East Germany is not yet available. 22% of German forges employ more than 200 workers, 20% have between 100 and 200 employees, 22% between 50 and 100 employees, and 36% have less than 50 employees. The major firms include Thyssen, Gerlach and Peddinghaus.

In Italy, which accounts for 19% of EC production, 30% of the national production is concentrated in the Canavese region. Other locations include Lombardy, Veneto and Emilia Romagna. The major companies are Teksid, a subsidiary of Fiat (90% of the output of which is destined for the automobile industry), Riganti and Casartelli. Other important Limited companies are Figli si S. Bertoldo Spa, Massucco Industrie Spa, Facem Spa, Canavera Spa and Benevenuta Spa.

In the United Kingdom, which is responsible for 12% of EC production, the majority of manufacturers of small forgings are located in the Midlands, in the vicinity of Birmingham, while larger forgings are produced principally in the region of Sheffield, in South Yorkshire. The largest company is United Engineering Steels Ltd., which accounts for roughly 45% of UK output. Other forges of importance are Firth-Rixon, the INCO Group and the Cameron Iron Works.

In France (10% of EC production), 72 companies are active in the industry. 35% of the firms are in the Ardennes, 8% in the Loire Region, and 19% are in Eastern France. Three firms dominate the sector: Ascometal, Forges Stephanoises and Forges de Courcelles.

In Spain (7% of EC production), 37 firms are in business in the field. About 80% of these are based in the Basque country, the remainder being spread over Cataluña, Arragón, Madrid and Galicia. The largest proportion of firms (40%) employ less than 50 workers. Eight companies employ more than 150 workers, five employ between 100 and 150, and nine employ between 50 and 100. The major companies of P. Echeveria SA, La Forge Casanova SA, Forgas de Villalba SA (Forjanor Group) and Forges de Galicia SA together account for around 60% of Spain's output.

In Belgium (1% of EC production), there are about ten companies active in the forging industry, five of which specialise in drop forging. Most of these are small businesses, located around Charleroi, Liège and Mechelen.

ENVIRONMENT

In recent years, a considerable proportion of investment in the forging industry has been devoted to measures to protect the environment. Emphasis has been on measures required by law for acoustic protection, to reduce or eliminate vibration, and to save energy, for example by equipping furnaces with recuperators, by replacing the expensive compressed-air drives of hammers by electro-hydraulic systems, and by utilising the waste heat from the forging process.

One advantage of forged products over certain substitutes is the excellent recyclability of forged materials. This has contributed to a reduction of substitution by plastic products, which had been an increasing tendency of consumers.

OUTLOOK

The rates of growth recorded in various European countries in recent years may not be achieved again in the foreseeable future. The trend towards larger business units will not only continue, but will speed up. Questions of location will have to be re-addressed, since the consumers of forged products have also been considering this problem. Steps taken by the forging industry to maintain its competitiveness in the market will ensure that forged products will continue to constitute a significant proportion of industrial output in the future.

Risks to the industry include a fall in demand for the products of their client industries, since forges continue to be dependent on their principal customers.

Increased competition from LDCs also poses a risk for the industry. However, the possibilities of innovative product development offer new opportunities for firms. In addition the reputation for high quality will help EC companies to compete with new foreign competitors.

Secondary transformation of metals

NACE 313

The primary sectors of the industry are fasteners and galvanising. These sectors supply outlets like the automotive and the building and construction sectors. Output increased in general during the 1980s, but production growth slowed in 1991. For the coming years an average output growth of 5% per year is expected. Markets are highly bounded by geography: international trade is relatively unimportant when compared with consumption. Major markets are France and Germany.

The increased use of new techniques and systems are necessary to meet market demand, such as for specially designed fasteners. This has led on the one hand to increased demand for skilled labour, and on the other hand to a decrease in labour requirements.

INDUSTRY PROFILE

Description of the sector

Data for the secondary transformation of metals industry are classified under NACE 313. The products of this industry are highly diversified and can be divided up into the following categories:

- manufacture of articles on turning machines or lathes, including the manufacture of turned screws (NACE 313.11);
- nuts, bolts, rivets, screws and related products (NACE 313.12);
- springs, except furniture and watch springs (NACE 313.2);
- sintering of metals (NACE 313.3);
- chains, except articulated link chains (NACE 313.4);
- treatment and coating of metals, including zinc coating, aluminising, anodising, enamelling etc. (NACE 313.5);
- general mechanical engineering on a subcontract basis (NACE 313.6).

In general, the most important subsectors are the fasteners industry (the first two sectors) and the treatment and coating industry.

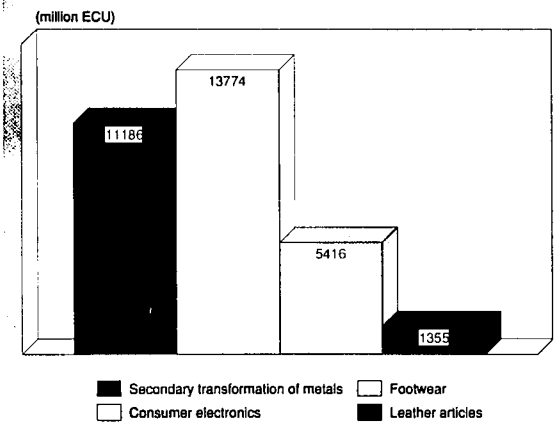
Fasteners can be divided into two main categories: those which are used for construction purposes, and those which are used for assembly purposes and which do not come under stress or load. From a market point of view, fasteners can be divided into common fasteners and special fasteners. In the first category price is important, in the second, quality, marketing and delivery time are important.

The purpose of galvanising is to improve the qualities of the metal. This can be done by several techniques, such as electrolysis. Galvanising, formally "hot-dip galvanising", involves coating steel with zinc by immersion in molten zinc metal.

Main indicators

Production grew in 1991, but at a slower rate than in the preceding decade. Production growth took place primarily in high quality products. The EC is a net exporter, but the trade balance deteriorated throughout the 1980s, despite growing exports. The market for products of secondary transformation of metals increased steadily, from 11.8 billion ECU in 1982 to 24.7 billion ECU in 1991.

Figure 1: Secondary transformation of metals Value added in comparison with other industries, 1991



Source: Eurostat

Employment grew in line with production to a record level of 355 000 in 1991. Since most of the enterprises in the industry employ less than 20 workers, however, this figure underestimates total employment. Between countries, there is a wide divergence in average firm size. For instance, the average firm in Spain in 1991 had 9 employees, whereas the average firm in West Germany had 129.

The West European output of steel galvanised as fabricated products in 1991 increased 5% from 1990, to a total of 4.4 million tonnes. Germany, France, Spain, Denmark, Austria and Norway had increases in output, whereas the UK, the Netherlands, Sweden, Switzerland and Finland experienced decreases. Other countries had a stable output.

The bulk of European production of secondary transformation of metals comes from France and Germany, which together account for 60% of EC production. According to Eurostat data, France is the leading manufacturer of secondary transformation of metals within the EC.

Recent trends

EC production in current value grew by 60% between 1985 and 1991, and in constant prices by 42%. In 1991, production in constant prices showed no growth compared with 1990.

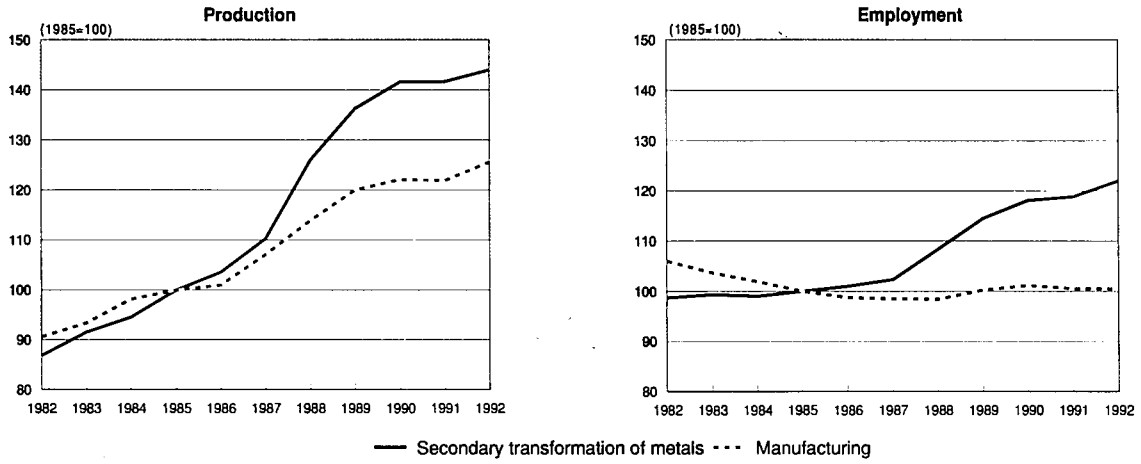
Figure 3: Secondary transformation of metals
Production and employment indices compared to EC manufacturing



Source: Eurostat

The general economic slowdown is reflected in the output of screws, bolts, springs and plates of galvanised steel. The growth rate of value added lagged behind production growth, in nominal as well as in constant prices. The investments of EC producers grew strongly in the 1980s.

In the 1980s, many firms went out of business as a result of strong international competition, especially in the mass market fastener sector. For instance, in Germany the number of employed people in the fastener industry declined 25% from 1978 to 1988. The number of people working in the entire industry of secondary transformation of metals, however, grew from 294 900 in 1982 to 355 000 in 1991, with the strongest growth in 1988 to 1990. The evolution varies from country to country. Employment is mainly concentrated in France and Germany, which account for 60% of employment. Italy, Spain and the UK are the other large producers and employers in the EC. Only in the UK did the industry as a whole experience an overall decrease in employment between 1989 and 1991.

International comparison

An international comparison is difficult to make, due to varying classification systems for industries in the EC countries, the USA and Japan. Some comparisons can be made, however.

In the USA, the market for industrial fasteners declined in 1991, reflecting the recession. The weak demand from the automotive sector added to this effect. On the other hand, US exports to the EC increased strongly (growth figures of 20% or more as regards several EC countries). US manufacturers are increasingly serving their client industries in overseas, as well as domestic, markets. Most US exports are high quality products, while their imports are mass market products from East Asia, especially Taiwan.

Due to their relatively high costs of production, Japanese fasteners have become less competitive.

Foreign trade

The EC experienced an almost continuous rise in imports until 1989, while exports grew at a lower rate with a temporary decline in 1986-1987. Therefore both the extra-EC export/import ratio and the trade balance declined in the 1980s. The trade balance is expected to be around zero in 1992. The development in nominal terms was reinforced by the decrease in the terms of trade since 1988. There was increased import penetration during the 1980s, 3.8% of consumption in 1982 to 4.5% in 1991.

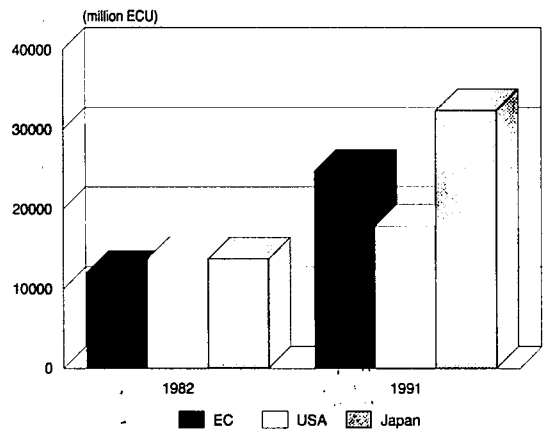
Germany and Italy are the only EC countries with positive internal and external trade balances. France has a positive extra-EC trade balance, but a negative intra-EC balance. Spanish trade balances (extra- as well as intra-EC) deteriorated substantially during the 1980s and turned from surplus to deficit.

The main export markets for the EC are the EFTA countries, which account for around 40% of extra EC exports. Mexico has also gained importance as a market for fasteners and related products.

Japan's place as the third largest exporter to the EC is becoming increasingly threatened by Taiwan, although Japan retains its proportion of total imports. Taiwan has already taken Japan's place as primary exporter to the USA. Taiwan's increased proportion of EC imports has come at the expense of EFTA and the USA's proportion of imports, rather than at the expense of Japan's.

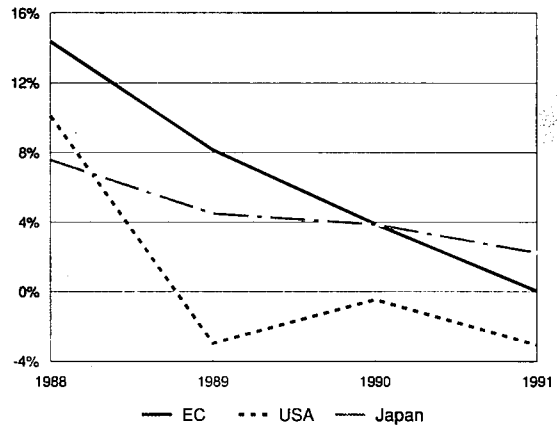
One of the major characteristics of this sector is its national, and often regional, orientation, reflected in the low ratio of exports to production. Even combined intra- and extra-EC trade amounts to only 13% of production. This figure is inflated

Figure 4: Secondary transformation of metals
International comparison of production at current prices



Source: Eurostat

Figure 5: Secondary transformation of metals International comparison of production growth at constant prices



Source: Eurostat

upward due to the relative increase of export and import prices versus EC producer prices.

MARKET FORCES

Demand

The primary client industry of the fastener industry is the automotive sector. Other important sectors are mechanical engineering, furniture, household appliances, construction and electronics. There is also a relatively small amount of consumer demand for screws, etc. The galvanising industry serves more or less the same branches, but with the addition of building and construction, which take up 39% of West European galvanising of fabricated products output.

Technical and logistical developments in the client industries have a strong impact on the fastener industry. Technologically, the ongoing automation and robotisation of production processes has influenced demand for speciality and high quality fasteners, interestingly often in a negative way. Most of the standards for screws, for example, are designed for manual fastening. These standards are widely used, and producers can take advantage of economies of scale. Therefore the price is normally relatively low. This has led to the use of these screws in automated production systems, even though in terms of quality of the end-product, the use of specially designed screws would be preferable.

Supply and competition

The world-wide overcapacity in the mass-market production capability of fasteners led to downward pressure on prices. Because of the competition in this part of the market, many manufacturers went out of business in the first part of the 1980s, in the USA as well as the EC.

The market power of the main clients of the secondary transformation industry, especially the automotive industry, continues to increase. In response, the associations in the industry opened dialogues with representatives of the automotive industry. But due to pressure from Japanese competition, EC automotive manufacturers require more security, just-in-time delivery, and increased quality from their subcontractors and suppliers. In this way the upstream industries bear both the costs and the risks. However, the tendency towards small, family-owned fastener producers precludes the availability of substantial R&D resources.

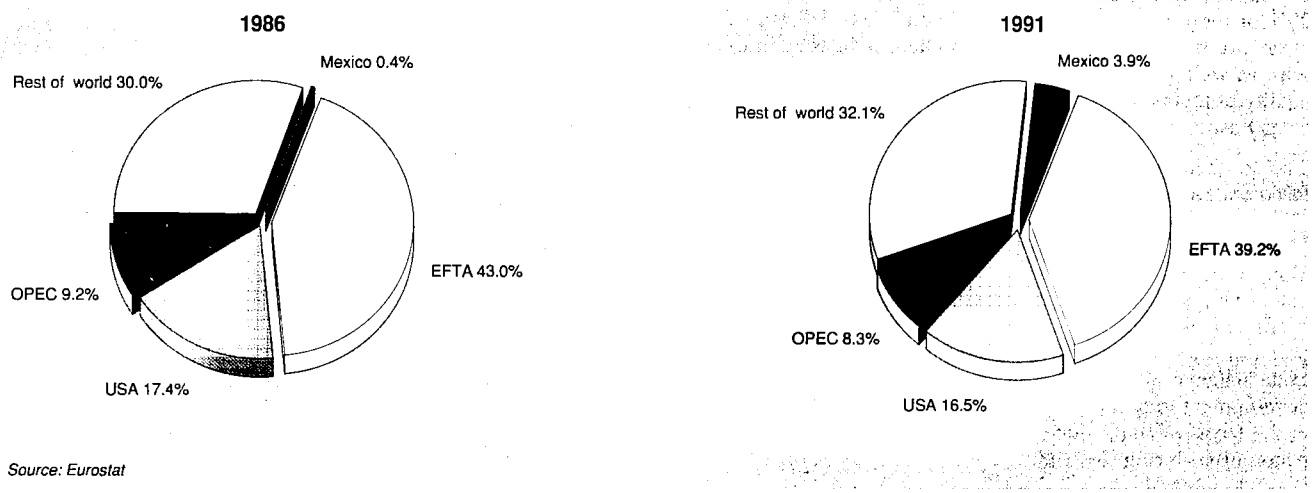
Other problems will develop in the future, as well. The growth of Japanese automobile production within the EC will necessitate cooperation between EC fastener manufacturers and Japanese motor-vehicle producers, who have different design specifications than European automobile manufacturers.

Another problem in the relationship between the secondary transformation industry and the automotive industry is the increasing use of single-sources by motor vehicle manufacturers, meaning less utilisation of subcontractors and fewer suppliers. Combined with the ongoing tendency towards concentration in the client industries, the mutual dependency of the supplier and client industries is growing.

The EC fastener industry is continuously faced with strong competition from East Asian countries in mass production of standard screws, nuts and bolts. In this area there is a world-wide overcapacity. Sophisticated, specially designed fasteners form the core of the competitive power of the EC industry. Competition takes place primarily in regards to price in the mass market. The standard nuts and bolts from outside Europe are usually destined for the consumer market.

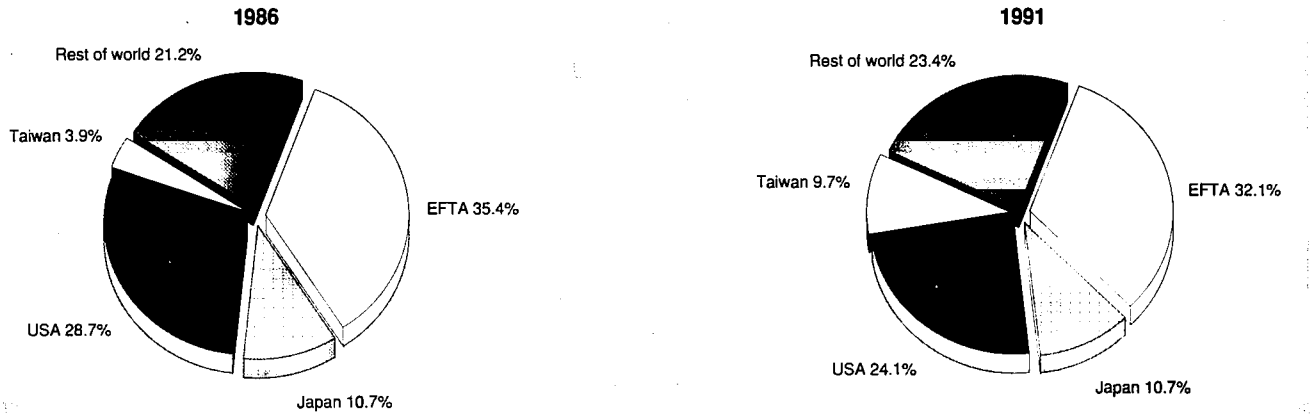
Although the amount of exports of the industry itself is not significant, the export of products in which a large amount of fasteners and treated metals is being used is substantial. These exports have been under pressure in the world markets, which has sharpened competition at home.

Figure 6: Secondary transformation of metals Destination of EC exports



Source: Eurostat

Figure 7: Secondary transformation of metals
Origin of EC imports



Source: Eurostat

Because of the competition, the fastener industry is seeking high volume markets, such as Germany. But manufacturers from East Asia and Eastern Europe are also seeking the interesting markets. The trend in trade is to export high value added products and to import low value added items.

Hot dip galvanising capacity increased in the early 1990s, in spite of the general economic slowdown. The West European output of steel products galvanised after manufacture was 4 410 000 tonnes in 1991, an increase of 4.8% over 1990. The production process has also become more efficeiant. The average throughout Europe in 1991 was 13 tonnes of steel galvanised for every tonne of zinc consumed, while the average in 1970 was 11 tonnes of steel per tonne of zinc.

Production process

Fasteners are products that to a large extent are standardised. On the other hand, the production of tailor-made screws is gaining in importance. An example are multifunctional screws, which can drill, tap and fasten all in one. Automation is necessary to fulfil the needs for more tailor-made fasteners.

The hot-dip galvanising industry has four separate areas: the coating of pre-fabricated products, the coating of steel sheets, the coating of steel wire, and the coating of steel tubes in automatic plants.

Electroplating techniques can be divided into three areas: upgrading of metals, plastic-galvanising and conductor plate technique. The methods include the use of zinc alloys and chromium alloys to fight rust, copper-nickel chromatising, chemical nickel and hard-chromium. The most important alloys in the conventional electroplating process are: copper-tin, copper-zinc, zinc-nickel, nickel-iron, lead-nickel and aluminium alloys. The electroplating technique has gained importance in the field of electronics and printed circuits, which has led to a more efficient use of zinc in electroplating.

Skilled labour is becoming more and more important, because of the increasing use of Computer Numerical Control (CNC), Computer Aided Design (CAD) and Flexible Manufacturing Systems. The use of these new machines and techniques is necessary to be able to produce new kinds of fasteners through cold-forming, for example. Lack of skilled labour is especially a problem here, although the techniques themselves, in particular CNC, help to alleviate part of the problem. Increasing use of CNC can lead to a decrease in labour requirements, which results in a decline in unit labour costs.

Unit labour costs rose an estimated 51% between 1982 and 1990, but there are significant differences between countries. In 1988, unit labour costs were 7600 ECU in Greece, and 24900 ECU in Luxembourg. Productivity in Greece declined over 20% between 1982 and 1989, while in Germany, for example, productivity increased with 20%.

INDUSTRY STRUCTURE

Companies

The galvanising of products industry can roughly be subdivided in three areas:

- small enterprises which use primarily hand-skilled labour;
- larger enterprises which operate more on a manufacturing scale, including in-house production of galvanised metal as part of the production process;
- supply of zinc, machines, chemicals, etc., for the galvanising process.

The fastener industry roughly follows a same pattern, with many small and medium sized enterprises. There are a few, however, that could be classified as medium to large enterprises, with sales over 100 million ECU. The largest companies and dealers are German, which is not surprising giving the importance of the German machinery and motor vehicle industries in Europe. Italian, French and British manufacturers are not far behind, however.In the galvanising and electroplating sector, Metaleurop (Germany) has sales of approximately 140 million ECU in 1990, and in continuous galvanising of steel sheet, Galvanage (Luxembourg) had annual sales of around 140 million ECU in 1989.

Strategies

Competition has been forcing producers to seek ways to lower production costs, especially through rationalisation. In addition, increased quality of products is required, because the low labour costs of some foreign producers are not an advantage in that part of the market. Quality standards and just-in-time delivery further demand continuous review of the logistics chain. These factors all lead to increased investment in new equipment.

In the subsector of speciality products, Computer Numerical Control (CNC) machines decrease the time and cost of changeovers. The trend toward orders for smaller lot sizes at more frequent intervals and with shorter lead times leads to increased numbers of changeovers for machinery. The use of CNC machinery partially alleviates the shortage of skilled labour as well.

All of these factors combined have resulted in increased specialisation and product development in both fastener and galvanising sectors. Subcontracting of galvanising will also become more important, despite the preference of some client industries for single sourcing.

REGIONAL DISTRIBUTION

In general, enterprises in the secondary transformation sector are located near the major industrial centres of Europe. Because of the small scale of many of the firms, long distance transport is not viable in general. To decrease transportation costs, firms must be located near their clients. For instance, in Germany the centre of the galvanising industry is in Nordrhein-Westfalen and in Baden-Württemberg.

ENVIRONMENT

The electroplating industry is looking for ways to reduce the amount of waste created, in particular the metal content of the effluent. The metals concerned are copper, chromium, nickel and zinc. Efforts are being made to develop production processes which generate less effluent by regenerating it and by extending the dipping time. Furthermore the use of techniques such as ultra filtration and electrolysis have the advantage that they do not use additional chemicals. The cascade-washing technique in combination with the recycling of metals could reduce the metal concentration in the effluent from 300 g/l to 0.3 g/l.

Furthermore, recycling of metals out of the galvanic waste disposal is an option, but only if the waste has a high enough metal content, preferably of a single metal. This is currently not very practical. Most of the small and medium sized enterprises use third party firms for recycling metals. Also, the traditional technique of the galvanic bath is more and more replaced by showering the metal plates. The main waste products of hot dip galvanising - zinc dross and zinc ash - are essential raw materials for the zinc chemicals industry.

REGULATIONS

Fasteners are highly dependent on standardisation. The quality of fasteners is usually indicated by the German quality standard (DIN).

Currently, a study is taking place for a directive on quality and consumer safety which would make ISO 9000 standards compulsory not only for EC manufacturers, but also for importers. This initiative has broad support from European producers, although some argue that it would be preferable to have individual quality controls rather than be bound by a general standard which is below standards already met by some manufacturers.

In the subsector of galvanising, the possibility of standardisation of hot dip galvanising of fabricated products is being studied. A draft based on ISO 1461 has been completed, and will presumably lead to generally accepted standards after a period in which comments are considered.

Table 5: Secondary transformation of metals

OUTLOOK

It is expected that the trend towards specialisation will continue, which will lead to a greater demand for a higher skilled labour force and, in general, to more quality. The expected economic recovery, even if moderate, will spur demand for products of secondary transformation. Growth in general will be caused by the sale of new products in which fasteners and the like are used, as opposed to repair services.

For the galvanising of products industry in particular, the development of the building and construction industry is particular important. Opportunities include the possible construction activities in Eastern Europe, which, however, is highly dependent on the general economic development in that area.

The production of secondary transformation of metals in the EC slowed down in 1991, reflecting the general economic slowdown. These circumstances are likely to continue in the short term, but growth will gradually pick up. Growth in demand is expected to be roughly 5.5%. Given some import penetration in the mass market products, production should grow by approximately 5% per year. This will be accompanied by some growth of employment figures in the coming years.

Boilers and metal containers

NACE 315

The boilermaking industry is highly dependent on its client industries, which are all affected by swings in the general economic outlook. Cutbacks in investment in some of these client industries have greatly affected production and employment. Overcapacity has forced restructuring and diversification in the industry. Boilermakers need to seek new outlets in rapidly growing industries and to update technical skills if they are to remain strong in an increasingly competitive market.

INDUSTRY PROFILE

Description of the sector

Data for the boilermaking industry are classified under NACE 315. The products of this industry can be divided up into the following categories: steam generators and boilers; nuclear boiler construction; fittings for steam generators and boilers; flat and tubular heat exchangers and condensers for nuclear reactors; water tanks, containers and cisterns; distillation, refining and similar equipment; pipework; miscellaneous activities, including installation and maintenance.

Since classifications differ within the EC, it is difficult to estimate the importance of the industry in each country.

Main indicators

Production in 1991 increased in nominal terms for the fifth consecutive year. In 1991, it stood at 18.4 billion ECU. In volume terms, however, production dropped slightly in 1991. Improvements in production in constant terms in France and the UK could not outweigh the declining production of the other EC countries. France is the largest producer in the EC, accounting for 36.3% of EC production in 1991, followed by Germany with 32.9%.

Employment dropped on average by 2.8% per year in the 1980s, but increased slightly in 1989 and 1990. Extra-EC trade is a small portion of production and consumption.

Recent trends

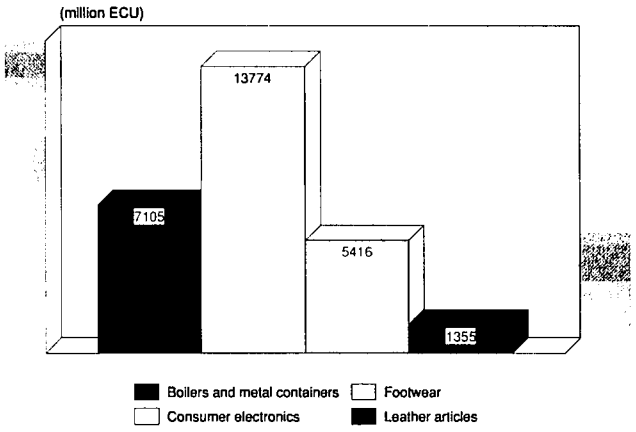
EC production in current value grew by 18.3% between 1985 and 1991. In constant prices this figure was only 0.3%. Investments by EC producers fluctuated in the 1980s, with strong growth in 1987 and 1988. No data are available for more recent years, but the expectation is that investment growth has declined.

French production increased by 1% per year between 1982 and 1991 and Italian production by around 2%. In the same period, production in Germany declined with 0.7% per year, and production in the United Kingdom declined 6.6% per year. In 1982, United Kingdom production was almost 74% of French production; by 1991, this proportion had dropped to 36%. Employment in the United Kingdom more than halved in that time. Employment dropped slightly in most Member States; only in Belgium, Denmark and Luxembourg did employment rise.

International comparison

The EC is by far the largest producer of boilers and metal containers in the world. In the USA, consumption has been subject to large fluctuations which affect production, but overall production and consumption declined in the 1980s. Japanese production and consumption, although also subject to large fluctuations, increased on average during the years 1980 to 1990.

Figure 1: Boilers and metal containers
Value added in comparison with other industries, 1991



Source: Eurostat

Foreign trade

Extra-EC exports fluctuated around 1.1 to 1.3 billion ECU per year between 1982 and 1991. Exports remained larger than imports, but due to higher growth in imports, the ratio of exports to imports deteriorated, from 7.11 in 1982 to 3.2 in 1991. During the 1980s, intra-EC trade became increasingly important. Intra-EC trade accounted for 9% of apparent consumption in 1991, while extra EC imports accounted for 2.2%. These low proportions underline the rather limited geographical coverage of most of the enterprises in the sector.

The EC as a whole had a positive trade balance in 1991. All Member States except Greece had a positive extra-EC trade balance in that year. France, Germany, Italy, Denmark and Portugal also had positive intra-EC trade balances. Other Member States, including the UK (a large producer country) had negative intra-EC trade balances.

The main export market for the EC is the EFTA countries, accounting for some 26% of extra-EC exports in 1991. OPEC is the second largest export market, but the importance of

the OPEC countries as export destinations is dependent on European construction activities in those countries. The methods by which Member States remain competitive on the world market vary from country to country. France has sold its specialised nuclear power station technology to industrialising countries, while West Germany maintains a positive trade balance by meeting existing demand, especially in Africa and the Middle East.

The EFTA countries are also the most important extra-EC suppliers of boilers and metal containers, supplying over 50% of total extra-EC imports in 1991. The share of the USA declined in line with its decreasing production figures during the second half the 1980s. Imports from East European countries have become more important, due to the need of producers in those countries to find new clients outlets.

MARKET FORCES

Demand

The boilermaking industry equips many branches of industry. Its products are used for the following purposes (in decreasing order of importance): the production of thermal and nuclear power; the oil and gas industry; the chemical, petrochemical and pharmaceutical industries; the food and drink industry; the construction industry; the iron and steel and metalworking industries; the paper industry; various other industries including automobiles, textiles, mechanical engineering, cement, rubber and electronics.

The importance of client sectors varies among Member States. In France, the main outlets are energy (nuclear and classical; 17%), oil and gas (7%), chemical industry (15%), the food and drink industry (11%) and building and construction (9%). In Germany, major downstream industries are the chemical, automotive, engine construction and energy industries. In the United Kingdom, oil, energy, harbour and shipping, iron and steel are primary outlets, while in Italy, energy, automobile, harbour and shipping and ventilation industries are major clients. The market has been subject to significant changes, including shifts in the relative importance of the main clients. For instance, demand from the nuclear power industry collapsed due to sharp cutbacks in investments. New major outlets are the food and drink industry and the chemical industry.

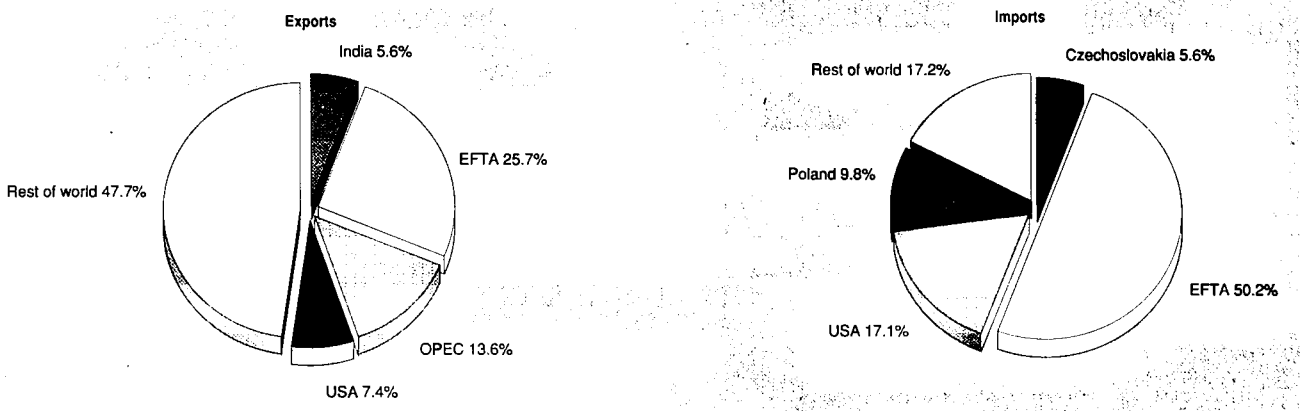
Figure 6: Boilers and metal containers
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

The market for boilers and metal containers is subject to large cyclical and structural up- and downswings. Energy prices have a sizeable impact on industry demand for boilers and energy-saving equipment (heat exchangers) since they affect investment decisions. The relatively low oil prices since the end of 1985 are one factor in recent demand trends. The sensitivity of this sector to the general economic development is another factor. Postponement of investments in downstream industries affects the position of the boilermaking industry. Enterprises specialising in large boilers for heavy industry, such as power stations, are particularly vulnerable to these swings.

Supply and competition

Overcapacity in the subsector providing boilers for heavy industry has forced several firms to reconsider their activities in this field. Estimated profitability (non-labour income in value added) declined significantly during the 1980s. The emergence of more dynamic competitors on the export market, especially from Japan and East Europe, increased the competition.

Declining investments in domestic markets and a slow down of investments in developing countries has caused the industry trouble. The emergence of East Asian boilermaking and the reduced purchasing power of OPEC countries increased the difficulty in obtaining profitable export contracts.

Production process

Unit labour costs rose an estimated 52% between 1982 and 1990. Between countries there are large differences. For instance, Greece has very low labour costs compared to Germany. However, productivity in Greece is low compared to German productivity. The rise in labour costs has not been matched by increases in productivity (measured as value added per worker), thereby putting the profitability of the industry under pressure. In current prices, productivity increased 44% between 1982 and 1990; in constant prices the increase amounted to only 5%.

Within the industry, system integrators are concentrating their activities on design, contracting and on-site installation. Much of the intermediate assembly work is contracted out to small local firms. The changing economic environment of the boilermaking industry - the need to improve productivity, for instance - increases the need for more skilled labour. Personnel training is a major concern.

INDUSTRY STRUCTURE

Companies

There are three types of firms in the boilermaking industry:

- System integrators (firms which install systems) are the smallest group, but the most powerful. They are usually medium-sized firms or divisions of large diversified industrial groups and have three activities: design and engineering, manufacturing and on-site installation. The principal characteristic of system integrators is the high value added content of their activities. Raw material input represents about 20% of turnover, whereas labour costs run at about 45% due to large design and engineering departments with highly-qualified technical staff.
- Product specialists (firms which supply equipment such as vessels, boilers and heat exchangers) can successfully export specific products because of the low unit costs of production. The enterprises, however, tend to be domestically oriented. The firms are normally medium-sized enterprises. Raw material input represent over a third of total turnover. The value added content is less than for system integrators.

- Activity specialists (firms which manufacture particularly specialised items, mostly from blueprint of the client) are the most common type of firm. They are sub-contractors of the system-integrators and operate on a small scale. Their rather weak basis due to their specialisation hinders export activity.

In general, enterprises in this sector can be found near the centres of heavy industry. The largest companies tend to be located in the countries which dominate the Single Market, although only one of the ten largest EC firms is located in Germany (Deutsche Babcock). In Germany, there are many medium sized enterprises. Babcock is a special case, however. If all activities of the enterprise in Germany, the United Kingdom and France are taken together, Babcock is the largest EC firm. Other large firms involved in the industry include CLN (I), Degremont (F), Sabroe Refrigeration (DK), Alsthom (F), Industria Cantieri Metallurgici (I), Dexion International (UK) which is a subsidiary of Interlake (USA), Ponticelli (F), Aallborg (DK), Cockerill Sambre (B) and Stork (NL). Both US and Japanese firms have subsidiaries in the United Kingdom.

Strategies

In this market, successful firms are mostly demand oriented, rather than innovative. The relatively weak development of demand, as well as the changing roles of the diverse outlets of the industry, has forced enterprises to reconsider their key activities. Many companies are attempting to lessen their dependence on the heavy industry as the main outlet.

Competition over labour costs forces the enterprises to turn to related areas of work: mechanical engineering, electricity and civil engineering. System integrators offer an ever wider range of maintenance services. Maintenance work is no longer lengthy and infrequent: the ageing of machines and the concern regarding the financial viability of the installations makes quick, frequent maintenance necessary. In areas which require a high level of skill, such as nuclear energy, firms are tending to broaden the scope of their services.

ENVIRONMENT

Environmental concern has its impact on the boilermaking industry in several ways. Tanks for underground storage of chemicals and oil products are of increasing concern, because of the danger of leakage. In response, much research has been done in the field of corrosion containment and substitute raw materials for tanks. In the USA, about 90% of all new tanks for oil stocking are made of plastic. The discovery that metal tanks corrode not only from outside but from inside as well, stimulated the use of plastic tanks. Installation of underground plastic tanks is very different from metal tanks, and demands a completely different organisation of the work. For instance, the use of a special glue allows only a limited amount of time to connect the pipework.

The market for environmental products such as for cleaning industrial waste water or air pollution is becoming increasingly important. This creates opportunities for the boilermaking industry. Enterprises are likely to have a competitive edge in countries where environmental regulation is already very strict (e.g. Germany and the Netherlands).

REGULATIONS

The opening up of the public procurement in power plant markets in 1993 is expected to induce great changes in electrical power equipment supplier firms. More generally, EC energy policy will have a major impact on the upstream industries of the energy sector. But harmonisation of the laws of Member States concerning pressure equipment is also needed to establish an internal market for boilers. The Commission is currently preparing a proposal for a directive on this subject.

Already in 1987 a directive on simple pressure vessels (87/404/EEC) was adopted. It relates to unfired vessels of a simple geometry which contain air or nitrogen. These vessels are mainly used as air receivers or braking cylinders. Simple pressure vessels have to fulfil several demands regarding safety in order to receive the CE mark. The directive does not apply to pressure vessels for nuclear installations, to pressure vessels for the propulsion of ships and aeroplanes or to fire extinguishers.

OUTLOOK

The trend towards diversification is expected to continue, leading to greater demand for higher and differently skilled labour force. Training will be an important means through which firms can update technical skills. Furthermore, the changes that have been taking place in the industry structure are likely to continue. Firms will redefine their core activities and seek cooperation, to survive in the competitive market. More engineering services are likely to be part of this.

Investments in heavy industry are not likely to pick up in the near future. Prospects for the chemical industry indicate low growth rates in the short term. The outlooks for the food and drink industry and the energy sector are of moderate growth. Combined with moderate growth and competition on the international market in the short term, low growth rates for the industry are expected in the short run. In the medium term production and consumption growth could increase. New opportunities stemming from environmental concerns in particular could stimulate demand for special boilers and heat exchangers.

Hand tools
NACE 316.11

In the early 1990s the trend of increasing production and consumption of hand tools came to a halt. For the medium term, the outlook however is more promising. Demand for quality products could then increase, which is favourable for European manufacturers. EC manufacturers are leaders in terms of product quality, technical innovation and after-sales service.

INDUSTRY PROFILE

Description of the sector

The tools industry comprises four principal segments: hand tools; tools for joinery; fixing tools for construction; and metal saws.

The sector manufactures products including axes, screwdrivers, saws, files, rasps, pliers, shears, spanners, tools for drilling, taps and dies, hammers, planes, chisels, etc.

Although both hand tools and power tools perform in some cases the same function and tools driven by hand are increasingly being replaced by electrically driven tools, they are different products, occupy different market segments and are subject to different regulations.

Main indicators and recent trends

Production of hand tools declined 2.3% in 1991 compared to 1990, although apparent consumption increased slightly. Almost all subsectors are experiencing weak demand. The trade balance was negative for the first time for the period starting in 1982. Exports stagnated while imports grew almost 11%.

Germany was by far the largest EC producer in 1991, with value added of 819 million ECU which represents 42% of total EC production. France and the United Kingdom trailed behind Germany with value added of 395 million ECU and 361 million ECU, respectively.

Major consumer countries are Germany (almost 40% of EC consumption), France and the United Kingdom.

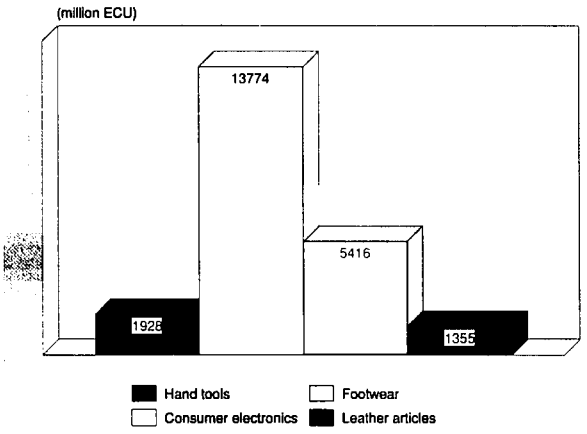
According to industry sources, screwdrivers, spanners (mostly used for home car repair) and wrenches are the most important sectors of the do-it-yourself (DIY) hand tool market. The spanner sector was by far the most important until the mid 1980s, but has since suffered a decline owing to a reduction in sales of socket sets. The screwdriver sector has been adversely affected by rising sales of cordless drills, which double as cordless screwdrivers. A fast growing segment is the market for replacement parts and accessories for power tools; growth will probably generated in this subsector at the expense of the power tools themselves.

EC production in current value grew 4.7% per year on average during the 1980s. Growth rates for the first and second halves of the decade were similar. Apparent consumption grew faster, however, at a rate of 5.7% per year, resulting in a diminishing trade balance.

International comparison

The EC is the world leader in the production of tools. Competition, however, is increasing, especially from the East Asian countries of Hong Kong, Singapore and South Korea, and from some East European countries. These countries are especially competitive through pricing. Of all EC countries for which data is available, only Germany has a positive trade balance. Spain had a positive trade balance until 1988.

Figure 1: Hand tools
Value added in comparison with other industries, 1991



Source: Eurostat, CEO

Foreign trade

Over the past decade, extra-EC imports rose faster on average than extra-EC exports. The trade balance declined steadily until it reached a deficit in 1991. EC imports totalled 48% of consumption in 1988 compared to 42% in 1982.

Extra-EC export destinations did not change much from 1986 to 1991. The main export markets for the EC were the EFTA countries, which accounted for around 31% of extra EC exports in 1991. The USA was second, with around 12% of extra-EC exports, while Japan trailed with a 3% share.

The origins of extra-EC imports shifted a little more than export destinations between 1986 and 1991. The EFTA remained the largest trade partner with a 27% share of imports. Taiwan's share increased from 15.4% in 1986 to 23.5% in 1991, raising it to the second largest supplier, ahead of the USA, although the USA lost only a small amount of its market share to Taiwan.

MARKET FORCES

Demand

Tools for private use have, in general, a long economic life. When the economy is strong, these tools have a high price

elasticity. However, declining disposable income is a strong factor in pushing demand towards the cheaper end of the product range.

Demand for hand tools for industrial use is linked to the general level of economic activity. Different factors are in this respect important. In the case of saws and tools for joinery machines and metal saws, demand is almost entirely a factor of investments made by downstream industries (furniture manufacturers, sawmills, mechanical engineering in general). Demand for tools for construction (including anchor bolts, masonry drills and power tools) is affected by the strength of the building and construction industry which is in turn dependent on the general economic climate. The explosive growth of office automation equipment is also responsible for increased demand for high-quality hand tools.

The DIY sector boomed in the 1980s with rising home ownership levels. As people became more confident about tackling DIY jobs, they tended to buy higher quality tools. Manufacturers have introduced more advanced products, such as hardpoint saws, to the DIY market in response to this change in demand.

Supply and competition

The EC countries can be split into three categories depending on the size of the market:

- leaders (already large and developed): Germany, the United Kingdom, France and Italy;
- developing: Ireland, Spain, Greece and Portugal;
- small: Belgium, Denmark, Luxembourg, the Netherlands.

The four leading countries account for 70% of the Single Market. Several distribution channels, which are used intensively, exist in these countries, which have a long tradition of tooling and DIY activities. In the second group, which accounts for an estimated 15% of the market, modern distribution networks are taking shape as distribution chains from the leader countries establish themselves in those countries. The small countries also account for around 15% of the market and have distribution channels similar to those in the leading countries.

In the leading countries, 50% to 60% of all sales of hand tools through the retail trade are accounted for by DIY superstores/multiples. These stores are characterised by wide product ranges, accessible presentation and competitive pricing. Another 15% or so of sales go through independent DIY stores, while specialist hardware stores account for a further 18%. Tools for joinery machines and metal saws are partly distributed by retailers and partly sold direct to manufacturers of plant and machinery. In the last few years, a stagnation in the DIY market has led to alterations in the distribution system. In France the medium-sized stores (around 3000 sq. metres) are having difficulties.

Production process

The cost of labour continued to grow in the early 1990s, despite the fact that the market for hand tools was showing signs of recession. This factor gave an extra stimulus for manufacturers to rationalise their production process and to concentrate production on products with a high value added content.

INDUSTRY STRUCTURE

Companies

The bulk of the enterprises in this sector are small: 65% have less than 20 employees. Many tool manufacturing companies are family-owned, which can be a limiting factor in the acquisition of capital. The largest part of production, however,

Table 3: Hand tools

comes from a few big companies, sometimes at the international level.

Factors responsible for the large number of small enterprises in the industry include: the low value added nature of the products; the wide diversity of products; and the small production runs per item.

There are a few, however, that could be classified as medium to large enterprises. These include Sandvik and Bahco (S), Stanley (F/UK), Rotherberger (D) and Hilti (CH). It is interesting to note that the Swedish manufacturers, Sandvik and Bahco, have several production facilities in the EC. US-based Stanley Works is also a large manufacturer and retail market leader in the EC, especially in the United Kingdom and France.

In power tools manufacturing, large enterprises include Bosch, Black & Decker, Metabo, Peugeot, Makita, Andreas Stihl KG, Kango, Hitachi, Hilti and AEG.

In the leading countries major manufacturers often have a large share of the market. Stanley and Draper (an importer/packager) hold 50% of the DIY market for screwdrivers in the United Kingdom; 75% of the DIY market for hand drills is covered by Stanley, Draper and Record Ridgway.

Strategies

The keen competition of prices caused by the increasing volumes of cheaper imports should force many manufacturers to improve their productivity or to restructure their business operations. These factors are particularly important in those countries where incomes are relatively high like Germany.

Product quality and after-sales service, areas in which European manufacturers are strong, are important to remain competitive in the market; however, these qualities are of greater importance in a booming economy than in a recessive economy.

Eastern Europe is a market with significant opportunities. As an example, Stanley Works recently set up a joint venture with Fabryka Narzędzi Kuznia (Poland) near Krakow. The deal has two objectives. Firstly, the new company will take over Kuznia's hand tools manufacturing capacity, and make further investments in new equipment and facilities later. Secondly, Stanley will be able to manufacture Stanley-branded products cheaply, for sale throughout Europe.

REGIONAL DISTRIBUTION

Because of the dependence on the demand from downstream industries like mechanical engineering, manufacturers tend to be located in areas where these industries are concentrated. This is especially true of the many small firms which supply the professional market (rather than the DIY market). Germany's strength in the important downstream industries for hand tools explains why so many of the manufacturers are located there.

REGULATIONS

Since 1978 there exists European standards (HD 400 series) on hand-held electric motor operated tools. These standards are referred to in the Low Voltage Directive. With the adoption of the Machine Directive in 1989 a certain overlap has arisen on the coverage of power tools by the two directives, which may lead to some uncertainties as to the standards and certification procedures to be applied. Efforts are being undertaken by the European Commission, CEN and CENELEC to solve this transient problem.

OUTLOOK

The economic slowdown at the beginning of the 1990s influenced the hand tools industry, especially because the building and construction industry was particularly hard hit. Since forecasts for the general economic situation do not show quick recovery, it is not expected that the hand tools manufacturing will experience fast growing demand in the mid-1990s. In

Table 5: Hand tools

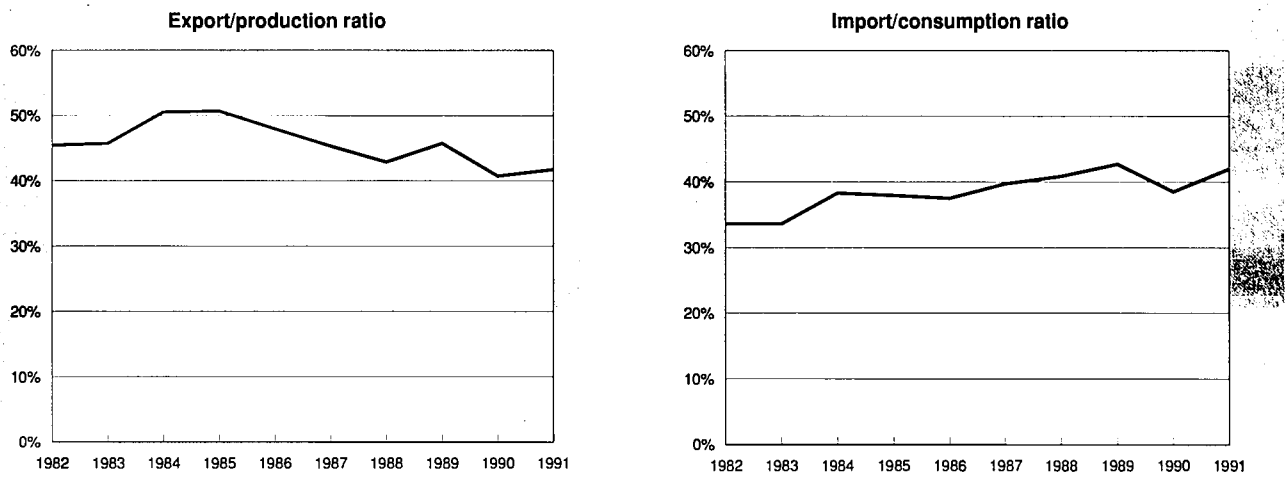
Figure 4: Hand tools
Trade intensities



Source: Eurostat

the medium term, however, the prospects are better, with expected growth rates of 2% to 2.5%.

Although there is an argument that poor economic conditions will increase the need for DIY products as people renovate their homes themselves instead of employing a professional, the overall decline on retail sales has mostly outweighed this influence. Declining disposable income pushes demand towards the lower end of the product range, but in the medium and longer term a pick up of economic growth will probably lead to more demand for high quality tools. Broadening of the product range found in the average householder's tool kit will lead to accruing sales opportunities. On the debit side, some impact will be felt during the 1990s from competition from power tools, especially from (rechargeable) cordless products.

In the professional market, the outlook in the medium term for the building and construction industry, as well as for mechanical engineering is one of some recovery from the recession years 1990-1992. This means faster growth for the tools sector as well.

However, for the EC industry it is essential to implement structural changes in order to maintain a competitive position into the future. More rationalisation is expected to take place in the form of take-overs, mergers and other types of alliances. This will put pressure on the smaller companies.

Light metal packaging
NACE 316.42

The light metal packaging industry has enjoyed sustained growth over the course of the last few years. Substantial production cost savings and significant productivity increases have been achieved, principally due to technological advances. The sector as a whole is characterised by a high degree of competitivity, given that a broad range of alternative processing and packaging options currently exist or are in development. The impact of environmental regulations and recycling is particularly important in this sector.

INDUSTRY PROFILE

Description of the sector

The term "light metal packaging" is applied to all metal packaging less than 0.49 mm thick and with a capacity below 40 litres. By contrast, the term "heavy metal packaging" is applied to packaging manufactured from cold-rolled sheet steel with a surface thickness equal to or greater than 0.5 mm and used in the fabrication of casks, cans and barrels with a capacity of between 30 and 220 litres.

The distinction between "light" and "heavy" metal packaging is by no means arbitrary: not only does it reflect different methods of using raw materials and different manufacturing technologies, it also relates to entirely distinct consumer markets.

Within the light metal packaging sector itself, further distinctions apply to specific product groups:

- packaging for foodstuffs, particularly cans for foods and beverages;
- various types of light multi-purpose packaging, notably removable-lid cans for paints and varnishes, oil cans, cans for cleaning agents, non-sealed cans for foodstuffs, decorative cans, aluminium dishes, and metal containers for specific industrial applications (e.g. electric battery cases);
- aerosol cans for use as containers for a mixture of gas and liquid, used primarily in the cosmetics, pharmaceutical and cleaning agents subsectors;
- lids and caps, including crown corks and other types of metal fastenings (especially for glass bottles), and screw-on caps and lids.

Main indicators

The value of the light metal packaging sector is estimated to be some 7.1 billion ECU. In 1991, the sector employed over 51 000 people in approximately 300 firms and used some 3.5 million tonnes of tinplate and 310 000 tonnes of aluminium. Net exports totalled about 300 million ECU in 1991 and apparent consumption reached 6.9 billion ECU.

Current estimates suggest that light metal packaging currently accounts for around 16% of the European packaging market as a whole, ranking it third in terms of packaging industry materials. By way of comparison, paper and board account for 30% of the packaging industry's current requirements, with plastic packaging accounting for a further 30%. The percentages for glass, heavy metal and wood are 7%, 4% and 4%, respectively.

Foreign trade

The metal packaging sector is one which is not traditionally characterised by major long-distance international trade. The EC is a net exporter in this sector. Imports, however, are growing at a faster rate than exports: the export/import ratio dropped from 7.1 in 1981 to 2.38 in 1991. Although imports currently represent little more than 3% of market demand, they have grown significantly over the course of the last few years. Intra-EC trade is increasing substantially and amounted to more than 1 billion ECU in 1991.

A permutation of sectoral restructuring and productivity-boosting measures has resulted in a steady fall in employment in this sector, which fell from 84,000 jobs in 1981 to around 51,000 jobs in 1991. Productivity over the same reference period increased from 70 000 ECU per employee in 1980 (at constant 1985 values) to more than 120 000 ECU in 1991.

MARKET FORCES

Demand

Although originally developed for food products, light metal packaging has developed an increasingly important role in everyday life, thanks to its unique properties compared with other forms of packaging. Food contained in metal packaging can be stored for long periods without any loss in nutritional value or any risk of corrosion or contamination. The primary advantage of this longevity is that products can be more readily transported and stored.

In recent years, economic growth within the sector has been relatively modest, ranging from 2% to 3% per year on average. This growth is primarily attributable to developments in the canned foods industry and the emergence of new market segments in canned beverages. As far as industrial packaging is concerned, the position is distinctly less positive; this is due to difficult conditions obtaining in certain consumer sectors (among them the construction industry) and to growing competition from the plastic packaging sector in terms of specific applications, notably motor oils and cleaning agents.

Overall, developments in the light metal packaging sector are strongly influenced by a number of external factors, e.g.:

Table 1: Light metal packaging

- changes in individual consumer preferences and patterns (including a trend towards individual portion packaging in the food industry and more sophisticated methods of preservation) which have prompted an increase in demand for packaging for pre-cooked dishes and aerosols;
- stiffer competition from new types of packaging (such as compound plastics on impregnated board, ultra-lightweight glass and flexible packaging) and new preservation technology (e.g. deep-freezing or freeze-drying);
- psychological aversion to certain types of packaging and product presentation, particularly where long-life foodstuffs are concerned.

Production process

At present, light metal packaging production can be broken down as follows: 60% food packaging (of which around 83% is accounted for by foodstuffs and 17% by beverages); 30% multi-purpose packaging; and 10% metal seals and accessories.

Tinplate, blackplate and aluminium are the three principal raw materials used in the manufacture of light metal packaging.

Tinplate is cold-rolled steel sheet less than 0.5 mm thick and coated on both sides with a thin (3g/m2) film of tin. It is used principally in the light metal packaging industry. Some 95% of annual tinplate production (which is to say, approximately 11 million tonnes) is used by this sector. Among the various properties which make it especially useful for the light metal packaging industry are high mechanical strength, susceptibility to decoration (it accepts print readily), and the fact that a vast range of products can be packaged using this material - notably food and chemical and pharmaceutical products.

Blackplate, usually referred to as tin-free steel, comprises a steel substrate coated with a chrome oxide compound. Although the technical properties of blackplate are inferior to those of tinplate, it has been widely used in recent years to manufacture products to less exacting specifications. Typical examples include can bases and lids, bottle caps, and so on. The principal factor in its favour is that it is approximately 10% less expensive than tinplate.

Aluminium is the third most popular base material for light metal packaging. Currently, around 10% of world aluminium production is earmarked for the packaging sector. Major uses include dishes, containers, flexible tubing, can lids and beverage cans. Use of aluminium for light metal packaging is varies significantly by region. Aluminium accounts for 95% of the can packaging for drinks market in the USA (with tinplate accounting for a modest 5%), about 40% in the United Kingdom and around 12% in Germany.

Changes in the relative cost of tinplate and aluminium largely dictate the use of these two materials in the metal packaging sector. At present, the preference is for tinplate, given the comparative stability of the price of tin over recent years. Aluminium, by contrast, has risen in price by some 50%. Over the longer term, however, this pattern could well change.

Packaging manufacturers, particularly in the foodstuffs subsector, rarely limit themselves to a single technology. The three leading groups worldwide each use a broad range of packaging materials.

All EC Member States are involved in the light metal packaging sector to varying degrees. The three largest producers are the United Kingdom, Germany and France, which together account for almost 60% of total EC output. EC output currently equals two-thirds of US output.

INDUSTRY STRUCTURE

Companies

The light metal packaging sector is relatively concentrated within the EC. Its structure is based on two categories of companies: large groups that manufacture predominantly standardised products and small to medium-size firms that specialise in customised products.

Table 3: Light metal packaging

Standardised products (i.e. those mass-produced on highly-automated production lines) are manufactured by a small number of large companies in each country. This is particularly true with respect to standard-size food and beverage cans, caps, and so on.

Several factors impact on concentration within the sector, not least of which is the capital investment implicit in large-scale production. A modern beverage can production line requires an initial outlay of up to 30 million ECU, so only major manufacturers have the requisite financial strength to make such investments. There is also the problem of access to advanced technologies. The trend towards mergers at the level of major industry clients such as food processing groups and brewers has also affected the structure of the light metal packaging sector. Finally, economies of scale implicit in mass-production are a factor in increased concentration.

M&A activity, joint ventures and cooperation agreements between firms is becoming increasingly common. As a result, beverage can production, for example, is now largely concentrated in the hands of five European manufacturers.

Customised products are manufactured in smaller quantities and for more limited markets. Customisation frequently relates to the shape of the packaging (conical or irregular shapes), non-standard sizes (outsize or mini-capacity packages), or product-specific decorative effects. Typically, such customised packaging is produced by small or medium-size firms employing between 20 and 200 people. General-line cans, where product variety and limited volume ensure optimal production flexibility, are manufactured principally by companies in this category.

REGIONAL DISTRIBUTION

The geographical spread of companies in the sector is largely determined by the nature of the products they manufacture.

Metal packaging offers the benefits of a comparatively low unit value (the sale price of a standard can is currently around 0.1 ECU) combined with large volume. As the packaging requires significant space in transporting for small unit gains, large-scale exporting or long-distance delivery is not very profitable. In practical terms, the maximum sales radius within which a firm can deliver its products on a competitive basis (i.e., taking account of transportation costs) is approximately 300 kilometres. It is for this reason that firms are so widely dispersed throughout every region of the EC. It is also for this reason that food can manufacturers are typically located in predominantly farming regions. A wider market network

is achieved as a result of the tendency for large national or regional groups of manufacturers to buy up the products.

ENVIRONMENT

In volume terms, packaging accounts for nearly one-third of the 100 million tonnes of waste generated by EC households. By weight, on the other hand, metal packaging represents less than 2%, with drinks cans representing less than 0.5%.

EC and national waste policies typically have two aims: to increase the proportion of recyclable packaging by discouraging the sale of large quantities of non-returnable packaging; and to promote new forms of environment-friendly recycling.

These priorities have been underpinned by a series of rules and regulations, including an EC Directive dated June 27, 1985 on the packaging of food liquids.

A proposed new Directive covering the packaging industry as a whole was approved by the European Commission on 15 July 1992 and forwarded to the EC Minister Council for final approval. This new measure aims at promoting substantial reductions in the total volume of packaging on the market and stepping-up significantly requirements relating to re-use and recycling of all types of packaging. In the long term, 90% of all packaging used in the EC marketplace will be required to be re-usable and/or recyclable.

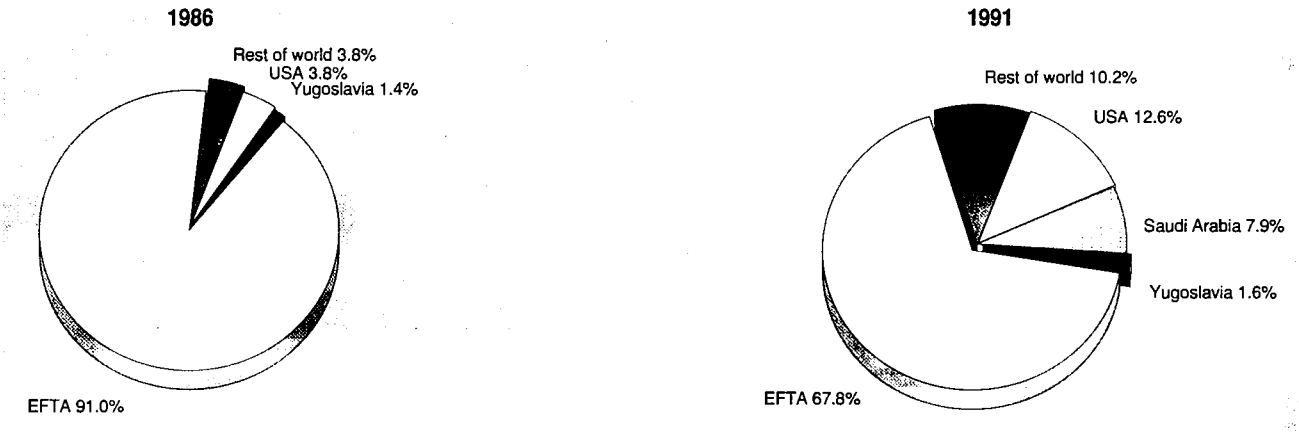
In this respect, the metal packaging industry seems well placed to comply with future EC legislative requirements because it represents a packaging process which is ecologically sound and capable of reducing waste to a minimum. The advantages for the light metal packaging industry include:

- the raw materials in question are in plentiful supply and will remain so for the foreseeable future;
- in the case of tinplate in particular, process, recycling and transport-related energy consumption is modest by comparison with other materials;
- elimination of downstream consumer waste is relatively simple to achieve given that the packaging material can be selectively recovered and recycled without difficulty.

Steel substrate-based packaging has a salient advantage in that it can be separated and recovered by magnetic means. This also means that steel packaging materials can be recovered even from non-separated domestic waste or after incineration.

As a non-magnetic material, aluminium does not offer this advantage. On the other hand, its high residual value constitutes a major incentive to selective recovery and recycling, an op-

Figure 3: Light metal packaging
Origin of EC imports



Source: Eurostat

eration that requires only one-twentieth of the energy required for primary smelting. After recovery, both aluminium and steel are readily reprocessed by raw materials producers in smelters or furnaces to derive new products which exhibit no quality loss.

As far as metal packaging recovery provisions are concerned, certain EC Member States - such as Denmark and Germany - have already introduced comparatively stringent regulations, whereas other jurisdictions have seen voluntary agreements negotiated at the level of public authorities, manufacturers and distributors. The recovery rate is already high - around 20% - but it will show a substantial improvement with the imminent passage of the new EC Directive. There are also grounds for optimism when one considers the situation in certain non-EC countries. In the USA, for example, more than 60% of beverage cans are now recovered and recycled. To this end, 22 international mass-market manufacturing and user firms, including several producers of light metal packaging, have decided to pool their efforts within the framework of an umbrella group known as the European Recovery and Recycling Association (ERRA) to develop and promote ecologically-sound and commercially cost-effective solutions to the problem of waste processing.

OUTLOOK

A diverging pattern of demand in various user sectors combined with increased competitive pressures exerted by plastic packaging across a broad spectrum of applications will act as a brake on output over the coming years in the light metal packaging sector. Thus:

- 1992 output is estimated at ECU 7.3 million, an increase of 2% compared to 1991;
- output in 1993 and 1994 is predicted to increase about 3% each year.

Certain market subsectors will outperform others. The food can industry seems poised on the threshold of a growth period and there is no indication that conventional food cans will be substituted by another type of packaging in the medium-term. The animal feed sector is currently expanding at between 6% and 10% per year and exhibits solid prospects for the years ahead. The total market for all kinds of beverage cans is projected to increase by close to 20% between 1991 and 1995, with metal cans predicted to increase substantially their current 15% share of this market. Nevertheless, certain EC manufacturers have over-reacted to this potential demand and committed substantial investment which could, in turn, lead to an excess of production capacity in certain regions of the EC. Packaging for miscellaneous applications (such as paints and detergents) should, at best, maintain its current position.

(1) Excluding Portugal
(2) Including former East Germany
Source: SEFEL

In addition to these specific market developments, there will be significant progress in the course of the next few years in terms of product quality and production-line yields. These forecasts are based on a variety of factors, including the development of new materials, the progressive ability to reduce the thickness and quantity of metal substrate as the quality of protective coatings improves, the use of laser welds, the rationalisation of production through the application of stricter standards, the introduction of more sophisticated printing techniques which enable packaging to play a more effective role in product promotion, and steady increases in productivity.

Overall, the tendency towards increased concentration noted in the metal packaging sector both within the EC and worldwide seems set to continue in the years ahead.

Mechanical engineering
NACE 32

Mechanical engineering produces almost exclusively capital goods, or components for such goods. Its development is therefore critically determined by the cyclical fluctuations of investment tendencies. The industry receives additional positive impetus from the progressive diffusion of the computer-aided generation of machines, the growing need for environmentally-sound technology, and the tendency toward its products providing ever more services. Mechanical engineering has hitherto been able to assert its leading international position. In the standard products area, however, it is coming under considerable pressure from the Far East.

INDUSTRY PROFILE

Description of the sector

Mechanical engineering accounts for about 8% of total EC industrial output.

Mechanical engineering is typified by the great variety of its products resulting from the function of supplying production equipment, or parts thereof, for all sectors and branches of the economy. It supplies everything from the most minute needle roller bearings through to complete production plant such as iron and steel works and rolling mills. Between these two extremes lie, inter alia, not only such traditional products as lathes, earth movers, cranes or circular knitting machines, but also the robot or the laser for metalworking.

With the integration of microelectronics in mechanical engineering products and the resultant advance of the computer in production the range of goods produced by the machine-builders has altered drastically: the centre of interest is no longer the stand-alone machine, but the integrated machine system, while the purchaser is increasingly demanding complementary services such as technical advice, training, maintenance or special software. Machine manufacturers already obtain over a tenth of their turnover from such services.

Recent trends

Mechanical engineering is experiencing regularly stronger cyclical fluctuations than most other industry groups. This is a result of its one-sided dependence on company investment activities, which react very sensitively to developments affecting the economy as a whole and thus rise and fall more abruptly than the other demand aggregates. This relationship is the key to any understanding of mechanical engineering in recent years.

In the 1988-90 period, the EC witnessed an unusually strong investment boom, which received added impetus from the backlog of demand from the first half of the 1980s and the preparation of industry and commerce for the Single Market. From 1987 to 1990, the demand for machines throughout the Community rose in real terms by 25%. Since this boom was anchored in a worldwide upswing machine-builders in the EC had healthy sales prospects in countries beyond the EC too. This occasionally brought about bottlenecks in machine production. On the one hand, technical capacities could not be expanded as quickly as desired, despite a major investment effort and, on the other, manufacturers were unable to find the necessary qualified workforce fast enough.

The next two years, 1991 and 1992, marked a sharp downturn in investment both within and outside the EC. Mechanical engineering was forced to reduce production, with the result that some of the growth achieved during the earlier upswing was lost again. The branches supplying components took especially severe punishment. Regarding roll bearings, gears, fluid aggregates and precision tools, clients had built up large stocks because they feared bottlenecks in supply. These stocks were now run down again in great haste, and the supplier's order books were consequently soon in a very sorry state, far below installation requirements.

During the downward gradient of 1991 and 1992, machine-builders had to shed jobs in order to adapt to reduced capacities. They proceeded with caution here because they knew the next upswing would bring fresh difficulties in finding suitably skilled workers. See-sawing demand for machines during last year has presented mechanical engineering once again with the task of reacting to the cyclical trend with extreme flexibility. There is evidence that the small- and medium-sized enterprises coped with the situation particularly ably; this is a further reason why they dominate the mechanical engineering industry.

International comparison

Having overtaken the market volume of the USA during the 1980s, the EC is now the world's largest machinery market. The EC is even more conspicuously in the lead since - unlike the USA - it is a stronger net exporter. The same applies also for Japan, whose output has caught up with the Americans. Going by present figures, American industry naturally looks to be in rather a bad shape in such comparisons within the triad because of the devaluation of the US dollar.

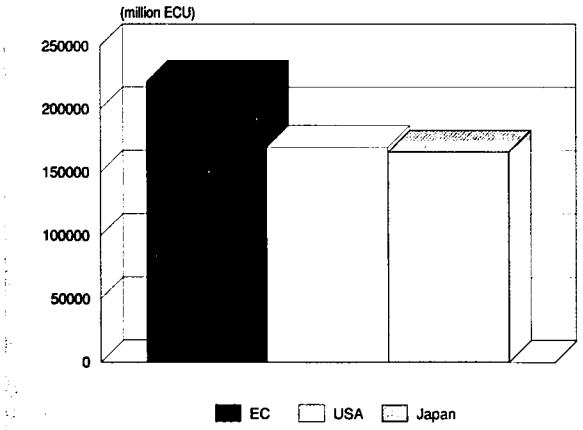
A glance at the current production development - as measured in the national production indexes - shows that the American machines industry had the slowest growth during the second half of the 1980s. On the other hand, strong growth was recorded in the EC and even more in Japan. There are two decisive reasons for this: first, Japanese demand for machines rose faster than in the EC; and the Japanese manufacturers did a great deal more than its European competitor to exploit the strong growth of demand throughout the threshold countries and developing countries of Eastern Asia in which they hold sway.

Foreign trade

Although EC countries do still continue to net a high surplus from the trade in machines with the rest of the world, that surplus has declined in the mid 1980s. Until 1990, this was mainly a result of the strong expansion of demand within the Community which well outstripped domestic production capacities and drew on available supplies from other countries to make up the difference. Come 1991 and 1992, the slackness of investments hamstrung exports, while imports profited from the tidal wave of demand unleashed by German reunification. The after-effects steadily reduced the export/import ratio of the EC in relation to other countries.

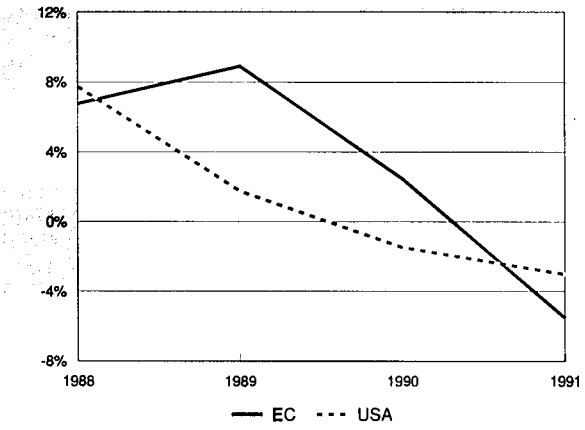
By the early 1990s, non-EC countries were supplying 18% of the EC machinery market, as against the 1982 import quota of 14%. Here, the largest share is held by the EFTA countries, with their market share of 7%, while the USA and Japan have taken as much as 5% and 3% respectively. Having said that, trade within the Community has also increased. At present, trade on the domestic market covers a third of the Community's mechanical engineering requirements.

Figure 4: Mechanical engineering
International comparison of production at current prices, 1991



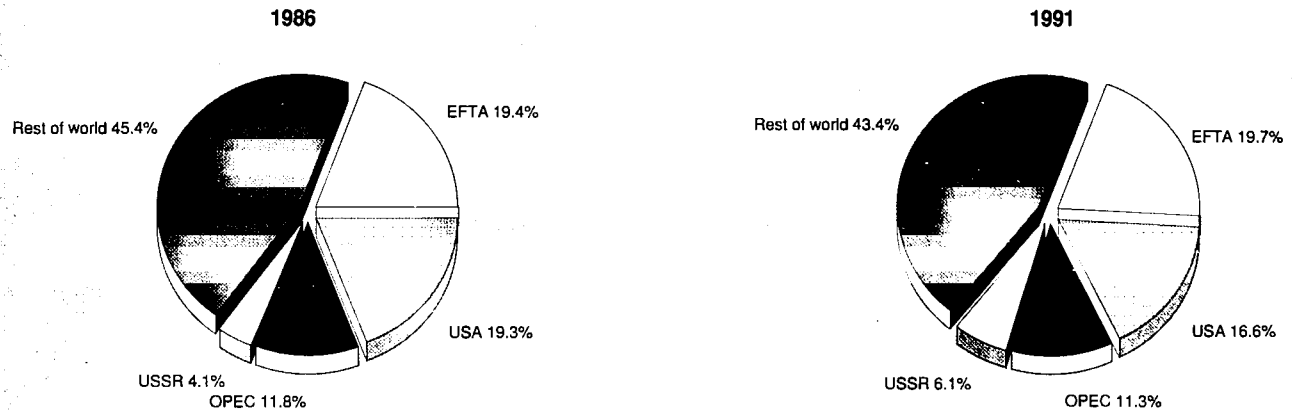
Source: Eurostat, Census of Manufacturers

Figure 5: Mechanical engineering
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Figure 6: Mechanical engineering
Destination of EC exports



Source: Eurostat

Taken as a whole, the EFTA countries are the biggest sales outlet for extra-EC machinery exports - their relative volume has even increased slightly over the last few years. The USA has lost ground because demand for machines met with less-than-favourable cyclical fortunes, and that the devaluation of the dollar handicapped exports from the EC. Japan - despite higher growth rates during the second half of the 1980s - continues to rank as a second-division export market. As a whole, the developing countries have proven to be fertile ground for sales of machinery from the EC, but thanks for this are to be ascribed simply to the burgeoning exports to Eastern Asian threshold countries and ASEAN countries. This region has for years shown itself to be the fastest-expanding mechanical engineering market anywhere in the world; machine-builders from the EC too have profited from it.

Mechanical engineering exports in recent years display a degree of convergent evolution: while intra-EC trade increased faster than production, exports to the rest of the world clearly hit an all-time low. This meant that domestic trade - which, in 1982, accounted for a bare 60% of exports to non-EC countries -had now, with almost 90%, all but caught up with them. The backdrop is, as already stated, largely a matter of cyclical trends. In spite of their below-average development, extra-EC mechanical engineering exports are still good for 30% of machinery production. This export quota is appreciably higher than those of the USA or Japan, which both score approximately 20%.

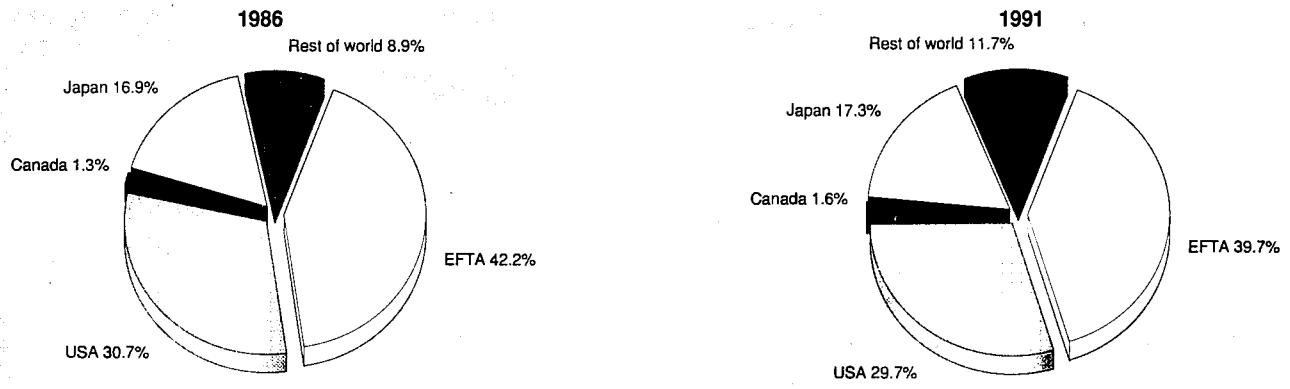
Machinery imports from outside the EC have since nudged their market share up to around 18%. This import quota already lies well above the quota for the USA, which has about 10% and Japan's modest 3%.

MARKET FORCES

Demand

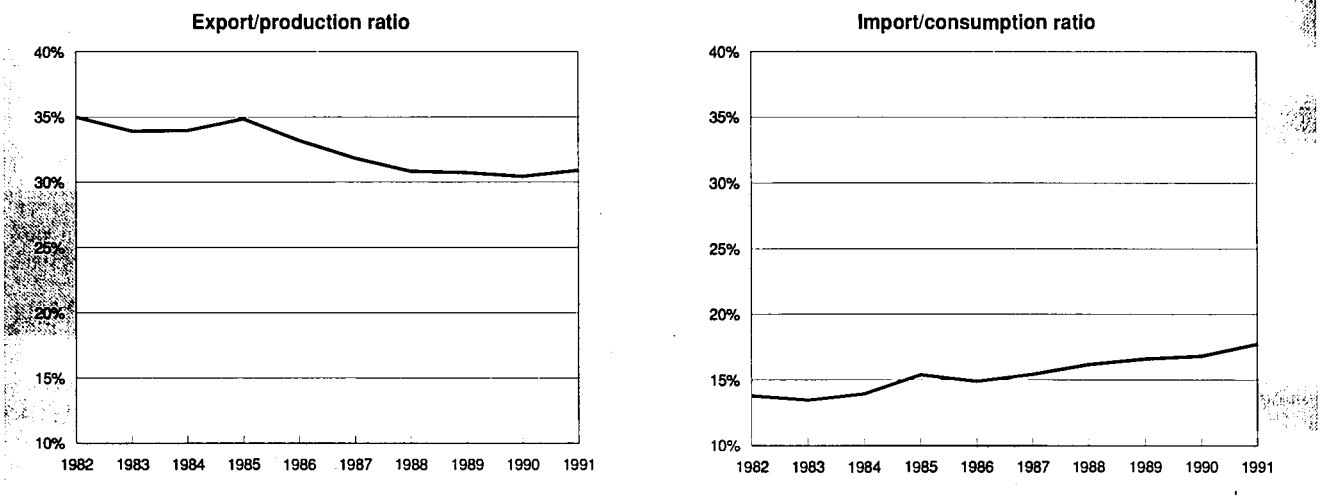
Considerably more than 50% of the goods produced by mechanical engineering are finished capital goods. The bulk of the remainder are parts and components for the construction of capital goods. These parts may be simple hydraulic elements, but also a complete turbine for the propulsion of a ship or an industrial furnace in a cement works. Only few such parts end up in consumer durables, e.g. a roller in a household washing machine. Therefore the demand for machinery - di-

Figure 7: Mechanical engineering
Origin of EC imports



Source: Eurostat

Figure 8: Mechanical engineering
Trade intensities



Source: Eurostat

rectly or otherwise- is completely dependent upon the investments climate.

The quantification of the dependence of mechanical engineering on demand from individual sectors of the economy is a more difficult undertaking than a description of these general connections, as there are not sufficient statistics to hand. In the case of Germany, the input-output tables compiled by the Statistisches Bundesamt, and the investment figures issued by the ifo Institute allows a reasonably accurate rating of the position of the branch in the home market: 72% of all mechanical engineering products goes to the processing industries, 7% to mains energy and water supply utilities and to mining, 6% to agriculture and forestry, 5% to the building and construction sector. The service sector takes a total of 8%, the State 2%. Given the high degree of intermeshing of parts for the processing industries, mechanical engineering is its own best customer, followed by the motor vehicle industry, the chemicals industry and electrical engineering.

Time and time again, this dependency pattern, binding mechanical engineering to the investment activities of industry, burdens the branch with serious fluctuations of demand. The industry is highly sensitive to actual or anticipated gain or loss in capacity, profit, financing costs and the general parameters when making decisions regarding investment. Particular attention is paid here to the enlargement investments which, given favourable odds, rise steadily but, under negative conditions, can fall back heavily.

The process of innovation in mechanical engineering has clearly gathered momentum over the last few years. Here, the role of pacemaker was played by microelectronics, which produced a new generation of machines back in the Seventies. Its distinctive feature is that production machines with conveyor devices, robots and automatic testing machines can be set up to computer-controlled systems; this not only attains high output, but also enables more flexible adaptation to variable production assignments. Using these machines therefore offers the investor ample opportunity for modernisation. The diffusion of this technology is already underway; it will bolster demand for mechanical engineering products during the years ahead.

In previous years, EC demand for machines benefited from the fact that undertakings in the Member States had stepped up investments with regard to the internal market. Research does, however, reveal that not all investments with an eye to the Single Market have yet been effected. This may give the coming upswing added impetus. Machine-builders in the EC can therefore expect a benign sales climate in the Community.

The sales outlook is equally good in most of the EC mechanical engineering export markets: the development tendencies in the EFTA countries regarding the "European Economic Space" are just as positive as in the EC, a marked increase in investment in the USA is forecast for 1993 and 1994, and the growth rate in East Asia during the 1990s will also remain higher than in any other region. Here, the machine manufacturers of the EC have not yet used up all their chances, since they have not as yet committed themselves fully enough to this market. At present, however, sales opportunities look rather forlorn in Eastern Europe, where suppliers from the EC have a good starting position, but economic reorganisation will require a considerable amount of time.

Supply and competition

The pronounced investment cycles saddle the machines industry with serious fluctuations in activity. The boom of 1989 and 1990, for instance, caused bottlenecks in capacity, while 1991 and 1992 were lean years. If we leave these extreme situations out of the equation, then mechanical engineering production capacities within the EC do more or less reflect the sales opportunities. However, these remarks do not apply to machine-building in East Germany, which could not find alternative sales openings after the collapse of its COMECON trade. East German production capacities are therefore very much reduced, but adaptation still cannot be ruled out in all sub-divisions.

Mechanical engineering in the EC is under constant pressure from Eastern Asian suppliers as regards prices. In the area of high-technology standard machines or components, Japanese competitors are able to undercut prices through mass production. Where simple products are concerned, manufacturers from Taiwan and South Korea are making inroads into the market through low prices, which in any event has hitherto had less of a knock-on effect within the EC than in other markets. On top of this, the devaluation of the US dollar and the yen have blunted the competitive edge of machine manufacturers from the EC over the last few years, as this gave the two big competitors a prices advantage in the world market.

Despite the pressure on prices, the EC's machine manufacturers can still stand their ground in international competition. They

Table 5: Mechanical engineering
Breakdown by size of enterprise, 1988

employees	number of enterprises	% of enterprises	% of employment	% of turnover
Less than 20	89 918	82.0	14.0	10.3
20-99	15 610	14.2	22.3	19.8
More than 99	3 428	3.8	63.7	69.9

Source: Eurostat

benefit from the fact that customers do not base their decision on the mere price of a machine, but also (and more importantly) on its technology quotient, its quality, and the complementary service. For this reason, elasticity of price is lower for the demand for machinery than for most other industrial products. In addition, the timelag between price movements and their visible effects on the production and turnover figures is greater, owing to generally longer negotiation and completion schedules.

Despite stiff international competition, manufacturers' prices for machines show mostly increased rates in excess of the industrial average. The causes for this phenomenon are: an above-average proportion of the costs going on wages and salaries, and a below-average development of productivity - both resulting from a client-specific production that relegated mass production very much to the exception rather than the rule. The present profit indexes show that mechanical engineering, despite higher price increases, usually makes comparatively smaller profits which are, moreover, prey to extreme oscillations.

Production process

Machine-building is a labour-intensive industry: in the EC, its personnel costs stand at just above 30%. To accomplish its production tasks, it needs not only a large proportion of engineers, but also a suitably qualified force of skilled workers. Having these qualifications is therefore a general local requirement for successful mechanical engineering. Impasses in building up the workforce occur with regularity during upturn phases, because the labour market is unable to bring forth the required skilled workforce as quickly as the industry would wish.

Turning now to parts and components for machine-building, which account for an aggregate of 60% of the production value, the bulk of deliveries come from within the branch itself. Second place goes to electrotechnics, which is gaining ground thanks to the advance of microelectronics. In both cases, the components in question are qualitatively high-grade. The most important basic material in the construction of machines continues to be steel, often bought in ready-processed form (cast steel, steelworking products). These advance operations are problem-free, because the EC has competent suppliers of its own as well as being able to buy in from the rest of the world.

The mechanical engineering production process obtains most of its innovatory impulses from the consistent use of data technology or from product innovation within the branch itself. Computer-aided design (CAD) and computer-aided manufacturing (CAM) of orders are now common in most businesses; manufacturing proper is determined by flexible production cells. Not only do these techniques mean shorter total turnarounds, but they also make for the more flexible accommodation of individual clients' wishes. The more complex the machines produced become, the more clients will come to need product-specific services, such as technical advice, training, special software or maintenance. Machine-builders accord these services a high strategic priority, which is why they often provide them from within their own executive ranks.

INDUSTRY STRUCTURE

Companies

The machine construction sector in the EC numbers just about 110 000 companies, nearly 90 000 of which employ at least 20 workers, which may be considered the bare minimum for the production of complex mechanical engineering products. Nearly four-fifths of these companies have fewer than 100 workers, while 10% have between 100 and 199, and 6% between 200 and 499. Slightly more than just 3% have 500 or more on the payroll, and that is not even 700 manufacturers.

This company size scattergram shows that mechanical engineering is mainly the concern of small- and medium-sized enterprises. As a general rule, they are very highly specialised; production is dominated by "one-off" and small batch runs, because - despite intensive export activity - the market segment they serve does not carry mass production. The numerically relatively few big companies tend for the most part to concentrate on areas where standard machines or components allow economies of scale or call for the construction of complete large installations with high personnel and financial capacities.

Table 6: Mechanical engineering

All studies on industrial concentration conclude that mechanical engineering is one of the least concentrated groups of industry. The turnover breakdown for Germany for 1990 indicates that the six largest enterprises together accounted for only 8.2% of the market, the ten largest only 11.3%, the 25 largest only 18.7% It should also be noted in this case that the percentage figures have continued to fall steeply in recent years; the 25 largest enterprises together accounted for 27.9% as recently as 1985.

Strategies

The decline in machine production during 1991 and 1992 reflects a fall-off of investment within the EC and in major countries elsewhere in the world. There is still room for the possibility that this cyclical trough will throw the structural problems of individual firms into sharper relief. The branch is endeavouring to ride out the seasonal slackness through strict cost management, which will simultaneously leave it strategically well placed in readiness for the next upswing. Many companies are redoubling product innovation efforts, because this is the main cornerstone of competitiveness.

The majority of machine-builders expect to have to face increased competitive pressure on completion of the Single European Market, but many also look forward to enhanced sales opportunities. In order to assert themselves in this tug-of-war, most enterprises are taking additional strategic measures. Expansion of their EC-wide sales operations is one obvious course of action, but there will also be recourse in this connection to increased innovation. In addition a minority will be pooling their resources to come up with more rational ways and means of opening markets.

The investment activities of mechanical engineering is very much dependent upon the cyclical situation of the industry group, and its investment quota stands at around 4%. The expansion of capacity being the burning investment topic of the day, companies stepped up their investments considerably during the second half of the 1980s. In 1991 and 1992, investment in machine construction within the EC had undergone a visible decline, and the accent now lay one-sidedly on modernisation plans, predominantly with the aim of controlling the rise in personnel costs.

REGIONAL DISTRIBUTION

The hub of EC mechanical engineering is undeniably Germany; in 1991, West Germany attained 46% of the EC total production. East Germany which, for statistical reasons, is not yet included in the EC figures, rated around 6% of the West German production value during the same period. The other big machine production countries are Italy, with an EC share of 17%, the United Kingdom, with 15%, and France, with 12% These are followed by country groups with shares of around 2% to 3%: these include Spain, the Netherlands, Belgium and Denmark. By the same token, all EC countries have regional mechanical engineering centres. Germany has Baden-Württemberg and Nordrhein-Westfalen, Italy has Lombardy and Emilia-Romagna, the United Kingdom has the South-East and the Midlands, France has the Bassin Parisien and Rhône-Alpes. This distribution shows that mechanical engineering always gravitates towards the industrial heartlands since it traditionally seeks the proximity of its main customers.

ENVIRONMENT

Machine construction does not as a rule cause great environmental problems. Noise-levels from metalworking used to be a problem, but modern machine-tools have reduced it considerably. Further problems arose from surface-finishing processes such as annealing and galvanising, but this work is nowadays contracted out to specialist firms from outside the machines industry. On balance, mechanical engineering does not generate much in the way of environmental protection costs.

At the same time mechanical engineering is one of the main suppliers of environmental technology. Only the construction industry invests more in such technologies. EC technical harmonisation is fostering a growing interest in environmental control among machine manufacturers.

REGULATIONS

The EC Machine Directive ensures that machinery placed on the EC market measures up to uniform basic safety requirements. EC Member States' regulations, which were often wielded as non-tariff trade barriers, are being replaced by national regulations which comply with the Directive. Trade with countries outside the EC must also make due allowance for the many and various special technical regulations which require that extra know-how from producers. However, machine-builders frequently face more serious problems from national export limitations, designed to prevent deliveries of high technology or armaments-related machinery to specific countries. This area requires not only EC harmonisation, but also administrative streamlining.

OUTLOOK

In the longer-term trend, which eliminates cyclical movements, machine-building within the EC will remain a growth industry. The most important arguments in support of this are as follows: the diffusion of the new computer-aided generation of machines is still progressing and contributes towards stabilisation of demand, besides which - thanks to microelectronics - the innovation potential of mechanical engineering is high. Environmental protection requirements offer further scope for activity. The internal market and the "European Economic Space" will provide additional impetus for investments during the coming years. In the longer-term perspective, better sales possibilities may be expected in Eastern Europe, which will benefit East German machine-builders in particular. Finally, the machine manufacturers within the EC have good chances of asserting their keen international competitiveness in future also. An indication can be found in the patents statistics, which show the EC with a clear lead over Japan and the USA.

Agricultural machinery
NACE 321

The agricultural machinery industry in the EC is confronted with shrinking markets in Western Europe as a consequence of the need to reduce surplus production of agricultural products in the EC. The uncertainty about the future of the agricultural sector hampers investment from farmers. Demand from developing countries also show signs of weakness, due to financing difficulties. In other developed countries, such as the USA, Australia and South Africa, market saturation has been reached.
In the coming few years the situation is not likely to improve significantly. The situation in Eastern Europe is so uncertain that it is currently not possible to foresee the recovery of the EC agricultural machinery sector thanks to increased demand from this potential market. Even if demand from this region does improve, the main market for EC agricultural machinery will remain the home market.

INDUSTRY PROFILE

Description of the sector

The following products are manufactured by the agricultural machinery sector: single-axle motor hoes, motor driven mowers and motor lawn-mowers; machinery and equipment for soil preparation or cultivation; machinery and equipment for sowing seed, planting or distributing fertilisers; mechanical appliances for crop protection or irrigation; harvesting machinery and equipment; machinery and equipment for threshing, drying, winnowing, cleaning, sorting, grading and treating crops; machinery and equipment for livestock husbandry; other agricultural and horticultural machinery and equipment; agricultural tractors.

The sector of agricultural and horticultural machinery and tractors is one of the largest sectors of the mechanical engineering industry, covering 8% of its total production. The industry covers a wide range of equipment, with roughly 450 different categories of machines produced in Europe alone. Within the EC, the industry can be divided into two main segments of similar size: tractors and other machinery and equipment. The vast majority of the firms operating in this industry are specialised in the manufacture of agricultural machinery only. The few large firms in the industry are mainly producing tractors and automotive harvesting equipment. The small and medium sized firms specialise usually in the production of a single type of equipment, or of a range of products used in a specific subsector of agriculture.

Main indicators

In 1991, EC firms in the industry exported roughly 24% of their production. The trade balance in the industry has been positive throughout the last decade. But while the trade surplus has been rising in the first half of the 1980s by roughly 7% per year in nominal terms, it started to decline by about 5% per year from 1985 to 1991. Employment in the industry declined by 2.3% per year during the last decade. Germany is by far the largest producer, with about 37% of total EC value added, followed by Italy (22%), France (13%) and the United Kingdom (8%). The smaller EC countries produce about 20% of total value added.

Recent trends

During the last decade, the situation of the industry has deteriorated markedly, particularly in the second half of the 1980s. Demand for the industry's products declined rapidly from 1989 to 1991, falling to 10 400 million ECU in 1991, compared to 12 300 million ECU in 1989. During the same period, the performance of production was similar. Weak growth in extra-EC exports and sharp increases in extra-EC imports contributed to production decline of nearly 13%.

International comparison

Japan shares with the EC the same uncertainty about the future of the agricultural sector: in fact, Japanese farmers have been forced to cut their rice-growing acreage, while rice prices remain static. This situation explains why farmers have been getting more and more reluctant to purchase farm machinery, and production shrank by about 10% for two years running in 1987 and 1988.

Foreign trade

The EC is a net exporter of agricultural machinery. But while exports increased only slightly from 1982 to 1991 (an increase of 13% in terms of value), imports nearly doubled during the same period. The deterioration of the trade balance, however, was less marked, as extra-EC imports represent only 40% of extra-EC exports. The most important markets for EC exports are the USA and the EFTA countries, which account together for about 45% of the total. The former USSR increased in importance over the last few years; its share of exports

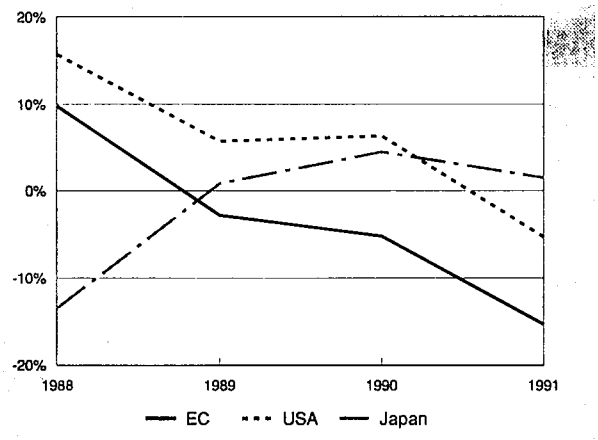
was about 12% higher in 1991 than in 1986. On the import side, the share of the USA in total extra-EC imports has risen from roughly 28% in 1986 to 41% in 1991, mainly to the detriment of the EFTA countries and Japan, which lost 7% each during the same period. Intra-EC trade grew by 3.6% per year during the last decade. However, due to the strong growth in extra-EC imports, the share of intra-EC trade over total imports decreased of 5.5% during the 1982-1991 period.

MARKET FORCES

Demand

Demand for agricultural machinery has been declining markedly over the last few years. The main external factor affecting the performance of the sector is the reform of the EC's Common Agricultural Policy (CAP), which is to progressively reduce production surpluses by reducing guaranteed prices and by imposing production quotas. Furthermore, rationalisation of agricultural production has caused the number of farms to decline, with the result of reducing the number of pieces of equipment needed, and at the same time causing a move towards larger pieces of equipment. Uncertainties regarding the future of the CAP, particularly in view of the difficulties encountered in the Uruguay Round of the GATT negotiations, have further hampered investment activities in agriculture.

Figure 4: Agricultural machinery
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Product innovation partly compensated for the decline in demand. Lately, a number of innovations have been introduced, using in particular electronics. Among these are: electronically controlled distribution of phytosanitary products and fertilisers, the electronic control of attachments, and the use of radar for adapting automatically the dosage of plant protection products to ground conditions. Progress has also been made in the field of safety, as many activities can now be carried out from the driver's seat.

Supply and competition

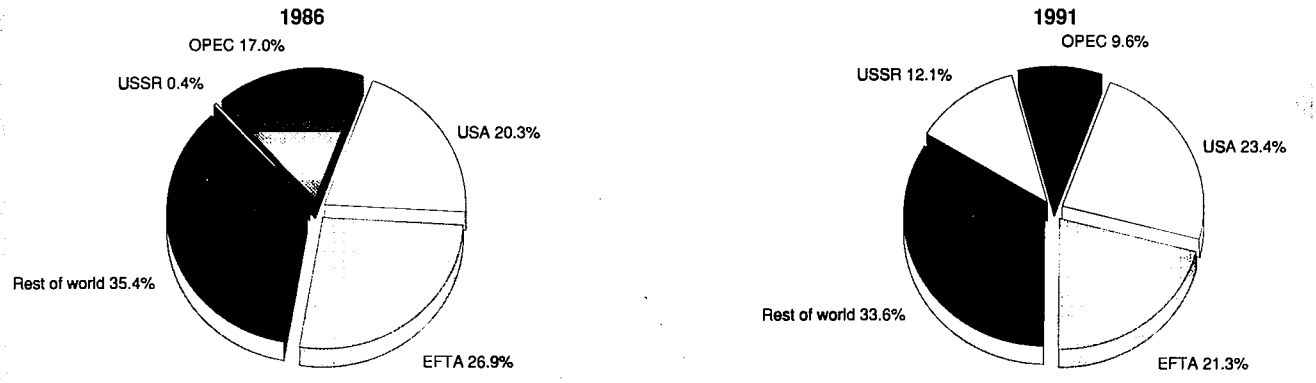
Despite the fact that it accounts for only about 7% of the world's population and 5% of total arable land, Europe is the world largest market for agricultural products. The importance of European agriculture has provided the basis for the development of the agricultural machinery industry and for its position among the world leaders. It should be pointed out, however, that the largest agricultural machinery producers in the Community are subsidiaries of US firms. EC producers find it more difficult to penetrate the US market due to the fact that the agricultural sector in the USA uses mainly larger and more powerful machines than those used and produced in the EC, given the large scale of farming enterprises there.

As demand for agricultural machinery declined over the last few years, the industry has been increasingly faced with excess capacity; equipment prices in the industry have therefore tended to decline, while prices of raw materials and labour have kept increasing, thus squeezing profits. This trend is likely to continue in the future as competition continues to stiffen.

Production process

The manufacturing process in the agricultural machinery industry is currently undergoing some restructuring. Sub-contracting, a traditional feature of the industry, is constantly on the increase. More and more firms restrict themselves to the design and assembly of products, as the increased use of hydraulics, electronics, and integrated data processing systems require a specific know-how which firms in the industry do not often have.

Figure 5: Agricultural machinery
Destination of EC exports



Source: Eurostat

Furthermore, producers are investing in robotics and in machining centres to increase flexibility, and to permit them to switch easily from one product to another and avoid costly accumulation of stocks. The efforts are illustrated by the rapid rise of inward investment, which increased at a rate of 8.3% per year from 1982 to 1988. These efforts of EC firms to rationalise production did not, however, bring about increased productivity, as the decline in value added during the last decade was even faster than the decline in employment. The stage is set, however, for fast increases in productivity, if and when demand and sales pick up.

INDUSTRY STRUCTURE

Companies

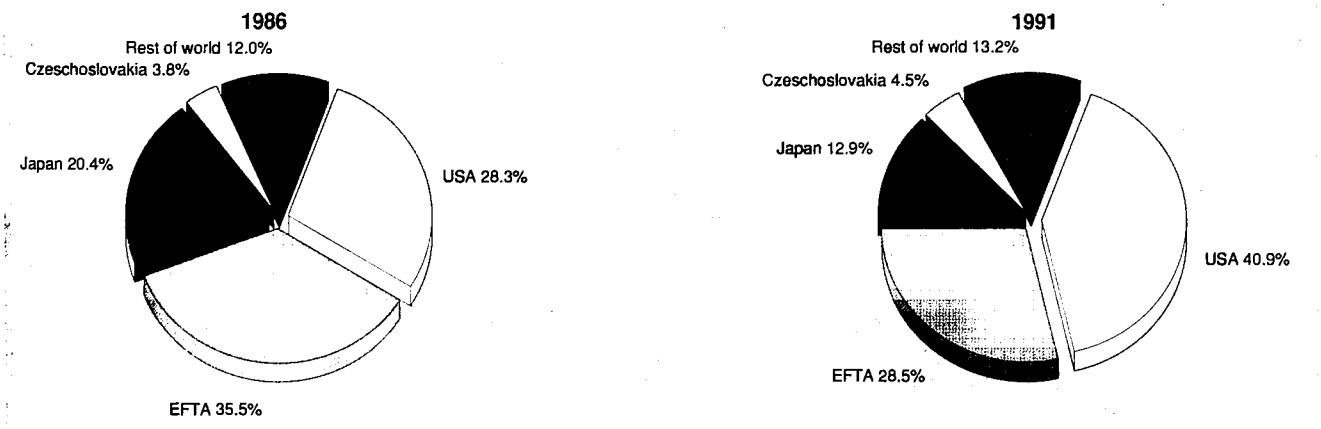
Given the extreme diversity in the types of equipment supplied by the EC agricultural machinery industry, it is very difficult to give a comprehensive picture of the companies in this sector. For its largest part, the industry is organised in a large number of small to medium-sized companies. The few larger firms in the industry are specialised in the manufacture of tractors and of automotive and trailed harvesting equipment for cereals and fodder. The main producers in the EC of these types of equipment are Fiat-Geotech (I), which consolidated its production of agricultural machinery with the European based US company Ford-New-Holland in 1991, Renault (F), KHD and Fendt (D), the Italian company Same (tractors), and Claas (harvesters) in Germany. Beside these companies, there are a few large US companies, based in Europe: Case International Harvester, John Deere and Massey-Ferguson. Altogether, large companies generate about 60% of the turnover of the industry. The remainder is produced by about 4000 companies, most of which are usually very specialised. The smallest firms occupy less than 10 employees, while the larger ones may have 1000 or more employees.

Since demand for farm machinery is not expected to grow in the medium-term, manufacturers are making all-out efforts to cultivate replacement demand by introducing multifunctional machines with added value. As demand for agricultural machinery has dropped, so has the number of companies in the sector. While leading manufacturers are diversifying as hard as they can and trying to penetrate overseas markets, a fair number of smaller firms are unfunded and find it increasingly difficult to operate on their own.

REGIONAL DISTRIBUTION

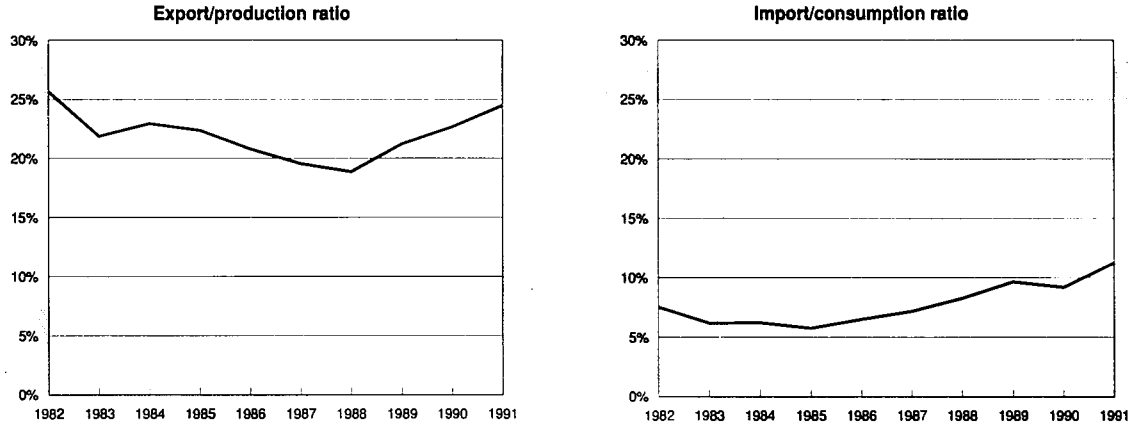
The largest producer of agricultural machinery in the EC is Germany, with 33% of total EC production in 1991, followed by Italy with about 21%, and France and the United Kingdom

Figure 6: Agricultural machinery
Origin of EC imports



Source: Eurostat

Figure 7: Agricultural machinery
Trade intensities



Source: Eurostat

with about 14% each. Germany is also the most important extra-EC exporter with 44% of the total, followed by the United Kingdom (21%), Italy (15%) and France (9%); regarding intra-EC trade, 31% is realised by Germany, followed by Italy (21%), and 13% by France and the United Kingdom. The agricultural machinery industries of France and Italy direct more than 60% of their total exports to other EC member countries. This explains why the decrease in production during the last decade was stronger in these two countries than in other large EC producers.

ENVIRONMENT

Ecological issues are gradually playing a more and more important role in the agricultural machinery industry. The use of agricultural machinery was traditionally linked with noise and smoke emissions, both relatively minor environmental problems, but considerable progress has been made in controlling them. Another environmental concern is the pollution of ground water by nitrates, dung water and other fertilisers and by phytosanitary products. The response of the industry has been electronically controlled distribution, to minimise the use of potential harmful products. Another innovation in this same context is the use of radar to measure ground conditions and to decide about the amount of fertilisers to be used. Progress has also been made to reduce soil compression thus limiting erosion. Thus, environmental concerns may offer new market opportunities to the industry, rather than represent a burden for it.

REGULATIONS

Directive 89/392 on machinery applies to all agricultural machinery and mechanical appliances with the exception of agricultural tractors. Agricultural tractors are subject of a large number of directives on type approval.

Any regulations affecting agriculture in the European Community may have heavy repercussions on demand for agricultural machinery. The most salient example of this is given by the recent decision to change the system of subsidies in the agricultural sector, in order to bring about a reduction in production. The final goal of the so-called McSharry plan is to progressively move EC agriculture to world prices. When implemented, this decision will reduce cultivated areas as well as the use of fertilisers and phytosanitary products in remaining cultivated areas - both of which will reduce needs for agricultural machinery.

OUTLOOK

Prospects for the agricultural machinery industry are not favourable. The above mentioned cuts in subsidies and the imposition of production quotas will hamper farming investment. The prospects for demand from abroad are not much better, at least in the short to medium term, limited by the already high level of market saturation in other developed countries.

In the USA and in Australia requirements for agricultural machinery are different from those of Western Europe, which makes it difficult for European producers to compete there with US producers. Although the prospects for the industry in Eastern Europe and in other developing countries are potentially good, the lack of financial resources might delay increases in sales. Until the situation in Eastern Europe improves, possibly in the second half of the nineties, production of agricultural machinery in the EC will increase only marginally. Environmental concerns, however, could generate new demand for the industry, particularly in relation to a newly defined role for the farmer, but its impact is not likely to be significant in the near future.

Machine tools
NACE 322

After the long period of growth during the second half of the 1980s, the favourable investment climate in the machine tool industry came to an end in 1990. Since then, the booming demand for machine tools changed into a strong decline.
The sector has a strong position in technology, and will be able to stay on the leading edge. The difficulties exist mainly with the application of adequate strategies in volume markets to meet the challenge of the Japanese competitors. Their advantage in economies of scale cannot be met by European companies, and the problem will not always be solved by the merging of independent firms.
The current recession is not expected to swing into an upward trend until the end of 1993. In the medium term, a growing demand for machines will solve the industry's most urgent problems, but competition among companies will remain high, partly because of continued penetration by Japanese companies. Under these circumstances, it is most important that the development of a homogeneous European industry continues.

INDUSTRY PROFILE

Description of the sector

The machine tool industry provides machines for the processing of metal. Machine tools can be divided into two broad product groups: cutting and forming machines. The first group, which accounts for three-quarters of the market volume, includes among its main products turning machines, milling machines, grinding machines, gear cutting machinery and machining centres. The group of forming machines comprises among its main products presses, bending machines and shearing machines. Non-mechanical manufacturing processes, such as electrical discharge manufacturing (EDM) and laser cutting are gaining importance.

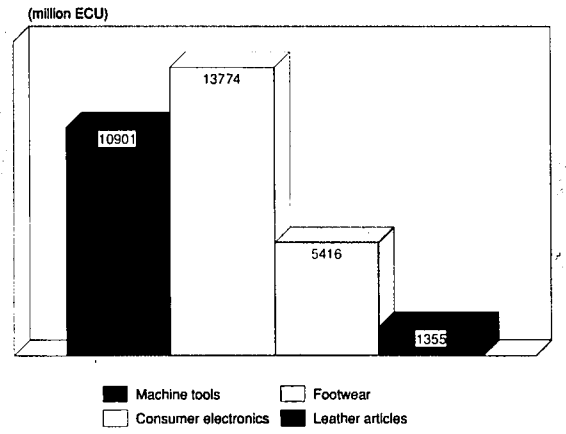
The industry's supply not only consists of stand-alone machines. Automated manufacturing using flexible manufacturing systems or flexible manufacturing cells (FMS/FMC) are also provided. They include controls, data processing equipment for the application of computer aided design (CAD), production planning (PPS), etc. Therefore, machine tool firms provide critical technology to manufacturing companies, and play an important role for the efficiency of the production in a broad range of industries.

Main indicators

European machine tool companies enjoyed a strong growth of the domestic market since the end of the recession in the first half of the 1980s. The major factors behind this development were the supply of advanced production technology and the preparation of manufacturing companies for increased competition in the Single Market. Moreover, capital stock was overaged due to the low investment activity in the EC during the previous decade, and a large part of machinery and equipment had to be substituted.

Between 1985 and 1990, production in real terms grew at a compound annual growth rate of 6%, outpacing EC export growth which had a compound annual growth rate of about 3% over the same period. Foreign competitors succeeded in penetrating the EC-market and now controls a share of about 23%. According to this development, the EC trade surplus in machine tools remained stable in the last decade, indicating that the European industry has lost some of its importance in world trade.

Figure 1: Machine tools
Value added in comparison with other industries, 1991



Source: Eurostat

Recent trends

The deep recession in 1982 and 1983 induced a sharp decline in the demand for capital goods. Compared with the overall cyclical development the market for machine tools showed a lag of nearly two years. By 1984, EC machine tool production volume was reduced by about one-fifth compared to 1980.

The economic development after 1982 and 1983 was stimulated by investment activity, and sectoral analysis proves that the demand for capital goods in manufacturing industries was most dynamic. Additionally, due to the long-lasting overall economic growth, the utilisation of machinery and equipment reached record heights and induced further demand for capital goods to expand capacities.

The situation for the EC machine tool industry started to deteriorate at the end of 1990, as a consequence of the structural problems for the European industry. Figure 3 shows the slump in 1991 and 1992 of the indices for the machine tool industry, which after 1984 had been constantly higher than those for overall manufacturing.

International comparison

The EC machine tool industry is by far the world's largest supplier, with a production share in current prices of about

40%. Japan is the second largest machine tool with about 28% of the world production. Japan rapidly expanded its output within the past decade. Japanese production volume grew at an average yearly rate of 13.2%, whereas EC production expanded at an yearly rate of 3.9%. The US machine tool industry declined sharply during the 1980s. During this period, its production volume decreased by almost half.

The reason for these strong differences in growth lies partly in the domestic markets. Japanese demand for machines expanded dynamically, whereas the US manufacturing industries reduced their investment activity. Japanese suppliers of machine tools conquered the US market and now hold a share of more than 50%.

The development of the Japanese machine tool industry is even more impressive as its output prices remained stable during the 1980s, whereas EC and US companies increased their prices each year at 4.5% and 3 %, respectively.

Foreign trade

The growth of the internal demand stimulated the intra-EC trade, which expanded at an average yearly rate (at current prices) of 12.5% between 1982 and 1990. This development can be partly regarded as a consequence of the process of achievement of the Single Market.

Extra-EC exports showed a less dynamic expansion at an average yearly growth rate of 5.8% at current prices. In 1987, there was a sharp decrease partly induced by some distortions in the financial markets and further intensified by the depreciation of the US dollar. The price competitiveness of European suppliers in the US market, which is the most important outside of Europe, has worsened. Extra-EC imports at current prices grew strongly at a rate of 12.8% per year and the size of the trade surplus was sharply reduced. The ratio of exports to imports decreased about 40% during the 1982 to 1991 period. Foreign suppliers could increase their share in the EC market from 20% to 25%.

Most machine tools delivered into the EC are from the EFTA countries, particularly Switzerland. The next major exporter of machine tools to the EC is Japan. Both countries were able to increase their share on total EC imports. On the contrary, US producers since 1985 have lost importance as exporters.

MARKET FORCES

Demand

The industry supplies capital goods for final demand and is dependent on the overall investment climate. Above all, machine tools are bought by manufacturing industries, of which the most important are capital-good manufacturers. During the past decade, the machine tool industry enjoyed a strong demand caused by high investment activity. Preparation for the Single Market has stimulated investment in new technologies and capacities. The automotive industry deserves particular mention for being a very active source of demand for the machine tool industry.

This development was partly induced by the demand for newly designed production technology. The application of numerically controlled (NC) technology has been spreading during the 1980s, and since the end of the decade a slowdown of the diffusion rates indicates saturation of this important technology. Within the EC, the share of NC machines on all machine tools has gained 60% and will likely expand up to 70%.

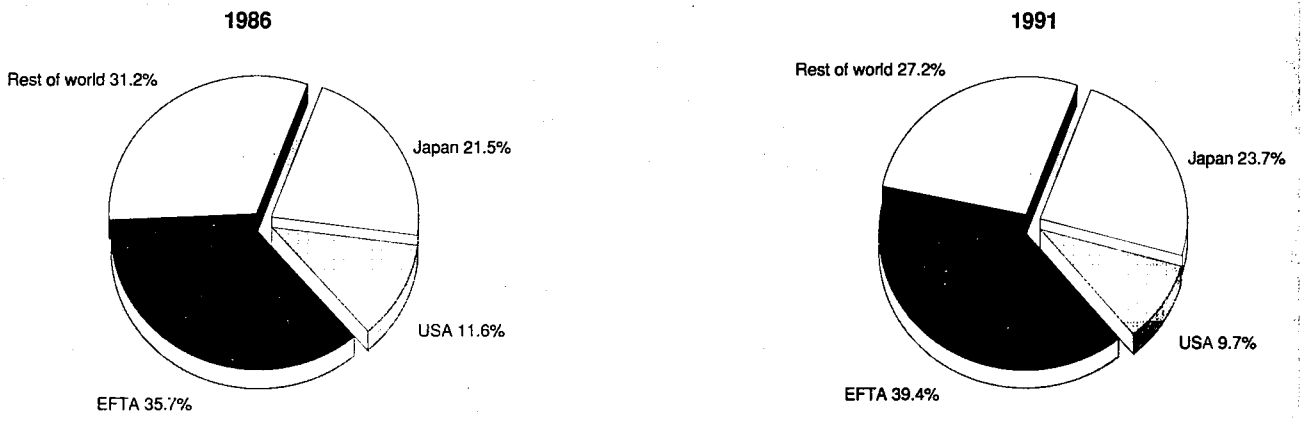
Supply and competition

The strong cyclical development of the demand for machines is a major factor affecting the companies of the industry. In a booming economy the supply can hardly follow the demand, while in a slowdown phase capacities are a burden and induce strong price competition. This environment is a challenge, especially for medium-sized enterprises, because it requires the ability to allocate resources for high investment volumes within short periods and the financing of a long-term liability.

In the past decade the market for standardised machinery has evolved to a volume market with global players. In this segment the price has got an increased importance. On the supply side, high discounts are accepted with regard to a long term strategic advantage in market shares. On the demand side standardised machines are homogeneous and a global supply provides alternatives that can be discriminated by the price.

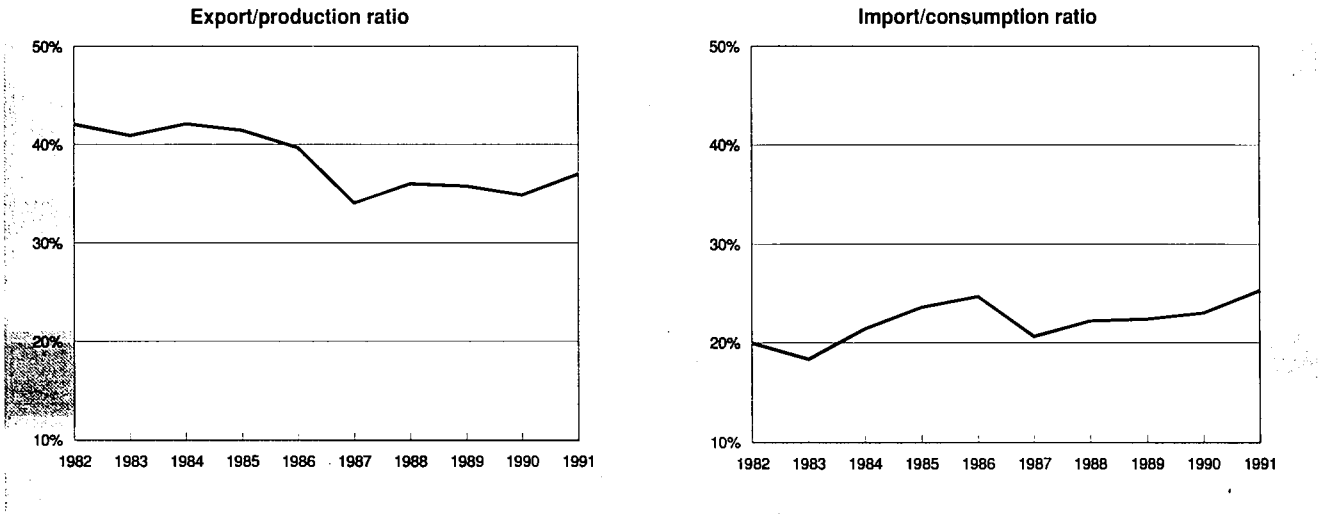
On the other hand, the growing level of automation in client industries requires an increasingly specialised supply, tailor-made systems, engineering and the development of software. In this market segment criteria other than price are of major importance. Clients use the technological know-how of a machine tool supplier for a specific process. This kind of co-operation can be regarded as outsourcing of production planning knowledge. In general, single purpose machines have lost some of their importance, whereas machining centres combining different processes and enabling multiple manufacturing with one chucking have raised their share in the EC production.

Figure 7: Machine tools
Origin of EC imports



Source: CECIMO, ifo Institute

Figure 8: Machine tools
Trade intensities



Source: CECIMO, Ifo Institute

Until now the EC machine tool industry has been a conglomerate of national industries with specific structures. The strong growth of the EC's internal trade within the past decade encourages a change in the industry's structure towards a more integrated EC machine tool industry.

The most important foreign competitors are Swiss and Japanese companies. Swiss firms often deliver to niche markets for specialised and high accuracy machines. Their main advantage lies in the technological know-how.

The Japanese are mainly supplying standardised machines. They hold a strong position in volume markets and have become global players, investing in large scale production and enjoying cost reduction effects. During the 1980s they penetrated the US market and set up transplants, and now control more than 50% of the US market in some product groups.

Simultaneously, Japanese companies have established footholds in Europe by making greenfield investments, acquiring companies, setting up cooperative agreements for knock-down production and issuing licenses. Japanese firms are prepared for the Single Market, and if demand improves, they will be able to expand their supply.

In comparison with the Japanese machine tool suppliers, European companies suffer a disadvantage in the volume production that can not be easily overcome. Nevertheless, they hold a strong position in research and development as well as in system technology. On one hand, their expenses for R&D as a percentage of total turnover is higher than for Japanese companies with 4.5% and 3.2%, respectively. It must be kept in mind that European companies are strong in customisation and some of their R&D funds are not spent for basic research but rather for a specific design. The analysis of the most important innovations proves that EC companies are technologically at the forefront. For instance, the number of important patents EC companies apply for is nearly double that for Japanese firms.

Production process

In former days, the manufacturing of a machine tool required many mechanical parts such as gears, transmission units, etc. The technological development of electrical drives and controls induced a substitution of mechanical components by electrical components that no longer had been produced in-house but procured by specialised suppliers. This development has reduced the value added share on total turnover in some cases down to 30%.

Outsourcing has become an important strategy to reduce costs as far as it concerns parts and components that are not of critical importance for the accuracy of the machine. But even casting requires a specific quality that makes it not easy to find an alternative supplier. For key components such as ball screws, the supply easily can create bottlenecks and hamper the expansion of the production when the demand for machine tools booms.

The procurement of the electronic and electrical equipment is strongly dependent on the design of the machine. Different components are combined by the R&D staff of a machine tool company to meet the requirements of a specific task. This procedure is typical for European firms, whereas Japanese companies focus on volume markets and prefer to use complete electrical/electronic packages, providing the advantage of lower R&D efforts and lower costs for the complete package.

Factory automation has been pushed in the industry. Some examples include flexible manufacturing systems and automated warehouses which have been installed in recent years. The improvements in the production process have induced some reductions in labour costs. The tendency of productivity in the EC machine tool industry indicates that there have been strong economies of scale at the end of the 1980s increasing the efficiency of labour inputs.

INDUSTRY STRUCTURE

Companies

The machine tool industry comprises about 1400 companies, of which about 370 have less than 20 employees. The average EC machine tool firm has a staff of about 120, although there are significant differences among Member States. For instance, German companies have an average number of employees of about 250, whereas Spanish companies only have about 53.

Among the largest EC machine tool firms are Schuler, Gildemeister, Maho, and Trumpf (D); Comau and Mandelli (I); The 600 Group and Bridgeport (UK); Brisard and Renault Automation (F).

In general, the machine tool industry is medium-sized by the number of employees. The analysis of the companies' turnover shows that there are no overwhelmingly large companies. The

top three enterprises account for less than 10% of the industry's output.

Compared with Japanese firms, EC firms are small. They have on average half as many employees, and a comparison of average turnover would indicate an even larger difference. In comparison with US firms, the average EC firm has only 75% as many employees.

Strategies

In the second half of the 1980s, EC machine tool suppliers expanded their investment budgets by about 50%, and as a percentage of the turnover the expenditures reached 7%. The increase was mainly induced by the objective to meet booming demand, but companies also invested in factory automation.

Apart from investment in existing facilities, companies tried to expand their distribution network, especially into other European countries. Mergers and acquisitions took place to complete their supply in the market or to improve market penetration abroad. Many companies have not been able to finance all these activities by themselves and had to open up new financing sources. Some family-held firms became joint-stock companies, others increased the equity or raised loans. Because of the dynamic development of the industry and the bright prospects it was relatively cheap to fund investments.

The quick worsening of the economic environment has damaged those firms which were most active in the preparation for the Single Market. High financial burden caused by investment in new capacities, a low utilisation of the production and a merging price pressure have become a trap for some companies.

Companies that want to survive in a volume market environment will have to expand their activities in coming years, with mergers and acquisitions being very important in reaching that objective. But the forging of groups out of former independent companies, as sometimes proposed, is no guarantee for success.

REGIONAL DISTRIBUTION

Germany and Italy provide three-quarters of the EC machine tool production. Both of these countries have been successful in the competition in the past decade. Next in the ranking by the output are the United Kingdom and France. The industries of both of these countries experienced difficulties in the market and lost some of their importance. Some companies left the industry and a restructuring took place. The Spanish industry, fifth in this ranking, has competitive prices and has caught up in the technological development.

In Germany the production of machine tools is concentrated in Nordrheinwestfalen, a traditional region for heavy engineering, and in Baden-Württemberg. The unified Germany has got another important region for machine tool production in the South of the new Länder. In Italy most of the industry is located in the North, in Lombardia, Piemonte, Emilia-Romagna and Veneto. French suppliers are concentrated around the Ile-de-France and Rhône-Alpes. In the United Kingdom the machine tool industry is located in the traditional industrialised region of the Midlands, in the South-East and in Yorkshire/Humberside. Spanish companies are centring in Euskadi, Catalunya and Madrid. In Portugal the industry is only concentrated around Oporto. In Denmark, Belgium and the Netherlands there are no particular areas of concentration.

ENVIRONMENT

The manufacturing of machine tools mainly consists of mechanical processes as turning, milling, boring, drilling, grinding and assembling. Most of the preliminary products are of metal, and the input of energy is of minor interest. Therefore, the major threat for the environment lies in the use of cooling and lubricating liquids which cannot be easily disposed other than by filtration which allows for a re-use of the liquids.

Hardening and galvanising are used to increase the durability and rigidity of materials and special surfaces such as slides. As hardening by heat treatment is not sufficient, chemical processes are necessary. Most of the machine tool companies do not have their own capacities for these processes and employ specialised subcontractors.

The technological progress has induced some changes in the products themselves. Advanced machine tools are equipped with controls, motors etc. New materials are used as composites and compounds for parts of the machines. Therefore, it is no longer easy to scrap an old machine. The recycling of its components will only be possible if the machine is adequately designed. Companies are only beginning to comply with such requirements.

REGULATIONS

There are few regulations hindering the international trade of machine tools. Most important of all, there is the COCOM rule which were introduced to hinder exports of advanced production technology to the countries of the former Eastern bloc. In spite of the recent developments, the regulation has not been abolished and hampers Western machine tool suppliers from increasing their exports.

There is no major hindrance for intra-EC trade, however the supplier must apply for a safety approval in order to deliver their machine tools in most other countries. The newly adopted Machine Directive ensures free circulation of machine-tools throughout the EC, reduces unnecessary administration and avoids duplication of essential safety requirements. Compliance with the directive is likely to reduce costs for manufacturers who meet harmonised standards.

Other regulations, as the electro-magnetic compatibility directive and the agreements on interfaces between data processing facilities set standards that ease the combination of products of different EC countries. These regulations are prerequisites for the Single Market and are very important for the set up of automated manufacturing processes.

OUTLOOK

The machine tool industry has been strongly hit by the interruption of overall economic growth. Demand declined worldwide at a double digit rate and posed problems to some companies in the industry. Presently there are no signs of a recovery.

Moreover, the breakdown of the economies in Eastern Europe had a negative impact on the machine tool industry. The medium-term perspectives for deliveries into East European countries remain bad and will not provide any compensation to the overall slackening demand.

However, a recovery of demand for machine tools from developing and newly industrialising countries is taking place.

Table 5: Machine tools

The South-East Asian countries provide particularly good opportunities for growth.

In the event of an overall economic recovery, and taking account of the cyclical nature of demand for machine tools, it is expected that the sector will enjoy more sustained growth in the 1994 to 1997 period. However, the expansion will be by far less dynamic than in the past. In this environment the growing efforts of Japanese suppliers to enter the European market will keep competition tough, with current price pressures will declining only slightly.

Written by: Dr. Hans-Günther Vieweg
The industry is represented at the EC level by: Comité Européen de Coopération des Industries de la Machine-Outil (CECIMO). Address: Rue Capitaine Crespel 9, B-1050 Brussels; tel: (32 2) 502 7090; fax: (32 2) 502 6082.

Textile machinery
NACE 323

The EC textile machinery industry is one of the most heavily export-oriented sectors in the Community. After a period of great prosperity during the latter half of the 1980s, the industry suffered a serious set-back in activity in 1991 due to a sharp decrease in demand which followed the Gulf crisis. Competition on the world market is increasing, especially from Japanese companies. The EC industry is suffering from world overcapacity in spinning and weaving and is striving to maintain its technological advantage by way of R&D investment.

INDUSTRY PROFILE

Description of the sector

NACE 323 covers the production of machines for textile processing and accessories for such machines. Its main products are: short-staple spindles (for short-staple fibres, e.g. cotton); long-staple spindles (for long-staple fibres, e.g. wool); open-end rotors for spinning; shuttle looms for weaving; shuttle-less looms for weaving. These machines spin (natural and synthetic) fibres into yarn; weave or knit the yarn into fabric; dye, print and finish the resulting fabric; and produce garments or other fabric products. NACE 323 also includes the manufacture of sewing machines, which are the subject of a specific paragraph below.

Main indicators

Production in current prices more than doubled between 1983 and 1990 and reached a record high at 9.9 billion ECU in 1990. In 1991 the industry was confronted with serious problems as a result of a combination of depressed demand, the fall of the US dollar and overcapacity. EC production decreased by 1.6 billion ECU (or 18% in real terms), EC consumption dropped by 24%. As a consequence, reductions in labour occurred, although these remained limited to 4%. In 1992 the set-back in economic activity is estimated to continue and no major improvements are expected.

The breakdown by country shows that Germany is by far the largest producer of textile machinery in the EC, nearly four times the size of the next largest producer, Italy. These two countries account together for nearly three quarters of total EC production.

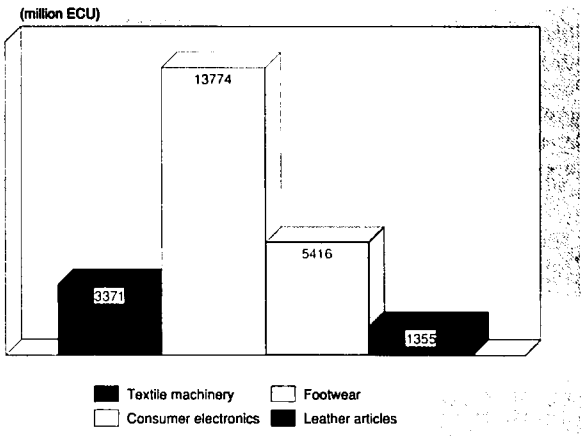
Recent trends

The industry underwent substantial difficulties during the period 1982-85, as it did not succeed in remaining competitive on both the domestic and the export markets. Since 1985 however, after having restructured, the industry was able to compete again, and production and employment started to recover. All over the 1980s and at the beginning of this decade, extra-EC exports accounted for about the half of total EC production, a fact that underlines the export-oriented nature of the industry.

International comparison

The EC is the world's largest producer of textile machinery. The size of the EC industry is nearly the double than the Japanese one and more than six times than that of the USA. In recent years, the traditional position of predominance of the EC industry has been seriously affected by the rapid development of the textile machinery industry in Japan and in the Newly Industrialised Countries (NICs). However, with the exclusion of some small subsectors, sales from Japan and the NICs represent a marginal, although fast growing competition for EC manufacturers on the European and US market,

Figure 1: Textile machinery
Value added in comparison with other industries, 1991



Source: Eurostat

the main thrust of Japanese and NICs competitors remaining in Asian markets. On the European market, Swiss textile machinery manufacturers are the most important competitors for the EC producers.

Foreign trade

The largest market for extra-EC exports is to be found in Asia. Textile manufacturers in countries like India, Indonesia, Korea, Taiwan, Pakistan and Thailand are investing heavily in new machinery, particularly in short-staple spindles and shuttle looms. Investment in these countries is both for replacement purpose and for the setting up of new firms. Another growing market can be found in the Commonwealth of Independent States (CIS) and the Eastern European countries. In 1991, 506 000 short-staple spindles were installed at CIS-textile manufacturers, and the CIS is also the largest market for open-end rotors. Domestic machinery manufacturers are not able to meet the demand both in terms of the volume of machinery requested and in terms of demanded technology. The North American market, although the second largest export market, has declined in importance since 1986, both as a share of total extra-EC exports and in absolute terms.

MARKET FORCES

Demand

Demand for textile machinery is naturally linked with developments in textile manufacturing. About 50% of world-wide capacities for textile manufacturing are in Asia. The share of North America and the EC amounts to some 10% each. Hence it is clear that for EC manufacturers the demand for textile machinery is mainly in foreign markets. Conventional (short-staple and long-staple) spindles still account for three quarters of world deliveries. They produce superior yarns for some end uses, especially in finer count ranges. The shift to open-end rotors seems to have come to a halt or has even reversed.

There are significant differences in the structure of demand by region. Asian countries are strongly investing in spinning machines with short staple spindles; in the EC, demand for long staple spinning machines used for high quality yarns prevails. The same difference exists in demand for weaving machines: nearly all shuttle looms are procured by Asian countries, whereas textile firms from industrialised countries mainly concentrate their purchases on advanced shuttle-less looms, especially rapier/projectile and air-jet spinning machines.

Within the EC, Italy is by far the most important market for textile machinery. Over 30% of EC demand for spinning and weaving machines comes from this country. In particular Italian textile companies invest considerably (up to 60% of total investment) in long-staple spindles. Important customers for open-end rotor spinning machines are in Italy, Germany, France and Spain. EC demand for weaving machines is focused on shuttle-less looms. Again Italy is the most important in demand for this type of machinery.

Sewing machines

The bulk of output goes to the industrialised countries. European producers sell about 70% of their output to customers in these countries. Germany as a supplier of mature specialised technology sells about three quarters of its exports to industrialised countries; the remaining quarter goes to developing countries. Japanese manufacturers sell about half of their exports to industrialised countries; the other half goes to developing countries.

Supply and competition

Japanese manufacturers are increasingly becoming a competitor on the world market. They are not only strong in producing

Figure 4: Textile machinery
International comparison of production at current prices

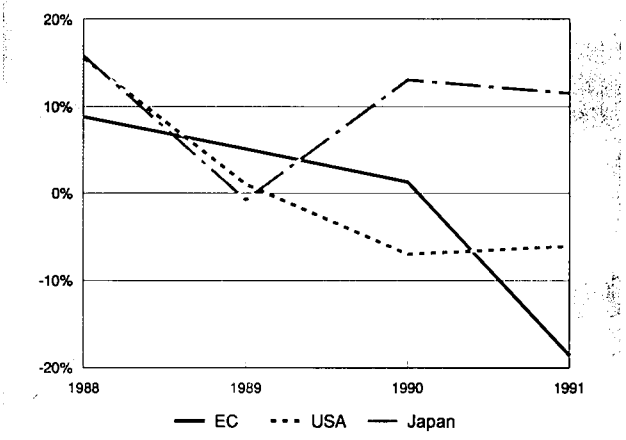
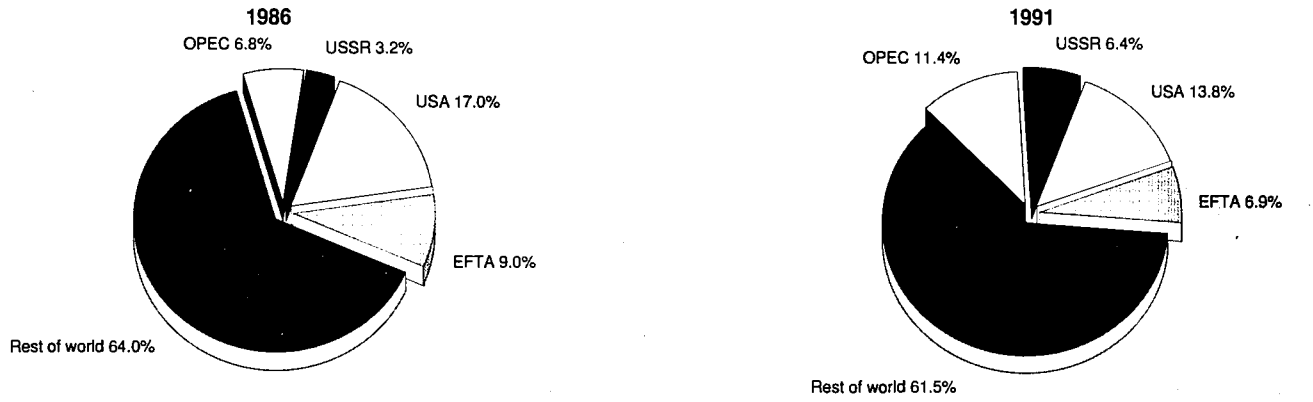
Figure 5: Textile machinery
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Figure 6: Textile machinery
Destination of EC exports



Source: Eurostat

machinery of traditional technological standards, but they have also obtained considerable strength in highly advanced machinery. The largest part of their production (ECU 2 266 million out of ECU 4 159 million in 1989) is exported. Already in the Asian markets the Japanese have been able to acquire strong market positions, where demand is more with standard technology machinery: some 60% of exports go to these markets. Their importance on European and American markets is also growing.

There is also growing competition from local companies in the newly industrialising countries in the Far East and South East Asia. These companies produce standard technology machines at low prices and become more and more an important competitor on the Far East and South East Asia markets. Companies in developing countries manufacture machinery under licenses of EC manufacturers, which essentially represents an import substitution policy.

Sewing machines

In terms of supply the most important manufacturers of sewing machines are located in Germany, Japan, the United States, Sweden, Switzerland and the NICs in Asia. Japan and Germany together account for over 50% of world trade in sewing machines or the corresponding technology. The NICs like Taiwan, Hong Kong, Singapore and South Korea have become serious competitors imitating Japanese technology, but selling at lower prices. Industry in PR China is developing and may soon capture the domestic market or even enter the international market.

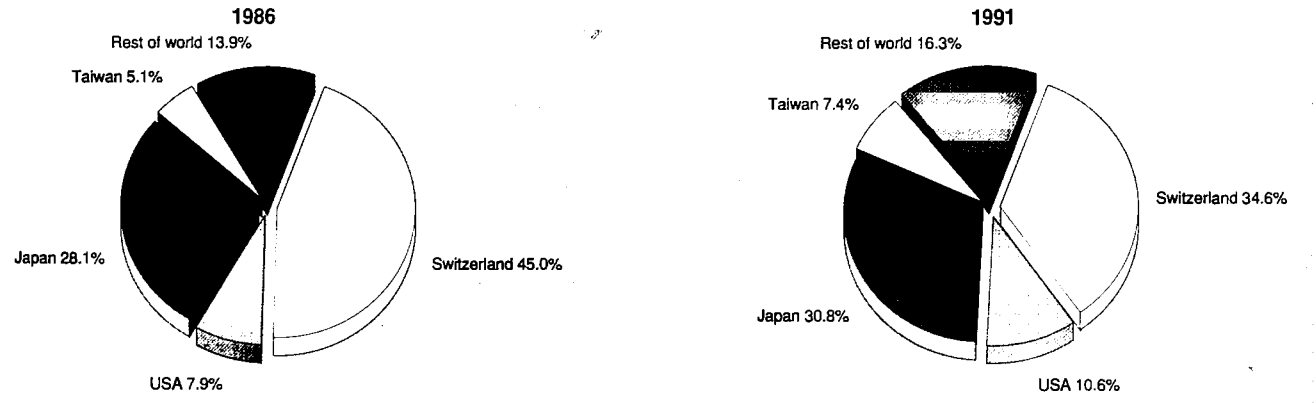
Production process

The EC textile machinery industry shows stable productivity at some ECU 37 000 per employee. During 1991 a sharp slump in sales caused a drop in productivity, as employment was not reduced accordingly. Unit labour costs on the other hand have grown considerably, whereas total unit costs have increased even more. This reveals the growing capital intensity of the sector.

EC enterprises have been highly investing in research and development (5% to 10% of turnover) to guarantee continuous technical and product innovation. Further marketing costs have also proliferated due to the need to attend international textile machinery exhibitions, especially to organise product promotion in developing markets.

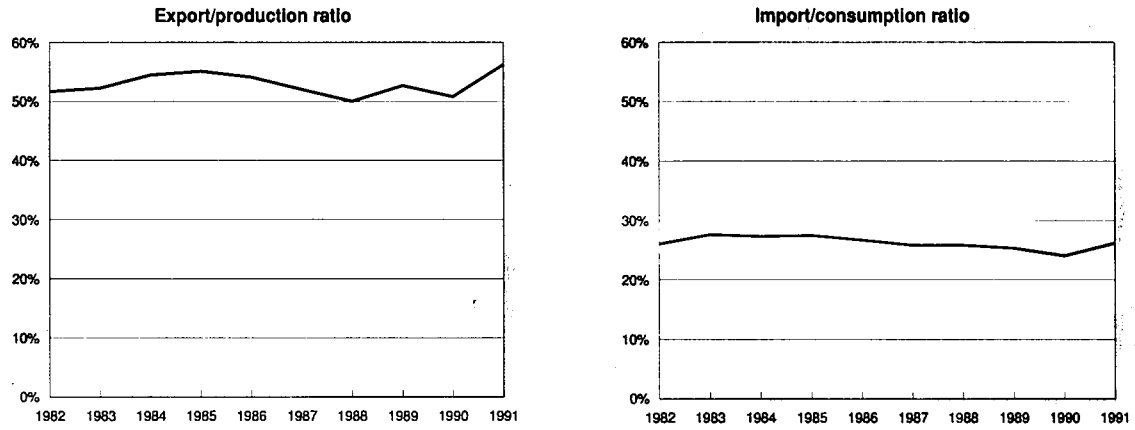
Technological innovation in the past has greatly improved productivity in textile manufacturing. Innovations have occurred in various fields, such as new automatic bale feeders, aerofeed systems, high-draft spinning, texturisation, shuttleless looms, needle punch machines, transfer printing, rotary

Figure 7: Textile machinery
Origin of EC imports



1Source: Eurostat

Figure 8: Textile machinery
Trade intensities



Source: Eurostat

screen printing and computer-integrated manufacture. This led to new machinery in all stages of the textile production process: material handling, yarn spinning, fabric weaving, dyeing, printing and finishing. It also led to automation of machinery functions.

INDUSTRY STRUCTURE

Companies

More than 1 100 companies in the EC are engaged in the manufacture of textile machinery, many of which are small or medium-sized enterprises. The largest textile manufacturers in the EC by type of machinery are the following:

- Spinning machines: Platt-Saco-Lowell (UK/USA) and Schubert & Salzer (D);
- Weaving machines: Dornier (D), Jumberca (E), Picanol (B) and Somet (I);
- Knitting machines: Mayer Albstad (D), Stoll (D), Sulzer Morat (D) and Terrot (D);
- Dyeing, printing, finishing: Adrioli and Co. (I), Kusters Corp. (D), Stork (NL) and Zimmer (D);
- All categories: Schlafhorst (D), Bentley (UK) and SAMT (F).

Two main factors determine the overall structural features of the EC textile machinery industry. First, the very high proportion of extra-EC sales indicate the global rather than regional nature of the industry. This is exemplified, for instance, by the fact that most major European textile machinery manufacturers have fully or majority-owned daughter companies in the US market, which enable them to serve the adjacent Canadian and Latin American regions. Other companies have similar arrangements or joint-ventures with local companies in other key regions such as the Far East.

Second, the high degree of specialisation of the EC textile machinery industry refers not merely to broad product categories such as spinning, but also to specialisation within these categories. Pressure on order volumes and profit margins and increased local competition in some developing markets have strengthened the movement towards specialisation.

Competition from outside the EC comes from large companies in Switzerland and Japan. Both countries are key players in the world market. With high efficiency and technologically advanced products they are able to capture a large share of

market demand even in countries with strong indigenous textile machine-making capacities.

Strategies

Some major manufacturers have adopted a strategy to reduce the number of variations of machine types within a particular product category or group. This enabled them to optimise the production of machine parts and to match production and orders in a better way.

The industry has also been confronted with internationalisation involving acquisitions, mergers and other forms of cooperation not only within the EC, but also at the international level. In this way specialised individual textile machinery manufacturers aim at becoming a more complete supplier to meet the growing demand for fully equipped, highly automated production plants. Examples are the French SAMT (merger of SACM and ARCT), Rieter (CH) acquiring 51% of Schubert & Salzer, Saurer (CH) having taken over Volkmann (D) and Schlafhorst acquiring Zinser.

REGIONAL DISTRIBUTION

The largest textile machinery companies within the European Community are mainly settled in Germany, a country with a long tradition in machinery manufacturing. Some 300 enterprises with a total employment of 56 550 account for 57% of total EC value added in 1991. In 1991 exports to EC countries absorbed 26% of total German exports. Germany's extra-EC exports in 1991 went to developing countries (46.6% of extra-EC exports), the USA (14.8%) and Japan (3.9%). Most of German exports consist of spinning and finishing machinery.

The second largest producer country is Italy: some 350 Italian companies employing over 18 000 persons take a share of 16% in EC value added. On average Italian manufacturers are substantially smaller in size than German manufacturers. The four largest companies only account for a third of total production. However, the relatively small size seems to be a factor working at the industry's advantage: it allows maximum specialisation and close customer relationships. Due to this specialisation output shows a large diversity with machinery covering practically every stage of the textile production process. Italy exports about 25% of total exports to other EC countries. Extra-EC exports are particularly destined for Third World countries (49.6% of total extra-EC exports in 1991) and the USA (10.9%).

The French industry employs some 6 600 workers in some 80 companies and accounts for 7.7% of EC value added. In output machinery for primary weaving and spinning takes a considerable share. Intra-EC exports from France constitute 44.6% of total exports. In 1991, 51% of extra-EC exports headed for Third World countries, while the share towards the USA amounted to 16.1%.

Textile manufacturers in Spain and the United Kingdom constitute 6.1% and 4.7% of 1991 EC value added respectively. Employment amounts to some 6 600 workers in Spain and about 7 100 workers (around 180 firms) in the UK. Spanish output covers the whole range of machines necessary for textile production; British output has an advantage in high technology areas, notably in tufting, yarn spinning and processing and the manufacture of non-wovens. In both countries a third of total exports is traded with EC countries. Important destinations for extra-EC exports are Third World countries (61.1% and 64.3% of 1991 extra-EC exports respectively) and the USA (10% and 12.8%).

REGULATIONS

Regulations in the field of trade mainly concentrate on the establishment of the internal market in the EC and the liberalisation of world trade through the GATT negotiations. Especially the latter is important for the European industry, given the importance of trade with Asian countries.

In this respect the Japanese Comprehensive Import Expansion Policy provides an interesting example. Already foreign producers take about 24% of the Japanese market for textile machinery, which amounted to 852 million ECU in 1989. Some 90% of these imports are handled by Japanese importers. The import policy, together with increasing sales efforts by importers, may cause the foreign share in the Japanese market to rise to the benefit of European producers.

Regulations on machine safety and health provisions are currently imposed on machine manufacturers. Provisions concern the design, the materials used, the way in which machine operations should be illuminated, machine operations itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. Machines complying with the EC regulations will obtain the EC mark.

Together with regulations on machine safety, provisions concerning technical standardisation are being developed. The European institutions on technical harmonisation CEN and CENELEC currently develop such standards applicable throughout the Community. Further international standards for quality control have been developed such as ISO 9000.

In the USA legislation was accepted in 1991 allowing subsidisation of R&D expenses of the US textile machinery industry in order to increase its technological competitiveness. The subsidies are to be financed by using a portion of the tariffs collected on imported machinery.

OUTLOOK

Textile machinery manufacturers will benefit from the integration of the EC market as a whole, although intra-EC competition will increase possibly causing downward pressure on prices and profit margins. However, the high productivity and the investments in R&D will safeguard the strong position on the world market, particularly on the important Asian market.

Essential for EC manufacturer's success will be the application of modern technology: sophisticated automation, electronics, and computer-to-computer communications. Another factor for future success will be the manufacture of machinery that allows the production of high-quality textile products with a high degree of machinery flexibility.

Especially in developing countries demand may not be for technologically advanced machinery, but more for machinery of accepted standard technology. The difference in productivity between both types of machinery may only be of limited importance, as labour costs in these countries are relatively low. These markets will become more important in the future.

Food, drink and tobacco processing machinery

NACE 324.11

As the market for food in the Western industrialised countries matures, not only food manufacturers but suppliers and manufacturers of food machinery and equipment as well have engaged in M&A activity to an increasing extent. Production of food is becoming centralised, causing demand for more flexible and efficient machinery to grow. As a consequence the application of robots and industrial automation systems in particular is growing.

INDUSTRY PROFILE

Description of the sector

The industrial production of food, drink and tobacco processing machinery accounted for an estimated 5% - 6% of total machinery production. Food processing machinery accounts for the greater part of the production of this NACE. The market of food processing machinery includes: flour milling equipment, noodle making machines, baking machines, confectionery machines, fermenting machines, dairy product processing machines, meat processing machines, seafood processing machines, rice & barley polishing machines, fruit and vegetable processing machinery, and other machinery.

In contrast with other machinery sectors, demand for, and consequently the supply of, food processing machinery is highly fragmented. Within the EC, meat processing machinery, bakery machinery and fruit and vegetable processing machinery are particularly important segments of the industry.

Main indicators

Germany strengthened its position as the largest manufacturer of food processing machinery throughout the 1980s, during which time French production stagnated. Strong in the production of other types of machinery (especially manufacture of packaging machinery with an estimated 30% of EC-production), Italy's share of the market for food processing machinery remains relatively low, with an estimated share of 17%.

Recent trends

German and Dutch production of food processing machinery recorded continuous growth during the 1980s, stimulated in particular by rising exports. However, in the early 1990s, German production was also stimulated by a booming domestic market as a result of the reunification.

Stagnating French production, together with increased German exports to France, suggests a weakening of the French competitive position, since demand remained high. Italian manufacturers, on the other hand, were confronted with stagnating domestic demand in 1991. The rise of Italian exports by 1.8% - resulting in an export share of 64% - was not sufficient to prevent a production decline in 1991.

International comparison

The production figures for Japan and the United States are in line with German production. As the applied definitions of the industry differ among the three countries, a definite comparison can not always be made.

The Japanese market is much more isolated than the US and EC markets. Japanese import penetration was only 2.8% in 1988, compared to 21% for the USA. For exports a similar picture can be identified: the Japanese ratio of exports to production was 3.3% in 1989, while the same ratio in the USA was estimated at 26%.

Foreign trade

The EC is the world's largest producer of food , drink and tobacco machinery. The market shares of Germany, the Netherlands and Italy increased during the 1980s. The export orientation of these countries have resulted in trade surpluses for the EC as a whole. Germany in particular is an extra-EC exporter, while Dutch and Italian producers mostly produce for European markets.

MARKET FORCES

Demand

Compared to packaging machinery, for example, the applications of the food processing machinery are less diverse and more limited to specific segments of the food processing industry. The demand for a variety of foods has a strong impact on the structure of the industry. Supply is highly fragmented, with manufacturers operating and specialised in one market segment, which can differ considerably in size. For instance, the manufacture of meat processing machinery, bakery machinery and processing machinery for fruits and vegetables are relatively large and important market segments with very specific applications. In other segments, changing consumer tastes together with intensifying industrial competition require flexible food processing techniques and equipment. Furthermore, the availability of reliable and non-perishable food products is increasingly a priority. Diet conscious consumers are reducing fat, salt, sugar and cholesterol intake while still demanding flavourful, wholesome and appealing foods along with greater convenience and variety. Negative publicity about smoking has caused a shift of demand towards light cigarettes. These trends create market challenges for both the food and tobacco industry and the food and tobacco processing machinery industry.

As the total market for food, drinks and tobacco consumption is maturing in the Western industrialised countries, it is essential for the food industry and machinery manufacturers to keep pace with the consumer trends in order to retain market positions and to look for any growth opportunities in order to strengthen these positions. This will result in a continuos search for new ideas and new products by the food industry, which will also have a positive influence on the machinery sector. Other growth opportunities could stem from the economic development of relatively less developed regions with high agricultural potential such as the former Eastern bloc countries. Demand from Eastern European countries is rising. The main problem for further developments is the lack of capital in these regions. The food industry and the food machinery industry are expected to benefit earlier than other industries from the industrial and political restructuring processes.

Supply and competition

Increasing concentration due to M&A activity has had significant consequences for the suppliers of food processing machinery. This concentration process is not limited to any one segment of the food industry; large multinationals such as Unilever and Nestlé are also diversifying into different segments of the food industry. This development also requires more concentration on the supply-side of the machinery manufacturing industry itself.

The high degree of concentration in downstream industries could result in price cuts and lower margins for the food processing industry in the long run. Furthermore, to fully benefit from the activities of these multinationals in the former Eastern bloc countries, a wide range of food processing machinery will need to be available.

Similar to the packaging machinery industry, the low Japanese export ratio can be explained by the industry's orientation on the large domestic market and the considerable requirements for after-sales service. Furthermore, the fragmented industry resulting from specific customer demand is not in line with the Japanese industry's general aim for more standardisation. When the industrial trend moves towards more standardised machinery and equipment, Japan could become a more serious threat on the international market.

Production process

The food processing industry is developing towards fewer, larger production centres producing a greater variety of products. Concentration of production is developing very strongly in the Western industrialised countries and some Asian countries in particular. Consequently, production and process systems have to meet more stringent requirements for flexibility and efficiency. These requirements have stimulated the widespread application of CAD, CAM and flexible manufacturing techniques within the food industry.

To keep pace with special market demands and increasingly complicated production processes, food processors and the machinery and equipment suppliers are developing joint R&D programs. These joint forces speeds the development, testing and introduction of new production equipment. The growing attention to R&D programs also demonstrates the importance of the quality of the labour force. In the future, the focus will be increasingly on the quality of education and training of employees.

INDUSTRY STRUCTURE

Companies

Until the beginning of the 1990s, the process of concentration was characterised by horizontal integration. In 1991, however, the Swedish-owned milk and juice packaging group Tetra Pak took over Alfa-Laval, the Swedish manufacturer of industrial equipment, the second largest sector of which was food equipment. The food machinery manufacturing industry remains fragmented by different patterns of demand for food worldwide. The majority of enterprises are medium-sized and specialise in one or more subsectors of the food machinery industry. However, among these firms a trend towards more concentration and internationalisation can be observed. In Italy the focus is especially on Eastern European countries. Within every segment of the industry one or more relatively large companies is operative. Companies with over 500 employees are especially active in international markets.

The trend towards more concentration by the merger or co-operation of specialised medium-sized companies enables them to offer tailor-made machinery and equipment to meet specialised customer needs. After the Tetra Pak/Alfa-Laval take-over, a development towards vertical integration can also be expected among medium-sized firms. Vertical integration increases the convenience for customers who can purchase packaging and processing machinery at the same location. On the other hand, horizontally integrated firms will be better equipped to face the future challenges in the largely untapped markets of the LDCs and Eastern Europe.

ENVIRONMENT

The growing importance of ecological issues is especially reflected in measures against packaging waste. For the manufacture of food processing machinery, however, no specific consequences can be recognised. The more stringent EC-regulations on sanitary conditions during the processing of foods and drinks might enhance the technical requirements for the applied machinery. In general, however, the resulting effects on the food processing machinery industry are expected to be quite modest.

The increasing number of measures against smoking will continue to discourage the use of tobacco. A possible prohibition of promotional activities by the tobacco industry on EC-level will undoubtedly affect the number of smokers.

REGULATIONS

The European Technical Committee for machinery safety and health regulations (CEN TC/153) will introduce safety standards in 1993 which will also apply to the manufacture of food processing machinery. The central issue of the new regulations - self-certification by the industry itself - will give the final responsibility to the various industries to set their specific standards. CEN - the European Normalisation Institute - has the final task of providing detailed European standards. Control on the use of the new standards has been given to the national governments. The European industry would like to see the CEN standards adopted by the International Standards Organisation (ISO) to remain competitive in non-EC markets.

In addition, Directive 89/392 will implement additional safety and health standards for this industry, as well as all other machinery producing sectors.

OUTLOOK

The recession in some major markets continues to influence world demand for food processing machinery in a negative way and the maturing food market in the Western economies affects demand for food processing machinery. EC-manufacturers must increase their export efforts in response to these two factors. The markets in the former Eastern bloc are still uncertain. Because of its nature as a primary consumable, however, the food sector is likely to benefit more quickly than other sectors from the political and economical restructuring processes in these countries. Taking into account all these factors, EC production of food, drink and tobacco processing machinery should grow by 2.4% from 1992 to 1993 and by 4.4% in the 1992-1996 period.

Chemical machinery
NACE 324.12

In 1990, chemical machinery production in the EC stood at around 5 billion ECU. The industry provides an estimated 90 000 jobs in the EC and is a net exporter. The dependence of this sector on the processing industries, including, but not confined to, chemical processing, played an important role in a number of changes that took place. In the 1980s, the chemical plant equipment industry was confronted with several setbacks, including the fall in oil prices, the depreciation of the dollar, the recession at the beginning of the 1980s and more competitive export markets. The outlook for the industry is positive, however.

INDUSTRY PROFILE

Description of the sector

Data for the chemical process machinery making industry are classified under NACE code 324.12. The products of this industry can be divided up into the following categories:

- producer-gas or water-gas generators;
- centrifuges and dryers;
- filtration and purifying machinery for liquids and gases.

Included in the three categories are: pressure vessels, heat exchangers, process towers and reactors, dryers (rotary, belt and adsorption), piping, filtering engineering, mixers, structural steel engineering, valves and fittings, heavy walled tubulars, air conditioning and jacketpiles.

Several products are not specific to the chemical industry. Since classifications differ within the EC, it is difficult to estimate the importance of the industry in each country. For instance, the production of water purification equipment is usually classified under the heading of chemical plant equipment, but not always. Other equipment which may or may not be considered chemical machinery in national statistics are furnaces, heat exchangers and pressure vessels. Data should be considered with care.

Data were available only for Belgium, Germany, France, Italy, the Netherlands and the United Kingdom.

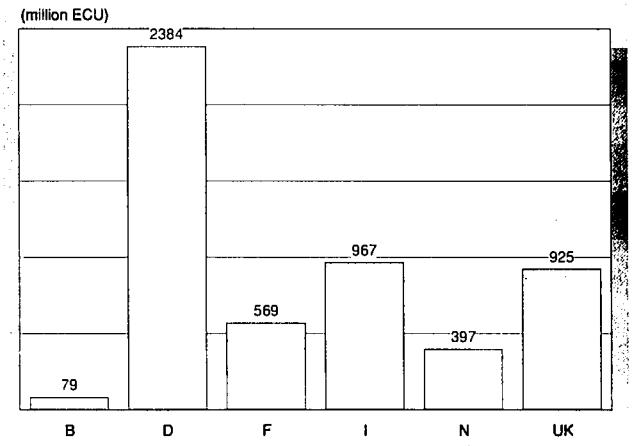
Main indicators

In 1990, production in most EC countries continued the growth which had characterised the second half of the 1980s with percentages varying between 1% and 9%. Capital spending in the chemical industry in the EC increasing by 8% in 1990, as well. Only German production slowed down in that year. 1991, however, proved to be a bad year for both the chemical industry and the chemical machinery industry. Investments in the chemical industry dropped below the 1990 level, partly as a consequence of the war in the Gulf.

Germany is the largest producer in the EC (of the countries for which data is available), accounting for 45% of EC production in 1990. France, Italy and the United Kingdom follow at a distance. However, due to the already mentioned differences in statistics, these figures give only an order of magnitude. It is presumed that the French figures underestimate the industry as several enterprises could be subsumed under the food processing machinery industry and under boilermaking.

The prediction made in mid-1991 by most chemical industry-experts of a recovery in the second half of 1991 and all of 1992 proved wrong. The stagnation in demand for most chemical products, combined with high input prices and low product prices, created a situation reminiscent of the early 1980s, when large restructuring of the chemical industry was necessary. However, the position of the chemical industry is not as bad as in those years, encouraging a relatively more optimistic view on the outlook of the chemical machinery industry.

Figure 1: Chemical machinery
Production by Member State, 1990



Source: National statistics; Italy: ANIMA

In general, spending for equipment and materials is estimated to be 50% of capital spending in the chemical industry. Using this criterion, demand for chemical and related machinery was an estimated 10.2 billion ECU in 1991.

Employment in the industry is estimated at around 90 000 people in the countries considered. This estimate is made on the assumption of a productivity of 60 000 ECU per employee in 1990 (roughly the figure in the Netherlands and Italy).

Recent trends

Following the recession after the second oil crisis in 1979, a large shake-up took place in the chemical machinery industry, resulting in a decrease in production capacity, which is currently still lower than 1980 levels. The declining activity in the chemical industry was transferred to upstream industries with a small time lag. The industry faced several setbacks:

- the decline in orders from the traditional industrial countries;

- the international debt crisis which forced several developing countries to stop or postpone investments;
- the subsequent fall in oil prices which put orders from OPEC countries under pressure;
- the fall of the US dollar which started in March of 1985, and, more generally, the volatility of the dollar exchange rate vis-a-vis the European currencies.

EC production at current prices grew by 35% between 1985 and 1990, and in constant prices by 10%. The fall in production in 1990 in Germany was an exception. For 1991 and 1992, a slowing down of this growth is estimated, due to the declining investments in the chemical industry and the economic slowdown in general.

In Italy, production in value increased with 16% per year between 1983 and 1990. In the same period, production in Germany, Belgium, the Netherlands and France grew 7% to 8% per year. Only production in the United Kingdom showed a slower growth of 4.5% per year. In volume, however, production in Belgium and the United Kingdom was lower in 1990 than in 1985.

International comparison

Production in the EC is several times that of Japan (no figures are available for the USA due to differences in industry classification). This is not surprising giving the weight of the European chemical and more general processing industries.

Capital investment in the chemical industry of Western Europe is by far the largest in the world, compared with the USA and Japan. Investment in Japan, however, grew faster than in Europe during the 1980s.

Foreign trade

Extra-EC exports fluctuate around 1.04 and 1.4 billion ECU per year. Although this figure is still several times higher than imports, the ratio of exports to imports declined from 3.5 in 1982 to 1.8 in 1991. During the 1980s, intra-EC trade became increasingly important, reflecting the degree of internationality of the market.

In 1991, all Member States except Greece had a positive extra-EC trade balance, but several countries had negative intra-EC balances, including the United Kingdom, one of the larger producers. France, Germany, Italy, Denmark and Portugal have positive balances.

The main export markets for the EC are the EFTA countries, accounting for some 22.4% of extra-EC exports. The importance of the OPEC is related with the European construction activities in those countries. Destinations of EC exports did not change much from 1986 to 1991.

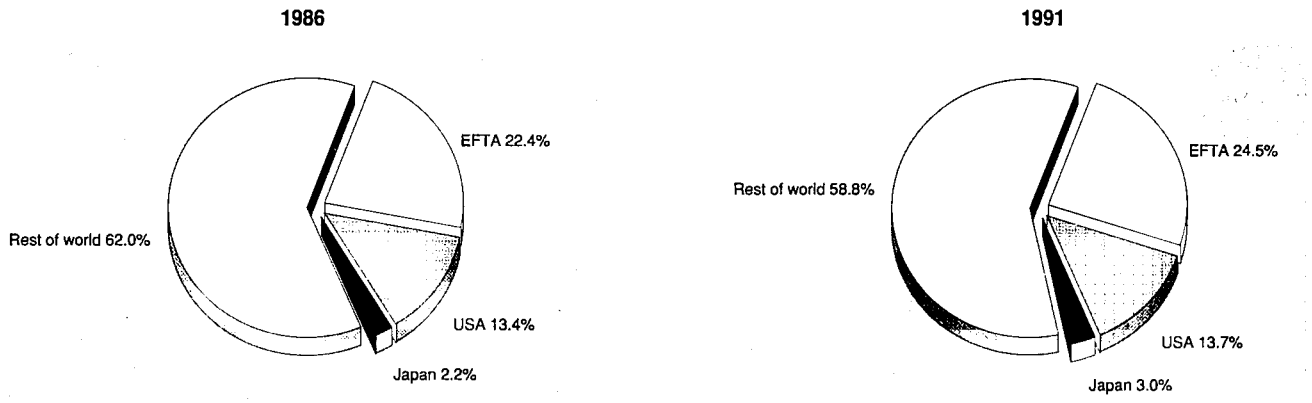
For imports, the USA plays the primary role. All three major suppliers (EFTA, USA, Japan), however, have lost supply share to smaller suppliers.

MARKET FORCES

Demand

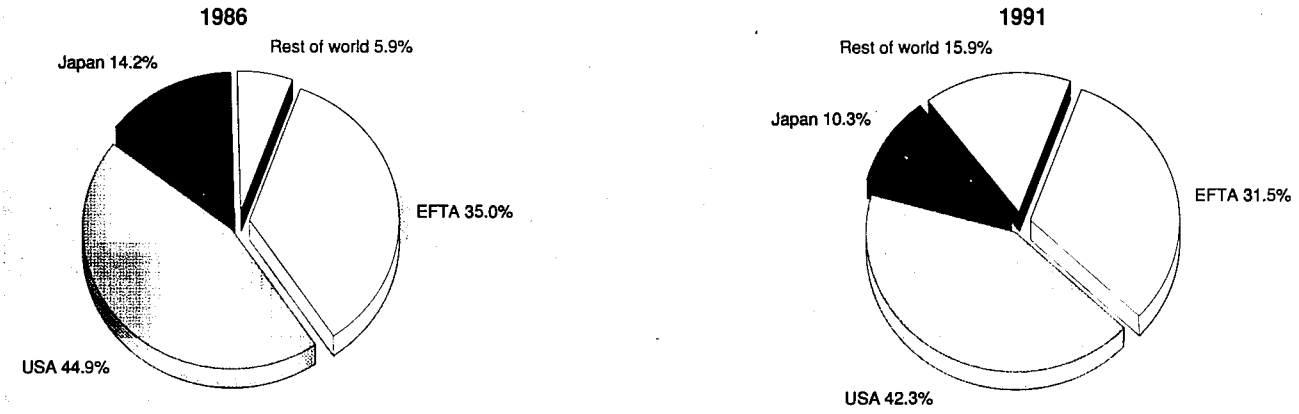
Besides the chemical industry, the chemical plant equipment industry has a number of clients, all of which are processing

Figure 3: Chemical machinery
Destination of EC exports



Source: Eurostat

Figure 4: Chemical machinery
Origin of EC imports



Source: Eurostat

industries. Among the outlets are: the chemical industry, the petrochemical industry, the pharmaceutical industry, the biochemical industry, the food processing industry, water purification utilities, oil and gas exploration and production companies, refineries, power generation, environmental applications, engineering contracting companies and government institutions.

The most important client industries for the chemical machinery manufacturers follow cyclical business patterns: they are vulnerable to swings of the business cycle. The development of capital spending in the chemical industries is of major importance for the processing machinery manufacturers.

During the upswing of the second half the 1980s, much of the spending in the chemical industry was directed towards de-bottlenecking, energy-efficiency, and environmental and safety measures, but real expansion investment was not common. The industry did manage to maintain high growth rates for a time.

Demand for chemicals began to decline in the middle of 1989, putting the chemical industry under pressure. With decreased capacity use, increased input prices, and output growing at barely the rate of inflation, the chemical industry does not have the resources to spend on capacity increases.

Factors which had a negative effect on the industry in 1991 included the war in the Gulf, the economic recession in some important export markets, the depreciation of the US dollar and Japanese yen. Only the increased demand from the former East Germany had an ameliorating effect, which was not strong enough to counter all the negative factors.

For the near future some of these factors, although not all, will continue to exist. The recent highs in capital spending as a percentage of turnover indicates that project commitments made during the economically strong years of 1987 to 1989 are still under way.

Chemical companies are taking a cautious approach to investment in Eastern Europe for the short term, at least until the direction of future economic and political developments is more clear.

Supply and competition

Chemical machinery manufacturers operate on the world market. Even small companies can have sales activities in the USA, India, Australia and Japan, as well as in European countries. One of the reasons behind this is the degree of international operation on the chemical and related markets, as well as the existence of large petrochemical multinationals. Since most of the machinery is designed for single-piece work, chemical machinery manufacturers from all over the world can bid for the specialised product needs of a multinational client. The competitiveness generated by this practice keeps prices low, and slow to respond to a booming market. On the other hand, in a recessive market, prices will tumble quickly.

One problem for EC exports remains the low dollar exchange rate, which affects not only exports to the USA. In a more indirect way, a depreciating dollar also affects competition in the EC market from competitors from abroad. In the past years, several orders have been lost due to high-valued EC currencies and the volatility of the US dollar.

The price of oil is an important factor for the market for chemical machinery, especially for the production of heat exchangers. The relatively low oil prices since the end of 1985 have had a significant impact on production.

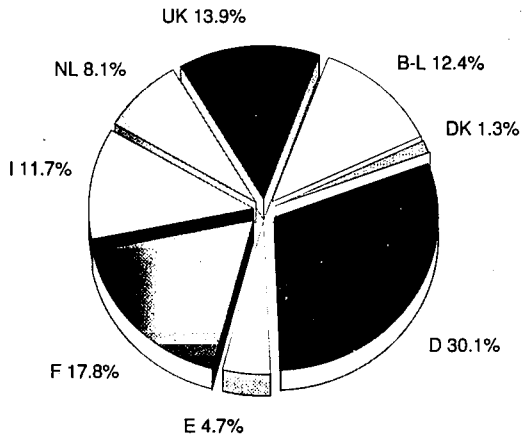
Capital investment by the chemical industry, 1990



Source: CEFIC

Chemical machinery manufacturers can deliver their products directly to the end-user, or indirectly through an engineering services firm, for which they act as a subcontractor. In recent years there has been a trend towards outsourcing of several engineering services by the chemical industry, which has led to a more important role for engineering firms as an outlet for the chemical machinery industry.

Production process

Quality control has been a major concern of the industry over the past years. Several companies already comply with ISO 9000/9001/9002 quality standards, and others are working to reach these standards. Most of the companies comply already with some national standards, which is necessary to serve different customers in a competitive market.

From the technological viewpoint, interesting developments are: size-reduction technology; energy-savings; new materials; new fibre finishes; computer aided manufacturing and engineering; and environmental engineering.

One of the topics that will influence the investments of the chemical industry in both the near and distant futures is pollution control. The Chemical Industries Association of the UK found through a survey that in 1989 spending on environmental protection represented 11% of total capital spending, and was expected to double between 1990 and 1992.

Growing activity in the field of biotechnical research will lead to growing demand for laboratory and production equipment, which will become an increasingly important part of the industry.

The increasing complexity of the machines as well as the higher quality standards with which they must comply, make it necessary to have more and better skilled labour. It is in this area that shortages are common. In-house training is a possible solution.

INDUSTRY STRUCTURE

Companies

There are two types of firms in the chemical machinery industry: product specialists and jobbers or activity specialists.

Product specialists are firms which design and develop equipment by themselves and can successfully export specific products due to low unit costs. The enterprises are normally medium sized enterprises, and usually more than half of production is exported. They will usually have technical knowledge of the process in which the machinery will be involved after production.

Jobbers, or activity specialists are firms which manufacture items from the client's blueprint and which are the most common type of firm. They are less export oriented than the product specialists; exports account normally for less than 50% of production. They have mostly a very small knowledge of the processes in which the machinery will be involved.

In this industry there are no large multinational enterprises, although most of the companies engage in exports.

Strategies

The strong dependency on the chemical industry makes the chemical machinery industry vulnerable not only to cyclical swings, but also vulnerable in more structural way. One-sidedness can lead to a product-oriented attitude which can be detrimental in a market in which competition is growing.

Knowledge of the chemical processes can be profitable for an enterprise, because it gives the company the ability to discuss with the customer not only the apparatus, but also the whole process in which it is a part. This is important because optimisation of the process cannot be achieved through optimisation of the individual units. An overall plan must be made.

Companies are diversifying in several ways. One of these is to engage in other markets than the chemical industry. Given the process oriented products, logical markets are the food, pharmaceutical, power and environmental industries. Other companies are applying knowledge of the chemical industry to develop new products for that industry. These companies tend to become niche players. While there are not too many real niches in the world, those companies which find one are much less affected by cyclical downswings.

ENVIRONMENT

It is estimated that in 1991 a world total of 4.4 billion ECU was spent for the prevention, containment, treatment and disposal of air, liquid and solid wastes in the petrochemical industry. A major focus of environmental control in the chemical industry will be waste minimisation.

Environmental concern has and will have a large impact on the chemical machinery industry. The market for environmental products for cleaning industrial waste water, for example, is increasingly important, opening new opportunities to the chemical machinery industry. In countries where environmental regulation is already very strict, such as Germany and the Netherlands, enterprises are likely to have a competitive edge in this area.

There is, however, a caveat: introduction of differing environmental regulations can distort the market. Competitive positions can be altered by the strictness of regulations in different countries. Imports from countries with a less stringent policy than the EC could become serious threats.

REGULATIONS

As in other sectors of mechanical engineering, the EC directive on machine safety is of primary importance. Provisions concern the design, the materials used, the application of screens and other safeguarding components, maintenance and machine indications and identifications. The directive is effective as of January 1, 1993. Until January 1, 1995 however, manufacturers have the option of complying either with the old standards used in the Member State where the products are sold or with the new EC standards. Those complying with the EC standards will have the advantage of being labelled with the 'CE mark', which provides free access to the markets of the EC countries.

The EC directive on compressed gases vessels (87/404/EEC) is also important for this sector. The directive concerns simple compressed gases vessels, especially for oxygen and nitrogen. Pressure vessels have to fulfil several requirements regarding safety; after positive testing the manufacturer receives a certificate and can add the CE mark to his product. The directive does not apply to pressure vessels for nuclear installations, pressure vessels for the propulsion of ships and aeroplanes or fire extinguishers.

OUTLOOK

Project activity in the petrochemical industry is expected to grow slowly in the near future, with important stimuli from the environmental and health and safety regulations. Prospects for the chemical industry indicate low growth rates in the short term. However, in the medium term, growth rates could increase. Combined with the competition on the international market, moderate growth rates of about 5% are expected for the mid-1990s. In the medium term production and consumption growth could increase. New opportunities stemming from environmental and safety concerns will stimulate demand.

It is expected that the trends of diversification and better and more quality control will continue, which will lead to a greater demand for higher and different skilled labour force.

Opportunities exist in environmental engineering; future strategies should include more knowledge of chemical processes and a more market/customer-oriented attitude.

Demand from Eastern European countries is not expected to increase significantly in the near future due to the relative unimportance of the chemical industry in those countries at this time. The need for restructuring, as well as the environmental need for upgrading plants, will lead to more demand for equipment. In the short term demand will be restricted by the slow recovery and the shortages of foreign exchange.

Bottling, packaging, wrapping and related machinery

NACE 324.2

The demand boom in former East Germany stimulated German production in 1991. In the export markets, however, German manufacturers lost market share to Italian firms, which have concentrated on improvements in engineering quality. This high quality has been the key factor for the dominant position of the EC on the world market. At the same time, this element could pose a major threat of the EC industry, as the growing need for high quality and more versatile products requires more R&D expenditure and a large and highly qualified labour force. If those requirements can not be met, EC competitiveness will weaken.

INDUSTRY PROFILE

Description of the sector

The purposes of the machinery belonging to this NACE vary widely in use. They include: form, fill and seal machines; combined filling and closing machines; group packaging and filling; accessories, parts and spares.

Approximately 59% of production is accounted for by these four groups. The other 41% is accounted for by "other machinery." These products are used in a few main downstream industries. According to a LEK study, there are 1100 producers in the EC.

Main indicators

In 1990, EC production totalled around 5 billion ECU. The two major manufacturing countries, Germany and Italy, accounted for 70% of EC production. Both countries export about 70% of their production. Among EC countries, Spain, France and the United Kingdom recorded trade deficits in 1990. The breakdown of production stresses the importance of form, fill and seal machinery and the combined filling and closing machinery. Both types of machinery are used mainly in the food, beverage and tobacco processing industries.

Recent trends

German manufacturers of packaging machinery recorded stronger growth than Italian manufacturers until 1990. The rise of production in both countries was partly due to flourishing exports. German unification could continue to cushion the declining capacity utilisation of the industry. The boom in domestic demand caused by unification, however, seems to have come to an end. The expected economic recovery of countries like France, the United Kingdom and the USA is expected to become the major stimulus for EC production.

International comparison

The EC accounted for 46% of 1991 world production, while Japan and the USA each constituted around 20%. Consumption in the latter two countries was also lower than EC consumption. In contrast with the USA and Japan, the EC was a net exporter of packaging machinery in 1991.

In contrast with other mechanical engineering industries, however, the Japanese packaging machinery industry mainly supplied the domestic market. Japanese exports have been comparatively low, indicated by an export share of only 7% in 1990.

Foreign trade

Germany and Italy dominate both extra-EC and intra-EC trade. Only a small proportion of EC imports come from the USA and Japan. The share of these countries together on the EC market is estimated at 10%. The USA, on the other hand, is a major market for European machinery. In 1991, Italy led Germany as the foremost US supplier. Both countries together accounted for more than 50% of the US import market. Wrapping machines for candy, tobacco products and sundries were the most important EC products.

The lack of competitive Japanese exports also enhances the market opportunities of EC manufacturers in East Asian countries. Market demand for European packaging machinery in countries such as China and Singapore recorded high increases in 1991.

MARKET FORCES

Demand

The food, beverage and tobacco industry account for an estimated 60% to 70% of total demand for packaging machinery, followed by the pharmaceutical, chemicals and related industries. These downstream industries each have their own specific markets. The fact that these industries meet primary consumer needs causes demand for packaging machinery to be cyclical to a lesser extent than demand for other machinery and equipment.

Within these downstream industries, demand for more efficient, reliable, flexible and versatile machinery is rising due to the quick change-overs needed for packaging for different products, various package sizes and variable quantity production runs. The further diversification of consumer demand will shorten product life cycles.

Supply and competition

In recent years, many Italian manufacturers have invested heavily in research and development, and production equipment in order to enhance the engineering quality of their products. Flexibility, production speeds and fast change-over times are the primary market requirements.

The minor Japanese share on the world market and low export ratio can be explained by the structure of the industry; the comparatively small business scales and the custom-tailored

products which require extensive after-delivery service. For this reason, Japanese firms have been focusing on the large domestic market. Should the industry move towards more standardised machinery and equipment, Japanese companies will be able to develop advantages similar to those they have in the automotive and other industries. For the coming years, however, when much attention will still be focused on engineering and tailor-made solutions, Japan's industry is not much of a threat.

In contrast with other US machinery industries, the packaging machinery industry benefited from the lower dollar exchange rate. US exports increased by 4% in 1991, but the export share remains relatively low (24%), if compared to Italy and Germany. US packaging machinery is noted for its strong construction and sophisticated electronics.

The high degree of concentration in downstream industries such as the food industry might result in price cuts and lower margins in the long run. The packaging machinery industry itself, however, is responding with a similar trend towards more concentration and increased internationalisation.

Production process

As with other mechanical engineering industries (especially where custom-tailored products are being produced) the labour force is an important factor in ensuring engineering quality. As a consequence, the quality of the labour force and thus the quality of the training programs are major influences in the success of EC industry in the long run. The quantity and quality of education and training must be maintained; otherwise the technological advantage of the industry could fall behind. Furthermore, when demand for well-trained employees exceeds the supply of labour, productivity losses are likely to occur.

Keeping the quality of the labour force high, however, should not lead to excessive wage increases. Sharp rises in input prices of materials and labour wages, as happened during the end of the 1980s and the beginning of the 1990s, would have a negative impact on the industry's profitability and cause reduction in investments which would weaken EC competitiveness.

Beside the quality of the labour force, the extent to which a manufacturer of packaging machinery is able to meet customer requirements is also determined by the quality and precision of the production equipment. The increasing demand for versatile machinery, for instance, requires advanced production equipment together with high labour skills and large investments in R&D.

INDUSTRY STRUCTURE

Companies

In general, the enterprises which deal exclusively with the manufacturing of packaging machinery are medium-sized and focus on one market niche, e.g. mostly one machine function for a specific industry. The German firm Uhlmann, for instance, deals only with blister machinery and equipment. Larger firms (such as the German enterprises Bosch and Krones, which offer a whole range of products for several downstream industries) are rare.

Vertical integration might become more common in the near future. The purchase of the Swedish Alfa-Laval (manufacturer of food and other industrial equipment) by Swedish Tetra Pak (milk and juice packaging group) the ability to purchase packaging and processing machinery through one supplier.

In general, the enterprises not only react to increased business due to the Single Market, German unification or from the political changes in the former Eastern bloc countries, but also to developments in specific markets which force them to review company strategies. The general trend towards more concentration by specialised companies merging or cooperating can also be explained by such developments. Cooperation enables them to offer tailor-made machinery and equipment to meet customer needs. A further explanation for the concentration of activities is the threat of increasing market power of some large multinationals which dominate the downstream markets. This might lead to lower margins for the manufacturers of packaging machinery.

On the other hand, the same multinationals, by their expansions in the former Eastern bloc countries, also offer market opportunities for the EC packaging machinery manufacturers. This trend of medium-sized companies penetrating more and more into these countries can also be observed within the Single Market. Further internationalisation will also increase the strength of current market positions and will enhance opportunities to benefit from the European unification.

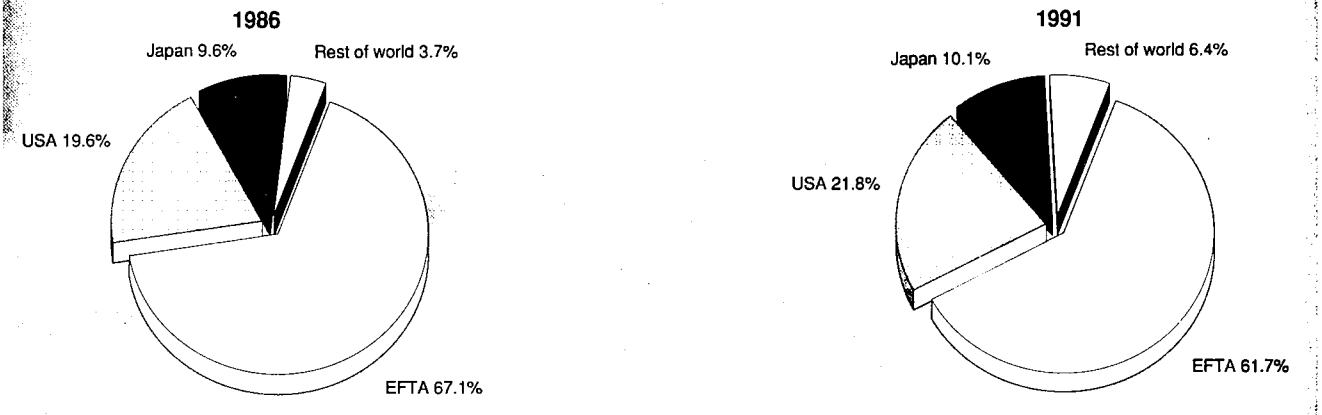
To remain competitive, European manufacturers should invest in new, more efficient and precise production equipment in order to enhance the engineering quality and to reduce costs. Italian firms' efforts to upgrade in particular are an example of successful investment. The increasing demand for more versatile machinery, however, will also require new investments by machinery manufacturers.

ENVIRONMENT

The growing consciousness among consumers regarding environmental issues, for example, has already been translated into more nature-friendly packaging and cost reductions have been a major stimulus for downsizing of packaging. Material usage and packaging sizes can still be best controlled by domestic government or EC legislation. However, especially in the northern EC countries, the increasing influence of the downstream industries and retail networks on packaging decisions is also becoming a determinant factor within the industrial chain. For instance, mutual agreements between the Dutch government, the food industry and retailers in the Netherlands led to voluntary decisions to retain recyclable glass bottles and move out of PVC packaging. When environmental measures are in line with commercial and financial objectives, more support and initiative can be expected from retailers.

For the near future, demand for form, fill and seal machinery is expected to grow, due to rising demand for snacks and

Figure 2: Bottling, packaging, wrapping, and related machinery
Origin of EC imports



Source: Eurostat

food in thermoform-packages. Further, growth is expected for combined filling and closing machinery and for group packaging.

REGULATIONS

Until now, environmental law and regulations have been limited to national levels. Germany and the Netherlands are in the lead in terms of actual measures, although other EC countries, especially those in the north, have also made progress with governmental legislation. In the Netherlands, mutual agreements are used. The German Packaging Ordinance, on the other hand, could constitute a barrier to free trade within the EC. In order to protect the Single Market principle, the European Commission has been urged to develop an EC directive in order to prevent the occurrence of differing national regulations.

In the beginning of 1992, a fourth draft of the EC Packaging Waste Directive was published. The stated objectives of the directive are:

- to reduce the amount of packaging waste produced;
- to require the recovery of packaging waste;
- and to minimise the amount of packaging waste which goes into final disposal.

Practical implementation, however, could take until the mid-1990s. The packaging industry will be confronted in the near future with discouragement policies which will affect growth of demand for packaging materials. Limitations on raw material usage, decreased weight of packages and more recycling do not necessarily imply a threat to the manufacturers of packaging machinery. Products need to be packaged, but the packaging material itself may change. Only if current level of packaging is forbidden might the industry be affected. Also, substitution of certain raw materials by less polluting materials, might have consequences for the applied machinery. Some currently applied machinery is able to process different types of material and/or reduce the quantity of materials used.

Enforcement of the development and production of new packaging materials could implement a stimulus for the manufacturers of packaging machinery. Demand for new and innovated machinery would rise and the extra expenses caused by the high development costs would probably be passed on to the end users.

The CENTEC 146 EC safety standards also apply to the packaging machinery. In each Member State, the packaging machinery manufacturers are cooperating with their national standardisation organisation to develop European standards. In addition, Directive 89/392 will implement additional safety and health standards for this industry, as well as all other machinery producing sectors.

OUTLOOK

The upswing of German demand caused by unification seems to have come to an end. In 1992 a general stabilisation is expected of the EC production of packaging machinery. For the years after 1992, the expected recoveries of the major countries' economies will stimulate overall demand, which will cause production to reach the 1980s growth rates. Companies entering the former Eastern bloc countries might further increase demand for packaging machinery.

A shift in demand to more versatile machinery will stimulate and require further technological development on the supply-side. The EC industry already has strong foothold on the world market. However, in order to retain its competitiveness, much effort and means have to be put into R&D.

The new EC Packaging Waste Directive will not necessarily harm the manufacturers of packaging machinery. While measures focus on recycling, less packaging quantities, and less waste of raw materials, the greater part of packaging is not excessive, and the machinery in use is often able to process different materials and packaging sizes.

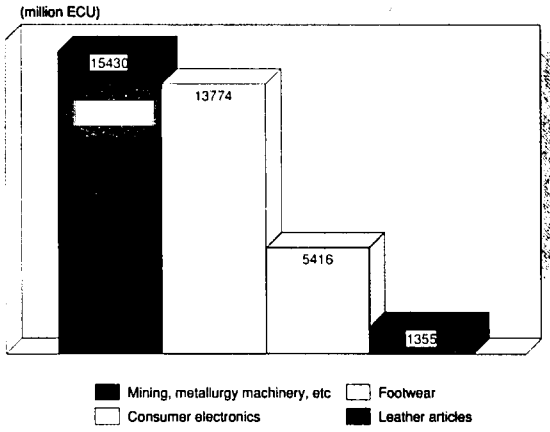
The industry is represented at the EC level by: Confederation of Packaging Machinery Association (COPAMA). Address: c/o VDMA, P.O.Box 710864, D-6000 Frankfurt/Main; tel: (49 69) 66 03 429; fax: (49 69) 66 03 211.

Machinery for mining, metallurgy, construction, lifting and handling

NACE 325

The industry of machinery for mining, metallurgy, construction, lifting and handling is very much dependent on the investment decisions of its client industries. The cyclical pattern of investment over time thus results in highly variable growth rates for the industry. While the EC industry covers around 90% of EC demand, this proportion has been falling as a result of strengthening imports. The EC is still the world leader in production, however, and remains a net exporter.
M&A activity has been strong over the past few years. Most companies in the industry tend to specialise in certain kinds of machinery, resulting in a high dependency on specific markets. Recognition of this dependency, as well as the expected increase in competition due to the Single European Market, underlie moves towards increased concentration.

Figure 1: Machinery for mining, metallurgy, construction, lifting and handling
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

NACE 325 includes a heterogeneous set of activities in machine manufacturing. It includes the manufacture of:

- mining machinery (NACE 325.1);
- plant for iron and steel and metallurgical industries and for foundries (NACE 325.2);
- brick making and other machinery for the preparation of building materials (NACE 325.3);
- construction and civil engineering equipment (NACE 325.4);
- mechanical lifting and handling equipment (NACE 325.5).

Manufacturers in this industry produce a broad variety of products. Examples are: bulldozers, construction cranes, shovel tractors, winders, conveyors, lorries for surface mining, hydraulic equipment, excavators, underground diesel locomotives, concrete handling machines, ground levelling machines, asphalt paving machines, and foundation work machines.

Products from the manufacture of mechanical lifting and handling equipment are generally referred to as "industrial trucks". These are defined as any wheeled vehicles, not running on rails, which are designed to carry, tow, push, or lift any kind of load. Examples are: elevators, escalators, ropeways and cablecars, cranes, pneumatic handling equipment, hoists (electric and pneumatic), elevating work platforms, storage and retrieval machines, etc. The production value of this industry has been estimated by FEM at around 16 billion ECU for 1989 in the EC and EFTA Member States.

Main indicators

Growth rates declined significantly in 1990, and even more severely in 1991, as a result of the Gulf war. In France, demand volume fell by 7% in 1991 and production volume decreased by 5.8%. In the United Kingdom a similar fall in demand occurred, and production volume was reduced by 16.8%. Exceptions to the general decrease included Germany, where the process of German reunification caused a higher demand for new machinery, and Portugal, where infrastructure investments and new construction projects led to the ordering of new equipment.

Recent trends

During the beginning of the 1980s, the sector encountered serious difficulties due to declining markets both within and outside the EC. Employment was reduced considerably. After a temporary improvement in 1985, problems continued in 1986 and 1987 despite a growing EC market. In 1988 and 1989, growth rates in production considerably improved as a result of a further increase in growth of EC demand. However, demand growth has been covered to a great extent by imports from outside the EC.

Production of industrial trucks declined at the beginning of the 1980s and recovered in the cyclical upswing after 1982-83. In 1981, total production amounted to 1 426 million ECU; in 1989 production equalled 2 650 million ECU (in current values). In volume terms, production decreased 12% annually from 1980 to 1983. After 1983, annual volume growth amounted to 7.3% until 1989. At the beginning of the 1990s, industrial truck production encountered a reduction similar to that in the entire industry.

International comparison

About 30% of Japanese production and 10% of EC and USA production is sold outside domestic markets. The EC is the largest manufacturer with a share of almost 50% of the Triad's total production.

EC production was experienced a negative growth rate of 2% in 1991. US production also declined, by 1%. Given the relatively high domestic market orientation of the sector, it is expected that production in Japan continued to grow, as the Japanese economy had only minor setbacks in growth rates, and as its exports to the EC increased.

Foreign trade

Extra-EC imports increased during the eighties from around 2 billion ECU in 1982 to about 4.7 billion ECU in 1991. The largest suppliers to the EC were the USA, Japan, Sweden, Austria and Switzerland. Extra-EC exports on the other hand fluctuated from some 7.5 billion ECU to about 8.9 billion ECU between 1982 and 1989. At the beginning of the nineties, exports increased considerably to approximately 9.7 billion ECU in 1990 and 9.5 billion ECU in 1991. Important destinations for exports were the USA, Switzerland, Austria, the former USSR and Sweden.

As a consequence of the stronger growth in imports, the export to import ratio declined over the years, from 4.4 in 1982 to 2.0 in 1991. The terms of trade improved only in the late eighties. The share of extra-EC imports in EC consumption increased from an average of 10% in the first half of the eighties to an average of 12% in the second half and the early 1990s.

MARKET FORCES

Demand

The industry basically produces capital goods. Demand for these products is highly dependent on the investment decisions in industries using this type of machinery, and thus on the development in the activities of these industries. An important aspect is the initiation of large civil engineering and construction projects.

Figure 4: Machinery for mining, metallurgy, construction, lifting and handling

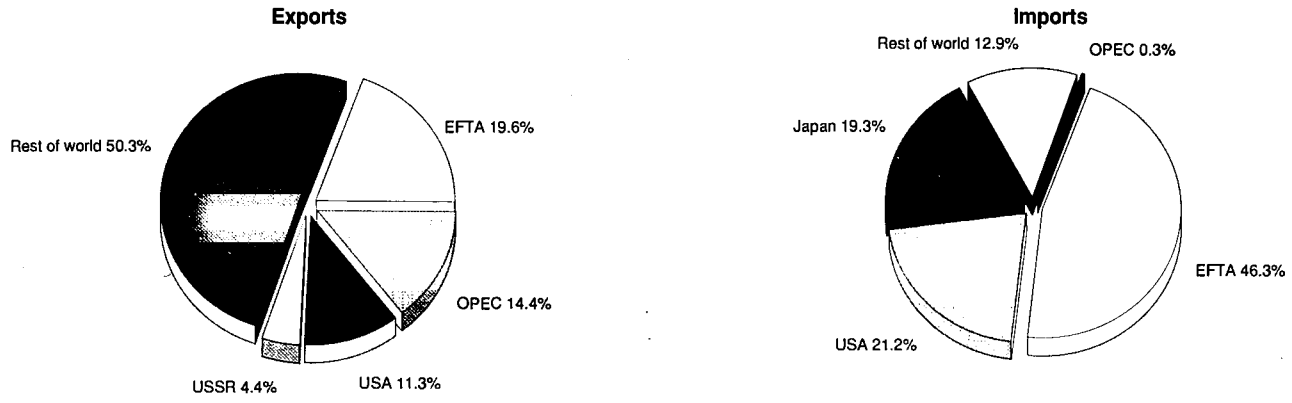
Figure 6: Machinery for mining, metallurgy, construction, lifting and handling
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

The cyclical variations in project initiations are reflected in the large volatility in annual growth rates for apparent consumption of the sector. Growth rates generally fluctuate between -25% and 50% in nominal terms.

Civil engineering projects are primarily public works investments and thus depend on public sector decision-making and budgets. Examples can be found in the building of new roads, railroads (e.g. high speed train networks like TGV in France, and underground systems), tunnels, bridges, airports (e.g. the new Munich airport), etc. Sometimes civil engineering projects are private sector operations, such as the Eurotunnel linking the United Kingdom and France and the extension of Schiphol Amsterdam Airport in the Netherlands.

Projects in construction are mostly undertaken by the private sector and vary according to developments in the national economy. Projects are often postponed during recessionary periods, while in boom cycles, numerous projects are begun. Examples can be found in the market for building office space and housing.

Different factors affect machinery for mining (including oil exploration and exploitation) and metallurgy. If demand for coal and steel is diminishing, mining, foundries and metallurgy companies prefer to hold off on investments in new machinery. Existing machinery may be upgraded, requiring only modest investments.

Demand for industrial trucks depends particularly on companies in the transport and warehousing sectors. In general, demand in the EC has reached a saturation level, implying that sales have become increasingly dependent on replacement investments, and on the application of trucks in new fields. Demand for all-purpose counterbalanced trucks has been losing ground to the more specialist trucks.

Supply and competition

The EC manufacturers are the most important suppliers of the EC market, covering 90% of EC consumption. In recent years however, competition from foreign suppliers, especially Japan, has become very strong. Non-EC manufacturers are gradually taking a larger share of the market.

In extra-EC exports, European manufacturers clearly lost market share. Whereas in the beginning of the 1908s EC companies exported about a third of total production to non-EC countries, in the latter half of the 1980s this share was reduced to only one fifth (22% in 1991).

Despite the high volatility in demand, profit rates have remained fairly stable and even improved at the end of the 1980s. In many industries, a declining market results in lower prices in order to fill existing capacities. However, lower prices have not affected profit margins considerably, implying that price competition is fairly limited. An explanation can be found in factors such as quality and technological level of products. Customers are prepared to pay more for high quality products, when efficiency improvements by these products result in a better return.

Production process

The production of machinery classified as heavy duty equipment requires high quality iron and steel inputs.

CAD/CAM systems are used to design and manufacture machines. Computerisation and the application of advanced electronics have also become a basic feature of new machinery, not only to improve the efficiency of the machine itself, but also for safety, pollution control, precision in operations and the like. Hence, innovation has become a top priority in maintaining competitive advantage.

The industry requires highly trained employees with a knowledge of modern technologies in machinery and equipment. Some companies have education facilities for their employees to keep them up to date with these technologies.

Productivity consistently increased throughout the 1980s by about 1.9% annually. Unit labour costs have grown with 5.1% on average over the years. After accounting for inflation, real unit wage cost increases are comparable to productivity increases.

Industrial trucks have increasingly become customised, rather than standard, products. The production process is designed in a modular fashion, using standardised parts and components. By combining different modules customisation becomes possible. This however, requires increased production flexibility, which is made possible by the application of modern technologies in the production process.

Technological development is also proceeding in the industrial truck itself. As a result of factory automation and automated warehousing, trucks have to be equipped with electronic devices for advanced handling systems. An example of a modern industrial truck is the automated straddle carrier able to locate and move containers without human interference.

INDUSTRY STRUCTURE

Companies

Companies in the industry tend to specialise in certain types of machinery. During 1991 and 1992, various companies ran into severe difficulties due to declining market growth. The French manufacturer of public works machinery Tenneco-Case-Poclain (a subsidiary of Tenneco USA) encountered a drop in sales of 21% in 1991. For 1992, a further reduction by 18% is expected.

The industrial truck market is dominated by multinationals. European suppliers like Linde/Still (D), Lansing (UK), Jungheinrich (D), Lancer-Boss (UK), and Manitou (F) compete with leading suppliers from Japan, such as. Toyota and Komatsu, and from the USA, such as Hyster and Clark. An important non-EC supplier from Scandinavia is Valmet, which has 60% of the world market in straddle carriers.

Strategies

In order to prepare for increased competition on the EC market after 1992, companies are increasing their involvement in mergers, acquisitions and strategic alliances with other companies. This process has also involved non-EC companies, driven by fears of the establishment of a strong EC Internal Market.

Japanese manufacturers have responded by building production facilities in European countries. Nissan set up a product line for industrial trucks in Spain in 1989, Toyota, Komatsu and Mitsubishi have concluded cooperative agreements with EC sited companies, JCB (UK) linked with Sumitomo; Fiat (I), Hitachi (J) and John Deere (USA) considered a joint venture. In addition, Krupp of Germany concluded an agreement with Komatsu for selling Krupp's mobile cranes in Japan. US manufacturers also have expanded top Europe: Clark and Caterpillar relocated factories to Europe during 1986.

Another reason for concentration is that companies want to centralise around the core activities in which they have acquired strong positions. By merging or entering into strategic alliances with larger entities, the risk of the dependency on specific markets is minimised by entering into larger entities.

REGIONAL DISTRIBUTION

German manufacturers dominate the EC supply of machinery in this NACE. In terms of value added, they accounted for 47% of the EC total in 1991. Second in rank were the UK manufacturers with 14.3%. Italy ranked third with 13.6%, with France in fourth position at 12.3%.

ENVIRONMENT

Energy efficient and less polluting machinery and equipment are increasingly being demanded by the customers of this industry. The customers themselves want their production processes to be as clean as possible, not only as a result of consumer demands, but also to stay ahead of increasingly restrictive government measures. R&D therefore focuses on these environmental issues.

For industrial trucks for outdoor use, fuel-powered equipment is most common, and restrictions on pollution from exhaust fumes have become more important. Industries are trying to improve on energy efficiency and exhaust pollutants. For battery-powered trucks, mainly for indoor use, battery obsolescence is given more and more attention. Noise reduction is also important.

REGULATIONS

The EC directive on machine safety is of particular relevance for the industries in this NACE, as it is for the other mechanical engineering industries. This Directive, already accepted in 1989, envisages the application of safety standards for EC-produced machinery by January 1, 1993. Until January 1, 1995, however, manufacturers have the possibility to comply with either the old standards used in the EC country where products are sold or with the Directive standards. The latter has the advantage of the products being labelled with the CE-mark, which gives it free access to the markets of all EC countries.

In 1991 the coverage of the Directive was extended to apply to cranes and other lifting installations and to mobile machines as well. This extension is especially relevant for machinery in the construction industry and industrial trucks in mining and warehousing.

Another important issue is the harmonisation of technical norms and standards throughout the EC. Two normalisation institutes, CEN and CENELEC, are currently working on proposals for European standards, covering, among others, quality standards as specified in ISO-9000. There is also a preference to develop standards which meet those on a world level.

Regulations influencing the customers of industries in this NACE could affect the sector in an indirect way. For example

Table 5: Machinery for mining, metallurgy, construction, lifting and handling
Manufacturers in the EC

Manufacturer	Main products
Barber-Greene (UK, USA)	Asphalt plants and finishers, belt conveyors, concrete mobiles
Trex (UK, USA)	Crawler dozers, motor scrapers, dump trucks, wheel loaders

Observator (NL)	Dredging instruments
JCB (UK)	Construction cranes

Source: NEI

the opening up of the Internal Market for public procurement by 1993 will influence activities in infrastructure construction and public works projects. Companies active in this field will need modern quality machinery in order to challenge the increased competition.

OUTLOOK

For 1992 and 1993 the perspectives are rather pessimistic, as order books do not yet reveal a revival. Further, the positive impact of German reunification on demand is diminishing rapidly. New orders are only expected to pick up again by mid-1993, when the business cycle is likely to enter the recovery phase. Growth rates may then gain momentum again.

Growth will, however, depend very much on the type of activity for which machinery is produced. In machinery for construction and brick making for example, volume growth is expected to be moderate due to a low level of project initiations for office buildings and dwellings. Currently, most machinery sold is for replacement of old machinery. In mining machinery, growth will depend on developments in energy consumption and metallurgy. In particular energy saving initiatives may cause the demand for mining machinery to be low. Demand for industrial trucks, on the other hand, may be growing stronger as the Internal Market will increase the need for transportation, distribution and warehousing facilities.

Transmission equipment
NACE 326.1, 326.2

Similar to the other industries in mechanical engineering, companies belonging to this NACE recorded drops in production, consumption and exports. The EC industry, however, is expected to recover from weak demand in major countries. In order to fully benefit from the economic recovery in the long run, and to remain competitive on the world market, EC manufacturers should internationalise and should continue to assure the quality of their labour force, which is a very important asset in international competition.

INDUSTRY PROFILE

Description of the sector

This chapter includes the manufacture of transmission equipment for motive power (NACE 326.1) and the manufacture of ball, roller and similar bearings (NACE 326.2). The manufacture of transmission equipment includes the manufacture of gears, gear assemblies (gear-boxes, variable speed gears, industrial gear-boxes, high-speed gears and differentials), transmission chains (including bicycle chains) and other transmission equipment. Not included is transmission equipment manufactured for the automotive industry nor hydraulic or pneumatic transmission equipment. Some of the companies in the industry deliver to both the automotive industry and other manufacturing industries, or offer a wide product range, thereby covering other products than transmission equipment, gears and bearings.

The industry is medium-sized if compared to other mechanical engineering industries. Transmission equipment, gears and bearings constitute approximately 3% to 4% of total production of the mechanical engineering industry.

Main indicators

Consumption, production and exports peaked in 1990, in current prices. The decline of consumption, production, trade and employment figures in 1991 is, however, not considered as a structural phenomenon.

Figure 2 shows the leading position, in terms of value added, of Germany as a manufacturer of transmission equipment. It is followed by Italy, the United Kingdom and France. In the other EC countries the manufacture of transmission equipment is of minor importance.

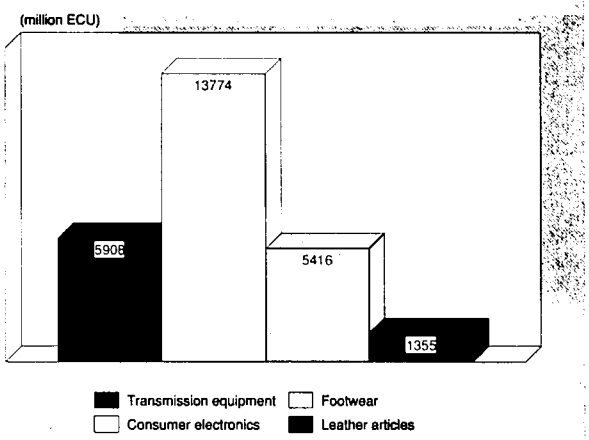
Recent trends

Production of the industry has grown since 1982. The industry demonstrated the highest growth just after the economic crisis of the early 1980s. While total employment dropped from 1982 to 1984, production increased by 15%. During the second half of the decade, the annual growth rates in current prices for production and consumption were low. The employment figure on the other hand remained rather stable, despite some fluctuations. During the same period, international trade increased. The development of the trade balance indicates a faster growth of extra-EC exports than of extra-EC imports, in current prices.

Foreign trade

The EFTA is the major trade partner of the EC, followed by the USA. The share of total EC imports from the latter country, however, are decreasing and have come down in 1991 to the same level as the Japanese share of the EC market.

Figure 1: Transmission equipment
Value added in comparison with other industries, 1991



Source: Eurostat

Intra-EC trade has been a great stimulus for EC production of transmission equipment. Both extra-EC exports and intra-EC trade have demonstrated strong growth rates in current prices. In volume, however, these increases were quite modest; during the 1980s the volume of extra-EC and intra-EC exports increased by an average annual growth rate of only 2.4% and 3% respectively.

The foreign share in total EC consumption of transmission equipment has been stable at around 16 to 17% over the 1982-91 period.

MARKET FORCES

Demand

The industry's products are characterised by a widespread use among several manufacturing industries. Demand for transmission equipment therefore depends to a high extent on investments in capital goods made by downstream industries. After a period of booming investments in the second half of the 1980s by some major client industries, production fell in 1991. This lower production figure of transmission equipment in 1991 can be explained by disappointing growth rates on the downstream markets within the EC, but also in the USA.

The drop in profits in the client industries, together with high interest rates, did not encourage investments in capital goods.

Electronics and miniaturisation increasingly play an important role. Especially in other transmission techniques, that compete with mechanical transmissions for some applications, like electrical, hydraulic and pneumatic means of transmission, technological developments are major impulses for relatively high growth rates. If and to what extent substitution is threatening the manufacture of mechanical transmission equipment, depends - among other factors - on the possible applications and on the extent to which transmission machinery and equipment based on other techniques can meet the customer's expectations. The increasing use and combination of different techniques by the manufacturers of transmission equipment makes it difficult to specify these substitution effects.

Supply and competition

Germany, France, Italy and the United Kingdom together produce 94% of total EC output. Germany alone constitutes almost 50% of total EC production. All four countries suffered from a production loss in 1991. Especially in Italy and Germany, a decrease in domestic consumption was the major cause. France and the United Kingdom mainly suffered from decreasing export figures to the USA, the EFTA countries and their former colonies.

In general, the production fall of transmission equipment in 1991 caused an excess capacity which is reflected in a lower aggregated productivity figure (see Table 4). Employment and total unit costs decreased, partly compensating the effect of a lower productivity. The evolution of the foreign shares on the EC market suggest that the EC industry does not seem to have lost competitiveness. Nevertheless, the weakness of demand will continue to put pressure on margins as competition will intensify.

Because many manufacturers of transmission equipment also deliver to the automotive industry (not covered by this NACE), the industrial production has concentrated in Germany, France, Italy and the United Kingdom, which are the countries with the major automotive industries.

Production process

Both capital goods and labour force are important inputs in the production processes of the industry. Furthermore, technological research and development (R&D) is highly important, as the EC industry's competitiveness depends to a high extent on technological know how. In this respect, it is essential for the industry to continue investments in R&D and in training programmes to keep the labour force up to date with the latest technology.

INDUSTRY STRUCTURE

The manufacture of bearings is relatively more important than the manufacture of gears and transmission equipment. The German company FAG Kugelfischer and the Swedish SKF are dominant parties on the market for bearings. On the market for speed changers, industrial high speed drives and gears, the A.F.Flender AG is an important manufacturer. The German multinational company Kloeckner is also represented with a subsidiary on this market.

The enterprises are medium-sized and often do not operate plants in other countries than the mother country. Only a few EC enterprises are present in several EC countries. Of the non-EC manufacturers, the Swedish enterprise SKF already has a strong foothold in the EC with production facilities in the major EC countries. In contrast, Japanese production is still concentrated in Japan and other Asian countries; within the EC only a few production plants are Japanese owned. Nevertheless, with the help of low cost production and a world-wide distribution network, the Japanese increase their share of extra-EC imports and acquire a solid foothold on the EC market.

The European companies still put a lot of effort in R&D in order to retain and extend their market position. However, in order to avoid foreign companies from easily penetrating the EC market, the EC companies should expand operations to a European scale in order to enjoy the opportunities of the EC Internal Market.

The German reunification could mean extra opportunities for the EC industry. FAG Kugelfischer has already acted and acquired eight production sites in the former East Germany. SKF, its main competitor from Sweden, has also invested in the same area. Some other companies are active in the former COMECON countries. In the short run, however, German reunification is expected to give the market more impulses than the restructuring processes in the Eastern European countries. These are likely to generate demand increases only in the medium to long run.

ENVIRONMENT

The industry does not seriously threaten the environment. The hardening and galvanising stages of the production process could cause serious harm to the environment, but measures have already been taken to prevent this. As far as products in mechanical power transmission are concerned, noise might be a problem, although noise levels have been greatly reduced as a result of improvements in production techniques. Costs arising from environmental protection in the industry are relatively low.

The EC Directive on machinery applies to the industry's products only to a limited extent. The greater part of the output is absorbed by the production of bearings, which do not have a direct impact on the safety of work conditions in the industry. Furthermore, the industry's products are generally used as a component of machinery products, and it is at this latter level that safety provisions have to be complied with.

For the production processes within the industry itself, however, improved safety conditions of the capital goods used will be favourably received.

Companies will have to invest in quality improvements to meet the ISO 9000 quality standards. In the long run, the industry's competitiveness could be harmed if these quality standards would not be met.

OUTLOOK

In general, the industry will be confronted in 1992 with a further stabilisation of production, caused by weak demand. After 1993, however, the average growth rates will rise as the economies of the major Western industrialised countries are expected to recover. The political and industrial restructuring processes in Eastern Europe are not expected to create increases in demand in the coming years. More impulses can be expected from German reunification. Some threats could result from the fast growth of alternative transmission systems, electronic and other, although it is not clear to what extent manufacturers will be hit by adverse substitution effects. Also, in the coming years, the relatively strong R&D position and the high level of training of the labour force will assure a strong competitive position.

Machinery for woodworking, paper production and processing, laundry and leather

NACE 327

Manufacturers of printing machinery and woodworking machinery were confronted in 1991 with weak markets. The machinery manufacturers for the leather processing and footwear industry have been suffering from low demand for a couple of years.
In 1991 the drop in demand was caused by the recession in the EC countries and the main export markets. Extra-EC exports especially felt the unfavourable economic conditions in the USA. A recovery of aggregated demand is only to be expected after 1992.

INDUSTRY PROFILE

Description of the sector

NACE 327 includes the manufacture of machinery and equipment for use in specific and quite diverse branches of industry. The following industries are categorised under this chapter:

- manufacture of machinery for working wood and similar materials (NACE 327.1);
- manufacture of paper, paper goods making, printing and bookbinding machinery (NACE 327.2);
- manufacture of laundry and dry cleaning machinery (NACE 327.3);
- manufacture of plant for the leather industry, including boot and shoe machinery (NACE 327.4).

The greater part of these four industries is concentrated in the same countries. Within the EC, Germany and Italy are the most important producers (together accounting for 78% of total EC production). Within the various branches a similar situation can be recognised. Outside Europe, Japan and the USA are the leading manufacturing countries.

Main indicators

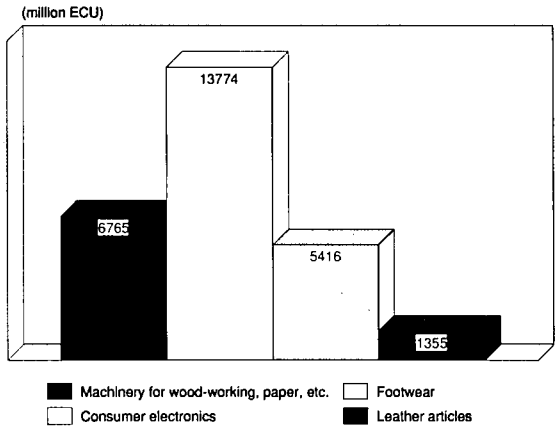
After the economic crisis of the early 1980s the industries went through a period of growth until 1990. A setback in production, consumption, extra-EC trade and the trade balance occurred in 1991. As a consequence, the steady growth in total labour force since 1986 stabilised in 1991.

More than 60% of total EC production is accounted for by printing machinery (NACE 327.2). The production share of machinery for working wood was estimated at 25% of total production, followed by much lower shares for plant for the leather industry and for the manufacture of laundry and dry cleaning machinery.

Recent trends

The high growth rates of EC demand during the 1980s enabled strong production growth, but also considerable increases in extra-EC imports. Especially after 1985, these imports recorded high growth rates, while the development of extra-EC exports has been disappointing since 1985. Total employment in 1990 was 15% higher than in 1985. The production fall in 1991 caused the growth of employment to stabilise.

Figure 1: Machinery for woodworking, paper production and processing, laundry and leather
Value added in comparison with other industries, 1991



Source: Eurostat

International comparison

In 1991 the EC was the world's largest producer of machinery for woodworking, paper production and processing, laundry and leather. EC production was about 12% higher than that of the USA and 2.5 times bigger than the Japanese one.

1991 also saw a worldwide slump in the industry. Within the EC production decreased by 5%, in the USA by 1.7% and Japan recorded a stagnation (+0.2%).

Foreign trade

In current prices, the trade surplus has grown from 1982 to 1986 and from 1988 to 1990. The decreasing exports/imports ratio (see Table 3), however, demonstrates the higher growth rate of the extra-EC imports compared to that of extra-EC exports. Despite the recession in some EC countries, extra-EC imports (in current prices) continued to grow in 1991, whereas extra-EC exports fell in the same year. This drop was mainly caused by falling exports to the USA, where a considerable decrease in investments in new machinery occurred. On the other hand, exports to Japan increased, mainly caused by a rise in domestic demand for printing machinery. Especially Germany took advantage of this Japanese import boom.

Despite the cheap dollar, the USA was not able to increase its market share in the EC. Similar to the general trend for mechanical engineering, the market position of this country is threatened by Japan. Although its share is still low, the growth of the EC imports from Brazil is remarkable.

The volume of intra-EC trade has increased at a lower rate than production (both figures in volumes). The disappointing development of extra-EC exports implies that production has been stimulated to a high extent by the domestic demand in the individual Member States. However, EC manufacturers were not able to fully benefit from the rise in EC demand, thereby giving non-EC manufacturers the opportunity to further penetrate on the EC internal market.

MARKET FORCES

Demand

The buyers of the overall industry's products can be mainly found in downstream industries. In the large manufacturing countries like Germany, Italy, USA and Japan there is a strong domestic demand. In some countries the export shares in total production are high. Germany, for example had an export share of 60% in the manufacture of woodworking machinery.

Printing machinery

The Italian market was stimulated by a boom in the turnover of newspapers and magazines during the second half of the 1980s. Also Germany's printing and paper processing industry could benefit from the ever increasing use of paperwork. However, the performance of the printing industry itself is highly sensitive to economic developments. As a consequence, the recession in 1991 caused demand to fall.

Woodworking machinery

For the manufacture of woodworking machinery, demand is with wood-processing industries. Hence, the final demand for wood and wood products is vital. Only in 1991 demand for woodworking machinery dropped, but expectations for 1992 are optimistic. The German and Italian industries observe an increasing demand for wood by the furniture industry. The construction market in both countries and in the USA are expected to fully recover in 1993. The former East Germany could become an important market area because of its rebuilding process. An increase of direct exports to the Commonwealth of Independent States (CIS) and the Eastern European countries is not expected at short notice, due to the economic and political restructuring processes currently going on.

Plant for the leather industry

The market for leather machinery is also weak due to the world recession. Demand in the CIS and the former Eastern Block countries has even disappeared. Although some markets are becoming more and more important (such as Mexico, China, Iran and Algeria), EC manufacturers also suffered from the low exchange rate of the US dollar. Further the recession in the USA resulted in a 20-25% fall in output in Italy, in 1991.

Supply and competition

The decrease of sales in the described markets caused an excess capacity, and will inevitably reduce profit margins as price competition will intensify to some extent. However, the heterogeneous composition of the industrial customers group leaves room for extra margins, especially if customer specific solutions are asked for. In this area, the EC industry is ahead of the competition from Japan and Taiwan. Within the EC, only Germany and Italy are important suppliers of machinery for specific branches. Compared to 1985 Germany had even gained some more market share in 1991 (62.6% against 55.9%). Italy lost some of its share, although total EC production increased. Also productivity was lower for Italy com-

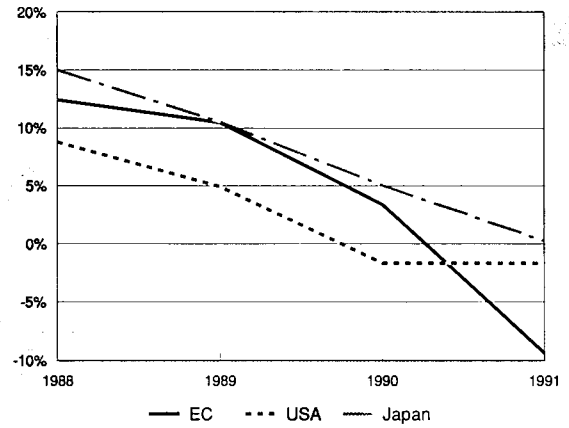
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

pared to Germany. On the other hand, unit labour costs have grown at a faster rate in the latter country than in Italy.

The productivity loss in all EC countries is not surprising as value added decreased while employment remained at a stable level. Despite the stable labour force, the industry succeeded in cutting total unit costs in 1991. A wage inflation in Germany should be avoided in order to keep costs low. In addition, it should be clear that the drop of demand should not lead to the cutting of costs that might endanger final product quality now and in the future (e.g. by cutting costs in R&D), as this is one of the most important elements which determine the success of the EC industry. In the field of woodworking machinery, for example, the German share in inventions worldwide was 31% during the 1982-86 period. The USA (17%), Japan (8%) and Italy (3%) followed at considerable distance. Also, in the other industries - especially in printing machinery - Germany became the leading country by offering high quality products against reasonable prices. Italy is especially strong in the manufacture of leather processing machinery and puts much effort in R&D in order to retain its dominant position.

Printing machinery

In Italy, the trend towards further specialisation in the production of offset-, rotary type and flexographic printing machinery is still proceeding. Some trends in technology will have, and already have had, consequences for the users of printing machinery. Firstly, the development of desktop publishing has enabled especially the small scale printing enterprises to utilise cheaper production facilities (print shops) to cope with small-scale individual printing demands. Secondly, the development of direct plate outputting technologies enables the realisation of a filmless platemaking process, which provides a considerable cost reduction and serves as the foundation for picture data bases. Thirdly, the development of sophisticated picture transmission systems for the printing industry enables reduction of picture transmission costs. Finally, the development of automated input technologies and automatic translation systems could result in cost reduction and more efficient printing.

Woodworking machinery

The German woodworking machinery which concentrates especially on labour intensive custom-made solutions, is negatively influenced by high wage costs due to increasing wages and decreasing effective working hours. On the US market competition is fierce and the low dollar exchange rate has a negative impact on German and Italian sales. The quality of the European machinery and after-sales service, however, are at a high level and constitute an important competitive advantage. In contrast with the European manufacturers, Japanese and Taiwanese firms tend to focus on the building and delivery of standard and low-cost machinery.

In the demand for woodworking machinery, a trend can be recognised towards further automation in order to save raw materials, to cut energy costs and to increase productivity and competitiveness. Furthermore, automation is aimed for in order to improve safety conditions in the woodworking industry.

Plant for the leather industry

The trend towards more automation can also be recognised in the leather machinery industry. New control systems are made for environmental protection in order to comply with governmental regulations. Demand for leather products in the consumer markets changes rapidly. As a consequence, technical innovations are needed to improve existing and develop new machinery and equipment in order to enable the leather processing industry to become more flexible to adapt to changes in consumer demand.

INDUSTRY STRUCTURE

Companies

Printing machinery

The Italian factories in this industry are relatively small. In 1988, 150 manufacturers employed 7250 people, which means an average of only 48 employees per enterprise. Only 10 factories employed more than 150 people. The major part (60%), however, had a labour force of less than 50 people. In Germany the total number of employees in this industry is roughly estimated at a total of 70 000 in 1990. The average number of employees per enterprise is much higher compared to Italy. Companies like J.M. Voith GMBH, Heidelberger Druckmaschinen AG, and Man Roland Druckmaschinen AG, for example, employed more than 33 000 people in 1990.

Woodworking machinery

Around 780 EC companies in the manufacture of woodworking machinery employed 46 500 people in 1990 (average 59-60 employees per enterprise), compared to a number of 42 000 in 1988. In Germany and the United Kingdom, the average number of employees is more than 100, whereas in Italy it was only 37 people per factory. Furthermore, the EC industry is more labour intensive - due to its higher degree of specialisation - as production per employee within the EC was ECU 100 000 while the same figure was ECU 115 000 for the rest of the world in 1990.

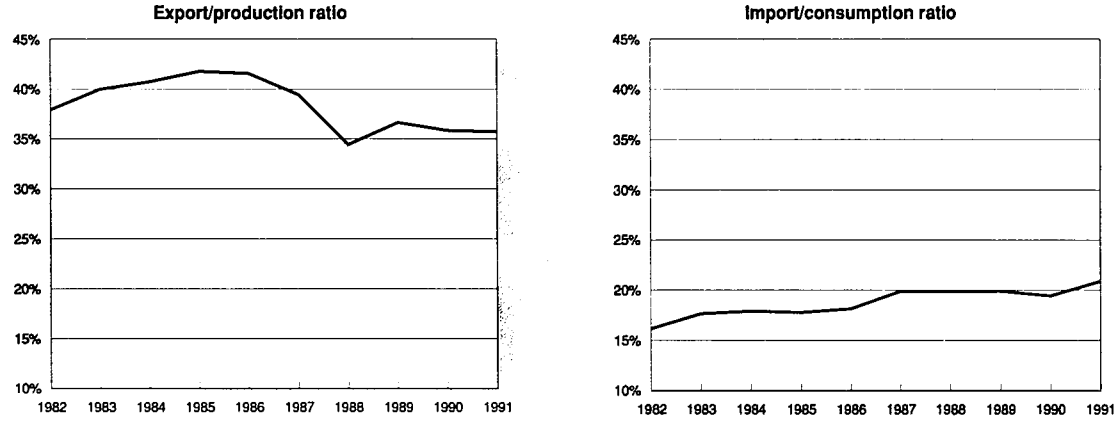
Strategies

Especially on the US market, where competition is fierce for the EC manufacturers, it will become more and more important to meet the specific market demands in order to retain market positions. In the former Eastern European countries companies from the Western industrialised countries (including EC countries) are looking for cooperation (joint ventures) in order to create a strong strategic position, anticipating economic growth in the future. Other manufacturers seem to focus on direct trade with these countries.

ENVIRONMENT

The manufacturers of leather processing plant and machinery are still looking for technological solutions to reduce pollution during the processing of leather and leather products. These problems, therefore, concern the downstream industries rather than the machinery industry itself. At the level of the industry itself, however, manufacturers also have to deal with environmental pressures to reduce pollution. For the manufacturers of woodworking machinery, possible measures against the

Figure 8: Machinery for woodworking, paper production and processing, laundry and leather
Trade intensities



Source: Eurostat

imports of tropical hardwood will inevitably affect demand for their machinery.

REGULATIONS

Directive 89/392 covers all types of machinery and defines their essential safety and health requirements.

In anticipation of EC regulations for a safer working environment the European manufacturers already put much effort in R&D for the improvement of safety conditions of their machinery. In the manufacture of woodworking machinery the trend towards more automation also implies less dangerous working conditions. The European Technical Committee for machinery safety regulations (CEN TC/142) will introduce its safety standards in 1993. The European industry, however, would like to see the CEN standards adopted by the International Standards Organisation (ISO) in order to safeguard the use of the same safety standards worldwide.

If ISO recognition does not happen, this legislation will probably result in European manufacturers having a two-tier production. Expensive machines with high safety standards will be built for the European market and cheaper versions will be built for other markets where safety standards are lower. This may allow European manufacturers to compete with emerging Asian manufacturers on a more equal footing.

OUTLOOK

For 1992, a low growth rate can be expected as the economic situation in the Western industrialised countries is gradually improving. The increase in intra-EC consumption and demand in foreign markets will cause production to grow by an estimated 1%. Employment, however, is not expected to show any growth, as the increase of production will be enabled by using the existing excess capacity.

Table 5: Machinery for woodworking, paper production and processing, laundry and leather
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	3.1	7.5

Extra-EC exports	1.9	3.2

Source: NEI

A recovery of aggregated demand is only to be expected after 1992. From 1993 on, EC production will reach annual growth rates of 5%. This growth is expected to originate from both a recovery of markets in Western industrialised countries, namely internal EC demand, and demand from foreign markets such as the USA. A rise of demand in the former Eastern Block, however, is only expected after 1995.

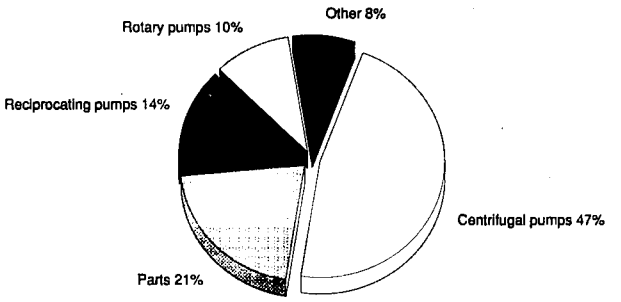
Liquid pumps
NACE 328.3

A boom in demand for liquid pumps in the former East Germany in 1991 camouflaged and partly compensated for weak export markets and order portfolios in the rest of the EC. Output growth over the next few years will not only depend on the economic recovery in the major countries and to a lesser extent on the progress of the restructuring process in Eastern Europe, but will also be stimulated by new demand for certain pumps (for instance, pumps for water purification) stemming from tighter water protection standards.

Figure 1: Liquid pumps
Breakdown by major product line in the EC, 1990



Source: Europump

INDUSTRY PROFILE

Description of the sector

NACE 328.3 includes the manufacture of compressors, pumps and equipment for operating machinery by hydraulic or pneumatic means. Besides liquid pumps, the sector also covers compressors and vacuum pumps. However, for these latter product groups little statistical information is available. As a consequence, the description of the sector will mainly cover liquid pumps.

The liquid pumps sector can be divided into six classes: hand pumps; plunger pumps; rotary displacement pumps; centrifugal pumps; other pumps (not elsewhere specified); and parts for pumps.

Recent trends

Between 1982 and 1990, production of liquid pumps in current prices increased by an average annual rate of 3.8%. In volume, however, production in 1990 had still not fully recovered from the drop in production caused by the economic crisis of 1981 to 1983. Production development of centrifugal pumps in particular was disappointing throughout the 1980s. Over the 1981 to 1989 period, real production of these pumps, which represents close to 50% of the pump industry's turnover, decreased by 1% per year. By contrast, plunger and rotary displacement pumps (25% of turnover) registered annual growth rates of 4% in real terms and represented the fastest growing segments.

Production growth has mainly been stimulated by an increase of EC demand. Apparent consumption in current prices increased by an average annual rate of approximately 5.5% during the 1982 to 1990 period, while net exports increased at an average annual rate of less than 1%. Extra-EC exports have suffered from the low dollar exchange rates since 1986.

Germany is the production leader in all categories of pumps, but has an especially strong lead in hand pumps, reciprocating pumps and rotary pumps. These markets, however, are relatively small. In total production, Germany was responsible for almost 49% of EC production, followed at a distant second by the United Kingdom with around 16%. Germany is the leading manufacturing country of vacuum pumps and compressors as well, although these pumps are not covered in the monograph. German production of vacuum pumps and compressors in 1991 was estimated at 1.7 billion ECU, compared to liquid pump production of 2.4 million ECU by Germany in 1990.

International comparison

Production of liquid pumps in the USA and Japan has fluctuated since 1985, partly due to significant variations in exchange rates. The EC remains the largest world's producer of liquid pumps, with a production nearly two times higher than that of the USA and nearly three times than that of Japan. If the general trend in mechanical engineering is applied to this sector, a continued weakening in the position of the USA and a growing Japanese share on the world market is likely.

Foreign trade

Germany had the highest export value as well as production value. Of all liquid pumps produced in Germany in 1991, 59% or 1248.1 million ECU were exported, of which 722.8 million ECU were extra-EC exports. The most important German extra-EC export markets were the USA with approximately 125 million ECU (8%) of German production, Switzerland with 85 million ECU (5.5%), and Sweden with 60 million ECU (4%). France and Italy are the most important EC markets for Germany, importing 165 million ECU (around 11%) and 135 million ECU (about 9%) of German production in 1990, respectively.

During the 1980s, and especially after 1988, growth in intra-EC exports was a major stimulus for production, caused by strong

demand in some major industries. Extra-EC exports on the other hand suffered from the low exchange rate of the US dollar. In 1990, however, the value of extra-EC exports was still higher than intra-EC exports.

Extra-EC imports remained around 20% of total consumption (in current prices) during the 1980s. In 1990, this share dropped to 17.7%. EC producers operate in relatively fast growing segments, while the Japanese firms, for example, are highly dependant on the market for centrifugal pumps, which has not been performing well. Both EC and US production are more diversified than Japanese production.

Figure 2: Liquid pumps
International comparison of production at current prices, 1990

Source: Europump

MARKET FORCES

Demand

Various factors have caused weak demand for EC pump products since 1990. The Gulf war, economic downswings in several important export markets and low exchange rates for the US dollar and Japanese yen have all had an negative effect on EC production. In 1991, the only positive factor was the 19% rise of demand in the former East Germany, which mostly affected German production.

Market demand can be divided into two groups of liquid pumps: standardised pumps and engineered pumps. Both categories have a wide range of products and a wide range of applications. Major markets for standardised pumps are the chemical industry, process industry, construction industry, food industry, shipping, horticulture, civil engineering and the original equipment manufacture (OEM) sectors. Engineered pumps are used in the petrochemical and chemical industries, power stations, irrigation and water supply. Both markets require custom solutions, which requires a flexible and efficient production.

Demand is expanding from the traditional applications of pumps for water management, construction and the chemical industry, into the energy sector. Liquid pumps are especially useful for environmental protection and water purification.

Supply and competition

The sharp increases in intra-EC trade in recent years in contrast with the low growth rates and decline in extra-EC imports, could be an indication of the strong competitiveness of EC industry. In contrast with Japan for instance, the EC industry in general seems to be more diversified into the various segments of the market for liquid pumps and has been able to benefit from growing sectors.

However, the weak international market intensifies price competition and, consequently, profit margins drop. Since the market for liquid pumps (for Germany in particular) follows the same cycles as the markets for machinery and equipment in general, diversification by companies such as Thyssen into other sectors of the machinery industry does not shield these firms from downswings in the business cycle.

Production process

Both capital goods and labour force are important inputs in the production processes of the various pump and compressor industries. The labour force is particularly important in regards to technological research and development. As a consequence, the quality of the labour force and of training programs is a major factor influencing the success of EC industry in the long run. Keeping the quality of the labour force at a high level should not lead to excessive wage increases, however. Sharp rises in labour wages next to increases in input prices of materials (as happened recent years) would have a negative impact on the industry's profitability and cause reductions in investments, which would weaken EC competitiveness.

INDUSTRY STRUCTURE

In general, most of the EC manufacturers of pumps are medium-sized and specialise in a certain kind of pump or concentrate on one or more branches of industry. Abel (Germany), for example, specialises in the development and production of pumps for the mining industry. ABS is the largest EC manufacturer of waste water pumps. Allweiler and Netzsch are both active in nearly all the different segments for liquid pumps. The multinational company Thyssen is also active in some parts of the market for liquid pumps, but its product range is less diverse than the range offered by Allweiler.

The completion of the Single Market will bring changes in the structure of the pump sector. In recent years, a number of buy-outs and mergers have resulted in some large pan-European companies such as KSB, SIHI, ABS-Pumps, Dresser and Grundfos. The industry is trying to internationalise in order to compete more aggressively in the Single Market. For the majority of the enterprises, specialised in smaller market niches, joint ventures with similar companies in other EC countries should be a better means to benefit from the advantages of the European unification process.

Weak markets have already forced many companies to capacity and cost reductions to retain competitiveness. The wide deployment of CAD/CAM/CIM (computer-aided design, computer-aided manufacturing, and computer-integrated manufacturing) has resulted in productivity improvements and consequently to labour cost savings. This trend is likely to continue. Widespread and efficient distribution networks on key markets are getting more and more important in the standardised pump sector. For most of the specialised companies, more effort in product innovation and product modification will be needed, both to retain competitive advantage to stimulate demand from the general trend towards increased environmental protection. The latter trend provides the industry with extra demand for pumps for water purification, for example. On the other hand the same trend has induced the industry to produce less polluting pumps (i.e. without leakage).

REGULATIONS

The European Technical Committee for machinery safety and health regulations (CEN TC/200) will introduce safety standards in 1993. These will also apply to the manufacture of liquid pumps. The central issue of the new regulations (self-certification by the industry) will give the final responsibility for setting standards to the various industries. CEN has the final task of providing detailed European standards.

Control on the use of the new standards has been given to the national governments. In Member States with a long industrial tradition (such as Germany), safety and health standards are already established at a high level. For these countries, new EC standards will not have a negative impact on the domestic industries. Other EC countries, however, such as Greece and Portugal, which currently have much lower standards, could have some difficulty in reaching the European CEN-norms. European industries would like to see the CEN standards adopted by the International Standards Organisation (ISO) in order to avoid unfair competition on foreign markets.

ENVIRONMENT

Besides the safety standards, more environmental regulations can be expected in the coming years. In the European Act of 1987, guidelines are set for the governments of the Member States to work on their own environmental laws. The industry fears unfair competition if these regulations are not applied on a European scale. The manufacturers of liquid pumps, however, are not expected to suffer from growing environmental pressures. Demand has risen for waste water pumps, partly due to the guideline (March 1991) addressing the management and processing of urban waste water.

Noise pollution has been considered a major problem for the industry, but thanks to steady improvements in production techniques and processes, noise has been and will be further reduced. Furthermore, due to growing environmental pressures, reflected in demand, the industry has been induced to manufacture less polluting pumps, with less leakage. Technologically developed manufacturers could take advantage of the environmental pressures if their products can meet the environmental requirements.

OUTLOOK

Some of the reasons underlying slack demand during 1991, such as the Gulf war, have been resolved. Other problems, however, are expected to continue. Recessions in some important export markets are expected to turn into slow recoveries. The exchange rate of the US dollar remains a big problem for EC exports to the USA. The political and economic restructuring processes of East Europe are proceeding very slowly, which makes any significant upswing of demand in these countries unlikely in the short term.

German domestic demand for the years after 1992 will depend to a large extent on the economic performance of its most important export markets. For the USA, Italy, the United Kingdom and France, low but improving economic growth rates are expected for the 1992-1995 period. This will have a positive impact on demand for liquid pumps. Additional demand can be expected from rising interest for environmental protection.

Other machinery
NACE 328

The cyclical character of activities in the various industries in this sub-chapter is reflected in a weak demand and in declining production growth figures. Until now, the former COMECON countries (except for the former East Germany) could not stimulate world demand. Extra-EC exports declined and extra-EC imports increased, possibly indicating a weakening competitiveness of the EC industry on the world market. The industry should put a lot of effort in R&D to maintain its technological advantage. Furthermore, wage increases risk eroding price-competitiveness.

INDUSTRY PROFILE

Description of the sector

This NACE includes the manufacture of a heterogeneous variety of machinery and equipment not elsewhere categorised. The manufacture of compressors, pumps and equipment for operating machinery by hydraulic or pneumatic means also makes part of the NACE 328, yet is discussed in a separate sub-chapter.

NACE 328 includes the manufacture of:

- internal combustion engines, except those for road vehicles and aircraft (NACE 328.1);
- water-wheels and water and heat-turbines and other mechanical energy producing machinery (NACE 328.2);
- space-heating, ventilating and air-conditioning equipment (NACE 328.4);
- refrigerating machinery (except domestic type refrigerators and domestic deep freeze units) (NACE 328.5);
- non-electric industrial furnaces and ovens (NACE 328.6);
- non-electric welding-equipment (NACE 328.7);
- taps, cocks, valves and similar appliances (NACE 328.8);
- machinery and appliances not elsewhere specified (NACE 328.9).

The entire industry, including NACE 328.3 (compressors and pumps, which is considered in the previous chapter), together generated an output worth about 75 billion ECU in 1991, with a total value added of more than 30 billion ECU. These figures stress the economic importance of the industry, that, in terms of value added, positions itself between other important industries such as the manufacture of motor vehicles, and consumer electronics.

The largest part of the machinery and equipment produced in the various industries is destined for industrial applications. A distinction can be made between machinery and equipment directly used or applied in production processes, and machinery and equipment with a more general use in the production environment. In both cases the machinery and equipment produced can find its applications in all kinds of industries.

In NACE 328.8, for instance, two main markets can be recognised: the industrial markets for valves, tubes etc., and the construction market for sanitary fittings. Similarly, air-conditioning equipment (NACE 328.4) can find its final destination in industrial production plants and office-buildings.

Investment in machinery and equipment in the downstream industries depend to a high extent on the final demand on their respective markets, which in turn is highly dependent on the overall economic situation. This makes the various industries particularly sensitive to cyclical developments in the economy.

Main indicators

The economic downturn translated into decreasing growth rates in 1991 for production, consumption and extra-EC exports, at current prices. Also, in the early 1980s, growth rates were relatively low compared to those in the latter half of the 1980s. Only in 1987 production fell, caused by a drop in both extra-EC exports and EC consumption. Employment varied over the years between 750 000 and 800 000 people.

The geographical breakdown of value added indicates the dominant position of Germany in the machinery industry. In this NACE, however, Germany is not directly followed by Italy, usually the second EC country in mechanical engineering. It is the United Kingdom that takes the second position, ahead of Italy and France.

Only for Germany and the United Kingdom a further breakdown is available for the industry. Germany is represented in all separate industries, among which the manufacture of pumps (NACE 328.3) and the manufacture of valves (NACE 328.8) are the most important sectors.

Recent trends

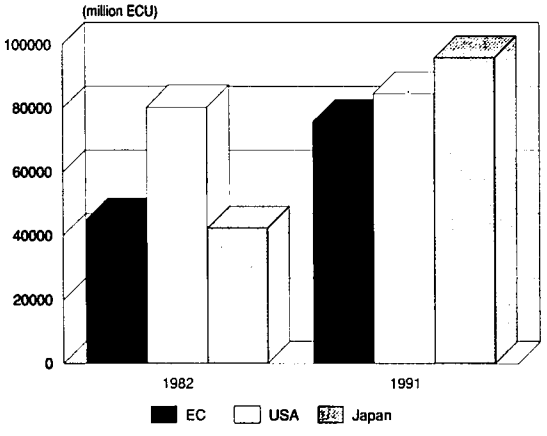
During the 1982-91 period, non-EC countries have absorbed a growing part of EC consumption in volume. Performance trends of the other machinery industry compare well to those of the entire mechanical engineering industry. The real growth rates of extra-EC imports - especially during the 1986-91 period - reveal a serious threat for EC producers. Furthermore, figures for extra-EC exports indicate a declining share on the world market.

In terms of real production growth, differences between EC countries exist. Germany and the United Kingdom were only able to increase production volume during 1982-91 by annual increases of 0.6% and 0.2% on average. France and Italy, however, have made strong progress throughout the 1980s: annual growth rates in real terms amounted to 4.5% and 6.1% respectively.

International comparison

Figures 4 and 5 reveal strong growth of the industry in both the EC and Japan, and a status-quo in the USA. Growth rates for both the EC and Japan, however, have been declining fast in recent years.

Figure 4: Other machinery
International comparison of production at current prices



Source: Eurostat, Census of Manufacturers

Foreign trade

The development of the export-import ratio testifies the worsening position of the EC industry. The ratio went down from nearly 3.0 in the beginning of the 1980s to 1.85 in 1991. Despite the adverse developments in exports and imports, the trade balance remained at a surplus of about 10 to 12 billion ECU.

The EFTA countries saw their share of imports into the EC halved, from 20% in 1986 to 10% in 1991. In contrast with other mechanical engineering industries, the share of the USA as destination for extra-EC exports has not decreased, despite the higher exchange rate of the ECU against the US dollar.

From Table 3 it appears that extra-EC imports and EC consumption in nominal terms developed in a parallel way throughout the 1982-91 period. The ratio shows that non-EC market share on the EC market was maintained at some 40%. In volume, however, the same share increased from 17.9% in 1982 to 21.7% in 1991.

Up to now, East European markets have not provided a significant stimulus to the demand for machinery and equipment capital goods. Besides the dissolution of the economic and political system, the lack of foreign currency hampers the acquisition of new orders on these markets. Also, joint ventures of EC manufacturers with East European counterparts have not yet proven to be very dynamic. In many cases, they only signify a foothold for the distribution of Western products.

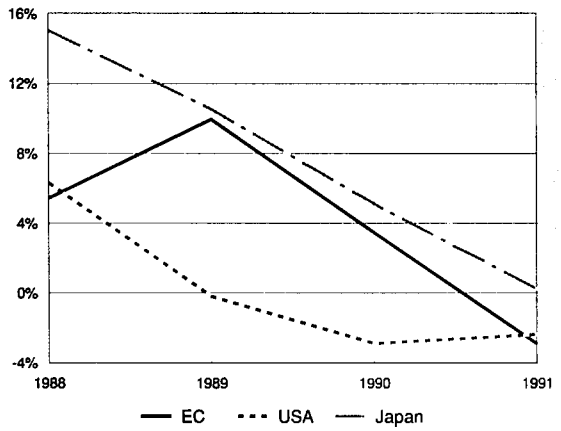
MARKET FORCES

Demand, supply and competition

Most of the mechanical engineering industries discussed in this sub-chapter, sell their goods to downstream industries of a varying nature. This heterogeneity implies a smaller degree of concentration of demand, which might allow the various industries to set higher prices and margins. The unification of the EC market, however, will lead to a further internationalisation and concentration of the client industries. This will put pressure on prices and margins.

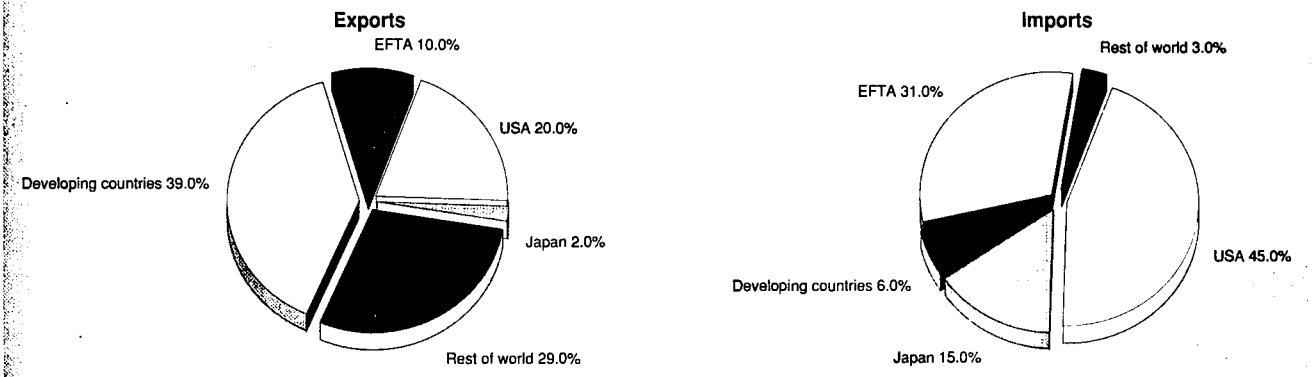
Foreign competition could also intensify. Especially, foreign companies with subsidiary production facilities within the EC could benefit from the European unification. As far as direct trade is concerned, the USA is expected to lose more share on the European market to Japan, despite improved price competitiveness.

Figure 5: Other machinery
International comparison of production growth at constant prices



Source: Eurostat, Census of Manufacturers

Figure 6: Other machinery
Destination of EC exports and origin of EC imports, 1991



Source: Eurostat

Within the EC, some divergent developments in terms of competitiveness can be observed between countries. Compared to the United Kingdom, the labour unit costs were as much as 50% higher in Germany in 1990. In contrast, total unit costs have been increasing more rapidly in the United Kingdom than in Germany. Italian and French manufacturers managed to increase production without significantly expanding their labour force, indicating productivity growth. UK manufacturers were able to improve their productivity while reducing the number of employees.

In order to remain competitive, EC manufacturers will have to strive towards further cost reductions, thereby increasing productivity. In addition, the big technological advantage of EC mechanical engineering products - especially of Germany - on the world market will have to be maintained in order to meet the challenges of the EC Single Market and to effectively withstand worldwide competition.

Production process

Labour remains one of the major inputs. As can be derived from Table 4, average unit labour costs have risen throughout the 1980s. A similar trend can be observed for total unit costs. Although the higher unit labour costs are partly compensated by an increasing labour productivity, real wage increases above overall productivity growth become a considerable threat for the competitiveness of the industry, especially in Germany.

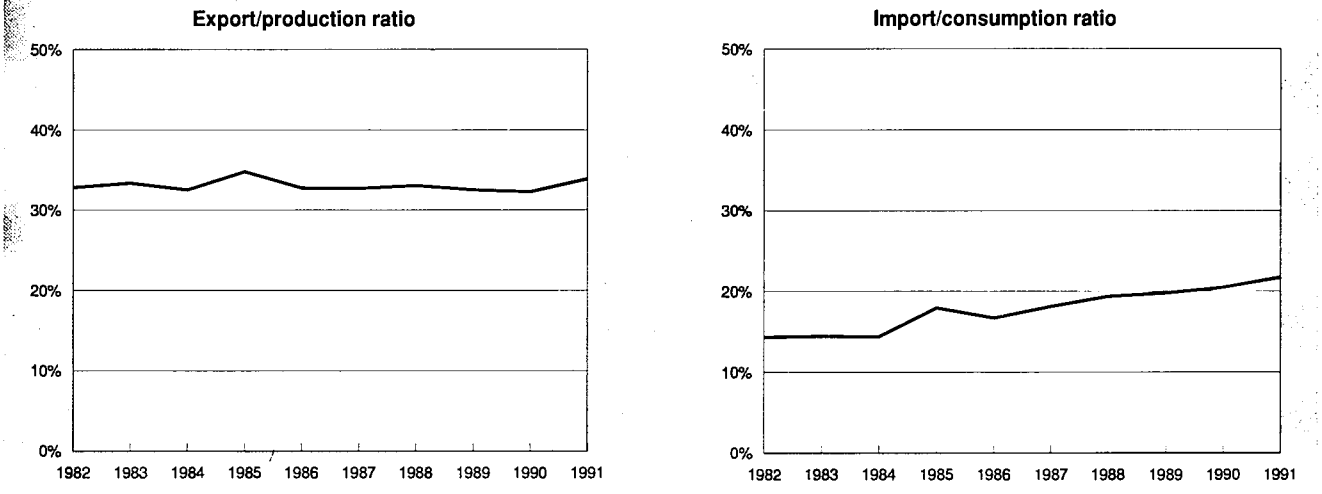
A trend towards further automation in order to improve the efficiency of production processes, not only within the factories of the industry itself, but also via their products in those of the downstream industries, can be signalled. This stresses the need for technical innovation. Another drive towards more technical innovation is coming from the increasing environmental pressures for more energy-efficient and less polluting machinery and equipment. Also, other elements as machine safety and the reduction of noise are gaining importance.

INDUSTRY STRUCTURE

Companies

The regional distribution of the various activities under this NACE heading is not very different from the general picture of the entire mechanical engineering industry. The major part

Figure 7: Other machinery
Trade intensities



Source: Eurostat

of the activities is concentrated in Germany, North Italy, the United Kingdom and France.

Some large, especially German, manufacturing companies are active in the various industries. Companies like Man-AG, Fried. Krupp Gesellschaft and Thyssen Industrie, active in one or more branches of the mechanical engineering industry, figure among the EC top ten. The French, English and Italian enterprises are smaller, but in general more specialised than their German colleagues.

In general, the European mechanical engineering industry consists of medium-sized companies. In order to avert the threat of non-EC companies penetrating into the EC market, the EC manufacturers should protect and improve their market position through further internationalisation. Through the conclusion of mergers, acquisitions or alliances, this strategy has already been followed by EC as well as non-EC manufacturers, and will continue to be followed in the future.

REGULATIONS

Directive 89/392 deals with all types of machinery and determines their essential safety and health requirements.

The European Technical Committee for machinery safety and health regulations (CEN TC/200) will introduce safety standards in 1993. The central issue of the new regulations - certification by the industry itself - will give the final responsibility to set specific standards to the various industries themselves. CEN - the European Normalisation Institute - has the final task to provide detailed European standards. Control on the use of the new standards lies at the level of the national EC governments.

The European industry would like to see the CEN standards adopted by the International Standards Organisation (ISO), in order to avoid unfair competition on foreign non-EC markets.

OUTLOOK

If apparent consumption trends during the 1980s are extrapolated, a further annual growth of 3% after 1992 can be expected until 1996. It is questionable, however, whether the EC production can fully benefit from these increases. The development of extra-EC exports has been disappointing and for the coming years no upswing is expected. As a result,

Table 5: Other machinery
Expected real annual growth rates

(%)	1992-93	1992-96
Apparent consumption	3.0	3.0
Production	2.0	2.0
Extra-EC exports	0.0	0.0

Source: NEI

further production growth will have to originate from the own EC market, on which the volume share of non-EC products is already increasing. Nevertheless, an annual growth of about 2% in real values can be expected for the 1993-96 period. The production growth will result from a more efficient capacity utilisation, without employment increases.

In order to maintain their competitiveness, the European manufacturers should try to keep their lead in R&D. In addition, the EC industry should strive towards further automation in order to reduce production costs.

Electrical and electronic engineering
NACE 34

The electrical and electronics industry, with a production value of more than 290 billion ECU and a workforce of 2.7 million in 1992, is one of Europe's largest industrial sectors. On the one hand, it profits from the strong growth of the markets for high-tech capital and consumer goods, goods for which it is one of the major buyers. On the other hand, its companies, with innovative technologies and products, are expanding the electrical and electronics markets in Europe.

INDUSTRY PROFILE

Description of the sector

NACE 34 includes the following sub-categories:

- insulated wires and cables (NACE 341);
- electrical machinery (including electric motors, generators, transformers, switchgears, etc.) (NACE 342);
- electrical equipment for industrial use and batteries and accumulators (NACE 343);
- telecommunications equipment, electrical and electronic measuring and recording equipment and electro-medical equipment (NACE 344);
- radio and television sets, sound reproducing and recording equipment (NACE 345);
- electric domestic appliances (NACE 346);
- electric lamps and other electric lighting equipment (NACE 347);
- assembly and installation of electrical equipment (NACE 348).

Given the difficulty of separating these sectors statistically, the electrical and electronics industries are considered together in this overview. Moreover, most companies in this sector have a foothold in both types of activity.

Main indicators

The sagging economic activity in Europe affected also the development of the electrical and electronics industry of the EC. In half of the EC Member States, production of electrical and electronic equipment declined in 1991, with only Germany, Ireland and Spain registering positive growth. The weak economic climate of 1992 also produced declines in the EC electrical and electronic engineering sector overall, although prospects for recovery seemed brighter by the end of the year.

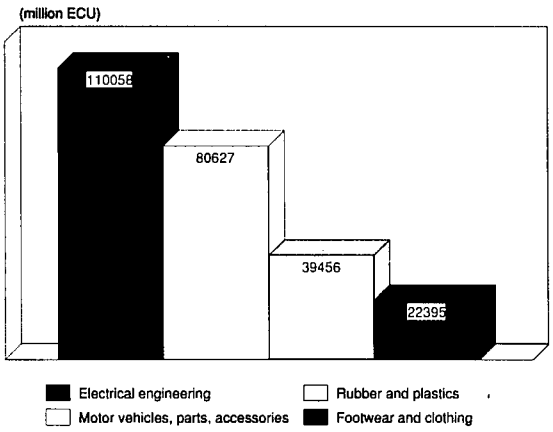
Production soared from 132.5 billion ECU in 1982 to 258.4 billion ECU in 1991. This gives an average growth rate of more than 6% per year in nominal terms (or 5% in real terms).

In terms of value added, the German electrical and electronics industry achieved 43% of the EC total compared to France, with 18%, Italy, with 14% and the United Kingdom, with 13%.

Recent trends

During the 1982-91 period, electrical and electronic engineering production growth in the major producer countries accelerated in real terms. Only in 1991 did this trend reverse in some countries. Of the countries reviewed, Germany ranked second in production growth after Japan and was above the average of the EC countries.

Figure 1: Electrical and electronic engineering Value added in comparison with other industrial sectors, 1991



Source: Eurostat

International comparison

In 1982, the world market for electrical and electronic products had reached a volume of around 700 billion ECU. By 1991, the market had almost doubled to just under 1 400 billion ECU.

The biggest shares in the world electrical/electronics market are accounted for by the USA, Japan and the EC. Together these three blocs make up 70% of the world electrical/electronics market (including the Eastern bloc).

Foreign trade

The electrical industry has always been an export-intensive sector. The period 1982-91 witnessed a strong expansion in world exports which rose from 150 billion ECU in 1982 to 290 billion ECU in 1991. The three major exporting countries, Japan, the USA and Germany, together accounted for around

three fifths of exports of electrical and electronic equipment. Other major exporters are the United Kingdom, France, Italy and the Netherlands.

The European electrical and electronics industry is the third largest exporter of electrotechnical products after Japan and the USA.

Export growth over the eighties of products such as electronic components was well above the average for the electrical and electronic industry while in segments such as electronic measurement and control, power engineering, telecommunications and consumer electronics, export growth was below the average.

Capital goods make up nearly two-thirds of electrical and electronic equipment exports while consumer goods and primary products account for less than one fifth each. These product areas vary in their export orientation. Their dependence on external markets is also considerably larger than is indicated by the export ratio, i.e. the level of goods exported as a proportion of manufacturers' sales. If account is taken of indirect exports, i.e. of equipment which is integrated into products further processed, the export ratios would be much higher. Apart from motor vehicle manufacturing, indirect exports primarily occur in the mechanical engineering sector.

The largest end markets of EC exports of electrical and electronic equipment are the EFTA countries and the USA. The main buyers in the "rest of world" category are primarily the developing countries though their importance as customers has levelled off in recent years.

The continued convergence of international markets which has accompanied stiffer competition has also had its effects on electrical imports. Back in the 1970s, electrical imports were already rising faster than exports. In the period from 1982 to 1991, this development continued. Extra-EC imports rose nearly threefold over the period with growth averaging around 8% per year.

As for exports, capital goods also dominate the import structure, accounting for more than three-fifths of EC imports. Consumer goods and primary products between them share the remaining two-fifths.

The import ratio, defined as the share of imports in total home market supply, rose steadily in the period under review and in 1991 stood at 19% for electrotechnical products.

The regional structure of electrical imports shows that the major suppliers, like the major buyers, are European countries. Other important supplier countries are Japan and the USA, accounting for around one fourth of extra-EC imports each. With imports from nearly all countries having risen in absolute terms, there have been shifts in the supply shares. Share gains have been scored mainly by the Japanese manufacturers, this expansion being almost exclusively due to consumer electronics imports.

In the 1980s, external trade in electrotechnical products further strengthened in all sectors of electrical and electronic engineering. This is a sign of the intensified international division of labour. In fact, external trade in electrotechnical products swung from a surplus to a considerable deficit position. In 1982, the surplus totalled around 5.8 billion ECU, in 1987, the balance was nearly even. Thereafter, imports rose much faster than exports and this development led to a negative balance of nearly 9 billion ECU in 1991.

MARKET FORCES

Demand

About one-third of the electrical industry's production is accounted for by intermediate demand, i.e. subcontractors' supplies of electrotechnical products for further use in the industry's own or in other industries' manufacturing processes, and two-thirds by final demand.

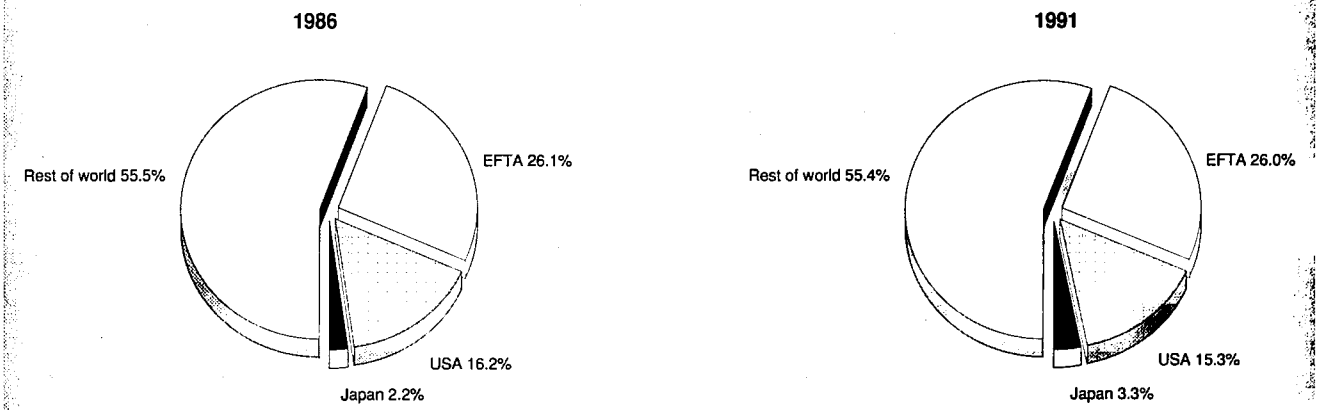
The electrical industry itself was the principal buyer of its own products for further processing or for integration into other products. Other important areas of intermediate consumption are mechanical engineering, the services sector and the motor vehicle industry.

If only capital goods of electrical and electronic production is taken, then the services sector was the main customer. Within this sector, traffic (including communications) was the weightiest consumer, followed by government and by road vehicle construction.

Supply and competition

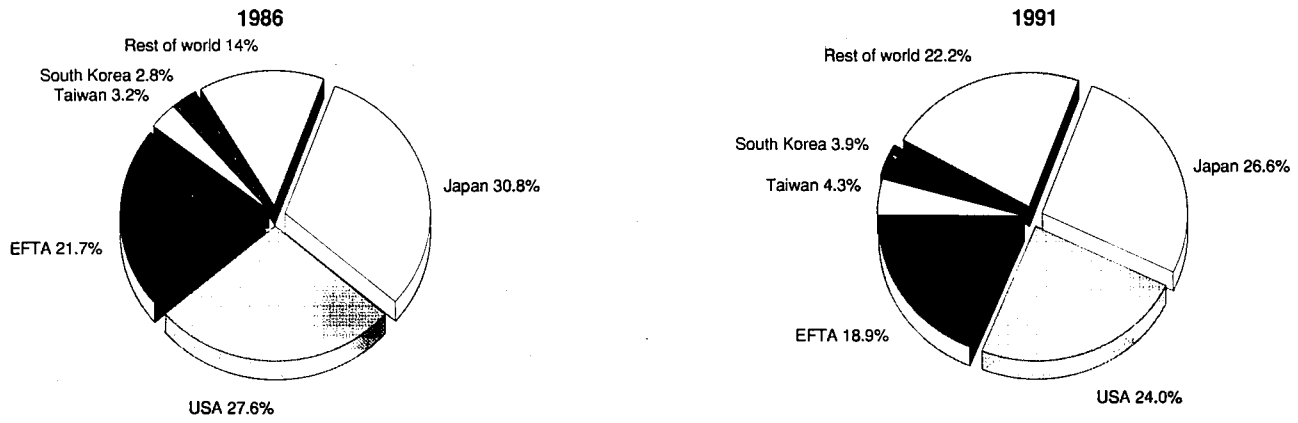
Measured by product types and applications, the electrical industry is a production sector of manifold and varied composition, with a spectrum ranging from microcomponents through to nuclear power plants. Therefore, the overall growth rate does not reflect the widely differentiated development patterns of the individual product areas. Here, output in terms of value is found to have risen highest in the area of electronic components, motor vehicle equipment and in measurement, control and automation. Slower growth can be found in elec-

Figure 6: Electrical and electronic engineering Destination of EC exports



Source: Eurostat

Figure 7: Electrical and electronic engineering
Origin of EC imports



Source: Eurostat

tricity distribution, in the domestic electrical appliances sector and in consumer electronics equipment. As in the whole electrical and electronics sector, all product areas have experienced an almost continuous rise in production over the period under review. The diverging developments in production for the individual product areas reflects the change in demand. Moreover, production growth is influenced by technological progress - the very differentiated production techniques of the electrical industry range from equipment found in heavy mechanical engineering to the miniaturisation used in precision mechanics - and by cost development, price movements and other factors.

The differences in the growth rates of the individual product groups led to a change in the production structure. Declines were registered especially for capital goods in the power engineering sector, for domestic electrical appliances and for consumer electronics. Growing shares were reported for capital goods in the electronics sector and for components.

Both on the demand and on the supply side, there are strong interdependencies between the electrical and electronics sectors and other sectors of the economy because of the extremely wide range of electrical and electronic products.

Advance performance covers many spheres of the economy and imports. Internal supplies, i.e. intra-corporate electrical supplies, make up nearly 50%. The major extra-sectoral field of supply is the services sector, where trade and traffic (including communications) prevail as major single segments.

The big suppliers in the processing sectors are the plastics and the non-ferrous metal industry. These industries, as well as the iron and steel-making industry, supply primarily raw materials and semi-manufactured goods while primary and intermediate products, i.e. specific supplies, come from various other areas (plastics processing, iron, sheet and metal working industries, mechanical engineering, paper and glass industry etc.)

The proportion of services in advance performance has risen steeply while the proportions of the primary and producer goods industries has in general declined. This is largely due to material savings in the production process as a result of

20-99	8 370	10.8	12.1	10.3
More than 99	2 936	3.8	78.9	82.9

(1) Estimates
Source: Eurostat

improved utilisation of materials and smaller product dimensions. At around 15%, the share of imports in advance performance has remained constant.

Among the industrial sectors from which the electrical and electronics industry procures capital goods, the mechanical engineering sector comes first. It supplied around half the electrical industry's gross fixed investment. The second largest supplier is the electrical industry itself, followed by the construction industry.

Production process

Of the processing industries, the electrical and electronics industry, besides mechanical engineering, is the biggest employer. In 1991 it provided jobs for 2 778 000 people. Employment went slightly up, compared with 1982.

Employment developed quite differently in the individual product areas. Above-average numbers were employed in product areas with above-average growth in production (e.g. measurement and control). By contrast, jobs were cut in areas with below-average growth rates (e.g. consumer entertainment electronics). This shows that labour productivity increased at different rates and it gives an idea of the varying degrees of rationalisation achieved in the individual product areas.

The electrical and electronics industry is one of the most research-intensive processing industries. Between 8 and 10% of its turnover are spent annually on research. This puts it at the top of the research-intensive sectors (excluding the aircraft and spacecraft industry).

INDUSTRY STRUCTURE

Companies

The EC electrical/electronic industry is a very concentrated one, as shown in Table 6: about 4% of all enterprises account for about 80% of employment and for more than 80% of total turnover.

In 1991, the three largest EC firms in the sector were Siemens (D), Philips (NL) and Alcatel-Alsthom (F). It is interesting to note the strong presence of EFTA firms among the top 15 firms, among which the most important were Asea Brown Boveri (CH/S), Electrolux (S) and Ericsson (S).

Strategies

Besides expanding exports, the electrical and electronics industry has continued pushing ahead its external commitment by foreign investments (establishment of production centres and marketing agencies), these activities being conducted to a wide extent in the developing countries. Foreign investments primarily serve the purpose of securing sales, related to the expansion or opening up of markets.

OUTLOOK

The liberalisation and standardisation of markets in the EC and technological progress will continue to determine the structural environment of the electrical and electronics industry.

According to ZVEI, the sector will grow at a slower pace during 1993, while a recovery is expected from 1994 onwards.

Based on current estimates, the world market for electrotechnical products will have nearly doubled its volume by the year 2000, compared with 1990. Here, the future-oriented research and development work of the companies and their investment activity play a key role.

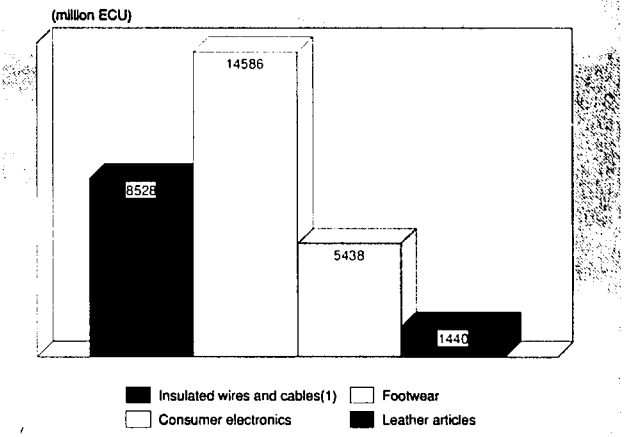
Written by: ZVEI
The industry is represented at the EC level by: Zentralverband Elektrotechnik -und Elektronikindustrie e.V. (ZVEI). Address: Stresemannallee 19 Postfach 701261, D-6000 Frankfurt am Main 70; tel: (49 69) 630 230 03; fax: (49 69) 630 2326.

Insulated wires and cables

NACE 341

The insulated wires and cables industry manufactures three main products: energy cables, information cables and winding wires. With more than 100 companies and more than 250 manufacturing facilities, the EC is the world's largest producer of insulated wires and cables, followed by the US and Japan. Demand for insulated wires and cables is influenced by two fundamental factors: the development of the infrastructure for electricity and telecommunications, and the general health of the economy.

Figure 1: Insulated wires and cables Value added by Member State, 1991



(1) Excludes wiring harnesses
Source: Eurostat, EUROPACABLE

INDUSTRY PROFILE

Description of the sector

The markets for insulated wires and cables are extremely diverse with applications in virtually all areas of modern life, from the winding wire in the electrical shaver to the optical fibre which provides the basis for the telephone call and to the energy cables which are used in the basic infrastructure of energy generation, transmission and distribution.

Electrical energy cables are fundamental to domestic life and all industrial and commercial activities in all parts of the Community. Wires and cables supply energy from the electricity generation centres to the individual point of utilisation, differing according to the voltage range.

Information cables have two important areas of application: telecommunications and electronic data/control and broadcasting. Current demand is strong in the field of telecommunications cables reflecting the massive surge in the demand for new telephones associated with the increasing use of fax machines as well as the demand associated with investment in the telecommunications infrastructure, particularly in those Member States which are modernising and extending the optical fibre network. Demand for information cables is also strong in the multifaceted area of electronic data/control applications and broadcasting. For many of the latest developments in information technology, communications cables, ranging from simple wires to coaxial cables, armoured cables and glass fibres, are an important element.

Winding wires are used in all forms of electrical equipment where a magnet is required. Thus every electric motor, transformer, generator, dynamo, etc. requires a magnet or winding wire that is enamelled or otherwise insulated.

Main indicators

The insulated wires and cables industry employs 105 000 people in the EC and is just over half the size of the consumer electronics industry measured in terms of value added, as shown in Figure 1.

Between 1985 and 1989, consumption and production rose steadily, with growth tailing off in 1990. The strength came more from domestic demand than external demand as extra-EC exports account for less than 15% of production and have remained fairly steady since 1985 (Table 1). A decline in employment reflects recent restructuring and the adoption of less labour-intensive production techniques.

The fastest growing segment of the insulated wires and cables is that of information cables. Between 1986 and 1990, the share of communications cables in total production rose from 23% to 32%, while the share of energy cables declined from 70% to 58%. Winding wires have maintained their position (Table 2).

Within the EC, Germany (west) is the most important producer of cables and insulated wires accounting for 25% of total production in 1990, a figure which rises to 31% if the eastern Länder are included. France and Italy follow in terms of importance with shares of 15% each (Figure 2).

International comparison

The EC is currently the largest producer of insulated wires and cables in the world (Figure 3). Proximity to the market is very important, particularly for heavy industrial cable, and investment in Europe's infrastructure has thus been a strong source of demand for EC producers. Furthermore, healthy growth in export markets combined to boost annual production growth to more than 5% a year, which is similar to rates achieved in Japan over the same period.

Foreign trade

EC cable-makers have always been an important source of cables worldwide with average exports over the past decade topping 1000 million ECU per year. The industry's trade balance, however, has declined sharply over the last several years. Traditionally strong net exporters such as Germany

and United Kingdom both became net importers in 1991. Imports have also gained headway recently, with their share of the EC market climbing from 9% in 1985 to 13% in 1991.

The source of the weakness in EC exports can be explained in part by the fact that many former principal export markets have established their own production facilities. Sluggish markets in the Middle East oil-producing countries have been exacerbated by a tendency to greater home production. Opportunities still exist for EC cable makers, however, in countries where the level of technology is still beyond domestic production capacity.

In terms of exports markets, the EFTA and OPEC countries are the single most important trading regions (Figure 4). The EFTA countries are not only the largest customers of insulated wires and cables, but they are also important suppliers, accounting for 33.2% of total extra-EC imports in 1991 (Figure 5). Although the US was as important a supplier as the EFTA countries in 1986, its share of total EC imports fell to 22.4% in 1991.

MARKET FORCES

Demand

The three main categories of insulated wires and cables, that is, winding wires, information cables and energy cables, are subject to very different forces of demand.

The demand for energy cables is dependent on increases in electricity consumption but also on the demand for new production and transmission facilities, as well as on replacement demand. In the long-term, demand for energy cables will keep pace with the growth of GDP and the associated growth in electricity consumption. The customer structure of the energy cable industry shows the overwhelming share of power utility companies, which in many cases are publicly owned. As a result, the demand for wires and cables can be severely affected by the energy policy; privatisation of the UK energy market was accompanied by a 35% fall in sales of the insulated wires and cables industry.

The demand for information cables is linked to both the development of a country's telecommunications market and the level of advancement of its telecommunications infrastructure. The overwhelming portion of the market is accounted for by the public telephone network operators. The strongest growth is in trunk (long-distance) traffic, where technological developments have substantially reduced cable-costs. The demand for electronic data control cables is expected to continue its steady rise.

The demand for winding wires is naturally linked to trends in end markets such as electric tools and electro-medical devices.

Supply and competition

The production capacity of the EC cable and wire industry has traditionally exceeded demand. Technological improvements, an increase in capital intensity which has changed production techniques, and shrinking home demand, are the key forces which have combined to change the environment in which manufacturers operate.

The EC cable and wire industry has achieved a world lead in numerous technologies which are important for cable production: non-ferrous metallurgy, insulation physics, rubber chemistry, hightech materials, superconductivity and electrical engineering for power cables with optical fibre technology for information cables. The industry's investment in R&D has also translated into new production techniques which have generated higher productivity and a steady decrease in employment and improvements in production efficiency.

Production process

Two raw materials are of particular importance to insulated wires and cables production: copper and aluminium. In the EC cable and wire industry more than 1 million tons of copper and about 150 000 tonnes of aluminium are used per year on average. The use of these two main inputs, however, varies according to their price, which fluctuates widely, taking into account the fact that about twice as much aluminium as copper is needed in electrical applications. The trend in copper prices provides an example of the degree of this price variability; the price per tonne of copper doubled from 1592 ECU per tonne in January 1986 to 2986 ECU in January 1989. The average price per tonne of copper in 1991 was 1772 ECU. Given these wide price fluctuations, not to mention currency fluctuations, the trends in consumption, production and foreign trade in insulated wires and cables which appear in this report should be analysed in light of the price trends of its main raw materials, copper and aluminium.

INDUSTRY STRUCTURE

Companies

There are more than 100 firms that produce cables and insulated wires in the EC with 250 production facilities and some 105 000 employees. Production sites are located in all Member States, with the exception of Luxembourg (Figure 2). The major manufacturers of insulated wires and cables are Alcatel (F), BICC (UK), Pirelli (I), Siemens (D). If all of Europe is considered, ABB (S/CH) should be added to the list. These large companies produce both energy and information cables as well as winding wires. Small enterprises tend to specialise in one product, often in energy cables, although this varies according to country. In the smaller countries, small companies often manufacture the whole spectrum of products. In the France, Germany and Italy, however, apart from the top four of five large producers, there are many small specialist producers.

In the past few years there have been several fusions and takeovers. Examples are Alcatel's acquisition of the German AEG Kabel AG, BICC's purchase of KWO (D), and Pirelli's purchase of STC (UK).

The increasing share of glass fibre cables in information cables has led to an increase in the average size of firms, due to the necessary capital foundation for the technologically demanding production process. There are now only about a dozen manufacturers of optical fibre in the EC.

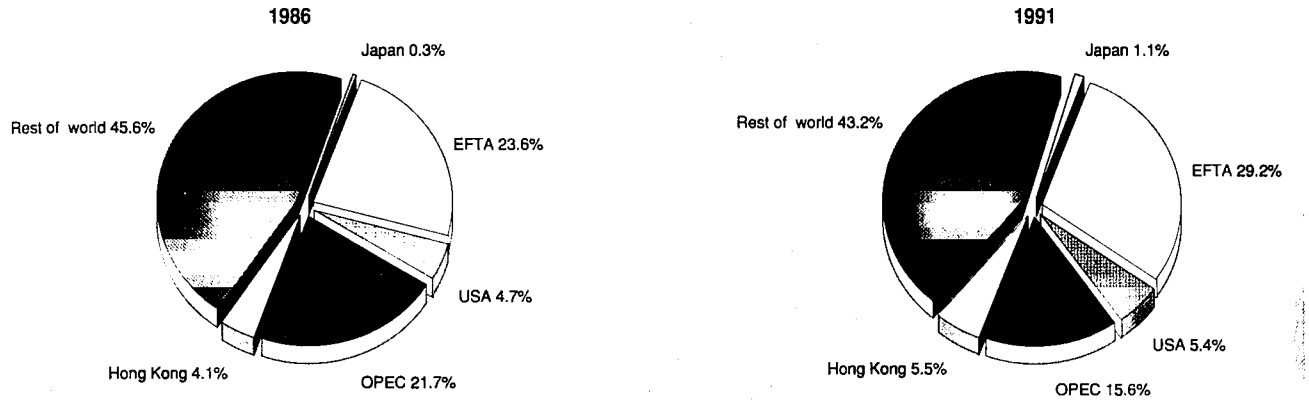
Destination of EC exports



Source: Eurostat

Strategies

To meet the challenges of increased competition there are three main strategies: investment, research and development, and cooperation and concentration. Investment activities have shown an upward trend, at least in the five EC countries for which figures are available. The main motive for investment is an increase in productivity and reduction in costs, especially labour costs. In the years when the cable business was booming, expansion was an additional objective.

Innovation in new products or new processes and production methods are other strategies for keeping up with the competitors.

Mergers, acquisitions, alliances, and corporations are organisational methods for increasing or at least maintaining competitiveness on the international market. Several large cable manufacturers have made cross-border investments within the EC, either for reasons of cost or for closer proximity to markets. Investments outside of the EC have been made above all by French and Italian, British and German cable producers; these have been primarily in North America (USA, Canada), Latin America (Mexico, Argentina, Brazil, Peru) and Africa (Lebanon, Morocco, Nigeria, South Africa).

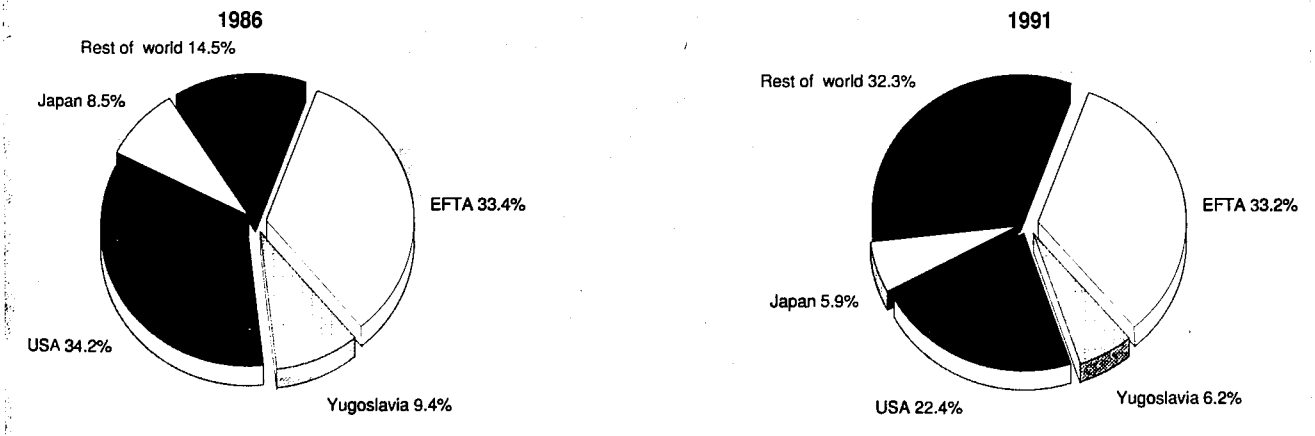
ENVIRONMENT

Generally speaking, cable manufacturing is not a burden on the environment. The manufacturing process is clean and the materials used are normally non-toxic; those posing potential risks are strictly regulated. The cable industry has been very responsive to environmental concerns in its use of raw materials and its design of products minimising the potential hazards of their installation and use. Specially designed cables with reduced flammability are available and there are already acceptable alternatives to PVC and other compounds in areas with fire risks. Cable makers no longer use materials containing dioxin and are investigating the possibilities of substituting materials containing halogens. Cable insulation without halogens emits little in the way of toxic fumes. This is particularly important in public areas, in transport and warehouses as well as any place frequented by people or housing combustible goods.

REGULATIONS

Regulations that relate to technical standards, the use of dangerous preparations, and health and safety, all have implications for cable makers although there are no specific directives which are directed to the industry. The directive on harmo-

Figure 5: Insulated wires and cables
Origin of EC imports



Source: Eurostat

nising national provisions on electromagnetic disturbance levels (89/336/EEC), for example, lays down the rules to which cables and other electrical equipment manufactures must adhere.

On another front are the public procurement directives which liberalise the awarding of public contracts. The market for insulated wires and cables has been dominated in the past by the public utilities (both in energy and telecommunications) which often favour national suppliers. With the liberalisation of the tender procedure and procurement, competition within the EC will intensify. Harmonised standards will also make it easier for EC manufacturers, and their foreign competitors, to penetrate other markets than their own.

OUTLOOK

A short term influence on demand for EC insulated wires and cables will be the expansion of the energy and telecommunications networks in the east German federal states. In general, although the requirement for insulated wires and cables in the former planned economies of Eastern Europe is enormous, a lack of finances will limit demand. Similarly, sales possibilities in Third World markets will increase only slightly; despite great needs, improvement in the infrastructure is making no or only very little progress due to limited financial leeway.

Production	3.0	3.5
Extra-EC exports	3.3	3.3

Source: ifo Institute

The development of the information technology market and the expected increase in personal communications will dramatically increase demand for information cables. Equally, if not more important, will be the impact of privatisation and the liberalisation of public procurement on the energy and telecommunications sectors. In the long-term, demand for energy cables will strongly depend on the growth in GDP and the associated increase in electricity consumption. The demand for data and control cables as well as for winding wires will be primarily influenced by overall trends in the manufacturing industry and services sectors in the EC.

This industry is represented at the EC level by: European Confederation of Associations of Manufacturers of Insulated Wires and Cables (EUROPACABLE). Address: Rue du Luxembourg 19-21, B-1040 Bruxelles; tel: (32 2) 513 0612; fax: (32 2) 502 2169.

Electrical machinery
NACE 342

The electrical machinery industry experienced a strong performance during the 1980s. At the end of the decade, however, production growth rates decreased, as investment activity of companies declined and overcapacity in the electricity sector dampened demand for products. Competition from outside the EC increased also, particularly from non-European competitors. In the medium term, prospects for the industry are favourable, thanks to the establishment of the Common Market, and to new sales outlets in the developing countries, China and Eastern Europe. Competition, however, will also rise and force EC firms to increase their cooperative efforts.

INDUSTRY PROFILE

Description of the sector

The electrical machinery industry can be subdivided into two groups: the manufacture of machines for the production and conversion of electricity and the manufacture of equipment for the distribution of electric power.

The manufacture of machines, apparatus and instruments for the production and conversion of electricity, includes the production of electric motors, electricity generators and rotary converters, transformers, current rectifiers and the production of electromagnets and electromagnetic apparatus.

The manufacture of equipment for the distribution of electric power includes the production of apparatus for closing, opening, and protecting electrical circuits 1 kV or more, installation equipment of up to 1 KV, and fixed and variable resistors, including potentiometers.

The large companies of the industry operate in a wide range of fields of electrical engineering, while smaller firms are usually active only in a few sectors of the industry, with some firms working in niche markets, producing one or two products.

Main indicators

The industry is highly export oriented; extra-EC exports were about 22% of EC production in 1991. The trade balance has been positive throughout the last decade, but has deteriorated considerably over time, due to higher growth in imports than exports.

Apparent consumption and production have both grown at steady rates, but apparent consumption has been growing at a faster rate since 1985, except in 1990 when production experienced a recovery.

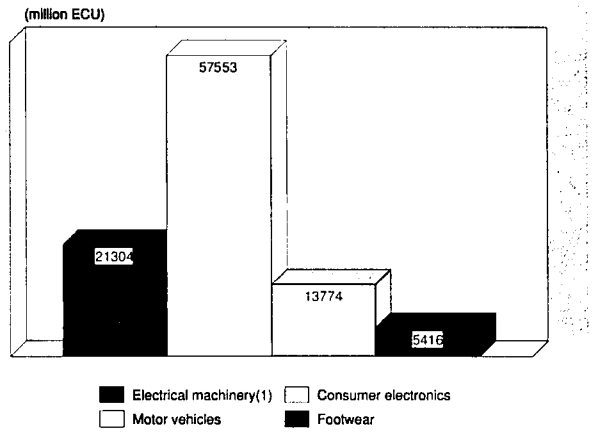
Germany is the most important producer in the EC, with about 45% of total EC production in terms of value added, followed by France (24%), the United Kingdom (15%) and Italy (7%). The production of the other EC member countries is about 9% of the total.

Recent trends

Production increased steadily from 1982 to 1992, with only one temporary setback in 1984. Growth in the industry lagged behind overall growth for manufacturing in the EC for that period.

The industry in the EC was characterised by favourable developments during the 1980s. Demand, measured by apparent consumption, grew considerably during this period. Production of electrical machinery, however, developed at a slower rate, as extra-EC imports increased remarkably, particularly in the period from 1985 to 1991. Exports developed favourably as well in the second half of the eighties; after a decline at the beginning of the decade, a sharp increase could be observed in the second half at rates of roughly 4% per year in volume.

Figure 1: Electrical machinery
Value added in comparison with other Industries, 1991



(1) BAK estimate
Source: Eurostat

International comparison

The EC industry is the most important producer within the Triad. Output of Japanese firms was roughly 84% of EC production in 1991, while US firms were in the third position with about 63% of EC production. The development of production over the last few years has been uneven. The most dynamic performance was experienced by Japanese firms, whose production increased by roughly 41% from 1987 to 1991, corresponding to an annual average growth rate of roughly 9% in volume. Production in the EC developed more moderately, at about 4% growth per year in volume. US production increased by only 2% per year during the same period. In contrast to the EC and Japan, where production increased steadily over the whole period, US production has been declining since 1989.

Foreign trade

Trade with extra-EC countries increased significantly during the last decade. Extra-EC exports grew by 5.5% per year in value from 1982 to 1991. The largest importers of products

from EC firms are developing countries, including the East Asian NICs, with about 40% of total EC exports in 1991. EFTA countries received about 27% and the USA about 14%. Imports, however, increased at an even faster rate of nearly 15% per year on average during the same period. Consequently, the surplus in the EC trade balance has been decreasing by around 5.4% per year.

The most important importer is the USA with a share of about 25% of total EC imports in 1991, followed by Japan with 20% and Switzerland with 14%. With the exception of Japan, however, most competitors lost shares on the EC market during the last few years, to the benefit of the developing countries, especially East Asian NICs, which increased their market share from approximately 11% in 1986 to 16% in 1991, with a total value of about 1391 million ECU. Intra-EC trade increased sharply, by 13% per year, during the period of 1982 to 1991.

MARKET FORCES

Demand

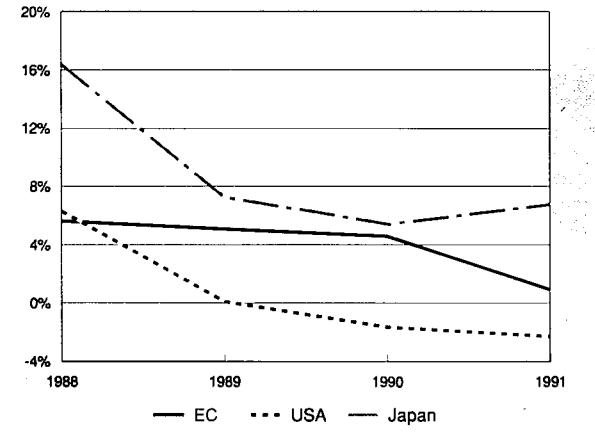
Demand for the products of the industry, measured in terms of apparent consumption, increased considerably during the last decade. In view of the great number of different products which respond to different demand patterns, the analysis of demand must distinguish between the different subsectors.

Demand for those products which are closely related to manufacturing processes profited the most from the investment boom which took place in the second half of the 1980s. Increased efforts of the EC manufacturing sector to expand their production capacities and to improve production efficiency in the expectation of the Single European Market, provided the producers of electric motors, electromagnetic apparatus, low- voltage switchgear (opening, closing and protecting electric circuits of less than 1 KV), installation equipment and fixed and variable resistors with rising demand. In addition, product innovations also played an important role in demand performance: for example, the switch from DC converters to three phase converters. At the end of the 1980s and beginning of the 1990s, however, demand for products of the industry grew more moderately, in line with declining investment activities.

Those industries which are closely related to the production and conversion of electricity experienced a quite different development pattern during the 1980s. Increased needs for energy at the beginning of the period resulted in an expansion in the field of energy supply and, therefore, in an expansion of distribution networks. Industries producing equipment such as electricity generators, transformers and high-voltage switchgear (opening, closing and protecting electrical circuits with more than 1 KV), benefited from this development during this period. Decisions to invest in power stations, however, are closely tied to expected growth in the GNP of a country. For this reason, this sector is affected by the general economic situation. While growth in the industry in the EC could be augmented by increased exports, problems arise in the international market. As equipment for the production of electric energy is considered "strategic," many industrial countries take protectionist measures which can limit the opportunities available to the EC manufacturers. In addition, less-developed countries, which have a great need for power stations and equipment, are often financially risky investments.

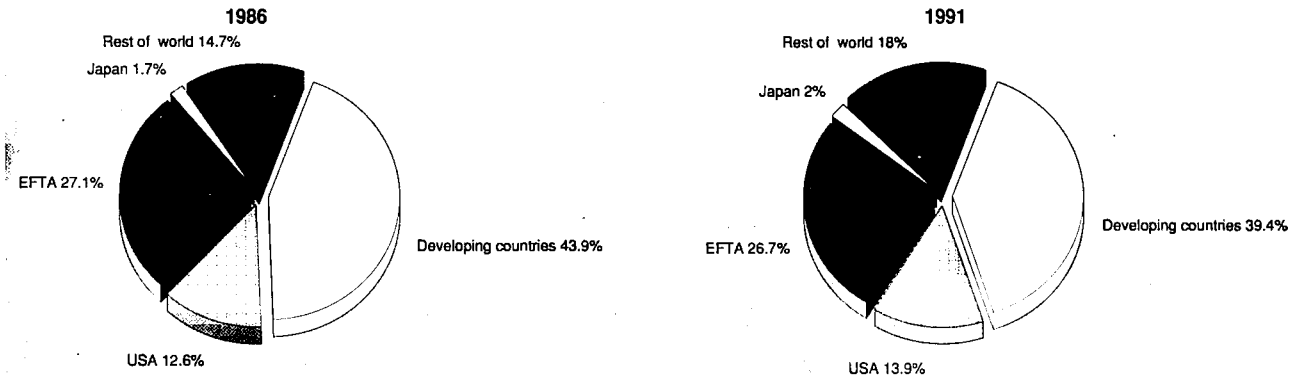
Towards the end of the 1980s, however, the picture changed. In line with the downturn in growth of the electricity sector, as a consequence of saturation effects, the fall in prices of fossil fuels and energy saving measures, demand for this type of product declined. Electricity distribution companies have now completed substantial investments in most of the EC countries, with the result that excess capacity is common.

Figure 5: Electrical machinery
International comparison of production growth at constant prices



EC is BAK estimate
Source: Eurostat, Census of Manufacturers

Figure 6: Electrical machinery
Destination of EC exports



Source: Eurostat

Investments in these areas will therefore be oriented towards replacement, rather than towards capacity widening, for a number of years at least.

Supply and competition

In line with increased demand for the products of the electrical machinery industry, EC production also grew significantly in the 1980s. The EC is the most important producer in the high-voltage switchgears sector, with a world production share of 35% in 1990. The US share reached roughly 28%, slightly above Japan's 26%. In the low-tension switchgear sector, the situation is similar, with EC firms in the leading position (35% in 1990), followed by US firms (24%) and Japanese firms (20%). The USA and the EC, however, lost production shares over the last decade, while Japan increased its share.

The trade balance of the EC deteriorated during the 1980s. The trade surplus in 1991 was only 40% of the surplus in 1982. In the field of transformers, imports increased sharply in the mid-1980s, causing the ratio of exports to imports to drop from 6.3 in 1982 to 2.0 in 1991. The most important competitors in the field of transformers are the USA and Japan, as well as Korea and the EFTA countries, chiefly Switzerland and Sweden.

Regarding high-voltage switchgear, world trade amounted to roughly 23% of world production. This relatively low share is explained by the protective measures of the governments of producing countries. Extra-EC competition in the field of low-tension switchgear increased also, mainly from Japan and the East Asian NICs. The latter are highly competitive in terms of prices, as a consequence of lower production costs and subsidised input prices and dumping policies. Japanese firms, which dominate the market in East Asia, tend towards mass production of standard types of equipment, which allows them to benefit from internal economies of scale.

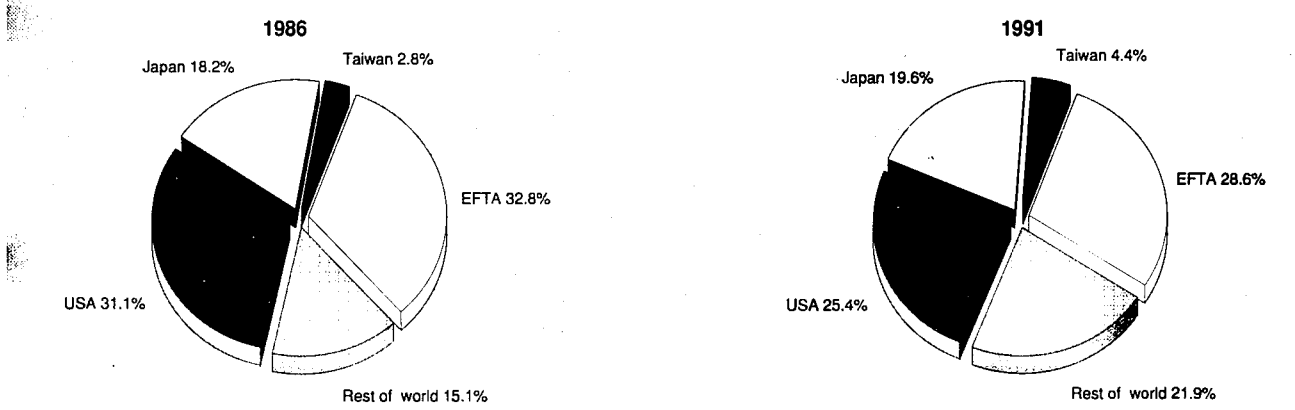
Intra-EC trade in the electrical machinery industry increased considerably as well. This development is mainly the result of the opening of electricity markets to competition, in line with the Single European Market in 1993, stimulating production to get a foothold in other EC countries.

INDUSTRY STRUCTURE

Companies

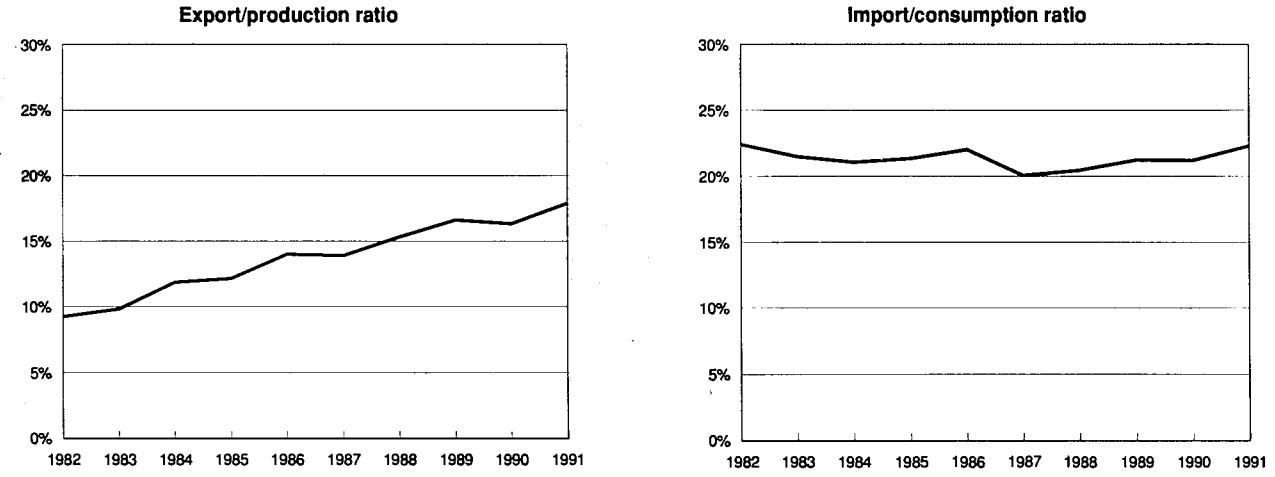
The industry is dominated by a small number of very large companies, which operate in a wide range of activities of the electrical engineering industry. The most important are ABB

Figure 7: Electrical machinery
Origin of EC imports



Source: Eurostat

Figure 8: Electrical machinery
Trade intensities



Source: Eurostat

(CH/S), the largest producer in the EC, Siemens and AEG (D) and GEC-Alsthom (UK/F).

Besides the few large companies, there is an important number of more specialised small and medium-sized companies, including Transfo (F) and Pauwels (B), which specialise in the production of transformers.

Around 35 000 people are employed in the high-voltage switchgear industry in the EC. In the field of low-voltage switchgears, Germany alone, the largest EC producer, employs 48 000 people.

The larger firms in the EC operate in the world market, where they meet strong competition from the USA and Japan. The smaller companies are oriented towards niche markets, and produce client-specific equipment. Consequently, these firms often operating only at the national or regional level.

Among the most important companies in the USA are the Westinghouse Electric Corporation, which is a premier producer of transformers. In Japan, the most important companies are Mitsubishi Electric Corp. and Kawasaki Heavy Industries Ltd, both working in the field of electric power generation equipment.

Strategies

The electrical machinery industry has a relatively strong position in the intra-EC market, with a number of important producers located within Western Europe.

Nevertheless, competition from outside the EC has been growing during the last few years, due mainly to cost advantages of the East Asian NICs. Efforts of the companies, therefore, have to be oriented towards cost reduction. On the other hand EC firms have to increase their R&D expenditures to increase the quality of their products. To meet these challenges, companies have already started their efforts to concentrate the industry.

In the field of transformers, the weakness of demand in the face of excess production capacity has brought about numerous structural changes, as many producers were forced to close production units and to reanalyse product ranges.

Other strategies of EC companies in this context could be an increase in export efforts towards growing markets, such as Eastern Europe, developing countries, and China. China will be an increasingly important potential market in the 1990s; its first nuclear power station went into operation in December, 1991. To be successful in these new markets, Siemens has formed a capital tie with Skoda, a Czech producer of heavy electrical equipment. These two companies plan to set up a joint venture in Czechoslovakia to manufacture equipment for nuclear, thermal and hydroelectric power generation plants, as well as anti-pollution devices. This development is mirrored internationally by a cooperative agreement between Hitachi (Japan) with General Electric Co (USA) for collaboration in the heavy electrical area; one result of the agreement has been the two firms' take-over of the Georgia, USA-based High Voltage Breakers Inc.

REGIONAL DISTRIBUTION

The largest EC producer is Germany, with production estimated at ECU 20 billion in 1991 (roughly 42% of the EC total), followed by France, with ECU 12 billion (26%). Within the various subsectors of the electrical machinery industry, the picture is similar. Germany is the largest producer in the transformer industry, as well as in high-tension and low-tension switchgear. Germany also leads in intra-EC exports of transformers (20% of intra-EC trade), as well as in extra-EC exports (29% of total EC exports).

In the field of high tension switchgear, the production share of the German firms has been declining during the last decade from 42% of total EC production in 1980 to 36% in 1990, mainly to the benefit of Italy, which increased its production share from 14% to 17% during the same period. In the same subsector, the German share of exports in total EC exports declined during the last decade from 36% in 1980 to 30% in 1990. French firms, in contrast increased their market share from 30% in 1980 to 44% in 1990.

ENVIRONMENT

Environmental concerns regarding the production processes are not of major importance for this industry. In the past, the use of PCB to isolate the wires in the body of transformers represented an environmental danger, but this practise ceased during the 1980s.

It is likely, however, that the industry will benefit indirectly from increased concerns about emissions damaging the environment. Carbon power plants, for example, may be substituted with cleaner energy generating methods.

REGULATIONS

Of particular importance to this industry is Directive 89/392, dealing with the standardisation of health and safety requirements of machines. Machinery must conform to these standards to be eligible for the EC label.

OUTLOOK

Prospects for the electrical machinery industry in the EC are characterised by moderate growth overall during 1992 and 1993. Those subsectors of the industry which are closely related to industrial investment activities will continue to suffer from the low propensity of companies in manufacturing to increase their production capacities. In line with the expected economic recovery, demand for this group of products is expected to increase in later years. New markets in developing countries in the short-to medium-term, and in Eastern Europe in the medium-term, will provide stable demand growth in the future. Demand from developed countries, on the other hand, is expected to grow only moderately. Competition from

outside the EC is expected to increase, particularly from the East Asian NICs and Japan.

Subsectors related to the building and expansion of power plants and distribution systems will experience moderate demand growth also. Recent investments in the expansion of electricity networks have led to overcapacities in EC countries; demand for new equipment is therefore expected to decline. Demand for replacement equipment, on the other hand, is expected to be stable. The trend towards more efficient use of energy is an additional factor for slower growth in the next years. Within the EC, new demand can be expected from the Southern European countries and from Ireland, with the building of infrastructure and high-tension links. New demand is also likely to come from the East Asian NICs, Eastern Europe and China. But competition on these markets will restrict the outlet possibilities of EC producers. In Eastern European markets, competition stems from Poland, Bulgaria and the CSFR, which are important manufacturers in the field of high-voltage transformers. In China and East Asian markets, Japanese companies will also be strong competitors.

Within the EC, competition is also expected to increase, as common technical standards and liberalisation aspects foster increased trade between EC member countries, but also ease penetration by non-European competitors.

Electrical equipment for industrial use

NACE 343.1

Most products in the electrical equipment for industrial use sector are used as intermediate inputs for other industries; demand is therefore highly sensitive to economic and business cycles, and can fluctuate widely. Demand was weak in the early 1990s, and is expected to remain so through 1993, when investment-led growth should revitalise demand in Western Europe and other developed countries.
The industry has been restructuring into fewer, larger firms, although a number of small firms remain in niche markets. Firms must maintain their ability to respond quickly to changes in market demand. The competitive position of the EC remains good, but the trade balance surplus is deteriorating.

INDUSTRY PROFILE

Description of the sector

The sector of electrical apparatus, appliances and equipment for industrial use comprises a number of subsectors:

- electrical equipment related to internal combustion engines, to motor vehicles and other means of transport and to traffic;
- electrical industrial and laboratory furnaces, ovens and other types of heating equipment;
- equipment, machinery and materials for electric welding and cutting of metals;
- hand held electrical tools;
- other electrical apparatus, appliances and equipment for industrial use.

Activities are spread among a large number of producers, some specialised, others active in a number of subsectors. In the absence of centralised sources of information and of meaningful statistical material on production and trade, analysis must be done on subsectors, rather than the sector as a whole.

Main indicators

In 1991, total consumption of welding equipment in Germany, France, Italy, the United Kingdom, Spain and the Netherlands was 870 million ECU. About half of the total represents arc welding equipment, 40% represents resistance welding equipment, and a little over 10% is other types of equipment, such as laser and electron beam machines. Germany was the largest consumer (44% of the total), followed by France (22%) and Italy (16%). No data are available on production, consumption and employment in the industry as a whole. In 1991, extra-EC exports for welding equipment were approximately 371 million ECU, compared to power tools export of around 439 million ECU.

Recent trends

Total extra-EC exports grew from 3.2 billion ECU in 1988 to 3.6 billion ECU in 1991, an average yearly increase of 4% in nominal terms. During the same period, extra-EC imports increased from 2.1 billion ECU to 2.85 billion ECU, an average yearly increase of 10.6%. The trade balance remained positive over the period, but the surplus has been declining. Intra-EC trade measured by imports grew at an average rate of around 8% per year during the same period, and represented over two-thirds of total imports in 1991.

Both exports and imports of welding equipment grew strongly in the 1980s. Extra-EC exports grew at an average rate of 4.2% per year from 1982 to 1991, while extra-EC imports grew at an average rate of 10.5% during the same period. As a result, the trade balance, while positive, has been deteriorating rapidly. Intra-EC trade accounts approximately for 60% of total imports of EC member countries.

Trade in power tools also experienced fast growth over the period 1982 to 1991. Extra-EC imports grew 10.4% per year on average, while extra-EC exports grew 6.6%. The trade balance is negative, and the deficit has worsened from a negligible level in 1987 to about 260 million ECU in 1991.

Foreign trade

Extra-EC exports in electrical machinery remain well above extra-EC imports, leading to a strongly positive trade balance. The surplus has been dwindling, however, as import growth consistently outstrips export growth. The share of intra-EC imports out of total imports has remained about 60%.

Destinations of exports are widely spread, with no dominant trading partner. The EFTA countries are the largest block of importers of EC products, as well as the largest exporters to the EC.

Extra-EC imports of power tools increased from about 380 million ECU in 1986 to some 740 million in 1991, representing an average yearly increase of 14% in value. During the same period, extra-EC exports increased at a much slower pace, 4% per year. Imports come mainly from the EFTA countries, especially Switzerland, and also from Japan. EFTA is the largest destination block for exports, absorbing 37% of the total. Germany is by far the largest source of intra-EC trade (52% of the total), followed by the UK (19%).

Extra-EC imports of welding equipment grew from about 170 million ECU in 1986 to some 313 million ECU in 1991, an annual growth rate of 13%. Extra-EC exports, on the other hand, grew by only 1.8% per year. The sources of extra-EC imports are EFTA, with 40% of the market in 1991; Japan with 15% and the US with 10%. As with power tools, extra-EC exports of welding equipment are much more widely spread, with EFTA countries, the largest client block, absorbing only

22%. Regarding intra-EC trade, Germany is the largest supplier (38% of the total), followed by Italy (18%) and France (13%).

MARKET FORCES

Demand

Apart from the subsector of power tools, whose demand is determined to a large extent by private household expenditure, all of the products of the electrical machinery sector are either intermediate goods used as inputs in other industries, or investment goods used to increase production capacities or production efficiency. Even welding consumables (filler materials) are not actually consumed but are used in connection with the production of durable investment or consumer goods such as cars and ships. Demand for the products of the sector, therefore, is determined mainly by the evolution of production of a large number of client sectors, primarily those that purchase investment goods.

For example, for electric equipment related to internal combustion engines, motor vehicles and other means of transport, demand is determined by the level of production of transport equipment, and by replacement needs.

For furnaces and ovens, demand is related mostly to the construction or re-equipping of certain types of manufacturing plants, as well as of levels of R & D activity.

The largest source of demand for welding equipment and materials is the transport industry (the construction of cars, ships, pipelines etc.) but a wide range of other activities such as the production of cans, cross-wire products and steel constructions can also have an effect.

Demand for electrical tools is driven mainly by small scale manufacturing, arts and crafts, hobbies and do-it-yourself activities.

For most products of the sector, swings in the general level of economic activity will cause even wider swings in demand. As economic growth falters, the first affected are the investment goods industries. A renewal of aggregate demand will bring about shortages in production capacity and trigger sharp increases in investments. Thus, the fast pace of economic growth which characterised most of the developed world during the second half of the eighties also brought fast growth in demand for electronic equipment for industrial use. The world-wide slowdown in economic activity, which started in 1990 and is widely expected to last until the end of 1992, caused sharp drops in demand for all the goods of the sector.

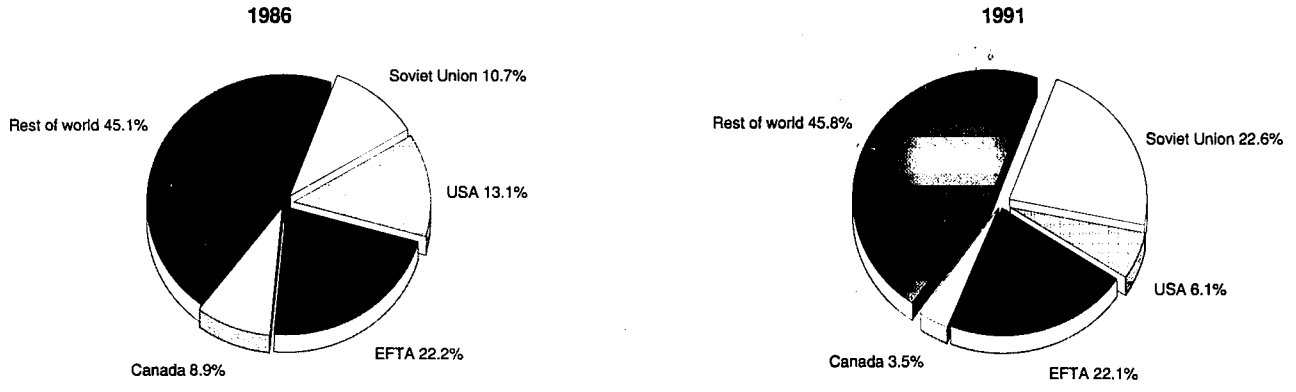
Figure 3: Welding equipment
Destination of EC exports



Source: Eurostat

Supply and competition

The EC is a long-standing leader in most of the subsectors of the industry, with a large number of firms catering to the needs of client industries. Competition is intense within the EC, but less so outside. Many of the products and types of equipment are custom-made according to the specific needs of the client industry, which increases the importance of geographical proximity and cooperation between supplier and user over pricing. For mass-produced products such as power tools, however, competition from low cost producers is potentially dangerous.

In welding equipment, especially in equipment for car assembly lines, EC-based producers usually have an advantage over potential suppliers from other countries. On the other hand, "transplant" production facilities are almost always equipped by in-house suppliers of the parent company. For example, Japanese car transplants in the UK buy all of their equipment from their home country. The same is true for European car transplants in other parts of the world, such as Latin America.

Price and profit trends in the industry follow the business cycle. In periods of fast demand growth, prices and profits are high, as production runs into capacity constraints. Shrinking markets heighten competition, and cause prices and turnover to drop, and profits to plunge.

Production process

For most of the sector's products, raw materials and energy represent a small portion of production costs. R&D is a very important input, as products must adjust to changes in production processes in the client industries. A major part of the labour force is skilled.

Technological change is evolutionary rather than revolutionary. The adoption of major innovations, such as laser cutting/welding technologies or electron-beam welding is held back by difficulties on the part of client industries to master new, untested production processes, as well as by other problems, such as the high cost of certification when a new technology is being introduced.

INDUSTRY STRUCTURE

Companies

Industry has been undergoing a restructuring process, with smaller firms merging into larger ones, both domestically and internationally. Within each subsector of the industry there are a small number of large integrated firms, often active in

Source: Eurostat

other sectors, in addition to smaller more specialised firms, which are strong in a particular field or in a niche-market.

The welding equipment subsector is divided into two fields: arc welding and resistance welding. In the arc welding field, where individual machines are of relatively small value but consumption of filler-materials represents a large part of welding cost, sales are usually made through a network of distributors. There are about half a dozen major companies which are the result of the consolidation process carried out over the 1980s: ESAB (S/UK), SAF (F), Lincoln (USA), with Messer-Griesheim (D), Oerlikon (CH). Hobart & Miller (USA) is also a major player in the European market. Further consolidation has been taking place in the early 1990s.

In the resistance welding field, the number of significant firms is much larger. A number of companies have grown out of the resistance welding field and into automation, and are mainly involved in the production of transfer lines used for the assembly of automobiles. These companies include: Sciaky (F), the major independent in Europe, Renault Automation (F), KUKA (D), Comau (I), a subsidiary of Fiat, Lamb-Technikon and Stadco (UK). Comau operates in other fields of activities as well, such as machining operations.

Another group of companies in the resistance welding field make more standard machines, such as classic spot welders, projection, seam welders or various types of specialised equipment. These comprise a number of very large companies (500 workers and more), including Sciaky, Comau and Renault Automation, and a large number of smaller companies in the range of 150 workers who sub-contract more of their work. Most of the firms in the industry operate internationally.

Strategies

The sector of electrical equipment for industrial use is strongly affected by economic cycles, with demand rising in times of investment-led growth, and plunging in times of slow growth. Firms in the sector must therefore be organised in ways which enable them to respond quickly to fluctuations in demand. R & D is an important factor in maintaining competitiveness, as is close cooperation with client sectors, to better adapt products to client needs and to build up customer loyalty.

ENVIRONMENT

Production processes in the sector of electrical equipment for industrial use have few environmental effects: energy consumption is low, emission of noxious fumes or other pollutants is negligible.

Recycling in the industry is rarely a problem, since the industry produces relatively low volume, high value added products, with a large share of recyclable metals in their materials composition. For the arc welding industry, fumes represent a problem at the user end, due to the special composition of the different types of electrodes used in the welding process. The danger is not to the environment but to the workers; aeration systems, filters, and masks are used to combat the problem.

REGULATIONS

The only regulations concerning the industry are those concerned the homogenisation of norms across the EC. Only standard components, such as transformers, electrodes and cables, are affected. Most of the equipment produced by the industry is highly specialised and built to satisfy specific requirements; there is little scope for imposed normalisation. Some types of equipment produce electro-magnetic radiation and the EC Commission is working on a regulation to reduce its possible negative effects on workers and the environment.

In addition, Directive 89/392 deals with the standardisation of safety and health requirements for machines throughout the EC.

OUTLOOK

The outlook for the industry of electrical equipment for industrial use is closely related to the outlook for its client industries.

The car industry has not been experiencing rapid growth since the end of the 1980s, and is not expected to recover significantly until the end of 1992. After that time, however, prospects are rather good, particularly in the longer run once the Eastern European market revitalises, after the mid 1990s. This in turn will foster growth in the subsectors related to the automobiles industry such as electrical components for motor vehicles and in the welding industry.

Demand for traffic related equipment has remained strong in a number of EC countries, mainly France, Spain and Germany, thanks to wide ranging railroad development projects. This is expected to continue in future.

Demand for other types of equipment is expected to benefit from the general recovery of business investment in the EC which is expected from 1993 onwards.

Demand and consumption for products will start growing slowly in 1993 and will reach relatively high growth rates in later years. Production is expected to grow at similar rates, as both extra-EC imports and exports should follow similar growth paths as demand. In the longer run, export growth should outstrip import growth, due to the development of demand in Eastern Europe.

Batteries and accumulators

NACE 343.2

The industry of batteries and accumulators has benefited from a favourable economic climate during the last decade. Increased demand for portable electronic equipment and booming sales of motor vehicles provided the industry with a stable growth path, although much of the demand for batteries and accumulators has been filled by imports, resulting in a negative trade balance.

The battery industry is highly concentrated; the top four producers account for 80% of the market. The accumulator market is less concentrated, but the competitive nature of the industry as well as the innovative requirements of client industries demand such high R&D costs that small companies are forced to merge to stay competitive.

East Asian competition in accumulators has been growing stronger on a price basis. EC environmental regulations could force EC producers to raise prices to cover costs, weakening their competitivity in relation to East Asian suppliers.

INDUSTRY PROFILE

Description of the sector

The batteries and accumulators industry can be subdivided into two main subsectors: the production of primary batteries, which are not rechargeable; and the production of rechargeable batteries, that is, accumulators.

There are six types of primary non-rechargeable batteries: zinc carbon batteries, which were the first dry batteries and are still in use today; alkaline manganese batteries, which have a longer life than zinc carbon batteries; mercuric oxide batteries; silver oxide batteries; zinc air batteries; and lithium batteries.

There are two main types of accumulators: lead acid batteries and nickel cadmium batteries.

Accumulators can be further subdivided into three types, depending on their use. Drive batteries are used to operate electric motors to propel vehicles, in particular handling equipment, but also electric cars. Stationary batteries, used mainly for the operation of emergency devices such as alarm and control systems, as back-up in case of power-breaks. Starter batteries, are used in motor vehicles to provide electric power until the internal combustion motor has been started.

Main indicators

Total sales of starter batteries in the EC rose by 2.3% per year from 1982 to 1990, and reached 47 million units by the end of the period. Domestic sales of European producers (including EFTA countries) increased by 1.6% on average during this period, with demand from car manufacturers (34% of domestic sales in 1990) the most significant force. In 1990, direct sales to car manufacturers declined by about 3.2%, but sales to other customers continued to increase, up to 4.7%. Imports from non European countries, excluding imports by Western European producers, increased by 4.5% per year during the 1980s, to reach 30% of total sales, compared to 15% in 1980. Intra-EC trade also increased, stimulated by competition between EC member countries, mainly with the establishment of the common market. As a consequence of the strong price competition from abroad, and in view of the overcapacities in the sector, it can be expected that prices will decline in the next few years.

In 1990, the primary battery industry employed roughly 15 000 people in Western Europe, in a total of 10 factories. In the accumulator industry, about 40 000 people were employed in roughly 80 factories. As a result of the slowing production growth and the need to increase productivity and to reduce costs in the face of stiffening competition world-wide, employment levels are expected to keep falling into the mid-1990s.

Foreign trade

Extra-EC trade in batteries and accumulators increased rapidly during the last decade. While exports grew by roughly 2% per year in value from 1985 to 1991, imports increased at an annual rate of about 13% for the same period. Thus, while extra-EC imports equalled only about 80% of exports in 1985, the balance turned negative by 1987, and imports exceeded exports by over 40% in 1991. Nearly all countries within the EC increased their imports by double digit growth rates each year by the end of the 1980s. The most important importers in the EC are Germany (35% of total EC imports in 1991), the United Kingdom (16%), France (13%), the Netherlands (11%) and Italy (10%). These countries together represent about 86% of total extra-EC imports.

Intra-EC trade also increased rapidly from 1985 to 1991, by roughly 8% per year.

MARKET FORCES

Demand

Demand for the products of the industry as a whole increased considerably during the 1980s. Different types of products respond to different demand patterns, however. The volume of the market of non-rechargeable primary batteries grew by about 2% per year on average at the end of the 1980s. Primary

batteries are used in high-fidelity equipment (50%), games (20%), lighting (11%), watches and alarms (11%), and photo equipment (8%).

Product innovations using nickel and cadmium resulted in batteries which are lighter and live longer (5 to 10 years) than the traditional storage batteries. In 1989, an estimated 9 million units of rechargeable batteries were sold in Europe.

Among accumulators, the largest market by far is for starter batteries, mainly used for motor vehicles. In Western Europe, this market represented some 45 million units by the end of the 1980s, about one third of which were used in new motor vehicles, and the remaining two thirds were mostly used as replacements in older motor vehicles.

Supply and competition

The most important producers of batteries and accumulators in the EC are Germany, Italy, the United Kingdom and the Netherlands. Outside the EC, the most important producers and strongest competitors are the United States and Japan. Since the most important producers of primary cell batteries have production facilities in EC countries, competition from outside the EC is not increasing significantly. In the field of accumulators, on the other hand, competition has been rising, particularly from Japanese, South Korean and Indonesian firms. Products from these countries are especially competitive in terms of price as a result of lower unit costs, including subsidised raw materials and an export-dumping policy, particularly in East Asian countries, according to EC producers. The fact that production of these products requires little skilled labour apparently represents an important comparative advantage for these countries, which have plentiful unskilled labour.

Production process

The relatively low level of sophistication of the production process eases automation efforts.

The performance development of portable electrical equipment, which requires a portable source of electricity, was made possible by product innovations in the field of batteries. The short-lived zinc-carbon battery has been partially substituted for by alkaline batteries, with a life three times longer; the latter accounts now for roughly 40% of the market in the EC. Even newer developments are in zinc-air and lithium batteries.

Rechargeable batteries (accumulators) are increasingly used in portable electric and electronic equipment, particularly in equipment which require relatively large amounts of energy such as computers, tools, and appliances. Demand for accumulators has been booming since 1985, when nickel-cadmium rechargeable batteries came on the market for the general public. The annual growth in sales is estimated at 15% to 20%.

INDUSTRY STRUCTURE

Companies

There are about 12 firms which produce primary batteries in Western Europe, the four largest of which cover about 80% of the market. These firms include the US based Duracell in the United Kingdom, Varta in Germany, Philips in The Netherlands and the US based Ralston Energy Systems in Switzerland. Other important manufacturers are the American Kodak, and the Japanese Sanyo and Matushita.

There are about 25 firms producing accumulators in the EC. The most important are Varta in Germany, the French company Saft and CEAC (jointly owned by the Italian company Fiat and the French Alcatel Alsthom), Hawker in the United Kingdom.

The largest firm in the EC is Varta, which is active in both primary batteries and accumulators; this company has 35 subsidiaries spread over the world. The group realises roughly

40% of its turnover in portable batteries, 27% in starter batteries and nearly 23% in storage batteries for industry. All firms in the industry are operating at least on the European market and many of them are operating globally.

Strategies

The EC industry is characterised by surplus production capacity, and by strong and growing competition from outside the EC. These factors together will continue to push prices down. To combat the squeeze on profits, companies have had to rationalise production to increase efficiency and reduce costs. In particular, efforts are oriented towards more concentration, in order to profit from economies of scale. The American Ralston (based also in Switzerland) for example, has taken over the French firms Wonder and Mazda. Companies are also investing with the goal of penetrating new, expanding markets. Examples are the German firm Varta, which is establishing subsidiaries in countries as diverse as Finland, Argentina, Mexico, Brazil and Singapore, and the French Saft, which is doing the same in Korea and Finland, from which they hope to penetrate markets in East Asia and Eastern Europe. In order to counteract competition from firms from outside the EC, some of which are highly competitive in terms of technology (USA and EFTA in particular), EC firms must increase R&D efforts, with a view towards bettering the quality of products. Improvements can be made in the direction of longer-life or in the context of environmental concerns.

Smaller companies are forced to operate in niche markets, which are very demanding in terms of technology and quality. These firms may face difficulties with the financing of R&D expenditures; cooperation in this field could offset these costs.

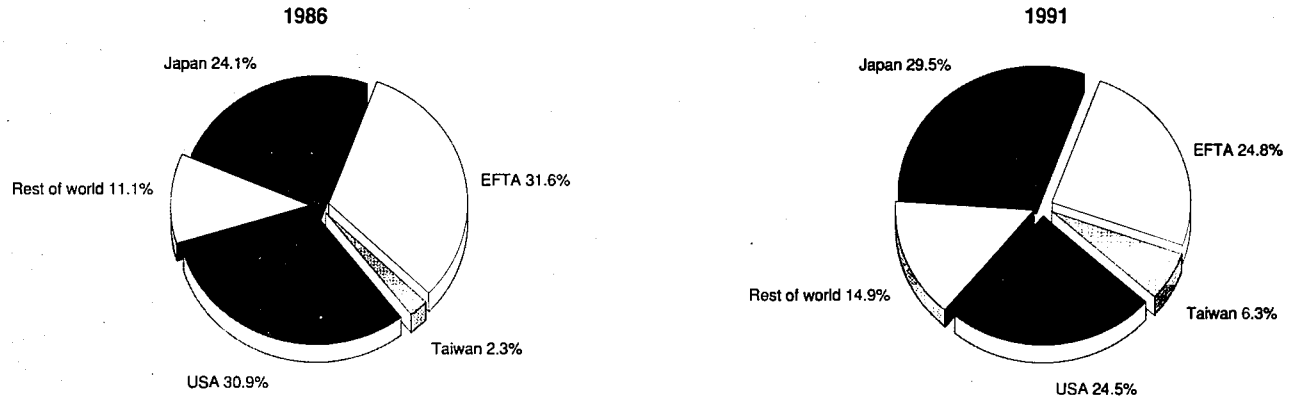
REGIONAL DISTRIBUTION

Within the EC, the main producers are Germany, Italy, the United Kingdom and the Netherlands. This is also where the most important firms are located. In rechargeable batteries, the leading EC producer is Saft (France); the biggest producers in the world, however, are the Japanese companies Sanyo and Matushita. In primary dry cell batteries, the world's largest producer is the American Duracell.

ENVIRONMENT

Some of the most important product innovations in the industry over the last few years have taken place in the context of the environment. The reduction of the heavy metals content

Figure 2: Batteries and accumulators
Origin of EC imports



Source: Eurostat

of non-rechargeable batteries is of primary concern. Mercury has been used traditionally in both saline and alkaline batteries. Two EC directives in 1982 and 1984 require the reduction of mercury waste, which is harmful to the environment. Since 1985, producers of primary batteries in the EC have cut the amount of mercury discharged from batteries to the environment by almost 50%, and plan to reduce this by another 84% by 1992. The reduction in mercury waste has been the result of two developments: the 97.5% reduction of mercury in alkaline-manganese batteries, compared to 1985 levels, which eliminated the need to collect these batteries separately; and the replacement of mercuric-oxide batteries (containing 30% mercury) by zinc-air batteries (around 1% mercury) and lithium batteries (0% mercury).

Other environmental efforts are oriented towards recycling batteries. Some Member States have already introduced separate waste collection for primary batteries containing mercury. In 1991, the EC Commission proposed a directive concerning batteries containing harmful substances, requiring producers to take back used batteries, so that the materials can be recycled. The required low energy and low emissions recycling techniques are not available at the moment, however, except for lead recycling. In the field of lead-acid accumulators the recycling quota is already close to 100%; in nickel-cadmium batteries it is about 60%. In addition to the technological aspects of the problems, the use of recycled materials in batteries is likely to increase production costs, with a corresponding increase in price. If international competition does not face the same requirements, EC producers could lose price competitiveness

OUTLOOK

Prospects for the industry are quite favourable for the early to mid-1990s. Increased use of portable electronic equipment is expected to bring about increases in demand for batteries and accumulators. In the field of primary batteries, demand growth is further stimulated by the development of better, longer lasting products, such as the relatively new lithium batteries, which last about seven times longer than ordinary batteries. The trend towards miniaturisation of appliances, requiring smaller and more powerful batteries, will further feed demand growth in the future. In the field of accumulators, the development of demand is not expected to be as favourable as in primary batteries in the short term, until sales of new cars start growing again. In the medium term, however, demand for accumulators should increase fed both by growing sales of new motor vehicles and by growing demand for replacement batteries. The challenge of competition from extra-EC countries, especially East Asia, will have to be met by increasing rationalisation efforts, as well as by fast rates of product improvement, fed by intensive R&D investments.

Domestic electrical appliances

NACE 346

EC production growth has slowed since the end of 1988, but was boosted in 1991 by the reunification of Germany, which enabled both German manufacturers to significantly increase production and other European manufacturers to increase sales within Germany. This one-time special growth has now lost momentum, and growth is expected to return to 1989 and 1990 rates.

As technological improvements continue to impact favourably on productivity, employment in the industry is likely to fall. Over-capacity, which has been a feature of recent years, will lead to continuing consolidation through M&A activity. The greatest movement in this area in recent years has been in Spain, where, as tariffs have been eliminated in line with integration within the EC, the majority of remaining independent companies have been acquired by major European manufacturers.

INDUSTRY PROFILE

Description of the sector

NACE 346 covers the manufacture of electrical appliances generally intended for domestic use. It included the following articles: microwave ovens; cookers (free-standing and built-in); dishwashers; home laundry products (including washing machines); spin-dryers and tumble dryers; refrigeration products (refrigerators and freezers); personal care products (hair dryers, etc.); small kitchen appliances; vacuum cleaners; irons; heating products.

Main indicators

In 1991, the value of EC production of electric domestic appliances amounted to about 24 billion ECU.

In 1990, the overall European market was distorted by the reunification process in Germany, which significantly inflated that market and therefore increased Germany's share of the total market to twice the size of the markets of the United Kingdom, France and Italy, all of which were similar in size. The Spanish market size was around half of the size of the three countries above.

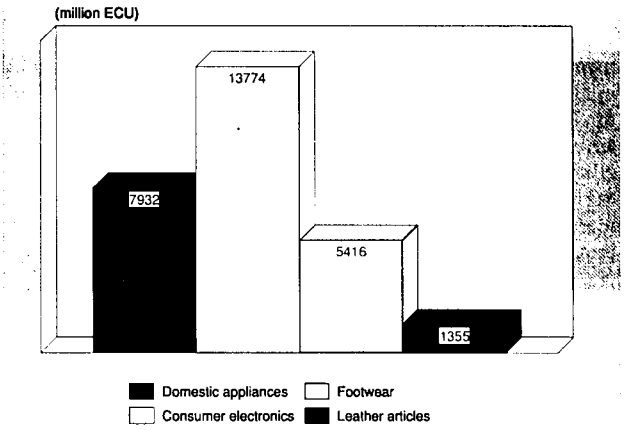
In production terms the German industry in 1990 remained the largest, representing around 36% of EC production, followed by Italy at 25%, the United Kingdom and France each with 12% and Spain with 7%.

International comparison

In major product areas, particularly in home laundry and refrigeration products, the EC remains a net exporter by value. In small appliances and microwave ovens, the level of imports from the Far East remains high, in recent years from South Korea, Taiwan and China rather than, as in earlier years, from Japan.

EC production and apparent consumption are both considerably higher than in the USA and Japan. However, Japanese production growth was higher than that of the EC or the USA in 1990 and 1991. EC growth was slow in those years, while the USA experienced negative growth.

Figure 1: Domestic electrical appliances Value added in comparison with other industries, 1991



Source: Eurostat

MARKET FORCES

Demand

Unlike the sectors of electrical equipment and telecommunications, which are driven by investment, domestic appliances depend on consumer demand and building activity. An important factor in consumption trends over the 1980s and early 1990s has been the degree of market saturation, which, for many products, has increased over the last decade. In 1989, 98% of households owned refrigerators, 89% owned washing machines, and 88% owned vacuum cleaners. Ownership of freezers and dishwashers is lower, and growth shows some variability, but overall both grew significantly from 1980 to 1989.

At high penetration rates, most products are purchased as replacements. However, socio-economic factors such as an increase in single person households have kept the number of households making first purchases growing.

The proportion of extra-EC exports to production remained steady from 1982 to 1991, at around 12%. The EC maintains a positive trade balance which has varied a bit due to variable imports, but which was slightly down in 1991 compared to 1982. Although international trade is highly competitive, trans-

portation costs keep foreign trade a small part of production and consumption. Three of the four most important markets for EC goods are located in Europe (Austria, Switzerland and Sweden). For EC imports, over 30% come from EFTA countries, followed at a distant second by China which provides 14%.

Supply

The domestic appliance industry is relatively highly concentrated compared to other industries; mass production methods and economies of scale are particularly important aspects in the manufacture of these types of products. Over the last three decades, industry concentration has increased, with a decline in the number of manufacturers which can be seen in Figure 6.

In the United Kingdom and France, the retail sector is increasingly dominated by hypermarkets and major chains, leading to a squeeze on margins at both the retail and manufacturing ends of the business. In other EC countries, the market remains in the hands of independent retailers, although mail-order companies with retail outlets, such as Quelle in Germany, are prominent.

INDUSTRY STRUCTURE

Companies

The enterprise with the largest market share is based outside the EC: Electrolux of Sweden. However Electrolux production is mainly within EC countries, as are all the other major enterprises. Most of the major enterprises market more than one brand-name. In particular, Electrolux markets the Zanussi brand through Europe, Arthur Martin in France, Tricity Bendix in the United Kingdom, Zanker in Germany, and Ibelsa and Domar in Spain. Whirlpool, who completed the purchase of the Philips major appliance business in 1991, still uses the Philips brand name in some countries, and the Bauknecht and Ignis brand in most countries.

Strategies

Consolidation of the industry through acquisitions and mergers, which was a feature of the 1980s, will continue through the 1990s. This decade will also see a number of large enterprises pooling technical information, particularly in meeting the requirements of environmental standards or regulations.

ENVIRONMENT

There is as yet no overt pressure from consumers on environmental issues, but the Domestic Appliance industry has a high profile with consumers, and therefore current environmental concerns impact strongly on the industry. Although domestic refrigeration products are not heavy users of CFCs (4.3% of Montreal Protocol base figure), the elimination of CFCs by end 1998, now advanced to 1996, presents the industry with major design and production problems.

The need for substitute products within a short time-scale that use materials satisfying flammability, toxicity, and carcinogenic criteria while maintaining a long economic life to satisfy consumers, is blocking other technological advances.

For home laundry products and dishwashers, the proposed eco-labelling schemes are setting challenges in the area of energy and water consumption and detergent usage.

OUTLOOK

The Domestic electricalal appliance industry relates closely to general economic circumstances. The major selling appliances operate in a mature market, and thus are reliant on general consumer confidence. Many products, in particular long-life products such as cookers and refrigerators and freezers, experience growth or slump in direct relationship to home

movements. Thus forward forecasts are only able to mirror overall economic conditions.

Nevertheless overall growth will occur through the 1990s with the continued growth of home ownership of dishwashers and microwave ovens, which have not yet reached the mature market state. Some manufacturers have been looking for a new growth market in air-conditioning products, but this is now more problematic due to environment related restraints.

Numbers of people in the industry employed in the industry will remain static or decline marginally as growth is matched by improved productivity and further rationalisation.

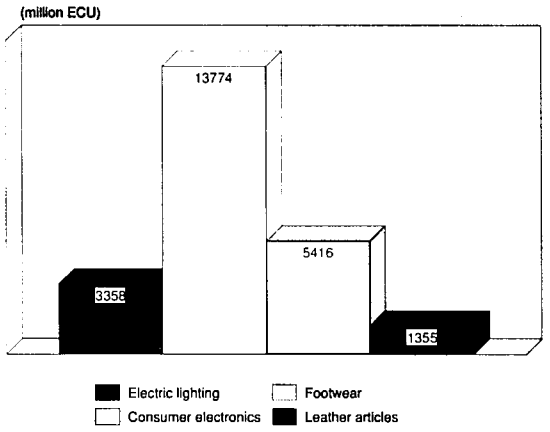
Electric lighting
NACE 347

After suffering a decline in production at the beginning of the 1980s, the EC electric lighting industry experienced fast growth in the second half of the decade. This was mainly the result of increased construction activity since 1986 which led to fast rises in demand for new lamps and lighting equipment. Competition from the East Asian NIC's has been increasing during the last few years, with the result that these countries have considerably increased their market share in the EC to the detriment of the more traditional sources of imports such as the EFTA countries, the USA and Japan.
Prospects in the medium-term are quite favourable, as demand will be stimulated by increased construction activity, as well as by product innovation.

Figure 1: Electric lighting
Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

The electric lighting industry can be divided into two main subsectors:

- electric lamps which includes incandescent lamps, discharge lamps and dual lamps, as well as the catch-all group of "other electric lamps";
- electric lighting equipment, which comprises indoor electric lighting equipment, special purpose electric lights, portable lights, outdoor lights, spotlights (excluding lights for motor vehicles) and parts for electric lights.

Main indicators

The EC electric lighting industry experienced fast growth in production and apparent consumption over most of the last decade. In 1991, about 16% of EC production was sold outside the EC. The share of extra-EC imports has been consistently low, below 12%, over the last decade, with a jump to 12.6% in 1991. The trade balance, however, which showed steady growth throughout the 1980s, declined in 1991 and is expected to decline further in 1992.

Germany had by far the highest value added in the industry in 1991; nearly three times the value added of the second biggest producer, the United Kingdom.

Recent trends

Production at constant prices rose during most of the 1980s, but decreased in 1991. It has still shown faster growth than production for manufacturing in general, however. Employment has been variable since 1982, but growth has been above growth for manufacturing since 1986

Demand for products of the electric lighting industry, measured in terms of apparent consumption at constant prices, increased considerably during the 1980s, particularly so in the second half of the decade. The development of demand was reflected in a similar rise in production over the same period. Extra-EC imports increased at a slightly faster pace than demand, but extra EC exports developed less favourably. As a result, the industry's trade balance has been deteriorating since 1985.

Foreign trade

Extra-EC exports increased 5.4% per year in value from 1982 to 1991; imports from outside the EC, on the other hand, increased by nearly 11% per year on average during the same period. The most important market for EC producers is the EFTA, which purchased nearly 40% of extra-EC exports in 1991. The United States, with 11% of the EC exports, and Japan, with 6%, are far behind. Exports to developing countries, including the East Asian NICs, declined by over 20% between 1985 and 1991. The largest percentage of imports still come from the EFTA countries, at about 27% of the total, but, in general, imports from the traditional suppliers have been declining in general, to the benefit of the developing countries; the latter have seen their imports into the EC double from 1986 to 1991 to reach 24% of the total at the end of that period.

Trade between EC member countries, measured in terms of intra-EC imports, increased by 11% per year from 1982 to 1991; the volume is more than twice as large as imports from outside the EC.

MARKET FORCES

Demand

Demand for the products of the electric lighting industry is determined by two main factors: replacement demand, and demand for the equipment of new buildings, dwellings and development projects. The first source of demand is relatively insensitive to economic cycles, although the pace of growth of disposable income, as well as technological developments

and fashion trends, can affect replacement rates to a certain extent.

The second source of demand, on the other hand, is highly cyclical, tied closely to the business cycle, and in particular to its effects on the level of building activity. Thus, electric lighting industry demand benefited considerably from the boom in the EC construction industry which took place in the second half of the 1980s. Similarly, demand is expected to suffer from the downturn in construction activity which hit the EC in 1991, and should continue to decline through 1992 and part of 1993.

As previously mentioned, product innovation may prove to be an important source of additional demand. The trend towards more efficient use of energy has brought about increased demand for low voltage discharge lamps and for compact fluorescent lamps; halogen lamps have increasingly gained acceptance in private households, after having been initially developed for industrial and outdoor uses.

Supply and competition

Among the Triad countries (the USA, the EC, and Japan) the USA is the most important producer of electric lighting equipment and lamps, with about 48% of total production in 1991, followed by the EC, with about 34%; and Japan with roughly 17%. As mentioned, extra-EC imports from outside the EC increased at a significantly higher rate than extra-EC exports. In particular, imports from Taiwan increased from 2.5% of total extra-EC imports to roughly 12% in 1991; China also managed to increase its market share in the EC. Imports from Japan, China and other East Asian countries increased particularly in the field of halogen lamps.

This does not indicate that EC firms have been losing competitiveness in all markets, however. There is a wide range of European produced lamps, especially compact fluorescent lamps and metal halide lamps, that have significantly increased exports. Similarly, high quality design luminaires from Europe have also shown export growth to many countries including Japan. Trade between EC member countries enjoyed fast growth as well during the last decade, at a rate of roughly 4% per year in real terms.

Production process

At the beginning of the 1980s the industry was characterised by significant declines in employment, following increased

Figure 4: Electric lighting

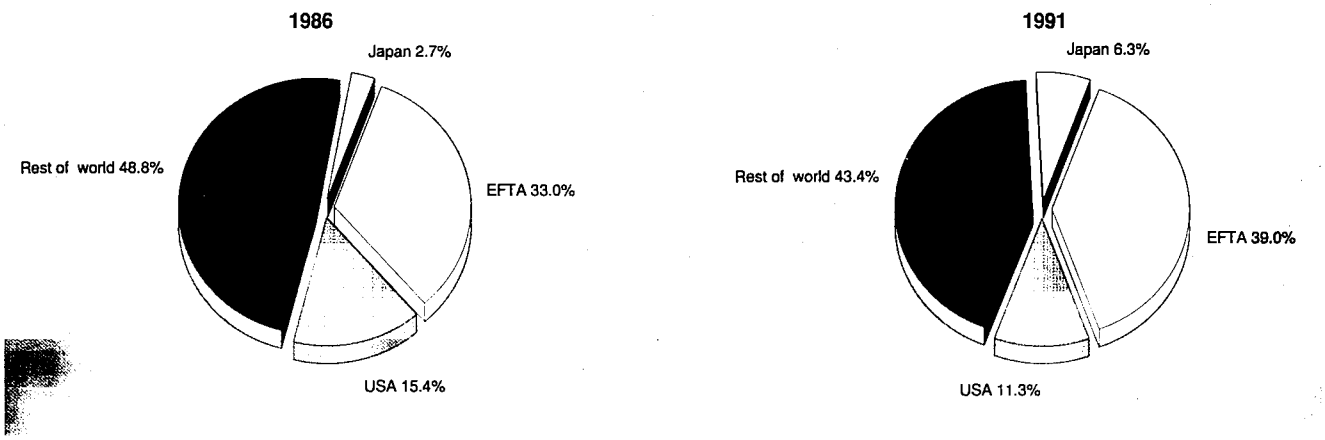
Figure 6: Electric lighting
Destination of EC exports



Source: Eurostat

efforts of firms to reduce production overcapacities and to adjust to declining demand during that same period. Total employment in the EC declined by roughly 5% during the period 1982 to 1986. In the second half of the 1980s, on the other hand, the rise in demand and in production was accompanied by a slow rise in employment of 1.4% per year. In 1991, total employment in the industry reached 102 000. Spain was most deeply affected by decreases in employment: from 1982 to 1989, employment fell about 53% percent from its 1982 level. In the other countries (with the exception of Portugal), the work force increased during the period 1982 to 1991. Productivity, on the other hand, increased by roughly 3% during the same period, as the increase in output (in terms of value added), was stronger than the increase in employment growth.

INDUSTRY STRUCTURE

Companies

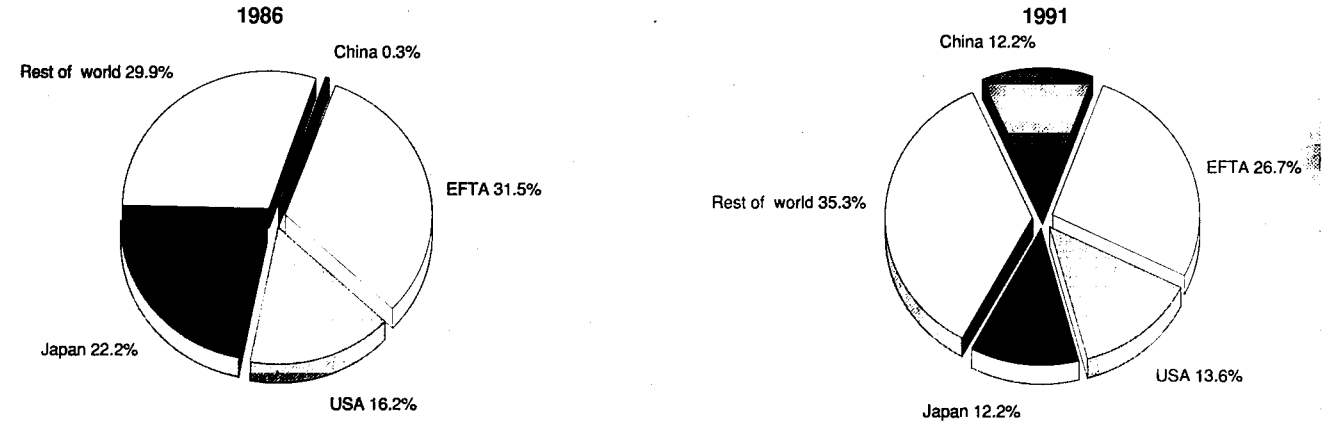
In the field of electric lamps, EC production is dominated by a small number of large firms which are able to profit from economies of scale and to muster the substantial resources necessary for R&D activities. All of these firms operate internationally. The most important firm in that sub-sector is Philips (NL), which plays a central role in assuring the dominant position of the Netherlands in the EC electric lamps sector. Another important firm is the Osram (D), a division of Siemens. General Electric (USA) bought the European firms Thorn EMI (UK) and Tungsram (Hungary) in the late 1980s. The fourth largest lamp company is Sylvania, which is a part of GTE (USA). Sylvania Europe will become part of a new company, Sylvania Lighting International, which will be owned by an investment group led by Citicorp.

In the subsector of electric lighting equipment, production is much more fragmented, and many of the firms operate regionally or locally. The most important firms are Siemens, Trilux and AEG in Germany, Philips in the Netherlands and Thorn Lighting in the United Kingdom. Important firms in other countries are Zumtobel (Austria) and Lithonia and Cooper, the two largest producers in the USA. Sylvania is also active in electric lighting equipment under various brand names.

Strategies

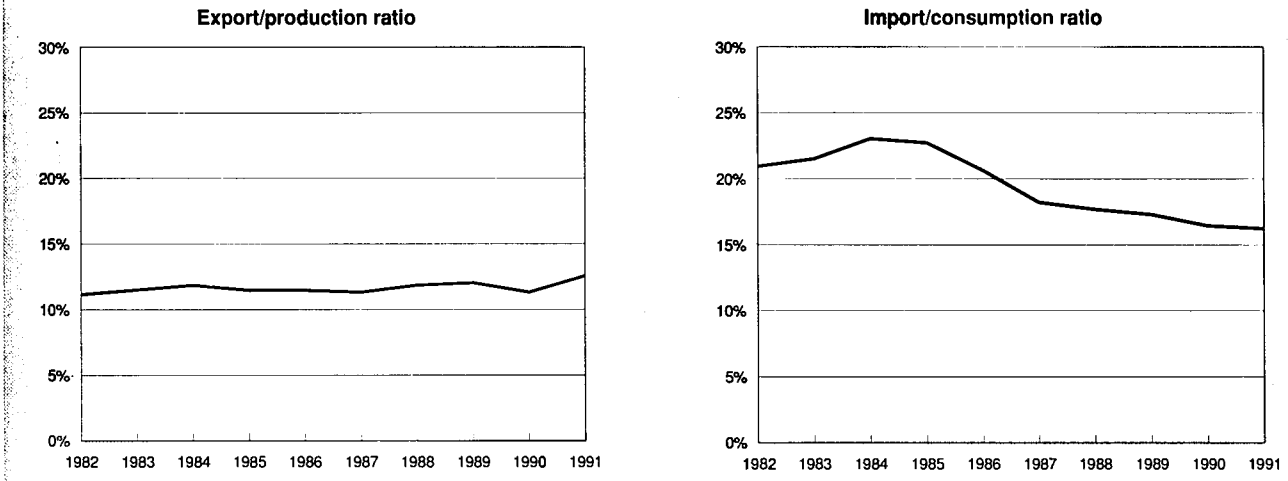
Europe is the leader in the field of technologically advanced products, both in new lighting technology and in luminaire

Figure 7: Electric lighting
Origin of EC imports



Source: Eurostat

Figure 8: Electric lighting
Trade intensities



Source: Eurostat

design, and is successfully exporting to the USA, Japan and other countries. EC firms in the electrical lighting industry are faced with stiff competition in the field of less technologically advanced products, by competitors from the East Asian NIC's and from China. The most important advantage of the latter is on the cost side, as costs of labour, raw materials and energy are lower than in EC countries. Consequently, EC firms must intensify efforts to improve production efficiency, to compensate for unit cost advantages in lower value added products, presumably through increased substitution of labour by capital, especially increased automation. Efforts have to be expended in quality improvement, as well. In the field of technologically advanced products, on the other hand, EC firms must increase R&D expenditures, to maintain competitiveness with other industrialised countries. Efforts in this field are already apparent, as shown by the increase in intra-EC investment, which doubled between 1980 and 1988. Consequently, the above mentioned trend towards increased size of firms is likely to continue in the 1990s. The concentration process will probably be accompanied by a reduction of the labour force in the industry.

REGIONAL DISTRIBUTION

The most important producer within the EC is Germany (West), with about 38% of total EC production (excluding the Netherlands, for which no data are available), followed by France with roughly 20%, the United Kingdom with about 17% and Italy with 10%. The most important intra-EC exporter is Germany (West), with about 30% of the total; followed by Italy (27%), and Belgium and France (12% each). Germany and France are the most important markets for other EC countries' exports, each accounting for about 20% of total intra-EC trade.

REGULATIONS

The penetration of the EC market by halogen lamp imports from Japan, China and other Eastern countries, has stimulated the EC Commission to impose provisional anti-dumping duties as high as 85.4% on halogen lamps imports from Japan for 1990.

The most important regulation in preparation concerns the harmonisation of norms applicable to electrical equipment, which has been undertaken by the EC Commission. This should have a positive impact on intra-EC trade, but will also strengthen competition from abroad, as foreign competitors will no longer have to adapt their products to different national systems.

OUTLOOK

The outlook for the electric lighting industry in the short-term is characterised by slow production growth, as investment activities of firms, as well as residential construction, are expected to stay flat during 1992 and 1993 in the EC as a whole, as well as in the United States and Japan.

In the medium-term, however, demand and production are expected to recover their previous high growth rates, as the general economic upswing and increased construction activity, along with product innovation, restimulate demand. Recent R&D efforts of EC firms are oriented towards electronically regulated lighting devices, towards improvements in light emitting efficiency and colour rendering and towards reducing still further the size of electric lamps. In the low technology end of the product range, competition from developing countries is likely to keep increasing.

Written by: BAK
The industry is represented at the EC level by: European Lighting Council (ELC). Address: Boulevard Lambermont 432, B-1030 Brussels; tel: (32 2) 245 0032; fax: (32 2) 245 8523.

Electronic engineering

NACE 33, 344, 345

The EC is now one of the major markets for electronic goods. With declines in their home markets, Japanese and American manufacturers have placed increased emphasis on developing market shares in Europe. Industry subsectors (consumer electronics, computer and office equipment and telecommunications equipment) are beginning to merge as new technologies and products are developed. European manufacturers, therefore, are facing increased competition in their traditional markets and the industry has undergone major changes in the form of acquisitions, reduced profits and rationalisation measures. In order to ensure future competitiveness on a global level, EC manufacturers are cooperating on joint ventures and research programmes while the EC is attempting to put fair competition legislation in place.

Figure 1: Electronic engineering
Value added in comparison with other industrial sectors, 1991

INDUSTRY PROFILE

Description of the sector

The electronics industry comprises computers and office equipment (NACE 33), telecommunications equipment (NACE 344), electronic components (NACE 345) and consumer electronics (NACE 345.1 and 345.2). Computing and office equipment includes computer hardware, peripherals, software and a range of office equipment from electronic cash registers to dictation equipment.

Telecommunications equipment includes radio communications, radar, medical equipment and measuring equipment as well as the obvious products, such as public switching and mobile communications.

Consumer electronics encompasses electronic components, audio-visual equipment (professional and consumer) and recorded music. The electronic components subsector comprises active, passive and electro-mechanical components.

Main indicators

Apparent consumption and production of electronic goods have consistently increased over the period 1982 to 1991, showing compound annual growth rates of 9.6% and 8.7% respectively (see Table 1). Extra-EC exports increased from 1982 to 1985, experiencing an 8% drop and then resumed growth to 1991. The compound annual growth rate for extra-EC exports over the period is 9%. Employment has experienced slight growth, with a compound annual growth rate of 0.7%. Computer and office equipment represents the largest proportion of consumption, production and extra-EC exports, followed by consumer electronics (see Table 2).

Recent trends

The main indicators have all grown in constant terms. Consumption, production and extra-EC exports have all almost doubled from 1982 to 1991 (see Figure 3). Employment has increased by 106% over the period.

Downturns in 1991 shown by consumer electronics consumption and production have been more than compensated for by increases in components, telecommunications and computer and office equipment.

International comparison

The international structure of the electronic goods market varies greatly from one NACE to another. For example, consumer electronics production is dominated by Japanese manufacturers, while computer and office equipment production is dominated by American and Japanese suppliers. In semiconductors, Japanese companies dominate key semiconductor technologies. Europe is of growing importance as a market for world suppliers. It now represents the largest consumer electronics market and second largest computer and office equipment market after the USA. Europe is also a major manufacturer of telecommunications equipment and consumer electronics.

Foreign trade

Extra-EC imports have grown more than extra-EC exports over the period 1982 to 1991. The data show a compound annual growth rate of 12.5% and 9.0%, respectively (see Table 4). The resulting trade balance is increasingly negative and stood at -26.5 billion ECU in 1991.

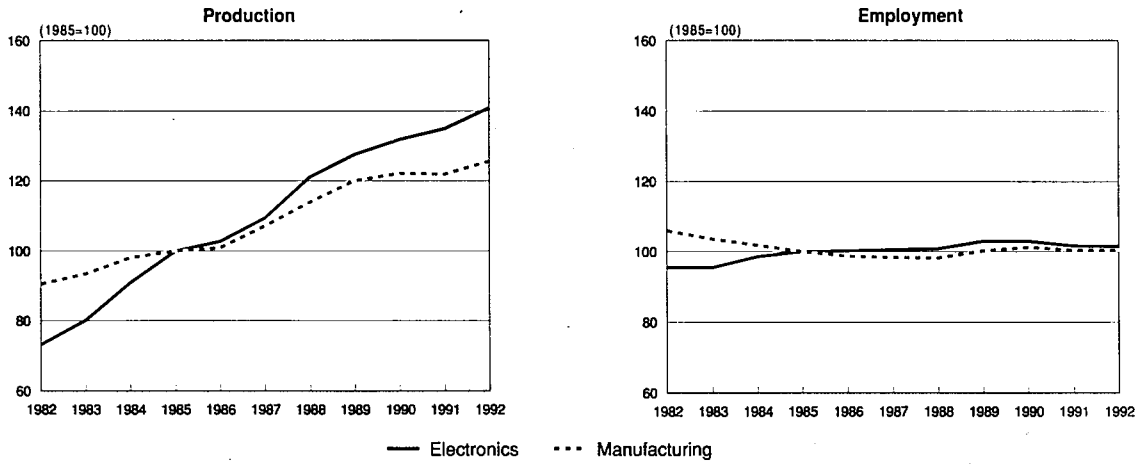
(1) Estimates
Source: Eurostat

Figure 3: Electronic engineering
Production and employment indices compared to EC manufacturing



1992 are BIS Strategie Decisions estimates
Source: Eurostat

Intra-EC trade has increased at a compound annual growth rate of 13.2% to its current value of 54.9 billion ECU. Production is positively and linearly correlated with extra-EC exports, as is consumption with extra-EC imports.

The main destinations for extra-EC exports are the EFTA countries and the USA, which account for 48.1% of total exports in 1991 (see Figure 6). Japan only receives 3.5% of total exports, an increase in percentage terms of almost 1% since 1986.

MARKET FORCES

Demand

The electronic goods industry has a wide customer base. Consumers account for the majority of sales of consumer electronics, whereas sales to professional organisations are small. In the telecommunications and components sectors, both private and public companies are the main purchasers, with relatively few sales to consumers. The computer and office equipment sector acts as an intermediary in this respect as both consumers and businesses demand such products.

The electronic goods industry is heavily dependent on general market conditions. Recession and a reduction in general income levels mean that consumers have less money to spend and businesses face cost cutting in the form of capital expenditure (on telecommunications, computing and office equipment) and inventory (of components). Despite this, the electronics industry has seen growth in demand in 1991, albeit less than in previous years (4.3% as opposed to a compound annual growth rate of 9.6% from 1982 to 1991). The opening up of Eastern Europe has contributed to this (with increased demand for components and equipment) as well as increased demand in the telecommunications sector from less developed EC members wishing to update networks. The only sector presently suffering is consumer electronics, which has seen a decline in consumption from 1990 to 1991.

Products for consumers and businesses alike are becoming more sophisticated. Product downsizing, increased intelligence and increased functionality in the allocated space are common in all areas of the electronic goods industry. Notebook and laptop computers, three function fax machines (incorporating fax, telephone and answering machine) and palm size camcorders have all appeared on the market. Innovation, in response to more demanding customers, is stimulating de-

Source: Eurostat

mand. Growth in demand is expected to come from value added and new categories of products. For example, portable computers in the computing and office equipment sector, European cellular standards in telecommunications and CD-I in consumer electronics. These will in turn influence products supplied by the components industry.

The convergence and interworking of three industry subsectors is occurring as manufacturers aim to provide sophisticated products for their customers. Software capability plays an increasingly important role in all electronic goods. Areas which would have previously been the domain of telecommunications or computing companies only are now being addressed by suppliers from other sectors. Examples of this are mobile communications and the home office which are being targeted by the consumer electronics industry and new products which merge computer and telecommunications technologies. The components industry has traditionally been dependent on the success of the other electronic goods subsectors as well as the automotive, industrial and military sectors.

Supply and competition

The supply of electronic goods is affected by a reduction in product life cycles, prices and margins. Product prices have decreased for many consumer electronics goods, telecommunications products aimed at the consumer, components and computing equipment. The depreciation of the yen and dollar has increased the competitiveness of Japanese and American suppliers. Production costs (particularly labour) tend to be higher in the EC than in the Far East. Japanese companies are frequently cited as having the advantage of vertical integration and are key suppliers in the components, consumer electronics and computing markets. However, most top European players in electronics components, such as Philips and Siemens, are vertically integrated to a degree.

Some American and Japanese manufacturers have established manufacturing bases within the EC or bought out organisations in order to maximise their presence in the Single Market. Japanese manufacturers tend to rely more on offshore manufacturing sites. Southern European countries (Spain for example) are becoming attractive locations for investment because of the relatively low labour and establishment costs.

Production process

The manufacture of electronic goods in Europe tends to rely on components sourcing. Traditionally, EC manufacturers have had to source components in the Far East and this has presented a barrier to EC competitiveness. Both consumer electronics and the components industry have become more capital-intensive over the years.

Production technology has become more advanced with increased automation. The case of printed circuit board production provides an example where productivity of the European electronics industry has improved overall. Improved design processes facilitate shorter product development times.

INDUSTRY STRUCTURE

Companies

Public and private organisations are active in the electronics goods sector. In each of the industry subsectors, two or three of the world's top ten players are European. These are Siemens-Nixdorf, Olivetti and Group Bull in the computer and office equipment sector, Philips and Thomson in the consumer electronics sector, Alcatel and Siemens in telecommunications equipment and Philips, SGS Thomson and Siemens in components.

Each company tends to have specific strengths within their marketplace; in telecommunications equipment this is transmission and public switching (this is where Alcatel's strengths lie) and in consumer electronics it is colour television (CTV) with Thomson as a European leader.

Table 5 concerns only the computer industry. The figures include such segments as hardware, software, services maintenance, etc.

Strategies

European manufacturers in this industry are seeking to achieve and enhance their global positioning compared to Japanese and American companies. Joint ventures, alliances and takeovers have been commonplace between European companies and between American or Japanese and European companies. Partnership agreements and European research ventures aim to give EC manufacturers a good base of technological leadership. In the components arena, alliances between users and suppliers of semiconductors are becoming more important for survival.

EC investment showed a compound annual growth rate of 12.6% from 1982 to 1988. The only setback to investment occurred in 1987 when it decreased by 7%. Investment has concentrated on R&D for new technology and product diversification.

The electronic goods industry worldwide has undergone rationalisation in recent years. In 1991, major players suffered losses, were forced to make large redundancies and, in some cases, reorganise.

ENVIRONMENT

There have been fewer direct pressures for legislation concerning ecological issues in the electronics goods industry compared to other industry sectors. However, manufacturers are beginning to respond to growing concerns and are introducing measures to ensure they produce environmentally friendly products.

Specific issues being addressed are the ability to recycle products (computer keyboards for example) and the use of safe raw materials and components. Germany has been particularly instrumental in this environmental consciousness.

The component industry has perhaps seen the most change in this respect. Consumer, computing and telecommunications products now demand safe components with the use of CFCs in semiconductors and printed circuit boards largely eliminated.

REGULATIONS

EC regulations concerning the electronic goods industry differ with each of the industry subsectors considered. In all cases, the main concern is to bring the 12 Member States into line with one another. In telecommunications, for example, the UK is at present the most liberalised market while the telecommunications infrastructure is less developed in countries such as Greece, Ireland and Portugal. In consumer electronics, recorded music royalties and reproduction rights are not similar in all countries (and may even be absent). In computer and office equipment software, protection rights are of concern.

The EC also provides funding for Member States, collaborative technology research programmes and individual European manufacturers in order to improve the competitiveness of the industry for the future. It also recognises the need to ensure parts availability for the success of all electronic goods industries. By regulating subsidies given by national governments to companies, the EC aims to encourage fair competition.

OUTLOOK

The future of the electronics goods industry depends on its response to the challenges it is currently presented with. Specific opportunities are presented by new and advanced technologies. For example, Integrated Services Digital Network (ISDN), satellite communications and high definition television (HDTV) offer a platform for European companies to become global leaders, given sufficient investment and development in their early stages. The former Eastern Bloc countries present attractive market opportunities because of their proximity and relatively untapped potential.

Table 6: Electronic engineering

(%)	1992-93	1992-96
Apparent consumption	4.5	4.7
Production	3.8	3.9
Extra-EC exports	6.1	6.4

Source: BIS Strategic Decisions

The convergence of products and target markets means that barriers between industry subsectors are being eroded. Hence companies traditionally involved in one subsector face increased competition and must prove capabilities in new areas. This in turn may necessitate a continued emphasis on co-operation and partnership between organisations. The decline in home markets and opening up of European markets will ensure that Japanese and American companies still remain a force to be challenged.

Written by: BIS Strategic Decisions

Electronic components
NACE 345

The electronics components market has experienced moderate growth worldwide in the past, however the world recession has had a noticeable effect on the components industry as users of components trim inventories and hesitate to replenish them. The threat from Japanese firms has continued to grow (particularly in the area of semiconductors) as Japanese investment has continued unabated. This outlook may have changed by the mid-1990s as most key Japanese semiconductor producers have announced cuts in investment due to poor results, higher capital costs and overcapacity risks. Industry players continued to seek alliances as a means to impose their standard, particularly in the key areas of microprocessors and Digital Signal Processors (DSPs). In particular, alliances were announced between IBM and Siemens, and between Philips and Thomson. The JESSI research programme continued on schedule. Future products will doubtlessly increase added value within the electronic components industry as even higher degrees of integration are attained.

INDUSTRY PROFILE

Description of the sector

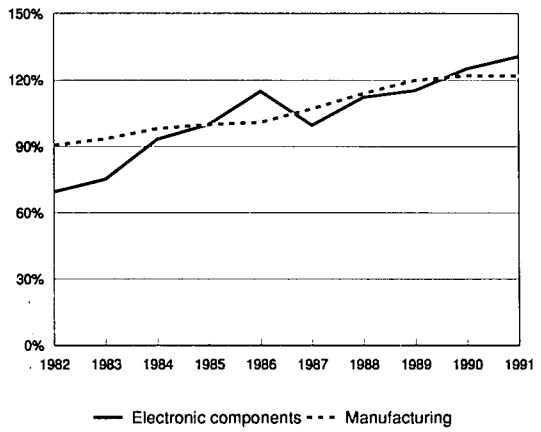
The electronic components industry comprises three broad categories: active, passive and electro-mechanical components. Passives comprise mainly resistors, capacitors and wound components, whereas electro-mechanical components include relays, switches, keyboards and printed circuit boards. Active components comprise semiconductors (integrated circuits and discrete semiconductors) as well as valves and tubes. Virtually every electronic system manufactured, whether for telecommunications, computing, or any other application, comprises components from all three families.

The components industry is entirely dependent upon the industries downstream, which use electronic components, such as the telecommunications, computing and consumer electronics industries. In addition, upstream links are vital to the semiconductor industry, in that access to the best semiconductor technology is crucial to continued growth; in this regard, Europe is particularly vulnerable, as most leading fabrication equipment suppliers are either Japanese or American.

Downward vertical integration is the rule rather than the exception in the semiconductor industry, as evidenced in companies such as Philips, Siemens and GEC Plessey. The significant exception is Thomson. Worldwide, virtually all major players are vertically integrated, including Japan's Matsushita, NEC and Fujitsu and the United States' Motorola and Texas Instruments. The only significant American semiconductor manufacturer not vertically integrated is Intel, whose microprocessor products form the core of many personal computers, and who consequently have a strong strategic position of added value.

Whereas the world semiconductor industry is highly concentrated among a small number of key players, both passives and electro-mechanical components form much more fragmented industries. European firms manufacturing either passives or electro-mechanical components tend to be small, and cater to niche markets. In addition, certain components such as printed circuit boards, are primarily manufactured for captive consumption and merchant sales come as an added source of revenue to the manufacturer.

Figure 1: Electronic components
Production index compared to EC manufacturing



1991 are BIS estimates
Source: EECA, Eurostat

Main indicators

Since 1982, apparent consumption has risen at a steady pace, with the exception of the semiconductor recession of 1987. However, for 1991, estimates are for slowed consumption growth of 2%, with renewed growth in 1992 as a result of the electronics industry finally leaving a recessionary period in mid-1992. In addition, the trade deficit has recently diminished in recent years, in part due to increased European plant construction by foreign manufacturers. Employment figures prior to 1990 are unavailable. Due to downsizing, in particular at Siemens and Philips, the 1990 figure of 242 200 employees is unlikely to have grown significantly.

Recent trends

Employment in the electronics components industry declined in the 1980s due to a variety of factors including higher levels of component integration, higher productivity, mergers of companies, and loss of market share to foreign manufacturers.

Consumption growth in electronics slowed down in the latter half of the 1980s to a compound annual growth rate of 5.2% for the period 1986 to 1990, compared to 14.3% for the period 1982 to 1985. This was due to several factors including a decline in the European share of world components consumption, a decrease in prices, and increased systems integration leading to demand for fewer components. Growth in production followed a similar trend, with an additional factor: loss of European share in components production. Consequently, whereas production had grown by an average annual rate of 12.9% in the period 1982 to 1985, growth declined to only 4.6% in the period 1985 to 1991.

Both exports and imports saw steady growth throughout the period 1982 to 1990, and, indeed the rate of growth in exports rose slightly through this period. One factor for this dual growth is the increased specialisation of active components manufacturers meaning lessened technological independence of any geographic region. In addition, the growth rate of imports declined slightly from the rate of 13.6% between 1982 and 1985 to 4.9% between 1985 and 1991. This was notably due to increased investment in European production capability on the part of non-European manufacturers.

International comparison

Intra EC trade in 1991 represented 45% of all imports into the EC. This figure remained almost constant over the period 1982 to 1992. The trade deficit grew between 1982 and 1989, peaking in 1989 at 8720 million ECU. It has since declined and stood at 8100 million ECU in 1991.

Foreign trade

Extra-EC exports have grown from representing 2663 million ECU in 1982 to 5400 million ECU in 1991. A small proportion of exports were destined for countries which are leaders in electronics in their own right. In 1991, 21.9% of exports were destined for the United States, followed by exports to Japan which accounted for 3.1% of exports. Eastern Europe, now accounts for 2.3% of EC components exports in 1991. This figure should grow rapidly, with the liberalisation of Eastern Europe and the relaxation of COCOM regulations. Exports to the rest of the world account for 72.7%.

EC trade balance in monolithic digital integrated circuits, 1990-91

Though Japan only accounted for 3.1% of EC exports, it did account for 25.1% of EC component imports. Taking into account Japanese-built semiconductor plants in Europe, the trade imbalance may be considered to be even more extreme. This is due in part to Japanese dominance of key semiconductor technologies combined with the fact that Europe masters few of the component technologies Japan lacks. The USA accounted for 26.0% of imports in 1991, compared to its share of 21.9% of EC exports. Taiwan and Singapore accounted for a significant proportion of EC component imports, with Taiwan accounting for 7.3% in 1991 and Singapore 5.8%. It should be noted that European companies such as Philips and Thomson have invested in plants in these countries.

MARKET FORCES

Demand

The main users of electronic components are Original Equipment Manufacturers (OEMs). They manufacture systems for a range of end markets, including telecommunications, automotive, industrial, computing, consumer and military. The health of the components industry is directly linked to the state of the OEM markets using electronic components.

Growing sophistication of end-markets has several implications for components markets. Overall, increased 'intelligence" placed within such systems as automotive or military will favour the use of electronic components, particularly integrated circuits such as microprocessors and Digital Signal Processors. At the same time, there is a strong trend to increase the degree of integration, so as to reduce size while increasing functionality of systems. Consequently, there will be an increased use of integrated circuits, often in the form of custom ICs, often known as Application Specific Integrated Circuits (ASICs), while the use of more traditional components, such as passive devices or printed circuit boards will be reduced. Printed circuit boards will inevitably continue to be used, as they are a vital part of an electronics system, however, they will be smaller, and a higher density of components will be placed upon them through the use of such techniques as multiple layers.

If one analyses the end-markets for components by electronics industry sector and by sector trends, it is possible to understand which components will be of more or less strategic importance.

In telecommunications, the advent of GSM (Global System for Mobile Communications) mobile telephony will require Digital Signal Processors. Broadband integrated system digital networks (ISDNs) will require components capable of switching and processing data at extremely high speeds. Both of

Table 8: Electronic components

Source: Dataquest Europe Ltd

these trends will favour the growth in Gallium Arsenide technology.

In computing, both microprocessors and memories will continue to be vital, as computers incorporate more and more processing power as well as memory. In addition, the growing popularity of small portable devices favours growth in integration and the use of integrated circuits with low power consumption.

In automotive systems, microprocessors and Digital Signal Processors show increased penetration, particularly in the area of Anti-lock Braking Systems (ABS). These microprocessors will lag behind those used in personal computers, but will nevertheless evolve in sophistication as automotive manufacturers use electronic sophistication as a basis for product differentiation.

Consumer electronics will require electronics of a sophistication never seen before in consumer electronics, particularly in High Definition Television (HDTV) and Personal Product applications. Personal Products are a new area of consumer electronics where computing and telecommunications are converging into small, intelligent products, requiring microprocessors and memories. HDTV, the emerging new standard in television, requires large memory devices as well as extremely fast Digital Signal Processors.

Components are extensively used in military systems of all types, ground, air or sea-based. Though defence procurement growth is now slowing, this will likely not be apparent in components procurement for defence applications, due to the ever-growing technical sophistication being integrated into systems.

Eastern Europe is emerging as a prime market for European components production. This market has grown from nought to more than 3% of EC exports between 1989 and 1991. By the year 2000, Eastern Europe should represent a quarter of the world's consumption of components and European firms are well positioned to export to this new market.

Supply and competition

It is important to note key differences in the components industry between active components (in particular integrated circuits) and passive or electro-mechanical components.

Passive and electro-mechanical components, while continuing to evolve, are in general more mature markets than integrated circuits, which continue evolving at much higher rates, attracting higher levels of investment. Indeed, integrated circuits continue to absorb system functionality previously provided by other components as fewer and fewer passive or electro-mechanical components are used relative to integrated circuits.

Furthermore, it is in integrated circuits and other active devices such as discrete semiconductors that the EC is best able to export. Ninety percent of EC integrated circuit production is exported, whereas only 11% of printed circuit board production is destined for export. One should be careful in interpreting these figures, however, in the sense that it is also some of the less exportable components such as passives that the EC is most self-sufficient. For instance, in printed circuit boards, the EC produces 76% of its internal consumption requirement whereas it produces only 3% of its consumption in integrated circuits.

It is clear that integrated circuits represent a much more international market, with higher levels of imports and exports worldwide, than do other components, such as passives, which are more local.

It is clear that the integrated circuit industry is the component sector most vital to the future health and growth of any electronics industry. Though Europe has several large semiconductor producers, competition from foreign manufacturers is extremely strong, as evidenced by the fact that Europe's IC production is only equivalent to 31% of its internal consumption. Furthermore, a significant proportion of this production is represented by European plants built by such American producers as Motorola and Texas Instruments, and Japanese producers including Fujitsu and NEC.

Production process

The production process is complex, and has many upward and downward dependencies. Upward dependencies consist primarily of buyers of electronic components, who play a large role in determining both future designs and the methods used to fabricate components; this is particularly true in the case of integrated circuits. Downward dependencies include the supply of manufacturing equipment and the choice of manufacturing location. The semiconductor manufacturing equipment market is dominated by American and Japanese players; ready access to their latest equipment types is determinant in developing new, competitive products. Manufacturing location will play a large role in determining competitiveness; even such a capital-intensive industry, cost of skilled labour can be a critical success factor. Consequently, certain European players such as SGS Thomson and Philips have chosen to locate facilities in Southeast Asia to take advantage of relatively inexpensive labour.

INDUSTRY STRUCTURE

Companies

The passive and electromechanical components industry is largely fragmented in Europe, with national markets frequently being dominated by a national supplier, particularly in the case of passives and printed circuit boards. In other cases, foreign suppliers have strong positions in Europe (frequently gained by local manufacture), as is the case with capacitors from Sprague, an American company which enjoys a large European market share.

Key European semiconductor players include Siemens (Germany), Philips (Netherlands) and SGS Thomson (France-Italy), all of whom are among the leading manufacturers worldwide. In addition, Europe has several medium-sized integrated circuit manufacturers including Matra MHS (France) and GEC Plessey (UK). All of these manufacturers (with the exception of SGS Thomson) are to some extent vertically integrated, and enjoy the benefits of captive markets and directed product development. The Japanese now have a slight lead in the world semiconductor market, and all of their major representatives are vertically integrated, as well as offering a broad product line. The only major players in the world semiconductor industry which are not vertically integrated are Thomson and Intel (USA). Intel enjoys the advantage of dominating the key microprocessor market.

Strategies

Strategies in the components industry vary widely depending on whether one is examining the active, passive or electromechanical components sectors. These strategies are of course largely dependent on the end markets' evolution, as electronics manufacturers' global dimension grows and industry rationalisation continues.

In both passives and electromechanical components there has been a tendency to grow through merger and acquisition, thereby gaining economies of scale and the ability to serve global players in each of their locations. The sole major exception to this is the printed circuit board industry, where smaller regional players continue to dominate.

In the semiconductor, and more generally the active components industry, the notion of 'critical mass' has become key, where 'critical mass' can be defined either as minimum market share, or production capacity necessary to compete. In effect, the semiconductor industry has become extremely capital intensive, and vast production volumes are now generally necessary in order to amortise a new product or production facility.

Alliances and mergers have also become commonplace, as players enter into partnerships to conduct research and development work, build production facilities, or act as a second-source for each others' products. In addition, technological alliances are becoming critical between users and suppliers of semiconductors. Key alliances tend to gravitate around new microprocessor technologies, as in the alliance involving Apple and Motorola, or SGS Thomson, IBM, and Bull.

An alternative strategy is that practised by some of the smaller semiconductor companies, whereby they specialise in so-called 'niches' (i.e. market segments which are possibly too small to be profitably exploited by larger players). This is the case of European Silicon Structures (ES2) and Matra Harris Semiconductor (MHS).

REGIONAL DISTRIBUTION

Traditionally, both Japan and the south-western United States were key semiconductor production areas. The Newly Industrialised Countries in Southeast Asia (South Korea, Taiwan, Hong Kong and Singapore) have become favoured sites for new semiconductor facilities, due to low costs and highly educated workforces. Japanese and American manufacturers of a variety of components, including semiconductors and passive devices, have found it advantageous to establish production facilities in Europe, particularly in southern regions.

For European and American enterprises, Southern Europe has been attractive for setting up manufacturing plants due to the relatively cheap labour and set-up costs without a reciprocal loss of expertise. Though Eastern Europe may prove to be a cost-effective site to locate new semiconductor facilities, the current strain on capital, combined with possible overcapacity, hinders development in this region for the near future.

ENVIRONMENT

The components industry is a heavy user of a variety of chemicals in production. This has led to environmental concerns, particularly in the case of CFCs, of which the semiconductor industry has been a heavy user. Generally speaking, industry players are phasing out use of CFCs and other dangerous chemicals in a self-regulated fashion.

REGULATIONS

Few regulations exist with regard to the trade of electronic components. Key concerns are often expressed in terms of treaties or practice. In particular, defence issues have tended to limit the export of many advanced semiconductors to Eastern Europe under the COCOM regulations; however these controls are now rapidly being lifted.

OUTLOOK

The short-term outlook for the European components industry is positive. As the world electronics industry leaves a recession, inventories should start to be developed again.

The long-term future of the European components industry will depend partially on the industry itself, and partially on the industries it supplies, namely the automotive, telecommunications, computing, consumer electronics, and defence industries.

Should the European electronics industry remain healthy, which it is likely to do so in at least some sectors, then the outlook is positive for European component manufacturers. This is especially true for those semiconductor manufacturers whose fortunes are tied to those of larger OEMs, such as Philips or Siemens. However, this health is dependent on OEMs recognising that the success of the underlying components industry is vital to their own longevity. Under this scenario, growth in production should be of the order of 4% compound annual growth for the period 1992 to 1996.

Programmes to link component supplier and user product development already exist, whether government sponsored or privately initiated. These vertical alliances are critical, not only to ensure a commercial outlet for European components production, but to ensure relevant new component product development. In addition, the JESSI programme of research and development, linking various European semiconductor manufacturers, has been proceeding on schedule to develop new semiconductor technologies to keep European companies competitive.

In addition, a healthy European manufacturing equipment industry is also vital to components industry. Traditionally, European components manufacturers have had purely commercial relations with their equipment suppliers. Now, initiatives such as JEMI (Joint Equipment Manufacturers Initiative) are underway.

The period 1992 to 1996 should see continued building of foreign-owned fabrication facilities in Europe. However, this growth will not be as rapid as previously expected, due to an increased cost of capital to Japanese manufacturers, coupled with the risk of overcapacity problems now becoming apparent.

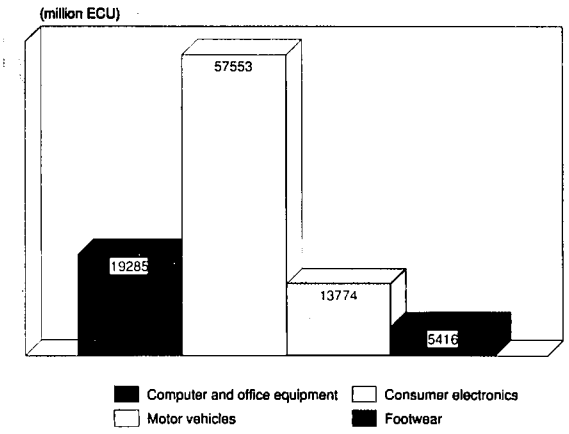
Computer and office equipment
NACE 33

Although the European computer and office equipment industry has experienced hard times in recent years, in the 1990s Europe may still become the fastest growing market in the world. The top three European computer manufacturers, Siemens, Olivetti and Bull are adapting to the new conditions of the market.
Important technological developments such as downsizing and system integration have changed the rules of the industry and contributed to the "commoditisation" of computer and office equipment. Faced with fierce competition from American and Japanese manufacturers, European companies are now pursuing strategic alliances and partnerships on common European research programmes with other industry players.

Figure 1: Computer and office equipment Value added in comparison with other industries, 1991



Source: Eurostat

INDUSTRY PROFILE

Description of the sector

This industry manufactures different categories of products: hardware (portables, notebooks, microcomputers, minicomputers, workstations, mainframes, network equipment, etc.), peripherals (printers, disks, screens, keyboards, etc.), software (packages and applications, information systems, systems engineering and services, etc.) and office equipment (electronic typewriters, electronic calculators, electronic cash registers, electronic accounting machines, dictation equipment, etc.). The data provided by Eurostat in the figures and tables correspond to hardware only.

Main indicators

Since 1982, apparent consumption and production of computer and office equipment have grown at a steady pace. Since 1990, consumption growth has been higher than production, resulting in an increased trade balance deficit. Extra-EC exports which had slowed in 1990 compared to 1989, thrived again in 1991 (+8%) (refer to Table 1). However, these exports account for only 20% of European production.

Employment dropped in 1991, registering the highest decrease for 10 years. This was mainly due to an economic recession prompted by a cautious attitude from employers. Employment is expected to be on the rise again in 1992, however.

Recent trends

In constant prices, all main indicators are higher than those for overall manufacturing. The computer and office equipment industry is thus one of potential growth. The average real annual growth rates of apparent consumption, production, extra-EC exports and imports prices were much higher during the 1982 to 1985 period than from 1986 to 1991. Price decreases in 1986 were largely responsible for the slower rate of inflation in the industry during the latter period. Overall, from 1982 to 1991, average annual growth rates were quite high for all indicators and have exceeded 10% (except for extra-EC exports) (refer to Table 2).

International comparison

The computer and office equipment and electronics industry combined account for 5% of Europe's GDP, compared to 5.5% in Japan and 6.2% in the United States. The US industry is experiencing a declining domestic business but is thriving in Europe. In 1989, the United States had a trade surplus of about 3400 million ECU, which is presently eroding.

The Japanese computer and office equipment industry is booming, both on the national and foreign markets (notably Europe). In 1989, Japan had a trade balance surplus with Europe of about 18200 million ECU. Production in Japan covers 140% of consumption (compared with 80% in Europe).

In 1989, the United States was the world's leading producer of computer and office equipment, followed by Japan and Europe. In terms of consumption, the United States was again positioned first, and Europe second. Peripherals are mainly manufactured in Japan (40% of world production) and to a lesser extent in the United States (25%). European production is only 15%.

Of the ten leading computer and office equipment firms on the world market, five are American, three are Japanese, and two are European.

Foreign trade

Extra-EC exports and imports have grown steadily since 1982. In 1991, extra-EC exports accounted for one-half of extra-EC imports. The share of extra-EC imports to total imports remained quite stable over the past ten years.

From 1986 to 1991, EC computer and office equipment exports to the United States remained quite stable, while EC exports

to the EFTA countries dropped slightly (refer to Figure 6). EC exports to Japan remained marginal. The EFTA countries represented the main destination of EC exports, but in 1991 the United States was not far behind. In 1986 and 1991, most EC imports came from the United States (refer to Figure 7). Japan, however, increased its share of EC imports, whereas the United States exported less in 1991 than in 1986 (a 10% decrease). The Member States' imports from the EFTA countries are low and decreased between 1986 and 1991. It is important to mention that the Four Dragons (South Korea, Taiwan, Hong Kong and Singapore) are increasingly taking market shares in Europe. Taiwan, for example, increased its exports to the EC by about 7 points between 1986 and 1991. EC imports from Singapore also expanded during this period.

Intra-EC trade has more than tripled over the last ten years. Over that period of time, intra-EC trade experienced higher growth than that of extra-EC exports and production. Consumption increased substantially from 1982 to 1991, and extra-EC imports more than tripled. As a result, extra-EC imports accounted for nearly one-third of consumption over the period. However, the extra-EC imports to consumption ratio has been on the rise, particularly since 1987.

MARKET FORCES

Demand

Demand at both the European and global level has a high potential for growth. Private and public companies as well as public markets are important market segments. Public-sector purchases make up about 15% of the European computer market and accounted for 600 billion ECU in 1990. Such purchases tend to be for rather heavy, expensive equipment.

Orders are mainly for large computers and they have created captive and protected markets. These public markets have contributed to the survival of national competition. As private companies want access to the most innovative products, they are the most demanding in terms of price conditions, delivery dates and after-sales service. Individual consumers represent a mass consumption market which requires high performance in terms of quality and price. The market is highly competitive and requires rapid innovation. Because of the experience acquired by end-users (whose demand is definitely moving towards more sophisticated systems) the European computer market is changing from one based predominantly on hardware towards a market focused on software and services. Customers

are putting increasing pressure on distributors. Some consumers even buy their computer and office equipment on the used equipment market. Sales for the second-hand market, however, remain marginal. Furthermore, after having led a computerisation race in which they bought considerable amounts of equipment, customers have now adopted a more thoughtful approach.

This shift in market demand had a definite impact on the electronics industry, particularly on component manufacturers. Product innovation is of great importance in the computer and office equipment industry; innovation stimulates demand as preferences emerge towards new categories of products.

Downsizing makes it now possible to have "the power of a mainframe on the desk". In fact, this downsizing phenomenon pervades the full range of computers. Mid-range computers now surpass the capability of mainframes manufactured only a few years ago. Powerful PCs and LANs (Local Area Networks) are replacing mid-range computers, and mainframes are being replaced by more specialised mid-sized computers. Downsizing has had a strong impact on prices. The average world price of a workstation fell by around 8% in 1990 and is expected to continue falling.

Portable computers represent the fastest growing segment of the market. By 1995, one out of four PCs purchased should be portable. Local Area Networks, which enable users to have their computers interconnected, are also growing in demand.

Market demand has induced software producers to make their software compatible. The ability to integrate software is very much desired by customers. The customer wants to be sure that what is purchased will be compatible not only with the vendor's products but also with others; Microsoft's Windows 3.0 is one example. Compatibility between other operating systems (OS/2, Unix...) is expected to develop in the near future.

Supply and competition

Internal EC competition is still active, particularly regarding public markets. Despite the advent of the Single Market, Europe remains a series of small markets, each with its own leading computer firm. More standardised systems have made it easier to enter the market but more difficult for vendors to differentiate products, leading to thinner margins for manufacturers.

This also means that hardware companies are being forced to move into new areas such as computer software and services. Therefore, hardware manufacturers are no longer simply competing with each other, but with existing software providers, computer services companies (software houses, etc.), and even the telecommunications groups as well. EC manufacturers have

Figure 7: Computer and office equipment
Origin of EC imports

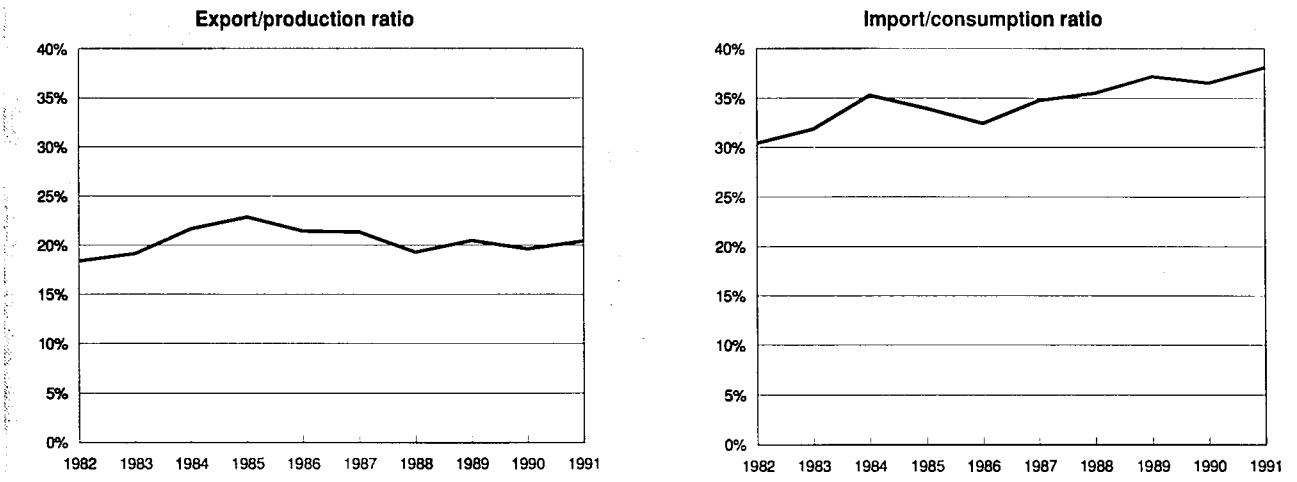
Figure 8: Computer and office equipment
Trade intensities



Source: Eurostat

lost their degree of competitiveness in an industry where American and Japanese suppliers are tough competitors.

A comparison of European and American computer equipment reveals striking price disparities. For example, a PC costs twice as much in Europe as in America. This ratio is even higher for applications, which sometimes cost three times more in Europe.

Moreover, the depreciation of the yen and the dollar have contributed to the degree of competitiveness of Japanese and American goods on the European market. The printers' market, for example, is dominated principally by US and Japanese companies. Among the leading 10 laser printer makers in Europe in 1990, not one company is European. This is also true for matrix printers. European software, however, is still competitive, although Japanese firms are becoming increasingly difficult to compete with. European computer makers have endeavoured to increase productivity by drastically reducing the number of employees. Again, labour productivity has increased but not as much as that of US companies.

Prices on an overall basis are decreasing and margins are tightening. Besides downsizing and open systems, which have made prices collapse in some segments, Europe has had to face falling demand and fluctuating foreign exchange rates. Components prices have fallen and, due to falling demand, manufacturers have chosen price competition rather than increasing their margins. PC prices have plummeted: from March 1991 to March 1992 they fell by as much as 50%. Even new products are faced with price cuts: the price of portables, for example, is falling far faster than costs.

In addition, product life cycles are becoming shorter. The life cycle of a micro-computer, for instance, no longer exceeds 1 year. Value-added resellers (VARs) are thriving in Europe and are trying to obtain the lion's share of the distribution market.

Production process

European production in 1991 hardly covered 80% of European consumption (refer to Table 1). Since European users are giving priority to US or Japanese-made information systems, the European industry tends to be below its production capacity.

In 1991, productivity largely exceeded its level of 1985 (refer to Table 4). It increased considerably from 1986 to 1987, but then dropped in 1989 compared to 1988. For ten years, unit labour costs have been on the rise. Total unit costs experienced a higher increase.

European production of computer equipment is weak and has for certain products disappeared altogether. The production of hard disks, for example, is no longer ensured by European firms. This is partly due to the lack of European components sourcing, as European manufacturing tends not to be profitable. A large part of the peripherals industry production now occurs in the US and Japan. In 1989, US firms accounted for 58% of computer equipment and 8% by Japanese companies. For these products, European production only reaches about 15%.

In Europe, vertical integration is relatively limited compared with American and Japanese companies. Some companies have tried in the past to integrate upstream activities by producing components for their own needs; because of a lack of a sufficient internal market, they were not able to reach the critical size thresholds of production and sustained investment levels.

Any production that requires the manufacture of printed circuits (peripherals, computers and office equipment) is mostly done by subcontractors. Part of this activity is carried out in South Asian countries. Producing in Europe is nevertheless attractive in certain geographical areas. Component construction is strong in Ireland and Scotland because companies benefit from low taxes and local government incentives.

INDUSTRY STRUCTURE

Companies

Nearly 6000 enterprises operate in the computer and office equipment sector in Europe (refer to Table 5). Only 3.6% of enterprises account for 92.8% of the industry's turnover, showing a high concentration in the industry.

European firms had an overall market share of about 40.2% in 1989, whereas US and Japanese companies had respectively 56.5% and 3.2%. The three main European computer and office equipment suppliers, Siemens-Nixdorf in Germany, Olivetti in Italy and Groupe Bull in France, are seeing their positions erode on the European market. On the other hand, the industry in general is facing a downturn on the world market and US and Japanese companies are also entering a difficult period. In the first decrease since 1978, the micro-computer market dropped 3% in Japan in 1991 while PC sales decreased about 8%. For Siemens-Nixdorf, the largest European-based computer company, it has taken longer than

Table 5: Computer and office equipment

(1) Estimates
Source: Eurostat

expected to integrate the Nixdorf company. Although its turnover reached 5.9 billion ECU from October 1990 to September 1991, losses were about 380 million ECU. In 1991, Olivetti's turnover was approximately 5.6 billion ECU, but losses reached about 217 million ECU.

Groupe Bull's sales in 1991 reached 4.8 billion ECU while losses were about 480 million ECU. 1200 people were dismissed in 1990, 1600 in 1991 and another 1100 people are to be dismissed by the end of 1992, bringing employment at La Compagnie des Machines Bull to approximately 13460 in France.

Strategies

In the past, the industrial strategies of European companies did not sufficiently exist on the EC dimension. However, they presently exploit the possibilities of cooperation with other European partners more deeply, particularly through European research programmes. Due to their lack of competitiveness, European computer makers base their strategies upon two dimensions: they can reach product marketing agreements and form strategic alliances with powerful partners, but they can also seek help from the EC through research programmes like Esprit, Jessi, Eureka, etc.

In 1991, an agreement was signed between La Compagnie des Machines Bull and NEC in which NEC took 4.7% of Bull's capital and Bull had access to the Japanese technology for large computers. Groupe Bull also reached a broad agreement with IBM last year. In signing this agreement, IBM pledged to provide its French counterpart with Risc microprocessors (chips which are the heart of computers) that will represent one of the largest sectors of the market for the 1990s. IBM holds 5.7% of Bull's capital.

Olivetti has clearly demonstrated two aspects of its strategy: the search for partnership and a new orientation towards services. The company recently signed an important agreement with Andersen Consulting to find new outlets in services in the banking, distribution and public administration sectors. Olivetti has also recently signed a partnership agreement with Canon. This joint venture is aimed at manufacturing 700 000 ink jet printers and includes R&D collaboration.

The three main computer manufacturers have also announced the creation of a common company aimed at creating extensive trans-European networks. The objective of this new structure is to harmonise the computer networks of the Member States.

US computer manufacturers (IBM, DEC, HP) have adopted a globalisation strategy to increase their presence on foreign markets (especially in Europe) by maintaining significant manufacturing and R&D operations in Europe.

Hewlett-Packard, for example has R&D operations in France (in Grenoble). After acquiring Mannesmann-Kienzle in December 1990, DEC extended its influence in Europe in 1991 by acquiring Philips Systemes Informatiques, a specialist in services and solutions to the banking sector, and CGE Composants, its main mini-computers' distributor.

As a result of the Japanese market stagnation, NEC, the second largest computer manufacturer in Japan, has decided to postpone the building of a PC manufacturing plant in Germany. Japanese suppliers are focusing on software production. Moreover, they are tackling the European market, notably with ICL, which now belongs to Fujitsu.

These strategic alliances are likely to continue in the future since they often represent the only potentially successful strategy for companies in the sector. At present, European computer makers spend almost as much as their US and Japanese competitors on capacity investment (respectively 9.5% and 8% of turnover). In order for the EC not to be absent from the supercomputers market, has decided to invest about 1 billion ECU, beginning in 1995. However, only 300 million ECU has been planned for the Esprit phase II. Europe's needs represent 30% of world sales. The United States and Japan are actively preparing for this scientific, technical and commercial challenge by investing heavily in this area.

ENVIRONMENT

The computer and office equipment industry is not strongly involved in ecological issues. However, pressure from the EC and socio-economic trends have induced European manufacturers to take care of the environment. Germany in particular, is leading the European ecological effort. Siemens-Nixdorf, for example, has recently marketed a keyboard which can be entirely recycled.

REGULATIONS

The standardisation of computer and office equipment at the European level is mainly represented by organisations such as the CEN (Committee of European Standardisation) and the Committee of European Electrotechnical Standardisation (CENELEC).

The computer and office equipment industry not only follows their official (*de jure*) standards, but also the standards, which are not recognised by these competent organisations although they lead the market (*de facto* standards). The latter have emerged from the users' desire to have heterogeneous computer sites and to be able to free themselves from relying on a single manufacturer.

The series of alliances and mergers, which had already started before 1991 with the Siemens-IBM alliance and the acquisition of ICL by the Japanese manufacturer Fujitsu, tends to put the EC in a difficult position: which is the status of EC companies which are now under American or Japanese control? ICL, which had started to participate in various R&D European programmes, had to withdraw from three Jessi programmes in 1991 because it no longer was a European company. Eventually, the European Commission decided that ICL could participate in the second phase of the RACE programme.

The twelve Research Ministers have finally suggested that a code of good behaviour should be adopted for EC help for those companies whose major capital is not European. On the other hand, the European Commission is also controlling the subsidies European companies receive from their national governments. Recently, French government equity injections into Groupe Bull have drawn the EC's attention.

Nearly 870 million ECU were planned for the Bull and Thomson groups. The concern of the European Commission is to check the conformity of French aid to the Rome Treaty and more specifically its compliance to European fair competition rules. France and the EC eventually came to a political compromise in which Groupe Bull will have to accept a restructuring plan aimed at ensuring financial stability and independence from the State.

In May 1991, the EC Council of Ministers also passed a directive on computer programmes protection which will was implemented by all EC Member States on the 1st of January, 1993. The text is aimed at protecting software against piracy. Software copying is authorised but is limited to the perspective of programmes' ability to interface with other systems. By adopting this directive, the EC intends to reduce royalties.

The share of EC resources dedicated to research in Esprit reaches 3.5% and is expected to rise to 6% in 1997. The Maastricht agreement is likely to provide the EC with a quicker legislative process for the implementation of the fourth programme, which will probably combine the Esprit's traditional activities with more targeted objectives on some key IT technologies. The EC also considers the initiative taken by Groupe Bull, Siemens and Olivetti to create a European software institution. As for Eureka, the programme accounts today for 521 projects which represent a global amount of about 12 million ECU. 121 new projects have been created in 1991, among which 14 are dedicated to electronic data processing.

OUTLOOK

Apparent consumption between 1992 and 1996 is expected to evolve positively at 5.9% compound annual growth rate. Production and extra-EC exports will grow a little slower. The industry needs to adapt to the growing importance of applications and services. Efforts are being undertaken by European manufacturers to increase competitiveness, notably by their participation toward a new generation of research programmes and attention to customer needs.

The emergence of new products in the industry has led to a technology merger between computer and office equipment and telecommunications; companies which were making telephone handsets are now moving into computers, and vice-versa. AT&T, for instance, has recently bought the Dataid company. Technologies in those industries are converging.

Telecommunications equipment
NACE 344

The telecommunications equipment industry has experienced high growth rates globally with the EC being no exception. Supply is very concentrated in three particular zones: the USA, Europe and Japan. Although the USA is the most established and liberal services market, EC advantages include the benefits gained from the convergence of the 12 Member States and the resulting strength of standardisation and liberalisation of markets; Alcatel of France is the world's largest telecommunications supplier, leading USA's AT&T. The Japanese industry is becoming more competitive and continuing with large R&D investments. As the focus of the equipment industry changes from domestic to worldwide, players are jockeying to reach the ultimate goal of being a "Global Player".
Future products and technologies will concentrate on value added services and equipment, mobile communications, intelligent networks and visual communications, with greater potential to optimise the yet untapped residential markets.

INDUSTRY PROFILE

Description of the sector

Any analysis of the telecommunications equipment market cannot be looked at in isolation; there are strong links to the telecommunications services sector, and many overlaps with other sectors of the electronics industry. For example, one finds within the industry upstream links with components, aerospace and software and downstream links to network operators, value added service providers, installers and retailers. Many firms are also involved in both the electronics and the telecommunications markets. European examples include Alcatel, Siemens and Ericsson (a major supplier to the EC of Swedish origin), with Motorola, IBM and Hitachi representing the USA and Japan.

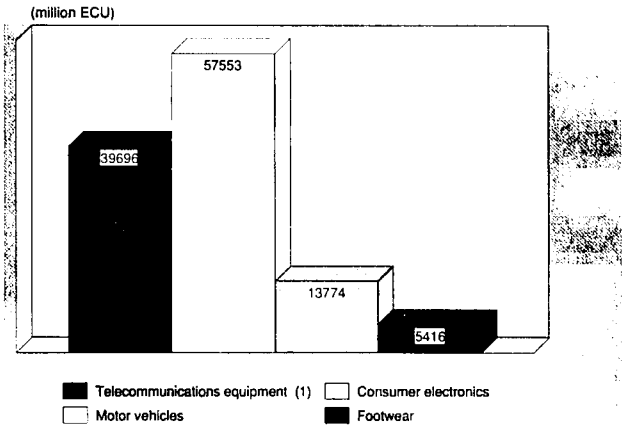
Telecommunications equipment main product categories are public switching, transmission, terminals, private switching, data communications and mobile communications. The technological advances towards full digitalisation has meant that the telecommunications industry has become a multi-product industry with the scope of equipment ranging from the provision of voice through telephone sets to image communications via video conference facilities.

Note that NACE 344 includes, in addition to the manufacture of telecommunications equipment, the manufacture of electrical and electronic measuring equipment, recording equipment and electro-medical equipment. Unless otherwise noted, however, the data in this monograph refer to the manufacture of telecommunications equipment alone. Furthermore, caution must be exercised when comparing pre-1988 and post-1988 figures due to the change in nomenclature for NACE 344 in 1988. The transition from the Nimexc trade nomenclature to the Combined nomenclature also means that pre-1988 trade figures cannot be compared with post-1988 trade figures.

Main indicators

The EC accounts for around 25% of the world's telecommunications equipment market. In 1990, public switching was the largest market by value in consumption, while terminals represented the highest revenues from extra-EC exports. Mobile and data communications are expected to be growth areas especially since the EC standardisation agreements for the pan-European digital GSM and ISDN (Integrated Services Digital Network).

Figure 1: Telecommunications equipment Value added in comparison with other industries, 1991



(1) Includes electrical and electronic measuring and recording equipment, and electro-medical equipment
Source: Eurostat

From 1982 to 1991, consumption in the EC rose at an average annual rate of 4.0% in real terms, with growth rates for individual years reaching as high as 12% (between 1983 and 1984). Production growth was slightly lower over the eighties averaging 2.7% per year (Table 3). EC exports expanded at an even slower rate of 2.2% between 1982 and 1991, which includes a sharp decline between 1985 and 1986 of 9.8%. Nevertheless, the EC's trade balance in nominal terms has risen since 1989. Employment in the EC telecommunications industry fell steadily from 1982 to 1991, a trend which is expected to continue.

Recent trends

Growth in telecommunications equipment markets in the last decade has moved hand in hand with that of telecommunications services. The market in the 1980s grew in line with the development of new services and network modernisation. The 1990s will be characterised by a growth in demand for value added and alternative services to be supported on more flexible networks.

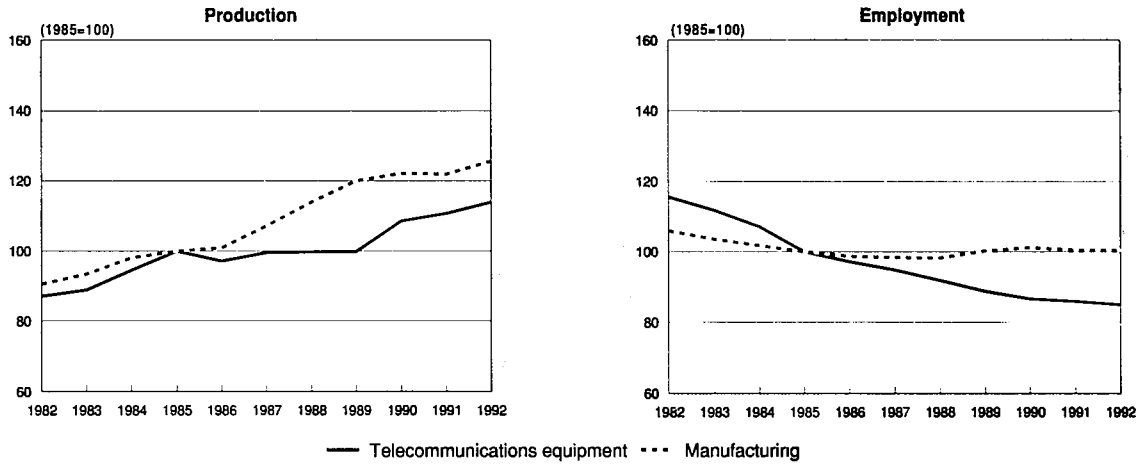
Figure 3: Telecommunications equipment
Production and employment indices compared to EC manufacturing



1992 are BIS Strategic Decisions estimates
Source: Eurostrategies ESTEL, Eurostat

Compared to overall manufacturing, employment in the telecommunications equipment industry experienced a rapid decline in the early 1980s mainly due to productivity improving developments in manufacturing and the high number of mergers and acquisitions in Europe.

EC production of telecommunications equipment grew more quickly in the earlier part of the eighties than the latter half although the industry experienced an upturn in 1990 which continued into 1991. This upturn can partly be attributed to the former Eastern block countries which are in desperate need of telecommunications equipment, and also to the mobilisation of those countries in Europe such as Greece, Portugal and Italy which are having to upgrade their networks in order to come into line with other EC countries.

With a compound annual growth rate in consumption between 1982 to 1991 of 4.0% and production growing at only 2.7%, extra-EC imports increased at a rapid rate, averaging 9.2% per year over the same period. Contributors to this growth include the surge of liberalisation in the early to mid-80s, especially in the UK. As markets opened up for telecommunications equipment, more and more companies began to share new technologies through joint venture (Alcatel of France-Qualcomm of the USA in the satellites area) or buyouts (Northern Telecom of Canada and STC of the UK in PABX).

Foreign trade

The EC's trade balance in telecommunications equipment has increased steadily over the last several years. The majority of exports are destined to the EFTA countries which had a 21.3% share of the total in 1991 (refer to Figure 4). The USA, the EFTA countries, the Four Dragons (South Korea, Taiwan, Hong Kong and Singapore) and Japan made up 38.1% of all EC exports; conversely, these same regions represented 84.9% of all EC imports.

The EC trade deficit with Japan reached 1192 million ECU in 1991. Japan imports very little EC equipment and accounts for only 1.2% of EC exports in 1991 (Figure 4). As illustrated by EC imports in 1991, Japanese equipment was the most important, representing 26.0% of all imports, ahead of equipment from the EFTA countries representing 22.8% and American equipment at 25.0% (refer to Figure 5).

EC exports worldwide were concentrated on terminal and transmission equipment representing 41.4% and 26.5%, respectively, of the value of all 1991 exports. Terminal equip-

ment, however, was also the EC's most imported telecommunications product, accounting for 59.2% of imports in terms of value. Japan once again exported the most terminal equipment to the EC, representing 30.7% (879 million ECU) of the value of all imported terminals.

Of this 879 million ECU, 65.2% is accounted for by fax machines and parts. Not surprisingly, Japanese exports to the EC are strong in fax machines where synergies exist between this type of terminal equipment and consumer electronics.

MARKET FORCES

Demand

The three key end markets for telecommunications equipment are the public telephone operators, businesses and residential consumers.

Operators are large buyers of all types of equipment, notably switching and transmission infrastructure. They also act as re-sellers for terminal equipment. This customer base, however, is fragmenting. In particular, service liberalisation is increasing the number of fixed and mobile network and service providers. Telecommunications operators no longer dominate the private equipment market so that distribution channels have become more complex. Furthermore, a growing proportion of user terminal equipment is coming to resemble consumer electronics in terms of design, manufacturing techniques, pricing and distribution which threatens the share of EC manufacturers of this market.

Business consumers use a range of equipment, from PABX to modems, as well as other customer premises equipment, to conduct their business. Demand for equipment for business users arises from the need to carry out the company's activities. Since the early 1980s, facsimile machines and telephones with a high number of functions (callback, repeat dialling, etc.) have become indispensable tools for business.

A number of large companies may have outright agreements with a manufacturer to buy directly from them rather than through the channel of the public telephone operator.

It is increasingly important for European business to be able to use the same terminal equipment in several countries. In response to this need and others, the players in the EC equipment makers market are agreeing to manufacturing equipment

under the same standards. The GSM (Global System for Mobile Communications) digital cellular standard is one of the initiatives that is moving industry in this direction.

Residential users historically have been buyers of telephone sets, but the value of the home market has seen recent expansion, notably as cordless hand sets substitute for or augment fixed telephones and as more sophisticated terminal equipment, such as facsimile machines, extends its presence. Residential users are also becoming more enthusiastic about having more than one telephone. In most households, there are normally at least two telephone sets, and functions, such as repeat dialling, are standard features rather than options. Residential users, however, tend to have a lower replacement/new purchase rate than businesses.

Residential users usually buy directly from the operator. However, in markets where telecommunications equipment supply has been liberalised following EC policy, consumers are able to buy directly from retailers. These trends will increase. In terms of price elasticity of demand, consumer products, such as telephone handsets, are more price sensitive than business/professional products. This has led to the proliferation of cheaper cordless terminals in many EC countries.

The rate of product innovation within the telecommunications equipment market has resulted in the continual introduction of new services and technologies onto the market, at times causing buyer confusion. Ever improving integration technologies allow for the production of multi-function platforms/terminals. Such equipment as faxes aimed at the home office worker can encompass three functions on the one small terminal (fax machine, telephone and answering machine).

Supply and competition

Manufacturers in France, Germany and UK are not only competing against each other in telecommunications equipment markets but also with the rising competition from outside the EC. Telephone handsets, for example, are mass manufactured in East Asia, especially in South Korea, at prices and quality standards which are acceptable to the final consumer. Another technology, mobile communications terminal equipment, will in the long term become attractive to consumer electronic suppliers (a technology area traditionally dominated by the Japanese).

Compared to East Asia, EC labour forces are generally more expensive to employ. European production costs tend to be higher due to three main reasons:

- European manufacturing is less automated than in Japan (although catching up);
- economies of scale are lower in Europe while the cost of labour is generally higher;
- government aid to telecommunications companies in Japan is significant, enhancing their ability to compete.

To ensure that EC manufacturers continue to be competitive in the telecommunications equipment market as it goes global, many companies have been forging joint ventures to profit from the know-how and distribution channels of other companies.

Non-EC manufacturers, notably the Japanese and Americans, have been carefully watching the Single European Market and have been preparing for some years to have a foothold in the market when it becomes liberalised. The UK has a large base of Japanese manufacturing companies who have achieved vertical integration in their production of both consumer goods, components as well as telecommunications equipment (e.g. Panasonic). AT&T, the USA giant, has established a manufacturing plant in Spain as has Ericsson. These corporate presences have had a very positive effect on Spain's intra-EC trade balance. Other means of entering the Single European Market include takeovers such as Northern Telecom's takeover of STC in the UK.

Pricing trends vary considerably across the telecommunications equipment markets. Mass market products, such as mobile terminals, have been subject to significant price reductions as a result of scale of economies in production and marketing, and mature technologies. However, niche market products, such as VSAT terminals, which are sold to the business sector, cannot take advantage of volume production techniques, and prices therefore tend to remain fairly stable.

Production process

In the development of telecommunications equipment, parts obtained from upstream industries or new technological developments in complementary industries affect the product innovation and the efficiency of telecommunications equipment.

The emergence of fibre optics has enabled formerly copper based networks to be upgraded to fibre optics, enabling the infrastructure to support new, value added services such as SDH and ATM technologies. These technologies represent strong business opportunities for vendors in the switching and transmission market. Network infrastructure based on Synchronous Digital Hierarchy (SDH) has just begun to be installed by public operators in order to replace or supplement existing plesiochronous systems. Asynchronous Transfer Mode (ATM) is emerging as the key technology for broadband, multimedia communications and will be used for both public and private networks.

New network technologies enable the provision of an increasing number of value added services, such as voice processing and electronic messaging, and intelligent networking functions such as freephone and personal numbering.

INDUSTRY STRUCTURE

Companies

Among the largest telecommunications firms are companies such as Alcatel, AT&T, Siemens, Northern Telecom, NEC and Ericsson. Towards the end of 1991, Alcatel overtook AT&T as the world's number one manufacturer through its latest acquisitions. Of the world's top six, two firms are accounted for by EC manufacturers: Alcatel (number one) and Siemens (number three). AT&T in second place, with Northern Telecom fourth, NEC fifth and Ericsson in sixth position.

Alcatel's strengths lie in transmission and public switching. The company has a strong presence in continental Europe but a weakness in the UK market. It is trying to penetrate the UK through the acquisition of cable and PABX companies. AT&T is heavily reliant on its domestic US market and has been forging alliances with EC manufacturers as a means of finding a European outlet for its products and to conforming to European technical standards. Siemens is particularly strong in public switching and transmission. Siemens in particular risks strong competition from Japanese manufacturers who are strong in data communications terminals.

Strategies

Players in the industry have recognised the need to alter their strategies to operate with a more global perspective in order to survive and expand outside their own domestic and EC markets. Serious threats are posed to some manufacturers in technologies which are closely linked to consumer electronics, such as the production of data communications equipment and handsets (including mobile communications terminals), and where competition from Japanese manufacturers is fierce.

The approaches taken to minimise the effects of competition and to build upon strengths have concentrated the telecommunications equipment industry. Two major forces behind these strategies are the need to share the vast R&D needed to develop key public network equipment (i.e. new switches) and the desire to acquire a local manufacturing base as a competitive advantage in selling to the (usually) state-owned telecommunications operators. Large companies are slowly absorbing both smaller and other large companies, alliances are being formed to profit from established distribution channels and customer base, and the sharing of technology.

Public bodies such as ETSI (European Telecommunications Standards Institute) have been vigorously trying to establish, and promote globally, EC standards. ETSI has been active in setting norms for a European ISDN system, mobile and personal communications, intelligent networks and terminal equipment.

The rate of EC investment in telecommunications equipment averaged 14.8% per year between 1982 and 1988, peaking in 1985. Investment slowed subsequently and declined by 1.9% in 1987. With the liberalisation of EC markets, manufacturers and bodies have realised that they need to spend on investment in order to ensure their competitiveness against new entrants in the Single Market. The objectives of investment include market diversification, taking advantage of market opportunities (due to the deregulation of the regulatory environment), and technological advancement.

REGIONAL DISTRIBUTION

The region of the Four Dragons (South Korea, Taiwan, Hong Kong and Singapore) is a mass market producer of mainly consumer equipment. Japanese and American industries have been moving into Europe to set up manufacturing plants for terminals and infrastructure.

For European and American enterprises, southern Europe has been attractive for setting up manufacturing plants due to the relatively cheaper labour and set-up costs without a reciprocal loss of expertise. As the barriers come down in Eastern Europe, there are likely to be more cost opportunities to be manufacturing locally in order to take advantage of unsatisfied local demand.

Already some 20 joint ventures for the manufacture of public network equipment have been formed in the CIS and Eastern Europe. Siemens and Alcatel have been the most aggressive with AT&T and Northern Telecom following. Initially these ventures will target the national and regional market but inevitably their existence will intensify global competition and, for the EC market this is likely to lead to the re-location of elements of production to these countries.

Table 6: Telecommunications equipment
Leading worldwide producers of telecommunications equipment, 1991

(million ECU)	Country	Telecom sales	Telecom sales/ overall sales (%)
Alcatel NV	EC	14 454	91.8
AT&T	USA	8 337	16.4
Siemens	EC	7 980	22.4
Northern Telecom	Canada	6 596	100.0
NEC	Japan	6 010	26.5
Ericsson	Sweden	5 751	93.9
Robert Bosch	EC	3 867	23.6
Motorola	USA	2 925	30.7
Fujitsu	Japan	2 405	14.9
IBM	USA	2 109	4.0
Ascom	Switzerland	1 741	100.0
Philips	EC	1 603	6.5
Italtel	EC	1 452	94.7
Nokia	Finland	1 305	42.2
Oki	Japan	1 107	27.1

ENVIRONMENT

The telecommunications equipment industry has not experienced any real problems in terms of ecological issues. There are no specific concerns particular to this industry which are not also found in others. There are concerns on the use of CFCs in semiconductors, but that is an issue which is being regulated by the components industry. There are fears of danger to health through over exposure to high frequencies but this is only caused by prolonged exposure at very high rates. Laying of cables and other transmission equipment has in the past posed an environmental problem, but these issues are usually resolved through agreement with local bodies and environmental groups.

REGULATIONS

As the EC moves closer to the Single Market, the European Commission, in partnership with National Regulatory Authorities, is attempting to regulate the services industry in the 12 Member States based on the model proposed in the 1987 EC Green Paper on Telecommunications and subsequently accepted. This model includes the:

- limitation of special and exclusive rights of telecommunications operators to the provision of network infrastructure and public voice telephony:
- unrestricted provision of all value added services;
- the complete liberalisation of the terminal equipment market;
- the introduction of the Open Network Provision programme to establish common conditions for network access including interfaces, tariffs and supply conditions;
- the creation of ETSI to promote EC-wide standards; and,
- the separation of the regulation of telecommunications services from operation.

Within the EC, procurement of equipment by the public telephone operators should become more open in the long run because of measures such as Directive 90/531 on procurement by companies with special rights. Telephone operators will be obliged to move to open public procurement for contracts above 600 000 ECU.
