

LMH6654/LMH6655

Single/Dual Low Power, 250 MHz, Low Noise Amplifiers

General Description

The LMH6654/LMH6655 single and dual high speed, voltage feedback amplifiers are designed to have unity-gain stable operation with a bandwidth of 250 MHz. They operate from $\pm 2.5V$ to $\pm 6V$ and each channel consumes only 4.5 mA. The amplifiers feature very low voltage noise and wide output swing to maximize signal-to-noise ratio.

The LMH6654/LMH6655 have a true single supply capability with input common mode voltage range extending 150 mV below negative rail and within 1.3V of the positive rail.

LMH6654/LMH6655 high speed and low power combination make these products an ideal choice for many portable, high speed application where power is at a premium.

The LMH6654 is packaged in 5-Pin SOT-23 and 8-Pin SOIC. The LMH6655 is packaged in 8-Pin MSOP and 8-Pin SOIC.

The LMH6654/LMH6655 are built on National's Advance VIP10™ (Vertically Integrated PNP) complementary bipolar process.

Features

($V_S = \pm 5V$, $T_J = 25^\circ C$, Typical values unless specified).

- Voltage feedback architecture
- Unity gain bandwidth 250 MHz
- Supply voltage range $\pm 2.5V$ to $\pm 6V$
- Slew rate 200 V/ μ sec
- Supply current 4.5 mA/channel
- Input common mode voltage $-5.15V$ to $+3.7V$
- Output voltage swing ($R_L = 100\Omega$) $-3.6V$ to $3.4V$
- Input voltage noise 4.5 nV/ \sqrt{Hz}
- Input current noise 1.7 pA/ \sqrt{Hz}
- Settling Time to 0.01% 25 ns

Applications

- ADC drivers
- Consumer video
- Active filters
- Pulse delay circuits
- xDSL receiver
- Pre-amps

Typical Performance Characteristics

VIP10™ is a trademark of National Semiconductor Corporation.

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/ Distributors for availability and specifications.

| | |
|---|--|
| ESD Tolerance (Note 2) | |
| Human Body Model | 2 kV |
| Machine Model | 200V |
| V _{IN} Differential | ±1.2V |
| Output Short Circuit Duration | (Note 3) |
| Supply Voltage (V ⁺ - V ⁻) | 13.2V |
| Voltage at Input pins | V ⁺ +0.5V, V ⁻ -0.5V |
| Storage Temperature Range | -65°C to +150°C |

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics Table.

Note 2: Human body model, 1.5 kΩ in series with 100 pF. Machine model: 0Ω in series with 100 pF.

Note 3: Continuous short circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature at 150°C.

Note 4: The maximum power dissipation is a function of $T_{J(MAX)}$, θ_{JA} and T_A . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(MAX)} - T_A)/\theta_{JA}$. All numbers apply for packages soldered directly onto a PC board.

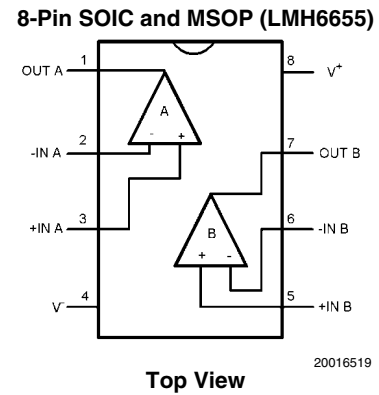

Note 5: Typical Values represent the most likely parametric norm.

Note 6: All limits are guaranteed by testing or statistical analysis.

Note 7: Offset voltage average drift is determined by dividing the change in V_{OS} at temperature extremes into the total temperature change.

Note 8: Slew rate is the slower of the rising and falling slew rates. Slew rate is rate of change from 10% to 90% of output voltage step.

Application Information

GENERAL INFORMATION

The LMH6654 single and LMH6655 dual high speed, voltage feedback amplifiers are manufactured on National Semiconductor's new VIP10 (Vertically Integrated PNP) complementary bipolar process. These amplifiers can operate from $\pm 2.5\text{V}$ to $\pm 6\text{V}$ power supply. They offer low supply current, wide bandwidth, very low voltage noise and large output swing. Many of the typical performance plots found in the datasheet can be reproduced if 50Ω coax and 50Ω R_{IN}/R_{OUT} resistors are used.

CIRCUIT LAYOUT CONSIDERATION

With all high frequency devices, board layouts with stray capacitance have a strong influence on the AC performance. The LMH6654/LMH6655 are not exception and the inverting input and output pins are particularly sensitive to the coupling of parasitic capacitance to AC ground. Parasitic capacitances on the inverting input and output nodes to ground could cause frequency response peaking and possible circuit oscillation. Therefore, the power supply, ground traces and ground plan should be placed away from the inverting input and output pins. Also, it is very important to keep the parasitic capacitance across the feedback to an absolute minimum.

The PCB should have a ground plane covering all unused portion of the component side of the board to provide a low impedance path. All trace lengths should be minimized to reduce series inductance.

Supply bypassing is required for the amplifiers performance. The bypass capacitors provide a low impedance return current path at the supply pins. They also provide high frequency filtering on the power supply traces. It is recommended that a ceramic decoupling capacitor $0.1\ \mu\text{F}$ chip should be placed with one end connected to the ground plane and the other side as close as possible to the power pins. An additional $10\ \mu\text{F}$ tantalum electrolytic capacitor should be connected in parallel, to supply current for fast large signal changes at the output.

FIGURE 1.

EVALUATION BOARDS

National provides the following evaluation boards as a guide for high frequency layout and as an aid in device testing and characterization.

| Device | Package | Evaluation Board PN |
|-----------|--------------|---------------------|
| LMH6654MF | 5-Pin SOT-23 | CLC730068 |
| LMH6654MA | 8-Pin SOIC | CLC730027 |
| LMH6655MA | 8-Pin SOIC | CLC730036 |
| LMH6655MM | 8-Pin MSOP | CLC730123 |

The free evaluation board are shipped automatically when a device sample request is placed with National Semiconductor.

The CLC730027 datasheet also contains tables of recommended components to evaluate several of National's high speed amplifiers. This table for the LMH6654 is illustrated below. Refer to the evaluation board datasheet for schematics and further information.

Components Needed to Evaluate the LMH6654 on the Evaluation Board:

- R_f, R_g use the datasheet to select values.
- R_{IN}, R_{OUT} typically 50Ω (Refer to the Basic Operation section of the evaluation board datasheet for details)
- R_f is an optional resistor for inverting again configurations (select R_f to yield desired input impedance = $R_g || R_f$)
- C_1, C_2 use $0.1\ \mu\text{F}$ ceramic capacitors
- C_3, C_4 use $10\ \mu\text{F}$ tantalum capacitors

Components not used:

1. C_5, C_6, C_7, C_8
2. R1 thru R8

The evaluation boards are designed to accommodate dual supplies. The board can be modified to provide single operation. For best performance;

- 1) do not connect the unused supply.
- 2) ground the unused supply pin.

POWER DISSIPATION

The package power dissipation should be taken into account when operating at high ambient temperature and/or high power dissipative conditions. In determining maximum operable

temperature of the device, make sure the total power dissipation of the device is considered; this power dissipated in the device with a load connected to the output as well as the nominal dissipation of the op amp.

DRIVING CAPACITIVE LOADS

Capacitive loads decrease the phase margin of all op amps. The output impedance of a feedback amplifier becomes inductive at high frequencies, creating a resonant circuit when the load is capacitive. This can lead to overshoot, ringing and oscillation. To eliminate oscillation or reduce ringing, an isolation resistor can be placed as shown in Figure 2 below. At frequencies above

$$F = \frac{1}{2 \pi R_{ISO} C_{LOAD}}$$

the load impedance of the Amplifier approaches R_{ISO} . The desired performance depends on the value of the isolation resistor. The isolation resistance vs. capacitance load graph in the typical performance characteristics provides the means for selection of the value of R_{ISO} that provides $\leq 3\ \text{dB}$ peaking in closed loop $A_v = 1$ response. In general, the bigger the isolation resistor, the more damped the pulse response becomes. For initial evaluation, a 50Ω isolation resistor is recommended.

FIGURE 2.

COMPONENTS SELECTION AND FEEDBACK RESISTOR

It is important in high-speed applications to keep all component leads short since wires are inductive at high frequency. For discrete components, choose carbon composition axially leaded resistors and micro type capacitors. Surface mount components are preferred over discrete components for minimum inductive effect. Never use wire wound type resistors in high frequency applications.

Large values of feedback resistors can couple with parasitic capacitance and cause undesired effects such as ringing or oscillation in high-speed amplifiers. Keep resistors as low as possible consistent with output loading consideration. For a gain of 2 and higher, 402Ω feedback resistor used for the typical performance plots gives optimal performance. For unity gain follower, a 25Ω feedback resistor is recommended rather than a direct short. This effectively reduces the Q of what

would otherwise be a parasitic inductance (the feedback wire) into the parasitic capacitance at the inverting input.

BIAS CURRENT CANCELLATION

In order to cancel the bias current errors of the non-inverting configuration, the parallel combination of the gain setting R_g and feedback R_f resistors should equal the equivalent source resistance R_{seq} as defined in *Figure 3*. Combining this constraint with the non-inverting gain equation, allows both R_f and R_g to be determined explicitly from the following equations:

$$R_f = A_V R_{seq} \text{ and } R_g = R_f / (A_V - 1)$$

For inverting configuration, bias current cancellation is accomplished by placing a resistor R_b on the non-inverting input equal in value to the resistance seen by the inverting input ($R_f // (R_g + R_s)$). The additional noise contribution of R_b can be minimized through the use of a shunt capacitor.

20016542

FIGURE 3. Non-Inverting Amplifier Configuration

20016543

FIGURE 4. Inverting Amplifier Configuration

TOTAL INPUT NOISE VS. SOURCE RESISTANCE

The noise model for the non-inverting amplifier configuration showing all noise sources is described in Figure 5. In addition to the intrinsic input voltage noise (e_n) and current noise ($i_n = i_{n+} = i_{n-}$) sources, there also exists thermal voltage noise $e_t = \sqrt{4kTR}$ associated with each of the external resistors. Equation 1 provides the general form for total equivalent input voltage noise density (e_{ni}). Equation 2 is a simplification of Equation 1 that assumes

20016544

FIGURE 5. Non-Inverting Amplifier Noise Model

$$e_{ni} = \sqrt{e_n^2 + (i_n + R_{seq})^2 + 4kTR_{seq} + (i_n - (R_f \parallel R_g))^2 + 4kT(R_f \parallel R_g)} \quad (1)$$

Noise Figure

Noise Figure (NF) is a measure of the noise degradation caused by an amplifier.

$$NF = 10 \text{LOG} \left[\frac{S_f/N_i}{S_o/N_o} \right] = 10 \text{LOG} \left[\frac{e_{ni}^2}{e_t^2} \right] \quad (3)$$

$R_f \parallel R_g = R_{seq}$ for bias current cancellation. Figure 6 illustrates the equivalent noise model using this assumption. The total equivalent output voltage noise (e_{no}) is $e_{ni} * A_V$.

20016545

FIGURE 6. Noise Model with $R_f \parallel R_g = R_{seq}$

$$e_{ni} = \sqrt{e_n^2 + 2 (i_n R_{seq})^2 + 4kT (2R_{seq})} \quad (2)$$

If bias current cancellation is not a requirement, then $R_f \parallel R_g$ does not need to equal R_{seq} . In this case, according to Equation 1, $R_f R_g$ should be as low as possible in order to minimize noise. Results similar to Equation 1 are obtained for the inverting configuration on Figure 2 if R_{seq} is replaced by R_b and R_g is replaced by $R_g + R_s$. With these substitutions, Equation 1 will yield an e_{ni} referred to the non-inverting input. Referring to e_{ni} to the inverting input is easily accomplished by multiplying e_{ni} by the ratio of non-inverting to inverting gains.

The noise figure formula is shown in Equation 3. The addition of a terminating resistor R_T , reduces the external thermal noise but increases the resulting NF.

The NF is increased because the R_T reduces the input signal amplitude thus reducing the input SNR.

$$NF = 10 \text{ LOG } \left[\frac{e_n^2 + i_n^2 (R_{seq} + (R_f \parallel R_g)^2) + 4kTR_{seq} + 4kt (R_f \parallel R_g)}{4kTR_{seq}} \right] \quad (4)$$

The noise figure is related to the equivalent source resistance (R_{seq}) and the parallel combination of R_f and R_g . To minimize noise figure, the following steps are recommended:

1. Minimize $R_f \parallel R_g$
2. Choose the Optimum R_s (R_{OPT})

R_{OPT} is the point at which the NF curve reaches a minimum and is approximated by:

$$R_{OPT} \approx (e_n/i_n)$$

Physical Dimensions inches (millimeters) unless otherwise noted

CONTROLLING DIMENSION IS MILLIMETER
VALUES IN [] ARE INCHES
DIMENSIONS IN () FOR REFERENCE ONLY

8-Pin SOIC
NS Package Number M08A

M08A (Rev M)

CONTROLLING DIMENSION IS INCH

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.
