MIL-PRF-38535J

This specification is approved for use by all Departments and Agencies of the Department of Defense.

This document is a performance specification. It is intended to provide the device manufacturers an acceptable established baseline in order to support Government microcircuit application and logistic programs. The basic section of this specification has been structured as a performance specification, which is supplemented with detailed appendices. These appendices provide guidance to manufacturers on demonstrated successful approaches to meeting military performance needs. These appendices are included as a benchmark and are intended to impose performance requirements. For QML microcircuits the manufacturer is required to develop a program plan that meets or exceeds the performance detailed in these appendices (see appendices A, G, H, and J). Appendix A is mandatory for manufacturers of device types supplied in compliance with MIL-STD-883 and forms the basis for QML classes Q and V. Appendix B is intended for space application and is required for V level devices. Appendix C is mandatory for devices requiring radiation hardness assurance (RHA). Appendix D is mandatory for statistical sampling, life test, and qualification procedures used with microcircuits.

1. SCOPE

1.1 Scope. This specification establishes the general performance requirements for integrated circuits or microcircuits and the quality and reliability assurance requirements, which are to be met for their acquisition. The intent of this specification is to allow the device manufacturer the flexibility to implement best commercial practices to the maximum extent possible while still providing product that meets military performance needs. Detail requirements, specific characteristics of microcircuits, and other provisions which are sensitive to the particular use intended will be specified in the device specification. Quality assurance requirements outlined herein are for all microcircuits built on a manufacturing line which is controlled through a manufacturer's quality management (QM) program and has been certified and qualified by the Qualifying Activity (QA) in accordance with requirements herein. Several levels of product assurance including RHA are provided for in this specification. The certification and qualification sections found herein outline the requirements to be met by a manufacturer to be listed on a Qualified Manufacturer Listing (QML). After listing of a technology flow on a QML, the manufacturer is to continually meet or improve the established baseline of certified and qualified procedures, the QM program, the manufacturer's review system, the status reporting, and quality and reliability assurance requirements for all QML products. The manufacturer may present alternate methods of addressing the requirements contained in this specification. These alternate methods shall be approved by the Qualifying Activity. This specification requires a manufacturer to establish a process flow baseline. If sufficient quality and reliability data is available, the manufacturer, through the QM program and the manufacturer's review system, may modify, substitute, or delete tests. Additional information on the QML process and its philosophy is available in 6.5 herein. Class T is not for use in National Aeronautics and Space Administration (NASA) manned, satellite, or launch vehicle programs without written permission from the applicable NASA project office (i.e., cognizant electrical, electronic, and electromechanical (EEE) parts authority).

2. APPLICABLE DOCUMENTS

2.1 General. The documents listed in this section are specified in sections 3, 4, or 5 of this specification. This section does not include documents cited in other sections of this specification or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in sections 3, 4, or 5 of this specification, whether or not they are listed.

MIL-PRF-38535J

2.2 Government documents.

2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

JESD625	- Requirements for Handling Electrostatic-Discharge-Sensitive (ESDS) Devices.

(Copies of these documents are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein (except for related specification sheets), the text of this document takes precedence. Nothing in this document, however, supersedes applicable laws and regulations unless a specific exemption has been obtained.

3. REQUIREMENTS

3.1 General. The manufacturer of QML microcircuits in compliance with this specification shall have or have access to and use of production and test facilities, and a QM program to assure successful compliance with the provisions of this specification. All microcircuits manufactured on a QML line shall be processed on a QA certified fabrication line, and shall be assembled on a QA certified assembly line. All microcircuits shall be electrically capable of meeting parameters over the specified temperature range in accordance with the device specification in a QA certified test facility. The QML manufacturer shall be capable of demonstrating their ability to develop hardware and software test programs before delivery of the product. The QML certification mark (3.6.3) indicates compliance to all the performance provisions of this specification. The requirements described herein shall be addressed in one of two ways. These are as follows:

- a. As specified herein.
- b. Demonstration to the qualifying activity (QA) and validation team when applicable, of an alternate method, that assures at least the same level of quality and reliability as defined by the requirements herein, or demonstration to the QA that the requirement is not applicable to the manufacturer's technology.

NOTE: A QML manufacturer may modify screening and Technology Conformance Inspection (TCI) requirements of the device specification or Standard Microcircuit Drawing (SMD) under special criteria defined within this specification and as defined in the manufacturer's QM plan. (For guidance on screening and QCI optimization see JEP121 - Requirements for Microelectronic Screening and Test Optimization and J.3.12 herein.) These changes cannot affect any thermal, mechanical, electrical parameters, or radiation levels (when applicable) which affect form, fit, or function of the device, defined within the device specification or SMD.

3.1.1 Reference to applicable device specification. For purposes of this specification, when the term "as specified" is used without additional reference to a specific location or document, the intended reference shall be to the device specification.

3.2 Item requirements. The individual item requirements, including temperature range, for integrated circuits delivered under this specification shall be documented in the device specification prepared in accordance with 3.5 herein. Devices produced under this specification may have any operating temperature range (case, ambient, or junction) as long as it is specified in the device specification, and any references to minimum or maximum operating temperatures shall refer to the respective lower and upper limits of this range. However, the manufacturer shall demonstrate the operating temperature range (case, ambient, or junction) capability of the technology being offered. The standard evaluation circuit (SEC) is typically used for this demonstration.

MIL-PRF-38535J

3.2.1 Certification of conformance and acquisition traceability. Manufacturers or suppliers including distributors who offer QML microcircuits described by this specification shall provide written certification, signed by the corporate officer who has management responsibility for the production of the QML microcircuits, (1) that the QML microcircuits being supplied have been manufactured and meet the performance defined in the specification whether or not the actual testing has been performed, (2) that all QML microcircuits are as described on the certificate of conformance which accompanies the shipment, and (3) that dealers and distributors have handled the QML microcircuit in accordance with the requirements of JESD625 and JESD31. The responsible corporate official may, by documented authorization, designate other responsible individuals to sign the certificate of conformance (such as members of the manufacturer's review system), but, the responsibility for conformity with the facts shall rest with the responsible corporate officer. The certification shall be confirmed by documentation to the Government or to users with Government contractors or subcontractors, regardless of whether the QML microcircuits are acquired directly from the manufacturer or from another source such as a distributor. When other sources are involved, their acquisition certification shall be in addition to the certificates of conformance and acquisition traceability provided by the manufacturer and previous distributors. The certificate shall include the following information:

a. Manufacturer documentation:

- (1) Manufacturer's name and address.
- (2) Customer's or distributor's name and address.
- (3) Device type.
- (4) Date code and latest re-inspection date, if applicable.
- (5) Quantity of devices in shipment from manufacturer.
- (6) Statement certifying QML microcircuit conformance and traceability.
- (7) Solderability re-inspection date, if applicable.
- (8) Signature and date of transaction.
- (9) If applicable, the certificate shall include a statement indicating that alternate die/fab requirements are being used ("QD" certification mark, see [3.6.3](#)).

b. Distributor documentation for each distributor:

- (1) Distributor's name and address.
- (2) Name and address of customer.
- (3) Quantity of devices in shipment.
- (4) Latest re-inspection date, if applicable.
- (5) Certification that this shipment is a part of the shipment covered by the manufacturer's documentation.
- (6) Solderability re-inspection date, if applicable.
- (7) Signature and date of transaction.

MIL-PRF-38535J

3.3 Quality management (QM) program. A QM program shall be implemented by the manufacturer (see [G.3.1](#)).

3.3.1 Manufacturer's review system. The Technology Review Board (TRB) (See [G.3.2](#)) shall implement a dedicated system of review. The TRB shall review, approve and document the implementation of the QM program, as reflected in the QM plan; maintenance of all certified and qualified processes; process change control; reliability data analysis, failure analysis (FA), and corrective actions; QML microcircuit recall procedures; and qualification status of the technology.

3.3.2 QM plan. A QM plan reflects the major elements of the manufacturer's QML process (see [G.3.3](#)). The QM plan shall be kept current and up-to-date and shall reflect all major changes. Whenever the TRB makes major changes to the QM plan, copies of the updated QM plan shall be submitted to the QA for review.

3.3.3 Self-assessment program. The manufacturer's TRB shall ensure that a self-assessment program is implemented and perform evaluations on a periodic basis of all areas controlled by the QM Plan. Results of the self-assessment including corrective actions shall be documented by the TRB and shall be made available for review to the QA (see [G.3.1](#)).

3.3.4 Change control procedures. The manufacturer shall have a system that shall provide notification of change that affects form, fit, function and radiation (when applicable) to all known acquiring activities prior to the release of the affected product. The manufacturer may make notification of this change of product through the Government-Industry Data Exchange Program (GIDEP) using the Product Change Notice. In any case, the manufacturer shall assure that all known acquiring activities are notified. The following processes and procedures shall be addressed (see [G.3.4](#)):

- a. Design methodology changes.
- b. Fabrication process changes.
- c. Assembly process changes.
- d. Package changes.
- e. Test facility changes.
- f. Location changes to fabrication, assembly, test, and qualification.

3.3.4.1 Discontinuation of products. The manufacturer shall have a system that provides notification of product discontinuation which comprises date of discontinuation and last times buy opportunity in advance (at least 6 month in advance) to the DLA Land and Maritime for purchasing devices.

3.4 Requirements for listing on a QML. To be listed on a QML, the manufacturer shall demonstrate compliance to the QML certification requirements (see [3.4.1](#)), demonstrate compliance to the QML qualification requirements (see [3.4.2](#)), and work with the DLA Land and Maritime to develop an SMD describing the candidate QML device(s) (see [3.5](#)). An existing MIL-M-38510 device specification may be used. The QA shall verify compliance to the requirements and shall list the manufacturer's technology on the QML.

MIL-PRF-38535J

3.4.1 QML certification requirements. The manufacturers shall meet the minimum procedures and requirements in this section for QML certification of a manufacturing line. The QA shall determine adequacy and compliance to the requirements as specified herein and shall report their findings and recommendations in writing to the manufacturer's TRB. Each portion of a QML microcircuit manufacturer's line capability, including any offshore operations, may be demonstrated independently, but validation by the QA shall assess a complete technology flow. To maintain certification the manufacturer shall provide notification of change to the process baseline to the QA. For generic qualification procedures, certification shall consist of:

- a. QM program documentation (see [G.3.1](#)).
- b. Process capability demonstration (see [3.4.1.1](#) and [H.3.1.9](#)).
- c. QA management and technology validation (see [3.4.1.2](#)).
- d. All procedures used to manufacture masks for monolithic fabrication (see [appendix H](#)).

3.4.1.1 Process capability demonstration. As part of certification, the manufacturer shall build devices, perform tests and run software benchmarks necessary to demonstrate that the manufacturer has a comprehension of the capability of the manufacturing process as related to quality, reliability and producibility. The summary of the results of all of these tests shall be available for review by the QA (prior to scheduling a validation review). These tests shall be designed to be used as a continual check of the process capability as well as an initial demonstration of such capability. The TRB shall determine when such tests are to be performed after initial certification.

Process capability demonstration shall consist of:

- a. Design.
 - (1) Circuit.
 - (2) Package.
- b. Wafer fabrication.
- c. Statistical process control (SPC) and in-process monitoring programs including the technology characterization vehicle (TCV) program, the SEC, and parametric monitors (PMs) (see [appendix H](#)).
- d. Wafer acceptance plan.
- e. Assembly and packaging.
- f. RHA (see [appendix C](#)).
- g. Testing (Wafer and Packaged level, as applicable).

3.4.1.1.1 New technology insertion. The supplier shall establish a new technology insertion program for the identification, management, and tracking of new technology. The program shall include a plan that defines the new technology, and the criteria and methodology for characterization and qualification of new technology. It shall also include the specific details of determining the potential failure mechanisms and activation energies and their respective mitigation strategies. The new technology insertion program, plan and methods shall be reviewed by the qualifying activity.

MIL-PRF-38535J

3.4.1.2 Management and technology validation. The validation by the QA shall include, as a minimum, the following applicable areas of each of the manufacturer's facilities (including second and third party facilities: Management quality assurance, design, mask, wafer fabrication, assembly and package, and test (electrical environmental and radiation (when applicable))). This validation procedure shall involve a QA review of the manufacturer's QM plan, self-validation and an on-site visit of the manufacturer's fabrication, assembly, test and other facilities as necessary.

3.4.1.3 On-site validation. Manufacturer shall make available to the QA all data needed to support QM policy and procedures. QA access to manufacturing (fab and assembly) , testing facilities and operators including offshore shall be required. For first time QML supplier certification, an on-site QA validation review of the manufacturer's design, wafer fabrication, assembly, and test facilities shall be required. After the initial qualification is accomplished and with the approval of the Qualifying Activity, an established manufacturer may add other design, wafer fabrication, assembly, and test facilities upon completion of the appropriate qualification testing, and a TRB self-assessment and approval. The QA reserves the right to perform on-site reviews of any facilities/technologies that the manufacturer plans to add to their QML listing. Validation of third party suppliers is the responsibility of the manufacturer.

3.4.1.3.1 Second and third party validations. A QML certified manufacturer may use second party facilities with the approval of the QA. A second party facility shall be a QML certified manufacturer facility or a facility that has been granted approval by the QA for the manufacture or test of QML product. The QA is responsible for the initial and periodic validation of second party facilities. The process used by the manufacturer's TRB to initially validate, and to periodically revalidate, a third party facility shall be reviewed during the initial QML validation process. For third party facilities the QA shall make a determination whether an onsite certification is required for class level S product. The QA reserves the right to visit third party facilities to verify that the manufacturer's on-going validation process is effective.

3.4.1.3.2 Radiation source of supply (RSS) validations. An RSS shall receive a QML validation for all processes listed in this specification and the RSS's program plan. This includes a QML validation of the manufacturing process and laboratory suitability of the RHA test facilities.

3.4.1.4 Technology validation. The manufacturer's technology flow shall be reviewed and approved by the QA. Some critical areas which shall be assessed by the QA, as applicable during the validation, are:

- a. Design center procedures.
- b. Design review procedures.
- c. Model verification.
- d. Software configuration and configuration management.
- e. Testability procedures and policies (e.g., Joint Test Action Group (JTAG)) as applicable.
- f. Archival system (e.g., very high speed integrated circuit (VHSIC) hardware description language (VHDL)).
- g. Mask validation/inspection procedures.
- h. TCV, SEC, PM tests, and data.
- i. Fabrication rework procedures.
- j. SPC program (all areas).
- k. Design rule documentation.
- l. Clean room procedures.
- m. Wafer traceability.

MIL-PRF-38535J

- n. Gallium Arsenide (GaAs) wafer boule evaluation procedure.
- o. Assembly rework procedure.
- p. Die attach procedures.
- q. Wire/ribbon bonding.
- r. Device traceability and travelers.
- s. Lot formation (wafer, device and inspection).
- t. Assembly area environmental control.
- u. Internal moisture vapor control program.
- v. Electrostatic discharge (ESD) control and testing.
- w. Visual inspection.
- x. Human contamination prevention procedures.
- y. Equipment calibration and maintenance.
- z. Training policy and procedures.
- aa. Electrical test procedures.
- bb. Screening procedure.
- cc. TCI procedures.
- dd. Third party design center procedures.
- ee. Change control procedure.
- ff. Chip encapsulation/molding.
- gg. Qualification test plan.
- hh. Characterization procedures.
- ii. Selection of suppliers.
- jj. New technology/materials evaluation.

3.4.1.4.1 Package design selection reviews. The manufacturer shall establish and implement systematic package design or selection reviews to ascertain compatibility of chip(s) and packages with respect to thermal, electrical and mechanical performance and manufacturing, testing, and reliability requirements. Manufacturer's package element material and finish shall be in accordance with [A.3.5.6](#) unless otherwise specified in the manufacturer's QM plan.

MIL-PRF-38535J

3.4.1.5 Manufacturer self-validation. The manufacturer shall perform a self-validation to determine compliance to the QM plan (see [appendix G](#)).

3.4.1.6 Change management system. The manufacturer shall have a system for change management. This system shall include a process to monitor internal changes and the assessment of those changes as to the impact to customers. The manufacturer shall analyze the impact of major changes and its effects on previously approved modifications of test (see [J.3.12](#)). An appropriate customer notification methodology shall be in place.

3.4.1.7 Deficiencies and concerns. Deficiencies and concerns shall be noted by the validation team during an exit critique and shall be followed up with a written report. The microcircuit manufacturer shall not receive a letter of certification until all certification requirements are met.

3.4.1.8 Letter of certification. After validation, the QA shall issue a letter of certification to the manufacturer, which shall include all certified site(s).

3.4.2 QML qualification requirements. Integrated circuits (ICs) furnished under this specification shall be products which are authorized by the QA for listing on the QML. Qualification testing shall be performed in accordance with the agreed upon qualification plan (see [appendix H](#)).

3.4.2.1 Qualification extension. When a basic plant desires to qualify a device or process flow that includes an offshore site, application for certification and qualification may be extended with QA approval under the following conditions:

- a. Control and approval of the design, fab, assembly and test operations by the manufacturer's TRB is required along with periodic self-assessments of the offshore sites. The manufacturer's TRB shall review all screening and TCI tests to determine whether they should be performed exclusively in the offshore site or reserved for the basic plant in order to assure quality and reliability. The manufacturer's TRB assessment shall be made available to the QA for review or approval as appropriate.
- b. QA certification of the offshore site is required. For class Q and V products all operations, sites, and plants shall be QA certified however, this certification may be issued through the manufacturer's TRB with QA approval. Validation of these offshore operations is also required. For assembly site(s) an initial site shall be certified and qualified by the QA. Additional assembly sites shall be assessed subsequent to the initial validation.
- c. All devices assembled in the offshore assembly site shall have a country of origin marking (see [3.6.5](#)) reflecting the assembly site. In addition, a unique code shall be marked on each device to assure traceability to the assembly site(s).
- d. All operations, flows, quality control procedures and test standards at the offshore site shall be under the control of the manufacturer's TRB. Alternately, the manufacturer shall establish a procedure for maintaining oversight of the offshore facility. All such operations, flows, procedures and test standards shall be baselined by the manufacturer's TRB and the offshore site at all times.
- e. The QA reserves the right to audit the offshore site(s) with a minimum notice. The basic plant site shall be responsible to facilitate all QA site assessments. Any refusal to allow such a site assessment may result in an immediate de-certification and QML removal.

MIL-PRF-38535J

3.4.3 Qualification to RHA levels. Qualification to a RHA level shall consist of approval by the QA of a radiation testing plan and qualification to the appropriate quality and reliability assurance level (class B, Q, S, V, or T) and RHA levels as defined below:

RHA levels:

RHA level designator (see 3.6.2.1)	Radiation and total dose (Rads (Si))
/ or -	No RHA
M	3000
D	10^4
P	3×10^4
L	5×10^4
R	10^5
F	3×10^5
G	5×10^5
H	10^6

3.4.4 QML listing. A certificate of qualification shall be issued upon successful completion of all qualification tests on the two demonstration vehicles and the acceptance of the qualification documentation by the QA. Issuance of the certificate of qualification shall coincide with listing of the manufacturing line and the SMD(s), or existing MIL-M-38510 device specification(s) on the QML. The manufacturer may be removed from the QML by the QA for cause.

3.4.5 Maintenance and retention of QML. In order to sustain qualification status after initial qualification, the manufacturer shall fabricate and perform qualification testing on the selected SEC and TCV, or approved alternate assessment procedure as defined in the QM plan.

3.4.6 QML line shutdown. If an extended shutdown of a QML certified/qualified flow is necessary, the TRB shall assess and ensure that the process is still capable when production is restarted and notify the QA.

3.4.7 Revalidation reviews. The interval between on-site revalidation reviews shall normally not exceed two years, but the QA shall adjust this interval based on the manufacturer's TRB reports, customer feedback, and other indications of the manufacturer's maintenance of the QML system.

3.4.8 Performance requirements for class T devices. The manufacturer of a class T device shall be a certified and qualified QML manufacturer approved by the QA. The class T devices shall be manufactured on a certified and qualified QML line as defined in 3.4 herein. The class T flow shall be developed and approved through the manufacturer's TRB; shall be qualified; shall be defined in the manufacturer's QM plan; and be approved by the QA. Each technology flow (e.g., wafer fabrication, assembly, screening, qualification, TCI, etc.) shall be developed and documented taking into account the application requirements of the customers. The device manufacturer shall demonstrate that the failure mode and mechanisms of the technologies are considered when developing the technology flow. Copies of each technology flow, including supporting documentation, shall be reviewed and approved by the QA prior to listing as an approved source of supply. Any modification to the approved technology flow shall be reviewed and approved by the TRB and the QA. The technology flow and supporting documentation shall be made available to the systems manufacturers, the Government, and customers for review. The customer shall be notified of major changes which affect form, fit, or function of the device defined within the device specification and the manufacturer's QM plan. Class T is not for use in NASA manned, satellite, or launch vehicle programs without written permission from the applicable NASA Project Office (i.e., cognizant EEE parts authority).

MIL-PRF-38535J

3.4.8.1 Class T radiation requirements. The device specification shall define all the radiation features offered by the QML manufacturer for the class T device. QML manufacturers supplying class T devices shall meet the requirements of TM 1019 of MIL-STD-883 and shall document in the QM plan the RHA level specified for the device offered. All devices supplied to this product class shall be marked with a RHA designator as specified in 3.4.3 herein. Traceability shall be established such that there is a technical basis for compliance to the specified RHA level designator as marked on the device.

3.5 Device specification. MIL-HDBK-780 details the SMD format to be used (SMD's are to be used except where the device specification is a MIL-M-38510 device specification or an altered item drawing is required by the device specification or SMD) and data requirements to be submitted with any device procured under this specification. The QML certification mark shall not be used until the device specification is approved (see 3.6.3).

3.6 Marking of microcircuits. Marking of QML microcircuits shall be in accordance with the following and the identification and marking provisions of the device specification or drawing. The marking shall be legible and complete. If any special marking (e.g., altered item drawing number) is used by the device supplier or user/equipment contractor, it shall be in addition to the existing/original marking as required herein and shall be visibly separate from and in no way interfere with the marking required herein. The following shall be placed on each microcircuit:

- a. Index point (see 3.6.1).
- b. Part or identification number (PIN) (see 3.6.2).
- c. Certification mark "Q", or "QML" or "QD": All Microcircuits acquired to, and meeting the requirements of this specification and the applicable SMD, device specification, or military temperature range data book parts, which are approved for supply under QML, the manufacturers shall bear the "QML" or "Q" certification mark (see 3.6.3), and for diminishing manufacturing sources (DMS) product using the alternate die/fabrication requirements of A.3.2.2 or other alternatives, the manufacturer shall use the "QD" certification mark in lieu of the "Q" or "QML" mark (see 3.6.3.1). The certification marks "Q", or "QML" or "QD" shall be separated and distinct from Part identification number (PIN).
- d. Manufacturer's identification (see 3.6.4).
- e. Country of origin (see 3.6.5).
- f. Date code (see 3.6.6).
- g. Special marking (see 3.6.7).
- h. Serialization; when specified by the procuring activity, each microcircuit shall be marked with a unique serial number assigned within that inspection lot prior to the first recorded electrical measurement in screening.
- i. Electrostatic discharge sensitivity identifier, if applicable (see 3.6.7.2).

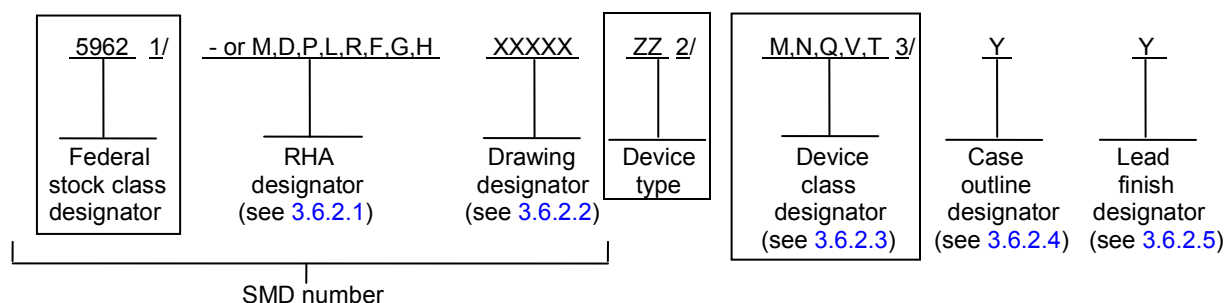

NOTE: For unpackaged die only items b. through i. shall apply and be marked on the wafer or die carrier and any other container external to the wafer or die carrier. For tape automated bonded (TAB) (see appendix F) devices marking shall be as defined in the procurement document.

3.6.1 Index point. The index point, tab, or other marking indicating the starting point for numbering of leads or for mechanical orientation shall be as specified in the device specification and shall be designed so that it is visible from above when the microcircuit is installed in its normal mounting configuration. The outline, or solid equilateral triangle(s), which are used as an electrostatic identifier (see 3.6.7.2), may also be used as the pin 1 identifier.

MIL-PRF-38535J

3.6.2 Part or identification number (PIN). Each QML microcircuit shall be marked with the complete PIN. The PIN may be marked on more than one line provided the PIN is continuous except where it "breaks" from one line to another. As of revision B of MIL-PRF-38535, several types of documents are acceptable for use when specifying QML microcircuits. They are MIL-M-38510 device specifications and SMD. The PIN marked on those parts under QML shall be the same as when supplied by the manufacturer prior to being listed on the QML-38535. The "Q" or "QML" designator combined with the listing of that PIN on a particular vendors QML listing shall indicate the fact that the manufacturer of the device is QML certified and qualified for the processes used to build that product. The PIN system shall be of one of the following forms, as applicable to the SMD or MIL-M-38510 device specification used for production:

a. SMD PINs shall be as follows:

For packages where marking of the entire SMD PIN and all other required topside markings are not possible due to space limitations, the manufacturer has the option of leaving the "5962-" off the marking. The allowance for optional marking will be indicated in the individual SMD. For RHA product using this option, the RHA designator shall still be marked.

b. Device specification documents, originally published prior to 27 July 1990, shall be as follows:

All new PINs specified by new documents, originally published after 27 July 1990, shall be in accordance with the one part-one part number system.

All PINs specified by existing device specifications with the number assigned prior to 27 July 1990, may use either the original assigned PIN or the one part one-part number system with the first two digits in the drawing designator being "38" and the last three being the device specification number (e.g., M38510/00101BAC shall become 5962-3800101BAC).

1/ Drawings initiated prior to 1986 may not contain a federal stock class designator.

2/ Low dose rate sensitivity shall be indicated in the device specification for those devices that are susceptible to enhanced low dose rate sensitivity (ELDRS) effects. For device type series that are marked 61, 62, 63, and so forth, the designator shall indicate that the device has been characterized/tested for ELDRS and is ELDRS sensitive.

3/ Non one-part SMDs do not contain a device class designator. See MIL-HDBK-103 for qualification information. Prior MIL-M-38510 device specifications converted to SMDs shall contain a B or S class designator.

MIL-PRF-38535J

3.6.2.1 RHA designator. A "-" or "/" indicates no radiation hardness assurance. Letters M, D, P, L, R, F, G, or H designations are defined RHA level in (rads(Si)) (see 3.4.3.).

3.6.2.2 Drawing designator. The first two characters of the designator shall consist of the last two digits of the year; the last three characters shall consist of unique characters assigned to the drawing by DLA Land and Maritime.

3.6.2.2.1 Military designator. The M38510 military designator for microcircuits means a "MIL" specification item produced in full compliance with this specification including qualification, and the device specification. Any device which does not meet all the requirements of this specification and the device specification shall not be marked M38510 and shall not make reference to MIL-PRF-38535.

NOTE: The military designator is optional for leadless chip carrier outlines that have a surface area smaller than the C-10 package.

3.6.2.3 Device class designator. The device class shall be designated by a single letter identifying the quality assurance level. For example:

<u>Military documentation format</u>	<u>Example PIN under new system</u>	<u>Manufacturing source listing</u>	<u>Document listing</u>
MIL-PRF-38535 SMDs	5962-XXXXXXZZ(N, Q, V, T (B or S))YY (see 6.4.27 through 6.4.33)	QML-38535	MIL-HDBK-103
1.2.1 of MIL-STD-883 SMDs	5962-XXXXXXZZ(M)YY (see 6.4.27 through 6.4.33)	MIL-HDBK-103	MIL-HDBK-103

3.6.2.4 Case outline. The case outline shall be designated by a single letter assigned to each outline within each device specification.

3.6.2.5 Lead finish. The lead finish (see A.3.5.6.3.2) shall be designated by a single letter as follows:

<u>Finish letter</u>	<u>Process</u>
A	Hot solder dip
B	Tin-lead plate
C	Gold plate
D	Palladium
E	Gold flash palladium
X	Either A, B, or C (mark on specification only)

NOTE: Lead finishes D and E are equivalent, and one may be substituted for the other, at the manufacturer's option.

3.6.3 Certification mark. All microcircuits acquired to and meeting the requirements of this specification and the applicable SMD, device specification, or military temperature range data book parts, which are approved for supply under QML, shall bear the "QML" or "Q" certification mark. The certification marks "Q", or "QML" shall be separated and distinct from Part identification number (PIN).

3.6.3.1 "QD" certification mark. QML manufacturers shall request QA approval for diminishing manufacturing sources (DMS) product using the alternate die/fabrication requirements of A.3.2.2 or other alternatives. Upon approval the manufacturer shall use the "QD" certification mark in lieu of the "Q" or "QML" mark. The certification mark "QD" shall be separated and distinct from Part identification number (PIN).

MIL-PRF-38535J

3.6.3.2 "JAN" or "J" mark. The "J" marking is a legacy certification mark that was required by MIL-M-38510 device specifications and qualified on a QPL part by part basis. Since the "J" is often mistakenly considered part of the PIN, it may continue to be marked in front of the military designator portion of the device specification part number at the QML vendor's option. This "J" was not and shall not be considered element of the official part number used to assign a national stock number.

3.6.4 Manufacturer's identification. Microcircuits shall, as a minimum, identify the manufacturer by the marking of name or trademark of the manufacturer. When space permits, the manufacturer may also mark the manufacturer's Commercial and Government Entity (CAGE) code. The identification of the equipment manufacturer may appear on the microcircuit only if the equipment manufacturer is also the microcircuit manufacturer. If the microcircuit manufacturer's designating symbol or CAGE code number is marked, it shall be as assigned by the Defense Logistics Information Service (DLIS). The designating symbol shall be used only by the manufacturer to whom it has been assigned and only on those devices manufactured at that manufacturer's plant. In the case of small microcircuits, the manufacturer's designating symbol may be abbreviated by omitting the first "C" in the series of letters.

3.6.4.1 Code for assembly sites. If the manufacturer has more than one offshore facility for assembly in a given country, a unique single letter code shall be assigned for the assembly sites used. This code shall be marked on the device immediately preceding or immediately after the date code. The assembly codes and the full address shall be included in the QML.

3.6.5 Country of origin. The name of the country of assembly or an appropriate abbreviation shall be marked in small characters below or adjacent to the other marking specified. Backside marking of the country of origin information is permitted.

3.6.6 Date code. Microcircuits shall be marked with a unique code to identify the first or the last week of the period (6 weeks maximum) during which devices in that inspection lot were sealed. The first two numbers in the code shall be the last two digits of the number of the year, and the third and fourth numbers shall be two digits indicating the calendar week of the year.

3.6.7 Marking location and sequence. The QML certification mark, the PIN, the date code, and ESD identifier, if applicable (see 3.6.7.2), shall be located on the top surface of leadless or leaded chip carriers, pin grid array packages, flat packages or dual-in-line configurations and on either the top or the side of cylindrical packages (TO configurations and similar configurations). When the size of a package is insufficient to allow marking of special process identifiers on the top surface, the backside of the package may be used for these markings except the ESD identifier, if applicable, which shall be marked on the top. Button cap flat packs with less than or equal to 16 leads may have the identifier marked on the ceramic. Backside marking with conductive or resistive ink shall be prohibited. For unpackaged die, marking is to be located on the container.

3.6.7.1 Beryllium oxide package identifier. If a microcircuit package contains beryllium oxide, the part shall be marked with the designation "BeO".

3.6.7.2 Electrostatic discharge (ESD) sensitivity identifier. Individual microcircuit ESD classification marking is not required. The manufacturer shall have an option of no ESD marking, marking a single ESD triangle or marking in accordance with the ESD device classification defined in test method (TM) 3015 of MIL-STD-883. Because it may no longer be possible to determine the ESD classification from the part marking, the Device Discharge Sensitivity classification shall have to be obtained through MIL-HDBK-103 or QML-38535.

MIL-PRF-38535J

3.6.8 QML marked product. For QML certified and qualified manufacturers and manufacturers who have been granted transitional certification (see [H.3.3](#)), standard product (Joint Army Navy (JAN), class M SMDs, and military temperature range class B data book product), produced on a QML flow may be marked with the "Q" or "QML" certification mark. This allowance applies to contractor prepared drawings covering standard product only if the drawing was released prior to 31 December 1993 or the date the manufacturer becomes QML whichever is the later date, and the part is marked with the standard part number. A list of the manufacturer's military temperature range product to be included under QML shall be submitted to the QA for approval. Contractor prepared drawings written for nonstandard parts may not be marked with a "Q" or "QML". The only exception to this requirement is an altered item drawing required by a device specification or SMD.

Only parts covered by a MIL-M-38510 device specification, an SMD, or generic parts that have been grandfathered (a list of eligible devices shall be submitted to DLA Land and Maritime-VA or DLA Land and Maritime-VQ for review) shall be listed on QML-38535. After 31 December 93, new QML products, which are marked with a "Q" or "QML" certification mark, shall be documented on an SMD (see [3.5](#)). Any device that is not processed in compliance with the provisions of MIL-PRF-38535 shall not be claimed to be compliant. Non-compliant products shall not contain "QML", "QMLV" or any variant thereof within the vendor part number or within any marking located on the package.

3.6.9 Marking on container. All of the markings specified in [3.6](#), except the index point, shall appear on the die container/package (e.g., waffle pack, etc.), carrier, unit pack (e.g., individual foil bag), unit container, or multiple carriers (e.g., tubes, rails, magazines) for delivery. For ESD sensitive devices, an industry standard symbol used to identify ESD sensitivity (e.g., JESD471 symbol) shall be marked on the carrier or container. However, if all the marking specified above is clearly visible on the devices and legible through the unit carrier or multiple carriers, or both, then the ESD marking only (MIL-STD-1285) shall be required on the multiple carriers. These requirements apply to the original or repackaged QML microcircuits by the manufacturer or distributor.

3.7 Remarking. QML microcircuits may be remarked provided that all remarking procedures are approved by the TRB. Remarking shall be in accordance with [3.6](#) herein.

3.8 Screening and test. All microcircuits delivered in accordance with this specification shall meet the screening and testing requirements of [4.2](#) herein whether or not the actual testing has been performed.

3.9 Technology conformance inspection (TCI). All microcircuits delivered in accordance with this specification shall meet the TCI requirements of [4.3](#) herein whether or not the actual testing has been performed.

3.9.1 TCI assessment. In the event the TRB determines that the TCI requirements are not met, the TRB shall notify the Qualifying Activity (QA) immediately, a list of the product shall be generated by the TRB, and the qualifying activity shall be notified of the decision.

3.10 Solderability. All parts shall be capable of passing the solderability test in accordance with TM 2003 of MIL-STD-883, on delivery.

3.11 Traceability. Traceability to the wafer lot level (for GaAs to wafer level) shall be provided for all delivered microcircuits. Traceability includes, as a minimum, the completion of each step required in design (when applicable), fabrication, assembly, test and any applicable qualified rework procedure.

3.12 ESD control. QML microcircuits shall be handled in accordance with JESD625 or other industry standard practices, to safeguard against discharge damage.

3.13 Recycled, recovered, or environmentally preferable materials. Recycled, recovered, or environmentally preferable materials should be used to the maximum extent possible provided that the material meets or exceeds the operational and maintenance requirements, and promotes economically advantageous life cycle costs.

MIL-PRF-38535J

3.14 Alternate test requirements. The manufacturer shall follow the test method requirements per MIL-PRF-38535 or TM 5004/5005 of MIL-STD-883. Upon approval from QA, as an option the manufacturer may follow TM 5004/5005 of MIL-STD-883 versus MIL-PRF-38535 test method. The manufacturer shall not be allowed to switch back and forth between TM 5004/5005 of MIL-STD-883 and MIL-PRF-38535 test method.

3.15 Passive elements. Passive elements are restricted to capacitors. Passive elements that are internally or externally utilized as an integral part of QML microcircuits shall meet the requirements of the following subparagraph. The microcircuits utilizing these passive elements shall be manufactured, processed, and verified to meet the requirements of this specification. The use of passive elements shall be documented on the applicable device specification and shall include, but not be limited to, the type of element, the value and ratings of the element, the governing specification for the element, and other information necessary to positively identify the element.

3.15.1 Capacitors. Discrete capacitors, that are included as integral parts of the microcircuit design shall be used to improve the microcircuit performance in areas of decoupling, signal conditioning, or noise conditioning and radiation hardened assurance performance. Discrete capacitors that are internally or externally utilized as part of QML microcircuits shall meet the following requirements: For class Q microcircuits, the capacitors shall either meet the requirements of MIL-PRF-55681 ("S" failure rate level) or be approved for use by the Qualifying Activity (QA). For class V microcircuits, the capacitors shall meet or exceed the requirements of MIL-PRF-123 or be approved for use by the QA. The microcircuit manufacturer shall document in their QM plan the processes used concerning the capacitors. This shall include, but not be limited to, inspection, assembly including attach procedures, testing including final electrical and groups A, D, and E.

MIL-PRF-38535J

4. VERIFICATION

4.1 Verification. A verification system shall be in place to verify the requirements of section 3 in accordance with [appendix J](#). Any screen or TCI test prescribed herein may be reduced, modified, moved, or eliminated by the QML manufacturer provided the product is still capable of meeting the screening and TCI testing groups A, B, C, D, and E for the applicable detail specification as approved by the QA.

4.2 Screening. All QML integrated circuits shall meet the requirements of the screens specified in tables IA and IB herein of the specification whether or not the actual testing has been performed. The procedures and accept and reject criteria for the screens shall have been certified by the QA. With QA approval the requirements of test method 5004 of MIL-STD-883 may be substituted for the screening requirements herein. When using TM 5004, class Q shall meet the requirements of the class level B screening flow whether or not the actual testing has been performed and class V shall meet the requirements of the class level S screening flow and appendix B herein whether or not the actual testing has been performed. The manufacturer, through its TRB, shall identify which tests are applicable to guarantee the quality and reliability of the associated technology or end product (e.g., wafer or die product, packaged product, plastic, etc.). The manufacturer may elect to eliminate or modify a screen based on supporting data that indicates that for the QML technology, the change is justified (see [J.3.12](#) herein). If such a change is implemented, the manufacturer is still responsible for providing product that meets all of the performance, quality, and reliability requirements herein.

4.2.1 Screen testing failures. Devices that fail any screen test shall be identified, segregated, or removed.

4.2.2 Screening resubmission criteria. When it has been established that a failure during screening tests is due to operator error or equipment failure and it has been established that the remaining QML microcircuits have not been damaged or degraded, the surviving microcircuits, as the case may be, may be resubmitted to the corrected screening test(s) in which the error occurred. Failures verified as having been caused by test equipment failure or operator error shall not be counted in the percent defective allowable (PDA) calculation (when applicable). ESD failures shall be counted as rejects and shall not be attributed to equipment failure or operator error.

4.2.3 Electrostatic discharge (ESD) sensitivity. ESD sensitivity testing shall be done in accordance with TM 3015 of MIL-STD-883 and the device specification. The testing procedure defined within JESD22-A114 may be used as an option in lieu of TM 3015 provided the manufacturer is able to demonstrate correlation between the two methods. In addition, the reported sensitivity classification levels shall be the ones defined within TM 3015 of MIL-STD-883 (see [3.6.7.2](#)). In addition, unless otherwise specified, tests shall be performed for initial qualification and product redesign as a minimum.

4.3 Technology conformance inspection (TCI). All product shipped shall be capable of passing TCI in accordance with tables II, III, IV, and V; for plastic packages see [table IB](#) herein. With QA approval when TM 5005 of MIL-STD-883 is used as a TCI option, class Q shall be capable of passing the class level B flow and class V shall be capable of passing the class level S flow. When selecting the TM 5005 TCI option for class V, the group B end-point electricals shall be the same as the group C end-point electricals, unless otherwise specified in the acquisition document. TCI testing shall be accomplished by the manufacturer on a periodic basis to assure that the manufacturer's quality, reliability, and performance capabilities meet the requirements of the QM plan (see [G.3.3](#)). Where appropriate, as an option, in place of the fixed sample size (Acceptance number) the manufacturer may use the sample size series (SSS) plan of [appendix D](#).

4.4 Qualification inspection. Qualification inspection shall be performed in accordance with [H.3.2.1.4](#) and [H.3.4](#)

MIL-PRF-38535J

TABLE IA. Microcircuit screening procedure for hermetic QML microcircuits.

Screen	MIL-STD-883, test method (TM), and condition
1. Electrostatic discharge (ESD) sensitivity	TM 3015 (see 4.2.3 , initial qualification only)
2. Wafer acceptance	TRB plan (see H.3.2.1.4)

TABLE IB. Tests/monitors for plastic packages. 1/

Test/monitor	MIL-STD-883 test method (TM) or industry standard
1. Wafer acceptance	TRB plan (see H.3.2.1.4)
2. Internal visual	TM 2010 or in accordance with manufacturers internal procedures
3. Temperature cycling/thermal shock	TM 1010/TM 1011
4. Resistance to solvents	TM 2015
5. Bond strength	TM 2011
6. Ball shear	ASTM F1269
7. Solderability	TM 2003
8. Die shear or stud pull	TM 2019 or TM 2027
9. Steady-state life test End-point electricals	TM 1005 In accordance with device specification
10. Physical dimensions	TM 2016
11. Lead integrity	TM 2004
12. Inspection for delamination	e.g., TM 1034 (dye penetrant test), cross-sectioning, C-mode scanning acoustical microscopy (CSAM), etc.
13. Highly accelerated stress testing (HAST)	100 hours, +130°C, 85% relative humidity (RH) <u>2/</u>
14. Autoclave	JESD 22-A102 (no bias) 2 atm., +121°C
15. Salt atmosphere	TM 1009
16. Adhesion to lead finish	TM 2025
17. Interim pre burn-in electricals	In accordance with device specification
18. Burn-in test	TM 1015, 160 hours at +125°C or manufacturers QM plan
19. Interim post burn-in electricals	In accordance with device specification
20. PDA or alternate procedure for lot acceptance	1% PDA or manufacturer's QM plan
21. Final electrical tests (see table III , herein, for definition of subgroups) a. static b. dynamic c. functional d. switching	In accordance with device specification
22. External visual	TM 2009 or JESD22-B101 or manufacturers internal procedures

1/ Test methods (TMs) are listed herein to give the manufacturer an available method to use. Alternate procedures and test methods may be used. Monitor frequency and sample plan shall be in accordance with manufacturer's QM plan.

2/ An alternate process monitor may be used; e.g., +85°C/85% relative humidity (RH).

MIL-PRF-38535J

TABLE II. Group B tests (Mechanical and environmental test). 1/

Subgroup	MIL-STD-883			Minimum sample size quantity (accept no.)
	Test	Test method	Condition	
1	Resistance to solvents	2015		3(0)
2	Bond strength (1) Thermo compression (2) Ultrasonic (3) Flip-chip (4) Beam lead Die shear test or stud pull	2011 2019 or 2027	(1) C or D (2) C or D (3) F (4) H	22(0) Based on the number of wires from 4 devices minimum 3(0)
3	Solderability	2003	Solder temperature +245°C ±5°C	22(0) based on leads from 3 devices minimum

1/ Group B test shall be performed on each inspection lot, for each qualified package type and lead finish.

TABLE III. Group A (electrical tests). 1/

Subgroup	Parameters	Quantity (accept no.)
1	Static tests at +25°C	116(0)
2	Static tests at maximum rated operating temperature	116(0)
3	Static tests at minimum rated operating temperature	116(0)
4	Dynamic tests at +25°C	116(0)
5	Dynamic tests at maximum rated operating temperature	116(0)
6	Dynamic tests at minimum rated operating temperature	116(0)
7	Functional tests at +25°C	116(0)
8	Functional tests at maximum (8A) and minimum (8B) rated operating temperature	116(0)
9	Switching tests at +25°C	116(0)
10	Switching tests at maximum rated operating temperature	116(0)
11	Switching tests at minimum rated operating temperature	116(0)

1/ The specific parameters to be included for test in each subgroup shall be as specified in the device specification. Where no parameters have been identified in a particular subgroup or test within a subgroup, no group A testing is required for that subgroup or test to satisfy group A requirements.

MIL-PRF-38535J

TABLE IV. Group C tests (Die related test).

6	Internal water vapor (cavity packages)	1018	5,000 ppm at +100°C	3(0) or 5(1)
7	Adhesion of lead finish	2025		15(0) based on leads from 3 devices minimum
8	Lid torque	2024	Glass frit seal only	5(0)
9 1/	a. Soldering heat	2036		3(0)
	b. Seal	1014	As applicable	
	(1) Fine			
	(2) Gross			
	c. Visual	2009		
	d. End-point electricals		As specified in the applicable device specification	

1/ This test is performed at qualification/re-qualification or design changes which may affect this test. The manufacturer shall determine for each package the applicable conditions from test method 2036 that are appropriate for the mounting conditions, and assure by testing, or through their assembly processes, that the part is subjected to an equivalent time/temperature stress.

MIL-PRF-38535J

5. PACKAGING

5.1 Packaging. For acquisition purposes, the packaging requirements shall be as specified in the contract or order (see 6.2). When packaging of material is to be performed by DoD or in-house contractor personnel, these personnel need to contact the responsible packaging activity to ascertain packaging requirements. Packaging requirements are maintained by the Inventory Control Point's packaging activities within the Military Service of Defense Agency, or within the military service's system commands. Packaging data retrieval is available from the managing Military Department's or Defense Agency's automated packaging files, CD-ROM products, or by contacting the responsible packaging activity.

5.2 Marking. Marking shall be in accordance with 3.6.9 herein.

6. NOTES

(This section contains information of a general or explanatory nature that may be helpful, but is not mandatory.)

6.1 Intended use. Microcircuits conforming to this specification are intended for use for Government microcircuit application and logistic purposes. For maximum cost effectiveness while maintaining essential quality and reliability requirements, it is recommended that, for initial acquisitions for original equipment complements, the device class appropriate to the need of the application be acquired.

6.1.1 Class T. As the requirements for class level T are specified in the manufacturer's Quality Management (QM) plan for each technology, the user is cautioned to review the manufacturer's QM plan to assure that the part being acquired meets the requirements/reliability of the system application. Class T is not for use in NASA manned, satellite, or launch vehicle programs without written permission from the applicable NASA Project Office (i.e., cognizant EEE parts authority).

6.2 Acquisition requirements. Acquisition documents should specify the following:

- a. Title, number, and date of the specification.
- b. PIN and compliance identification (if applicable).
- c. Packaging requirements (see 5.1).

6.3 Qualification. With respect to products requiring qualification, awards will be made only for products which are, at the time of award of contract, qualified for inclusion in Qualified Manufacturer's List, QML-38535, whether or not such manufacturers have actually been listed by that date. The attention of the contractors is called to these requirements, and manufacturers are urged to arrange to have the products that they propose to offer to the Federal Government tested for qualification in order that they may be eligible to be awarded contracts or orders for the products covered by this specification. Information pertaining to qualification of products may be obtained from DLA Land and Maritime, ATTN: DLA Land and Maritime-VQ, Post office. Box 3990, Columbus, Ohio 43218-3990.

6.4 Terms and definitions. For the purpose of this specification, the terms, and definitions of MIL-STD-883 and MIL-HDBK-1331, and those contained herein apply and should be used in the applicable device specifications wherever they are pertinent.

6.4.1 Microelectronics. The area of electronic technology associated with or applied to the realization of electronic systems from extremely small electronic parts or elements.

6.4.2 Element (of a microcircuit or integrated circuit). A constituent of the microcircuit, or integrated circuit, that contributes directly to its operation.

MIL-PRF-38535J

6.4.3 Substrate (of a microcircuit or integrated circuit). The supporting material upon, or within which, the elements of a microcircuit or integrated circuit are fabricated or attached.

6.4.4 Integrated circuit (microcircuit). A small circuit having a high equivalent circuit element density, which is considered as a single part composed of interconnected elements on or within a single substrate to perform an electronic circuit function.

6.4.4.1 Multichip microcircuit. An integrated circuit or microcircuit consisting of elements formed on or within two or more semiconductor chips which are separately attached to a substrate or package.

6.4.4.2 Monolithic microcircuit. An integrated circuit or microcircuit consisting exclusively of elements formed in situ on or within a single semiconductor substrate with at least one of the elements formed within the substrate.

6.4.4.3 Microcircuit module. An integrated circuit, which is an assembly of microcircuits or an assembly of microcircuits and discrete parts, designed to perform one or more electronic circuit functions, and constructed such that for the purposes of specification testing, commerce, and maintenance, it is considered indivisible.

6.4.5 Production lot. A production lot of devices manufactured on the same production line(s) (QM technology flow) by means of the same production technique, materials, controls, and design.

6.4.6 Inspection lot. A quantity of integrated circuits submitted at one time for inspection to determine compliance with the requirements and acceptance criteria of the applicable device specification. Each inspection lot is to be manufactured on the same production line through final seal by the same production techniques.

6.4.7 Wafer lot. A wafer lot consists of integrated circuit wafers formed into a lot at the start of wafer fabrication for homogeneous processing as a group, and assigned a unique identifier or code to provide traceability.

6.4.8 Percent defective allowable (PDA). PDA is the maximum observed percent defective which permits the lot to be accepted after the specified 100 percent test.

6.4.9 Delta limit. The maximum change in a specified parameter reading that will permit a device to be accepted on the specified test, based on a comparison of the present measurement with a specified previous measurement.

NOTE: When expressed as a percentage value, it should be calculated as a proportion of the previous measured value.

6.4.10 Rework. Any processing or reprocessing operation documented in accordance with the manufacturer's QM plan, other than testing, applied to an individual device, or part thereof, and performed subsequent to the prescribed non-repairing manufacturing operations which are applicable to all devices of that type at that stage.

6.4.11 Final seal. The manufacturing operation that completes the enclosure of a device so that further internal processing cannot be performed without disassembling the device.

MIL-PRF-38535J

6.4.12 Acquiring activity. The organizational element which contracts for articles, supplies, or services; or it may be a contractor or subcontractor when the organizational element has given specific written authorization to such contractor or subcontractor to serve as agent of the acquiring activity. A contractor or subcontractor serving as agent of the acquiring activity does not have the authority to grant waivers, deviations, or exceptions to this specification unless specific written authorization to do so has been given by the organization (i.e., preparing activity, qualifying activity).

6.4.13 Qualifying activity (QA). The organizational element of the Government that grants certification and qualification for the specific technology flow in accordance with this specification.

6.4.14 Parts per million (PPM). Parts per million is as defined in EIA-557.

6.4.15 Device type. The term device type refers to a single specific microcircuit configuration.

6.4.16 Die type. A microcircuit manufactured using the same physical size, materials, topology, mask set, process flow, on a single fabrication line.

6.4.17 Radiation hardness assurance (RHA). The portion of product assurance that assures that parts continue to perform as specified or degrade in a specified manner when subjected to the specified radiation environmental stress. The radiation hardness assurance capability level (RHACL) is the radiation level that the manufacturer chooses for each radiation environment appropriate to his technology as a consistently achievable exposure level that does not cause degradation in the microcircuit beyond the specified level of performance.

6.4.18 Electrostatic discharge (ESD) sensitivity. ESD sensitivity is defined as the level of susceptibility of a device to damage by static electricity. The level of susceptibility of a device is found by ESD classification testing and is used as the basis for assigning an ESD class.

6.4.19 Package family. A group of package types with identical configuration and process techniques (e.g., cerdip, side braze, cerpack).

6.4.20 Technology flow. A technology flow is that specific manufacturing line from design, fabrication, assembly, packaging, and test in a given technology from which a manufacturer designs, builds, and tests integrated circuits. Once a manufacturer's technology flow has been certified and qualified by the QA, it is listed on the QML.

6.4.21 Qualified Manufacturer's Listing (QML). The QML is a listing of the manufacturers and their parts which utilize a certified and qualified technology flow.

6.4.22 Third party design center. A subcontract design center, or an original equipment manufacturer (OEM) design center, that uses a microcircuit manufacturer's design tools (including approved industry/third party tools), interface procedures, design rules, and design controls.

6.4.23 Radiation source of supply (RSS). A company (e.g., original equipment manufacturer (OEM)) who establishes a relationship with a device manufacturer for the sole purpose of developing qualified RHA product and has the responsibility to incur the radiation response of said product to the requirements of MIL-PRF-38535, the applicable detail specification, and the RSS program plan. The RSS will be listed in the QML for those devices covered by the RSS's QML. All requests for this product will be submitted through the RSS.

MIL-PRF-38535J

6.4.24 Form. The shape, size, dimension, mass, weight, and other visual parameters which uniquely characterize an item. For software, form denotes the language and media.

6.4.25 Fit. The ability of an item to physically interface, or interconnect with, or become an integral part of another item.

6.4.26 Function. The action or actions that an item is designed to perform.

6.4.27 Class M. Items which have been subjected to and passed all applicable requirements of appendix A herein and are documented on an SMD. This product is intended for military applications.

6.4.28 Class N. Items which have been subjected to and passed all applicable requirements of this specification including qualification testing, screening testing, and TCI/QCI inspections, and are encapsulated in plastic. This product must be assessed by the user to determine if it is appropriate for use in users' application.

6.4.29 Class Q. Items which have been subjected to and passed all applicable requirements of this specification and applicable appendices including qualification testing, screening testing, and TCI/QCI inspections.

6.4.30 Class V. Items that meet all the class Q requirements, and have been subjected to, and passed all applicable requirements of appendix B herein.

6.4.31 Class B. Items which have been subjected to and passed all applicable requirements of this specification including qualification testing, screening testing, and TCI/QCI inspections and are documented on a MIL-M-38510 specification sheet.

6.4.32 Class S. Items that meet all the class B requirements, and have been subjected to, and passed, all applicable requirements of appendix B herein and are documented on a MIL-M-38510 specification sheet.

6.4.33 Class T. Class T is a quality level whose requirements are defined by 3.4.8 herein and as documented on an SMD. Class T is not for use in NASA manned, satellite, or launch vehicle programs without written permission from the applicable NASA Project Office (i.e., cognizant EEE parts authority).

6.4.34 Qualified manufacturer's line. The specified line, which is the certified and qualified technology flow, of a manufacturer from which QML integrated circuits may be purchased.

6.4.35 Test optimization. The process used by the manufacturer to optimize testing utilizing the best commercial practices available while still assuring all applicable performance, quality, and reliability requirements are met. Any screen or TCI test prescribed herein may be reduced, modified, moved, or eliminated by the QML manufacturer provided the product is still capable of meeting the screening and TCI testing groups A, B, C, D, and E for the applicable detail specification as approved by the QA.

6.4.36 Audit team. The audit team shall be led by DLA Land and Maritime personnel and comprised of government representatives (e.g. NASA, NRO, ARMY, NAVY, USAF and DTRA) as designated by the qualifying activity.

6.4.37 Class level B. Class level B requirements contained in this document define the requirements for class Q and class B, including SMDs and M38510 JAN slash sheet product. Class level B is the standard military quality level, it is intended for high reliability military applications.

6.4.38 Class level S. Class level S requirements contained in this document define the requirements for class V and class S (Space Level Product), including SMDs and M38510 JAN slash sheet product. Class level S is the highest reliability level provided for in this specification, it is intended for space applications.

MIL-PRF-38535J

6.4.39 Class level vs Class. This specification defines the requirements for two class levels of product, class level S and class level B. Each class level is made up of multiple classes of product, class level S contains the requirements for class S and V product and class level B contains the requirements for class B and Q product.

6.4.40 Second party facility. A second party facility is a QA approved facility that acts as a subcontractor to a QML device manufacturer (e.g. QML Company X using QML Company Y to fabrication die, or test lab performing TCI testing).

6.4.41 Third party facility. A third party facility is a manufacturer whose facility does not have QML certification. The process or line used by the QML manufacturer has been certified through the manufacturer for those products supplied as QML by the manufacturer (e.g. QML Company X using non-QML Company Z to Fab die, only the line or process of the non-QML company is evaluated for use by the QML manufacturer not the entire facility).

6.4.42 New technology. New technology is defined as a product family, material, or process that has never been previously characterized and qualified by the manufacturer for a military or space level application.

6.4.43 Mature technology. A mature technology is defined as one which the manufacturer has previously released to production and has a continuous reliability monitor plan in place to identify major reliability life-limiting mechanisms, detect long-term product shifts, and generate process data or established proof of stable process and/or equipment with negligible wear out.

6.4.44 Lot date code. Lot date code shall be assigned to identify the devices with the assembly processing and assembly location. Devices shall be traceable through the lot date code to the assembly year, sealing week and assembly location.

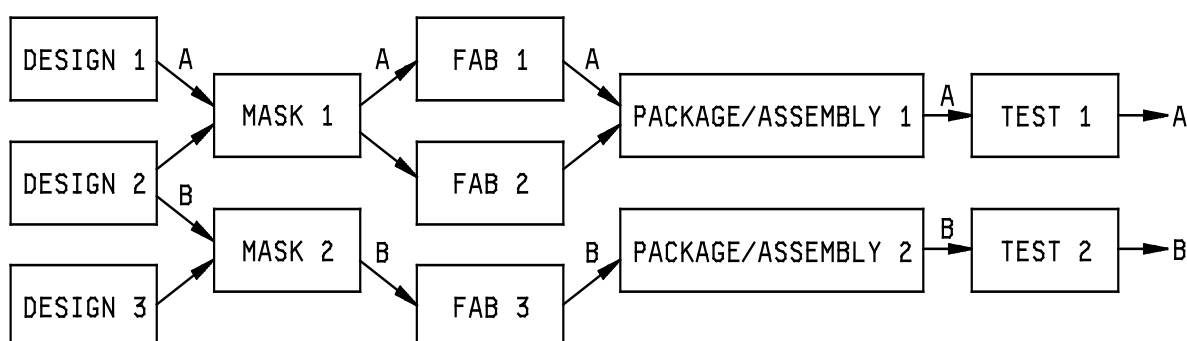

6.4.45 Storage temperature. The optimal storage temperature range is defined as -65°C to +150°C.

MIL-PRF-38535J

6.5 Discussion. The foundation of generic qualification is the requirement for a Quality Management (QM) program within the manufacturing environment. QM requires that all levels of management and non-management be actively involved in the commitment to quality. Also, a TRB is to be established to control, stabilize, monitor and improve the qualified technology. The TRB should develop a QM plan that outlines how the manufacturing operation for a given technology is controlled, monitored and improved throughout its entire "life cycle". Key aspects of this plan are the establishment of statistical process control (SPC), field failure return programs, corrective action procedures, quality improvement, and any other approaches required to control and improve product quality and reliability. These requirements are detailed in this specification. Further, this specification describes procedures and requirements for manufacturer's listing on the QML for integrated circuits. Manufacturers listed on the QML will be able to produce microcircuits without the need for extensive end-of-manufacturing qualification testing and QCIs on each device design. The reduction of the end-of-manufacturing testing will be replaced with in-line monitoring and testing and SPC. Also, surrogate devices, such as the SEC will be used to assess the technology's reliability. Introduction of this methodology shifts the emphasis from the need of individual microcircuit qualification to process (technology) certification and qualification. This will accelerate the microcircuit insertion cycle of high quality and reliable microcircuits.

The generic qualification philosophy, leading to QML, is a process by which a manufacturer acquires a manufacturing line or technology flow certification and qualification. Ongoing monitoring techniques will be used to maintain QML status. The manufacturing line consists of facilities and procedures appropriate to accomplish the design, mask making, wafer fabrication, assembly, package and testing of microcircuits (see [figure 1](#)). [Figure 2](#) illustrates six possible combinations of a manufacturing line utilizing three design centers, two mask fabrication facilities, three wafer fabrication facilities, two package and assembly sites and two test facilities. The procedure of generic qualification is accomplished in two stages; certification and qualification. The process of certification is the recognition of evidence by the QA that the manufacturing line is capable of producing microcircuits of high quality and compliant with the requirements of this specification. Qualification is the actual demonstration of the certified manufacturing line capabilities by producing "first pass" microcircuits compliant with the requirements of this specification and the device specification. On [figure 2](#), each block can be individually reviewed, but is to be certified as a flow. The only process flow which would be qualified (QML listed) would be the group of blocks which are linked together and tested during qualification. The letters "A" and "B" indicate a QML flow where qualification testing has qualified a complete path. The other paths are not QML until certification and qualifications testing of those processes are done.

MIL-PRF-38535J

FIGURE 1. The QML manufacturing line.FIGURE 2. Combinations of a manufacturing line.

QM does not stop with a manufacturer listed on the QML. This specification identifies the necessary screens which QML devices are to be capable of meeting. These screens can be reduced or changed by the manufacturers' TRB when gathered reliability data on the technology indicates that such changes are substantiated. The philosophy of generic qualification incorporates the idea that high quality and reliable microcircuits can be obtained without excessive testing if the processes are properly monitored and controlled at each step of the manufacturing line. The following describes the monitors and controls that may be used.

- a. The design procedure and tools are controlled in such a manner that the ensuing microcircuit design performs only with limits that have been shown to be reliable for the technology being used, within the constraints of established design rules (electrical, geometric and reliability).
- b. The mask fabrication facility is controlled such that an error free mask is produced from the microcircuit design database. Monitoring, controlling and reducing defect density is helpful in obtaining error free masks.
- c. The wafer fabrication process is controlled with the following: Use of in-line statistical control; a parametric monitor structure for measuring electrical parameters; a TCV structure to study intrinsic reliability mechanisms; and a SEC to monitor the fabrication process and to serve as a surrogate microcircuit for reliability testing.
- d. The package and assembly facility is controlled with emphasis on in-line statistical process control of all assembly steps.
- e. The test area controls consist of test equipment accuracy and calibration as well as a controlled interface to the microcircuit design center.

MIL-PRF-38535J

- f. The overall control of the process are under the auspices of a TRB which is established by the manufacturer. The TRB is solely responsible for the QML flow that has been certified and qualified.
- g. For RHA devices, procedures and requirements are integrated into this specification for establishing and demonstrating a RHACL for the technology. Many device-oriented tests can be reduced or eliminated when correlation data for models and test structures have been established by the TRB. The main concern in the RHA community is whether the device specification accurately describes the device performance in the radiation environment specified. Until such models and test structures are developed, some actual device radiation testing will be required.
- h. Appendix B to this specification defines an implementation transition approach which may be used for space or other critical environment applications.

6.8 List of acronyms.

AQL	- acceptable quality level
ANSI	- American National Standards Institute
ASIC	- application specific integrated circuit
ASTM	- American Society for Testing and Materials
BV	- breakdown voltage
CAD	- computer aided design
CAGE	- Commercial and Government Entity
CMOS	- complimentary metal oxide semiconductor
CSAM	- C-mode scanning acoustical microscopy
CSI	- contractor source inspection
DFT	- design-for-test
DMS	- diminishing manufacturing sources
DNA	- Defense Nuclear Agency
DRC	- design rules check
DSCC	- Defense Supply Center, Columbus
DTL	- diode transistor logic
ECL	- emitter coupled logic
EEE	- electrical, electronic, and electromechanical
EEPROM	- electronically erasable programmable read only memory
EIA	- Electronic Industries Alliance
ELDRS	- enhanced low dose rate sensitivity
EPI	- epitaxial
ERC	- electrical rules check
ESD	- electrostatic discharge
FA	- failure analysis
FAST	- Fairchild Advanced Schottky TTL
FET	- field effect transistor
FIFO	- first in, first out
FSC	- federal stock class
GaAs	- gallium arsenide
GCR	- galactic cosmic rays
GIDEP	- Government - Industry Data Exchange Program
g_m	- linear transconductance
GSI	- Government Source Inspection
HAST	- highly accelerated stress testing
HCMOS	- high-speed CMOS
HDBK	- handbook
IC	- integrated circuit
ILB	- inner lead bond

MIL-PRF-38535J

JAN	- Joint Army Navy
JEDEC	- (Formerly known as Joint Electronic Device Engineering Council)
JEP	- JEDEC publication
JESD	- JEDEC standard
JTAG	- Joint Test Action Group
LET	- linear energy transfer
LET _{TH}	- linear energy transfer threshold
MIL	- military
MOS	- metal oxide semiconductor
MTTF	- mean time to failure
NASA	- National Aeronautics and Space Administration
NDBP	- nondestructive bond pull
OEM	- original equipment manufacturer
PDA	- percent defective allowable
PIN	- part or identifying number
PIND	- particle impact noise detection
PIPL	- post - irradiation parameter limits
PLA	- programmable logic array
PM	- parametric monitor
PPM	- parts per million
PROM	- programmable read only memory
QA	- qualifying activity
QAR	- quality assurance representative
QCI	- quality conformance inspection
QM	- quality management
QML	- qualified manufacturer listing
QPL	- qualified products list
RAM	- random access memory
RH	- relative humidity
RHA	- radiation hardness assurance
RHACL	- radiation hardness assurance capability level
RMS	- root mean square
ROM	- read only memory
RSS	- radiation source of supply
SAE	- Society of Automotive Engineers
SEC	- standard evaluation circuit
SEE	- single event effects
SEM	- scanning electron microscope
SEP	- single event phenomenon
SEU	- single event upset
SMD	- Standard Microcircuit Drawing

MIL-PRF-38535J

SOI	- silicon on insulator
SOS	- silicon on sapphire
SPC	- statistical process control
SSS	- sample size series
STD	- standard
TAB	- tape automated bonded
TCI	- technology conformance inspection
TCV	- technology characterization vehicle
TDDB	- time dependent dielectric breakdown
TLD	- thermo luminescence dosimetry
TM	- test method (e.g. MIL-STD-883)
TRB	- technology review board
TTL	- transistor transistor logic
UL	- Underwriters Laboratory
VHDL	- VHSIC hardware description language
VHSIC	- very high speed integrated circuit
VT	- threshold voltage

6.9 Environmentally preferable material. Environmentally preferable materials should be used to the maximum extent possible to meet the requirements of this specification. As of the dating of this document, the U.S. Environmental Protection Agency (EPA) is focusing efforts on reducing 31 priority chemicals. The list of chemicals and additional information is available on their website <http://www.epa.gov/osw/hazard/wastemin/priority.htm>. Included in the EPA list of 31 priority chemicals are cadmium, lead, and mercury. Use of the materials on the list should be minimized or eliminated unless needed to meet the requirements specified herein (see Section 3).

6.10 Changes from previous issue. Marginal notations are not used in this revision to identify changes with respect to the previous issue due to the extent of the changes.

MIL-PRF-38535J

APPENDIX A

MICROCIRCUIT SPECIFICATION REQUIREMENTS

A.1 SCOPE

A.1.1 Scope. This appendix establishes the minimum requirements for MIL-STD-883 compliant class level B and S, monolithic and multichip microcircuits and the quality and reliability assurance requirements that are to be met in the acquisition of these microcircuits. This appendix shall also be required as a performance baseline for qualified manufacturer listing (QML) class level B and S microcircuits. Detail requirements, specific characteristics of microcircuits, and other provisions which are sensitive to the particular use intended are to be specified in the applicable device specification. Two levels, class B and S, of product assurance requirements and control for monolithic and multichip microcircuits are provided for in this appendix. It is the intent of the Government that a compliant manufacturer can use this appendix as the first step to becoming a qualified manufacturer under the QML program. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance. However, for QML microcircuits the manufacturers may offer approved alternatives that demonstrate a process control system that achieves at least the same level of quality and reliability as could be achieved by this appendix.

A.2 APPLICABLE DOCUMENTS

A.2.1 General. The documents listed in this section are specified in sections [A.3](#), [A.4](#), or [A.5](#) of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in sections [A.3](#), [A.4](#), and [A.5](#) of this appendix, whether or not they are listed.

A.2.2 Government documents.

A.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE SPECIFICATION

- | | |
|-------------|---|
| MIL-I-46058 | - Insulating Compound, Electrical (For Coating Printed Circuit Assemblies). |
| MIL-M-38510 | - Microcircuits, General Specification for. |

DEPARTMENT OF DEFENSE STANDARDS

- | | |
|--------------|--|
| MIL-STD-883 | - Test Method Standard Microcircuits. |
| MIL-STD-1285 | - Marking of Electrical and Electronic Parts. |
| MIL-STD-1835 | - Interface Standard Electronic Component Case Outlines. |

DEPARTMENT OF DEFENSE HANDBOOKS

- | | |
|---------------|--|
| MIL-HDBK-103 | - List of Standard Microcircuit Drawings. |
| MIL-HDBK-505 | - Definitions of Item Levels, Item Exchangeability, Models, and Related Terms. |
| MIL-HDBK-780 | - Standard Microcircuit Drawings. |
| MIL-HDBK-1331 | - Parameters to be Controlled for the Specification of Microcircuits Handbook For. |

MIL-PRF-38535J

APPENDIX A

A.2.2.2 Other Government documents, drawings, and publications. The following other Government documents, drawings, and publications form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DSCC-VQC-42 - Baseline Sheet for Microcircuits Materials and Construction.

(Copies of DSCC-VQC-42 are available from DLA Land and Maritime (ATTN: DLA Land and Maritime-VQC), P.O. Box 3990, Columbus, OH 43218-3990.)

QML-38535 - Qualified Manufacturers List of Products Qualified Under Performance Specification MIL-PRF-38535 Integrated Circuits (Microcircuits) Manufacturing, General Specification for.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

A.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

AMERICAN SOCIETY FOR TESTING AND MATERIALS (ASTM)

ASTM F15	- Standard Specification for Iron-Nickel-Cobalt Sealing Alloy.
ASTM F30	- Standard Specification for Iron-Nickel Sealing Alloy.
ASTM B170	- Standard Specification for Oxygen-Free Electrolytic Copper-Refinery Shapes.
ASTM B487	- Standard Test Method for Measurement of Metal and Oxide Coating Thickness by Microscopical Examination of a Cross Section.
ASTM B567	- Standard Test Method for Measurement of Coating Thickness by the Beta Backscatter Method.
ASTM B568	- Standard Test Method for Measurement of Coating Thickness by X-Ray Spectrometry.

(Copies of these documents are available online at <http://www.astm.org/> or from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.)

AMERICAN NATIONAL STANDARDS INSTITUTE (ANSI)

ANSI/NCSL Z540.3 - Calibration Laboratories and Measuring and Test Equipment - General Requirements.

(Copies of these documents are available online at <http://www.ansi.org/> or from American National Standards Institute, Incorporated, 25 West 43rd Street, 4th Fl. New York, NY 10036.)

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

JESD471	- Symbol & Label for Electrostatic Sensitive Devices.
EIA541	- Packaging Material Standards for ESD Sensitive Items.
JESD22-A114	- Electrostatic Discharge (ESD) Sensitivity Testing Human Body Model (HBM).
JESD31	- General Requirements for Distributors of Commercial and Military Semiconductors.
JESD625	- Requirements for Handling Electrostatic-Discharge-Sensitive (ESDS) Devices.
JEP114.01	- Guidelines for Particle Impact Noise Detection (PIND) Testing, Operator Training and Certification.

(Copies of these documents are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

MIL-PRF-38535J

APPENDIX A

INTERNATIONAL ORGANIZATION FOR STANDARDIZATION (ISO) STANDARDS

- ISO 14644-1 - Clean rooms and Associated Controlled Environments – Part 1: Classification of Air Cleanliness.
- ISO 14644-2 - Clean rooms and Associated Controlled Environments – Part 2: Specifications for Testing and Monitoring to Prove Continued Compliance with ISO 14644-1.

(Copies of these documents are available online at <http://www.iest.org/> or from Institute of Environmental Sciences and Technology (IEST), 940 East Northwest Highway, Mount Prospect, IL 60056-3444.)

SOCIETY OF AUTOMOTIVE ENGINEERS (SAE)

- SAE-AMS-I-23011 - Iron-Nickel Alloys for Sealing to Glasses and Ceramics.

(Copies of this document are available online at <http://www.sae.org/> or from Society of Automotive Engineers, 400 Commonwealth Dr., Warrendale, PA 15096-0001.)

(Non-Government standards and other publications are normally available from the organizations that prepare or distribute the documents. These documents also may be available in or through libraries or other informational services.)

A.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein (except for related device specifications), the text of this document takes precedence. Nothing in this document, however, supersedes applicable laws and regulations unless a specific exemption has been obtained.

A.3 REQUIREMENTS

A.3.1 General. The manufacturer of microcircuits in compliance with this appendix shall have and use production and test facilities and a quality and reliability assurance program adequate to assure successful compliance with the provisions of this appendix, the manufacturer's baseline (DSCC-VQC-42 or equivalent) and the device specification or drawing. The individual item requirements shall be as specified herein, and in accordance with the device specification or drawing.

The requirements of this appendix, or 1.2.1 of MIL-STD-883 are met or exceeded by product built to a QML certified flow by a QA certified and qualified manufacturer or by a manufacturer who has been granted transitional certification to MIL-PRF-38535. The QML flow as documented in the QM plan allows modification to processes and tests used in producing QML devices (See J.3.12 herein). These changes shall not affect the form, fit, function or radiation hardness assurance level (when applicable) of any QML devices. These devices are marked with the "Q" or "QML" certification mark to reflect the QML flow used.

A.3.1.1 Reference to device specification or drawing. For purposes of this appendix, when the term "as specified" is used without additional reference to a specific location or document, the intended reference shall be to the device specification or drawing which constitutes the applicable individual device specification.

MIL-PRF-38535J

APPENDIX A

A.3.1.2 Conflicting requirements. In the event of conflict between the requirements of this appendix, this specification and other requirements of the applicable device specification, the precedence in which requirements shall govern, in descending order, is as follows:

- a. Applicable device specification or drawing.
- b. This appendix.
- c. Specifications, standards, and other documents referenced in [A.2.2](#) and [A.2.3](#).

A.3.1.3 Terms, definitions, and symbols. For the purpose of this appendix, the terms, definitions, and symbols of MIL-STD-883 and MIL-HDBK-1331, and those contained herein shall apply and shall be used in the applicable device specifications or drawings wherever they are pertinent. The definitions of part, subassembly, assembly, unit, group, set, and system, as well as the ancillary terms accessory and attachment are contained in MIL-HDBK-505. To further define a particular type of microcircuit, additional modifiers may be prefixed.

A.3.1.3.1 Microelectronics. That area of electronic technology associated with or applied to the realization of electronic systems from extremely small electronic parts or elements.

A.3.1.3.2 Element (of a microcircuit or integrated circuit). A constituent of the microcircuit or integrated circuit that contributes directly to its operation. (A discrete part incorporated into a microcircuit becomes an element of the microcircuit.)

A.3.1.3.3 Substrate (of a microcircuit or integrated circuit). The supporting material upon or within which the elements of a microcircuit or integrated circuit are fabricated or attached.

A.3.1.3.4 Microcircuit. A small circuit having a high equivalent circuit element density, which is considered as a single part composed of interconnected elements on or within a single substrate to perform an electronic circuit function. (This excludes printed wiring boards, circuit card assemblies, and modules composed exclusively of discrete electronic parts.)

A.3.1.3.4.1 Multichip microcircuit. A microcircuit consisting of elements formed on or within two or more semiconductor chips which are separately attached to a substrate or package.

A.3.1.3.4.2 Hybrid microcircuit. A microcircuit consisting of elements that are a combination of the film microcircuit type (see [A.3.1.3.4.4](#)) and the semiconductor types (see [A.3.1.3.4.1](#) and [A.3.1.3.4.3](#)) or a combination of one or both of the types with discrete parts.

A.3.1.3.4.3 Monolithic microcircuit (or integrated circuit). A microcircuit consisting exclusively of elements formed in situ on or within a single semiconductor substrate with at least one of the elements formed within the substrate.

A.3.1.3.4.4 Film microcircuit (or film integrated circuit). A microcircuit consisting exclusively of elements which are films formed in situ upon an insulating substrate.

A.3.1.3.5 Microcircuit module. An assembly of microcircuits or an assembly of microcircuits and discrete parts, designed to perform one or more electronic circuit functions, and constructed such that for the purposes of specification testing, commerce, and maintenance, it is considered indivisible.

MIL-PRF-38535J

APPENDIX A

A.3.1.3.6 Production lot. A production lot shall consist of devices manufactured on the same production line(s) by means of the same production technique, materials, controls, and design. Where a production lot identification is terminated upon completion of wafer or substrate processing, or at any later point prior to device sealing, it shall be permissible to process more than a single device type in a single production lot provided traceability is maintained by assembling devices into inspection lots, as defined herein, at the point where production lot identification is terminated.

A.3.1.3.7 Inspection lot - class level S. An inspection lot for class level S microcircuits shall consist of a single device type from a single wafer lot in a single package type and lead finish unless otherwise specified in the QM plan. With qualifying activity approval, a maximum of 4 wafer lots may be used to form a class level S inspection lot. All devices shall be sealed within a single week. All assembly operations from die mounting through package sealing shall be completed within the same 6-week period. Each inspection subplot shall be uniquely identified to maintain traceability of that subplot from the wafer lot to the inspection lot (see A.3.4.6 and A.4.3.3).

A.3.1.3.8 Inspection lot - class level B. A quantity of microcircuits submitted at one time for inspection to determine compliance with the requirements and acceptance criteria of the applicable device specification. Each inspection lot shall consist of microcircuits of a single device type, in a single package type and lead finish. Each inspection lot shall be manufactured on the same production lines through final seal by the same production techniques and sealed within the same period not exceeding 6 weeks. Inspection lot identification shall be maintained from the time the inspection lot is formed through the time the lot is accepted, and shall be traceable to the production lot(s) from which the inspection lot was formed (see A.3.4.6 and A.4.3.3).

A.3.1.3.9 Inspection subplot - class level S. An inspection subplot for class level S microcircuits shall be a division (one wafer lot maximum) of parts in an inspection lot into smaller quantities of parts (see A.4.5.2 herein).

A.3.1.3.10 Inspection lot split - class level B. A class level B inspection lot split shall be a further division of the number of parts in an inspection lot into smaller quantities of parts (see A.4.5.2 herein).

A.3.1.3.11 Wafer lot. A wafer lot consists of microcircuit wafers formed into a lot at the start of wafer fabrication for homogeneous processing as a group, and assigned a unique identifier or code to provide traceability, and maintain lot integrity throughout the fabrication process (see A.4.3.3 herein).

A.3.1.3.12 Package type. A package with a unique case outline (see MIL-STD-1835), configuration, materials (including bonding wire and die attach), piece parts (excluding pre-forms which differ only in size), and assembly processes.

A.3.1.3.13 Microcircuit group. Microcircuits which are designed to perform the same type of basic circuit function (e.g., for linear: Amplifier, comparator, sense amplifier, regulator, etc.; for digital: Logic gate buffer, flip-flop, combinational gate, sequential register/counter) within a given circuit technology (e.g., diode transistor logic (DTL), non-Schottky transistor transistor logic (TTL), emitter coupled logic (ECL), Schottky TTL, linear, hybrid, metal oxide semiconductor(MOS)) which are designed for the same supply, bias and signal voltages and for input-output compatibility and which are fabricated by use of the same basic die construction and metallization; the same die attach method; and by use of bonding interconnects of the same size, material and attachment method.

A.3.1.3.14 Percent defective allowable (PDA). Percent defective allowable is the maximum observed percent defective which will permit the lot to be accepted after the specified 100 percent test.

A.3.1.3.15 Delta limit (Δ). The maximum change in a specified parameter reading which will permit a device to be accepted on the specified test, based on a comparison of the present measurement with a specified previous measurement. NOTE: When expressed as a percentage value, it shall be calculated as a proportion of the previous measured value.

MIL-PRF-38535J

APPENDIX A

A.3.1.3.16 Rework. Any processing or reprocessing operation documented in accordance with [A.4.8.1.1.6h](#) herein, other than testing, applied to an individual device, or part thereof, and performed subsequent to the prescribed non-repairing manufacturing operations which are applicable to all devices of that type at that stage.

A.3.1.3.17 Final seal. That manufacturing operation which completes the enclosure of a device so that further internal processing cannot be performed without disassembling the device.

A.3.1.3.18 Acquiring activity. The organizational element of the Government which contracts for articles, supplies, or services; or it may be a contractor or subcontractor when the organizational element of the Government has given specific written authorization to such contractor or subcontractor to serve as agent of the acquiring activity. A contractor or subcontractor serving as agent of the acquiring activity shall not have the authority to grant waivers, deviations, or exceptions to this appendix unless specific written authorization to do so has also been given by the Government organization (i.e., preparing activity).

A.3.1.3.19 Qualifying activity. The organizational element of the Government that grants certification and qualification for the specific associated end-product in accordance with this appendix and the applicable device specification or drawing. For non-JAN product built in accordance with this appendix, the qualifying activity shall be either the acquiring activity or quality organization within the manufacturer's company that is independent of the group(s) responsible for device production screening and marketing or by an independent organization outside the manufacturer's company.

A.3.1.3.20 Device type. The term device type refers to a single specific microcircuit configuration. Samples of the same device type will be electrically and functionally interchangeable with each other at the die or substrate level even though made by different manufacturers using different mechanical layouts and possibly different materials. The electrical and environmental limits will be the same (but not necessarily the inherent reliability) for a given device type even though the device class, the case outline, the lead finish, the lot identification code, and the manufacturer may be different.

A.3.1.3.21 Die type. A microcircuit manufactured using the same physical size, materials, topology, mask set, and process flow, on a single fabrication line.

A.3.1.3.22 Antistatic. An antistatic material resists triboelectric charging upon contact and separation with another material. Plastic materials impregnated with antistatic agents (antistats) are antistatic if their surface resistivity is between 10^9 and 10^{14} ohms/square.

A.3.1.3.23 Conductive. A conductive material is one capable of electrostatic field shielding and having a volume resistivity of 10^3 ohm-cm maximum or a surface resistivity less than 10^5 ohms/square.

A.3.1.3.24 Insulating. An insulating material is defined as having a volume resistivity of 10^{12} ohm-cm minimum, or a surface resistivity of 10^{14} ohms/square minimum.

A.3.1.3.25 Dissipative. A dissipative material is defined as having a surface resistivity between 10^5 and 10^9 ohms/square.

A.3.1.3.26 Radiation hardness assurance (RHA). The portion of product assurance which insures that parts continue to perform as specified or degrade in a specified manner when subjected to the specified radiation environmental stress.

A.3.1.3.27 Electrostatic discharge (ESD) sensitivity. Electrostatic discharge sensitivity is defined as the level of susceptibility of a device to damage by static electricity. The level of susceptibility of a device is found by ESD classification testing and is used as the basis for assigning an ESD class (see [A.3.4.1.4](#)).

MIL-PRF-38535J

APPENDIX A

A.3.1.3.28 Custom microcircuit. A nonstandard microcircuit, the design, and right(s) to the design (for example, ownership, control, or proprietary rights) of which are under the control of the purchaser-user of the microcircuit.

A.3.1.3.29 Die family. All devices manufactured by the same basic process (e.g., low power Schottky, high speed CMOS (HCMOS), Bipolar linear, CMOS linear, MOS memory, etc.) as specified in tables A-VI, A-VII, A-VIII, and A-IX.

A.3.1.3.30 Package family. A set of package types with the same package configuration (e.g., side brazed, bottom brazed) material type (e.g., alumina, beryllium oxide (BeO)) package construction techniques (e.g., single layer, multilayer) terminal pitch, except for can packages in which pin circle diameter can be used in place of terminal pitch, lead shape (e.g., gullwing, J-hook), and row-spacing (i.e., dual-in-line packages only) and with identical package assembly techniques (e.g., material and type of seal, wire bond method and wire size, die attach method and material).

A.3.1.3.31 Military operating temperature range. The military temperature range or military operating temperature range is defined as -55°C to +125°C.

A.3.1.3.32 Process monitor. The regularly scheduled periodic sample measuring of a parameter during normal performance of production operations in accordance with the manufacturers approved program plan. The parameter to be measured, the frequency of measurement, the number of sample measurements, the conditions of measurement, the analysis of measurement data shall vary as a function of the requirements, capability and criticality of the operation being measured.

A.3.1.3.33 Device specification. The terms device specification or Standard Microcircuit Drawing (SMD) shall be used exclusively to reference or describe Government published documents with the combined purposes of standardization and procurement which detail the specific requirements of performance based microcircuits.

A.3.1.3.34 Class level B. Class level B requirements contained in this document are intended for use for class Q and class M products, as well as class B M38510 JAN slash sheet product. Class level B requirements are also intended for use for product claimed as 883 compliant or 1.2.1 compliant for high reliability military applications.

A.3.1.3.35 Class level S. Class level S requirements contained in this document are intended for use for class V, as well as class S M38510 JAN slash sheet product. Class level S requirements are also intended for use for product claimed as 883 compliant or 1.2.1 compliant for space level applications.

A.3.2 Item requirements. The individual item requirements for microcircuits delivered under this appendix shall be documented in the device specification or SMD or other drawing (SMD format, in accordance with MIL-HDBK-780, shall be used for drawings). Unless otherwise specified in the device specification or drawing, all devices procured under this appendix shall have an operating ambient temperature range from -55°C to +125°C and any references to minimum or maximum operating temperatures shall refer to the respective lower and upper limits of this range. Contractor-prepared specifications or drawings shall be approved by the acquiring activity as acceptable for the requirements of a specific contract or order, at the time of acquisition.

A.3.2.1 Electrical test requirements. The electrical test requirements (parameters, test conditions, test limits, and applicable test temperatures) which apply to electrical screening (i.e., final electrical parameters), group A Quality Conformance Inspection (QCI), and end-point electrical testing for other QCI subgroups shall be clearly documented by the manufacturer as to the actual parameters, conditions, methods, limits, burn-in/life test circuits, and test temperatures used in device testing. All those parameters important to the design application of the device shall be specified over the full military operating temperature range and supply voltage range and be included in the testing requirements of the applicable specification(s). For devices whose initial release date is after 29 May 1987, the subgroups to be tested, and the parameters that constitute a subgroup shall, as a minimum, be equivalent to those of the most similar device specification or drawing. The manufacturer's electrical test specification shall be documented in a device specification table I format, or equivalent, that is clear to the user and shall be available to the user upon request.

MIL-PRF-38535J

APPENDIX A

A.3.2.2 Alternate die/fabrication requirements. When deemed necessary by the preparing or acquiring activity, (e.g., a class M SMD device, a DLA Land and Maritime drawing device, a MIL-STD-883 compliant device, or a Qualified Products List/Qualified Manufacturers List (QPL/QML) device or a unique package/die combination is not available from a DLA Land and Maritime drawing, SMD, QML, or QPL source that meets the full wafer fabrication requirements of this appendix), the DLA Land and Maritime drawing, SMD, JAN specification sheet or other procurement document (i.e., contractor-prepared drawing for "D" certification only) may be modified to provide a source for logistics support. This modification shall allow either a detailed certificate of compliance (itemized listing of die fabrication requirements from this appendix - see example in [A.3.2.2.1](#) herein) or a die evaluation as defined by [A.3.2.2.2](#) herein to be used in lieu of meeting the full die/fabrication requirements of this appendix. Alternate die fabrication requirements of [A.3.2.2.1](#) and [A.3.2.2.2](#) are permitted only for product that does not have the required traceability of [A.3.4.6](#). These alternate requirements are acceptable only when the manufacturer planning to use this allowance has information on the wafer lot number, date of fabrication of the die, the fabrication line where the die was processed, and that the die was previously qualified by a QML/QPL manufacturer (for QML product) or by a MIL-STD-883 compliant manufacturer (for MIL-STD-883 compliant product). The manufacturer that meets the die/fabrication requirements of [A.3.2.2.1](#) or [A.3.2.2.2](#) is required to perform QCI testing of groups C and D (and E if applicable) on the first inspection lot of each wafer lot and shall replace the "C" certification mark with a "D" certification mark. An additional complete group D test is not required if the manufacturer already has group D coverage on the package family; however, subgroups D3 and D4 shall be required on the first inspection lot of the wafer lot. For excess die from the evaluated wafer lot, an additional group C and group D (subgroups D3 and D4 only) tests are not required for subsequent inspection lots built solely from die from that wafer lot. If the product is built in full compliance to the requirements of this appendix (the alternate die/fabrication allowance of [A.3.2.2](#) is not being used), the "C" certification mark shall be used on the device.

A.3.2.2.1 Example C of C. This C of C from the wafer manufacturer certifies that the product identified by fabrication code XXXXXX meets the fabrication requirements of appendix A of MIL-PRF-38535 (1.2.1 of MIL-STD-883) including the following itemized requirements:

- a. Change to product requirement of [A.3.4.2](#).
- b. Internal conductor (current density) requirements of [A.3.5.5](#).
- c. Traceability requirements of [A.3.4.6](#).
- d. Glassivation thickness requirements of [A.3.5.8](#).
- e. Die thickness requirement of [A.3.5.9](#).
- f. Quality assurance program requirements of [A.4.8](#).
- g. Control and traceability of design documentation requirements of [A.3.5.4](#).
- h. Workmanship and rework provisions of [A.3.7](#).
- i. Design and construction baseline requirements of [A.4.8.1.3.8](#).

MIL-PRF-38535J

APPENDIX A

A.3.2.2.2 Die evaluation requirements. The following requirements shall be met for each wafer lot. The results of this evaluation shall demonstrate compliance to this appendix for wafer manufacturing requirements.

- a. Functional diagram and high power photomicrographs.
- b. Analysis of internal conductor materials.
- c. Composition of glassivation material and thickness measurement.
- d. Total die thickness measurement.
- e. SEM analysis of metallization.
- f. Adhesion of gold backing.
- g. Calculated current density in accordance with this appendix.

A.3.3 Classification of requirements. The requirements of the microcircuits are classified herein as follows:

<u>Requirement</u>	<u>Paragraph</u>
Quality assurance requirements	A.3.4
Qualification	A.3.4.1
Compliance validation	A.3.4.1.1
Process Monitor Programs	A.3.4.1.2
Qualification to RHA levels	A.3.4.1.3
Qualification to ESD classes	A.3.4.1.4
Change to product or QA program	A.3.4.2
Screening	A.3.4.3
Quality conformance inspection	A.3.4.4
Wafer lot acceptance	A.3.4.5
Traceability	A.3.4.6
Design and construction	A.3.5
Marking of microcircuits	A.3.6
Workmanship	A.3.7

MIL-PRF-38535J

APPENDIX A

A.3.3.1 Certification of conformance and acquisition traceability. Manufacturers or suppliers including dealers and distributors who offer the product described by this appendix shall provide written certification, signed by the corporate officer who has management responsibility for the production and assurance of the quality and reliability of the product, (1) that the product being supplied has been manufactured and tested in accordance with this appendix and conforms to all of its requirements, and can be reasonably expected to remain in conformance indefinitely unless destructively mishandled, (2) that all products are as described on the certificate which accompanies the shipment, and (3) that dealers and distributors have handled the product in accordance with the requirements of JESD625 and JESD31. The responsible corporate official may, by documented authorization, designate other responsible individuals to sign the certificate, but, the responsibility for conformity with the facts shall rest with the responsible corporate officer. The certification shall be confirmed by documentation to the Government or to users with Government contractors or subcontractors, regardless of whether the products are acquired directly from the manufacturer or from another source such as a distributor. When other sources are involved, their acquisition certification shall be in addition to the certificates of conformance and acquisition traceability provided by the manufacturer and previous distributors. The certificate shall include the following information:

a. Manufacturer documentation:

- (1) Manufacturer's name and address.
- (2) Customer's or distributor's name and address.
- (3) Device type and product assurance level.
- (4) Lot date code and latest re-inspection date, if applicable.
- (5) Quantity of devices in shipment from manufacturer.
- (6) Statement certifying product conformance and traceability.
- (7) Solderability re-inspection date, if applicable.
- (8) Signature and date of transaction.
- (9) If applicable, the certificate shall include a statement indicating that alternate die/fab requirements are being used, see [A.3.2.2](#) ("D" cert mark).

b. Distributor documentation for each distributor:

- (1) Distributor's name and address.
- (2) Name and address of customer.
- (3) Quantity of devices in shipment.
- (4) Latest re-inspection date, if applicable.
- (5) Certification that this shipment is a part of the shipment covered by the manufacturer's documentation.
- (6) Solderability re-inspection date, if applicable.
- (7) Signature and date of transaction.

MIL-PRF-38535J

APPENDIX A

A.3.4 Quality assurance requirements. The quality assurance provisions provided in this appendix are intended to provide a compliant MIL-STD-883 class level B or level S device (see A.3.1.3.34 and A.3.1.3.35). Devices or lots which have failed to pass any tests applied or acceptance criterion (PDA) shall not be downgraded to any lower quality assurance level even though that test or criterion may not be a requirement of the lower level (a failed device or lot shall not be accepted). Where shown, method references are in accordance with MIL-STD-883.

A.3.4.1 Qualification. The manufacturer supplying devices in compliance to this appendix shall perform sufficient product qualification testing to assure the devices supplied meet the minimum class level B or S performance requirements as described herein. The manufacturer shall maintain documentation of qualification testing for review of the preparing or acquiring activity upon request.

A.3.4.1.1 Compliance validation. Although on-site audits are not a condition to begin supplying under the requirements of this appendix, all manufacturers supplying in compliance to this appendix are subject to periodic Government compliance validation audits on a drop-in basis with a minimum of notice.

A.3.4.1.2 Process monitor programs. Process monitor programs performed by the manufacturer shall be established as a minimum for the following processes: Scanning Electron Microscope (SEM), wire bonding, die attachment, lid seal, particle detection, lead trimming, and final lead finish thickness. The implementing procedures shall provide for frequency, sample size, reject criteria, allowable rework, and disposition of failed product/lot(s). With the exception of the particle detection monitor, a procedure is required for the traceability, recovery, and disposition of all units monitored since the last successful test. As with all monitors, the particle detection procedure shall provide for continual process improvement. Records of these monitors and procedures shall be maintained and available for review.

A.3.4.1.2.1 Inspection by scanning electron microscope (SEM). A continuing SEM program shall be established to ensure adequate process control and coverage of metallization at oxide steps, contact openings, and general metallization. A monthly (minimum frequency) SEM evaluation shall be performed on product that is in the manufacturing process. The SEM program shall establish routine control over metallization processes by process families or inspection of products.

A.3.4.1.2.2 Wire bonding. The manufacturer shall monitor the wire bond strength in accordance with the manufacturer's documented procedure. The frequency of this procedure shall be performed at machine setup and at the end of the production run as a minimum. At the manufacturer's option, this procedure shall consider shift start and stop, change of operators, spools, packages, wire size, lot size, and other related factors.

A.3.4.1.2.3 Die attachment. The manufacturer shall monitor the die attachment integrity in accordance with the manufacturer's documented procedure. This procedure shall be performed at each equipment setup and at the end of the production run as a minimum. At the manufacture's option, this procedure shall consider other related factors.

A.3.4.1.2.4 Lid seal. The manufacturer shall monitor, as a minimum, glass frit packages for seal integrity in accordance with the manufacturer's documented procedure. A sample and test plan shall be available for review by the qualifying or preparing activity.

A.3.4.1.2.5 Particle detection. The manufacturer shall establish a particle detection monitoring program which assesses the particle contamination of sealed devices on an individual manufacturing line basis. The monitor shall have provisions for testing in accordance with TM 2020, condition A of MIL-STD-883. JEP114, "Guidelines for Particle Impact Noise Detection (PIND) Testing, Operator Training and Certification" may be used as a guideline. Suitable data for each manufacturing line shall be used to establish an appropriate need, sample size, and sampling frequency for each package family. Unless otherwise approved by the qualifying activity (QA), the minimum sampling frequency of those devices in production shall be once each month in accordance with per package family. Investigative and corrective actions shall be established which address noted deficiencies. Records of this monitor shall be made available for review and shall represent at least the six-month period preceding the audit.

MIL-PRF-38535J

APPENDIX A

A.3.4.1.2.6 Lead trimming and final lead finish thickness. The manufacturer shall monitor the package lead lengths to assure meeting the applicable device specification or drawing for proper lead length and the final lead finish thickness in accordance with this appendix. The frequency of the lead length monitor shall be performed at each equipment setup as a minimum. A sample and test plan shall be available for review by the qualifying or preparing activity.

A.3.4.1.3 Qualification to RHA levels. Qualification to an RHA level shall consist of qualification to the appropriate quality and reliability assurance level (class level S or B) plus group E tests in accordance with, test method 5005 of MIL-STD-883. RHA levels are defined as follows:

Radiation hardness assurance (RHA) level

RHA level designator (see A.3.6.2.2)	Radiation and total dose (Rads (Si))
/ or -	No RHA
M	3000
D	10^4
P	3×10^4
L	5×10^4
R	10^5
F	3×10^5
G	5×10^5
H	10^6

MIL-PRF-38535J

APPENDIX A

A.3.4.1.4 Qualification to ESD classes. Initial qualification to an ESD class, or requalification after redesign, shall consist of qualification to the appropriate quality and reliability level (class level S or B) plus ESD classification in accordance with test method 3015 of MIL-STD-883. The test procedure defined within JESD22-A114 (see A.4.4.2.8) may optionally be used provided the manufacturer is able to demonstrate correlation with test method 3015 of MIL-STD-883, but the classification levels defined below shall be reported.

ESD classification levels are defined as follows:

<u>ESD class designator</u>	<u>Prior destination category</u>	<u>Optional individual part marking</u>	<u>Optional package marking</u>	<u>Electrostatic voltage</u>
0	---	Δ0	Δ0	< 250 V
1A	---	ΔA	ΔA	250 V – 499 V
1B	---	ΔB	ΔB	500 V – 999 V
1C	---	ΔC	ΔC	1,000 V – 1,999 V
1 (see note)	A	Δ (see note)	Δ (see note)	0 V – 1,999 V
2	B	ΔΔ	ΔΔ	2,000 V – 3,999 V
3 (see note)	---	ΔΔΔ (see note)	ΔΔΔ (see note)	≥ 4,000 V
3A	---	ΔΔΔA	ΔΔΔA	4,000 V – 7,999 V
3B	---	ΔΔΔB	ΔΔΔB	≥ 8,000 V

NOTE: ESD class designator 1 has been replaced with designators 0, 1A, 1B, and 1C as of 15 March 2006. The manufacturer shall test and may mark the tested level obtained under "Optional individual part marking" and the optional individual part marking may be used as the pin one identifier. Also, ESD class designator 3 has been replaced by 3A and 3B ESD class designators. ESD class designation 3 may continue to be used for devices tested before 15 March 2006. After 15 March 2006, for newly developed products, the 3A and 3B designators shall be used. Prior designation category devices previously classed by test as category A may be marked as class 1 (Δ) and devices previously classified as category B may be marked as class 2 (ΔΔ).

- Devices existing prior to 30 September 1989 that were not ESD classification tested shall be marked as class 1 until classified. Devices previously classified by test as category A shall be marked class 1. Devices previously classified by test as category B shall be marked as class 2. If it can be shown that test results obtained using TM 3015.3 of MIL-STD-883 correlate with results using TM 3015.6 of MIL-STD-883 (or later versions) or JESD22-A114 (see A.4.4.2.8) and give correct ESD classification, retesting of previously tested devices is not required except where redesign has occurred.
- Beginning no later than 31 December 1988 but prior to 15 March 2006, all newly designed or redesigned device types shall have been classified as ESD class 1, 2, or 3 in accordance with TM 3015 of MIL-STD-883 or JESD22-A114 (see A.4.4.2.8). After 15 March, 2006 the device types shall be classified as above.
- After 30 September 1989, in order to be compliant with this appendix or 1.2.1 of MIL-STD-883, all other device types for use in new system or equipment designs or system or equipment redesigns shall have completed classification in accordance with test method 3015 of MIL-STD-883 or JESD22-A114 (see A.4.4.2.8). All devices of existing design (i.e. not subject to A.3.4.1.4b above) shall be marked class 1 except when known by test to be, in fact, class 2 or better, in which case they shall be correctly identified for ESD.
- Although little variation due to case outline is expected, if a device type is available in more than one package type or case outline, ESD testing and classification shall be applied to at least that one package type shown by experience to be worst case for ESD.
- ESD testing classification results (or class one marking assigned without test) shall be submitted to DLA Land and Maritime-VA for all SMD devices built in compliance to this appendix. ESD testing classification results for non-SMD devices built in compliance to this appendix shall be retained by the manufacturer and made available to the acquiring or preparing activity upon request.

MIL-PRF-38535J

APPENDIX A

A.3.4.2 Changes and notification of change to product or quality assurance program. The manufacturer shall be responsible for the implementation of any major changes(s) or class 1 changes of the product or quality assurance program which may affect performance, quality, reliability, radiation hardness assurance (when specified), ESD class or interchangeability (see [table A-I](#)). The information needed to support these changes shall include acceptable engineering data, quality conformance inspection data, or a test plan sufficient to demonstrate that the changes(s) shall not adversely affect performance, quality, reliability, interchangeability, radiation hardness, or electrostatic discharge sensitivity and that the product will continue to meet the specification requirements. Notification to the acquiring activity of change of product involving devices acquired to any detail specification/drawing/data sheet is required for class 1 changes. Class 1 changes are those changes that may affect the performance, quality, reliability, or interchangeability of the product. Major changes as defined in [table A-I](#) shall, as a minimum, be reviewed to determine whether notification to the users is required. The manufacturer shall make this notification to the acquiring activity at the time of acceptance of a new order or delivery of an existing order. The manufacturer may make notification of this change of product through the GIDEP using the Product Change Notice; in any case the manufacturer shall assure that all known acquiring activities for this product are notified.

A.3.4.2.1 Discontinuation of products. The manufacturer shall have a system that provides notification of product discontinuation which comprises date of discontinuation and last times buy opportunity in advance (at least 6 month in advance) to the DLA Land and Maritime for purchasing devices.

A.3.4.3 Screening. All microcircuits to be delivered or submitted for quality conformance in accordance with this appendix shall have been subjected to, and passed, all the screening tests detailed in TM 5004 of MIL-STD-883 for the type of microcircuit and quality assurance level (device class) specified.

A.3.4.4 Quality conformance inspection (QCI). Microcircuits shall not be accepted or approved for delivery until the inspection lot has passed QCI (see [A.4.5](#)).

A.3.4.5 Wafer lot acceptance. Class level S microcircuits furnished under this appendix shall be products from wafer lots that are subjected to and successfully meet the wafer lot acceptance inspections and tests specified in test method 5007 of MIL-STD-883 or equivalent procedures approved by the acquiring activity.

A.3.4.6 Traceability. Traceability shall be provided for all microcircuit quality assurance levels. Each delivered microcircuit shall be traceable to the inspection and wafer lot(s) (see [A.4.8.1.2](#)).

A.3.4.6.1 Lot travelers. The manufacturer shall maintain lot travelers to document the completion of each required processing step from wafer diffusion for class level S (and class level B radiation hardened devices) and beginning with assembly for class level B with wafer lot identification through microcircuit assembly and screening test. Travelers shall provide space for those items specified in [A.4.8.1.3.7](#). The lot travelers shall provide traceability to all prior processing steps and shall be identifiable through assembly and acceptance testing and shall be monitored by the manufacturer's quality control organization.

A.3.4.7 Government source inspection. Government source inspection is required as detailed in the contract or order.

A.3.5 Design and construction. Microcircuit design and construction shall be in accordance with all the requirements specified herein and in the device specification or drawing.

MIL-PRF-38535J

APPENDIX A

A.3.5.1 Package. All devices supplied under this appendix shall be hermetically sealed in glass, metal, or ceramic (or combinations of these) packages. No organic or polymeric materials (lacquers, varnishes, coatings, adhesives, greases, etc.) shall be used inside the microcircuit package unless specifically detailed in the device specification or drawing (e.g., polyimide interlayer dielectric). Alpha Particle protection is permitted if permitted by the device specification or drawing. Desiccants may be used in the microcircuit package (except for class level S devices where they are prohibited) only if each lot is subjected to and passes an internal water vapor test, test method 1018 of MIL-STD-883, with a limit of 1,000 ppm at +100°C for a sample of 3(0) or 5(1). The internal moisture content for class level S devices, after completion of all screening, shall not exceed 5,000 ppm at +100°C. Polymer impregnations (backfill, docking, coating, or other uses of organic or polymeric materials to effect, improve, or repair the seal) of the microcircuit packages shall not be permitted. Polymer coating used to effect or improve marking adhesion shall not be applied over lid seal area.

NOTE: Packages containing beryllia shall not be ground, sand-blasted, machined, or have other operations performed on them which shall produce beryllia or beryllium dust. Furthermore, beryllium oxide packages shall not be placed in acids that shall produce fumes containing beryllium.

A.3.5.1.1 Polymeric die attach materials. All internal polymeric materials of the microcircuits shall meet the requirements TM 5011 of MIL-STD-883. Polymeric die attach materials shall be allowed under the following conditions. Polymeric materials shall be approved by the acquiring or preparing activity.

A.3.5.1.2 Package configurations. Package configurations (e.g., 14-lead flat package, 16-lead DIP, 20-terminal SQ.CCP, etc.) defined in MIL-STD-1835 shall be in accordance with the case outline of MIL-STD-1835. Package configurations not defined in MIL-STD-1835 shall be specified in the applicable acquisition document, and require approval of the acquiring activity.

A.3.5.2 Metals. External metal surfaces shall be corrosion-resistant or shall be plated or treated to resist corrosion. External leads shall meet the requirements specified in [A.3.5.6](#).

A.3.5.3 Other materials. External parts, elements or coatings including markings shall be inherently non-nutrient to fungus and shall not blister, crack, outgas, soften, flow or exhibit defects that adversely affect storage, operation, board assembly (e.g., permanently attached organic bumpers), or environmental capabilities of microcircuits delivered to this appendix under the specified test conditions.

A.3.5.4 Design documentation. Design, topography, and schematic circuit information for all microcircuits supplied under this appendix shall be available for review by the acquiring activity and the preparing activity upon request. Control and traceability of design documentation for all new designs and redesigns shall follow the guidelines of [A.3.5.4.1](#) through [A.3.5.4.4](#). This design documentation shall be sufficient to depict the physical and electrical construction of the microcircuits supplied under this appendix, and shall be traceable to the specific part, drawing, or type numbers to which it applies, and to the production lot(s) and inspection lot codes under which microcircuits are manufactured and tested so that revisions can be identified.

A.3.5.4.1 Die topography. For semiconductor die (monolithic die or dice for inclusion in multichip microcircuits), there shall be a photograph, drawing(s), mask list with revisions, or other representation defining the topography of the elements of the die without the intraconnection pattern.

A.3.5.4.2 Die intraconnection pattern. There shall be an enlarged photograph(s) or transparency of diazotypes of the mask set to the same scale as the die topography (see [A.3.5.4.1](#)) showing the specific intraconnection pattern used to connect the elements on the die so that elements used and those not used can be easily determined. For multichip microcircuits, this requirement shall apply to the substrate and all conductor pattern and active or passive circuit elements deposited thereon, as well as to semiconductor die, as applicable.

MIL-PRF-38535J

APPENDIX A

A.3.5.4.3 Die to terminal interconnection. There shall be an enlarged photograph(s), transparency, or drawing(s) to scale and of sufficient magnification to clearly depict the interconnection pattern for all connections made by wire or ribbon bonding, beam leads or other methods between the semiconductor die, other elements of the microcircuit, substrate(s) and package terminals or lands as applicable to the specific type of microcircuit supplied. If these interconnections show clearly on the die intraconnection pattern photograph, an additional photograph or drawing is not required.

A.3.5.4.4 Schematic diagrams. For microcircuits supplied under this appendix, the actual schematic diagram(s), logic diagram(s), or combination thereof shall be maintained, sufficient to represent all electrical elements functionally designed into the microcircuit together with their values (when applicable). For simple devices, this shall be a complete detailed schematic circuit showing all functional elements and values. For complex devices, or those with redundant detail, the overall microcircuit may be represented by a logic diagram in combination with schematic details. Minimum details that shall be included are: A schematic presentation of input/output stages and protection network details identified by appropriate pin numbers. Sufficient details to depict addressing or other device elements where the test parameters, conditions, or limits are sensitive to the specific device schematics. Where parasitic elements are important to the proper functioning of any microcircuit, they shall be included in the schematic diagram.

A.3.5.5 Internal conductors. Internal thin film conductors on semiconductor die or substrate (metallization stripes, contact areas, bonding interfaces, etc.) shall be designed so that properly fabricated conductors shall not experience in normal operation, over the operating temperature range (see A.3.1.3.31) (at worst case specified operating conditions), a current density in excess of the maximum allowable value shown below for the applicable conductor material:

<u>Conductor material</u>	<u>Maximum allowable current density</u>
Aluminum (99.99 percent pure or doped) without glassivation or without glassivation layer integrity test	$2 \times 10^5 \text{ A/cm}^2$
Aluminum (99.99 percent pure or doped) glassivated (see A.3.5.5.4)	$5 \times 10^5 \text{ A/cm}^2$
Refractory metals (Mo, W, Ti-W, and Ti-N) glassivated (see A.3.5.5.4)	$5 \times 10^5 \text{ A/cm}^2$
Gold	$6 \times 10^5 \text{ A/cm}^2$
Copper	$1 \times 10^6 \text{ A/cm}^2$
All other	$2 \times 10^5 \text{ A/cm}^2$

The current density shall be calculated at the point(s) of maximum current density (i.e., greatest current (see A.3.5.5a) in accordance with unit cross section) for the specific device type and schematic or configuration. Individual device calculations are not required when appropriate documented design rules or requirements have been used, which limit or control the current density in the resulting design.

- Use a current value equal to the maximum continuous current (at full fan-out for digitals or at maximum load for linear) or equal to the simple time averaged current obtained at maximum rated frequency and duty cycle with maximum load, whichever results in the greater current value at the point(s) of maximum current density. This current value shall be determined at the maximum recommended supply voltage(s) and with the current assumed to be uniform over the entire conductor cross-sectional area.
- Use the minimum allowed metal thickness in accordance with manufacturing specifications and controls including appropriate allowance for thinning experienced in the metallization step. The thinning factor over a metallization step is not required unless the point of maximum current density is located at the step.
- Use the minimum actual design conductor widths (not mask widths) including appropriate allowance for narrowing or undercutting experienced in metal etching.
- Areas of barrier metals, not intended by design to contribute to current carrying capacity, and non-conducting material shall not be included in the calculation of conductor cross section.

Thick film conductors multichip substrates (metallization strips, bonding interfaces, etc.) shall be designated so that no properly fabricated conductor shall dissipate more than 4 watts/cm^2 when carrying maximum design current.

MIL-PRF-38535J

APPENDIX A

TABLE A-I. Testing guidelines for changes identified as major.

Major changes		Testing, TM 5005 of MIL-STD-883 (All electrical parameters in accordance with the device specification or drawing 1/)
a.	Doping material source concentration Process technique	Group A and C-1 deltas (variables only when deltas are required)
b.	Diffusion profile	Group A and C-1 deltas (variables only when deltas are required)
c.	Die structure	Group A and C-1 deltas (variables only when deltas are required)
d.	Mask changes affecting die size or active element	Variable group A, C-1 prior to shipment, and notify the qualifying activity if new area is smaller/larger in applicable package than previously qualified.
	Wafer diameter	Group A, C-1 prior to shipment
	Final die thickness	Group D-3
e.	Passivation/glassivation	Group A, C-1 and glass integrity test if current density is over 2×10^5
f.	Metallization changes	Group A, C-1, and B-5
g.	Die attach method	D-3 and D-4
h.	Die attach process	D-3 and D-4
i.	Bond process	B-5 and D-3
j.	Bond wire material/dimension	B-5 and D-3
k.	Package or lid structure	D-1 (variables), D-3, D-4, D-8 (lid torque) (variables)
	Package or lid material	D-3, D-4, D-5, D-6 (variables), and D-8 (lid torque) (variables)
	Package or lid dimension	D-1 (variables), D-2, and D-8 (lid torque) (variables)
	Lead frame material	See A.4.4.2.7
	Lead frame dimension	D-1 (variables) and D-2
	Cavity dimension	B-5, D-2, D-6 (variables), and D-8 (lid torque) (variables)
l.	Sealing profile	D-3, D-4, D-6 (variables), and D-8 (lid torque) (variables)
	Sealing material	D-3, D-4, D-6 (variables), and D-8 (lid torque) (variables)
	Frame attach	B-3, D-3, D-4, D-6 (variables), and D-7 (adhesion of lead finish) (variables)
	Frame cleaning	B-3, D-2, D-3, and D-7 (adhesion of lead finish)

MIL-PRF-38535J

APPENDIX A

TABLE A-I. Testing guidelines for changes identified as major. - Continued.

Major changes		Testing, TM 5005 of MIL-STD-883 (All electrical parameters in accordance with the device specification or drawing <u>1/</u>)
m.	Implementation of test methods	Notify qualifying activity (may involve test demonstration)
n.	Critical documents (see A.4.8.1.3b)	Notify qualifying activity (may involve test demonstration)
o.	Fab move	Group A and C
p.	Assembly move	Group D in accordance with each package family (see A.3.1.3.30) prior to ship
q.	Test facility move	Notify qualifying activity
r.	Scribe/die separation	5 SEM photographs of randomly selected die showing one full edge of die front and back
s.	Qualification/QCI procedures	Notify qualifying activity
t.	Passivation for RHA	Group A, E, C-1, and glass integrity test if current density is over 2×10^5
u.	Diffusion profile for RHA	Group A, E, and C-1 deltas (variables only when deltas are required).
v.	Sinter/anneal for RHA	Group A, E, C-1, and B-5
w.	Modification of programming algorithms	Notify qualifying activity

1/ This table is for class level B subgroups only. For class level S, use the equivalent class level S subgroups.

A.3.5.5.1 Metallization thickness. For class level S microcircuits the metallization thickness shall be adequate to satisfy the current density requirements of [A.3.5.5](#).

A.3.5.5.2 Internal wire size and material. For class level S microcircuits, the internal wire diameter shall be .001 inch minimum (0.0254 mm) or of sufficient diameter to meet the minimum fusing requirements and bond pull strength requirements with the approval of qualifying activity. The internal lead wire shall be the same metal as the die metallization.

MIL-PRF-38535J

APPENDIX A

A.3.5.5.3 Internal lead wires. Internal lead wires or other conductors which are not in thermal contact with a substrate along their entire length (such as wire or ribbon conductors) shall be designed to experience, at maximum rated current, a continuous current for direct current, or a root mean square (RMS) current (peak current divided by $\sqrt{2}$), for alternating or pulsed current, not to exceed the values established by the following relationship:

$$I = Kd^{3/2}$$

Where: I = Maximum allowed current in amperes.

d = Diameter in inches for round wire (or equivalent round wire diameter which would provide the same cross-sectional area for other than round wire internal conductor).

K = A constant taken from [table A-IA](#) below for the applicable wire or conductor length and composition used in the device.

Composition	"K" values for bond-to-bond total conductor length	
	Length \leq 0.040 inch (0.10 cm)	Length > 0.040 inch (0.10 cm)
Aluminum	22,000	15,200
Gold	30,000	20,500
Copper	30,000	20,500
Silver	15,000	10,500
All other	9,000	6,300

A.3.5.5.4 Verification of glassivation layer integrity. Where the current density of aluminum metallization for a device type to be qualified exceeds the allowable current density for unglassivated aluminum, the device type shall be subjected to and pass the requirements of TM 2021 of MIL-STD-883 prior to qualification and the glassivation layer integrity sample used along with and a photograph of the etched die shall be documented and maintained. One resubmission is permitted at twice the sample size. Unless otherwise specified by the qualifying activity (QA), the device type shall be tested after sealing (or after exposure to the time/temperature sealing profile) in the package type that receives the highest temperature range during sealing for which the device type is to be qualified. Changes in design, materials, or process, which affect current density or glassivation, shall also be evaluated using TM 2021 of MIL-STD-883. This evaluation applies only when the current density requirements for unglassivated aluminum are exceeded.

A.3.5.6 Package element material and finish.

A.3.5.6.1 Package material. Package body material shall be metal, glass, or ceramic in accordance with [A.3.5.1](#).

MIL-PRF-38535J

APPENDIX A

A.3.5.6.2 Lead or terminal material. Lead or terminal material shall conform to one of the following compositions:

- a. Type A: Iron-nickel-cobalt alloy: SAE-AMS-I-23011, class I, ASTM F15.
- b. Type B: Iron-nickel alloy (41 percent nickel): SAE-AMS-I-23011, class 5, ASTM F30.
- c. Type C: Co-fired metallization such as nominally pure tungsten. The composition and application processing of these materials shall be subject to QA approval and submitted with application to test and as otherwise requested by the QA.
- d. Type D: Copper-core, iron-nickel ASTM F30 alloy (50.5 percent nickel). The core material shall consist of copper (oxygen-free), ASTM B170, grade 2.
- e. Type E: Copper-core ASTM F15 alloy. The core material shall consist of copper (oxygen-free) ASTM B170, grade 2.
- f. Type F: Copper (oxygen-free) ASTM B170, grade 2. This material shall not be used as an element of any glass-to-metal seal structure.
- g. Type G: Iron-nickel alloy (50.5 percent nickel): SAE-AMS-I-23011, class 2, ASTM F30.

A.3.5.6.3 Microcircuit finishes. Finishes of all external leads or terminals and all external metal package elements shall conform to either [A.3.5.6.3.2](#) or [A.3.5.6.3.3](#), as applicable. The use of pure tin, as an underplate or final finish, is prohibited both internally and externally. The tin content of solder shall not exceed 97 percent. Tin shall be alloyed with a minimum of 3 percent lead by weight. The lead finish designator (see [A.3.6.2.7](#)) shall apply to the finish of the leads or terminals. The leads or terminals shall meet the applicable solderability and corrosion resistance requirements. The other external metallic package elements (including metalized ceramic elements) shall meet the applicable corrosion resistance requirements. Finishes on interior elements (e.g. bonding pads, posts, tabs) shall be such that they meet the lead bonding requirements and applicable design and construction requirements. The use of strike plates is permissible to the maximum thickness of 10 microinches (0.25 micrometer). All plating of finishes and undercoats shall be deposited on clean, non-oxidized metal surfaces. Suitable de-oxidation or cleaning operations shall be performed before or between plating processes. All parts shall be capable of meeting the following requirements of MIL-STD-883:

- a. Test method 2004, lead integrity, test condition B1, B2, or D, or test method 2028, pin-grid package destructive lead pull test, as applicable.
- b. Test method 1009, salt atmosphere.
- c. Test method 2003, solderability (plus time/temperature exposure of burn-in except for devices which have been hot solder dipped or have undergone tin fusing after burn-in).
- d. Test method 2025, adhesion of lead finish.

Compliance to the above requirements shall be demonstrated when and as specified.

MIL-PRF

-38535J

APPENDIX A

A.3.5.6.3.1 Finish thickness measurements. Lead finish thickness measurements shall be taken at the seating plane on surface mount leads (such as J-bend and gull-wing type leads) and approximately halfway between the seating plane and the tip of the lead on all other lead types. (This requirement is to avoid having the inspector select a non-typical portion of the lead on which to perform the measurement.) On all lead shapes other than round, the finish thickness measurement shall be taken at the crest of major flats. Measurements taken on the shorting bar shall be correlated by direct measurement on the lead. Finish thickness measurements for package elements other than leads shall be taken at the center of major flats. Finish thickness measurements shall be performed in accordance with one of the following procedures:

- a. AST M B487.
- b. AST M B567.
- c. AST M B568.

The aforementioned ASTM methods are provided as reference methods to be used when the failure to pass other finish requirements suggests deficiencies in plating thickness. Compliance to the finish thickness requirements shall be demonstrated when and as specified.

A.3.5.6.3.2 Lead finish. The finish system on all external leads or terminals shall conform to one of the combinations listed in [table A-II](#), and to the thickness and composition requirements of [table A-III](#). The finish system shall also conform to the requirements of [A.3.5.6.3.4](#) and [A.3.5.6.3.5](#), where applicable.

A.3.5.6.3.3 Package element (other than lead or terminal) finish. External metallic package elements other than leads and terminals (e.g., lids, covers, bases, and seal rings) shall meet the applicable environmental requirements without additional finishing of the base materials or else they shall be finished so they meet those requirements using a finish system conforming to one of the combinations listed in [table A-IV](#), and conforming to the thickness and composition requirements of [table A-III](#). The finish system shall also conform to the requirements of [A.3.5.6.3.4](#) and [A.3.5.6.3.5](#), where applicable.

A.3.5.6.3.4 Hot solder dip. The hot solder dip shall be homogeneous and shall be applied as follows:

- a. All outlines with hot solder dip over compliant coating. The hot solder dip shall extend beyond the effective seating plane. If the seating plane is not defined, the hot solder dip shall extend to within 0.040 inch (1.02 mm) of the lead/package interface and is bound by the lead/package interface. For dual inline type termination forms (through hole and surface mount), the plane of the two longest lead/package interfaces will define this bound. For leadless chip carrier devices, the hot solder dip shall cover a minimum of 95 percent of the metalized side castellation or notch and metalized areas above and below the notch, except the index feature if not connected to the castellation. Terminal area intended for device mounting shall be completely covered. For top brazed flat pack packages, the hot solder dip shall extend to within 0.070 inch (1.78 mm) of the lead/package interface.
- b. All outlines with hot solder dip over base metal or noncompliant coating. The solder shall extend to the glass seal or point of emergence of the metalized contact or lead through the package wall. If solder is applied up to the seal, a hermeticity test (TM 1014 of MIL-STD-883, and TM 5004 of MIL-STD-883, [Table I](#), footnote 12/) shall subsequently be performed and passed. For leadless chip carrier devices, the hot solder dip shall completely cover the metalized side castellation or notch and metalized areas above and below the notch, except the index feature if not connected to the castellation.

MIL-PRF-38535J

APPENDIX A

A.3.5.6.3.5 Tin-lead plate. Tin-lead plate may be fused after plating before or after burn-in by heating above its liquidus temperature. Tin-lead plate shall be visually inspected after fusing and shall exhibit a dense, homogeneous, and continuous coating. The visual inspection after fusing shall be conducted on a sample basis by the manufacturer as an in-process control. Visual inspection of the fusing shall be performed at a frequency sufficient to assure continuous compliance with these requirements on the finished product. The manufacturer shall monitor the tin-lead content of the leads to assure a minimum of 3 percent lead by weight.

A.3.5.7 Die plating and mounting. Pure glass shall not be used for microcircuit die mounting. Metal glass die mounting and Silver Cyanate Ester (see Rome Labs letter 31 May 1994 for guidelines) are acceptable with QA approval. (Contact the preparing activity for the Rome Labs letter.) Electroplated and electroless plated gold backing on dice shall not be used, with the exception of gallium arsenide (GaAs) dice which may use electroplated gold backing.

TABLE A-II. Lead finish systems.

Finish	Applied over	Required underplate		
	Gold plate	Electroplated nickel	Electroless nickel <u>1/</u>	None
Hot solder dip <u>2/</u> Hot solder dip <u>2/</u> Hot solder dip <u>2/</u> Hot solder dip <u>2/</u> Hot solder dip <u>2/</u>	 X X	 X X	 X X	 X
Tin-lead plate <u>3/</u> Tin-lead plate <u>3/</u> Tin-lead plate <u>3/</u>		 X	 X	 X
Gold plate Gold plate		 X	 X	
Palladium		 X		
Gold flash palladium		 X		

1/ Electroless nickel shall not be used as the undercoat on flexible or semi-flexible leads (see 3.3.1 and 3.3.2 of TM 2004 of MIL-STD-883) and shall be permitted only on rigid leads or package elements other than leads.

2/ Hot solder dip shall be applied in accordance with A.3.5.6.3.4.

3/ Fusing of tin-lead plating is permitted in accordance with A.3.5.6.3.5.

MIL-PRF-38535J

APPENDIX A

TABLE A-III. Coating thickness and composition requirements.

Coating	Thickness (microinch/micrometer)		Coating composition requirements
	Minimum <u>1/</u>	Maximum <u>2/</u>	
Hot solder dip (for all round leads) <u>3/</u>	60/1.52	NS	The solder bath shall have a nominal composition of Sn60 or Sn63.
Hot solder dip (for all shapes other than round leads which have ≤ 25 mil pitch) <u>3/</u>	150/3.80	NS	The solder bath shall have a nominal composition of Sn60 or Sn63.
Hot solder dip (for all shapes other than round leads with > 25 mil pitch) <u>3/</u>	200/5.08	NS	The solder bath shall have a nominal composition of Sn60 or Sn63.
Tin-lead plate (as plated) <u>4/</u>	300/7.62	NS	Shall consist of 3 to 50 percent by weight lead (balance nominally tin) homogeneously co-deposited. Shall contain no more than 0.05 percent by weight co-deposited organic material measured as elemental carbon. <u>5/</u>
Tin-lead plate (fused) <u>4/</u>	200/5.08	NS	
Gold plate	50/1.27	225/5.72	Shall contain a minimum of 99.7 percent gold. Only cobalt shall be used as the hardener.
Nickel plate (electroplate)	50/1.27	350/8.89	The introduction of organic addition agents to nickel bath is prohibited. Up to 40 percent by weight cobalt is permitted as a co-deposit.
Nickel plate (electroless)	50/1.27	250/6.35	The introduction of organic additive agents to nickel bath is prohibited.
Nickel cladding	50/1.27	350/8.89	
Palladium	20/0.51	84/2.13	
Gold flash palladium	20/0.51	84/2.13	

1/ Package elements having noncompliant coatings are permitted provided they are subsequently hot solder dipped in accordance with [A.3.5.6.3.4b](#).

2/ NS = Not specified.

3/ See [A.3.5.6.3.4](#).

4/ See [A.3.5.6.3.5](#).

5/ The maximum carbon content (and minimum lead content in tin-lead plate) shall be determined by the manufacturer on at least a weekly basis. The determination of carbon and lead content may be made by any accepted analytical technique (e.g., for carbon: pyrolysis, infrared detection (using an IR212, IR244 infrared detector, or equivalent); for lead: X-ray fluorescence, emission spectroscopy) so long as the assay reflects the actual content in the deposited finish.

MIL-PRF-38535J

APPENDIX A

TABLE A-IV. Package element (other than leads/terminals) finish systems.

Finish	Applied over	Required underplate			
	Gold plate	Electroplated nickel <u>1/</u>	Electroless nickel <u>1/</u>	Nickel cladding <u>1/</u>	None
Hot solder dip Hot solder dip Hot solder dip Hot solder dip Hot solder dip Hot solder dip Hot solder dip	 X X X	 X X 	 X X 	 X X 	 X
Tin-lead plate <u>2/</u> Tin-lead plate <u>2/</u> Tin-lead plate <u>2/</u> Tin-lead plate <u>2/</u>	 	 X 	 X 	 X 	 X
Gold plate <u>3/</u> Gold plate <u>3/</u> Gold plate <u>3/</u>	 	 X 	 X 	 X 	
Electroplated nickel <u>1/</u> Electroless nickel <u>1/</u> Nickel cladding <u>1/</u>	 	 	 	 	 X X X
Palladium		X			
Gold flash palladium		X			

1/ Combinations of electroplated nickel and electroless nickel and nickel cladding are permitted.

2/ Fusing of tin-lead plate is permitted in accordance with [A.3.5.6.3.5](#).

3/ Multilayer gold and nickel finish structures are acceptable provided the outer gold layer meets a minimum thickness of 25 microinches (0.635 micrometer), the total of the gold layers meet a minimum thickness of 50 microinches (1.27 micrometers), and each of the nickel undercoats meet the thickness requirements of [table A-III](#) with the total nickel thickness not to exceed 450 microinches (11.43 micrometers). For multilayer finish structures, nickel plate, nickel cladding, or gold plate are permitted on the base metal.

A.3.5.8 Glassivation. All microcircuits shall be coated with a transparent glass or other approved coating, except where glassivation is omitted by documented design rules (e.g., probe opening, fuse pads, etc.) The minimum glassivation thickness shall be 6,000 Å (600 nm) for SiO₂, 2,000 Å (200 nm) for Si₃N₄, or approved thicknesses for approved coatings. The composition and minimum thickness of other approved coatings are subject to approval by the QA. The glassivation/nitridation shall cover all electrical conductors except the bonding or test pads. NOTE: For GaAs microwave microcircuits, the glassivation or nitride dielectric shall cover the semiconductor regions (e.g., field effect transistor (FET)) of the device and planar thin film resistors as a minimum. Furthermore; for class S devices, the glassivation or nitride dielectric shall cover regions where conductors are separated by less than the minimum 1 mil particle size detectable by a PIND test. For RF/microwave GaAs microcircuits, the manufacturer shall define appropriate glassivation thickness requirements for the technology in the internal baseline documentation.

MIL-PRF-38535J

APPENDIX A

A.3.5.9 Die thickness. Appropriate die thickness requirements for each product or process shall be defined in the manufacturer's baseline documentation. This thickness shall be sufficient to avoid die cracks due to handling, die attach, wire bonding or other process stresses, which could lead to latent field failure.

A.3.5.10 Laser scribing. For class level S microcircuits, laser scribing shall not be used for die separation except for backside scribing of silicon on sapphire (SOS) wafers. Laser trim of resistors and shorting bars and laser scribed package external markings are not prohibited unless otherwise specified.

A.3.5.11 Internal lead separation for class level S devices. For class level S devices, the minimum separation of the internal leads (excluding conductors which are at the die or substrate potential) from the unglassivated surface of the die shall be a minimum of 1.0 mil. This design requirement shall be verified during design verification, qualification and during group B internal visual and mechanical tests in accordance with TM 5005 of MIL-STD-883.

A.3.6 Marking of microcircuits. Marking shall be in accordance with the requirements of this appendix, and the identification and marking provisions of the device specification or drawing. The marking shall be legible and complete, and shall meet the resistance to solvents requirements of TM 2015 of MIL-STD-883. When laser marking is performed, it shall be clearly visible through those conformal coatings approved for use in MIL-I-46058, (see TM 2015 of MIL-STD-883 if contrasting material or ink is used to highlight the trace). Laser marked metal surfaces shall have been submitted to and passed all group D test requirements. If any special marking is used, it shall in no way interfere with the marking required herein, and shall be visibly separated from the required marking. The following marking shall be placed on each microcircuit. If any special marking (e.g., altered item drawing number) is used by the device supplier or user/equipment contractor, it shall be in addition to the existing/original marking as required herein and shall be visibly separate from, and in no way interfere with, the marking required herein. The following shall be placed on each microcircuit:

- a. Index point (see [A.3.6.1](#)).
- b. PIN (see [A.3.6.2](#)).
- c. Identification codes (see [A.3.6.3](#)).
- d. Manufacturer's identification (see [A.3.6.4](#) and [A.3.6.5](#)).
- e. Country of origin (see [A.3.6.6](#)).
- f. Compliance indicators (see [A.3.6.7](#)).
- g. Serialization, when applicable (see [A.3.6.8](#)).
- h. Special marking (see [A.3.6.9](#), [A.3.6.9.1](#)).
- i. Electrostatic discharge (ESD) sensitivity identifier, if applicable (see [A.3.6.9.2](#)).

NOTE: All devices shall be marked by the manufacturer in such a manner as to leave space for additional unique marking (assigned and applied by the user or called out in the order or contract).

A.3.6.1 Index point. The index point, tab, or other marking indicating the starting point for numbering of leads or for mechanical orientation shall be as specified (see MIL-STD-1835) and shall be designed so that it is visible from above when the microcircuit is installed in its normal mounting configuration. The outline or solid equilateral triangle(s) (Δ) which may be used as an electrostatic identifier (see [A.3.6.9.2](#)), may also be used as the pin 1 identifier.

MIL-PRF-38535J

APPENDIX A

A.3.6.2 PIN. Each microcircuit shall be marked with the complete PIN. The PIN may be marked on more than one line provided the PIN is continuous except where it "breaks" from one line to another. The PIN system shall be as described in 3.6.2a and 3.6.2b for microcircuits produced in accordance with this appendix and either an SMD, or device specification. For devices produced in accordance with this appendix, which are not documented on SMDs, the PIN shall be the vendor's generic part number or the contractor's part number as applicable.

A.3.6.2.1 Military designator. Any device that does not meet all the requirements of this appendix and the applicable device specification, except as allowed by H.3.3, shall not be marked M38510 and shall not make reference to MIL-M-38510 or MIL-PRF-38535.

A.3.6.2.2 RHA designator. A "/" or "-" indicates no radiation hardness assurance. Letters M, D, P, L, R, F, G, or H designator levels are defined in A.3.4.1.3.

A.3.6.2.3 Device specification. When used in association with this specification or appendix (i.e., QML), the M38510 device specification shall consist of three digits from 001 to 999 as applicable.

A.3.6.2.4 Device type. The device type number shall be as specified in the device specification or SMD. The numbers shall consist of two digits assigned sequentially, from 01 to 99, within each device specification or SMD.

A.3.6.2.5 Device class. The device class shall be designated by a single letter identifying the quality assurance level. For devices built compliant to this appendix and documented on a one part-one part number SMD, the device class designator shall be an 'M'.

A.3.6.2.6 Case outline. The case outline shall be designated by a single letter assigned to each outline.

A.3.6.2.7 Lead finish. Lead frame or terminal material and finish shall be as specified in A.3.5.6. The lead finish shall be designated by a single letter in table A-V.

TABLE A-V. Lead finish.

Lead finish letter	Lead frame or terminal material and finish (see note below)
A	Types A, B, C, D, E, F, or G with hot solder dip
B	Types A, B, C, D, E, F, or G with tin-lead plate
C	Types A, B, C, D, E, F, or G with gold plate
D	Types A, B, C, D, E, F, or G with palladium
E	Types A, B, C, D, E, F, or G with gold flash palladium
X	Types A, B, C, D, E, F or G with finishes A, B, or C (see note below)

NOTE: Finish letter "X" shall not be marked on the microcircuit or its packaging. This designation is provided for use in drawings, part lists, orders, or other documentation where lead finishes A, B, or C are all considered acceptable and interchangeable without preference. For Government logistic support, the A lead finish shall be acquired and supplied to the end user when the X is included in the PIN for lead finish. If the PIN is not available with the A lead finish, the same PIN shall be acquired except with the B or C lead finish designator as determined by availability. Type C terminal material is a fired on metallization used with leadless chip carriers.

A.3.6.2.8 Drawing designator. For new one part-one part number drawings without existing device specifications, the first two characters of the drawing designator shall consist of the last two digits of the year and the last three characters shall consist of unique characters assigned to the drawing by DLA Land and Maritime. When an existing MIL-M-38510 device specification PIN is converted to a one part-one part number PIN via a substitution statement, the first two characters of the drawing designator of the one part-one part number shall be replaced with the first two digits of MIL-M-38510 (i.e., 38), and the last three characters of the one part-one part number shall be replaced with the three digit identifier assigned to the device specification (e.g., M38510/00101BAC shall become 5962-3800101BAC).

MIL-PRF-38535J

APPENDIX A

A.3.6.3 Identification codes. Identification codes shall be as follows:

A.3.6.3.1 Class level B die fabrication date code. Class level B microcircuits may be marked with a unique code to identify the year and quarter in which the die fabrication was started (or completed at the manufacturer's predesignated option). The first character of the code shall be the last digit of the year in which die fabrication started (or completed at the manufacturer's predesignated option). The second character of the code shall be a letter (A, B, C, or D) respectively designating the first quarter (weeks 1 - 13), the second quarter (weeks 14 - 26), third quarter (weeks 27 - 39), or fourth quarter (weeks 40 - 52 or 53) of the calendar year of die fabrication.

A.3.6.3.2 Inspection lot identification code for class levels S and B. Microcircuits shall be marked with a unique code to identify the inspection lot (see [A.3.1.3.7](#) and [A.3.1.3.8](#)) and identify the first or the last week of the period (6 weeks maximum) during which devices in that inspection lot were sealed. At the option of the manufacturer, the actual week of seal may be used. The first two numbers in the code shall be the last two digits of the number of the year, and the third and fourth numbers shall be two digits indicating the calendar week of the year. When the number of the week is a single digit, it shall be preceded by a zero. Reading from left to right or from top to bottom, the code number shall designate the year and week, in that order. When two or more different inspection lots (or class level S sublots), each having the same part number, are to be marked with the same identification code, a unique suffix letter representing each additional inspection lot (or class level S subplot) shall appear immediately following the identification code except the unique suffix letter may be omitted when an alternate lot identifier is used which maintains the unique traceability required. Once assigned, the inspection lot identification code shall not be changed.

NOTE: These die fabrication date codes may be combined with the inspection lot identification code as shown:

FAB YR	FAB QTR	ASSY YR	ASSY WK	Unique suffix
6	B	87	10	A
1986	2nd qtr	1987	10	First lot

A.3.6.4 Manufacturer's identification. Microcircuits shall be marked with the name or trademark of the manufacturer. The identification of the equipment manufacturer may appear on the microcircuit only if the equipment manufacturer is also the microcircuit manufacturer.

A.3.6.5 Manufacturer's designating symbol. The microcircuit manufacturer's designating symbol or CAGE code may also be marked on each device in addition to the manufacturer's identification. If the microcircuit manufacturer's designating symbol or CAGE code number is marked, it shall be as assigned by the Defense Logistics Information Service (DLIS). The designating symbol shall be used only by the manufacturer to whom it has been assigned and only on those devices manufactured at that manufacturer's plant. In the case of small microcircuits, the manufacturer's designating symbol may be abbreviated by omitting the first "C" in the series of letters.

A.3.6.6 Country of origin. The identifier of the country in which assembly is performed shall be marked on all devices supplied under this appendix. If abbreviations are used, a cross reference should be published in the manufacturer's data books or catalogs.

A.3.6.7 Compliance indicator/certification mark. The compliance indicator "C" shall be marked on all devices built in compliance to this appendix. The "D" certification mark shall be used for diminishing manufacturing sources (DMS) product using the alternate die/fab requirements (see [A.3.2.2](#)) in lieu of the "C" certification mark for product built to this appendix. The compliance indicator "C" shall be replaced with a "Q" or "QML" certification mark or the "Q" or "QML" certification mark added when product is built to a QML process (see [A.3.1](#)). The "J" or "JAN" certification mark may not be used on devices built in compliance to this appendix.

A.3.6.8 Serialization. Prior to the first recorded electrical measurement in screening each class level S microcircuit, and when specified, each class level B microcircuit shall be marked with a unique serial number assigned consecutively within the inspection lot. This serial number allows traceability of test results down to the level of the individual microcircuit within that inspection lot. For class level S, inspection lot records shall be maintained to provide traceability from the serial number to the specific wafer lot from which the devices originated.

MIL-PRF-38535J

APPENDIX A

A.3.6.9 Marking location and sequence. The certification mark, the PIN, identification codes and ESD identifier shall be located on the top surface of leadless or leaded chip carriers, pin grid array packages, flat packages, or dual-in-line configurations and on either the top or the side of cylindrical packages (TO configurations and similar configurations). When the size of a package is insufficient to allow marking of special process identifiers on the top surface, the backside of the package may be used for these markings except the ESD identifier, if marked, shall be marked on the top. Button cap flat packs with less than or equal to 16 leads may have the identifier marked on the ceramic. Backside marking with conductive or resistive ink shall be prohibited.

A.3.6.9.1 Beryllium oxide package identifier. If a microcircuit package contains beryllium oxide (see A.3.5.1 note), the part shall be marked with the designation "BeO".

A.3.6.9.2 Electrostatic discharge (ESD) sensitivity identifier. Microcircuits shall be ESD classified in accordance with A.3.4.1.4, however, ESD classification marking is not required. The manufacturer shall have an option of no ESD marking, marking a single ESD triangle or marking in accordance with the ESD device classification defined in test method 3015 of MIL-STD-883. Because it may no longer be possible to determine the ESD classification from the part marking, the device Discharge Sensitivity Classification shall be as listed in MIL-HDBK-103 or QML-38535.

A.3.6.10 Marking on container. See A.5.2.2 for additional marking requirements.

A.3.6.11 Marking option for controlled storage of class level B. Where microcircuits are subjected to testing and screening in accordance with some portion of the quality assurance requirements and stored in controlled storage areas pending receipt of orders requiring conformance to the same or a different level, the inspection lot identification code shall be placed on the microcircuit package along with the other markings specified in 3.6 sufficient to assure identification of the material. As an alternative, if the microcircuits are stored together with sufficient data to assure traceability to processing and inspection records, all markings may be applied after completion of all inspections to the specified level.

A.3.6.12 Marking option for qualification or quality conformance inspection (QCI). The manufacturer has the option of marking the entire lot or only the sample devices to be submitted to qualification or groups B, C, and D (and E if applicable) QCI, as applicable. If the manufacturer exercises the option to mark only the sample devices, the procedures shall be as follows:

- a. The sample devices shall be marked prior to performance of groups B, C, and D (and E if applicable) qualification or QCIs, as applicable.
- b. At the completion of inspection, the marking of the sample devices shall be inspected for conformance with the requirements of A.3.6.
- c. The inspection lot represented by the conforming qualification or quality conformance sample shall then be marked and any specified visual and mechanical inspection performed.
- d. The marking materials and processing applied to the inspection lot shall be to the same specifications as those used for the inspection sample.

MIL-PRF-38535J

APPENDIX A

A.3.6.13 Remarking. If sealed devices are remarked (to change or correct the marking as specified in A.3.6), the reason for remarking, and a description of the process shall be recorded in the qualification test report and quality conformance test record. In addition to the tests described below for qualification of the remarking procedure, subgroup B-2 and internal visual and mechanical tests (TM 2014 of MIL-STD-883 with sample size/(accept no.) of 1(0) for class B devices and subgroups B-2a and B-2b (TM 2014 of MIL-STD-883 only) for class level S devices shall be performed on each remarked lot to assure marking permanency and that markings and device type coincide. An appropriate group A test, with a sample size/(accept no.) of 116(0), (100 percent for class level S) may be performed, in lieu of internal visual and mechanical tests, to demonstrate that the markings and device types coincide. Remarking procedures shall be approved by the qualifying activity. Approval shall be required once only for each package material (i.e., lid, base) composition (regardless of package configuration), or at change of remarking procedures or materials. For qualification of the remarking procedure, a sample of remarked devices shall be tested to the following test methods according to TM 5005 of MIL-STD-883:

- a. TM 2015, resistance to solvents (3 devices).
- b. TM 1011, thermal shock (test condition B, 15 cycles minimum).
- c. TM 1004, moisture resistance.
- d. TM 1009, salt atmosphere.

NOTE: Electrical tests are not required. Visual inspection, after each test in accordance with applicable failure criteria, shall be conducted.

A.3.7 Workmanship. Microcircuits shall be manufactured, processed, and tested in a careful and workmanlike manner in accordance with good engineering practice, with the requirements of this appendix, and with the production practices, workmanship instructions, inspection and test procedures, and training aids prepared by the manufacturer in fulfillment of the quality assurance program (see A.4.8 herein).

A.3.7.1 Rework provisions. All rework (see A.3.1.3.16) permitted on microcircuits acquired under this appendix shall be accomplished in accordance with procedures and safeguards documented in accordance with A.4.8.1.1.6 and available for review by the preparing and acquiring activity. In addition, all rework operations shall be clearly identified on each process flowchart. Allowable rework of sealed packages includes recleaning of any microcircuit or portion thereof, any rebranding (see A.3.6.13) to correct defective marking and lead straightening (provided the reworked devices meet the requirements of A.4.6.2 for conditions of leads). For monolithic wafers of any class, the strip and redeposition of a layer or additional processing to correct a nonconformance to a specification limit is not allowed, except for the strip and redeposition of sacrificial layer(s) used exclusively as a masking function (e.g., photoresist, nitride, nitride glass). Documenting rework of these sacrificial layers on the flow chart is not required. In the event of equipment failure beyond manufacturer control, continuation of processing is permitted and is considered allowable rework provided the manufacturer assures, through evaluation, that no alteration in material film properties occurs (e.g. oxidation, corrosion, grain size, film stress, adhesion) and baselined limits are met. The strip and redeposition of backside metallization is considered allowable rework. No delidding or package opening for rework shall be permitted for microcircuits of any class. For monolithic microcircuit wafers of any class, the strip and redeposition of a layer or additional processing to correct a nonconformance to a specification limit is not allowed, except as specified above. For class level S, any assembly rework operation prior to package seal is not allowed, except as specified in A.3.7.1.1. Other than already stated in the rework provisions above, rework is not allowed for class level S product without substantiating data and written approval of the qualifying activity.

A.3.7.1.1 Rebonding of monolithic devices. Visual criteria for rebonding and rebonding limitations for class level B monolithic microcircuits shall be in accordance with TM 2010, Internal Visual (Monolithic), of MIL-STD-883, (see 3.2.1.4i and 3.2.1.5 of TM 2010 of MIL-STD-883). For class level S devices, rebonding is not allowed without substantiating data and written approval of the qualifying activity. Rebonding of class level B shall be limited to the bonding operation only.

MIL-PRF-38535J

APPENDIX A

A.4 VERIFICATION

A.4.1 Responsibility for inspection. Unless otherwise specified in the contract or order, the contractor is responsible for the performance of all inspection requirements as specified herein and in the device specification or drawing.

A.4.1.1 Inspection during manufacture. The manufacturer shall establish and maintain in-process production controls, quality controls and inspections at appropriately located points in the manufacturing process in accordance with the procedures described in [A.4.8.1.1](#) to assure continuous control of quality of materials, subunits, and parts during manufacture and testing. These controls and inspections shall be adequate to assure compliance with the applicable acquisition documentation and quality standards of microcircuits manufactured to this appendix and the applicable device specification or drawing.

A.4.1.1.1 Metal package isolation test for class level S devices. Prior to die mounting, each metal-bodied package with leads glass-isolated within .005 inch (0.13 mm) of the metal body shall have 600 V dc applied between the case and leads not connected to the case. Packages which exhibit leakage greater than 100 nA shall be rejected.

A.4.1.2 Control and inspection of acquisition sources. The manufacturer shall be responsible for assuring that all supplies and services used in the manufacture and test of microcircuits conform to all the requirements of this appendix, the device specification or drawing, and other provisions of the applicable acquisition documentation.

A.4.1.3 Control and inspection records. The manufacturer shall maintain objective evidence documenting that each lot has been subjected to all processing controls, inspections, and tests accomplished in accordance with [A.3](#) and [A.4](#) herein. Records shall be retained as specified in [A.4.8.1.2](#).

A.4.1.4 Government source inspection (GSI). Source inspection (GSI and contractor source inspection (CSI)) shall be required only when specified in the order or subcontract. Notification of test initiation shall be given to the acquiring activity.

A.4.1.5 Manufacturer control over its distributors. The manufacturer shall be responsible for assuring that its distributors maintain adequate controls to assure that products sold are of the same quality as products acquired directly from the manufacturer.

A.4.1.6 Distributor inventory, traceability and handling control. Distributors shall, as a minimum, maintain adequate inventory control system, traceability documentation required by this specification and their appropriate certification, adequate handling, storage, and repackaging methods to protect quality and prevent damage and degradation of products.

A.4.2 Solderability. All parts shall be capable of passing the solderability tests in accordance with TM 2003 of MIL-STD-883, on delivery.

A.4.3 General inspection conditions. The general requirements of MIL-STD-883 shall apply.

A.4.3.1 Classification of inspections and tests. The inspections and tests required to assure conformance to the specified quality assurance levels of microcircuits or lots thereof are classified as follows:

<u>Requirement</u>	<u>Paragraph</u>
Qualification procedures	A.4.4
Quality conformance inspection	A.4.5
Screening	A.4.6
Test results	A.4.7
Quality Assurance Program	A.4.8

MIL-PRF-38535J

APPENDIX A

A.4.3.2 Sampling. Statistical sampling for qualification and quality conformance inspections (QCI) shall be in accordance with the sampling procedures of [appendix D](#) of this specification, and as specified in the device specification or drawing, as applicable. Reserve sample devices may be tested with the subgroups to provide replacements in the case of test equipment failure or operator error (see [A.4.3.5](#) and [A.4.4.2.1.1](#)). These devices shall be used in predesignated order. Initial samples (and added samples, when applicable) shall be randomly selected from the inspection lot or subplot, as applicable. After a test has started, the manufacturer may add an additional quantity to the initial sample, but this may be done only once for any subgroup with a specified sample size number (accept number). Add-on samples are not allowed for fixed sample size subgroups or for resubmitted lots. The added samples shall be subjected to all the tests within the subgroup. The total samples (initial and added samples) shall determine the new acceptance number. The total defectives of the initial and second sample shall be additive and shall comply with the specified sample size number (accept number). The manufacturer shall retain sufficient microcircuits from the lot to provide for additional samples.

A.4.3.2.1 Disposal of samples. Devices subjected to destructive tests or which fail any test shall not be shipped on the contract or order as acceptable product. They may, however, be delivered at the request of the acquiring activity if they are isolated from, and clearly identified so as to prevent their being mistaken for acceptable product. Sample microcircuits, from lots which have passed quality assurance inspections or tests and which have been subjected to mechanical or environmental tests specified in groups B, C, and D inspection and not classified as destructive, may be shipped on the contract or order provided the test has been proved to be nondestructive (see [A.4.3.2.3](#)) and each of the microcircuits subsequently passes final electrical tests in accordance with the applicable device specification.

A.4.3.2.2 Destructive tests. The following MIL-STD-883 tests, or other test as specified, shall be classified as destructive:

- Internal visual and mechanical (TM 2014).
- Bond strength.
- Solderability (for lead finishes B and C).
- Moisture resistance.
- Lead integrity.
- Salt atmosphere.
- SEM inspection for metallization.
- Steady-state life test (accelerated).
- Die shear strength test.
- Total dose radiation hardness test.
- Neutron irradiation.
- Electrostatic discharge (ESD) sensitivity classification test.
- Lid torque test.
- Adhesion of lead finish.
- Vibration, variable frequency.
- Internal water vapor test.
- Single-event-effects (ASTM F1192 or JESD57)
- Dose-Rate Upset

All other mechanical or environmental tests (other than those listed in [A.4.3.2.3](#)), shall be considered destructive initially, but may subsequently be considered nondestructive upon accumulation of sufficient data to indicate that the test is nondestructive. The accumulation of data from five repetitions of the specified test on the same sample of product, without evidence of cumulative degradation or failure to pass the specified test requirements in any microcircuit in the sample, is considered sufficient evidence that the test is nondestructive. Any test specified as a 100 percent screen shall be considered nondestructive for the stress level and duration or number of cycles applied as a screen.

MIL-PRF-38535J

APPENDIX A

A.4.3.2.3 Nondestructive tests. The following tests are classified as nondestructive:

- Barometric pressure
- ** Steady-state life
- ** Intermittent life
- *** Solderability (for lead finish A only)
- Seal
- External visual
- Internal visual (pre-cap)
- ** Burn-in screen
- Radiography
- Particle impact noise detection (PIND)
- Physical dimensions
- Nondestructive 100 percent bond pull test where stress does not exceed the specified pull force and positive tolerance
- Resistance to solvents

** When the test temperature exceeds the maximum specified junction temperature for the device (including maximum specified for operation or test), these tests may be considered destructive. To ship these tested devices, the manufacturer shall have data to support that the test is not destructive and has not degraded the device.

*** For glass sealed devices, lead finish A shall be considered nondestructive unless electrical test, visual inspection, or other evaluation shows that package integrity or electrical performance has been degraded.

A.4.3.3 Formation of lots. Microcircuits shall be segregated into identifiable production lots as defined in [A.3.1.3.6](#) as required to meet the production control and inspection requirements of [A.4.8](#). Microcircuits shall be formed into inspection lots as defined in [A.3.1.3.7](#) and [A.3.1.3.8](#) as required to meet the quality assurance inspection and test requirements of this specification.

Wafer lot processing, as a homogeneous group (see [A.3.1.3.11](#)), shall be accomplished by any of the following procedures, providing process schedules and controls are sufficiently maintained to assure identical processing in accordance with process instructions of all wafers in the lot:

- a. Batch processing of all wafers in the wafer lot through the same machine process step(s) simultaneously.
- b. Continuous or sequential processing (wafer by wafer or batch portions of wafer lot) of all wafers through the same machine or process step(s).
- c. Parallel processing of portions of the wafer lot through multiple machines or process stations on the same certified line, provided statistical quality control assures and demonstrates correlation between stations and separately processed portions of the wafer lot.

MIL-PRF-38535J

APPENDIX A

A.4.3.3.1 Resubmission of failed lots. Resubmitted lots shall be kept separate from new lots and shall be clearly identified as resubmitted lots. When any lot submitted for qualification or quality conformance inspection fails any subgroup requirement of group B, C, or D (and E if applicable) tests, it may be resubmitted once for that particular subgroup using tightened inspection criteria (as defined in [D.4.2](#)). Resubmission for group A inspection failure is not permitted. In case of group B, subgroup B-2a failure, the entire lot may be remarked as defined in [A.3.6.13](#). The remarked lot shall not be acceptable for alternate group B (class level B only) coverage of a standard lot (see [A.4.5.8.2](#) for recovery). For fixed sample size subgroups, lots may be resubmitted one time only at double the sample size with zero failures allowed. All submissions shall be subject to the sampling requirements of [A.4.3.2](#). A second resubmission (class level S lots shall be resubmitted one time only) using a second tightened inspection criteria is permitted only if failure analysis is performed to determine the mechanism of failure for each failed microcircuit from the prior submissions and it is determined that failure(s) is (are) due to:

- a. A defect that can be effectively removed by rescreening or reworking the entire lot (see [A.3.7.1](#)).
- b. Random type defects which do not reflect poor basic device design or poor basic processing procedures.

In all instances where analysis of the failed devices indicates that the failure mechanism is due to poor basic processing procedures, a basic design fault or non-screenable defects, the lot shall not be resubmitted.

A.4.3.4 Test method deviation. Deviations from test methods or test circuits specified are allowed provided that it is demonstrated to the preparing activity that such deviations in no way relax the requirements of this appendix and that they are approved by the preparing activity before testing is performed. The preparing activity shall be notified by the device manufacturer of any proposed test method deviation. For proposed electrical test deviations, schematic wiring diagrams of the test equipment shall be made available for review.

A.4.3.5 Procedure in case of test equipment failure or operator error. Whenever a microcircuit is believed to have failed as a result of faulty test equipment or operator error, unless otherwise specified in the test method, the failure shall be entered in the test record which shall be retained for review along with a complete explanation verifying why the failure is believed to be invalid.

NOTE: ESD failures shall be counted as rejects and not be attributed to equipment/operator error for screening, group A, and end-point electrical tests of TM 5005 of MIL-STD-883.

A.4.3.5.1 Procedure for sample tests. When it has been established that a failure is due to test equipment failure or operator error and it has been established that the product has not been damaged or degraded, a replacement microcircuit from the same inspection lot may be added to the sample. The replacement microcircuit shall be subjected to all those tests to which the discarded microcircuit was subjected prior to its failure and to any remaining specified tests to which the discarded microcircuit was not subjected prior to its failure. The manufacturer, at their own risk, has the option of replacing the failed microcircuit and continuing with the tests before the validity of the test equipment failure or operator error has been established.

A.4.3.5.2 Procedure for screening tests. When it has been established that lot failure(s) during screening test(s) are due to operator or equipment error and it has been established that the remaining product has not been damaged or degraded, the lot or surviving portion of the lot, as the case may be, may be resubmitted to the corrected screening tests(s) in which the error occurred. Failures verified as having been caused by test equipment failure or operator error shall not be counted in the PDA calculation (when applicable).

A.4.3.5.3 Failure and corrective action reports. When the procedures of [A.4.3.5.1](#) and [A.4.3.5.2](#) are utilized in continuing sample tests or resubmitting lots for screening tests, the manufacturer shall document the results of their failure investigations and corrective actions and shall make this information available to the Government Quality Assurance Representative (QAR), the acquiring activity, or the qualifying activity, as applicable.

A.4.3.6 Electrical test equipment verification. The manufacturer shall verify the measurement/operation characteristics of the electrical test equipment in accordance with 4.5 of MIL-STD-883.

MIL-PRF-38535J

APPENDIX A

A.4.3.7 Manufacturer imposed tests. Any manufacturer imposed test(s) (i.e., gross and fine leak) which exceed the minimum class level B requirements herein shall be documented on the manufacturer's process baseline. If any manufacturer imposed test(s) detects a problem, the manufacturer shall submit all devices in the lot to those tests to eliminate rejects and shall take steps to determine and eliminate the cause of failure (e.g., rough handling which has produced gross leaks).

A.4.4 Qualification procedures.

A.4.4.1 General. The manufacturer shall perform sufficient qualification inspection to assure that the devices supplied to this appendix meet the minimum class level B or S performance requirements as defined herein. Qualification to a given quality assurance level qualifies the product for all lower quality assurance levels provided the product for all levels is manufactured on the same line and meets all the requirements of the lower level.

A.4.4.2 Qualification. A manufacturer should qualify individual devices by subjecting them to, or assuring that, they satisfy all the groups A, B, C, and D (and E if applicable) requirements of TM 5005 or TM 5010, as applicable of MIL-STD-883 for the specified device class and type of microcircuits. A.4.4.2.1 through A.4.4.2.7 herein should be used as guidelines.

A.4.4.2.1 Inspection routine. Except where the use of electrical rejects is allowed, all microcircuits subjected to groups B, C, and D (and E if applicable) tests should have previously been subjected to and passed all tests of group A inspection specified as end-point electrical parameters. The microcircuits should then be divided into the subgroups for groups B, C, and D (and E if applicable) inspection. When necessary to meet subsequent sample requirements, all failures found in the course of group A inspection should be replaced by microcircuits which have passed group A tests prior to subjection to group B, C, or D (and E if applicable) tests. All tests should be applied to and all acceptance criteria referenced to the entire lot or subplot as applicable, not to an arbitrary quantity of devices tested.

A.4.4.2.1.1 Sample. The number of microcircuits to be tested should be chosen (independent of lot size) by the manufacturer and should be adequate to demonstrate conformance to the inspection criteria for each subgroup of groups A, B, C, and D (and E if applicable) inspection. All qualification test samples for subgroups which require variables data should be serialized prior to qualification tests.

A.4.4.2.2 Group A electrical testing. The parameters, conditions of test, and limits for group A testing should be as specified in test method 5005 of MIL-STD-883 and the applicable device specification or drawing. Group A testing may be performed in any order. If an inspection lot is made up of a collection of splits or class level S inspection subplot, each split or class level S inspection subplot should pass group A inspection as specified.

A.4.4.2.3 Group B testing. Group B tests should be as specified in TM 5005 of MIL-STD-883.

A.4.4.2.4 Groups C and D testing. Groups C and D tests should be as specified in TM 5005 of MIL-STD-883.

A.4.4.2.5 Group E testing. Group E tests should be conducted as specified in TM 5005 of MIL-STD-883. Group E is required for initial qualification and after process or design changes that may affect radiation hardness (see A.3.4.2). Qualification for RHA should be for a specific microcircuit die and package type, except as authorized by the qualifying activity. Microcircuits which pass the quality assurance and RHA requirements to a higher reliability or RHA level should be acceptable to a lower level or as non-RHA parts if all other applicable requirements and pre- and post irradiation electrical parametric and timing limits are met.

MIL-PRF-38535J

APPENDIX A

A.4.4.2.6 Approval of other lead finishes. After qualification of one package type with a single lead finish, other lead finishes may be approved by submitting a single device type for each additional lead finish in the previously approved package family to group B, subgroup 3 and group D, subgroups 1, 3, 5, and 7 tests. Subgroup D-7 testing should not be required for hot solder dip over lead finishes B or C (tin-lead, gold plate) which have been qualified on the same package family.

A.4.4.2.7 Approval of other lead material. After the first lead material is qualified with a particular package family, the new lead material for the package family can be considered qualified provided the required lead finish tests specified (see A.4.4.2.6) with the addition of subgroup D-2, are successfully performed. Subgroup D-6 should be completed when the lead frame extends into the die cavity.

A.4.4.2.8 Electrostatic discharge (ESD) sensitivity. ESD classification testing shall be done in accordance with TM 3015 of MIL-STD-883 (The testing procedure defined within JESD22-A114 may be used as an alternate with acceptable correlation data.), and the applicable device specification or drawing (see A.3.6.9.2). Devices shall be handled in accordance with the manufacturer's in-house control documentation, which shall be maintained by the manufacturer. Guidance for device handling is available in JESD625.

A.4.5 Quality conformance inspection (QCI).

A.4.5.1 General. Quality conformance inspection shall be conducted in accordance with the applicable requirements of groups A, B, C, and D (and E if applicable) of TM 5005 (or TM 5010 when applicable), of MIL-STD-883, for the specified device class and TM 5007 of MIL-STD-883, when applicable. Inspection lot sampling shall be in accordance with [appendix D](#) of this specification. Test results shall be recorded by inspection lot identification code (see A.3.6.3) for each inspection lot.

A.4.5.2 Group A inspection. Group A inspection shall be performed on each inspection lot in accordance with MIL-STD-883 and shall consist of electrical parameter tests specified for the specified device class. If an inspection lot is made up of a collection of class level B splits or class level S inspection sublots, it shall be recombined into an inspection lot before the group A inspection sample is taken or a group A inspection sample shall be taken from each split or class level S inspection subplot.

A.4.5.3 Group B inspection. Group B inspection shall be performed in accordance with MIL-STD-883 on each inspection lot for each package type and lead finish. As an alternate, except for class level S (at the manufacturer's option) group B inspection may be performed on each package type and lead finish in accordance with 3.5.2 of TM 5005 or 3.4.2.1 of TM 5010 of MIL-STD-883. For class level S, group B, subgroups 1A, 2, 3, and 4 inspections shall be performed on each subplot (split) when the manufacturer elects to keep the sublots (splits) separate from each other after screen tests are completed. Except as otherwise specified in TM 5005 of MIL-STD-883, samples for this inspection shall be completed and fully marked devices from lots which have been subjected to and passed the post burn-in +25°C final electrical static tests (subgroup 1). Class level S steady-state life test, subgroup B-5, results shall not be used to support class level B shipments.

A.4.5.4 Group C inspection for class level B only. Group C inspection (die-related tests) shall be in accordance with MIL-STD-883 and shall include those tests specified which are performed periodically. Group C shall have been completed on product with a die fabrication date code within four calendar quarters prior to the die fabrication date code of product being submitted for acceptance. Group C tests are required for devices from each microcircuit group (see A.3.1.3.13) in which a manufacturer is supplying product. Group C tests for each microcircuit group shall be performed on one inspection lot of the most complex device type available at the time of selection from production devices produced on each certified die fabrication line once per calendar year.

MIL-PRF-38535J

APPENDIX A

A.4.5.4.1 Group C sample selection. Samples selected for group C inspection shall meet all of the following requirements:

- a. Shall be chosen at random from any inspection lot comprised only of die from the quarter of the year (see [A.3.6.3.1](#)) for which quality conformance inspection is being established in a particular microcircuit group (see [A.3.1.3.13](#) and tables [A-VI](#), [A-VII](#), [A-VIII](#), and [A-IX](#)) for each certified die fabrication line.
- b. Shall be chosen from an inspection lot that has been submitted to and passed group A quality conformance inspection (QCI) (regardless of whether that inspection lot has been submitted and passed group B QCI).
- c. The inspection lot from which the samples are selected shall be the one with the most complex device type available at the time of selection.
- d. On multichip microcircuits, the group C die fabrication date code requirement shall be determined by considering only the latest date code of the most complex die contained within the package.

A.4.5.4.1.1 Microcircuit group assignments. Microcircuits group assignments and technologies/die family assignments shall be as specified in tables [A-VI](#), [A-VII](#), [A-VIII](#), [A-IX](#), and [A.3.1.3.13](#). Microcircuit groups shall be structured such that they appropriately group all of the devices produced by the manufacturer, including those that do not coincide with any of the current microcircuit groups listed. In the tables, each number represents a different microcircuit group. Each letter in the top row of the table represents a different technology group. Each table entry in the line below the technologies (e.g., Standard TTL, Schottky TTL, CMOS, etc.) represent a separate die family (e.g., 93, 93H, LS, etc).

A.4.5.4.1.2 Product acceptable for delivery. Product shall be acceptable for delivery only after the successful completion of all group C testing and shall be comprised of die meeting the following requirements:

- a. Manufactured on the same die fabrication line as the sample selected for [A.4.5.4.1](#).
- b. In the same microcircuit grouping as the sample selected in [A.4.5.4.1](#).
- c. Which was started (or completed, at the manufacturer's pre-designated option) within the same year the sample selected in [A.4.5.4.1](#).
- d. Group C coverage is required for each year of material production on each microcircuit group.

NOTE: The above group C inspection and corresponding marking system shall be implemented on all devices with an inspection lot date code (seal week) of 8840 and later for JAN product and 8939 and later for non-JAN product. Inspection lots formed using die fabricated prior to 1988 for JAN product and prior to 1989 for non-JAN product shall be grandfathered according to the previous group C QCI requirements and marked with "GF" for the die fab symbolization (see [A.3.6.3.1](#)).

A.4.5.5 Group D inspection. Group D inspection (package related tests) shall be in accordance with test method 5005 of MIL-STD-883 and shall include those package or case related tests which are performed periodically. Group D tests shall be performed every 26 calendar weeks on each package family for each assembly line (traceable to the inspection lot identification code of the week tested). If no production is performed for an extended period of time, coverage can be reestablished on the next available production run for the package family in need of coverage. Group D results can be used to support any class provided all of the group D sampling criteria are met. Each additional lead finish for each package family shall be subjected to subgroups 3, 5, and 7 of group D. Subgroup D-7 testing is not required for hot solder dip over lead finishes B or C (tin-lead, gold plate) which have been periodically tested for quality conformance inspection on the same package family. For hot solder dipped leadless chip carriers, the B3 and L3 dimensions may be measured prior to solder dip. In addition, laser marked devices for each package family, which do not have group D coverage for laser marking, shall be subjected to subgroups 3 and 5 of group D.

MIL-PRF-38535J

APPENDIX A

A.4.5.5.1 Group D sample selection. Sample selection for group D shall be as follows:

- a. The package types selected for group D inspection shall be either rotated among the package types available at the time of sample selection from the allotted package family or worst case available from the allotted package family. Worst case shall be determined by the manufacturer based on an incoming vendor material control program (see [A.4.5.5.2](#)). For glass-sealed packages (e.g., cerdips, cerpacks), worst case is based on the minimum seal area and the maximum cavity size (in most cases this shall be two packages). Under the rotation option, if a package type has not been tested for 3 years, then the next assembled lot of that package type shall receive group D inspection. If the manufacturer has a single package, which cannot be grouped into a package family, the manufacturer has the option to perform the group D testing once per calendar year on that package.
- b. The product accepted for delivery shall be the inspection lot identification codes of the 36 successive weeks, except as allowed in [A.4.5.5.1a](#), beginning with the inspection lot identification code of the successful group D sample for the package family.
- c. Different device types may be used for different subgroups. Testing of a subgroup using a single device type enclosed in the intended package type shall be considered as complying with the requirements for that subgroup for all the device specifications or drawings utilizing the qualified package family and lead finish.
- d. Technical justification shall be given for device selections for subgroups D-3 and D-4 in regards to device technology electrical performance and package interaction. If a package and technology interaction is present, subgroup D-3 and D-4 shall be performed on the affected combination separately or used as coverage for the whole package family. Rotation of device technology is allowed to address this requirement. For nonconformance see [A.4.5.8](#).

A.4.5.5.2 Incoming vendor material control program. The manufacturer who utilizes the worst case group D option shall have in place an incoming vendor material control program for the piece parts used in packaging (e.g., vendor SPC program). The methods and procedures used to control inspection, storage, and handling of incoming materials shall be documented.

A.4.5.6 Group E inspection. Group E inspection shall be in accordance with test method 5005 of MIL-STD-883 and, at the contractor's option, is allowed anytime following completion of wafer fabrication. A device type which fails group E inspection may not be certified as an RHA microcircuit at the failed or higher level, but may be used as a non-RHA microcircuit or certified at another (lower) level if the microcircuit meets the lower level requirements and all other applicable requirements including pre- and post-irradiation electrical and timing parametric limits.

A.4.5.6.1 Group E sample selection. Sample selection shall be in accordance with test method 5005 of MIL-STD-883 and shall be from each wafer prior to assembly or from each inspection or wafer lot. QCI requirements for class level B wafer lots shall be satisfied if all wafers used in that lot have been tested individually in accordance with class level S requirements. For traceability, see [A.3.4.6](#).

A.4.5.7 End-point tests for groups B, C, and D (and E if applicable) inspections. End-point measurements and other specified post-test measurements shall be made for each microcircuit of the sample after completion of all other specified tests in the subgroup. The test limits for the end-point measurements shall be the same as the test limits for the respective group A subgroup inspections. Different end-points may be specified for group E tests in the device specification or drawing. Any additional end-point electrical measurements that may be performed at the discretion of the manufacturer, shall be accomplished in accordance with [A.3.4.3](#) (i.e., tests performed on sample devices subjected to groups B, C, and D (and E if applicable) tests shall be performed as a 100-percent screen on all production devices represented by the sample) and shall be documented on the test travelers.

MIL-PRF-38535J

APPENDIX A

A.4.5.8 Nonconformance. Lots that fail subgroup requirements of groups B, C, and D (and E if applicable) may be resubmitted in accordance with the provisions of A.4.3.3.1. A failed lot that is reworked (see A.3.7.1) or is rescreened (resubmittal to inadvertently missed process steps is not considered a rescreen) may not be resubmitted to the failed subgroups (and shall be counted as a failure) for periodic group B, C, or D (or E if applicable) quality conformance inspection (QCI) coverage. The lot may be resubmitted only to the failed subgroup to determine its own acceptance. If a lot is not resubmitted or fails the resubmission, the lot shall not be shipped, and all references to MIL-PRF-38535, or this appendix, shall be removed. For RHA microcircuits where group E tests are performed, and a sample plan of 18(1) and 38(1) is utilized for two successive lots of the same device type or for more than 10 percent of the lots during the preceding 18 months, data as specified herein shall be provided. Resubmission for RHA qualification inspection, in this case, may be required. Lots that are not resubmitted, fail the resubmission, are withdrawn from compliance consideration, reworked, or rescreened (excluding resubmittal to final electricals when test conditions or limits are not changed) due to the failure of a PDA or QCI requirement of this appendix shall be recorded and properly dispositioned. The reporting of these lots shall include the following, as applicable:

- a. PIN.
- b. Inspection lot identification code.
- c. Quantity of lot.
- d. Point of scrap in manufacturer's flow.
- e. Test results and date of failure (including all rescreening, reworks, and resubmissions).
- f. Reason for failure or scrapping including applicable test results.
- g. Date of scrapping or withdrawal from military consideration.
- h. Disposition action of affected lots.

NOTE: The Government reserves the right to request and receive information concerning implementation of corrective actions and justification for rework and rescreening.

A.4.5.8.1 Group B failure. When a lot failure occurs for a group B subgroup, then all other sublots within the inspection lots shall be submitted to the failed subgroup.

A.4.5.8.2 Alternate group B failure. When a failure has occurred in group B using the alternate group B procedure, samples from three additional inspection lots of the same package type, lead finish and week of seal as the failed package shall be tested to the failed subgroups. If all three inspection lots pass, then all devices manufactured on the same assembly line using the same package type and lead finish and sealed in the same week may be accepted for group B inspection. If one or more of the three additional inspection lots fails, then no inspection lot containing devices manufactured on the same assembly line using the same package type and lead finish sealed in the same week shall be accepted for group B inspection until each inspection lot has been subjected to and passed the failed subgroups.

MIL-PRF-38535J

APPENDIX A

A.4.5.8.3 Group C failure. When a group C failure occurs, samples from subsequent wafer lots submitted for acceptance in the same microcircuit group (see [A.3.1.3.13](#)), produced on the same die fabrication line, and started (or completed at the manufacturer's option) die fabrication during the same year shall be subjected to group C. The testing shall be performed on a wafer-lot-by-wafer-lot basis until three consecutively tested wafer lots from the same microcircuit group and year of fabrication pass group C; the testing may then return to periodic testing. A device type that fails a group C inspection shall not be accepted until the device type that failed successfully completes group C. In addition, any other inspection lots using die from the same failed wafer lot shall successfully complete group C prior to shipment until three successive inspection lots from the same wafer lot have passed group C using a tightened sample size number (accept number) with $C = 0$. In the event of a group C failure, the manufacturer shall evaluate the possible impact on product that has been manufactured since the last acceptable group C test (based on wafer fab code), from the failed microcircuit group.

A.4.5.8.4 Group D failure. When a failure occurs for a group D subgroup(s), samples from subsequent lots submitted for acceptance of the same package family and lead finish shall be subjected to all the tests in the failed subgroup(s). The testing shall be performed on a lot-by-lot basis until three successive lots of the same package family pass the failed subgroup(s). Testing of the package family may then return to periodic testing. The package type that failed the group D subgroup(s) shall be tested on a lot-by-lot basis until three successive lots pass the failed subgroup(s) at which time it may return to periodic inspection coverage. Under the worst case conditions option, when a glass sealed package fails, every package type in the package family shall pass the failed group D subgroup, prior to shipping the device. Failed package types shall be tested on a lot-by-lot basis until three successive lots of the same package type pass the failed subgroup(s) at which time it may return to periodic inspection. In the event of a group D failure, the manufacturer shall evaluate the possible impact on product that has been manufactured since the last acceptable group D (based on seal or encapsulation date code), for the failed package family.

A.4.6 Screening. Each microcircuit shall have been subjected to and passed all the screening tests detailed in TM 5004 or TM 5010, as applicable, of MIL-STD-883 for the specified quality assurance level and type of microcircuit in order to be acceptable for delivery. When a PDA (see [A.3.1.3.14](#) and TM 5004 or TM 5010 of MIL-STD-883) or delta limits (see [A.3.1.3.15](#)) has been specified or other conditions for lot acceptance have been imposed, the required data shall be recorded and maintained as a basis for lot acceptance. Devices that fail any test criteria in the screening sequence shall be removed from the lot at the time of observation or immediately at the conclusion of the test in which the failure was observed. Once rejected and verified as a device failure, no device may be retested for acceptance.

A.4.6.1 Burn-in. Burn-in shall be performed on all microcircuits where specified and the specified pre- and post-burn-in electrical parameters shall be measured.

A.4.6.1.1 Lots and sublots resubmitted for burn-in. Inspection lots, lot splits, and class level S sublots may be resubmitted for burn-in one time only and may be resubmitted only when the observed percent defective does not exceed twice the specified PDA (10 percent) or 2 devices, whichever is greater. Any lot that exceeds the allowable resubmission PDA, (greater than 10%, but less than 20%), the manufacturer may resubmit the lot provided analysis is performed to a level sufficient to determine the mechanism of failure for the lot with TRB approval and written notification (letter or email) to the Qualifying Activity prior to shipment. The lot may be resubmitted using tightened inspection criteria. Resubmitted inspection lots, lot-splits, and class level S sublots shall contain only parts which were in the original lot or subplot. Resubmitted inspection lots, lot splits, and class level S sublots shall be kept separate from new lots and sublots and shall be inspected for all specified characteristics using a tightened inspection PDA equal to the next lower number in the sample size series (see [appendix D](#)), or one device, whichever is greater.

MIL-PRF-38535J

APPENDIX A

A.4.6.1.2 Burn-in acceptance criteria. The PDA for each inspection lot or class level S subplot submitted to burn-in and interim (post burn-in) electrical parameters (see test method 5004 of MIL-STD-883) shall be 5 percent (or one device, whichever is greater) on all failures. In addition, for class level S, the PDA shall be 3 percent (or one device, whichever is greater) on functional failures. A manufacturer may elect to divide inspection lots into splits for burn-in and interim electrical parameter measurement and calculate a PDA for each split, or the manufacturer may elect to add all failures from the constituent splits together to calculate a PDA for the original inspection lot. If a PDA is calculated for each split, it shall be used as accept/reject criteria for that split only and shall not be combined with the PDA from any other lot or split for any reason related to lot or split acceptance. If a PDA is calculated for an inspection lot by adding the failures found in the various constituent splits, this PDA shall be used as accept/reject criteria for the entire lot and shall, in no way, be used as accept/reject criteria for any grouping of devices other than the entire lot. Delta limits shall be defined in the device specification or drawing. When the PDA applies to delta limits, the delta parameter values measured after burn-in (100 percent screening test) shall be compared with the delta parameter values measured prior to that burn-in. Lots may only be resubmitted when the observed percent defective does not exceed twice the specified PDA (10 percent) or 2 devices, whichever is greater. Any lot that exceeds the allowable resubmission PDA, (greater than 10%, but less than 20%), the manufacturer may resubmit the lot provided analysis is performed to a level sufficient to determine the mechanism of failure for the lot with TRB approval and written notification (letter or email) to the Qualifying Activity prior to shipment. The lot may be resubmitted using tightened inspection criteria. The delta criteria applying to such resubmissions shall be in accordance with the following procedure:

- a. Devices having delta drift values in excess of the device specification or drawing limits shall be rejected.
- b. The remaining devices shall then be submitted to the balance of inspections and tests as specified herein.

A.4.6.1.2.1 Failure analysis of burn-in screen failures for class level S devices. Catastrophic failures (i.e., shorts or opens measurable or detectable at +25°C) subsequent to burn-in shall be analyzed. Analysis of catastrophic failures may be limited to a quantity and degree sufficient to establish failure mode and cause and the results shall be documented and made available to the Government representative.

A.4.6.2 External visual screen. The final external visual screen shall be conducted in accordance with TM 2009 of MIL-STD-883 after all other 100 percent screens have been performed to determine that no damage to, or contamination of, the package exterior has occurred.

A.4.6.3 Particle impact noise detection (PIND) test for class level S devices. The inspection lot (or sublots) shall be submitted to 100 percent PIND testing a maximum of five times in accordance with test method 2020 of MIL-STD-883, condition A. PIND prescreening shall not be performed. The lot may be accepted on any of the five runs if the percentage of defective devices is less than 1 percent (zero failures allowed for lots of less than 100 devices). All defective devices shall be removed after each run. Lots that do not meet the 1 percent PDA on the fifth run, or exceed 25 percent defectives cumulative, shall be rejected and resubmission is not allowed.

A.4.6.4 Lead forming. When lead forming (bending) is specified for any device class, a sample fine and gross seal test shall be performed in accordance with test method 5004 of MIL-STD-883 after the lead forming operations and prior to final visual inspection of these devices, and devices which fail any test shall be removed from the lot.

A.4.6.5 Nondestructive bond pull test for class level S devices. Nondestructive 100 percent bond pull test shall be performed for class level S devices. The total number of failed wires and the total number of devices failed shall be recorded. The lot shall have a PDA of 2 percent or less based on the number of wires pulled in specified lot. The test shall be performed in accordance with test method 2023 of MIL-STD-883. Devices from lots that have been subjected to the nondestructive 100 percent bond pull test and have failed the specified class level S, PDA requirement shall not be delivered as class level B product.

MIL-PRF-38535J

APPENDIX A

A.4.7 Test results. The results of all qualification and quality conformance tests and inspections and the results of all required failure analysis shall be recorded and maintained in the manufacturer's facility in accordance with [A.4.8](#). The Quality Assurance Program Plan, qualification test reports, summary of QCI data, and any other data reports required by the applicable acquisition document shall be maintained by the manufacturer (or submitted to the acquiring activity when specified in the purchase agreement). The disposition of all lots or samples submitted for wafer lot acceptance, screening (when PDA is specified), quality conformance inspection or qualification shall be fully documented and lots which fail any specified requirement shall be recorded as failed lots whether resubmitted or withdrawn. Disposition of resubmitted lots shall likewise be recorded so that a complete history is available for every lot tested from initial submission to final disposition including all failures, resubmissions, and withdrawals.

A.4.7.1 Screening test data for class level S microcircuits. When specified in the acquisition document, a copy of the attributes test data, a copy of the variables data, and the delta calculations resulting from the applicable delta parameter tests before and after each burn-in, and a copy of the X-rays required by the device specification or drawing shall accompany each lot of class level S microcircuits shipped. The manufacturer shall maintain one complete copy of all screening data for 5 years after delivery of the parts. This data shall be legible and shall be correlatable to the applicable PIN, the lot date code, and the individual serial number. The data shall be verified by the manufacturer's quality assurance organization and shall bear evidence of such verification.

A.4.8 Quality assurance program.

A.4.8.1 Manufacturer certification. The manufacturer shall establish, implement, and maintain a quality assurance program in accordance with [A.4.8](#) through [A.4.9.3.8](#) (summarized in [table A-X](#)) in order to be a manufacturer of class level B microcircuits. The manufacturer's quality assurance program shall demonstrate and assure that design, manufacture, inspection and testing of microcircuits are adequate to assure compliance with the applicable requirements and quality standards of this specification. Where the manufacture or any portion of the manufacturing and testing operation is other than the manufacturer's facility, it shall be the responsibility of the manufacturer to secure and prove the documentation and control of the quality assurance program as described herein. The program shall be documented as follows:

- a. Design, processing, manufacturing, and testing instructions ([A.4.8.1.1](#)).
- b. Records to be maintained ([A.4.8.1.2](#)).
- c. Quality assurance program plan ([A.4.8.1.3](#)).

All required documentation shall be available at, and continually effective in, the manufacturer's plant while it is producing microcircuits which are intended to be offered for qualification and quality conformance inspections under this specification. All required program documentation and records shall be available for review by acquiring activity upon request. The acquiring activity shall have access to nonproprietary areas of the manufacturer's plant for the purpose of verifying its implementation, and the Government shall have access to all areas of the manufacturer's plant for the purpose of verifying its implementation.

Personnel performing quality functions shall have sufficient well defined responsibility, authority, and the organizational freedom to identify and evaluate quality problems and to initiate, recommend, and provide solutions.

MIL-PRF-38535J

APPENDIX A

A.4.8.1.1 Design, processing, manufacturing, and testing instructions. The manufacturer shall have in effect documented instructions covering, as a minimum, these areas:

- a. Conversion of customer requirements into manufacturer's internal instructions (see [A.4.8.1.1.1](#)).
- b. Personnel training and testing (see [A.4.8.1.1.2](#)).
- c. Inspection of incoming materials, utilities, and work in-process (see [A.4.8.1.1.3](#)).
- d. Quality-control operations (see [A.4.8.1.1.4](#)).
- e. Quality-assurance operations (see [A.4.8.1.1.5](#)).
- f. Design, processing, manufacturing equipment, and materials instructions (see [A.4.8.1.1.6](#)).
- g. Cleanliness and atmosphere control in work areas (see [A.4.8.1.1.7](#)).
- h. Design, material, and process change control (see [A.4.8.1.1.8](#)).
- i. Tool, gauge, and test equipment maintenance and calibration (see [A.4.8.1.1.9](#)).
- j. Failure and defect analysis and feedback (see [A.4.8.1.1.10](#)).
- k. Corrective action and evaluation (see [A.4.8.1.1.11](#)).
- l. Incoming, in-process, and outgoing inventory control (see [A.4.8.1.1.12](#)).
- m. Schematics (see [A.4.8.1.1.13](#)).
- n. ESD handling control program (see [A.4.8.1.1.14](#)).

Detailed requirements for coverage of these items are stated in [A.4.8.1.1.1](#) through [A.4.8.1.1.14](#). These requirements shall normally be expected to be met by the manufacturer's standard drawings, specifications, process instructions, and other established manufacturing practices. If particular requirements are not covered by the manufacturer's established practices, suitable documentation shall be added to satisfy those requirements.

A.4.8.1.1.1 Conversion of customer requirements into manufacturer's internal instructions. The procedure by which customer requirements, as expressed in specifications, orders, etc., are converted into working instructions for the manufacturer's personnel shall be documented.

A.4.8.1.1.2 Personnel training and testing. The motivational and work training and testing practices employed to establish, evaluate, and maintain the skills of personnel engaged in reliability-critical work shall be documented as to form, content, and frequency of use.

A.4.8.1.1.3 Inspection of incoming materials and utilities, and of work in-process. Inspection operations shall be documented as to type of inspection, sampling and test procedures, acceptance-rejection criteria, and frequency of use.

A.4.8.1.1.4 Quality-control operations. Quality-control operations shall be documented as to type, procedures, rating criteria, action criteria, records, and frequency of use.

A.4.8.1.1.5 Quality-assurance operations. Quality-assurance operations shall be documented as to type, procedures, equipment, judgment and action criteria, records, and frequency of use.

MIL-PRF-38535J

APPENDIX A

TABLE A-X. Quality assurance program requirements.

In-house documentation covering these areas (see A.4.8.1.1)	In-house records covering these areas (see A.4.8.1.2)	A program plan covering these areas (see A.4.8.1.3)	Self-audit plan covering these areas (see A.4.9)
a. Conversion of customer requirements into manufacturer's internal instructions (see A.4.8.1.1.1) b. Personnel training and testing (see A.4.8.1.1.2) c. Inspection of incoming materials and utilities and of work in-process (see A.4.8.1.1.3) d. Quality-control operations (see A.4.8.1.1.4) e. Quality assurance operations (see A.4.8.1.1.5) f. Design, processing, manufacturing equipment, and materials instructions (see A.4.8.1.1.6) g. Cleanliness and atmosphere control in work areas (see A.4.8.1.1.7) h. Design, material, and process change control (see A.4.8.1.1.8) i. Tool, gauge, and test equipment maintenance, and calibration (see A.4.8.1.1.9) j. Failure and defect analysis and feedback (see A.4.8.1.1.10) k. Corrective action and evaluation (see A.4.8.1.1.11) l. Incoming, in-process, and out-going inventory control (see A.4.8.1.1.12) m. Schematics (see A.4.8.1.1.13) n. ESD handling control program (see A.4.8.1.1.14)	a. Personnel training and testing (see A.4.8.1.2.1) b. Inspection operations (see A.4.8.1.2.2) c. Failure and defect reports analysis (see A.4.8.1.2.3) d. Initial documentation and subsequent changes in design, materials, or processing (see A.4.8.1.2.4) e. Equipment calibrations (see A.4.8.1.2.5) f. Process utility and material controls (see A.4.8.1.2.6) g. Product lot identification (see A.4.8.1.2.7) h. Product traceability (see A.4.8.1.2.8) i. Self-audit report (see A.4.9.3.6)	a. Functional block organization chart (see A.4.8.1.3.1) b. Examples of manufacturing flowchart (see A.4.8.1.3.2) c. Proprietary documents identification (see A.4.8.1.3.3) d. Examples of design, material, equipment, visual standard, and process instructions (see A.4.8.1.3.4) e. Examples of records (see A.4.8.1.3.5) f. Examples of design, material, and process change control documents (see A.4.8.1.1.8 and as required in A.3.4.2) g. Examples of failure and defect analysis and feedback documents (see A.4.8.1.1.10) h. Examples of corrective actions and evaluations documents (see A.4.8.1.1.11) i. Manufacturer's internal instructions for internal visual inspection (see A.4.8.1.3.6) j. Examples of test travelers (see A.4.8.1.3.7) k. Examples of design and construction baselines (see A.4.8.1.3.8) l. Manufacturer's self-audit (see A.4.9.1)	a. Self-audit program (see A.4.9.3.1) b. Self-audit representatives (see A.4.9.3.2) c. Audit deficiencies (see A.4.9.3.3) d. Audit follow-up (see A.4.9.3.4) e. Audit schedules and intervals (see A.4.9.3.5) f. Self-audit report (see A.4.9.3.6) g. Self-audit areas (see A.4.9.3.7) h. Self-audit checklist (see A.4.9.3.8)

MIL-PRF-38535J

APPENDIX A

A.4.8.1.1.6 Design, processing, manufacturing equipment, and materials instructions. Device design, processing, manufacturing equipment and materials shall be documented in drawings, standards, specifications, or other appropriate media which shall cover the requirements and tolerances for all aspects of design and manufacture including equipment test and prove-in, materials acquisition and handling, design-verification testing and processing steps. As a minimum requirement, detailed documentation shall exist for the following items and shall be adequate to assure that quantitative controls are exercised, that tolerances or limits of control (limits shall be established for baselined and other critical wafer fabrication process monitors used for acceptance of class levels B and S product) are sufficiently tight to assure a reproducible high quality product and that process and inspection records reflect the results actually achieved:

- a. Incoming materials control (wafers, substrates, packages, active and passive chips or elements for hybrid or multichip microcircuits, wire, water purification, etc.).
- b. Masking, photoresist, and mask registration.
- c. Epitaxy and diffusion.
- d. Oxidation and passivation.
- e. Metallization and film deposition.
- f. Die, element, and substrate attachment.
- g. Bonding.
- h. Rework.
- i. Sealing.

A.4.8.1.1.7 Cleanliness and atmosphere control in work areas. The requirements for cleanliness and atmosphere control in each work area in which unsealed devices, or parts thereof, are processed or assembled shall be documented. During manufacture, transit, and storage, prior to seal, microcircuit die/wafers shall be protected from human contamination, machine overspray, or other sources of contamination which may occur due to human error or machine design which does not totally eliminate the possibility of overspray or other forms of contamination. Airborne particulate class limits shall be as defined by ISO 14644-1. A method for class verification and reverification shall be documented and implemented. ISO 14644-2 may be used as a guideline. The manufacturer shall establish action and absolute control limits (at which point work stops until corrective action is completed) based on historical data and criticality of the process in each particular area. For foreign material identification and control, see internal visual inspection requirements test method TM 2010 of MIL-STD-883.

A.4.8.1.1.8 Design, material, and process change control. The methods and procedures for implementation and control of changes in device design, material and processing, and for making change information available to the acquiring activity, when applicable, shall be documented.

A.4.8.1.1.9 Tool, gauge, and test equipment maintenance and calibration. The maintenance and calibration procedures, and the frequency of scheduled actions, for tools, gauges, manufacturing and test equipment shall be documented and in accordance with in-house requirements. ANSI/NCSS Z540.3 or equivalent should be used as a guideline. Failure to perform scheduled maintenance, repair and recalibration requirements critical to a process (as defined by the manufacturer) shall require corrective action.

MIL-PRF-38535J

APPENDIX A

A.4.8.1.1.10 Failure and defect analysis and feedback. The procedures for identification, handling, and analysis of failed or defective devices and for dissemination of analysis data shall be documented, including the procedure for informing the qualifying activity of analysis results, when applicable.

A.4.8.1.1.11 Corrective action and evaluation. The procedure and responsibility for decisions regarding the necessity for corrective action as a result of failure or defect analysis, and for evaluation and approval of proposed corrective actions, shall be documented. If the procedure for evaluation and approval of changes proposed for other reasons, such as cost reduction or product improvement, differs from the above, it shall also be documented.

A.4.8.1.1.12 Incoming, in-process, and outgoing inventory control. The methods and procedures shall be documented which are used to control storage and handling of incoming materials, work in-process, and warehoused and outgoing product in order to (a) achieve such factors as age control of limited-life materials; and (b) prevent inadvertent mixing of conforming and nonconforming materials, work, or finished product. Tests and inspections performed by the manufacturers on acquired materials and supplies shall include verification of chemical, physical, and functional characteristics required by manufacturer drawings and specifications. Procedures shall be prepared and maintained for controlling the receipt of acquired materials and supplies. The procedures shall provide the following:

- a. Withholding received materials or supplies from use pending completion of the required inspection or tests, or the receipt of necessary reports.
- b. Segregation and identification of nonconforming materials and supplies from conforming materials and supplies and removal of nonconforming subassemblies and parts.
- c. Identification and control of limited-life materials and supplies.
- d. Identification and control of raw materials.
- e. Assurance that the required test reports, certification, etc., have been received.
- f. Clear identification of materials released from receiving inspection and test to clearly indicate acceptance or rejection status of material pending review action.

A.4.8.1.1.13 Schematics. Schematics pertaining to the testing of microcircuits shall be under document control. This includes device schematics or burn-in schematics in accordance with the applicable device specification or drawing.

A.4.8.1.1.14 ESD handling control program. The ESD handling control program documentation shall be under document control. This includes methods, equipment and materials, training, packaging, handling, and procedures for handling ESD sensitive devices.

A.4.8.1.2 Records to be maintained. The records required by this section shall be continuously maintained during the manufacture of microcircuits that are intended to be submitted for quality conformance inspection under this specification. The records pertaining to production processes, incoming and in-process inspections shall be retained as detailed in A.4.8.1.2.b. Those pertaining to screening and quality conformance inspection shall be retained for a minimum of 5 years after performance of the inspections. Records shall be maintained as a minimum for:

- a. Personnel training and testing (see A.4.8.1.2.1) (1-year active file retention; 5-year total record retention).
- b. Inspection operations (see A.4.8.1.2.2) (1-year record retention for production processes, incoming and in-process; 5-year record retention for screening, qualification, and quality conformance inspection).
- c. Failure and defect reports and analyses (see A.4.8.1.2.3) (5-year record retention).

MIL-PRF-38535J

APPENDIX A

- d. Initial documentation and subsequent changes in design, materials, or processing (see [A.4.8.1.2.4](#)) (5-year record retention).
- e. Equipment calibrations (see [A.4.8.1.2.5](#)) (see ANSI/NCCL Z540.3 for records).
- f. Process, utility, and material controls (see [A.4.8.1.2.6](#)) (1-year record retention).
- g. Product lot identification (see [A.4.8.1.2.7](#)) (5-year record retention).
- h. Product traceability (see [A.4.8.1.2.8](#)) (5-year record retention).
- i. Self-audit report (see [A.4.9.3.6](#)) (4-year retention).

Altered records shall not be considered acceptable data unless documented instructions are followed which shall include:

- j. For changed data:
 - (1) Identification of individual making new entry.
 - (2) Maintain identity of all original data entries (white out is not permitted).
 - (3) Justification and date noted for change and verification by a second party (QA shall verify screening, qualification and quality conformance inspection records) when change affects lot jeopardy (i.e., lot originally considered to be rejected is changed to pass status).
- k. For transferred data to new test record:
 - (1) Identification of individual transferring data.
 - (2) All original record entries shall be transferred.
 - (3) New test record entries shall be verified against the original test record by a second party.
- l. Computerized records are optional provided they clearly and objectively indicate that all the requirements, of the specified device class, of this appendix have been met. The computerized records for traceability, screening and quality control inspection shall be readily accessible and available to Government personnel for review and an appropriate electronic/hard copy provided when required. The requirements below shall be met.
 - (1) Entry verification:
 - (a) Each individual making shall be uniquely identified.
 - (b) All manually entered data shall be verified at the time of entry by the same operator.
 - (c) All accepted transactions (i.e., entered data) shall be identified by time/date or date/entry sequence to protect against "out of sequence" entries. No recorded transactions shall be deleted or changed.

MIL-PRF-38535J

APPENDIX A

- (2) Control procedures for lot history records:
 - (a) Lot histories may be modified only by additions (i.e., original entries plus corrective addenda).
 - (b) All corrective addenda shall meet all the requirements of [A.4.8.1.2 i.](#)
 - (c) Only limited designated operators shall be able to access lot history computer records for corrective addenda. Documented security procedures shall be followed to assure that limited access is maintained (e.g., restricted terminals, passwords, etc.).
 - (d) A quality assurance representative shall verify screening, qualification, and quality conformance inspection records when corrective addenda affect lot jeopardy.
- (3) Control of computerized lot history records:
 - (a) All computer lot history records shall have an accurate tape or equivalent backup generated prior to lot shipment. Within 3 months of lot shipment, the backup record shall be transferred to a secure location to be archived.
 - (b) These archived tapes or equivalent media shall be kept for a minimum of 5 years.

A.4.8.1.2.1 Personnel training and testing. Records shall cover the nature of training or testing given, the date thereof by week and length in hours, and the group(s) of personnel given work training and testing. Records are required only for product-related training and testing as distinguished from safety, first aid, etc.

A.4.8.1.2.1.1 Training of operators and inspectors. All critical processes and production inspection shall be performed by personnel who have been trained by the manufacturer to perform their assignment task in accordance with manufacturer's in-house standards, including a formal training (e.g., classroom or on the job training supervised by a certified trainer) and test procedure to assure the proficiency of each individual. Each individual shall be retested or retrained at the end of a designated period or when personnel performance indicates poor proficiency. Personnel shall not be used in critical processes or inspections until the required level of proficiency has been demonstrated.

A.4.8.1.2.2 Inspection operations. Records of inspection operations shall cover the tests or inspections made, the materials group (lot, batch, etc.) inspected, the controlling documentation, the date of completion of inspection, the amount of material tested, and acceptance, rejection, or other final disposition of the material.

A.4.8.1.2.3 Failure and defect reports and analyses. Records of failed or defective devices shall cover the source from which each device was received, the test or operation during which failure occurred or defects were observed, and prior testing or screening history of the device, the date of receipt, and the disposition of the device. Records of failure and defect analyses shall cover the nature of the reported failure or defect (failure or defect mode), verification of the failure or defect, the nature of any device discrepancies which were found during analysis (failure or defect mechanism), assignment of the failure-activating cause if possible, the date of completion of the analysis, identification of the group performing the analysis, disposition of the device after analysis, and the distribution of the record. The record shall also treat the relationship of observed failure or defect modes in related lots or devices and, where applicable, corrective action taken as a result of the findings.

A.4.8.1.2.4 Initial documentation and subsequent changes in design, materials, or processing. Records shall cover the initial documentation and all changes with the date upon which each change in design, materials, or processing becomes effective for devices intended to be submitted for quality conformance inspection under this specification, the documents authorizing and implementing the change, and identification of the first production and quality conformance inspection lot(s) (as applicable) within which product incorporating the change is included shall be maintained when the change requires notification of the qualifying activity (see [A.3.4.2](#)).

MIL-PRF-38535J

APPENDIX A

A.4.8.1.2.5 Equipment calibrations. Records shall cover the scheduled calibration intervals for each equipment item, the dates of completion of actual calibration, identification of the group performing the calibration, and certification of the compliance of the equipment with documented requirements after calibration, (use ANSI/NCCL Z540.3 or equivalent, as a guideline).

A.4.8.1.2.6 Process, utility, and material controls. Records shall cover the implementation of devices such as control charts (e.g., X bar R charts) or other means of indication of the degree of control achieved at the points in the material, utility, and assembly process flow documented in the manufacturing instructions. Records shall also indicate the action taken when each out-of-control condition is observed, and the disposition of product processed during the period of out-of-control operation.

A.4.8.1.2.7 Product lot identification. Records shall be maintained to identify when each production or inspection lot or both was processed through each area. Records shall be capable of identifying for each production and acceptance inspection lot (as applicable) of finished product, these items as a minimum:

- a. The acceptance inspection tests performed on the lot, and their results.
- b. The serial numbers (when applicable) of all devices in the lot.
- c. The date of completion of acceptance inspection of the lot.
- d. Identification of the lot.
- e. The pertinent device specification or drawing under which inspection was performed.
- f. Final disposition of the lot (withdrawn, not accepted, accepted).
- g. Acquiring activity source inspection consideration of the lot.
- h. The number of devices, by device type, in each lot at the time of seal.
- i. Independently identify, by device type, the number of devices shipped and the number of devices in stock inventory.

A.4.8.1.2.8 Product traceability. The traceability system shall be maintained such that the qualifying activity can trace and determine that the microcircuits passed the applicable screening, qualification, and quality conformance inspections; that the microcircuits were assembled on the proper certified assembly line, and processed on the correct wafer process line.

A.4.8.1.3 Quality assurance program plan. The quality assurance program plan shall be established and maintained by the manufacturer, and shall be reviewed by the qualifying activity (QA). It shall consist of a volume or portfolio, or series of same, which shall serve to demonstrate that the manufacturer's understanding of a complete quality assurance program, as exemplified by their documentation system, is adequate to assure compliance of their product with the applicable specifications and quality standards. If the quality assurance program exemplified is applied consistently to all product lines intended to be submitted for acceptance inspection under this specification, only one program plan is required for each manufacturing plant; any difference in treatment of different product lines within a plant shall be stated and explained in the program plan, or separate program plans prepared for such different lines. The program plan shall contain, as a minimum, these items:

MIL-PRF-38535J

APPENDIX A

a. Documents representing the manufacturer's quality organization:

- (1) Functional block organization chart (see [A.4.8.1.3.1](#)).
- (2) Example of manufacturing flowchart (see [A.4.8.1.3.2](#)).
- (3) Proprietary-document identification (see [A.4.8.1.3.3](#)).
- (4) Examples of design, material, equipment, visual standard, and process instructions (see [A.4.8.1.3.4](#)).
- (5) Examples of records (see [A.4.8.1.3.5](#)).
- (6) Examples of design, material and process change control documents (see [A.4.8.1.1.8](#)).
- (7) Examples of failure and defect analysis and feedback documents (see [A.4.8.1.1.10](#)).
- (8) Examples of corrective action and evaluation documents (see [A.4.8.1.1.11](#)).
- (9) Manufacturer's internal instructions for internal visual inspection (see [A.4.8.1.3.6](#)).
- (10) Examples of test travelers (see [A.4.8.1.3.7](#)).
- (11) Examples of design and construction baseline (see [A.4.8.1.3.8](#)).
- (12) Manufacturer's self-audit program (see [A.4.9](#)).

NOTE: Where a manufacturer's lot/test traveler (see [A.4.8.1.3.7](#)) contains all the information required for a flowchart (see [A.4.8.1.3.2](#)), it may be used to satisfy the requirement for the flowchart.

b. Critical documents which are to be kept current and on file by the qualifying activity:

- (1) SPC program plans/milestones, as applicable.
- (2) Process flowcharts and baselines (wafer fabrication, assembly and test).
- (3) General QCI procedures.
- (4) Major change notification procedure.
- (5) Internal visual inspection procedure.
- (6) QM Plan

A.4.8.1.3.1 Functional block organization chart. This chart shall show, in functional block-diagram form, the lines of authority and responsibility (both line and staff) for origination, approval, and implementation of the several aspects of the quality assurance program. Names of incumbents are not required in this chart.

A.4.8.1.3.2 Examples of manufacturing flowchart. The flowchart for all devices shall reflect the complete manufacturing processes being used at the time and shall show all manufacturing, inspection, testing and quality verification points and the point where all materials or subassemblies enter the flow. The flowchart shall clearly show any utilization of third party activities. The chart shall identify all major documents pertaining to the inspection of materials, the production processes, the production environments, and production controls that were used. The documents shall be identified by name and number. Changes approved thereafter shall be treated in accordance with the approved document change control procedures in [A.3.4.2](#).

MIL-PRF-38535J

APPENDIX A

A.4.8.1.3.3 Proprietary-document identification. A listing of proprietary documents and areas shall be included in the program plan and maintained on a current basis (see [A.4.8.1](#)).

A.4.8.1.3.4 Examples of design, material, equipment, visual standard, and process instructions. An example of each type of design, material, equipment, visual standard, and process instruction used in the manufacture of microcircuits intended to be submitted for acceptance inspection under this specification shall be included in the program plan. These may be either dummies or actual working documents, but shall, in either event, show the form of the pertinent document; blank forms shall not be included.

A.4.8.1.3.5 Examples of records. Examples of records, complying with the requirements of [A.4.8.1.3.4](#) for instructions, shall be included in the program plan.

A.4.8.1.3.6 Manufacturer's internal instructions for internal visual inspection. The manufacturer's internal instructions for internal visual inspection in accordance with test method 2010 or test method 2017, as applicable, of MIL-STD-883 for the applicable device class, shall be included in the program plan.

A.4.8.1.3.7 Examples of travelers. Wafer fab, assembly, screening, and groups A, B, C, D (and E, if applicable) travelers shall be included in the program plan and maintained on current basis. The traveler utilized for QCI lots may be the same traveler as used for qualification lots. When in-line inspections are allowed (i.e., alternate group A or B) the traveler shall include documentation of required inspections. The travelers shall include all manufacturer imposed tests. The test traveler shall include all the following minimum information (if applicable):

- a. Identification as to whether the lot is qualification or QCI.
- b. Name or title of operation and specification number of each process or test.
- c. PIN, date code, and manufacturer internal lot identification number(s).
- d. Date(s) of test and operator identification.
- e. Calibration control number or equipment identification of all major equipment components used for test.
- f. Quantity tested and rejected for each process or test and actual quantity tested, if sampled.
- g. Serial numbers of passing and failing devices when applicable.
- h. Time in and out of process or test if critical to process or test results (i.e., burn-in and 96-hour window).
- i. Specific major conditions of tests that is verifiable by operator including times, temperatures, RPMs, etc. (Not required for screening and QCI traveler.)
- j. The percent defective calculated for burn-in.
- k. Burn-in/life test board serial number or test circuit identification number and revision.
- l. All required variables data except for electrical tests (attachments permitted). (Not required for QCI traveler.)
- m. For electrical tests, test program number and revision and identify when variables data is required.

MIL-PRF-38535J

APPENDIX A

A.4.8.1.3.8 Examples of design and construction baseline. The design and construction baseline information (e.g., DSCC-VQC-42 "DSCC Microcircuit Materials and Construction Baseline Sheet", or equivalent) shall be included in the manufacturer's program plan and maintained under document control. The baseline form shall clearly show any utilization of third party activities.

A.4.9 Self-audit requirements

A.4.9.1 Self-audit requirements. The intent of the self-audit program is to assure continued conformance to specification requirements.

A.4.9.2 Definitions

A.4.9.2.1 Self-audit. The performance of periodic survey by the device manufacturer's designated personnel to evaluate compliance to specifications.

A.4.9.2.2 Audit checklist. A form listing specific items which are to be audited.

A.4.9.3 General

A.4.9.3.1 Self-audit program. The manufacturer shall establish an independent self-audit program under the direction of the quality organization to assess the effectiveness of the manufacturer's compliance to all applicable specifications. The manufacturer's self-audit program which identifies key review areas, their frequency of audit, and the corrective action system to be employed when variations from the approved procedures or specification requirements are identified shall be included in the program plan. The self-audit program shall, as a minimum, incorporate the following requirements.

A.4.9.3.1.1 Correction of deficiencies. A system to identify and correct any deficiencies (e.g., processing and testing) or deviations from the specification requirements.

A.4.9.3.1.2 Deviation from critical documents. Provide for review of all deviations from critical documents, such as, baseline(s), flowchart(s), traveler(s), QCI procedures, etc.

A.4.9.3.1.3 Training and retraining of auditors. Specify the selection and training/retraining requirements for auditors.

A.4.9.3.1.4 Self-audit schedule and frequency. Specify the self-audit frequencies and require that a schedule be established and adhered to.

A.4.9.3.2 Self-audit representatives. The quality assurance representatives or the designated appointees shall perform all self-audits. The designated auditors shall be independent from the area being audited. If the use of an independent auditor is not practical, then as a minimum, another individual should be assigned to participate in the audit or review the results with the auditor from the area. The auditors shall be trained in the area to be audited, in the applicable specification requirement and provided with an appropriate checklist for annotating deficiencies. Prior to the audit, the assigned auditor(s) shall review the previous audit checklist to assure corrective actions have been implemented and are sufficient to correct the deficiencies.

A.4.9.3.3 Audit deficiencies. All audit deficiencies shall be documented on the appropriate form and a copy submitted to the department head for corrective action(s). All corrective actions shall be agreed to by the quality organization or Material Review Board.

MIL-PRF-38535J

APPENDIX A

A.4.9.3.4 Audit follow-up. All audit reports shall be filed and maintained by the quality organization. The quality organization shall establish a procedure to follow up on all audit deficiencies to assure that the corrective actions have been implemented in a timely manner. A system (e.g., Management Review) shall also be established to review the acceptability and timeliness of all corrective actions and to determine if any deficiencies have repeated since the last required self-audit. If any deficiencies have occurred two or more times in the predetermined time period, additional corrective actions shall be taken to assure immediate correction of the problem and the qualifying activity (QA) shall be notified. The self-audit team shall perform a follow-up verification within 6 months of corrective actions covering all deficiencies found during the QA audit and annual self-audit to assure corrective actions are adequate and maintained.

A.4.9.3.5 Audit schedules and intervals. The original audit interval shall be established with a schedule by the quality organization but in no case exceed 1 year for each area, unless authorized by the qualifying activity (QA). A self-audit shall be conducted and corrective actions completed prior to the initial QA audit. Changes to the audit schedule, due to being consistently above or below average performance on the self-audit, shall require approval of the QA.

A.4.9.3.6 Self-audit report. The self-audit report shall be signed by the quality assurance representative responsible for the quality assurance program's overall success or failure. The manufacturer shall make available to the qualifying activity, during audits, the self-audit report, deficiencies, and corrective actions taken. This report shall include a summary report of self-audit results categorized by deficiency type (i.e., nonconformance to specification requirement(s), occurrences affecting product reliability, recurring deficiencies).

A.4.9.3.7 Self-audit areas. The self-audit shall be performed to assure conformance to the checklist and specification in at least the following areas:

Calibration and preventive maintenance	Deionized (DI) water controls
Fabrication	Training
Assembly operations	Failure analysis
Electrical test	Qualification/QCI system
Test methods	Document control
Environmental control	Design change control
Incoming inspection	Statistical process control, as applicable
Inventory control and traceability	Third party subcontractors (see note)
ESD handling control program	

NOTE 1: The QA approval of a subcontractor second and third party facility does not alleviate the manufacturer of validating product specific requirement.

NOTE 2: The self-audit shall include any activities performed by a subcontractor, and shall ensure full compliance by the subcontractor to this appendix and the device specification or drawing. Any deviations or questionable areas shall be brought to the attention of the qualifying activity. QA approval of subcontracted second party facilities may be used to satisfy the subcontractor audit requirement.

A.4.9.3.8 Self-audit checklist. The audit checklist shall be prepared by the quality organization and maintained under document control. The checklist shall assure that the quality assurance system is adequate and followed by all personnel in each area.

MIL-PRF-38535J

APPENDIX A

A.5 PACKAGING

A.5.1 Packaging. For acquisition purposes, the packaging requirements shall be as specified in the contract or order (see [6.2](#)). When packaging of material is to be performed by DoD or in-house contractor personnel, these personnel need to contact the responsible packaging activity to ascertain packaging requirements. Packaging requirements are maintained by the Inventory Control Point's packaging activities within the Military Service or Defense Agency, or within the military service's system commands. Packaging data retrieval is available from the managing Military Department's or Defense Agency's automated packaging files, CD-ROM products, or by contacting the responsible packaging activity.

A.5.2 Packaging requirements. The packaging of microcircuits shall prevent mechanical damage to the device during shipping and handling and the packaging material shall not be detrimental to the device. In addition, microcircuits which have been determined to require electrostatic discharge protection, category A or class 1 or 2 by test method 3015 of MIL-STD-883 (see [A.4.4.2.8](#)), shall be packaged in conductive material or packaged in accordance with one of the following:

Category A.

- (1) Unit container suitable for ESD protection.
or
- (2) Conductive noncorrosive rail with noncorrosive and conductive or antistatic foam plugs at both ends of each rail which prevents movement.
or
- (3) Antistatic noncorrosive rail with noncorrosive and conductive or antistatic foam plugs at both ends of each rail which prevents movement. Antistatic rails shall be packaged in conductive, electrostatic field shielding material.

(Other packaging methods shall require the approval of the acquiring activity.)

NOTE: Rails (i.e., multiple carriers) coated but not impregnated with antistats shall be used only if the antistatic properties are proven to be intact on the surface. These measurements shall conform to [A.3.1.3.22](#) and EIA541.

A.5.2.1 Carrier and container. When specified on the detail specification or order, microcircuits shall be supplied mounted in the carrier (unit or multiple) and carrier container, or carrier and unit container. Marking on the carrier or unit container shall be as specified in [A.5.2.2](#).

A.5.2.2 Marking of container. All of the markings specified in [A.3.6](#), except the index point and serialization, shall appear on the carrier, unit pack (e.g., individual foil bag), unit container, or multiple carriers (e.g., tubes, rails, magazines) for delivery. An industry standard symbol for identifying ESD sensitive items (e.g., JESD471 symbol) shall be marked on the carrier or container. However, if all the marking specified above is clearly visible on the devices and legible through the unit carrier or multiple carriers, or both, then the ESD marking only (in accordance with MIL-STD-1285) shall be required on the multiple carriers. These requirements apply to the original or repackaged product by the manufacturer or distributor.

A.6 NOTES

(This section contains information of a general or explanatory nature that may be helpful, but is not mandatory.)

A.6.1 Intended use. Microcircuits conforming to this appendix are intended for use for Government microcircuit application and logistic purposes. For maximum cost effectiveness while maintaining essential quality and reliability requirements, it is recommended that, for initial acquisitions for original equipment complements, the device class appropriate to the need of the application (see [A.3.4](#)) be acquired.

MIL-PRF-38535J

APPENDIX A

A.6.2 Acquisition requirements. Acquisition documents should specify the following:

- a. Title, number, and date of the specification.
- b. PIN and compliance identification (if applicable).
- c. Test data to be furnished.
- d. Packaging Requirements (see [A.5](#)).
- e. Requirement for radiation hardness assurance testing (see [A.4.4.2.5](#) and [A.4.5.6](#)).

A.6.2.1 Lead finish designator. For Government logistic support, the A lead finish will be ordered and supplied to the end user when X is used in place of the A, B, C, D, or E lead finish designator. If the device type is not available with lead finish A, the same PIN will be ordered except that B, C, D, or E will be used as the lead finish designator depending upon which is available.

MIL-PRF-38535J

APPENDIX B

SPACE APPLICATION

B.1 SCOPE

B.1.1 Scope. This appendix presents the requirements that are to be used to supplement this specification and the other applicable appendices for space level microcircuits. The manufacturer's process may include innovative and improved processes that result in an equivalent or higher quality product, provided that the process used to evaluate and document these changes has been reviewed and approved by the qualifying activity after coordination with the government space community (e.g. DTRA, NASA, NRO, and AFSMC). The approach outlined in this appendix is a proven baseline that contains details of the screening and technology conformance inspection (TCI) procedures. Manufacturers are to be able to demonstrate a process control system that achieves at least the same level of quality as could be achieved by complying with this appendix. This appendix is intended for product to be used in space applications. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance.

B.2 APPLICABLE DOCUMENTS.

B.2.1 General. The documents listed in this section are specified in sections B.3 or B.4 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in sections B.3 and B.4 of this appendix, whether or not they are listed.

B.2.2 Government documents.

B.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE SPECIFICATION

MIL-M-38510 - Microcircuits, General Specification for.

DEPARTMENT OF DEFENSE STANDARDS

MIL-STD-883 - Test Method Standard Microcircuits.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

B.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

AMERICAN SOCIETY FOR TESTING AND MATERIALS (ASTM)

ASTM F1192 - Standard Guide for the Measurement of Single Event Phenomena (SEP)
Induced by Heavy Ion Irradiation of Semiconductor Devices.

(Copies of these documents are available online at <http://www.astm.org/> or from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.)

MIL-PRF-38535J

APPENDIX B

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

JESD57 - Test Procedures for the Measurement of Single-Event Effects in Semiconductor Devices from Heavy Ion Irradiation.

(Copies of this document are available online at <http://www.jedec.org> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

(Non-Government standards and other publications are normally available from the organizations that prepare or distribute the documents. These documents also may be available in or through libraries or other informational services.)

B.3 REQUIREMENTS

B.3.1 General. Microcircuits supplied to this appendix shall be manufactured and tested in accordance with approved baselines and the requirements herein as applicable. Only class "V" level product marked with an RHA designator is required to meet [table B-1](#) herein. Upon approval from the Technology Review Board (TRB) and the qualifying activity (QA), screening and TCI may be modified for qualified manufacturer listing (QML) class V level product, provided substantiating data is submitted to demonstrate that the manufacturer has a defined capability on the manufacturing line which is controllable, and in control. These changes cannot affect any thermal, mechanical or electrical parameters, which affect form, fit, function or radiation hardness assurance level (when applicable) of the device, defined within the device specification or standard microcircuit drawing (SMD). The space community (e.g. DTRA, NASA, NRO, and AFSMC) and the customer shall be notified of major changes to the manufacturer's quality management (QM) plan. Any optimization proposed by the manufacturer must be presented to the qualifying activity and coordinated with the space community with accompanying supporting data to validate the proposed change. The optimization must be approved by the QA in writing prior to implementation.

B.3.1.1 Acquiring activity. When specified by the acquisition document (purchase order), the acquiring activity may:

- a. Require prior notification of major changes to the baselined processes, procedures, or testing.
- b. Require independent verification of wafers (unprobed) or packaged devices (technology characterization vehicle (TCV), standard evaluation circuit (SEC), or actual devices) by original equipment manufacturer's (OEM's) or Government agencies.
- c. Request screening and TCI summary data is delivered with the devices.

B.3.2 Conflicting requirements. In the event of conflict between the requirements of this appendix and other referenced documents, the order of precedence shall be as follows:

- a. The acquisition document (order).
- b. Applicable device specification.
- c. This appendix.
- d. MIL-PRF-38535.
- e. Specifications, standards, and other documents referenced in [2.1](#) of MIL-PRF-38535.

NOTE: The acquisition document may specify additional requirements, but shall not reduce or waive any requirements herein.

MIL-PRF-38535J

APPENDIX B

B.3.3 Validation (certification). Validation of a manufacturing line for production of integrated circuits for use in space systems shall be accomplished by a team headed by DLA Land and Maritime with members from the space community (e.g. NASA, NRO, DTRA, and AFSMC), other interested services, and the customer as necessary.

B.3.4 Manufacturing verification. When specified, the manufacturing verification procedure for new technology shall include characterization of actual devices at -55°C and 125°C (or high and low temperature as specified in the device specification) with DC, AC and full functional electrical parameters (where applicable). Life testing of new technologies shall be determined by the manufacturer based on characterization with full temperature testing and read and record measurements every 1000 hours. Characterization shall also include a complete evaluation of potential failure mechanisms and mitigations strategies, calculation/evaluation of activation energy and acceleration factors for voltage, temperature, frequency, etc, and establishment of long term reliability failure rates. The life test may be modified based on the determination of failure mechanisms and activation energy (see TM 1016 for guidance with a goal of 15 year operating life at $+65^{\circ}\text{C} \leq T_J \leq 95^{\circ}\text{C}$). The manufacturer shall determine worst case for their devices). Additional requirements for characterization are included in appendices G and H (see [H.3.1.9 c \(v\)](#)), and are a requirement for class level S and class V devices.

B.3.5 Design verification. When specified, a fully functional VHSIC Hardware Description Language (VHDL) model shall be available.

B.3.6 Part or identifying number (PIN). Each V level QML microcircuit shall be marked with the device class designator "V" in place of the "Q" designator in the PIN format, see [3.6.2a](#) herein. Devices procured to MIL-M-38510 PINs shall be marked in the format in [3.6.2b](#) herein with the device class designator "S".

B.3.7 Serialization. Prior to the first recorded electrical measurement in screening, each class V microcircuit shall be marked with a unique serial number assigned within the level of the individual microcircuit within that inspection lot.

B.3.8 Traceability. For class V, inspection lot records shall be maintained to provide traceability from the device serial number to the specific wafer lot or to the specific wafer when testing to any group E subgroup (see [table B-I](#)), is performed on a wafer by wafer basis.

B.3.9 New technology requirement. For class level S product, this is a product family, material, or process that has never been previously characterized and qualified by the manufacturer for space applications, and is detailed in the manufacturer's new technology insertion program (see [3.4.1.1](#) and [6.4.42](#)). Existing devices that meet the major change criteria of [table A-I](#) are to be evaluated in conjunction with the qualifying activity to determine if the change should be classified as a new technology, as defined in [3.4.1.1](#) prior to finalized qualification plan implementation.

MIL-PRF-38535J

APPENDIX B

B.4 VERIFICATION

B.4.1 Screening. In addition to the screening tests specified in the main body of this specification, the screening tests specified below shall be performed, unless prior approval for deletion or modification is given by the qualifying activity.

- a. Nondestructive bond pull (NDBP) in accordance with TM 2023 of MIL-STD-883, or approved alternate verified during validation, on each interconnect bond. An alternate method, if necessary, shall consider a 100 percent visual inspection of the elements to be bonded (i.e., bond pads and posts) prior to the bonding operation, as one part of an overall alternate method.
- b. Internal visual inspection in accordance with TM 2010 of MIL-STD-883, condition A, or approved alternate verified during validation on each microcircuit. An alternate method, if necessary, shall address all the inspection topics of TM 2010 of MIL-STD-883.
- c. Particle impact noise detection (PIND) in accordance with TM 2020, condition A of MIL-STD-883 on each device.
- d. Reverse bias burn-in in accordance with TM 1015 of MIL-STD-883 on each device as specified in the applicable device specification.
- e. Radiograph inspection in accordance with TM 2012 of MIL-STD-883 on each device. Only one view is required for flat packages and leadless chip carriers having lead terminal metal on four sides.
- f. Burn-in test in accordance with TM 1015 of MIL-STD-883, on each device for 240 total hours at +125°C. For a specific device type, the burn-in duration may be reduced from 240 to 160 hours if three consecutive production lots of identical parts, from three different wafer lots pass percent defective allowable (PDA) requirements after completing 240 hours of burn-in. Sufficient analysis (not necessarily failure analysis) of all failures occurring during the run of the three consecutive burn-in lots shall not reveal a systematic pattern of failure indicating an inherent reliability problem which would require that burn-in be performed for a longer time. Other burn-in conditions may be considered by a class V validation team. The manufacturer's burn-in procedures shall contain corrective action plans, approved by the validation team, for dealing with lot failures. PDA shall be in accordance with TM 5005 of MIL-STD-883 for class S.
- g. Wafer lot acceptance testing in accordance with TM 5007 of MIL-STD-883 or an alternative which meets the minimum requirements of TM 5007 on each wafer lot producing class V or S devices (see [H.3.2.1.4](#)).

MIL-PRF-38535J

APPENDIX B

B.4.2 Technology conformance inspection (TCI). In addition to the TCI tests specified in the main body of this specification, unless otherwise noted herein, the TCI requirements listed below apply on each lot of deliverable devices. The group and table references correspond to those contained herein. These requirements do not replace the normal TCI testing requirements of this specification.

- a. [Table III](#), group A electrical test shall be performed on each deliverable lot using actual devices. For those lots having a quantity of less than 116 devices, the tests shall be imposed on a 100 percent basis and the lot accepted on zero test rejects. If a microcircuit fails a group A test parameter as a result of faulty test equipment or operator error, the cause shall be determined and documented, and corrective action shall be implemented and documented.

The affected lot may then be accepted by being resubmitted to the failed test parameters using a 116/0 or 100 percent/0 sample. If a microcircuit fails a group A test due to a previously unscreened parameter, the affected lot may be accepted by screening the lot 100 percent for the failed parameters, and resubmitting a group A sample to the failed subgroup using a 116/0 or 100 percent/0 sample. Any failures resulting from the second screen shall count toward the lot total percent defective. PDA shall be in accordance with TM 5005 of MIL-STD-883 for class level S.

Group A electrical tests are not required to be performed when the following conditions are met:

- (1) The final electrical tests of the 100 percent screening test (see [table I](#)) includes all required group A tests (see [table III](#)).
- (2) The test setup and test conditions are verified by a certified monitor other than the test operator.
- (3) Analysis of failures does not indicate a generic or lot related reliability problem.

In no event shall the absence of separate group A testing result in a failure to satisfy the data requirements of section [B.3.1.1c](#).

- b. [Table II](#), group B, shall be performed on actual devices except as noted herein. Empty device packages or electrical rejects may be used for subgroups B-1 and B-3, and electrical rejects that have been subjected to the 100 percent screening tests may be used for subgroup B-2. The electrical rejects and empty packages shall have been produced under equivalent conditions as the production lot. The TRB shall determine that the intent of the tests is not violated. The sample size of [table II](#) is acceptable provided the 22(0) bond strength and solderability criteria has been applied to at least two separate devices (i.e., 11 leads per device), and the die shear test is applied with a 2(0) criteria.

MIL-PRF-38535J

APPENDIX B

c. The group C or group B, Subgroup 5 life test requirements shall be met using one of the procedures below.

- (1) Life test shall be performed on a quantity (accept) criteria of 22(0) for 2000 hours @ 125°C or equivalent per TM 1005 to attain 44,000 device hours. The criteria of 45(0) for 1000 hours is also acceptable. For lots greater than 200, actual devices shall be used. For lots less than or equal to 200, the number of actual devices shall be the greater of 5 devices or 10 percent of the lot, and the SEC shall supplement actual devices to result in a sample of 22 unless acceptable group C data from the SEC is available for the previous 3 months. The SEC shall have been produced under equivalent conditions as the production lot and as close in time as feasible, but not to exceed a 3-month period.

Note: For ASICs, a sample size of 5 actual devices may be used with the balance being made up of the SEC.

- (2) Group C life tests shall be performed on the initial production lot of actual devices from each wafer lot, in accordance with [table IV](#). Group C life tests are not required to be performed on subsequent production lots when all the following conditions are met:

- (a) Subsequent production lots utilize die from the same wafer lot as the initial production lot.
- (b) Wafers or die remaining from the initial production lot are to be stored in dry nitrogen or equivalent controlled storage, and in covered containers.
- (c) No major changes to the assembly processes have occurred since the group C test was performed on the wafer lot.

d. Group D test requirements, following package technology style characterization testing (see [table H-IIA](#) and [H-IIB](#)), and group D testing on the initial production lot utilizing the package family of interest, shall be in accordance with MIL-PRF-38535 and the manufacturer's approved QM plan. A package family consists of a set of package types with the same package configuration (e.g., side brazed, bottom brazed), material type (e.g., alumina, beryllium oxide (BeO)), package construction techniques (e.g., single layer, multilayer), terminal pitch, except for can packages in which pin circle diameter can be used in place of terminal pitch, lead shape (e.g., gullwing, J-hook), and row spacing (i.e., dual-in-line packages only) and with identical package assembly techniques (e.g., material and type of seal, wire bond method and wire size, die attach method and material). All new alternate sources of package elements shall be qualified to the applicable group D tests.

e. Group E inspection shall be performed in accordance with [table B-I](#) below. Metal oxide semiconductor (MOS) microcircuits, when specified, shall be tested for time dependent effects post total dose irradiation. When 100 percent latch-up screen is specified, the PDA shall be 5 percent or one device, whichever is greater. The devices used for group E testing shall pass the specified group A electrical tests. An alternate procedure to [table B-I](#) may be used upon approval of the qualifying activity.

MIL-PRF-38535J

APPENDIX B

TABLE B-I. Group E (RHA) TCI, Class V. 1/

Test	Test method (MIL-STD-883)	Quantity (accept number)	Notes
<u>Subgroup 1</u> Neutron irradiation	1017	2(0) devices/wafer or 11(0) devices/wafer lot	<u>2/ 3/ 10/ 6/</u> <u>2/ 3/ 10/ 6/</u>
<u>Subgroup 2</u> Total ionization dose	1019	2(0) devices/wafer or 22(0) devices/wafer lot	<u>2/ 9/ 10/</u> <u>2/ 10/</u>
		1(0) device/wafer + 4(0) test structures/wafer or 5(0) devices/wafer lot + 4(0) test structures/wafer	<u>2/ 4/ 5/ 10/</u> <u>2/ 4/ 5/ 10/</u>
<u>Subgroup 3</u> Transient ionization	1021	2(0) devices/wafer or	<u>6/</u>
	1023	11(0) devices/wafer lot	<u>6/</u>
<u>Subgroup 4</u> Dose-rate latch-up	1020	As specified in the device specification	<u>6/ 7/</u>
<u>Subgroup 5</u> Single-event effects	ASTM F1192 or JESD57	4(0) devices	<u>8/ 6/</u>

- 1/ Group E tests may be performed prior to device screening. End-point electrical parameters are specified in the detail specifications. Read and record critical parameters.
- 2/ Parts used for one subgroup test may not be used for other subgroups, but may be used for higher levels in the same subgroup. For subgroup 2, total dose exposure shall not be considered cumulative unless testing is performed within the time limits of the test method.
- 3/ Not required for MOS devices unless bipolar elements are included by design.
- 4/ For device types with greater than 100,000 equivalent transistor per die.
- 5/ The test structures shall be randomly selected from the wafer. An X-ray source may be used on test structures at the wafer level provided correlation has been established between the X-ray and the Cobalt-60 source.
- 6/ Test to be conducted only when specified in the order or contract.
- 7/ Latch-up testing is not required for silicon on sapphire (SOS), silicon on insulator (SOI), and dielectrically isolated technologies when latch-up is physically not possible. Test conditions, sample size, test temperature, and the electrical parameters to be measured pre, post and during irradiation shall be specified in the acquisition document.
- 8/ Single event effects (SEE) testing shall be performed during qualification and after any design or process change that may affect SEE response.
- 9/ Traceability to the specific wafer is required.
- 10/ Subgroups shall be invoked when radiation hardness assurance capability level (RHACL) specification requirements listed in [table C-I](#) are not met.

MIL-PRF-38535J

APPENDIX B

(This page intentionally left blank.)

MIL-PRF-38535J

APPENDIX C

RADIATION HARDNESS ASSURANCE

C.1 SCOPE

C.1.1 Scope. This appendix presents the requirements which are to be used to supplement MIL-PRF-38535 for device manufacturers supplying radiation hardness assurance (RHA) microcircuits. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance.

C.2 APPLICABLE DOCUMENTS

C.2.1 General. The documents listed in this section are specified in sections C.3, C.4, or C.5 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in sections C.3, C.4, and C.5 of this appendix, whether or not they are listed.

C.2.2 Government documents.

C.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE STANDARDS

MIL-STD-883 - Test Method Standard Microcircuits.

DEPARTMENT OF DEFENSE HANDBOOKS

MIL-HDBK-814 - Ionizing Dose and Neutron Hardness Assurance Guidelines for Microcircuits and Semiconductor Devices.

MIL-HDBK-815 - Dose-Rate Hardness Assurance Guidelines.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

C.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

AMERICAN SOCIETY FOR TESTING AND MATERIALS (ASTM)

ASTM F1192 - Standard Guide for the Measurement of Single Event Phenomena (SEP) Induced by Heavy Ion Irradiation of Semiconductor Devices.

ASTM F1892 - Standard Guide for Ionizing Radiation (Total Dose) Effects Testing of Semiconductor Devices.

(Copies of these documents are available online at <http://www.astm.org/> or from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.)

MIL-PRF-38535J

APPENDIX C

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

JESD57 - Test Procedures for the Measurement of Single-Event Effects in Semiconductor Devices from Heavy Ion Irradiation.

(Copies of this document are available online at <http://www.jedec.org> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

(Non-Government standards and other publications are normally available from the organizations that prepare or distribute the documents. These documents also may be available in or through libraries or other informational services.)

C.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein (except for related device specifications), the text of this document takes precedence. Nothing in this document, however, supersedes applicable laws and regulations unless a specific exemption has been obtained.

C.3 REQUIREMENTS

C.3.1 General. Microcircuits supplied to this document shall be manufactured and tested in accordance with approved baseline manufacturing flow and the requirements herein. RHA qualified manufacturer listing (QML) manufacturers shall meet all of the requirements of MIL-PRF-38535 and the additional requirements specified herein. The Technology Review Board (TRB) shall not make major changes to the baselined design rules, processes, procedures, or testing without notifying the qualifying activity prior to implementation of the change.

C.3.2 TRB duties. The TRB duties shall be as outlined in [G.3.2.2](#).

C.3.2.1 TRB/RSS. In the case of a Radiation Source of Supply (RSS) (see [6.4.23](#)), the RSS shall establish a TRB and representatives from the device manufacturer, assembly facility, and test facility shall be part of the TRB. The RSS TRB shall be responsible for all aspects of the device manufacturing process. Details of how all aspects of the device manufacturing processes are controlled shall be documented in the RSS quality management (QM) plan. These include conversion of customer requirements, design, wafer fabrication, assembly, test, RHA testing and verification, and characterization for device specification.

C.3.3 RHA QM plan. A RHA QM plan shall be developed to document the major elements of the manufacturer's QML process ([G.3.3](#)). This plan establishes the procedures to be followed to ensure that the devices meet the Radiation Hardness Assured Capability Level (RHACL). The RHA QM plan shall be kept current and up-to-date and reflect all major changes to the RHACL.

C.3.4 RHA/QML certification requirements. See [3.4.1](#) herein. In addition to standard flow certification the manufactures RHA certification testing shall be performed by a laboratory that has received suitability from the qualifying activity (QA).

MIL-PRF-38535J

APPENDIX C

C.3.4.1 Process capability demonstration. The manufacturer shall meet the requirements in 3.4.1.1 and shall also meet the following for an RHA device. A RHACL shall be established for the environments selected by the TRB and consistently demonstrated for a technology at the specified level of electrical performance. Changes in the RHACL may require reevaluation of these capabilities by the TRB. Listed below are the radiation environments that shall be addressed:

a. Natural:

- (1) Total ionizing dose and time dependent effects for ionizing radiation (MIL-HDBK-814, ASTM F1892 and TM 1019 of MIL-STD-883).
- (2) Single-Event-Effects (SEE): Including upset, latch-up, burnout, gate rupture caused by Galactic Cosmic Rays (GCR), Solar Enhanced Particles, and energetic neutron and protons (ASTM F1192 or JESD57).
- (3) Displacement damage: Caused by energetic neutrons and protons.

b. Weapon:

- (1) Dose rate: Upset, latch-up, burnout (MIL-HDBK-815, TM 1020, TM 1021, and TM 1023 of MIL-STD-883).
- (2) Neutron irradiation (MIL-HDBK-814 and TM 1017 of MIL-STD-883).
- (3) Total ionizing dose (MIL-HDBK-814 and TM 1019 of MIL-STD-883).

C.3.4.1.1 Design. The manufacturer shall address the design methodology for the following areas of design:

(NOTE: These are also applicable to third party design centers.)

- a. Model verification. Model verification shall provide evidence that models defining device response in radiation environments accurately predict the nominal and worst-case circuit response over operating voltage limits and over the temperature range selected for the technology at the RHACL.
- b. Design rule verification. The vendor shall document his design rules for radiation hardening his technology and demonstrate his procedures for verifying rule compliance in the context of Design Rules Check (DRC), Electrical Rules Check (ERC) and reliability checking procedures (see [G.3.1.b](#), [G.3.4.1.c](#), [H.3.2.1.1.1 b](#)). These rules cover, as a minimum:
 - (1) DRC: Geometric and physical.
 - (2) ERC: Shorts and open, connectivity.
 - (3) Reliability verification: Electromigration (current density), latch-up, electrostatic discharge (ESD), and fuse/anti-fuse reliability.
 - (4) RHA rules: The vendor shall document their design rules for radiation hardening in their technology and the procedures for verifying rule compliance.
- c. Performance verification. The vendor shall demonstrate his ability to predict the response of the post-irradiation performance at the RHACL including the effects of the specified limits for temperature and voltage variations and the influence of process variations (see [H.3.2.1.1.1.c](#)). Any deviation from these requirements shall receive qualification activity approval.

MIL-PRF-38535J

APPENDIX C

C.3.4.1.2 Wafer fabrication. As part of certification, the manufacturer shall identify a specific technology or technologies for the wafer fabrication (see [H.3.2.1.2](#)).

- a. Statistical process control (SPC) and in-process monitoring program for RHA. SPC is especially critical for maintaining a technology's RHACL. This occurs since relatively minor changes in a process flow can drastically effect device radiation performance. The manufacturer shall identify and document all critical process nodes associated with RHA. See [H.3.2.1.3](#) for a general list of critical process steps, any deviation from this list shall receive qualifying activity approval.
- b. Technology characterization vehicle (TCV) program. The TCV program is an integral part of a technology's RHA and shall be carefully configured to ensure the accurate characterization of a technologies radiation capability. The TCV program shall be designed to support RHA activities, parametric extraction, model development and validation, SPC and failure mode analysis. (see [H.3.2.2.2.1](#)) The TCV structures shall be used to determine a technology's RHACL and in addition determine failure modes and mechanisms by irradiation to 2x RHACL or failure, whichever comes first. Failure can be either functional or parametric.
- c. TCV certification. When radiation hardness is a requirement of the technology, special structures shall be incorporated into the TCV program to characterize the technology's capability for producing devices with assured radiation hardness to the RHACL. To determine that the RHACL is appropriate for the technology, the vendor shall irradiate the TCV to 2x the RHACL or until failure to determine failure mode and mechanism(s). Also, the bounds of the radiation response shall be determined by testing the appropriate TCV test structures for worst case bias conditions, annealing conditions, and temperature.
- d. Standard evaluation circuit (SEC). The SEC shall utilize all relevant radiation hardness assurance design rules and shall be used to demonstrate the specified level of performance at the RHACL. When radiation hardness assurance is a requirement of the technology, the SEC shall be used to certify and monitor the RHACL of a specific fabrication technology in a specific fabrication facility. The SEC shall be designed so it can be used to assess and monitor the radiation hardness of the fabrication process and design rules (see [H.3.4.3](#)). The SEC reliability data, including failure analysis results, shall be available for review by the qualifying activity. For RHA environments, the manufacturer shall irradiate SEC to 2x the requested RHACL or to failure (whichever occurs first) under worst case bias, annealing and temperature conditions as a demonstration of the technology's capability to meet the RHACL. A different SEC may be required whenever the design rules, the materials, the basic processes, or the basic functionality of the technology differ.
- e. Process monitor (PM). The process monitor is an integral part of a technology's RHA SPC program for in-line process monitoring. The structures shall be carefully designed and configured to ensure the accurate characterization of a technology's radiation performance and capability. The PM shall support wafer acceptance testing and TCI (see [H.3.2.1.3.2](#)). Any deviation from this guidance shall be justified to the qualifying activity.

When RHA is a requirement of the QML line, as a minimum, process monitors for RHA qualified technologies shall include test structures to support the following:

(1) Metal oxide semiconductor (MOS) RHA parameters:

- (a) Gate oxide thickness; Structures shall be included to ensure gate oxide thickness since this is a critical parameter affecting radiation performance.
- (b) The following parameters shall be measured as a function of total ionizing dose:
 - (i) Threshold voltage (V_T); The linear V_T for each transistor in a cell.
 - (ii) Linear transconductance (g_m); The linear g_m for a set of transistors.

MIL-PRF-38535J

APPENDIX C

- (iii) I_{on}/I_{off} (leakage current).
 - (iv) Propagation delay time (t_{PD}); A test structure in the form of a functional circuit such as an inverter or register chain shall be available to support this measurement.
 - (v) Field transistor leakage; Field transistor leakage for the minimum design/layout rules.
- (2) Bipolar parameters. The bipolar parameters should be those found in [H.3.2.1.3.2 c](#) and shall be measured as a function of total ionizing dose and neutron fluence (as appropriate).
- (3) Gallium arsenide (GaAs) parameters. The following parameters should be measured as a function of total ionizing dose and neutron/proton fluence (as appropriate).
- (a) Sheet resistance.
 - (b) Isolation; An ohmic transmission line structure should be included to measure contact resistance and transfer length.
 - (c) FAT FET; A long length gate FET suitable for the measurement of Schottky barrier height, ideality factor, carrier concentration, and channel depth should be available.
 - (d) GaAs FET parameters; see [H.3.2.1.3.2 d](#).
- (4) Radiation hardness assurance. When RHA is a requirement of the technology, the PM shall include test structures to monitor the following phenomena, as applicable:
- (a) Dose-rate latch-up.
 - (b) Dose-rate upset.
 - (c) Single-event effects (SEE).
 - (d) Total ionizing dose.
 - (e) Displacement damage from neutron or proton irradiation.
- (5) Other RHA considerations. In addition, test structures to monitor and characterize radiation response mechanisms and for linear circuit applications shall be included (as appropriate). These structures would include but not be limited to:
- (a) Matched transistor pairs for offset current and voltage characterization.
 - (b) Annular and dual or multi-edged transistor sets for sub threshold I-V characterization.
 - (c) Four contact devices for charge pumping measurements.

MIL-PRF-38535J

APPENDIX C

C.3.4.1.3 Wafer acceptance plan. The TRB shall develop and demonstrate a wafer acceptance plan based on electrical and radiation measurement of parametric monitors (PMs). PMs shall be used to determine wafer and wafer lot uniformity and latch-up immunity (when specified). Further testing of the actual device to [table C-I](#) may be required. As an option to actual device testing, after initial establishment of device specification and device post-irradiation parameter limits (PIPL), the following procedures are presented as examples for the specified radiation environments:

- a. Latch-up: The PM should utilize worst case latch-up structures to determine latch-up holding voltage at maximum temperature. The holding voltage shall be greater than the maximum rated voltage.
- b. SEE: The PM should utilize SEE structures such as cross-coupling resistors to memory cells to assure critical parameters agree with worst case acceptance criteria.
- c. Dose rate: The PM should utilize structures to ensure rail span collapse does not cause upset or burnout or both and that the metallization resistivity, contact resistance, via resistance, epitaxial layer (EPI), substrate resistivity, and minority carrier lifetime specifications are met.
- d. Total ionizing dose: The PM should utilize structures such as capacitors and transistors to ensure that critical parameters agree with worst case PIPL values.

C.3.5 On-site validation. In addition to the requirements in [3.4.1.3](#) the on-site validation shall include RHA test procedures and RHA data reduction.

C.3.5.1 Technology validation. The general requirements for a technology validation are defined in [3.4.1.4](#). For RHA technology the following items shall be added:

- a. Radiation test procedures.
- b. RHA data reduction (e.g., interface state and oxide trapped charge separation).

C.3.6 RHA packages. Packages used for RHA microcircuits shall be characterized for effects that may influence the hardness of packaged product. Characterization shall include impedance of the power and ground distribution network, impedance contributions of bond wires and die attach, and the impedance associated with any passive elements included as integral parts of the package. Qualification of the same die in different packages shall require demonstration either by test or similarity analysis.

C.3.7 Demonstration vehicles. The demonstration vehicles shall be as described in [H.3.4.1.3](#). Each demonstration vehicle shall operate and perform in compliance with the device specification and to the RHACL for a radiation hardened process (which shall be submitted to the qualifying activity) and shall be manufactured in packages which have been tested to [C.3.6](#) herein prior to use for qualification. For a technology that has die as its primary product, the demonstration vehicle shall be suitably packaged to allow evaluation of the technology without adversely affecting the outcome of the tests.

C.3.7.1 Qualification test plan. See [H.3.4.2](#). Note that for RHA, the die traceability shall be to the individual wafer.

C.3.7.2 Qualification test report. For RHA testing, the pre and post irradiation, electrical parameters and the transient and SEE test conditions shall be retained by the manufacturer.

MIL-PRF-38535J

APPENDIX C

C.4 VERIFICATION

C.4.1 Traceability. Traceability to the wafer lot level (for GaAs to wafer level) shall be provided for all delivered microcircuits. Traceability shall document, as a minimum, the completion of each step required in design (when applicable), fabrication, assembly, test and any applicable qualified rework procedure.

C.4.2 Design requirements. The manufacturer shall show evidence that all QML/RHA product has been through the qualified RHA technology flow. For RHA devices, sample testing of each design to verify PIPL shall be conducted to determine total dose and neutron hardness level, dose rate upset threshold, latch-up immunity (when specified) at maximum temperature and voltage, and linear energy transfer threshold (LET_{TH}) for upset and latch-up as well as the cross section for SEE. If simulation models can be verified by test to address these concerns, they would be acceptable. It is anticipated that several designs of each ASIC family shall be tested.

C.4.3 Radiation response characterization. When specified in the acquisition document, radiation response characterization data shall be provided for QML microcircuits in those environments specified in the device specification. The characterization shall be obtained in increments of irradiation levels to failure or to a radiation level at or beyond the specification level as determined by the TRB. The characterization data shall be accompanied by the mean and standard deviation of the critical parameters. The results obtained from [table C-I](#) testing herein shall be added to the characterization data (at fluence level, dose rate, and parameter levels defined in the device procurement specification test conditions) periodically.

C.4.4 End-of-line technology conformance inspection (TCI) testing (option 1). Group E inspection shall include radiation hardness assurance (RHA) tests on each wafer lot. The PIPL, transient and single event phenomenon (SEP) response (as applicable), and test conditions shall be as specified in the device specification. End-of-line TCI testing shall be performed as recommended in [table J-I](#) herein. Requirements as detailed in TM 5005 of MIL-STD-883 may be used, with qualifying activity approval, in place of the TCI requirements herein. All group E testing shall be performed on microcircuits to be delivered as RHA QML microcircuits.

Group E inspection is required only for parts intended to be marked as RHA. RHA quality conformance inspection sample tests shall be performed at the level(s) specified and in accordance with [table C-I](#) herein. The applicable subgroups of group E shall be performed when specified in the acquisition document. The actual devices used for group E testing shall be assembled in a qualified package and, as a minimum, shall pass [table I](#), group A, subgroups 1, 7, and 9 at +25°C prior to irradiation. If a manufacturer elects to eliminate a quality conformance inspection step by substituting an in-process control or statistical process control procedure, the manufacturer is only relieved of the responsibility of performing the TCI operation associated with that step. The manufacturer is still responsible for providing a product which meets all of the performance, quality, and reliability requirements herein and in the device specification. Documentation supporting substitution for TCI shall be retained by the manufacturer and available to the qualifying activity upon request. For some devices, there are differences in the total dose radiation response before and after burn-in. Unless it has been shown by prior characterization or by design that burn-in has negligible effect (parameters remain within post-irradiation specified electrical limits) on the total dose radiation response, one of the following shall be done:

- a. The manufacturer shall subject the radiation samples to the specified burn-in conditions prior to conducting total dose radiation testing.
- b. The manufacturer shall develop a correction factor (which is acceptable to the parties to the test) taking into account the changes in total dose response resulting from subjecting product to burn-in. The correction factor shall then be used to accept product for total dose response without subjecting the test samples to burn-in.

MIL-PRF-38535J

APPENDIX C

C.4.4.1 End-point tests for group E. End-point measurements and other specified post-test measurements shall be made for each sample after completion of all other specified tests in the subgroup. The test limits for the end-point measurements shall be the same as the test limits for the respective group A subgroup inspections. Different end-points may be specified for group E tests in the detailed specifications. Any additional end-point electrical measurements may be performed at the discretion of the manufacturer.

C.4.5 In-line TCI testing (option 2). In-line control testing shall be performed through the use of the approved SEC or QML microcircuit. The following shall be addressed for RHA devices; group E testing shall be performed on the SEC or product meeting SEC complexity at intervals set by the TRB in the QM plan. Burn-in shall be addressed as per C.4.4 a or C.4.4 b above.

TABLE C-I. Group E (RHA testing), Class Q. 1/

TEST	MIL-STD-883		RHACL/SPEC <u>2/</u>	Quantity <u>3/</u> (accept no.)
	Method	Condition		
<u>Subgroup 1</u> Neutron irradiation <u>4/</u>	1017	+25°C	> 10 > 1 ≤ 10	No testing required 2(0) devices/wafer 5(0) devices/wafer lot 11(0) devices/inspection lot <u>5/</u>
End-point electrical parameters		As specified in the applicable device specification		
<u>Subgroup 2</u> Total ionizing radiation dose	1019	+25°C	> 10 > 1 ≤ 10	No testing required 2(0) devices/wafer 5(0) devices/wafer lot 22(0) devices/inspection lot <u>6/</u>
End-point electrical parameters		As specified in the applicable device specification		
<u>Subgroup 3</u> Single event effects (SEE)	JESD57 or ASTM F1192	+25°C		<u>4/</u>

- 1/ Parts used for one subgroup test may not be used for other subgroups but may be used for higher levels in the same subgroup. Total dose exposure shall not be considered cumulative unless testing is performed within the time limits of the test method. For class V level product see [table B-1](#).
- 2/ The RHACL/SPEC is the ratio of the capability level to the specification level of fluence.
- 3/ Based on each wafer lot. Alternatively, each wafer may be accepted on a 2(0) quantity (accept) number. If the alternate is chosen, a PDA of 10 percent or equivalent shall apply to the lot.
- 4/ Test to be conducted only when specified in the order or contract.
- 5/ In accordance with inspection lot. If one part fails, 16 additional parts may be added to the test sample with no additional failures allowed, 27(1).
- 6/ In accordance with inspection lot. If one part fails, 16 additional parts may be added to the test sample with no additional failures allowed, 38(1).

APPENDIX D

STATISTICAL SAMPLING, TEST, AND INSPECTION PROCEDURES

D.1 SCOPE

D.1.1 Scope. This appendix contains statistical sampling, life test, and qualification procedures used with microcircuits. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance.

D.2 APPLICABLE DOCUMENTS

(This section is not applicable to this appendix.)

D.3 REQUIREMENTS

D.3.1 Definitions. The following definitions shall apply for all statistical sampling procedures:

- a. Sample size series: The sample size series is defined as the following decreasing series of values: 50, 30, 20, 15, 10, 7, 5, 3, 2, 1.5, 1, 0.7, 0.5, 0.3, 0.2, 0.15, and 0.1.
- b. Tightened inspection: Tightened inspection is defined as inspection performed using the next sample size value in the sample size series lower than that specified.
- c. Acceptance number (c): The acceptance number is defined as an integral number associated with the selected sample size which determines the maximum number of defectives permitted for that sample size.
- d. Rejection number (r): Rejection number is defined as one plus the acceptance number.

D.3.2 Symbols. The following symbols shall apply for all statistical sampling procedures:

- a. Acceptance number (c).
- b. Rejection number (r).

D.4 STATISTICAL SAMPLING PROCEDURES AND TABLE

D.4.1 General. Statistical sampling shall be conducted using the sample size method. The sample size method as specified herein is a sampling plan which provides a high degree of assurance that a lot having a percent defective greater than or equal to the specified sample size value shall not be accepted. The procedures specified herein are suitable for all quality conformance requirements.

D.4.1.1 Selection of samples. Samples shall be randomly selected from the inspection lot or inspection sublots. For continuous production, the manufacturer, at their option, may select the sample in a regular periodic manner during manufacture provided the lot meets the formation of lots requirement.

D.4.1.2 Failures. Failure of a unit for one or more tests of a subgroup shall be charged as a single failure.

D.4.2 Single-lot sampling method. Quality conformance inspection information (sample sizes and number of observed defectives) shall be accumulated from a single inspection lot to demonstrate conformance to the individual subgroup criteria.

MIL-PRF-38535J

APPENDIX D

D.4.2.1 Sample size. The sample size for each subgroup shall be determined from table D-I or D-II and shall meet the specified sample size series. The manufacturer may, at their option, select a sample size greater than that required; however, the number of failures permitted shall not exceed the acceptance number associated with the chosen sample size in table D-I or D-II. In table D-II, the sample size series column to be used for sample size determination shall be that given in the lot size column which is nearest in value of the actual size of the submitted lot, except that if the actual lot size is midway between two of the lot sizes given in the table, either of the bounding lot size columns may be used at the manufacturer's option. If, in table D-II, the appropriate lot size column does not contain a sample size series value equal to or less than the specified sample size series value, 100 percent inspection shall be used. In table D-II, the sample size series value in the appropriate lot size column that is numerically closest to the specified sample size series value shall be used to determine the sample size.

D.4.2.2 Acceptance procedure. For the first sampling, an acceptance number shall be chosen and the associated number of sample devices for the specified sample series selected and tested (see D.4.2.1). If the observed number of defectives from the first sample is less than or equal to the preselected acceptance number, the lot shall be accepted. If the observed number of defectives exceeds the preselected acceptance number, an additional sample may be chosen such that the total sample complies with D.4.2.3. The table (D-I or D-II), which is used for the first sampling of a given inspection lot for a given subgroup shall be used for any and all subsequent samplings for the same lot and subgroup for each lot submission.

D.4.2.3 Additional sample. The manufacturer may add an additional quantity to the initial sample, but this may be done only once for any subgroup and is limited to the initial sample (i.e., does not apply to resubmitted lots after initial failure). The added samples shall be subjected to all the tests within the subgroup. The total sample size (initial and added samples) shall be determined by the new acceptance number selected from table D-I or D-II).

D.4.2.4 Multiple criteria. When one sample is used for more than one acceptance criterion, the entire sample for a subgroup shall be used for all criteria within the subgroup. In table D-I, the acceptance number shall be that one associated with the largest sample size in the appropriate sample size series column which is less than or equal to the sample size used. In table D-II, the acceptance number shall be that one associated with the specified samples size series, in the appropriate lot size column, for the sample size used.

D.4.2.5 One hundred percent inspection. Inspection of 100 percent of the lot shall be allowed, at the option of the manufacturer, for any or all subgroups other than those which are called "destructive". If the observed percent defective for the inspection lot exceeds the specified samples size series value, the lot shall be considered to have failed the appropriate subgroup(s). Resubmission of lots tested on a 100 percent inspection basis shall also be on a 100 percent inspection basis only and in accordance with the tightened inspection sample series value and other requirements of A.4.3.3.1.

D.4.2.6 Tightened inspection. Tightened inspection shall be performed by testing to the criteria of the next sample size series value lower than that specified in the series 1, 1.5, 2, 3, 5, and 7 times 10^n , where n is an integral number.

TABLE D-I. Sample size series (SSS) sampling plan. 1/ 2/ 3/

1/ Sample sizes are based upon the Poisson exponential binomial limit.

2/ The minimum quality (approximate acceptable quality level (AQL)) required to accept (on the average) 19 of 20 lots is shown in parenthesis for information only.

3/ Minimum size of sample to be tested to assure with a 90 percent confidence that a lot having percent-defective equal to the specified sample size series value will not be accepted (single sample).

APPENDIX D

TABLE D-II. Hypergeometric sampling plans for small homogenous lot sizes of 200 or less. - Continued.

Table D-II gives the acceptable quality level (AQL) and sample size series (SSS) values associated with certain single sampling plans (acceptance number, sample size, and lot size). The table has the following features:

- a. Calculations are based upon the hypergeometric distribution (exact theory) for lot sizes 200 or less.
- b. The AQL of a sampling plan is defined as the interpolated percent defective for which there is a 0.95 probability of acceptance under the plan. The AQL so defined need not be a realizable lot percent defective for the lot size involved (e.g., 12 percent is not a realizable percent defective for a lot size of 20).
- c. The sample size series of a sampling plan is defined as the interpolated percent defective for which there is a 0.10 probability of lot acceptance under the plan. The sample size series value so defined need not be a realizable lot percent defective for the lot size involved.
- d. The sequence of sample sizes and lot sizes are generated by taking products of preceding numbers in the respective sequences.

GENERAL PROVISIONS FOR TAPE AUTOMATED BONDED MICROCIRCUITS

F.1 SCOPE

F.1.1 Scope. This appendix contains provisions for tape automated bonded (TAB) microcircuits. It provides design guidelines, in-process controls, screening and technology conformance inspection (TCI) requirements, and general manufacturing guidelines in order to produce a compliant TAB microcircuit. It is intended for use in conjunction with a manufacturer's compliancy program. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance. However, for QML microcircuits the manufacturers may offer approved alternatives that demonstrate a process control system that achieves at least the same level of quality and reliability as could be achieved by this appendix.

F.2 APPLICABLE DOCUMENTS

F.2.1 General. The documents listed in this section are specified in sections F.3 or F.4 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in sections F.3 and F.4 of this appendix, whether or not they are listed.

F.2.2 Government documents.

F.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE STANDARD

MIL-STD-883 - Test Method Standard Microcircuits.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

F.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

JESD22-A101	- Steady-State Temperature Humidity Bias Life Test.
JESD22-A112	- Moisture-Induced Stress Sensitivity for Plastic Surface Mount Devices.
J-STD-020D.01	- Joint IPC/JEDEC Standard for Moisture/Reflow Sensitivity Classification For Nonhermetic Solid State Surface Mount Devices.

(Copies of these documents are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

(Non-Government standards and other publications are normally available from the organizations that prepare or distribute the documents. These documents also may be available in or through libraries or other informational services.)

F.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein (except for related specification sheets), the text of this document shall take precedence. Nothing in this document, however, shall supersede applicable laws and regulations unless a specific exemption has been obtained.

MIL-PRF-38535J

APPENDIX F

F.3 REQUIREMENTS

F.3.1 Marking. Marking shall be in accordance with the device specification and in an appropriate medium. The following should be used as guidance: Marking may be in ink, laser marked or etched in the copper of the lead frame tape. Ink-marking may be performed before or after burn-in. Ink-marked parts shall be subjected to resistance to solvents (TM 2015 of MIL-STD-883, (see [F.4.7.2.1](#) herein)). In either the ink-marked or tape design case, the following should be included on each device:

- a. On the excised portion of the tape (that portion which remains with the microcircuit):
 - (1) Name of manufacturer or Commercial and Government Entity (CAGE) code.
 - (2) Inspection lot date code (determined by the date of final assembly operation, such as date of encapsulation or date of bonding operation).
- b. The following should also be marked on each device, but location may be on the non-excised portion of the tape, the individual device carrier, or the excised portion of the tape at the manufacturers option:
 - (1) Part or identifying number (PIN).
 - (2) Electrostatic discharge (ESD) identifier.
 - (3) Compliance indicator or certification, whichever is applicable.
 - (4) Serialization, if applicable.

F.3.2 Process monitors. The applicable process monitors of [A.3.4.1.2](#) shall be performed. The quality assurance provisions described below within this appendix shall be used to address some of these process monitors.

F.3.3 Lead finish. Lead finish shall be gold, designated a "C", unless otherwise specified in the device specification.

F.3.4 Item requirements. The individual item requirements for TAB microcircuits delivered under this appendix shall be documented in the device specification prepared in accordance with [3.5](#) of this specification.

MIL-PRF-38535J

APPENDIX F

F.4 VERIFICATION

F.4.1 General operation flow. The following represents the general operational flow that TAB microcircuits follow.

<u>Reference paragraph</u>	<u>Operation</u>
F.4.6.1	Internal visual (optional)
F.4.3	Bump (100 percent)
F.4.3.1	Bump visual
F.4.4.1	Bond process characterization (100 percent)
F.4.4.2	Visual inspection of bond Visual
F.4.6.2	Internal visual (100 percent)
F.4.5	Encapsulant (optional)
F.4.5.1	Encapsulant visual
F.4.6.3	Temperature cycle (100 percent)
F.3.1	Mark (100 percent)
F.4.6.4	Pre burn-in electrical (optional)
F.4.6.4	Burn-in (100 percent)
F.4.6.4	Post burn-in electrical (100 percent)
F.4.6.5	PDA
F.4.6.6	External visual (100 percent)
F.4.7	Quality conformance inspection

F.4.2 Tape. Procurement of tape shall be baselined by the manufacturer to include the following items [F.4.2 a](#) through [F.4.2 f](#). Items e and f shall be sampled on a frequency basis necessary to demonstrate process control.

- Design configuration.
- Tape composition.
- Coefficient of thermal expansion.
- Test for delamination of layers.
- Plating thickness and composition.
- Dimensions (lead, terminal, external, and window).

F.4.3 Bump. The bump process shall be baselined by the manufacturer to include the following items [F.4.3a](#) through [F.4.3j](#). Items [F.4.3f](#) through [F.4.3j](#) shall be sampled on a frequency basis necessary to demonstrate process control.

- Minimum glassivation overlap.
- Barrier metal system - deposition, composition.
- Step coverage (bump to glassivation).
- Design configuration.
- Thickness of barrier metal.
- Thickness of bump.
- Hardness.
- Bump height uniformity.
- Bump shear.
- Bath purity.

MIL-PRF-38535J

APPENDIX F

F.4.3.1 Visual examination of bump. Visual examination of the bump is required prior to bond. Sample size and accept/reject limits shall be documented and determined by the manufacturer, and, at a minimum, address the following areas:

- a. Alignment of bump to pad.
- b. Contaminants, conductive residue.
- c. Bleeding bump (metallization exposed to higher than normal temperature excursions).
- d. Ineffective or improper photoresist application or removal.
- e. Cracks, voids.
- f. Partial or missing bumps.
- g. Nodules or malformed bumps.
- h. Discolored bumps.
- i. Mechanically damaged bumps.

F.4.4 Bond. Bond requirements shall be as specified in [F.4.4.1](#) through [F.4.4.2](#) inclusive.

F.4.4.1 Bond process characterization. Process characterization of inner lead bond (ILB) is critical to the quality and reliability of a TAB device and shall be performed and documented to ascertain the minimum, maximum, and mean destructive bond pull limits to meet the requirements set forth herein. During the process characterization the following factors shall be considered and included as appropriate:

- a. Tape composition.
- b. Bond force.
- c. Bond temperature.
- d. Bond pressure.
- e. Underlying layers such as:
 - (1) Bump configuration.
 - (2) Glassivation composition.
 - (3) Bond pad opening.
- f. Any underlying metallization and passivation.
- g. Cracking (the manufacturer shall evaluate the significance of any cracking throughout the device including around and below the bump area).

MIL-PRF-38535J

APPENDIX F

F.4.4.2 Visual inspection of bond. Visual inspection of bond is required prior to encapsulation. Sample size and accept/reject limits shall be documented and determined by the manufacturer, and, at a minimum, shall include the following criteria:

- a. ILB lead to bump alignment.
- b. Lead contact length; bond lead contact length (L) shall be greater than the lead width (W). (See [figure F-1](#).)
- c. Lead side edge overhang shall be evaluated.
- d. No open/lifted, peeling, or missing leads.
- e. No visual shorts.
- f. Cracks in bumps, thin film gold bump pad, glassivation, metal, or active area adjacent to the inner lead bond bumps shall not exceed the characterization requirements in [F.4.4.1](#).
- g. For single point bonds, the tool impression shall cover 100 percent of the lead to bump contact width.
- h. For alloy bonds, fillet shall be visible on at least one side of the lead continuously across the bump.

F.4.5 Encapsulant. The following items a - h, as a minimum, shall be baselined by the manufacturer, and items g - h shall be sampled on a frequency basis necessary to demonstrate process control.

- a. Coefficient of thermal expansion and relationship to underlying layers.
- b. Presence of volatile components.
- c. Gel time and temperature.
- d. Cure profile (initial, ramp, and final): Time and temperature.
- e. Final properties of cured polymer.
- f. Storage of encapsulant.
- g. Thickness.
- h. Viscosity.

MIL-PRF-38535J

APPENDIX F

F.4.5.1 Visual examination of encapsulant. Visual inspection of the applied encapsulant post-cure is required. Sample size and accept/reject limits shall be documented and determined by the manufacturer, and, at a minimum, address the following areas:

- a. Cracks.
- b. Voids.
- c. Lack of interfacial adhesion.
- d. Poor uniformity.
- e. Stress on underlying layers.
- f. Coverage of desired area.

F.4.6 Screening. One hundred percent screening shall be performed in accordance with TM 5004 of MIL-STD-883, with the following deletions and additions:

F.4.6.1 Optional internal visual. An optional internal visual examination may be performed prior to bump utilizing applicable criteria within TM 2010 of MIL-STD-883 or manufacturer's internal criteria in order to screen die defects. Sample size and accept/reject criteria shall be determined and documented by the manufacturer.

F.4.6.2 Internal visual screen. One hundred percent internal visual examination shall be performed prior to encapsulant utilizing applicable criteria within TM 2010 of MIL-STD-883 to screen die defects. At the manufacturer's option, bump visual and ILB visual may be combined with this internal visual examination provided 100 percent of the product is examined.

F.4.6.3 Temperature cycle. One hundred percent temperature cycle shall be performed in accordance with TM 1010 of MIL-STD-883, test condition C.

F.4.6.4 Burn-in. One hundred percent pre, interim, and post burn-in electrical test shall be performed in accordance with the device specification. One hundred percent burn-in shall be performed in accordance with TM 1015 of MIL-STD-883.

F.4.6.5 Percent defective allowable (PDA). PDA shall be calculated in accordance with TM 5004 of MIL-STD-883.

F.4.6.6 External visual. One hundred percent external visual examination shall be performed in accordance with TM 2009 of MIL-STD-883 or manufacturer's applicable external criteria.

F.4.7 Quality conformance inspection (QCI). QCI shall be performed in accordance with TM 5005 of MIL-STD-883 with the following deletions and additions:

F.4.7.1 Group A inspection. Group A inspection shall be in accordance with TM 5005 of MIL-STD-883 and the applicable device specification.

F.4.7.2 Group B inspection. Group B inspection shall be in accordance with the following:

F.4.7.2.1 Resistance to solvents. Resistance to solvents (TM 2015 of MIL-STD-883) shall be performed when ink marking is utilized. Sample size shall be in accordance with TM 5005 of MIL-STD-883.

F.4.7.2.2 Attachability. Attachability of the outer lead bond shall be assured as documented in the device specification and shall include sample size and accept/reject limits.

MIL-PRF-38535J

APPENDIX F

F.4.7.2.3 Destructive bond strength. Destructive bond strength (TM 2011 of MIL-STD-883) shall be performed, prior to encapsulation, on inner lead bonds and may be performed during the assembly operation, prior to burn-in. Sample size shall be in accordance with TM 5005 of MIL-STD-883. The minimum value of destructive bond strength shall be documented in the device specification. Defect criteria shall include identification of the site of failure at one or more of the following areas:

- a. Lead lift.
- b. Lead break at bump.
- c. Lead break away from bump.
- d. Lead break at tape window.
- e. Metal peels off tape.
- f. Bump delamination from thin film metal.
- g. Thin film metal delamination.
- h. Crater under bump.
- i. Not bonded.
- j. Error (operator, machine, hook slips, etc.).

F.4.7.2.4 Constant acceleration. Constant acceleration (TM 2001 of MIL-STD-883, test condition E (min), Y1 direction only) shall only be required if documented in the device specification.

F.4.7.3 Group C inspection. Group C inspection shall be performed in accordance with TM 1005 of MIL-STD-883. Sample size shall be in accordance with TM 5005 of MIL-STD-883. Initial group C shall be completed utilizing TAB packaging, while subsequent group C inspections may be performed utilizing alternate packaging technology.

F.4.7.4 Group D inspection. Group D inspection shall be in accordance with TM 5005 of MIL-STD-883 with the following deletions and additions:

- a. Subgroup 1 of [table IV](#) shall be performed as specified.
- b. Subgroups 2, 6, 7, and 8 of [table IV](#) of TM 5005 shall not be performed.
- c. Subgroup 3 of [table IV](#) of TM 5005 shall be performed as specified with the exception of moisture resistance (TM 1004) and seal (TM 1014).
- d. Subgroup 4 of [table IV](#) of TM 5005 shall be performed as specified with the exception of constant acceleration (unless specified in the device specification) (TM 2001) and seal (TM 1014).
- e. Subgroup 5 of [table IV](#) of TM 5005 shall be performed as specified with the exception of seal (TM 1014).

MIL-PRF-38535J

APPENDIX F

F.4.7.4.1 Highly accelerated stress testing (HAST). HAST shall be performed in accordance with J-STD-020, and shall be performed using a sample size number (accept number) of 15(0) for 50 hours at +130°C at 85 percent relative humidity and a voltage bias applied. As an option, 85/85 testing in accordance with JESD22-A101 shall be performed using 15(0) sample size (accept number) for 1,000 hours.

F.4.7.4.2 Post-test visual examinations. Post-test visual examinations shall be performed in accordance with F.4.6.6 of this appendix.

F.4.8 Major changes. Major changes shall be as set forth in MIL-PRF-38535 as applicable. In addition, the following shall be considered as a major change:

- a. Any change to baselined items in this appendix.
- b. Bond characterization parameters.

$$L > W$$

FIGURE F-1. Lead contact length.

MIL-PRF-38535J

APPENDIX G

THE QUALIFIED MANUFACTURERS LISTING PROGRAM

G.1 SCOPE

G.1.1 Scope. The Qualified Manufacturers Listing (QML) program measures and evaluates the manufacturers' manufacturing process against a baseline for that process. This baseline can include innovative and improved processes that result in an equivalent or higher quality product, provided that the process used to evaluate and document these changes has been reviewed and approved. Changes to the process baseline can be made by the manufacturer's Technology Review Board (TRB) after achieving QML status with documented reliability and quality data. The approach outlined in this appendix is a proven baseline which contains details of the quality management (QM) program including the TRB, the QM plan, and change control procedures. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance. However, for QML microcircuits the manufacturers may offer approved alternatives that demonstrate a process control system that achieves at least the same level of quality and reliability as could be achieved by this appendix.

G.2 APPLICABLE DOCUMENTS

G.2.1 General. The documents listed in this section are specified in section G.3 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in section G.3 of this appendix, whether or not they are listed.

G.2.2 Other Government documents, drawings, and publications. The following other Government documents, drawings, and publications form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DSCC-VQC-42 - Baseline Sheet for Microcircuits Materials and Construction.

(Copies of DSCC-VQC-42 are available from DLA Land and Maritime (ATTN: DLA Land and Maritime-VQC), P.O. Box 3990, Columbus, OH 43218-3990.)

G.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

EIA557 - Statistical Process Control Systems.

(Copies of this document are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

G.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein, the text of this document shall take precedence. Nothing in this document, however, shall supersede applicable laws and regulations unless a specific exemption has been obtained.

MIL-PRF-38535J

APPENDIX G

G.3 REQUIREMENTS. The requirements of the microcircuits are classified in the generic qualification flow diagram (see [figure G-1](#)).

G.3.1 QM program. A quality management program shall be developed and implemented by the manufacturer and documented in the QM plan (see [G.3.3](#) herein). Also, the manufacturer shall have a self-assessment program with an evaluation system similar to that posed by the Malcolm Baldrige National Quality Award, and the results of this assessment shall be made available for review. The manufacturer is encouraged to apply for the Malcolm Baldrige National Quality Award within 5 years of initial request for QML status.

G.3.2 Manufacturer's review system. The manufacturer's review system, known as the TRB, is responsible for development of the QM plan, maintenance of all certified and qualified processes, process change control (see [3.3.4](#)), reliability data analysis, failure analysis, corrective actions, QML microcircuit recall procedures, and qualification status of the technology.

G.3.2.1 Organizational structure. The manufacturer's TRB should insure communication is established and maintained among representatives from device design, technology development, wafer fabrication, assembly, testing, quality assurance and third party organizations. Records of the TRB deliberations and decisions should be maintained. These records shall be made available to the qualifying activity (QA). The manufacturer shall submit the name(s) and telephone numbers of their TRB systems' contact person(s) to the QA.

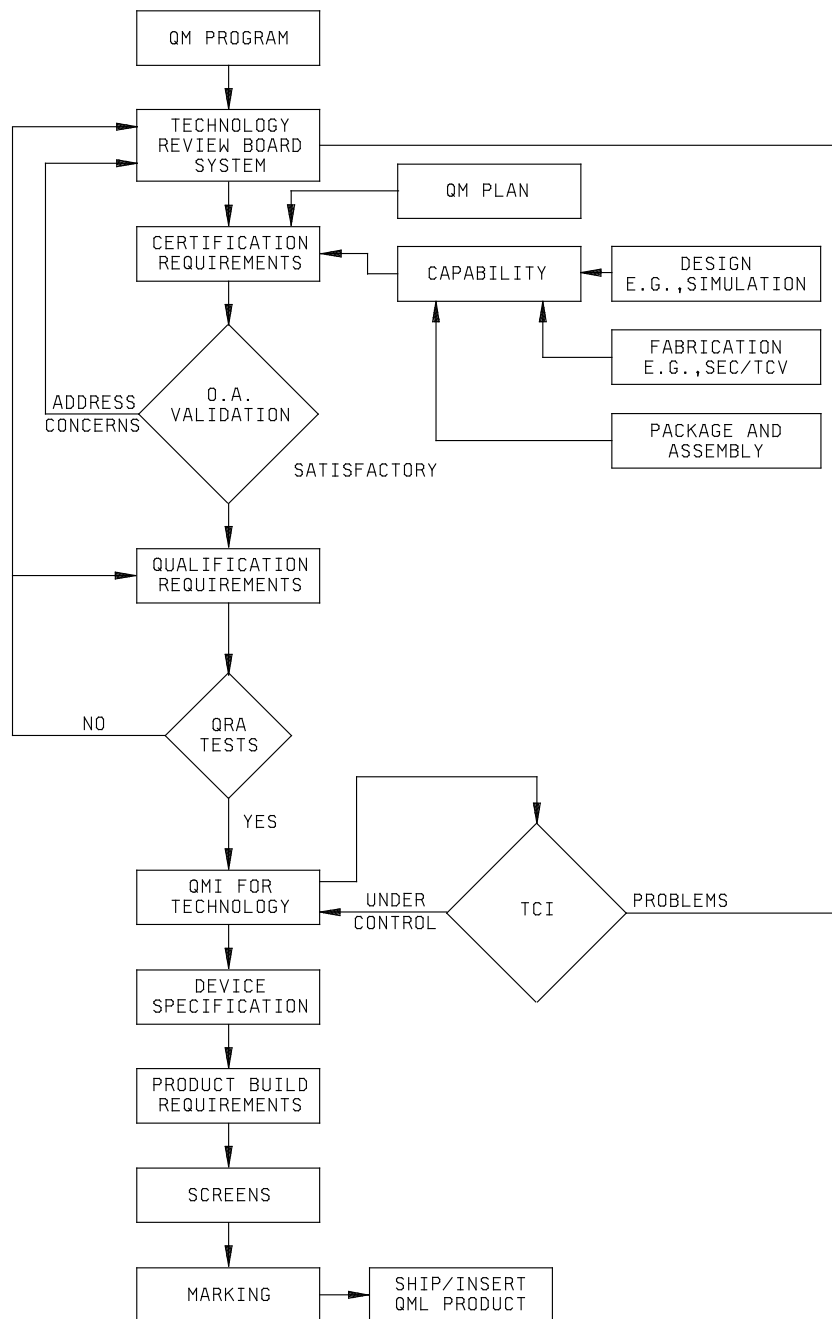

G.3.2.2 TRB duties. The TRB shall keep the QA updated on the status of QML technology and products. The TRB should have a methodology in place for assessing the current status of the quality and reliability of its microcircuits by review of the Statistical Process Control (SPC) procedures and QM status of the manufacturer's process technology, reliability test data (i.e., parametric monitor (PM), Technology Characterization Vehicle (TCV), Standard Evaluation Circuit (SEC) and device), and the Failure Analysis (FA) results of burn-in/screening failures and board/assembly failures and field returns, as applicable. A method or procedure to verify correlation between test structures and actual product should be approved by the TRB. The TRB shall maintain records, available for QA review, of conditions found and the action taken. The TRB is required to report periodically to the QA on the status of the QML technology and products (see [G.3.2.3](#) herein). The TRB should also address the impact of key managerial/TRB personnel changes and business plans in order to evaluate any impact they may have on the QML system.

When the reliability data indicates corrective action is required, the TRB should determine and implement the appropriate action in a timely manner. The SEC and TCV (see [G.3.3f](#) herein) data are to be used as a tool for monitoring the quality and reliability of the manufacturer's line and do not automatically disqualify a manufacturer when trends or limits require corrective action.

When reliability of shipped microcircuits is called into question, the TRB should provide evaluation and corrective action and prompt notification to the QA to preserve the manufacturer's qualified status and assure that defective product is not shipped.

MIL-PRF-38535J

APPENDIX G

FIGURE G-1. Generic qualification flow diagram.

MIL-PRF-38535J

APPENDIX G

G.3.2.2.1 QML certification and qualification test plan (see [G.3.3 g](#)). Before a management and technology validation is scheduled, the manufacturer should submit to the QA a TRB approved test plan with milestone charts outlining the tests to be used to certify processes and the tests and devices to be used to qualify the certified processes to the requirements of [3.4.1](#). The TRB shall determine the tests to be accomplished on the TCV, SEC, and parametric monitor and submit to the QA a test plan with parametric limits and accept and reject criteria.

G.3.2.3 Status report. The manufacturer's TRB shall submit a status report to the QA describing the health of the QML manufacturer's line including all changes and the criticality of the changes in microcircuit quality, reliability, performance, and interchangeability. The manufacturer should retain the support test data. The QA can request to review the supporting data. The following areas should be addressed in each status report: (The information in the status report may be addressed in various ways, such as, copies of TRB meeting minutes, summary of major actions, etc.)

- a. Field returns and corrective actions.
- b. SPC and continuous improvement program update (e.g., defect density summary, in-process reliability monitors, Capability Index of process center (Cpk) programs, etc.).
- c. SEC and TCV test data summary, including radiation data if applicable.
- d. Design facility.
- e. Fabrication line.
- f. Assembly facility.
- g. Test facility.
- h. Major changes.
- i. Newly qualified packages.
- j. Third party activities.
- k. Yield issue trends and corrective actions.

The interval of the status reports to the QA shall be determined by the TRB, but should be as a minimum, quarterly for the first year following the attainment of QML status and as a minimum, semiannually (no further than six months apart) thereafter. If major problems with the technology are encountered, more frequent reports may be required by the QA to keep informed of the status. In addition to the above report, the manufacturer shall make a presentation yearly to the QA outlining the status of the technology, products offered, future trends and other strategic business plans of the technology including foreseen changes. At the discretion of the QA, this presentation may be in lieu of a status report.

MIL-PRF-38535J

APPENDIX G

G.3.3 QM plan. The TRB shall oversee and approve the QM plan consisting of the following activities and initiatives, as a minimum:

- a. Quality improvement plan. This plan documents the specific procedures to be followed by the manufacturer to assure continuous improvement in quality, and reliability of the process and the product being produced.
- b. Failure analysis program. This program establishes the procedures that a manufacturer self-imposes to test and analyze sufficient failed parts to determine each failure category from all stages of manufacturing and the field. This program should also identify corrective actions or specify the use of a corrective action plan based on the findings of the failure analysis.
- c. SPC plan. A specific plan defining the manufacturer's SPC program, within the manufacturing process, to the requirements of EIA557.
- d. Corrective action plan. This plan should specify the specific steps followed by the manufacturer to correct any process that is out of control or found to be defective.
- e. Change control program. This program addresses the process by which a manufacturer addresses changes to the technology. Further information of areas to be considered critical for change control are outlined in [G.3.4](#) herein.
- f. SEC and TCV assessment program. The frequency, testing methods, and criteria for evaluations of the SEC or the TCV or both, including correlation of test structures and actual product, are to be determined by the TRB based on the manufacturer's assessment of risk. The manufacturer's SEC and TCV evaluation plan shall be documented.
- g. Certification and qualification plan. The certification and qualification plan should be defined in [appendix H](#) including self-assessment and corrective actions.
- h. Retention of data. This program establishes the requirements for data retention (see [A.4.8.1.2](#) as a guideline).

G.3.3.1 QM plan outline. The following should be addressed in the QM plan. Submittal of the QM plan is required before the validation (certification) meeting.

NOTE: Many of these items and their associated documentation may be reviewed during the validation.

- a. Index of certified baseline documents. A list of the specification titles, document numbers, and revisions that make up the QML program. This is the baseline the manufacturer was certified to at a validation review.
- b. Conversion of customer requirements. A system for converting all customer's requirements into in-house requirements. This includes determining if certification and QML coverage exist. The following are both part of the QM plan and the manufacturer's conversion system:
 - (1) Device specification requirements (Standard Microcircuit Drawing (SMD)).
 - (2) Controlled design procedures and tools (established geometric, electrical, and reliability design rules).
 - (3) Mask generation procedure within the controlled design procedures of [G.3.3.1b.\(2\)](#).
 - (4) Wafer fabrication and assembly capabilities baselined.
 - (5) Design, mask, fabrication, assembly, and test flows.

MIL-PRF-38535J

APPENDIX G

- (6) QML listing coverage.
- (7) SEC, TCV or alternate assessment procedure, and PM programs and test procedures (see [G.3.3f](#)).
- (8) Incoming inspection and vendor procurement document covering design, mask, fabrication, and assembly.
- (9) Screening and traveler.
- (10) Technology conformance Inspection (TCI) procedures, including identification of destructive/nondestructive classification of tests.
- (11) Marking.
- (12) Rework.
- c. Functional organization chart covering the TRB, quality assurance, and production.
- d. Change control program (see [G.3.4](#) herein). This item shall consist of a system by which changes to the QML program are classified and necessary actions taken. The following shall be addressed, as a minimum:
 - (1) Major changes.
 - (2) Required testing.
 - (3) TRB responsibility (e.g., notification policy).
 - (4) TRB MIL-PRF-38535 program interface for DLA Land and Maritime.
- e. Failure analysis (see [G.3.3 b](#)).
- f. Self-audit program and audit results.
- g. TRB reporting to DLA Land and Maritime, including checklist and procedure.
- h. Yield improvement program (see [G.3.3 a](#)).
- i. SPC program (EIA-557 should be used as a guideline) including, goals and plans of implementation, in-line Process Monitors , SPC measurement points (including location and procedure number on applicable flow charts; see [G.3.3 c](#)).
- j. List of test methods for laboratory suitability including any outside lab.
- k. Major test methods for which data may be requested to be submitted:
 - (1) Burn-in.
 - (2) Temperature cycle.
 - (3) Fine and gross leak.
 - (4) Particle impact noise detection (PIND).
 - (5) Temperature/humidity testing.

MIL-PRF-38535J

APPENDIX G

- (6) Preconditioning (board assembly/rework simulation.)
- (7) Wafer (lot) acceptance.
- (8) Internal visual.
- (9) Nondestructive bond pull (NDBP).
- (10) Scanning electron microscope (SEM) or nondestructive SEM.
- (11) Life test.
- (12) Radiographic inspection.
- (13) Radiation testing.
- l. Calibration.
- m. Retention of qualification.
- n. Training.
- o. Cleanliness and atmospheric controls.
- p. Electrostatic discharge (ESD) sensitivity program.
- q. Certification and qualification test plan (see [G.3.2.2.1](#)).
- r. Process for control of third party activities.
- s. Characterization procedures for new technology validation.

G.3.4 Change control procedures. The following paragraphs outline areas of concern where a change may require action by the manufacturer. All changes to any part of a QML manufacturer's line are to be governed by the manufacturer's TRB and made available to the QA. All changes should be documented as to the reason for the change with supporting data taken to support the change, including reliability data as appropriate. The decision as to the criticality of the change shall be guided by the potential effect of the change on quality, reliability, specified radiation hardness assurance levels (when applicable), performance and interchangeability of the resulting microcircuits. For any change that merits consideration for requalification, the TRB should decide if requalification is needed. Microcircuits should be shipped following a change only upon approval of the TRB. Modifications to screens and TCI's are allowed but shall be justified, documented, and submitted to the QA. Notification of the change should be made concurrently to the QA for a period of not less than one year after initial QML listing. Thereafter, notification should be made in the TRB status reports (see [G.3.2.3](#) herein). The manufacturer may make notification of this change of product through the Government-Industry Data Exchange Program (GIDEP) using the Product Change Notice; in any case, the manufacturer should assure that all known acquiring activities are notified. For major changes to class level "S" microcircuits, the manufacturer's TRB shall notify the QA who will coordinate with the space community of changes prior to shipment. The manufacturer shall review all changes for applicability to previous test optimizations and alternate test methods.

MIL-PRF-38535J

APPENDIX G

G.3.4.1 Design methodology change. Changes in the design methodology to be evaluated by the TRB shall include, but not be limited to, changes in the following areas:

- a. Technology database (cell/design library).
- b. Design flow.
- c. Design system (computer automated design (CAD), design rules).
- d. Software updates.
- e. Model or modeling procedures.
- f. Configuration management.
- g. Radiation hardness assurance (RHA) (if applicable).
- h. Electrical performance.
- i. Geometry size reduction.

G.3.4.2 Fabrication process change. Changes in the fabrication process to be evaluated by the TRB shall include, but not be limited to, changes in the following areas:

- a. Fabrication process sequence or process limits.
- b. Fabrication process materials or material specifications, including epitaxial (EPI) layer thickness.
- c. Photoresistive materials or material specifications.
- d. Doping material source, concentration, or process technique (e.g., ion implantation versus diffusion).
- e. Cross section diffusion profile.
- f. Passivation or glassivation material, thickness or technique (including addition or deletion of passivation).
- g. Metallization system (pattern, material, deposition or etching technique, line width or thickness).
- h. Baseline (DSCC-VQC-42 form or equivalent).
- i. Conductor, resistor, or dielectric materials.
- j. Wafer fabrication move from one line, or building, to another.
- k. Passivation, or glassivation, process temperature and time.
- l. Oxidation or diffusion process, oxide composition and thickness, oxidation temperature and time.
- m. Sintering or annealing temperature and time.
- n. SEC and how it is tested.
- o. Method of mask making.
- p. Parametric monitor and how it is tested.

MIL-PRF-38535J

APPENDIX G

- q. Wafer acceptance criteria.
- r. TCV and how it is tested.
- s. Sample plans (quantity and acceptance numbers).
- t. Gate formation process, material, technique.
- u. Backside process to include wafer thinning and backside metallization.
- v. Ohmic contact formation.
- w. Starting material qualification (i.e., gallium arsenide (GaAs) boule).
- x. Lot formation.

G.3.4.3 Assembly process change. Changes in the assembly process to be evaluated by the TRB shall include, but not be limited to, changes in the following areas:

- a. Die attach material, method, or location.
- b. Wire/ribbon bond interconnect method.
- c. Wire material composition and dimensions.
- d. Seal technique (materials or sealing process, gas composition (e.g., for RHA)).
- e. Implementation procedures for internal visual and other test methods.
- f. Assembly flow.
- g. Assembly operation move.
- h. Scribing and die separation method.
- i. TCI procedures including manufacturer imposed tests.
- j. Screening tests.
- k. Sample plans (quantity and acceptance numbers).
- l. Die back surface preparation.
- m. Bond pad geometry, spacing, or metallization.
- n. Molding material, method, or location.
- o. Chip encapsulation/coating material and technique.
- p. Device marking process.
- q. Lot formation.

MIL-PRF-38535J

APPENDIX G

G.3.4.4 Package change. Changes in the package qualification to be evaluated by the TRB shall include, but not be limited to, changes in the following areas:

- a. Vendor.
- b. External dimensions.
- c. Cavity dimensions.
- d. Number of leads or terminals.
- e. Lead or terminal dimensions (length times width or diameter).
- f. Lead or terminal base material.
- g. Lead or terminal plating material.
- h. Lead or terminal plating thickness (range of).
- i. Body material.
- j. Body plating material.
- k. Body plating thickness (range of).
- l. Die pad material.
- m. Die pad plating.
- n. Die pad plating thickness (range of).
- o. Lid material.
- p. Lid plating materials (range of).
- q. Lid plating thickness (range of).
- r. Lid seal (preform) material.
- s. Lid glass seal material.
- t. Lead glass seal material.
- u. Lead glass seal diameter (range of).
- v. Leads or terminals spacing.
- w. Lead configuration (e.g., J-lead, gull-wing).
- x. Die size.
- y. Device marking process.
- z. Lead attachment.

G.3.4.5 Test facility change. Changes in the test facility to be evaluated by the TRB shall include, but not be limited to, changes in the following areas:

- a. Implementation procedures for internal visual and other test methods.
- b. Testing flow.
- c. Test facility (with laboratory suitability) move from one facility or building to another.
- d. Sample plans (quantity and acceptance numbers).
- e. Test procedures (including test vector generation).
- f. Lot formation.

APPENDIX G

(This page intentionally left blank.)

MIL-PRF-38535J

APPENDIX H

CERTIFICATION, VALIDATION, AND QUALIFICATION

H.1 SCOPE

H.1.1 Scope. The qualified manufacturers listing (QML) program applies quantifiable measurement techniques that evaluate a manufacturer's ability to define and follow a baseline of its process. This baseline can include innovative and improved processes that result in an equivalent or higher quality product, provided that the methods used to evaluate and document these changes have been reviewed and approved. Once QML status is achieved, the manufacturer's Technical Review Board (TRB) may approve change(s) to the process baseline based on appropriate reliability and quality data upon concurrent with notification of the Qualifying Activity (QA). The approach outlined in this appendix contains a proven baseline that includes details of the certification, validation, and qualification programs. The necessary characterization, screening, and qualification testing applicable to new technologies is also included. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance. However, for QML microcircuits the manufacturers may offer approved alternatives that demonstrate a system that achieves at least the same level of quality and reliability as could be achieved by this appendix.

H.2 APPLICABLE DOCUMENTS

H.2.1 General. The documents listed in this section are specified in section H.3 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in section H.3 Requirements of this appendix, whether or not they are listed.

H.2.2 Government documents.

H.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE SPECIFICATION

MIL-M-38510 - Microcircuits, General Specification For.

DEPARTMENT OF DEFENSE STANDARD

MIL-STD-883 - Test Method Standard Microcircuits.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

MIL-PRF-38535J

APPENDIX H

H.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

EIA557	- Statistical Process Control Systems.
JESD78	- IC Latch-up Test.
JESD22-A102	- Accelerated Moisture Resistance – Unbiased Autoclave.
JESD22-A104	- Temperature Cycling.
JESD22-A106	- Thermal Shock.
JESD22-A110	- Highly – Accelerated Temperature and Humidity Stress Test (HAST).
JESD22-A114	- Electrostatic Discharge (ESD) Sensitivity testing Human Body Model (HBM).

(Copies of these documents are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

AMERICAN SOCIETY FOR TESTING AND MATERIALS (ASTM)

ASTM D2863	- Standard Test Method for Measuring the Minimum Oxygen Concentration to Support Candle-Like Combustion of Plastics (Oxygen Index).
ASTM F1269	- Test methods for Destructive Shear Testing of Ball Bonds.
ASTM G21	- Standard Practice for Determining Resistance of Synthetic Polymeric Materials to Fungi.

(Copies of these documents are available online at <http://www.astm.org/> or from ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.)

UNDERWRITERSLABORATORIES INC. (UL)

UL 94	- Tests for Flammability of Plastic Materials for Parts in Devices and Appliances.
-------	--

(Copies of this document are available online at <http://www.ul.com/> or from Underwriters Laboratories Inc. (UL), 333 Pfingsten Road, Northbrook, IL 60062-2096.)

H.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein, the text of this document shall take precedence. Nothing in this document, however, shall supersede applicable laws and regulations unless a specific exemption has been obtained.

H.3 REQUIREMENTS

H.3.1 General. The qualifying activity (QA) shall evaluate the manufacturer's approach to the process baseline. The manufacturer shall have a quality management (QM) plan specifying the characterization, certification, and qualification plans of technologies and product (see appendix G). New technologies shall also be included and have a checklist defining the necessary requirements for calculate/evaluation of failure mechanism, activation energy, characterization plan, qualification plan and validation. The QM plan shall be submitted to the QA for approval (see G.3.3.1s). For class level S product, the manufacturer shall evaluate the changes listed in table A-I in conjunction with the QA to determine if a change should be classified as a new technology.

H.3.1.1. Characterization requirements. Testing performed with the intent to understand the technology part, materials, and processes used to determine an item's capability. The manufacturer should evaluate of their process to determine the long term reliability of the product. For class level S product, a detailed characterization plan identifying critical parameters, test conditions, durations, required measurements, sample size, and temperatures shall be documented, including a detailed physics-of-failure analysis considering mechanical, thermal, electrical, and chemical properties that could contribute to failures. A failure modes effects analysis approach must be followed to ensure to the maximum extent possible that all significant failure mechanisms have been defined and appropriate mitigation techniques have been identified.

MIL-PRF-38535J

APPENDIX H

H.3.1.2 Certification. Validation, by the QA, that the manufacturer has the capability of producing product which meets or exceeds the requirements contained in this specification. The manufacturer shall document the certification plan as documented in their QM plan. The qualifying activity shall be notified if deviations or exception are taken from the approved plan.

H.3.1.3 Validation. Verification by the QA that the manufacturer has met or exceeded the requirements utilizing data, demonstration, other approved techniques, or a combination thereof.

H.3.1.4 Transitional certification. Temporary certification (approximately 2 years maximum) given by the QA to manufacturers working toward full QML certification.

H.3.1.5 Qualification requirements. Evidence that the characterization testing and evaluations of failure mechanisms show the technology meets or exceeds documented requirements. The qualification methodology will vary depending upon the technology. The manufacturer shall document the qualification plan that is applicable to each technology. The qualification testing for new technologies shall consist of standard military test methods as outlined in MIL-PRF-38535, MIL-STD-883, or the QM plan as approved by the QA, including any tests deemed necessary by the characterization and physics-of-failure analysis.

H.3.1.6 New technology requirements. For class level B product, this is a product family, material, or process, that has never been previously characterized and qualified by the manufacturer, and is detailed in the manufacturer's new technology insertion program (see [3.4.1.1.1](#) and [6.4.42](#)).

For class level S product, this is a product family, material, or process, that has never been previously characterized and qualified by the manufacturer for space applications, and is detailed in the manufacturer's new technology insertion program (see [3.4.1.1.1](#), [6.4.42](#) and [B.3.9](#)).

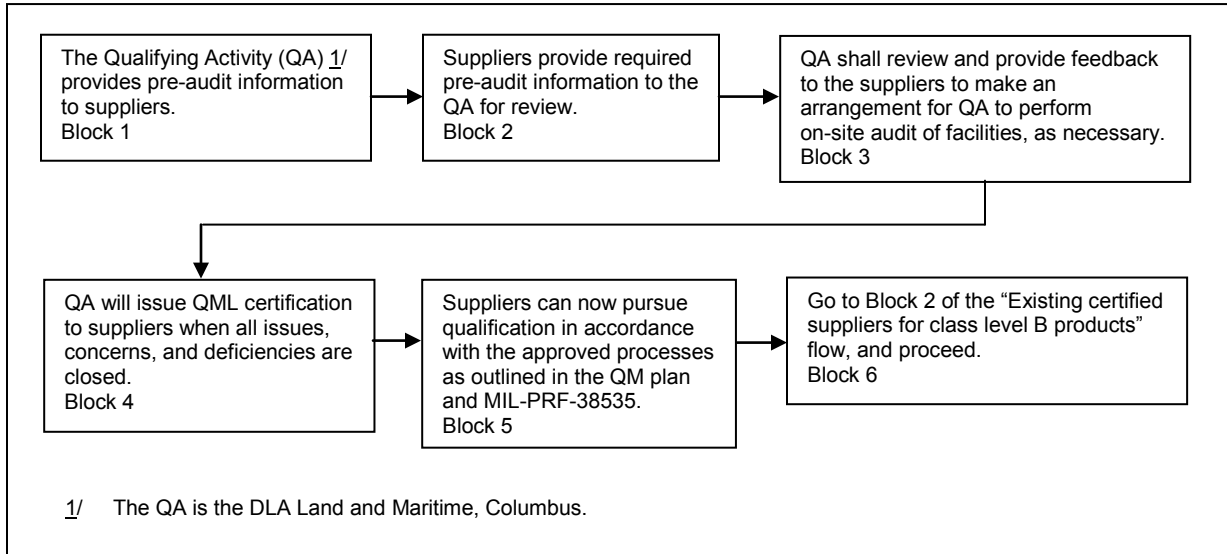

H.3.1.7 Mature technology requirements. A mature technology is one which the manufacturer has previously released to production the techniques, materials, controls, design, and has a continuous reliability monitor plan in place to identify major reliability life-limiting mechanisms, establish activation energy, detect long-term product shifts, and generate process data or established proof of stable process and/or equipment with negligible wear out (see [6.4.43](#)).

H.3.1.8 General QML process flows. The general QML process flows for new suppliers, and existing certified suppliers, providing class level B products is shown in [figure H-1](#), and for new suppliers, and existing certified suppliers, providing class level S products is shown in [figure H-2](#).

APPENDIX H

H.3.1.9 Overview of QML Approval Process. The process for achieving QML approval is outlined below in six basic stages and is further described in detail in the subsequent sections. The stages are listed in the normal sequence to be accomplished; however, several stages may occur concurrently.

- a) Design, wafer fabrication, assembly, and test certification;
 - 1) Design methodologies:
 - i) Reliability and radiation hardness assurance (RHA) design rules.
 - 2) Wafer fabrication/foundry processes:
 - i) SPC controls
 - ii) Metallization controls
 - iii) Reliability monitors
 - 3) Assembly processes
 - 4) Screening and Test Methodologies
 - 5) Audit/approval
- b) Physics of failure/TCV reliability assessment;
 - 1) Plan approval
 - i) Electromigration (EM)
 - ii) Time dependent dielectric breakdown (TDDB)
 - iii) Hot carrier injection (HCI)
 - iv) Threshold voltage instability, including Negative Bias Temperature Instability (NBTI) for 130 nm and smaller CMOS technologies.
 - v) Others as applicable
 - 2) Report approval
- c) Process technology validation/SEC qualification;
 - 1) Plan approval
 - i) Screening flow
 - ii) Process performance characterizations
 - iii) Process qualification tests
 - iv) For class level B products, life test on a minimum of 1 wafer lot for 1000 hrs minimum at 125°C ambient, or equivalent.
 - v) For class level S products, long term life test shall meet the requirements of paragraph B.3.4, appendix B, or shall meet long term life test on a minimum of 1 wafer lot for 4,000 hours minimum at 125°C ambient, or equivalent.
 - 2) Report approval
- d) Product qualification (From existing qualified process technology)
 - 1) Plan approval
 - i) Screening flow
 - ii) Product performance characterizations
 - iii) Product qualification tests
 - iv) 1,000 hour life test or equivalent
 - 2) Report approval
- e) Standard Microcircuit Drawing (SMD)
 - 1) Draft development
 - 2) User coordination
 - 3) SMD release
- f) QML listing

MIL-PRF-38535J

APPENDIX H

H.3.1.10 Manufacturer's Responsibility. It is the manufacturer's responsibility to ensure all of the defined systems and controls are fully implemented and operational as defined in this specification, appendices, and applicable standards and specifications. The manufacturer shall provide a focal point representative for the coordination and communication of QML program.

H.3.1.11 Qualifying Activity (QA) Responsibility. The QA is responsible for the coordination between the government agencies in the performance of quality audits and report approvals. The QA shall consolidate concerns and observations from the various agencies to provide a jointly agreed position to provide to the manufacturer in addressing audit deficiencies and in meeting the specified requirements.

Any request for data, additional testing, or new manufacturing requirements, for a QML manufacturer, that were not part of the QA approved certification, qualification test plan, or DLA Land and Maritime audit results, must be provided to and approved by the QA. Supporting data for the request shall also be provided to the QA. Upon approval by the QA, the QA shall submit the request or requirement to the QML manufacturer. The QA shall arrange any necessary conference calls or site visits with the QML manufacturer.

H.3.2 Certification.

H.3.2.1 Design, Wafer Fabrication, Assembly, and Test Certification. The QA shall perform certification validation of the Design, Wafer Fabrication, Assembly, and Test capabilities of the manufacturer. The QA validation shall include analysis of data, and demonstration of the manufacturer's capability, to meet the requirements for certification in the following areas:

H.3.2.1.1 Design. The manufacturer should address the design methodology for the following areas of design.

NOTE: These are also applicable to third party design centers.

H.3.2.1.1.1 Circuit design. QML microcircuits should address the circuit design requirements and performance characteristics herein:

- a. Model verification. Provide evidence that all models utilized in the design process are functional, predictable, and accurate over the worst case temperature and electrical extremes. Examples of these models are: electrical (transistor, passives, interconnect, package), behavioral, logic, fault, timing, signal integrity, power estimation and thermal conductivity.
- b. Layout verification. Demonstrate the capability of the automated or manual procedures routinely used for design, electrical, and reliability rule checking to catch all known errors, singularly and in combination. These rules cover, as a minimum:
 - (1) Design rules check (DRC): Geometric and physical.
 - (2) Electrical rules check (ERC): Shorts and open, connectivity.
 - (3) Reliability rules: Electromigration and current density, IR drops, latch-up, single event upset (SEU), hot carrier injection (HCI), electrostatic discharge (ESD), burnout backgating (for gallium arsenide (GaAs) technology).
- c. Performance verification. The manufacturer should design and construct a chip or set of chips to assess the process capability to perform routing and to accurately predict post-routing performance. The manufacturer should demonstrate that the actual measured performance for each function over temperature and voltage falls between the two worst case performance limits or is covered by statistical models. All critical minimum geometric and electrical design rules should be stressed via devices or structures located on the SEC, TCV, or PMs. The electrical stress requirements for the transistors, passive devices and interconnects on these structures should be determined by worst case circuit conditions. Failure analysis (FA) should be conducted to identify the failure mechanisms occurring in any failed devices and/or structures. Corrections to the design or to the verification/screening method shall be undertaken to mitigate any future occurrences of failures. These changes shall be presented to the QA prior to implementation if part of a new technology test plan. It is allowed that the manufacturer may choose actual product for their TCV or SEC.

MIL-PRF-38535J

APPENDIX H

- d. Testability and fault coverage verification. The manufacturer should demonstrate a design style and a design-for-test (DFT) methodology that, in conjunction with demonstrated CAD for test tools, can provide 99 percent or greater fault coverage on a design of reasonable complexity. The manufacturer should also address their approach for a testability bus to groups such as the Joint Test Action Group (JTAG). The manufacturer should demonstrate the fault coverage measurement (fault simulation, test algorithm analysis, etc.) capability that is used to provide fault coverage statistics of the design using the demonstrated design style, DFT method and CAD for test tools. Measurement of fault coverage should be in accordance with the procedures defined in TM 5012 of MIL-STD-883. For non-digital microcircuits, the fault coverage requirement may not be applicable, but should be supplemented as measures of analog fault coverage become better defined. For microcircuits with both analog and digital functions, this requirement fully applies to the digital portions of the microcircuits.

H.3.2.1.1.2 Design checklist (Class level S) . The following items shall be used as minimum requirements, as applicable for the technology, for the manufacturer and QA in evaluating the new technology for class level S product:

- a. Design environment/infrastructure.
 - (1) Project schedule.
 - (2) Resource management (i.e. designers, hardware, software development).
 - (3) Historical factors (i.e. any pertinent information based on previous designs, design rules, lessons learned, etc.).
 - (4) Tools and design flow.
 - (5) ASIC cell library and design kit.
 - (6) Intellectual property (IP, i.e. any pertinent information such as use of 3rd party licensed IP, IP developed by another entity or manufacturer, etc.).
 - (7) Models (for those developing their own cell libraries, and ASIC design kits), for analog/signal integrity simulations, and power calculations.
- b. Detailed design hardware description language (HDL) coding (first phase of design).
 - (1) Specification development guidelines (i.e. what design information must be included in the specification).
 - (2) HDL coding guidelines.
 - (3) Design for test (DFT) insertion and fault testing.
 - (4) Built-in self test (BIST).
- c. Validation/verification of modules and top level design.
 - (1) Fault coverage percentage.
 - (2) Emulation/prototyping.
 - (3) Radiation effects mitigation.
- d. Synthesis, static timing.
 - (1) Foundry synthesis guidelines – Handoff to design team
 - (2) Formulation of constraints from specification/requirements.
 - (3) Synthesis and statically timed net list – Correlated with original HDL.

MIL-PRF-38535J

APPENDIX H

e. Physical design.

- (1) Foundry physical design guidelines – Handoff to design team
- (2) Placement based on partitioning, architecture, I/O location.
- (3) Static timing analysis, with iterated placement, cell sizing and routing to achieve timing closure.

f. Release to foundry.

- (1) Foundry run rule checks
- (2) Critical design/final design review, utilizing foundry checklists.

H.3.2.1.1.3 Package Design. Packages used for QML microcircuits should address the design requirements and performance characteristics herein. Characterization may be performed by the microcircuit manufacturer, by an external lab, or by the package supplier. In any case, the manufacturer's assembly of QML microcircuits should address all the testing requirements herein. The manufacturer shall address package design/construction quality and reliability. The manufacturer is responsible to maintain documented validation of all characterization methods used, including all supporting data.

- a. Thermal characterization. The thermal resistance should be determined for all packages used in the manufacture of QML parts. This value may be obtained by direct or indirect measurements, or by simulation tools or calculations. TM 1012 of MIL-STD-883 may be used for this calculation. If the thermal resistance is obtained by a calculation or simulation tool, this procedure should be certified. To certify such a method of theoretical estimation, the manufacturer shall demonstrate a correlation between the theoretically estimated value and the actual measured value for at least one package of the same style with equal or greater pin count.
- b. Electrical characterization. The following electrical characterization parameters should be addressed:
 - (1) Ground and power supply impedance. Packages used in the manufacture of QML microcircuits should be minimal contributors to ground and power supply noise. The above requirement can be met either through the use of documented package design rules or through testing of the packages, either individually or by similarity, in accordance with TM 3019 of MIL-STD-883.
 - (2) Cross-coupling effects. Cross-coupling of wideband digital signals and noise between pins in packages used for digital QML microcircuits should be minimized. The above requirement can be met either through the use of documented package design rules or through testing of the packages, either individually or by similarity, in accordance with TM 3017 and TM 3018 of MIL-STD-883.
 - (3) High voltage effects. The voltage applied to a QML package should not produce a surface or bulk leakage between adjacent package conductors (including leads or terminals). The above requirement can be met either through the use of documented high voltage package design rules aimed at minimizing bulk or surface leakage, or through testing of the high voltage packages, either individually or by similarity, in accordance with TM 1003 of MIL-STD-883.

MIL-PRF-38535J

APPENDIX H

H.3.2.1.2 Wafer fabrication. This includes the manufacturer's in-house fabrication or the subcontractor's fabrication. The wafer fabrication quality systems and controls include statistical process control (SPC) and in-process monitoring programs including the technology characterization vehicle (TCV) program or the Standard Evaluation Circuit (SEC) or alternate assessment procedure with the approval of qualifying activity and parametric monitors (PMs).

As part of certification, the manufacturer should identify a specific technology or technologies for the wafer fabrication. A technology consists of the fabrication sequence, design rules and electrical characteristics. Demonstration of wafer fabrication capability consists of the fabrication sequence, design rules, electrical characteristics, and process information. All supporting documentation and data shall be made available to the qualifying activity before or during the management and technology validation (see [G.3.2.2.1](#)).

A plan shall also be presented that provides for an on-going reliability monitor and failure rate calculations.

H.3.2.1.2.1 Wafer fabrication checklist (Class level S). The following items shall be used as minimum requirements, as applicable for the technology, for the manufacturer and QA in evaluating the new technology for class level S product:

- a. Process development
 - (1) Design of experiments (This information may not be readily available for older technologies especially when a process is transferred from another facility).
 - (2) Process sensitivity (This will define what parameters within the process would identify if the process is stable or marginal. Process variation is different and shows the process can yield even when the parameters are at minimum or maximum).
 - (3) Modeling and simulation.
 - (4) Producibility and yield analysis.
- b. Process characterization.
 - (1) Voltage.
 - (2) Temperature (Minimum range of -55°C to +125°C, otherwise provide justification).
 - (3) Process variability.
 - (4) Best and worst case or statistical simulation models considering independent variation of device types (e.g. NFET and PFET).
 - (5) Frequency (Defined by the electrical requirements of the device specification).
 - (6) Radiation ([see appendix C](#))
 - (7) Performance margins (until failure).
 - (8) Process optimization.
 - (9) Process maturity assessment.

MIL-PRF-38535J

APPENDIX H

- c. Process qualification.
 - (1) Test vehicle.
 - (2) Single or 1 lot.
 - (3) Environmental conditions (This is for fabrication, test, assembly, and storage).
 - (4) Accept/reject criteria.
 - (5) Perceptivity of tests (This means that the test vehicle and electrical tests must be capable of discerning whatever the critical parameters are that define acceptance/rejection i.e. 2ns timing delays if that is the failure criterion).
 - (6) Process baselined for qualification (Process has been characterized and no changes are required).
 - (7) Qualification by test, similarity, or space heritage (A process or device that has been produced and passed space level testing and has flown in a space environment similar to the environment expected for this process/device).
- d. Fabrication.
 - (1) TRB program (or equivalent) (see [G.3.2.2](#)).
 - (2) SPC and in-process monitoring program (see [H.3.2.1.3](#)).
- e. Radiation hardness assurance (RHA) (see appendix C).

H.3.2.1.3 SPC and in-process monitoring program. An in-process monitoring system should be used by the manufacturer to control key processing steps to insure device yield, reliability, and RHA if applicable. The monitoring system can utilize various test structures, methods, and measurement techniques. The critical operations to be monitored should be determined by the manufacturer based on their experience and knowledge of their processes. The resulting data should be analyzed by appropriate SPC methods (in accordance with the requirements of EIA557) to determine control effectiveness. The following should be addressed for the wafer fabrication process, as a minimum, by the manufacturer:

- a. Incoming mask and fabrication process materials.
- b. Equipment used for wafer fabrication.
- c. Doping material concentration.
- d. Cross section diffusion or concentration profile, and epitaxial (EPI) layer.
- e. Passivation or glassivation.
- f. Metallization deposition.
- g. Resultant line width.
- h. Passivation process temperature and time.
- i. Diffusion, implant anneals process temperature, and time, or both.
- j. Sintering or annealing temperature and time.
- k. All reliability test data including the standard evaluation circuit (SEC).
- l. Mask inspection and defect density data.
- m. Parametric monitor test data.
- n. Photoresistive processing (including rework procedures).

MIL-PRF-38535J

APPENDIX H

- o. Ion implant.
- p. Wafer backside preparation.
- q. Wafer probe acceptance criteria.
- r. Rework policy.
- s. Oxide process.
- t. Gate formation.
- u. Air bridge process.
- v. Via hole process.
- w. Clean room procedures.
- x. Change control system/notification.
- y. Lot travelers (Lot travelers shall document steps required and what specification to use at that step and then fill in who performed a step and when. Specifications shall document SPC requirements as part of the operating instructions at the particular step and spell out the format to use).
- z. Equipment calibration and maintenance.
- aa. Wafer traceability.
- ab. Wafer acceptance plan.

H.3.2.1.3.1 SPC and in-process monitor checklist (Class level S) . The following items shall be used as minimum requirements, as applicable for the technology, for the manufacturer and QA in evaluating the new technology for class level S product:

- a. Define SPC monitor points.
- b. Define control limits and absolute limits.
- c. Review of data by the manufacturer and QA.
- d. Out of control (OOC) action plans.
- e. Radiation performance.
- f. Process capability (C_{PK}) trigger level.
- g. Sample data for any prime lot review by the manufacturer and QA (Prime lot is defined as a lot meeting all process monitor requirements with no MRB or out of control actions implemented).
- h. SPC controls in place audited by the QA.

MIL-PRF-38535J

APPENDIX H

H.3.2.1.3.2 Parametric monitor (PM) . The manufacturer should have PMs to be used for measuring electrical characteristics of each wafer type in a specified technology. The PM test structures can be incorporated into the grid (kerf), within a device chip, as a dedicated drop-in die or any combination thereof. Location of the PM test structures should be optimally positioned to allow for the determination of the uniformity across the wafer. A suggested location scheme is one near the wafer center and one in each of the four quadrants of the wafer, at least two-thirds of a radius away from the wafer center. The manufacturer should establish, and document, reject limits and procedures for parametric measurements including which parameters shall be monitored routinely and which shall be included in the SPC program. Documentation of the PM should also include PM test structure design, test procedure (including electrical measurement at temperature and the relationship between the measured limits and those determined in the manufacturer's circuit simulations), design rules and process rules. Alternate measurement techniques, such as in-line monitors, are acceptable if properly documented. The following parameters are to be used as a guideline by the manufacturer's TRB in formulating the PM.

a. General electrical parameters.

- (1) Sheet resistance: Structures should be included to measure the sheet resistance of all conducting layers.
- (2) Junction breakdown: Structures should be included to measure junction breakdown voltages for all diffusions.
- (3) Contact resistance: Structures should be included to measure contact resistance of all inter-level contacts.
- (3) Ionic contamination and minority carrier life time: Structures should be included to measure ionic contamination, such as sodium, in the gate, field, and inter-metal dielectrics and minority carrier lifetime.

b. MOS parameters.

- (1) Gate oxide thickness: Structures should be included to measure gate oxide thickness for both "N" and "P" gate oxides as applicable.
- (2) MOS transistor parameters: A minimum set of test transistors should be included for the measurement of transistor parameters. The minimum transistor set should include a large geometry transistor of sufficient size that short channel and narrow width effects are negligible, and transistors that can separately demonstrate the maximum short channel effects and narrow width effects allowed by the geometric design rules. Both "N" and "P" transistors should be included for a complimentary metal oxide semiconductor (CMOS) technology. If there is more than one nominal threshold voltage for either the "N" or "P" transistor type the minimum set should be included for each threshold. The transistor parameters to be measured are given below:
 - (a) Threshold voltage: The linear threshold voltage (V_T) for each transistor in the minimum set of transistors should be measured.
 - (b) Linear transconductance: The linear transconductance (g_m) for the full minimum set of transistors should be measured.
 - (c) Effective channel length: The effective channel length for the minimum channel length of each transistor type should be measured.
 - (d) I_{on} : I_{on} for representative transistors in the set.
 - (e) I_{off} : I_{off} for representative transistors in the set.
 - (f) Propagation delay: A test structure should be available in the form of a functional circuit from which propagation delay information can be measured at room temperature.
 - (g) Field leakage: Field transistor leakage for the minimum spaced adjacent transistors at the maximum allowed voltage should be measured.

MIL-PRF-38535J

APPENDIX H

- c. Bipolar parameters. Care should be taken in the manner and sequence in which all breakdown voltage and current measurements are taken so as to not permanently alter the device for other measurements.
 - (1) Sheet resistance: Structures should be included which can be used to measure sheet resistance of all doped regions (e.g., emitter, buried collector.)
 - (2) Schottky diode parameters: The following measurements should be made on Schottky diodes representative of the size used in the technology:
 - (a) Reverse leakage: The reverse leakage current (I_R) should be measured at a specified reverse voltage.
 - (b) Reverse breakdown: The reverse breakdown voltage (BV) should be measured at a specified current.
 - (c) Forward voltage: The forward turn-on voltage (V_f) should be measured at a specified current.
 - (3) Bipolar transistor parameters: The following measurements should be made on bipolar transistors representative of the size and type used in the technology. The types should include NPN, Schottky clamped NPN, vertical PNP, substrate PNP, and lateral PNP transistors as applicable.
 - (a) Transistor gain: The common emitter dc current gain (H_{fe}) should be measured on representative transistors over three decades of collector current, the highest point of which is at the maximum rated current of the device.
 - (b) Leakage currents: The leakage currents (I_{CEO} , I_{CBO} , and I_{EBO}) should be measured on representative transistors at a specified voltage.
 - (c) Breakdown voltages: The breakdown voltages (BV_{EBO} , BV_{CBO} , and BV_{CEO}) should be measured on representative transistors at specified currents.
 - (d) Forward voltages: The forward voltages (V_{BE0} and V_{BC0}) should be measured on representative transistors at the rated currents.
 - (e) Propagation delay: A test structure should be available in the form of a functional circuit from which propagation delay information can be measured at room temperature.
 - (4) Isolation leakage: The isolation leakage current (I_L) between minimum spaced adjacent transistor collectors should be measured at a specified voltage.
- d. GaAs parameters.
 - (1) Sheet resistance: Structures should be included which can be used to measure sheet resistance of each of the conducting layers.
 - (2) Metal-insulator-metal (MIM) capacitor: Capacitor test structures should be included so that dc and rf capacitance, leakage, and breakdown can be measured.
 - (3) FAT FET: A long gate length FET suitable for measurement of Schottky barrier height and ideality factor, carrier concentration and mobility, and channel depth should be included.
 - (4) Isolation: A structure for use in measuring substrate isolation breakdown should be included.
 - (5) Ohmic contacts: An ohmic contact transmission line structure should be included so that specific contact resistance and transfer length can be measured.

MIL-PRF-38535J

APPENDIX H

- (6) GaAs FET parameters: FET test structures should be included, suitable for RF probing, which can be used for measurement of both DC and RF FET parameters. The following parameters should be measured:
 - (a) I_{dss} - saturated drain current at zero gate bias.
 - (b) g_m - transconductance at saturation and at 50 percent I_{dss} .
 - (c) Pinch off voltage.
 - (d) Gate-drain leakage and breakdown voltage.
 - (e) Gate-source breakdown voltage.
 - (f) Source and drain resistance.
 - (g) S-parameters of FET over frequency range of technology.
- e. Fast-test reliability structures. Fast-test reliability structures are structures meant to evaluate, within a few seconds of testing, a particular known reliability failure mechanism to insure that the processing which an individual wafer received is consistent with the reliability goals of the technology. The fast-test structures are in general new and, with the exception of hot carrier aging structures, are not sufficiently mature. Development work on them is intense however, and it is intended that these structures when mature, shall become a mandatory part of the PM. For this reason it has been decided to include information regarding fast-test reliability structures in the following paragraphs. Documentation should be available which shows the correlation between fast-tests and the results of the more traditional accelerated aging tests performed on the TCV.
 - (1) Hot carrier aging: A fast-test structure should be included to evaluate the susceptibility of MOS transistors to hot electron aging. This structure may be one of the PM test transistors.
 - (2) Electromigration: Worst-case design rule fast-test structures should be included to evaluate the susceptibility of each metal level and the associated contacts to electromigration.
 - (3) Time dependent dielectric breakdown (TDDB): Fast-test structures should be included that can evaluate the long-term reliability of gate oxides.
 - (4) Contact resistance: Fast-test structures should be included that can evaluate the long-term reliability of contacts.
 - (5) Gate diffusion: Fast-test structures should be included that can evaluate the long-term reliability of the gate contact.
 - (6) Threshold voltage instability, including Negative Bias Temperature Instability (NBTI) for 130 nm and smaller CMOS technologies.

H.3.2.1.4 Wafer acceptance plan. The TRB should develop and demonstrate a wafer acceptance plan based on electrical and radiation (if applicable) measurement of PMs. This plan should utilize the PM and should include visual criteria, if applicable. For wafer lot acceptance testing in accordance with TM 5007 of MIL-STD-883 or an alternative which meets the minimum requirements of TM 5007 on each wafer lot producing class V or S devices (see B.4.1.g). The use of TM 5013 of MIL-STD-883 is encouraged for GaAs technology devices. In addition, this plan should address the concerns detailed in TM 2018 of MIL-STD-883 (e.g., metallization, step coverage). The use of TM 2018 is encouraged, however alternate procedures utilizing PMs and in-line monitors are accepted if approved during validation. PM data should be recorded and made available for review. This plan can be either a wafer by wafer acceptance plan or a wafer lot acceptance plan, but shall address the following concerns:

- a. Small lots.
- b. Large lots.
- c. Specialty lots.

MIL-PRF-38535J

APPENDIX H

H.3.2.1.5 Assembly and packaging. This includes the manufacturer's in-house assembly or the subcontractor's assembly processes. The assembly quality systems and controls include statistical process control (SPC) and in-process monitoring programs shall be demonstrated.

As part of certification, the manufacturer should identify the specific assembly technologies. An assembly technology consists of the materials and processes used for wafer saw, die attach, wire bond, flip chip attachment, package sealing, lead attach, solder dipping, marking, and any other process involved with the construction of the product. All supporting documentation and data shall be made available to the qualifying activity before or during the management and technology validation (see [G.3.2.2.1](#)).

The following items shall be used as minimum requirements by the manufacturer and the QA in evaluating assembly and packaging for class level S product:

- a. Assembly processes.
 - (1) Die attach.
 - (2) Wire bond/bump.
 - (3) Encapsulation.
 - (4) Process monitors/SPC.
 - (5) Inspections.
 - (6) Tests – Mechanical, thermal, optical.
 - (7) Incoming tests or accompanying C of C on materials (i.e. package, die attach material, etc.).
- b. Package processes and technology.
 - (1) Design.
 - (2) Materials selection.
 - (3) Assembly under supplier control.
 - (a) By supplier.
 - (b) Subcontracted.
 - (4) Thermal characterization.
 - (a) Hot spots.
 - (b) Thermal impedance.
 - (5) Electrical characterization.
 - (a) At specification levels including voltage, full temperature range, and other excitation conditions.
 - (b) Beyond specification conditions to determine margin.
 - (c) Plan to address unspecified or untested parameters (Review analysis to ensure critical untested parameters are specified or addresses)
 - (6) Package qualification data.
 - (a) Incoming package tests on bare package.
 - (b) Incoming tests on raw materials (i.e. die attach, etc.)
 - (c) Mechanical tests.
 - (d) Thermal tests.
 - (e) Electrical tests.
 - (f) Thermal impedance.

MIL-PRF-38535J

APPENDIX H

H.3.2.1.5.1 SPC and in-process monitoring program. A process monitoring system should be used by a manufacturer to control key processing steps to insure product yield and reliability. The monitoring system can utilize various test chips, methods and measurement techniques. The critical operations to be monitored shall be determined by the manufacturer based on their experience and knowledge of their processes. The resulting data should be analyzed by appropriate SPC methods to determine control effectiveness. The following should be addressed, as a minimum, by the manufacturer:

- a. Incoming assembly process materials.
- b. Incoming package acceptance.
- c. Equipment used for assembly.
- d. Wafer acceptance criteria.
- e. Die attach.
- f. Chip to package interconnect (wire/ribbon bond, tab, flip chip).
- g. Package seal.
- h. Marking.
- i. Rework.
- j. Lead trim, form, and final finish.
- k. Atmosphere and cleanliness control.
- l. Chip encapsulation/molding.
- m. Encapsulant purity.
- n. Internal water vapor.

H.3.2.1.6 Test Capability. The manufacturer shall document within their quality system the implementation of all of the screening and qualification and technology conformance test conditions in accordance with the applicable Standard Military Drawing (SMD), MIL-PRF-38535, and MIL-STD-883, as applicable to the product.

H.3.2.1.7 Certification Approval. Upon the successful demonstration of meeting the certification requirements the QA will issue certification approval including identity of approved alternatives and test optimizations. Documentation and data presented by the manufacturer during the certification process do not need to be provided as part of the reliability assessment and qualification stages.

H.3.2.2 Physics of Failure/TCV Reliability Assessment

H.3.2.2.1 Reliability Assessment Plan. For class level S product, the manufacturer shall provide to the QA a reliability assessment plan for the technology. The plan shall account for all significant failure mechanisms as listed in the following sections.

H.3.2.2.2 Wafer Fabrication. A TCV program should be implemented by the manufacturer for the technology or process being considered for certification. The program should contain, as a minimum, those test structures needed to characterize a technology's susceptibility to intrinsic reliability failure mechanisms such as electromigration, time dependent dielectric breakdown (TDDB), gate sinking, ohmic contact degradation, sidegating/backgating, hot carrier aging and threshold voltage instability, including Negative Bias Temperature Instability (NBTI). If other wear out mechanisms are discovered as integrated circuit technology continues to mature, test structures for the new wear out mechanisms should be added to the TCV program. The TCV program shall be used for the following purposes: Certification of the technology; reliability monitoring; radiation hardness assurance and monitoring, when applicable; change control; and the characterization of fast-test intrinsic reliability structures.

NOTE: The test structures necessary to monitor intrinsic reliability failure mechanisms do not have to be a single die or location, but can appear on the PM, the SEC, or the device itself. The TCV program (see [G.3.3.f](#)) should, however, indicate where the structures are located and how they are tested and analyzed.

MIL-PRF-38535J

APPENDIX H

H.3.2.2.2.1 TCV certification. For initial reliability assessment, sufficient TCV test structures for each wear-out mechanism should be subjected to accelerated aging experiments. The TCV test structures should be randomly chosen from and evenly distributed from three homogeneous wafer lots in the technology to be certified in the fabrication facility to be certified. These wafers shall have passed the wafer or wafer lot acceptance requirements. The accelerated aging experiments should produce an estimate of the mean time to failure (MTTF) and a distribution of the failure times under worst case operating conditions and circuit layout consistent with the design rules for each wear-out mechanism. From the MTTF and distribution of failures a worst case operating lifetime or a worst case failure rate can be predicted. Test structures should be from completed wafers which have been passivated/ glassivated. A summary of the accelerated aging data and analysis should be available for review by the qualifying activity. The initial certification MTTF, failure distribution and acceleration factors should be used as benchmarks for the technology to which subsequent TCV results shall be compared. This includes evaluation of activation energy, acceleration factors based on voltage, temperature, frequency, etc for the technology, long term reliability and known failure mechanism (FMEA) and mitigation strategies. The current density and temperature acceleration factors for electromigration should be determined and a MTTF and failure distribution determined for the worst case current, temperature, and layout geometry allowed in the technology. From the MTTF and failure distribution, a failure rate for electromigration in the technology should be calculated.

All of the TCV test structures shall use the same packaging materials and assembly procedures as standard circuits in the technology. The TCV structures need not use a fully qualified package since qualified packages shall tend to have lead counts far in excess of those needed for intrinsic reliability studies. The packaging requirement for the TCV may be waived by the qualifying activity if the manufacturer can supply documentation showing the equivalence of wafer level and packaged accelerated aging results.

NOTE: In those cases where this may not be possible, the TCV should use a suitable package to allow for the evaluation of the chip technology to be qualified, without adversely affecting the outcome of the test.

An example of the requirements of packages for TCV test structure concerns the hydrogen content of a ceramic package and its effect on hot carrier aging, and can differ substantially for packaged and non-packaged devices. The minimum requirements to be addressed for the TCV structures for specific mechanisms are given below.

- a. Hot carrier aging. The TCV should use structures that monitor hot carrier aging applicable to the technology to be used in QML microcircuits. Device degradation is to be characterized in terms of both linear transconductance (g_m) and threshold voltage (V_{TH}) and the resistance to hot carrier aging is to be based on whichever parameter experiences the manufacturers' specified degradation limit for the minimum channel length and width allowed in the technology. A wafer level fast-test screen should be established for technologies that are susceptible to hot carrier aging. This test should be part of the wafer acceptance criteria.
 - (1) Metal oxide semiconductor (MOS). The TCV should have structures to characterize the effects of hot carrier aging as a function of channel length for MOS transistors for each of the nominal threshold voltages used in the technology. Degradation should be characterized in terms of g_m and V_{TH} .
 - (2) Bipolar. The TCV should contain structures for characterizing hot carrier aging of diodes in bipolar technologies.
- b. Electromigration. The TCV should contain structures for the worst case characterization of metal electromigration over:
 - (1) Flat surfaces.
 - (2) Worst case noncontact topography.
 - (3) Through contacts between conductive layers.
 - (4) Contacts to the substrate.

MIL-PRF-38535J

APPENDIX H

- c. Time dependent dielectric breakdown (TDDB) (MOS). The TCV should contain structures for characterizing TDDB of gate oxides. The structures should have gate oxide area and perimeter dominated structures. Separate perimeter structures should be used for the gate ending on a source or drain boundary and where the gate terminates over the transistor-to-transistor isolation oxide. The electric field and temperature acceleration factors for TDDB should be determined and a MTTF and failure distribution determined for the worst case voltage conditions and thinnest gate oxide allowed in the technology. From the MTTF, a failure rate for TDDB in the technology should be calculated.
- d. TCV fast test structure requirements. The structures to be used for the fast test reliability monitoring of hot electron aging should be included in the TCV program so that correlations of the fast-test measurements with the accelerated aging results may be made.

NOTE: It is strongly recommended that fast test intrinsic reliability structures for electromigration and TDDB be included in the TCV program so that correlations can be made with longer term aging experiments. It is likely that these structures shall be required for wafer acceptance in the future.

- e. Ohmic contact degradation. The TCV should have a structure for assessing the degradation of ohmic contacts with time at temperature, especially for gallium arsenide (GaAs).
- f. Sidegating/backgating. A structure should be included for evaluating sidegating/backgating of field effect transistor's (FET's) in GaAs technology.
- g. Sinking gate. A FET structure should be included for evaluating the sinking gate degradation mechanism and other channel degradation mechanisms of GaAs FET's.
- h. Threshold voltage instability, including Negative Bias Temperature Instability (NBTI) for 130 nm and smaller CMOS technologies. The NBTI test structure evaluates the effect due to interface traps (oxide energy states) in the gate oxide that form under DC inversion stress. Holes in the PMOS devices are known to interact with these traps more easily than electrons, and so this is a PMOS dominated mechanism. These trapped holes cause the threshold voltage (V_{TH}) of the affected transistor to shift lower (more negative) with increasing temperature, degrading device performance.

H.3.2.2.3 Assembly and Packaging. The manufacturer should list the assembly and packaging processes (die-attachment, wire/ribbon bonding, seal molding and part marking) that is expected to be listed on the QML and used in QML microcircuit assembly.

H.3.2.2.3.1 Assembly Process Technology. New assembly process technologies shall be characterized to determine the mechanical and thermal performance. The technology's susceptibility to intrinsic reliability failure mechanisms shall be characterized to determine potential failure modes. The characterizations may include performance of thermal stresses at multiple temperature levels to develop derating curves.

H.3.2.2.3.2 Packaging Technology. The manufacturer shall address package design/construction quality and reliability. The manufacturer is responsible to maintain documented validation of all characterization methods used, including all supporting data (see [H.3.2.1.1.3](#))

MIL-PRF-38535J

APPENDIX H

H.3.2.2.4 Reliability Assessment Report. For Class Level S product a reliability assessment report shall be submitted to the QA for review and approval in demonstrating that the reliability assessment was successfully completed.

H.3.3 Transitional certification.

H.3.3.1 Transitional certification and qualification. Manufacturers may be granted transitional certification based on the following requirements:

- a. The manufacturer has qualifying activity (QA) approval that all facilities covered by the transitional certification supply product built to the previously certified and qualified MIL-M-38510 product flows. Facilities not meeting this condition are eligible for transitional certification, but they may require an audit if deemed necessary by the QA.

If the manufacturer has never received MIL-M-38510 certification and qualification, but has been approved by DLA Land and Maritime for class M products only, an audit of the facilities under QML consideration shall be required. If these facilities have been audited by DLA Land and Maritime under the class M (SMD) random audit program, the audit may not be necessary, as determined by the QA.

Facilities that have never been audited by DLA Land and Maritime are eligible for transitional certification and an audit will be required unless the QA determines that an audit is not necessary.

- b. The manufacturer should submit a plan for achieving full QML. The plan should include a self-assessment, quality improvement plan, SPC plan, and a plan to upgrade any DLA Land and Maritime drawing or SMD part to one part-one part number Q level devices.
- c. The manufacturer should comply with all requirements of [appendix A](#) of this specification until the QA has approved the manufacturer for full QML certification at which time the previous MIL-M-38510 (appendix A of MIL-PRF-38535) requirements shall be superseded by the requirements of the main body of this specification and all applicable appendices. As the manufacturer moves toward full QML certification, the QA can allow variations to [appendix A](#) as part of the transition process. For class level S only, the manufacturer should notify the space community (e.g. NASA, NRO, DTRA, and AFSMC) of any proposed major variations to appendix A requirements. Further review by these organizations may be necessary before these variations can be sanctioned.
- d. Any major changes to the transitional certification lines should be approved by the QA until such time as the QA approves the manufacturers TRB system and QM plan. This includes any deletion of test requests.
- e. If any re-qualifications are required they should be in accordance with the guidelines of [appendix A](#) or as approved by the QA.

The QML allowances given by this transitional certification shall be approved after the on-site verification and certification by the QA, but prior to shipment of any product under this specification. In addition, the manufacturer shall make a commitment to becoming QML certified for all portions of the process under transitional certification. If this commitment is not met, the QA reserves the right to remove the transitional certification and all benefits associated with that certification.

NOTE: The transitional certification is not permanent (approximately 2 years maximum, unless extended by the QA) but allows the manufacturer some flexibility while still working toward QML on the remainder of the processes committed to QML. No class level S product shall be shipped until a full QA on-site certification is achieved.

MIL-PRF-38535J

APPENDIX H

H.3.4 Qualification.

H.3.4.1 Technology Qualification. The process for qualification is outlined below and is further described in detail in the subsequent sections.

a. Plan Approval.

- (1) Screening Flow.
- (2) Process performance characterization plans and data.
- (3) Process qualification test plans and data.
- (4) For class level B products, life test on a minimum of 1 wafer lot for 1000 hrs minimum at 125°C ambient, or equivalent.
- (5) For class level S products, long term life test shall meet the requirements of paragraph [B.3.4](#), appendix B, or shall meet long term life test on a minimum of 1 wafer lot for 4,000 hours minimum at 125°C ambient, or equivalent.

b. Report Approval.

For initial technology qualification, a sufficient number of SEC devices is required, from wafers passing the wafer screen requirements and randomly chosen and evenly distributed from three wafer lots for life testing and total ionizing dose requirements (RHA products only). The testing shall be in accordance with MIL-PRF-38535 Groups A, B, C, D, and E (if applicable) or to the agreed to alternatives and test optimizations defined in the QM plan. The number of SEC device failures shall serve as a qualification benchmark for the technology. Failure analysis (FA) should be done on failed SEC's to determine each failure category and action taken to correct any problems found. The SEC reliability data, including FA results, should be available for review by the QA. For RHA environments, irradiate SEC to demonstrate radiation hardness assurance capabilities limit (RHACL).

MIL-PRF-38535J

APPENDIX H

For new class level S product, if the technology is mature at other levels, the manufacturer may provide a supplemental/alternative data submittal to the QA for the reliability demonstration above. The alternative data submittal may include, but is not limited to the following:

- a. Historic product shipment summary - total quantity shipped of similar product/family on same process.
- b. Field returns summary. (NOTE: Proprietary information such as program names and individual customer names shall not be revealed.)
- c. Reliability summary data - from the reliability monitor program & Failure rate calculation.
- d. Historic qualification data - from similar product(s) from the same process family.
- e. Examples of process monitors and data showing performance & trends from recent lots.
- f. Examples of wafer lot acceptance reports.

H.3.4.1.1 Process Technology Validation. The manufacturer shall perform sufficient technology qualification testing to assure the devices supplied meet the minimum class level B or S performance requirements as described herein. The manufacturer shall maintain documentation of qualification testing for review by the preparing or acquiring activity upon request.

H.3.4.1.2 Technology Qualification eligibility. Design, wafer fabrication, assembly, and qualification testing of the demonstration vehicles may begin before certification is granted. However, if deficiencies and concerns found during the validation require changes to the process flows, the design, wafer fabrication, assembly, and testing shall be redone on the new process flows. In all cases, start of the qualification testing should begin no later than 6 months after the letter of certification is received in order to retain the manufacturer's initial certification. Completion should be achieved in a timely manner or recertification may be necessary.

H.3.4.1.3 Demonstration vehicles. The manufacturer should produce, on the certified manufacturing line, the demonstration vehicles, as applicable, as documented in the qualification plan. The demonstration vehicles should be of such complexity as to be representative of the microcircuits to be supplied by the manufacturer. The demonstration vehicles will be assembled and screened to the appropriate QML Q or V flow including all applicable test alternatives and test optimizations. Each demonstration vehicle should operate and perform in compliance with the device specification and to the RHACL for a radiation hardened process and should be manufactured in packages representing the packaging technology.

NOTE: For a technology which has die as its primary product, the demonstration vehicle should be suitably packaged to allow evaluation of the technology without adversely affecting the outcome of the tests.

H.3.4.2 Technology Qualification test plan. The manufacturer shall submit a qualification test plan which details the test flow, test limits, test data to be measured, recorded and analyzed, test sampling techniques, and traceability records. The test plan should detail materials, manufacturing construction techniques (including design CAD tools), testing and reporting techniques and should be made available to the qualifying activity at the time of certification. The test plan should include traceability documentation, milestone charts and the proposed demonstration vehicle descriptions. All test limits should be in accordance with the requirements of the SMD. All demonstration vehicles shall be representative of the manufacturing and screening processes. For class level S product new technology items, the plan shall include any screening tests or additional qualification tests required as a result of the characterization and physics of failure evaluations.

MIL-PRF-38535J

APPENDIX H

H.3.4.3 Wafer Fabrication Technology Validation. A manufacturer should have an SEC for the technology or process being considered for certification. A manufacturer's SEC should be used to demonstrate fabrication process reliability for the technology. The SEC design documentation should address: The design methodology, the software tools used in the design, the functions it is to perform, its size in terms of utilized transistor or gate count, and simulations of its performance. Documentation procedures for the SEC and standard production devices should be the same so that correlation can be made. The SEC may be designed solely for its role as a quality and reliability monitoring vehicle or it may be a standard product. (For RHA environment, see appendix C.) The SEC should address the following requirements:

- a. **Complexity.** The complexity of the SEC for digital microcircuits should contain, as a minimum, one-half the number of transistors expected to be used in the largest microcircuit to be built on the QML line. Digital ASICs should include one or more test vehicles or SEC that represents all the cells types including memory, and operates at a minimum of 75% of the intended product frequency for burn-in and electrical tests. For analog microcircuits, the SEC should exercise the functionality of the process technology flow, be of a representative complexity and be comprised of major circuit element types.
- b. **Functionality.** The SEC should contain fully functional circuits capable of being tested and screened in a manner identical to the QML microcircuits.
- c. **Design.** The SEC should be designed to stress the design capabilities of the process (see [H.3.2.1.1.1c](#)). The architecture of the SEC should be designed so that failures can be easily diagnosed.
- d. **Fabrication.** The SEC should be processed on a wafer fabrication line that is intended to be, or already is, a certified QML line.
- e. **Packaging.** The SEC should be packaged in a package qualified in accordance with requirements in [3.4.1.4.1](#) herein.

NOTE: A different SEC may be required whenever the design rules, the materials, the basic processes, or the basic functionality of the technology differ.

H.3.4.4 Assembly/Packaging Technology Validation. The manufacturer shall demonstrate the capability of the assembly and package processes by qualifying the SEC package or actual product to the package certification and qualification procedures. The manufacturer shall document how packages used in the manufacture of QML products are grouped together as a package family for qualification and change control purposes. The technology qualification demonstration shall be conducted on samples pulled from 3 different assembly lots. The qualification testing shall be conducted in accordance with MIL-PRF-38535 Groups A, B, and D or to the agreed to alternatives and test optimizations defined in the QM plan. Tables H-IA and H-IB identify the assembly process qualification testing which shall be addressed for the technology being used. Tables H-IIA and H-IIB identify the key package characteristics for which testing shall be addressed on each QML package technology.

2	Resistance to moisture	Preconditioning Electrical testing, Biased HAST (500 hours, +130°C, 85% RH) End-point electricals	<u>2/</u> In accordance with device specification. JESD22-A110 <u>3/</u> In accordance with device specification.
3	Susceptibility to corrosion	Salt atmosphere	TM 1009
4	Susceptibility to leakage and corrosion	Autoclave (no bias) (pressure pot) 2 atm., +121°C	JESD22-A102 (data to be provided for 96 hours and 168 hours)
5	Leads	Lead integrity	TM 2004, condition A, B2 or D
6	Susceptibility to moisture induced cracking at reflow soldering for surface mount and applicable through hole packages	Moisture intake Reflow simulation Inspection for Delamination and cracks	168 hours at +85°C/85% RH or bake + minimum guaranteed time at +30°C/60% RH Vapor phase (+219°C, no preheat) or Infrared (+240°C maximum) Cross-section at 1000X, ultrasonic (CSAM) etc.
7	Safety	Flammability	UL 94, ASTM D2863
8	Fungus resistance	ASTM G21	Required only if fungus is a concern
9	Susceptibility to electrostatic discharge (ESD) sensitivity	ESD	TM 3015 or JESD22-A114 <u>4/</u>
10	Susceptibility to latch-up	Latch-up test	JESD78 or manufacturers internal procedures
11	Thermal resistance	Thermal characteristics	TM 1012

1/ Performed as either characterization or as part of qualification.

2/ The manufacturer shall define a "preconditioning" procedure that simulates board assembly of plastic surface mount devices. This procedure should include moisture intake and reflow simulation. Exposure to soldering fluxes (possible source of corrosiveness) and to board cleaning agents is also recommended for preconditioning the devices.

3/ Five hundred hours of highly accelerated stress testing (HAST) is preferred but the qualifying activity shall consider the manufacturers overall processing and testing to evaluate this requirement. The actual HAST hours or alternate testing shall be included in the QM plan.

4/ ESD classification level is as defined within test method 3015.

MIL-PRF-38535J

APPENDIX H

H.3.4.5 Technology Qualification Report Approval. The technology qualification report shall be submitted to the QA for their review and approval in successfully demonstrating compliance to the qualification test plan.

H.3.4.6 Qualification test report. The manufacturer should present to the qualifying activity (QA) an analysis of the qualification data. The aim of this analysis is to show that all process variables are under control and repeatable within the certified technology and that parametric monitor, TCV, and SEC data monitoring are adequate and correlatable to the process. The QA should be notified of any improvements/changes to the certified QML technology flow as a result of evaluating the qualification testing data. The following data, if applicable, should be addressed and retained by the manufacturer to support the results:

- a. Simulation results from the design process (can be reviewed during the validation).
- b. Parametric monitor test data.
- c. Results of each subgroup test conducted, both initial and any resubmissions.
- d. Number of devices tested and rejected.
- e. Failure mode and mechanism for each rejected device.
- f. Read and record variable data on all specified electrical parameter measurements.

NOTE: Specified electrical tests from a serialized, random sample (minimum of 22 devices) may be used to satisfy this requirement. The manufacturer may submit variables data in histogram format giving mean and standard deviation or equivalent for passing microcircuits.

- g. Where delta limits are specified, variable data, identified to the microcircuit serial number, should be provided for initial and final measurements.
- h. For physical dimensions, the actual dimension measurements on three randomly selected microcircuits, except where verification of dimensions by calibrated gauges, overlays, or other comparative dimensions verification devices is allowed.
- i. For bond strength testing, the forces at the time of failure and the failure category, or the minimum and maximum readings of the microcircuits if no failures occur.
- j. For die shear or stud pull strength testing, the forces at the time of the failure and the failure category, or the die shear or stud pull reading if no separation occurs.
- k. A copy of the test data on nondestructive bond pull testing as required by TM 2023 of MIL-STD-883.
- l. For RHA testing, pre-test and post-test end-point electrical parameters, transient and single event phenomenon (SEP) response and test conditions (if applicable).
- m. For lid torque strength testing, the forces at the time of failure or the actual torque, if no separation occurs.
- n. For internal water vapor content readings, report all gases found.

H.3.4.7 Qualification test failures. If any particular testing results are not successful, the manufacturer should perform failure analysis and take necessary corrective action. The manufacturer should notify the qualifying activity of any decision not to pursue qualification of any material or manufacturing construction technique previously certified. After corrective actions have been implemented, qualification testing should restart.

MIL-PRF-38535J

APPENDIX H

H.3.4.8 Product qualification (extension from existing qualified technology) . If the manufacturer wants to qualify additional product types from previously QA approved process technologies, the qualification plan shall reference the process technology information (physics of failure, description, etc.) and define the specific characterization, screening, and qualification tests required for the new product including the life test duration, conditions, and rationale.

a. Product Qualification (Extension from existing qualified process technology)

- 1) Plan Approval
 - i) Screening Flow
 - ii) Product Performance characterization plans and data
 - iii) Product Qualification Test plans and data
 - iv) 1,000 hour life test or equivalent
- 2) Report Approval

H.3.5 Standard microcircuit drawings (SMDs) . SMD depicts the Government's requirements for an existing commercial item, tested for a military application, disclosing applicable configuration, envelope dimensions, mounting and mating dimensions, interface dimensional characteristics, specified performance requirements, and inspection and acceptance test requirements as appropriate for a military environment. The general steps of SMD preparation by the preparing activity (PA) are as follows:

- a. Draft Development
- b. User Coordination
- c. SMD Release

H.3.6 Listing of microcircuits on the Qualified Manufacturer's List (QML) . To be listed on the QML for this specification, the manufacturer shall demonstrate compliance to the QML certification requirements (see [3.4.1](#)), demonstrate compliance to the QML qualification requirements (see [3.4.2](#)), and work with the PA, the DLA Land and Maritime, to develop a SMD describing the candidate QML device(s) (see [3.5](#)).

Upon approval of the final draft of the SMD, the manufacturer shall submit a completed certificate of compliance (C-of-C) to DLA Land and Maritime. Acceptance of the C-of-C by the qualifying activity results in the device being listed on the QML and provides authority for the manufacturer to ship the QML devices in accordance with the SMD.

Manufacturers are officially QML qualified to a given SMD when the SMD is dated and the C-of-C and qualification report is approved by the QA. Manufacturers are able to ship SMD devices upon being QML qualified to the given SMD. Manufacturers will receive notification of approval from the QA.

MIL-PRF-38535J

APPENDIX H

(This page intentionally left blank.)

MIL-PRF-38535J

APPENDIX J

TECHNOLOGY CONFORMANCE INSPECTION AND SCREENING INFORMATION

J.1 SCOPE

J.1.1 Scope. The qualified manufacturer listing (QML) program measures and evaluates the manufacturers' manufacturing process against a baseline for that process. This baseline can include innovative and improved processes that result in an equivalent or higher quality product, provided that the process used to evaluate and document these changes has been reviewed and approved. Changes to the process baseline can be made by the manufacturer's Technology Review Board (TRB) after achieving QML status with documented reliability and quality data. The approach outlined in this appendix is a proven baseline which contains details of the screening and technology conformance inspection (TCI) procedures. This appendix is a mandatory part of the specification. The information contained herein is intended for compliance. However, for QML microcircuits the manufacturers may offer approved alternatives that demonstrate a process control system that achieves at least the same level of quality and reliability as could be achieved by this appendix.

J.2 APPLICABLE DOCUMENTS

J.2.1 General. The documents listed in this section are specified in section J.3 of this appendix. This section does not include documents cited in other sections of this appendix or recommended for additional information or as examples. While every effort has been made to ensure the completeness of this list, document users are cautioned that they must meet all specified requirements of documents cited in section J.3 of this appendix, whether or not they are listed.

J.2.2 Government documents.

J.2.2.1 Specifications, standards, and handbooks. The following specifications, standards, and handbooks form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

DEPARTMENT OF DEFENSE STANDARD

MIL-STD-883 - Test Method Standard Microcircuits.

(Copies of these documents are available online at <https://assist.daps.dla.mil/quicksearch/> or from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094.)

J.2.3 Non-Government publications. The following documents form a part of this document to the extent specified herein. Unless otherwise specified, the issues of these documents are those cited in the solicitation or contract.

ELECTRONIC INDUSTRIES ALLIANCE (EIA)

EIA557 - Statistical Process Control Systems.
JEP121 - Requirements for Microelectronic Screening and Test Optimization.

(Copies of these documents are available online at <http://www.jedec.org/> or from JEDEC Office, 3103 North 10th Street, Suite 240-S, Arlington, VA 22201-2107.)

J.2.4 Order of precedence. In the event of a conflict between the text of this document and the references cited herein, the text of this document takes precedence. Nothing in this document, however, supersedes applicable laws and regulations unless a specific exemption has been obtained.

MIL-PRF-38535J

APPENDIX J

J.3 TCI AND SCREENING INFORMATION

J.3.1 Mask requirements (when applicable). If the mask shop is internal to the manufacturing organization, all designs shall be checked for errors utilizing appropriate design rule checkers before start of the mask making. Before use, the mask shall be inspected for flaws and errors. The final photolithographic mask to be used for QML microcircuit wafer fabrication shall be compliant with the critical dimensions. Measurements shall show that the pattern sizes and positions are consistent with the design rules. All masks shall be maintained under an inventory control program which outlines the inspection and the release of masks to fabrication, recording of usage, cleaning cycles, and maintenance repair. All conditions for removal of masks from inventory shall be documented.

J.3.1.1 Wafer fabrication process. The wafer fabrication process shall be monitored and controlled using a standard evaluation circuit (SEC), technology characterization vehicle (TCV) or alternate assessment procedure, and parametric monitors (PMs) in accordance with 3.4.1. The wafer fabrication sequence to produce finished wafers shall be established with processing limits for each wafer fabrication step. Specific items to be addressed are detailed below:

<u>Procedure</u>	<u>Paragraph</u>
Traceability	3.11
Lot travelers	As required (TRB determined)
Glassivation/passivation	A.3.5.5, A.3.5.8
Parametric monitors	H.3.2.1.3.2
Wafer acceptance	C.3.4.1.3, H.3.2.1.2, H.3.2.1.4
Standard evaluation circuits	C.3.4.1.2, H.3.4.3
Technology characterization vehicles	H.3.2.2.2.1
Rework	In accordance with QM plan
Internal conductors and metallization thickness	In accordance with applicable design rules

J.3.2 Assembly process procedures. The following assembly process procedures shall be used, as applicable, to assemble QML microcircuits. The manufacturer shall control all phases of the assembly line to ensure that contamination from any source or equipment operation and human intervention does not degrade the reliability of the assembly process or QML microcircuit. Specific items to be addressed are shown below:

<u>Assembly and package procedure</u>	<u>Paragraph</u>
Incoming inspection	H.3.2.1.3
Eutectic die attach	TM 2010 of MIL-STD-883, H.3.2.1.3
Non-eutectic die attach	TM 2010, TM 5011 of MIL-STD-883, H.3.2.1.3 (as applicable)
Internal visual	TM 2010 of MIL-STD-883, 3.4.1.4 w
Hermeticity	TM 1014 of MIL-STD-883, TM 1018 of MIL-STD-883
Handling (electrostatic discharge (ESD))	G.3.3.1 p or 3.4.1.4 v herein
Human contamination	3.4.1.4 x
Rework	J.3.2.1
Internal water vapor content	TM 1018 of MIL-STD-883
Wire bonding	3.4.1.4 q herein

J.3.2.1 Assembly rework requirements. All QML microcircuit rework procedures shall be certified and documented in the quality management (QM) plan.

J.3.3 Internal visual inspection. Internal visual inspection shall be performed to the appropriate level of TM 2010 of MIL-STD-883. Microcircuits awaiting pre-seal inspection, or other accepted, unsealed microcircuits awaiting further processing shall be stored in a dry, inert, controlled environment until sealed. Alternate procedures, such as those provided in TM 5004 of MIL-STD-883 or some other TRB approved alternate, may be used. For gallium arsenide (GaAs) devices only, TM 5013 of MIL-STD-883 should be used.

MIL-PRF-38535J

APPENDIX J

J.3.4 Constant acceleration. All microcircuits shall be subjected to constant acceleration, except as modified in accordance with 4.2 in the Y1 axis only, in accordance with TM 2001 of MIL-STD-883, condition E (minimum). Microcircuits which are contained in packages that have an inner seal or cavity perimeter of two inches or more in total length, or have a package mass of five grams or more, may be tested by replacing condition E with condition D in TM 2001 of MIL-STD-883. For packages that cannot tolerate the stress level of condition D, the manufacturer shall have data to justify a reduction in the stress level. The reduced stress level shall be specified in the manufacturers QM plan. The minimum stress level allowed in this case is condition A.

J.3.5 Burn-in. Burn-in shall be performed on all QML microcircuits, except as modified in accordance with section 4.2, at or above their maximum rated operating temperature (for devices to be delivered as wafer or die, burn-in of packaged samples from the lot shall be performed to a quantity accept level of 10(0)). For microcircuits whose maximum operating temperature is stated in terms of ambient temperature (T_A), table I of TM 1015 of MIL-STD-883 applies. For microcircuits whose maximum operating temperature is stated in terms of case temperature (T_C), and where the ambient temperature would cause T_J to exceed +175°C, the ambient operating temperature may be reduced during burn-in from +125°C to a value that will demonstrate a T_J between +175°C and +200°C and T_C equal to or greater than +125°C without changing the test duration. Data supporting this reduction shall be available to the acquiring and qualifying activities upon request.

J.3.6 Final electrical measurements. Final electrical testing of microcircuits shall assure that the microcircuits tested meet the electrical requirements of the device specification and shall include the tests of table III, group A, subgroups 1, 2, 3, 4 or 7, 5 and 6 or 8, and 9, 10, and 11, unless otherwise specified in the device specification.

J.3.7 Seal (fine and gross leak) testing. Fine and gross leak seal tests shall be performed, as specified in 4.2, between temperature cycling and final electrical testing after all shearing and forming operations on the terminals in accordance with TM 1014 of MIL-STD-883.

J.3.8 Pattern failures. Pattern failure criteria may be used as an option for any screen provided that pre burn-in testing is done. When acceptance is based on pattern failures (multiple device failures - two or more caused by the same basic failure mechanism) shall apply as specified in the acquisition document. If not otherwise specified, the maximum allowable failures shall be five devices for each failure pattern established. Accountability shall include burn-in through final electrical test.

J.3.8.1 Pattern failure rejects. When the number of pattern failures exceeds the specified limits, the burn-in lot shall be rejected. At the manufacturer's TRB option, the rejected lot may be resubmitted to burn-in one time provided:

- a. The cause of the failure has been determined and evaluated.
- b. Appropriate and effective corrective action has been completed to reject all microcircuits affected by the failure cause.
- c. Appropriate preventive action has been initiated.

J.3.9 TCI. TCI testing shall be accomplished by the manufacturer on a periodic basis to assure that the manufacturer's quality, reliability, and performance capabilities meet the requirements of the QM plan. The manufacturer of QML microcircuits shall be certified by the qualifying activity to use one or a combination of both of the TCI procedures described below. The two TCI procedures are end-of-line TCI (option 1, see J.3.10) and in-line TCI testing (option 2, see J.3.11).

NOTE: All tests may not be appropriate for the technology (e.g., for wafer or die product, group B, subgroups 1 and 3 and group D do not apply). The manufacturer's TRB shall determine that the appropriate tests are completed to assure conformance of the product to be delivered.

MIL-PRF-38535J

APPENDIX J

J.3.9.1 General. Any QML or SEC integrated circuit used for either TCI option (see J.3.10 or J.3.11) shall be screened in accordance with 4.2.

J.3.9.2 TCI reporting. Summary of TCI tests analysis shall be submitted to the qualifying activity in accordance with 3.9.1 requirements. If TCI requirements are not met, the TRB shall notify the qualifying activity immediately and all products manufactured and delivered between the last TCI and the failed TCI shall be placed in suspect status. The manufacturer shall analyze the failure, determine the reason for failure and submit a corrective action plan. An assessment of whether to recall all suspect products shall be made by the TRB and the qualifying activity shall be notified of the decision. Recertification and requalification of the QML line may be required based on the nature of the problem and action taken by the manufacturer. Procedures for end-of-line TCI and in-line TCI testing for a QML line are described in the following paragraphs.

J.3.10 End-of-line TCI (option 1). End-of-line TCI testing shall be performed every TCI interval, as recommended in table J-1 herein. Quality conformance inspection (QCI) requirements as detailed in TM 5005 of MIL-STD-883 may be used, with qualifying activity (QA) approval, in place of the TCI requirements herein. Each end-of-line TCI vehicle shall pass the end-of-line quality conformance. All groups A, B, and E (as applicable) testing shall be performed on microcircuits to be delivered as QML microcircuits. Groups C and D testing shall be done on either the SEC or QML microcircuits. Groups A, B, C, D, and E requirements are found in tables II through V and table C-I.

Group E inspection is required only for parts intended to be marked as radiation hardness assurance (RHA) (see 3.4.3). RHA TCI sample tests shall be performed at the level(s) specified and in accordance with appendix C. The applicable subgroups of group E, (see appendix C) shall be performed when specified in the acquisition document. The actual devices used for group E testing shall be assembled in a qualified package and, as a minimum, shall pass table III, group A, subgroups 1, 7, and 9 at +25°C prior to irradiation.

NOTE: If a manufacturer elects to eliminate a TCI step by substituting an in-process control or statistical process control procedure, the manufacturer is only relieved of the responsibility of performing the TCI operation associated with that step. The manufacturer is still responsible for providing a product that meets all of the performance, quality, and reliability requirements herein and in the device specification. Documentation supporting substitution for TCI shall be retained by the manufacturer and available to the QA upon request.

Each group may contain individual subgroups for the purposes of identifying individual tests or groups of tests. Subgroups within a group of tests may be performed in any sequence but individual tests within a subgroup (except table II, group B, subgroup 2) shall be performed in the sequence indicated for groups B, C, D, and E tests herein. Electrical reject devices from the same inspection lot may be used for all subgroups when electrical end-point measurements are not required.

J.3.10.1 Group A inspection. Group A inspection shall be performed on each inspection lot and shall consist of electrical parameter tests specified for the specified device. Group A inspection may be performed in any order.

J.3.10.2 Group B inspection. Group B inspection shall be performed on each inspection lot, for each qualified package type and lead finish. Group B shall consist of mechanical and environmental tests for the specified device class. Resubmission procedures shall be documented in the QM plan. For solderability, a statistical sound sample size (sample sizes indicated in TM 5005 of MIL-STD-883 are acceptable, as a minimum) consisting of leads from several packages shall be tested with zero failures. The actual number shall be determined by the TRB and detailed in the TCI procedures in the QM plan.

J.3.10.3 Group C inspection. Group C inspection shall include die related tests specified which are performed periodically. Resubmission procedures shall be documented in the QM plan. Where group C end-points are done on actual devices, group C end-points shall be specified in the device specification.

J.3.10.4 Group D inspection. Group D inspection shall include package related tests which are performed periodically. Resubmission procedures shall be documented in the QM plan. Where group D end-points are done on actual devices, group D end-points shall be specified in the device specification.

MIL-PRF-38535J

APPENDIX J

J.3.10.5 Group E inspection. When applicable, group E inspection shall include RHA tests on each wafer lot. The post-irradiation parameter limits (PIPL), transient, and single event phenomenon (SEP) response (as applicable), and test conditions shall be as specified in the device specification.

J.3.10.6 End-point tests for groups C, D, (E if applicable). End-point measurements and other specified post-test measurements shall be made for each sample after completion of all other specified tests in the subgroup. The test limits for the end-point measurements shall be the same as the test limits for the respective group A subgroup inspections. Different end-points may be specified for group E tests in the detail specifications. Any additional end-point electrical measurements may be performed at the discretion of the manufacturer.

J.3.10.7 End-of-line TCI testing (option 1). All microcircuits used in end-of-line TCI testing that meet the requirements of this specification and the device specification and are subjected to destructive tests or which fail any test shall not be shipped on the contract or order as acceptable QML product. They may, however, be delivered at the request of the acquiring activity, if they are isolated from, and clearly identified so as to prevent their being mistaken for acceptable product. Sample microcircuits, from lots which have passed quality assurance inspections or tests and which have been subjected to mechanical or environmental tests specified in groups B, C, and D inspection and not classified as destructive, may be shipped on the contract or order provided the test has been proven to be nondestructive (see [A.4.3.2.3](#)) and each of the microcircuits subsequently passes final electrical tests in accordance with the applicable device specification.

J.3.11 In-line TCI testing (option 2). In-line control testing shall be performed through the use of the approved SEC or QML microcircuit. The in-line control test plan shall show how all the groups A, B, C, D, and E test conditions are incorporated under statistical process control or process control to allow in-line control monitoring. The following shall also be addressed. Groups A, B, C, D, and E requirements are found in [tables II through V](#) and [table C-I](#).

TABLE J-I. End-of-line TCI testing procedure (option 1). ^{1/}

Table	TCI requirements	TCI vehicle	Interval
Table III	Group A electrical testing	Actual device	Each inspection lot
Table II	Group B testing	Actual device	Each inspection lot
Table IV	Group C testing	SEC or actual device	Every 3 months
Table V	Group D testing	SEC or actual device	Every 6 months
Table C-I	Group E testing	Actual device	Each wafer lot

^{1/} Each group may contain individual subgroups for the purposes of identifying individual tests or groups of tests.

J.3.11.1 Group A electrical testing. Group A electrical testing shall be satisfied by in-line inspections performed in accordance with the applicable procedure of MIL-STD-883 on actual devices.

J.3.11.2 Group C life tests. Life tests shall be performed on the SEC at intervals set by the TRB in the quality management plan.

MIL-PRF-38535J

APPENDIX J

J.3.12 Test optimization requirements. The process used by the manufacturer to optimize testing utilizing the best commercial practices available while still assuring all performance, quality and reliability requirements herein. All of the applicable JEP121 process elements shall be addressed for test optimization. Any screen or TCI test prescribed herein may be reduced, modified, moved, or eliminated by the QML manufacturer provided the following considerations are addressed as a minimum.

- a. Nodes critical to test outcome, called test critical nodes, have been identified and are in control in accordance with EIA557.
- b. Test critical nodes have exhibited sufficient capability to assure low product defect rates.
- c. An understanding and control of assignable causes at test critical nodes.
- d. The long term reliability of devices remains unaffected or is improved.
- e. Low defect rates in the process and delivered product are maintained.
- f. Measurements taken for out of control conditions along with corrective actions are recorded and this data is maintained for a time period consistent with data retention requirements herein.
- g. Method and frequency for revalidation of optimized tests shall be defined in the manufacturer's documentation.

The manufacturer is expected to maintain the established process control and evaluate the effect on quality and reliability of any out of control conditions that may exist at critical nodes. The manufacturer shall also evaluate if a relationship exists between any optimized test and any field failure returns, take appropriate corrective actions, and report this information as part of the TRB status reports. Regardless of testing modifications, the manufacturer shall supply product capable of passing any screening or TCI/QCI test prescribed herein. As a part of the QML philosophy and the conversion of customer requirements the manufacturer shall communicate variations in screening, end-of-line testing with customers as appropriate. This information shall be available from the manufacturer and to the QA.

DESCRIPTION

PAGE

(This page intentionally left blank.)

MIL-PRF-38535J

Custodians:

Army - CR
Navy - EC
Air Force - 85
NASA – NA
DLA - CC

Preparing activity:

DLA - CC

Review activities:

Army - MI, SM
Navy - AS, CG, MC, OS, SH, TD
Air Force - 19, 99

(Project 5962-2010-006)

Civil agency:

DOT-FAA (RD-650)
