

Resemblances and Disparities of two Biotas

A Comparison Study of Vascular Plant Biodiversity of two Locations in Uppsala and Beijing

Ziwei Zhang

Degree project in biology, Bachelor of science, 2013 Examensarbete i biologi 15 hp till kandidatexamen, 2013 Institutionen för biologisk grundutbildning och Avd för växtekologi och evolution, Uppsala universitet Handledare: Håkan Rydin

Abstract

This paper focuses on the flora distribution and difference in biodiversities of two chosen locations in Uppsala and Beijing, through inventorial and analytic methods. The factors that may cause the difference were also discussed from theoretical perspectives. Inventories of vascular plant species were carried out in two locations of the two cities. The collected species data were then grouped into families as well as life forms; and were compared with each other as well as with the statistics from the entire species pool in the chosen city. Both resemblances and disparities were found. The statistical analyses with Minitab supported the hypotheses that the floral compositions of these two locations differ to a great extent. Various factors such as climate, grazing, human impacts, historical reasons, precipitation, humidity and evolution, can account for the disparities.

1. Introduction

1.1 Motivation and Content of this paper

The biotas of Uppsala and Beijing are located in two different continents and biomes, although they share certain common features and similarities. Inventory lists were generated from both field trips as well as existing data so that differences in plant composition can be analysed and displayed. Two nature reserves were studied in Uppsala and Beijing in order to do this. It should be noted that these two chosen areas cannot fully represent the biotas; with limited time and resources, this study only aims to show trends and patterns of similarities as well as dissimilarities.

The most common families of both biotas are then compared with the largest families worldwide, under the hypothesis of a high degree of overlap. The five largest families of the world are Asteraceae, Fabaceae, Orchidaceae, Rosaceae and Poaceae. The reasons for the highly occurring families were discussed from viewpoints such as unique features of these families; the reasons for the disparities in species distribution between these two biotas are also argued, such as the climate, biome, evolution, elevation, etc.

The resemblance and correlation with the two biotas of Uppsala and Beijing are studied. The hypothesis is that the compositions of flora in these locations differ, both in forms of families as well as life forms. In order to testify this, Minitab was used and a null hypothesis is proposed, stating that the compositions of flora in these two locations are somewhat identical; both in the form of families and life forms.

1.2 Biomes of Uppsala and Beijing

A biome is a natural community of wide extent, characterised by distinctive, climatically controlled groups of plants and animals (Raven *et al.*, 2004). Whittaker (1978) established a classification method based on two abiotic factors: precipitation and temperature. According to Sjörs (1999), Uppsala locates in the boreo-nemoral zone (Fig. 1), with long, cold winters and temperate summers. The boreo-nemoral (hemi-boreal) zone is also sometimes referred to as the southern coniferous forest region. Although dominance is usually of conifers, deciduous trees are widespread.

Beijing on the other hand belongs to the biome of temperate deciduous forest (Hou *et al.*, 1982; Haxeltine & Prentice, 1996), with lower average temperature and hotter summers, as well as less precipitation, where deciduous trees are common. In the project BIOME3, detailed vegetation maps of China were generated. In Fig. 2, natural vegetation map of China, consists of 18 BIOME3 categories assigned from 113 vegetation type units digitilised from the 'Vegetation Map of the People's Republic of China at 1:4,000,000 scale (Hou *et al.*, 1982).

Figure 1. Vegetational zonation in Sweden (Sjörs, 1999) SB = southern boreal, MB = middle boreal, NB =northern boreal, BN = boreo nemoral.

Figure 2. Vegetation map of China (Hou *et al.*, 1982), different colours represent different vegetation types.

China is ranked the 3rd in the world when it comes to biodiversity richness, including 2200 species and 106 families of mosses, accounting for 70% of the world's total number of moss families; 2600 species and 52 families of ferns, accounting for 80% of the total number of fern families. There are a total number of 15 families and 79 genera of gymnosperms in the world and in China alone are 10 families and 34 genera present. China possesses roughly 54% of the total families and 24% of the total genera present in the world (Chen & Ma, 2011).

According to Flora of Beijing (He, 1992), 2056 vascular plants that belong to 869 genera and 169 families are recorded in Beijing, in which, 20 families, 30 genera and 75 species are ferns; 9 families, 18 genera, 37 species are gymnosperms; 104 families, 821 genera and 1944 species are angiosperms. The composition of plant species share common characteristics in Northern China. Moreover, Eurasian Steppe elements are seen in the plains, such as *Tribulus terrestris*, *Salsola collina*, *Tamarix chinensis*, and *Suaeda glauca*. European and Siberian elements are retained in mountain areas, such as *Larix principis-rupprechtii*, *Picea asperata*, *Pyrola rotundifolia*, and *Maianthemum bifolium*. Plants with tropical characteristics are also found in lower mountains and plains, including *Ailanthus altissima*, *Ziziphus jujube*, *Merremia spp.*, and *Bothriochloa ischaemum*. These reflect the complex and diverse composition of vegetation in Beijing.

In the regional flora for the Uppland province in which Uppsala is located (Jonsell 2010), it is mentioned that the inventory Project of "Uppland's Flora" has been carried out from 1929 to the 1970s. During the inventory process, 1991 vascular plant species were registered in total, 1193 of which are local residents and 798 are more or less temporary. It is a typical

boreo-nemoral habitat with dominance of *Picea abies* and *Pinus sylvestris* with their companion species (Jonsell 2010).

2. Materials and Methods

The two studied areas chosen were Hågadalen outside of Uppsala and Beijing Botanical Garden located in outer area of Beijing. For detailed locations and a brief overview, see attached maps shown in Figures 3 and 4.

Figure 3. Map of Hågadalen (Source: Google Map); green arrow represents city centre while the orange arrow "A" represents Hågadalen.

Figure 4. Map of Beijing Botanical Garden (Source: Google Map); green arrow represents city centre while the red arrow "A" represents Beijing Botanical Garden.

As shown the above maps, Hågadalen is situated about 5.3 kilometres away from Uppsala city centre while Beijing Botanical Garden is situated roughly 28.1 kilometres away from Beijing city centre.

The initial tentative plan was to study the difference in major plants found in the two cities and draw conclusions based on the field trips, by picking 15 places in each nature reserve and make an inventory list on the plant species found within a transect area of 1m x 1m. These should be ideally of different geographic conditions e.g. meadow land, dry land, hill, "junk land", roadsides, and groves; however this method turned out to be rather unpractical and this sample size is too small to give a whole picture of the biota. Therefore an alternative method was used, which was to only pick one venue in each city, and simply record all the vascular plant species seen within the area, repeating for 5 times each, with not less than 1 hour each time, until no new species were observed. No transects were laid in this method. This method should not be treated as a fully representative image of the biodiversities in these cities. Both of the inventories were carried out between July and August, 2011.

If more time was available, there are much more complex and systematic inventory methods, for the purpose of doing an accurate and formal inventory of plant species, like those of the previously mentioned projects BIOME3 and Uppland's flora.

Identification keys and nomenclature for vascular plants follow He (1992) and Krok and Almquist (2001). They were then grouped into families in order to provide a clearer comparison between the two floras.

Minitab was used in order to test differences in distribution of genera and life forms of these two areas. Chi square tests were used in order to test the difference in the major species composition between the two biotas. Null hypothesis were proposed and tested.

3. Results

3.1 Patterns of Distribution

The vascular plant species in the two locations were grouped into families, shown in Appendix 1. The detailed lists obtained from the field trip in the Beijing Botanical Garden (114 species in total, grouped in families in descending order) and from Hågadalen (199 species in total, grouped into families in descending order) are listed in Appendix 2 and 3.

In addition, the collected species lists were divided into groups of life forms, consisting of ferns, graminoids, herbs, hydrophytes, parasites, woody plants, and vines (Table 1; Appendix 1 and 2). It is noted that the biodiversity is more abundant in Hågadalen comparing with that of Beijing Botanical Garden, both from the perspective of families as well from the aspect of varied life forms.

Table 1. Nulliber (or vascular plant species in	the two locations by the forms
Life forms	Hågadalen, Uppsala	Beijing Botanical Garden
Fern	3	0
Graminoid	32	2
Herb	120	27
Hydrophyte	4	0
Parasite	1	0

Table 1. Number of vascular plant species in the two locations by life forms

Woody plant	39	83	
Vine	0	1	

As the complete species lists from the two locations (Appendix 2 and 3) contain several small values and are from many non-overlapping families, it is impossible and impractical to compare the total plant species in one area with another; we need to figure out a convenient method as first to convert the species into some comparable data. Hence they were grouped into families as well as life forms. The 12 most common families shared by both locations (criteria is that the sum of species in the same family in two locations is larger than 5) were chosen to be shown individually in the pie chart, and the rest families containing small number of species were grouped into category called "others", for better visualisation. The data used for grouping into life forms were however the complete data set. The illustrated results are shown in pie charts demonstrated in Figures 5-6.

Figure 5a. Composition of flora in Hågadalen by families

Figure 5b. Composition of flora in Beijing Botanical Garden by families

In Figure 5, the 12 most common families in both locations are Rosaceae, Poaceae, Cyperaceae, Asteraceae, Fabaceae, Ericaceae, Apiaceae, Lamiaceae, Ranunculaceae, Caprifoliaceae, Aceraceae, and Caesalpiniaceae. Their respective percentage distributions vary, with Rosaceae being the most common family observed (8% and 15% respectively), followed by Asteraceae (7% and 5% respectively) and Fabaceae (5% and 8% respectively).

Figure 6a. Composition of flora in Hågadalen by life forms

Figure 6b. Composition of flora in Beijing Botanical Garden by life forms

In Fig. 6, we see that the composition of flora in Uppsala Hågadalen (6 life forms) is more varied than that of Beijing Botanical Garden (4 life forms).

3.2 Statistical Analysis

The following two groups of data were tested using the chi-square test, results cited as follows:

(1) Chi-Square Test, grouped as families: Uppsala Hågadalen, Beijing Botanical Garden. Data from Appendix 1 gave invalid results in Minitab due to large number of small values. Thus only the most common families shared by both locations (criteria is that the sum of species in the same family in two locations is larger than 5) were chosen to be shown in Table 2. This set of data corresponds with the data used in the pie charts illustrated in Fig. 5a and 5b. 103 species in Hågadalen and 89 species in Beijing Botanical Garden fulfilled this criterion and are shown in Table 2.

	1 1	2
Families	Hågadalen, Uppsala	Beijing Botanical Garden
Rosaceae	17	17
Poaceae	16	1
Cyperaceae	15	1
Asteraceae	14	6
Fabaceae	10	9
Ericaceae	8	2
Apiaceae	7	1
Lamiaceae	7	4
Ranunculaceae	5	1

Table 2. Number of vascular plant species in the two locations by families

Caprifoliaceae	3	37
Aceraceae	1	5
Caesalpiniaceae	0	5

Chi-Square contributions generated by data in Table 2 are shown in Appendix 4. Chi-Sq = 40.637, DF = 11, P-Value = 0.000

The p-value is smaller than 0.05, assuming 95% confidence level. This rejects the null hypothesis that the flora compositions by families between the two locations are identical. Conclusion can be drawn that the dominating families in these two locations differ to a great extent. This may also be visually observed in Figures 5a and 5b.

(2) Chi-Square Test, grouped as life forms: Uppsala Hågadalen, Beijing Botanical Garden. Data from Table 1 gave invalid results in Minitab due to some results containing small values. Thus the less interesting data were grouped into category "others", and only life forms of graminoid, herb and woody plant were kept, as shown in Table 3.

Table 3. Life forms of vascular plants in the two locations (simplified)			
Life forms Hågadalen, Uppsala Beijing Botanical Gard			
Graminoid	32	2	
Herb	120	27	
Woody plant	39	83	
Others	8	1	

Table 3. Life forms of vascular plants in the two locations (simplified)

Chi-Square contributions generated by data in Table 3 are shown in Table 4.

	Uppsala	Beijing	Total
Graminoid	32	2	34
	21.69	12.31	
	4.906	8.639	
Herb	120	27	147
	93.76	53.24	
	7.344	12.933	
Woody plant	39	83	122
	77.81	44.19	
	19.361	34.095	
Others	8	1	9
	5.74	3.26	
	0.889	1.566	
Total	199	113	312

Table 4. Chi square test results between locations by life forms. The first line gives the observed values, the second the expected, and the third the contribution to Chi-square.

Chi-Sq = 89.733, DF = 3, P-Value = 0.000

The p-value is smaller than 0.05, assuming 95% significance level. This rejects that null

hypothesis that the flora compositions by life forms between the two locations are identical. Conclusion can be drawn that the main life forms in these two locations differ to a great extent. This may also be visually observed in Figures 6a and 6b.

4. Discussion

4.1 Resemblance and Disparity

As a detailed overview of the Uppland's flora is missing, no general comparison could be made between flora of Beijing and Uppsala. However, a rather integral picture of Beijing's flora is currently provided by scholars such as He *et al.* (1992). The largest families by order are ranked as follows: Asteraceae, Poaceae, Fabaceae, Rosaceae, Liliaceae, Cyperaceae, Caryophyllaceae, Polygonaceae, Scruphylariaceae, Apiaceae, Brassicaceae and Lamiaceae.

It is observed that the composition of families differs from that of the Beijing Botanical Garden, however have somewhat more similarities with that from the Hågadalen nature reserve. This indicates further that two randomly picked locations from two biomes cannot fully be represented as the while picture of the local biodiversity.

Focusing on the life forms in both locations (Fig. 6), in Hågadalen the dominating life forms are herbs (61%), woody plants (20%) and graminoids (16%); on the other hand, in Beijing Botanical Garden the distributions of herbs, woody plants and graminoids are 24%, 73% and 2%, respectively. The former consists of abundant herbaceous plants whilst the latter consists of impressive diversity of woody species.

In Figure 5, the Rosaceae species are abundant in both locations. In Hågadalen, there are large proportions of Poaceae and Cyperaceae, and Beijing Botanical Garden instead consists of large proportions of Fabaceae and Caprifoliaceae. These major families such as Asteraceae, Poaceae, Fabaceae, etc., the resemblance is that they are successful almost worldwide. For instance, one of the dominant species in both locations, Asteraceae, is the 4th largest family worldwide. This mainly accounts on their high adaptive fitness. Taking one of the five families as the example, which is also the largest family in the world, The Asteraceae, are found as high as above elevation of 5000 meters on the Himalayas, and as dry as in the deserts. Another unique feature, its capitulum arrangement, is considered the most derived and dense form of inflorescence. Hence it is possible that this form of inflorescence helps attract greater amount of insects for pollination. Its connate anthers can protect pollen and prolonged style brings out the pollen. The small seeds can transfer for a long distance. Asteraceae is also known to be efficient spreading their seeds. The seeds, or rather the fruit called achenes, have typically adjuncts that facilitates the spread of seeds, for instance the tails of the Taraxacum ssp. seeds, and the barbs of Bidens pilosa can attach to people's clothes and animals' fur and have their seeds carried efficiently in this way (Raven *et al.*, 2004).

Apart from the similarities of the major families between Uppsala and Beijing, there are a number of disparities in the composition of species, both biotic and abiotic, including the different environmental conditions of the biomes they are located in, the evolutionary and cultural causes, *etc.*. The statistical tests have rejected the null hypotheses that the

compositions of flora in these two locations are identical. In other words, the composition flora in Beijing Botanical Garden and Hågadalen in Uppsala are very different. This corresponds with our initial hypothesis.

4.2 Factors Affecting the Difference in Flora

Many biotic and abiotic factors may decide whether or not a species is suitable to live in an environment, such as biomes, temperature gradients, and so on. *Corynephorus canescens*, for instance, is a grass of more open sands found in Europe, with its northern border almost halfway across Great Britain as well as Scandinavia (Fig. 10). Marshall (1967) has researched the factors which can be responsible for maintaining its northern boundary line, and he found that both flowering and germination were affected by low temperature. When the temperature is below 15°C, the germination process is slowed down, and the seeds inseminated after October has a low survival rate. This explains why the northern border of this grass corresponds with the isotherm of 15°C in July. Hence, the vegetation in Uppsala and Beijing with different temperature zones differ. Many studies have shown to support this theory. A study on biodiversity in Africa showed that climate accounts for 77.8% of the variation in species richness (O'Brien, 1993).

Figure 8. Distribution map and photo of Corynephorus canescens(Marshall, 1967)

Geographically, the native vegetation of Beijing should be pine-oak mixed broad-leaved deciduous forest, especially in the lower mountains around the Beijing area. However, long-term large-scale human activities—deforestation, farmland clearing, and urbanization—have altered the original vegetation as well as its character. Within the city and in outlying suburban areas, farmland, orchards, and villages have long since replaced the native forest (He *et al.*, 1992). Although forests have been well preserved in majority lands of Sweden, the flora of Uppsala has also changed somewhat in the last century, the 451 taxa include species that were considered less common to rare in the early 1900s, while excluding the commonest as well as the rarest species. Complex changes in land use (sharp decline in traditional management and the area of semi-natural grasslands, intensified agriculture and

forestry, drainage and exploitation), regulation of natural water level fluctuations in water courses, and eutrophication seem to be the main drivers of the observed changes in the vascular plant flora of the province of Uppland during the 20th century.

Some factors that may cause differences in the biota composition in the two areas include human activities, water and oxygen in the air, annual precipitation, altitude, soil acidification and fauna in the area, *etc.*. All these factors may affect and interact with each other, for instance the close interaction between fauna and flora. Grazing should be taking into account which may interfere with the local plant species while it is not relevant for Beijing, as according to the *Beijing Agricultural Policies [2001]-57* and *[2005]-1*, grazing is gradually minimised and eventually forbidden. Grazing can affect the species pools. Grazed sites generally have high proportions of legumes, therophytes, species with basal position of leaves and with regeneration by means of a persistent seed bank. Abandonment of grazing favour monocots, geophytes, species with vegetative regeneration and (partly) leafy canopy structure. Some differences between grazed and abandoned sites were confined to either the smallest or largest plot sizes, indicating different responses of matrix and interstitial species. (Dupré & Diekmann, 2001)

5. Conclusions

Inventories of plant species were done in two nature reserves in two countries, located in different biomes. They were then compared with each other. Patterns of distribution are analysed through statistical software Minitab and patterns were shown. With statistical analysis, the floral compositions of the two locations differ both by families and life forms.

The reason for filtering out the smaller values in the original datasets is due to avoidance of invalidity of the tests performed. In future studies, inorder to obtain a valid and more credible statistical result, a much larger and more complete list should be provided. In this case, the sample sizes are too small. However combining with the data of Beijing Flora, it is found that the families of Rosaceae (the rose family), Poaceae (the grass family), Asteraceae (the daisy family), Fabaceae (the legume family), and Cyperaceae (the sedge family) are in great extent overlapped. While other components of plant species vary, depending on various factors such as climate, human impacts, grazing, historical reasons, precipitation, moisture in the air, evolution, etc.

Due to limitations of time and resources, this project still leaves great space for improvement and correction. The initial objective of this paper is to practice inventory skills, as well as to explore a field which has been less paid attention to. Proper inventory field work can be carried out in detail in order to obtain the reliable and up-to-date data suitable for comparison. Although no or little previous analytic studies have been done comparing species pools in two areas, this topic helps future cultivation and promotion of regional vegetation planning, introduction of new plant species into other areas, etc. More inventory work can be done in order to provide a less arbitrary and ambiguous species list, and consequently generates a more statistically significant report.
