Abstract

Since Bezzi's (1928) review of the Diptera Brachycera of the Fiji Islands, few additional muscid species have been described or recorded from the islands. Pont (1989) recorded 27 muscids from Fiji (including two doubtful records). Recent material was collected by the Fiji Bioinventory of Arthropods (FBA), a two-year survey of arthropods occurring in the Fiji Islands and using various trapping methods. The project was part of the Fiji Terrestrial Arthropod (FTA) survey that was awarded a grant from the National Science Foundation (NSF) to inventory the insects and spiders of the Fiji Islands. Between September 2002 and May 2004, the FBA project was funded by the Schlänger Foundation. The authors received the material sorted by family and have prepared and identified about 2,000 specimens. Fijian muscids from other collections were added to the material examined. A total number of 44 species in 18 genera were studied, 39 recognized as member of the Fijian fauna, including 16 endemics. Seven new species are described: *Coenosia fijiensis* Pont & Couri, sp. nov.; *Limnophora penicillata* Pont & Couri, sp. nov.; *Limnophora shinonagai* Pont & Couri, sp. nov.; *Parvisquama curvicerca* Pont & Couri, sp. nov.; *Parvisquama femorata* Pont & Couri, sp. nov.; *Parvisquama longicerca* Pont & Couri, sp. nov.; and *Parvisquama longiseta* Pont & Couri, sp. nov. The following species were newly recorded from the Fiji Islands: *Atherigona bidens* Hennig, *Atherigona matema* Curran, *Atherigona oryzae* Malloch, *Lispe bengalensis* (Robineau-Desvoidy) and *Lispe pectinipes* Becker. The genus

Coenosia Meigen is newly recorded from the Fiji Islands. *Dichaetomyia taveuniiana* Pont & Evenhuis is newly recorded from Vanua Levu.

Key words. descriptions, new species, new records, taxonomy, morphology

INTRODUCTION

The Fijian Archipelago is one of the most faunistically unusual areas in the entire Pacific region. Scientific expeditions have visited Fiji since the first European sighting in 1643 by Abel Tasman, but there is little current comprehensive information published on the arthropod fauna of the islands. The NSF-Fiji Terrestrial Arthropod Survey aims to provide a more complete knowledge of the arthropod fauna of the Fijian Islands. A summary and overview of the NSF-funded project was given by Evenhuis & Bickel (2005), who also summarized previous surveys of the islands. The Fiji Arthropod Survey homepage (<http://hbs.bishop-museum.org/fiji/>) gives a list of recent publications on the Fijian fauna.

The muscoids from the Fiji Islands were first monographed by Bezzi (1928), who recorded eleven previously known species and described eight new ones. In the same year, Malloch (1928a, 1928b) also described some new species from the Fiji Islands. Emden (1942) studied the Fijian Coenosiini, recording seven species and assigning some of Bezzi's species to different genera. Almost thirty years later, Pont (1970b) gave notes on the location of the types of Bezzi's species, and a new species was described by Vockeroth (1972). All muscid records were summarised by Pont (1989), and his catalogue has served as the basis for the present paper. Pont recorded 27 species, two of them as doubtful records: *Lispe tentaculata* (De Geer) and *Haematobia irritans* (Linnaeus). More recently, Pont & Evenhuis (2006) described a new species of *Dichaetomyia* Malloch, and Pont (2006) published a key to the genera of the Muscoidea (Diptera) recorded from the Fiji Islands. A summary of Fiji muscid taxa over the years is given in Table 1.

MATERIAL AND METHODS

The project management plan for the NSF-Fiji Terrestrial Arthropod Survey, including the collecting sites, collecting protocol and collecting techniques, was described by Evenhuis & Bickel (2005). Most of the Muscidae were collected by Malaise traps placed in different ecosystems on the different islands. The material was processed and sorted to family by local parataxonomists. About 2,000 specimens of Muscidae have been pinned, labelled and identified. This material is listed under "FAS" in the "Material examined" section below. In addition, material from other institutions has also been examined and is listed under "Other material examined". The following acronyms are used for institutions where this material is located:

ANIC	Australian National Insect Collection, CSIRO, Canberra, Australia
BMNH	the Natural History Museum, London, UK
BPBM	Bernice P. Bishop Museum, Honolulu, Hawai'i, US
CAS	California Academy of Sciences, San Francisco, USA
CNC	Canadian National Collection, Ottawa, Canada
HNHM	Hungarian Natural History Museum, Budapest, Hungary
IPP	Institut Pasteur, Paris, France
LSL	Linnean Society of London, UK
MCSNM	Museo Civico di Storia Naturale, Milan, Italy
MNHN	Muséum National d'Histoire Naturelle, Paris, France
MNRJ	Museu Nacional, Rio de Janeiro, Brazil
NBCL	Naturalis Biodiversity Centre, Leiden, The Netherlands

NMW	Naturhistorisches Museum, Vienna, Austria
NRS	Naturhistoriska Riksmuseet, Stockholm, Sweden
NSMT	National Science Museum, Tokyo, Japan
OUMNH	Oxford University Museum of Natural History, Oxford, UK
USNM	National Museum of Natural History, Washington, USA
ZMHU	Zoologisches Museum der Humboldt-Universität, Berlin, Germany
ZMUC	Danish Museum of Natural History, Copenhagen, Denmark
ZSMH	Zoologisches Institut und Zoologisches Museum, Hamburg, Germany

Of the material collected by the NSF project (FAS – Fiji Arthropod Survey), the types of the new species are deposited in the Bernice P. Bishop Museum, Honolulu (BPBM). The remaining FAS material is temporarily held in the Bishop Museum, pending deposition in Fiji, but some specimens have been retained by the authors in the Museu Nacional, Rio de Janeiro, Brazil (MNRJ) and the Natural History Museum, London, UK (BMNH), as indicated in the material examined.

For each recorded genus, a diagnosis and comments are given, and for each recorded species, a diagnosis, a description where appropriate together with genitalia illustrations, a list of all the material examined, comments (when pertinent), distribution and biological data are also given. Dissected terminalia have been placed in glycerine in microvials pinned with the respective specimen.

The morphological terminology follows McAlpine (1981) in the main, and for the special characters of *Atherigona*, such as the trifoliate process, we follow Pont (1986b) and Pont & Magpayo (1995). “Postpedicel” is used for “antennal flagellomere”, following

Stuckenbergs (1999). Data on the regional distribution of the species are taken mainly from Pont (1989). The key for the identification of Fijian muscid genera and species is modified from Pont (2006).

SYSTEMATICS

KEY TO THE FIJIAN GENERA AND SPECIES OF MUSCIDAE

1. Anepimeron partly setulose 2
- . Anepimeron bare 19
2. Proboscis adapted for piercing: elongate, strongly sclerotised and non-retractile, tapering from a broad base to a slender apex and with labella atrophied 3
- . Proboscis not adapted for piercing: moderately or weakly sclerotised and retracted into head, not tapering strongly to apex, and with labella well-developed and often fleshy 6
3. Palpus about one-third as long as labium. Meron and disc of proepisternal depression setulose. Notopleuron with numerous setulae in addition to the two setae 4
- . Palpus about three-quarters as long as labium. Meron and disc of proepisternal depression bare. Notopleuron without setulae 5
4. Tergites 3 and 4 each with black hind-marginal bands. Tibiae and tarsi mostly yellow, at most hind tibia rather brown. Setulae on ventral surface of vein R_{4+5} extending almost as far as cross-vein r-m or even beyond. Frons narrower in both sexes, its width at middle 1/7 to 1/9 (males) or 1/3 (females) of greatest head-width *Stomoxys indicus* Picard
- . Tergites 3 and 4 each with a pair of paramedian oval black spots. Legs black, tibiae narrowly yellow at base. Setulae on ventral surface of vein R_{4+5} usually confined to base. Frons broader in both sexes, its width at middle 1/4 (male) or almost 1/2 (female) of greatest head-width *Stomoxys calcitrans* (Linnaeus)
5. Convergent frontal setae fewer in number, 8–10 pairs. Palpus yellow. Male: thoracic hairs and setae shorter, for example acrostichal hairs with few exceptions much shorter than length of postpedicel; hairs on dorsal surface of hind tarsomeres 2 and 3 considerably longer than the width of the tarsomeres *Haematobia exigua* Meijere
- . Convergent frontal setae more numerous, 11–13 pairs. Palpus usually brown. Male: thoracic hairs and setae longer, for example acrostichal hairs fully equal to length of postpedicel; hairs on dorsal surface of hind tarsomeres 2 and 3 not longer than the width of the tarsomeres *Haematobia irritans* (Linnaeus)
6. Lower calypter broad, truncate posteriorly, its posterior margin following scutellar margin before diverging away 7
- . Lower calypter narrow, tongue-like, its posterior margin at right-angles to scutellum right from its base 11
7. Large coal-black species with deep yellow wing-base, body-length at least 11 mm. Anterior katepisternal seta absent. Base of vein R_{4+5} bare *Mesembrina meridiana* (Linnaeus)
- . Differently coloured and smaller species, body-length rarely even 9 mm. Anterior katepisternal seta present. Base of vein R_{4+5} setulose at least on ventral surface 8
8. Not metallic green species. Supra-squamal ridge bare. Greater ampulla, subcostal sclerite and face bare. Mid tibia without a posteroventral seta 9
- . Metallic green, blue or violet species. Supra-squamal ridge setulose along its entire length. Greater ampulla, subcostal sclerite and face above mouth-edge setulose. Mid tibia with a strong posteroventral seta beyond middle 10

9. Scutum with 4 undusted black vittae, the vittae separate and not fused either before or after suture. Sternite 1 setulose. Proepisternal depression setulose. Male: syntergite 1+2 yellow, at most with a brown median vitta. Female: tergites at least partly yellow; fronto-orbital plates usually yellowish grey pruinose ... *Musca domestica* Linnaeus
- Scutum with the two undusted black vittae on each side separated before suture but fused into a single vitta behind suture, the scutum thus appearing bivittate after suture. Sternite 1 bare. Proepisternal depression bare. Male: syntergite 1+2 entirely black. Female: tergites entirely dark; fronto-orbital plates white to greyish white pruinose *Musca vetustissima* Walker
10. Palpus and antenna yellow. Legs mostly though often indefinitely yellow. Body violet. Parafacial, face and gena golden pruinose. Abdominal tergite 5 silvery dusted and contrasting with the rest of the abdomen *Neomyia simmondsi* (Bezzi)
- Palpus and antenna dark. Legs wholly dark. Body bright green to blue-green. Parafacial and face silvery grey pruinose, gena brown. Abdominal tergite 5 usually undusted and not contrasting with the rest of the abdomen *Neomyia greenwoodi* (Bezzi)
11. Parafacial with one or more irregular rows of fine hairs for most or all of its length. Palpus moderately to strongly broadened in apical part. Vein R_{4+5} wholly bare. Prosternum bare. Male frons about one-third of head width 12
- Parafacial bare. Palpus slender or very slightly broadened in apical part. Vein R_{4+5} setulose at least on ventral surface. Prosternum setulose. Male frons at most one-sixth of head-width 16
12. 1 strong presutural dorsocentral seta. Fore tibia with a submedian posterior seta; hind tibia without a posterodorsal seta. Male: hind tibia with 2 anteroventral setae, and with a row of 6 fine, erect, posteroventral setae on apical half, longer than tibial depth; mid femur on apical fifth with a comb of dense, short, stout posteroventral setulae *Lispe pectinipes* Becker
- 1–2 short weak presutural dorsocentral setae. Fore tibia without a submedian posterior seta except for *L. assimilis* which also has hind tibia with a posterodorsal seta. Male: hind tibia with 1 anteroventral and without posteroventrals; mid femur without such a comb of posteroventral setulae 13
13. Fore tibia with a submedian posterior seta. Hind tibia with 1 posterodorsal. Vein M rather curved forward towards vein R_{4+5} in its apical part. Hind femur with 2 anteroventrals, one just after middle and one before apex, and without posteroventrals *Lispe assimilis* Wiedemann
- Fore tibia without a submedian posterior seta. Hind tibia without posterodorsal. Vein M not curved forward towards vein R_{4+5} , running straight to the wing margin. Hind femur without anteroventral setae except at apex, but if present (*L. bengalensis*) then posteroventral setae also present 14
14. Palpus brown. Hind tibia with a posteroventral apical seta. All femora in apical half with rows of anteroventral and posteroventral spinules. Tergite 5 entirely light grey dusted *Lispe bengalensis* (Robineau-Desvoidy)
- Palpus yellow. Hind tibia without a posteroventral apical seta. Femora without ventral spinules 15
15. Meron bare above hind coxa. 3 strong postsutural dorsocentral setae. 1 postsutural intraalar. Male: hind tarsomere 1 strongly expanded posteriorly to form a flap *Lispe* sp. indet., male
- Meron with a few setulae above hind coxa. 2 strong and 2 weak postsutural dorsocentral setae. 2 postsutural intraalars. Female: tergites 3 and 4 almost wholly dark brown, with a little yellowish grey dust along mid-line and laterally on hind margins *Lispe* sp. indet. female

16. Tegula dark brown. Ground-colour of abdomen dark. Femora black *Dichaetomyia* sp. A
 [1 female in very poor condition and too poor to assign to species-group; it could be mislabelled.]
- . Tegula yellow. Ground-colour of abdomen yellow. Femora yellow 17
17. Scutum wholly yellow, without dark vittae. Pleura yellow. Scutellum bare on lateral and ventral surfaces. 4 postsutural dorsocentral setae. Palpus brown. Wing clear. Male: mid and hind legs simple, not modified in shape or bristling *Dichaetomyia vicaria* (Walker)
- . Scutum yellow, with a pair of broad black vittae running from neck posteriorly on to basal lateral angle of scutellum. Pleura mostly dark. Scutellum with dark setulae on lateral and ventral surfaces. 3 postsutural dorsocentral setae. Palpus yellow. Foremargin of wing conspicuously darkened between tips of veins R_1 and R_{2+3} . Male: mid and hind legs with striking modifications in shape and bristling (see Bezzi, 1928: fig. 52 on p. 178, as *prodigiosa*) 18
18. Central part of scutum, between the broad black paramedian vittae, orange-yellow in ground-colour. Wing tinged with orange in basal half, conspicuously dark smoky in apical half. Male: mid femur with the long fine posterior to posteroventral setae continued from base almost to apex of femur, mid tarsus with the posterior hairs on tarsomeres 1 and 2 curled at tips; hind femur with the anterodorsal row of setae complete, with the anterior row of setae becoming longer and more anteroventral in apical half and the 4–5 short anteroventrals after the last strong seta curved downwards as normal; hind femur on posteroventral surface with the median group of short setae consisting of 7 setae in a single row; hind tibia with the dorsal to anterodorsal hairs that cover the whole length longer and denser, and the anterodorsal hairs on tarsomere 1 long and fine, longer than the tarsal depth, apical half of hind tibia and tarsomere 1 also with long posterodorsal hairs; ventral process at middle of hind tibia with the spoon-shaped piece shorter and broader, and the inner piece shorter and square-ended *Dichaetomyia elegans* Malloch
- . Central part of scutum, between the broad black paramedian vittae, black in ground-colour. Wing uniformly dark smoky. Male: mid femur with the long fine posterior to posteroventral setae confined to basal two-fifths of femur; mid tarsus with the posterior hairs on tarsomeres 1 and 2 curled along their whole lengths; hind femur with the anterodorsal row absent, the anterodorsal to anteroventral surfaces in basal half covered with dense setae and setulae, the 6 short anteroventrals after the last strong seta upcurved, not downcurved; hind femur on posteroventral surface with the median group of short setae consisting of 12 setae, more extensive and not uniserial; hind tibia with the dorsal to anterodorsal hairs that cover the whole length shorter and sparser, and the anterodorsal hairs on tarsomere 1 inconspicuous and not as long as tarsal depth, apical half on hind tibia and tarsomere 1 without any posterodorsal hairs; ventral process at middle of hind tibia with the spoon-shaped piece longer and narrower, and the inner piece longer and smoothly rounded at tip *Dichaetomyia taveuniana* Pont & Evenhuis
19. Node at base of vein R_{4+5} with 1 or more setulae on dorsal as well as ventral surfaces ... 20
- . Node at base of vein R_{4+5} bare on dorsal surface, bare or setulose on ventral surface ... 25
20. Lower calypter broad, truncate posteriorly, its posterior margin following scutellar margin before diverging away. Several pairs of presutural and postsutural acrostichal setae present. Meron with a few setulae above hind coxa and, sometimes, below spiracle. Female: frontal vitta with many setulae and a pair of crossed setae 21
- . Lower calypter narrow, tongue-like, its posterior margin at right-angles to scutellum right from its base. Without acrostichal setae except for 1 pair before scutellum. Meron entirely bare. Female: frontal vitta bare 22

21. Post-alar wall bare. Eye bare. Abdomen very thinly dusted, appearing matt black in dorsal view. 1 intraalar seta. Palpus black. Scutum with brownish grey to golden-grey dust and with conspicuous vittae *Passeromyia veitchi* Bezzı
- . Post-alar wall with a tuft of setulae. Eye densely haired. Abdomen densely blue dusted. 3, rarely 2, intraalar setae. Palpus yellow, rarely brown. Scutum with dense ash-grey or blue-grey dust and very weak vittae *Passeromyia indecora* (Walker)
22. Prosternum bare. Mid femur with an anterior preapical seta. Hind tibia with a dorsal and an anterodorsal preapical seta. Prealar seta short but distinct. Arista long-plumose. Body, antenna, palpus and legs yellow *Myospila effeminata* Vockeroth
- . Prosternum setulose. Mid femur without an anterior preapical seta. Hind tibia with only the dorsal preapical seta, the anterodorsal absent. Prealar seta wholly absent. Arista at most short-plumose. Body, antenna, palpus and legs black 23
23. Knob of halteres black. 3 strong postsutural dorsocentral setae. Presutural acrostichal setulae in 2 rows. Scutellum in posterior view brown dusted. Male: frons broad, about 1/3 of head width. Very small species *Limnophora penicillata* Pont & Couri, sp. nov.
- . Knob of halteres yellow. 4 postsutural dorsocentrals setae. Presutural acrostichal setulae in 4 rows. Scutellum in posterior view matt black 24
24. Combined aristal hairs less than half width of postpedicel. Dust on abdominal tergites light grey. Calypters with brown borders. All postsutural dorsocentrals strong. Male: frons narrow, not much broader than width of postpedicel *Limnophora shinonagai* Pont & Couri, sp. nov.
- . Combined aristal hairs equal to width of postpedicel. Dust on abdominal tergites yellowish or brownish grey. Calypters wholly creamy white. Anterior 2 pairs of postsutural dorsocentrals weak, much shorter than the others. Male: frons broad, one-third of head-width *Limnophora mesolissa* Bezzı
25. Prosternum setulose. Scutellum with numerous setulae on sides and at ventral angle. Vein M curved forward towards vein R_{4+5} in apical part so that cell r_{4+5} is very narrow at tip. Body colour dark, except for the orange tergite 5 *Synthesiomyia nudiseta* (Wulp)
- . Prosternum bare. Scutellum bare on sides and at ventral angle (except *Muscina*, which has femora mainly dark and scutellum dark with a yellow tip). Vein M straight ... 26
26. Head subquadrate in lateral view, with the antenna long and inserted just below level of upper eye-margin. Presutural dorsocentral setae short and weak, hardly distinguishable from the ground-setulae. Fore femur with 0–2 posteroventral setae, situated near apex ... *Atherigona* Rondani 27
- . Head variable in shape, but never subquadrate, and antenna inserted well below level of upper eye-margin. Presutural dorsocentral setae distinct and strong, longer than the ground-setulae. Fore femur with a complete row of posteroventral setae 33
27. Presutural acrostichal setulae in 4–6 rows at suture. Cross-vein r-m placed at or beyond middle of cell dm. Basal lateral scutellar setula at least 1/3 length of subbasal lateral seta. Male: fore femur with a preapical dorsal excavation (Fig. 15); hypopygial prominence and trifoliate process absent (Fig. 14). Female: tergite 8 without a pair of small anterior platelets (Fig. 18) 28
- . Presutural acrostichal setulae in 2–3 rows at suture. Cross-vein r-m placed basad of middle of cell dm. Basal lateral scutellar setula at most 1/4 length of subbasal lateral seta. Male: fore femur without a preapical dorsal excavation; hypopygial prominence and trifoliate process present (Figs 2–5). Female: tergite 8 with a pair of small anterior platelets (Fig. 22) 30

28. Hind femur with a preapical dorsal seta. Dark vittae on scutum usually weak. Ground-colour of pleura mostly black. Frontal vitta yellow to orange. Male: hind femur and tibia without a ventral keel; abdominal tergite 3 not extended ventrally *Atherigona orientalis* Schiner
- Hind femur without a preapical dorsal seta. Dark vittae on scutum broad, distinct and well-marked. Frontal vitta dark brown. Ground-colour of pleura mainly yellow. Male: hind femur and hind tibia each with a ventral keel; abdominal tergite 3 extended ventrally (Fig. 14) 29
29. Wing clear. Male: palpus yellow to brown *Atherigona poecilopoda* Bezzi
- Wing with a dark cloud at tip between veins R_{2+3} and M. Male: palpus brown *Atherigona hendersoni* Malloch
30. Occiput and fronto-orbital plate shining black. Male: hypopygial prominence and trifoliate process as in Figs 19–21, the trifoliate process extremely flattened *Atherigona splendens* Bezzi
- Occiput and fronto-orbital plate pruinose. Male: hypopygial prominence and trifoliate plate different 31
31. Male: fore tarsomeres 3 and 4 with some distinct erect hairs along dorsal and anterodorsal surfaces, some of them longer than length of the tarsomere on which they are situated; hypopygial prominence and trifoliate process as in Figs 2–5 *Atherigona bidens* Hennig
- Male: fore tarsomeres simple, without long hairs 32
32. Male: subcosta with a dark smudge at tip; hypopygial prominence and trifoliate process as in Figs 10–13 *Atherigona oryzae* Malloch
- Male: subcosta clear, without a dark smudge at tip; hypopygial prominence and trifoliate plate as in Figs 6–9 *Atherigona matema* Curran
33. Katepisternal setae not arranged in an equilateral triangle, the anterior one further separated from the posterior 1–3. Lower proepimeral seta directed upwards 34
- Katepisternal setae arranged in an equilateral triangle, the lower one equidistant from the upper two. Lower proepimeral seta directed forwards and downwards 35
34. Subcosta very close to vein R_1 for most of its length, diverging from it only near apex of subcosta, its course sinuous rather than smooth. Vein M curved forward towards vein R_{4+5} in apical part. Arista plumose. Tip of scutellum and tibiae yellow. Posterior margin of eye not concave below *Muscina stabulans* (Fallén)
- Subcosta diverging from vein R_1 at a point very close to the base of both veins, running in a smooth curve to costa. Vein M running straight to the wing margin. Arista pubescent. Body and legs dark. Posterior margin of eye concave below *Hydrotaea spinigera* (Stein)
35. Head with only one pair of reclinate orbital setae. Hind tibia with 1 anterodorsal seta. 1 presutural dorsocentral seta *Coenosia fijiensis* Pont & Couri, sp. nov.
- Head with 2 pairs of reclinate orbital setae. Hind tibia with 2 anterodorsal setae. 1 or 2 presutural dorsocentral setae 36
36. Mid tibia with 2 submedian posterior setae. Frontal triangle small and confined to the area of the ocelli, not nearly reaching lunule. Fore tibia with a strong submedian posteroventral seta. Arista very long plumose on basal half and bare on apical half, the longest hairs twice width of postpedicel 37
- Mid tibia with 1 submedian posterior seta. Frontal triangle large or at least long and narrow, more or less reaching lunule. Fore tibia without a posteroventral seta. Arista shorter plumose, the longest hairs equal to width of postpedicel and continued evenly to tip of arista 38

37. Mid femur with 2 preapical posterior setae. Frons with 2 pairs of frontal setae, both strong, and fronto-orbital plate bare. Male: tergite 4 with a long patch of short dense curled setulae on sides; hind femur with 2 anteroventral and 2 posteroventral setae in basal quarter, both very long and strong *Pygophora ctenophora* Bezzii
- Mid femur with 1 preapical posterior seta. Frons with 4 pairs of frontal setae, 2 strong and 2 weak, and fronto-orbital plate outside the frontal setae with short proclinate setulae. Male: tergite 4 without a patch of setulae; hind femur with only a few short fine posteroventral setae in basal half *Pygophora* sp.
38. Lower calypter normal in size, projecting beyond upper one. Scutellum with the basal setae absent. Wing milky white along posterior and apical margins, brown along anterior margin, and elsewhere pale smoky brown. Hind tibia with only 1 short submedian posterodorsal seta *Orchisia costata* (Meigen)
- Lower calypter reduced, linear, not projecting beyond upper one. Basal scutellar seta half as long as apical one. Wing completely clear. Hind tibia with 2 posterodorsal setae 39
39. Palpus dark brown 40
- Palpus yellow 41
40. Mid femur with short, decumbent hairs along posteroventral edge, as on disc. Male: mid coxa without any particularly long setae; abdomen yellowish, dark spots on tergites 4 and 5 longer, only a little separated from fore- and hind-margins of the tergites. Female: tergites 3 and 4 with the dark median vitta and lateral spots broader and bolder, each spot and vitta much broader than the yellow space separating them; male sternite 5 without long setae on margin *Parvisquama dolichocera* Bezzii
- Mid femur with a comb-like series of strong setae in apical third of posteroventral surface. Male: mid coxa with strong setae on ventral surface; syntergite 1+2 yellowish, tergites 3 and 4 with grey pollinosity, yellow only on the apical margin, tergite 5 with no yellow marks; tergites 3 and 4 with lateral and median brown clouds, tergite 5 with two round lateral clouds; male sternite 5 with long setae on margin *Parvisquama longiseta* Pont & Couri, sp. nov.
41. Mid femur with 4–5 short stout spinules in apical sixth of posteroventral surface; male surstyli shorter than height of epandrium *Parvisquama femorata* Pont & Couri, sp. nov.
- Mid femur with more than 5 spinules on posteroventral surface; male surstyli as long as or much longer than height of epandrium 42
42. Male: mid coxa on lower anterior edge with several stout setae; cercal plate as long as height of epandrium *Parvisquama tripuncta* (Malloch)
- Male: mid coxa at lower anterior edge without any particularly long setae; cercal plate more than twice as long as height of epandrium 43
43. Abdomen largely yellow, almost without grey pollinosity especially in females and with brown marks; male cercal plate sinuous in lateral view *Parvisquama curvicerca* Pont & Couri, sp. nov.
- Abdomen yellow with grey pollinosity on tergites 4 and 5 and with brown marks; male cercal plate not sinuous in lateral view, curved inwards at apex *Parvisquama longicerca* Pont & Couri, sp. nov.

A total number of 44 species, 39 recognized as members of Fijian fauna and distributed in 18 genera, were studied, including 16 endemics (41%). Seven new species are described; four species and one genus are newly recorded from the Fiji Islands.

Atherigoninae

Genus *Atherigona* Rondani

Atherigona Rondani, 1856: 97. Type species: *Anthomyia varia* Meigen, 1826, by original designation.

Diagnosis. *Atherigona* can be easily distinguished from all other muscid flies by the characteristically angular head, with long face and antennal postpedicel; arista bare; one pair of reclinate orbital setae; palpus strongly differentiated between the two sexes and between the two subgenera *Atherigona* s.str. and *Acritochaeta* Grimshaw (Fig. 1, a-c); dorsocentral setae reduced; katepisternals 1+2; hind tibia without calcar; wing veins bare; males of sg. *Atherigona* with a hypopygial prominence (Figs 2–3) and a trifoliate process (Fig. 4–5); females with (sg. *Atherigona*) or without (sg. *Acritochaeta*) a pair of small anterior plates on tergite 8 of the ovipositor. Small flies, uniform in general appearance and structure; general colour grey or yellowish grey, with very short setae on scutum and legs.

Comments. Seven species are known to occur: *A. orientalis* Schiner, throughout the Old and New World tropics and subtropics; *A. oryzae* Malloch and *A. bidens* Hennig, mainly Indo-Australasian in distribution; *A. matema* Curran, a Melanesian species; *A. hendersoni* Malloch, a Pacific species; *A. poecilopoda* Bezzii and *A. splendens* Bezzii are endemic to Fiji.

1. *Atherigona (Atherigona) bidens* Hennig, new record (Figs 2–5)

Atherigona tridens Malloch, ssp. *bidens* Hennig, 1952: 67. Holotype male, Flores Island, Ende, in SDEI [seen].

Atherigona bidens; Davies & Reddy, 1981: 35; Pont, 1986b: 37, figs 148–164; Pont, 1989: 681; Pont & Magpayo, 1995: 54, figs 126–148, 635–638.

Male

Head. All setae and setulae black. Ground-colour mainly dark beneath the pruinosity, only yellow on parafacial, face and gena; frontal plate dark brown, reddish towards lunule in immature specimens. Occiput and ocellar tubercle grey pruinose; fronto-orbital plate, parafacial, face and gena light grey pruinose. 4–5 pairs of moderate inclinate frontal setae. Scape and pedicel mainly brown on disc; postpedicel dark brown, red at most at extreme base; arista brown. Parafacial at lunule a little over 1/2 width of postpedicel. Palpus yellow, dull or brown at extreme base. Prementum dark brown, glossy.

Thorax. Ground-colour of thorax dark, postpronotal lobes and proepisternal area slightly paler beneath dusting; scutellum dark. Prosternum dark brown, shining. Scutum densely grey dusted, tinged with yellowish behind, with traces of 3 dark vittae running through the dorsocentral and acrostichal rows, the acrostichal vitta broadest. Postpronotal lobes and pleura yellowish white dusted. Scutellum grey dusted. 1 strong and 1–2 weak proepimeral setulae. Disc of scutellum with 6–11 setulae.

Legs. Coxae and trochanters yellow. Fore femur wholly yellow. Fore tibia mainly yellow, darkened on apical 1/4. Fore tarsus brown. Mid and hind legs yellow, the tarsus dull. Fore tibia without setae except at apex. Fore tarsus along anterodorsal and dorsal surfaces with quite long fine hairs at tip of tarsomere 2 and on tarsomeres 3–4, some of which are longer than length of the segments on which they are situated.

Wing. Clear. Calypters creamy white. Knob of halteres creamy white.

Abdomen. Ground-colour yellow. Syntergite 1+2 unmarked; tergite 3 with 2 oval spots, occupying 1/4–1/3 of tergal length, and with or without a very faint partial median vitta; tergite 4 with 2 small oval spots, 1/4–1/3 of tergal length, and a partial median vitta; tergite 5 unmarked. Tergites grey to yellowish grey dusted: syntergite 1+2 dusted posteriorly and medially; tergites 3 and 4 dusted except on the dark markings; tergite 5 thinly dusted.

Terminalia. As in Figs 2–5. Hypopygial prominence yellow; consisting of 2 large, forwardly-directed tubercles and, on posterior part of stalk, with 2 small protuberances (Figs 2, 3). Trifoliate process with the stalk short, three times length of a lateral plate; stalk at base and tip, shoulders and basal half of lateral plates yellow, rest of process light brown to dark brown (Figs 4, 5).

Measurements. Length of body, 3.0 mm. Length of wing, 2.5 mm.

Female

Not known from Fiji. Described by Pont (1986b) and Pont & Magpayo (1995).

Material examined. FIJI: Viti Levu: Lautoka, Mar 1976, N.L.H. Krauss, 2♂ (BPBM); 0–50 m, Mar 1976, N.L.H. Krauss, 2♂, 7♀ (USNM); Tavua, 50–150 m, Feb 1971, N.L.H. Krauss, 1♂ (BPBM).

Comments. New record for Fiji.

Distribution. Nepal, India, Taiwan, Philippines, Flores, Papua New Guinea, Australia, Norfolk Island.

Biological data. It has been reared from several species of Gramineae (Davies & Reddy, 1981; Pont & Magpayo, 1995).

2. *Atherigona (Acritochaeta) hendersoni* Malloch

Atherigona hendersoni Malloch, 1923: 184. Holotype male, Henderson Island, in BMNH [seen].

Atherigona hendersoni; Hardy, 1981: 72–73, fig. 25; Pont, 1989: 681.

Diagnosis. Very similar to *Atherigona poecilopoda* Bezzi, and distinguished primarily by the faint dark cloud at the apex of the wing between the tips of veins R_{2+3} and M, visible in both sexes. Male palpus brown (yellow in *A. poecilopoda*).

Male

Head. All setae and setulae black. Ground-colour mainly dark beneath the pruinosity, only parafacial, gena, face and lowest occiput yellow; frontal plate wholly dark. Occiput light-grey pruinose; fronto-orbital plate yellowish white pruinose; parafacial and gena white, slightly tinged with yellowish. 5–7 pairs of moderate inclinate frontal setae. Antenna black. Arista brown. Parafacial at lunule only 1/3 width of postpedicel. Palpus brown; rather long, and with apical ventral pubescence relatively short and pale. Prementum dark brown, subshining.

Thorax. Ground-colour of scutum black, postpronotal lobe, pleura and most of scutellum yellow. Prosternum brownish yellow. Scutum grey to yellowish grey dusted, with 3 narrow but distinct dark vittae running along the acrostichal and dorsocentral lines from neck almost to scutellum, the acrostichal vitta continuing and expanding on scutellar disc. Postpronotal lobe yellowish white dusted, pleura pale golden dusted. Scutellum in posterior view with yellowish white dust. Presutural acrostichal setulae in 4 rows at suture, with a bare strip separating these rows from another row of setulae and the dorsocentral rows. 1 strong and 4–5 weak proepimeral setulae. Basal scutellar setula 1/2 as long as sub-basal lateral seta. Disc of scutellum with 22–27 setulae.

Legs. Wholly yellow, including tarsi. Fore femur with a strong preapical dorsal excavation; with 3–4 posterodorsal setae near base, and before apex with 2 posteroventrals. Fore tibia without setae except at apex. Fore tarsus not modified in shape, and with only the usual clothing-setulae. Mid femur with 1 preapical posterior setae. Hind femur without a dorsal preapical seta. Hind femur and tibia each with a distinct ventral keel.

Wing. Clear, but with a distinct but diffuse darkening at the tip between veins R_{2+3} and M. Cross-vein r-m at or slightly basad of middle of discal cell. Calypters creamy, the lower one sometimes yellow. Knob of halteres white.

Abdomen. Ground-colour mostly yellow. Tergites 3–5 each with a pair of round dark paramedian spots. In posterior view, tergites white to yellowish white dusted except on the spots. Tergite 3 produced ventrally and with sparse golden setulae along lower edge.

Measurements. Length of body, 3.5 mm. Length of wing, 3.0 mm.

Female

Much darker, and differing from the male as follows:

Head. Ground-colour dark but frontal plate more orange below. Pruinosity on fronto-orbital plate, parafacial, face, gena and occiput whitish grey. Palpus dark brown, weakly swollen apicad.

Thorax. Mostly black in ground-colour, postpronotal lobe and scutellar margin yellow. Pleura light grey dusted.

Legs. Coxae and trochanters yellow. Fore femur black, yellow at base and at tip; fore tibia yellow, but apical third dark. Mid and hind femora and tibiae obscurely yellow, hind tibia brown in apical half. All tarsi brown to black. Fore femur unmodified, with a short row of posterodorsal setae, and 1 strong and a few short posteroventrals before apex. Hind femur and tibia without keel.

Wing. Lower calypter pale yellow.

Abdomen. Ground-colour mostly dark, with variable amounts of yellow on basal segments; tergites 3–5 each with a pair of dark subtriangular to oval spots and with a narrow brown median vitta. The dark areas on tergites 3–5, except for the dark spots and median vitta, with dense grey to yellowish grey dust.

Measurements. Length of body, 3.0–3.5 mm. Length of wing, 2.5–3.0 mm.

Material examined (FAS): FIJI: Vanua Levu: Bua Prov., Batiqere Range, 6 km NW Kilaka Village, 98 m, 26 Jun–21 Jul 2004, 15.80° S, 178.991° E, Malaise 5, Schlinger, Tokota'a, FBA 141829 (♂). Other material: **FIJI:** bred from decaying fruit, no date, Compère, 2♀ (USNM); **Viti Levu:** Koronivia Research Station, coconut, 1 Mar 1963, C.M. Yoshimoto, 1♂ (BPBM); Suva, 23 Sep 1920, H.W. Simmonds, 1♀ (BMNH).

Comments. First recorded from Fiji by Pont (1989). There is a description with illustrations of the male terminalia, wing and fore femur in Hardy (1981).

Distribution. Fiji, Hawaiian Is, Henderson I., Pitcairn Is, Tonga, Western Samoa.

Biological data. Adults were attracted to baits of rotten organic matter, and adults were reared from rotting stems and bark of various trees and shrubs in Hawai'i (Hardy, 1981: 72).

3. *Atherigona (Atherigona) matema* Curran, new record (Figs 6–9)

Atherigona matema Curran, 1936: 56. Holotype male, Santa Cruz Group, Matema Island, in CAS [seen]. *Atherigona matema* Curran; Pont, 1986b: 27, figs 85–92; Pont, 1989: 681; Pont, 1991: 180.

Male

Head. All setae and setulae black. Ground-colour mainly yellow beneath the pruinosity, only the occiput and upper frons dark; frontal vitta wholly dark. Occiput grey pruinose. Ocellar tubercle and most of fronto-orbital plate light grey pruinose; lower fronto-orbital plate, parafacial, face and gena yellowish pruinose, almost pale golden. 4–5 pairs of moderate inclinate frontal setae. Scape and pedicel reddish, darkened on disc, postpedicel black. Arista, dark brown. Parafacial at lunule a little over 1/2 width of postpedicel. Palpus entirely yellow. Prementum dark brown.

Thorax. Ground-colour of scutum mainly dark, postpronotal lobe, notopleuron, supraalar area and postalar lobe yellow; pleura wholly yellow, scutellum dark. Prosternum dark brown. Scutum yellowish grey dusted, grey at neck, with traces of 3 narrow dark vittae running from neck almost to scutellum through the acrostichal and dorsocentral rows, the acrostichal vitta broader than the dorsocentral ones. Postpronotal lobe and notopleuron yellowish white, the

pleura golden pollinose. Scutellum yellowish grey dusted on the darkened part. Ground-setulae all black. 1 strong and 1 weak proepimeral setulae. Disc of scutellum with 9–10 setulae.

Legs. Coxae and trochanters yellow. Fore femur yellow, apical third dark. Fore tibia yellow on basal half, otherwise dark. Fore tarsus dark, the apical 2 tarsomeres dull yellow. Mid and hind femora, tibiae and tarsi yellow. Fore tibia without setae except at apex. Fore tarsus not modified in shape, and with only the usual clothing-setulae.

Wing. Clear. Calypters creamy. Haltere creamy white.

Abdomen. Ground-colour yellow. Tergites 1+2 and 5 without dark markings; tergites 3 and 4 each with a pair of elongate-quadrata dark brown spots, occupying 1/3 of tergal length. Tergites in extreme posterior view with a little yellowish white dust: on the hind margin of syntergite 1+2, between the dark spots on tergites 3 and 4, and on most of tergite 5.

Terminalia. Hypopygial prominence yellow, small, knob-like, not expanded laterally, more or less rounded dorsally (Figs 6,7). Trifoliate process with the stalk moderate, 4 times as long as the lateral plate; stalk and base of shoulder brown, rest of shoulder and process black (Figs 8–9).

Measurements. Length of body, 2.5 mm. Length of wing, 2.0 mm.

Female

Differs from the male as follows.

Head. Palpus brown in basal half (3 females) or wholly brown (1 female).

Thorax. Dark vittae on scutum very distinct. Scutellum with 6–8 discal setulae, 2 of which are twice as long as the others.

Legs. Fore femur black, yellow at base. Fore tibia black, yellow at base or on basal 1/6. Fore tarsi black. Hind tibia brownish.

Abdomen. Syntergite 1+2 without spots; tergites 3–5 each with a pair of large quadrata dark spots occupying well over half of tergal length, and with a narrow less distinct median vitta. Dusting yellowish white to yellowish grey, on hind-margin of syntergite 1+2 and on tergites 3–5 except for the dark spots.

Measurements. Length of body, 2.5–3.0 mm. Length of wing, 2.5–3.0 mm.

Material examined. FIJI: Taveuni: Waiyevo, 0–100 m, Jan 1972, N.L.H. Krauss, 1♂, 4♀ (BPBM).

Comments. New record for Fiji. This male is darker than Melanesian *A. matema* that we have seen, but appears to be this species which has a characteristic hypopygial prominence. In Melanesian males of *A. matema*, the frontal vitta is red to orange below, the basal part of postpedicel is reddish, and fore femur is wholly yellow.

Distribution. Solomon Islands, Australia, Fiji.

Biological data: Nothing is known.

4. *Atherigona (Acritochaeta) orientalis* Schiner

Atherigona orientalis Schiner, 1868: 295. Holotype female, Nicobar Is: Tellnschong, in NMW [Pont, 1986b: 18].

Coenosia excisa Thomson, 1869: 560. Lectotype male, Cocos-Keeling Is, in NRS [designation by Pont, 1986b: 18].

Atherigona trilineata Stein, 1900: 157. Syntypes females, Papua New Guinea: Friedrich-Wilhelm-Hafen [= Madang], not found in ZMHU and presumed lost [Pont, 1969a: 89].

Acritochaeta pulvinata Grimshaw, 1901: 42. Lectotype male, Hawai‘i I: Ola‘a, in BMNH [designation by Pont, 1986b: 18].

Atherigona pulvinata; Aldrich, 1921: 94.

Atherigona excisa; Bezzi, 1928: 171; Greenwood, 1929: 352; Lever, 1944c: 77; Lever, 1965: 154.

Atherigona excisa var. *trilineata*; Bezzi, 1928: 171; Emden, 1942: 95.

Atherigona orientalis; Hennig, 1961: 500; Hinckley, 1963: 31; Pont, 1973a: 59–62; Pont, 1986b: 18; Pont, 1989: 681; Pont in Cahill, 1992: 53–54; Pont & Magpayo, 1995: 21–23, figs 11–12, 526–531.

Atherigona excisa ssp. *trilineata*; Lever, 1965: 154.

Diagnosis. Presutural acrostichal setulae in 4–5 rows, and male without hypopygial prominence or trifoliate process. Differing from the other two species of sg. *Acritochaeta* by the presence of a dorsal preapical seta on hind femur, frontal vitta yellow or reddish, at least above lunule, scutum with the dark vittae indistinct, pleura black in ground-colour, male without a ventral keel on hind femur and tibia.

Material examined (FAS): FIJI: Kadavu: Solodamu, 25 Aug–23 Oct 2003, FJ-41D Malaise in coastal limestone forest, M. Irwin, E. Schlinger, M. Comments. First recorded from Fiji by Aldrich (1921). Fijian material was also listed by Pont (in Cahill, 1991: 53–54).

Distribution. Widespread through the Pacific, including American Samoa, Belau, Bonin Is., Easter I., French Polynesia, Guam, Hawaiian Is., Johnston Atoll, Kiribati, Marcus I., Marshall Is., Micronesia, Nicobar Is., Niue, Northern Marianas, Palmyra Atoll, Tonga, Vanuatu, Volcano Is., Wake Is., Western Samoa; pantropical, Old World and New World.

Biological data. Reared in Fiji from diseased or rotting cotton bolls (Bezzi 1928; Greenwood 1929), oranges (Bezzi 1928), rotting banana containing larvae of *Nacoleia octasema* (Bezzi 1928), and bat guano in caves (Lever 1944c, 1965). A list of hosts in Fiji is given by Hinckley (1963): *Brassica oleracea*, *Citrus* sp., *Gossypium* sp., *Musa* sp., and *Zea mays*. The biology is discussed in detail for Guam by Bohart & Gressitt (1951: 111), and a recent summary is given by Pont (1973a). The species is a minor public health hazard.

5. *Atherigona (Atherigona) oryzae* Malloch, new record (Figs 10–13)

Atherigona oryzae Malloch, 1925b: 117. Holotype male, India: Tamil Nadu, Coimbatore, in USNM [seen]. *Atherigona oryzae*; Snyder, 1965: 252; Pont, 1973a: 47–51, fig. 13; Pont, 1986b: 442, figs 201–214; Pont, 1989: 682; Pont & Magpayo, 1995: 60–64, figs 211–243, 658–663.

Male

Head. Setae and setulae black. Ground-colour black beneath the pruinosity, except on parafacial, face and gena; frontal vitta dark brown, occiput and ocellar tubercle grey pruinose; fronto-orbital plate, parafacial, face and gena light grey pruinose. 4 pairs of moderate inclinate frontal setae. Scape and pedicel reddish, partly darkened on disc; postpedicel dark brown. Arista brown, paler near base. Palpus yellow, sometimes dull or brown at base. Prementum dark brown, glossy.

Thorax. Ground-colour of scutum dark; postpronotal lobes yellow; pleura yellow anteriorly, darker posteriorly; scutellum dark. Prosternum brown, shining. Scutum densely grey to yellowish grey dusted, with very faint traces of 3 dark vittae through the acrostichal and dorsocentral rows. Postpronotal lobes and pleura yellowish white dusted. Scutellum grey to

yellowish grey dusted. 1 strong and 1 weak proepimeral setulae. Disc of scutellum with 6–14 setulae.

Legs. Coxae and trochanters yellow. Fore femur yellow, darkened on apical 1/3. Fore tibia yellow, darkened on apical 3/5. Fore tarsus dark, the apical 1–2 or 3 tarsomeres pale. Mid and hind legs yellow. Fore tibia without setae except at apex. Fore tarsus not modified in shape, and with only the usual clothing-setulae.

Wing. Clear except for a conspicuous dark smudge at the tip of subcosta. Calypters yellowish, the lower one usually quite deep, even rather smoky. Knob of halteres creamy white.

Abdomen. Ground-colour yellow. Tergites 1+2 and 5 unmarked; tergite 3 with a pair of elongate-triangular or -quadrate spots, occupying 1/2 to 1/3 of tergal length, and with or without a partial median vitta; tergite 4 with a pair of oval spots, 1/3 of tergal length. Tergites yellowish grey dusted: syntergite 1+2 dusted medially, laterally and on hind margin; tergites 3 and 4 wholly dusted except on the dark markings; tergite 5 thinly dusted.

Terminalia. As in Figs 10–13. Hypopygial prominence large and bifurcate (Figs 10–11), trifoliate process with the stalk long, just over 4 times as long as the lateral plate, and strikingly expanded around middle (Fig. 12); stalk and shoulder brown; lateral plates dark brown; median piece pale, membranous (Figs 12–13).

Measurements. Length of body, 3.0–3.5 mm. Length of wing, 2.5–3.0 mm.

Female

Differs from the male as follows.

Head. Antenna usually darker, only tip of pedicel reddish. Palpus yellow, dark on up to basal 1/2, but sometimes wholly brown; with dark setulae.

Legs. Coxae and trochanters yellow; mid and hind femora and tibiae yellow, their tarsi dull yellow to brown. Fore femur mainly dark, yellow at tip and on basal 1/3–1/4. Fore tibia mainly dark, yellow on basal 1/4–1/2. Fore tarsus dark brown.

Wing. Clear. Calypters creamy white, lower one sometimes deeper yellow as in male.

Abdomen. Ground-colour yellow. Dark markings rather variable: tergites 1+2 to 5 with a weak or strong partial median vitta; tergite 3 with 2 spots, small, weak, 1/5 of tergal length, or strong, triangular, 1/2–1/3 of tergal length; tergite 4 with 2 triangular spots, 1/3–2/3 of tergal length, and fore margin sometimes darkened; tergite 5 with 2 small spots, and fore margin sometimes darkened. Tergites yellowish to golden-white dusted on the hind-margin and sides of syntergite 1+2, and on all of tergites 3–5 except for the dark spots.

Ovipositor. Sternite 6 as wide as long, or very slightly longer than wide, or even up to 1½ times as wide as long.

Measurements. Length of body, 3.0–3.5 mm. Length of wing, 2.5–3.0 mm.

Material examined (FAS): FIJI: Viti Levu: Sigatoka Sand Dunes Nat. Park, 1.1 km SSW Volivoli Village, 55 m Malaise trap [18.1594, 177.4847], 5–17 Apr 2004, Schlinger, Tokota'a, FJVL6b_M02_19, FBA 089815 (♂), FBA 089802 (♂), FBA 089798 (♂), FBA 089786 (♂), FBA 089803 (♂), FBA 089809 (♂), FBA 089813 (♂), FBA 089785 (♀), FBA 089797 (♀), FBA 089794 (♀), FBA 089795 (♀), FBA 089811 (♀). Other material examined: **FIJI: Moala:** 13 Jul 1924, E.H. Bryan, 1♂ (BPBM). **Viti Levu:** Lautoka, Mar 1976, N.L.H. Krauss, 1♂ (BPBM); Nandi, 0–100 m, 5 Jun 1973, N.L.H. Krauss, 1♂ (USNM).

Distribution. Widespread throughout the Oriental and Australasian/Oceanian regions. In the Pacific known from Belau, Lord Howe I., New Caledonia, Tonga, Vanuatu, Volcano Is., Western Samoa and Fiji (new record).

Biological data. The species is an important pest of rice, and its biology was discussed in detail by Pont (1973a). A full list of the wild and cultivated Gramineae hosts is given in Pont & Magpayo (1995: 62).

6. *Atherigona (Acritochaeta) poecilopoda* Bezzi
(Figs 14–15)

Atherigona poecilopoda Bezzi, 1928: 172. Lectotype male, Fiji: Suva, in BMNH [designation by Pont, 1970b: 422].

Atherigona poecilopoda; Greenwood, 1929: 352; Lever, 1938a: 23; Greenwood, 1940: 218; Emden, 1942: 95; Hinckley, 1963: 31; Pont, 1989: 682.

Diagnosis. Very similar to *Atherigona hendersoni* Malloch, and distinguished primarily by the clear wing in both sexes. Male palpus yellow (brown in *A. hendersoni*).

Male

Head. All setae and setulae black. Ground-colour mainly dark beneath the pruinosity, only parafacial, gena, face and lowest occiput yellow; frontal plate wholly dark. Occiput light-grey pruinose; fronto-orbital plate yellowish white pruinose, slightly brownish along inner margin; parafacial and gena white, slightly tinged with yellowish. 5–7 pairs of moderate inclinate frontal setae. Antenna black, tip of pedicel orange. Arista dark, yellow on basal half. Parafacial at lunule only 1/3 width of postpedicel. Palpus yellow to orange; rather long, and with apical ventral pubescence relatively short and golden. Pmentum dark brown, subshining.

Thorax. Ground-colour of scutum black, postpronotal lobe, pleura and most of scutellum yellow. Prosternum brownish yellow. Scutum yellowish grey dusted, with 3 narrow but distinct dark vittae running along the acrostichal and dorsocentral lines from neck almost to scutellum, the acrostichal vitta continuing and expanding on scutellar disc. Postpronotal lobe yellowish white dusted, pleura pale golden dusted. Scutellum in posterior view with yellowish white dust. Presutural acrostichal setulae in 6 rows at suture, occupying all the space between the dorsocentral rows. 1 strong and 4–5 weak proepimeral setulae. Basal scutellar setula ½ as long as sub-basal lateral seta. Disc of scutellum with 22–27 setulae.

Legs. Wholly yellow, tarsi yellow to brown. Fore femur with a strong preapical dorsal excavation; with 1–2 posterodorsal setae near base, and before apex with 2 posteroventrals. Fore tibia without setae except at apex. Fore tarsus not modified in shape, and with only the usual clothing-setulae. Mid femur with 1 preapical posterior seta. Hind femur without a dorsal preapical seta. Hind femur and tibia each with a distinct ventral keel.

Wing. Clear. Cross-vein *r-m* slightly beyond middle of discal cell. Calypters creamy, the lower one sometimes yellow. Knob of halteres white.

Abdomen. Ground-colour yellow on syntergite 1+2 and part of tergite 3, the rest of the tergites black. Tergites 3–5 each with a pair of round dark paramedian spots. In posterior view, tergites white to yellowish white dusted on the dark areas. Tergite 3 produced ventrally (Fig. 14) and with dense golden setulae along lower edge.

Terminalia. Figs 16–17.

Measurements. Length of body, 3.5 mm. Length of wing, 3.0 mm.

Female

Much darker, and differing from the male as follows:

Head. Ground-colour dark but frontal plate more orange below. Pruinosity on fronto-orbital plate, parafacial, face, gena and occiput whitish grey, inner margin of fronto-orbital plate brown. Palpus dark brown, filiform.

Thorax. As in male.

Legs. Coxae and trochanters yellow. Fore femur black, yellow at base and at tip; fore tibia yellow, but apical third dark. Mid and hind femora and tibiae yellow. All tarsi brown to black. Fore femur unmodified, with a short row of posterodorsal setae, and 1 strong and a few short posteroventrals before apex. Hind femur and tibia without keel.

Wing. Lower calypter pale yellow.

Abdomen. Ground-colour mostly dark, with variable amounts of yellow on basal segments; tergites 3–5 each with a pair of dark subtriangular to oval spots and with a narrow brown median vitta. The dark areas on tergites 3–5, except for the dark spots and median vitta, with dense grey to yellowish grey dust.

Measurements. Length of body, 3.5 mm. Length of wing, 3.0 mm.

Bryan, 1♀ (BPBM).

Comments: Some males have the hind tibia strikingly bicoloured, yellowish white in basal half and black in the apical half, but this appears to be an artefact as most have the hind tibia clear yellow.

In the series of males from Koronivia, there are indications of faint darkening at the wing tip, and there is one male in which the darkening is very much more marked and which we have identified as *A. hendersoni*. It seems possible to us that *A. poecilopoda* and *A. hendersoni* are synonymous, as there appears to be no consistent difference between the males, but for the present we are maintaining them as distinct.

Distribution. Fiji. Other Pacific records given by Pont (1989) are based either on misidentifications or on specimens misplaced in the BMNH collection.

Biological data. It has been reared on several occasions from the Tahitian chestnut, *Inocarpus edulis* (Greenwood, 1929, 1940; Lever, 1938a). A list of host plants is given by Hinckley (1963): *Artocarpus altilis*, *Datura* sp., *Erythrina lithosperma*, *Gossypium* sp., *Inocarpus fagifer*. We can add *Citrus maxima* to this list.

7. *Atherigona (Atherigona) splendens* Bezzı (Figs 19–23)

Atherigona splendens Bezzı, 1928: 173. Lectotype male, Fiji: Suva, in BMNH [designation by Pont, 1970b: 423].

Atherigona laeta; Malloch, 1929b: 158; Pont, 1989: 681 [misidentification].

Atherigona splendens; Emden, 1942: 95; Pont, 1989: 682.

Diagnosis. Easily distinguished from the other Fijian species by the shining black occiput and fronto-orbital plate.

Male

Head. All setae and setulae black. Ground-colour black, only parafacial and gena yellow beneath the pruinosity; frontal vitta dark brown. Occiput on a broad band running alongside eye from vertex to lower eye margin, ocellar tubercle and fronto-orbital plate wholly shining black; parafacial and gena silvery white pruinose. 3–4 pairs of moderate inclinate frontal setae. Scape, pedicel and base of postpedicel orange to brown, rest of postpedicel dark brown. Arista yellow in basal half. Parafacial at lunule over half width of postpedicel. Palpus yellow, of unusual shape and length for a species of this subgenus (Fig. 1c). Prementum dark brown, shining.

Thorax. Ground-colour of scutum and scutellum black; postpronotal lobe, notopleuron and pleura yellow. Scutum thinly brown dusted, more grey laterally; dusting on postpronotal lobe and pleura yellowish white, almost pale golden; scutellum thinly brown dusted. Prosternum yellow, shining. Ground-setulae all black. 1 strong and 1–2 weak proepimeral setulae. Disc of scutellum with 6–7 setulae, lateral margins bare.

Legs. Coxae and trochanters yellow. Fore femur yellow. Fore tibia brown, yellow on basal third to half. Fore tarsus dark. Mid and hind legs yellow. Fore tibia without setae except at apex. Fore tarsus with setulae on the anterodorsal surface at the tip of tarsomere 3 and along tarsomeres 4 and 5, these much longer than depth of tarsomeres.

Wing. Clear. Upper calypter creamy; lower calypter mostly yellow to dull yellow. Knob of halteres yellowish white.

Abdomen. Ground-colour orange-yellow, with few dark markings though often darkened through post-mortem decay of the internal organs: syntergite 1+2 with a dark median vitta; tergite 3 with a median mark and with a pair of very small weak spots in posterior half; tergite 4 with a broad quadrate median mark occupying whole of tergal length; tergite 5 unmarked. Tergites subshining, with a little light grey dust.

Terminalia. As in Figs 19–21. Hypopygial prominence small, with two low diverging arms (Fig. 19). Trifoliate process (Fig. 21) with the stalk 3 times as long as a lateral plate; stalk and trifoliate process brown to dark brown; trifoliate process dorso-ventrally flattened, in lateral view blade-like (and therefore impossible and uninformative to draw).

Measurements. Body-length, 3.0–3.5 mm. Wing-length, 2.5–3.0 mm.

Female

Differs from the male as follows:

Head. Antenna black, at most articulation between pedicel and postpedicel orange. Palpus brown, slender, curved.

Legs. Coxae and trochanters yellow. Fore femur yellow, dark on apical third to quarter. Fore tibia black, narrowly yellow at base. Fore tarsus black, hind tarsus brown to dull yellow. Fore tarsus simple in structure and bristling.

Abdomen. Ground-colour orange-yellow, with a broad black median vitta running from the fore-margin of syntergite 1+2 to the hind-margin of tergite 5. Tergites subshining, with little visible dust.

Ovipositor. As in Figs 22–23. Sternite 6 twice as long as broad. Tergite 8 broadly divided longitudinally.

Measurements. Body-length, 3.0 mm. Wing-length, 2.5 mm.

Sedlacek, 1♂ (BPBM). **Wakaya:** 17 Oct 1924, E.H. Bryan, 3♂, 5♀ (BPBM).

Comments. Pont (1989) erroneously listed both *A. laeta* (Wiedemann) and *A. splendens* from Fiji. *Atherigona laeta* is reliably known only from the Oriental region.

Distribution. Fiji, an endemic species.

Biological data. Nothing is known of the habits and biology.

Muscinae

Muscini

Genus *Mesembrina* Meigen

Mesembrina Meigen, 1826: ix, 10. Type species: *Musca meridiana* Linnaeus, 1758, by subsequent designation of Stephens in Richardson (1836: 116).

Diagnosis. *Mesembrina* can be recognised by its appearance: a large, coal-black fly with conspicuous yellow wing-base and calypters; eye bare or with sparse hairs; vein R₄₊₅ curved forwards at apex, the veins bare; scutellum with strong marginal setae.

Comments. The genus includes 11 species, all of which are restricted to temperate areas of the Holarctic. One species, *M. meridiana* (Linnaeus), introduced from Europe in 1932 for housefly control but not established.

8. *Mesembrina meridiana* (Linnaeus)

Musca meridiana Linnaeus, 1758: 595. Holotype male, Europe, in LSL [Pont 1981: 170].

Mesembrina meridiana; Simmonds, 1932: 9; Dumbleton, 1957: 6; Bornemissza, 1968: 674; Pont, 1989: 677.

Diagnosis. A large species, 10–12 mm in length; general colour shining black.

Material examined. No *Mesembrina* was found among the material studied.

Comments. This introduction appears to have been unsuccessful as the species is no longer a member of the Fijian fauna.

Distribution. Not Australasian/Oceanian [unsuccessfully introduced to Fiji] (Pont 1989).

Biological data. The larvae of this conspicuous black species are voracious carnivores in cattle dung (see Skidmore 1985: 189), and so the species was introduced from England to Fiji in 1931 for housefly control (Simmonds 1932; Dumbleton 1957). However, it failed to become established (Bornemissza 1968).

Genus *Musca* Linnaeus

Musca Linnaeus, 1758: 589. Type species: *Musca domestica* Linnaeus, 1758, by subsequent designation of I.C.Z.N. (1925: 295) [Opinion 82].

Diagnosis. Can be recognised by the non-metallic body colour and the sharply-angled forward bend of vein M. Male holoptic; eye bare; arista enlarged on basal fourth, long-plumose;

presutural acrostichals not developed; dorsocentrals 2:4; katepisternals 1:2; anepimeron setulose; prosternum setulose; lower calypter broad, truncate posteriorly, extending under base of scutellum; mid tibia without ventral seta; vein M with an angular forward bend towards vein R_{4+5} in apical part.

Comments. Most larvae live in dung and are coprophagous, but a few live in a much wider range of substrates. *Musca domestica* is omnivorous and breeds in any substrate where there is a high rate of fermentation. Predominantly an Old World genus of some 63 species, with only three common species spreading into the Oceanian region: the bush fly (*M. vetustissima*), the dog dung fly (*M. sorbens*), and the house fly (*M. domestica*). In the Fiji Islands, two species are recorded, both introduced: *M. domestica* Linnaeus, the common house fly, cosmopolitan; *M. vetustissima* Walker, the Australian bush fly.

9. *Musca domestica* Linnaeus

Musca domestica Linnaeus, 1758: 596. Syntypes ?sex, Europe and America, not located and presumed destroyed, not in LSL [Pont, 1973b: 170, and 1981: 168].

Musca oceanica Le Guillou, 1842: 316. Lectotype male, Australia: Hobart, in MNHNP [designation by Pont, 1973b: 170].

Musca australis Macquart, 1843: 309 (152). [Junior primary homonym of *Musca australis* Gmelin, 1790.] Lectotype male, Australia: Hobart, in MNHNP [designation by Pont, 1967: 187].

Musca vicina Macquart, 1851: 226 (253). Syntypes 2 males and 1 female, America: Martinique, in MNHNP [Pont, 1973b: 169].

Musca domestica; Gräffe, 1866: 589; Bahr, 1914: 294–296; Jepson, 1915: 24–25; Jepson, 1917: 23; Veitch & Greenwood, 1921: 517; Veitch & Greenwood, 1924: 161; Veitch, 1925: 379; Simmonds, 1925: 85; Bezzi, 1928: 183; Simmonds, 1928: 12 ff; Greenwood, 1929: 352; Simmonds, 1929a: 35; Simmonds, 1929b: 46; Simmonds, 1929c: 46–47; Bryan, 1931: 403; Simmonds, 1932: 9; Simmonds, 1940a: 197; Simmonds, 1940b: 21; Baxter, 1940a: 66–70; Baxter, 1940b: 96–98; Lever, 1941: 47; Lever, 1943: 83; Lever, 1944b: 73; Lever, 1945b: 89; Lever, 1946: 23; James, 1947: 140; Laird, 1951: 19; West, 1951: 1–584; Dumbleton, 1957: 6, 12, 20, 22; Saccà & Rivescchi, 1958: 1158; DeBach, 1962: 72; Hinckley, 1963: 18; Hennig, 1964a: 997–1008; Hennig, 1964b: 1009–1011; Bornemissza, 1968: 681; Swaine, 1971: 26, 310, 339, 356; Pont, 1973b: 168–179; Pont, 1989: 677.

Musca domestica vicina; Lever, 1938b: 15; Lever, 1944a: 49; Emden, 1965: 55; Rao, 1971: 21.

“Houseflies”; Simmonds, 1922: 24; Carment, 1922: 1–5; Simmonds, 1923a: 5; Simmonds, 1923b: 4; Lever, 1938c: 15; Anon, 1946: 111; Verrier, 1948: 87; O’Connor, 1950: 53–54.

Diagnosis. *Musca domestica* can be recognised by the presence of fine setulae on the proepisternal depression.

Material examined (FAS): FIJI: Kadavu: 0.25 km SW, Solodamu Village, 50 m, 7 Mar–11 Apr 2004, Malaise 3, Schlinger, Tokota'a, 19.078° S, 178.121° E, FBA 111699 (♂). **Taveuni:** Cakaudrove Prov., Tavuki Village, Mt. Devo, 892 m, 31 Jul–14 Aug 2004, Malaise 4, E.I. Schlinger, M. Tokota'a, 15.837° S, 179.973° W, FBA 113181 (♀). **Viti Levu:** Vuda Prov., Koroyanitu N.H.O., Savuione Trail, FJ-1, Malaise in montane forest, 21 Sep–7 Oct 2002, M. Irwin, E. Schlinger, M. Tokota'a, 17.40° S, 177.33° E, 450 m, FBA 002599 (♀). Other material examined: **FIJI:** no further data, R.A. Lever, 2♂, 2♀ (BMNH); no locality, ex horse manure, 4♂, 4♀ (USNM); no locality, 18 Apr 1954, H.W. Simmonds, 1♂ (BMNH); Delanavesi, cow dung, 1966, Dept. Agric., 3♀ (BMNH). **Kadavu:** no further data, R.A. Gibbons, 4♂, 4♀ (BMNH), & 33♂, 43♀ (ANIC); no locality, 7 Jun 1929, R.A. Gibbons, 1♂ (BMNH), 4♂, 1♀ (ANIC); in house, 30 May 1929, R.A. Gibbons, 1♂, 1♀ (BMNH), 4♂, 2♀ (ANIC); in house, 7 Jun 1929, R.A. Gibbons, 1♂, 1♀ (BMNH), 7♂, 2♀ (ANIC); no locality, 9 Jun 1929, R.A. Gibbons, 1♀ (ANIC); Wai Salima, 30 Apr 1941, N.L.H. Krauss, 1♀ (BPBM). **Lau:** Lakemba I., 2 & 3 Sep 1924, E.H. Bryan, 2♂, 1♀ (BPBM); Lakemba I., Tubou, 0–10 m, 11 Feb 1970, N.L.H. Krauss, 1♀ (BPBM); Tuvutha, 10 Sep 1924, E.H. Bryan, 16♂, 3♀ (BPBM), 1♂, 1♀ (BMNH); Avea, 22 Sep 1924, E.H. Bryan, 1♂, 1♀ (BPBM); Namuka, 13 Aug 1924, E.H. Bryan, 1♂, 2♀ (BPBM); Oneata, 16 Aug 1924, E.H. Bryan, 1♂ (BPBM); Vanua Vatu, 13 Sep 1924, E.H. Bryan, 1♀ (BPBM); Wangava, 27 Aug 1924, E.H. Bryan, 1♀ (BPBM). **Rotuma:** Soloroa, 200 ft, 11 Aug 1938, H. St. John, 1♂, 9♀ (BPBM); near Konga, 13 Aug 1938, H. St. John, 2♀ (BPBM); Melisa, Aug 1938, H. St. John, 1♀ (BPBM); Paho, 100–650 ft, 8 Aug 1938, H. St. John, 1♂, 2♀ (BPBM); Fapufa, 15 ft., 15 Aug 1938, H. St. John, 1♀ (BPBM). **Taveuni:** Sogula, house,

27 Jun 1938, R.A. Lever, 1♀ (USNM). **Thikombia**: 26 Sep 1924, E.H. Bryan, 5♀ (BPBM). **Totoya**: Tovo, 19 Feb 1971, N.L.H. Krauss, 2♂, 1♀ (BPBM). **Vanua Levu**: Nasese, cow dung, 9 Aug 1937, R.A. Lever, 1♂, 1♀ (USNM); Navakuru to Nakawanga, 7 Oct 1955, J.L. Gressitt, 2♂, 2♀ (BPBM); Urone, Liba [?] Lavu, seashore, 18 Aug 1938, Y. Kondo, 1♀ (BPBM). **Viti Levu**: Nadi, 12 Jun 1913, J.F. Illingworth, 1♀ (BPBM); Nasinu, chicken manure, 1966, Dept. Agric., 2♂ (BMNH); Natova, 17 Mar 1916, R. Veitch, 1♂, 1♀ (BMNH), and 17 Mar 1910, 1♀ (BMNH) (Bezzi 1928); Suva, bred from cow dung, 9 Jan 1927, H.W. Simmonds, 2♂, 2♀ (BMNH) (Bezzi 1928); Suva, ex cow dung, 22 May 1928, H.W. Simmonds, 6♂ (USNM); Suva, 13 Jan 1928, H.W. Simmonds, 5♂, 6♀ (BMNH); Suva, duck dung, 2 Mar 1945, R.A. Lever, 2♂ (USNM); Suva, Nov 1957, N.L.H. Krauss, 1♂ (BPBM); Suva Bay, 4 Jul 1925 (G.P. Wilder), 2♀ (BPBM); Vunidawa, 2 May 1941, N.L.H. Krauss, 3♂ (BPBM), and 4 May 1941, 1♀ (BPBM); Koronivia Research Station, coconut, 1 Mar 1963, C.M. Yoshimoto, 1♂, 3♀ (BPBM); Nandi, Mar 1956, N.L.H. Krauss, 1♀ (BPBM); Nandi, 24 Oct 1945, D.G. Hall, 1♀ (USNM); Nandi airport, 6 Dec 1958 C.R. Joyce, 1♂, 3♀ (BPBM); Nandi, 6–7 Dec 1958, C.R. Joyce, 3♂, 15♀ (BPBM); Lautoka, 0–50 m, Mar 1976, N.L.H. Krauss, 1♂ (USNM).

Comments. The species has been described, with illustrations of the male and female genitalia, by Pont (1973b: 168, figs 25, 30, 35, 40, 45, 59, 60). Some of the syntypes of *Musca australis* Macquart were from the Fiji Islands (“îles Viti”) and a variety was from Vanoo (Viti). Vanoo is actually a misreading of the label which says “Vavao” = Vava’u islands, Tonga group, equidistant from Tongatapu and Fiji (see Pont, 1967: 186). The syntypes of *Musca australis* are also the syntypes of *Musca oceanica*: see Pont (1973b: 170–171).

Distribution. This is the common house fly, a cosmopolitan species and probably present on Fiji since the first settlement by man. The earliest published record is by Gräffé (1866).

Biological data. In Fiji, it breeds mainly in cow dung, in the field (Simmonds 1940b; Lever 1944a) and in stable manure (Jepson 1915; Carment 1922). It has also been recorded as breeding in pig dung (Lever 1944a), excrement (Veitch & Greenwood 1921), compost (Verrier 1948), onions (Bezzi 1928), rotting *Vigna catjang* Walp. in Linnaea (Veitch & Greenwood 1924). Label data indicate the following additional media: chicken manure, horse manure, duck dung. A list of breeding media in Fiji was given by Bornemissza (1968). An account of its bionomics in Fiji was given by Baxter (1940a, 1940b).

Public health and medical aspects caused considerable concern in the early part of the 20th century in Fiji as elsewhere. The connection between houseflies and dysentery epidemics in Fiji was established by Bahr (1914). Simmonds (1940b) considered that outbreaks of houseflies were caused by breeding in cowpats in the field.

There was a sustained campaign for over half a century to reduce the numbers of houseflies in Fiji. DeBach (1962) judged this to be partially successful and that the housefly was more or less under control. Reviews of biocontrol projects using Coleoptera and Hymenoptera were reviewed by Simmonds (1940a) and Rao (1971). A list of predators and parasites was given by Hinckley (1963), and the introductions discussed by O’Connor (1950) and Dumbleton (1957).

Biocontrol agents for dung-breeding flies consist in the main of dung-feeding larval beetle competitors, beetle larvae that prey on fly immatures, ants which remove the fly immatures, hymenopterous parasitoids that attack pupae, and mites that feed on fly eggs and young larvae. A review of methods for the biocontrol of synanthropic flies was given by Patterson & Rutz (1986). In Fiji, the following biocontrol agents are discussed in the literature: Hymenoptera, parasitoids: *Melittobia indicum* Silvestri (Anon 1946); *Spalangia muscidarum* Richardson (Dumbleton 1957); *Spalangia nigroaenea* Curtis (Hinckley 1963); *Spalangia cameroni* Perkins, introduced from Hawai’i in 1928 (Simmonds 1929a) but effect negligible (Lever 1938b); *Spalangia* sp. (Simmonds 1922; originally recorded as *Polistes* sp. by Carment 1922), though Bouček (1963: 506) recorded only *Spalangia cameroni* from Fiji (from all hosts); *Pachycrepoides dubius* Ashmead (Lever 1945b). Hymenoptera, ants: *Pheidole megacephala* Fabricius, introduced around 1910, and effective in reducing numbers of houseflies (Simmonds 1925; Veitch 1925; Hinckley 1963) though this was disputed by Bornemissza (1968).

Coleoptera, larval predators: *Platylistes chinensis* Quensel, introduced from Java in 1938 (Simmonds 1940b; Lever 1941); *Hister chinensis* Quensel, introduced from Guam (Lever 1938c); *Copris incertus* var. *prociduus* Say, introduced 1929 and established (Simmonds 1929b). Diptera, larval predator: *Mesembrina meridiana* Linnaeus (Muscidae), introduced 1931 (Simmonds 1932), but not established [see above].

West's (1951) monograph provides considerable basic information on the structure, biology and control of the housefly (updated by the bibliography by West & Peters 1973). A more up-to-date review was given by Greenberg (1973). James (1947) dealt with its association with myiasis (the infestation of living animal tissue by fly maggots). Stoffolano (1970) listed the nematodes that cause disease in animals for which flies of the genus *Musca* are the vectors. Greenberg (1971) has reviewed all the organisms associated with *Musca domestica* (and other synanthropic flies). Other useful reviews of the housefly are by Hennig (1964a, 1964b) and, for Australia, by Pont (1973b).

The tropical form of the housefly, generally smaller than European examples and with paler abdomen and narrower frons, was frequently classified as *M. vicina* Macquart by authors in the 1920s to 1940s, either as a separate species or as a subspecies of *M. domestica*. However, this form has been shown to be a temperature-controlled phenotype of *M. domestica*, without separate genetic status.

10. *Musca vetustissima* Walker

Musca vetustissima Walker, 1849: 902. Holotype female, "New Holland" [Australia], in BMNH (Pont, 1973b: 148).

Musca vetustissima; Pont, 1973b: 147–160; Pont, 1989: 678.

Diagnosis. *Musca vetustissima* can be recognised by the characteristic pattern of dark vittae on the mesonotum, where the pair of dark vittae on each side coalesces behind the suture to form a single vitta.

The species has been described, with illustrations of the male and female genitalia, by Pont (1973b: 147, figs 23, 28, 33, 38, 43, 55, 56, 159).

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Kadavu:** no locality, 7 Jun 1929, R.A. Gibbons, 1♀ (ANIC); in house, 30 May 1929, R.A. Gibbons, 1♂ (ANIC); Wai Salima, 30 Apr 1941, N.L.H. Krauss, 1♀ (BPBM). **Matuku:** 7 Jun 1924, E.H. Bryan, 1♂ (BPBM). **Ovalau:** Cape Horn, 0–20 m, 30 Dec 1969, N.L.H. Krauss, 1♂, 3♀ (BPBM); Levuka, 0–200 m, Dec 1969, N.L.H. Krauss, 1♂, 3♀ (BPBM); Levuka, 0–150 m, Mar 1969, 1♀ (BPBM); Levuka, 0–200 m, Feb 1972, 1♀ (BPBM); Levuka, 0–100 m, Nov 1975, 1♀ (BPBM); Waitovu, 0–20 m, 29 Mar 1969, N.L.H. Comments. This is the bush fly, an important pest species in Australia and apparently widespread in the Pacific. It is long-established in Fiji, but apparently does not reach the pest proportions that it does elsewhere. The earliest Fijian specimen that we have seen was collected in 1924, but, curiously, the species was not noted by Bezzi (1928).

Distribution. Originally described from “New Holland”; widespread in Indonesia and Australia to the Hawaiian Is., Micronesia, Tuvalu.

Biological data. The primary larval food appears to be cow dung, though the faeces of other mammals are used under certain circumstances (see Pont 1973b; Hughes *et al.* 1972). A campaign to control or manage the bush fly has been waged in Australia for over 50 years.

Paterson & Norris (1970) recognised three species in the *Musca sorbens*-complex (i.e. *M. sorbens* of earlier authors). What appears to be conspecific with the “broad-frons” African species (*M. sorbens*) is known from the Papuan subregion and the Pacific (e.g. Hawai‘i). The “narrow-frons” Australian species (*M. vetustissima*) is widespread in the Pacific, and in places can be the sole member of the complex through competitive exclusion of *M. sorbens* (see Legner 1976). We have no evidence for the occurrence of any species of the *sorbens*-complex other than *M. vetustissima* on the islands of the Fiji group. The male frons/head ratio matches well the range of the Australian bush fly (see Fig. 24): it is slightly broader than in most bush flies, but consistently and considerably narrower than in *M. sorbens*. The number of proclinate parafrontal setulae is somewhat variable, sometimes as low as 8 or 9 but generally between 12 and 17.

Genus *Neomyia* Walker

Neomyia Walker, 1859b: 138 (as a subgenus of *Musca* Linnaeus). Type species: *Musca (Neomyia) gavisa* Walker, 1859b, by monotypy.

Orthellia Robineau-Desvoidy, 1863: 837. Type species: *Orthellia rectinervis* Robineau-Desvoidy, 1863 [= *Lucilia viridescens* Robineau-Desvoidy, 1830]], by subsequent designation of Townsend (1916: 8).

Diagnosis. Metallic green to blue or violet flies; eye bare; arista plumose; suprasquamal ridge setulose; postalar ridge with fine setulae on posterior half; prosternum setulose; greater ampulla with setulae; lower calypter broad, truncate posteriorly, of the *Musca*-type; anepimeron setulose, katepisternals usually 1+3; vein M strongly curved forward towards vein R₄₊₅ before apex; subcostal sclerite with short setulae; distiphallus with strong spinules.

Comments. *Neomyia* is the only muscid genus on Fiji with metallic green to blue species. There are some 80 species of *Neomyia*, found mainly in the Old World tropics. One species has been introduced into the New World and into Hawai‘i.

The two species dealt with here are both endemic to Fiji. They agree with the generic descriptions given by Pont (1973b: 189–190) and Nihei & Carvalho (2009: 17), but the following features should be noted: 2 short presutural dorsocentral setae; anterior anepisternal seta present; posterior spiracle large; katatergite with long dark setulae; anatergite bare; hind tibia with the calcar absent (sometimes present in male *N. greenwoodi*), and with anterodorsal preapical well developed; basicosta black; wing-membrane entirely covered with microtrichiae; costa bare ventrally after tip of subcosta; vein M without a dip after bend. Both species differ from the widespread and common *N. timorensis* (Robineau-Desvoidy) by the absence of the hind tibial calcar and by the long setulae on the katatergite.

It is difficult to discern the relationships of these two species. The general features are those of the group of Oriental species that includes *N. timorensis* (Robineau-Desvoidy), *N. rufitarsis* (Stein), *N. steini* (Aubertin), and *N. cuprea* (Shinonaga & Tumrasvin), but these features are probably all plesiomorphous in the genus (e.g. 2 presutural dorsocentral setae, wing-membrane wholly haired, scutum dusted anteriorly). They do not show any obvious affinity with the group of Papua New Guinea species described by Shinonaga & Kano (1983), which are characterised by the apomorphous feature of a single strong presutural dorsocentral seta. The presence of strong setulae on the katatergite is apomorphous and is found only in these two species. The species were not included in the cladistic analysis of the Muscini by Nihei & Carvalho (2007). Geographically too they are isolated: the genus does not otherwise occur east of the Solomon Islands except for Hawai'i (one species, introduced from North America).

The larvae live almost exclusively in bovine dung and are strictly coprophagous. Two species in Fiji ls, both endemic: *N. simmondsi* (Bezzi) and *N. greenwoodi* (Bezzi).

11. *Neomyia greenwoodi* (Bezzi) (Figs 25–31)

Orthellia greenwoodi Bezzi, 1928: 181. Holotype female, Fiji: Lautoka Mts, in BMNH [Pont 1970b: 420]. *Neomyia greenwoodi*; Pont, 1989: 679.

Diagnosis. *Neomyia greenwoodi* can be distinguished by the dark brown antenna, palpus and legs. The colour tends to be bright green or blue green; the scutum is less dusted and the wing less smoky than in *N. simmondsi*; it is also on average a slightly smaller and narrower species.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Taveuni:** Samosomo, 0–200 m, Jan 1972, N.L.H. Krauss, 1♀ (BPBM). **Vanua Levu:** Navakuru to Nakawanga, 7 Oct 1955, J.L. Gressitt, 1♀ (BPBM). **Viti Levu:** Lautoka, mountains, 2 Jan 1920 W. Greenwood, holotype ♀ (BMNH); Mt. Bryan, 2♀ (BPBM); Tholo-i-Suva, Mar 1951, N.L.H. Krauss, 1♀ (BPBM); Tholo-i-Suva, Sep 1950, N.L.H. Krauss, 1♀ (BPBM); Navai, 700–800 m, 10 Feb 1971, N.L.H. Krauss, 2♀ (BPBM); Savura Creek, Malaise trap, 26–31 Aug 1981, R.A. Beaver, 1♀ (OUMNH); Nausori Highlands, 450–500 m, 9 Oct 1971, N.L.H. Krauss, 1♀ (BPBM); Nandarivatu, 850 m, 8–13 Mar 1963, C.M. Yoshimoto, 1♂, 5♀ (BPBM); Nandarivatu, 1100 m, 16–22 Aug 1979, S. & J. Peck, 1♀ (CNC); 10 km N Galoa, 300 m, 1 Sep 1978, S. & J. Peck, 1♀ (CNC).

Comments. The original description is still adequate for the general features and appearance of this species. The male and female genitalia are illustrated in Figs 25–31; the ovipositor in this species (and in *N. simmondsi*) is unusually long. The aedeagus has a most remarkable development at the tip of the distiphallus: the membranous juxta and field of spines (cf. Fig. 34 of *N. simmondsi*) are reduced, and the distiphallus is enlarged to form two rather flat, expanded, posteriorly-directed lobes. The dorsum of the ovipositor, between tergites 8 and 9, has a narrow pilose band; the spinules on the intersegmental membrane are smaller than in *N. simmondsi*.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

12. *Neomyia simmondsi* (Bezzi)
(Figs 32–36)

Orthellia simmondsi Bezzi, 1928: 180. Lectotype male, Fiji: Ovalau, in BMNH [designation by Pont, 1970b: 423].

Orthellia simmondsi; Malloch 1929a: 264; Lee *et al.* 1956: 334.

Neomyia simmondsi; Pont 1989: 679.

Diagnosis. *Neomyia simmondsi* can be distinguished by the yellow antenna and palpus and the mainly yellow legs. The body-colour is violet to violet-blue; the scutum is rather densely grey dusted anteriorly, and the wings, especially in the male, are decidedly smoky; it is on average rather larger and broader than *N. greenwoodi*.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **Fiji:** “Ba, Fiji”, Jan 1906, F. Muir, 1♀ (BPBM). **Ovalau:** no locality, 22 Oct 1921, H.W. Simmonds, lectotype ♂ and paralectotype 1♀ (BMNH); no locality or collector, 23 Oct 1921, 1♀ “scotype” (USNM); no locality, 7 Dec 1921, H.W. Simmonds, 1♂ (USNM); Levuka, 0–200 m, Dec 1969, N.L.H. Krauss, 2♂, 4♀ (BPBM); Levuka, 11 May 1928, T.D.A. Cockerell, 1♀ (BMNH); Tholo-i-suva, 15 Nov 1970, H.S. Robinson, 1♂ (BMNH). **Viti Levu:** no data, Mus. Godeffroy, 1♂, 1♀ (USNM) (Malloch 1929a); Lautoka Mountains, 2 Jan 1920, W. Greenwood, paralectotype 1♀ (MCSNM); Lautoka, Mar 1976, N.L.H. Krauss, 1♀ (BPBM); Savura Creek, Malaise trap, 22–27 May 1981, R.A. Beaver, 1♂ (OUMNH); same locality, 11–15 Aug 1981, 1♀, and 18–22 Oct 1981, 1♀ (both OUMNH); 70 km W of Suva, 0–200 m, 2 Mar 1978, S. Shinonaga, 1♂ (BMNH); Mt. Victoria, 1000 m, 4–6 Mar 1978, S. Shinonaga, H. Shima, H. Kurahashi, 2♂, 3♀ (BMNH); Colo-i-Suva, 28 Jun 1924, E.H. Bryan, 1♀ (BPBM); Colo-i-Suva, 3–6 Mar 1963, C.M. Yoshimoto, 1♂, 3♀ (BPBM); Tholo-i-suva, Oct 1950, N.L.H. Krauss, 1♂, 1♀ (BPBM); Nandarivatu, 850 m, 8–13 Mar 1963, C.M. Yoshimoto, 2♂, 2♀ (BPBM); Nandarivatu, 1100 m, 16–22 Aug 1979, S. & J. Peck, 1♀ (CNC); Navai, 700–800 m, 10 Feb 1971, N.L.H. Krauss, 1♀ (BPBM); 2–10 km S Nandarivatu, 600–700 m, 4 Aug 1979, G.M. Nishida, 4♀ (BPBM).

Comments. The original description is still adequate for the general features and appearance of this species. The male and female genitalia are illustrated in Figs 32–36; the male sternite 5 is as in *N. greenwoodi*, except that the hind-margin is more obviously straight. The ovipositor is even longer than in *N. greenwoodi*: it is almost 4 times as long as tergite 5; segment 6 itself (only the membranous posterior half is shown in the figure) is almost twice as long as segment 5.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

Stomoxyini

Genus *Haematobia* Le Peletier & Audinet-Serville

Haematobia Le Peletier & Audinet-Serville in Latreille *et al.*, 1828: 499. Type species: *Conops irritans* Linnaeus, 1758, by subsequent designation of Westwood (1840: 140), validated by I.C.Z.N. (1974: 157). [Opinion 1008].

Diagnosis. General coloration dark greyish, with yellowish tinge and often yellow setae; head 1.25 times as wide as high; arista plumose only on dorsal surface; palpus spatulate, a little narrowed on basal quarter to half, grooved inside, reaching tip of haustellum when the proboscis is flexed; prosternum setulose; proepisternal depression and postalar wall bare; prealar seta barely differentiated or vestigial; lower calypter about twice as long as upper one; vein A₁ long.

Comments. This group of biting flies can be recognised by the short piercing proboscis and relatively long palpus. Vein M is gently inclined towards vein R₄₊₅ in its apical section.

Haematobia is widespread in the Old World and contains 7 species. Two species are serious pests of cattle, *H. exigua* Meijere ("buffalo fly") and *H. irritans* (Linnaeus) ("horn fly"). Both species are recorded from Fiji, but it is improbable that both species actually occur there. We have seen no material of this genus from Fiji. In the *Catalog of Australasian and Oceanian Diptera* (Pont 1989: 680), *H. irritans* was mentioned from Fiji with a query but *H. exigua* was not listed.

Allegedly two species: *H. exigua* Meijere, the buffalo fly, widespread Indo-Australasian; *H. irritans* (Linnaeus), the horn fly, Palaearctic and introduced into the New World.

13. *Haematobia exigua* Meijere

Haematobia exigua Meijere in Schat, 1903: 17. Lectotype female, Java: Pasoeroean, in NBCL [designation by Pont 1970a: 86].

Lyperosia exigua; Lever 1945a: 87; Bouček 1963: 506; Pont 1973b: 265–273; Zumpt 1973: 74.
Haematobia exigua; Pont 1989: 680.

Diagnosis. The male of *H. exigua* can be easily recognised by the yellowish palpus and the longer erect curled posterodorsal setulae on tarsomeres 2 and 3 of the hind leg that are much longer than the tarsal depth.

Material examined (FAS). No specimen was found among the Fiji Arthropod Survey material. No material from Fiji is in the BMNH or in any of our other sources of material; in fact, nothing east of the Solomons, PNG and Australia. Handschin (1933) did not mention *H. exigua* from Fiji by name, nor was it recorded in the standard works of Emden (1965) and Zumpt (1973). The only mention we have found is in Bouček (1963: 506), who listed the parasitoid hymenopteran *Spalangia cameroni* Perkins from *H. exigua* from Fiji and the Solomon Islands.

Comments. We do not believe that this species is present on Fiji, though it may very well be introduced and become established via the cattle trade at some time in the future.

Distribution: Australia, Bismarck Archipelago, Marianas, Micronesia (including Belau), New Guinea, Solomon Is, East Asia and Oriental region; Seychelles.

Biological data. The buffalo fly is a serious pest of cattle. The adults bite cattle, and the larvae live in fresh droppings. Reviews of the species are given by Pont (1973b) and Zumpt (1973).

According to Lever (1945a), the predatory beetle *Pachylister chinensis* Quensel was sent to Taveuni (and Australia) as a predator against buffalo fly. Bouček (1963) recorded *Spalangia cameroni* Perkins as a parasitoid of this species in Fiji.

14. *Haematobia irritans* (Linnaeus)

Conops irritans Linnaeus, 1758: 604. Lectotype male, Sweden, in LSL [designation by Pont, 1981: 169].
Lyperosia irritans; Handschin, 1933: 463; Bouček, 1963: 506.

Haematobia irritans; Zumpt, 1973: 73; Pont, 1989: 680.

Diagnosis. The male of *H. irritans* can be easily recognised by the dark brown palpus and the shorter erect posterodorsal setulae on tarsomeres 2 and 3 of the hind leg that are hardly as long as the tarsal depth.

Material examined. No specimen was found among material studied.

Comments. *Haematobia irritans* was mentioned from Fiji by Handschin (1933) and its parasitoid *Spalangia cameroni* Perkins in Fiji by Bouček (1963). We have seen no material of this species from Fiji. We do not believe that this species is now present on Fiji, though it may very well be introduced and become established via the cattle trade at some time in the future.

Distribution. ?Fiji, Hawai‘i; Nearctic, Neotropical and Palaearctic regions.

Biological data. The horn fly is also a serious pest of cattle, the adults biting cattle and the larvae living in fresh droppings. A detailed review of the species is given by Zumpt (1973).

Genus *Stomoxys* Geoffroy

Stomoxys Geoffroy, 1762: 449, 538. Type species: *Conops calcitrans* Linnaeus, 1758, by subsequent designation of I.C.Z.N. (1957: 85) [Opinion 441].

Diagnosis. This group of biting flies can be recognised immediately by the long piercing proboscis and short yellow palpus. General colour brownish grey to yellowish brown; head slightly wider than high, at vertex about one-fourth of head width in male and well over one-third in female; arista plumose; palpus slender and short, subcylindrical, and less than half as long as the elongated and non-retractile piercing proboscis; postpedicel about 2.5 times as long as pedicel; prosternum and proepisternal depression setulose; prealar seta absent; anterior katepisternal absent. Vein M curved forward towards vein R₄₊₅ in its apical section.

Comments. The larvae are usually found in mammalian excrement, but *S. calcitrans* breeds more widely, for example in grass clippings or vegetable compost where there is a high degree of bacterial fermentation. Adults are obligate blood suckers and have a proboscis adapted for piercing skin.

Stomoxys is widespread in the Old World, with 19 species of which one (*S. calcitrans*) is cosmopolitan. As biting flies, they are easily spread with man, cattle and horses.

Two species recorded from Fiji: *S. calcitrans* (Linnaeus), cosmopolitan; *S. indicus* Picard, an Oriental species.

15. *Stomoxys calcitrans* Linnaeus

Conops calcitrans Linnaeus, 1758: 604. Lectotype female, probably Sweden, in LSL [designation by Pont, 1981: 168].

Stomoxys calcitrans: Summers, 1912: 196; Veitch & Greenwood, 1921: 517; Bezzi, 1928: 184; Simmonds, 1928: 15–16; Greenwood, 1929: 352; Bryan, 1931: 403; Lever, 1946: 23; James, 1947: 133; Hinckley, 1963: 110–111; Bouček, 1963: 507; Hennig, 1964b: 1039; Börnemissza, 1968: 681; Swaine, 1971: 297; Pont, 1973b: 259–264; Zumpt, 1973: 101; Munro, 1978: 92; Pont, 1989: 680.

Diagnosis. *Stomoxys calcitrans* can be distinguished from *S. indicus* by the pattern of dark spots on the abdomen (see key), and the broader male and female frons. The tibiae and tarsi are mainly dark; the body dusting tends to be more sandy grey, and the pruinosity on the fronto-orbital plates more yellowish or even brownish grey.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI:** **Viti Levu:** Suva, 26 Jan 1927, H.W. Simmonds, 1♀ (BMNH) (Bezzi 1928); Ravawai, 2 Nov 1915, R. Veitch, 3♂, 1♀ (BMNH) (Bezzi 1928); Nadi, 0–100 m, Mar 1976, N.L.H. Krauss, 1♀ (BPBM); Suva Bay, 16 Jul 1923, O.H. Swezey, 1♀ (BPBM); Nausori, Apr 1951, N.L.H. Krauss, 1♀ (BPBM); Nadi, 12 Jun 1913, J.F. Illingworth, 1♂, 1♀ (BPBM), 1♀ (BMNH); Nadi, 28 Jun 1913, J.F. Illingworth, 1♂ (BPBM); Nadi, 29 Jun 1913, J.F. Illingworth, 1♂, 1♀ (BPBM); Nadi, 20 Aug 1913, J.F. Illingworth, 1♂ (BPBM); Nadi, 24 Aug 1913, J.F. Illingworth, 1♀ (BPBM).

Comments. The species has been described, with illustrations of the male and female genitalia, by Pont (1973: 259, figs. 142, 145–149, 155–156, 170). First recorded from Fiji by Summers (1912).

Distribution. Widespread through the Pacific region; cosmopolitan.

Biological data. Adults attack man and horses (Veitch & Greenwood 1921; Hinckley 1963; Munro 1978). Larvae breed mainly in heaps of decaying grass cuttings (Greenwood 1929), including stable sweepings of urine-soaked straw. A list of breeding media in Fiji was given by Bornemissza (1968), and the fly was reviewed in Fiji by Swaine (1971).

Adults are responsible for the transmission of habronemiasis in horses. Greenberg (1971) listed the associated organisms. Biocontrol agents in Fiji include the hymenopterous parasitoids *Spalangia* sp. (Simmonds 1928) and *Spalangia cameroni* Perkins (Bouček 1963), and the ant predator of eggs and larvae, *Pheidole megacephala* Fabricius (Simmonds 1928).

General reviews were given by Hennig (1964b), Pont (1973b) and Zumpt (1973). Its biology and relationship to disease transmission were discussed by Greenberg (1973).

16. *Stomoxys indicus* Picard

Stomoxys indica Picard, 1908: 20. Syntypes 2♂ and 1♀, India: Calcutta, in IPP [seen].

Stomoxys limbata Austen, 1909: 292. Syntypes ♂, India: Calcutta & Port Canning, in BMNH.

Stomoxys limbata; Bezzī, 1928: 185; Malloch, 1929b: 175.

Stomoxys indica; Hinckley, 1963: 110, 111; Hennig, 1964b: 1044; Emden, 1965: 161; Zumpt, 1973: 118; Munro, 1978: 92.

Stomoxys indicus; Pont, 1989: 680.

Diagnosis. *Stomoxys indicus* can be distinguished from *S. calcitrans* by the pattern of dark bands on the abdomen (see key), and the narrower male and female frons. The tibiae and tarsi are mainly yellow; the body dusting tends to be browner, especially in the male, and the pruinosity on the fronto-orbital plates is grey.

Material examined (FAS): FIJI: Taveuni: Cakaudrove Prov., 5.6 km SE Tavuki Village, Devo Peak [15.843, 179955], 1187 m, Malaise trap, 14–21 Nov 2002, E.I. Schlinger, M. Stoner, 1♀ (USNM); Walu Bay, 13 Jun, D. Stoner, 1♂ (USNM); Suva, 22 Oct 1988, R.A. Beaver, 1♂ (OUMNH); Suva, swept waste ground, 20 Nov 1988, R.A. Beaver, 2♂ (OUMNH); trail Yayu-Nandrau, 27–29 Jun 1958, B. Malkin, 1♂ (BPBM); Nandi, 0–50 m, Apr 1981, N.L.H. Krauss, 1♂ (BPBM); Tavua, 7 Mar 1963, C.M. Yoshimoto, 1♀ (BPBM); 40 km E of Nadi, 26 Jul 1967, J. & M. Sedlacek, 1♀ (BPBM); Yeidanu, 6 May 1919, R. Veitch, 1♂ (BMNH) (Bezzī 1928).

Comments. The species has been described, and the male and female genitalia illustrated, by Zumpt (1973: 118, figs 82–84).

Distribution. Fiji, ?Samoa; Oriental Region.

Biological data. On Fiji, adults are recorded biting man (Hinckley 1963) and horses (Munro 1978). They are also known to bite cattle. The larvae live in cattle and horse dung.

Azeliinae

Azeliini

Genus *Hydrotaea* Robineau-Desvoidy

Hydrotaea Robineau-Desvoidy, 1830: 509. Type species: *Musca meteorica* Linnaeus, 1758, by subsequent designation of Curtis (1839: plate 768).

Diagnosis. Male holoptic; eye bare; general colour usually black or bluish black, rarely metallic; arista very short pubescent; gena with a strong upcurved seta; female with crossed interfrontal seta; dorsocentrals 2+4; notopleuron covered with setulae, the two setae similar in size; anepimeron bare; katepisternals 1+1; some males with fore femur on ventral surface with a preapical excavation with 2 toothed processes and fore tibia flattened along basal half or two-thirds of ventral surface; M straight; distiphallus with apical part of juxta spinulose; ovipositor long, with narrow tergites.

Comments. The larvae are facultative to obligate carnivores and live in a wide range of decaying organic substances where there is a high rate of bacterial fermentation. They prey on other insect larvae in the substrate, mainly Diptera larvae. Adult females of some species are sweat-flies.

Hydrotaea spinigera (Stein), a widespread Old World tropical filth fly, is the only species known from Fiji. However, two other species may very well be introduced in the future: *Hydrotaea aenescens* (Wiedemann), a tropical and subtropical filth fly introduced from the New World to the Old World, and *H. chalcogaster* (Wiedemann), with an Old World tropical distribution similar to that of *H. spinigera*.

17. *Hydrotaea spinigera* (Stein)

Ophyra spinigera Stein, 1910: 555. Holotype male, Malaysia: Singapore, now destroyed, formerly in HNHM [Pont 1973b: 238].

Ophyra spinigera; Pont, 1973b: 238.

Hydrotaea spinigera; Pont, 1989: 677.

Ophyra nigra of authors, not Wiedemann [misidentifications]; Bezzi, 1928: 176; Greenwood, 1929: 352; Bryan, 1931: 403.

Diagnosis. This species can be recognised by the entirely black palpus and tarsi, and the concave posterior eye-margin below.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Taveuni:** 9 Nov & 9 Dec 1921, H.W. Simmonds, 2♂ (BMNH) (Bezzi 1928). **Viti Levu:** Suva, ex offal, 12 Apr 1924, H.W. Simmonds, 2♀ (BMNH) (Bezzi 1928).

Comments. Reared in Fiji from offal (Bezzi 1928; Greenwood 1929). The adult was fully described by Pont (1973b: 238–242).

Distribution. Australia, Belau, Fiji, Guam, Indonesia (Maluku), Micronesia, Bismarck Archipelago, PNG, Solomon Is, Vanuatu, Samoa; East Asia and Oriental Region.

Biological data. Summary of biology and parasites in Pont (1973b) and Skidmore (1985: 115–117).

Reinwardtiini**Genus *Muscina* Robineau-Desvoidy**

Muscina Robineau-Desvoidy, 1830: 406. Type-species: *Musca stabulans* Fallén, 1817, by subsequent designation of Coquillett (1910: 571).

Diagnosis. Male holoptic, eye bare; arista plumose with hairs on basal three-fourths and bare on the apical fourth; interfrontal setae present in female; anterior postsutural intraalar seta placed behind level of supraalar seta; presutural acrostichals developed; prealar seta short, but distinct; anepimeron bare; meron setulose; wing with apical section of vein M slightly curved forward, veins bare; calcar strong, submedian; sternite 1 setulose.

Comments. Only *M. stabulans* has been recorded from the Fiji Is.

18. *Muscina stabulans* (Fallén)

Musca stabulans Fallén, 1817: 252. Lectotype male, Sweden: probably Skåne province, in NRS [designation by Pont, 1984: 294].

Muscina stabulans; Lever, 1940: 18; Emden, 1965: 216; Pont, 1989: 675.

Diagnosis. As for the genus. The palpus, tip of scutellum and tibiae are yellow.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined: **FIJI: Taveuni**: Waiyevo, 0–100 m, Jan 1972, N.L.H. Krauss, 1♀ (USNM); **Viti Levu**: Suva, introduced in potatoes from [New] Ireland, 7 Jun 1939, R.A. Lever, 1♂, 1♀ (BMNH).

Comments. Stated to be absent from Fiji by Malloch (1929b), but subsequently recorded by Lever (1940) from puparia found in potatoes imported from New Ireland.

Distribution. Sweden, widespread Australia, Fiji, Hawaiian Is, Lord Howe I., New Caledonia, New Zealand (Auckland I.), Norfolk I., Bismarck Archipelago, Vanuatu; cosmopolitan.

Biological data. *Muscina stabulans* is an important controller of fly populations, but the larvae can also prey on other insect larvae such as those of Lepidoptera. They prey heavily on *Musca domestica*, drastically reducing its populations (Skidmore 1985).

Genus *Passeromyia* Rodhain & Villeneuve

Passeromyia Rodhain & Villeneuve, 1915: 592. Type species: *Muscina heterochaeta* Villeneuve, 1915, by monotypy.

Diagnosis. Frons dichoptic in both sexes, broader in female; arista short, with the dorsal plumes longer and sparser than the ventral ones; dorsocentral setae 2+4; prealar seta present; post-alar wall setulose or bare; katepisternals 1+2; metathoracic spiracle large, with no setae on margins; hind tibia with a short calcar.

Comments. Two species in the Fiji Islands, their larvae parasitic on nestling birds: *P. indecora* (Walker), otherwise known only from Australia, and *P. veitchi* Bezzi, endemic (Pont 1974).

19. *Passeromyia indecora* (Walker)

Morellia indecora Walker, 1858: 215. Holotype female, Australia: New South Wales, in BMNH [Pont, 1974: 358].

Passeromyia indecora; Pont, 1974: 358; Pont, 1989: 676.

Diagnosis. This is the only species with yellow palpus and hairy eye. A complete description was given by Pont (1974: 358–363).

Material examined (FAS). No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Viti Levu:** Colo-i-Suva, Malaise trap, 3–6 Mar 1963, C.M. Yoshimoto, 1♀ (BPBM) (Pont 1974).

Comments. Known from Fiji only from the above female which was recorded by Pont (1974: 361).

Distribution. Australia, Fiji

Biological data. The haematophagous larvae are subcutaneous parasites of nestlings, but if the nestling dies the larvae are capable of feeding on the carcase until ready to pupate.

20. *Passeromyia veitchi* Bezzī

Passeromyia veitchi Bezzī, 1928: 183. Holotype female, FIJI: Natova, in BMNH [Pont, 1970b: 423].
Passeromyia veitchi; Pont, 1970b: 423; Pont, 1974: 365; Pont, 1989: 676.

Diagnosis. This is the only species of the genus to have the wing membrane entirely covered with microtrichia, without bare patches; also eye bare, frons dark brown, ocellar seta short and strong, antenna with pedicel reddish and postpedicel dark brown, one intraalar seta, wing broadly yellow at base.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Viti Levu:** Natova, 1916, R. Veitch, holotype ♀ (BMNH).

Comments. The holotype is still the only known specimen, and it was redescribed by Pont (1974: 365–366). The species is endemic to Fiji.

Distribution. Fiji.

Biological data. The larvae must be associated with birds, either as endo- or ectoparasites or as scavengers in the nests. It is possible that the species is extinct.

Genus *Synthesiomyia* Brauer & Bergenstamm

Synthesiomyia Brauer & Bergenstamm, 1893: 96, 110, 178. Type species: *Synthesiomyia brasiliiana* Brauer & Bergenstamm, 1893 [= *Cyrtoneura nudiseta* Wulp, 1883], by original designation.

Diagnosis. Eye bare; arista with very short hairs; presutural acrostichal setae not differentiated; prealar seta strong; katepimeron and anepimeron bare; dorsocentrals 2+4; katepisternals 1+2; wing veins bare; vein M strongly curved forward apically; lower calypter very enlarged; sternite 1 setulose.

Comments. One species: *Synthesiomyia nudiseta* (Wulp), a widespread filth fly in the Old and New World tropics and subtropics.

21. *Synthesiomyia nudiseta* (Wulp)

Cyrtoneura nudiseta Wulp, 1883: 42. Holotype female, Argentina, NBCL [reported as missing by Pont (1970a) but subsequently found].

Synthesiomyia brasiliiana Brauer & Bergenstamm, 1893: 96, 110. Syntypes 6 females, Brazil, in NMW [seen].

Synthesiomyia nudiseta; Bezzī, 1928: 179; Bryan, 1931: 403; Emden, 1965: 192; Pont, 1989: 676.

Synthesiomyia brasiliensis [sic]; Simmonds, 1928: 17.

Diagnosis. Easily distinguished by the reddish orange antenna, bare arista, and reddish orange tip of abdominal tergite 5.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Viti Levu:** Lautoka, 15 Mar 1921, R. Veitch, 1♂ (BMNH) (Bezzi 1928); Cuvu, Feb 1918, R. Veitch, 1♂, 1♀ (BMNH); Nadi, 1914, D.S. North, 1♂ (BMNH) (Bezzi 1928); Nadi, 12 Jun 1913, J.F. Illingworth, 1♂ (BPBM).

Comments. As this species has not been collected in Fiji for a century, it seems likely that it was introduced from time to time through commercial traffic but failed to establish on a permanent basis.

Distribution. Australia, Bonin Is, Easter I., Fiji, French Polynesia (Marquesas, Society Is.), Guam, Hawaiian Is, Lord Howe I., Norfolk I., PNG, Samoa, Tonga, Vanuatu, Wake I.; pantropical.

Biological data. *Synthesiomyia nudiseta* is a synanthropic species and has importance in forensic entomology. The larva was described by Skidmore (1985: 62–64). Larvae live in many kinds of decaying organic matter, especially mammalian corpses, where they feed semi-carnivorously.

Phaoniinae

Dichaetomyiini

Genus *Dichaetomyia* Malloch

Dichaetomyia Malloch, 1921: 163. Type species: *Dichaetomyia polita* Malloch, 1921 [preocc., = *Dichaetomyia emdeni* Pont, 1969], by original designation.

Diagnosis. *Dichaetomyia* can be recognised by the row of dark setulae along the lower margin of the posterior thoracic spiracle, together with the setulose prosternum and anepimeron. Eyes of male narrowly separated by the diameter of anterior ocellus or more; eyes in female widely separated; proclinate orbital and crossed interfrontal setae absent; arista long-plumose; dorsocentrals 2+2, 3 or 4; prealar seta present; postalar wall with sparse hairs or bare; vein M only slightly curved forwards before apex; hind tibia with a well developed anterodorsal preapical in addition to dorsal one, calcar absent.

Comments. There are some 224 species, found throughout the Old World tropics. Of the three species on Fiji, two (*D. elegans* Malloch, *D. taveuniiana* Pont & Evenhuis) are endemic but clearly belong to a group of species centered on the Papuan subregion and with a few plesiomorphous representatives in the Oriental Region (*armata*-group: see Pont 1969b: 211); the other (*D. vicaria* (Walker)) is widely distributed in the Malesian area and Australia, and has reached many island groups in the Pacific.

22. *Dichaetomyia elegans* Malloch (Figs 37–42)

Dichaetomyia elegans Malloch, 1928a: 468 [April]. Holotype female, FIJI: Suva, in BMNH [Lee *et al.*, 1956: 315; also seen].

Dichaetomyia prodigiosa Bezzi, 1928: 176 [June]. Lectotype male, FIJI: Cuvu, in BMNH [designation by Pont, 1970b: 422].

Dichaetomyia elegans; Hinckley, 1963: 17; Pont, 1989: 683.

Diagnosis. See key. Male terminalia as in Figs 37–40. Female ovipositor as in Figs 41–42.

Material examined (FAS): **FIJI: Kadavu:** 0.25 km SW Solodamu Village, Moanakaka Bird Sanctuary, 60 m, 28 May–11 Jun 2003, Malaise 4, Schlinger, Tokota'a, 19.078°S, 178.121°E, FBA 135140 (♂).

Simmonds, paralectotypes of *prodigiosa* 1♂ (MCSNM), and 1♀ (BMNH).

Comments. *Dichaetomyia elegans* (and *D. taveuniana*) can be distinguished from *D. vicaria* by the two very broad dark vittae on the scutum and by the abundant setulae all down the lateral margins of the scutellum. It is a much larger and more elongate species than *D. vicaria*. In the male, the mid and hind legs have special modifications consisting of tubercles, protuberances, setae and hairs. The original descriptions of *D. elegans* and *D. prodigiosa* are still adequate for the general features and appearance of this species, and there are excellent figures of the male mid and hind legs (Bezzi 1928: fig. 52, as *prodigiosa*). The appearance of this species is particularly striking because the two broad black vittae on the scutum and scutellum are matt while the yellow area between them is covered with dense yellowish white dust. The male and female genitalia are illustrated in Figs 37–42.

Dichaetomyia elegans belongs to the *armata*-group (see Pont 1969b: 211), which includes some 10 described species (and several still undescribed species) mostly from Melanesia.

This striking species (together with *D. taveuniana*) is in a mimicry group together with the lauxaniid *Sapromyza acrotoma* Bezzi and the calliphorid *Melinda elegans* Kurahashi.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology. It has been recorded as prey of the crabronid wasp *Rhopalum* [now *Neodasyproctus*] *veitchii* (Turner) (Hinckley 1963).

23. *Dichaetomyia taveuniana* Pont & Evenhuis

Dichaetomyia taveuniana Pont & Evenhuis, 2006: 5. Holotype male, Fiji, Taveuni: Devo Peak, 5.3 km SE Tavuki Village, 1064 m, 28 Jan–11 Feb 2005, 16°50'27.4"S, 179°59'4.1"W, Malaise, P. Vodo (FBA 515573–515654), in BPBM.

Diagnosis. See key.

Material examined (FAS): FIJI: Taveuni: Cakaudrove Prov., 5.6 km SE Tavuki Village, Devo Peak, 1187 m, Malaise trap [15.843, 179.955], 3–10 Jan 2003, E.I. Comment. This striking species (together with *D. elegans*) is in a mimicry group together with the lauxaniid *Sapromyza acrotoma* Bezzi and the calliphorid *Melinda elegans* Kurahashi.

Distribution. Known only from Fiji; previously known only from Taveuni Island, and newly recorded here from Vanua Levu.

Biological data. Nothing is known of the habits and biology.

24. *Dichaetomyia vicaria* Walker

Aricia vicaria Walker, 1859a: 130. Holotype female, Indonesia, Kai I., in BMNH [Pont 1966: 98].

Spilogaster rufa Stein, 1900: 132. Lectotype male, Papua New Guinea: Friedrich-Wilhelm-Hafen [= Madang], in ZMHU [designated by Pont 1969a: 88].

Dichaetomyia rufa Stein var. *personata* Bezzi, 1928: 176. Lectotype male, Fiji: Suva, in BMNH [designation by Pont 1969b: 242].

Dichaetomyia rufa; Malloch, 1925a: 326.

Dichaetomyia rufa var. *personata*; Malloch, 1929b: 171.

Dichaetomyia vicaria; Pont, 1969b: 242; Pont, 1989: 684.

Diagnosis. *Dichaetomyia vicaria* can be distinguished from *D. elegans* and *D. taveuniana* by the entirely yellow thorax and the absence of setulae on the lateral margins of the scutellum. It is a smaller stouter species than these two, and the male mid and hind legs have no special modifications.

Comments. The species has been described, with illustrations of the male genitalia, by Pont (1969b: 242, figs. 1, 9, 11, 13, 72, 75, 78).

Distribution. *Dichaetomyia vicaria* is widely distributed from Sabah and the Philippines eastwards through Melanesia and into the Pacific (to Tokelau, Samoa, Niue). Previously recorded by Pont (1969b) from Ovalau, Taveuni, Kadavu. *D. vicaria* belongs to the *vicaria*-group (see Pont 1969b: 230), which includes some 14 species in the Oriental, Australian and Oceanian regions. It is the most widespread species of the group.

Biological data. Little is known of its habits, and nothing of the biology.

Mydaeinae

Genus *Myospila* Rondani

Myospila Rondani, 1856: 91. Type species: *Musca meditabunda* Fabricius, 1781, by original designation.

Diagnosis. Male dichoptic (in Fijian species); female frontal vitta without crossed setae; only 1 pair of reclinate orbitals in both sexes; arista plumose; intraalars 2; dorsocentrals 2+3 (in Fijian species); prealar minute; postalar ridge, suprasquamal ridge, prosternum, anepimeron and meron bare; katepisternals 1+2; posterior spiracle bare on margins; vein M hardly inclined forward towards vein R_{4+5} before apex; vein R_{4+5} with a few setulae at base on both wing surfaces; hind tibia without calcar; sternite 1 bare.

Comments. The larvae are obligate carnivores and live in mammal dung, rotting fruit and the diseased parts of plants. Only one species recorded from Fiji, *M. effeminata* Vockeroth, endemic (Vockeroth 1972).

25. *Myospila effeminata* Vockeroth

Myospila effeminata Vockeroth, 1972: 109. Holotype male, FIJI: Viti Levu, Nandarivatu, in BPBM.

Myospila effeminata; Pont, 1989: 689.

Diagnosis. Delicate yellowish species; male frons nearly as broad as that of the female and with the same frontal bristling; antenna broad and long, reaching oral margin (Vockeroth, 1972, Fig. 101); palpus yellow; thorax yellow, disc of scutum dark medially in male, brownish yellow in female, with two broad grey vittae; legs yellow; ovipositor as in Fig. 126 of Vockeroth (1972).

Comments. Vockeroth (1972) gave a detailed discussion of the characters of the head structure, including the possible functional significance of a broad male frons and enlarged antenna among the Muscidae.

Distribution. Endemic to Fiji.

Biological data. Nothing is known of the habits and biology.

Coenosiiinae**Limnophorini****Genus *Limnophora* Robineau-Desvoidy**

Limnophora Robineau-Desvoidy, 1830: 517. Type-species: *Limnophora palustris* Robineau-Desvoidy, 1830 [= *Anthomyia maculosa* Meigen, 1926], by designation of Coquillett (1910: 561).

Diagnosis. Eye usually bare; prestomal teeth developed; prealar seta absent; lower proepimeral seta upcurved; prosternum with lateral setulae; postsutural dorsocentral setae 3 or 4; vein M slightly curved forwards just before apex; wing with setulae at the base of vein R₄₊₅ on dorsal and ventral surfaces; sternite 1 bare or with a few setulae; female ovipositor with segment 8 directed upwards and with small spicules; hypoproct elongated and with spinules.

Comments. The larvae are obligate carnivores. Many are aquatic and live in running water where they prey on oligochaetes and small insect larvae. Others are terrestrial and breed in dung or decaying organic matter. Adults are also carnivorous, taking other small soft-bodied insects as prey.

Three species seen from Fiji, of which *L. mesolissa* Bezzi is Australasian in distribution whilst the other two are endemic to Fiji.

26. *Limnophora mesolissa* Bezzi
(Figs 43–46)

Limnophora (Pseudolimnophora) mesolissa Bezzi, 1928: 175. Lectotype male, Fiji: Taveuni [designation by Pont 1970b: 420].

Limnophora mesolissa; Malloch, 1929c: 330; Bornemissza, 1968: 681; Pont, 1973c: 188; Pont, 1989: 692.

Diagnosis. *Limnophora mesolissa* is a very small species, and can be recognised by the yellow haltere, 4 postsutural dorsocentrals, and subplumose arista.

Stoner, 1♀ (USNM); Navua, 26 Jun, D. Stoner, 1♀ (USNM). **Wakaya:** 17 Oct 1924, E.H. Bryan, 1♀ (BPBM). Tahili, 24 Dec 1921, H.W. Simmonds, 1♀ (BMNH). Dobucheva, reared ex cow dung, 6 Jun 1966 (—), 2♂ (BMNH). Vivia, 15 Jun, D. & L. Stoner, 2♀ (USNM).

Comments. It is very close to the Oriental and Afrotropical *L. exigua* (Wiedemann), which it replaces in the Australasian and Oceanian region. There is an area of overlap between the two species in Papua New Guinea.

Distribution. American Samoa, Australia, Belau, French Polynesia, Guam, Indonesia (Maluku), Lord Howe I, Micronesia, New Caledonia, Northern Marianas, Bismarck Archipelago, PNG, Samoa, Solomon Is, Tonga, Vanuatu.

Biological data. In Fiji this species has been reared from cowpats and cow manure, horse droppings, poultry droppings and manure, and abattoir refuse; the larvae are probably predaceous (Bornemissza 1968).

27. *Limnophora penicillata* Pont & Couri, sp. nov.

(Figs 47–49)

Diagnosis. The male is easily recognised by the pencil of very long dense setae on cercal plate (Figs 48,49).

Male

Head. Ground-colour black. Eye bare. Frons broad, at middle of head 0.38 of head-width at this point, more or less parallel-sided from vertex to lunule. Ocellar strong, subequal to inner vertical; outer vertical a little shorter than this. Fronto-orbital plate wholly brown pruinose. Parafacial brownish yellow, almost golden. Ocellar triangle broad, velvety dark brown, reaching

lunule. Frontal vitta dark, almost completely suppressed by the frontal triangle. Face and gena brown pruinose, occiput brownish grey. Fronto-orbital plate narrow, at middle of frons a plate 0.11 width of frontal vitta. 2 pairs of inclinate frontal setae and 1 pair of reclinate orbital setae, with several short setulae outside them on fronto-orbital plate. Antenna black; postpedicel 2.4 times as long as wide and almost reaching mouth margin, rather angular at anterior tip. Arista short-pubescent, the longest individual hairs shorter than its basal width. Parafacial narrow, narrowing sharply below where it is not as wide as diameter of anterior ocellus, bare. Mouth edge behind level of profrons. Facial ridge with a few short setulae above vibrissa. Gena narrow, depth below lowest eye margin 0.1 of length of postpedicel; setae fine. Palpus black, slender. Prementum of proboscis glossy, black.

Thorax. Ground-colour black. Scutum and scutellum brown to brownish grey dusted, without vittae or pattern, sometimes with weak grey dust before scutellum; postpronotal lobe and notopleuron light grey. Pleura brown dusted. Prothoracic spiracle brown. Acrostichals 0+1, the single (prescutellar) pair weak, the presutural setulae in 2 rows. Dorsocentrals 2+3. Katepisternals 1+2, the anterior and lower ones very short and fine. Proepisternal depression, notopleuron (except for setae), anepimeron and meron bare. Scutellum with a few discal setulae; lateral margins and ventral surface bare.

Legs. Black. Fore femur with a complete row of fine uniform posteroventral setae. Fore tibia without submedian setae. Mid femur without ventral setae, the posteroventral ground-setulae short but erect; 0 anterior and 0 posterior preapical setae. Mid tibia without setae except at apex. Hind femur without ventral setae except for 1 strong anteroventral before apex. Hind tibia without setae except for very weak dorsal and anteroventral apical setae.

Wing. Clear, veins yellow. Basicosta black, tegula yellow. Costal spine minute. Veins bare except for costa and a few setulae on the node at the base of vein R_{4+5} . Cross-vein r-m slightly basad of the point where vein R_1 enters costa. Cross-vein dm-cu almost straight. Veins R_{4+5} and M_1 parallel at wing margin. Calypters white, margins creamy. Knob of haltere black.

Abdomen. Ground-colour black. Dark brown dusted, with whitish grey markings as follows: a median vitta on tergites 3–5, and each of these tergites with an inverted triangular patch in lateral anterior corner which extends a short distance on to sides of tergites. Tergites without strong setae, with a few lateral marginals on tergites 3 and 4 and a marginal row on tergite 5. Sternite 1 bare.

Terminalia. Figs 47–49. Characterised by the pencil of very long dense setae on cercal plate.

Measurements. Length of body, 2.5 mm. Length of wing, 2.5 mm.

Female

Differs from the male as follows:

Head. Frons at middle 0.38 of head-width at this point. Ocellar triangle less velvety. At middle of frons a fronto-orbital plate 0.1 width of frontal vitta. Antennal postpedicel 2.4 times as long as wide. Depth below lowest eye-margin 0.11 of length of postpedicel.

Thorax. Scutum dark as in male, with a narrow grey median vitta and a pair of similar vittae, each placed just outside the dorsocentral rows, all three running along the whole length of scutum but not strongly marked.

Legs. Mid femur with 1 posterior preapical seta. Mid tibia with 2 posterior setae. Hind tibia with 1 anterodorsal and 1 anteroventral.

Abdomen. Markings as in male. Setae weak.

Ovipositor. Not examined.

Measurements. Length of body, 3.0 mm. Length of wing, 2.5 mm.

Material examined. Holotype ♂, FIJI: Wakaya Island: 17 Oct 1924, E.H. Bryan (BPBM). Paratypes 12♂, 14♀: Wakaya: same data as holotype, 2♂, 3♀ (BPBM). Lau: Thithia, 15 Sep 1924, E.H. Bryan, 1♂ (BPBM). Matuku: 7 Jul 1924, E.H. Bryan, 7♂, 9♀ (5♂, 7♀ BPBM, 1♂, 1♀ each BMNH & MNRJ); same data but 8 Jul 1924, 1♂ (BPBM). Viti Levu: Naqali, Nov 1957, N.L.H. Krauss, 1♀ (BPBM); Nausori Highlands, 500–700 m, Nov 1976, N.L.H. Krauss, 1♀ (BPBM). Jakaya, 12 Oct 1924, E.H. Bryan, 1♂ (BPBM).

Etymology. The name comes from the Latin word *penicillus* and refers to the pencil of very long dense setae on cercal plate of male terminalia.

Distribution. This species is endemic to the Fiji Islands.

Biological data. Nothing known.

28. *Limnophora shinonagai* Pont & Couri, sp. nov.
(Figs 50–52)

Diagnosis. *Limnophora shinonagai* can be recognised by the yellow haltere, 4 postsutural dorsocentrals, arista pubescent, lower calypter white with the outer part of disc smoky to brown and margins brown, and by the colour pattern of the scutum.

Male

Head. Ground-colour black. Eye bare. Frons narrow, at narrowest point a little over twice diameter of anterior ocellus. Ocellar short and hair-like. Fronto-orbital plate brown pruinose when viewed from in front, with some silvery pruinosity below; parafacial and lower occiput silvery white pruinose; gena light grey pruinose. At middle of frons, a fronto-orbital plate hardly as wide as diameter of anterior ocellus, but the plates separated throughout by a distinct frontal vitta. 7–10 pairs of fine inclinate frontal setae, decreasing in length above, and reaching as far as 1–2 pairs of proclinate setulae at level of anterior ocellus. Antenna black; postpedicel 2.8–3.0 times as long as wide, smoothly rounded at tip. Arista pubescent, the longest combined hairs half width of postpedicel. Parafacial narrow, at middle half as wide as width of postpedicel, bare. Mouth-edge behind level of profrons in lateral view. Depth below lowest eye-margin equal to width of postpedicel. Genal setae well developed. Palpus black, slender. Prementum of proboscis glossy, black.

Thorax. Ground-colour black. Scutum dark brown dusted with more thinly dusted but still weakly developed areas as follows: indications of a pair of paramedian presutural vittae; a patch around presutural intraalar and supraalar setae; and a pair of postsutural vittae between dorsocentrals and intraalars; with a thin brown dusted line along anterior edge of suture, from notopleuron to outer acrostichal row. Postpronotal lobe and notopleuron silvery-white dusted, and a similar coloured patch between between prescutellar dorsocentral and postalar callus. Pleura whitish grey. Prothoracic spiracle dirty whitish. Scutellum dark brown dusted, with a small spot of pale dust on each side at base, below the basal lateral and subbasal lateral setae. Acrostichals 0+1, the presutural setulae in 3–4 rows at suture. Dorsocentrals 2+4. Postsutural intraalar 1. Proepimeral seta with 3–4 additional short setulae. Katepisternals 1+1. Proepisternal depression, notopleuron (except for setae) and meron bare. Scutellum uniformly setulose on disc; lateral margins and ventral surface bare.

Legs. Black. Fore femur with a complete row of uniform posteroventral setae. Fore tibia without submedian setae. Mid femur without anteroventral setae, with 2–4 weak posteroventral setae in basal quarter, hardly equal to femoral depth; with several weak anterior setae in basal half, and a strong seta at middle; 0 anterior and 2 posterior preapical setae. Mid tibia with 2–3 posterior setae. Hind femur without ventral setae except for 3–4 anteroventrals in apical third, rarely with a short fine posteroventral near base. Hind tibia with 1 anterodorsal and 1 anteroventral seta; 1 dorsal preapical, anterodorsal preapical absent. Tarsomeres not modified.

Wing. Slightly smoky. Basicosta and tegula black. Costal spine inconspicuous. Veins bare except for costa and a few setulae on the node at the base of vein R_{4+5} . Cross-vein r-m slightly basad of the point where vein R_1 enters costa. Cross-vein dm-cu weakly sinuous. Vein M curved slightly towards vein R_{4+5} in apical section. Calypters white, margins brown, lower one with the outer part of disc smoky to brown. Haltere yellow.

Abdomen. Ground-colour black. With silvery white dust, becoming brownish on the median line of each tergite, pregenital tergites and epandrium brown. Tergites with black markings as follows: syntergite 1+2 mostly black except on median line and at sides; tergites 3

and 4 each with a pair of large triangular spots, reaching from fore-margin to hind-margin and laterally to the side of each tergite; tergite 5 with a single large triangular spot, also reaching from fore-margin to hind-margin and laterally to sides of tergite. Setae on sides of tergites well developed and fine; tergite 4 with a lateral discal and 2 lateral marginal setae, tergite 5 with discal and marginal rows. Sternite 1 bare, rarely with a fine setula on each side.

Terminalia. Figs 50–52.

Measurements. Length of body, 4.5–5.0 mm. Length of wing, 4.0–4.5 mm.

Female

Differs from the male as follows:

Head. Frons at level of anterior ocellus 0.32 of head-width at this point, broadening gradually from vertex to lunule. Outer vertical seta only slightly shorter than inner vertical. Ocellar triangle indistinct but reaching lunule. Ocellar setae long and strong. At middle of frons a fronto-orbital plate 0.14 width of frontal vitta. 5 pairs of inclinate frontal setae and 2 pairs of reclinate orbitals; fronto-orbital plate outside the setae with a row of short proclinate setulae. Postpedicel only twice as long as wide. Parafacial slightly wider, tapering below. Mouth-edge distinctly in front of profrons in lateral view. Depth below lowest eye-margin slightly greater than width of postpedicel.

Thorax. Pattern of scutum as in male. Anterior postsutural intraalar short but distinct.

Legs. Mid femur with the posterovenital setae very weak or absent. Mid tibia with 2 posterior setae. Hind femur usually with only 2–3 anteroventrals in apical half; posteroventrals absent.

Wing. Calypters with the margins only partly brown and disc of lower calypter with the darkened area reduced or indistinct.

Abdomen. The black spots of the male fused so that the tergites are black except for an inverted triangle of silvery white dust in anterior lateral corners of tergites 3 and 4; tergite 5 with the median black spot large, diamond or even pentagonal in shape and occupying most of disc.

Ovipositor. Not examined.

Measurements. Length of body, 5.0–5.5 mm. Length of wing, 4.5–5.0 mm.

Material examined. Holotype ♂, Fiji: Viti Levu: Mt. Victoria, 1000 m, 4–6 Mar 1978, S. Shinonaga (NSMT). Paratypes 52♂, 28♀: same data as holotype, 44♂, 26♀ (NSMT, with 2♂ and 1♀ each in BMNH, OUMNH, BPBM, CAS, MNRJ); same data but collector H. Shima, 8♂, 2♀ (NSMT).

Etymology. The species is dedicated to Dr Satoshi Shinonaga, for his great contribution to the knowledge of the Oriental and Melanesian muscid fauna.

Distribution. The species is endemic to Fiji, Viti Levu.

Biological data. Nothing known.

Genus *Lispe* Latreille

Lispe Latreille, 1797: 169. Type-species: *Musca tentaculata* De Geer, 1776, by subsequent monotypy (Latreille, 1802: 462).

Diagnosis. Male dichoptic; palpus enlarged apically, spatulate; prestomal teeth strongly developed; head without interfrontal or proclinate orbital setae; parafacial setulose; dorsocentral setae 0–2+2–4; prealar seta absent; anepimeron setulose in centre; lower proepimeral seta upcurved; katepisternals 1+2; posterior spiracle with some strong setulae on posterior margin; sternite 1 setulose; male surstylos absent; female ovipositor with segment 8 directed upwards and with spinules, hypoproct elongated and with spines

Comments. The larvae are obligate carnivores, and live in wet sand or mud with a high organic content. Adults are voracious and aggressive predators, mainly of the immature stages of Culicidae and Chironomidae. Five species have been seen: *L. bengalensis* is known from the southern Palaearctic, Afrotropical, Oriental and Australasian/Oceanian regions; *L. assimilis* is known from the southern Palaearctic, Oriental and Australasian/Oceanian regions; *L. pectinipes* is insufficiently known but has a distribution similar to that of *L. assimilis*; two species, known respectively from one male and two females, remain undescribed and may represent endemic Fijian species. One species (*Lispe tentaculata* (De Geer)) has been erroneously recorded from Fiji and is deleted from the list of Fijian species.

29. *Lispe assimilis* Wiedemann (Figs 53–55)

Lispe assimilis Wiedemann, 1824: 51. Lectotype male, “ex India orientali” [East Indies], in ZMUC [designation by Shinonaga & Pont, 1992: 720].

Lispa [sic] *assimilis*; Bezzi, 1928: 174.

Lispe assimilis; Pont, 1989: 692; Shinonaga & Pont, 1992: 718–719; Pont, 2019: 144–150.

Diagnosis. This species can be immediately recognised by the forward curvature of vein M towards vein R₄₊₅. In addition, fore tibia has a submedian seta and hind tibia has a posterodorsal seta. Male terminalia as in Figs 53–55; male and female terminalia also illustrated in Pont (2019: figs 310–316).

Material examined (FAS): **FIJI:** Kadavu: 0.25 km SW Solodamu Village, Moanakaka Bird Sanctuary, 50 m, 7 Mar–11 May 2004, Malaise 3, Schlinger, Tokota'a, 19.078° S, 178.121° E, FBA 111742, 1♀ (BMNH). Other material examined. **FIJI:** Viti Levu: Natova, Apr 1918, R. Veitch, 1♀ (BMNH) (Bezzi 1928); Lautoka, 12 Feb 1919, W. Greenwood, 1♀ (BMNH) (Bezzi 1928); Namaka, 20 Aug 1943, R.A. Lever, 1♀ (BMNH); Nandi, 0–50 m, Mar 1981, N.L.H. Krauss, 1♂ (BPBM); Nandrau, 660 m, 28–29 Jun 1958, B. Malkin, 1♂ (BPBM); Nadi, 12 Mar 1978, S. Shinonaga, H. Kurahashi, 1♂, 1♀ (NSMT); 40 mi E of Nadi, 26 July 1967, J. & M. Sedlacek, 1♀ (BPBM).

Comments. These specimens all belong to *L. assimilis* rather than to the closely-related *L. pacifica* Shinonaga & Pont. The species was described by Pont (2019: 144–150).

Distribution. Bonin Is, Caroline Is, Fiji, New Caledonia, Vanuatu, Samoa, Tonga, French Polynesia (Society Is); Oriental, Australasian/Oceanian and southern Palaearctic regions.

Biological data. Nothing is known of the habits and biology.

30. *Lispe bengalensis* (Robineau-Desvoidy), new record (Figs 56–58)

Limnophora bengalensis Robineau-Desvoidy, 1830: 518. Holotype female, “Bengale” [India or Bangladesh], in MNHNP [seen].

Lispe tetrastigma Schiner; Hennig, 1960: 458.

Lispe bengalensis; Pont, 1989: 692; Pont, 2019: 215–221.

Diagnosis. The only Fijian species to have a brown palpus and an apical posteroventral seta on hind tibia. All femora with rows of anteroventral and posteroventral spinules in apical half. Male terminalia as in Figs 56–58; male and female terminalia illustrated in Pont (2019: figs 453–459).

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI:** Viti Levu: Nadi, 12 Mar 1978, S. Shinonaga, H. Kurahashi, 1♂, 1♀ (NSMT), 1♂, 1♀ (BMNH); Nadi, 27 Jun 1913, J.F. Illingworth, 1♀ (USNM); Nadi, 12 Jun 1913, J.F. Illingworth, 1♀ (USNM); Nadi, 2 Aug 1913, J.F. Illingworth, 1♀ (USNM).

Distribution. Fiji, French Polynesia (Marquesas), Society Is, Australia; Oriental, Afrotropical and southern Palaearctic regions.

Comments. The species was described by Hennig (1960: 458–459, as *tetrastigma* Schiner), and by Pont (2019: 215–221).

Biological data. Adults have been reported in Ghana, West Africa, as preying on mosquitoes (Werner & Pont 2006: 94), but otherwise nothing is known of the life history and biology.

31. *Lispe pectinipes* Becker, new record (Figs 59–60)

Lispa pectinipes Becker, 1903: 113. Lectotype ♂, Egypt, Cairo, in ZMHU [designation by Lyneborg, 1970: 43].

Lispe pectinipes; Hardy, 1981: 85; Pont, 1989: 693.

Diagnosis. This species can be immediately recognised by the presence of a single strong pair of presutural dorsocentral setae placed midway between suture and neck. In addition, fore tibia has a submedian posterior seta. The scutum has a very distinct broad dark median vitta that continues to the tip of scutellum and is flanked by a vitta on each side between the dorsocentral and intraalar rows. Abdominal tergites 1+2 to 5 each with a large median quadrate black mark which covers most of the dorsal surface on tergites 1+2 to 4. The male has mid femur with a comb of short dense posteroventral setulae in apical fifth, and hind tibia with a row of 6 fine erect posteroventral setae in apical half. Male terminalia as in Figs 59–60.

Material examined (FAS): FIJI: Taveuni: Cakaudrove Prov., Soqulu House in Soqulu Estate, 140 m, 21 Nov–13 Dec 2002, Malaise 1, E.I. Schlinger, M. Tokota'a, 15.833° S, 180° W, FBA 125277, 1♂ (BPBM).

Comments. Paterson (1953) found that Afrotropical *L. leucospila* consisted of several, previously confused species, and Lyneborg (1970) later showed that *Lispe pectinipes* and *Lispe leucospila* (Wiedemann, 1830) are distinct species. This was confirmed by Vikhrev (2011, 2014). *Lispe pectinipes* has been found to be widely but sparsely distributed, and Hawaiian specimens of the *Lispe leucospila* group also proved to belong to *L. pectinipes* (Hardy 1981). The species was described by Hardy (1981: 85–87) together with illustrations of the diagnostic characters and the male and female terminalia.

Distribution. Hawai'i; widely distributed in the southern Palaearctic, Afrotropical and Oriental regions, though its exact range is not completely known due to the earlier confusion with *L. leucospila*.

Biological data. Nothing is known of the habits and biology.

32. *Lispe tentaculata* (De Geer)

Musca tentaculata De Geer, 1776: 86. Sweden, Uppland, probably Lövsta district. Syntypes, ?sex, not in NRS, presumed destroyed [Persson *et al.* 1984: 93].

Lispa [sic] *tentaculata*; Malloch, 1929b: 153.

Lispe tentaculata; Pont, 1989: 693.

Diagnosis. Easily recognised in the male sex by a curious modification to the fore tarsomere 1 and in the female sex by the patch of dense pubescence on the posterior half of scutum, between the dorsocentral setae.

Material examined. No specimen was found among material studied.

Comments. Recorded from Viti Levu by Malloch (1929b), from one specimen in ZSZMH, which was probably destroyed in World War II. Malloch's record was quoted with a query by Pont (1989: 593), but it seems certain that it was a misidentification, perhaps of a female, or may even have been a mislabelled specimen.

Distribution. Holarctic region, also from Central America and north-west India.

33. *Lispe* sp. indet. male

Diagnosis. A single male with bare meron and hind tarsomere 1 expanded and flattened.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Lau:** Komo, 20 Aug 1924, E.H. Bryan, 1♂ (BPBM).

Comments. This male is in poor condition and cannot be identified with any known Australasian or Oceanian species. It may belong to an endemic Fijian species, but more and better material is needed.

Biological data. Nothing is known of the habits and biology.

34. *Lispe* sp. indet. female

Diagnosis. Two females with some short setulae on meron just above hind coxa, and mid femur with a strong anterior seta at middle and, just apicad of it, with another strong seta between anterior and anteroventral surfaces.

Material examined (FAS): No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Rotuma:** 17–27 Apr 1971, G.S. Robinson, 2♀ (BMNH).

Comments. These two females cannot be identified with any known Australasian or Oceanian species and may belong to an endemic Fijian species, but more material and males are needed. They are clearly related to *Lispe pumila* (Wiedemann) and *L. angustipalpis* Stein, both of which are known from the Oriental region and Australia (Pont 2019). Other species in this small group, which all have the characteristic pair of setae on mid femur and setulae in lower posterior corner of meron and, in the male, long fine bushy setae on posterior surface of fore coxa, include *L. isolata* Malloch (Samoa) and several undescribed species from Papua New Guinea and the Bismarck Archipelago.

Biological data. Nothing is known of the habits and biology.

Coenosini

Genus *Coenosia* Meigen, new record

Coenosia Meigen, 1826: 210. Type-species: *Musca tigrina* Fabricius, 1775, by subsequent designation of Westwood (1840: 143) and confirmed by I.C.Z.N. (2015: 173) [Opinion 2360].

Diagnosis. Male dichoptic; one pair of reclinate orbital setae; frons parallel-sided, longer than wide; labella reduced, prestomal teeth well developed; prealar seta absent; lower proepimeral seta directed downwards; dorsocentrals 1+3 (rarely 2+3); anepimeron bare; katepisternals 1:1:1, arranged in an equilateral triangle; scutellum with both pairs of setae developed; lower calypter about 1.8 times as long as the upper one; hind femur with two preapical setae, one anterodorsal and one dorsal, the posterodorsal absent; hind tibia with one submedian anterodorsal seta and usually one anteroventral; median posterior or posterodorsal setae absent; sternite 1 bare; male hypandrium tubular; female ovipositor long and with many microtrichia.

Comments. Adults are probably all predatory on insects inhabiting the herb layer (Skidmore 1985). The larvae are obligate carnivores, living in soil, humus, leaf litter, or decaying vegetation. The biology is known for only a few species.

This is the first record of a true species of *Coenosia* from the Fiji Islands as Fijian species previously described in *Coenosia* or recorded as species of *Coenosia* belong to other genera.

35. *Coenosia fijiensis* Pont & Couri, sp. nov.
(Figs 61–63)

Coenosia pumilis [sic] Stein; Curran, 1929: 7 [misidentification].

Diagnosis. Easily recognised by the single pair of reclinate orbital setae; antenna, palpus and legs yellow in male; 1 proepisternal seta; 1 preapical posterior seta on mid femur; male with many setae on head, pleura and legs yellow, and tibiae without setae except for the apicals.

Male, female

Head. Ground-colour black but frons yellow beneath the pruinosity. Frons broad, just above lunule about 1/3 of maximum head-width (in frontal view). Eye bare. Fronto-orbital plate and frontal vitta silvery and without any line separating them (male), matt yellowish white from most angles with the fronto-orbital plate slightly greyer (female); parafacial, face, gena and lower occiput silvery pruinose, rest of occiput light grey. Fronto-orbital plate narrow, at middle about 1/5 to 1/6 of width of frontal vitta at this point. Ocellar tubercle grey, frontal triangle not visible. Setae white except for inner vertical and post-ocular setulae (male) or all black as usual (female). Upper post-ocular setulae in one row. Ocellar seta as long as (male) or longer than (female) orbital seta. 2 pairs of inclinate frontal setae and 1 reclinate orbital, the upper frontal closer to orbital than to lower frontal, these three short and pale in male, normal in length in female. Antenna yellow (male), or scape and pedicel orange and postpedicel black (female); postpedicel moderate, twice as long as pedicel in frontal view, falling short of mouth-edge by over half of its own length, the anterior tip produced into a point. Arista long, almost bare, the individual hairs not as long as its basal width. Parafacial moderate, at level of postpedicel insertion equal to width (male) or half width (female) of postpedicel. Vibrissal angle behind level of profrons; vibrissa minute and pale (male), or strong, black, crossed (female). Gena moderate, the depth below lowest eye-margin equal to length (male) or half length (female) of postpedicel. Mentum of proboscis dark brown, glossy. Palpus pale yellow (male) or dull yellow (female).

Thorax. Ground-colour black and entirely light grey dusted, almost silvery in male; scutum sometimes weakly tinged with yellow medially, without even traces of dark vittae. Acrostichal setulae in 2 rows. Dorsocentrals 1+3. Postpronotal lobes with setulae, none of them spinulose; inner seta short, fine, less than half length of outer seta. 2 postsutural intraalars. 1 proepisternal seta, this and the 2 proepimerals yellow in male. Katepisternals and anepisternals yellow in male. Scutellum with the usual apical and sub-basal lateral setae; disc with circa 4 setulae.

Legs. Yellow, only apical few tarsomeres on mid and hind legs brown, coxae partly darkened in female. All setae on coxae and trochanters yellow in male. Tarsomeres not expanded. Fore femur with the posteroventral row sparse, the setae yellow in male. Fore tibia with a strong submedian posterior seta in female, absent in male. Mid femur with 1 yellow posteroventral in basal half in male, and 2 short posteroventrals in basal half in female; a black anterior seta at basal third, and 0 anterior and 1 posterior preapical seta. Mid tibia without setae in male, with 1 anterodorsal and 1 anteroventral in female. Hind femur in male with 1 anteroventral, 1 posteroventral, 2 anterodorsals and 1 dorsal, all yellow and all in basal half; in female with an anterodorsal row, 1 preapical posterodorsal, 1 anteroventral in basal half and 2 in apical half, and 1 posteroventral at middle. Hind tibia in male without setae except for a tiny dorsal preapical; in female with the dorsal preapical strong, and also 1 anterodorsal and 1 anteroventral.

Wing. Clear, veins yellowish brown. Tegula and basicosta yellow. Veins bare, except for costa which is setulose to tip of vein R_{4+5} . Costal spine inconspicuous. Cross-vein r-m below the point where R_1 enters costa; dm-cu straight. Calypters white, margins white; lower calypter long, projecting beyond upper one by almost length of upper one. Haltere yellow.

Abdomen. Ground-colour yellow on syntergite 1+2, tergite 3, and tergite 4 anteriorly in male, partly yellow on syntergite 1+2 and tergite 3 in female, otherwise black, or even wholly black in female; light grey dusted on the dark areas. Without dark spots or other markings. Tergites with a few weak setae, all yellow in male. Sternite 1 bare.

Terminalia. Male terminalia as in Figs 61–63.

Measurements. Length of body, 2.5 mm. Length of wing, 2.0 mm.

Material examined (FAS): Holotype ♂, FIJI: Viti Levu: Sigatoka Sand Dunes Nat. Park, 1.1 km SSW Volivoli Village, 55 m, Malaise trap [18.1594, 177.4847], 14–22 Dec 2002, E.I. Schlinger, M. Tokota'a, FJVL6b_M02_03, FBA 089842 (BPBM). Paratypes 4♂, 26♀: same data as holotype (BPBM except where stated), FBA 089855 (♀), FBA 089857 (♀) (BMNH), FBA 089856 (♀), FBA 089854 (♀), FBA 089853 (♀), FBA 089852 (♀), FBA 089851 (♀), FBA 089850 (♀), FBA 089849 (♀), FBA 089866 (♀), FBA 089865 (♀), FBA 089843 (♀), FBA 089844 (♀), FBA 089845 (♀), FBA 089836 (♀), FBA 089837 (♀), FBA 089864 (♀), FBA 089867 (♀), FBA 089868 (♂), FBA 089814 (♀), FBA 089839 (♂), FBA 089840 (♀), FBA 089841 (♀), FBA 089792 (♀), FBA 089793 (♀), FBA 089838 (♀), FBA 089848 (♂), FBA 089801 (♀), FBA 089807 (♀), FBA 089847 (♂) (BMNH). Other material examined (paratypes). FIJI: Cicia: Mabula, 0–10 m, 13 Feb 1970, N.L.H. Krauss, 1♀ (BPBM). Mothe: 15 Aug 1924, E.H. Bryan, 1♀ (BPBM). Yangasa Cluster: Navutu-i-Loma, 8 Aug 1924, E.H. Bryan, 1♂ (BPBM).

Comments. *Coenosia fijiensis* is very similar to *C. pumilio* Stein from New Guinea (types seen), having 1 proepisternal seta, and, in the male, yellow antenna and palpus and tibiae without setae on the shaft. It differs from *pumilio* by having mid femur with 1 posterior preapical seta (2 in *pumilio*) and many of the setae on head, pleura and legs yellow (all black in *pumilio*).

Etymology. The species name refers to the place where the material was collected.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

Genus *Orchisia* Rondani

Orchisia Rondani, 1877: 279. Type species: *Sapromyza costata* Meigen, 1826, by original designation.

Diagnosis. Head with two pairs of reclinate frontal setae; arista with hairs along its entire length; prestomal teeth developed; frontal triangle reaching lunule; dorsocentrals 1+3; prealar absent; katepisternals 1:1:1; scutellum with only the apical pair of setae strong; fore tibia without a median posterior seta; hind tibia with a very small submedian posterodorsal seta.

Comments. Biology unknown. Adults are assumed to be predaceous. One species: *O. costata* (Meigen), throughout warm regions of the Old World.

36. *Orchisia costata* (Meigen)

Sapromyza costata Meigen, 1826: 266. Holotype female, W Europe, in MNHNP (Pont 1986a: 218). *Orchisia costata*; Bezzia, 1928: 170; Emden, 1942: 98; Snyder, 1965: 217; Pont, 1989: 697.

Diagnosis. With a very distinct wing pattern: wing with a brown elongate spot along the costal vein; scutellum with only the apical pair of setae.

Material examined (FAS). No specimen was found among the Fiji Arthropod Survey material. Other material examined. **FIJI: Lau**: 14 Aug 1924, E.H. Bryan, 1♀ (BPBM). **Matuku**: 5 Jul 1924, E.H. Bryan, 1♀ (BPBM). **Viti Levu**: Nausori, Oct 1920, R. Veitch, 1♀ (BMNH) (Bezzi 1928); Rewa, Nov 1905, F. Muir, 1♀ (BPBM); Rewa, Apr 1906, F. Muir, 1♂ (BPBM); Rewa, Mar 1905, F. Muir, 1♂ (BPBM).

Distribution. Australia, Belau, Bonin Is., Fiji, Micronesia, New Caledonia, Northern Marianas, Samoa; Afrotropical, Oriental and Palaearctic Regions.

Biological data. Nothing is known of the habits and biology.

Genus *Parvisquama* Malloch

Lispocephala Pokorny, subgenus *Parvisquama* Malloch, 1935: 662. Type-species: *Lispocephala (Parvisquama) pahangensis* Malloch, 1935, by original designation.

Diagnosis. Small species, about 3.5 mm long; ocellar triangle long and narrow, reaching lunule; lower calypter reduced, linear; basal scutellar seta half as long as apical one; fore tibia without setae at middle; mid tibia with only one posterior seta; hind tibia with one median anterodorsal and posterodorsal setae, one supra-median anterodorsal and posterodorsal setae and one submedian anteroventral.

Comments. Previously only two species were known from Fiji, *P. tripuncta* (Malloch) and *P. dolichocera* (Bezzi), both endemic. The material examined included a large number of specimens of this genus. Four new species are here described and illustrated. They are very similar morphologically, so a complete description is made only for *P. femorata* sp. nov. and only the differentiating characters of the other new species are given. The main characters used to separate *Parvisquama* species are: colour of palpus, colour pattern of abdomen, series of anteroventral and posteroventral setae in the apical third or half of mid femur in males, and male terminalia. There is still a quantity of material to be examined, especially unidentified females, so that it appears that the Fiji *Parvisquama* fauna is much richer than suggested here.

37. *Parvisquama curvicerca* Pont & Couri, sp. nov.

(Figs 64–68)

Diagnosis. Palpus yellow, brownish yellow in some females; antenna short, with scape brown and postpedicel largely yellowish, at least on inner surface, especially in males; males with apical third of posteroventral surface of mid femur with a row of about 8 similar setae (Fig. 64); anteroventral and posteroventral rows in the apical half of mid femur in female fine and similar, the ones on posteroventral surface a little longer, abdomen largely yellow, almost without grey pollinosity in females; males with tergites 4 and 5 with dark round lateral brown spots; females with tergites 3–5 with lateral brown spots and tergites 1+2–4 with a median brown area; male with cercal plate yellow and long, more than twice as long as height of epandrium (Fig. 65) and curved forward medially in lateral view (Fig. 66); ovipositor as in Figs 67–68.

Material examined (FAS): Holotype ♂, **FIJI: Vanua Levu**: Bua Prov., 5 km NW Kilaka Village, 145 m [15.815, 178.986], Malaise, 15–28 Jun 2004, Schlinger, Tokota'a, FJVN58d_M01_07, FBA 090194 (BPBM). Paratypes: **Vanua Levu**: Bua Prov., Batiqere Range, 5 km NW Kilaka Village, 98 m, 3–10 Jun 2004, Malaise 5, Schlinger, Tokota'a, 15.807° S, 178.991° E, FBA 093870 (♀); 28 Jun–21 Jul 2004, Malaise 5, Schlinger, Tokota'a, 15.807° S, 178.991° E, FBA 141849 (♀); 6 km NW Kilaka Village, 113 m [16.732, 179], Malaise, 15–28 Jun 2004, Schlinger, Tokota'a, FJVN58d_M01_07, FBA 090199 (♀); 145 m [15.815, 178.986], Malaise, 15–28 Jun 2004, Schlinger, Tokota'a, FJVN58d_M01_07 FBA 090195 (♂); 98 m, 28 Jun–21 Jul 2004, Malaise 5, Schlinger, Tokota'a, 15.807° S, 178.991° E, FBA 141850 (♀); Macuata prov., 0.4 km S Rokosalase Village [15.532, 179.019], 118 m, 23 Apr–8 May 2004, Malaise, Schlinger Tokota'a, FJVN57c_MO2_O3, FBA 090144 (♀); Macuata Prov., Dogotuki, 2.5 km E of Nasavu River [15.256, 179.783], 105–226 m, Malaise trap, 7 Jul 2003, Schlinger, Tokota'a, FJVN91_M01_01, FBA 090227 (♀),

FBA 090230 (♀). **Taveuni:** Cakaudrove Prov., Soqulu House in Soqulu estate, Malaise trap [15.833, 190], 140 m, 25 Sep–2 Oct 2002, E.I. Schlinger, M. Tokota'a, FJTA7a_MO1_01, FBA 089949 (♀), FBA 089952 (♀); 13–20 Dec 2002, Malaise 1, E.I. Schlinger, M. Etymology. The name refers to the curved cercal plate of the male terminalia.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

38. *Parvisquama dolichocera* (Bezzi)
 (Figs 69–76)

Coenosia dolichocera Bezzi, 1928: 169. Holotype male, FIJI: Lautoka Mts, in BMNH [Pont 1970b: 419].
Coenosia microlepis Bezzi, 1928: 168. Lectotype female, FIJI, Taveuni, in BMNH [designation by Pont 1970b: 421].

Lispocephala dolichocera; Emden, 1942: 97.

Parvisquama dolichocera; Pont, 1970b: 419; Pont, 1989: 697.

Diagnosis. Palpus dark brown; postpedicel long, reaching mouth edge, broad and truncate at tip (Fig. 69); mid femur with series of fine and short anteroventral and posteroventral setae, similar on both surfaces (Fig. 70); abdomen yellowish; tergites 1+2–4 with a faint greyish brown median line; rounded brown spots on tergites 3–5 (those on tergite 3 faint in male); apex of abdomen as in Fig. 71; male terminalia yellow; cercal plate as long as height of epandrium; sternite 5, cercal plate and aedeagus as in Figs 72–76.

Material examined (FAS): FIJI: **Vanua Levu:** Bua Prov., Batiqere Range, 5 km NW Kilaka Village, 98 m, 28 Jun–21 Jul 2004, Malaise 5, Schlinger, Tokota'a, 15.807° S, 178.991° E, FBA 141836 (♂), FBA 141832 (♂), FBA 141834 (♂); 3–10 Jun 2004, Malaise 3, Schlinger, Tokota'a, 15.811° S, 178.988° E, FBA 114405 (♂). **Taveuni:** Cakaudrove Prov., Soqulu House in Soqulu estate, 140 m, 13–20 Dec 2002, Malaise 1, E.I. Schlinger, M. Tokota'a, 15.833° S, 180° W, FBA 120383 (♂), FBA 120352 (♂), FBA 120355 (♂), FBA 125272 (♂), FBA 120351 (♂); 5.3 km SE Tavuki Village, Mt. Devo, 15.6027.4° S, 179.58.1° W, 1054 m, 31 Oct–14 Nov 2002, Schlinger, Tokota'a, Malaise, FJTA9c_M03_06, FBA 089173 (♂). **Viti Levu:** Naitasiri Prov., 2 km E Navai Village, old trail to Mt. Tomaniivi, 700 m, 26 Sep–11 Oct 2003, Malaise 3, Schlinger, Tokota'a, 17.621° S, 178° E, FBA 124615 (♂), FBA 124531 (♂), FBA 124617 (♂), FBA 124626 (♂), FBA 124606 (♂), FBA 124521 (♂); Vuda Prov., 1.5 km SW Vaturu Dam, 550 m, 2–14 Jul 2004, Malaise 1, E. Schlinger, M. Tokota'a, 17.744° S, 177.575° E, FBA 135871 (♂); 1 mile SW Vaturu Dam, 520 m, 2–14 Jul 2004, Malaise 3, Schlinger, Tokota'a, 17.754° S, 177.665° E, FBA 175449 (♂). Other material examined. **FIJI: Viti Levu:** Lautoka Mountains, 11 Apr 1920, W. Greenwood, holotype ♂ of *dolichocera* (BMNH); Nandarivatu, 850–950 m, 2 Apr 1973, 6♂, 7♀, N.L.H. Krauss (BPBM); the same, but 2 Mar 1973, 5♂, 3♀ (USNM); Lami, 20–200 m, Mar 1974, 1♂, N.L.H. Krauss (BPBM); Nausori Highlands, 500–600 m, 9 Feb 1971, 1♀, N.L.H. Krauss (BPBM); Mt. Victoria (now Mt. Tomaniivi), 600–1000 m, 30 Jul 1967, 1♀, J. & M. Sedlacek (BPBM). **Ovalau:** Levuka, 0–200 m, Dec 1969, 1♀, N.L.H. Krauss (BPBM). **Taveuni:** 21 Dec 1921, H.W. Simmonds, lectotype ♀ and paralectotype 1♀ of *microlepis* (Bezzi's "type male and female") (BMNH). **Vanua Levu:** Mt. Dalaikoro, summit area, 700–790 m, 10 Oct 1979, 1♀, S.N. Lal, G.A. & S.L. Samuelson (BPBM).

Comments. The long postpedicel easily separates this species from the others. As pointed out by Emden, Bezzi's type-series of male and female *P. microlepis* actually consists of females of two different species of *Parvisquama*. The lectotype and paralectotype females from Taveuni belong to *P. dolichocera* and the paralectotype female from Cuvu belongs to *P. tripuncta*.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

39. *Parvisquama femorata* Pont & Couri, sp. nov.
 (Figs 77–80)

Diagnosis. Palpus yellow, brownish at base in some specimens; postpedicel short; males on posteroventral surface of mid femur with 4–5 short stout spinules in apical sixth (Fig. 77); hind femur with comb-like posteroventral setulae in apical half; surstyli shorter than height of epandrium, curved inwards at apex in lateral view; cercal plate and aedeagus as in Figs 78–79. Ovipositor and spermatheca as in Fig. 80.

Description

Male

General coloration. Occiput, fronto-orbital plate, parafacial, face, gena and ocellar triangle with silver pollinosity, frons dark brown; antenna and arista brown, sometimes apex of scape and base of postpedicel yellowish; palpus yellow, brownish at base in some specimens; thorax brown with opaque grey pollinosity; scutum with 3 very faint vittae along acrostichal and dorsocentral lines; haltere white, wing and calypters clear; legs yellow; abdomen with grey pollinosity on all tergites, with few yellow areas, only on apical margins of tergites 1+2–4; some males with yellow lateral areas on syntergite 1+2, tergites 3–5 with lateral dark brown clouds, those on tergite 5 round, and a median brown line. Male with surstylos yellow.

Head. Inner and outer vertical setae short; frontal row with 4 setae; postpedicel about 1.8 times the length of pedicel; arista with short hairs; vibrissa long, inserted at oral margin.

Thorax. Acrostichals in two irregular rows of setulae; dorsocentrals 1+3; intraalars 1+2; notopleurals 2, the anterior one longer; postpronotals 2, one long and one short; scutellum with one short subbasal seta and one very long apical, about 3 times the length of the subbasal, and with scattered setulae on disc; anepisternum with a row of 4 setae on upper half, the third one longer, and one seta an apex of lower half.

Legs. Fore femur with a well-spaced row of anteroventral and anterodorsal setae, the last one stronger. Fore tibia with a preapical seta on anteroventral, anterodorsal and dorsal surfaces. Mid femur with 1–3 anterior setae on middle third, a row of anteroventral setae in basal half, posteroventral surface with 4–5 short stout spinules in apical sixth (Fig. 72); one preapical posterior seta. Mid tibia with apical setae on dorsal, anteroventral, posteroventral and ventral surfaces, the last one long. Hind femur with an anterodorsal row of setae and one irregular row of anteroventrals, the middle 3 and the preapical stronger; with comb-like posteroventral setulae in apical half.

Abdomen. Tergites 1+2–5 each with a marginal row of fine setae; tergite 5 with a discal series of 4 setae.

Terminalia. Cercal plate curved inwards at apex in lateral view. Cercal plate and aedeagus as in Figs 73–74.

Measurement. Length of body, 2.8–3.5 mm.

Female

Similar to the male, differing as follows: mid femur with the anteroventral and posteroventral row of setae in the apical half fine and similar in both surfaces. Ovipositor and spermathecae as in Fig. 75.

Measurement. Length of body, 2.6–3.5 mm.

Etymology. The name refers to the short stout spinules in the apical sixth of mid femur.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

40. *Parvisquama longicerca* Pont & Couri, sp. nov. (Figs 81–85)

Diagnosis. Antenna brown, apex of scape and base of postpedicel yellow; palpus yellow; mid femur of male with a row of comb-like setulae in the apical half of anteroventral and posteroventral surfaces, the ones on posteroventral surface more developed (Fig. 81); hind femur with a row of comb-like posteroventral setulae in apical half; abdomen yellow with grey pollinosity on tergites 4 and 5; apex of abdomen as in Fig. 82; tergites 1+2–4 with a median brown longitudinal cloud, tergites 4–5 with round lateral brown clouds; male sternite 5 as in Fig. 83; male with cercal plate very long, about three times the height of epandrium and curved inwards at apex in lateral view (Figs 84–85).

Material examined (FAS): Holotype ♂, FIJI: Viti Levu: Sigatoka Sand Dunes Nat. Park, 1.1 km SSW Volivoli Village, 55 m, Malaise trap [18.1594, 177.4947], 23 Sep–8 Oct 2002, E.I. Schlinger, M. Tokota'a, FJVL6b_MO3_O1, FBA 089669 (BPBM). Paratypes: Viti Levu: data as for holotype, FJVL6b_MO3_O1, FBA 089705 (♂), FBA 089704 (♂) (BMNH). Taveuni: Cakaudrove Prov., 5.6 km SE Tavuki Village, Devo Peak [15.843, 179.955], 1187 m, Malaise trap, 30 Jun–14 Jul 2004, 1188 m, E.I. Schlinger, M. Tokota'a, FJTA8b_MO2_O2, FBA 089959 (♂).

Etymology. The name refers to the long cercal plate of the male terminalia.

Comments. This may be the same as a species in BMNH from Vanuatu. Female unknown.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

41. *Parvisquama longiseta* Pont & Couri, sp. nov.
(Figs. 86–89)

Diagnosis. Palpus brown, postpedicel about 2.2 times the length of the yellow pedicel; mid coxa with strong setae on ventral surface; mid femur with a comb-like series of strong setae in apical third of posterovenital surface (Fig. 86); hind femur with a comb-like series of fine posterovenital setae in apical half; abdominal syntergite 1+2 yellowish, tergites 3–4 with grey pollinosity, yellow only along the apical margin, tergite 5 with no yellow marks; tergites 3–4 with lateral and median brown clouds, tergite 5 with two round lateral clouds; apex of abdomen as in Fig. 87; male sternite 5 with long setae on margin, as in Fig. 88; cercal plate a little longer than height of epandrium in lateral view and a little sinuous; terminalia in lateral view as in Fig. 89.

Material examined (FAS): Holotype ♂, FIJI: Taveuni: Cakaudrove Prov., 5.3 km SE Tavuki Village, Mt. Devo, 1054 m, 10–17 Oct 2002, E.I. Schlinger, M. Tokota'a, 16.841° S, 179.958° W, FJTA9C_M03_03, FBA 090075 (BPBM).

Etymology. The name refers to the long setae on the margin of male sternite 5.

Comments. Female unknown.

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

42. *Parvisquama tripuncta* (Malloch)
(Figs 90–98)

Lispocephala tripuncta Malloch, 1928b: 80. Holotype female, FIJI: Nadi, in BPBM (Lee *et al.* 1956: 338).
Lispocephala tripuncta; Emden, 1942: 97.
Parvisquama tripuncta; Pont, 1970b: 421; Pont, 1989: 697.

Diagnosis. Palpus yellow; postpedicel short; abdomen yellowish, sometimes more or less infuscated and greyish dusted; tergites 3–5 with brown rounded spots on each side and a brown median cloud; mid femur with anteroventral and posterovenital rows in the apical half, the latter denser (Fig. 90). Apex of male abdomen as in Fig. 91; sternite 5 as in Figs 92 (dorsal view) and 93 (ventral view); cercal plate as long as height of epandrium; cercal plate as in Figs 94 (dorsal view) and 95 (lateral view). Ovipositor, spermathecae and egg as in Figs 96–98.

Material examined (FAS). **FIJI:** **Vanua Levu:** Bua Prov., Batiqere Range, 5 km NW Kilaka Village, 145 m, 28 Jun–21 Jul 2004, Malaise 1, Schlinger, Tokota'a, 15.815°S, 178.986°E, FBA 104937 (♀), FBA ? Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

Genus *Pygophora* Schiner

Pygophora Schiner, 1868: 295. Type-species: *Pygophora apicalis* Schiner, 1868, by original designation.

Diagnosis. Frons high, much wider at anterior margin than at vertex; two pairs of reclinate orbital setae and usually 2 frontal setae; frontal triangle short; arista with long hairs on basal half; prestomal teeth developed; dorsocentrals 1+3, the presutural seta sometimes preceded by a second short one; prealar seta absent; anepimeron bare; fore tibia with one median seta on posterior surface; hind tibia with one anteroventral, 2 anterodorsal and 2 posterodorsal setae.

Comments. Biology unknown; adults predaceous. Two species: *P. ctenophora* Bezzi, endemic, and a second unnamed but apparently endemic species known from a single male

43. *Pygophora ctenophora* Bezzi

Pygophora ctenophora Bezzi, 1928: 169. Lectotype male, FIJI, Natova, in BMNH [designation by Pont, 1970b: 419].

Pygophora ctenophora; Malloch, 1929b: 160; Emden, 1942: 95, fig. 2; Crosskey, 1962: 465, figs 58, 95; Pont, 1989: 698.

Diagnosis. Antenna long, yellowish; face golden; palpus whitish in male, yellowish in female; legs yellow, mid femur in male with a double row of short posteroventral setae on apical third; male with the sides of tergite 4 bare, and the sides of tergite 5 with areas of dense short fine matted hairs.

Material examined (FAS): FIJI: **Taveuni:** Cakaudrove prov., 5.6 km SE Tavuki Village, Devo Peak, Malaise trap [15.843, 179.955], 31 Oct–14 Nov 2002, 1187 m, Schlinger, Tokota'a, FJTA8a_M01_05, FBA 089541 (♂); 5.3 km SE Tavuki Village, Mt. Devo [15.841, 179.958], 1054 m, Malaise trap, 14–21 Nov 2002, E.I. Schlinger, M. Park, 1.1 km SSW Volivoli Village, 55 m, Malaise trap [18.1594, 177.4847], 14–22 Dec 2002, E.I. Schlinger, M. Tokota'a, FJVL6b_M02_03, FBA 089859 (♀), FBA 089832 (♀), FBA 089820 (♀), FBA 089860 (♀), FBA 089817 (♂), FBA 089858 (♂); Naitasiri Prov., 1.8 km E Navai Village, 700 m, old trail to Mt. Tomaniivi, 7–26 Jan 2004, Malaise 4, Schlinger, Tokota'a, 17.621° S, 177.998° E, FBA 120011 (♀); Vuda Prov., Koroyanitu N.H.O., Savuione Trail, FJ-1, Malaise in montane forest, 21 Sep–7 Oct 2002, M Irwin, E. Schlinger, M. Tokota'a, 17.40° S, 177.33° E, 450 m, FBA 002598 (♀). Other material examined. **Fiji:** **Lau:** Oneata, 19 Aug 1924, E.H. Bryan, 1♀ (BPBM) (Crosskey 1962); Namuka, 12 Aug 1924, E.H. Bryan, 1♀ (BPBM); Lakemba, Tubou, 0–50 m, 20 Feb 1971, N.L.H. Krauss, 1♂ (BPBM); Avea, 22 Sep 1924, E.H. Bryan, 1♀ (BPBM); Kambara, Naikaleyaga, 0–100 m, 22 Feb 1971, N.L.H. Krauss, 1♀ (BPBM). **Ovalau:** May 1921, H.W. Simmonds [not June as stated by Bezzi], paralectotype 1♀ (BMNH). **Taveuni:** 15 Jul 1924, S. Evans, 1♀ (BMNH). **Vanua Levu:** Nasese, 31 Jul 1921, H.W. Simmonds, paralectotype 1♀ (BMNH). **Viti Levu:** Natova, May 1918, R. Veitch, lectotype ♂ (BMNH); Natova, Apr 1918, R. Veitch, 1♂ (BMNH) (Crosskey 1962); Lautoka, 23 Mar 1910, R. Veitch, paralectotype 1♂ (MCSNM); Lami, Mar 1951, N.L.H. Krauss, 1♀ (BPBM) (Crosskey 1962); Lami, May 1951 N.L.H. Krauss, 1♀ (BPBM); Nadarivatu, 850 m, 8–13 Mar 1963, C.M. Yoshimoto, 1♀ (BPBM). **Yangasa Cluster:** Navutu-i-Loma, 8 Aug 1924, E.H. Bryan, 1♀ (BPBM) (Crosskey 1962).

Distribution. Known only from Fiji.

Biological data. Nothing is known of the habits and biology.

44. *Pygophora* sp.

A single male has been seen of a second species of *Pygophora*, but as it is not in good condition (not fully hardened) we refrain from describing it. It is very similar to *P. pallipalpis* (Stein, 1910) known from Madagascar and the Seychelles (Crosskey, 1962: 522–524; Couri *et al.*, 2006: 873–874), as it has mid femur with 1 posterior preapical seta, frons with 2 strong and 2 weak frontal setae, and fronto-orbital plate with short setulae outside the frontal setae. It differs from *P. pallipalpis* by the shorter postpedicel, fore tibia without anterodorsal setae, hind tarsomere 1 of normal length, and hind tibia with the apical dorsal seta short, less than half as long as hind tarsomere 1.

Material examined: Fiji: **Viti Levu:** Mt. Victoria, Tholo North, west slope, 3000 feet, beating, 16 Sep 1938, E.C. Zimmerman, 1♂ (BPBM).

Comments: As this species has not been found since the original capture in 1938, it seems likely that it is now extinct.

Distribution: Known only from Fiji.

ACKNOWLEDGEMENTS

The authors are very grateful to all members of the Fiji Arthropods Survey for the opportunity to study this material and also to the Schlänger Foundation and the U.S. National Science Foundation for their support of the project. MSC thanks the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq, process 3013012007–7), and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES, process BEX3123–04–9), agencies of the Brazilian Government fostering scientific and technological development, for a research grant and financial support for this project. ACP is supported by personal funds.

ILLUSTRATIONS

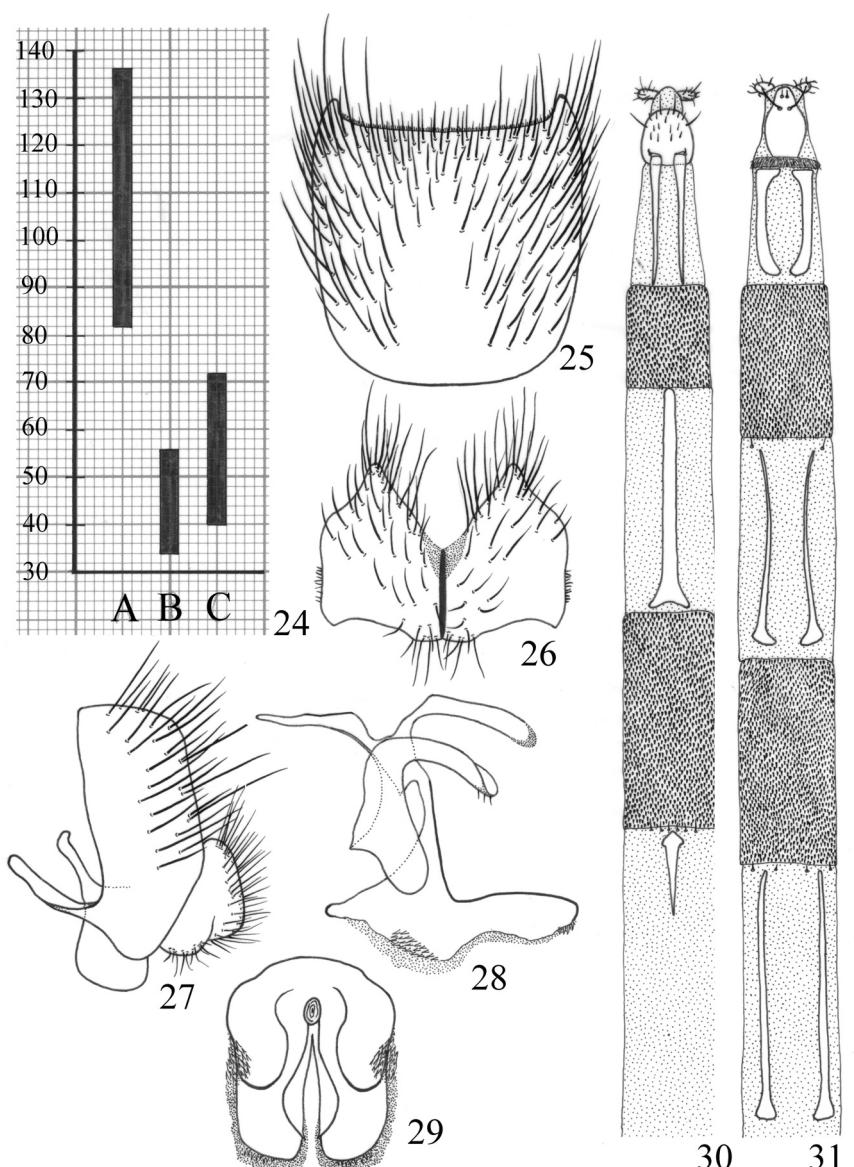

Figures 1–9. **Fig. 1.** Male palpus, lateral view, of (a) *Atherigona varia* (Meigen) (Europe), (b) *Atherigona orientalis* Schiner (Fiji), (c) *Atherigona splendens* Bezzi (Fiji). Scale lines 0.5 mm. **Figs 2–5.** *Atherigona bidens* Hennig. 2, male hypopygial prominence, dorsal view; 3, male hypopygial prominence, lateral view; 4, male trifoliate process, dorsal view; 5, male trifoliate process, lateral view. Viti Levu Island, Lautoka, Mar 1976 (N.L.H. Krauss). Scale lines 0.1 mm. **Figs 6–9.** *Atherigona matema* Curran. 6, male hypopygial prominence, posterior view; 7, male hypopygial prominence, lateral view; 8, male trifoliate process, dorsal view; 9, male trifoliate process, lateral view. Taveuni Island, Waiyemo, 0–100 m, Jan 1972 (N.L.H. Krauss). Scale lines 0.1 mm.

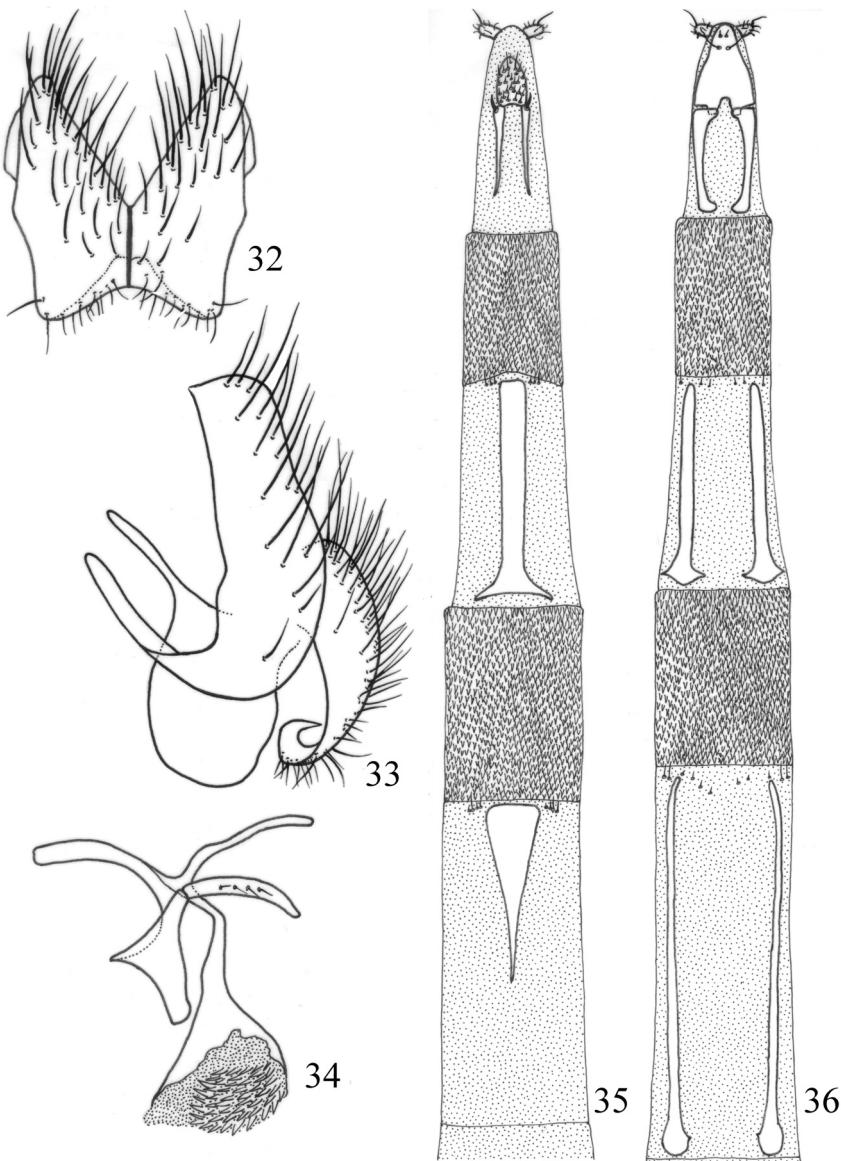

Figures 10–15. Figs 10–13. *Atherigona oryzae* Malloch. **10**, male hypopygial prominence, posterior view; **11**, male hypopygial prominence, lateral view; **12**, male trifoliate process, dorsal view; **13**, male trifoliate process, lateral view. Moala Island, 13 Jul 1924 (E.H. Bryan). Scale lines 0.1 mm. Figs 14–15. *Atherigona poecilopoda* Bezz. **14**, male abdominal segments 1+2 to 5, lateral view; **15**, male fore femur, posterior view. Viti Levu Island, Savura Creek, 19 Mar 1981 (R.A. Beaver) (14); Viti Levu Island, Koronivia Research Station, 1 Mar 1963 (C.M. Yoshimoto) (15). Scale lines 0.5 mm (14) and 0.25 mm (15).

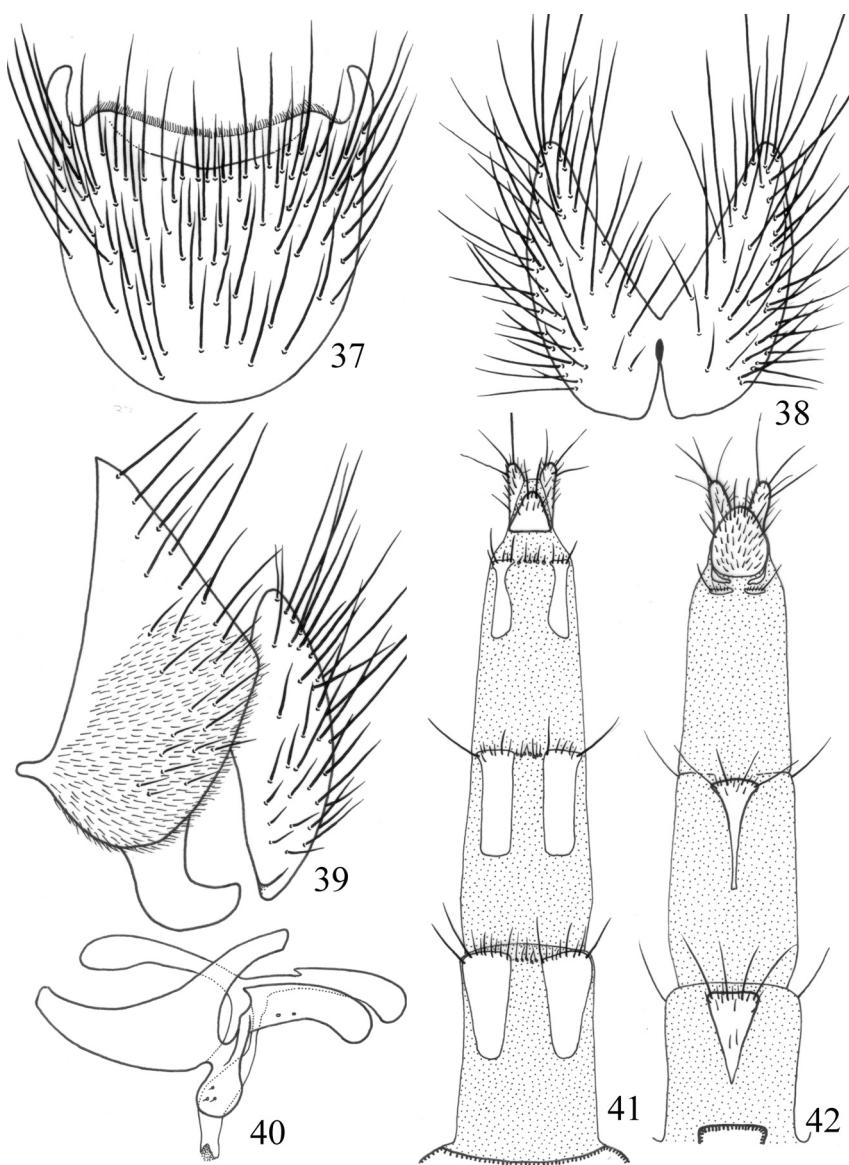

Figures 16–23. Figs 16–18. *Atherigona poecilopoda* Bezzii. 16, male hypopygium, dorsal view; 17, male hypopygium, lateral view; 18, female tergite 8. Viti Levu Island, Savura Creek, 19 Mar 1981 (R.A. Beaver) (male), and Lau Islands, Vanua Masi, 5 Sep 1924 (female). Scale lines 0.2 mm (16, 17) and 0.25 mm (18).
Figs 19–23. *Atherigona splendens* Bezzii. 19, male hypopygial prominence, posterior view; 20, male hypopygial prominence, lateral view; 21, male trifoliate process, dorsal view; 22, female tergite 8; 23, female sternite 6. Viti Levu Island, Suva Bay, Pipe Trail, 22 Jul 1924 (E.H. Bryan) (male), and Matuku Island, 5 Jul 1924 (E.H. Bryan) (female). Scale lines 0.1 mm (19–21) and 0.25 mm (22–23).

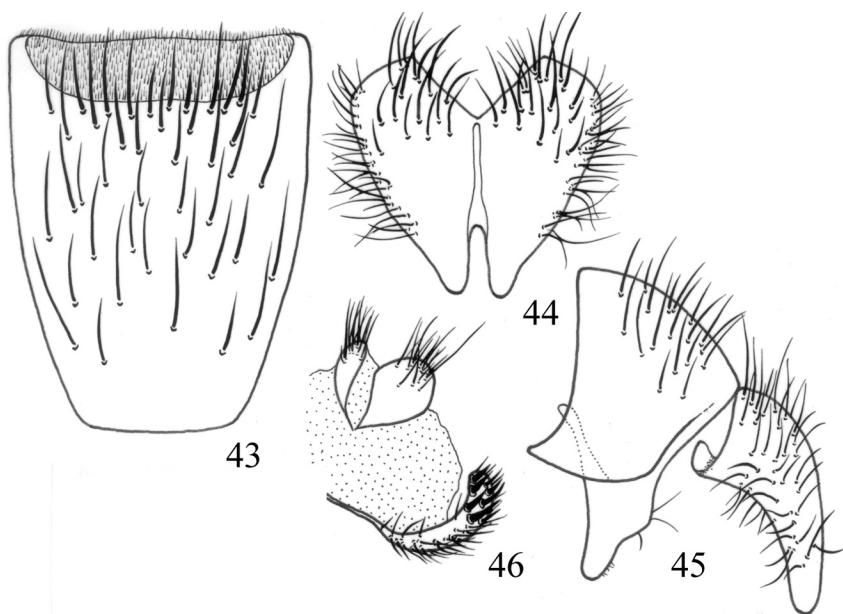

Figures 24–31. Fig. 24. *Musca sorbens* complex. Male frons/head ratio in African (A; n=11), Australian (B; n=10) and Fijian (C; n=16) specimens. Frons measured at narrowest point (at middle) and head at broadest point (viewed from in front). Figs 25–31. *Neomyia greenwoodi* (Bezzi). 25, male sternite 5; 26, male cercal plate, dorsal view; 27, male epandrium, cercal plate and surstyli, lateral view; 28–29, male phallic complex; 30, female, ovipositor, dorsal view; 31, female, ovipositor, ventral view. 40 km east of Nadi, 26 Jul 1967 (male); Colo-i-Suva, 30 Jun 1924 (female).

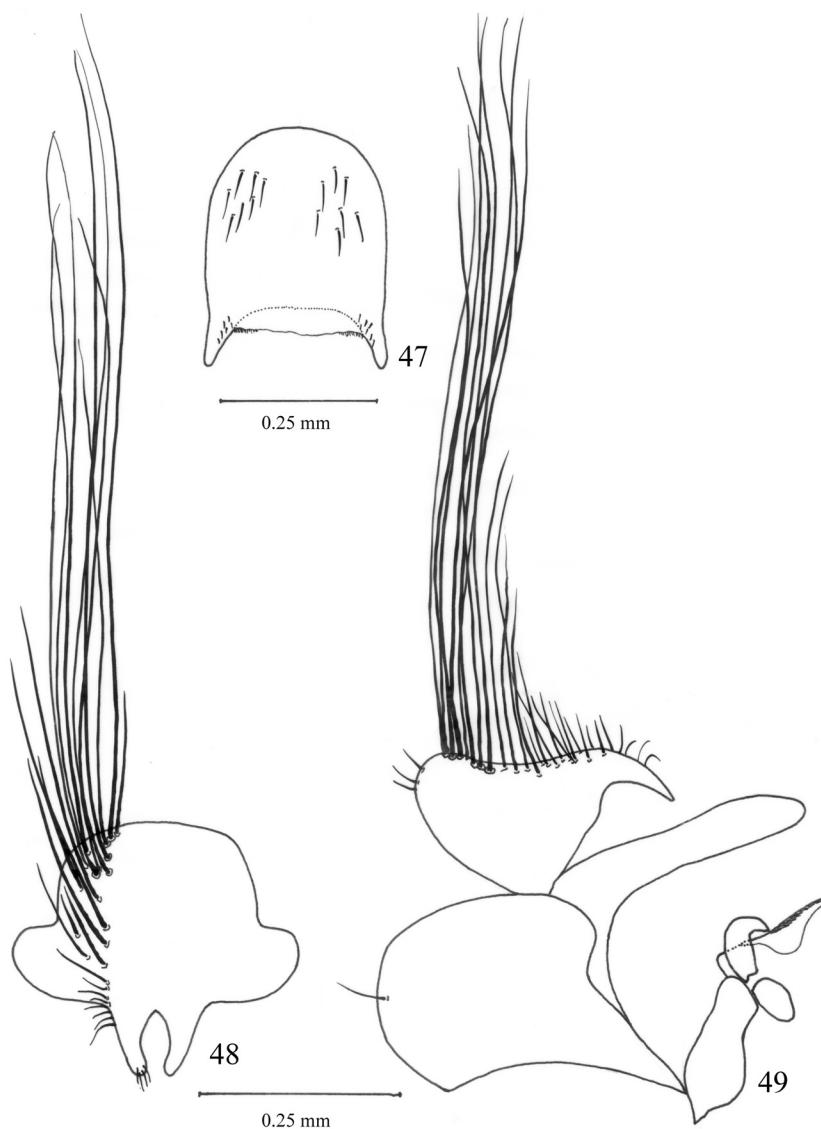

Figures 32–36. *Neomyia simmondsi* (Bezzi). 32, male cercal plate, dorsal view; 33, male epandrium, cercal plate and surstylus, lateral view; 34, male phallic complex; 35, female, ovipositor, dorsal view; 36, female, ovipositor, ventral view. Nandarivatu, 8–13 Mar 1963 (male); Ba, Fiji (Muir) (female).

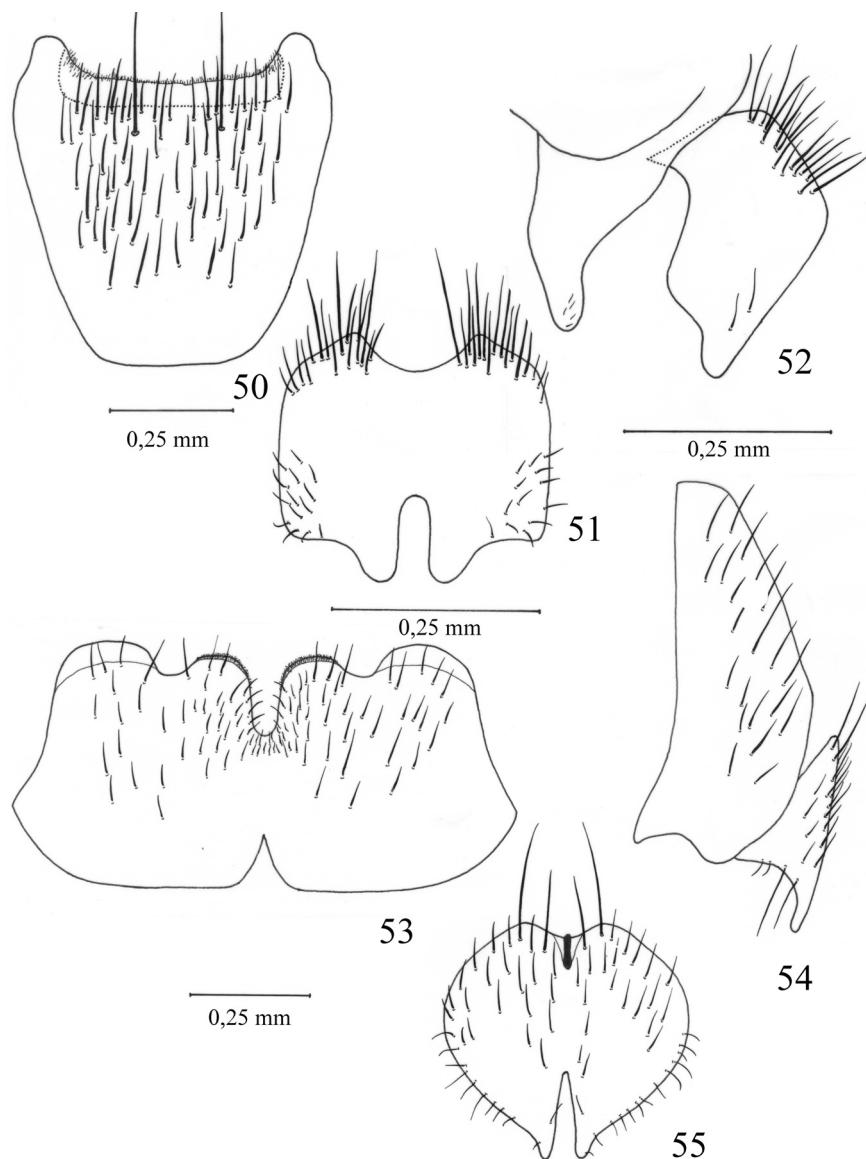

Figures 37–42. *Dichaetomyia elegans* Malloch. **37**, male sternite 5; **38**, male cercal plate, dorsal view; **39**, male epandrium, cercal plate and surstyli, lateral view; **40**, male phallic complex; **41**, female, ovipositor, dorsal view; **42**, female, ovipositor, ventral view. Vanua Levu, trans-insular road, above summit, 500–550 m, 6–9 Oct 1979 (male); Viti Levu, Nandarivatu, 2 Apr 1973 (female).

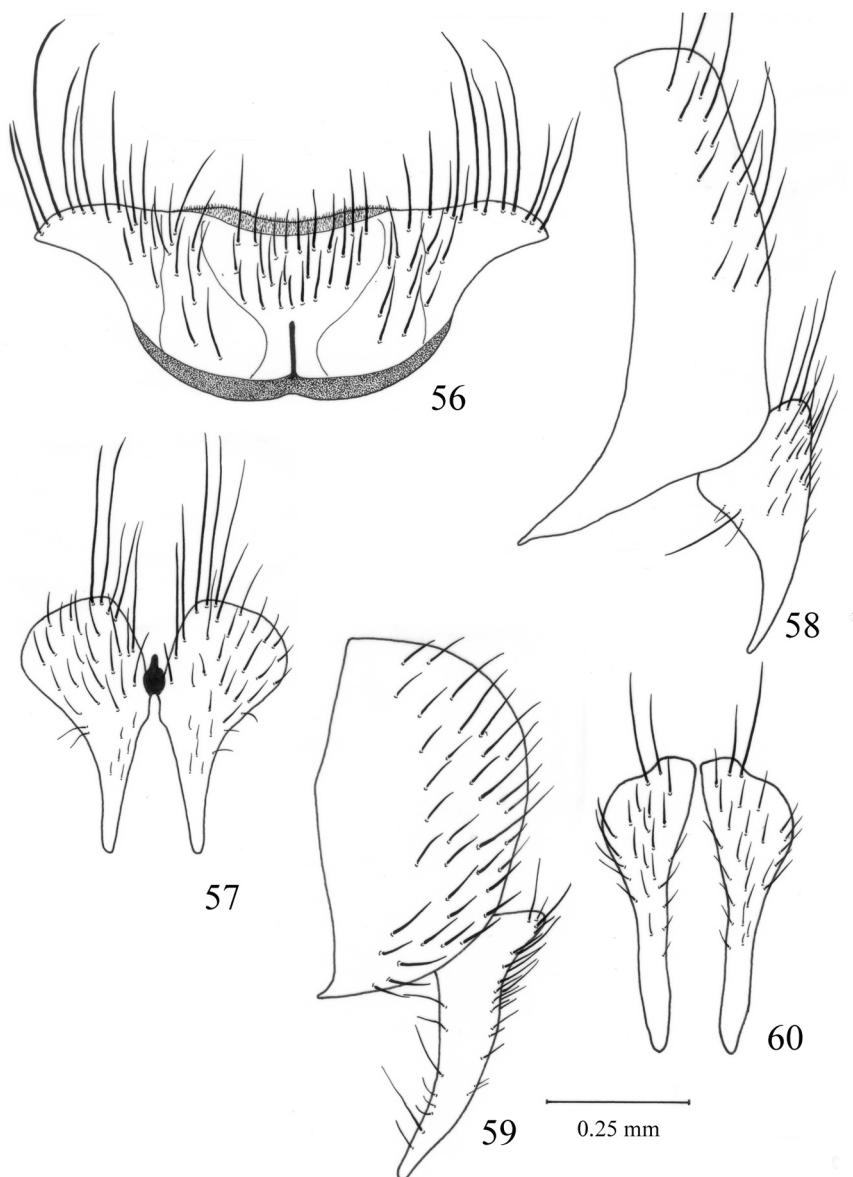

Figures 43–46. *Limnophora mesolissa* Bezzi. **43**, male sternite 5; **44**, male cercal plate, dorsal view; **45**, male epandrium, cercal plate and surstyli, lateral view; **46**, female, ovipositor, apex, lateral view. 40 km E of Nadi, 26 Jul 1967 (J. & M. Sedlacek) (male); Nadi, 1 Jul 1913 (J.F. Illingworth) (female).

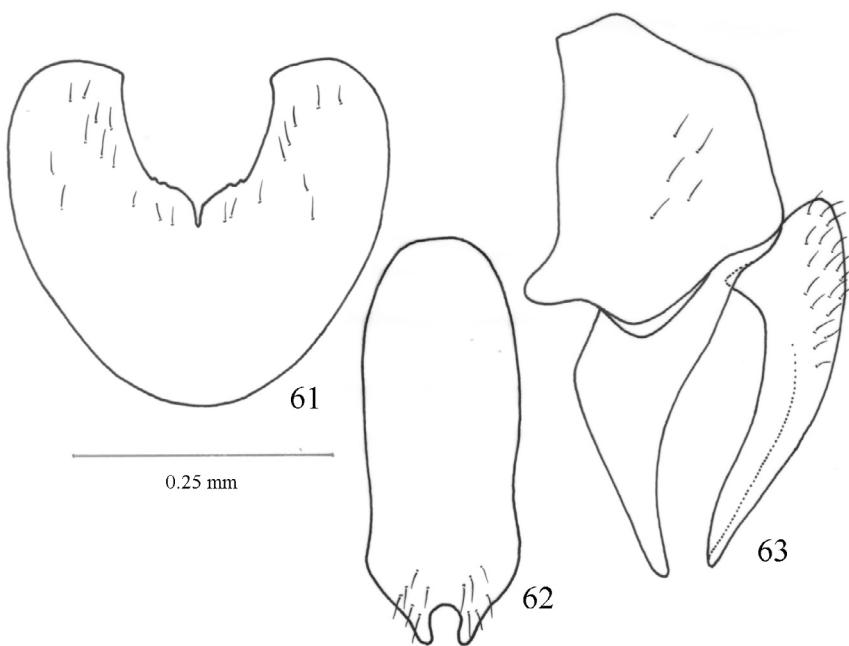

Figures 47–49. *Limnophora penicillata* Pont & Couri, sp. nov. **47**, male sternite 5; **48**, male cercal plate, dorsal view; **49**, male epandrium, cercal plate, surstyli and phallic complex, lateral view. Male paratype from Matuku Island, 7 Jul 1924 (E.H. Bryan). Scale lines 0.25 mm.

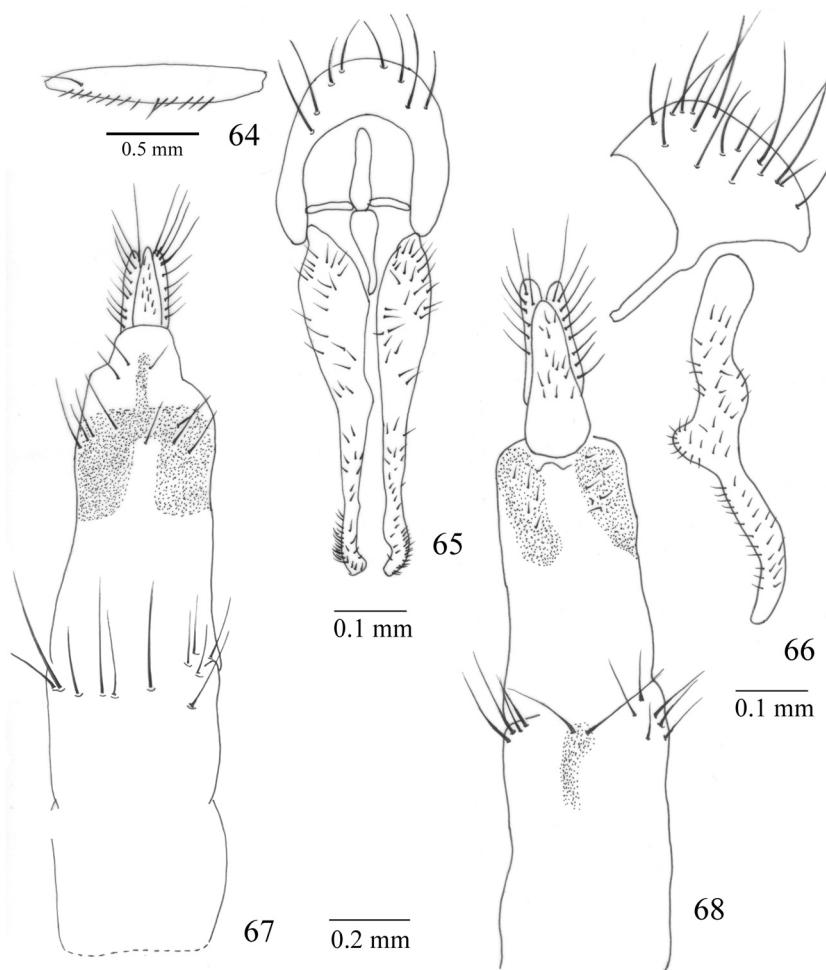

Figures 50–55. Figs 50–52. *Limnophora shinonagai* Pont & Couri, sp. nov. 50, male sternite 5; 51, male cercal plate, dorsal view; 52, male epandrium and surstyli, lateral view. Male paratype from Viti Levu, Mt. Victoria, 1000 m, 4–6 Mar 1978 (H. Shima). Scale lines 0.25 mm. Figs 53–55. *Lispe assimilis* Wiedemann. 53, male sternite 5; 54, male cercal plate, dorsal view; 55, male cercal plate and epandrium, lateral view. Male from Viti Levu, Nadi, 12 Jul 1978 (S. Shinonaga). Scale line 0.25 mm.

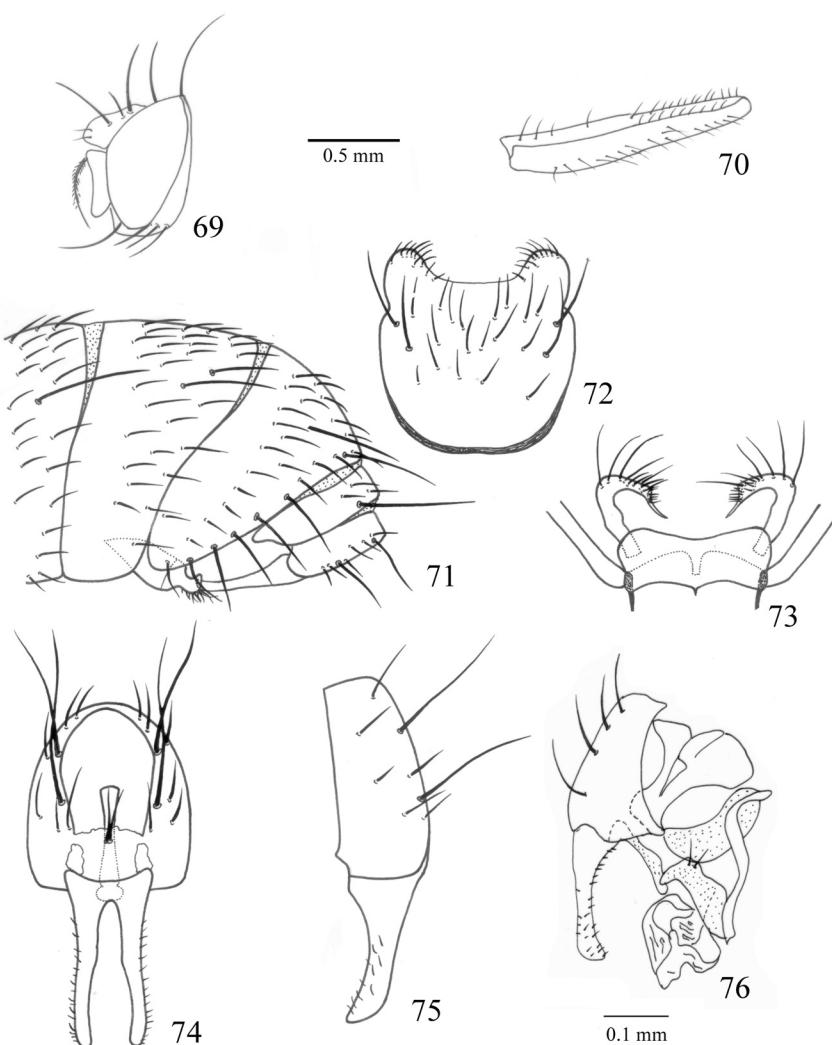

Figures 56–60. Figs 56–58. *Lispe bengalensis* (Robineau-Desvoidy). 56, male sternite 5; 57, male cercal plate, dorsal view; 58, male cercal plate and epandrium, lateral view. Male from Nadi, 12 Mar 1978 (H. Kurahashi). Scale line 0.25 mm. Figs 59–60. *Lispe pectinipes* Becker. 59, cercal plate, dorsal view; 60, male cercal plate and epandrium, lateral view. Male from Taveuni, Cakaudrove Prov., Soqulu House in Soqulu Estate, 140 m, 21 Nov–13 Dec 2002, Malaise 1 (E.I. Schlinger, M. Tokota'a). Scale line 0.25 mm.

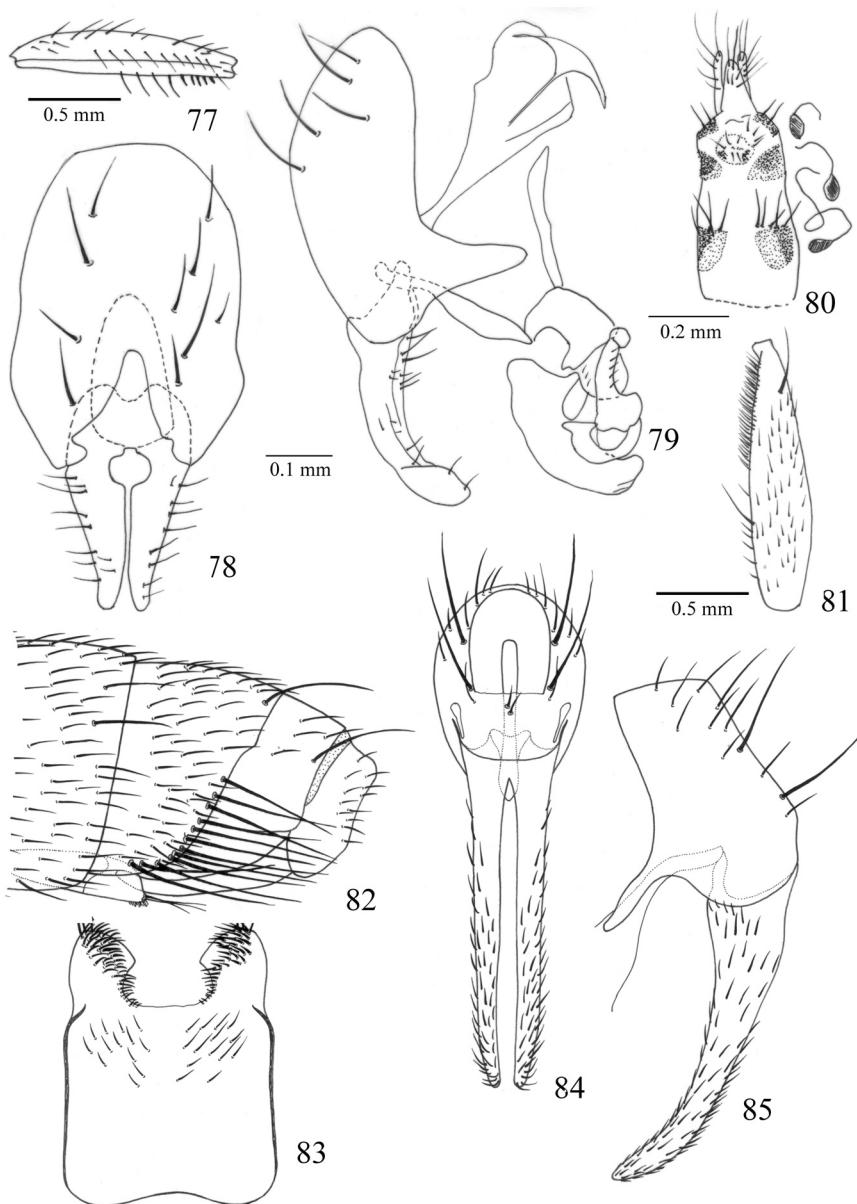

Figures 61–63. *Coenosia fijiensis* Pont & Couri, sp. nov. **61**, sternite 5, dorsal view; **62**, cercal plate, dorsal view; **63**, epandrium, cercal plate and surstyli, lateral view. Male from Viti Levu Island, Sigatoka Sand Dunes National Park, 1.1 km SSW Volivoli village, 55 m, Malaise trap, 14–27 Dec 2002 (E.I. Schlänger). Scale line 0.25 mm.

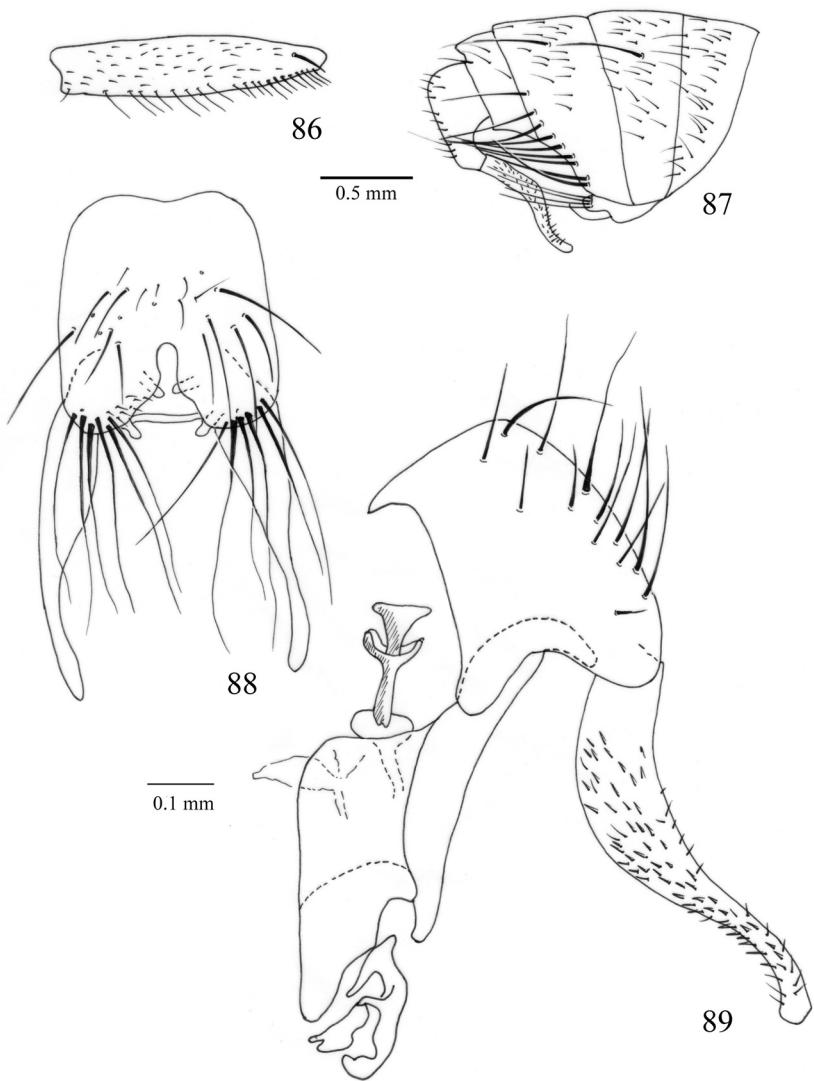

Figures 64–68. *Parvisquama curvicerca* Pont & Couri, sp. nov. **64**, male mid femur; **65**, epandrium, cercal plate, dorsal view; **66**, epandrium and cercal plate, lateral view; **67**, female ovipositor, dorsal view; **68**, female ovipositor, ventral view. Scale lines 0.5 mm (64), 0.1 mm (65–66), 0.2 mm (67).

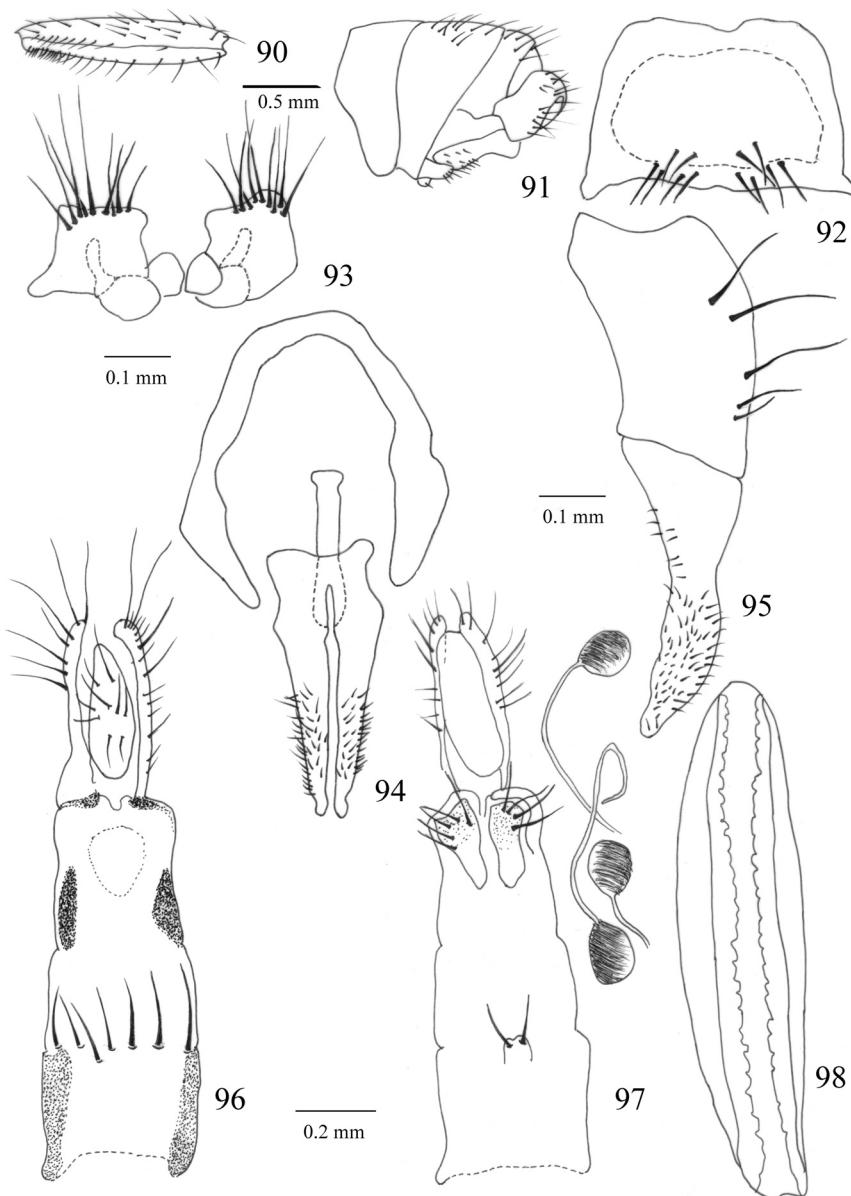

Figures 69–76. *Parvisquama dolichocera* (Bezzi). **69**, male head, lateral view; **70**, male mid femur; **71**, male, apex of abdomen; **72**, sternite 5, dorsal view; **73**, sternite 5, ventral view; **74**, epandrium, cercal plate and surstyli, dorsal view; **75**, epandrium and surstyli, lateral view; **76**, phallic complex, lateral view. Scale lines 0.5 mm (69–70), 0.1 mm (71–76).

Figures 77–85. Figs 77–80. *Parvisquama femorata* Pont & Couri, sp. nov. 77, male mid femur; 78, epandrium, cercal plate and surstylus, dorsal view; 79, epandrium, cercal plate, surstylus, and phallic complex, lateral view; 80, female ovipositor and spermathecae. Scale lines 0.5 mm (77), 0.1 mm (78–79), 0.2 mm (80). Figs 81–85. *Parvisquama longicerca* Pont & Couri, sp. nov. 81, male mid femur; 82, male, apex of abdomen; 83, sternite 5, dorsal view; 84, epandrium and cercal plate, dorsal view; 85, epandrium and cercal plate, lateral view. Scale lines 0.5 mm (81–82), 0.1 mm (83–85).

Figures 86–89. *Parvisquama longiseta* Pont & Couri, sp. nov. **86**, male mid femur; **87**, male, apex of abdomen; **88**, sternite 5, dorsal view; **89**, terminalia male, lateral view. Scale lines 0.5 mm (86–87), 0.1 mm (88–89).

Figures 90–98. *Parvisquama tripuncta* (Malloch). **90**, male mid femur; **91**, apex of male abdomen; **92**, sternite 5, dorsal view; **93**, sternite 5, ventral view; **94**, epandrium and cercal plate, dorsal view; **95**, epandrium and cercal plate, lateral view; **96**, ovipositor, dorsal view; **97**, ovipositor and spermathecae, lateral view; **98**, egg. Scale lines 0.5 mm (90), 0.1 mm (91–95), 0.2 mm (96–98).
