

ON THE SYSTEMATIC POSITION OF THE GENUS SASAOKAEA (BRYOPHYTA) О СИСТЕМАТИЧЕСКОМ ПОЛОЖЕНИИ РОДА SASAOKAEA (BRYOPHYTA)

M.S. IGNATOV¹ & I.A. MILYUTINA²

М.С. ИГНАТОВ¹, И.А. МИЛЮТИНА²

Abstract

The monospecific East Asian genus *Sasaokaea* was traditionally considered as a member of the Amblystegiaceae, or sometimes Neckeraceae. Analysis of nr ITS and chloroplastic *trnL*-F data both indicate its position in the Leskeaceae. The morphological characters supporting this placement are discussed.

Резюме

Восточноазиатский монотипный род *Sasaokaea* обычно относили к семейству Amblystegiaceae, иногда к Neckeraceae. Анализ ДНК ядерной ITS и хлоропластной *trnL*-F в обоих случаях указывает на положение рода в Leskeaceae. Обсуждаются морфологические признаки, согласующиеся с таким положением рода.

KEYWORDS: Amblystegiaceae, ITS, Leskeaceae, mosses, *Sasaokaea*, *trnL*-F

INTRODUCTION

The splitting of the large family Amblystegiaceae into Calliergonaceae and Amblystegiaceae (Vanderpoorten et al., 2002) or even further with the segregation of the Scorpidiaceae (Ignatov et al., 2007) left some small genera outside of analysis, mostly due to unavailability of fresh material for sequencing. Among others remains the genus *Sasaokaea* that includes the only species, *S. aomoriensis* (Paris) Kanda, known in Japan and in a single locality in Far East Russia. Originally this species was described in the genus *Hypnum* that in the beginning of XX century included representatives of many genera and families of pleurocarps. Shortly after that it was classified in *Drepanocladus* (Brotherus, 1908), in the Amblystegiaceae. However later, Brotherus (1929) described another species in a new monotypic genus, *Sasaokaea japonica* Broth. in the Neckeraceae. Noguchi (1939) synonymized *Sasaokaea japonica* with *Drepanocladus aomoriensis*, and then, in revision of Japanese Amblystegiaceae, Kanda

(1976) accepted this species and also the genus *Sasaokaea*, mentioning a number of important characters differentiating these genera.

Having long narrow paraphyllia one might presume the closest affinity to *Palustriella*. However Ochyra (1988), who revised this complex of genera, excluded *Sasaokaea* from Amblystegiaceae and again suggested its position in Neckeraceae, close to *Metaneckera*. The latter suggestion met no wide acceptance and most of recent authors accepted *Sasaokaea* within Amblystegiaceae (<http://www.tropicos.org>; Goffinet et al., 2009; Iwatsuki, 2004; Noguchi, 1991).

As the molecular phylogenetic methods provide a powerful tool for checking affinities of plants, including pleurocarpous mosses, a small analysis was undertaken to resolve this problem using our previous and GenBank data.

Nuclear ITS, as one of the most polymorphous markers, was used in this study, as well as *trnL*-F intron, as their independent analysis could be a double evidence for the position of the taxon in question.

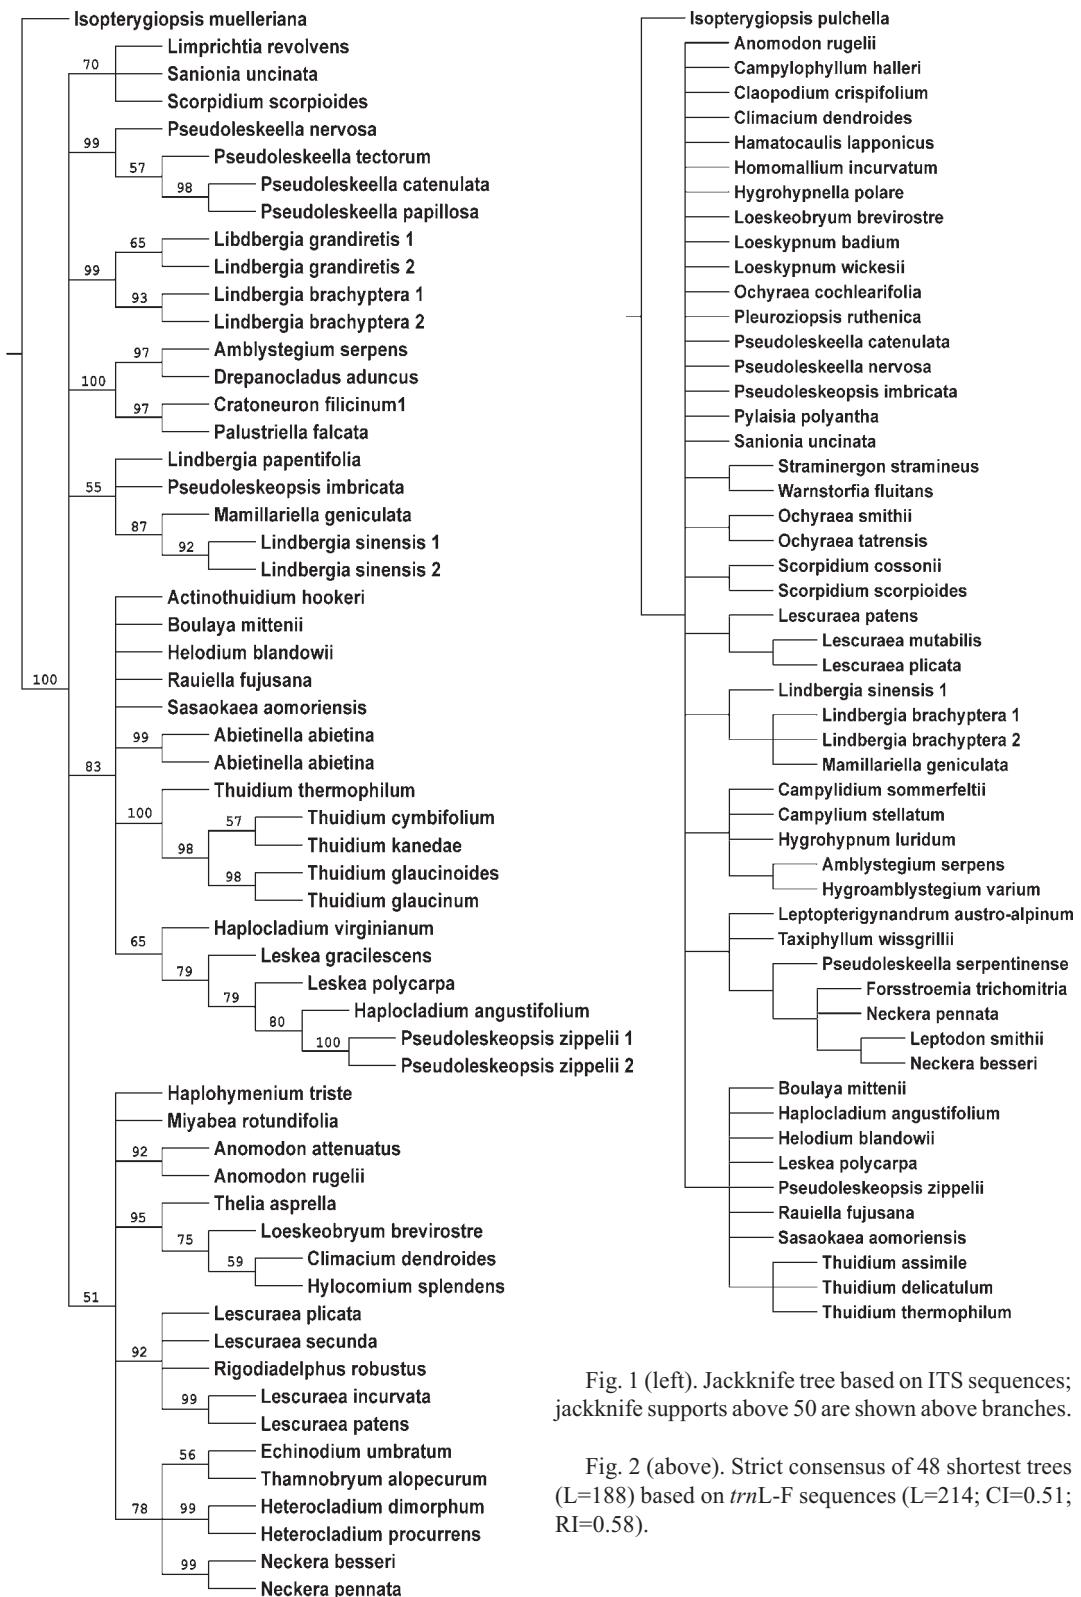

Fig. 1 (left). Jackknife tree based on ITS sequences; jackknife supports above 50 are shown above branches.

Fig. 2 (above). Strict consensus of 48 shortest trees ($L=188$) based on *trnL-F* sequences ($L=214$; $CI=0.51$; $RI=0.58$).

MATERIAL AND METHODS

Sasaokaea was studied by specimen from S: "Honshu, Aichi-ken, Minami-shidara-gun, Tsukude-mura, Iwanami, 450 m a.s.l. In bog. N. Takaki, 1974-09-28; Musci Japonici exsiccati nr. 1314". Its sequences of nr ITS and chloroplastic *trnL*-F were analyzed with the data from a previous analysis of pleurocarps (Ignatov et al., 2007). This previous set was reduced, so mostly taxa with paraphyllia or their closest relatives were retained, as they were considered possibly related to *Sasaokaea*. Specimen vouchers and GenBank accessions are in Table 1.

The laboratory protocol was essentially the same as in some of our previous analyses (e.g. Gardiner et al., 2005). Maximum parsimony analysis was performed in Nona (Goloboff, 1994) under Winclada shell (Nixon, 1999). Jackknife support was calculated for 2000 iterations (N searches 10, hold 10, max trees 100, Do max).

RESULTS

Jackknife ITS tree is not well resolved, although the support of clades with well-known representatives of the Amblystegiaceae (100), Pseudoleskeaceae (92), Pseudoleskeellaceae (99), etc. is high. A biggest clade that includes representatives of Neckерaceae, Climaciaceae, Hylocomiaceae, Pseudoleskeaceae, Anomodontaceae got a low support of 51. *Sasaokaea* was found in a clade with the Leskeaceae (excluding the Pseudoleskeellaceae and *Lindbergia* s.l.) plus the Thuidiaceae, with a rather high support of 83. Within this clade it is in a basal unresolved polytomy, with genera *Actinothuidium*, *Boulaya*, *Helodium*, *Rauiella*, whereas this clade includes also *Thuidium* s. str. (5 species, with high support, 100) and one another clade, *Leskea*+*Haplocladium*+*Pseudoleskeopsis zippelii* (6 species, with moderate support, 65).

Jackknife analysis for *trnL*-F data supports almost no clades and is not shown here, but the strict consensus tree (Fig. 2) found clades similar to that in ITS analysis. *Sasaokaea* was found in a clade with *Boulaya*, *Haplocladium*, *Helodium*, *Leskea*, *Pseudoleskeopsis*, *Rauiella*, and *Thuidium*.

DISCUSSION

The topologies from analyses of both nuclear and chloroplastic genomes clearly indicate position of *Sasaokaea* in the Leskeaceae, in case of ITS with a sufficient statistical support.

As far as we know, the idea of such a place-

ment of subaquatic *Sasaokaea* into a mostly xerophytic family has never been suggested. The specific character of Leskeaceae+Thuidiaceae is the presence of branched paraphyllia, a rare character in pleurocarps, known in only one another group of Climaciaceae+Hylocomiaceae.

There is a specific pattern in the Climaciaceae where paraphyllia are arranged in longitudinal rows and likely not homologous to paraphyllia in other groups of pleurocarps (Norris & Ignatov, 2000). In the Hylocomiaceae paraphyllia when present are very dense up to ultimate branches, obscuring the understanding of their homology, although likely having the same origin as in the Climaciaceae, i.e. without tendency to concentrate around branch initials. The latter is obvious in the Leskeaceae (*Leskea*, *Haplocladium*, etc.), while in *Thuidium* this pattern can be seen on the secondary branches (as on the stem paraphyllia are too dense). In *Sasaokaea* paraphyllia are dense on the stem, but scattered on branches, where their position next to branch initials is obvious (Figs. 3, 4: 1-4), identical to the Leskeaceae–Thuidiaceae pattern, which supports this new placement of *Sasaokaea*.

Metaneckera is another genus that was considered related to *Sasaokaea*. It also has paraphyllia concentrated around branch initials. However paraphyllia in *Metaneckera* are unbranched, very dense on the stem and moderately dense in ultimate branches, where the specific pattern occur: paraphyllia are clustered between neighboring leaf corners (Figs. 4: 5-6).

ACKNOWLEDGEMENTS

We are grateful to Lars Hedenäs for the permission to study DNA from S specimen and to Anna Ivanova for improving English. The work was partly supported by RFBR 10-04-00678 and Biodiversity Program of Russian Academy of Sciences.
