Instructions to Authors

Catathelasma publishes original and reviewed contributions to the better knowledge of fungi preferably in Slovakia and central Europe. Papers should be on diversity (mycofloristics), ecology, taxonomy and nomenclature, conservation of fungi, and book reviews and notices. Manuscripts have to be submitted in English with a Slovak or Czech summary.

Elements of an article submitted to Catathelasma

- title: informative and concise
- author's name: full first and last name
- author's mailing and e-mail addresses
- key words: max. 5 words, not repeating words in the title
- text: written in Arial, without any special type of text formatting except for italic and bold options, not exceeding 15 pages
- figures: line drawings, photographs, diagrams and/or graphs (scanned and "jpg" or "tif" formatted) with their legends should be self-explanatory; legends to the figures must be written at the end of the text file
- abstract/summary in Slovak or Czech: max. 10 lines (starting with author's name and the title of the article); the journal is responsible for the translation of abstracts into Slovak for foreign authors
- studied voucher specimens should be kept in the public herbaria
- list of references:

LIGNICOLOUS MACROMYCETES IN SPRUCE MONOCULTURES AT VRCH DOBROČ LOCALITY (CENTRAL SLOVAKIA)

Ivan Mihál¹ & Eva Luptáková²

¹Institute of Forest Ecology, Slovak Academy of Sciences, Štúrova 2, 960 53 Zvolen, Slovakia; mihal@savzv.sk

²Technical University in Zvolen, Faculty of Ecology and Environmental Sciences, T. G. Masaryka 24, 960 53 Zvolen, Slovakia; luptakova@savzv.sk

Mihál, I. & Luptáková, E. 2017. Lignicolous macromycetes in spruce monocultures at Vrch Dobroč locality (Central Slovakia). *Catathelasma* 18: 5–17.

The first part of our mycological research at the Vrch Dobroč locality (Veporské vrchy Mts.) was accomplished in 1989–2003. Six permanent plots were established in Norway spruce monocultures planted on former non-forest land and mycocoenological features, such as species diversity, abundance, distribution of sporocarps, dominance and succession of species and biomass production of epigaeic sporocarps were observed. Sixty species of lignicolous macromycetes were identified, eight of them parasitic (*Armillaria ostoyae*, *Fomitopsis pinicola*, *Heterobasidion annosum*, *Neonectria fuckeliana*, *Schizophyllum commune*, *Stereum sanguinolentum*, *Trichaptum abietinum* and *Verticillium* sp.) and 52 saprotrophic. Species richness on the permanent plots was more or less similar (number of species varied from 21 to 29). Lignicolous macromycetes occurred most frequently in the oldest stands where dead wood was available. The permanent plots were dominated by *Calocera viscosa*, *Dacrymyces stillatus* and *Hypholoma fasciculare*. Presence of rotting spruce trees in the first 14 years of growth stands was negligible, while in the 23 years old stands was accounted for 28%. Sporocarps of important pathogens *Armillaria ostoyae* and *Heterobasidion annosum* were firstly noticed in the 33 years old spruce stands. The highest values of sporocarp production were found in the oldest, 40 years old stands (133.49 and 57.19 kg·ha⁻¹), the lowest in the youngest, 16 to 22 years old plantations (13.01 and 31.6 kg·ha⁻¹).

Mihál, I. & Luptáková, E. 2017. Lignikolné makromycéty v smrekových monokultúrach na lokalite Vrch Dobroč (stredné Slovensko). *Catathelasma* 18: 5–17.

V rokoch 1989–2003 prebiehala na lokalite Vrch Dobroč (Veporské vrchy) prvá etapa mykologického výskumu. V porastoch smrekových monokultúr rastúcich na bývalej nelesnej pôde sa vytýčilo šesť trvalých plôch, na ktorých sa skúmali vybrané mykocoenologické pomery (druhová diverzita, abundancia, distribúcia plodníč, dominancia a sukcesia druhov, produkcia biomasy epigeických sporokarpov a iné). Celkovo sa zistilo 60 druhov lignikolných makromycétov, z nich osem parazitických (*Armillaria ostoyae*, *Fomitopsis pinicola*, *Heterobasidion annosum*, *Neonectria fuckeliana*, *Schizophyllum commune*, *Stereum sanguinolentum*, *Trichaptum abietinum*, *Verticillium* sp.) a 52 saprotrofných. Počet a druhové zastúpenie makromycétov bolo na trvalých plochách viac-menej vyrovnané (počet druhov varioval od 21 do 29). Najčastejšie

a viac-menej pravidelne sa makromycéty vyskytovali vo vekovo najstarších porastoch, kde bol dostatok drevného substrátu. Na trvalých plochách dominovali druhy *Calocera viscosa*, *Dacrymyces stillatus* a *Hypholoma fasciculare*. Prejavy hniloby smrekov v prvých 14 rokoch rastu porastov boli prakticky zanedbateľné, pričom v 23 ročných porastoch predstavovali už 28%. Sporokarpy významných patogénov, *Armillaria ostoyae* a *Heterobasidion annosum*, sme po prvýkrát zaznamenali v 33 ročných smrekových porastoch. Najvyššie hodnoty produkcie biomasy sporokarpov sme zistili v najstarších, 40-ročných porastoch (133,49 a 57,19 kg.ha⁻¹), najmenej v najmladších, 16 až 22-ročných porastoch (13,01 a 6,31 kg.ha⁻¹).

Key words: wood-inhabiting fungi, *Picea abies*, non-forest soils, permanent plots, Veporské vrchy Mts.

Introduction

Data gathered on fungi in Norway spruce plantations may serve also for comparison of mycoflora in natural spruce stands or in natural mixed forests. It is of course important to observe not only the dynamics and species diversity, abundance, fructification and production affinity of terrestrial saprotrophic and ectomycorrhizal fungi, but also of lignicolous species.

Area Vrch Dobroč is appropriate for long-term monitoring of the succession of fungi associated with Norway spruce stands because of the uniformity of planted stands. First permanent research plots were established in 1989 by Pavel Lizoň joined by Dušan Mlynářík, Miloslav Procházka, Vincent Kabát, Pavol Škubla, Ľudovít Varjú and Ján Gáper. The area was introduced and proposed by Jozef Kodrík who was teaching at the Technical University in Zvolen at that time. Four permanent research plots (PRP) were designated (each of 1250 m²) in different aged stands – the PRP A and PRP B in the 24 years old stands, PRP C in 7-year old stand and the PRP D in 2-year young spruce culture. Later, the area was often visited by researchers and mycological excursions (see Mihál et al. 2016).

The research at the locality was originally focused on colonization and succession of macromycetes in spruce stands of different ages (Gáper & Lizoň 1995, 1997, Mihál 2005b), as well as the biomass production of fungi (Mihál 1999), later on macromycetes species diversity (Mihál 2005a), ectomycorrhizal potential and rotting of spruce trees (Gáper & Mihál 2008), the mutual ratio of ectomycorrhizal and saprotrophic macro-mycetes (Gáper 2005) and monitoring of lignicolous fungi (Mihál 2005a).

Our project presented here focused on selected mycological rela-

tions of lignicolous macromycetes in permanent plots at the Vrch Dobroč locality was accomplished in 1989–2003. The objectives of our research were to study: i) species diversity of lignicolous macromycetes, ii) ecological classification and possible parasitic occurrence of lignicolous species, iii) abundance and distribution of sporocarps, iv) species dominance and succession, v) sporocarp biomass production.

Material and Methods

The research was carried out at six permanent research plots (PRP) established in Norway spruce monoculture stands of various ages on formerly non-forest soil at the Vrch Dobroč locality. The locality is situated in the western part of mountain range of Slovenské Rudohorie, Veporské Vrchy Mts., in the woods of Forestry district Kriváň, in the area of the Ipel' river basin (48° 32' N, 19° 34' E). The geological and soil conditions at the Vrch Dobroč locality are the following: geological substrate: granodiorite, soil type: cambisol typical, humus form: mull moder. Other basic characteristics of all the PRP are given in Table 1.

Tab. 1. The characteristics of the mycological permanent research plots (PRP A–F) at Vrch Dobroč locality

Characteristics / PRP	A	B	C	D	E	F
Afforested in year	1965	1965	1982	1989	1965	1965

Exposition	SW	SW	SW	E	SE	SW
pH of soil (H ₂ O) in 1994	4.28	4.56	5.44	5.27	–	–

It should be noted that permanent research plots A and B were heavily damaged by wind and snow storms in 1993 and 1994. PRP B was completely destroyed and PRP A considerably damaged. Due to the calamity, all trees were removed from PRP B and the plots were reforested in 1995. In PRP A, E and F thinning and selection felling were carried out before 1993 and harvested trees were removed from the stand. Selective felling and partial thinning was carried out also in the PRP B before 1993, but harvested trees were left at the ground. Stands at PRP C and D were planted by the „hole method“. Seedlings at PRP D came from air pollution tolerant clone from the Orava (northern Slovakia) provenience, reproduced vegetatively. In spruce stands at the PRP C, D, E and F some hardwoods from natural seeding (birch, aspen) were mixed in. The PRP D was located on mesophilic moved meadow, formerly an orchard and with some remains of decaying stumps of fruit trees (cherry, apple, pears).

The data presented here include data collected by the senior author of this paper in 1992–2003, as well unpublished data and published papers by Gáper (2005), Gáper & Lizoň (1997), Gáper & Mihál (2008), Gáper & Molnárová (2000), Mihál (1999, 2005a). Selected ecological characteristics of mycocoenoses of lignicolous fungi were studied in the project. The species diversity has been documented and identified in the field and/or in the laboratory. Abundance (number of sporocarps – A) and distribution (number of occurring places of sporocarps – D) were recorded, the value of dominance of each species (Do) was calculated ($A + D = Do$). The values of sporocarp biomass production of selected macromycetes have been calculated by average weight of one exemplar of sporocarp multiplied by total abundance of evaluated species (present as fresh weight $\text{kg} \cdot \text{ha}^{-1}$). Specific methodologies evaluating the mycoflora and the characteristics of the research plots at Vrch Dobroč locality are presented by Gáper (2005), Gáper & Lizoň (1997), Gáper & Mihál (2008), Gáper & Molnárová (2000), Mihál (2005a, 2005b).

Fruitbodies were identified according to the determination keys by Breitenbach & Kränzlin (1984), Červenka et al. (1972), Hagara (1987, 1992), Hagara et al. (1999), Hansen & Knudsen (1997), Jülich (1984), Keizer (1998), Moser (1963, 1983), Papoušek (2004), Vesely et al. (1972) and other sources. Herbarium specimens of the selected specimens are deposited in the Institute of Forest Ecology, Slovak Academy of Sciences in Zvolen. The scientific nomenclature of lignicolous species follows Cooper & Kirk (2017). For some photos see pages 67, 68.

Results

1st part of mycological research at Vrch Dobroč locality

There were identified 60 lignicolous macromycetes species in six permanent mycological research plots from 1989 to 2003 (Tab. 2). It represents 30.8 % of all 195 recorded macromycetes. From 60 lignicolous macromycetes eight species can be classified as parasitic (4.1%) and 52 as saprotrophic (26.6%).

<i>Tricholomopsis rutilans</i>		

The occurrence of parasitic macromycetes in particular PRP is presented in Table 3. These species act as parasites on living trees and also as saproparasites on dying or dead trees. The rest of recorded lignicolous macromycetes can be classified as saprotrophic fungi.

Tab. 3. The occurrence of parasitic lignicolous macromycetes in the permanent research plots (PRP A–F) at Vrch Dobroč locality (1989–2003)

The highest biomass of sporocarps production of lignicolous macromycetes (Tab. 5) was recorded in the oldest, 40 years old stands (in PRP F, totally 133.49, and in PRP B, 57.19 kg.ha⁻¹); the lowest values were in the youngest, 16 to 22 years old stands (in PRP D, totally 13.01, resp. in PRP C, only 6.31 kg.ha⁻¹). Out of all species, the highest values of the biomass of sporocarp production were recorded for *Hypholoma fasciculare* (241.71 kg.ha⁻¹), *Rhodocollybia maculata* (24.83 kg.ha⁻¹) and *Armillaria ostoyae* (6.21 kg.ha⁻¹).

Discussion

We expected that the majority of species belong to parasites, but it was not confirmed. Most of recorded species live as saproparasites or as lignicolous saprotrophes. When comparing the occurrence of parasitic macromycetes within the particular PRP, their occurrence is very low. For example, *Stereum sanguinolentum* in younger spruce stands is often connected with the bark damage of trees by deer. Čermák & Strejček (2007) discovered in 40 years old spruce stands, out of the total of 16,700 evaluated trees, that 44% trees were damaged by deer's peeling and bark stripping, followed up by *S. sanguinolentum* which was acting as parasite, while 4,997 (30%) trees were affected out of the total amount of deer damaged trees. The wounds on the spruce bark caused by deer are often infected by so called "wound" fungi parasites, e.g. *S. sanguinolentum* (Čermák & Strejček l.c.).

Parasitic occurrence of species *Neonectria fuckeliana* in PRP C was surprising. The species belongs to the group of tracheomycotic parasites of the genus *Nectria* s. l., parasitizing on a variety of forest trees. Another tracheomycotic species recorded in the young spruce stands at the Vrch Dobroč locality was *Verticillium* sp. Species of the genus *Verticillium* significantly affect the survival of young spruce stands because after the infection by these tracheomycotic parasites, the top terminals of the spruce trees suffer from necrosis that leads to death of the whole tree. Zúbková et al. (1994) noted a gradual mass dying off of spruces from the main terminal caused by *Botrytis cinerea*, *Gremmeniella abietina*, *Verticillium albo-atrum*, and by various sucking and biting insects, whilst all trees are susceptible to this sort of disease after prolonged periods of drought.

A parasitic occurrence of *Schizophyllum commune* was also unusual. Even it occurs also in spruce stands, it is associated first of all with beech stands. According to Bondarceva & Parmasto (1986), the species is a typical saprotrophic fungus with possible parasitic occurrence mainly in surface tree wounds. They consider this species to be xerophilic fungus, seeking substrate in dry and sunny places. Janitor & Vizárová (1994) treat *S. commune* as parasitic and saprotrophic species. We recorded the parasitic occurrence of this species mostly on the forest edge in PRP A that was exposed to sun after the clearance of PRP B. Beside species typical for conifers, there were recorded also species typically associated with deciduous trees, such as *Durella commutata*, *Bjerkandera adusta*,

Crepidotus variabilis, *Daedalea quercina*, *Lentinus arcularius*, *Lenzites betulina*, *Phanerochaete laevis*. These fungi occurred mainly in PRP C, E and F where deciduous trees species from natural regeneration (e.g. birch, aspen) were present. The PRP D is located on mesophilic meadow formerly with an orchard and has still remains of decaying stumps of fruit trees (cherry, apple, pear).

One of the most important pathogens in cultivated spruce stands is *Armillaria ostoyae*. In 1998, we found 41 sporocarps on the edge of PRP F and in 1999 28 sporocarps in PRP F directly on root butts. The occurrence of *A. ostoyae* in the stands of Vrch Dobroč locality was not surprising. When mull moder humus is prevalent, the fungus turns to the parasitic way of nutrition (Málek 1967, Risbeth 1982). Similarly, Konôpková (1992) also observed increased decay of spruce stands growing on formerly agricultural soils with good humification. Černý (1989) and Jankovský (1995) mention parasitic occurrence of *A. ostoyae* mostly on weakened or old trees and they explain an eventual mass occurrence of *A. ostoyae* in spruce monocultures by planting trees in marginal conditions for the optimal spruce occurrence, where spruce suffers from summer drought and the lack of precipitation.

Several environmental and climatic factors such as snow and wind storm, unsuitable woody species composition and provenience of spruce seedlings influence also lignicolous mycocoenoses at the Vrch Dobroč locality. It is known that snow and wind calamities are frequent causes of high level of decay in such stands. Vicena & Vokroj (1991) studied the impact of the decay on the tree's resistance to crown break under heavy snow. Trees with the surface rot advancing from the outer circumference of the stem towards the wound were substantially more vulnerable than trees with so called core rot, advancing mostly from roots to the stem. The effect and degree of decay in spruce stands of the Vrch Dobroč locality was studied by Gáper & Mihál (2008). They found the decay in the first 14 years of stands development was almost negligible, whilst in 23 years old stands it was 28%. The most dangerous agents of decay were *Armillaria ostoyae* and *Heterobasidion annosum* which fructified for the first time in 33 years old spruce stands.

The relationships of macromycetes production in spruce monocultures at the Vrch Dobroč locality are influenced by several edaphic and climatic

– ecological factors. One of the significant factors is a degree of shade – spruce canopy cover, which substantially influences mainly the amount of precipitation penetrating the crowns, falling on the soil and the transfer of sunlight and heat radiation. The production of biomass was the lowest in PRP C (due to small amount of wood substrate) and the maximum production of biomass was found in PRP F and B (because of available wood substrate). Positive effect of a closed canopy of the stand on the abundance (also on the sporocarp biomass production) was observed by Jansen & De Nie (1988) and Gáper & Lizoň (1995). The decline of sporocarps abundance, low biomass production and changes in the succession of macromycetes species in the stands after felling operations are presented by Ohenoja (1988) and Wästerlund & Ingelög (1981). In connection with the negative impact of harvests in forest stands on the abundance and biomass production of macromycetes, it should be noted that in suitably placed, even if artificially planted forest stands, we can expect higher levels of biomass production in a particular succession stage compared to natural forests. It was documented by Lagana et al. (2002), who noted an increase of macromycetes sporocarp biomass in fir-beech stands established on previously agricultural soil compared to natural fir-beech forest stands.

2nd part of mycological research at Vrch Dobroč locality

Monitoring mycocoenoses in various spruce stands at the Vrch Dobroč locality will continue (2016 to 2019). The plan is to continue in evaluating the dynamics of species diversity of macromycetes (including lignicolous fungi) and selected mycocoenological factors (abundance and distribution of sporocarps, dominance and succession of species, ecotrophy and biomass of sporocarp production). At the same time, greater attention will be paid to the evaluation of abiotic factors impact at the researched area. We would like also to study phylogenetic relationships and taxonomic validity of selected genera and species of macromycetes by molecular-genetic methods, e.g. the taxa *Armillaria*, *Heterobasidion*, *Laccaria*, *Mycena alcalina*). While studying lignicolous fungi in research plots with sufficient dead woody substrate, the mass and degree of woody substrate decay will be quantified.

Acknowledgements

The reviewers, Vladimír Kunca (Zvolen) and Pavel Lizoň (Bratislava) are thanked for reading and commenting the manuscript. This paper is a part

of the grant VEGA No. 1/0362/13: Changes in biodiversity of forest ecosystems, depending on their economic exploitation.

BOOK NOTICES

Pavel Lizoň

Bolets de Catalunya de la Península Ibèrica i de les Illes Balears.

XXXVI col·lecció. Pl. 1751-1800. Catalan Mycological Society (Societat Catalana de Micologia), Barcelona, Spain. ISSN 0212-3460. Orders: scm73@micocat.org.

Volume 36 has, as all previous volumes, 50 plates on laminated loose pages. On the back of each plate is description both in Catalan and Spanish, and information about locality, author of the picture and voucher specimen. The series is focused on macrofungi but occasionally are included also microfungi or/and slime-moulds (*Puccinia phragmitis*, *Physarum compressum* in this volume). Of course, some of depicted species are common (such as *Pleurotus cornucopiae*, *Russula badia*, *Trametes gibbosa*) but many are rare not only in Catalonia or Spain in general (such as *Trichoglossum tetrasporum*, *Tricholomopsis sulphureoides*, *Gyromitra martini*, *Lentaria epithnoa*).

Index of all volumes of Bolets and general index of taxa are available on the Society webpage (www.micocat.org).

Catalan Mycological Society publishes also series Fitxes Tècniques, monographs, a scientific journal Revista Catalana de micologia. It started in 1974 and one issue is released annually (vol. 38 in 2017). There is posted also an index of photographs published both in Bolets and Revista.

DISTRUBUTION AND ECOLOGY OF SCOPULOIDES RIMOSA IN SLOVAKIA

Ladislav Hagara

Mišíkova 20/A, 811 06 Bratislava, Slovakia; irpex.sk@gmail.com

Hagara, L. 2017. Distribution and ecology of *Scopuloides rimosa* in Slovakia. *Catathelasma* 18: 19–32.

The paper summarise the knowledge on the distribution of *Scopuloides rimosa* in Slovakia based on the herbarium collections. Recently, 95 specimens are known from our country from the years 1889–2012. Dominant host trees of the species are beech and alder.

Hagara, L. 2017. Rozšírenie a ekológia *Scopuloides rimosa* na Slovensku. *Catathelasma* 18: 19–32.

Článok zhŕňa doterajšie poznatky o rozšírení druhu *Scopuloides rimosa* na území Slovenska na základe herbárových zberov. Dosiaľ sa z nášho územia eviduje 95 zberov z rokov 1889–2012. Dominantnými hostiteľskými drevinami daného druhu sú buk a jelša.

Key words: corticioid fungi, Central Europe, host trees, vertical distribution

Introduction

One of the corticioid fungi occurring in all continents is *Scopuloides rimosa* (Cooke) Jülich, species originally described by British mycologist M. C. Cooke as *Peniophora rimosa* in 1881. First seven Slovak specimens were collected in the Štiavnické vrchy Mts. by Andrej Kmet' in the same decade.

Fungus has been described as distinct species by several authors: as *Peniophora terrestris* by G. E. Massee in 1887, as *Odontia conspersa* by G. Bresadola in 1897 (he marked by this name collections by A. Kmet' from 1889); its synonyms are also *Peniophora crystallina* Höhn. et Litsch. in 1907, and *Peniophora hydnoides* Cooke et Massee in 1888.

Peniophora rimosa was described as having smooth hymenophore and *P. hydnoides* as having serrulated hymenophore, but they are microscopically identical. In this paper, under the name *Scopuloides rimosa* are also included the specimens originally named as *Odontia conspersa* and *Scopuloides hydnoides*.

Material and Methods

Material studied includes 95 voucher specimens of *Scopuloides rimosa*, of them 54 deposited in the herbarium BRA, 34 in PRM, two in S and five in the private herbaria. The institutional herbaria acronyms follow Thiers (2017). Data on the specimens are presented in their original form. Taxonomic concept of *S. rimosa* follows Eriksson et al. (1984). Macromorphological characters are based on the fresh material collected and processed by the author. Micromorphological characters were examined from dried specimens by Olympus BX51 light microscope using an oil immersion lens at a magnification of 1000x All tissues were examined in Melzer's solution. Statistical calculations of microscopic characters are based on 20 measurements and given as minimum and maximum. Geomorphological map is prepared based on the concept by Mazúr & Lukniš (1986).

Results

Scopuloides rimosa (Cooke) Jülich, (see page 1, 2) *Persoonia* 11(4): 422 (1982)

Description: *Scopuloides rimosa* has resupinate fruitbodies, usually thinner than 0.1 mm (25–120 µm). They are closely attached to the substrate, firmly gelatinous and semi-translucent when fresh, ceraceous when dry, surface smooth, granulous, verrucose, finely serrulated (teeth 0.1–0.3 high, 4–8 teeth per 1 mm), tips of cystidia protruding (seen under lens) and giving the fungus velvety look. Hymenium is gray to blue gray, sometimes with pink violet, yellowish-olive or cream tones. Microscopically is the fungus characterized by 1) densely arranged clampless hyphae with wall 0.3–1.5 µm thick (1.5–3 µm in subhymenium, 3–7 µm in subiculum), by 2) clavate basidia with 4 sterigmata, 10–16 × 3–5 µm, by 3) ellipsoid spores, on the base flat to slightly depressed, smooth, 3.5–4.5 × 1.7–2.2 µm, by 4) two types of cystidia – common tapered lamprocystidia, 25–80 × 5–12 µm (with thickened walls, first smooth, then covered by tiny crystals), and less common cylindrical septocystidia, 60–150 × 7–15 µm (with clampless septa, thickened walls and covered by crystals above the attenuate smooth base) (see micro photo).

Scopuloides rimosa: lamprocystidia and one septocystidium. Slovakia, Borská nížina, Šaštín-Stráže village, 22 August 2012, L. Hagara (private herbarium). Photo L. Hagara.

Ecology: The species grows all year long in Central Europe (except of freezy months), generally from June to September. In Slovakia, it was recorded from May to December (Tab. 1). It occurs from lowlands to alpine belt, from 100 to ca. 1500 m a. s. l. in Slovakia (Tab. 2), up to 1900 m a. s. l. in Austrian Alps.

Tab. 1. Fenology of *Scopuloides rimosa* based on the included Slovak collections

Month	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
No. of collections	7	19	22	13	20	10	3	1

Tab. 2. Vertical distribution of *Scopuloides rimosa* based on the included Slovak collections

Altitude [m a. s. l.]	< 200	201–300	301–400	401–500	501–600	601–700	701–800	801–900	901–1000	1001–1100	1101–1200	1201–1300	1301–1400	1401–1500
No. of collections	15	20	12	5	13	4	9	7	5	1	2	0	1	1

Scopuloides rimosa is one of the most abundant corticioid species. It generally colonizes fallen decorticated trunks and branches that are in final stage of decomposition. It is associated first of all with *Fagus* and *Alnus* and same hosts are recorded also in the Austrian database (<http://austria.mykodata.net>) and *Fagus* is most important host also in Baden-Württemberg, Germany and United Kingdom. In Europe, *S. rimosa* grows often on *Fraxinus* and *Carpinus*, less frequently on other deciduous trees, such as *Acer*, *Corylus*, *Betula*, *Populus*, *Tilia*, *Salix*, rarely on *Ulmus*, *Sorbus*, *Prunus*, *Sambucus*, *Malus*, *Crataegus*, *Rosa*, *Clematis*, *Hedera*, *Calluna*, *Ilex* and *Ulex*. Among conifers it is associated with *Picea* more frequently (21 records in Austria) and also with *Pinus*, *Larix* and *Juniperus*. Herbs (*Rubus*, *Tanacetum*, *Angelica* and *Arctium*), and dead fruitbodies (*Phellinus*, *Inonotus*, *Fomes*, *Daedaleopsis* and *Byssomerulius*) might also host this fungus (Bernicchia & Gorjón 2010, <http://austria.mykodata.net>, Krieglsteiner 2000, www.fieldmycology.net/frdbi/asp).

According to the included Slovak collections, **host plants** of *Scopuloides rimosa* are: 25× *Fagus sylvatica*, 19× *Alnus* (16× *A. glutinosa*, 3× *A. incana*), 9× *Populus* (8× *P. tremula*, 1× *P. sp.*), 7× *Acer* (3× *A. platanoides*, 2× *A. campestre*, 1× *A. pseudoplatanus* and *A. sp.*), 7× *Salix* (5× *S. alba*, 1× *S. caprea*, *Salix* sp.), 6× unidentified deciduous tree, 4× *Corylus avellana*, 3× *Picea abies*, 2× *Abies alba*, *Quercus* sp., *Robinia pseudacacia* and *Sorbus* (1× *S. aucuparia* and *S. torminalis*), 1× *Cornus mas*, *Clematis vitalba*, *Crataegus* sp., *Carpinus betulus*, *Fraxinus excelsior*, *Ulmus glabra* and *Phellinus* sp.

For the occurrence of *Scopuloides rimosa* in Slovakia see the Map and Specimens studied.

Map. The occurrence of *Scopuloides rimosa* in Slovakia. Shaded are the geomorphological units in which the occurrence of the species is backed up by the herbarium specimen(s).

Author of the map L. Majdanová.

Specimens studied

Specimens are ordered within the geomorphological units of Slovakia by Mazúr & Lukniš (1986). Data (letter/number) in the square bracket refers to their map position.

Borinka, okr. Malacky, breh Stupavského potoka, na ležiacom kmeni jelše (*Alnus glutinosa*), 275 m n. m., 04. 10. 1997, leg. et det. L. Hagara (BRA CR25513).

Lozorno, okr. Malacky, breh Suchého potoka, na ležiacom kmeni i konári jelše (*Alnus glutinosa*), 230 m n. m., 11. 10. 1997, leg. et det. L. Hagara (BRA CR25514).

Marianka, okr. Malacky, Svätý vrch, na ležiacom konári buka (*Fagus sylvatica*), 320 m n. m., 07. 12. 1997, leg. et det. L. Hagara (BRA CR25510).

Bratislava, časť Vinohrady, breh potoka Bystríčka, na ležiacom kmeni jelše (*Alnus glutinosa*), 235 m n. m., 16. 05. 1998, leg. et det. L. Hagara (BRA CR25511).

Chtelnica, okr. Trnava, breh potoka Výtok, na opadanej kôre vŕby (*Salix alba*), 265 m n. m., 23. 05. 1998, leg. et det. L. Hagara (BRA CR25504).

Borinka, okr. Malacky, breh potôčika medzi vrchmi Hajdúch a Svätý vrch, na ležiacom kmeni buka (*Fagus sylvatica*), 295 m n. m., 27. 05. 1998, leg. et det. L. Hagara (BRA CR25505).

Bratislava, časť Vinohrady, breh potoka Vydrica, na ležiacom kmeni javora (*Acer pseudoplatanus*), 260 m n. m., 07. 06. 1998, leg. et det. L. Hagara (BRA CR25506).

Bratislava, 1. obvod, Horský park, na ležiacom konári javora (*Acer platanoides*), 210 m n. m., 17. 05. 1999, leg. et det. L. Hagara (BRA CR25518).

Bratislava, 1. obvod, Horský park, na koreňoch ležiaceho kmeňa javora (*Acer platanoides*), 198 m n. m., 16. 11. 2000, leg. et det. L. Hagara (BRA CR25493).

Bratislava, časť Záhorská Bystrica, Svätý vrch, na holom ležiacom kmeni duba (*Quercus sp.*), 380 m n. m., 06. 08. 2002, leg. et det. L. Hagara (BRA CR25490).

[10] Považský Inovec

Sokolovce, okr. Piešťany, les 1 km severne od kostola, na hnilom ležiacom konári javora (*Acer campestre*), 260 m n. m., 07. 06. 1997, leg. et det. L. Hagara (BRA CR25467).

[11] Tríbeč

Veľký Klíž, okr. Partizánske, vrch Rázdiel, na ležiacom kmeni buka (*Fagus sylvatica*), 510 m n. m., 14. 09. 2006, leg. et det. L. Hagara (BRA CR25485).

[12] Strážovské vrchy

Seč, okr. Prievidza, vrch Hájna hora, na ležiacom kmeni buka (*Fagus sylvatica*), 550 m n. m., 07. 05. 1999, leg. et det. L. Hagara (BRA CR25496).

Uhrovec, časť Látkovce, okr. Bánovce nad Bebravou, Jankov vršok, na ležiacom kmeni buka (*Fagus sylvatica*), 510 m n. m., 30. 09. 2002, leg. et det. L. Hagara (BRA CR35474).

[15] Malá Fatra

Kláčno, okr. Prievidza, južná úboč vrchu Reváň, na ležiacom konári buka (*Fagus sylvatica*), 940 m n. m., 29. 09. 2002, leg. et det. L. Hagara, súkromný herbár L. Hagaru.

[16] Veľká Fatra

Ľubochňa, okr. Ružomberok, breh potoka Ľubochnianka, na holom ležiacom kmeni jelše (*Alnus glutinosa*), 510 m n. m., 23. 10. 1997, leg. et det. L. Hagara, BRA CR25475.

Belá-Dulice, okr. Martin, lokalita Mažiarky, na ležiacom konári listnáča, okolo 900 m n. m., 24. 07. 2002, leg. H. Deckerová, det. K. Čížek (BRA CR14049).

[19] Tatry

Pribyliná, LM, Červené vrchy, časť Vráta, na ležiacom kmeni jarabiny (*Sorbus torminalis*), okolo 1 500 m n. m., 06. 08. 1963, leg. et det. Z. Pouzar ako *S. hydnoides* (PRM 848132).

[20] Nízké Tatry

Bacúch, okr. Brezno, vrch Biela skala, na ležiacom kmeni osiky (*Populus tremula*), okolo 900 m n. m., 14. 08. 1953, leg. F. Kotlaba, det. Z. Pouzar ako *S. hydnoides* (PRM 803774).

[24] Hornonitrianska kotlina

Diviacka Nová Ves, okr. Prievidza, les Vŕšky, na holom ležiacom kmeni

liesky (*Corylus avellana*), 270 m n. m., 25. 09. 2002, leg. et det. L. Hagara (BRA CR25476).

[26] Podtatranská kotlina

Vysoké Tatry, časť Tatranské Matliare, na hnilom odkôrnenom konári jelše (*Alnus incana*), okolo 900 m n. m., júl 1924, leg. A. Pilát, det. G. Bresadola ako *Odontia conspersa* (PRM 719485).

Vysoké Tatry, časť Tatranská Lomnica, okr. Poprad, poniže hotela Morava, na ležiacom konári jelše (*Alnus glutinosa*), 860 m n. m., 15. 06. 1998, leg. et det. L. Hagara (BRA CR25508).

Vysoké Tatry, časť Tatranská Lomnica, okr. Poprad, povyše hotela Praha, na ležiacom kmeni jedle (*Abies alba*), 910 m n. m., 14. 06. 1998, leg. et det. L. Hagara (BRA CR25507).

Štrba, časť Štrbské Pleso, okr. Poprad, breh Štrbského plesa, na ležiacom kmeni jarabiny (*Sorbus aucuparia*), 1 355 m n. m., 18. 06. 1998, leg. et det. L. Hagara (BRA CR25509).

Vysoké Tatry, časť Tatranská Lesná, okr. Poprad, les Valy pri Ceste Slobody, na holom ležiacom kmeni jelše (*Alnus incana*), 940 m n. m., 26. 06. 2003, leg. et det. L. Hagara (BRA CR25491).

[29] Vtáčnik

Kamenec pod Vtáčnikom, okr. Prievidza, breh potoka v Gepniarovej doline, na póroch odumrenej plodnice *Phellinus sp.*, 560 m n. m., 26. 10. 2000, leg. et det. L. Hagara (BRA CR25501).

Kamenec pod Vtáčnikom, okr. Prievidza, breh potoka v Gepniarovej doline, na dreve i kôre ležiaceho kmeňa *Alnus glutinosa*, 510 m n. m., 28. 06. 2001, leg. et det. L. Hagara, v súkromnom herbárii L. Hagaru.

[31] Štiavnické vrchy

Prenčov, okr. Banská Štiavnica, hájovňa Malé Sitno, na ležiacom kmeni osiky (*Populus tremula*), 650 m n. m., 14. 05. 1889, leg. A. Kmet' det. L. Hagara (BRA CR2309).

Prenčov, okr. Banská Štiavnica, lokalita Čierne blato, na hnilom dreve jelše (*Alnus glutinosa*), okolo 520 m n. m., 04. 07. 1889, leg. A. Kmet' det. G. Bresadola ako *Odontia conspersa*, nom. prov., (S).

Prenčov, okr. Banská Štiavnica, lokalita Čierne blato, na hnilom dreve jelše (*Alnus glutinosa*), okolo 520 m n. m., september 1889, leg. A. Kmet' det. L. Hagara (BRA CR2284).

FIRST RECORD OF HEMILEUCOGLOSSUM LITTORALE IN SLOVAKIAViktor Kučera¹, Anna G. Fedosova²¹Plant Biology and Biodiversity Center, Institute of Botany, Slovak Academy of Sciences, Dúbravská cesta 9, 845 23, Bratislava, Slovakia; viktor.kucera@savba.sk²Laboratory of Systematics and Geography of Fungi, Komarov Botanical Institute, Russian Academy of Sciences, Prof. Popov Str. 2, 197376, Saint Petersburg, Russia; anna.fedosova@gmail.com

Kučera, V. & Fedosova, A. G. 2017. First record of *Hemileucoglossum littorale* in Slovakia. *Catathelasma* 18: 33–38.

Recorded for the first time in Slovakia, *Hemileucoglossum littorale* is characterized by setose hairs on the stipe, predominantly hyaline mature ascospores and paraphyses agglutinated by a dense brown amorphous material. Among other species of the genus, *H. littorale* stands out due to short ascospores with only few septa. Our contribution to the global knowledge about the taxon is informative.

Kučera, V. & Fedosova, A. G. 2017. Prvý nález *Hemileucoglossum littorale* na Slovensku. *Catathelasma* 18: 33–38.

Hemileucoglossum littorale je nový druh slovenskej mykoflóry. Huba je charakteristická prítomnosťou setozných chlpov na hlúbiku, prevažne hyalínnymi dospelými výtrusmi a parafyzami stmelenými tmavou hnedou hmotou. Od ostatných zástupcov rodu sa *H. littorale* odlišuje krátkymi askospórami, ktoré majú menej priehradok. Násprvok ku svetovému rozšíreniu je informatívny.

Key words: Ascomycetes, biodiversity, *Geoglossaceae*, new records, distribution

Introduction

The species of earth tongues with setose hairs on the stipe, ascospores remaining hyaline for a long time and becoming slightly coloured in maturity, and paraphyses strongly agglutinated by a dense brown amorphous material belongs to the genus *Hemileucoglossum* (Geoglossomycetes, Ascomycota). Having united such combination of characters, four species of *Geoglossum* were transferred by Arauzo & Iglesias (2014) to the new genus *Hemileucoglossum* with the following combinations: *H. alveolatum* (E. J. Durand ex Rehm) Arauzo, *H. elongatum* (Starb. ex Nannf.) Arauzo, *H. intermedium* (E. J. Durand) Arauzo, and *H. littorale* (Rostr.) Arauzo. The type species of the genus, *H. littorale*, was described as *Leptoglossum littorale* by Rostrup in 1892 from Denmark (Rostrup 1892). Next records of this fungus were made only 100 years later in Sweden (Kers & Carlsson 1996). Since that time a number of collection is known

from other European countries (see distribution). The species mostly occurs on the oligotrophic lake shores with *Littorella uniflora*.

During our field excursion to the Stolické vrchy Mts. in 2011, we have found an earth tongue with hyaline septate ascospores, agglutinated paraphyses, and setose hairs on the stipe. Below we describe and discuss our collection of *Hemileucoglossum littorale*, a new member of Slovak mycobiota. In this paper, the collection is described and illustrated.

Material and Methods

Only one collection of *Hemileucoglossum littorale* was collected in Slovakia. Macromorphological characters were observed in fresh material. Micromorphological structures were studied in dried specimen using light microscope with an oil immersion lens. Tap water, 5% KOH, Melzer's reagent (MLZ), Lugol's solution (IKI), and solution of Congo red in ammonia were employed as mounting media. Micromorphological characters were estimated as an average (\pm SD) of 30 measurements (10 and 90 percentiles are given in parentheses) taken from tap water mounts. Morphological identification is based on Kers & Carlsson (1996). Locality is georeferenced, the coordinates are presented in WGS 84 system. Description is based on voucher specimen deposited in the fungarium of the Institute of Botany, Slovak Academy of Sciences (SAV). The DNA extraction, amplification and sequencing of ITS and LSU regions were provided on commercial base in Alvalab (Spain). Sequences generated for this study were submitted to GenBank (MF353089 and MF353092).

Results

Hemileucoglossum littorale (Rostr.) Arauzo, Errotari 11: 177 (2014)

≡ *Leptoglossum littorale* Rostr. Botanisk Tidsskrift. XVIII: 76 (1892)

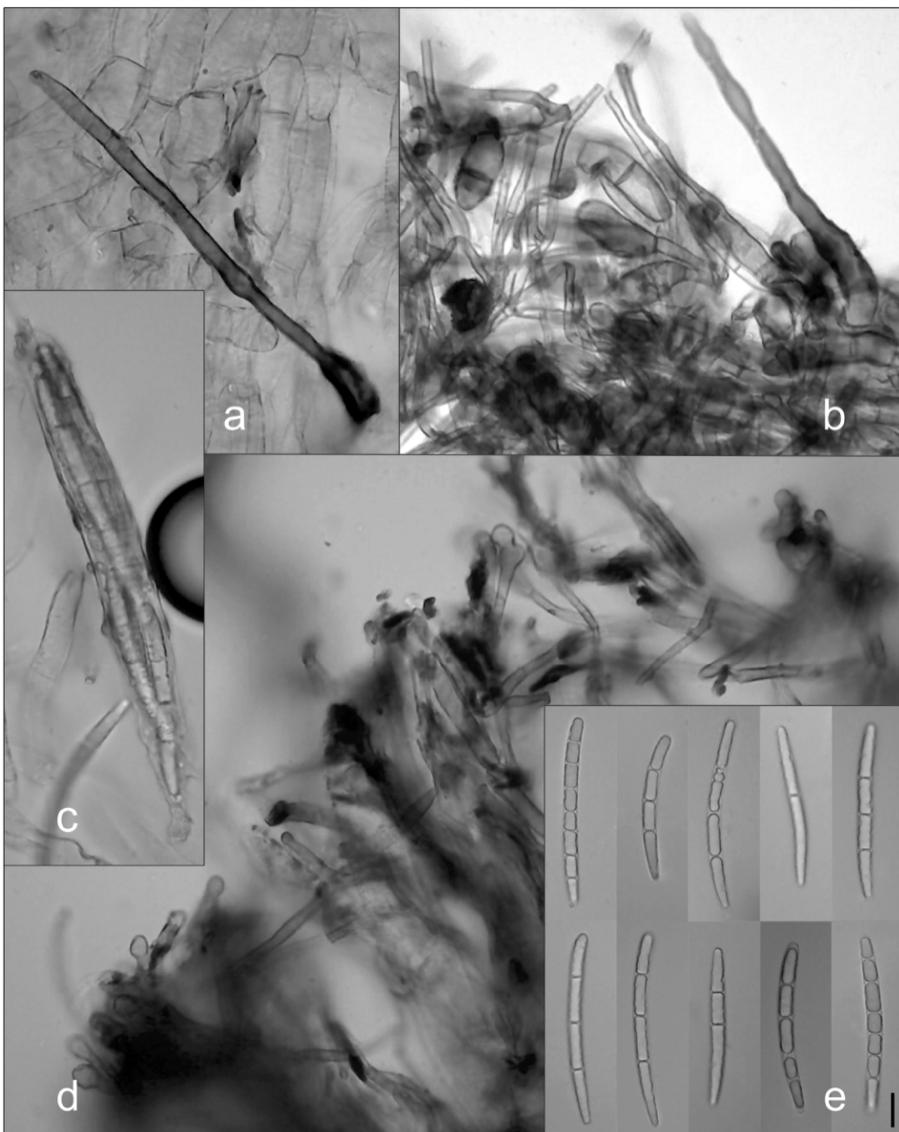

≡ *Geoglossum littorale* (Rostr.) Nannf. Ark. Bot. 30: 34 (1942)

Ascocarps scattered, clavate, stipitate, 0.8–3.5 cm tall, 0.1–0.5 cm wide, black throughout. Fertile part clavate, ca 1/3–1/2 of the total ascocarp length, 0.8–1.2 cm long, black, concolour with the stipe, oval in cross section, sharply delimited from the stipe, smooth both in fresh and dry conditions. Stipe terete, cylindrical, oval in cross section, slender, conspicuously hairy with dark brown setose hairs in tufts in the upper part of the stipe when fresh, rough to squamulose when dry. Ascii clavate (118)132.6–182(194.4) x (13.2)13.8–18.2(20.9) µm, Q = (8.9)9.1–

10.4(10.4), 8-spored, with euamyloid apical ring and wall in MLZ and IKI. Ascospores elongate-clavate, narrowed to the base, slightly curved, (51.2)55.7–66.4(68.1) x (4.4)4.7–5.7(6.3) µm, Q = (9.7)10.3–13.4(13.9), hyaline, predominantly 3–4-septate, rarely with 0–5–7(9) septa. Ascoconidia 3.7 x 2.4 µm. Paraphyses cylindrical, sparsely septate, longer than asci, 2–3 µm diam., straight or slightly curved, inflated at the apex, hyaline at basal part to pale brown at the apex, embedded in a dense brown amorphous material. Apical cells of paraphyses usually inflated and constricted in the middle or pyriform, sometimes proliferating (12.5)18.7–21(29) x (4.6)8.1–9.5(10.5) µm. Stipe surface with tufts of dark brown setose septate hairs (75)90–110(141) µm long, straight, moderately septate, basal cells usually inflated (8.5)9–10(12) µm, medial cells (4.9)6.5–7(9.5) µm and apical cells 2(3) µm with rounded apex (see micro photo).

Specimen studied. Slovakia, Stolické vrchy Mts., Muránska Zdychava village, ca 2.6 km N of the village, settlement Karafová, fen-meadow with *Eriophorum* sp., *Salix* sp. *Phragmites australis* and mosses, N 48° 45' 40.13" E 20° 08' 26.38", alt. 649 m, 4 October 2011, V. Kučera & V. Kautman (SAV F-10486).

Habitat and distribution. On wet soil of oligotrophic lake shores in Spain, Germany, Denmark, Sweden, Norway (Arauzo & Iglesias 2014, Rostrup 1892, Lüderitz 2010, Læssøe 1997, Kers & Carlsson 1996, Johansson 2007), on soil in a fen-meadow in Slovakia (this paper).

Hemileucoglossum littorale (SAV F-10486): a, b – setose hairs, c – ascus, d – paraphyses, e – ascospores. Bar = 10 µm.
Photo V. Kučera.

Discussion

Members of the genus *Hemileucoglossum* are relatively easy to identify. They are black and at least in upper part of the stipe have setose hairs. Neither setose hairs nor setae are present in the fertile part which is the main delimiting character from *Leucoglossum* and *Trichoglossum*. Four species were accepted in *Hemileucoglossum* (Arauzo & Iglesias 2014). *Hemileucoglossum littorale* possess less septate spores than *H. alveolatum* and *H. intermedium* (Durand 1908) and differs from *H. elongatum* in lack of curvation of apical cells of paraphyses (Nannfeldt 1942). Interestingly, the production of ascoconidia within the asci is reported before only in the collections of *H. littorale* studied by Arauzo & Iglesias (2014), no mention is made of this phenomenon in any previous treatment of the species (Rostrup 1892, Lind 1913, Nannfeldt 1942). *Littorella uniflora* was not noted in the Slovak locality of *H. littorale* and it seems that its presence is not necessary for occurrence of *H. littorale*. We suppose water level fluctuations is of much more importance. The Slovak collection studied in the present work displays some differences in morphology when compared with the original description by Rostrup (1892). Slovak material has longer and thicker asci (132.6–182 x 13.8–18.2 µm) and spores (55.7–66 x 4.7–5.7 µm) than the type collection from Denmark (asci 100–120 x 16–18 µm and spores 50–60 x 5 µm). *Hemileucoglossum littorale* is variable taxon and critical morphological study is needed as well as collection of a new material and DNA sequencing for future taxonomical revision.

Acknowledgements

We would like to thank Václav Kautman and Stanislav Glejdura for the assistance in the field. Alvalab is acknowledged for processing DNA samples. The reviewer, Eugene Popov (Saint Petersburg), is thanked for reading the manuscript and making several useful suggestions. This study was supported by the Russian Foundation for Basic Research (project 16-34-00510 mol_a) to AGF and grant VEGA 2/0008/15 to VK.

How to read the index

Each entry is arranged in this order: consecutive number of the specimen, original name as presented on the label (corrected only the spelling; authorities of taxa as used by Rehm, their abbreviations unified to standard forms), collection(s) acronym with accession number (**boldface**)

¹ for dates of issue of exsiccatae see *Catathelasma* 16: 27–40, 2015 (the 1st part); for notes on labels, extra numbers, new taxa and location of collections see *Catathelasma* 17: 35–74, 2016 (the 2nd part)

² abbreviated as Hedw. in the list

indicates the type), all in parentheses, double slash // is followed by the name published in Rehm's list. When the name on the label and in the published list is the same it is not repeated after double slash; but it is repeated (and followed by the reference) if representing a new name (**boldfaced**) or new combination (*italicized*, reference supplemented by the basionym). Specimens originating from Slovakia are recognized.
