The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado publishes a range of reports that address natural resource topics of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Technical Report Series is used to disseminate results of scientific studies in the physical, biological, and social sciences for both the advancement of science and the achievement of the National Park Service mission. The series provides contributors with a forum for displaying comprehensive data that are often deleted from journals because of page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available from the Lewis and Clark National Historical Park website (<http://www.nps.gov/lewi/naturescience/plants.htm>), the North Coast and Cascades Network Inventory and Monitoring website (<http://science.nature.nps.gov/im/units/nccn/reportpubs.cfm>), and the Natural Resource Publications Management website (<http://www.nature.nps.gov/publications/nrpm>).

Abstract

A study to review the status and distribution of vascular plants at Lewis and Clark National Historical Park was initiated in 2009 and completed in 2010 by the Oregon Natural Heritage Information Center at Oregon State University. This study built on previous inventories conducted under the National Park Service's Inventory and Monitoring Program which was initiated in 1992 to collect baseline data on the number and status of biological resources within the parks (National Park Service 2001). The North Coast and Cascades Network of national parks conducted vascular plant inventories in seven Pacific Northwest parks from 1999 to 2003 (Rochefort et al. 2009). At that time, inventories focused on the lands included within Fort Clatsop National Memorial (FOCL), documenting 246 vascular plant species. In 2004 the Fort Clatsop National Memorial was expanded to become Lewis and Clark National Historical Park (LEWI), encompassing several units of state and federal parkland in Oregon and Washington. As this expansion occurred after completion of the initial vascular plant inventory of FOCL, vascular plant species present in the new park units had yet to be documented.

Field surveys were completed between February 2009 and September 2010. Species new to the park were documented with specimen vouchers, GPS locations, and field notes. Point locations and population estimates were made for rare species and for non-native, invasive species of concern. Locations of rare communities were noted. Existing vouchers in the LEWI herbarium were verified and re-labeled with up-to-date nomenclature, mis-identifications were annotated, and species were keyed to variety or subspecies where applicable.

Upon completion of field work and data mining research, an additional 180 species were documented as occurring within the legislative boundary of the park, bringing the total number of vascular species to 467. In addition, the locations of six rare community types, 10 rare species, and 18 non-native species of concern were mapped in park units. These mapped species are discussed in detail and management strategies are presented. An annotated checklist of the vascular plants of the park documents each species recorded for the park and describes their range, nativity, population size within the park, and associated habitats.

Acknowledgments

We would like to thank the following individuals for their assistance with this project: Carla Cole and Nancy Eid at Lewis and Clark National Historical Park assisted with design and implementation of field surveys, provided known locations of rare species and communities, reviewed reports, and participated in frequent discussions on survey results. Deborah Wood at Lewis and Clark National Historical Park provided herbarium resources and Zachary Bolitho guided project development and deployment. Catharine Thompson and Ronald Holmes with the North Coast and Cascades Network assisted with project development and deployment, commented on coastal ecology and specific species, database input, report design, and provided project review.

Kathleen Sayce of ShoreBank Pacific provided advice on finding certain species and was a valuable resource for the species and communities at Cape Disappointment. Richard Halse at Oregon State University identified and verified troublesome specimens. David Giblin at the University of Washington provided advice on herbarium specimen preparation and annotation. Gay Hunter at Olympic National Park provided herbarium annotation advice and forms. Noel Bacheller of the Oregon Parks and Recreation Department provided information on Fort Stevens and Sunset Beach resource management.

Evan Roberts of Long Beach Area State Parks kindly provided a canoe for access to O'Neil Lake at Cape Disappointment State Park. The Oregon Military Department provided plant lists and inventory reports for species found at Camp Rilea compiled by Scott Sundberg while working at the OSU Herbarium. The Nature Conservancy's volunteers helped with internet research on plant characteristics. Christina Schull and Melissa Reich with the Oregon Biodiversity Information Center assisted in field work and specimen preparation. Erin Doyle with the Oregon Biodiversity Information Center assisted with research on habitat use, range, and phenology for the appendices. John Christy and Eric Nielsen at the Oregon Biodiversity Information Center contributed ecology and wetland expertise, project design and review, and aided in field work.

Research was conducted under permit # FOCL-2009-SCI-0002 for study number FOCL-00005

1 Introduction

The National Park Service's primary mission is to conserve unimpaired the natural and cultural resources and values of the national park system for the enjoyment of present and future generations. Fort Clatsop National Memorial (FOCL) was established in 1958 in Astoria, Oregon to commemorate the site of Fort Clatsop. The fort was built in 1805 by Meriwether Lewis and William Clark and their company during their expedition to the Pacific Ocean to house them over the winter before their return trip to Missouri. When established, FOCL consisted mainly of inland lowland forest and riparian wetlands adjacent to the Lewis and Clark River around the site of the Fort replica and visitor center.

In 1992, the National Park Service's (NPS) Inventory and Monitoring Program identified a list of candidate elements and processes for initial inventory in all natural resource parks. The National Parks Omnibus Management Act of 1998 recognized the need for good scientific information to manage parks. The act mandated a "program of inventory and monitoring of National Park System resources to establish baseline information and to provide information on the long-term trends in the condition of National Park System resources" for the purpose of informing park management through greater scientific knowledge (NPS 1998). Baseline species and ecological data from each park would allow the service to track changes over time and provide benchmarks for species and habitat conservation in an ecological setting.

In 1999, the National Park Service initiated the Species Inventory Program focusing on vertebrates and vascular plants. This program was created to provide park resource managers with comprehensive, scientifically-based information about the nature and status of biological resources within park boundaries. The North Coast and Cascades Network (NCCN) of parks developed a plan in 1999 to inventory and document vertebrate and vascular plant species in the network (Rocheffort et al. 2009). The goals of this program were to compile lists of vascular plants and vertebrates list for each network park and to verify the occurrence of at least 90% of the species on each park list through written records or voucher specimens. Development of species lists and verification of occurrence was accomplished by summarizing existing park information, data mining (i.e., searching museum records and other reliable outside datasets), and finally conducting field surveys to document species presence through specimen collection. All data was then entered into the NPS NPSpecies database. Data entry followed a two step process of data entry and then certification. The NCCN Inventory program was conducted from 1999 to 2003 and at that time, FOCL had a list of 246 vascular plant species that were verified at the 90% level (Rocheffort et al. 2009), precluding the need for additional inventory.

The Lewis and Clark National Historical Park Designation Act of 2004 authorized FOCL to expand to become Lewis and Clark National Historical Park (LEWI). This expansion added several units to the park, including lands in Washington State and along the Oregon coast. Several thousand acres were added along with several habitat types, and the park determined that a vascular plant inventory was needed on the new parklands. In 2008, the Pacific West Region provided funding for the park to conduct a plant inventory of the newly added lands. LEWI partnered with the Oregon Natural Heritage Information Center at Oregon State University to complete the inventories, drawing on the heritage program's previous work with NPS and vascular plant inventories. During the completion of the project, the Oregon Natural Heritage Information Center was transferred to Portland State University, where it became the Oregon

This report has had confidential information regarding species of management concern locations removed.

Biodiversity Information Center (ORBIC), and it will be referred to as ORBIC throughout this report.

1.1 Background and justification

The expansion of Lewis and Clark National Historical Park in 2004 necessitated a new inventory of additional park lands to meet the goals laid out in the NCCN Inventory Program. In addition, a new inventory allowed for rare and non-native, invasive species locations to be mapped, rare plant communities to be identified and discussed, and for the park's existing herbarium collections to be reviewed.

1.2 Objectives

The objectives of this project were to complete a vascular plant inventory of the new lands, including collection and processing of voucher herbarium specimens. Specific goals of the inventory were to:

1. Document and map locations of special status plants including federal or state listed threatened, endangered, species of concern or special status plant species.
2. Document and identify important locations of plant communities of special interest or concern.
3. Document and map locations of non-native species of concern.
4. Collect and process voucher specimens for any species encountered that were not previously represented in the LEWI herbarium.
5. Develop an annotated checklist and technical report documenting current and previous floristic work at LEWI.

1.3 Study area

1.3.1 History and setting

In May 1804, the Corps of Discovery led by Meriwether Lewis and William Clark by order of President Thomas Jefferson began their journey from Missouri to cross the American continent; creating maps, collecting specimens, and making contact with native peoples as they went. A year and a half later, their journey west would end at the mouth of the Columbia River and the Pacific Ocean. Before heading back east, they built Fort Clatsop on the Netul River, now called the Lewis and Clark River, and stayed for three months while they wrote reports, annotated maps, and processed their collections and waited for the winter to pass. They left in March of 1806 to return home. It was in appreciation of the achievements and importance of the Lewis and Clark Expedition that the Fort Clatsop site became a National Memorial in 1958.

Since the National Memorial designation was made in 1958, the park has continued to expand. In 1979 the 0.2 acre Salt Works parcel was purchased in Seaside and added to the park. The Fort Clatsop unit was expanded to about 1200 acres in 2002 under the Fort Clatsop Boundary Expansion Act. The major expansion came in 2004 with the passage of the Lewis and Clark National Historical Park Designation Act, which added units in Washington and additional sites in Oregon. With the 2004 Act the park area now stands at 3,358 acres.

Lewis and Clark National Historical Park is located on the Pacific coast in Clatsop County, Oregon and Pacific County, Washington (Figure 1). There are five main Park Service units: Cape Disappointment, Middle Village/Station Camp, Dismal Nitch, Sunset Beach/Yeon, and Fort

This report has had confidential information regarding species of management concern locations removed.

Clatsop. There is also a sixth small Park Service property, the Salt Works, which is a treed city lot with an interpretive panel and reproduction of a salt cairn similar to that described in the Lewis and Clark journals as having been used by expedition members. The lot is inland from the beach due to the fact that several hundred feet of shoreline have accreted over the last 200+ years. There are also three associated State Park units: Fort Columbia, Fort Stevens, and Ecola. In addition to their historical significance, the Lewis and Clark NHP lands preserve coastal habitats that support rare plant species and provide important resources for wildlife.

Three units are located in Washington State. The largest is Cape Disappointment State Park, located on the peninsula at the extreme south-western tip of Washington. It includes headlands, forests, wetlands, dunes and several miles of beach line. While this unit continues to be managed by Washington State Parks, it is within the legislative boundaries of LEWI as defined in the 2004 LEWI designation act. The other two Washington units are located upstream along the Columbia River. They are Middle Village/Station Camp, a site of both pre- and post-contact significance located west of the Astoria Bridge, and Clark's Dismal Nitch, a smaller unit located just east of the Astoria Bridge. Both these sites are largely composed of forests on the bluffs overlooking the Columbia River.

The original national memorial site, Fort Clatsop, is located on the Lewis and Clark River south-east of the city of Astoria, Oregon. Aside from the wetlands and riparian habitats along the river, this 1,200 acre unit is a mostly forested area which now includes the Fort to Sea trail east of Highway 101, connecting the fort to the ocean. The Fort to Sea trail terminates at Sunset Beach State Recreation Area, which is owned by Oregon State Parks but is within the legislative boundaries of LEWI, and is cooperatively managed between the two agencies. Directly south of Sunset Beach is the recently acquired Yeon property. Collectively, these two properties comprise the Sunset Beach/Yeon unit.

In addition to the six units that fall within the legislative boundaries of LEWI, there are three state parks that have special cooperative relationships with LEWI and have been included in this study, though they were given less intensive investigation as the focus was on the units within the legislative boundary. They are: Fort Columbia State Park, including 626 acres of forests and the historic fort located on the Columbia River immediately northwest of the Station Camp unit in Washington; Ecola State Park located north of Cannon Beach, Oregon, which includes nine miles of coastline and the most pristine forests of any of the units; and Fort Stevens State Park located on the peninsula at the extreme north-western tip of Oregon. Fort Stevens is the largest unit at over 3,000 acres and includes the largest area of salt marsh and sand dunes within any of the units associated with LEWI.

This report has had confidential information regarding species of management concern locations removed.

Figure 1. Locations and names of Lewis and Clark National Historical Park and State Park units.

1.3.2 Geology and Climate

The mountains of the Pacific Coast Range run north-south from Alaska to California. They were formed from a volcanic island chain that collided with the North American continent about 50 million years ago. The subduction of the Juan de Fuca plate under the North American Plate in the Pacific Northwest causes uplift along the coast, creating marine terraces (Roering 2008). Marine sediments that have since collected around the mountains form the lands west of the range, where the Lewis and Clark units are located. The climate along these coasts is cool and wet, with average rainfall ranging around 70-100 inches per year. Winters and summers are mild with an average high of 67° F and low of 35° F. Storms frequently cause landscape-level changes at the coast, contributing to erosion of beaches and wind throw of trees in forested areas. Recently, storms in 1999 and 2007 have caused blow downs and beach erosion in Park units. Beaches behind the North Jetty at Cape Disappointment have been eroding since the 1950s (Washington DOE 2008). In the summer of 2010 the Littoral Drift Project was completed by the Army Corps of Engineers to restore eroded areas along the North Jetty and Benson Beach using dredged material from the mouth of the Columbia. If successful, the dredging and dumping could occur at Cape Disappointment annually (Great Lakes Dredge and Dock Company 2010; Lower Columbia River Solutions Group 2011). These processes have led to large areas of Cape Disappointment and Fort Stevens being created within the last 100 years (Figures 2 and 3).

1.3.3 Vegetation

In the early 1800s surveyors hired by the General Land Office (now the Bureau of Land Management) parceled out the western frontier into public and private sections. Their notes contain witness tree measurements and landscape descriptions that allow mapping of historical vegetation for this era (Figures 2 and 3). The lands that are now Lewis and Clark National Historical Park were a mosaic of spruce forests, swamps, shrublands, dry prairies, dunes, coastal headlands, and salt marshes in the 1800s and early 1900s (Christy et al. 2009). Although urbanization, dune stabilization, non-native species, and accretion have changed the size and ratio of these habitats, this mosaic is still present across most of the LEWI units. Several habitats are present in Park units that have been identified as conservation targets by NatureServe and The Nature Conservancy (NatureServe 2010; TNC 2006). North Pacific Hypermaritime Sitka Spruce Forest, North Pacific Maritime Coastal Sand Dune and Strand, and North Pacific Coastal Herbaceous Bald and Bluff are ecosystems present in park units that are noted as having a limited distribution on the Pacific Coast and therefore are a priority for conservation (TNC 2006). These ecosystem types correspond to the rare communities mapped in this report, with the addition of other communities that are locally rare. A new vegetation map for LEWI is currently under development, also being developed through a partnership between ORBIC and NPS. The results of this mapping project will be published in a future Technical Report.

Historical Vegetation Cover, Northwest Oregon Coast

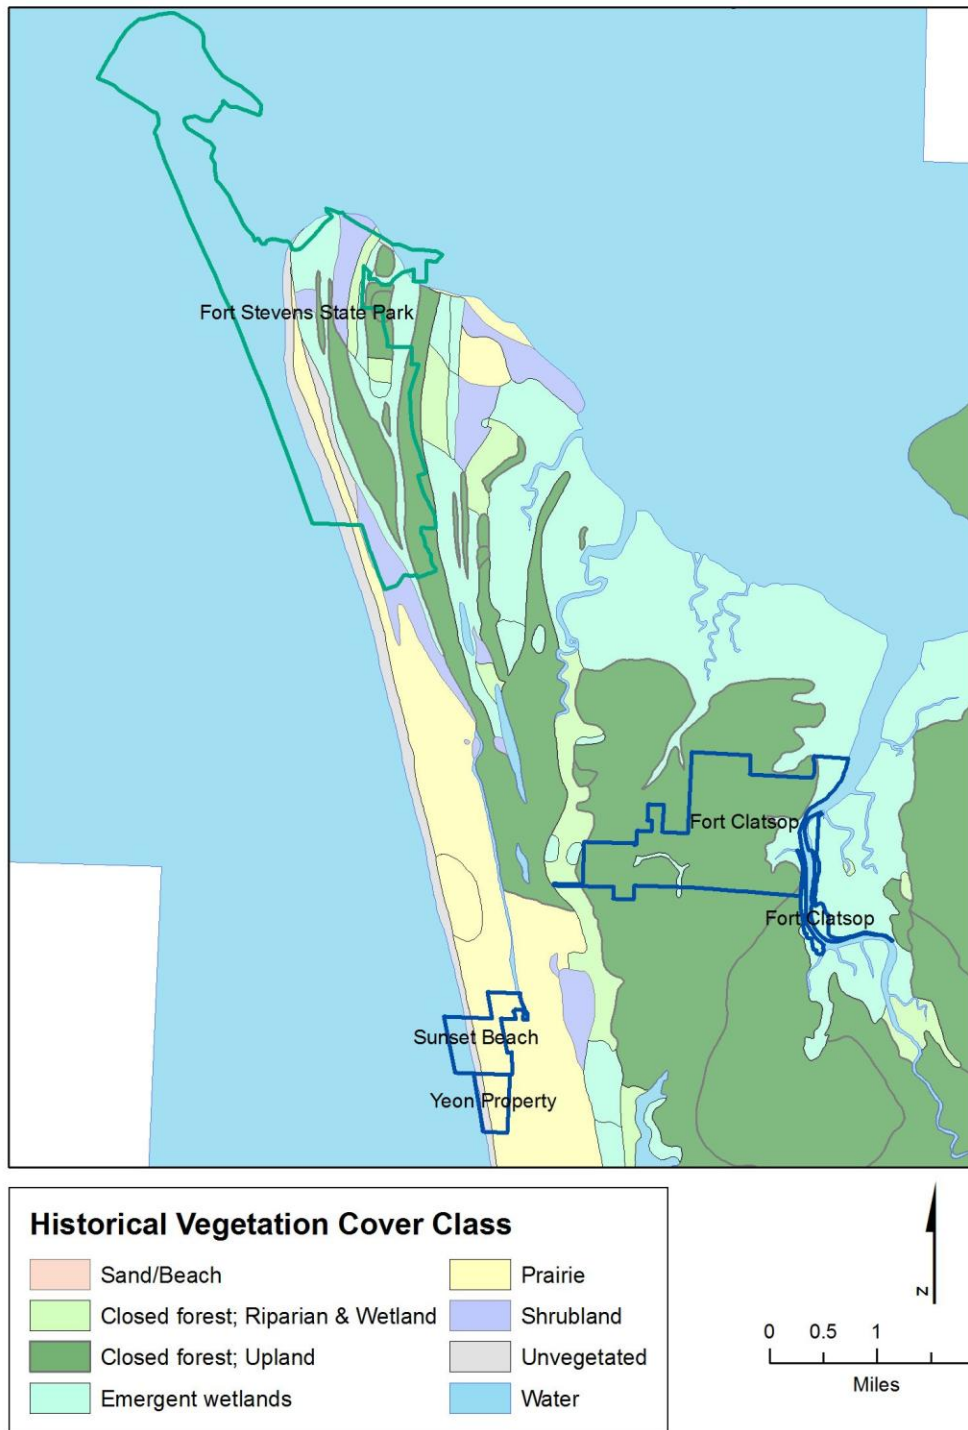

Figure 2. Historical vegetation cover of the northwest Oregon coast, as recorded in field surveyor notes during General Land Office Surveys in the 1800s and early 1900s. The area in the historical map that is water at Fort Stevens and part of Sunset Beach is now land that has been added relatively recently by deposition of river sediments and sand influenced by the building of the jetty from 1885 to 1895.

Historical Vegetation Cover, Cape Disappointment

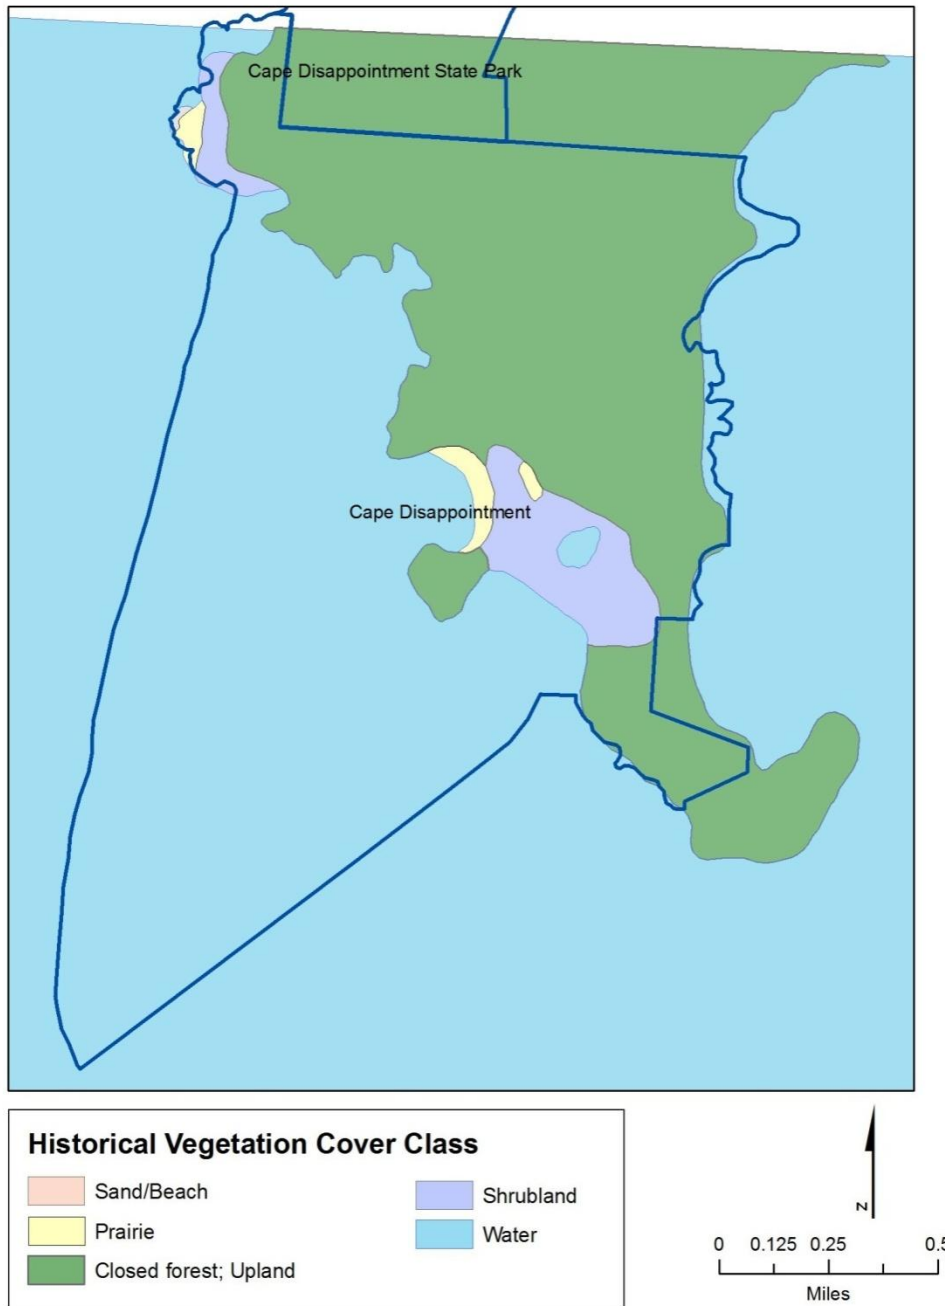

Figure 3. Historical vegetation cover of the Cape Disappointment area in southwest Washington, as recorded in field surveyor notes during General Land Office Surveys in the 1800s and early 1900s. The area within the current boundary of Cape Disappointment that was historically water has been added relatively recently by deposition of river sediments and sand influenced by the building of the North Jetty from 1914 to 1917.

This report has had confidential information regarding species of management concern locations removed.

1.3.4 Previous botanical studies

Formal herbarium specimens have been collected at LEWI since the Lewis and Clark Expedition in 1805. Notable early collectors include the botanist Wilhelm (William) Suksdorf who collected extensively in Washington State in the late 1800s and early 1900s, including the area of Cape Disappointment. Thomas Howell and L. F. Henderson made forays from Portland to Fort Stevens to collect plants in the 1880s. C.L. Hitchcock, co-author of the *Flora of the Pacific Northwest* (Hitchcock and Cronquist 1973) collected at Cape Disappointment in the 1960s. More recent collectors from the 1990s and 2000s, in addition to park staff, include Mark Eggers, Peter F. Zika, Ben Legler, Sarah Gage, and Sharon Rodman. Most of these specimens are held at the Burke Museum Herbarium at the University of Washington in Seattle, Washington or at the Oregon State University Herbarium in Corvallis, Oregon. Many Pacific Northwest herbaria records can be accessed online from the Consortium of Pacific Northwest Herbaria online portal (Consortium of Pacific Northwest Herbaria 2007).

The Cape Disappointment unit underwent a vascular plant and plant community inventory in 2004 (Sayce and Eid 2004). Most of the unit was surveyed on foot, with the rest being inventoried by binoculars or aerial photographs. Locations of different plant communities within the unit were noted and a list of vascular plant species generated. The Fort Clatsop vascular plant inventory was certified in 2005 with additional surveys taking place from 2006 to 2008.

2 Methods

In August 2008 the National Park Service and the Oregon Biodiversity Information Center (ORBIC) agreed to work together to inventory vascular plants on the new lands within LEWI. In March 2009, the existing specimens at the Lewis and Clark Herbarium were reviewed, with name changes and mis-identifications noted as needed. Those specimens requiring identification confirmation were sent to the Oregon State University herbarium for confirmation by Dr. Richard Halse. In February 2010 a second trip to the LEWI Herbarium was made to affix formal annotation labels to the existing specimens and to deposit new collections that had been made during the field season.

Name changes on specimens were in accordance with the Flora of North America (1993). This nomenclature was selected rather than the Integrated Taxonomic Information System (ITIS) for two reasons: there is a lag between general acceptance of new names by taxonomists and academics and their subsequent incorporation into ITIS; and ITIS generally follows the Flora of North America in time. However, where the Flora of North America is incomplete or final determinations have not been made, label nomenclature followed ITIS.

Field surveys were conducted from April 2009 to September 2009 and from March 2010 to September 2010. Walk-over surveys were completed at all park units at several times during the growing season. Systematic transects or randomly generated survey points were not employed because our goal was to concentrate on newly acquired habitats and known or suspected locations of reported but unconfirmed species, and avoid re-surveying areas and habitats that had been well documented at FOCL during previous survey efforts. In addition, by using a walk-over survey method, multiple revisits to areas of botanical interest were easily incorporated into the survey, allowing for collection of plants across the growing season at single locations.

Surveys for this project focused on the newly acquired units within the legislative boundary at LEWI (Cape Disappointment, Dismal Nitch, Middle Village/Station Camp, and Sunset Beach/Yeon Property) and, in particular, the less common habitats contained within those additions. These areas were identified using satellite imagery and existing vegetation maps, as well as following recommendations from park staff on known locations of target species. As the Fort Clatsop unit is primarily lowland spruce forest that had previously been inventoried, habitats such as salt marsh and dunes were surveyed more intensively than spruce forest areas. Confirmed and unconfirmed species lists for the individual units were provided by park staff to assist in the inventory. A list of non-native species of concern as identified by the park and the North Coast Cooperative Weed Management group was provided by the park and all of these species were mapped where encountered.

Rare plants, rare communities, and non-native species of interest were mapped using a Garmin Etrex GPS unit in the NAD 83 geodetic datum. Maps of these species were created using ArcMap version 9.3.1 (ESRI 1999). Species observations were recorded in field notebooks with habitat notes, notable environmental variables, and associated species. Whole plants were collected, pressed, and mounted onto archival herbarium paper for specimen vouchers, submitted to the LEWI herbarium and to the Oregon State University herbarium. Newly documented species were entered into the NPSpecies database version 2.21, the National Park Service's

This report has had confidential information regarding species of management concern locations removed.

standard species observation database run on the Windows XP operating system in MS Access 2002/2003.

Although the Fort Stevens, Fort Columbia, and Ecola units were not within the legislative boundary of LEWI, they were visited during field work for the LEWI vegetation mapping project, occurring concurrently with the vegetation survey project, and for their floristic interest. Emphasis was placed on collecting at rare communities that had not previously been surveyed such as salt marshes and grassy headlands.

For the purpose of this report the vascular plant checklist and herbarium inventory include only those species documented at the following units: Fort Clatsop, Sunset Beach/Yeon, Dismal Nitch, Middle Village/Station Camp, and Cape Disappointment. This is due to the fact that the Park Service does not directly manage the natural resources at the other units and they are not within the legislative boundaries of LEWI. Maps for rare species or invasive species were created for all units in which they were encountered and are found in the Appendices.

3 Results

3.1 Summary of the flora of Lewis and Clark National Historical Park

Plant inventories prior to 2008 had resulted in a vascular plant species list of 287 species in LEWI, 267 of which were verified by vouchered specimens (Table 1). During the course of this project, 180 species were added to the park list, including 142 new species documented by voucher specimens. Searches through the online Consortium of Pacific Northwest Herbaria yielded another 17 species with vouchers held at other herbariums. The number of species without verification increased to 12 based on reports of species on the newly acquired Park units. Several of these unverified species were located in nearby areas but were outside the legislative boundary of the park. Of the new species documented at LEWI, only 19 were located within the FOCL unit; 168 were found in new areas within the park’s legislative boundary. These efforts brought the total number of species within the legislative boundary of the park up to 467 species.

Table 1. Summary of species verification at LEWI by stage of inventory.

Stage of Inventory	# of species (total % verification)	# verified by voucher (%)	# verified by reference (%)	# verified by observation (#)	# without verification (%)
Initial Inventory (2000)	246 (90%)	211 (86%)	9 (4%)	2 (1%)	24 (10%)
Certified List (10/05/2005)	254 (99%)	232 (91%)	17 (7%)	3 (1%)	2 (1%)
NPS Surveys (2006 -2008)	287 (99%)	267 (93%)	17 (6%)	1 (1%)	2 (1%)
Current Study (2009-2010)	467 (98%)	426 (92%)	5 (1%)	24 (5%)	12 (2%)

A complete list of vouchered species for LEWI is found in Appendix A. Potentially present species are found in Appendix B. Species removed or rejected from the list are provided in Appendix C along with the reasons for their removal. The list of confirmed species with ecological notes is found in Appendix D.

3.2 Lifeform and biogeographical diversity

The park’s flora is dominated by perennial forbs and graminoids. Perennial forbs represent 39% of all taxa, while perennial graminoids make up 14% of taxa. Annual or biennial forbs represent 25% of the park flora, with annual graminoids representing 4%. Trees and shrubs make up a relatively small percentage of the flora (9% and 8% respectively) but contribute greatly to habitat structure and community characteristics. Most of species occurring in the park have a wide distribution, also occurring in neighboring states or countries. In contrast, 7% are regional endemics occurring only on the Pacific coast within a limited area, and 1% are local endemics occurring only within a 150 mile radius of the park.

Although the majority of the park’s plants are native species, a large proportion of the flora (40%) are non-native, introduced species and this number may increase if new species are introduced by winds, tides, animals, visitors, and vehicles. Native species are also introduced through these vectors, though non-native, invasive species often have advantages over native species by possessing characteristics that make them highly competitive in their new environment (Bryson and Carter 2004). While some introduced plants may have minimal impact

This report has had confidential information regarding species of management concern locations removed.

on native species, aggressive non-natives can displace native species, altering plant community structure and function. As a result, controlling these species is a management priority for the NPS (Table 4, discussed in section 3.5).

3.3 Plant communities of special concern

At the start of the project a list of rare plant communities thought to be present or potentially present in the park was developed by park staff and ORBIC staff. These communities were mapped wherever encountered, during the survey, within the park. Thirteen are considered to be rare in Oregon or Washington with a NatureServe Global Rank of G1 or G2, or with a State Rank of S1 or S2. All species and plant communities in Oregon and Washington have been assigned a state and global rank by ORBIC, the Washington Natural Heritage Program, or NatureServe. These ranks range from highly imperiled, with a rank of 1, to demonstrably secure, with a rank of 5. A detailed description of the methodology used to rank species and habitats and instructions for its use are found within the NatureServe Conservation Assessment: Methodology for Assigning Ranks (Faber-Langendoen et al. 2011). Six rare community types were confirmed and mapped at LEWI (Table 2).

These community types follow the National Vegetation Classification system (NVC) developed by USDA Forest Service, USGS, and NatureServe through a cooperative partnership and adopted in 2008 by the federal geographic data committee (FGDC) as a national standard (USNVC 2011). The classification is hierarchical, including broad scale vegetation classes, such as “Evergreen Forest” or “Temperate or subpolar needle-leaved evergreen forest” at the highest levels. The plant association level is the finest or most detailed level of the classification, and the plant communities listed here represent plant associations in the NVC. This classification is widely used in the USA for characterizing vegetation types and provides a standard classification for inter-agency and multi-partner projects. Maps of known locations of rare communities can be found in Appendix E.

This report has had confidential information regarding species of management concern locations removed.

Table 2. List of rare plant communities potentially present in at Lewis and Clark NHP and survey results.

Scientific Name	Common Name	RANK ¹	Present in Park?	Comments
<i>Carex macrocephala</i> Herbaceous Vegetation	Big-Headed Sedge	G1G2S1	yes	Cape D; Ft. Stevens (small area)
<i>Picea sitchensis</i> / <i>Carex obnupta</i> - <i>Lysichiton americanus</i> Forest	Sitka Spruce / Slough Sedge -Skunk Cabbage Swamp	G2G3S1	yes	Cape Disappointment
<i>Festuca rubra</i> coastal headland	Red Fescue Coastal Headland	G2S2	yes	Cape Disappointment headlands; Ecola
<i>Calamagrostis nutkaensis</i> - <i>Elymus glaucus</i> Perennial Grassland	Pacific Reedgrass - Blue Wildrye	G2S1	yes	Cape D North Head headland; may occur on Ecola headlands
<i>Carex lyngbyei</i> - <i>Argentina egedii</i> Herbaceous Vegetation	Lyngby sedge - Pacific Silverweed Salt Marsh	G4S2	yes	Fort Clatsop; Ft. Stevens; and Cape D
<i>Salicornia virginica</i> Herbaceous Vegetation	Glasswort Salt Marsh	G3G4S2	yes	Ft. Stevens
<i>Deschampsia caespitosa</i> - <i>Argentina egedii</i> Herbaceous Vegetation	Tufted Hairgrass - Pacific Silverweed High Salt Marsh	G3G4S2	no	May be at Ft. Stevens salt marsh
<i>Empetrum nigrum</i> - <i>Gaultheria shallon</i> Dwarf-shrubland	Crowberry - Salal Oceanfront Shrubland	G2S2	no	Known from southern OR
<i>Festuca rubra</i> - <i>Ambrosia chamissonis</i> Herbaceous Vegetation	Red Fescue - Beach Bursage Herbaceous Vegetation	G1S1	no	Known only from Puget Lowlands
<i>Festuca rubra</i> Stabilized Dune Herbaceous Vegetation	Red Fescue Stabilized Sand Dunes	G1S1	no	Sensitive to trampling, vehicles, beachgrass
<i>Leymus mollis</i> ssp. <i>mollis</i> - <i>Abronia latifolia</i> Herbaceous Vegetation	Unstabilized Coastal Dune Wildrye	G1S1	no	Needs unstabilized dunes
<i>Pinus contorta</i> var. <i>contorta</i> / <i>Gaultheria shallon</i> - <i>Rhododendron macrophyllum</i> - <i>Vaccinium ovatum</i> Forest	Shore Pine / Western Rhododendron - Evergreen Huckleberry	G1S1	no	Known from southern OR
<i>Pseudotsuga menziesii</i> - <i>Tsuga heterophylla</i> / <i>Mahonia nervosa</i> Forest	Douglas-fir - Western Hemlock / Dwarf Oregon-grape Forest	G2	no	Known from Puget Lowlands; fire-dependent

1. Global Ranks as reported by NatureServe. State rank for Oregon as determined by Oregon Biodiversity Information Center. Rank Definitions: G=Global, S=State, T=Taxon (variety, subspecies). 1=Critically imperiled; 2=Imperiled; 3=Rare, uncommon, or threatened; 4=Not rare and apparently secure; 5=Demonstrably widespread, abundant, and secure; NR=Not Ranked.

This report has had confidential information regarding species of management concern locations removed.

3.3.1 *Carex macrocephala* Herbaceous Vegetation

Carex macrocephala (big-headed sedge) Herbaceous Vegetation occurs in Oregon, Washington, and British Columbia on open sand on spits, berms, or small dunes that are protected from high wind and wave energy but are still subjected to inundation by storms. Big-headed sedge is always dominant, and cover ranges between 20-50% with open sand between. Other species do not exceed 5% cover and can include yellow sand-verbena (*Abronia latifolia*), silver bur-sage (*Ambrosia chamissonis*), or beach morning-glory (*Calystegia soldanella*) (Kagan et al. 2004, Christy et al. 1998). Many of these sites are threatened by exotic species encroachment, recreational activities, and changing coastal geomorphological processes (NatureServe 2010). This community occurs along the jetty and in smaller populations on the beaches at Beards Hollow and Benson Beach in Cape Disappointment Park. There are also two very small patches at Fort Stevens State Park (less than 1/10 acres total).

Figure 4. Big-headed sedge herbaceous alliance at Beards Hollow beach in Cape Disappointment. The sedges are the brighter green, low rosettes. Dark-brown heads of the female culms are visible. Note encroachment by non-native beachgrass. Japanese sedge was found nearby scattered amongst the native big-headed sedges. Photo taken in August 2010.

3.3.2 *Picea sitchensis*/*Carex obnupta* – *Lysichiton americanus* Forest

Picea sitchensis (Sitka spruce)/*Carex obnupta* (slough sedge) – *Lysichiton americanus* (skunk cabbage) Forest occurs in California, Oregon, and Washington in coastal wetlands, usually on floodplains near perennial streams or rivers. It can also be found in depressions in older, stabilized sand dunes. They are typified by a spruce-dominated canopy with slough sedge and skunk cabbage in perennially wet soils with high organic content. Other species present may include salmonberry (*Rubus spectabilis*), red alder (*Alnus rubra*), or salal (*Gaultheria shallon*) on drier hummocks. The distribution of this community reaches from northern California to British Columbia. Due to the accessibility of these stands, their occurrence on private lands, and the value of timber within them, this community is now rare throughout its range, especially old-growth stands (Christy et al. 1998).

This report has had confidential information regarding species of management concern locations removed.

A variant of this community type is present in Cape Disappointment. A number of stands of Sitka spruce with slough sedge ground cover are present in several locations in this unit, but skunk cabbage is absent (Sayce and Eid 2004). While Sitka spruce and slough sedge occur together at Fort Stevens as well, these occurrences are found on the accretion zone behind the jetty and along the dunes. Spruce trees here grow in a Krummholz form, usually with beachgrass or introduced dunegrass present. Due to the differences in associated species, growth form, and habitat, the Krummholz dune spruce community was determined to be sufficiently different from the rare forest type that it was not mapped.

Figure 5. Sitka spruce / slough sedge – skunk cabbage forest at Cape Disappointment. This is an example of the association where skunk cabbage is not present. Photo taken in April 2010.

3.3.3 *Festuca rubra* Coastal Headland

The *Festuca rubra* (red fescue) Coastal Headland community occurs on rocky cliffsides along the Pacific coast from central California to southern Washington. These forb rich grasslands occur on shallow-soiled bluffs or cliffs with extreme to moderate slopes and exposure to salt spray and persistent winds. Soils are well-drained, often with a high gravel content. Most known sites have been heavily impacted by encroachment of non-native species, usually introduced on the larger sites as a result of past livestock grazing (NatureServe 2010). This community is present at the Cape Disappointment and Ecola units.

This report has had confidential information regarding species of management concern locations removed.

Figure 6. Degraded red fescue coastal headland at Cape Disappointment. Red fescue cover is less than 1% while non-native grasses are more plentiful (Sayce and Eid 2004). Photo taken in May 2010.

3.3.4 *Calamagrostis nutkaensis* – *Elymus glaucus* Perennial Grassland

The *Calamagrostis nutkaensis* (Pacific reedgrass) – *Elymus glaucus* (blue wildrye) Perennial Grassland community occurs along the coast from northern California to southwest Washington on open bluffs with exposure to high winds and salt spray. Pacific reedgrass is the dominant species with an average of 60% cover. Blue wildrye composes about 2-3% cover. This community often occurs between the Red fescue Coastal Headland type and Sitka spruce forest. This grassland is present at the North Head headland in Cape Disappointment and is the only occurrence in southwest Washington and one of three occurrences for the entire state (Washington State Parks and Recreation Commission 2004). This type is a bit more common in Oregon, and is found at Ecola state park, although it also is often impacted by introduced perennial grasses introduced from historic livestock use (Kagan et al. 2004).

Figure 7. Pacific reedgrass – Blue wildrye Herbaceous Vegetation at Cape Disappointment. Pacific reedgrass is the light-colored bunchgrass. The brown clumps are bracken fern (*Pteridium aquilinum*). Photo taken in April 2010.

This report has had confidential information regarding species of management concern locations removed.

3.3.5 *Carex lyngbyei* – *Argentina egedii* Herbaceous Vegetation

The *Carex lyngbyei* (Lyngbye sedge) – *Argentina egedii* (Pacific silverweed) association occurs in brackish marshes and deflation plains in estuaries from British Columbia south to northern California. This community is influenced by tides and storm surges which bring salt water into the stand, rework sediments, and deposit logs and debris. Stands are strictly herbaceous with Lyngbye sedge cover up to 90% (Christy et al. 1998). This community is present at Fort Clatsop, Cape Disappointment, and Fort Stevens. Only three occurrences of this wetland type are known to occur in Washington State (Washington State Parks and Recreation Commission 2004). [Specific location information has been removed].

Figure 8. Lyngbye's sedge – pacific silverweed herbaceous vegetation type in a Bakers Bay salt marsh at Cape Disappointment. Photo taken in June 2010.

3.3.6 *Salicornia virginica* Herbaceous Vegetation

The *Salicornia virginica* (common pickleweed) association occurs in salt marshes from California to British Columbia. Stands can be on beaches or rocky shores with a sparse to continuous herbaceous layer where common pickleweed is dominant or co-dominant with other species (Evens and San 2005). This community is present at Fort Stevens. [Specific location information has been removed].

Figure 9. Common pickleweed plant (left) and salt marsh community (right) at Fort Stevens State Park. Photo taken in September 2010.

3.4 Rare or sensitive plant species

Thirteen rare plant species (those tracked by the states or by Natural Heritage offices) that were known to occur or had the potential to occur at LEWI were targeted for survey at LEWI (Table 3). Of these, ten species were located and mapped at the park. Henderson's sidalcea (*Sidalcea hendersonii*) was intentionally planted as part of a native landscaping project at Cape Disappointment. Ocean-bluff bluegrass (*Poa unilateralis*) occurs on headlands and former headlands at Cape Disappointment and has been reported from but not documented at Ecola. The Washington Natural Heritage Program has listed ocean-bluff bluegrass on their list of threatened plants for Washington State.

Pink sandverbena (*Abronia umbellata* ssp. *breviflora*) is on the Oregon endangered species list but was last reported in Clatsop County near Gearhart in 1993; there are no documented sightings of this species in LEWI units (ORBIC 2010). Coyotebrush (*Baccharis pilularis*) is listed as threatened in Washington State and is present at Cape Disappointment. This population is the northernmost known location for coyotebrush.

Table 3. Rare or sensitive species surveyed for at Lewis and Clark NHP. Washington ranks were last updated in January 2009; Oregon ranks in October 2010.

Scientific Name	Common Name	State Status	Global Rank*	OR Rank*	WA Rank*	In Park
<i>Abronia umbellata</i> ssp. <i>breviflora</i>	Pink sandverbena	OR:LE	G4G5T2	S1	S1

<i>Sidalcea hendersonii</i>	Henderson's sidalcea		G3	S1	SNR	x
<i>Viola adunca</i>	Early blue violet		G5	SNR	SNR	x

* Global Ranks as reported by NatureServe. State rank for Oregon as determined by Oregon Biodiversity Information Center, and Washington as determined by Washington Natural Heritage. Rank Definitions: G=Global, S=State, T=Taxon (variety, subspecies). 1=Critically imperiled; 2=Imperiled; 3=Rare, uncommon, or threatened; 4=Not rare and apparently secure; 5=Demonstrably widespread, abundant, and secure; NR=Not Ranked.

The following sections describe species that were encountered and mapped during field surveys. Maps of sensitive species locations for each unit are found in Appendix F.

3.4.1 *Baccharis pilularis* – coyotebrush

Coyotebrush is an evergreen shrub in the Aster family found in coastal ecosystems from California to Washington. It is common in California and southern Oregon where it is found in oak woodlands and on ocean bluffs. In Washington it is only known from Cape Disappointment, where a few patches and individual shrubs are scattered in the dunes and along cliffs. Sea cliff habitat has changed with the building of the jetty, filling these areas in with dunes that are gradually becoming shrubland and forestland. Changing habitat and encroachment of invasive species such as Scots broom (*Cytisus scoparius*) are threats to these Washington plants. This species has also been reported at Fort Stevens, but no plants were encountered in the 2009 or 2010 field seasons.

3.4.2 *Callitriche hermaphroditica* – autumnal water starwort

Autumnal water starwort is a delicate aquatic plant in the water-starwort family usually found in shallow water and occurs over much of western and northern North America and Canada. While it is ranked as critically imperiled in the north-eastern extent of its range, it is not currently ranked in Oregon or Washington. Autumnal water starwort is present in the Fort Clatsop and Cape Disappointment units.

3.4.3 *Carex brevicaulis* – short-stemmed sedge

Short-stemmed sedge is found on stabilized sand dunes free of European beachgrass from California to British Columbia. It grows 2 to 20 cm tall and is reddish at the base of the stems. The inflorescences have terminal and lateral male spikes and female basal spikes, most being less than a centimeter long. This sedge is losing habitat due to dune stabilization by European beachgrass, succession of shore pine, and housing developments (Wilson et al. 2008). There is a small population of short-stemmed sedge in the Sunset Beach/Yeon unit.

3.4.4 *Carex macrocephala* – big-headed sedge

Big-headed sedge (Figure 10) is one of the few sedges that live in shifting sand from California to Alaska. Its large fruiting heads are distinctive, being 3.5-8 cm long and 2.5-5 cm wide, deep brown, with spreading spikes. Once a dominant dune community species, big-headed sedge has lost habitat to dune stabilization by beachgrass and housing developments (Wilson et al. 2008). Several large populations are present at Cape Disappointment, where there are still large stretches of open beach habitat. Two small patches were also found at Fort Stevens.

There is a look-alike sedge native to Asia, Japanese sedge (*Carex kobomugi*), that occurs in similar habitats and can be confused with big-headed sedge (Figure 11). Japanese sedge differs from big-headed sedge in having slightly smaller fruiting heads ranging from 3-6 cm long and 2-4 cm wide which are generally green-tinged rather than deep brown with ascending rather than spreading spikes. Perigynia of Japanese sedge have 12 or more ventral nerves, whereas the perigynia of big-headed sedge have only 7 to 9 ventral nerves (Wilson et al. 2008). Japanese sedge was planted for dune stabilization on the east coast of North America, where it is now being eradicated as it has spread to cover many miles of beaches. Japanese sedge is present and expanding at Cape Disappointment where it can be found alongside big-headed sedge.

This report has had confidential information regarding species of management concern locations removed.

Figure 10. *Carex macrocephala* (big-headed sedge) male culm (left) at Del Rey Beach and female culm (right) at Cape Disappointment. Note spreading perigynia and dark color of female inflorescence. Photo at left taken in July 2010, photo at right taken in August 2010.

Figure 11. *Carex kobomugi* (Japanese sedge) male culms (left) and female culm (right) at Cape Disappointment. Perigynia are more ascending and greener than the native *Carex macrocephala*, as well as having more lines on the ventral surface. See paragraph above for more detail. Photo at left taken in April 2010; photo at right taken in August 2010.

3.4.5 *Hydrocotyle ranunculoides* – floating marsh-pennywort

Floating marsh-pennywort is an aquatic plant in the carrot family found in much of the southern United States as well as California, Oregon, and Washington. It is generally found in slow-moving waters or ponds. It has long, thin stems that can float on the water surface and bright green, glossy, lobed leaves. It is endangered in Illinois, New Jersey, and New York and was historically present in British Columbia but is not currently ranked for Oregon or Washington. Floating marsh-pennywort is present at Cape Disappointment, Fort Clatsop, Fort Stevens, Fort Columbia, and Sunset Beach.

3.4.6 *Lilaea scilloides* – flowering quillwort

Flowering quillwort is a small wetland plant in the arrow-grass family that is native to western North America. It has fleshy, grass-like leaves and small flowering spikes that are much shorter than the leaves. It is an easily overlooked plant found in shallow waters or coastal tide flats in alkaline, saline, or brackish areas (Washington DOE 2010). Flowering quillwort is present at the Fort Clatsop unit.

3.4.7 *Poa unilateralis* – ocean-bluff bluegrass

Ocean-bluff bluegrass is a short perennial bunchgrass growing 15-40 cm tall growing on rocky headlands, sea cliffs, or sandy coastal bluffs in California, Oregon, and Washington. Though it is rare due to its limited habitat, those populations growing on steep or protected cliffs appear to be stable (NatureServe 2010; Sayce and Eid 2004). Ocean-bluff bluegrass is present at Cape Disappointment.

3.4.8 *Samolus valerandi* ssp. *parviflorus* – water-pimpernel

Water-pimpernel is a clumping wetland perennial in the primrose family found in much of the United States, Canada, and South America. It grows to 40 cm tall with a basal rosette of broad, light-green leaves and a raceme of small white flowers. It is found in wet soils in lowland wetlands generally below 1300 m elevation (Washington Natural Heritage Program 2005). Water-pimpernel is present in the Fort Clatsop unit.

3.4.9 *Sidalcea hendersonii* – Henderson’s sidalcea

Henderson’s sidalcea is a showy perennial in the mallow family found from Oregon to Alaska. It grows to 150 cm tall and has a spikelike inflorescence of large deep pink to pink-lavender flowers. It is found along the coast, generally on or near tidelands (Hitchcock and Cronquist 1973). Henderson’s sidalcea was planted at Cape Disappointment as part of a native landscaping project using plants sprouted from seeds collected from a Baker’s Bay population (Kathleen Sayce, personal communication, 14 October 2009).

3.4.10 *Viola adunca* – early blue violet

Early blue violet is a perennial violet found in much of the United States and Canada. It is found in dry to moist meadows, woods, and on open ground (Hitchcock and Cronquist 1973). It is the larval host plant for the Oregon silverspot butterfly (*Speyeria zerene hippolyta*), a federally listed threatened species that had a small population near the park in the 1990s (ORBIC 2010). The Clatsop County population of the Oregon silverspot, like the Washington State populations, has likely vanished, but the recovery plan includes a viable population in this area. Due to the importance of early blue violet to the Oregon silverspot, early blue violet locations are being mapped as a way to assess the potential for restoration or management of silverspot habitat. Multiple small patches of early blue violet occur at the Sunset Beach/Yeon unit.

Figure 12. Remnant prairie habitat for early blue violet in the Yeon section of Sunset Beach. Photo taken in April 2010.

3.5 Non-native species

A list of 59 non-native, invasive species of interest that could possibly occur at LEWI was constructed using the Oregon Department of Agriculture Noxious Weed List and the Washington State Noxious Weed List, as well as input from the local weed boards, ORBIC, and NPS (Table 4). Of these, 35 have been documented in the park either with voucher specimens or observations during this project. Each of these species was ranked for management priority by park staff and ORBIC staff, considering the potential for harm to the native ecosystem, aggressiveness of spread of the species, amount of cover already present at the park, and estimated cost of removal.

Eight species have been identified by the North Coast Cooperative Weed Management Group as early detection, rapid response (EDRR) species. These invasive plants have not yet become well-established in Clatsop County, Oregon and are targeted for public education and prevention. They are: garlic mustard (*Alliaria petiolata*), false brome (*Brachypodium sylvaticum*), traveler's joy (*Clematis vitalba*), spurge laurel (*Daphne laureola*), shining geranium (*Geranium lucidum*), herb robert (*Geranium robertianum*), policeman's helmet (*Impatiens glandulifera*), and common reed (*Phragmites australis*). Park staff are removing or treating these species as soon as they are encountered on Park lands.

This report has had confidential information regarding species of management concern locations removed.

Table 4. Non-native, invasive species that were surveyed for at Lewis and Clark NHP.

Scientific Name	Common Name	Mgt Priority ¹	OR Listing ²	WA Listing ³	In Park ⁴

1. Management priorities: 1=top, 2=high, 3=medium, 4=low.

2. Oregon List A and B are both quarantined in Oregon. List A weeds can potentially (and should) be eradicated. List B weeds are more widely distributed but are priorities for control or containment. Ranks current as of Feb. 4, 2010.

3. Washington List A weeds are required by law to be eradicated. List B weeds should be controlled and contained where feasible and new infestations prevented. List C weed control may be enforced by individual counties at their discretion.

4. x - denotes species has been documented in the park, but may not persist due to treatments or life cycle. ? - denotes the presence of this species on a local unit list but its presence has not been documented and was not encountered in the 2009-2010 field seasons.

The following sections describe species that were encountered and mapped during field surveys. Maps of invasive species found in each unit are found in Appendix G.

3.5.1 *Cirsium arvense* – Canada thistle

Canada thistle is an herbaceous perennial growing 1.5 to 4 feet tall with lobed, prickly leaves and clusters of purple flower heads. It is a major agricultural pest in North America and can crowd out native species in many habitats including prairies, savannas, dunes, and meadows. Canada thistle spreads by seed or by lateral roots. Control can be done by hand removal (provided the root mass is removed), mowing, burning, or herbicides (Roddy 2009). Canada thistle is present in the Cape Disappointment, Sunset Beach, and the Fort Clatsop units. In Fort Clatsop, it has been found at South Clatsop Slough, Otter Point, and on the east shore of the Lewis and Clark River and is manually and chemically treated annually.

3.5.2 *Daphne laureola* – spurge laurel

Spurge laurel is a shade-tolerant evergreen shrub in the Thymelaeaceae family native to Europe and the Mediterranean. Spurge laurel grows 2 to 4 feet tall and has densely whorled shiny green

This report has had confidential information regarding species of management concern locations removed.

leaves. It has escaped from gardens and become naturalized in some areas of Washington (King County 2010). An infestation on the Yeon Property of the Sunset Beach unit was first noted in spring 2009 and is being manually and chemically removed by Park staff. This was the first documented population of spurge laurel in Clatsop County.

3.5.3 *Geranium lucidum* – shining geranium

Shining geranium is a low-growing annual native to Eurasia that can spread through semi-open areas to form carpets of vegetation that exclude native species. The common name comes from the shiny appearance of the leaves, which are round to kidney-shaped with 5 to 7 lobes. Spread is by seed rather than vegetatively, so hand-control and removal is possible for small populations. Herbicide treatment may be necessary for larger populations. Shining geranium was found alongside herb robert at a Fort Stevens campsite.

3.5.4 *Geranium robertianum* – herb robert

Herb robert is a low-growing annual or biennial that is shade-tolerant and can spread under forest canopies. It is an escaped garden plant with weak, hairy-sticky red stems, dissected leaves, and small pink flowers. Its other common name “stinky bob” comes from the strong skunky odor given off when its stems are broken or leaves crushed. Due to its shallow roots hand-pulling is an effective control (King County 2010). Herb robert was located in the Cape Disappointment, Fort Stevens, Dismal Nitch, and Fort Clatsop units. Plants will be pulled and locations monitored.

3.5.5 *Hedera helix* – English ivy

English ivy is a shade-tolerant woody evergreen vine in the ginseng family. It is extensively used in landscaping and gardening projects and can escape into nearby wooded areas. Control by hand-pulling or cutting can be effective but resprouting from remaining rhizomes is common so multiple-year treatment or herbicide is needed. English ivy is present in all Park units. A large infestation was present at Beards Hollow in Cape Disappointment, but it has been undergoing treatment for several years and is much reduced, though ongoing maintenance is needed for the remaining plants. English ivy is manually and chemically controlled at the Fort Clatsop unit.

3.5.6 *Ilex aquifolium* – English holly

English holly is a shade-tolerant evergreen tree with spiny, glossy green leaves and red berries. It is grown for ornamental products as well as for landscaping and gardening. The berries are good forage for birds, which provide a dispersal mechanism for this species. Hand-pulling of small saplings is possible but larger trees need to be cut and treated with herbicide as the tree will resprout from the stump. English holly is found in all Park units scattered along trails and throughout wooded areas, with the most trees being encountered in Fort Stevens around Coffenbury Lake. It has been actively controlled by Park staff in the Fort Clatsop unit since 2000 using both manual controls and treatment with the herbicide Garlon.

3.5.7 *Iris pseudacorus* – yellow flag iris

Yellow flag iris is a showy wetland plant native to Europe and the Mediterranean region. It is used in landscaping and gardens that has escaped cultivation. It displaces native vegetation along streambanks, ponds, and shorelines. Its floating seeds can be dispersed along the waterways on which it grows. Yellow flag iris has a very strong root system, creating mats of rhizomes which make manual control of large populations very difficult. In addition, chemicals present in the leaves and rhizomes can be a skin irritant. Large infestations may require herbicide treatment. (King County 2010). Yellow flag iris is present in the Cape Disappointment, Dismal Nitch, Fort

This report has had confidential information regarding species of management concern locations removed.

Columbia, Sunset Beach, and Fort Clatsop units. It has been actively controlled in the Fort Clatsop unit since 2000, and by the Exotic Plant Management Team (EPMT) at the Dismal Nitch unit since 2009. Beards Hollow and Middle Marsh at Cape Disappointment have the largest concentrations of yellow flag iris, with several hundred stems present. The small populations at Dismal Nitch and Fort Columbia are found around lagoons off the Columbia River. Fort Clatsop has small populations scattered along the Lewis and Clark River. Yellow flag iris has been reported on the shore of Sunset Lake with highest abundance near the Astoria Golf Course and along the middle section of the lake (Sytsma 2005). These plants could potentially spread north into the Sunset Beach unit.

3.5.8 *Lathyrus latifolius* – everlasting peavine

Everlasting peavine is a trailing perennial in the pea family with winged stems and deep pink flowers that has been used for erosion control but can escape and displace native vegetation. Hand-pulling is possible for smaller infestations, while herbicide may be necessary for larger areas or on slopes where hand-pulling could cause slope destabilization. Everlasting peavine is present in the Fort Clatsop unit at Netul Landing and is being manually and chemically treated annually. Small populations are also present at North Head Lighthouse and near the Waikiki Beach parking area at Cape Disappointment.

3.5.9 *Lonicera periclymenum* – European honeysuckle

European honeysuckle is a deciduous perennial twining woody vine with opposite oval-shaped leaves, showy and fragrant white flowers that can be tinged with yellow or purple, and red berries. It is grown as an ornamental and has escaped cultivation. European honeysuckle was encountered in the Fort Stevens, Sunset Beach, Fort Clatsop, and Cape Disappointment units. Manual and herbicide control of European honeysuckle began in 2006 at Fort Clatsop, and at Sunset Beach where it is a serious infestation. It is especially abundant at the Yeon site, where the source of infestation may be specimens that were planted in the ornamental border surrounding the house.

3.5.10 *Lythrum salicaria* – purple loosestrife

Purple loosestrife is a perennial emergent wetland plant growing to 3 meters in height with a tall showy inflorescence of bright magenta flowers. It is planted as an ornamental but has become a widespread and problematic weed in wetlands throughout much of North America. Purple loosestrife can create monoculture thickets along waterways that exclude native species and alter wetland ecosystems. Once established, large populations of loosestrife are very difficult to eliminate. (Washington DOE 2010). Purple loosestrife is found in the Dismal Nitch, Fort Columbia, Fort Stevens, Fort Clatsop, and Cape Disappointment units. The Fort Columbia and Dismal Nitch populations are found in lagoons off the Columbia River, and population numbers are low. A few scattered plants are present along the northwest shore of Trestle Bay in Fort Stevens. Several plants were found around O'Neill Lake at Cape Disappointment, with the highest concentration of plants seen at the northwest end of the lake. A few young plants were seen at Fort Clatsop along the Lewis and Clark River on the Netul Landing trail in 2010. Purple loosestrife has been reported at the southern end of Sunset Lake (Sytsma 2005) and could spread north into the Sunset Beach unit. The plants around the lagoon at Dismal Nitch have been manually controlled by Park staff since 2007, and plants in the Fort Clatsop unit have been manually removed since 2000. Biocontrol agents are also effective and may be available from local government.

3.5.11 *Myriophyllum aquaticum* – parrot feather watermilfoil

Parrot feather watermilfoil is a freshwater rhizomatous perennial aquatic plant used in the aquarium trade and as an aquatic garden plant which has escaped cultivation. Parrot feather has both submerged and emergent leaves. The emergent leaves are a bright green color with many-divided leaves that give it a feathery appearance. It is most successful in slow-moving, nutrient-rich waterways. (Washington DOE 2010). Parrot feather was found in the Fort Clatsop unit on the Skipanon River, in a ditch at the northeast boundary of the unit, on log rafts in the Lewis and Clark River, and in a pond along the Fort to Sea trail in the Sunset Beach unit just west of Highway 101. The source of the Skipanon River population is most likely Cullaby Lake and Cullaby Creek upstream of the Skipanon, which are both moderately infested with parrot feather and could potentially introduce more plants. The Sunset Beach population covered much of the banks of the pond and numbered several hundred plants. Control of this species has not been undertaken. Another non-native watermilfoil, Eurasian watermilfoil (*Myriophyllum spicatum*) has been reported at Cape Disappointment (Washington State Parks and Recreation Commission 2004). An established method of control for parrot feather is herbicide application using time release capsules, but as this is a non-targeted treatment it is not an ideal method (Lindsay Cornelius, personal communication).

3.5.12 *Nymphaea odorata* – American white waterlily

American white waterlily is an attractive aquatic plant with large floating lily pad leaves and showy white or pink flowers. Because of its aesthetic appeal it has been used in water gardens and plantings in lakes, but it is now known to be an aggressive invader. White waterlily spreads both by seeds and rhizomes. It can be controlled through cutting, harvesting, covering, or aquatic herbicides (Washington DOE 2010). American white waterlily was found in the Sunset Beach unit in Sunset Lake where the Fort to Sea Trail crosses the lake at the northeast corner of the unit.

White waterlily has been present in Sunset Lake for more than 40 years and has become a significant detriment to those that use the lake for boating, fishing, and recreation as well as decreasing the quality of habitat for wildlife (Sytsma 2005). Due to the importance of recreation and aesthetic use to the surrounding community, Sytsma et al. recommended a modified high-level of control in Sunset Lake including public education, prevention, monitoring, and small-scale hand removal for most invasives, and large-scale harvesting for waterlily.

3.5.13 *Phragmites australis* – common reed

Common reed is a tall, rhizomatous perennial grass growing in wetlands, estuaries, and swamps on several continents. Its height is its distinguishing characteristic: it can grow to 3-4 meters tall. The canes and leaves have been used for thatch, forage for livestock, and cellulose production. It can rapidly expand by rhizomes, creates thick monocultures that excludes native plants, and can change wetland hydrology (Saltonstall 2009). Several states have given common reed noxious weed status. Stands of common reed have been located just outside the Fort Clatsop unit on the Lewis and Clark River, and in Trestle Bay in the Fort Stevens unit.

The taxonomy of common reed is currently in review, but there appear to be three strains present in North America, two of which are considered native and one that is invasive (Kartesz 2010). Although a thorough determination of physical characteristics has not been made of the common

This report has had confidential information regarding species of management concern locations removed.

reed populations that are present in or near the park, the growth form and rapid expansion of these patches suggest that these plants are the invasive haplotype.

3.5.14 *Polygonum cuspidatum* – Japanese knotweed

Japanese knotweed is a large, broad-leaved herbaceous perennial that grows to 1-3 meters tall and is native to Asia. Its hollow stems resemble bamboo and it has been planted as an ornamental and also as a food plant as the young stems are edible. It spreads mainly by stout rhizomes and has become a common invasive in riparian zones. Pulling or digging can be effective for removing small or young plants, but larger infestations require other tactics. Japanese knotweed is present at Dismal Nitch and was reported to be in Cape Disappointment by Sayce and Eid in 2004. Several plants of knotweed (species unknown, likely *P. cuspidatum*) were also located on the east side of the spit at Fort Stevens. The closely related giant knotweed (*Polygonum sachalinense*) has similar invasive characteristics and was found just outside the Fort Stevens boundary east of the historical area. Japanese knotweed and Himalayan knotweed (*Polygonum polystachyum*) were present at Cape Disappointment at historic homesites, but were not encountered during the field season, potentially as these species have been treated by the park for some years (Washington State Parks and Recreation Commission 2004). The three locations of Japanese knotweed at Dismal Nitch have been treated since 2007 by cutting, herbicide, and flaming, yet the plants have regrown each year. All three plants are rooted into the rivershore riprap, rendering manual removal of the roots impossible.

3.5.15 *Ranunculus ficaria* – fig buttercup

Fig buttercup is a shiny-leaved herbaceous perennial with yellow flowers that is native to Eurasia. It is planted as an ornamental but spreads rapidly due to the production of bulblets which break off in the soil and produce new plants. This leads to carpets of fig buttercup which crowds out native vegetation. Fig buttercup resembles the native marsh marigold (*Caltha palustris*), but marsh marigold does not produce bulblets or form carpets of vegetation as fig buttercup does. Due to the difficulty of removing all bulblets in the soil, fig buttercup is often treated with herbicide unless the population is small enough to remove all pieces of the plant (Swearingen 2010). A few plants of fig buttercup were found at Dismal Nitch west of the parking lot. Park staff physically removed the plants and surrounding soil in 2009, and returned to remove about three dozen new plants in 2010. Removal and monitoring will be ongoing for this population until it is eradicated.

3.5.16 *Sorbus aucuparia* – European mountain ash

European mountain ash is a perennial deciduous shrub or tree with pinnately divided leaves and orange or red berries. It is native to Eurasia but has been widely planted for ornamental purposes. It is shade tolerant and can grow under forest canopy. Birds act as a dispersal mechanism by eating the fruits. European mountain-ash does not spread vegetatively (USDA 2010). European mountain ash is present in the Fort Clatsop unit. Hand-cutting and removal of seedlings was started in this unit in 2008, and larger trees have been cut and treated.

3.5.17 *Ulex europaeus* – gorse

Gorse is a perennial, spiny, woody shrub growing 3-7 meters tall and is native to Europe. It can form dense thickets of spiny shrubland that can exclude native species. As mature shrubs can have thick woody stems, cutting off at the ground is often necessary rather than digging or pulling. Plants with stems less than two inches in diameter can be effectively removed using a

This report has had confidential information regarding species of management concern locations removed.

weed wrench. For leverage on sandy soils, a plywood base can be attached to the wrench. Once cut stumps can be treated with herbicide or cut again next year to continue to deplete the plant's energy stores. Young plants can be hand pulled or hoed, and as the seeds can persist in the seed bank for many years monitoring of populations for regrowth is necessary.

Six gorse plants were found in the Dismal Nitch unit in 2006, on the east side of Megler Road, just south of the gate. The large top growth was removed by cutting and the stems were treated with Garlon. The area is monitored for resprouting annually. In 2010 one plant that had resprouted was cut and the stem treated with Garlon. Gorse is also reported from the Fort Stevens and Cape Disappointment units. Several small plants were hand pulled from south Netul Landing in the Fort Clatsop unit in 2001 and 2002, but no regrowth has since occurred at that site.

3.5.18 Other non-native plants of interest

Several other non-native plants of interest are present in the park, but their abundance makes it impractical to map their locations. Of particularly wide distribution are Scots broom and Himalayan blackberry (*Rubus armeniacus*, synonymous with *Rubus discolor*). Cut-leaf blackberry (*Rubus laciniatus*) is also present in lower abundance. These species are capable of widespread distribution and habitat change, replacing native communities and altering landscapes. However, due to their long establishment in the Pacific Northwest control can be costly or impractical. A few larger areas of Scots broom and the two blackberry species at the Fort Clatsop unit have been treated by the EPMT. Hand removal of Scots broom at Cape Disappointment has occurred in the past. Control of these species could be prioritized to treat areas with sensitive species, rare communities, or high restoration potential to maximize the effectiveness of the cost of treatment.

Aquatic non-native species pose additional management problems. Many aquatic plants can spread vegetatively, from plant fragments, or have floating seeds that are easily spread along waterways. If an exotic species is established upstream or elsewhere along the coastline, populations can be reintroduced after their downstream removal. Recreational boat traffic can also be a dispersal mechanism and a way for these species to become reintroduced. Chemical treatments of aquatic plants can be damaging to native aquatic species and must be applied with caution, for example through targeted injection or wick application. The inaccessibility of aquatic invasive species rooted at the bottom of lakes and rivers also adds to the difficulty of treatment.

In addition to the non-native aquatic plants that were discussed above, others known to occur in the park are fanwort (*Cabomba caroliniana*) found in Sunset Lake and Coffenbury Lake, water celery (*Vallisneria americana*) found in Sunset Lake and Coffenbury Lake, Brazilian waterweed (*Egeria densa*) found in the Skipanon River along the Fort to Sea trail, and pond water starwort (*Callitriche stagnalis*) found in Sunset Lake. Some of these species are reported from the Fort Clatsop unit as well.

4 Discussion

4.1 Sensitive communities and rare plant species management

Several new locations of rare communities were recorded within the park's boundaries and associated state park units. The two units with the greatest number and coverage of these rare communities were Cape Disappointment and Fort Stevens State Parks. Their locations on the Columbia River estuary and the amount of protected acreage these parks represent translate to a wealth of habitat types, including headlands and salt marshes which have geographically limited distributions.

Both the upland and wetland Sitka spruce forests represent important conservation targets for LEWI. Cape Disappointment has large areas of the Sitka spruce / Slough sedge – Skunk cabbage Forest type, or rather a natural variant of this type where skunk cabbage is not always present. The park can continue to support Sitka spruce conservation by planting seedlings or removing competing species in peripheral habitats where spruce is beginning to recolonize. Invasive species such as Scots broom can be removed from Sitka spruce stands to encourage natural reseedling of spruce trees; Scots broom and Sitka spruce occur together on the accretion zone behind the jetty in Cape Disappointment.

Both wetland and upland Sitka spruce forests were identified as conservation targets (TNC 2006) due to their limited habitat range and the forest's value for timber, which has led to a decrease in Sitka spruce cover over time. In addition Sitka spruce old growth forest provides critical habitat for the federally threatened marbled murrelet (*Brachyramphys marmoratus*). Current management such as thinning of the upland forests at the Fort Clatsop unit to promote late successional conditions will contribute to recovery efforts, in spite of natural setbacks by windthrow from major storms. The development trajectory is on track in most locations and little change in management is required. Only in some of the early seral spruce forests at Ecola are there locations where removal or cutting of red alder might speed the pace of succession.

By and large, the management prescriptions for both the upland and wetland Sitka spruce forests are the same. Non-native trees, shrubs and forbs need to be controlled. For the upland stands, removing some red alder which is slowing growth and regeneration of conifers can help in moving from early and mid-seral stands, to the more important late seral stands. The Nature Conservancy explored this at Tillamook Head, before transferring this property to the Oregon Parks and Recreation Department. While there is little doubt this would be effective, its cost and the potential disturbance created makes it a difficult management prescription to follow. However, it appears to be especially needed in the most eastern upland Spruce forests at Ecola State Park.

Coastal headlands are present at Cape Disappointment and Ecola. As Ecola is outside the legislative boundary of LEWI, its headlands were not mapped and will not be discussed here. The Cape Disappointment headlands are degraded by non-native species, particularly graminoids such as ripgut brome (*Bromus diandrus*), soft brome (*Bromus hordaeceus* ssp. *hordaeceus*), and sweet vernal grass (*Anthoxanthum odoratum*) (Sayce and Eid 2004). However, the rare species ocean-bluff bluegrass is found on several headlands at Cape Disappointment, and red fescue is also occasionally present, representing a remnant of the Red fescue Coastal Headland rare community type. The North Head headland at Cape Disappointment hosts an occurrence of

This report has had confidential information regarding species of management concern locations removed.

Pacific reedgrass - blue wildrye Herbaceous Vegetation, one of a few occurrences known in Washington State. Removal and management of non-native species where ocean-bluff bluegrass or Pacific reedgrass is present is recommended to preserve these populations. However, completely restoring these grasslands to be dominated or co-dominated by native grasses is unlikely due to the prevalence of non-native grasses and the heavy use of headlands by people and ungulates that act as reintroduction agents of these non-native species. Consequently, management emphasis is focused on conservation of existing rare community types and areas where rare species are present. Geography is also acting against headland communities that have been cut off from the ocean by accretion. The reduction of salt spray in these areas will lead to a steady decline in salt-dependent headland species and a gradual transition to shrub or forest types.

The Big-headed sedge Herbaceous Vegetation type is present in large amounts at Cape Disappointment and in very small remnant patches at Fort Stevens. The major threat to this community type is the encroachment of non-native beachgrasses (*Ammophila* spp.). Big-headed sedge grows on shifting, open sand, and the invasion of beachgrass decreases the available habitat and introduces competition for resources. Removal or control of beachgrass is difficult and potentially labor-intensive and expensive but treatment can open up areas of dunes to native species and allow for expansion or restoration of native communities (Pickart 1997). Due to the presence of native species interspersed within the beachgrass stands and the high amount of public use of these beaches and dunes, manual removal would be recommended over mechanical or chemical treatment. Pickart (1997) determined that manual removal of beachgrass by California Conservation Corps at a Nature Conservancy preserve in California had a cost of \$21,831 per acre of beachgrass removed, not including the cost of transportation. It could be possible to mitigate this cost by using volunteer work parties and by targeting small patches around rare plants. The Columbia Land Trust has found that the “adopt a plot” model has worked very well for costly weed control in communities where stewardship ethic is high (Lindsay Cornelius, personal communication). Pickart also noted that by selectively removing beachgrass and preserving native plants on-site, there was no need to revegetate the project site after beachgrass removal as these retained native species successfully recolonized the site.

The US Forest Service and Bureau of Land Management have removed beachgrass for snowy plover management on some beaches in Oregon. The snowy plover is a federally listed bird species that nests in or near open sand. Federal agencies have managed beachgrass in plover nesting areas by bulldozing and removing beachgrass, then following up with either manual removal or direct application of herbicide for resprouts. Treatment costs for a combination of mechanical removal, burning, and herbicide treatment ranged in cost from \$2,000 to \$6,000 per acre in the 1990s (USDA Forest Service 1994).

Another non-native species that has the potential to be very detrimental to the big-headed sedge populations at Cape Disappointment is Japanese sedge. This sedge has a similar growth form, habit, and appearance to big-headed sedge and has been seen growing amongst big-headed sedge on Cape Disappointment beaches. Japanese sedge is considered a noxious weed in some eastern US states, despite being used as a dune stabilizer in the past, and has spread over many hundreds of acres of beaches there. The populations of Japanese sedge at Cape Disappointment are currently limited, so proactive control or eradication may yet be possible. McGough et al. (2003) tested low-impact management strategies for Japanese sedge in New Jersey and found that

This report has had confidential information regarding species of management concern locations removed.

repeated narrowly-focused spray application of Roundup® was effective in greatly decreasing the number of Japanese sedge stems while producing limited loss of nearby native species. The densities of Japanese sedge McGoug *et al.* were testing were significantly denser (hundreds of stems per meter) than the patches found at Cape Disappointment (dozens of stems per meter) so this method of treatment combined with manual digging of remaining stems and rhizomes could be effective at removing these relatively small patches.

Management to promote or restore other native and rare sand dune communities historically found at Fort Stevens and Sunset Beach is a bit more problematic. No other rare dune plant communities were identified from the park, but most of the native forb and grass dominated, partially stabilized dune communities described from the Oregon Dunes National Recreation Area (Christy *et al.* 1998) are at risk. Based on the historical vegetation from the area, most of these were likely present in these two park units. In addition, a number of partially stabilized types, particularly shorepine woodland communities such as shore pine / hairy manzanita (*Pinus contorta* var. *contorta* / *Arctostaphylos columbiana*) and shore pine / kinnikinnik (*Pinus contorta* var. *contorta* / *Arctostaphylos uva-ursi*) might provide good restoration objectives for the pasture or non-native forests included in the new acquisitions at Sunset Beach. Detailed descriptions of these shore pine communities can be found on NatureServe Explorer (NatureServe 2010) or in Christy *et al.* 1998.

Only small amounts of the Lyngby sedge – pacific silverweed Herbaceous Vegetation type are present within the legislative boundaries of the park, but these marshes are sufficiently rare to merit management. While the hydrographic conditions that influence these salt marshes are out of control of the park, control of non-native species can help maintain the quality of these marshes. Knotweeds, purple loosestrife, and yellowflag iris are common invasive species that will be periodically introduced to these marshes via tides. If these sites are periodically monitored, these invasive species can be removed before their populations can become large enough to impact the salt marsh. Common reed is also an encroaching threat as it is present just outside the boundary of Fort Clatsop on the east bank of the Lewis and Clark River and is also found in the salt marsh at Fort Stevens. The subspecies of these populations have not been determined, but the density of stems and its recent colonization suggests these patches are the non-native subspecies. Should common reed turn up inside Park units, and the evidence points to it being the non-native subspecies, efforts should be made to eradicate the population before it reaches an unmanageable size. Saltonstall (2009) recommended repeated glyphosphate-based herbicide treatments in late summer or fall, and optional burning after herbicide treatment to remove above-ground biomass and further set back the common reed population. Mechanical control is unlikely to eradicate common reed.

There is an occurrence of Virginia glasswort Herbaceous Vegetation on Clatsop Spit in the Fort Stevens unit. Although outside the legislative boundary of the park, it is notable for its size and rarity. There are small patches of Virginia glasswort at Cape Disappointment but its numbers are not great enough to support this community type. Should Fort Stevens be included within the legislative boundary in the future, this site should be managed for removal or control of invasive species and any proposed jetty work should be studied for impact on the marsh before action is taken.

This report has had confidential information regarding species of management concern locations removed.

By taking the management actions suggested above to conserve rare habitats, rare species that depend on these habitats may also be protected. For example, a few of the rare plants at LEWI are also the main component of a targeted rare community, such as the Big-headed sedge community and the grassy balds where ocean-bluff bluegrass is present. Other species will require their own targeted management. All rare species will benefit from control of invasive species, but due to the time and cost of weed removal, priority sites should be identified based on either the health or uniqueness of the rare species population or, as some rare species occur in the same habitats, the species richness of rare species. In addition, visitor activities may need to be managed for certain populations and treated areas protected so that native vegetation has time to recolonize the area. Beaches and headlands are the most impacted by visitors due to their scenic beauty and opportunities for recreation. If small areas are treated, roping off areas and providing interpretive signs may be enough to close off an area until plantings or existing native species can become established.

4.2 Non-native plant species management

The park has been actively treating and monitoring many non-native plant species for several years. The Exotic Plant Management Team's work in Park units and surrounding areas, reporting on locations of invasive species by local groups, and involvement of Cooperative Weed Management Groups (CWMGs) represent a valuable collaborative approach to invasive species management that should be fostered. The Early Detection, Rapid Response (EDRR) protocol and lists created by CWMGs and other groups can prevent new invasive species from becoming established by removing them before their populations become unmanageable. The park has also involved the public by hosting volunteer work parties; this too is a valuable and effective way to control non-native species while giving park visitors and local residents opportunity to become invested in these habitats and the park. These relationships and protocols should continue to be maintained to increase the effectiveness and defray costs of weed management in the park.

While non-native species represent significant cover of Park units, priorities can be made for where and how to treat or manage non-native species. Priority should be given to areas with rare species or rare communities present, or where visitor experience is being negatively impacted by non-native species. Visitor education can be useful in preventing introductions of weeds by making visitors aware of simple preventative measures such as cleaning hiking boots before entering the park and washing water craft before boating on Park lakes. Boot brushes can be provided at parking lots and trail heads. Interpretive signs can show photographs of EDRR species and provide a way to report target non-native species locations. Asking visitors to pull and dispose of these target non-native species can help Park staff who do not have the time to patrol all areas of the park themselves, although care must be taken to make sure visitors do not confuse target non-native plants with native species.

Before developing a management plan for individual non-native species, tried-and-tested methods should be reviewed in the literature and contact made with other local weed managers for their expertise. Some specific management strategies are proposed in the sensitive communities management section above.

4.3 Updated species list and future floristic work

During the course of this project the park vascular plant list was increased from 267 species to 467, and there was a 75% increase in the number of verified species. All but 19 of the species

This report has had confidential information regarding species of management concern locations removed.

added were located in the new areas of the park. There are undoubtedly more species yet to be documented, as annuals crop up some years and not others, perennials are encountered when not in flower or fruit and identification cannot be confirmed, and new species continue to be introduced by natural or anthropogenic means. The Middle Village/Station Camp unit was the most under-surveyed of the new additions to the legislative boundary of LEWI, due to the relative inaccessibility of the majority of the property and the lack of unique habitat types. One arduous trip was made to the top of the slope in this unit, and no new species or communities of interest were discovered during the outing. While it is possible there are new species in this unit to discover, it was felt that our time was more productively spent surveying less common habitats and more accessible areas in the other units.

Fort Stevens, Fort Columbia, and Ecola state parks were not thoroughly surveyed, being outside the current legislative boundary of LEWI. Species noted in these cooperative management areas during field work were documented in a separate database provided to the park, allowing these observations to easily be incorporated should these parks become incorporated into the legislative boundary of LEWI in the future.

This report has had confidential information regarding species of management concern locations removed.

Appendices

The following appendices contain annotated checklists of vascular flora at Lewis and Clark National Historical Park.

Appendix A lists confirmed, historical, and reported taxa that have been documented by specimen voucher, reliable observation, or official reports. Vouchers were examined at the Fort Clatsop Herbarium and queried from the NPSpecies database. NPSpecies is the National Park Service's standard database for tracking species observations, specimens, and scientific names. The LEWI NPSpecies dataset is a compendium of previous botanical work and has been certified by Park staff. Specimens contained at the University of Washington Burke Museum and the Oregon State University Herbarium were queried using the Consortium of Pacific Northwest Herbaria's online database. Observations were collected in the field in 2009 and 2010 and also queried from the NPSpecies database. Reported taxa were queried from the NPSpecies database.

Appendix B lists potentially occurring, but unconfirmed taxa that have a) been reported but not documented within the park or b) have been found in neighboring areas or in units that are not part of the legislative boundary of Lewis and Clark National Historical Park.

Appendix C lists taxa rejected from the park list due to false or questionable reports.

Appendix D lists the same confirmed taxa as Appendix D but describes habitat use in the park and is organized by life form rather than family in order to better meet the needs of NPS interpretive specialists.

The codes and abbreviations for each field in the appropriate appendices are summarized below.

Family, Species Name (Appendices A, B, C, and D)

Family and species nomenclature and concepts follow the Integrated Taxonomic Information System (ITIS), except where recent taxonomic changes were incorporated following the Flora of North America.

Synonyms/Taxonomic Notes (Appendices A, B, and C)

Pertinent synonyms are listed for taxa with alternative names in local flora or commonly used historical names.

Common Name (Appendices A, B, C, and D)

Common names are derived mainly from the USDA PLANTS database and ITIS.

Nativity (Nat) (Appendices A and D)

Nativity indicates whether a species is native (Nat) to Oregon and/or Washington (academically accepted as naturally occurring in the Pacific Northwest for hundreds or thousands of years) or non-native (Non) (introduced through human interference in recent, post-European settlement

This report has had confidential information regarding species of management concern locations removed.

history). Nativity is based on the Oregon Flora Project and the USDA PLANTS database. Native hybrid (Nat Hybd) is used to denote hybrid plants determined to be native.

Life Form (Appendices A, B, and D)

Life form was obtained from the USDA PLANTS database. Trees (Tree) are woody perennials, normally with a single stem growing to greater than four meters. Shrub (Shr) refers to a woody perennial with multiple stems, usually not growing to greater than four meters. Subshrubs (Sub) are woody perennials with multiple stems not growing to more than one-half meter in height. Forb/herbs (Forb) are non-woody perennials, annuals, or biennials. This classification includes ferns, horsetails, lycopods, and whisk-ferns but excludes graminoids. Graminoids (Gram) are grasses or grass-like plants, including grasses, sedges, rushes, quillworts, and arrow-grasses. Vines (Vine) are climbing or twining plants with relatively long stems that may or may not be woody. Where a plant can display characteristics of multiple life forms, these are listed and separated by commas.

Duration (Dur) (Appendix A)

Duration refers to the lifespan of the species. Annual (Ann) species live for one year or season only. Biennial species (Bien) may live for two years. Perennial (Per) species persist for several years.

Range (Appendices A, B, and C)

Range represents the distribution of the species in northwest Oregon and southwest Washington and the relation to its distribution in North America. Range distribution was determined primarily by the Biota of North America Program and the Oregon Flora Project. Nativity was not taken into account when determining range; this field reports how widely a species is found, whether or not it evolved here or was introduced from its native range. Wide (Wide) ranging taxa are present in at least 10% of Oregon and Washington and are also found in neighboring states. Regional (Reg) ranging taxa is only found in the Pacific Northwest (may include parts of Canada and Alaska). Local (Loc) taxa in only found in southwest Washington and/or northwest Oregon (defined as about a 150-mile radius from the extreme northwest and southwest tips of Oregon and Washington). Disjunct (Disj) taxa is one that is found in Oregon or Washington and is not found in adjacent states, but is present in other areas of North America. Lastly cultivated (Cul) taxa are present in the park but are a garden or ornamental plant that was intentionally planted.

Park Status (Appendices A and D)

Park Status denotes the present status of the taxa in the park. Present (Pres) taxa were recently (since 1970) confirmed to be occurring in the park. Historical (Hist) taxa were documented from before 1970 but have not since been observed. Reported (Rep) taxa were noted in official reports but have not been confirmed by observation or voucher. Unconfirmed (Uncon) taxa have been noted anecdotally or found in nearby locales, but have not been documented in the park.

This report has had confidential information regarding species of management concern locations removed.

Population Size (Appendix A)

Population size describes the abundance and frequency of a species in the park. Abundance information was queried from the NPSpecies database and based on personal observation. Abundant (Abun) taxa have large populations and are often key components in one or more vegetation types, or are widely distributed across the park. Common (Com) taxa have large populations but may be restricted in their habitats or only occur in a few locations in the park. Uncommon (Unc) taxa have small to medium sized populations and are found in few vegetation communities or have a low occurrence in several community types. Rare (Rare) taxa have low populations within the park and are not often encountered. Taxa that were present historically but that do not have an extant population within the park are noted as (NA), not applicable.

Source (Appendix A)

Source gives a reference for the assigned park status. These are Park staff, associated contractors, researchers, and accredited databases reporting documented species occurrences within the park.

Year Doc. (Appendix A)

Year documented is the year the species status within the park was confirmed or reported. This does not indicate the year the first documented specimen was collected, which may be a much earlier date.

Comments (Appendices B and D)

Comments give more detail or speculation about the status of a species in the park, or speculation on its status.

Flower time (Appendix D)

Flower time refers to the months or seasons when a species is most likely to be in flower. Indeterminate or insufficient is given when a species' phenology is not determined. Non-flowering is given for species with spores, e.g. ferns and horsetails. Gymnosperms, while not flowering plants, are given a flower time for when their pollen is generally released. The main source for flower time was the USDA PLANTS database.

Habitat (Appendix D)

The distribution of species across a generalized set of habitats is denoted by an 'x' in the columns for habitats where that species occurs, based on observations in the field and general literature. The habitat types are: Headland/Sea cliff, Dune/Deflation Plane/Meadow (includes beaches and weedy grasslands but not manicured lawn areas), Lowland Forest, Estuary/Wetland (includes aquatics, salt marsh species), and Disturbed/Developed (includes roadsides, campgrounds, lawns, etc).

Appendix B. Potential (unconfirmed) taxa of Lewis and Clark National Historical Park.

Family	Species name	Synonyms	Common name	Park Status	Comments
Asteraceae	<i>Adenocaulon bicolor</i>		American trailplant	Uncon	Reported from Ft Columbia
Brassicaceae	<i>Capsella bursa-pastoris</i>		shepherd's purse	Uncon	Observed in Fort Stevens
Cyperaceae	<i>Carex aquatilis var. dives</i>	<i>Carex sitchensis</i>	Sitka sedge	Uncon	Reported to be at Cape Disappointment
Fabaceae	<i>Lupinus rivularis</i>		riverbank lupine	Uncon	Collected at Fort Stevens
Fabaceae	<i>Trifolium campestre</i>		Field (Big-hop) clover	Uncon	In BONAP database
Fabaceae	<i>Vicia villosa</i>		winter vetch	Uncon	On 1972 Fort Clatsop species list
Hydrocharitaceae	<i>Myriophyllum subspicatum</i>		Eurasian watermilfoil	Uncon	Reported to be at Cape Disappointment
Hydrophyllaceae	<i>Hydrophyllum occidentale</i>		squaw-lettuce	Uncon	On 1972 Fort Clatsop species list
Onagraceae	<i>Epilobium brachycarpum</i>		autumn willowherb	Uncon	In BONAP database
Ranunculaceae	<i>Ranunculus occidentalis</i>		western buttercup	Uncon	On 1972 Fort Clatsop species list
Rosaceae	<i>Prunus laurocerasus</i>		cherry laurel	Uncon	Collected at Fort Stevens

This report has had confidential information regarding species of management concern locations removed.

Appendix C. Rejected (falsely reported or questionable) taxa of Lewis and Clark National Historical Park.

Family	Species name	Synonyms	Common name	Life form	Comments
Alismataceae	<i>Alisma plantago-aquatica</i>		European water plantain	Forb	mis-ID of <i>Alisma triviale</i>
Caryophyllaceae	<i>Stellaria humifusa</i>		saltmarsh starwort		mis-ID of <i>Stellaria calycantha</i>
Ericaceae	<i>Vaccinium alaskaense</i>		Alaska huckleberry	Shrub	Specimens are actually <i>V. ovalifolium</i> ; definition of species has changed.
Juncaceae	<i>Luzula campestris</i>		field woodrush	Gram	Re-alignment of species. Previously noted for Park as <i>L. campestris</i> var. <i>congesta</i> , which is synonymous with <i>L. congesta</i> .
Rosaceae	<i>Prunus subcordata</i>		Klamath plum	Tree	Falsely reported from Fort Clatsop

This report has had confidential information regarding species of management concern locations removed.

Appendix D. Confirmed, historical, and reported taxa of Lewis and Clark National Historical Park, organized by life form with ecological notes

Family	Species name	Common name	Nat	Life form	Park stat	Flower time	Headlnd/ Sea cliff	Dune/ Mdw	Lowland Forest	Estry/ Wtlnd	Dist/ Dev
Aceraceae	<i>Acer circinatum</i>	vine maple	Nat	Tree, Shr, Vine	Pres	Spring			x		
Aceraceae	<i>Acer macrophyllum</i>	bigleaf maple	Nat	Tree	Pres	Mid Spring			x		
Aceraceae	<i>Acer platanoides</i>	Norway maple	Non	Tree	Pres	Early Spring			x		x
Alismataceae	<i>Alisma triviale</i>	northern water-plantain	Nat	Forb	Pres	Mid Summer				x

Appendix G. Maps of non-native species of interest by unit.

Non-Native Plants, Cape Disappointment

Non-Native Plants, Dismal Nitch

Legend

- | | |
|-----------------------|----------------------|
| ○ Herb robert | ● Purple loosestrife |
| ● English ivy | ○ Japanese knotweed |
| ● English holly | ● Fig buttercup |
| ○ Yellowflag iris | ● Gorse |
| ● Everlasting peavine | ■ Purple loosestrife |
| ● Bachelor's button | ■ Yellowflag iris |

Non-Native Plants, Fort Clatsop

Legend

- | | | |
|-----------------------|-------------------------------|------------------------|
| ● Canada thistle | ● Parrot feather watermilfoil | ■ Cutleaf blackberry |
| ○ Herb robert | ● Common reed | ■ Himalayan blackberry |
| ● English ivy | ● European mountain ash | ■ Scots broom |
| ● English holly | ○ European honeysuckle | |
| ○ Yellowflag iris | ● Purple loosestrife | |
| ● Everlasting peavine | | |

Non-Native Plants, Fort Stevens

Legend

- | | |
|------------------------|----------------------|
| ○ Herb robert | ● Purple loosestrife |
| ● English ivy | ● Common reed |
| ● English holly | ● Giant knotweed |
| ● Yellowflag iris | ● Knotweed sp. |
| ○ European honeysuckle | |

This report has had confidential information regarding species of management concern locations removed.

Non-Native Plants, Station Camp, Fort Columbia

Non-Native Plants, Sunset Beach/Yeon

Legend

- | | |
|------------------------|-------------------------------|
| ● Canada thistle | ● Parrot feather watermilfoil |
| ● English ivy | ○ American white waterlily |
| ● English holly | ■ Spurge laurel |
| ○ European honeysuckle | |

The Department of the Interior protects and manages the nation's natural resources and cultural heritage; provides scientific and other information about those resources; and honors its special responsibilities to American Indians, Alaska Natives, and affiliated Island Communities.
