PICTURED KEY TO SOME COMMON FILAMENTOUS RED ALGAE OF SOUTHERN AUSTRALIA PART II (2ND EDITION): ALGAE WITH WHORL-BRANCHLETS OVERLAPPING, RHIZOIDAL COVERING DENSE

Red Algae.	With some 800 species, many of which are endemic
	(found nowhere else), southern Australia is a major
	centre of diversity for red algae. Classification is based
	on detailed reproductive features. Many species
	unrelated reproductively have similar vegetative form
	or shape, making identification very difficult if the
	technical systematic literature is used.
This key	Fortunately, we can use this apparent problem to
	advantage - common shapes or morphologies will
	allow you to sort some algae directly into the level of
	genus or Family and so shortcut a systematic search
	through intricate and often unavailable reproductive
	features. The pictured key below uses this artificial
	way of starting the search for a name. It's designed to
	get you to a possible major group in a hurry. Then you
	can proceed to the appropriate fact sheets within this
	website.
Scale:	the coin used as a scale is 24mm or almost 1" wide.
	Microscope images of algae are usually blue stained.

This key is restricted to algae with

- *threads* (filaments) of cells, growing in a single line (*uniaxial* algae)
- no compact wrappings (cortication) of regularly arranged (pericentral) cells around at least main branches, although there may be a dense, loose sheaths of rhizoids
- long main branches (axes) with rings of short side branches (whorl-branchlets)

This includes Tribes in the Ceramiaceae such as the Crouanieae, Wrangelieae and Dasyphileae. It excludes algae with cortication so complete that the thread or filamentous construction is completely obscured. This latter group is covered in Part I a separate pictured key containing algae with overlapping whorl-branchlets forming a continuous, loose axial sheath.

Part II, the key below, contains algae with well-separated, whorl-branchlets and is largely based on that in the Flora of southern Australia, volume IIIC

- 2a. side branches *opposite* on main axes, irregular in whorl-branchlets which consist of long, thin filaments, giving the whole plant a woolly appearance. Tetrasporangia divided in a cross pattern (cruciate) or in 2 opposite pairs (decussate). Figs 1-3
- 3a. main axes with 4-5 irregularly branched, overlapping whorl-branchlets per axis cell, producing a fluffy effect; axes thickly coated with rhizoids. Figs 4-9 Tribe: Wrangelieae (Wrangelia: 5 species)
- 3b. main axes and branches initially with *2 opposite* alternately branched whorl-branchlets per axis cell, rapidly obscured by rhizoids Figs 10-13Tribe: Lasiothalieae (1 species, next page)

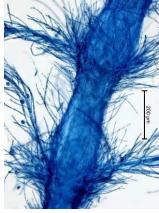

Fig. 3: Warrenia comosa, tetrasporangia in a whorlbranchlet

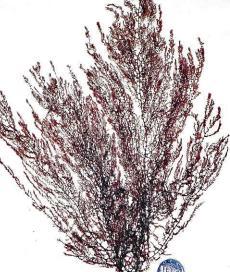

Fig. 4.: Wrangelia nobilis

Fig. 5: Wrangelia nobilis overlapping whorl-branchlets producing a "fluffy" effect

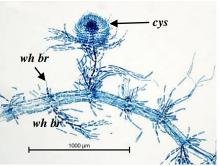

Fig. 6.: Wrangelia penicillata with relatively exposed whorl-branchlets (wh br) and terminal female structure (cystocarp, cys)

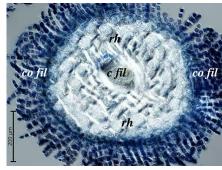

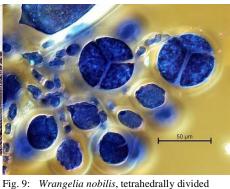

Fig. 7: Wrangelia nobilis, cross section: mass of rhizoids (rh) wrapped around central filament, (c fil) producing short chains of cells (cortical filaments, co fil)

Fig. 8: Wrangelia nobilis, branch tips

Wrangelia nobilis, tetrahedrally divided tetrasporangia in delicate branch clusters within whorl-branchlets

Fig. 10: Lasiothalia hirsuta

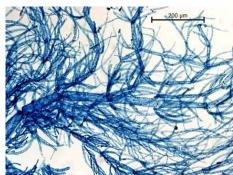

Fig. 11: Lasiothalia hirsuta, near a branch tip showing exposed opposite pairs of whorl-branchlets

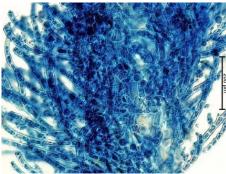

Fig. 12: Lasiothalia hirsuta, main axis densely wrapped in rhizoids and curved, branched filaments

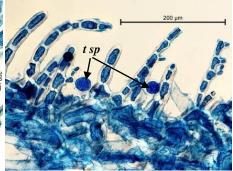

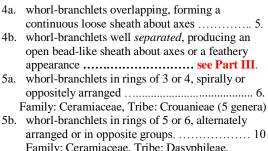

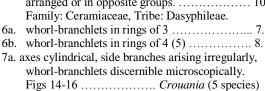

Fig. 13: Lasiothalia hirsuta, axis edge densely wrapped in branching rhizoids; tetrahedrally divided sporangia (t sp) in protruding

7b. axes flattened, side branches flat-branched (pinnate), whorl branchlets embedded in thin, strap-like fronds. Figs 17-19

Fig. 14: Crouania mucosa

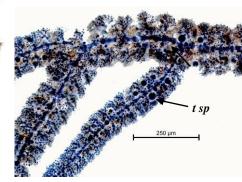

Fig. 15: *Crouania shepleyana*, overlapping whorlbranchlets; tetrasporangia (*t sp*)

Fig. 17: Gattya pinella

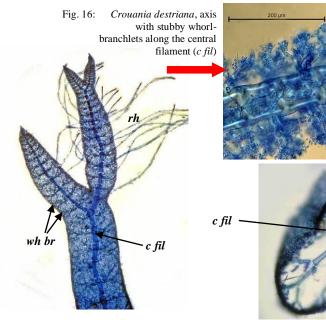

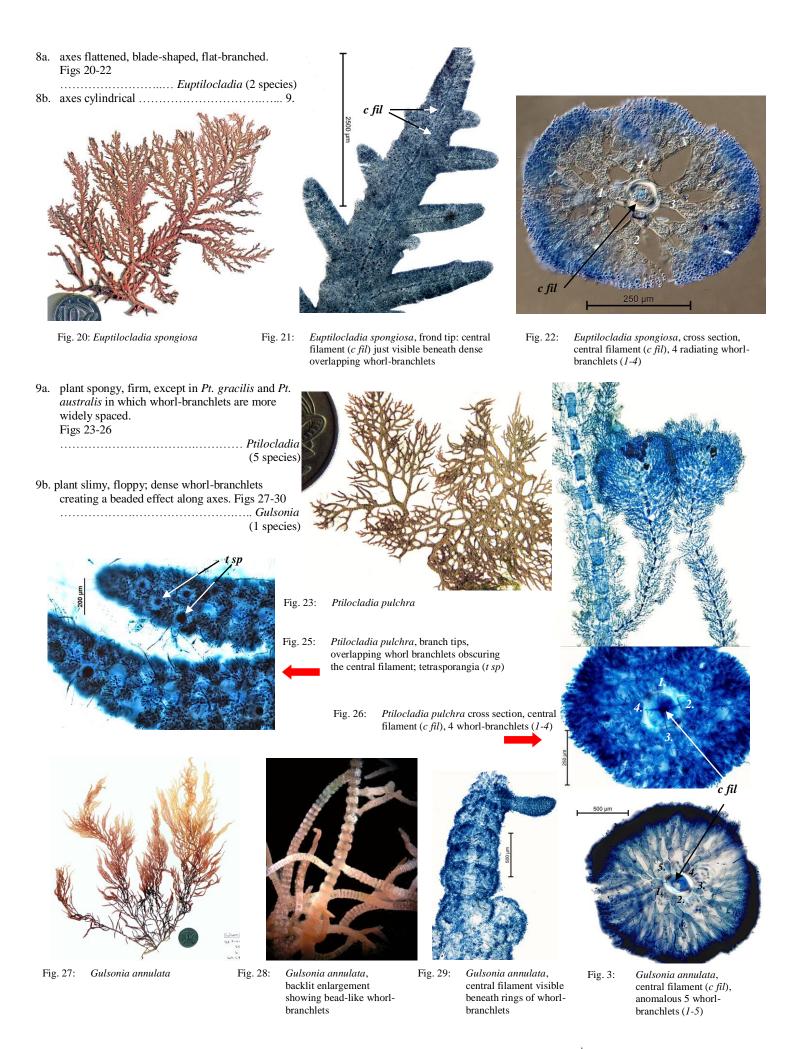

Fig. 18: *Gattya pinella*, blade tip, central filament (*c fil*), whorl branchlets (*wh br*) beneath surface cells, rhizoids (*rh*)

Fig. 19: Gattya pinella cross section, central filament (c fil), whorlbranchlets (1-3s)

Baldock, R. N. (2019). Pictured key to some common filamentous red algae of southern Australia. Part II. 2nd edition. 4 pp. *Algae Revealed*.: State Herbarium of South Australia. flora.sa.gov/algae_revealed

10a. axis cells with rings of 6 whorl-branchlets; sporangia at tips of short filaments. Figs 31-34 Dasyphila preissii

10b. axis cells with rings of 5 whorl-branchlets; sporangia stalkless within lower parts of whorlbranchlets. Figs 35-38

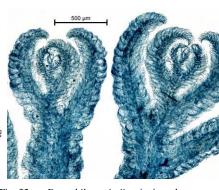

Fig. 32: Dasyphila preissii, axis tips, alternate branches reaching the same height

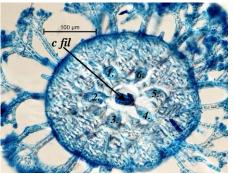

Fig. 33: Dasyphila preissii: cross section, central filament (c fil), origin of whorlbranchlets (1-6) within a mass of rhizoids

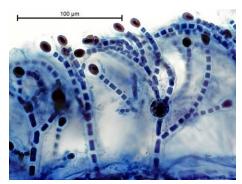

Fig. 34: Dasyphila preissii, sporangia (some as yet undivided) at tips of whorl-branchlets

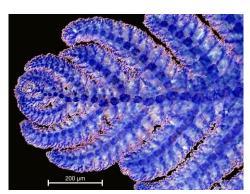

Fig. 36: Muellerena wattsii, axis tip

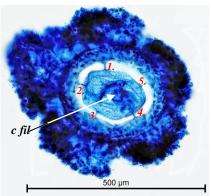

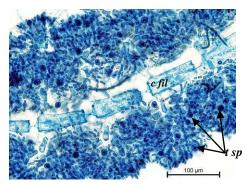

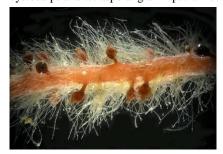

Fig. 37: Muellerena wattsii cross section, central Fig. 38: filament (c fil), origin of whorl-branchlets (1-5)

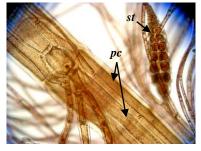

Muellerena wattsii, tissue squash exposing the central filament (c fil), dense whorl-branchlets stalkless tetrasporangia (t sp) within

Look-alike algae

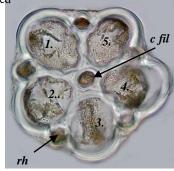

Some *Dasya* and *Doxodasya* species have a central filament and hair-like tufts (trichoblasts), but close inspection shows they have blocks of closely-fitting sheath (pericentral) cells, flask-shaped cystocarps and tetrasporangia in specialized branches (stichidia) and belong elsewhere

Dasya extensa: stalked, flask-shaped cystocarps; dense hairy trichoblasts

Doxodasya hirta: blocks of pericentral cells (pc) on axes; lance-shaped branch (stichidium, st) bearing tetrasporangia

Doxodasya hirta cross section: central filament (c fil); pericentral cells (1-5); rhizoids (rh)
