

## Electronic Supplement

**Zonnveld BJM (2019) The DNA weights per nucleus (genome size) of more than 2350 species of the Flora of The Netherlands, of which 1370 are new to science, including the pattern of their DNA peaks. Forum geobotanicum 8: 24–78**

**Table 5** (next page)

Table 5 gives an overview of all over 6400 plants measured. It contains the Latin name, DNA weight and peak pattern, as in Table 1, with a summary of more than 2350 species. In addition, the following information has been added to these basic data: the collecting sites, the measured plant part, the number of the experiment, the date of the measurement, the voucher number and the name of the collector. The latter are indicated by a three-letter code for the florists participating (usually one letter of the first name + two first letters of the surname) as shown below. The names of the cooperating florists were largely filled in halfway through the study. It is possible that the authors name (BZO) was afterwards accidentally entered where it should not belong.

For some genera that have been published earlier, a summary only is given, insofar as these species occur in The Netherlands: *Conifers s.l.*, *Ficaria*, *Gagea*, *Galanthus*, *Helleborus*, *Narcissus* and *Tulipa*. Of other not yet published genera, only those species found in The Netherlands are shown: *Erigeron*, *Fritillaria*, *Hieracium*, *Dryopteris* and other ferns, *Leucojum*, *Plantago*, *Rubus*. This explains why in Table 1 a larger number of plants measured is counted, almost 7000, than in Table 5 with more than 6400 plants measured. In addition, Table 5 does not include all measurements made earlier with the Partec device as many data, like peak profiles, were not recorded at that time.
