#### ABSTRACT

A morphological study of 38 species of *Baccharis* used in traditional medicine was carried out to provide some epidermal characters that will contribute to the knowledge of the genus. The present study revealed: 1) seven different types of trichomes: conical, aseptate flagellate, filiform flagellate, 1-armed, 2-4-armed, bulbiferous flagellate, and glandular biseriata; 2) that 28 of the total of 38 species have trichomes in tufts; 3) six different types of stomata: anomocytic, anisocytic, cyclocytic, actinocytic, tetracytic, and staurocytic; 4) that some trichome types, such as 2-4-armed (*B. dracunculifolia*) and aseptate flagellate branched (*B. trinervis*), show a high diagnostic value; 5) that the stomata types can be used to differentiate species with similar trichomes type (e.g. *B. trimera* and *B. articulata*). Illustrations of the studied characters are provided.

**Key words.** *Baccharis*, Compositae, medicinal species, stomata, trichomes.

#### RESUMEN

Se realizó un estudio de caracteres epidérmicos de las hojas de las 38 especies de *Baccharis* usadas en la medicina popular. El análisis de los caracteres revela: 1) siete tipos de tricomas: cónicos, flageliforme aseptados, filiformes flagelados, 1-armados, 2-4-armados, bulbíferos flagelados y glandulares biseriados; 2) que 28 especies del total de 38 especies medicinales estudiadas presentan tricomas en "nidos pilosos"; 3) que seis tipos de estomas están presentes: anomocíticos, anisocíticos, ciclocíticos, actinocíticos, tetracíticos y estaurocíticos; 4) que algunos tricomas muestran un alto valor diagnóstico, por ejemplo, los tricomas 2-4-armados son exclusivos de *B. dracunculifolia* y los flagelados-aseptados ramificados están presentes sólo en *B. trinervis*; 5) que los tipos de estomas permiten la diferenciación de especies con igual tipo de tricoma, (por ejemplo *B. trimera* de *B. articulata*). Se incluyen ilustraciones de los caracteres diagnósticos.

**Palabras clave.** *Baccharis*, Compositae, especies medicinales, aparatos entomáticos, tricomas.

## INTRODUCTION

*Baccharis* L. is one of the largest genera of the tribe Astereae (Nesom, 1994). It comprises c. 400 American species of shrubs or subshrubs, occasionally small trees and herbs, nearly all dioecious.

According to Zin (1922), Amat (1983), Zardini (1984), Girault (1987), Boldt (1989), Correa & Bernal (1990), Iharlegui & Hurrell (1992), Soria (1993), Heinrich (1996), Rojas *et al.* (1999), Pérez-García *et al.* (2001), Erazo *et al.* (2002), Baggio *et al.* (2003), Vidari *et al.* (2003), Souza (2004), and a recent webpage (Harding-Barlow), 38 medicinal species of *Baccharis* with folk medicinal use (or mentioned at least as medicinal herbs) are recognized (Table 1); many of these species can be distinguished by their leaf or winged stem morphology (Appendix 1). In 22 of these species biological activity was tested (Gutkind *et al.* 1981, Vidari *et al.* 2003, Verdi *et al.* 2005). *Baccharis megapotamica* and *B. pedunculata* are also included in this study since they can be considered promisory medicinal species judging from their tested biological activity (Verdi *et al.* 2005).

Heering (1899), Volkens (1890), Quentin (1911), Ariza Espinar (1973), Barroso (1976), Pertusi (1987), Hellwig (1990, 1992), Müller (2006) and, are among authors who have contributed most to the solving taxonomic problems through the analysis of micromorphology of leaf surface in *Baccharis*.

Epidermal traits, i.e. epidermal cells, stomata, and hairs, have proven to be an important tool in taxa delimitation in many plant families (e.g. Lackey 1978, Metcalfe & Chalk 1950-1979, Sinclair & Sharma 1971, Uphof *et al.* 1962), and also in distinguishing medicinal species since

drugs of pharmaceutical use are made up of dried and bruised parts in which the different macroscopical characteristics of the species are not generally distinguishable (e.g. Amat, 1988; Rapisarda *et al.*, 1997). Within this context, this study pretend to contribute to the knowledge of the medicinal species of the genus *Baccharis*.

## MATERIAL AND METHODS

The study was performed using dried leaves or winged stems (if only bract-like leaves are present) taken from herbarium specimens (Appendix 2). Accepted names, synonyms, vernacular names, distribution, medicinal uses, and biological activity for each studied species are given in Table 1.

The epidermal microcharacters were studied in samples cleared using the technique of Dizeo de Strittmatter (1973), and stained using safranin in 80% ethanol. Measurements of stomata (length) were taken using a Nikon light microscope equipped with an ocular micrometer. The average size of stomata was determined based on measurements performed on 15-20 replicates per sample.

Descriptive terminology for the trichomes basically follows Ramayya (1962). Whenever possible, additional synonyms of trichome terminology were added (Ariza Espinar 1973, Metcalfe & Chalk 1989, Müller 2006). The classification of anticlinal epidermal cell wall patterns follows Stace (1965). Stomata types were classified according to Stace (1965), Van Cotthem (1970), Metcalfe & Chalk (1979). The nomenclature of the included species follows Matuda (1957), Cuatrecasas (1967), Ariza Espinar (1973), Barroso (1976), Giuliano (2000) and Oliveira *et al.* (2006). Drawings were made by the authors using a microscope Leitz SM Lux with *camera lucida*.

**Table 1.** Distribution, vernacular names, folk medicinal uses and tested biological activity of *Baccharis* species. AN = Antilles; AR = Argentina; BO = Bolivia; BR = Brazil; CH = Chile; CO = Colombia; CR = Costa Rica; EC = Ecuador; ES = El Salvador; GU = Guatemala; HO = Honduras; ME = Mexico; NC = Nicaragua; PA = Paraguay; PE = Peru; PN = Panama. UR = Uruguay; US = United States; VE = Venezuela.

Species	Distribution	Vernacular name	Folk medicinal use	Tested biological activity
<i>Baccharis anomala</i> DC. <i>Pingraea anomala</i> (DC.) F.H. Hellwig	AR, BR, PA, UR	--	vagina and wounds wash, general infections (Souza, 2004)	--

## RESULTS AND DISCUSSION

### Epidermal characters (Table 2)

*Leaf pubescence.* All studied species of *Baccharis* are pubescent (only a few, e.g. *B. dracunculifolia* and *B. trinervis* are subglabrous at maturity). Two major groups of indumentum can be distinguished within the medicinal species, one consisting of isolated trichomes and the other with trichomes in tufts (= “nidos pilosos”, Ariza Espinar, 1973; = “Haarnester”, Hellwig 1992).

Seven different types of trichomes were found:

(1) *Conical trichomes*: uniseriate, 5-6-celled with body gradually narrowed to a sharp point. Cells longer distally, often nodulose at the joints. Lateral and cross walls slightly thickened. This trichome type is present in *B. anomala* and *B. decussata*. (Fig. 1 A). Similar trichomes were illustrated by Müller (2006) for *B. decussata* subsp. *jelskii* (sub “pedestal hair”) and by Ariza Espinar (1973) for the non-medicinal *B. pulchella*.

(2) *Aseptate flagellate trichomes* (or whip trichomes, Metcalfe & Chalk 1989): uniseriate, 2-3-celled with body differentiated in stalk and a long, whip-like terminal cell. Stalk 1-2-celled, cells usually isodiametrical or broader than long.

(2) (a) *Simple*: terminal cell very long, flagellate, tubular, as wide as the cells of the stalk. This trichome type is present in *B. artemisioides* and *B. grisebachii* (Fig. 1 E), which have discolorous leaves with white-lanate abaxial surface. Trichomes of *B. artemisioides* were previously analyzed and illustrated by Ariza Espinar (1973) and Pertusi (1987). The aseptate flagellate trichomes of *B. grisebachii* were illustrated by Hellwig (1992) and by Müller (2006), sub “flagellate filiform” and “filiform hair” respectively.

(2) (b) *Branched*: three to five whip trichomes (with stalk 1-4-celled) appearing

stellately branched from the only stalk cell. This trichomes type is present isolated only in *B. trinervis* (Fig. 1 B).

(3) *Filiform flagellate trichomes*: uniseriate, many-celled, body filiform to cylindrical and slightly tapering above. Cells usually broader than long, isodiametrical, or slightly longer than broad, with lateral walls convex. Terminal cell relatively short, tail-like and pointed (*B. multiflora*, *B. serrifolia* and *B. wrightii*, in the latter the trichomes are only found on the stem, Fig. 1 C) or pear-like and rounded at the apex (*B. megapotamica*, Fig. 1 D); those with tail-like apical cell can be straight or incurved. Dense contents have been seen in the terminal cell of these trichomes, which probably have secretory function.

(4) *1-armed trichomes*: uniseriate, 3-4-celled, with body differentiated into stalk and head. Stalk 2-3-celled, cells usually broader than long, lateral walls straight. Head 1-celled (occasionally branched at the base), with thick lateral and cross walls and pointed or rounded at the apex. This trichome type is present forming tufts or pilose nests only in *B. crispa* (Fig. 1 F). It was previously analyzed and illustrated by Ariza Espinar (1973) for *B. crispa*. Hellwig (1992) found trichomes 1-armed in a non-medicinal species, *B. rhomboidalis* and also in *B. macraei* and *B. pilcensis* (Hellwig, 1990).

(5) *2-4-armed trichomes*: uniseriate, 4-5-celled, with body differentiated into stalk and head. Stalk 3-4-celled, cells broader than long with lateral walls convex. Head 1-celled, cell 2, 3 or 4-branched (falls/collapsing at maturity). This trichome type is present forming tufts or pilose nests (associated or not to glandular trichomes) only in *B. dracunculifolia*. (Fig. 1 G). Müller (2006) described and illustrated these trichomes of *Baccharis dracunculifolia* as “uniseriate hairs with branched terminal cells”. Hellwig (1992) found 4-armed trichomes in a non-medicinal species *B. erioclada*.

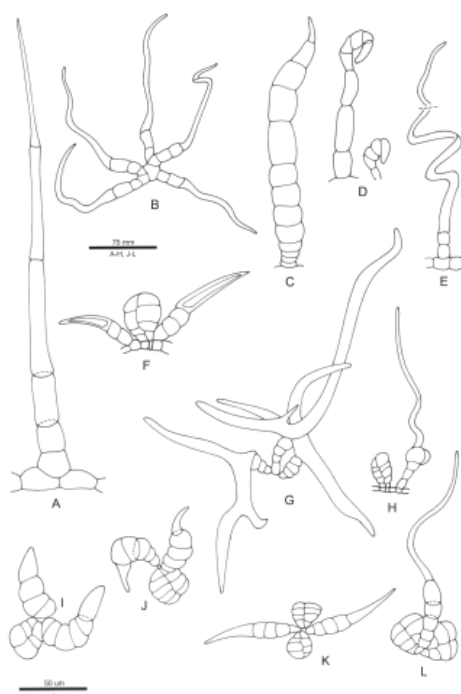

**Table 2:** Epidermal characters

**Trichomes isolated or paired**

Trichomes conical		Trichomes a septate flagellate		Trichomes filiform flagellate	
Trichomes glandular present	Trichomes glandular absent	branched	simple	Trichomes with apical cell pear-like	Trichomes with apical cell tail-like
<i>B. decussata</i>	<i>B. anomala</i>	<i>B. trinervis</i>	<i>B. artemisioides</i> <i>B. grisebachii</i>	<i>B. megapolamicca</i>	<i>B. multiflora</i> <i>B. serrifolia</i> <i>B. wrightii</i>

**Trichomes in tufts**

Trichomes 2-4-armed		Trichomes 1-armed		Trichomes bulbiferous flagellate subtype c									
<i>B. dracunculifolia</i>		<i>B. crispa</i>		Apical cell triangular		Apical cell tail-like		Stomata large: 75-100µm long		Stomata medium: (35) 40-60 µm long		Stomata small: 20-30 µm long	
Stomata cyclocytic		Stomata cyclocytic		Stomata actinocyctic		Stomata actinocyctic		Stomata anomocyctic		Stomata cyclocytic		Anticlinal epidermal cell walls sinuate	
<i>B. articulata</i>		<i>B. heterophylla</i>		<i>B. conferta</i>		<i>B. linearis</i>		<i>B. douglasii</i>		<i>B. genistelloides</i>		<i>B. pentlandii</i>

**Figure 1. Trichomes.-** A-E, Isolated trichomes. A: conical, *B. anomala*; B: aseptate flagellate branched, *B. trinervis*; C and D, Filiform flagellate. C: *B. multiflora*; D: *B. megapotamica*; E: aseptate flagellate simple, *B. artemisioides*; F-L, Tufted trichomes (“pilose nest”) of eglandular trichomes and biseriate glandular trichomes. F: 1-armed trichome, *B. crispa*; G: 2-4-armed trichomes, *B. dracunculifolia*; H: bulbiferous flagellate, subtype a, *B. boliviensis*; I and J, Bulbiferous flagellate, subtype b. I: *B. notoserghila*; J: *B. teindalensis*; K and L, Bulbiferous flagellate, subtype c. K: *B. pedunculata*; L: *B. tola*.

(6) *Bulbiferous flagellate trichomes*: uniseriate, 5-6-celled, usually forming tufts or pilose nests with glandular trichomes. According to the number of subapical cells and the length of the apical cell, three subtypes can be distinguished:

*Subtype a*: body differentiated into stalk and head. Stalk 2-3-celled, cells slightly

longer than broad or isodiametrical, terminal cells of the stalk 2, swollen, spherical or oblong-ovoid in shape. Head 1-celled, long, flagellate. This trichome type is present only in *B. boliviensis*. (Fig. 1 H). Similar trichomes are also present in the unrelated non-medicinal *B. pingraea* (Hellwig, 1992).

*Subtype b*: body with cells usually enlarging above, resulting cuneate in shape. Terminal cell short with dense contents, broadly triangular (broadly triangular in *B. notoserghila* or narrowly triangular in *B. articulata*, *B. gaudichaudiana*, and *B. trimera*) or more often tail-like, i.e. sharply delimited from the subapical cell (*B. conferta*, *B. heterophylla*, *B. pilularis*, *B. teindalensis*, *B. tricuneata*, *B. vaccinioides*). (Fig. 1 I, J). Trichomes of *B. articulata* and *B. trimera* were previously analyzed and illustrated by Pertusi (1987). Hellwig (1992) found trichomes with tail-like apical cell in the unrelated non-medicinal *B. paniculata*.

*Subtype c*: this type represents a modification of the *subtype a* with a differentiated head constituted by a flagellate cell, equal or longer than body, tapering above. This trichome type is present as isolated trichomes in three species, *B. anomala*, *B. coridifolia*, and *B. trimera*, and forms tufts or pilose nests in 16 of the 38 studied species. (Fig. 1 K, L). Bulbiferous trichomes with flagellate apical cell of the medicinal species *B. linearis* and *B. salicifolia* were previously illustrated by Ariza Espinar (1973) and Hellwig (1992) respectively. Müller (2006) illustrated for *B. coridifolia* two types of trichomes, i.e. bulbiferous flagellate subtype b (*sub* “uniseriate hairs”) and aseptate flagellate (*sub* “filiform hairs”).

(7) *Biseriate glandular trichomes*: such trichomes are constituted by 2 rows of cells in the body. Biseriate glandular trichomes are widespread in many taxa studied. They form tufts with non-glandular trichomes;

occasionally, tufts are constituted exclusively by two or three glandular trichomes (e.g. *B. vaccinioides*).

**Stomata** (Fig. 2): eleven species (*B. boliviensis*, *B. conferta*, *B. linearis*, *B. nitida*, *B. odorata*, *B. pilularis*, *B. salicifolia*, *B. sarothroides*, *B. teindalensis*, *B. tola*, and *B. tricuneata*) have actinocytic stomata (Fig. 2 A, B), with five to seven subsidiary cells radially. One species (*B. crispa*) has anisocytic stomata (Fig. 2 C), with three subsidiary cells, of which one is smaller than the other two. Six species (*B. articulata*, *B. gaudichaudiana*, *B. genistelloides*, *B. heterophylla*, *B. illinita*, and *B. notoserigila*) have cyclocytic stomata (Fig. 2 E, F), with four to seven subsidiary cells forming a narrow ring. In three species (*B. boliviensis*, *B. conferta*, *B. salicifolia*) with predominantly actinocytic stomata, a few tetracytic stomata are present (Fig. 2 B), which have four subsidiary cells, two lateral and two polar. Only one of this species (*B. conferta*) has also staurocytic stomata (Fig. 2 A), with four subsidiary cells with anticlinal walls arranged crosswise to its guard cells. The remaining species have anomocytic stomata (Fig. 2 D, G).

Cyclocytic stomata in *B. articulata*, anisocytic stomata in *B. trimera*, and anomocytic stomata in *B. artemisioides* were previously reported by Pertusi (1987). Ariza Espinar (1973) analyzed and illustrated actinocytic stomata in *B. salicifolia* (anomocytic *sensu* Ariza Espinar), anomocytic stomata in *B. coridifolia*, and anisocytic stomata in *B. crispa* (anomocytic *sensu* Ariza Espinar).

The majority of the species have stomata between 20 to 60  $\mu\text{m}$  long. In only three species the stomata are more than 60  $\mu\text{m}$  long, i.e. *Baccharis articulata* and *B. gaudichaudiana*, between 60 to 75  $\mu\text{m}$  long, and *B. illinita* with stomata between 75 to 105  $\mu\text{m}$  long.

Most of the species analyzed have amphistomatic leaves, only twelve species,

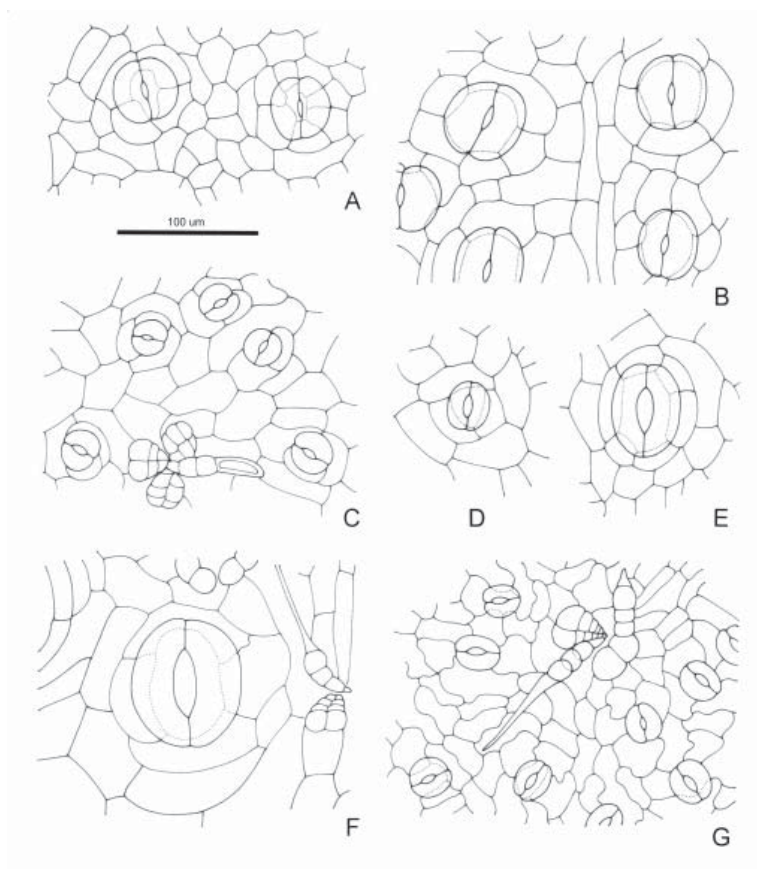

i.e. *Baccharis anomala*, *B. decussata*, *B. dracunculifolia*, *B. grisebachii*, *B. heterophylla*, *B. illinita*, *B. latifolia*, *B. megapotamica*, *B. multiflora*, *B. pedunculata*, *B. serrifolia*, and *B. trinervis*.

**Anticlinal epidermal cell walls** (on abaxial surface): only three species (*B. anomala*, *B. decussata*, and *B. pentlandii*) amongst the medicinal species, have sinuate anticlinal wall (Stace's types 5-6). The remaining species have straight to slightly undulate anticlinal walls (Stace's types 1-2).

## CONCLUSIONS

Certain anatomical characters allow to the distinction of medicinal species of *Baccharis*. For example: 1) *B. trinervis* is recognized from other medicinal species by its branched aseptate flagellate trichomes that are unique within the whole genus; 2) filiform trichomes with pear-like apical cell are exclusive of *B. megapotamica*; 3) only two species, among medicinal species, *B. artemisioides* and *B. grisebachii*, have aseptate flagellate trichomes; 4) *B. boliviensis* and *B. dracunculifolia* can be recognized among medicinal species by its bulbiferous trichomes with two subapical cell and 2-4-armed trichomes, respectively; 5) *B. illinita* is distinguished from other medicinal species by its large stomata of 75-100  $\mu\text{m}$ .

Other characters, such as stomata type and epidermal cell walls, can be used to differentiate species with similar type of trichomes, as a secondary feature. In *B. articulata*, *B. gaudichaudiana*, *B. notoserigila*, and *B. trimera*, the trichomes are bulbiferous flagellate with triangular apical cell; however, *B. trimera* can be distinguished by its anisocytic stomata. In *B. heterophylla* the trichomes are bulbiferous flagellate with tail-like apical cell, as well as in *B. conferta*, *B. pilularis*, *B. teindalensis*, *B. tricuneata*, and *B. vaccinioides*; however, *B. heterophylla* can be differentiated from them by its cyclocytic stomata. *Baccharis pentlandii* has

**Figure 2. Stomata.**- A: actinocytic and staurocytic stomata, *B. conferta*; B: actinocytic and tetracytic stomata, *B. boliviensis*; C: anisocytic stomata, *B. crispa*; D: anomocytic stomata, *B. trimera*; E: cyclocytic stomata, *B. notoserghila*; F: cyclocytic stomata, *B. illinita*; G: anomocytic stomata, *B. pentlandii*.

bulbiferous flagellate trichomes with long apical cell, which is a common type within medicinal species, but it can be distinguished by its sinuate anticlinal epidermal cell walls on abaxial surface.

#### ACKNOWLEDGEMENTS

Thanks are given to Jochen Müller and two anonymous reviewers for their valuable comments on the manuscript. Special thanks to the curators of the following herbaria: F, GH, LP, and US for the loan of specimens. We also thank Víctor H. Calveti for inking our

pencil illustrations and Anabela S. de Oliveira and Arturo Granda Paucar for providing relevant bibliography. Support for this study by the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina, is gratefully acknowledged.
