

## ***Hieracium angustisquamum*** (Pugsley) Pugsley     **Red-tinted Hawkweed**

Native

GB: Least Concern

England: Endangered

GB Rare

VC5 Absent; VC6 Rare

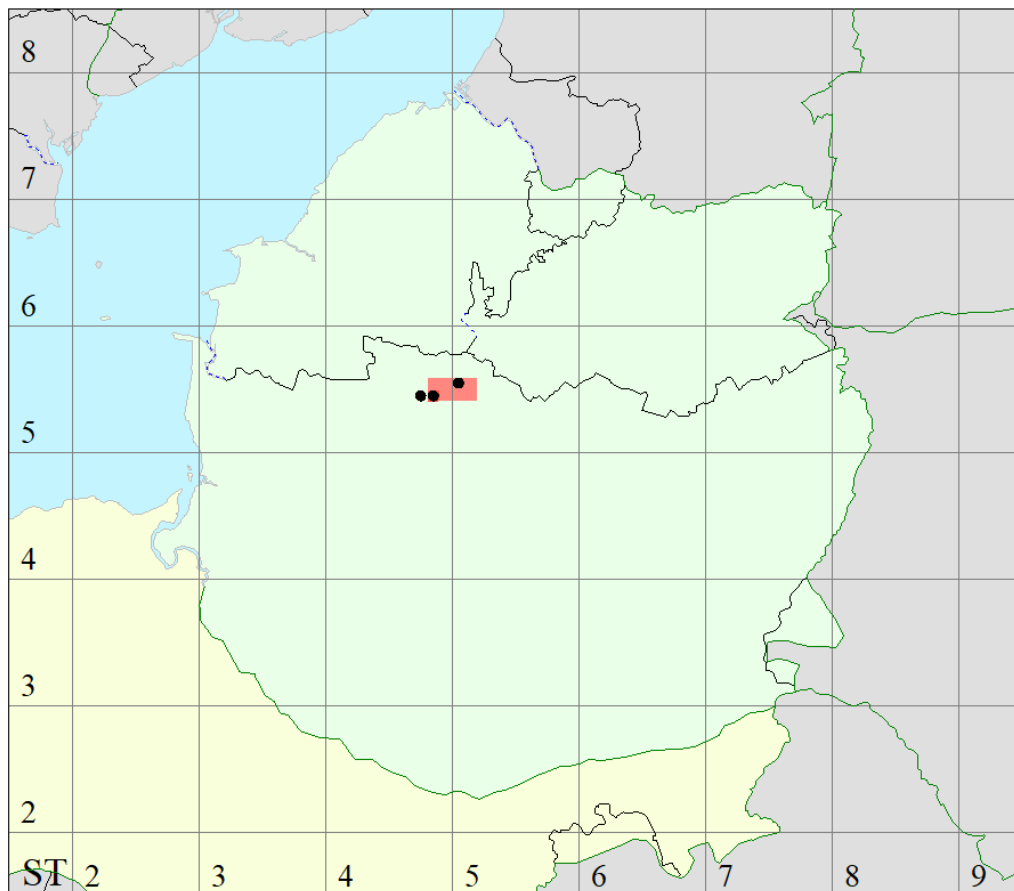

A rare perennial herb of limestone rock outcrops, cliffs and screes, endemic to Britain and Ireland. First discovered at Cheddar by Rev. Augustin Ley in 1905, after he noticed specimens in Mr Hanbury's herbarium and **BM** of a hawkweed from Cheddar labelled *H. flocculosum* and went in search of that species. He found no specimens resembling *H. flocculosum* but collected a specimen (<http://herbariaunited.org/specimen/351793/>) of *H. rubiginosum* (White, 1912); this species is now *H. angustisquamum*. The earlier specimen in **BM** was found to be identical to Ley's *H. rubiginosum* (Marshall, 1909). Marshall collected a specimen from Cheddar in 1908 (<http://herbariaunited.org/specimen/351614/>). In June 1952, Claude Andrews found this species on the north side of Cheddar Gorge (specimen in **BIRM**) and in 1976 it was collected (specimen in **BM**) by R.J. Pankhurst and M.J. Mullin on stable limestone scree, north side of the road (ST473544). This species still occurs sparingly on the north side of Cheddar Gorge, with 8 plants found in 2016, most of them at the upper end of the gorge. In 1987 *Hieracium angustisquamum* was found by John Keylock at Ubley Warren, east of Cheddar Gorge. Here it occurs on several low cliffs within the "rakes" quarried for lead; 159 plants were recorded in 2016. In Somerset this species has always been extremely rare. Within Cheddar Gorge it is found in critically low numbers; at Ubley Warren some rock faces are completely obscured and others are threatened by encroaching brambles. *Hieracium angustisquamum* has been found at sparsely scattered sites in Britain and Ireland; since 2000 it has only been recorded at the two sites in Somerset, one site in West Sussex and one in North-east Yorkshire. The Somerset populations are at the south-western edge of its range.
