A B S T R A C T

Two new species of fairy shrimp from North America, *Streptocephalus henridumontis* and *Streptocephalus thomasbowmani*, are diagnosed and figured. A brief account on the conservation status of the New World species of the genus and an updated species identification key are included. *Streptocephalus thomasbowmani* n. sp., endemic to New Mexico, U.S.A., is morphologically similar to *S. dorotheae*. *Streptocephalus henridumontis* n. sp., whose populations occur along the Sonoran desert in northwestern México and southwestern United States, is morphologically similar to *S. mackini*. The peduncle of the antennal distal outgrowth of the two new species is of the long type. *Streptocephalus thomasbowmani* has uniramous ovaries, whereas *S. henridumontis* has biramous ovaries. With the inclusion of the new taxa, the number of species of the genus recorded from the American continent is 15. Seven (*S. dorotheae*, *S. henridumontis*, *S. linderi*, *S. mackini*, *S. sealii*, *S. similis*, and *S. texanus*) have a wide geographical distribution and seem to be under no immediate threat. Conversely, eight species have a restricted distribution. Thus, *S. antillensis*, *S. kargesi*, and *S. potosinensis* can be considered as Critically Endangered (CE), and *S. thomasbowmani*, *S. guzmani*, *S. mattoxi*, *S. moorei*, and *S. woottoni* as Endangered species (EN), following the IUCN red list criteria.

The genus *Streptocephalus* Baird, 1852, occurs in all continents except in Antarctica (Belk and Brtek, 1995, 1997; Maeda-Martínez *et al.*, 1995b; Herbert and Timms, 2000). In the New World, it is distributed from the Canadian provinces of Alberta and Saskatchewan in the north to Belize and the Caribbean islands of Barbuda and Desirade in the south. To date, 13 species have been recognized for this area (Maeda-Martínez *et al.*, 1995a, 2002). One species is endemic to Mona Island, Puerto Rico (Mattox, 1950), but the other 12 species occur mostly in México and the southern United States (Creaser, 1930; Moore, 1958, 1966; Belk, 1975; Spicer, 1985; Eng *et al.*, 1990; Maeda-Martínez *et al.*, 1995a, 2002).

The taxonomy of the New World streptocephalids has been studied by Packard (1883), Daday (1910), Creaser (1930), and Moore (1966). Keys to species have been elaborated by Mackin (1942), Dexter (1959), and Belk (1975), and for taxa of the U.S.A. by Pennak (1953, 1978, 1989). The most recent systematic review, which included an updated diagnosis, phylogeny, and scanning electron microscope (SEM) figures of the 13 species, was published by Maeda-Martínez *et al.* (1995a).

In the genus *Streptocephalus*, the male second antenna is a uniramous, two-jointed appendage. From the distal end of the antennal basal joint, a typical distal outgrowth is borne, which consists of a peduncle that terminates in a scleroid cheliform structure (the so-called ‘hand’). On the basis of the length of the peduncle of the antennal distal outgrowth, the *Streptocephalus* species were sorted into three categories; those with short, intermediate, and long peduncles (Maeda-Martínez *et al.*, 1995b). Using the length of the peduncle plus the morphology of the frontal appendage and ovaries, Maeda-Martínez *et al.* (1995b) distinguished nine species groups, of which only three are represented by the 13 New World species; 1) the *dendyi* group, with a short antennal peduncle, frontal appendage simple and short, and unir-

amous ovaries, with only one species, *Streptocephalus kargesi* Spicer, 1985; 2) the *sealii* group, with an intermediate antennal peduncle, frontal appendage simple and short, and uniramous ovaries, represented by three species, *S. sealii* Ryder, 1879, *S. similis* Baird, 1852, and *S. woottoni* Eng, Belk, and Eriksen, 1990; and 3) the *torvicornis* group, including two subgroups, 3a) the *torvicornis* subgroup, with a long antennal peduncle, frontal appendage simple and short, and uniramous ovaries, represented by two species, *S. guzmani* Maeda-Martínez *et al.*, 1995a, and *S. mattoxi* Maeda-Martínez *et al.*, 1995a; and 3b) the *mackini* subgroup, with a long antennal peduncle, frontal appendage simple and short, and biramous ovaries, represented by seven species, *S. antillensis* Mattox, 1950, *S. dorotheae* Mackin, 1942, *S. linderi* Moore, 1966, *S. mackini* Moore, 1966, *S. moorei* Belk, 1973, *S. potosinensis* Maeda-Martínez *et al.*, 1995a, and *S. texanus* Packard, 1871. However, these species groups were not supported by a recent molecular study (Daniels *et al.*, 2004).

In this paper, we present the diagnosis of two new species. One of them has populations in the Sonoran desert region of northwestern México and southwestern United States, and exhibits an antennal morphology similar to *S. mackini*. The second one is endemic to New Mexico, U.S.A., and exhibits an antennal morphology similar to *S. dorotheae*. Thus, the present study included an extensive examination of *S. dorotheae* and *S. mackini* material including type specimens. Finally, we summarize the conservation status of the New World species of *Streptocephalus* and present an updated species identification key.

MATERIALS AND METHODS

The material examined came from collections deposited at the National Museum of Natural History, Smithsonian Institution, U.S.A. (USNM);

Fig. 1. *Streptocephalus henridumontis* new species (paratype), male, SEM photographs. A, Left antenna in inner view; B, hand of left antenna in inner view; C, hand of right antenna in lateral view. aj = apical joint, bj = basal joint, fa = frontal appendage, fi = finger, pd = peduncle, sp = spur, th = thumb.

Centro de Investigaciones Biológicas del Noroeste, S.C., La Paz, Baja California Sur, México (CIB); Escuela Superior de Biología, Universidad Juárez del Estado de Durango, México (UJED); Facultad de Ciencias Biológicas, Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León (FCB); and from the private collection of D. Belk (currently deposited at the Smithsonian Institution). Measurements of type materials were made using a vernier caliper under a stereoscopic

microscope. The standard length is the distance from the anterior margin of head to the posterior margin of telson between cercopods. Morphological terminology follows Maeda-Martínez *et al.* (1995b). Terminology for cyst description follows Gilchrist (1978) and Mura (1992). For scanning electron micrographs, fixed specimens were critical-point dried, coated with gold, and analyzed under a JEOL (SEM) at 10 kV. The conservation status of the species was evaluated according to the IUCN Red List Categories and Criteria (2001).

#### SYSTEMATICS

#### Streptocephalidae Daday, 1910

#### *Streptocephalus* Baird, 1852

#### *Streptocephalus henridumontis* n. sp. Maeda-Martínez and Obregón-Barboza Figs 1 A–C, 3 C–D

*Streptocephalus mackini* Moore.—Maeda-Martínez, 1991 (in part); Campoy-Favela and Quijada-Mascareñas, 1993; Maeda-Martínez *et al.*, 1995a (in part).

*Streptocephalus* sp.—Maeda-Martínez *et al.*, 1997; Maeda-Martínez *et al.*, 2002.

*Streptocephalus dumontii* Daniels *et al.* 2004. (*Nomen nudum.*)

*Type Locality.*—Km 1.5 to Querobabi, Federal highway No. 15, Hermosillo-Santa Ana, Sonora, México.

*Type Material.*—Holotype male, standard length 13.3 mm, cercopods 1.4 mm, total length 14.7 mm. Allotype female, standard length 12.4 mm, cercopods 1.6 mm, total length 14.0 mm. Paratypes: 20 males, standard length 11.7–14.0 mm; 20 females, standard length 10.6–12.7 mm; CIB-205, collected 06 September 1996 by A.M. Maeda-Martínez, H. García-Velazco, C. Orozco-Medina, and M. Prieto-Salazar.

*Diagnosis.*—Male: Frontal appendage simple, short, usually bilobed at tip; second antennae with peduncle of distal outgrowth of long type, without pulvinus, but with series of about 12 conical protuberances on inner side of distal part; inner dorsal side of base of hand with spiniform structure anteriorly directed; spur triangle-shaped, apex with swollen digitiform prolongation; lateral lamella with acute angle between distal part of thumb and spur; inner lamella medioventrally produced forming cavity; distal part of thumb geniculate, with pronounced elbow on ventral side, dorsal margin inerm, apex acuminate; finger bigeniculate, 2 teeth on inner dorsal side of proximal part; distal tooth broad at base, its anterior margin anterodorsally prolonged forming digitiform structure; proximal tooth shorter, subacuminate and anteriorly oblique; dorsal lamella of finger narrow at first geniculation, with straight border at second geniculation; apex of finger acuminate, with subapical swollen part armed with ventrolateral spiniform structure; genitalia without linguiform outgrowths; cercopods separate, setose along inner and lateral borders; anus terminal.

Female. Ovaries biramous, variably extending from thoracic segments 4–8 to abdominal segments 4–6; brood-pouch ends at abdominal segments 6–7.

Cyst. Spherical, ornamented by ribs forming polygonal areas; shell composed of single spongy cortex.

*Differential Diagnosis.*—*Streptocephalus henridumontis* is morphologically similar to *S. mackini*. Both species have a long antennal peduncle, frontal appendage simple and short, and biramous ovaries. Their main differences are (1) the distal tooth of finger in *S. henridumontis* has its anterior margin anterodorsally prolonged forming a semirectangular

digitiform structure (Fig. 1 A, B), in *S. mackini* the distal tooth is acuminate (Maeda-Martínez *et al.*, 1995a, fig. 10 C); (2) the dorsal lamella of the finger in *S. henridumontis* is narrow at the first geniculation, and shows a straight border at the second geniculation (Fig. 1 A, B), in *S. mackini* the dorsal lamella is broad at the first geniculation, and its border is curved to the apex of finger (Maeda-Martínez *et al.*, 1995a, fig. 10 C); (3) the spiniform structure at the apex of the finger in *S. henridumontis* is ventrolaterally inserted (Fig. 1 C), in *S. mackini* the same structure is in lateral position (Maeda-Martínez *et al.*, 1995a, fig. 10 D, E).

**Molecular Information.**—Sequences of fragments of the mitochondrial DNA 12S rRNA and Cytochrome oxidase subunit I (COI), and of the nuclear DNA 5.8S-ITS-1-18S of *S. henridumontis* are deposited in the GenBank (accession numbers: AY519779, AY519829, and AY519847) (Daniels *et al.*, 2004). Molecular phylogenetic analyses of nine New World *Streptocephalus* species showed that *S. henridumontis* is genetically more related to other forms (e.g., *S. texanus*) than to *S. mackini* (Daniels *et al.*, 2004).

**Distribution.**—*Streptocephalus henridumontis* is recorded from the Mexican states of Baja California (Norte), Sinaloa, and Sonora. In the U.S.A., this species is known from Arizona and New Mexico (Fig. 4).

**Conservation Status.**—Given its extent of occurrence (Fig. 4), *Streptocephalus henridumontis* appears under no immediate threat (Least Concern).

**Etymology.**—The species is named in honor of Prof. Dr. Henri J. Dumont in recognition to his contributions to the knowledge of the biology and biodiversity of the Crustacea Branchiopoda.

*Streptocephalus thomasbowmani* n. sp. Maeda-Martínez  
and Obregón-Barboza  
Figs 2 A–D and 3 A–B

*Streptocephalus bowmani* Daniels *et al.* 2004. (*Nomen nudum.*)

**Type Locality.**—10 miles W of Lordsburg, Hidalgo County, New Mexico, U.S.A.

**Type Material.**—Holotype male, standard length 12.0 mm, cercopods 1.6 mm, total length 13.6 mm. Allotype female, standard length 13.5 mm, cercopods 1.4 mm, total length 14.9 mm. Paratypes: 22 males, standard length 10.3–14.7 mm; 15 females, standard length 11.9–14.0 mm; USNM Acc. No. 30597, collected 13 August 1955 by J. E. Lynch.

**Diagnosis.**—Male: Frontal appendage simple, short, and bilobed at tip; second antennae with peduncle of distal outgrowth of long type, without pulvinus, but with series of about 8 conical protuberances on inner side of distal part; inner dorsal side of base of hand with spiniform structure, anteriorly directed; spur triangle-shaped, apex with digitiform prolongation; lateral lamella with acute angle between distal part of thumb and spur; inner lamella medioventrally produced, forming cavity; inner margin of proximal part forming deep cleft; distal part of thumb geniculate, forming pronounced elbow on ventral side, dorsal margin inerm, apex acuminate; finger bigeniculate, 2 teeth on inner dorsal side of proximal part, proximal one a small acute tooth

medially directed, distal one a long digitiform tooth dorsally directed; 1 stout tooth on lateral side; dorsal lamella of finger narrow at first and second geniculation; apex of finger acuminate; genitalia without linguiform outgrowths; cercopods setose along inner and lateral borders; anus terminal.

Female. Ovaries uniramous extending from genital segment 1 to abdominal segments 5–7; brood-pouch ending on abdominal segments 5–6.

Cyst. Spherical, with surface ornamented by ribs forming polygonal areas; shell with subcortical space present, outer cortex and inner alveolar layer not completely separated from one another.

**Differential Diagnosis.**—*Streptocephalus thomasbowmani* is morphologically similar to *S. dorotheae*. Both species have a long antennal peduncle, and frontal appendage simple and short; however, *S. thomasbowmani* has uniramous ovaries, whereas *S. dorotheae* has biramous ovaries. The most important differences in antennal morphology between these species are found in the finger; *S. thomasbowmani* has a stout tooth on the lateral side (Fig. 2 D) and a narrow dorsal lamella at first geniculation (Fig. 2 B, C); in *S. dorotheae* the finger has no tooth in the lateral side, and the dorsal lamella is wide at first geniculation (Maeda-Martínez *et al.*, 1995a, fig. 8 A–C).

**Molecular Information.**—Sequences of fragments of the mitochondrial DNA 12S rRNA and Cytochrome oxidase subunit I (COI), and of the nuclear DNA 5.8S-ITS-1-18S of *S. thomasbowmani* are deposited in the GenBank (accession numbers: AY519781, AY519825, and AY519846) (Daniels *et al.*, 2004). Molecular phylogenetic analyses of nine New World *Streptocephalus* species showed that *S. thomasbowmani* is genetically more related to other forms (e.g., *S. guzmani*) than to *S. dorotheae* (Daniels *et al.*, 2004).

**Distribution.**—*Streptocephalus thomasbowmani* is endemic to New Mexico, U.S.A. It is known only from the type locality (Fig. 4).

**Conservation Status.**—We assess *S. thomasbowmani* as an Endangered species (EN) because its distribution range is less than 5000 km<sup>2</sup>, it exists at no more than five locations, and exhibits extreme fluctuations in the number of mature individuals.

**Etymology.**—The species is named in memory of Dr. Thomas E. Bowman in recognition to his contributions to the knowledge of the Crustacea.

## DISCUSSION

The morphological similarity of the two new species with previously described species caused their misidentification in the past. The original lot of *Streptocephalus thomasbowmani* n. sp. was labeled by its collector as *S. dorotheae*. Given that the last species was previously reported with biramous ovaries (Maeda-Martínez *et al.*, 1995a), a careful examination of the original lot allowed us to realize that such material represented a new, undescribed species with females having uniramous ovaries. We confirmed that females of the type material of *S. dorotheae* (Santa Fe,

Fig. 2. *Streptocephalus thomasbowmani*, new species (paratypes), males, SEM photographs. A, Left antenna in inner view; B and C, hand of left antenna in inner view of two different individuals; D, hand of right antenna in lateral view. aj = apical joint, bj = basal joint, fa = frontal appendage, fi = finger, pd = peduncle, sp = spur, th = thumb.

New Mexico, U.S.A., USNM 79019) have biramous ovaries. The uniramous condition of the ovary can be considered as the plesiomorphic state of that organ given that it is exhibited by most of the species of the genus (Maeda-Martínez *et al.*, 1995a, b). The biramous condition (apomorphic state) seems to have evolved only in the New World *Streptocephalus*, specifically in the new species *S. henridumontis* and in the eight species of the *mackini* subgroup proposed by Maeda-Martínez *et al.* (1995a, 2002). However, the monophyly of the species group with biramous ovaries is not supported by the molecular analyses of Daniels *et al.* (2004), who reported *S. guzmani*, *S. thomasbowmani*, and *S. woottoni* with uniramous ovaries in monophyly with *S. henridumontis* and *S. texanus* with biramous ovaries.

*Streptocephalus henridumontis* was mistakenly reported as *S. mackini* by Maeda-Martínez (1991), Campoy-Favela and Quijada-Mascareñas (1993), and Maeda-Martínez *et al.* (1995a) for the Mexican states of Sinaloa and Sonora. The consistency of the differential characteristics exhibited by *S. henridumontis* populations across the Sonoran desert is the morphological evidence that this form is a separate species. Our extensive revision revealed the occurrence of males of *S. henridumontis* and *S. mackini* in the same pool at

the same time in a site in Cochise, County, Arizona, U.S.A. (D. Belk's collection DB-99). Such a co-occurrence and the molecular analyses of Daniels *et al.* (2004) confirm the validity of *S. henridumontis*.

Although the structural morphology of cross-sectioned cyst shells has been studied in a few anostracans (Gilchrist, 1978; De Walsche *et al.*, 1991; Lee *et al.*, 1994; Rosowski *et al.*, 1997; Hill and Shepard, 1997), interspecies differences have been found within the genera *Branchinecta* (Obregón-Barboza *et al.*, 2002) and *Streptocephalus* (De Walsche *et al.*, 1991). De Walsche *et al.* (1991) reported the cyst shell of the Indian *Streptocephalus dichotomus* Baird, 1860, was composed of an outer cortex and two inner alveolar layers, and that of the Arabian *Streptocephalus torvicornis* (Waga, 1842) with a single spongy cortex. Differences in the cyst-shell structure is also found between the new species; *S. thomasbowmani* exhibits a bilayered cyst-shell, whereas *S. henridumontis* has a single "spongy" cyst shell (Fig. 3).

Comparing their geographical distributions, *S. thomasbowmani* is known from one locality in New Mexico, U.S.A., whereas *S. dorotheae* has a wider distribution, occurring in the Mexican states of Baja California Sur and Sonora (Maeda-Martínez *et al.*, 2002), and in the western states of

Fig. 3. A, B, cyst of *Streptocephalus thomasbowmani* new species (paratype); C, D, cyst of *Streptocephalus henridumontis* new species (paratype). A, C, whole cyst; B, D, cross section of cracked cyst. al = alveolar layer, cm = yolk particles and embryonic cells, co = outer cortex.

the U.S.A. in Arizona, New Mexico, Oklahoma, Texas, Utah, and Wyoming (Mackin, 1942; Koehn and Cole, 1964; Maynard and Romney, 1975; Belk, 1975, 1983) (Fig. 4). *Streptocephalus henridumontis* and *S. mackini* are widely distributed species; however, *S. henridumontis* occurs mostly in the Sonora desert, with records in the south in a Mexican tropical area in the southern part of the state of Sinaloa (22°46' N, 105°40' W), through Sonora and Baja California (Norte), México, and Arizona and New Mexico, U.S.A., in the north. *Streptocephalus mackini*, the most common Anostracan species in México (Maeda-Martínez, 1991), occurs mostly in the Chihuahua desert, with records in the south from Oaxaca, through Central Mexico, and Arizona, New Mexico, and Texas, U.S.A., in the north (Maeda-Martínez et al., 2002).

The long mountainous chain Sierra Madre Occidental, which separates the Chihuahuan and Sonoran deserts in northern México, appears to function as a geographical barrier between the southern populations of *S. henridumontis* and *S. mackini*; however, the northern ranges of these species overlap in the states of Arizona and New Mexico (Fig. 4), just in the area where the deserts mentioned above are in contact (MacMahon and Wagner, 1985).

The discovery of *S. henridumontis* and *S. thomasbowmani* brings the number of *Streptocephalus* species recorded

from North America to 15. Seven of these (*S. dorotheae*, *S. henridumontis*, *S. linderi*, *S. mackini*, *S. sealii*, *S. similis*, and *S. texanus*) show a wide geographical distribution and seem to be under no immediate threat (Least Concern) (Table 1). Conversely, eight species have a restricted distribution, all of them recorded from only one or few locations. Thus *S. antillensis*, *S. kargesi*, and *S. potosinensis* are considered as Critically Endangered (CE), and *S. thomasbowmani*, *S. guzmani*, *S. mattoxi*, *S. moorei*, and *S. woottoni* as Endangered species (EN). *Streptocephalus moorei*, *S. guzmani*, and *S. woottoni* were listed in the IUCN Red List (IUCN, 1996).

Key to the New World species of *Streptocephalus*

Note.—Morphological identification of the species can be done only on adult male second antenna; however, given its relevance, the type of ovaries is also included in the key.

- 1. Thumb without spur; finger without teeth; ovaries uniramous: . . . . . *S. kargesi* Spicer, 1985
- Thumb with spur; finger with teeth on dorsal side of proximal part: . . . . . 2
- 2. Male with spinose cercopods; ovaries uniramous: . . . . . 3
- Male with setose cercopods: . . . . . 4

Fig. 4. Geographical distribution of *Streptocephalus dorotheae* (triangles), *S. henridumontis* n. sp. (closed squares), *S. mackini* (open squares), and *S. thomasbowmani* n. sp. (star).

- 3. Finger with two teeth on inner dorsal side of proximal part; genitalia with a pair of linguiform lateral outgrowths on base of penes: . . . . . *S. sealii* Ryder, 1879
- Finger with three teeth on inner dorsal side of proximal part; genitalia without a pair of linguiform lateral outgrowths on base of penes: . . . . . *S. similis* Baird, 1852

- 4. Genitalia with a pair of linguiform lateral outgrowths on base of penes; ovaries uniramous: . . . . . *S. woottoni* Eng, Belk, and Eriksen, 1990
- Genitalia without a pair of linguiform lateral outgrowths on base of penes: . . . . . 5
- 5. Dorsal margin of thumb crenate or spinose: . . . . . 6

Table 1. General distribution and conservation status of the New World *Streptocephalus* species.

<i>Streptocephalus</i>	Distribution	Conservation status	Reference
<i>antillensis</i>	Endemic to Mona Island, Puerto Rico	Critically endangered	Maeda-Martínez <i>et al.</i> (1995a)
<i>dorotheae</i>	Widely distributed in two northwestern states of México, and six western states of the U.S.A.	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>guzmani</i>	Endemic to Coahuila, México	Endangered	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>henridumontis</i>	Widely distributed in three northwestern states of México, and two southwestern states of the U.S.A.	Under no immediate threat	This study
<i>kargesi</i>	Endemic to Veracruz, México	Critically endangered	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>linderi</i>	Coahuila, Nuevo León, and Tamaulipas, México; Texas, U.S.A.	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>mackini</i>	Widely distributed in México, and Arizona, New Mexico, and Texas, U.S.A.	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>mattoxi</i>	Endemic to Kenedy County, Texas, U.S.A.	Endangered	Maeda-Martínez <i>et al.</i> (1995a)
<i>moorei</i>	Chihuahua, México, and New Mexico, U.S.A.	Endangered	Maeda-Martínez <i>et al.</i> (2005)
<i>potosinensis</i>	Endemic to San Luis Potosí, México	Critically endangered	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>sealii</i>	Widely distributed: México, U.S.A., and Canada	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>similis</i>	Widely distributed: Belize, Hispaniola, Puerto Rico, Jamaica, México, and U.S.A.	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>texanus</i>	Widely distributed: Barbuda, Desirade, México, and U.S.A.	Under no immediate threat	Maeda-Martínez <i>et al.</i> (1995a, 2002)
<i>thomasbowmani</i>	Endemic to New Mexico, U.S.A.	Endangered	This study
<i>woottoni</i>	Endemic to northern Baja California, México, and southern California, U.S.A.	Endangered	Eng, Belk, and Eriksen (1990); Simovich (1998); Maeda-Martínez <i>et al.</i> (1995a, 2002)

- Dorsal margin of thumb inerm: . . . . . 8
- 6. Dorsal margin of thumb crenate; ovaries uniramous: . . . . .  
*S. mattoxi* Maeda-Martínez, Belk, Obregón-Barboza, and Dumont, 1995
- Dorsal margin of thumb spinose; ovaries biramous: . . . . . 7
- 7. Finger with a single hump-like tooth on inner dorsal side of proximal part; dorsolateral side of base of hand, with long anteriorly curved process: . . . . . *S. moorei* Belk, 1973
- Finger with two teeth on inner dorsal side of proximal part; dorsolateral side of base of hand, without a long process: . . . . .  
*S. antillensis* Mattox, 1950
- 8. Finger with a small hump-like proximal tooth on inner dorsal side of proximal part; peduncle without spiniform protuberances on inner side; ovaries uniramous: . . . . .  
*S. guzmani* Maeda-Martínez, Belk, Obregón-Barboza, and Dumont, 1995
- Finger with a well-developed proximal tooth; peduncle with spiniform protuberances on inner side: . . . . . 9
- 9. Finger with proximal tooth larger than distal tooth: . . . . . 10
- Finger with proximal tooth smaller than distal tooth: . . . . . 11
- 10. Distal tooth of finger spatulate; ovaries biramous: . . . . .  
*S. potosinensis* Maeda-Martínez, Belk, Obregón-Barboza, and Dumont, 1995
- Distal tooth of finger with an anterior cuspid; ovaries biramous: . . . . .  
*S. linderi* Moore, 1966
- 11. Apex of finger without a lateral process: . . . . . 12
- Apex of finger with a lateral process; biramous ovaries: . . . . . 13
- 12. Finger with stout tooth on the lateral side; finger with a narrow dorsal lamella at first geniculation; uniramous ovaries: . . . . .  
*S. thomasbowmani* n. sp.
- Finger without a tooth on the lateral side; finger with a wide dorsal lamella at first geniculation; biramous ovaries: . . . . .  
*S. dorotheae* Mackin, 1942
- 13. Apex of finger with a lamellar process: . . . . .  
*S. texanus* Packard, 1871
- Apex of finger with a spiniform process: . . . . . 14
- 14. Distal tooth of finger with anterior margin anterodorsally prolonged forming a semirectangular digitiform structure; dorsal lamella of finger narrow at first geniculation, and forms a straight border at second geniculation: . . . . . *S. henridumontis* n. sp.
- Distal tooth of finger acuminate; dorsal lamella of finger broad at first geniculation, and forms a curved border at second geniculation: . . . . .

#### ACKNOWLEDGEMENTS

Our gratitude to Denton Belk and Mary Belk for their hospitality during the visit of the senior author to D. Belk's collection in San Antonio, Texas, U.S.A. We thank D. Christopher Rogers for the critical review of the manuscript, and Janice Clark and Chad Walter for their help during the visit of the senior author to the crustacean collection at the Smithsonian Institution. This study forms part of the projects "Taxonomía y distribución de los filópodos (Crustacea: Branchiopoda: Anostraca, Notostraca, Spinicaudata y Laevicaudata) de México" (H068), and "Biología y cultivo de Branquiópodos" (ABM-13) supported by the Comisión Nacional para el Conocimiento y Uso de la Biodiversidad (CONABIO), and Centro de Investigaciones Biológicas del Noroeste, S.C. (CIBNOR). We also thank Marcelo Silva-Briano and Araceli Adabache-Ortiz for the SEM study made at the Universidad Autónoma de Aguascalientes, and E. Glazier for editing the English-language text.
