Prevalence of Inflammatory Arthritis Conditions in the First Nations Population of Alberta. Cheryl Barnabe[1], C. Allyson Jones[2], Don Voaklander[3], Deborah Marshall[1], Christine Peschken[4], Sasha Bernatsky[5], John Esdaile[6] and Brenda Hemmelgarn[1]. [1]University of Calgary, Calgary, AB, [2]Departments of Physical Therapy and School of Public Health, University of Alberta, Edmonton, AB, [3]University of Alberta, Edmonton, AB, [4]University of Manitoba, Winnipeg, MB, [5]McGill University Health Centre, Montreal, QC, [6]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Canada's First Nations population reports higher rates of physician-diagnosed arthritis and rheumatism, and is known to have twice the rate of osteoarthritis. The prevalence of inflammatory arthritis conditions of Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS), Psoriatic Arthritis (PsA), Reactive Arthritis (ReA), and Crystal Arthritis has not been widely studied, although variations between FN populations based on tribal ancestry are hypothesized. The Alberta First Nations population is rich in diversity with numerous Tribal Nations represented, including Blackfoot, Chipewyan, Cree, Dene, Sarcee, Saulteaux and Sioux Nations. Prevalence estimates from Alberta would therefore provide a good overall view of the arthritis landscape among First Nations populations in Canada. We report the prevalence of these inflammatory arthritis conditions in the population of Alberta, Canada, comparing rates in First Nations and non-First Nations.

Methods: Population-based healthcare administrative data (years 1993 to 2011), including physician billing claims and hospitalizations, was used to define cohorts of patients with RA, AS, Ps, ReA and crystal arthritis based on ICD-9-CA and ICD-10-CM codes (2 physician billing codes or 1 hospitalization). First Nations patients were identified based on premium payer status. Disease prevalence rates were calculated for fiscal year 2008/2009 as cases per 1000 persons, and the rate ratio calculated for First Nations relative to non-First Nations.

Results: RA, AS and ReA were estimated as being twice as frequent in the First Nations population (Table 1). In contrast, PsA was slightly less frequent in First Nations. Crystal arthritis surpassed RA as the most frequent type of inflammatory arthritis in the non-First Nations population, with a rate ratio three times that of the First Nations cohort.

Table 1. Prevalence Rate of Inflammatory Arthritis Conditions in Alberta (per 1000 persons), and Rate Ratio for First Nations compared to non-First Nations

Condition	Prevalence Rate in First Nations	Prevalence Rate in non-First Nations	Rate Ratio (95%CI), p value
Rheumatoid Arthritis	19.00	10.51	1.81 (1.74–1.88), $p<0.001$
Psoriatic Arthritis	0.65	0.85	0.77 (0.62–0.94), $p=0.0118$
Ankylosing Spondylitis	3.58	2.08	1.72 (1.57–1.88), $p<0.001$
Reactive Arthritis	0.09	0.04	2.23 (1.23–4.02), $p=0.0063$
Crystal Arthritis	4.44	12.82	0.35 (0.32–0.37), $p<0.001$

Conclusion: Our estimates demonstrate that RA is the most frequent inflammatory arthritis in the First Nations population of Alberta, whereas crystal arthritis is the most frequent inflammatory arthritis diagnosis in non-First Nations. RA, AS and ReA prevalence estimates in First Nations are twice that of the non-First Nations population, whereas PsA and crystal arthritis are less frequent. These results further explain the higher self-reported rates of arthritis conditions in the First Nations population beyond degenerative arthritis conditions, and validate the need for enhanced inflammatory arthritis health services to address disease burden.

2024

Prevalence of Rheumatoid Arthritis in French West Indies, an African Ancestry Population. the Eppra Study. Michel De Bandt[1], Rishika Banydeen[2], Lauren Brunier[3], Katleen Polomat[4], Veronique Dehlinger[5], Serge Arfi[4], Christophe Deligny[4], Benedicte Garnery[6], Helene Cormier[1], Fabienne Dubreuil[7], Patrick Numeric[5], Danielle Dufrenot[8], Sabine Molcard[1], Loic Brithmer[1], Olivier Fuhrer[1], Lucien Louis-Joseph[7], Sylvie Merle[2] and Georges Jean-Baptiste[5]. [1]Unit of rheumatology, Fort de France, France, [2]Unit of epidemiology and biostatistics, Fort de FRance, France, [3]Unit of rheumatology, CHUM, 97200 Fort de France, France, [4]unit of internal medicine, Fort de France, France, [5]Unit of rheumatology, CHUM, Fort de France, France, [6]Unit of internal medicine, Fort de France, France, [7]Unit of rheumatology, Fort de FRance, France, [8]Unit of rheumatology, Fot de France, France.

Background/Purpose: Rheumatoid arthritis (RA) is a disabling chronic disease, regarded as the most frequent inflammatory rheumatism in adults, with a prevalence estimated between 0.3 and 1 %, and a feminine ascendancy. In metropolitan France this prevalence is estimated from 0.3 % to 0.5% of the general population. No precise data is available for French West Indies, and the prevalence of RA in this population of African ancestry is poorly evaluated.

Methods: The objective of the study is to estimate RA prevalence in the FWI by a census forward-looking epidemiological survey in the hospital and liberal sectors for one year duration. It is a unique tour with clinical examination, self-administered questionnaires and declaration. Secondary objectives are description of clinical and socio economical aspects of RA and cardiovascular comorbidities. We present the results for Martinique. Our survey was widely distributed (radio, press, patients' associations. . .) to ensure a good completeness. Data were analysed using SAS 9.3 software (SAS Institute Inc., Cary, NC, USA). Throrough descriptive analysis of collected variables was conducted. Crude prevalence rates were adjusted to a standard population of Martinique (nationwide census in 2010). The 95% CIs were calculated using the Poisson distribution.

Results: Our completeness is good. 538 RA were collected, giving a prevalence in Martinique of 0.184% of the adult population (290 000), respectively 0.049 for men and 0.292 for women. 44% of these patients are treated in private practice and 56% in hospital. This cohort is composed of 88% women and 12% men; 92% were born in Caribbean and 7.7% elsewhere. Patients self declared of Afro Caribbean origin in 92.7%, Caribbean White in 1.7%, caucasian in 3% and other in 2.1%. Their mean disease duration was 9.7+10 years. RF and ACPA were positive in 82.2% (FR+ 392, ACPA+349, 35% low level, 65% high level) : CCP+FR+ in 306, FR+CCP- in 77, FR-CCP+ in 41, FR-CCP- in 96. 17% had extra articular manifestations. ACR1987 and ACR2010 criteria were pos in 94.4% and 78%. HAQ was <1 in 74%, >1and <2 in 20% and >2 in 3%. DAS28 were respectively <2.6 in 59%, <3.2 in 15.4%, <5.1 in 23% and >5.1 in 3%. Less than 5% are ever smoker. Parodontopathy is infrequent. Cardiovascular risk factors were noticed in 89,4% with a mean of 2 CVRF beside RA.

Conclusion: This work clarifies the prevalence of RA in this population of African origin. Some characteristics as: reduced prevalence, strong female representation, strong seropositivity, high levels of anti-CCP, no tobacco, differentiate our patients from other populations and evoke another etiology than tobacco.

Factors Associated with Time to Diagnosis from Symptom Onset in Early Rheumatoid Arthritis Patients. Yoon-Kyoung Sung[1], Soo-Kyung Cho[1], Dam Kim[1], Soyoung Won[1], Jiyoung Lee[1], Jung-Yoon Choe[2], Chan-Bum Choi[1], Seung-Jae Hong[3], Jae-Bum Jun[4], Tae-Hwan Kim[4], Eunmi Koh[5], Hye-Soon Lee[6], Jisoo Lee[7], Dae-Hyun Yoo[4], Bo Young Yoon[8] and Sang-Cheol Bae[1]. [1]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Catholic University of Daegu School of Medicine, Daegu, South Korea, [3]Kyung Hee University, Seoul, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [6]Hanyang University Guri Hospital, Guri, South Korea, [7]Ewha Womans University School of Medicine, Seoul, South Korea, [8]Inje University Ilsan Paik Hospital, Goyang, South Korea.

Background/Purpose: Early diagnosis and treatment is an optimal target for better outcomes in rheumatoid arthritis (RA) in clinical practice. To make an early diagnosis, it would be helpful to know the sociodemographic or clinical factors for recognition of disease. On this study, we aimed to identify the factors associated with time to diagnosis after symptom onset in early RA patients

Methods: Early RA patients with less than 1 year of disease duration in the KORean Observational study Network for Arthritis (KORONA) database were included in this analysis. The time to diagnosis was defined as the duration between symptom onset and the diagnosis of RA in each patient. Early RA patients were further divided into two groups according to the time to diagnosis: early diagnosis group (time to diagnosis <1year) and late diagnosis group (time to diagnosis°Ã1year). Using the multivariate regression model, we identified the factors associated with the early diagnosis. We also compared the disease status such as disease activity, hand radiographic change and functional disability on the point of RA diagnosis between early diagnosis group and late diagnosis group.

Results: Among the 714 early RA patients, 401 patients (56.2%) and the other 313 patients (43.8%) were classified as early diagnosis group and late diagnosis group, respectively. In multivariate analysis, older onset age (OR 1.03, 95%CI 1.02–1.05), higher education level (OR 1.72, 95%CI 1.15–2.57) and higher income (OR 1.47, 95%CI 1.03–2.10) were identified as associating factors for early diagnosis (See table). Disease activity scores (DAS) using 28 joints on diagnosis (3.81 ± 1.44 vs. 3.82 ± 1.42, p=0.92) and functional disability (0.65 ± 0.61 vs. 0.57 ± 0.62, p=0.07) were not different between two groups. However, hand joint erosions on X-ray (37.8% vs. 25.6% p<0.01) was common in late diagnosis group than early diagnosis group.

Conclusion: Old age at symptom onset, higher education level or income were the factors associated with short time to diagnosis in early RA patients. Hand joint erosion was more common in late diagnosis group when they diagnosed as RA.

Table. Factors associated with time to diagnosis in early RA patients

	Crude OR (95% CI)	Multi-adjusted OR (95% CI)
Onset age	1.01 (1.00–1.03)*	1.03 (1.02–1.05)*
Male	0.92 (0.64–1.32)	0.78 (0.52–1.15)

2026

Treatment Delays and Worse Outcomes Associated with Lower Socioeconomic Status in Rheumatoid Arthritis. Emily Molina[1], Jose Felix Restrepo[2], Inmaculada del Rincon[1], Daniel Battafarano[3] and Agustin Escalante[2]. [1]University of Texas Health Science Center, San Antonio, TX, [2]University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX.

Background/Purpose: Prompt and routine care in rheumatoid arthritis (RA) is critical for best outcomes. Low socioeconomic status (SES) RA patients use fewer health services and have higher disease activity. We sought to examine the role of SES, distance to the rheumatologist (DTR), and delays in DMARD treatment as determinants of outcome in RA.

Methods: RA outpatients were recruited from public, private, military and Veteran's Affairs rheumatology clinics. The recruitment period spanned nearly 15 years. We assessed SES based on education, occupation and income using the Nam & Powers scale. The time from RA symptom onset to DMARD initiation (DMARD lag) was determined by self-report of the two dates. The distance from a patient's address to the rheumatologist was obtained using Google Maps. We examined three specific clinical outcomes in RA: disease activity, determined by DAS28ESR; joint damage, determined from hand radiographs using the Sharp score; and physical disability, determined by the Modified Health Assessment Questionnaire (MHAQ). We used linear regression models to examine the association of the clinical outcomes with SES, DTR, and DMARD lag, adjusting for other confounders such as age, sex, ethnicity and duration of RA.

Results: We recruited 1,209 RA patients, 1159 of whom had received DMARD treatment. Average DMARD lag was 6.9 ± 8.9 years. Greater DMARD lag was associated with older age ($P \leq 0.001$), longer disease duration ($P \leq 0.001$) and worse status on all three clinical outcomes ($P \leq 0.001$). Lower SES was associated with a longer DMARD lag (beta coeff. -0.120, $P \leq 0.001$) and a shorter DTR (beta coeff. 0.261, $P \leq 0.001$). On average, patients with lower SES waited 8.5 ± 10.2 years after onset of RA symptoms to begin DMARD treatment, which was significantly longer than those in middle and upper SES tertiles who waited 6.1 ± 7.9 years ($P = 0.002$) and 6.1 ± 8.6 years ($P = 0.009$), respectively. Adjusting for confounders including DTR and DMARD lag, SES remained inversely associated with DAS28ESR (beta coeff. −0.282, $P \leq 0.001$), Sharp score (beta coeff. −0.135, $P \leq 0.001$) and MHAQ (beta coeff. −0.296, $P \leq 0.001$).

Conclusion: Low SES RA patients experience a significantly greater delay in DMARD treatment. Low SES and greater DMARD lag were independently associated with worse clinical outcomes, despite adjusting for potential barriers to care such as distance to the rheumatologist and other confounders. Strategies to reduce treatment delay in low SES RA patients are needed.

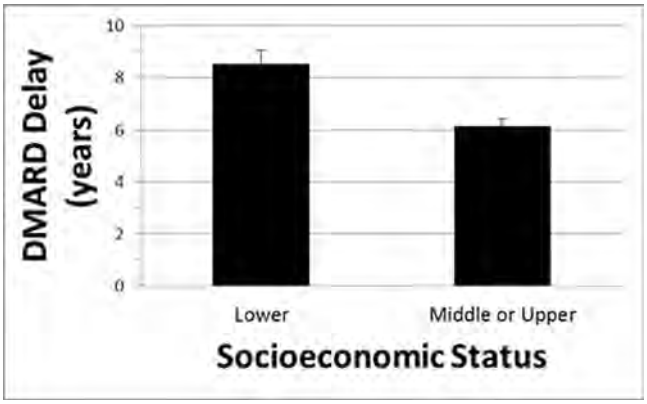

Figure 1. Average time from RA symptom onset to DMARD initiation according to socioeconomic status.

2027

Higher Educational Level Correlates with Retarded Onset and Less Severe Disease in Rheumatoid Arthritis Patients. Michael Zaenker[1], Udo Schwill[2], Petra Reutermann[3], Joachim Listing[4] and Christel Kordbarlag[5]. [1]Immanuel Klinikum Bernau, Rheumatology Center Northern Brandenburg, Bernau, Germany, [2]Immanuel Klinikum, Bernau, Germany, [3]KMG Elbtal Kliniken, Rheumatology Center Northern Brandenburg, Bad Wilsnack, Germany, [4]German Rheumatism Research Center, Berlin, Germany, [5]Ruppiner Kliniken, Rheumatology Center Northern Brandenburg, Neuruppin, Germany.

Background/Purpose: Compared to the general population, patients with RA are endangered by poverty due to treatment-related expenses, disability, unemployment, or early retirement. Additionally, there is impact of poverty on disease management and, still unexplained, increased prevalence of RA is associated with higher mortality in individuals with lower educational level. In this study we evaluate interrelationship between socioeconomic status of RA-patients and their disease severity in an unselected community-based cohort in Northern Brandenburg, Germany.

Methods: Prospective, cross-sectional study among 158 consecutively recruited RA-patients treated in our outpatient-clinic (Bernau) during 3 months. Inclusion criteria were written consent and diagnosis of RA, fulfilling ACR/EULAR-criteria. Using anonymized questionnaires, monthly disposable income, treatment-related expenses and effects of RA on social life were evaluated.

Results: Of all 155 returned questionnaires (return rate 98%), 143 were evaluable. Patient mean age±SD was 60.5±11.7 years, 64% females, mean age at RA-manifestation was 45.5±15.1 years. Monthly median equivalized disposable income (EDI) of RA-patients (1133€, IQR 835–1350) was 86% of the median EDI in the region (1323€), 80% of the median EDI in Germany (1413€). The at-risk-of-poverty-rate (RPR) using the 60% threshold (794 €) of mean EDI of the State Brandenburg was significantly higher compared to the population in the region (22% vs. 14% OR 1.83 $p<0.001$). Subgroups with different educational levels were equal with regard to mean age and gender. Further comparing subgroups with different educational level, we found in RA-patients with university degree and resulting higher median EDI (1333 IQR 967–1667 vs. 1000 IQR 735–1333 €) a mean age at disease onset that was 10 years higher (53.3 ±10.6 vs. 43.2±15.5 years, $p=0.001$), less functional limitations (mean FFbH 79.0±26.4 vs. 66.8±27.1%, $p=0.043$) and a lower rate of early retirement (9.7% vs. 30.4%, $p=0.021$) than in patients with lower educational level. Additionally, we found trends for lower rate of active smokers (19 vs. 28%, $p=0.48$) and higher proportion of early treatment within 6 months after disease onset (48 vs. 37%, $p=0.30$) in the group with university degree. Proportion of patients with biologics was higher in the group with lower educational level (53 vs. 35%, $p=0.11$), reflecting more severe disease.

Conclusion: Our data support the notion that poverty is not only result of disabling RA but educational level and income themselves may influence disease course. The factors contributing to less severe disease and later manifestation in individuals with higher educational levels are mostly unclear and need more elucidation.

2028

Effect of Age at Rheumatoid Arthritis Onset on Clinical, Radiographic, and Functional Outcomes: The Espoir Cohort. Thomas Krams[1], Adeline Ruyssen-Witrand[1], Delphine Nigon[1], Bruno Fautrel[2], Francis Berenbaum[3], Alain G. Cantagrel[4] and Arnaud Constantin[5]. [1]Purpan University Hospital, Toulouse, France, [2]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France, [3]INSERM - UMR S 938, Paris, France, [4]CHU Purpan - Hôpital Pierre-Paul Riquet, Toulouse, France, [5]Purpan University Hospital, Toulouse Cedex 9, France.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease with peak incidence in the fourth and fifth decades of age. To investigate whether age at disease onset determines clinical, radiographic or functional outcomes in a cohort of early RA, taking into consideration possible age-related differences in treatment modalities.

Methods: The ESPOIR cohort is a longitudinal, prospective, multicenter, observational study of adult patients with early arthritis. For this study, we selected data for patients fulfilling the 2010 American College of Rheumatology/European League Against Rheumatism criteria for RA during the first 3 years of follow-up. Patients were pooled into 3 groups by age at RA onset: <45 years (young-onset RA [YORA]), 45 to 60 years (intermediate-onset RA [IORA]) and >60 years (late-onset RA [LORA]). The following outcomes were compared at baseline and during the first 3 years of follow-up by age at disease onset: Simple Disease Activity Index (SDAI) remission rate, one additional erosion, and Health Assessment Questionnaire Disability Index (HAQ-DI) score < 0.5. We also assessed first disease-modifying anti-rheumatic drug (DMARD) survival rate. A multivariate model (logistic regression) was built.

Results: We included 698 RA patients (median [interquartile range] age 50.3 [39.8–57.2] years; female 78.2%), 266 YORA, 314 IORA, and 118 LORA. The median SDAI was 28.5 (20.6–38.6) and median

HAQ-DI score 1 (0.5–1.5). At 1 year, SDAI remission was greater for patients with YORA than IORA and LORA (<0.0001). Having at least one additional erosion was greater for LORA and IORA than YORA patients after 1 year (41.1% [39/95] and 29.7% [81/272] vs 23.8% [51/214], p=0.009) and 3 years (48.2% [41/85] and 44.3% [105/237] vs 32.81% [63/192], p=0.017). The proportion of patients with HAQ score < 0.5 was greater for YORA than IORA and LORA at 1 year (p=0.007) and remained significant at 2 and 3 years. The first DMARD survival rate was lower for YORA than IORA and LORA patients during the 3 years (p=0.005). On multivariate analysis, young age at RA onset was independently associated with SDAI remission at 1 year, no additional erosion at 3 years and HAQ score < 0.5 at 1, 2 and 3 years.

Conclusion: In a cohort of early RA, young age at disease onset is associated with high rate of remission at 1 year, low radiographic progression at 3 years and low functional score during 3-year follow-up. Young age at disease onset is associated with low first DMARD survival rate over 3 years, which suggests that late-onset RA patients may receive less aggressive treatment strategies than younger patients.

2029

Treatment Patterns of Multimorbid Rheumatoid Arthritis Patients: Results from an International Cross-Sectional Study. Helga Radner[1], Kazuki Yoshida[2], Ihsane Hmamouchi[3], Maxime Dougados[4], Josef Smolen[5] and Daniel H Solomon[6]. [1]Medical University Vienna, Vienna, Austria, [2]Kameda Medical Center, Kamogawa, Japan, Kamogawa, Japan, [3]Mohamed V Souissi University, Rabat, Morocco, [4]Descartes University, Cochin Hospital, Paris, France, [5]Medical University of Vienna, Vienna, Austria, [6]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: The presence of multimorbidity could lead to less intensive treatment of RA. This can increase RA disease activity and worsen outcomes such as function, quality of life and mortality.

The aim of the study is to describe the treatment profile of multimorbid RA patients in contrast to patients with RA only, and compare it across different international regions.

Methods: COMORA is a cross-sectional study assessing morbidities, RA related outcomes and treatment of RA patients, recruited in 17 countries worldwide. Patients were grouped according to their multimorbidity profile assessed by a counted multimorbidity index (cMMI), enumerating the particular number of morbidities for each patient. Treatment for RA was categorized according to the use of biologic DMARDs (bDMARD) and TNF-inhibitors (TNFi) in particular, use of synthetic DMARDs only (sDMARD), NSAID use and use of steroids for patients by their cMMI. Adjusted logistic regression models were examined to determine the odds ratio (OR) and 95% confidence interval (CI) of use of bDMARD, TNFi, sDMARD, NSAID or steroids, based on a patient's cMMI and global region, after adjusting for age, disease activity, disease duration, and previous DMARD therapy.

Results: The study cohort consisted of 3920 patients, and 2563 (65.4%) were multimorbid. Overall, 92.6% of the patients were on DMARD therapy, 32.7% received bDMARD; 59.2% sDMARD only; 51.1% NSAIDs and 54.8% corticosteroids. Regional differences could be observed with the most frequent use of bDMARDs in US (46.5%) and lowest frequency in North Africa (9.0%) (**Figure**). After adjusting for confounders in logistic regression analyses, the OR for use of bDMARDs was reduced for each additional morbidity (OR 0.90, 95%CI 0.83–0.97). Similarly, the probability for use of TNFi was also reduced (OR 0.92, 95%CI 0.84–0.99), whereas the OR for use of sDMARD was increased (OR 1.12, 95%CI 1.04–1.21). No change of OR was found for NSAID or steroid use (**Table**).

Conclusion: In our cohort, differences in bDMARD prescribing exist across global regions. After adjusting for covariates, the OR of bDMARD and TNFi use decreases 10% for each additional chronic morbid condition as assessed by cMMI, whereas the OR of sDMARD use increased, probably reflecting rheumatologists' greater comfort using these agents in patients with a greater multimorbidity burden.

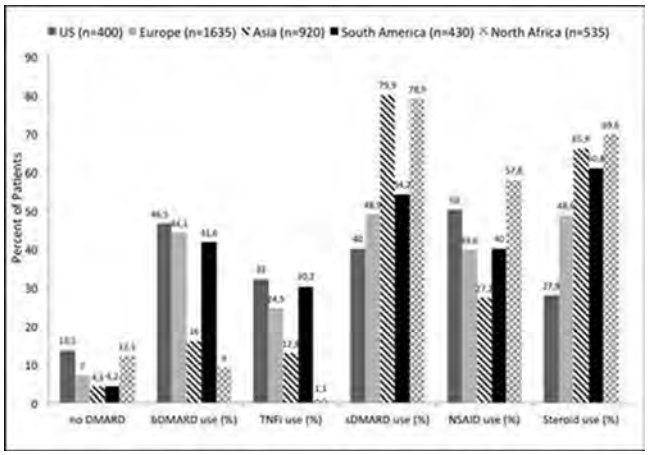

Figure: Regional differences of current treatment status

Predicting Failure of Conventional Disease Modifying Antirheumatic Drugs in Treatment Naive Early Rheumatoid Arthritis Patients: A Single Centre Inception Prognostic Factor Cohort Study. Mette Axelsen[1], Trine Bay Laurberg[1], Robin Christensen[2], Ulrich Fredberg[3] and Torkell Ellingsen[4]. [1]Silkeborg Hospital, Silkeborg, Denmark, [2]MSU, The Parker Institute, Copenhagen University Hospital, Frederiksberg, Denmark, [3]Diagnostic Centre Region Hospital Silkeborg Denmark, Silkeborg, Denmark, [4]Diagnostic Centre Region, Hospital Silkeborg Denmark, Odense, Denmark.

Background/Purpose: Finding prognostic factors for treatment failure on synthetic disease modifying antirheumatic drugs (DMARD) in early treatment naive rheumatoid arthritis (RA) is a challenge. The purpose of this study is to investigate whether baseline characteristics and disease activity variables add value to predict failure of classical DMARD treatment in a multivariable model.

Methods: The study included DMARD naive patients consecutively diagnosed with RA according to the ACR/EULAR criteria 2010. The patients were enrolled between 1.10.2009 and 1.11.2012. They were followed for one year. Disease activity was registered in the DANBIO registry: number of swollen joints (NSJ)(38 joints), number of tender joints (NTJ)(40 joints), Health Assessment Questionnaire (HAQ), visual analog scales (VAS) 0–100 were used to assess pain, fatigue, patient and physician global assessment and DAS28-CRP, CRP, IgM-RF and anti-CCP. Treatment was oral methotrexate 15 mg per week initiated at time of diagnosis increased to 20 mg per week at week 6. If DAS28-CRP at this point was higher or equal to 3.2 and one or more swollen joints were present, treatment was intensified according to guidelines aiming at triple therapy (if tolerated). Intra-articular glucocorticoid injections were given in swollen joints. Treatment with biologics was applied according to guidelines. COX regression analysis was used to investigate if

baseline characteristics and disease activity variables could predict failure of DMARD treatment requiring substitution or addition of biologic treatment. Primary outcome was failure DMARD defined as mentioned above.

Results: 230 patients (41 % males), with a mean age of 59 yrs (range: 16–85 yrs) were enrolled at baseline. A total of 16 patients initiated biologic treatment during the first treatment year. Univariate COX regression analysis showed significant association between the need for biologic treatment and age (hazard ratio (HR) 0.95 (95% CI: 0.92 to 0.98), $p < 0.001$; i.e. inversely associated), CRP (HR 1.01 (95% CI: 1.00 to 1.02), $p=0.04$), VAS fatigue (HR 1.03 (95% CI: 1.01 to 1.05), $p=0.01$)) and VAS global (HR 1.04 (95% CI: 1.01 to 1.06), $p=0.007$). In the subsequent multivariable analysis (incl. the above mentioned variables simultaneously) age and CRP remained significantly associated (HR 0.95 (95% CI: 0.91 to 0.98), $p=0.002$; HR 1.03 (95% CI: 1.01 to 1.04), $p=0.002$, respectively). After one year of follow-up no significant differences in disease activity was found between the patients still on DMARD treatment (DAS28-CRP: 2.1) compared to the 16 patients that had initiated biologic therapy (DAS28CRP: 2.3).

Conclusion: In a pragmatic, single centre inception cohort, using the ACR/EULAR 2010 criteria for the diagnosis of early RA, regression analyses showed that young age and high CRP was significantly associated with failure on initial classical guideline applied DMARD strategy ($p=0.002$).

Early Adherence to Methotrexate in Rheumatoid Arthritis (RA) Is High: a Prospective Longitudinal Study of New Users. Holly Hope[1], Kimme Hyrich[2], James Anderson[1], Lis Cordingley[3] and Suzanne Verstappen[2]. [1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom, [2]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [3]Centre for Musculoskeletal Research, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Methotrexate (MTX) is the recommended first-line DMARD for rheumatoid arthritis (RA) in most countries, however response is not universal. Non-adherence may explain this to some degree. The aim of this analysis was to (1) describe patient self-reported adherence to MTX over the first 6 months of therapy and (2) identify factors associated with non-adherence.

Methods: Patients were enrolled in the Rheumatoid Arthritis Medication Study (RAMS) a 1 year prospective study of MTX new-users for RA in the UK. At baseline, data was collected on demographic factors, alcohol and smoking history, disease activity (DAS28) and disease duration. In addition patients completed the Health Assessment Questionnaire (HAQ), visual analogue scales (VAS) for pain and fatigue, The Beliefs about Medicines Questionnaire (BMQ), Brief Illness Perceptions Questionnaire (B-IPQ), Hospital Anxiety and Depression Scale (HADS), the EQ-5D quality of life questionnaire and the Compliance Questionnaire–Rheumatology (CQ-R), a self-report adherence measure. To measure adherence during the first 6 months after MTX commencement patients completed a weekly MTX diary detailing any missed doses including reasons. Proportional adherence was determined using number of non-adherent weeks compared to total number of eligible weeks. Nonadherence was defined as ≥1 dose missed against medical advice. The associations between patient characteristics, measures of illness and medicine cognitions, and adherence were assessed applying adjusted (age, sex, disease duration and disease activity) univariate logistic regression analysis.

Results: Analyses included the first 392 patients recruited to RAMS who completed the 6 month diary (median age 61 years, 70% female, mean DAS28 = 4.3 [sd 1.3]. In total, 20% (n=80) of patients reported 174 non-adherent weeks. Reasons for non-adherent weeks included (% weeks): no reason given (30%), adverse effects (28%), feeling unwell/ suspected infection (18%), forgetting (12%), taking a drug holiday (9%) or delayed prescription refill (3%). Overall mean proportional adherence was very high (98%). Of adherent patients, 19% missed at least one dose under medical advice. Factors associated in adjusted analyses with being ever non-adherent included higher baseline DAS28 score (OR 1.31 per unit DAS28 (95%CI:1.06, 1.61) and lower baseline CQ-R score (0.95 per unit CQ-R 95%CI:0.92, 0.99). BMQ concern and necessity scores, HADS depression score, illness perceptions and other patient characteristics were not associated with adherence.

Conclusion: Over 20% of individuals were nonadherent although as many patients missed doses under medical advice. The effects of relatively low levels of non-usage of MTX, either due to non-adherence or to advised withdrawal, on disease outcomes is yet to be evaluated, however, these data suggest that levels of overall adherence to MTX over the first 6 months of therapy were very high.

Table 1: Baseline characteristics of cohort and association with nonadherence

Baseline variable	n	Adherent	n	Nonadherent	Adjusted odds ratio (95%CI)‡	p
Age (years)	304	61.4 (51.5–70.1)	79	59.7 (48.6–69.0)	0.98 (0.96–1.00)	0.103

Psychological Factors Predict Adherence to Methotrexate (MTX) in Rheumatoid Arthritis (RA); Findings from a Systematic Review of Rates, Predictors and Associations with Patient Outcomes. Holly Hope[1], James Bluett[1], Kimme Hyrich[2], Lis Cordingley[3] and Suzanne M. Verstappen[2]. [1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom, [2]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [3]Centre for Musculoskeletal Research, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Methotrexate (MTX) is a first line therapy for Rheumatoid Arthritis (RA). Treatment response to MTX is not universal, and nonadherence may partially explain poor treatment response to MTX, therefore it is imperative to investigate adherence to MTX specifically. Previous systematic reviews have evaluated adherence to all DMARDs. The aims of this systematic review were: 1) to summarise existing rates of adherence to MTX, 2) to identify predictors of adherence and 3) assess the association between non-adherence with patient outcomes.

Methods: A systematic search of papers published between January 1980 to 2014 was conducted in PubMed, PsycINFO, EMbase and CINAHL databases. Studies were eligible for inclusion if; 1) MTX was used as monotherapy or in combination with other therapies, 2) MTX was used in an RA or inflammatory polyarthritis population, 3) adherence was defined and measured as the extent to which patients followed their MTX regimen during the period of prescription, and 4) it was an original piece of research. Papers were reviewed by two researchers and consensus agreed with a third. A quality assessment (QA) tool formally assessed each included article.

Results: In total, ten studies met the inclusion criteria and eight were evaluated high quality using the QA tool. Rates of adherence ranged widely from 59% to 107%, and exposed differences in definitions of adherence, study methodologies and sample heterogeneity. The methods used to assess adherence included; Medication Event Monitoring Systems (n=2), Pharmacy Refill (n=5), validated self-report questionnaire (n=2) and 7 day diary (n=1) (Table 1). Twenty-one potential predictors of MTX adherence were identified; the strongest evidence occurred for beliefs in the necessity and efficacy of MTX, absence of low mood, mild disease and MTX as a monotherapy. Disease activity was the only patient outcome where the effect of nonadher-

ence was assessed. Three studies tested this association and each found nonadherence associated with poor treatment response.

Conclusion: Psychological factors were the strongest predictors of adherence rates in this first systematic review specific to MTX. It was the first to include synthesis of evidence on patient outcomes and show nonadherence to MTX affects treatment response in RA.

Table 1. Comparison of MTX rates of adherence across studies

Author	QA score	High/low quality	Adherence method used	Definition of MTX adherence	n	MTX adherence	95% CI/SD

2033

Patient Factors Associated with Oral Glucocorticoid Prescribing Patterns in UK Primary Care for Patients with Rheumatoid Arthritis. Rachel J. Black[1], Rebecca Joseph[1], Benjamin Brown[2], Mohammad Movahedi[1], Mark Lunt[3] and William G Dixon[1]. [1]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [2]Centre for Health Informatics, Institute of Population Health, The University of Manchester, Manchester, United Kingdom, [3]University of Manchester, Manchester, United Kingdom.

Background/Purpose: Oral glucocorticoids (GCs) are commonly used in the treatment of rheumatoid arthritis (RA) and GC prescriptions are often issued in the primary care setting. The objective of this study was to describe the patterns of GC prescribing for patients with RA in UK primary care and to identify patient characteristics that are associated with GC use.

Methods: 16 536 patients with incident RA were identified from the Clinical Practice Research Datalink, a large UK general practice database. Descriptive statistics were used to identify patterns of GC prescribing for these patients. For patients who received more than one GC prescription over the observation period, the mean, minimum and maximum prednisolone equivalent doses were calculated. The median of these values across all treated patients was then calculated. Stepwise linear regression was used to identify baseline patient characteristics associated with GC prescriptions including: Demographics, Inflammatory comorbidities, GC-associated comorbidities and DMARDs.

Results: 7749 patients (47%) received at least one GC prescription during the follow up period. The median proportion of time spent on GCs was 24.3% (IQR 36.2%-64.2%). The median mean dose per treated patient was 7.5mg per day (IQR 5–15.7mg), the median minimum dose per treated patient was 5mg per day (IQR 2.5–7.5mg) and the median maximum dose per treated patient was 15mg per day (IQR 7.5–30mg).

Each 10-year increase in age was found to be associated with a 17% greater likelihood of being prescribed GCs (95%CI 1.14–1.20). There was no association with patient gender. Higher GC prescribing was seen in patients with inflammatory comorbidities of the lung: asthma (OR 1.59, 95%CI 1.43–1.76), chronic obstructive pulmonary disease (OR 1.65, 95%CI 1.35–2.01) and lower respiratory tract infections (OR 1.21, 95%CI 1.10–1.33). However, there was no association with inflammatory conditions of the skin or GI tract. The association with GC-associated comorbidities was less consistent. GC prescribing was higher in patients with cardiovascular disease (OR 1.27, 95%CI 1.05–1.53) and in current smokers (OR 1.22, 95%CI 1.13–1.32) but lower in patients with diabetes (OR 0.71, 95%CI 0.62–0.82) and high cholesterol (OR 0.86, 95%CI 0.76–0.97). There was no association with other GC-associated comorbidities including osteoporosis, avascular necrosis, myopathy, insomnia, depression, hypertension, peptic ulcer disease or pancreatitis. A previous GC prescription prior to RA diagnosis was the strongest predictor of ever use post-diagnosis (OR 9.38, 95%CI 8.41– 10.46). GC prescribing was lower with methotrexate (OR 0.81, 95%CI 0.66–0.98) and sulfasalazine use (OR 0.69, 95%CI 0.58–0.83), but higher with leflunomide (OR 1.76, 95%CI 1.19–2.61) and other DMARD use (OR 1.73, 95%CI 1.33–2.26).

Conclusion: The presence of certain comorbidities at diagnosis, in particular inflammatory lung conditions, influenced GC prescribing. GC therapy was prescribed more commonly in higher risk patients, including older patients and those with CVD. Other GC-associated comorbidities, such as diabetes and hyperlipidaemia, were associated with less GC prescribing.

2034

A Treat-to-Target Strategy Preserves Work Capacity in Early Rheumatoid Arthritis (RA). Mihir D. Wechalekar[1], Steve Quinn[2], Susan Lester[3], Ella Shanahan[4], Robert Metcalf[5], E. Michael Shanahan[6] and Susanna Proudman[4]. [1]Flinders University School of Medicine, Adelaide, Australia, [2]Flinders University, Adelaide, Australia, [3]Queen Elizabeth Hospital, Woodville South, Australia, [4]Discipline of Medicine, Adelaide, Australia, [5]University of Adelaide, Adelaide, Australia, [6]Flinders University, Bedford Park, South Australia, Australia.

Background/Purpose: Historical data [(1)]indicate a third of patients with RA are unable to work within the first 5 years of diagnosis. Our aim was to quantify work disability in an inception cohort of patients with early (<12 months) RA (fulfilling ACR 1987 revised classification criteria) receiving treat-to-target combination DMARD therapy.

Methods: Patients received initial triple therapy (methotrexate, sulfasalazine and hydroxychloroquine) with escalation (using other DMARDs or biologic DMARDs) to achieve DAS28(ESR) remission. Patients completed an annual validated work and arthritis questionnaire. Random effect mixed modelling was used to assess associations between the primary outcome, average hours worked per week, and baseline prognostic factors, with subject entered as a random effect to account for correlated observations. Hours worked per week (HWPW) were compared with age, gender and period matched population averages.

Results: There were 541 observations on 139 patients. Patients were included in the analysis if they had complete data and were working at any time point, that is, those with at least one positive value for hours worked; this included 67 patients with 313 observations. The mean (SD) age at disease onset was 42.8 (11.0) years; 55/67 (82%) were women; median (IQR) duration of polyarthritis was 16 (12–28) weeks. The median (IQR) follow up time was 3 (2.0–5.2) years. At baseline, the proportion of patients in work at baseline was 67% and this did not significantly change with time (73% at the end of the follow-up period).

Males worked more hours; there was no significant loss of working hours over the mean follow-up period (Table 1). Anti-cyclic citrullinated peptide antibody positivity was associated with loss of working hours; there was no relationship between baseline or area-under-the-curve DAS28 and HAQ and working hours lost. When examined by profession 50% working as labourers

on enrolment gave up work on follow up as compared to only 7% of those in managerial roles. For the matched population averages HWPW increased by 3.7 over a comparable follow-up period (p=0.001).

Table 1.

	p-value
Males worked 14.5 (95% CI 6.4, 22.6) hours/ week more than females	<0.001
Patients with anti-cyclic citrullinated peptide (CCP) positivity were more likely [7.4 (95%CI 1.3, 13.7)] to reduce working hours	0.017
Loss of working hours over mean follow-up period was 0.85 (95%CI –1.65, 3.4)	0.52

Conclusion: In contrast to the era before the advent of more intensive treatment approaches, a treat-to-target strategy mainly using conventional DMARDs preserves work capacity in patients with RA over the first few years of disease. Patients with ACPA or in manual labouring roles were more likely to reduce working hours.

Joint Distribution and Outcome in 350 Patients with Monoarthritis of Less Than 16 Weeks Duration: Data from a Multicenter Longitudinal Observational Study in Eastern Norway.

Ellen Sauar Norli[1], Gina Hetland Brinkmann[2], Tore K. Kvien[2], Olav Bjørneboe[1], Anne Julsrud Haugen[3], Halvor Nygaard[4], Cathrine Thunem[5], Elisabeth Lie[2] and Maria Dahl Mjaavatten[2]. [1]Martina Hansens Hospital, Sandvika, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Østfold Hospital Trust, Fredrikstad, Norway, [4]Revmatismesykehuset Lillehammer, Lillehammer, Norway, [5]Betanien Hospital, Skien, Norway.

Background/Purpose: Cohort studies are essential to provide better understanding of the prognosis of acute monoarthritis, but few studies have focused on this issue. Our objective was to study the joint distribution and 2-year outcome of patients with new-onset monoarthritis, with a particular focus on outcome according to the joint involved.

Methods: 1119 patients (age 18–75 years) with arthritis of less than 16 weeks duration were included in the NOR-VEAC study from 2004 to 2010. Patients with crystal arthritis, septic arthritis, osteoarthritis or arthritis due to trauma were excluded. 364 patients (33%) had monoarthritis (clinical synovitis of one joint only) at baseline. Follow-up data were available for 350 patients (96%), and 221 (63%) had 2-year follow-up data. Patients with incomplete follow-up were included to avoid bias, as more patients achieving versus not achieving remission tended to be lost to follow-up before 2 years.

Results: Median (25–75 percentiles) duration of joint swelling among the 350 patients with monoarthritis was 23 (7–48) days, mean (SD) age was 46 (14) years, 52.0% were females, 6.6% anti-CCP pos. (14% missing), 8.6% RF pos. (11% missing), 11% anti-CCP and/or RF pos. (14% missing). The most frequently affected joints were the knee (49.1%), ankle (16.9%) and wrist (14.0%) and relatively few patients had small joint involvement (table).

15 patients (4.3%) fulfilled the 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA) at baseline; these had mostly wrist and small joint involvement. Two patients with clinical synovitis of the knee fulfilled the criteria as a result of additional tender joints. Nine additional patients fulfilled the criteria during follow-up, of whom 8 presented with large joint arthritis (table). No patient with ankle monoarthritis ever fulfilled the criteria, nor progressed to a clinical diagnosis of RA within 2 years of follow-up.

55 patients (16%) were diagnosed with reactive arthritis at baseline, 11 patients (3%) with psoriatic arthritis (PsA) and 3 patients (1%) with other spondyloarthritides (SpA). During follow-up only 5 more patients were classified as PsA and 2 more as other SpA. The patients finally diagnosed with PsA had monoarthritis of the knee (n=8), wrist (n=4), hand (n=2), elbow (n=1) and foot (n=1) at presentation. The corresponding numbers for other SpA were knee (n=2), ankle (n=2) and hip (n=1). In addition 5 (1.4%) patients were diagnosed as Lšfgren's sarcoidosis. In 261 patients (74.6%) the arthritis had resolved without DMARD treatment at last follow-up. 49 patients (14.0%) were prescribed with DMARDs, 188 (53.7%) received intra-articular corticosteroids, and 80 (22.9%) systemic corticosteroids.

Baseline and follow-up data according to joint distribution in 350 patients with monoarthritis

	Swollen joint at baseline	Fulfillment of RA criteria * at baseline	Fulfillment of RA criteria * later	DMARD use	Arthritis resolved **
	n=350	n=15 (4.3%)	n=9 (2.7%)	n= 49 (14.0%)	n=261 (74.6%)
Hand ***	23 (6.6%)	5 (21.7%)	0	5 (21.7%)	16 (69.6%)
Wrist	49 (14.0%)	5 (10.2%)	1 (2.3%)	14 (28.6%)	31 (63.3%)
Elbow	5 (1.4%)	0	0	1 (20.0%)	3 (60.0%)

Biologic Disease-Modifying Antirheumatic Drugs and Risk of High-Grade Cervical Dysplasia and Cervical Cancer in Women with RA.

Seoyoung C. Kim[1], Sebastian Schneeweiss[1], Jun Liu[1], Elizabeth W. Karlson[2], Jeffrey N. Katz[1], Sarah Feldman[1] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Human papillomaviruses (HPV) are causes of high-grade cervical dysplasia and cervical cancer. Persistent HPV infection, the major risk factor for cervical cancer, is associated with several factors including HPV genotypes, multiple sexual partners, history of sexually transmitted disease (STD), and immunosuppression. A recent large cohort study found a higher risk of high-grade cervical dysplasia and cervical cancer in patients with rheumatoid arthritis (RA) compared to non-RA patients. The objective of this study was to assess the risk of high-grade cervical dysplasia or cervical cancer related to use of biologic disease-modifying antirheumatic drug (DMARD) versus only non-biologic DMARDs for RA.

Methods: Using U.S. commercial insurance claims data (2001-12), we conducted a cohort study to examine the incidence rates (IR) of high-grade cervical dysplasia or cervical cancer in women who initiated biologic or non-biologic DMARDs for RA. The index date was defined as the date of the first biologic or non-biologic DMARD after ≥2 diagnoses of RA. Patients were required to have an enrollment period of ≥365 days prior to the index date for baseline covariate assessment. High-grade cervical dysplasia or cervical cancer was defined by a validated claims-based algorithm with a positive predictive value of ≥81%. The number of gynecologic (Gyn) visits or procedures during follow-up was also assessed. To control for potential confounders such as age, being sexually active, comorbidities including STD, medications, prior Papanicolaou test, and healthcare utilization, biologic DMARD initiators were matched to non-biologic DMARD initiators on the propensity score (PS) with a 1:1 ratio.

Results: 7,539 PS-matched pairs of biologic and non-biologic DMARD initiators were included with a mean age of 50 years. 39% had a Papanicolaou test at baseline. During a mean (SD) duration of active treatment of 1.4 (1.5) years, 20 developed high-grade cervical dysplasia or cervical cancer. The IR of high-grade cervical dysplasia or cervical cancer per 1,000 person-years was 1.12 in biologic DMARD initiators and 0.70 in non-biologic DMARD initiators. The hazard ratio was 1.63 (95%CI 0.62–4.27) for biologic DMARD compared to non-biologics (**Table**). The number of outpatient Gyn visits (Rate ratio [RR] 0.96, 95%CI 0.88–1.04) and Gyn procedures (RR 0.94, 95%CI 0.86–1.02) was not different between the groups.

Conclusion: Among women with RA, initiation of biologic DMARDs may be associated with a moderately increased, albeit not statistically significant, risk of high-grade cervical dysplasia or cervical cancer, although the absolute risk was low. Both biologic and non-biologic DMARD initiators had a similar number of Gyn visits and procedures during follow-up. Future

research should determine the need for more intensive cervical cancer screening strategy in RA patients.

Table. Risk of high-grade cervical dysplasia or cervical cancer associated with initiation of biologic versus non-biologic DMARDs: 1:1 propensity score matched as treated analysis

	Biologic DMARD (N=7,538)				Non-biologic DMARD (N=7,538)			
	Event	Person-years (PY)	IR * (95%CI)	HR (95%CI)	Event	Person-years (PY)	IR * (95%CI)	HR (95%CI)
High-grade cervical dysplasia or cervical cancer	14	12,452	1.12 (0.66–1.89)	1.63 (0.62–4.27)	6	8,536	0.70 (0.31–1.56)	Ref

* IR is per 1,000 person-years.
The propensity score model includes age, sex, calendar year, comorbidities, HPV vaccine, being sexually active, STD, other comorbidities, medication use including oral contraceptives and steroids, Pap test, HPV DNA test, and other health care utilization factors.

2037

Incidence and Prevalence of Myasthenia Gravis in Rheumatoid Arthritis Patients with and without Treatment Compared with the General Population. Neil Accortt[1], Mary Anthony[1], Jennifer Schenfeld[2], Travis Wheeling[2], Anna Hassebroek[2], Cynthia O'Malley[1] and Michael Sprafka[1]. [1]Amgen, Inc., Thousand Oaks, CA, [2]Docs Global, Inc, North Wales, PA.

Background/Purpose: There is a dearth of information on the incidence rate of myasthenia gravis (MG) in the US and specifically among rheumatoid arthritis (RA) patients. RA patients have been shown to be at risk for other autoimmune diseases so we sought to describe the rate of MG among RA patients, with and without treatment.

Methods: We conducted a retrospective cohort study using an administrative claims database. There were 8 study cohorts: General population (GP); incident RA population regardless of treatment; and 6 RA sub-cohorts defined by treatment exposure. Inclusion criteria included a minimum of 2 years of continuous enrollment with pharmacy coverage between 01/01/2005 – 12/31/2011. To ensure incident RA, patients could not have any RA claims during the first 12 months of enrollment. RA patients were followed forward and assigned to exposure sub-cohorts: Untreated (RA-U), 3 cohorts of different disease modifying anti-rheumatic drugs (RA-DMARDS1, RA-DMARDS2, RA-DMARDS3); TNF-inhibitors (RA-TNF); and other biologic therapies (RA-OB). Patients could be in ≥ 1 sub-cohort. MG diagnosis was captured using diagnostic and procedure claims. Prevalent MG cases in the GP and RA cohorts were identified during the first 12 months of enrollment. Follow-up for GP began on day 366 following enrollment; for RA and RA-U it began on date they met the criterion for RA diagnosis, and for RA sub-cohorts it began on medication start date. Follow-up continued until MG diagnosis, disenrollment from the database, end of study, and for the sub-cohorts, 90 days after discontinuation or switch in treatment. Incidence rates and 95% confidence intervals per 100,000 person years were estimated for MG, excluding prevalent cases. Incidence and prevalence estimates were age- and sex- standardized to the GP.

Results: The mean age and sex distribution were 37.1 years and 52% female for GP and 56.3 years and 74% female for RA. Gender and age distributions in the RA sub-cohorts were similar to RA. Prevalence of MG was 24.3 per 100,000 in the GP cohort and 86.8 per 100,000 in the RA cohort while the incidence was 10.4 per 100,000 and 35.8 per 100,000 in the GP and RA cohorts, respectively. MG incidence was highest in the RA DMARD3 (azathioprine, cyclosporine, cyclophosphamide, gold salts or penicillamine) sub-cohort. Due to the small number of MG cases, there was no discernable incidence pattern in the other sub-cohorts. Sensitivity analyses allowing for different follow-up times or using different algorithms to define MG showed little difference in the results.

Conclusion: As with other autoimmune diseases, subjects with RA appear to be at a higher risk from MG than the general population. We found both the prevalence and incidence of MG to be 3–4 times higher among RA patients compared to GP, however, with the exception of the RA DMARD-3 cohort, treatment did not appear to influence the incidence of MG following RA diagnosis.

2038

Respiratory Cause Mortality Was Significantly Predicted By Incident Rheumatoid Arthritis (RA) and Higher Pre-RA Levels (0.50+ SD) of Soluble Interleukin-2 Receptor Alpha (sIL-2Rá): Results of a 21-Year Community-Based Cohort Survival Analysis. Alfonse T. Masi[1], Azeem Rehman[1], Huaping Wang[1] and Jean Aldag[2]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL, [2]University of Illinois College of Medicince at Peoria, retired, Peoria, IL.

Background/Purpose: Interstitial lung disease (ILD) mortality is reported to be increased in RA (Bongartz T et al. A&R 2010; 62: 1583-91). However, non-malignant respiratory mortality has not been reported in population-based RA and CN subjects. This study aimed to analyze predictors of non-malignant respiratory cause mortality in a community-based cohort of incident RA vs non-RA control (CN) subjects as well as the relation of higher baseline levels of immunological biomarkers.

Methods: Total incident cases (n = 54) had onset of ACR-positive RA, 3 to 20 (mean 12) years, after cohort entry (n = 21,061 adults) in 1974. Cases were matched at entry with 203 CN by age, gender, and race (all Caucasian). All subjects (n=257) had baseline data on: demographic, cigarette smoking, and inflammatory or cytokine biomarkers (n = 7) tested on stored (−70°C) sera. A total of 113 deaths were identified from 1992 to 2013, and 100 of them had completed death certificates retrieved. Two investigators independently determined underlying causes of death from the completed certificate codes, without knowledge of RA vs CN status. The few differences in interpretation were also "blindly" resolved. Multiple imputation and aggregate methods were used to enter values for a minority of randomly missing test results on the analyzed biomarkers: acute serum amyloid A (ASAA); C-reactive protein (CRP); IL-1β; IL-1ra; TNFα; sTNF-R1, and sIL-2Rα. Biomarker values were normalized using z-scores within sexes to adjust for any dimorphic differences. Critical limits of biomarker levels were searched to identify associations with total mortality, e.g., 0.50+SE for sIL-2Rα. Non-malignant respiratory diseases included ICD-9 codes, 460–519, and ICD-10 codes, J00-J99. Cox regression models were used to estimate hazard ratios (HRs) for respiratory causes of death vs remaining subjects, adjusting for covariates.

Results: Non-malignant respiratory deaths occurred in 8 (14.8%) of 54 RA vs 5 (2.5%) of 203 CN, p = 0.001 by Fisher's exact test. The HR for respiratory deaths was 14.3 (95% CI 3.07–66.82), p = 0.001, in RA vs CN, after adjusting for cohort entry age, cigarette smoking, years of education, and the 7 immunological biomarkers. Respiratory death was independently predicted by: RA vs CN; entry age, and higher levels (0.50+SE) of sIL-2Rα, as shown in the below Cox survival model, adjusted for 9 additional covariates.

Conclusion: Respiratory deaths were significantly (p = 0.001) greater in incident RA (14.8%) than CN (2.5%), with an HR of 14.3 (3.07–66.82), and higher sIL-2Rα levels significantly (p = 0.001) predicted respiratory cause mortality, which deserve further investigation.

Variables in the Model	HR (95% CI)	P values
CN vs RA (CN=0, RA=1)	14.32(3.07-66.82)	0.001
Cohort Entry Age (yrs)	1.29(1.13-1.46)	0.000
sIL-2Rα (0.50+ SD), no = 0, yes = 1	37.65(4.68-302.90)	0.001
Degree of Smoking (7-scale)	1.01(0.65-1.59)	0.960
Sex (F= 0, M = 1)	2.71(0.57-12.90)	0.211
Completed Education (yrs)	0.95(0.72-1.24)	0.690
ASAA (0.0+ SD), no = 0, yes = 1	1.05(0.25-4.48)	0.948
CRP (0.0+ SD), no = 0, yes = 1	0.42(0.11-1.65)	0.214
IL-1β (continuous)	2.27(0.77-6.71)	0.139

2039

Among Persons Assayed with Lower Serum Interleukin-1 Beta (IL-1β) Levels, Serum Androstenedione (Δ4A) and Testosterone (T) Were Significantly Lower in a Community-Based Cohort of Rheumatoid Arthritis Multi-Years before Clinical Onset (Pre-RA) Than in Non-RA Matched Control (CN) Subjects. Alfonse T. Masi, Azeem A. Rehman and Jean C. Aldag. University of Illinois College of Medicine at Peoria, Peoria, IL.

Background/Purpose: Dysregulations in androgenic-anabolic (A-A) steroids and cytokines are recognized in RA and pre-RA subjects (Rheum Dis Clin N Am 2005; 31: 131-60). However, deviations in correlations of these interacting systems have not been reported. This study analyzed baseline serum levels of the IL-1 profile (IL-1β and IL-1ra), A-A steroids, and cigarette smoking in a cohort of pre-RA and CN subjects.

Methods: The community-based cohort enrolled 21,061 adults (12,381 F, 8,680 M) in 1974. Over 3–20 (median 12) yrs, 54 (36 F, 18 M) cases developed RA by 1988 ACR criteria. Four CN who did not develop RA were matched to each case on age (±2 yrs), sex, and race. Baseline stored (−70°C) sera were assayed in pre-RA-CN sets at national referral laboratories without knowledge of status. IL-1β and IL-1ra were assayed using ELISA immunoplates (R&D Systems Inc., Minneapolis, MN) and A-A steroids by RIA. Multiple imputation and aggregate methods were used to enter values for a minority of randomly missed test results. Biomarkers were normalized using z-scores within sexes to adjust for any dimorphism. Logistic regression searched for independent predictors of dependent lower vs higher IL-1β z-score subgroups. Predictors of A-A levels were identified by linear regression. Frequency distributions were determined for the dichotomous IL-1β subsets and the pre-RA vs CN subgroups with A-A steroids, IL-1ra, and baseline cigarette smoking (7-scale), and evaluated by Fisher's exact test.

Results: In 257 total subjects (54 pre-RA, 203 CN), lower (n=165) vs higher (n=92) IL-1β z-score subgroups strongly ($p < 0.0001$) associated with combined RA and CN lower vs higher IL-1ra frequencies (Table 1). Logistic regression confirmed that only IL-1ra levels predicted the IL-1β dichotomy, including 6 other variables in the model (Table 2). In 165 lower IL-1β subjects (36 pre-RA, 129 CN), pre-RA had significant deficits of higher Δ4A ($p < 0.0001$) and T ($p < 0.001$) vs CN (Table 1). Linear regression confirmed that the dependent A-A steroid levels were predicted by the pre-RA vs CN status at strengths equivalent to known negative correlations with age. In the 92 higher IL-1β subgroup, 9 (50%) of 18 pre-RA vs 8 (10.8%) of 74 CN had higher cigarette usage ($p < 0.001$), consistent with an inflammatory association of smoking and RA risk.

Conclusion: Androstenedione and testosterone levels were significantly lower in pre-RA than CN subjects who had lower IL-1β levels, whereas cigarette usage was respectively greater in the RA subjects who had higher IL-1β levels. The new findings support neuroendocrine immune interactions in the risk of developing RA.

Table 1. Frequency Distributions of Lower vs Higher and Total IL-1β z-Scores

Bivariates Subgrouped by Lower vs Higher Z-Scores	Lower IL-1β Z-Scores		Higher IL-1β Z-Scores		Total IL-1β Z-Scores	
	36 RA*	129 CN†	18 RA*	74 CN†	54 RA	203 CN
IL-1ra: Lower‡	21 (113)	92	9 (38)	29	30	121
: Higher	15 (52)	37	9 (54)	45	24	82
p-values (2×2 Frequencies)		0.158		0.434		0.642
Androstenedione: Lower	30	67	5	36	35	103
: Higher	6	62	13	38	19	100
p-values (2×2 Frequencies)		<0.0001		0.123		0.068
Testosterone: Lower	29	65	4	40	33	105
: Higher	7	64	14	34	21	98
p-values (2×2 Frequencies)		<0.0001		0.019		0.282
Clg7 Scale: Lower	32	119	9	66	41	185
: Higher	4	10	9	8	13	18
p-values (2×2 Frequencies)		0.508		0.0006		0.004

*In 54 RA alone, lower vs higher randrostenedione ($p < 0.0001$) and testosterone ($p < 0.0001$) correlated oppositely with lower vs higher IL-1β z-scores.
†In 203 CN alone, lower vs higher IL-1ra correlated positively with lower vs higher IL-1β z-scores, i.e. 92, 37, 29, 45 ($p < 0.0001$).
‡In 257 combined RA and CN, lower vs higher IL-1ra frequencies associated positively with lower vs higher IL-1β z-scores, i.e. 113, 52, 38, and 54 ($p < 0.0001$).

Table 2. Regression Analyses of Lower vs Higher IL-1β and Other Dependent Outcome Variables

Study Sample	N	Dependent Outcome Variable	Independent Predictors	p values	Exponent B	Non-significant Variables
Total subjects	257	Lower vs Higher IL-1β	IL-1ra	<0.001	2.269	Baseline age, sex, CN=0/RA=1, cigarettes (1–7), androstenedione, testosterone
Lower IL-1β	165	Androstenedione	CN=0/RA=1	0.001	−0.388	Sex, cigarettes

Background/Purpose: Biological drug therapy is frequently used to treat autoimmune diseases.

These drugs have an increased risk of infections, among them opportunistic infections.

To evaluate the frequency and type of opportunistic infections in patients with auto immune rheumatic diseases treated with biologic drugs compared to controls.

Establish whether disease and treatment features influence frequency and severity of opportunistic infections.

Methods: Biobadasar is database of rheumatic diseases patients treated with biologic drugs in Argentina. Created in 2010, it includes patients with a diagnosis according to accepted criteria treated with biologic drug therapy and controls not treated with biologic drugs.

Opportunistic infections (OI) are caused by pathogens (bacteria, viruses, fungi, parasites or protozoa), that usually do not cause disease in a healthy person (WHO).

The purpose of this work is to study the characteristics of opportunistic infections in patients with rheumatic diseases on biologic drug therapy compared with controls using the BIOBADAR database.

Statistical analysis was done using Chi-square test and t test with a significant $p \leq 0.05$.

Results: We included 2356 patients, 1275 54% on biologic drug therapy and 1081, 46% controls; 1862/2356, 79% were women, mean age 53.83 (SD6.02) years. Rheumatoid arthritis was the most common diagnosis 1829/2356, 77.6%.

Opportunistic infections were diagnosed in 40/1275 3.1% of patients treated with biologics, while 11/1081,1% of controls ($p = 0.0004$, OR 3.1, 95% CI 1.6–6.1).

Herpes Zoster was observed in 37 patients followed 6 Candidiasis, 2 Histoplasmosis, and one patient for each of the following, Cytomegalovirus, Pneumocystis jirovecii, hominis Blastocystis, Cryptosporidium, Echinococcus and Proteus.

Hospital admission was needed for 6/51, 11.7% of patients.

The median number of months from disease onset to the OI was 127 (IQR 46–223) months and from biological treatment onset to OI was 9 (IQR 4–18.5) months.

Table 1: Demographic Characteristics, Pathology and Treatment According to the Presence of Opportunistic Infections in Patients Treated with Biologics N: 1275

	With Opportunistic Infection (N:40)	Without Opportunistic Infection (N: 1235)	p	OR (IC95%)
Female n (%)	33 (82.5)	969 (72.5)	0.69	0.77 (0.33-1.76)
Years m±DS	**59.5 ± 14**	**53 ± 16**	**0.02**	
Month history M (RIQ)	60 (49-69)	56 (44-65)	0.07	
Neoplasia n (%)	**4 (10)**	**16 (1.3)**	**0.003**	**8.46 (2.69-26.59)**
Lymphoma n (%)	0	2 (0.2)	1	0.96 (0.95-0.97)
ischemic heart disease n (%)	1 (2.5)	18 (1.5)	0.45	1.73 (0.22-13.31)
Diabetes n (%)	3 (7.5)	78 (6.3)	0.73	1.2 (0.36-3.98)
kidney failure n (%)	**3 (7.5)**	**12 (1.0)**	**0.01**	**8.26 (2.23-30.5)**
Heart Failure n (%)	1 (2.5)	18 (1.5)	0.45	1.73 (0.22-13.31)
EPOC n (%)	0	26 (2.1)	1	0.96 (0.95-0.97)
Corticosteroids n (%)	**28 (70)**	**622 (51.0)**	**0.02**	**2.24 (1.12-4.44)**
Methotrexate n (%)	**17 (42.5)**	**892 (73.1)**	**0.00009**	**0.27 (0.14-0.51)**
Leflunomide n (%)	10 (25)	253 (20.7)	0.51	1.27 (0.61-2.64)
Sulfasalazine n (%)	1 (2.5)	96 (7.9)	0.36	0.30 (0.04-2.21)
Azathioprine n (%)	2 (5.0)	13 (1.1)	0.79	4.89 (1.06-22.43)

Conclusion: Opportunistic infections were more frequent in patients treated with biological drugs than in controls.

The most common opportunistic infection was Herpes zoster.

A history of cancer and renal failure, and concomitant treatment with corticosteroids were associated with of opportunistic infections.

Methotrexate therapy was not associated with OI.

Performance of a Two-Step Latent Tuberculosis Screening Algorithm in Patients with Rheumatoid Arthritis, Psoriatic Arthritis or Ankylosing Spondylitis Prior to Treatment with Tumor Necrosis Alpha Inhibitors: Prospective Observational Data from the Biorx.Si Registry, 2014 Update.

Ziga Rotar[1] and Matija Tomsic[2]. [1]University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]BioRx.si, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background/Purpose: Reactivation of latent tuberculosis infection (LTBI) is a serious concern in patients treated with TNF-α inhibitors (TNFi). Conversely, TB chemoprophylaxis (CP) is time consuming, delays the initiation of required treatment, adds to the overall cost of treatment, and carries risk of adverse events itself. Since 2002 our national guidelines require following a two-step screening algorithm prior to the initiation of the first TNFi. The first step includes tuberculin skin test (TST), and a chest X-ray (CXR). If TST < 5 mm, and the radiologist finds no changes consistent with TB on CXR TNFi is prescribed. If any test is abnormal, the patient is evaluated by a pulmonologist who usually orders QuantiFERON TB Gold IT (QF) and decides whether TB CP (rifampicin/isoniazid 600/300 mg qd for 3 months) is required prior to TNFi treatment.

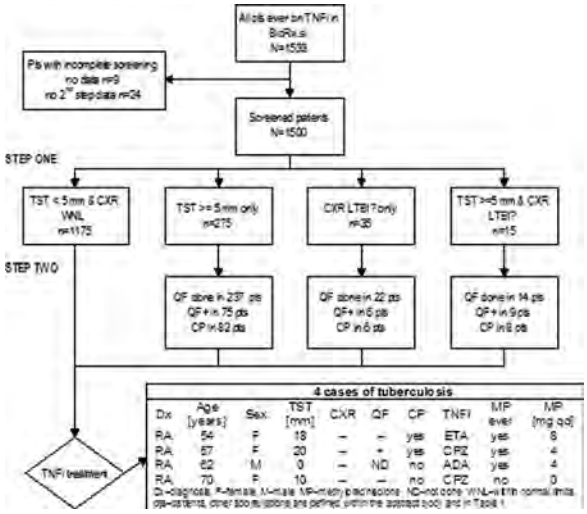
In February 2002 we showed that in a setting with low background annual TB incidence rate (IR) (i.e. 8.4 per 10^5) following of this algorithm resulted in TB IR of 0.11 (95% CI 0.01–0.38), and 0.16 (95% CI 0.02–0.58) per 100 person years (PY) overall, and in RA patients, respectively. The costly QF and CP were required in 13.9%, and 5.2% of patients, respectively. Our aim was to reevaluate the performance of this algorithm.

Methods: In March 2014 we cross-linked the data from the obligatory national registry of patients treated with biological DMARDs and the national TB registry to identify cases of TB in patients who were ever treated with TNFi.

Results: 1533 patients were treated with at least one TNFi for 3,846 PY (Table 1). Flow of patients through the screening algorithm and case patient characteristics are depicted in Figure 1. QF was performed in273/1500 (18.2%). 96/1533 (6.3%) patients received CP. Four cases of TB were identified, hence IR was 0.10 (95% CI 0.03–0.27), and 0.19 (95% CI 0.05–0.48) per 100 PY overall, and in RA patients, respectively. Only RA patients developed TB. The TB IR for certolizumab vs. other TNFi prescribed for RA was 1.3 (95% CI 0.16–0.47) vs. 0.1 (95% CI 0.01–0.37) per 100 PY ($p=0.027$ Fisher's exact test). The first two received appropriate CP (adherence was good, isolated M. tuberculosis strains were susceptible to CP) prior to TNFi, in the third patient the screening was stopped after 1st step and in the fourth one after the 2nd step. Interestingly, the 3rd case was screened for TB again before switching to rituximab. At repeated screening two months prior to TB diagnosis the TST was 10 mm, CXR neg. and QF–.

Table 1

	Rheumatoid arthritis	Ankylosing Spondylitis	Psoriatic arthritis
N (%)	**875 (57.1)**	**440 (28.7)**	**218 (14.2)**
% female	82	34	41
Age at screening (SD)	54.8 (12.1)	44.5 (13.4)	47.8(16.3)
% glucocorticoids at screening	46.9	/	/
% ever glucocorticoids	64.3	/	/
TNFi exposure years	2121	1205	520
% Adalimumab (ADA)	42.8	38.0	44.3
% Certolizumab (CZP)	7.1	0.0	0.3
% Etanercept (ETA)	36.7	29.1	26.3
% Golimumab (GOL)	3.2	9.0	12.1
% Infliximab (IFX)	10.2	23.9	17.0



Conclusion: At follow-up our two-step algorithm is still performing well. Further vigilance is warranted, especially in RA patients and those treated with CZP.

Tuberculin Conversion in Patients with Autoimmune Arthropathies Receiving Biologic Therapy.

Osvaldo Luis Cerda[1], Maria de los Angeles Correa[2], Amelia Granel[3], Ana Inés Marcos[3], Claudia L. Giraldo[4], Oscar L. Rillo[5] and Gustavo Citera[1]. [1]Instituto de Rehabilitación Psicofísica, Buenos

Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica de Buenos Aires, Buenos Aires, Argentina, [3]Hospital San Roque de Gonnet, La Plata, La Plata, Argentina, [4]Hospital Gral. de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [5]Hospital General de Agudos Dr. E. Tornú, Buenos Aires, Argentina.

Background/Purpose: Patients receiving biologic DMARDs are at increase risk of developing tuberculosis (TB). Tuberculosis skin test (TST) is recommended to screen for TB infection prior starting biologic DMARDs. However, TST during treatment with biologic DMARDs is not routinely assessed. Objective: To investigate the frequency of TST conversion in patients receiving biologic DMARDs who initially had a negative result.

Methods: Patients with Rheumatoid Arthritis (RA), Juvenile Idiopathic Arthritis (JIA) and Spondyloarthritis (SPA) under treatment with anti-TNFα, Tocilizumab and/or Abatacept and who had a previous negative TST were included. A second TST was performed in all patients within a period of 2 months to 2 years after of the first TST. TST convertion was defined as a variation greater than 5 mm between the two tests. Sociodemographic and clinical data were recorded. Moreover, presence of comorbidities as alcoholism, diabetes (DM), malnutrition, poverty and overcrowding, previous infection, or contact with TB and concomitant treatment (steroids, DMARDs and biologic treatment) were also taken into account for the analysis. Chi^2 test, Mann Whitney U test and logistic regression analysis were performed.

Results: Eighty-five patients were included, 78.8% females, mean age 51.76±11.9. 74.1% had diagnosis of RA, 16.5% Psoriatic arthritis, 4.7% JIA, and 4.7% AS. 75.3% were receiving anti-TNF treatment, 15.3% tocilizumab, and 9.4% abatacept. 84.7% were receiving concomitant MTX, 21.2% leflunomide and 18.8% were on high doses of steroids. 12, 9% lived in overcrowded conditions, 10.6% had controlled DM, 5.9% had TB (complete treatment), and 2.4% reported having had contact with TB patients. Other risk factors were infrequent. TST conversion was observed in 9.4% (8 patients) being more common in males 62.5% vs. females 37.5% (p=0.009) and among those with longer mean disease duration 226±109 month in TST conversion patients vs. 130±105 month in TST negative patients (p=0.017). These results persisted even after adjusting for confounders. No association was observed with treatments and comorbid conditions. All patients with TST conversion received prophylactic isoniazid treatment, and one patient developed active TB and received appropiated treatment.

Conclusion: In patients receiving biologic DMARDs, TST conversion rate was 9.4% and was more frequent in males and in those with longer disease duration. No association was observed between TST conversion and underlying rheumatic disease, presence of comorbidities or treatments used.

How Correct Are the Assumptions Made for Tuberculosis Screening Algorythms before TNF-Alpha Antagonists? Aysa Hacioglu[1], Yesim Ozguler[2], Sermin Borekci[3], Vedat Hamuryudan[1], Hanefi Deniz Kecebas[1], Ethem Koray Tascilar[2], Melike Melikoglu[4], Serdal Ugurlu[1], Emire Seyahi[1], Izzet Fresko[2], Huri Ozdogan[1], Sebahattin Yurdakul[1], Gul Ongen[3] and Gulen Hatemi[1]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [3]University of Istanbul, Cerrahpasa Medical Faculty, Department of Pulmonary Diseases, Istanbul, Turkey, [4]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: During the development of algorythms for screening latent tuberculosis before starting TNF-alpha antagonists, it is assumed that BCG vaccination causes false positive PPD and that concomitant medications such as corticosteroids cause false negative PPD results, favoring the use of Quantiferon or Elispot in these patients. Moreover it is assumed that INH is difficult to tolerate in this patient group. However we hypothesized that these assumptions may be wrong since there is a long time between BCG vaccination and TNF-alpha antagonist use in most of the rheumatology patients; there is no consistent data to show that disease modifying agents and corticosteroids in doses used for rheumatologic conditions are associated with negative PPD results; and INH is usually well tolerated by most of our patients.

Methods: We included patients who were prescribed a TNF-alpha antagonist for the first time between January 2011 and December 2012 in our clinic. Patients who had a previous tuberculosis infection were excluded since this could cause PPD positivity. We used logistic regression to analyse the determinants of a positive PPD (≥ 5mm). The variables were having a BCG scar, drugs (prednisolone, methotrexate, leflunomide, azathioprine, cyclosporine-A and cyclophosphamide), age, gender, diagnosis and disease duration. We also evaluated the frequency of being able to complete 9 months of INH treatment, the reasons for discontinuation and the frequency of developing tuberculosis among those who used and who did not use INH.

Results: A TNF-alpha antagonist was started in 961 patients (503 men, 458 women, mean age 41.28 ± 13.10 years, disease duration 6.54 ± 6.80 years). We excluded 75 patients who had previously used a TNF-alpha antagonist and 33 patients who had previous tuberculosis treatment. Among the remaining 853, an initial PPD test was available in 671 patients. At least one BCG scar was present in 592 patients. Logistic regression showed that BCG vaccination (OR=3.45, 95%CI 2.51–4.75, p<0.0001) and a diagnosis of ankylosing spondylitis (OR=1.79, 95%CI 1.21–2.65, p=0. 003) were associated with PPD positivity, while corticosteroid use was associated with a negative PPD (OR=1.96, 95%CI 1.09–3.51, p=0.023). INH was started in 525 patients and 391 had reliable data regarding INH use. 346 patients (87%) completed 9 months of treatment, 22 with interruptions. 45 had to stop INH after 3.85 ± 2.46 months. The reasons for discontinuation were hepatotoxicity in 26, allergic dermal reactions in 2, nausea in 2, dizziness in 2, pregnancy in 1, shortness of breath in 1, pancreatitis in 1 patient and non-willingness in 10 patients. Among the 26 who had to stop INH for transaminase elevation 13 were using concomitant methotrexate. None of the patients developed tuberculosis during our follow-up of up to 3 years.

Conclusion: BCG vaccination may still be a cause of false positive PPD in candidates for treatment with TNF-alpha antagonists. Corticosteroids seem to be associated with negative PPD while DMARDs are not. INH prophylaxis is generally well tolerated despite concomitant methotrexate. Longitudinal follow-up is necessary to determine the long term efficacy of INH treatment for preventing tuberculosis in these patients.

Systematic Review of the Effect of Anti-Rheumatic Therapies upon Vaccine Immunogenicity. Megan Whittaker[1], James Galloway[1] and Sujith Subesinghe[2]. [1]King's College London, London, United Kingdom, [2]King's College Hospital NHS Foundation Trust, London, United Kingdom.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of infection compared to the general population. The increased risk is attributable to factors relating to the underlying disease as well as the use of immunosuppression as the mainstay of management. Minimizing infection is an important challenge facing rheumatologists. Vaccination represents a unique opportunity to achieve this.

Current UK and European guidelines recommend annual influenza and one-off pneumococcal vaccination, however uptake of these vaccinations is poor. There is a paucity of data regarding vaccine immunogenicity in the context of rheumatic disease, and the evidence base for proving whether vaccinations reduce infections and associated mortality in RA is limited.

We conducted a systematic review of vaccination immunogenicity in the setting of anti-rheumatic therapy.

Methods: Studies evaluating the immunogenicity of either pneumococcal or influenza vaccinations in the setting of rheumatoid arthritis were identified using Pubmed, (Ovid, EMBASE). Search terms included (inflammatory arthritis OR rheumatoid arthritis) AND (immunization OR vaccination OR vaccine OR pneumovax OR prevenar).

This identified 3670 results, and1853 after limiting to humans. Abstracts were then manually reviewed by two authors (JG and MW) to identify articles reporting immunogenicity data for the vaccines of interest in adult patients with RA. The final selection identified 24 articles.

Results: The immunogenicity of vaccinations is influenced by factors including age, vaccine type, vaccine strain, disease and drugs. Concomitant drug therapy has the greatest effect on vaccine immunogenicity.

Two types of pneumococcal vaccines are currently licensed for use in the adult population, subunit polysaccharide (Pneumovax) and conjugate (Prevenar). Direct comparison between these vaccines demonstrated similar antibody responses.

Methotrexate, Rituximab and Abatacept are associated with decreased immunogenicity to both influenza and pneumococcal vaccination. Anti-TNF biologics, Tocilizumab and Sulphasalzine do not appear to have a negative effect on immunogenicity, although data is limited for the latter two.

Of the studies reporting the effect of vaccination on disease activity, none reported a significant change following vaccination.

Picture false

Table 1.

Drug	Control	Vaccine			
		Polysaccharide pneumococcal	Conjugate pneumococcal	Seasonal influenza	Pandemic influenza
Sulphasalazine	HV	(N) 1	No data	(N)1	No data
Methotrexate	HV	(Y) 2	(Y) 2	(N) 2[a] ⇓ 1	(Y) 4[b]
	RA	(N) (1) ⇓ (1)	No data	(Y) 2[c]	(Y)1
TNF	HV	(N) 2	(N) 1	(N) 3	(N) 3 (Y) 1[d]
	RA	(N) 3	No data	(N) 3 (Y) 1[e]	(N) 3
RTX	HV	No data	No data	(Y) 2[f]	(Y) 1
	RA	⇓ 2	No data	(Y) 3[g]	(Y) 1
Abatacept	HV	No data	No data	No data	(Y) 2
	RA	No data	No data	No data	(Y) 1
Tocilizumab	RA	No data	No data	(N) 1	No data

Key:
(N) no difference in response related to control
(Y) decreased response related to control
number= number of studies with findings with this result
[a]seroresponse decreased for one strain only, seroprotection not decreased vs RA controls
[b]seroprotection not decreased in 1 study
[c]seroresponse decreased for 2 strains, seroprotection not decreased
[d]third study found rates of seroconversion and seroprotection to be decreased for 1 of 7 serotypes only vs RA
[e]seroresponse decreased, but not seroprotection not decreased
[f]one study found seroresponse decreased to all strains. Seroprotection decreased to one strain only
[g]one study found decreased for 1 strain of 3 only.
Seasonal influenza vaccine: typically contains two strains of influenza A virus and one strain of influenza B virus (inactivated)
Pandemic influenza vaccine: contains one strain of influenza A H1N1, the agent responsible for the 2009 influenza pandemic

Conclusion: Although the humoral response to vaccination may be reduced by immunosuppressive agents, protective post vaccination titres are frequently achieved and accordingly vaccination is not precluded in this 'at-risk' population. Pneumococcal and influenza vaccination is safe in rheumatic disease and should be encouraged as part of the holistic management of RA patients. Challenges lie in determining the real world effectiveness of vaccination in RA, as well as how to maximise vaccine uptake through collaborative initiatives between primary and secondary care.

Interaction Effects Between Genes and Blood Lead Level on a Composite Score of Multiple Joint Symptoms: The Johnston County Osteoarthritis Project. Youfang Liu[1], Amanda Nelson[2] and Joanne M. Jordan[3]. [1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina Dept of Epidemiology, Chapel Hill, NC.

Background/Purpose: Previous studies suggested that blood lead level is associated with multiple joint symptoms. In this study, we conducted a Genome-Wide Gene-Environment Interactions analysis to search for genetic variations which may modify such associations.

Methods: Caucasians from the Johnston County Osteoarthritis Project (JoCo) with valid covariates and cleaned genotype data were included in this study. A composite score of multiple joint symptoms was calculated as the mean of summed 0–3 scores (none=0, 1=mild, 2=moderate, 3=severe) from seven joint sites including the hands, knees, hips and low back as previously reported. Whole blood lead level was measured by inductively coupled plasma-dynamic reaction cell-mass spectrometer analysis at the Centers for Disease Control and Prevention (Atlanta, GA). Genotyping was done using Illumina Infinium 1M-Duo bead arrays at Expression Analysis (Durham, NC). Original SNP data were imputed by software MACH using HapMap II Caucasian as the reference data. Linear models were applied across the genome-wide genetic data with adjustment for age, body mass index (BMI), sex, current alcohol use, smoking, and blood lead level. The residuals of the regression followed the normal distribution.

Results: Participants included 805 individuals, 63% of whom were women, with mean age 67 years (SD=10.5) and mean BMI of 30 (SD=6.4) kg/m^2. Log transformed blood lead level (median=0.53) was associated with multiple joint symptoms score with a p-value at 0.02. Two interactions between SNPs (rs2885880 and rs1598457) and lead significantly modified lead association with the multiple joint symptoms score (interaction P-value < 5x10E-08). Rs2885880 is located in gene RNF121 (ring finger protein 121). Based on Gene Ontology (GO) annotations, RNF121 might be related to zinc ion binding. Rs1598457 is located in gene GUCY1A2 (Guanylate Cyclase 1, Soluble, Alpha 2). Guanylyl Cyclases (GC) are a group of enzymes whose function requires the presence of metal ions such as Mg2+ or Mn2+. An additional promising interaction between fifteen SNPs (Table) and lead were identified (interaction p-values < 1E-06). For all the identified SNPs, the main effects of those SNPs were also significant with p-values < 0.05.

Conclusion: Two interactions between lead and SNPs were identified by the Genome-Wide Gene-Environment Interaction analysis. Those two SNPs are located in RNF121 and GUCY1A2, both related to handling of metals. These two genes may influence the impact of blood lead level upon symptoms in multiple joints. These results will require validation in independent datasets.

Perceived Discrimination in Individuals with Radiographic Knee and Hip Osteoarthritis. Rebecca J. Cleveland[1], Jordan B. Renner[2], Joanne M. Jordan[3] and Leigh F. Callahan[4]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina Department of Radiology, Chapel Hill, NC, [3]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [4]University of North Carolina, Chapel Hill, NC.

Background/Purpose: To describe the characteristics of participants who reported feelings of discrimination among a cohort of participants with radiographic osteoarthritis (rOA) of the knee and/or hip in the Johnston County Osteoarthritis Project (JoCo).

Methods: A cross-sectional analysis was carried out on 766 individuals with rOA who were assessed in the second follow-up evaluation (2006–2010) of JoCo. rOA was defined as Kellgren-Lawrence grade ≥ 2 in at least one knee or one hip. Any perceived discrimination was assessed using a validated measure asking "how often have you been treated with less courtesy or less respect than other people?" Responses were assessed on a likert scale ranging from 1 to 4 (1=never, 2=occasionally, 3=frequently, 4=always). If indicating any discrimination, follow-up questions asked for the more specific reasons for discrimination such as gender, age, race, disability, education, religion and body size (yes or no). Descriptive characteristics were assessed and Chi-square statistics were performed to examine whether a participant perceived any type of discrimination, and if so, the specific reason for the discrimination. Additionally, we assessed discrimination according to whether an individual had knee or hip rOA, and according to demographic characteristics.

Results: Participants were on average 68 years old, mostly women (67.7%), African American (30.5%), and had a mean BMI of 31.5. There were 520 participants with knee rOA and 473 with hip rOA. Thirty-nine percent of participants reported feeling discrimination at least occasionally (36.7% occasionally, 2.5% frequently, 0.3% always). The most commonly

reported reason for perceived discrimination was disability (20.5%) followed by age (10.9%) and race (10.6%). Those with hip rOA reported any discrimination more often than those with knee rOA (40.6% vs. 36.5%) (Table 1.). Any perceived discrimination tended to be reported more often among those who were male and younger than age 67 and lived in areas with less poverty. Age discrimination was reported more often among those who lived in higher poverty areas ($p<0.01$) while those who reported discrimination for religion lived in lower poverty areas ($p=0.01$). African Americans reported discrimination for skin color more often than whites ($p<0.01$) and racial discrimination was reported more frequently among men ($p<0.01$).

Conclusion: Perceived discrimination is frequently reported in people with knee and/or hip rOA in this racially diverse population in North Carolina, with disability being the most commonly reported reason. Discrimination is also associated with several demographic characteristics that could have an important impact on rOA outcomes.

No Association of Serum Uric Acid with Hip Fracture Risk in Older Men and Women from the Framingham Original Cohort. Shivani Sahni[1], Kelsey Mangano[1], Katherine Tucker[2], Caroline Fox[3], Douglas P. Kiel[4], Xiaochun Zhang[5] and Marian T. Hannan[1]. [1]Institute for Aging Research, Hebrew SeniorLife, Dept. of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]University of Massachusetts, Lowell, MA, [3]NHLBI's Framingham Heart Study and Center for Population Studies, Framingham, MA, [4]Institute for Aging Research, Hebrew SeniorLife, Dept. of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [5]Institute for Aging Research, Hebrew SeniorLife, Roslindale, MA.

Background/Purpose: Serum uric acid (UA) has been linked with fractures in older men. Three different studies in older men showed conflicting results. The objective of this study was to examine the association of UA with hip fracture risk over 19.9y follow-up in men and women from the Framingham Original Cohort.

Methods: 2,969 men & women had measured UA concentration (mg/dl) at baseline (1973-76) and were followed for hip fracture until 2009. We used Cox-proportional hazards regression to estimate Hazard Ratios (HR) adjusting for age, sex and menopausal status (men, pre- and post-menopausal women), weight and height. An interaction between UA and sex was tested. Analysis was conducted on a combined sample of men and women, if the interaction term was not significant ($P>0.05$).

Results: The mean age was 66y (SD: 7.7, range: 53–85). 368 hip fractures occurred over the follow-up (mean of 19.9 years). The mean ± SD (mg/dl) uric acid at baseline was: 5.3 ± 1.4. Interaction between UA and sex was not statistically significant ($P=0.72$); therefore, men and women were analyzed together. An increase in one unit of UA was associated with a 7% decrease in hip fracture risk in the crude model [HR(95%CI): 0.93 (0.86–1.0); $P=0.048$]. Similar associations were observed when UA was analyzed as tertile categories (*P*-trend: 0.08). Participants in the highest tertile of UA [HR (95%CI):0.79 (0.61–1.03)] tended to have lower risk of hip fracture than those in the lowest tertile ($P=0.08$).These associations became non-significant after adjustment for covariates.

Conclusion: These results suggest that serum UA is not a risk factor for hip fracture risk in older adults.

Table. Association of serum uric acid (mg/dl) with risk of hip fracture in men and women

	N	HR(95% CI)	P-value
Crude	2,969	0.93 (0.86,1.0)	0.048*
Adjusted[1]	2,966	1.01 (0.93,1.1)	0.850

Disability in Discretionary Valued Life Activities and Self-Efficacy Explain a Significant Portion of RA Patients' Global Assessments. Patricia P. Katz, Jennifer Barton, Chris Tonner, Jinoos Yazdany, Mary Margaretten, Gabriela Schmajuk and Ed Yelin. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Patient global assessments are components of RA disease activity calculations. Patient global assessments, however, do not consistently agree with physician assessments. This discrepancy leads to the question of how patients form global assessments, specifically the role of factors beyond generally recognized RA symptoms and health status. In this analysis, we evaluate the role of demographic factors, health status, functional limitations, psychological status, and disability in patient global assessments.

Methods: Data were from the Rheumatoid Arthritis Outcomes Study ($n = 438$), collected in structured telephone interviews conducted in English or Spanish. Patient global assessments were obtained with the item: "Considering all the ways that your arthritis affects you, how well are you doing?", with responses on a 0 – 100 (very poor – very well) scale. Demographic (age, sex, language, race/ethnicity, and education), health status (comorbid conditions, ratings of pain and fatigue, and current use of a DMARD, biologic therapy, or prednisone), functional limitations (measured with the Health Assessment Questionnaire, HAQ), depression, disability in valued life activities (VLAs), and self-efficacy were entered into sequential linear regression models to examine the contribution of each variable or group of variables to the overall disease assessment. The VLA scale was scored to provide mean difficulty in obligatory (i.e., necessary for independence and self-sufficiency), committed (associated with major life roles), and discretionary (e.g., socializing and engaging in activities that provide relaxation and pleasure) activities.

Results: Respondents were 88% female, mean age 60±13 years, 18% Spanish-speaking, and mean RA duration 23±12 years. Demographic factors alone yielded a model R^2 of 0.13 (Table 1). Addition of RA, health status and medications increased R^2 to 0.20; addition of functional limitations increased R^2 to 0.23. $R^2$was further increased by adding depression, VLA disability, and self-efficacy. Yet, the final model (Table 2) accounted for only 30% of the variation in patient global assessments, leaving the majority of such variation unexplained.

Conclusion: Difficulty in participating in discretionary valued life activities and self-efficacy – perhaps representing impact of disease on patients' daily lives and their evaluations of their ability to cope with RA – play significant roles in RA patients' global assessments of disease. The importance of these factors may provide insight into discrepancies between patient and physician assessments of disease.

Table 1. Summary of results of sequential linear regression models to estimate patient global assessments

	Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Model R^2	0.13	0.20	0.23	0.24	0.27	0.30
F (p-value) for difference in model from previous		4.24 (<0.001)	14.43 (<0.001)	9.26 (<.0001)	4.44 (<.0001)	17.58 (<.0001)

Model 1: age, sex, Spanish-speaking, African American, Asian, education
Model 2: Model 1 + comorbid conditions, pain, fatigue, use of DMARD, use of biologic, use of prednisone
Model 3: Model 2 + functional limitations (Health Assessment Questionnaire [HAQ])
Model 4: Model 3 + depression (Patient Health Questionnaire [PHQ] ≥ 5)
Model 5: Model 4 + VLA difficulty in obligatory, committed, and discretionary activities
Model 6: Model 5 + self-efficacy (Self-Efficacy for Managing Chronic Disease Scale)

Table 2. Variables in final regression model with $p<0.10$

	β

Fatigue Is a Risk Factor for Subsequent Functional Decline in SLE. Patricia P. Katz, Laura Trupin, Jennifer Barton, Gabriela Schmajuk, Mary Margaretten and Edward H. Yelin. University of California, San Francisco, San Francisco, CA.

Background/Purpose: In geriatrics, fatigue has been shown to be a harbinger of future functional decline. Fatigue is associated with poor function in systemic lupus erythematosus (SLE), but previous studies have not examined the longitudinal relationship between fatigue and poor function. In this analysis, we examine whether fatigue is a risk factor for subsequent functional decline among individuals with SLE.

Methods: Analyses use data from the Lupus Outcomes Study (2003–2011) obtained through annual structured telephone interviews. All participants have physician-confirmed SLE. Fatigue was measured with the SF-36 Vitality subscale. Scores range from 0–100, and higher scores reflect greater fatigue. Function was measured with the Valued Life Activities (VLA) disability scale, which has been validated in SLE. The VLA presents 28 life activities ranging from self-care to social, recreational, and work activities; respondents rate the difficulty they have in performing each on a 0 (no difficulty) to 3 (unable to perform) scale. Two VLA scores were calculated: mean difficulty and the percent of VLAs an individual was unable to perform. Analyses aimed to determine if fatigue at one time point (T1) was a risk factor for a decline in functioning between T1 and the subsequent year (T2). Declines were defined to approximate a clinically important difference: an increase of 0.5 SD in mean difficulty (0.3 points) or an increase ≥10% in the percent of VLAs unable to perform. Analyses include up to 8 pairs of years of interviews, using generalized estimating equations to account for multiple observations of individuals. Multivariate analyses controlled for age, sex, disease duration, disease activity (Systemic Lupus Activity Questionnaire, SLAQ), depressive symptoms (Center Epidemiologic Studies Depression scale, CESD), and presence of end-stage renal disease. A secondary analysis included only individuals under age 65.

Results: The primary analysis included 5105 observations of 1019 individuals, 92% female, with mean age 47±13 years, and mean disease duration 13±9 years. At initial interviews, mean fatigue score was 54.1±23.7. In 11.8% of paired observations, there was a functional decline by mean difficulty, and in 7.8%, a decline by percent of activities unable to perform. In bivariate analysis, T1 fatigue was a significant risk factor for subsequent functional decline between T1 and T2 (see table). After adjustment, T1 fatigue remained a significant risk factor for functional decline. Results of analyses including only age‹65 were similar.

Conclusion: Fatigue appears to be a risk factor for subsequent functional decline among individuals with SLE, even after accounting for other factors. Moreover, the risk is not confined to those age ≥65. High levels of fatigue may be a signal for impending functional decline, so can serve as an indicator for proactive intervention to prevent or minimize such declines.

Odds of functional decline associated with 10-point worsening of fatigue score

Knee Arthritis Is Positively Associated with Physical Impairment: Conclusion Based on Physical Examinations from a Cross-Sectional Study of 17708 Chinese Residents. Qiang Liu, Xu Tang Sr., Xu Wu, Zhengming Cao and Jianhao Lin. Peking University Health Science Center, Beijing, China.

Background/Purpose: The prevalence of knee arthritis is high in both urban and rural China. Although the association between knee arthritis and limitation of daily activity has been well documented in self-rated studies, no such conclusion has been made based on physical examinations from population-based study in China.

Methods: CHARLS (China Health and Retirement Longitudinal Study) is a population-based longitudinal survey among Chinese retired populations. During the baseline cross-sectional study period between 2011 and 2012, 17708 residents were recruited using door-to-door enumeration in 450 randomly selected communities in China. Subjects completed a home interview with a set of questions on self-rated health status and had a battery of performance-based physical examinations including test of balance, the 5 chair rise test and the gait speed. All the subjects were required to take the balance and the 5 chair rise test, while gait speed was examined only in those aged ≥60 years. Balance was evaluated by asking subjects to keep a stance with heel of one foot pressing the big toe of the other for at least 10 seconds. The 5 chair rise test was conducted using the regular method and gait speed was measured by recording the time each subject needed to pass 2.5 meters. Knee arthritis was only identified when both pain in knees and diagnosis of arthritis/rheumatism by a doctor were present. The association between knee arthritis and gait speed was examined using Linear regression, while the relation of knee arthritis to capacity of balance and the function of repeated sitting to standing was analyzed by Binary logistic regression, adjusting for age, sex, body mass index (BMI), smoking and drinking history, history of injury and hip fracture, and comorbidities.

Results: Among 17708 participants (men: 47.9%, mean age: 59.1 years, mean BMI: 23.4 kg/m^2), the prevalence of knee arthritis was 9.1%. 13521 (76.4%) and 13240 (74.8%) subjects, respectively, consented to take the test of balance and the 5 chair rise test. 5725 (72.7%) subjects participated the gait speed test. After adjustment for age, sex and other potential confounders, subjects with knee arthritis had increased failure rate of completing the test of balance (odds ratio=1.7, 95% confidence interval (CI): 1.3–2.3) and the 5 chair rise test (odds ratio=2.1, 95% confidence interval (CI): 1.5–2.9), as well as impaired gait speed (mean difference=0.204, 95% confidence interval (CI): 0.003–0.406) (Table).

Conclusion: Physical examination outcomes from the CHARLS study indicated that knee arthritis was positively associated with impaired physical function among the residents in China.

Modification of Effects of Household Income and Homeownership By Block Group Poverty on Health Outcomes in a Cohort of African Americans with Rheumatoid Arthritis. Rebecca Cleveland[1], Jennifer Smith[2], Antoine A. Baldassari[1], Beth L. Jonas[1], Doyt L. Conn[3], Larry W. Moreland[4], S. Louis Bridges Jr.[5] and Leigh F. Callahan[6]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Ohio University, Athens, OH, [3]Emory Univ School of Medicine, Atlanta, GA, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]University of North Carolina, Chapel Hill, NC.

Background/Purpose: We previously found that household income less than $30k/yr and not owning a home influenced rheumatoid arthritis (RA) disease severity measures. We sought to further expand our findings to explore whether block group poverty (BGP) modified the associations between income and homeownership with RA health outcomes (RAHO).

Methods: We carried out a cross-sectional analysis in 898 African American participants with RA in the CLEAR Registry. We assessed the main effects of BGP (≥20% vs. <20%) on RAHO, and explored whether BGP modified the associations between income or homeownership and RAHO. Multivariate regression models for continuous, binary and count outcomes were used to estimate beta coefficients (β), odds ratios (OR) and prevalence rate ratios (PRR), respectively, and their 95% confidence intervals (CI). Associations between income and homeownership on RAHO were stratified by BGP and interaction p-values calculated. All analyses were

adjusted for gender, age, body mass index, disease duration, pack-years of smoking, number of comorbidities, current Methotrexate/Leflunomide use, current biologics use and study site.

Results: The cohort had a mean age of nearly 55 years, was largely female, and had disease duration of nearly 8 years. In regression models comparing the effects of BGP ≥20% with BGP <20% on RAHO, we observed strong positive associations with DAS, JSN and joint erosions as well as with HAQ score (Table 1). Stratification of the effect of income on RAHO by BGP poverty revealed no statistically significant interaction. However, when stratifying the analyses of homeownership, we observed effect modification that narrowly missed statistical significance (Table 2). Notably, among those who lived in an area with BGP ≥20%, non-homeowners had a 69% higher Joint Alignment and Motion (JAM) score than homeowners (PRR=1.69; 95% CI=1.09–2.62), whereas there was no association with JAM score for homeownership among those living in an area with BGP <20% (interaction p-value=0.11). Other associations which narrowly missed statistically significant interactions were observed for joint space narrowing, joint erosion, and DAS (interaction p-values=0.13, 0.05, and 0.14, respectively).

Conclusion: Our results suggest that block group poverty modifies the association between homeownership and joint damage measures. These findings suggest that further research is warranted to identify the underlying factors for these associations; for example monetary reasons precluding medication purchase or access to adequate medical care.

Foot and Ankle Characteristics Associated with Falls in Adults with Rheumatoid Arthritis. Angela Brenton-Rule[1], Nicola Dalbeth[2], Priya Parmer[1], Sandra Bassett[1], Hylton B. Menz[3] and Keith Rome[1]. [1]AUT University, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]La Trobe University, Bundoora, Victoria 3086, Australia.

Background/Purpose: People with rheumatoid arthritis (RA) have an increased risk of falls. The consequences of falls can be devastating including loss of confidence and independence, injury and death. The foot is a common site of pathology in RA and foot problems are reported in up to 90% of patients with established disease. Previous studies in non-RA populations have identified that foot and ankle problems are associated with falls and falls risk in older adults. The aim of this study was to determine whether foot and ankle characteristics are associated with falls in people with RA.

Methods: Adults with RA according to the 2010 ACR/EULAR classification criteria were recruited from rheumatology outpatient clinics in Auckland, New Zealand. All participants reported whether they had fallen in the preceding year, and the number of falls. The Prevention of Falls Network Europe (ProFanE) definition of, "an event that results in a person coming to rest unintentionally on the ground or other lower level", was used to identify falls. RA characteristics, common fall risk factors, and foot and ankle variables were measured. Foot and ankle testing included foot deformity, plantar sensation, muscle strength, ankle range of motion, gait speed, peak plantar pressures, postural stability, foot pain and self-reported foot impairment. Univariate parametric and non-parametric analysis compared fallers and non-fallers on all variables to determine significant differences. Logistic regression analysis identified variables independently associated with falls.

Results: Two hundred and one participants were prospectively recruited. At least one fall in the preceding 12 months was reported by 119 (59%) participants. Significant factors associated with falls in the univariate analysis are presented in Table 1. Fallers had significantly longer mean disease duration, more co-morbid conditions, slower gait speed, higher mid-foot peak plantar pressures and were more likely to have a history of stroke than non-fallers. Fallers also reported greater difficulty with the activities of daily living, increased fear of falling and greater self-reported foot impairment. In logistic regression analysis, including age, sex and all variables at a level of $p<0.15$ in the univariate analysis, increased mid-foot peak plantar pressures (odds ratio 1.12 [for each 20kPa increase], $p=0.037$) and self-reported foot impairment (odds ratio 1.16 [for each 3 point increase], $p=0.007$) were independently associated with a fall in the preceding 12 months.

Conclusion: Elevated mid-foot peak plantar pressures and self-reported foot impairment are associated with falls in people with RA. Assessment of foot deformity, foot function and self-reported foot impairment may be of benefit when considering falls prevention in people with RA.

Table 1. Significant factors associated with falls in univariate analysis. Data are presented as mean (SD) unless specified.

Mortality Decreases in Patients with Rheumatoid Arthritis: a 15-Year Prospective Cohort Study. Joëlle van den Hoek[1], Hendriek C. Boshuizen[2], Leo D. Roorda[3], Gerard J. Tijhuis[4], Mike T. Nurmohamed[4], Trudi van den Bos[5] and Joost Dekker[6]. [1]Reade, Rehabilitation Rheumatology, Amsterdam, Netherlands, [2]National Institute of Public Health and the Environment, Bilthoven, Netherlands, [3]Amsterdam Rehabilitation Research Center Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [4]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [5]Academic Medical Center, Amsterdam, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands.

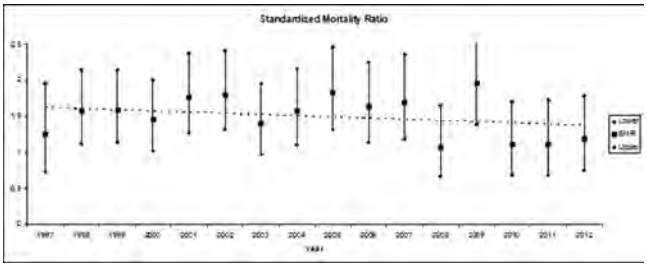
Background/Purpose: Patients with rheumatoid arthritis (RA) have a higher mortality risk than the general population, with similar patterns over the last decades. However, more recent studies show conflicting results. Given these conflicting results, there is an obvious need to evaluate the risk of mortality in patients with RA, over a long period, using more recent mortality data.

Objectives: To investigate a) the mortality in a clinical cohort of patients with established rheumatoid arthritis in comparison with the general Dutch population over 15 years, b) the trend in the mortality ratio during the study period, and c) the causes of death and compare these with the general population.

Methods: In 1997, a sample of 1222 patients was randomly selected from the register of a large rheumatology outpatient clinic in Amsterdam. Their mortality and causes of death between 1997 and 2012 were obtained from Statistics Netherlands. The Standardized Mortality Ratio (SMR) for all-cause mortality and the number of life-years lost in the study period were calculated. Linear poisson regression analysis was performed to evaluate change in all-cause SMR over time. Finally, the SMRs for cause-specific mortality were calculated.

Results: The mean age of the population at baseline was 60.4 (*SD* 15.4) years and 72.6% of the patients were women. The estimated SMR (95% CI) for all-cause mortality was 1.54 (1.41, 1.67) with about one life-year lost over the study period. The SMR decreased with 2% annually ($p = .05$). Mortality increased for diseases of the circulatory system, respiratory system, musculoskeletal system, and digestive system ($p < .05$).

Conclusion: The observed mortality among patients with RA was more than 50% higher than in the general population. More than one life-year was lost over 15 years and the mortality seemed to decrease over time. The most frequent causes of death were the same as those in the general population.



Annual Standardized Mortality Ratio and 95% Confidence Interval.

Physical and Mental Functioning in Patients with Established Rheumatoid Arthritis over an 11-Year Follow-up Period: The Role of Specific Comorbidities. Joëlle van den Hoek[1], Leo D. Roorda[2], Hendriek C. Boshuizen[3], Gerard J. Tijhuis[4], Trudi van den Bos[5] and Joost Dekker[6]. [1]Reade, Rehabilitation Rheumatology, Amsterdam, Netherlands, [2]Amsterdam Rehabilitation Research Center Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [3]National Institute of Public Health and the Environment, Bilthoven, Netherlands, [4]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [5]Academic Medical Center, Amsterdam, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Comorbidity in patients with Rheumatoid Arthritis (RA) is highly prevalent and plays an important role in determining RA related outcomes. Several studies have reported the negative association of comorbidity with functioning in general. The information about the association of specific comorbidities with functioning in patients with RA is limited. Evaluating specific comorbidities will provide valuable information for clinical practice and the management of patients with RA.

The aim of this study was to investigate the long term association of a wide range of specific comorbidities with physical and mental functioning in patients with RA.

Methods: Longitudinal data over a period of 11 years were collected from 882 patients with RA at study inclusion. Somatic comorbidity was measured at baseline, with a questionnaire including 20 chronic diseases, from which 9 categories of chronic somatic comorbidity were created. Comorbid depression was measured at baseline, with the Center for Epidemiologic Depression Scale. Physical functioning was measured with the Health Assessment Questionnaire (HAQ) and with the physical component summary of the Short Form 36 health survey (SF-36). Mental functioning was measured with the mental component summary of the SF-36. To determine the impact of specific comorbid conditions on functioning and on change in functioning we performed a longitudinal analysis.

Results: The mean age of the patients at was 59.3 (*SD* 14.8) years, 72% of the patients were women, their median disease duration was 5.0 (*IQR* 2.0–14.0) years, and 68% had ≥ 1 comorbid condition. The mean HAQ score for an average patient was 0.98 on average over the 11-years follow-up period. Circulatory conditions (mean HAQ score + 0.28) and depression (+0.38) were associated ($p<.05$) with low physical functioning according to the HAQ. An average patient with a circulatory condition had a mean HAQ score of 0.98 + 0.28 = 1.46. Circulatory (mean SF-36 score −3.23), respiratory (−2.74), musculoskeletal conditions (−2.85), cancer (−5.26) and depression (−3.36) were associated ($p<.05$) with low physical functioning according to the SF-36, while respiratory conditions (−2.28) and depression (−12.81) were associated ($p<.05$) with low mental functioning. The improvement in physical functioning according to the HAQ was 0.01 annually for an average patient. Genitourinary conditions were associated with a decline in physical functioning over time ($p<.05$). An average patient with a genitourinary condition declined in physical functioning with 0.01 – 0.04 = −0.03 annually. Digestive conditions were associated ($p<0.05$) with a decline in mental functioning.

Conclusion: Patients with specific comorbid conditions have an increased risk of low or declining functioning on the long term. Targeted attention for these specific comorbid conditions by clinicians and general practitioners is important. Diagnostics during the course of the disease, adequate referral to and working together with other specialists might improve physical and mental functioning in patients with RA.

Are There Immunological Abnormalities in Fibromyalgia Patients: Flow Cytometry Analysis. Robert S. Katz[1], Hannah Bond[2] and Daniel Pickrell[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: Fibromyalgia is not thought to have an immunological pathogenesis: However, few studies have been done to evaluate immunological abnormalities. We analyzed lymphocyte subsets in fibromy-

algia syndrome (FMS) patients and compared the results to established normal values in healthy controls.

Methods: 25 Patients (22 female and 3 male) with fibromyalgia meeting 2010 ACR criteria and followed in a rheumatology office practice had their blood analyzed by flow cytometry. Normal values for healthy controls were established by the University of Miami Immunology Laboratory where the analyses were performed.

Results: The following immunologic tests were abnormal in fibromyalgia patients

	Cd+4+CD38+	CD8+CD38+	CD8+CD95+	CD8+CD11a
Normal Cells/uL Range	0–138	125–595	160–473	139–472
FMS Patients Mean cells/uL	316.4	57.1	36.6	112.4

Conclusion: CD4+CD38+ helper Tcells were elevated in the FMS patients. CD8+CD38+, CD8+CD95+ and CD8+CD11a were reduced in FMS compared to normal healthy levels. This suggests possible increased T helper cell function and reduced CD8 cytotoxic/suppressor T cells in this group of fibromyalgia patients.)

The immune system could play a yet undetermined role in fibromyalgia.

Fibromyalgia Symptoms Beyond the Pain and Its Impact on the Patient. Abdelmoneim Helal[1], Dia MF Mohasseb[1], Noha AH El-Sawy[1] and Yousra H. Abdel-Fattah[2]. [1]Professor, Alexandria, Egypt, [2]Faculty of Medicine, University of Alexandria, Alexandria, Egypt.

Background/Purpose: Fibromyalgia (FM) has been promoted as the commonest cause of chronic, widespread non-articular musculoskeletal pain, stiffness and fatigue. Although pain is the central feature of FM there are other common clinical features associated with the disease including: sensations of muscle tension and morning stiffness, chronic headaches, non restorative sleep, fatigue and waking unrefreshed, post-exertional muscle pain, and cognitive dysfunction.

Methods: Twenty five female patients with a mean age of 30 years (18 to 57) diagnosed with primary FM according to 1990 American College of Rheumatology (ACR) diagnostic criteria as well as the 2010 ACR preliminary diagnostic criteria for FM were included in this study. Demographic characteristics and clinical data were collected from all patients. Pain severity, impact of the disease, sleep disturbance, severity of depression and anxiety where assessed by McGill Pain Questionnaire (MPQ), Fibromyalgia Impact Questionnaire (FIQ), visual analogue scale (VAS) for sleep evaluation, Hamilton Depression Rating Scale (HRSD) and Hamilton Anxiety Rating Scale (HAM-A) respectively.

Results: The median complaint duration was 24 months (3 to 180), and the median number of tender points was 14 (11 to 18). Fourteen patients (56%) complained of numbness with normal neurological examination. The median score of the MPQ presenting pain intensity - Visual Analogue Scale (PPI-VAS) was 80 (50 to100) and for the overall intensity was 3 (2 to 5). The FIQ showed a median score of 59.41 (41 to 76). Twenty two patients (88%) had irregular sleep patterns and poor sleep quality. Nineteen patients (76%) showed mild depression by HRSD with a median score of 14 (6 to 26). Fifteen patients (60%) showed mild anxiety by HAM-A with a median score of 15 (6 to 33).

There was a highly negative linear statistically significant correlation between the overall pain and sleep VAS ($p = 0.003$). There was as highly positive linear statistically significant correlation between the degree of anxiety and the degree of depression ($p<0.001$). Also the degree of anxiety & depression had a highly positive linear statistical significant correlation with the impact of the disease on the patients' life ($p<0.001$ & $p<0.001$).

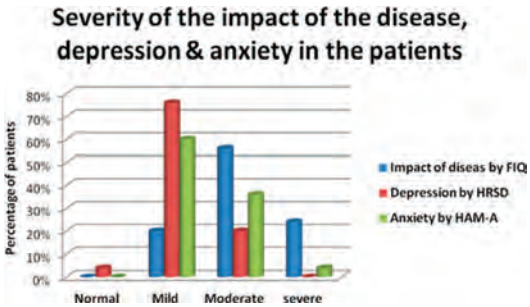

Figure (1): Distribution of FM patients according to severity of the impact of the disease, depression and anxiety.

Conclusion: Fibromyalgia highly influences the quality of life of the patients, and the severity of pain and associated symptoms significantly correlate with the impact of FM on the patients' life. There is a significant correlation between the severity of pain and the severity of associated symptoms of FM as depression and anxiety; in the same context depression as well as anxiety were found to be strongly associated with FM.

Electrophysiological Evaluation of Autonomic Nervous System and Cutaneous Silent Period in Patients with Fibromyalgia Syndrome. Isil Ustun[1], Ilker Yagci[2], Gulseren Akyuz[3] and Feyza Unlu,Ozkan[4]. [1]Bagcilar Training Hospital, Istanbul, Turkey, [2]Marmara Universitesi T?p Fakultesi, Istanbul, Turkey, [3]Marmara University School of Medicine, Istanbul, Turkey, [4]Fatih Sultan Mehmet Training Hospital, Istanbul, Turkey.

Background/Purpose: This study was designed to investigate the autonomic nervous system (ANS) and spinal inhibitory circuits in FMS by electrophysiological studies and compare the results with healthy controls.

Methods: Thirty patients with FMS diagnosed according to ACR classification criteria and thirty 30 age matched healthy controls were recruited to the study. Patients were clinically examined and evaluated by Beck depression scale, SF-36 and fibromyalgia impact questionnare scales. Upper and lower extremity nerve conduction studies were performed to both groups to detect a large diameter peripheral neuropathy such as carpal tunnel syndrome or polyneuropathy. For evaluating the ANS, sympathetic skin response (SSR), R-R interval variation (Heart rate variability-RRIV) were studied. Spinal inhibitory circuits were assessed with cutaneous silent period (CSP).

Results: There were no statistically significant differences in distal latencies, amplitudes and nerve conduction velocities of motor and sensory nerves ($p>0.05$). Latencies and amplitudes of SSR recorded from median and tibial nerve, CSP latency and duration recorded from abductor pollicis brevis muscle and tibialis anterior muscle in FMS and healthy controls were also similar ($p>0.05$). Heart rate variability (RRIV) recorded from FS patients were significantly lower in comprasion to healthy controls ($p<0.05$).

Conclusion: Heart rate variability was the only significant abnormal electrophysiological parameter in patients with FMS which suggested that there was an ANS dysfunction in FMS. Despite SSR is one of the classical methods for the assesment of sympathetic fibers impairment to evaluate peripheral neuropathies, patients with FMS had no abnormality. We thought that this parameter is not sensitive enough to detect an abnormality in patients with FMS. We also evaluated cutaneous silent period (CSP) which refers to the brief interruption in voluntary contraction that follows strong electrical stimulation of a cutaneous nerve. The CSP is a protective reflex that is mediated by spinal inhibitory circuits and is reinforced in part by parallel modulation of the motor cortex. According to our study this reflex was not effected in patients with FMS.

2058

The Impact of Environmental Stress on Pain in Fibromyalgia Patients. Robert S. Katz[1], Ben J Small[2] and Susan Shott[3]. [1]Rush Medical College, Chicago, IL, [2]MacNeal Hospital, Berwyn, IL, [3]Rush University Medical Center, Chicago, IL.

Background/Purpose: Many fibromyalgia syndrome (FMS) report that their illness is significantly affected by environmental stress. We compared FMS and RA patients with respect to the impact of a variety of environmental conditions on their pain.

Methods: 211 office patients with either FMS (150; 130 women and 20 men; mean age 51±12) or RA (61; 45 women and 16 men; mean age 55±15) completed a questionnaire about the effect of various environmental conditions on their pain, rated as 1 = no effect, 2 = mildly worse, 3 = moderately worse, and 4 = severely worse. The two-sided Mann-Whitney test was done to compare FMS and RA patients with respect to these ratings, using 0.05 significance level.

Results: Compared to RA patients, FMS patients had significantly worse ratings for cold weather (2.7 ± 1.1 vs. 2.2 ± 1.0, $p = 0.003$), humidity (2.5 ± 1.1 vs. 2.0 ± 0.9, $p = 0.004$), rain (2.6 ± 1.1 vs. 2.2 ± 1.0, $p = 0.027$), weather change (2.8 ± 1.0 vs. 2.3 ± 0.9, $p = 0.004$), smells (1.4 ± 0.8 vs. 1.1 ± 0.4, $p = 0.002$), season change (2.2 ± 1.0 vs. 1.8 ± 0.9, $p = 0.018$),

loud noises (1.5 ± 0.8 vs. 1.1 ± 0.5, p = 0.001), emotional stress (2.6 ± 1.1 vs. 2.1 ± 1.0, p = 0.002), physical stress (2.7 ± 1.0 vs. 2.2 ± 1.0, p = 0.001), and air travel (1.8 ±1.0 vs. 1.4 ± 0.7, p = 0.007).

Conclusion: FMS patients, compared with RA patients, report significantly worse impact on their pain from many environmental conditions. Whether the etiology of fibromyalgia relates to central sensitization, hypervigilance, or an inherited somatoform trait, these patients are generally quite sensitive to environmantal stresses.

Disclosure: R. S. Katz, None; **B. J. Small**, None; **S. Shott**, None.

2059

Muscle Tension Is Increased in Fibromyalgia. Robert S. Katz[1] and Kerri Swiatnicki[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: Fibromyalgia patients have and widespread pain and tender muscles. Muscle tenderness was part of the older ACR criteria for the diagnosis of fibromyalgia. We studied muscle pressure in fibromyalgia patients.

Methods: A Stryker Pressure Monitor was inserted into the trapezius muscle to measure muscle pressure. Usually this monitor is used to detect anterior compartment syndrome in the swollen leg of a patient following trauma.

Results: 10 fibromyalgia patients meeting 2010 ACR criteria for the diagnosis and 5 controls were evaluated. The mean age of the fibromyalgia patients was 36.8; 9 females, 1 male. The mean age for the controls without fibromyalgia was 39.4; 3 females, 2 males. The fibromyalgia patients were, as expected, more tender than controls. Using dolorimetry, the pressure until an uncomfortable feeling occurred, was 8.9 in fibromyalgia, and 14.2 pounds of pressure in controls.

The mean muscle pressure, in millimeters of mercury using the Stryker Pressure Monitor was 36.8mmHg in fibromyalgia patients and 7.8mmHg in controls.

Conclusion: Muscle pressure is increased in fibromyalgia patients. This may be an important finding in explaining the widespread pain and muscle tenderness present in these patients. Methods to reduce muscle tension may be therapeutic.

2060

Do Fibromyalgia Patients Have a Distinct Sleep Signature? Robert S. Katz[1] and Jessica L. Polyak[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: Fibromyalgia patients are known to have poor sleep, but no distinct sleep signature has been identified. We use a simple device called Jawbone to evaluate sleep in patients with fibromyalgia and controls.

Methods: Patients meeting the 2010 ACR criteria for the diagnosis of fibromyalgia were given the Jawbone device to wear on their wrist to monitor sleep. Controls also wore the same device. Patients' sleep was evaluated from the standpoint of number of awakenings, total duration of sleep, how deep was the sleep, and other factors.

Results: The total number of awakening of 12 of the fibromyalgia patients was 2.68, with the mean age being 46.5yrs, while the controls awakened an average of 1.2 times per night, with a mean age of 40.7.

The average period awake for the fibromyalgia group was 59 minutes, compared to 45.6 minutes for controls. Other totals were total sleep average 7.4 hours Fibromyalgia, 6.5 hours Controls. Sound sleep average, 4.0 hours Fibromyalgia, 3.2 hours Controls. Light Sleep average 3.4 hours fibromyalgia, 3.3 hours Controls. Total hours in bed, 8.4 hours fibromyalgia, 7.3 hours Controls. Time to fall asleep 17.7 minutes fibromyalgia, 27.7 minutes Controls. Out of the 12, most of the fibromyalgia patients were on a sleep aid, Elavil (7 patients), Doxepin (3 patients). The sleep study was preformed over one evening.

Conclusion: Fibromyalgia patients are known to sleep poorly. In this study we found that they awaken more often than controls and appear to be awake for longer periods of time. The reasons for this are unclear, but if there is a sleep pattern associated with fibromyalgia, it may simply be based on the number of awakenings in those without another clear factor, such as obstructive sleep apnea.

Using a sleep monitoring device, such as the Jawbone UP in this study, may be a simple method for patients and clinicians to monitor sleep, including the number of awakenings and the duration of non-sleeping time in FMS patients. One approach would be to evaluate patients' sleep before and after tricyclic treatment.

2061

Unexpectedly High Prevalence of Immunoglobulin Deficiency in Fibromyalgia. Xavier Caro and Earl Winter. Fibromyalgia Research and Treatment Center, Northridge, CA.

Background/Purpose: It has recently been shown that Fibromyalgia (FM) is commonly associated with clinical evidence of neuropathic pain language, laboratory evidence of small fiber and demyelinating neuropathy, and serologic evidence of a low-grade cytokinopathy. All of these findings suggest the presence of immune dysfunction leading to an immune mediated neural injury in FM. Any indication of a preexisting pro-inflammatory milieu in FM might help explain the presence of this immune dysfunctional state. Since primary immune deficiency (PID) states are well known to predispose to autoimmunity we surveyed a series of FM subjects for evidence of selected immunoglobulin (Ig) deficiency. We report our early findings here.

Methods: We retrospectively reviewed serum Ig concentration values on all FM subjects seen between July 2012 and December 2013 in an outpatient, rheumatology office setting. No other diagnosis precluded inclusion in the study unless it was likely that it might predispose to Ig deficiency. Charts on a total of 120 FM subjects were screened; 13 were excluded (e.g., family history of PID, SLE, Sjögren's syndrome, prior irradiation or cancer chemotherapy, or use of a DMARD). Data on 107 remaining FM subjects were reviewed; 38 (36%) had coincident RA (47 % of RA/FM subjects were positive for IgM RF). Ig deficiency was defined as an Ig value of at least 2 standard deviations (SD) below the mean reported by our reference laboratory; all deficient specimens were tested in duplicate. Ig abnormalities were confirmed by repeat analysis 6 – 9 weeks later.

Results: Our findings are listed below:

Serum Ig Deficiency in 107 FM Subjects Compared to Literature Based Controls

	Fibromyalgia Subjects				
Immunoglobulin	No. with Ig deficiency	No. without Ig deficiency	Prevalence of FM Ig Deficiency	Estimated Normal Prevalence†	P-value (2-tailed)††
IgG Subclass 1	48	59	45%	1/1200	<0.0001
IgG Subclass 2	13	94	12%	1/1200	<0.0001
IgG Subclass 3	47	60	44%	1/1200	<0.0001
IgG Subclass 4	6	101	6%	1/1200	<0.0001
IgA	12	95	11%	1/500	<0.0001
IgM	16	91	15%	3/100	0.003
IgE	4	103	4%	2.5/100	0.34
Any Ig	70	37	65%	1/1200	<0.0001

†Schroeder HW, et al: Immunoglobulin Structure and Function. *In* Fundamental Immunology. 7thEd. Ed: Paul, WE. Lippincott, New York 2013. †† Analysis was by X^2 test.

Our data showed that 71% of the FM subjects deficient in IgG Subclass 1 were also deficient in IgG Subclass 3. Thirty-one percent of those deficient in IgG subclass 2 were also deficient in IgG Subclass 4. A coincident diagnosis of RA did not significantly affect the prevalence of Ig deficiency. Of 56 FM subjects in whom Mannose Binding Lectin (MBL) was measured, 18 (32%) had levels <500 ng/ml, 9 (16%) had levels <100 ng/ml, and 8 (14%) had levels <50 ng/ml. The Odds Ratio (OR) for an FM subject having any Ig deficiency, compared to literature based norms, was 784 (95% CI 108 to 5703).

Conclusion: Our study shows that Ig deficiency, particularly IgG subclass deficiency, is a common accompaniment to FM. It also strengthens the argument that FM may be a disorder associated with immune dysregulation. The precise mechanism of this interaction remains unclear, but deserves further investigation.

Vall D'Hebron Hospital, Barcelona, Spain, [4]Professor of French., Madrid, Spain, [5]Professor of Spanish language and Literature, Madrid, Spain, [6]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain, [7]Internist. Marqués de Valdecilla Hospital. IDIVAL, Santander, Spain.

Background/Purpose: The Fibromyalgia Rapid Screening Tool (FiRST) is a brief, simple and straightforward self-administered questionnaire with excellent discriminative value, of potential value for the detection of fibromyalgia in patients with diffuse chronic pain. To evaluate the usefulness of a Spanish version of the FiRST questionnaire for the detection of fibromyalgia (FM) in primary health care centers.

Methods: The Spanish translation of the original FiRST French questionnaire was carried out by Rheumatologists and Professors of French and Spanish Language. Translation was performed in second person, to enable self or hetero application (see annex). This study is prospective and multicenter, including 404 consecutive patients diagnosed with FM according to the 1990 ACR modified criteria and 2010 ACR criteria. FM was diagnosed by specialists in Rheumatology. We also included a control group of similar age and sex, consisting of 147 Rheumatoid Arthritis (RA) patients and 219 Osteoarthritis (OA) patients. The modified 2010 ACR criteria was applied, the number of tender points was evaluated, and the FiRST questionnaire and Fibromyalgia Impact Questionnaire (FIQ) were completed. Sensitivity, specificity and predictive value were analysed for each of the 6 items of the FiRST questionnaire and for the global score (5 or 6 positive items), as well as the correlation between the global score and other parameters. The results obtained were expressed as median and interquartile range and were analyzed with the Mann –Whitney U test using SPSS 15. P values less than 0.05 were considered significant.

Results: The mean age of patients with FM was 51.67 years. The mean FIQ score was 73.29. The median disease evolution was 12 years (IC: 6–21). Median tender points was 16 (IC: 14–18). 356 of 404 FM patients who met the 1990 ACR criteria and the 2010 modified criteria had a positive FiRST (scores 5 or 6). In the control group (AR + OA), 16 subjects had a positive FiRST and 343 a negative FiRST (scores or 4 or less). The sensitivity value for global score (5–6 positive ítems) with 95% interquartile range was 92 (88.9–95.1), the specificity 87.4 (80.8–94), positive predictive value 95.7 (93.3–98.1), and negative predictive value 78.2 (70.6–85.9). There was a significant correlation between total FiRST (scores 5 or 6) and Widespread Pain Index ($p < 0.0001$), Symptom Severity Scale ($p < 0.0001$), time to disease progression ($p < 0.0001$) and FIQ ($p < 0.0001$).

Conclusion: In patients with FM who met the 1990 ACR criteria and the 2010 modified ACR criteria, the overall sensitivity of the Spanish translation of the FiRST was slightly higher than in the original study. This questionnaire is easy to use and useful for the detection of FM patients in primary health care centers.

Assessment of the Spanish Version of the American College Rheumatology Preliminary Diagnostic Criteria for Fibromyalgia. B Casanueva[1], F Garcia-Fructuoso[2], R Belenguer[3], C Alegre[4], R López-Mejías[5], F Genre[5], J.V. Moreno[6], J.L. Hernandez[7] and MA González-Gay[5]. [1]Rheumatologist. Rheumatology Service at the Specialist Clinic of Cantabria, Santander, Spain, [2]Rheumatologist. CIMA Hospital, Barcelona, Spain, [3]Rheumatologist. 12 de Octubre Hospital., Valencia, Spain, [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [5]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain, [6]Rheumatologist. Vall D'Hebron Hospital, Barcelona, Spain, [7]Internist. Marqués de Valdecilla Hospital. IDIVAL., Santander, Spain.

Background/Purpose: Fibromyalgia (FM) requires an expert clinical examination that impedes an easy assessment of diagnostic criteria of American College Rheumatology (ACR) 1990 in some health settings. This problem delays its diagnostic, treatment, and referral to specialized services. To solve this drawback, a new screening criteria, the ACR Preliminary Diagnostic Criteria for FM was created. The aim of this study is to investigate the reliability and validity of the Spanish version of the 2010 ACR Preliminary Diagnostic Criteria for FM.

Methods: The traslation and cultural adaptation process of the ACR Preliminary Diagnostic Criteria for FM were adjusted to Spanish version to the perspective of the Rheumatology Spanish Society Study Group of Fibromyalgia. We recruited FM patients who met the previous criteria of the ACR 1990 diagnosed by a Rheumatologist, and other patients with diseases associated with chronic pain such as Rheumatoid Arthritis (RA) and Osteoarthritis (OA) who had not been diagnosed previously with FM, as control group, in a multicenter study. Informed consent was obtained and then baseline data were collected. Ethical Committee of the regional health authority approved the study protocol. FM were evaluated by tender points (TP), Fibromyalgia Impact Questionnaire (FIQ), Widespread Pain Index (WPI), and Symptom Severity Scale (SS). RA and OA patients were evaluated by WPI and SS. **Results** were expressed as median and interquartile range (IC) and data was analyzed with the Mann-Whitney U test. Sensitivity, specificity and predictive values were calculated. We used the SPSS 15 software for statistical analysis. P values < 0.05 were considered significant.

Results: This study included 1169 patients, divided into the FM group (777 females and 26 males) and non-fibromyalgia group (147 RA, and 219 OA). The mean of FIQ in the FM group were 73.29. The median of TP were 16 (Interquartile range 14–18). In the beginning of this study, the preliminary ACR 2010 criteria were satisfied by 665 FM patients. In the non-fibromyalgia group (RA + OA), 112 patients fulfill ACR 2010 criteria whereas 254 not achieve criteria. The comparison of FM patients who fulfill ACR 2010 criteria versus FM patients who no meet the criteria, exhibit significant differences in the number of TP ($p < 0.03$), FIQ ($p < 0.0001$), WPI ($p < 0.0001$) and SS ($p < 0.0001$). The sensitivity of the Spanish version of the modified 2010 ACR criteria was 87.7% (IC 95%: 85.3 to 90.1), the specificity was 69.4% (95% IC: 64.5 to 74,3), the positive predictive value was 85.6% (95% IC: 83.0 to 88.1) and the negative predictive value was 73.2% (95% IC: 68.4 to 78.0).

Conclusion: Our findings indicate that sensitivity of Spanish version of ACR preliminary diagnostic criteria (87.7%) were similar to the original study (88.1%). The specificity and predictive value of this version might be suitable for assessing FM among Spanish chronic pain populations.

2065

A Cross-Sectional Analysis of Psychological Symptoms, Sleep Quality, and Functional Balance in Fibromyalgia. Vicky Chen[1], William F. Harvey[2], Jeffrey B. Driban[2], Mei Chung[1], Lori Lyn Price[2] and Chenchen Wang[2]. [1]Tufts University School of Medicine, Boston, MA, [2]Tufts Medical Center, Boston, MA.

Background/Purpose: Previous studies suggest that FM may be associated with worse balance and falls. Balance requires the coordination of motor, sensory (ex. visual and vestibular), and cognitive abilities. These may be affected by the psychological symptoms present in FM. Depression, anxiety, and stress, have both cognitive (reduced attention) and somatic features (poor sleep quality and psychomotor slowing); and may therefore be related to the balance problems in FM. We intend to evaluate these relationships in this study.

Methods: We analyzed baseline data from a randomized trial comparing Tai Chi to aerobic exercise in individuals with FM. Balance was measured using a One-Leg Balance Test (OLBT): time standing on preferred leg with eyes closed; max time = 30 seconds. Psychological symptoms of depression, anxiety, and stress were measured using validated scales: Beck Depression Inventory (BDI-II); Participant-Reported Outcomes Measurement Information System (PROMIS) Emotional Distress rating of Anxiety; and Perceived Stress Scale (PSS). Higher scores reflect greater symptom severity. The mental component of the Medical Outcomes Study 36-Item Short Form Health Survey (SF-36 MCS) measured mental health related quality of life. Higher scores indicate better health status. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI). Higher scores reflect poor sleep quality. Chronic Pain Self-Efficacy Scale (CPSS) measured confidence in ability to perform a particular behavior or task. Higher scores reflect improved status. We used a logistic regression model to detect associations between balance times $\leq$3.02 seconds (defined by first quartile) and measures of psychological symptoms, self-efficacy, mental health-related quality of life, and sleep quality. Independent variables were analyzed in tertiles. Analyses were adjusted for age, gender, and BMI.

Results: 234 screened participants were included in our analysis. 90% were female. Mean age was 51.3 ± 11.8 years and mean BMI was 29.7 ± 6.8 kg/m^2. The median performance on OLBT was 4.7 seconds. **Table 1** shows the odds ratios for OLBT $\leq$3.02 seconds and BDI-II, PSS, SF-36 Mental Component, PROMIS anxiety, PSQI, and CPSS. Better sleep quality and fewer depressive symptoms were weakly associated with improved balance, but no significant associations were found between balance and measures of psychological symptoms and sleep quality.

Conclusion: We were unable to demonstrate any significant associations between balance and psychological symptoms or sleep quality. Small sample size may limit data interpretation and evaluation of the results. We recom-

mend that future studies assess factors more directly related to balance such as muscle strength, proprioception, and attention. Such research is critical to understanding the mechanisms underlying balance problems in FM and may identify novel therapeutic targets for future longitudinal studies.

Table 1. Descriptive Statistics and Odds Ratios: Adjusted for age, sex, and BMI.

Measure (range)	Tertile (Minimum, Maximum)	Odds Ratio (95% CI) One Leg Balance Test With Eyes Closed ≤3.02 seconds	P-Value

Ultra Orthodox Religious Orientation Associated with Reduced Rates of Pain, Anxiety and Fatigue in a Population Based Study. Valerie Aloush and Jacob N. Ablin. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

Background/Purpose: Chronic pain, disturbed sleep and fatigue, as well as anxiety and depression, are symptoms characteristic of the fibromyalgia syndrome. These symptoms, as well as the syndrome itself, have often been associated with the effect of traumatic life events, as well as with external stress. Cognitive parameters, such as internal locus of control, are considered to have a positive effect on fibromyalgia symptoms, can be correlated with neuroimaging findings and are considered a target of cognitive behavioral therapy. On the other hand, spirituality and religiosity, characteristics which imply reliance on an external source of strength, are considered to be sources of resilience in the face of adversity.

The effect of religiosity on the spectrum of symptoms characteristic of fibromyalgia is not known.

Objective: To evaluate the effect of extreme religiosity on symptoms characteristic of the fibromyalgia syndrome in an Israeli population survey.

Methods: As part of a broader study, a telephone survey was conducted among 2030 Individuals residing in two Israeli towns, Sderot and Ofakim. As previously reported, these two similar populations were chosen to represent two basic conditions, i.e. a state of ongoing stress caused by continues cross – border missile attacks on Sderot, versus a state of relative normal conditions (Ofakim).

As part of the study protocol, individuals responding to the survey were questioned regarding their religious orientation. Individuals were thus ranked as belonging to either 'Haredi' (ultra – orthodox) Jewish level of religiosity, 'Orthodox', and 'religious' 'conservative – religious', 'conservative – not religious' or 'secular'. Haredi Jews belong to a highly traditional and relatively homogeneous religious group and adhere to strict traditions which encompass every aspect of life (e.g. clothing, diet etc).

Individuals were additionally questioned regarding the presence of symptoms including pain, fatigue, anxiety, depression, irritable bowel etc. Responses were ranked on a scale between 0 (no symptom present) and 10 (extreme symptom present).

Results were analyzed using one-way ANOVA with Tukey post- hoc test for multiple comparisons, using SPSS-17 software.

Results: Haredi individuals (174), reported significantly lower levels of sleep disturbances (mean 224) compared to all other individuals (total – 1780) ($P<0.01$).

Haredi individuals reported significantly lower levels of pain (mean – 2.9 vs. 3.7) lower levels of anxiety (mean 2.7 vs 4.5) and depression (mean – 1.2 vs 2.8) as compared with all other groups ($p<0.01$). No significant difference in the rate of IBS symptoms was observed.

Conclusion: Ultra-orthodox religiosity may be associated with reduced levels of symptoms, including pain, sleep disorders as well as anxiety and depression and may modulate the effect of stress and trauma on these symptoms. These results constitute a novel aspect in the analysis of the effects of locus-of-control and belief on these symptoms and on the association between religious faith and resilience. Further research may shed additional light on the role of spirituality/religious faith and on the mechanisms involved in these apparent protective effects.

Understanding the Factors Influencing Time to Diagnosis in Fibromyalgia. Howard Amital[1], Yaeli Bar-On[2], Varda Shalev[3], Dahlia Weitzman[3] and Gabriel Chodick[4]. [1]Department of Medicine B, Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, [2]Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel, [3]Maccabi Healthcare Services, Tel Aviv, Tel-Aviv, Israel, [4]Healthcare Services, Tel Aviv, Tel-Aviv, Israel.

Background/Purpose: Fibromyalgia (FM) is a chronic debilitating disorder considered to be part of a spectrum of central sensitization syndromes. The diagnosis of FM is a complex one, affected by many different factors including stigmatization of the disease, confounders such as comorbidities and different characteristics of patient and doctor.

Aim: Investigating the time passing from initial complaints till final diagnosis by an expert rheumatologist, and delineating the patient and physician characteristics affecting that time, using the comprehensive database of a large HMO in Israel.

Methods: Using a retrospective database search we identified patients diagnosed with FM by a rheumatologist or at release from hospitalization during ('confirmed FM patients'), and sex and age matched FM-free enrollees. Different complaint patterns were tested, to ascertain time of initial complaints. The pattern with the best combination of sensitivity and specificity was applied on an FM population of all patients diagnosed by a *primary physician*, rheumatologist, or at release from hospitalization, during the same period ('primary physician population'). Patient and primary physician factors associated with time between initial complaints and FM diagnosis were assessed. A multilevel generalized mixed linear model with a log-linked gamma distribution was used to account for clustering of patients associated with the same primary physician.

Results: Our study included 4,603 'confirmed FM patients', of whom 90.8% were women, with a mean age of 50.63 years (±11.37). The complaint pattern chosen, as time of initial complaints, comprised of >= 4 complaints within 6 months. This pattern was found in 73.2% (1,944/2,656) of the 'confirmed FM patients', 18.4% (1,685/9,173) of the FM-free patients. Applying this pattern on the primary physician population, revealed a mean time to diagnosis of 4.7±3.6 years. Within this time, the mean (SD) time that FMS patients were associated with the 'physician at diagnosis' was 2.9±2.8. The patient factors most significantly associated with a longer time to diagnosis, were older age, female gender and low socioeconomic status. The physician characteristics most significantly associated with a longer time to diagnosis were older age, internal or general specialty vs. family specialty, and physician's medical studies in West vs. East Europe.

Conclusion: The time to diagnosis of FM is significantly influenced by patients a and physician characteristics. This knowledge can contribute to future research and to better planning of physician education, concerning this disease.

2068

Joint Hypermobility Syndrome and Postural Orthostatic Tachycardia Syndrome (HyPOTS). Artan Kaso and Ali Askari. University Hospital Case Medical Center, Cleveland, OH.

Background/Purpose: Joint hypermobility syndrome (JHS) is a chronically disabling disorder manifested as a widespread musculoskeletal pain and/or fatigue, in the presence of generalized joint hypermobility. It is often masquerading as Fibromyalgia or Chronic fatigue syndrome. It is a condition that is often overlooked by clinicians.

Methods: Currently in our clinic, we have observed 25 patients between 22 and 58 yr who were diagnosed with JHS using the Brighton Criteria (1). All of them presented with one or more of these symptoms: chronic fatigue,

generalized musculoskeletal pain (arthralgias and myalgias), pre-syncope, palpitations, dizziness caring the diagnosis of fibromyalgia. They do not have any Marfanoid features or certain types of Ehlers-Danlos syndrome or skin involvement.

Out of 25 patients 16 (64%) had a positive diagnostic tilt table test consistent with the diagnosis of postural orthostatic tachycardia syndrome (POTS), 6 (24%) have not had a tilt table test done yet (financial, non compliance, etc) and 3 (12%) had a negative tilt table test.

Patient	Age	Gender	*Symptoms of Autonomic dysfunction	Tilt table test
1	22	F	+	+
2	39	F	+	+
3	38	F	+	+
4	28	F	+	+
5	32	F	+	Not done
6	40	F	+	-
7	37	F	+	+
8	28	F	+	+
9	32	F	+	+
10	48	F	+	-
11	36	F	+	+
12	32	F	+	+
13	38	F	+	+
14	39	F	+	+
15	36	F	+	+
16	35	F	+	-
17	35	F	+	Not done
18	26	F	+	+
19	33	F	+	Not done
20	22	F	+	+
21	36	F	+	Not done
22	33	F	+	+
23	55	F	+	+
24	58	F	+	Not done
25	28	F	+	Not done

*Patient presented with Symptoms of Autonomic dysfunction like, orthostatic hypotension, palpitation, dizziness, passing out, fatigue.

Results: We have noticed that most of these patients are young female with a mean age of 35 with a presentation consistent with fibromyalgia or chronic fatigue syndrome, however further work up showed presence of autonomic dysfunction clinically and confirmed by tilt table test in 64%. By applying standard of care treatment for POTS with fludrocrotison, increasing water and salt intake, using Ted Hose stocking, they showed improvement in their clinical presentation.

Conclusion: We conclude that there is a selective group of patients with JHS who have autonomic dysfunction which can contribute to the clinical presentations of these patients. These patients frequently are misdiagnosed as having Fibromyalgia or Chronic fatigue syndrome.

We have acronymed this entity "HyPOTS".

Potential manifestations of autonomic dysfunction include cardiac dysrhythmias, postural orthostatic tachycardia syndrome, orthostatic hypotension and orthostatic intolerance. Mechanisms leading to such phenomena in JHS patients may include weakened vascular tissue elasticity and impaired peripheral vasoregulation as a consequence of adrenoceptor or neuronal abnormalities (6, 7).

The pathophysiological basis for these symptoms needs to be further explored.

IRB approval for chart review was gained from University Hospital Case Medical Center.

2069

Investigation of the Effects of Physical Exercise on the Control Mechanisms of Cutaneous Circulation in Patients with Fibromyalgia Syndrome. Emre Esen and Alp Cetin.MD, Ankara, Turkey.

Background/Purpose: Sedentary lifestyle and disabling widespread pain in patients with fibromyalgia syndrome (FMS) may alter cardiovascular functions and can induce endothelial dysfunction. We evaluated cutaneous microvascular functions and their correlations with severity of disease assessed by revised fibromyalgia impact questionnaire (FIQ) and pain visual analog scale (VAS) in FMS patients, before and after participation in a moderate intensity 4-wk aerobic physical exercise program.

Methods: Forty female FMS patients without any known cardiovascular diseases and 20 healthy age-matched female controls were included in the study. Cutaneous blood flow was measured by a laser Doppler flowmeter (LDF) at the volar skin site of the forearm. Spectral analysis of LDF signals was used to assess the relative contribution of control mechanisms. The local thermal hyperemia was used to test the microvascular functions.

Results: Exercise improved pain VAS (from 8.5±1.5 to 4.7±1.4; $p<0.0001$) and FIQ scores (from 69.7±7.5 to 43.7±6.4; $p<0.0001$) and, improvement in myogenic and neurogenic mechanisms showed negative correlations with increase in FIQ scores. In contrast, cardiac signal was positively correlated with the FIQ scores, after exercise. Endothelial function was under the influence of pain, and basal nitric oxit (NO) activity was positively correlated with pain VAS.

Conclusion: These results suggest that the microvascular functions are impaired in FMS patients and, improvement in FIQ/pain score and the enhancement in vascular functions are possible by moderate exercise training.

Disclosure: E. Esen, None; **A. Cetin**, None.

2070

Elevated Serum Leptin Concentrations in a Subset of Fibromyalgia Patients with High Inflammatory Markers. Anne Quismorio[1], John Solyman[2], Lisa Asfahani[1] and Samy Metyas[3]. [1]Covina Arthritis, Covina, CA, [2]Research Associate, Covina, CA, [3]Assistant Clinical Professor Of Rheumatology, Covina, CA.

Background/Purpose: Previous studies suggest heterogeneity in the presentation of fibromyalgia (FM) with differences in biological variables including elevated sedimentation rate (ESR), cytokine profile, and hormone levels. Whether these variables identify subgroups within FM population remains to be established. We have previously reported primary FM patients with elevated inflammatory markers(Metyas SK, *et al*. Ann Rheum Dis, 2007;66(Suppl II):625.).

The diagnosis of FM is largely clinical, and specific biomarkers have yet to be identified. Vectra®DA is a multi-biomarker disease activity score, validated to measure disease activity in rheumatoid arthritis (RA). It is a commercially available test designed to measure serum concentrations of 12 biomarkers in RA.

The purpose of the study is to measure biomarkers using the Vectra®DA in FM patients with elevated inflammatory markers.

Methods: A cross-sectional, prospective study of 33 patients seen in an outpatient-based rheumatology practice in Los Angeles County was undertaken. Each met the 2010 ACR classification criteria for FM and had elevated ESR and/or CRP. None had clinical evidence of RA or other systemic rheumatic disease. Tests were negative for rheumatoid factor, anti-CCP antibodies, and HLA-B27. Serum specimens were tested using the Vectra®DA.

Results: Mean age was 43.5 years, 94% were female and 6% were male. The Vectra®DA was elevated for all patients with a mean score of 46.5 (range 30 to 84, or moderate to high activity). Among the twelve biomarkers (including IL-6 and CRP) serum concentrations were within the range reported in RA except leptin. 45% of subjects had leptin concentrations exceeding the range reported in RA (1–45 ng/mL). The mean leptin was 42.3 ng/mL (range 30–81 ng/mL).

There was a positive correlation between leptin concentration and BMI in the entire cohort; however, this correlation was not observed in the patient subgroup with leptin levels above the range in RA ($P= 0.6$). CRP but not ESR was positively correlated with the Vectra®DA score.

Conclusion: We have identified a subset of FM patients with elevated ESR and/or CRP. The elevated Vectra®DA scores support the concept of an associated inflammatory process in this subset of patients. The elevated levels of leptin in this subset, independent of BMI, suggest that factors other than obesity may account for this elevation. The emerging evidence that leptin plays a significant pro-inflammatory and immunomodulatory role warrants further investigation in the pathogenesis of this clinical subset of FM. Understanding this clinical subset may lead to different diagnostic and therapeutic strategies in FM.

2071

Chronic Widespread Pain Versus Multi-Site Pain: Does the Distribution Matter? Marcus Beasley and Gary J. Macfarlane. University of Aberdeen, Aberdeen, United Kingdom.

Background/Purpose: The ACR 1990 diagnostic criteria for fibromyalgia includes a definition for chronic widespread pain (CWP) that depends on a particular distribution of pain sites. The new proposed ACR 2010 criteria instead has a Widespread Pain Index which takes into account the number of sites only. The purpose of this analysis was to see, amongst persons reporting multi-site pain, if the distribution of pain sites has any association with a number of potential risk markers after adjustment for the number of sites.

Methods: The MUSICIAN survey was a general population survey aimed at identifying people with CWP for an intervention study. A questionnaire was sent by post to adults registered at family doctors in two areas of the United Kingdom. Questions included age, gender, employment status, smoking behaviour, height, weight, and questions on pain included a manikin in 35 sections to indicate the location of the pain. Respondents were included in the analysis who indicated that they had between 3 and 16 areas of pain, and that the pain had lasted 3 months or more. (People with less than 3 sites could not meet the ACR 1990 definition of widespread pain, while most of those with more than 16 sites did). Participants were classed as having pain that was widespread or not according to the ACR 1990 criterion. A number of potential associations with having widespread pain were tested using logistic regression to provide odds ratios (OR) with 95% confidence intervals (CI). These models were then adjusted for number of pain sites to see if any associations with the distribution pattern remained after accounting for having pain in multiple areas.

Results: 14680 people responded to the questionnaire, of which 7536 reported some chronic pain (prevalence 51.3%). In those with chronic pain, the median number of pain sites was 5 (interquartile range 3 to 9), and the prevalence of pain that met the ACR 1990 criterion for being widespread was 32.1%. Included in the analysis were 5715 respondents with chronic pain in 3 to 16 areas, of which 2037 (35.6%) met the criterion for widespread pain. Gender age, smoking and employment status all had significant associations with ACR 1990 widespread pain (see table). After adjustment for number of pain sites most of these associations either became non-significant or were attenuated.

Conclusion: We have shown that when number of pain sites was taken into account, the particular distribution of sites did not continue to have significant relationships with many associated factors. This might indicate that is not so much that the pattern of pain locations that is important as the multiplicity of areas. This may have implications in conditions such as fibromyalgia where pain across multiple areas is involved. Based on this data, the use of a measure that looks at the number of pain sites rather than a particular distribution is acceptable as a diagnostic criterion.

	Not widespread		Widespread		Unadjusted		Adj for no. of sites	
	Number	Percentage	Number	Percentage	OR	95% CI	OR	95% CI

Ultrasound Assessment of Both Hands in Fibromyalgia Patients: What Could We Detect? Maximiliano Bravo[1], Javier Rosa[2], Santiago Ruta[1], Ricardo Garcia-Monaco[3] and Enrique Soriano[1]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, Argentina.

Background/Purpose: Pain is the hallmark symptom of fibromyalgia (FM). The relationship with inflammation and/or structural changes in patients with fibromyalgia with pain localized in the hands is not clear. The aim of the present study was to describe the prevalence of different US abnormal findings at hand level in patients with FM.

Methods: Consecutive patients with FM according to 1990 ACR criteria in whom a scan of the small joints of both hands due to the presence of pain was performed, were included. Patients with other definite inflammatory autoimmune rheumatic condition and/or with a secondary FM were excluded. US examinations were performed by the same experienced rheumatologist blinded to all clinical data using a My Lab 70 machine (Esaote) provided with a linear transducer of 6–18 MHz. US assessments included both grayscale and power Doppler (PD) US and were performed according to reference standard methods. The following US abnormal findings were evaluated bilaterally at joint level (wrist, metacarpophalangeal (MCP), proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints): joint cavity widening (JCW) due to the presence of joint effusion and/or synovial hypertrophy, PD signal due to the presence of an increased abnormal vascularization and degenerative changes (osteophytes). Tenosynovitis due to the presence of tendon sheath distension (TSD) and/or PD signal (increased abnormal vascularization) was assessed at tendon level (flexor finger tendons and extensor tendons compartments of the wrist).

Results: A total of 94 patients with FM and with an US examination of both hands were included. Ninety-one (96.8%) patients were female, mean age was 57.4 years (SD: 12.1) and mean disease duration was 2.7 years (SD: 1.8). JCW was detected in 6 (6.4%) patients at PIP joints, in 6 (6.4%) patients at MCP joints and in 8 (8.1%) patients at wrist level. Tenosynovitis due to the presence of TSD was found in 12 (12.7%) patients at extensor tendon compartments of the wrist and in 7 (7.4%) patients at finger flexor tendons. None of the patients with JCW at joint level and/or TSD at tendon level showed increased abnormal vascularization by PD signal.Thirty (32%) patients showed osteophytes at small joints and 19 (20.2%) patients had also degenerative changes at trapeziometacarpal level (rizarthrosis).

There were no significant statistical differences regarding ESR, CRP, rheumatoid factor and CCP levels between patients with and without US abnormal findings ($p \geq 0.05$ for all comparisons).

Conclusion: A minority of patients with FM and hand pain showed US inflammatory abnormal findings on grayscale assessment and none of them showed abnormal vascularization by PD signal. The presence of degenerative changes (osteophytes) was the most frequent US abnormal finding.

Is Susceptibility to Fibromyalgia a Trait? Robert S. Katz[1], Ben J Small[2], Lauren Kwan[3], Hannah Bond[3], Jessica L. Polyak[3] and Susan Shott[4]. [1]Rush Medical College, Chicago, IL, [2]MacNeal Hospital, Berwyn, IL, [3]Rheumatology Associates, Chicago, IL, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: We asked patients, as part of an in-office survey, whether their immediate or extended family members had FMS.

Methods: 211 office patients with either FMS (150; 130 women and 20 men; mean age 51 +/− 12) and RA (61; 45 women and 16 men; mean age 55 +/−15) completed a questionnaire about FMS in family members. The chi-square test of association was used to compare the responses of FMS and RA patients, with a 0.05 significance level.

Results: FMS patients were significantly more likely than RA patients to report that members of their immediate families had FMS (24% vs. 7%, $p = 0.005$), and that members of their extended families had FMS (17% vs. 6%, $p = 0.041$). FMS patients were also significantly more likely than RA patients to report that some members of their families had widespread pain and chronic fatigue (52% vs. 18%, $p < 0.001$).

Conclusion: Patients with FMS appear to have more family members affected by this illness, compared to RA controls. One quarter to one half of family members of FMS patients may have fibromyalgia according to the patients. This suggests that widespread pain and the other symptoms of fibromyalgia may be inherited as a trait and may be present commonly in family members.

2074

Hypervigilance and FMS. Robert S. Katz, Rush Medical College, Chicago, IL.

Background/Purpose: In dangerous environments, hypervigilance conveys a survival value. A cave dweller who sleeps lightly and startles easily might escape a prowling bear while he is peacefully slumbering neighbor becomes a midnight snack. In safer environments.hypervigilance may cause dysfunctional stress. Some fibromyalgia syndrome (FMS) patients report symptoms of hypervigilance. We compared FMS and RA patients with respect to hypervigilance symptoms, and FMS patients with and without each hypervigilance symptom with respect to environmental stress.

Methods: 211 office patients with either FMS (150; 130 women and 20 men; mean age 51±12) or RA (61; 45 women and 16 men; mean age 55±15) completed a questionnaire about hypervigilance symptoms (present or absent) and the effect of various environmental conditions on their pain (rated as 1 = no effect, 2 = mildly worse, 3 = moderately worse, and 4 = severely worse). The chi-square test of association was done to compare FMS and RA patients with respect to percentages.

Results: Compared to RA patients, significantly higher percentages of FMS patients woke up more than once during the night (84% vs. 71%, $p = 0.033$), had trouble getting to sleep (63% vs. 38%, $p = 0.001$), and startled easily (53% vs. 30%, $p = 0.003$). FMS patients were uncomfortable in crowds (median 2.3 vs. 1.8, $p < 0.001$), FMS patients were made uncomfortable by people standing behind them (median 2.4 vs. 1.9, $p < 0.001$), FMS patients startled easily (median 2.1 vs. 1.9, $p = 0.004$), FMS patients did not feel at ease with strangers (median 2.2 vs. 1.9, $p = 0.029$), and FMS patients did not find it easy to trust strangers (median 2.3 vs. 1.9, $p = 0.009$).

Conclusion: FMS patients were significantly more likely to report hypervigilance symptoms compared to RA patients. The hypervigilance trait may be present in many fibromyalgia patients and could explain their hyper sensitivity traits to perceived environmental threats.

Disclosure: R. S. Katz, None.

The Lumbar Spine in Fibromyalgia. Robert S. Katz[1], Alexandra Small[2] and Anthony Farkasch[3]. [1]Rush Medical College, Chicago, IL, [2]University of Illinois College of Medicine, Chicago, IL, [3]Rheumatology Associates, Chicago, IL.

Background/Purpose: Radiographs of the lumbar spine appear normal in fibromyalgia. However, a previous study (ArthRheum50:134, 2004) found a reduced lordotic curve in the cervical spine of patients with fibromyalgia. We measured the Cobb angle on radiographs of the lumbar spine in patients with fibromyalgia and other rheumatic disease patients.

Methods: Fibromyalgia patients meeting the 2010 ACR criteria with a complaint of back pain, and patients with other rheumatic disease disorders who had back pain (osteoarthritis, spinal stenosis, degenerative joint disease, herniated disc and other forms of lumbar radiculopathy, and ankylosing spondylitis) were evaluated for lumbar spine straightening using the Cobb angle of lateral lumbar spine radiographs.

The Cobb angle was measured by drawing a line parallel to the superior portion to L1 and another line parallel to the inferior portion to L5 and measuring the angle where the two lines intersect.

Results: The number of fibromyalgia patients studied was 148 and the number of non-fibromyalgia patients with back pain but not fibromyalgia was 59. The mean ages were 45.4 years for fibromyalgia patients and the mean age for the non-fibromyalgia patients 52.5 years. In the fibromyalgia group there were 136 females, and 12 males; and in the non-fibromyalgia group w back pain, who served as controls, there were 46 females, and 13 males.

The mean Cobb angle in the fibromyalgia patients was 14.0 degrees, and the mean Cobb angle in the rheumatic disease controls with back pain was 20.9 degrees.

Conclusion: FMS patients have a straight lumbar spine. We propose that increased muscle tension may be the cause of the reduced Cobb angle in these patients. Fibromyalgia patients have widespread pain over large muscle groups, muscle tenderness, and also have straight cervical spines and straight lumbar spines, by measuring the Cobb angle. It is quite possible that much of the pain experienced by fibromyalgia patients relates to increased muscle tension.

Predictive Modeling of a Fibromyalgia Diagnosis: Increasing the Accuracy Using Real World Data. Birol Emir[1], Jack Mardekian[1], Elizabeth T. Masters[1], Andrew Clair[1], Max Kuhn[2] and Stuart L. Silverman[3]. [1]Pfizer Inc, New York, NY, [2]Pfizer Inc., Groton, CT, [3]Cedars-Sinai Medical Center, UCLA Center of Excellence, Los Angeles, CA.

Background/Purpose: The number of symptoms and comorbidities associated with the chronic pain condition of fibromyalgia (FM) complicates its identification and diagnosis.

Methods: This retrospective analysis used structured de-identified electronic health records from the 2011–2012 Humedica database, including demographics, clinical characteristics, and healthcare resource use. An FM cohort was defined as subjects ≥18 years in 2011 with ≥2 ICD-9 codes for FM (729.1) ≥30 days apart during 2012; the no-FM cohort did not have the ICD-9 code. Univariate analyses characterized between-cohort differences and determined the demographic, clinical, and healthcare resource variables associated with an FM diagnosis. A Random Forest (RF) model was used to predict FM and non-FM subjects by entering all variables into the model (1500 bootstraps) with internal down-sampling (to account for imbalance between cohorts). Importance of the variables was computed using RF to determine the trade-off on accuracy when only the top 10 variables were fitted. For practical clinical application, a rule-based model was used to derive simple statements to help explain which patient sets have the largest effect on the likelihood of an FM diagnosis.

Results: Significant differences were observed between the FM (n=4,296) and no-FM (n=583,665) cohorts for demographics ($P<.0001$) except for age, for most evaluated comorbidities ($P<.0001$), and for healthcare resource use ($P<.0001$), with more comorbidities and resource use in FM subjects. Resources included proportions of subjects with utilization, and units used per subject for emergency room visits, outpatient visits, hospitalizations, and medications. The top 10 variables for predicting an FM diagnosis were identified from the RF models based on level of importance as reflected by the percent of model iterations in which the variable was predictive (Figure). A receiver operator characteristic curve confirmed the predictive accuracy of the model variables (area under the curve of 0.810). Rules were developed to identify patients with high predicted probability of an FM diagnosis; e.g., the average predicted probability of 0.54 for a subset of patients with outpatient visits excluding office visits >0 and prescriptions administered/ordered ≤3 and the number of musculoskeletal pain conditions >0 was more than double the 0.22 predicted probability for those not in the subset. Similarly, a rule to identify non-FM (opioid prescriptions administered/ordered/written =0; visits where diagnostic/laboratory tests were ordered =0; and number of musculoskeletal pain conditions =0) correctly classified 100% of the sample.

Conclusion: Random forest modeling can be applied to determine likelihood of an FM diagnosis. Rules can simplify this method with good accuracy. Further validation of RF may help facilitate earlier diagnosis and enhance management strategies.

A New Tender Point on the Plantar Arch in Primary Juvenile Fibromyalgia: A Potential Point to be Considered. Walter J. Spindler, Cecilia Santarelli, Alberto J. Spindler, Alberto Berman, Horacio Berman and Mirta Santana. Centro Medico Privado de Reumatologia, Tucuman, Argentina.

Background/Purpose: Juvenile Primary Fibromyalgia Syndrome (JPFS) is a chronic and complex musculoskeletal disorder that may cause diffuse pain accompanied by defined tender points. Diagnostic dilemmas may frequently arise since 10 of these tender points are located on the cervical and shoulder area (ACR'90 Fibromyalgia Classification Criteria). For this reason, a tender point reproducible in a different area may be an advantage on the diagnosis of JPFS. The objective of this study was to assess sensitivity and specificity of a tender point located infero-medially in the distal third of the longitudinal plantar arch in JPFS patients and healthy controls.

Methods: The study included consecutive patients with JPFS (ACR'90) and healthy controls matched by age and gender. Informed consent was obtained for all study subjects. Pairs of the proposed point, those accepted by the ACR and control points (biceps, quadriceps and lateral foot area) were assessed with digital pressure of approximately 4 Kg/cm2 by previously trained rheumatologist and pediatrician in both subject groups. Sensitivity and specificity of all tender and control points examined were compared by unpaired t-test, ROC curve and the McNemar test.

Results: Out of a total of 22 JPFS patients, 19 were female (F) and 3 were male (M), ages between 13 and 17 (14±0.30). The healthy control group included 27 high school students of similar age (14±0.23) and gender (21 F and 6 M) than the patients. The new plantar point was positive in 20/22 JPFS patients (90.9%), bilaterally in 20 and unilaterally in 2 patients. None of the control group subjects had pain on the new plantar point. Sensitivity and specificity for the new tender point were 90.9% and 96.4% respectively (positive LR of 25.25, ROC Area = 0.937 with CI 95% =0.856 –1.00). Several ACR tender points presented lower sensitivity and/or specificity than the new plantar point: occiput was positive in 19/22 (86.4%) JPFS patients and in 6/27 (22%) of the control group, 86.4% sensitivity, 75% specificity (positive LR of 3.46 ROC Area = 0.807 with CI 95% =0.68 – 0.934), supraspinatus was positive in 20/22 (90.9%) JPFS patients and in 5/27 (18%) of the control group, 90.9% sensitivity, 78.6% specificity (positive LR of 4.25 (ROC Area = 0.847 with CI 95% =0.733 – 0.962), second rib was positive in 19/22 (86.4%) JPFS patients and in 1/27 (3.7%) of the control group, 86.4% sensitivity, 92.9% specificity (positive LR of 12.17 ROC Area = 0.896 with CI 95% =0.795 –0.997), lateral epicondyle was positive in 19/22 (86.4%) JPFS and in 1/27 (3,7%) of the control group, 86.4 sensitivity, 92.9 specificity (positive LR of 12.17 ROC Area = 0.896 with CI 95% =0.795 –0.997). In patients with JPFS, control points were negative in 17/19 patients (89%). The plantar site had good concordance in JPFM patients with tender sites such as occiput, trapezius, supraspinatus, lateral epicondyle (test McNemar, $p > 0.12$).

Conclusion: The plantar arch tender point has high sensitivity and specificity in patients with JPFS. Additionally, it presented higher specificity than other recognized tender points. Further investigations on this novel site appear warranted.

A Proposed Simple 3-Variable Index for Identification of Fibromyalgia, Analogous to Classification Criteria for RA and SLE. Sung-Hoon Park[1], Jung-Yoon Choe[2], Seong-Kyu Kim[3], Hwajeong Lee[4] and Theodore Pincus[5]. [1]Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]Catholic University of Daegu School of Medicine, Daegu, South Korea, [3]Catholic University of Daegu,Daegu, South Korea, Daegu, South Korea, [4]Catholin university of Daegu School of medicine, Daegu, South Korea, [5]Rush univeristy medical center, Chiacago, IL.

Background/Purpose: A cumulative index that includes various quantitative data has been useful in developing classification criteria for various rheumatic diseases, including rheumatoid arthritis (RA)[1] and systemic lupus erythematosus (SLE).[2] Previous reports indicate that self-report patient scores on a multidimensional health assessment questionnaire (MDHAQ) provide clues to identify patients with fibromyalgia (FM).[3,4] Since the diagnosis of FM is made primarily on the basis of patient report of pain and other symptoms, a cumulative scale of quantitative patient self-report scores as well as a physician estimate of a level of FM might be useful to identify patients with FM. To analyze a simple 3-variable cumulative scale to identify patients with FM, and distinguish them from patients with RA, SLE, and ankylosing spondylitis (AS) seen in a usual care setting in Korea.

Methods: All patients seen at a Korean rheumatology setting complete an MDHAQ/RAPID3 (routine assessment of patient index data), which includes scores for physical function, visual analog scales (VAS) for pain, global status and fatigue, and a list of 60 symptoms as a checklist review of symptoms. Physicians also complete a RHEUMDOC form which includes a 0–10 VAS physician global estimate of patient status, and 0–10 VAS subscales for inflammation, damage, and level of symptoms not explained by inflammation and damage, such as FM. Preliminary cross tabulations were performed to compare scores for MDHAQ variables in patients with FM versus RA, SLE, and AS. Based on these preliminary analyses, a 3-variable cumulative scale was developed: ***1)*** VAS pain score of ≥5 out of 10, ***2)*** symptom checklist of ≥15 out of 60 symptoms, and ***3)*** physician estimate of FM level ≥3 out of 10. The numbers of patients with FM, RA, SLE and AS who scored 0, 1, 2, or 3 were computed; chi square tests and receiver operator curves (ROC) were used to analyze statistical significance.

Results: Data were available concerning 32 patients with FM, 18 with AS, 17 with SLE and 277 with RA. Overall, 53% of patients with FM had scores of 2 or 3 of these criteria, compared to 5.5% with AS, 20.2% with RA and 5.8% with SLE ($p \leq 0.001$). ROC area was 0.734, with standard error of 0.047 and 95% confidence interval of 0.642–0.826. A score of 2, which does not require any physician data, was associated with a positive likelihood ratio for FM of 2.9, sensitivity of 53.1 and specificity of 81, with 79% correctly classified. A score of 3 was associated with a positive likelihood ratio for FM of 7.1, with 90% correctly classified.

Dx	FM score, N (%) of patients				Total N
	0	1	2	3	
AS	10 (55.6%)	7 (38.9%)	1 (5.5%)	0	18
FM	5 (15.6%)	10 (31.3%)	9 (28.1%)	8 (25.0%)	32
RA	130 (46.9%)	91 (32.9%)	45 (16.2%)	11 (4.0%)	277
SLE	8 (47.1%)	8 (47.1%)	1 (5.8%)	0	17
Total	153 (44.5%)	116 (33.7%)	56 (16.3%)	19 (5.5%)	344

Chi square=38.32, p<0.001

Conclusion: A cumulative score analogous to classification criteria for RA or SLE may be useful in helping to identify FM. A limitation of this study is that it did not identify patients with a diagnosis of RA, SLE,or AS who might also have FM, who may account for patients with inflammatory rheumatic diseases and scores of 2 or 3 on the preliminary FM index.

The Association Between Straight Neck and Fibromyalgia. Omar-Eloy Muñoz-Monroy[1], Laura-Aline Martinez-Martinez[2], Manuel Martínez-Lavín[2], Blanca-Adela Mota-Mondragón[1] and Evalorena Martínez-Hernández[1]. [1]Hospital Central Militar, Mexico City, Mexico, [2]Instituto Nacional de Cardiologia, Mexico City, Mexico.

Background/Purpose: It has been suggested that patients with fibromyalgia very often have radiographic straight neck. According to one study, 71% of patients with fibromyalgia lose the normal radiographic cervical lordosis. In this report, straight neck was defined as a Cobb angle < 14 degrees. (Katz & Farkasch. Abstract 1086, 2013 ACR Annual Meeting).

Objective: Our objective was to further investigate this potentially important clinical association. We set to define the prevalence of radiographic cervical spine straight neck in patients with fibromyalgia as compared with patients suffering from other musculoskeletal diseases.

Methods: Adult patients attending an outpatient rheumatology clinic of a military hospital were invited to participate in the study. A lateral cervical radiograph in neutral position was obtained in all instances. Cobb angle was used to label the radiographs as "normal" (Cobb angle > 18 degrees) "borderline" (Cobb angle between 14 and 18) and "straight neck" (Cobb angle < 14). A rheumatologist blinded to the radiograph results prospectively examined each patient from the "normal" and "straight neck" groups. The 1990 and 2010 ACR criteria were used to define the presence of fibromyalgia.

Results: Are summarized in the table. A total of 56 patients were studied. Only 14 of them had "normal" radiographic cervical lordosis. Of the total group, 35.7% fulfilled either the 1990 or the 2010 ACR fibromyalgia diagnostic criteria. Fibromyalgia was more frequent in the "normal" radiograph group (64%) than in the "straight neck" group (26%) ($p = 0.022$).

Conclusion: Fibromyalgia is very frequent in this military rheumatology clinic. Contrary to our working hypothesis, our results show that patients with

fibromyalgia have less radiographic straight neck when compared to patients with other rheumatic diseases.

Carryover Effects in Crossover Design Studies in Fibromyalgia and Other Pain Conditions. Lynne Pauer[1], Birol Emir[2], Ed Whalen[3], Joseph Scavone[1] and Andrew Clair[2]. [1]Pfizer Inc, Groton, CT, [2]Pfizer Inc, New York, NY, [3]Pfizer Inc., New York, NY.

Background/Purpose: Explore carryover effects and their influence on crossover and randomized withdrawal design (RWD) studies.

Methods: We examine pregabalin crossover and RWD studies in fibromyalgia (FM), painful diabetic peripheral neuropathy (pDPN), and post-herpetic neuralgia (PHN). Data visualization methods and meta-analytic summaries are used to explore the difference in carryover effects across studies and pain types. Weekly mean pain scores are compared for 4 crossover studies of similar design, 2 in FM (studies 1165 and 1275) and 2 in pDPN (1268, 1269), for patients randomized to the pregabalin to placebo treatment sequence (Pgb - Pla) or to the placebo to pregabalin (Pla - Pgb) treatment sequence (Figure 1).

Results: In fibromyalgia crossover studies, a greater return of pain occurred following pregabalin treatment than in the pDPN studies (Figure 1). There was a differential effect of period one treatment on period two outcomes. FM crossover studies returned to a common pain level regardless of period one treatment, whereas DPN crossover studies did not. Similar results hold for the pregabalin to placebo arm in the FM vs DPN RWD studies.

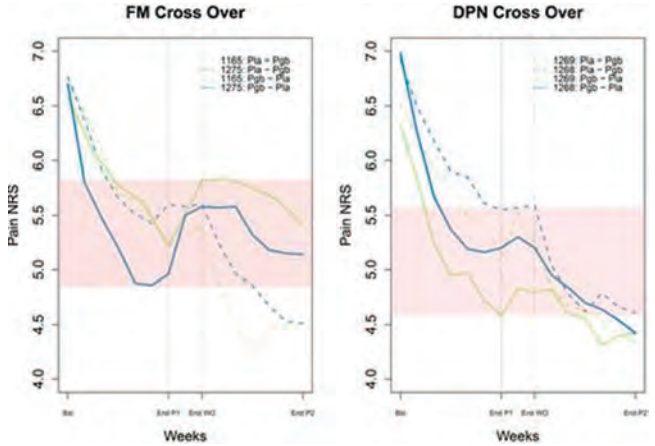

Figure 1. Crossover Studies in Fibromyalgia and Painful Diabetic Peripheral Neuropathy

FM: Fibromyalgia; DPN: Painful Diabetic Peripheral Neuropathy; Pain NRS: Pain Numeric Rating Scale; Pgb: Pregabalin; Pla: Placebo; Bsl: Baseline; P1: Period 1; P2: Period 2; W/O: placebo washout period.

Conclusion: The type of pain under study may affect the ability of crossover or RWD studies to determine the magnitude of treatment effect; pain type should be carefully considered when choosing among study designs for pain.

Ehlers-Danlos Hypermobile (EDS-HT) Patients and Postural Instability: Another Clue to Explain Pain and Fatigue? Roland Jaussaud[1], Elodie Vlamynck[2], Rami Haidar[3], Dorothée Lambert[4], Violaine Laurant-Noel[5] and Amélie Servettaz[5]. [1]CHU de Reims, REIMS, France, [2]Cabinet d'Orthopédie, Versailles, France, [3]Cabinet d'Orthopédie, Lille, France, [4]CHU Reims, Reims, France, [5]Hôpital Robert Debré. CHU de Reims, Reims, France.

Background/Purpose: Postural instability was found in several functional disorders including dyslexia, chronic pain and fibromyalgia. Furthermore, the link between vertical heterophoria (VH) and postural control is now clearly established. EDS-HT patients shared symptoms usually encountered in patients presenting postural instability.

Methods:

Aim: To assess the presence of postural instability and the role of vertical heterophoria among patients suffering from EDS-HT.

Design of study: 30 patients meeting the Villefranche criteria for diagnosis of EDS-HT (generalized joint hypermobility, skin involvement, recurring joint dislocations, chronic joint/limb pain and positive family history) were prospectively examinated. Their postural performance was compared to that of 15 healthy subjects.

Methods: To measure postural instability, we used a force platform. The surface of the center of pressure (CoP) excursions, the standard deviations of lateral (SDx) and antero-posterior (SDy) body sways and the variance of speed were recorded. The surface area was measured with confidence ellipse including 90% of the CoP positions sampled, eliminating the extreme points. Vertical heterophoria (VH) was qualitatively detected with Maddox' rod. Pain was evaluated using a subjective visual analogical scale (VAS) of 10 cm validated for chronic pain. Fatigue severity scale (FSS) was used.

Results: Among the EDS-HT patients the mean VAS score was 67 mm. 84% had a FFS > 6. All these patients presented with symptoms of muscle hypertonia, disturbance of spatial location and other perception disorders. With respect to EDS-HT patients, they used more energy to stabilize postural sway during quiet upright stance than healthy subjects. The presence of vertical heterophoria was associated with a greater antero-posterior postural sway. Most of them had abnormal footprints (asymmetrical or hollow feet).

Conclusion: These data suggested that a dysfunction implicating somesthetic signals or central neurological integration could affect the balance control performance following the example of patients suffering from chronic low back pain. VH and hypermobility both or alone could be the sign or the trigger of this dysfunction. Postural instability could explained part of the symptoms of pain and fatigue in EDS-HT.

Presence of Acrocyanosis in Patients with Joint Hypermobility. Ayhan Dinc[1] and Göksal Keskin[2]. [1]Patio Clinic, Ankara, Turkey, [2]Medical School of Ankara, Ankara, Turkey.

Background/Purpose: Joint hypermobility is a common but often poorly recognized connective tissue condition with joint laxity in the absence of any hereditary systemic disease. Acrocyanosis is symmetric, painless, blue discoloration in the distal parts of the body with aggravation by cold exposure, and frequent association with local hyperhidrosis of hands and feet. Primary acrocyanosis is mostly a disease of young adults, only few cases persist into middle age.

Methods: During 18 months, a group of 350 consecutive rheumatology patients (<45 yrs. old) investigated for joint laxity and acrocyanosis. For each patient a Beighton score measured and those with a score of >4 regarded as benign joint hypermobility due to Brighton criteria. Acrocyanosis was diagnosed clinically by proper history and physical examination. Other relevant clinical findings were also recorded.

Results: A total of 43 patients (F: M, 26:17) were diagnosed as hypermobility. Nearly all patients had a mild-moderate hypermobility. The mean Beighton score was 4.9±0.7. Of those patients, 19 had also acrocyanosis (44.1%). In the group lacking hypermobility (303), only 6 cases of acrocyanosis detected (0.02%). In the acrocyanosis patients, whether or not accompanied with hypermobility, average hand and foot sizes per stature are larger than those without.

Conclusion: It has been known that, patients with hypermobility may have some vascular problems, including Raynaud's phenomenon and vari-

cose veins. Our observation points out that, besides joint hypermobility, probable vessel wall laxity might cause to passive engorgement of vascular structures, namely acrocyanosis.

Evaporative Dry-Eye Disease and Aqueous Deficient Dry-Eye Disease Associated with Fibromyalgia. William Pachas[1], Jack Greiner[2] and Paula Oliver[3]. [1]Center for Rheumatology, Osteoporosis and Fibromyalgia, Boston, MA, [2]The Boston Ocular Surface Center, Boston, ME, [3]The Boston Ocular Surface Center, Boston, MA.

Background/Purpose: Fibromyalgia (FM) patients with ocular discomfort often describe symptoms characteristic of dry eye diseases, but frequently do not fulfill criteria diagnostic of Sjögrens syndrome. Thus, ophthalmologic subjective and objective testing were performed to (1) establish the association of FM with dry eye diseases and (2) attempt to identify the type(s) of dry eye diseases associated with FM.

Methods: Consecutive patients (n=30) meeting American College of Rheumatology criteria for FM were evaluated as part of a comprehensive rheumatological examination. Subjective evaluation employed dry eye questionnaires, Ocular Surface Disease Index (OSDI) and Standard Patient Evaluation of Eye Dryness (SPEED). Objective tests included determination of minimum tearfilm lipid layer thickness (LLT), tearfilm osmolarity (TOSM), tearfilm break-up time (TBUT), Schirmer tear test (STT), corneal fluorescein-staining, and meibomian gland assessment (MGA) scores.

Results: Measurements were compared with widely accepted "Normal Values" (NV). OSDI 32.38±SD 20.7 (range, 2.27–79.16) 60% higher than NV(<13); SPEED 11.38±7.1 (range, 0–23.5) 47% higher than NV (≤6); LLT 49.72±17.2 nm (range, 28–90) 38% lower than NV (≤80nm); TOSM 312.2±14.1 mOsm/l (range, 290–341) higher than NV (300 mOsm); TBUT 5.01±3.1 sec (range, 1–15.24) 50% lower than ≥(10 sec); STT 6.02±3.9 nm (range, 0–11.5) 40% lower than NV (≥10 mm); and MGA scores 11.70±5.1 (range, 4–27) lower than NV(>12).

Conclusion: Fibromyalgia patients demonstrate evidence for both evaporative and aqueous-deficient dry eye diseases. FM patients should be routinely questioned for signs or symptoms of dry eye disease(s) and referred for a comprehensive evaluation to determine the type(s) of their dry eye disease(s) in order to recommend appropriate treatment(s).

Are Genetic Markers Associated with Myocardial Infarction in Patients with Early Rheumatoid Arthritis? Lisbeth Ärlestig[1], Petros Zamout[2], Lena Innala[2], Eva Freyhult[3], Solveig Wållberg Jonsson[2] and Solbritt Rantapää-Dahlqvist[2]. [1]Institution of Public health and clinical medicine/Rheumatology, University of Umeå, Rheumatology, Sweden, Umea, Sweden, [2]Institution of Public health and clinical medicine/Rheumatology, University of Umeå, Rheumatology, Sweden, Umeå, Sweden, [3]Bioinformatics Infrastructure for Life Sciences, Uppsala, Sweden.

Background/Purpose: Cardiovascular disease (CVD) are increased in patients with rheumatoid arthritis (RA). Traditional as well as disease related risk factors seem to contribute to the development.

To evaluate the impact of genetic makers for development of myocardial infarction (MI) or angina pectoris (AP) leading to coronary intervention (PTCA or CGBP) in patients with early RA in relation to inflammation and traditional risk factors.

Methods: Patients with early RA (1987 American College of Rheumatology criteria) from northern Sweden and consecutively recruited since Dec 1995 into a national register were followed prospectively for disease progression, treatment and into a register for presence of CV risk factors. Of the patients 899 had donated DNA and were analysed for the genetic markers. The follow-up started at inclusion and ended at the first MI/AP, death or until Dec 31 2011 by co-analysing with the national registers of hospitalization and death in Sweden using classification of diseases (ICD-9 and 10). Genetic polymorphisms were analysed using Immunochip (SNP&SEQ Technology Platform Uppsala, Sweden). Univariate Cox regression and a likelihood ratio test was adopted to find SNPs most strongly associated with MI/AP. The potentially important (likelihood ratio p<0.05) clinical factors were also identified using univariate Cox regression. Selected clinical factors were combined with one SNP at the time in a multivariate Cox regression model and a likelihood ratio test was adopted to assess whether the SNP added significant information to a model based on only the selected clinical factors.

Results: Analysis using the Immunochip yielded 131,523 SNPs, whereof 44,367 independent SNPs were identified after linkage analyses. In total 795 patients are included in the statistical analyses (some are excluded due to many missing values in the genetic data). The total follow-up time was 5607 person years until first MI/AP after RA disease onset. 52 patients had experienced a MI or AP leading to intervention. The strongest SNPs related to MI/AP were rs241425 (p=3.02e-06), rs2239701 (p=8.12e-06), rs9262155 (p=8.62e-06), rs2269706 (p=1.41e-05), and rs222418 (p=3.08e-05). Besides sex and age, hypertension, previous CV event, HLA-shared epitope, and oral corticosteroids were indicated as important in univariate Cox models (p<0.05). Likelihood ratio p-values after adjusting for the clinical factors were slightly lower than in the univariate models; rs241425 (p=1.04e-04), rs2239701 (p=4.75e-04), rs9262155 (p=9.20e-05), rs2269706 (p=5.55e-05), and rs222418 (p=1.87e-04).

Conclusion: SNPs analysed by Immunochip could be associated with MI/AP in patients with RA unrelated to more traditional risk factors.

Association of Circulating Mirnas with Spinal Involvement in Patients with Axial Spondyloarthritis. Klára Prajzlerová[1], Markéta Fojtíková[1], Šárka Forejtová[1], Astrid Jüngel[2], Steffen Gay[2], Karel Pavelka[1], Jiri Vencovsky[1], Ladislav Senolt[1] and Mária Filková[1]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [2]Zurich University Hospital, Zurich, Switzerland.

Background/Purpose: The altered expression of miRNAs and dysregulation of their target genes has been shown to contribute to the development and maintenance of autoimmune diseases. In addition, cell-free circulating miRNAs appear promising diagnostic and/or prognostic biomarkers. Our aim was to identify circulating miRNAs in patients with axial spondyloarthritis (AxSpA) and to investigate their relationship with spinal involvement.

Methods: The study included 20 patients with non-radiographic AxSpA (nr-AxSpA) according to the ASAS criteria with sacroiliitis confirmed by MRI, 48 patients with radiographic AxSpA (with and without spinal involvement, including 5 patients with a bamboo spine), and 29 healthy controls (HC). Total RNA from plasma was isolated using phenol-chloroform extraction and equal amount of RNA was used for reverse transcription. A comprehensive analysis of miRNAs was performed using TaqMan® Low Density Array (TLDA) in 5 samples from each group. dCt method was used for relative quantification as follows: dCt= Ct(array average)-Ct(miRNA) followed by x-fold change calculation. The expression of selected miRNAs was further validated by single assays in the remaining samples and the levels of miRNAs were normalized to an average of 3 spike-in controls of C. elegans origin: dCt= Ct(spike-in average)-Ct(miRNA). Data were analyzed using one-way ANOVA and unpaired t-test with Welch's correction.

Results: Out of total 760 miRNAs analysed by TLDA, 162 miRNAs were detected in a group of HC, 156 miRNAs in patients with nr-AxSpA and 110 in patients with radiographic AxSpA. All patients with AxSpA had at least 2-fold lower levels of 56 miRNAs when compared with HC. In patients with radiographic AxSpA, 72 miRNAs showed at least 2-fold decrease in comparison with nr-AxSpA.

Twenty-one miRNAs were selected according to the differential expression between groups of patients and possible relationship to the pathogenesis of AxSpA for further analysis. Out of 21 selected miRNAs, 14 miRNAs were significantly lower (p<0.05) in all patients with AxSpA compared to HC. MiR-625* (p=0.0055) and miR-222 (p=0.045) showed significantly lower levels in patients with nr-AxSpA compared with HC. In all patients with radiographic AxSpA, 20 miRNAs were significantly lower in comparison with the group of nr-AxSpA patients and HC, in particular miR-24, miR-27a, miR-106a, miR-222 or miR-223 (p<0.0001). Levels of these miRNAs were significantly lower (p<0.01 for miR-24, -27a, -106a, -223, p<0.05 for miR-222) in a subgroup of patients with bamboo spine compared with other patients with AxSpA.

Conclusion: Expression of circulating miRNAs is altered in patients with AxSpA. Reduced expression of several miRNAs was associated with the degree of spinal involvement, with the lowest expression observed in patients with the bamboo spine. Given the involvement of these dysregulated miRNAs in innate immunity and new bone formation, our data suggest their role in the pathogenesis of AxSpA and potential use of circulating miRNAs as biomarkers of disease progression.

Replication of PTPRC As Genetic Biomarker of Response to TNF Inhibitors in Patients with Rheumatoid Arthritis. Antonio Gonzalez[1], Aida Ferreiro-Iglesias[2], Juan Gomez-Reino[1] and on Behalf of Their Collaborators[3]. [1]Instituto Investigacion Sanitaria- Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [2]Insitituto Investigacion Sanitaria-Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [3]multiple, multiple, Spain.

Background/Purpose: The use of biomarkers to predict response to the different drugs available for treating rheumatoid arthritis (RA) is a very desirable goal. However, success of the many studies already performed has been limited. Genetic studies of response to the TNF inhibitors (TNFi) have reported multiple associations. At least 14 are from relative large candidate gene studies including hundreds of patients and other 16 are from GWAS also with hundreds of patients. A couple of them, in the *PTPRC* and *PDE3A-SLCO1C1* loci, have been replicated in a second study, but none has yet been confirmed with full confidence. We aimed to replicate here the 14 genetic associations proposed in large candidate gene studies.

Methods: We analyzed the response to TNFi treatment of 755 patients with RA naïve to biologic DMARDs and of European ancestry. They have been treated with the three most common TNFi (infliximab, N = 397; etanercept, N = 155; adalimumab, N = 203). Their response to these drugs was evaluated either as change in DAS28 (ΔDAS28) between baseline and 3, 6 and 12 months of treatment, or as classification according to the EULAR response criteria (good + moderate responders *vs.* non responders) at the same time points. The genotypes of the 14 previously associated SNPs plus the putative causal SNP at one of them were obtained with a single-base extension multiplex methodology. We considered the SNPs according to an additive genetic model in linear and logistic regression analyses, for ΔDAS28 and EULAR criteria, respectively. Baseline DAS28, gender and treatment were considered as covariates. Statistica 7.0 (Statsoft, Tulsa OK) software was used to perform these analyses.

Results: All the SNPs were successfully genotyped (call rate = 99.1 %; HWE $P > 0.05$). Only one of the 14 loci was associated with response to TNFi. This was the *PTPRC* SNP rs10919563 that is a confirmed RA susceptibility locus. The RA risk allele (G) of this SNP was associated with higher ΔDAS28 at 6 months (B = 0.33, [95% CI] 0.09 to 057, P = 0.006) and showed a trend to association with good response as defined with the EULAR criteria (odds ratio [OR] 1.49, [95% CI] 0.94 to 2.33, P=0.08). A second *PTPRC* SNP, rs6683595, very correlated with rs10919563, which is a putative causal polymorphism of this RA locus because it maps in an active regulatory region in $CD4^+$ T_{reg} cells showed an even stronger association: its G allele was associated with higher ΔDAS28 at 6 months (B = 0.39, [95% CI] 0.18 to 0.61, P=0.0003) and with good response (OR = 1.56, [95% CI] 1.04 to 2.37, P= 0.03).

Conclusion: We have obtained a new replication of the association of the PTPRC RA risk locus with response to TNFi. In this way, it has become the most replicated to date of the genetic biomarkers of response to these drugs with three studies including hundreds of patients each showing consistent results. In addition, we have found stronger association with a putative causal polymorphism in this locus that pave the way for functional studies exploring its involvement in RA and its treatment.

Defective Regulation of L1 Endogenous Retroelements in Primary Sjogren's Syndrome and Systemic Lupus Erythematosus: Role of Methylating Enzymes. Clio Mavragani[1], Adrianos Nezos[1], Irina Sagalovskiy[2], Surya V. Seshan[2], Kyriakos A. Kirou[2], Haralampos M. Moutsopoulos[1] and Mary K. Crow[2]. [1]School of Medicine, University of Athens, Athens, Greece, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: To investigate whether deranged methylating mechanisms are involved in the inappropriate expression of LINE-1 (L1) retroelements in primary Sjogren's syndrome (SS) and systemic lupus erythematosus (SLE).

Methods: Minor salivary glands (MSG) were obtained from 35 patients with primary SS [23 without adverse predictors for lymphoma development (SS-low risk) and 12 complicated by B-cell lymphoma (SS-lymphoma)] and 17 sicca controls (SC). Additionally, kidney biopsy specimens and PBMCs were obtained from 23 and 73 lupus patients respectively. Relative mRNA expression was quantified for full-length L1 transcripts, along with mediators of methylation. In an independent set of 22 MSG samples (8 SS-low risk, 11 SS-lymphoma and 3 SC), methylation levels of the L1 promoter were determined by bisulphite pyrosequencing.

Results: A strong positive correlation was demonstrated between L1 transcripts and gene products that mediate de novo and constitutive DNA methylation, DNA methyltransferase (DNMT)3B, DNMT1, and methyl CpG binding protein 2 (MeCP2), in both SS MSG and lupus renal tissues. A significantly negative correlation was observed between expression of L1 and lymphoid-specific helicase (LSH, encoded by HELLS) in both SS MSG and SLE kidney tissues, as well as between DNMT3A transcripts and L1 expression in SLE kidney tissues and PBMCs. Reduced levels of L1 promoter methylation along with increased DNMT3B, DNMT1, and MeCP2, but reduced LSH levels were detected in SS-low risk patients compared to both SS-lymphoma and SC. The SS-lymphoma group was also characterized by a profound decrease of MeCP2 and DNMT3B compared to SC.

Conclusion: Our data support a contributory role of altered methylation mechanisms in the pathogenesis of systemic autoimmune disorders and related lymphoproliferative processes and suggest that LSH and DNMT3A should be investigated as candidate upstream mediators of decreased L1 promoter methylation and increased L1 expression.

Association of TNFAIP3 Gene Polymorphisms with the Risk for RA and Prediction of Therapy Outcome of TNFα-Blocker Treatment. Susanne Drynda, Marietta Gloetzner and Joern Kekow. Univ of Magdeburg, Clinic of Rheumatology, Vogelsang-Gommern, Germany.

Background/Purpose: The TNFα inducible protein 3 (TNFAIP3=A20) is an important regulatory protein for the inhibition of NFkB activation in TNFaR and TLR pathways. It belongs to a group of genes that have been described as regulated differentially in mononuclear blood cells from patients with rheumatoid arthritis treated with TNFα-blockers early in the course of treatment in association to the clinical outcome. Recently published studies demonstrated that sequence variations in the TNFAIP3 gene are associated with the risk for several autoimmune diseases including RA, SLE and psoriasis. It was the aim of our study to analyze the frequency of two independent SNPs (rs583522 T/C intron, and rs2230926 T/G, exon 3) in the TNFAIP3 gene in CCP-antibody positive and negative RA patients and to determine their potential role as a predictive biomarker for therapy outcome of anti-TNFα treatment.

Methods: 423 RA patients with high disease activity and 93 healthy controls were included in the study. Genotyping was performed with pre-designed TaqMan assays for rs583522 and rs2230926 in 5μl reaction mixtures containing 10 ng genomic DNA. HLA-Genotyping was performed using the HLA-DRB1 Shared epitope reverse Hybridization Kit (AID GmbH Germany). CCP-antibody levels were determined with the CCP-2 assay (Menarini, Italy). Disease activity and therapy response were assessed according to the EULAR criteria.

Results: For the intronic SNP rs583522 (T/C) a significant lower frequency of the minor allele was observed in RA patients compared to controls (p=0.014), no significant differences were seen in the allele frequency between CCP-antibody positive and negative RA patients nor in association to the shared epitope encoding alleles. A higher frequency of the

minor allele (G) was found in RA patients compared to controls for rs2230926 (T/G), without reaching statistical significance (p=0.160). CCP-antibody negative patients had a higher frequency of the T/G genotype compared to CCP-antibody positive patients. In contrast to the entire RA group, the subgroup of CCP-antibody negative RA patients had a significant higher allele frequency of the minor allele compared to healthy controls (p=0.042). Disease activity was comparable for the three genotypes of the intronic SNP. For rs2230926 a significant higher disease activity was observed in T/T genotype in contrast to T/G genotype (DAS28 5.78+0.08 vs 5.07+0.31, mean+SEM). No differences were found in the genotype distribution for both SNPs between TNF-blocker responders and non-responders.

Conclusion: Our data confirm earlier reports of an association of the non-synonymous polymorphism rs2230926 in exon 3 resulting in an amino acid substitution Phe/Cys with the risk for RA, particularly for CCP-negative disease. The association of the intronic SNP rs583522 with the risk for RA has not been described before. A predictive importance of the analyzed polymorphisms for therapy outcome of TNF-blocker therapies could not be observed. Due to the low frequency of the minor allele of rs2230926 data have to be considered preliminary and confirmed in larger cohorts.

Disclosure: S. Drynda, None; **M. Gloetzner**, None; **J. Kekow**, None.

The APOL1 Gene Is Not Associated with Lupus Nephritis in Individuals with Enriched Amerindian Ancestry. Julio Molineros[1], Hannah Ainsworth[2], Robert Kimberly[3], Michelle A. Petri[4], Rosalind Ramsey-Goldman[5], Luis M. Vilá[6], John D. Reveille[7], Elizabeth E. Brown[8], Swapan Nath[1], Carl D. Langfeld[9], Bernardo Pons-Estel on behalf of GENLES[10], Graciela S. Alarcon[11] and Marta E. Alarcon Riquelme[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Wake Forest, Winston-Salem, NC, [3]University of Alabama, Birmingham, AL, [4]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [5]Northwestern University and Feinberg School of Medicine, Chicago, IL, [6]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [7]University of Texas Health Science Center at Houston, Houston, TX, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Wake Forest University Health Sciences, Winston-Salem, NC, [10]Sanatorio Parque, Rosario, Argentina, [11]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.

The APOL1 Gene is not Associated with Lupus Nephritis in Individuals with Enriched Amerindian Ancestry Background/Purpose: The APOL1 gene coding variants G1 and G2 have been described to be associated with chronic renal disease and end-stage Renal Disease (ESRD) in patients of African descent with different nephropaties. The association of these genes with ESRD but not lupus nephritis (LN) per se has also been recently reported in SLE patients of African descent (1). Amerindian ancestry has been found to be associated with the occurrence of lupus (2) and LN (3) but whether risk variants in the APOL1 gene would be preferentially observed in those who develop LN and have a large Amerindian ancestral component has not been determined.

Methods: Patients with SLE (ACR criteria) from various sources across North and South America were genotyped for a complete GWAS using the OMNIv1 Illumina array. Data was QC filtered and analyzed using PLINK. Cases were those SLE patients who had LN as per the corresponding ACR criterion and compared to healthy controls. We used PCAdmix to determine local ancestry across the genome and selected the data within the APOL1 locus. We also investigated if we identified proxies for the G1 or G2 variants. The frequency distribution of Amerindian ancestry and APOL1 genes was then compared between cases and controls and a T-test was used to investigate differences between cases and controls within ancestries in the genomic segment.

Results: There were 400 cases and 1200 healthy controls. Table 1 shows the distribution of European (CEU), West African (YRI) and Amerindian (NAH) ancestry within the segments (windows) of APOL1 variants studied between cases and controls covering 322 SNPs. As the G1 and G2 variants were not genotyped, we attempted to identify proxies using GWAS data for Latin Americans. Two proxies for G1 were observed, but none for G2. The G1 proxies were nearly monomorphic in the Amerindian enriched individuals (maf = <1%). The proportion of African ancestry within the locus was <4%.

Table 1. Ancestry within the APOLI Genomic Segment is similar between cases with LN and health the segment was non-significant

Local ancestry windows	From SNP	start position	pos1M	Case_ CEU	Case_ YRI	Case_ NAH	Control_ CEU	Control_ YRI	Control_ NAM
APOLI Window1 [182 SNPs]	rs1573708	34757430	34,76	0.406648	0.030223	0.56313	0.4094346	0.0299441	0.54062129
APOL1 Window2 [141 SNPs]	rs2160907	35765846	35.77	0.40974	0.049058	0.541202	0.4157275	0.0455918	0.53868068

Conclusion: Variants within the nephropathy gene APOL1 were not associated with the occurrence of LN among these SLE patients from the Americas exhibiting a large Amerindian ancestral background. Our results can be ascribed to the low proportion of African ancestry within the locus.

2090

Contribution of MTHFR Gene Polymorphisms in Sjogren's Syndrome Related Lymphomagenesis. Sofia Fragkioudaki[1], Adrianos Nezos[1], Aristea Papageorgiou[1], Michael Voulgarelis[1], Mary K. Crow[2], Haralampos M. Moutsopoulos[1] and Clio Mavragani[1]. [1]School of Medicine, University of Athens, Athens, Greece, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: Sjogren's syndrome (SS) exhibits the highest susceptibility, among systemic autoimmune diseases, to non-Hodgkin lymphoma (NHL) development. Genetic instability and DNA methylation have been previously implicated in the pathogenesis of lymphoproliferative disorders. Methylene tetrahydrofolate reductase (MTHFR) is an enzyme essential in DNA synthesis and methylation pathways. Two common polymorphisms of the MTHFR gene, C677T and A1298C, have been implicated in the development of NHL, as they reduce the MTHFR enzyme activity and may affect DNA methylation and stability. The aim of this study was to investigate the possible contribution of the MTHFR C677T and A1298C polymorphisms in SS-related lymphomagenesis.

Methods: 189 SS patients without NHL, 72 SS patients with NHL (57 with MALT and 15 with non-MALT lymphoma), 160 healthy controls (HC) and 124 rheumatoid arthritis (RA) patients were genotyped for the detection of the MTHFR gene polymorphisms (C677T and A1298C) using polymerase chain reaction followed by restriction fragment length polymorphism (PCR-RFLP). Methylation levels of CpG islands of the promoter of the long interspersed nuclear element 1 (LINE-1) -a marker of global methylation status- were also evaluated by pyrosequencing in genomic DNA derived from 23 salivary gland tissues from SS (10 with NHL and 13 without) patients.

Results: Non NHL SS patients had significantly reduced rates of the A1298C AC heterozygous genotype compared to both RA patients and HC (OR=0.57, 95%CI=0.36–0.91, p=0.02 and OR=0.57, 95%CI=0.37–0.88, p=0.01 respectively). In contrast, the prevalence of both MTHFR C677T and A1298C polymorphisms did not significantly differ between SS patients complicated by NHL compared to uncomplicated SS, RA and HC groups. Further analysis according to the lymphoma subtype revealed 677 T as a risk allele and the 1298 C as a protective allele for non-MALT NHL development in patients with SS (OR=2.1, 95%CI=0.99–4.45, p=0.05 and OR=0.19, 95%CI=0.04–0.80, p=0.01). The concomitant presence of 1298 AA and 677 TT genotype conferred an increased risk for non-MALT NHL development among SS patients (OR: 3.4, 95%CI: 1.1–10.9, p=0.04). Of interest, an association was observed between the presence of the MTHFR 677 T -but not MTHFR 1298 C allele- with lower methylation levels (TT vs CT vs CC: 67.9±2.2 vs 69.7±2.9 vs 72.3±2.1, p=0.027, by Kruskal Wallis-test), implying methylation defects as potential underlying mechanisms in the pathogenesis of SS related non-MALT lymphoma.

Conclusion: In the current study, we identified novel associations of MTHFR polymorphisms with non NHL SS as well as with SS complicated by non-MALT lymphoma. Preliminary data suggest that alterations of global methylation related to the presence of MTHFR 677 T variants may contribute to the pathogenesis of non-MALT lymphoma among SS patients.

Plasma Microparticle Protein Features Distinctively Classify Systemic Lupus Erythematosus and Systemic Sclerosis and Their Clinical Phenotype. Ole Østergaard[1], Christoffer T. Nielsen[2], Line V. Iversen[3], Anders A. Bengtsson[4], Søren Jacobsen[5] and Niels H. H. Heegaard[6]. [1]Statens Serum Institute, Copenhagen S, Denmark, [2]University Hospital Rigshospitalet, Copenhagen, Denmark, [3]Statens Serum Institut, Copenhagen, Denmark, [4]Lund University, Lund, Sweden, [5]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [6]Odense University Hospital, Odense C, Denmark.

Background/Purpose: Plasma microparticles (MPs) comprise a heterogenous population of submicron membraneous vesicles shed from the cell-surface both constitutively and as a consequence of pathological processes. We isolate MPs from well-characterized patients with systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and from healthy controls (HCs) for thorough comparative analysis at the proteome levels.

Methods: MPs were isolated from 1 mL platelet poor citrate plasma by repeated ultracentrifugation using a standard protocol (1) before in-solution digestion with trypsin followed by analysis by tandem mass spectrometry for protein identification and quantification (2). In total, MPs from 45 SLE patients and 37 SSc patients (all fulfilled the relevant American College of Rheumatology Disease Criteria) were analyzed and compared to MPs from 35 age- and sex-matched healthy controls.

Results: More than 1000 proteins were identified from each group. Univariate statistics, hierarchical clustering, and principal component analysis were applied to analyze the protein intensities to search for disease classifiers. Samples from SLE patients showed increased levels of complement factors, immunoglobulin, galectin-3-binding protein, CD5-like protein and decreased levels of organellar and membrane associated proteins. In addition, proteins intensities from C1q, G3BP and 14-3-3 showed correlation with disease activity. SSc samples showed increased levels of complement factors and extracellular matrix proteins (fibulin, fibronectin) and decreased levels of tropomyosin-1 and various mitochondrial proteins. Principal component analysis on the centered dataset could differentiate the SLE samples from the NOR and SSc samples.

Conclusion: In-depth proteomic characterization of plasma MPs in SLE and SSc supports their putative role in disease pathology, immune regulation and as biomarkers.

Proteomic Phenotyping of Rheumatoid Arthritis Disease Activity. Yauheniya Cherkas, Sarah Lamberth, Carrie Brodmerkel and Mark Curran. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: The use of objective biomarkers of clinical disease characteristics such as disease activity would be beneficial in informing patients, physicians and payers. Recently, a number of potential biomarkers for RA disease diagnosis, prognosis and activity have been described in the literature. However, the majority of these have not been validated in independent cohorts.

Methods: We assessed the performance of available biomarkers of RA disease as well as developed and validated novel tests using samples from multiple cohorts of moderate to severe RA patients. Serum samples from subjects enrolled in two Phase III studies (GO-FURTHER and GO-SAVE; clinicaltrials.gov – NCT00973479 and NCT01004432) and a Phase II study (NCT00718718) were obtained at multiple timepoints. Using samples from the GO-FURTHER (NCT00973479) cohort we evaluated commercially available correlates of disease activity as well as developed novel molecular readouts of disease activity.

Results: We were able to develop two serum-based alternatives to DAS28-CRP score with similar performance using both informed and inclusive approaches to protein selection. The two tests were developed using a set of proteins profiled via ELISA; and a highly multiplexed (SomaLogic) proteomic platform. The tests had consistently good performance in samples from cross-validation runs and samples from same subjects left out of the modeling step. We have also observed similar or better performance in patients enrolled in independent cohorts coming from other two clinical trials and additional replication is underway.

Conclusion: Validation of objective biomarkers of clinical disease state is important for advancing the evaluation and comparison of novel therapeutics in RA.

Improvement of Rituximab Response Prediction in Rheumatoid Arthritis Via Correction for Prednisone-Related Suppression of Type I Interferon Response Gene Expression. Tamarah D. de Jong[1], Saskia Vosslamber[1], Marjolein Blits[1], Gertjan Wolbink[2], Michael T. Nurmohamed[2], Connie J. van der Laken[1], Gerrit Jansen[1], Alexandre E. Voskuyl[1] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands.

Background/Purpose: Elevated type I IFN response gene (IRG) expression has been described to be clinically relevant in predicting the non-response to rituximab in rheumatoid arthritis (RA) patients. Interference between glucocorticoids (GCs) and type I IFN signaling has been demonstrated in vitro. Since the use and dose of oral GCs is highly variable among patients prior to the start of treatment with rituximab, we aimed to determine what the effect of GC usage is on the IRG expression in relation to the clinical response to rituximab.

Methods: The study was performed in two independent cohorts of established RA patients (n=32 and n=182) and a third cohort of 40 established RA patients that were candidates for rituximab therapy, recruited from the VU University medical center and the Jan van Breemen Institute Reade in Amsterdam. All patients fulfilled the revised American College of Rheumatology (ACR) 1987 criteria for the diagnosis of RA. In all patients, peripheral blood gene expression of 8 IRGs was determined by microarray or multiplex quantitative (q)PCR and an IFN-score was calculated. GC use consisted of oral prednisone in doses varying from 2.5–10mg/day in 19%, 29% and 70% of the patients in the three cohorts, respectively. The clinical response to rituximab was determined after 6 months of therapy based on the change in 28 joints Disease Activity Score (ΔDAS28); patients with ΔDAS28>1.2 were considered responders. The IFN score was tested for its predictive value using Receiver Operating Characteristics (ROC) curve analysis in the patients who started with rituximab (n=40).

Results: In all three cohorts, we consistently observed suppression of the IFN-score in patients using prednisone ($PREDN^+$) compared to patients that were not using prednisone ($PREDN^-$). No clinical differences were observed between $PREDN^-$ and $PREDN^+$ patients. The suppression of IFN-score appeared to be dose-dependent as it was most pronounced in the highest dose range (>10mg/day). In the rituximab cohort, separate ROC analysis on $PREDN^-$ patients alone revealed improved prediction of non-response to rituximab by baseline IFN-score with an AUC of 0.969 compared to 0.848 when analyzed in all patients, whereas prednisone use itself had no predictive value in this cohort. Using a subgroup-specific cutoff of the IFN-score in the $PREDN^-$ and $PREDN^+$ groups the sensitivity increased from 41% in all patients up to 88% in the $PREDN^-$ group, combined with a specificity of 100%.

Conclusion: Prednisone use in RA patients causes suppression of IRG expression. Rituximab response prediction based on the IFN-score at baseline could be considerably improved when prednisone use is taken into account.

Deep Sequencing Reveals Differential RNA Expression during Malignant Transformation in Major Salivary Glands in a Mouse Model of Sjogren's Syndrome. Kaiyu Jiang[1], Long Shen[2], Zihua Hu[3], Julian Ambrus[4] and James Jarvis[5]. [1]The University at Buffalo, Buffalo, NY, [2]SUNY at Buffalo, Buffalo, NY, [3]University at Buffalo, Buffalo, NY, [4]University Of Buffalo, Buffalo, NY, [5]SUNY Buffalo School of Medicine, Buffalo, NY.

Background/Purpose: – Sjšgren's syndrome (SS) is a chronic autoimmune disease of unknown etiology that targets salivary and lacrimal glands and may be accompanied bymultiorgan systemic manifestations. To further the understanding of immunopathology associated with SS and identify potential therapeutic targets, we examined the transcriptomeof salivary glands in a mouse models of Sjogren's syndrome through disease progression.

Methods: We isolated RNA from salivary glands of interleukin-14 alpha-transgenic mouse, a model of SS, at 3 different disease stages: pre-autoimmune, autoimmune and malignant. RNA samples were prepared for sequencing using the Illumina TruSeq RNA prep kit. Sequencing was performed using the Illumina HiSeq 2500. The pass filter reads were mapped to the genome (NCBI/build 37.2) using TopHat (version 2.0.4). Probable transcripts were assembled using Cufflinks (version 2.0.2), and differential expressed transcripts were determined using DESeq. Fold change (FC) calculations were obtained using the log2(FPKM) ratio, where FPKM is the fragments per kilobase of exon model per million mapped fragments.

Results: Salivary glands RNAs demonstrated disease-stage specificity. For example, when we compared autoimmune to pre-autoimmune stages, there were 26 DE genes (10 down-regulated, 16 up-regulated) that demonstrated a 2.46 fold change or greater. We found 22 DE genes (3 down-regulated, 19 up-regulated) that showed a 2.4 fold of greater difference when we compared malignant *vs* pre-autoimmune. Ingenuity pathway analysis demonstrated that the DE genes are associated with cancer, development disorders, hereditary disorder, ophthalmic disease, organismal injury and abnormalities, and reproductive system disease (e.g. *GSK3A, KRT12, KRT34, KRT36, KRTAP9-4, NEUROD6, OAS2, PRDM5, RHPN2, TPCN1*). Sixteen DE genes, including type I IFN response genes OAS2, were common to the autoimmune to pre-autoimmune and the malignant to pre-autoimmune comparisons. Further evidence that the 16 DE genes, which expression are up-regulated associated disease severity, i.e. gene expression level in malignant is higher than in autoimmune; and in autoimmune higher than in pre-autoimmune.

Conclusion: The sensitivity and dynamic range of RNAseq allow a detailed view of salivary glands transcriptome. Multiple RNA transcripts show disease-state specificity, suggesting that they may be directly involved in pathogenesis. These finding are expected to lead to new insights into SS pathogenesis and biologic processes leading to SS-associated malignancy.

Two Novel Serum Urate Levels Associated Genetic Loci Identified By GWAS in European Were Confirmed in Chinese Han Population. Minhui Hua[1], Wenfeng Tan[2] and Miaojia Zhang[3]. [1]the first affliated hospital with Nanjing medical university, nanjing, China, [2]THE FIRST AFFILIATED HOSPITAL OF NANJING MEDI, NANJING, China, [3]the first affliated hospital with nanjing medical univercity, nanjing, China.

Background/Purpose: Previous GWAS have identified four novel loci (SNP rs11264341, rs6770152, rs2941484 and rs7224610) were significant with serum urate levels in European. Here, we further assess the association of these 4 loci in the phenotypic expression of hyperuricemia in Chinese Han population.

Methods: A total of 1341 unrelated participants (701 hyeruricemia participants and 640 healthy individuals) were enrolled into our study. All individuals of this study participated from Jiangsu and Anhui Province. DNA samples were genotyped using TaqMan probes that specifically target the alternate alleles. We used χ^2-test to determine whether the genotypes of cases and controls of all SNPs deviated from Hardy-Weinberg equilibrium. Differences in allele frequencies between dichotomous traits were calculated employing the same method. Differences in continuous variables between groups were calculated using a two-tailed unpaired t-test. Power analysis was carried out using QUANTO1.2.4.

Results: SNP rs11264341 and rs7224610 were newly discoverred susceptible loci in mainland Chinese Han hyperuriccemia population. The distributions of SNP rs11264341 and rs7224610 were significantly different in hyperuricemia participants and healthy controls. The study also confirmed the association of SNP rs11264341 and rs7224610 with hyperuricemia ($p<0.05$) in Chinese Han population. C-allele in SNP rs11264341 seemed to be a risk factor in the influence of serum uric acid level. C-allele in SNP rs7224610 played a role of protection in the mean serum urate concentration ($p<0.05$).

Conclusion: This study confirmed 2 newly SNP rs11264341 and SNP rs7224610 were significant associated hyperuricemia susceptibly in Chinese Han and the genetic variation of these two SNPs could affect the serum urate concentration in Chinese Han population.

Assessment of RA Heterogeneity in Two Independent Cohorts of Patients. Joshua Joung, Yauheniya Cherkas and Sarah Lamberth. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: RA is known to be a heterogeneous disease, with heterogeneity existing in both clinical symptoms and responses to therapies. Molecular assessment of this heterogeneity would help to describe novel aspects of RA pathogenesis and potentially allow for more accurate predictions of which treatments will be most beneficial to a given patient. We examined the question of whether similar immune-relevant pathways are significantly enriched in different RA populations focusing on whole blood gene expression profiles of 2 large cohorts of clinical trial subjects.

Methods: Both cohorts included men and women aged ≥18 yrs with active RA for ≥ 3 months with inadequate response to methotrexate (MTX). Messenger RNA (mRNA) was collected from 487 baseline whole blood samples in Cohort 1 (Clinical study NCT00973479) and 89 baseline whole blood samples in Cohort 2 (Clinical study NCT01597739). Additionally, non-RA serum samples (healthy controls; Cohort 1 n=22, Cohort 2 n=24) were obtained from Bioreclamation (Hicksville,NY). All samples were profiled using the HT HG-U133+ PM Array (Affymetrix). Comparisons between the healthy control and diseased experimental groups were performed using iReport (Ingenuity; Redwood, CA) and pathway analyses were performed using IPA (www.ingenuity. com), NextBio (www.nextbio.com), and MetaCore (www.thomsonreuters.com/metacore). Statistical significance is based on p-value 0.05 and fold change 1.2.

Results; The disease profiles (DP) comparing baseline gene expression levels of RA and healthy controls contain 2203 and 1282 differentially expressed genes (DEGs) for Cohorts 1 & 2 respectively. There were 324 DEGs shared between the two cohorts, encompassing 14.7% and 25.5% of Cohort 1 and 2. On a pathway level, IPA identified 119 pathways that were present and significant (Fisher's Exact Test p-value) in at least one cohort. Of these, 21 (17.6%) were shared and significant in both cohorts and included inflammatory and immune response related pathways. 17 and 81 pathways were uniquely significant to Cohort 1 and Cohort 2 and included complementary pathways such as cell and cytokine signaling pathways. Analysis via MetaCore identified 406 total pathways; 134 were shared and significant to both cohorts, and 102 and 170 were uniquely significant to Cohorts 1 and 2 respectively. Shared and significant pathways primarily included those related to immune response; pathways unique to only one cohort were enriched for immune response signaling and inflammatory response.

Conclusion: Analysis of disease profiles from 2 independent cohorts via IPA and MetaCore analysis tools showed that the significant pathways common to both cohorts are enriched in inflammatory and immune response pathways. The uniquely significant pathways of Cohort 2 were notably enriched in inflammatory pathways and cell/cytokine signaling. A complimentary approach via MetaCore identified more enriched sets of overlapping and unique pathways relevant to Cohorts 1 and 2, as well as similar trends for unique and common pathways. These results reflect the complexity and diversity of RA across different cohorts and enhance understanding of the interplay of pathways in a given patient.

Identification of Diagnostic and Activity Metabolomic Urine Biomarkers in Six Immune-Mediated Inflammatory Diseases. Arnald Alonso[1], Jesús Tornero[2], Antonio Fernandez Nebro[3], Juan D. Cañete[4], Eugeni Domènech[5], Javier P. Gisbert[6], Carlos Ferrándiz[5], Eduardo Fonseca[7], Valle García[8],

Francisco Blanco[7], Jesus Rodriguez[9], Jordi Gratacós[10], Patricia Carreira[11], Toni Julia[1], Raül Tortosa[1], María América López-Lasanta[1], Xavier Correig[12] and Sara Marsal[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]Hospital Universitario Guadalajara, Guadalajara, Spain, [3]Hospital Regional Carlos Haya, Biomedical Research Institute of Malaga (IBIMA), Malaga, Spain, [4]Hospital Clinic, Barcelona, Spain, [5]Hospital Universitari Germans Trias I Pujol, Badalona, Spain, [6]Hospital Universitario de la Princesa, Madrid, Spain, [7]Complejo Hospitalario Juan Canalejo, A Coruña, Spain, [8]Hospital Universitario Reina Sofía, Córdoba, Spain, [9]Hospital Universitari de Bellvitge, Barcelona, Spain, [10]Hospital Parc Taulí, Sabadell, Spain, [11]Hospital Universitario 12 de Octubre, Department of Rheumatology, Madrid, Spain, [12]Metabolomics Platform, Reus, Spain.

Background/Purpose: Metabolomics is an emergent research field within the omics sciences aimed at characterizing the metabolome in complex biological samples. It provides a powerful approach to identify physiopathological processes and metabolites can be useful biomarkers in clinically relevant applications. The present study represents the first metabolomic analysis on a large cohort including multiple immune-mediated inflammatory diseases (IMIDs). Its objective is the identification of diagnostic and activity biomarkers through the analysis of the whole urine metabolome of 6 IMIDs.

Methods: Proton nuclear magnetic resonance (^{1}H-NMR) data of urine samples was acquired among 6 IMID cohorts (n=200 Spanish patients per cohort) including: rheumatoid arthritis (RA), psoriasis (PS), psoriatic arthritis (PA), Crohn's disease (CD), ulcerative colitis (UC) and systemic lupus erythematosus (SLE). Each IMID cohort was selected in order to include low and high activity patients according to the consensus activity indexes of each disease. Distributions of sex, age, extraction time and fasting time were matched between these cohorts to avoid false positive associations due to these confounding variables. ^{1}H-NMR data of 100 control individuals was also acquired in this study. Spectral processing was performed using Focus. Mann-Whitney U test was used to evaluate potential diagnostic and activity biomarkers. A multivariate analysis (i.e. logistic regression) was also performed to avoid false positive associations due to confounding epidemiological or clinical variables. A clustering analysis was also conducted to evaluate disease similarity according to the urine metabolome.

Results: After processing the spectral data n=473 peaks were identified. This set was reduced to n=145 peaks after applying several quality control filters. The statistical analysis identified 45 metabolic peaks significantly associated (*P*-Value<1E-4) in at least one of the performed disease diagnostic or activity tests (Figure 1). When analyzing each IMID cohort separately, RA, CD and UC obtained the largest number of diagnostic biomarker candidates: n=27, n=18 and n=21 respectively. Interestingly, CD and UC shared common metabolic disturbances although differential biomarkers between them were also identified. PS and PA showed a little impact on their metabolic profiles. On the other side, when comparing low to high disease activity patients a lower number of significant associations were observed, mainly related to CD and RA.

Conclusion: A significant number of diagnostic biomarker candidates have been identified on this first large cohort of IMIDs. Several candidates were found to be global IMID biomarkers and could target the common inflammatory process shared by these diseases. RA showed the largest burden on urine metabolic disturbances and interesting activity biomarkers were identified for RA and CD.

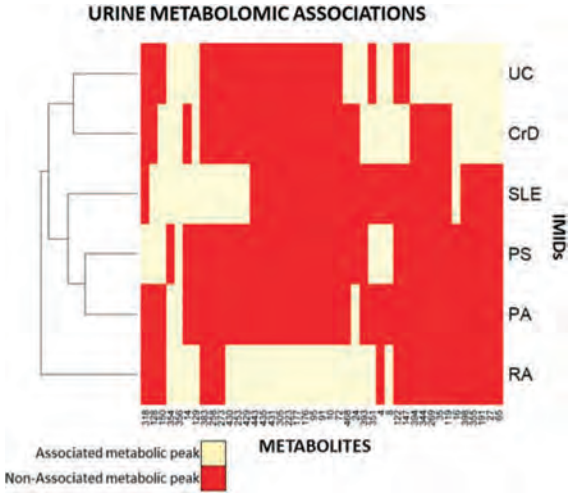

Figure 1. Urine metabolomic associations

Genetic Variants of the NLRP3 Inflammasome Are Associated with Stroke in Patients with Rheumatoid Arthritis. Alf Kastbom[1], Lisbeth Ärlestig[2] and Solbritt M. Rantapää-Dahlqvist[2]. [1]Linköping University, Linköping, Sweden, [2]Umeå University, Umeå, Sweden.

Background/Purpose: Inflammasomes are intra-cellular protein complexes important for the production of pro-inflammatory cytokines such as interleukin-(IL-)1β and IL-18. Cardiovascular disease is over-represented in patients with rheumatoid arthritis (RA), and chronic inflammation is believed, at least partly, to underlie this circumstance. Recent studies have suggested that the NLRP3 inflammasome influences both the severity of RA and development of atherosclerosis. NLRP3-Q705K and CARD8-C10X are functional polymorphisms which have been shown to influence inflammasome function, and to associate with plasma IL-1β levels in healthy individuals. Also, a number of reports have described synergistic effects between these polymorphism. Therefore, we sought to determine whether NLRP3-Q705K and CARD8-C10X influence the risk of cardiovascular disease (CVD) in patients with RA.

Methods: The incidence of CVD was assessed in 522 patients with established RA fulfilling the 1987 ACR criteria by a retrospective survey of medical records in combination with a 6 year prospective follow-up. CV events were defined as myocardial infarction (MI), severe verified angina pectoris treated with coronary artery bypass graft surgery (CABG) or percutaneous coronary intervention, or stroke/transient ischaemic attack (TIA). NLRP3-Q705K and CARD8-C10X genotypes were analysed in relation to CVD by logistic regression analysis adjusting for traditional risk factors in addition to event preceding RA, treatment for RA, cumulative disease activity, and age at the onset of RA.

Results: From the onset of RA to the 6-year follow-up, 121 patients were recorded as undergoing a CV event(s): 74 had suffered an MI, 20 had angina pectoris with intervention and 50 experienced a stroke/TIA. Carriage of the minor allele of NLRP3-Q705K was associated with an increased risk of stroke/TIA (Odds ratio (OR) = 2.01, 95% Confidence interval (CI) 1.0–4.1, p=0.05), whilst CARD8-C10X did not associate with any type of CV event. Patients with ≥1 variant allele in both polymorphisms had an increased risk of a CV event (OR 2.2, 95% CI 1.1–4.5, p=0.026) when compared with those homozygous for the major alleles of each polymorphism. Stratification showed that this risk was exclusively confined to stroke/TIA (OR 3.4, 95% CI 1.5–7.7, p=0.003) and not to MI and/or angina pectoris (OR, 1.5, 95% CI 0.6–3.4). Adjusting for traditional risk factors and RA severity yielded higher ORs regarding any CV event (OR 2.6, 95% CI 1.1–5.9, p=0.023) and stroke/TIA (OR 5.9, 95% CI 2.1–17, p=0.001). Stratification for sex consistently showed higher risk estimates among female patients.

Conclusion: Genetic variants of the NLRP3 inflammasome influence the risk of stroke/TIA, but not of MI/angina pectoris in patients with established RA. Future work should include genetic variants in upstream signaling pathways. Also, the possible clinical value of NLRP3 and CARD8 genotyping of RA patients, in relation to the risk of CVD and its prevention, calls for further attention in larger patient cohorts.

Serum C-X-C Motif Chemokine 10 (CXCL10) Is Elevated in Psoriasis Patients Prior to Psoriatic Arthritis Onset. Remy Pollock[1], Fatima Abji[1], Husain Shakil[1], Kun Liang[2], Vinod Chandran[1] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Psoriatic arthritis (PsA) is a potentially destructive disease that develops in about 30% of patients with cutaneous psoriasis. Biomarkers that can predict which psoriasis patients are destined to develop PsA may help early diagnosis of PsA. This study aimed to determine if T cell and NK cell-associated cytokines IFNA2, IL-15, IL-17A, IL-23, and TRAIL, and chemokine CXCL10, are elevated in the serum of psoriasis patients who progress to develop PsA, compared to psoriasis patients who do not develop PsA.

Methods: Psoriasis patients were followed prospectively beginning in 2006, and were assessed yearly by a rheumatologist for the presence of PsA. Psoriasis patients who developed PsA were termed 'converters', and serum samples were taken at baseline from all and again at PsA diagnosis from a subset of converters. Age and sex-matched patients who did not develop PsA over the same duration of psoriasis were termed 'non-converters'. Serum CXCL10, IFNA2, IL-15, IL-17A, IL-23, and TRAIL were measured using a multiplexed microsphere-based assay on the Luminex 200 platform. Protein levels were compared between samples taken before and after PsA diagnosis by paired t-test, and between converters and non-converters by logistic regression.

Results: Forty-six psoriasis patients developed PsA. At baseline, these converters were 54.3% males, with a mean age of 46.1 ± 13.0 years, mean psoriasis duration of 25.5 ± 14.9 years, mean age at psoriasis onset of 20.9 ± 16.5 years, and mean PASI of 7.0 ± 7.2. Converters were compared to 46 non-converters who were 50% males, with a mean age of 45.5 ± 12.3 years, mean psoriasis duration of 27.5 ± 16.0 years, mean age at psoriasis onset of 18.9 ± 16.3 years, and mean PASI of 6.3 ± 6.1. Candidate biomarkers were first tested in half of the converter and non-converter samples (discovery cohort), then were validated in the remaining samples. In the discovery cohort, CXCL10 was significantly elevated in baseline samples from converters compared to non-converters (OR=1.6, 95% CI 1.2–2.2, p=0.005). TRAIL was also elevated in converters at baseline (OR=1.0, 95% CI 1.0–1.1, p=0.05) however it was not independent of CXCL10 in multivariate analyses. IFNA2, IL-15, IL-17A, and IL-23 were below the detectable range in several samples and were not significant. CXCL10 remained significantly elevated (OR=1.3, 95% CI 1.1–1.5, p=0.003) in a combined analysis of the discovery and validation cohorts. Twenty-three converters had samples taken at both baseline and at PsA diagnosis. Although mean CXCL10 level was high in baseline samples, it declined significantly following PsA onset from 932 ± 458 pg/ml to 543 ± 310 pg/ml (p<0.001), which is not significantly different from the mean CXCL10 levels observed in non-converters (421 ± 218 pg/ml, p=0.06).

Conclusion: We demonstrated that CXCL10 was elevated in the serum of psoriasis patients who later developed PsA, but following PsA onset returned to levels closer to those observed in psoriasis patients who did not develop PsA. Further studies are needed to elucidate of the dynamics of serum CXCL10 levels in the progression from psoriasis to PsA, and to determine how well CXCL10 levels indicate PsA risk in psoriasis patients.

Activation of NFkβ Pathways in Sjögren's Syndrome Related Lymphomagenesis-Role of the His159Tyr Mutation of the BAFF-R Receptor. Clio Mavragani[1], Adrianos Nezos[1], Aristea Papageorgiou[1], Haralampos M. Moutsopoulos[1], Athanasios G. Tzioufas[2] and Michael Voulgarelis[1]. [1]School of Medicine, University of Athens, Athens, Greece, [2]School of Medicine, National University of Athens, Athens, Greece.

Background/Purpose: Sjögren's Syndrome (SS) bears the highest risk for lymphoma development among all autoimmune diseases. A growing body of evidence suggests activation of NFκB pathways as a critical step in the pathogenesis of both SS and B-cell non Hodgkin's lymphomas (NHL), the major type of SS-related lymphomas. The mutation His159Tyr of the BAFF receptor has been found to confer increased risk in patients with NHL through activation of the NF-kB pathway. The aim of the current study was to evaluate the contribution of NFκB pathways activation in SS related lymphomagenesis and explore the potential role of the His159Tyr BAFF-R mutation.

Methods: Quantitative gene expression of both NFκβ1 and NFκβ2 transcripts was measured by real-time PCR in peripheral blood (PB) derived from 31 SS, 13 SS-lymphoma and 30 healthy controls (HC), in isolated B cells from 2 SS, 6 SS-lymphoma and 5 HC as well as in minor salivary gland tissues (MSG) tissues from 31 SS, 10 SS-lymphoma and 17 sicca controls (SC). The BAFF-R His159Tyr mutation was evaluated in 247 SS patients (177 non lymphoma and 70 SS-lymphoma patients), 145 systemic lupus erythematosus (SLE) patients, 101 rheumatoid arthritis (RA) patients and 180 healthy controls (HC), by PCR-RFLP and PCR-sequencing.

Results: NFκβ2 transcripts were significantly upregulated in the PB, MSG tissues and isolated B cells derived from SS patients complicated by lymphoma compared to HC in PB and B-cells, and to both SS-non lymphoma patients and SC in MSG tissues. At PB level, an opposite pattern was observed in regard to NFκβ1 transcripts; they were found to be significantly reduced in SS patients complicated by lymphoma compared to the HC group. As a result, NFκβ2/NFκβ1 ratio was significantly increased in the peripheral blood from SS patients complicated by lymphoma compared to both SS and SC with an area under the receiver operating characteristic (ROC) curve of the NFκβ2/NFκβ1 being 0.804, p=0.002, 95%CI (0.670–0.938). In regard to His159Tyr BAFF-R mutation, we observed an increased prevalence in SS patients compared to HC [17 out of 247 (6.9%) vs 3 out of 180 (1.7%), p=0.01)]. No such statistically significant difference was found among SS, SLE and RA groups, (6.9% vs 3.5% and 3% respectively, p-values>0.05 in all comparisons). Both SS subgroups exhibited significantly higher frequencies of the His159Tyr BAFF-R mutation compared to HC (SS-lymphoma: 8.6% and SS-non lymphoma: 6.2% vs 1.7% in HC). When we stratified the SS-lymphoma subgroup according to the lymphoma subtype and the age of SS onset, the His159Tyr BAFF-R mutation was detected in 71.4% of patients with mucosa associated lymphoid tissue (MALT) NHL and an age of SS onset between 31–40 years old, conferring an 147.5 fold increased risk compared to HC [(95% CI): (20.0–1087.5, p<0.0001)].

Conclusion: Taken together, our data suggest activation of alternative NFKB pathways as a central pathogenetic event in the malignant transformation in the setting of SS, with mutation of the BAFF-R receptor being a main contributor particularly in MALT patients with a SS onset at the fourth decade of life, though other concomitantly operating mechanisms cannot be excluded.

Epigenetic Study of Advanced Ankylosis in Patients with Ankylosing Spondylitis. Darren O'Reilly[1], Yuhua Zhang[2], Nayef Al Ghanim[1], Rose Ardern[1], Alexandra Munn[1], Sean Hamilton[1], Guangju Zhai[2] and Proton Rahman[1]. [1]Memorial University of Newfoundland, St. John's, NF, [2]Discipline of Genetics, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF.

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory spinal disease characterized by ankylosis of the spine. A subset of patients develops significant ankylosis resulting in mobility issues. In this pilot study, we hypothesized that epigenetic modifications may account for differences in the degree of ankylosis of the axial spine.

Methods: AS patients satisfying the New York criteria with advanced ankylosing (characterized clinically with spinal flexion) and radiographically with at least 4 continuous ankylosed vertebrae were categorized as advanced ankylosis. Control AS patients had normal posture on clinical evaluation and had absence of syndesmophytes on plain radiographs. All patients were Caucasians of Northern European Ancestry. Genome-wide DNA methylation profiling was performed on the blood DNA samples from 23 AS patients with advanced ankylosis and 25 patients with no syndesmophytes. The profiling was performed using Illumina HumanMethylation450k Beadchip, which measures up ~480,000 different CpG sites per sample and covers 96% of RefSeq genes. The methylation level at each CpG site was measured by β values varying from 0 (no methylation) to 1 (100% methylation).

Results: Advanced ankylosis patients were predominantly males (22/23), with mean of disease onset at age 21.9 years and age at time of assessment (ankylosis) was 43.72. Meanwhile, AS patients with no syndesmophytes were also predominantly males (24/25), with mean of disease onset at age 24.6 years and age at time of assessment was 44.1 years. Methylation data were normalized using BMIQ method and no batch effects were detected by PCA analysis. Methylation analysis was performed on 382,232 autosomal CpG sites after quality controls. One outlier was identified and excluded in the subsequent analysis. Analysis revealed 100 locations where there was a difference between patients with and without spinal ankylosis. The three locations that differentiated the most included CPG sites in *KIAA0319* (hypomethylated) ($p=1.7x10^{-5}$); *JAKMIP3* ($p=6.4x10^{-5}$) and *LYG2* ($p=9.6x10^{-4}$). Based on functional relevance to AS pathogenesis, particularly antigen presentation, cytokine signalling, and bone remodeling, 5 candidate genes (4 hypomethylated; 1 hypermethylated) emerged: *GPC5* (beta diff=-0.222; p=0.006), SMAD3 (beta diff=-0.16664; p=0.047), *AKAP11*(beta diff=-0.177; p=0.007), *MATN4* (beta diff=0.119; p=0.008), and *NLRC5* (beta diff=-0.11542; p=0.052).

Conclusion: These preliminary results demonstrate that the global DNA methylation pattern in advanced AS differs from AS patients with no spinal damage. High priority candidate genes identified in this study warrants further validation.

A Tissue-Specific Lincrna in the TRAF1-C5 Risk Locus As a Putative Cis-Regulator, Bridging Genetics and Disease. Tobias Messemaker, Rute Marques, Tom Huizinga, Alwin Adriaans, Aleida Bakker, Arend Berendsen, Nina Daha, R E M Toes, Harald Mikkers and Fina Kurreeman.Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: In the last decade genome wide association studies (GWAS) have identified genetic polymorphisms that associate with Rheumatoid arthritis (RA). However, the way these genetic regions contribute to disease remains ill defined. We previously identified the *TRAF1-C5* locus as a predisposing risk factor to the development of RA. In the present study we investigated functional consequences of this risk locus.

Methods: We finemapped likely causal variants by querying Eqtl datasets and identified a strong signal between TRAF1 and C5. We measured by RT-PCR the intergenic region in different tissue panels. We performed knockdown of the intergenic region using shRNA.

Results: Using expression quantitative trait loci (eQTL) datasets, we observed an association between the risk allele and expression of *TRAF1* and *C5* at the mRNA level in various blood-related cell types. As part of an underlying mechanism we identified a novel large non-coding RNA intergenic of *TRAF1* and *C5 (C5T1-lincRNA)*. The lincRNA is transcribed in the same orientation as *TRAF1* and *C5* by RNA polymerase II, is highly transcribed in liver, and its expression is rapidly induced in different immune cells by specific immune stimuli. Expression of *C5T1-lincRNA* correlated with either *C5* or *TRAF1* expression in a tissue specific manner. In addition, knockdown of the intergenic transcript in a hepatocyte cell line resulted in decreased C5 levels.

Conclusion: Together our data support the involvement of a novel lincRNA in regulating *C5* and *TRAF1* expression. We propose that this lincRNA, which is fully located within the associated region, is responsible for the RA associated altered RNA levels of TRAF1 and C5 and plays a role in RA susceptibility.

Benefits of Early Onset of DAS28 (CRP) E Alemao[1], S Joo[2], H Kawabata[1], S Banerjee[1], M Frits[3], C Iannaccone[3], N Shadick[3] and M Weinblatt[3]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Hopewell, NJ, [3]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Guidelines in RA recommend that treatment should be aimed at reaching a target of remission or low disease activity (LDA) as soon as possible, and that treatment should be adjusted frequently (every 3–6 months) in patients (pts) not at target. However, there are limited data from clinical practice on the benefits of attaining rapid remission/LDA. The objective of the current analysis was to compare the clinical and resource use benefits of attaining LDA (DAS28 [CRP] <2.6) within 1 yr in pts with RA in a clinical practice setting.

Methods: Pts enrolled in the Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS) Registry, established in 2003, were analyzed. The BRASS Registry mostly comprises pts with established RA who were evaluated semi-annually on multiple clinical patient-reported outcomes and resource utilization parameters. The current analysis is based on the first 5 yrs of pt follow-up in BRASS and includes pts who were not at DAS28 (CRP) <2.6 at baseline. Pts attaining DAS28 (CRP) <2.6 at 1-yr follow-up were considered as 'DAS <2.6 Soon' and those attaining DAS (CRP) <2.6 later than 1 yr were considered as 'DAS <2.6 Late'. Clinical (physical functioning measured by MHAQ), quality of life (QoL; measured by EQ-5D, SF-12 physical component summary [PCS], Patient Health Questionnaire-9 [PHQ-9]); and resource utilization (hospitalization, ER visits, durable medical equipment [DME] use) outcomes up to 5 yrs were compared in univariate analysis between pts attaining 'DAS <2.6 Soon' vs 'DAS28 <2.6 Late'. To control for differences in baseline covariates, generalized linear models were used for continuous outcomes of HAQ, SF-12, EQ-5D and PHQ-9; logit models were used for categorical outcomes of resource use. Covariates in the multivariate analysis included baseline demographics, duration of RA disease, smoking status, baseline disease status, and treatment.

Results: 417 pts with RA were included in the current analysis: 151 (36.2%) were 'DAS <2.6 Soon' and 266 (63.8%) were 'DAS <2.6 Late'. At baseline, pts in the two groups were similar, respectively, in sex (83 vs 84% females), mean age (SD) (54.2 [12.7] vs 58.3 [13.0] yrs) and never smoked status (53.0 vs 48.9%). Fewer pts in the 'DAS <2.6 Soon' group were on biologic DMARDs than in the 'DAS <2.6 Late' group (31.1 vs 38.7%, respectively). Pts in the 'DAS <2.6 Soon' group had significantly better MHAQ and QoL, as well as fewer hospitalizations, DME use and ER visits in univariate analysis than the 'DAS28 <2.6 Late' group. Similar findings for all outcomes, except hospitalization/ER visits, were observed in multivariate analysis (see table).

Table: Difference in Outcomes at 1 year and 2 years in Patients Attaining DAS28 <2.6 Soon vs Late

	1-year post evaluation		2-year post evaluation	
Outcomes	**Mean difference between DAS <2.6 Soon vs Late**	**p-value**	**Mean difference between DAS <2.6 Soon vs Late**	**p-value**
HAQ	−0.127	0.003	−0.097	0.0213
SF-12 PCS	Not available	–	3.84	0.0034
PHQ-9	Not available	–	−1.16	0.0035
EQ-5D	0.057	0.0001	0.036	0.0234
	Odds ratio for DAS <2.6 Soon vs Late	95 % CI	Odds ratio for DAS <2.6 Soon vs Late	95 % CI
Hospitalization	0.57	0.29-1.12	0.58	0.24-1.42
DME use	0.55	0.32-0.92	0.49	0.26-0.92
ER	1.17	0.34-4.03	1.52	0.40-5.68

Conclusion: Pts achieving LDA within 1 year benefit more (i.e. more improvement in HAQ and QoL outcomes and lower DME use during follow-up) vs those attaining LDA later. Programs geared towards earlier achievement of guideline targets can improve overall clinical and economic outcomes in RA.

Effectiveness of a Workplace Integrated Care Intervention on Work Productivity in Workers with Rheumatoid Arthritis. Myrthe van Vilsteren[1], Cécile Boot[1], Dirkjan van Schaardenburg[2], Romy Steenbeek[3], A.E. Voskuyl[4] and Johannes Anema[5]. [1]Department of Public and Occupational Health, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, [2]Reade, Amsterdam, Netherlands, [3]Body@Work, Research Center Physical Activity, Work and Health, TNO-VU University Medical Center, Amsterdam, Netherlands, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Research Center for Insurance Medicine AMC-UMCG-UWV-VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease with a profound impact on a person's working life. Besides permanent work disability and sick leave, at-work productivity is often impacted by RA. It was shown that reduced at-work productivity has the greatest impact on costs for RA patients, followed by wage loss from stopping or changing jobs, decreased hours, and finally missed work days (absenteeism). At-work productivity decreases when a person is present at work, but is limited in meeting work demands. The Care for Work intervention program is a multidisciplinary intervention with the aim to improve at-work productivity. The intervention program consists of integrated care, coordinated by a clinical occupational physician, and a participatory workplace intervention, coordinated by an occupational therapist. The intervention was evaluated in a randomized controlled trial (RCT) which includes 113 participants.

Objectives: To determine the effects of the intervention program on work productivity, work instability, and supervisor support after 6 months of follow up in workers with rheumatoid arthritis compared to usual care.

Methods: This study is an RCT. Participants were RA patients who are involved in paid work for at least 8 hours per week, recruited from outpatient clinics of rheumatology. Outcome measures were at-work productivity

(measured with the Work Limitations Questionnaire, a higher score indicates more limitations at work), work instability (measured with the RAWIS, a higher score indicates more work instability), and supervisor support (measured with the subscale Supervisor Support of the Job Content Questionnaire, a higher score indicates more supervisor support). Data were analyzed using linear regression models according to the intention-to-treat principle.

Results: The intervention program did not show an effect on at-work productivity (B: 0.328, 95% CI -0.560 – 1.217), work instability (B: -0.697, 95% CI -2.05 – 0.66), and supervisor support (B: 0.10, 95% CI -0.12 – 0.32).

Conclusion: The intervention program did not show beneficial effects on at-work productivity, work instability and supervisor support after 6 months.

Nonsurgical Treatment Patterns in Patients with Chronic Spinal Cord Injury. Brian Le[1], Monique Bethel[1], Lauren Bailey[2], Frances Weaver[2], Stephen Burns[3], Jelena Svircev[3], Michael Heggeness[4] and Laura Carbone[5]. [1]Georgia Regents University, Augusta, GA, [2]Edward Hines Jr. VA Hospital, Chicago, IL, [3]VA Puget Sound Healthcare System, Seattle, WA, [4]University of Kansas School of Medicine, Kansas City, KS, [5]Charlie Norwood VA Medical Center, Augusta, GA.

Background/Purpose: Sublesional loss of bone mineral density is a common complication in patients with chronic spinal cord injury (SCI) putting them at high risk for low-impact fractures. Fracture management in patients with SCI is predominantly nonsurgical. However, to our knowledge, there are no large scale studies which report which nonsurgical procedures are most commonly used. The purpose of this study is to evaluate the distribution of nonsurgical treatments at different fracture sites in patients with SCI.

Methods: Males with chronic, traumatic SCI were identified from the Veterans Administration Spinal Cord Dysfunction data from fiscal years 2002–2007. From this population, patients with incident fractures were identified, excluding fractures due to external ("E-coded") and pathologic fractures. *Current Procedural Terminology* (CPT) codes for nonsurgical treatments of fractures were collected and subsequently categorized into four categories: splints, casts, closed reduction without internal fixation, or "other." The "other" category included knee immobilizers, walking boots, and other orthotic devices. These CPT codes were identified within six weeks following an incident upper extremity, lower extremity or unspecified fracture site. Differences in medical treatment modality were determined among fracture locations.

Results: 1,453 males with chronic traumatic SCI with non-traumatic and non-pathologic incident fractures were identified from 33,452 male SCI patients. 388 CPT codes for nonsurgical treatments of fracture were identified within 6 weeks post-fracture for 282 unique fractures. Fracture sites were grouped by number and location: single upper extremity, single lower extremity, single unspecified or multiple. Among fracture sites, there were significant differences among the types of nonsurgical treatments for single upper extremity fractures ($P=0.017$). Among single upper extremity fractures, forearm fractures were most frequently casted; carpal and metacarpal fractures, splinted; and phalangeal fractures, treated with closed reduction without internal fixation. In comparison, single lower extremity fractures were commonly treated with closed reduction for pelvic and femoral fractures; "other" for patellar, tibial/fibular, ankle, and tarsal/metatarsal fractures. Single unspecified fractures were frequently treated with closed reduction. In cases of multiple fractures, "other" outnumbered all other treatment modalities.

Conclusion: There are a number of different nonsurgical treatments done for single upper extremity, single lower extremity, single unspecified, and multiple fractures in men with chronic SCI.

2106

Surgical Compared with Nonsurgical Management of Fractures in Men with Chronic Spinal Cord Injury. Monique Bethel[1], Lauren Bailey[2], Frances Weaver[2], Brian Le[1], Stephen Burns[3], Jelena Svircev[3], Michael Heggeness[4] and Laura Carbone[5]. [1]Georgia Regents University, Augusta, GA, [2]Edward Hines Jr. VA Hospital, Chicago, IL, [3]VA Puget Sound Healthcare System, Seattle, WA, [4]University of Kansas School of Medicine, Kansas City, KS, [5]Charlie Norwood VA Medical Center, Augusta, GA.

Background/Purpose: Patients with a chronic spinal cord injury (SCI) develop osteoporosis and are at high risk for fracture. However, there is limited information on how these fractures are currently treated. The purpose of this report was to examine treatment modalities (surgical compared with nonsurgical) of incident appendicular fractures in men with a chronic SCI of traumatic etiology.

Methods: Patients with a chronic spinal cord injury (SCI) develop osteoporosis and are at high risk for fracture. However, there is limited information on how these fractures are currently treated. The purpose of this report was to examine treatment modalities (surgical compared with nonsurgical) of incident appendicular fractures in men with a chronic SCI of traumatic etiology.

Results: 1453 male Veterans with 2464 incident fractures met inclusion criteria for the study. These fractures included 345 upper extremity fractures (ICD-9 codes 810.x-819.x), 1667 lower extremity fractures (ICD-9 codes 808.x, and 820.x-828.x) and 452 unspecified fractures (ICD-9 829.x). 875 patients (60%) sustained a single fracture, while the remainder had 2 or more fractures over the five year time period of the study. Only a minority of subjects (9.6%) were treated with surgical intervention, most commonly for hip fractures. Amputations accounted for 20.6% (32/155) of total surgical procedures, or 1.3% of all fractures. There were 20 above the knee amputations (AKAs), 6 below the knee amputations (BKAs), 4 occurring at other sites (foot, toe and finger) amputations, and 2 hip disarticulations one of which was associated with a femur fracture and the other a trochanteric hip fracture. Of the 32 amputations, 72% were done as delayed procedures.

Conclusion: Current patterns of appendicular fracture treatment in SCI indicate that the majority of fractures are managed nonsurgically within the VA healthcare system. A substantial number of surgical procedures were amputations. Many amputations were delayed, suggesting that they may represent failures of initial nonsurgical fracture treatment. There is a critical need to prospectively address optimal treatment (nonsurgical vs. surgical) by fracture site in patients with SCI. **Acknowledgements:** This material is based upon work supported by the Department of Veterans Affairs, Veterans Health Administration, Office of Research and Development and the Rheumatology Research Foundation, Ephraim P. Engleman Resident's Preceptorship Award. **Disclaimer:** This work does not reflect the views of the Veterans Health Administration or the United States government.

2107

Characterization of Social Stigma in Rheumatic Diseases and Correlation with Quality of Life and Medication Adherence. Gihyun Myung[1], Nancy D. Harada[2], Stephanie L. Fong[3], Cleopatra Aquino-Beaton[4] and Meika A Fang[3]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]UCLA David Geffen School of Medicine, Long Beach, CA, [3]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [4]UCLA School of Nursing, Los Angeles, CA.

Background/Purpose: Patients with rheumatoid arthritis and other rheumatic conditions may have physical deformities and functional limitations which make them vulnerable to health-related stigma. The objectives of this study were 1) to examine the prevalence of anticipated, enacted (discrimination), and internalized stigma (self-stigma) among people with rheumatologic conditions and 2) to assess the relationships between stigma, medication adherence, and quality of life.

Methods: We conducted a descriptive cross-sectional study by surveying patients from rheumatology clinics at a Veterans Affairs Healthcare System. Patients completed five sets of questionnaires including 1) sociodemographic questionnaire, 2) 12- item Chronic Illness Anticipated Stigma Scale (CIASS, score range from 1 [very unlikely] to 5 [very likely]) for anticipated sigma, 3) Neurology Quality-of-Life Stigma short form (Neuro-QoL, score range from 1 [never] to 5 [always]) for enacted and internalized stigma, 4) short form-36v2 (SF-36) for quality of life measurement, and 5) 8-item Morisky

Medication Adherence Scale (MMAS-8, score range 0–8.0 with higher scores reflecting better adherence). Pearson's correlation and analysis of variance were used to evaluate for any associations and significant differences respectively between stigma scores (anticipated, enacted, and internalized), quality of life, and medication adherence.

Results: 85 adults completed the questionnaires, including 74 males and 11 females. Mean age was 59 ± 13 years. The top five diagnoses were rheumatoid arthritis (38.8%), psoriatic arthritis (11.6%), gout (11.6%), osteoarthritis (10.9%), and ankylosing spondylitis (7.8%). 67% of the patients were working or retired. 62% of the participants had poor adherence to rheumatic disease medications. 29.4% of patients were somewhat to very likely to anticipate stigma from coworkers and employers versus 4.7% from family/friends and 9.4% from health care workers. 15.3% of patients were sometimes to always experience internalized stigma and 4.7% were sometimes to always experience enacted stigma. There was a significant negative correlation between the work-related CIASS stigma scores and the SF-36 physical ($p = 0.0003$) and mental composite scores ($p < 0.0001$). Higher work-related CIASS stigma score was significantly correlated with poor medication adherence ($p = 0.004$). Similarly, when participants were divided into poor versus good medication adherence groups, significantly more people in the poor adherence group were somewhat to very likely to anticipate work-related stigma.

Conclusion: These findings indicate that about 30% of patients with rheumatologic conditions anticipate stigma from co-workers and employers. Few patients reported anticipated stigma from family and friends, anticipated stigma from healthcare providers, enacted stigma, or internalized stigma. Anticipated work-related stigma was negatively correlated with mental and physical well-being and with medication adherence. Interventions to reduce anticipated work-related stigma have the potential to improve the health of patients with rheumatic diseases.

2108

Anxiety in Caregivers of Patients with Chronic Rheumatic Conditions. Anna Kristina Gutierrez-Rubio, Geraldine Racaza, Maria Lourdes Dianongco and Ester Penserga.Philippine General Hospital, Manila, Philippines.

Background/Purpose: People caring for patients with chronic illnesses, such as systemic lupus erythematosus, rheumatoid arthritis, or osteoarthritis, may experience depression and anxiety due to the burdens of managing debilitating and disabling diseases. Our primary objective was to determine the prevalence of anxiety and depression in caregivers of patients with SLE, RA, and OA.

Methods: Persons acting as the primary caregiver to patients with SLE, RA or OA were included in this study. Demographic data were collected. The hospital anxiety and depression scale (HADS), a 14-item rating scale with independent subscales for anxiety and depression, was administered to each patient. A score of 11 or higher indicated probable depression or anxiety.

Results: A total of 438 patients were included in this study. All patients included were acting as the caregiver of an individual with a rheumatic condition, with 182, 151, and 107 caring for patients with SLE, RA, and OA, respectively. The prevalence of probable depression among caregivers of patients with SLE, RA, and OA were 2.2 ± 10%, 0 ± 0%, and 1.9 ± 10%, respectively with a 95% CI. The prevalence of probable anxiety among caregivers of patients with SLE (17.58 ± 10%) was significantly higher than, RA and OA (9.93 ± 10% $p = 0.05$, and 8.57 ± 10% $p = 0.04$, respectively). Other variables, such as low income, presence of comorbid illnesses, or the number of hours per day spent caring for the patient were not found to be significant factors.

Conclusion: The prevalence of anxiety among caregivers of patients with SLE were found to be significantly higher than those of OA and RA, implying that the illness of the patient they are caring for impacts their risk for anxiety. More studies are needed to determine risk factors for anxiety among caregivers of patients with SLE, and the impact this may have on patient care.

2109

Are Patient Ratings of Providers and Health Plans Associated with Technical Quality of Care in SLE? Edward H. Yelin, Laura Trupin, Jinoos Yazdany and Chris Tonner.University of California, San Francisco, San Francisco, CA.

Background/Purpose: Prior research has shown that the technical quality of SLE care is associated with the degree of subsequent accumulated damage. However, it is not known whether the patient experience with providers and health systems is associated with the technical quality of care.

Methods: We analyzed data from the UCSF Lupus Outcomes Study (LOS), a national sample of persons with SLE interviewed annually using a structured telephone survey. The survey includes batteries from AHRQ's Consumer Assessment of Health Plans (CAHPS) and the Interpersonal Processes of Care Scales (IPC) to rate care along six dimensions of patient care experiences with providers (patient-provider communication, shared decision-making, and trust) and health systems (promptness/timeliness of care, care coordination, and assessment of health plans) from 0–100. Because ratings were highly skewed, we dichotomized the measures at the lowest versus the highest three quartiles. The survey also includes the 13 technical quality indicators (QIs) for SLE that have been validated for patient report. The QIs were aggregated into a pass rate, defined as the number of QIs received as a proportion of those for which one is eligible. We used generalized estimating equations to model the relationship of the QI pass rate with being in the lowest quartile of ratings of each individual dimension and with being in the lowest quartile on 0, 1–3, and 4–6 of the dimensions. Models were adjusted for age, race/ethnicity, education, poverty status, presence and kind of health insurance, specialty of principal SLE physician, disease duration, disease activity (measured by SLAQ), and disease damage (measured by BILD).

Results: 640 LOS participants with ≥1 visit to their principal SLE provider in the year prior to interview were eligible for analysis. Mean age was 52.8±12.6 years and mean disease duration was 20.1±8.8 years. 38% were non-whites and 14% were in poverty. Overall pass rate was. 70 (95% CI. 68,. 71). Being in the lowest quartile of ratings on any one individual dimension was not associated with a statistically significant difference in QI pass rates. Being in the lowest quartile of ratings on 4–6 dimensions was associated with significantly lower pass rates (.63 vs.. 70 and. 71 for those in the lowest quartile on 1–3 or 0 dimensions, respectively [Table 1]).

Conclusion: Consistently low ratings on multiple dimensions of health care experiences may be a sentinel for poor technical quality of care. Because ratings of providers and health plans are in the public domain, individuals with SLE may find this information useful when choosing where to receive clinical care.

Table 1. Technical Quality of Care Pass Rates, by Number of Dimensions with Ratings of Health Care Experiences with Providers and Health Systems in the Lowest Quartila

Number of Dimensions	Q1 Pass Rate (95% CI)
None	.71 (.68, .74)
1–3	.70 (.67, .72)
4–6	.63 (.58, .68)

Quality Measures and Adherence: Potential Hazards of Using Administrative Claims to Measure Biologic Specialty Pharmaceutical Immunology Product Adherence When days' Supply Is Unspecified. Chris Kozma[1], Andrew Paris[2] and Michael P. Ingham[3]. [1]CK Consulting, Saint Helena Island, SC, [2]Vigilytics, Victor, NY, [3]Janssen Scientific Affairs, LLC, Horsham, PA.

Background/Purpose: Published data on adherence of biologics shows a wide range of calculation methods. To compare methods of calculating adherence and persistence for immunology biologics.

Methods: Administrative medical and pharmacy claims from 11/1/2008 through 12/15/2011 were sourced from a leading national health care provider. The first biologic claim between 5/1/2009-6/30/2010 was the patient's index date (Index). Four methods of assigning days' supply were tested. Method I used the pre-Index period to establish induction period status and assign dosing intervals based on product labeling. Methods II & III were adaptive and infliximab (IFX)-specific, using either the first to second infusion interval criteria of ≤ 21 days (Method II), or alternatively, activity in the pre-Index period (Method III), to establish induction period status, followed by assignment of dosing intervals based on product labeling. Method IV used either days' supply from the pharmacy claim or estimated values for medical benefit transactions. These estimated values were based on

a qualitative a priori review of medical benefit transaction reporting frequencies. Adherence was measured using Proportion of Days Covered (PDC-"fixed period" 364 days post-index) and Medication Possession Ratio (MPR-"variable period" index to cessation of treatment or end of observation). Several new methods of reporting adherence were tested, including: Proportion of Patients with treatment gap ≥20% of expected (PPgap≥20), Sum of Gap Days ≥20% of expected (SoGD≥20), Sum of any Gap Days (SoGD), and Number of Gaps ≥10% of expected (NoG≥10). Persistence alternatives included Number of days from Index to a gap ≥90 days, and Number of days from Index to a gap ≥10% of expected interval. **Results** are reported descriptively using means, standard deviations (SD), and percentages.

Results: 636 patients had IFX claims; while in a separate sample, 523 chart review patients had only subcutaneous claims (SQ). Method III produced comparatively low adherence and persistence rates. PDC-type fixed period vs. MPR-type variable period consistently reported a 10–15% lower adherence rate, and a 30–50 day shorter time to event rate. For Method IV, variable period techniques – the IFX cohort had an MPR of 0.94 (SD 0.12) while the SQ cohort had MPR of 0.82 (SD 0.19). For alternative adherence measures, using Method IV, variable period techniques, comparing infusion (IFX cohort) vs. self-administered (SQ cohort) showed the PPgap≥20 was 39.8% vs. 74.2% respectively. The SoGD≥20 was more than twice as great for the SQ vs. IFX cohort (56.1 (SD 65.0) vs. 23.2 (SD 46.3) respectively). The SQ cohort reported more than 2.5 times the NoG≥10 vs. IFX cohort (2.59 (SD 2.14) vs. 0.97 (SD 1.22) respectively).

Conclusion: Substantial differences may result from assumptions made regarding missing days' supply and calculation methods for persistence and adherence when using medical claims. Quality reporting should include all details for days' supply assumptions and calculation methods. Alternative methods of reporting adherence may have greater clinical significance than MPR or PDC.

Overcoming Barriers to Acute Patient Access: Is There a Need for Urgent Care Clinics in Rheumatology Practices? Ruchi Jain, Narender Annapureddy, Isabel Castrejón, Theodore Pincus, Daniel Garcia and Joel A. Block.Rush University Medical Center, Chicago, IL.

Background/Purpose: Urgent access for patients with rheumatic disease is limited in the United States, and it is often difficult to accommodate patients' requests to be seen for urgent issues such as flare. No reports of Rheumatologists with urgent care clinics (UCC) built into practices similar to primary care are available. Currently many Rheumatologists use reserved slots in a provider's schedule for urgent patients. This may be inadequate as these slots may be filled, particularly in academic practices which comprise providers who see patients only a few days per week, and may produce daily unpredictability in schedules. The primary objective of our study was to analyze a validated patient survey to determine a possible need to institute a dedicated UCC in our academic practice.

Methods: 390 patients were given validated surveys measuring access: Did you call for a concern that required urgent attention in the past 12 months? If so how often did you get an appointment as soon as you felt needed: Always Usually, Sometimes or Never. Patients in the Always group were compared with the group who marked Usually, Sometimes or Never. Confidence in the practice was measured using a visual analog scale (VAS): 0= not confident and 10= most confident. Patient demographic and primary diagnosis was collected. MDs were separated into those who provided clinical care 5 days per week and those who were available only 1–2 days weekly. Chi-square tests were used to compare categorical variables. Independent t-tests were used to compare continuous variables. A p-value of 0.05 was considered significant.

Results: 390 patients were surveyed, mean age 53.9, 83% female and 45% African Americans. 192 (49.2%) patients reported a need for urgent care in the past 12 months. 89 (46 %) felt they "always" were given a timely appointment (Adequate Access). 103 (53%) believed that they "usually", "sometimes", or "never" (Not Adequate Access) were given timely appointments to meet an urgent need. Mean available Confidence score for patients of 5 days providers (n=190) was 9.00 (1.76) compared with 8.26 (2.49) for non 5 day available providers (p=0.001). Mean Confidence scores for patients who did request an urgent appointment in past 12 months was 8.3 (2.50), compared with scores for patients who did not was 8.9 (1.82) (p=0.006) Table 1.

	5 Day Available Providers N=190	Non 5 Day Available Providers N=200	P-Value
Percentage of patient group who reported Not Adequate Access in obtaining urgent/timely appointment (N=103)	37.8% (39)	62.1% (64)	**0.002**
Mean confidence that future concerns will be addressed in a timely manner? (All patients)	9.0 (1.7)	8.2 (2.5)	**0.002**
Mean confidence that future concerns will be addressed in a timely manner among patients who had required urgent care in the last 12 months (N=191)	8.8 (2.0)	7.9 (2.8)	**0.012**
Not Adequate Access group (n=102)	7.4 (2.4)	6.9 (2.9)	0.349
Adequate Access group (n=89)	9.7 (0.9)	9.5 (1.3)	0.508
Mean confidence scores based on accessibility Adequate Access group vs. Not Adequate Access group	9.6 (1.1) vs. 7.1 (2.8)		**<0.001**

Patients reporting: Always= Adequate access group; Usually, Sometimes or Never= Not-Adequate Access group. All values are in means and standard deviations unless specified

Conclusion: We observed an unmet need to provide urgent care access for patients with rheumatic diseases in our academic practice. This need is heightened especially in patients of providers with limited clinics in a week. Furthermore, mean confidence scores appear to be driven more by access than by the frequency that the provider practices clinically. A dedicated UCC might improve patient access and confidence in Rheumatology practices.

Patterns of Medication Use Before, During, and After Pregnancy Among Women with Systematic Lupus Erythematosus: A Population-Based Study. Mary De Vera[1], Eric C. Sayre[2], Corisande Baldwin[3], Jessica Galo[3] and J. Antonio Avina-Zubieta[2]. [1]University of British Columbia Faculty of Pharmaceutical Sciences, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]University of British Columbia, Vancouver, BC.

Background/Purpose: Systemic lupus erythematosus (SLE) disproportionately affects women during childbearing years. Given the limited data on perinatal medication use among patients, our objective was to characterize real-world therapy patterns among women with SLE before, during, and after pregnancy.

Methods: Our data include all visits to health professionals and all hospital admissions from Jan 1, 1990 to Dec 31, 2010 and all dispensed medications from Sept 1, 1995 to Dec 31, 2010. The case definition for SLE was: **a)** diagnosis of SLE on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; or **b)** diagnosis of SLE on at least one visit by a rheumatologist or from hospitalization. Cases with an ICD-9 code for SLE prior to 1996 were excluded. From this, we assembled a cohort of women, aged 18 or older, with pregnancies ending in a delivery as identified using ICD-9 codes in the hospitalization database. We calculated the estimated date of conception (EDC) as the date of delivery minus 270 days and created the following periods: **1)** pre-conception 1 (91–180 days before EDC); **2)** pre-conception 2 (90 days before EDC); **3)** 1st trimester; **4)** 2nd trimester; 5) 3rd trimester; **6)** post-delivery 1 (90 days after delivery); and **7)** post-delivery 2 (91 – 180 days after delivery). Using information on prescription date and days' supply, we determined the use of medications including disease modifying anti-rheumatic drugs (DMARDs), biologics, glucocorticosteroids, and non-steroidal anti-inflammatory drugs (NSAIDs) for each period.

Results: We identified 100 pregnancies with delivery date at age 18–45 and at least 450 days after SLE onset, from an incident cohort of 4,297 women with SLE. At delivery, mean age was 32.1 ± 4.4 years and SLE duration was 3.8 ± 1.9 years. We tabulated the proportion of exposed pregnancies according to each period and medication class (**Table**). The majority of DMARD pregnancy exposures were to hydroxychloroquine and/or chloroquine (41 to 45% of exposed pregnancy trimesters). In contrast to the decline in use during pregnancy compared to pre-conception periods for DMARDs and NSAIDs, we observed an increase in glucocorticosteroid exposures during pregnancy, as well as post-delivery.

Conclusion: This population-based study provide data on real-world patterns of perinatal medication use among women with SLE. Findings emphasize the importance of counseling women regarding childbearing decisions as well as the need for evaluation of the risk-benefit profiles of medications in pregnancy.

	Exposed SLE Pregnancies (%)						
	Pre-conception 1	Pre-conception 2	1st trimester	2nd trimester	3rd trimester	Post-delivery 1	Post-delivery 2
DMARDs	52	49	50	45	45	45	52
Biologics	0	0	0	0	0	0	0
Glucocorticosteroids	19	21	22	24	26	30	23

2113

The Number of Morbidities Drives the Health Care Expenditures and Presence of a Musculoskeletal Condition Is Additionally Accountable for Higher Costs. Antje van der Zee-Neuen[1], Polina Putrik[2], Sofia Ramiro[3], Andras Keszei[4], Astrid M. Chorus[5], Rob de Bie[1] and Annelies Boonen[2]. [1]Maastricht University, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [4]RWTH Aachen University, Aachen, Germany, [5]Netherlands Organization for Applied Scientific Research, Leiden, Netherlands.

Background/Purpose: In Europe, 70– 80% of all healthcare expenses are attributable to chronic diseases and a large part of these are musculoskeletal conditions (MSKC).Having >1 disease (multimorbidity) is likely to increase the costs of care but little is known about the association of multimorbidity and health care costs (HCC) and the specific role of MSKC as co-morbid disease in this association. We aimed to explore1) whether the number of morbidities has an important association with costs of care and 2) whether MSKC have an additional impact when occurring as co-morbid disease.

Methods: In a Dutch cross-sectional study, 8904 subjects (>18 years) completed a questionnaire on sociodemographic and lifestyle factors, self-reported physician-diagnosed diseases (MSKC, diabetes, cardiovascular diseases, cancer, migraine, respiratory, skin, mental and bowel conditions) and health care use (general practitioner, rheumatologist, orthopedist, physiotherapist, other specialists, hospitalization in regular/academic hospital or nursing home, home care and domestic help).The total HCC were computed for a 3-months period using reference prices of the Dutch manual for pharmacoeconomic healthcare evaluations 2010, accounting for inflation by Consumer Price Index. Missing values were imputed by means of multiple imputation. To deal with skewness, zero-inflated negative binomial regression (ZINB) models were computed to assess 1) the association of number of diseases and HCC and 2) which disease or combination of diseases (in- or excluding MSKC) was associated with the largest increase of HCC using the healthy as reference. Models were adjusted for age, gender, education, origin (western vs. non-western), smoking status and BMI. For each of the different subgroups, based on number or combination of morbidities, raw and predicted 3-months HCC were presented for male/female patients. Predicted HCC were derived from the ZINB-models.

Results: SKC occurred in 1766 cases (20%).Multimorbidity was present in 1722 cases (19%). HCC increased steeply with increasing number of morbidities (e.g. HCC for 1 morbidity were approximately 2 times higher than for the healthy, exp(β)=1.8 [1.7–2.0]). Compared to any other condition, MSKC was associated with higher HCC when occurring alone or when occurring as co-morbid disease. For example, when 2 morbidities other than MSKC were co-occurring HCC were approximately 2 times higher than in the healthy (exp(β)=2.2 [2.0–2.7]) while when one of the two morbidities was MSKC the costs were 3 times higher than in the healthy(exp(β)=3.0 [2.7–3.7]) (Table 1).

Conclusion: The total HCC increase with increasing number of morbidities. MSKC are accountable for higher costs of care compared to other diseases independent of the number of morbidities. These important findings deserve the attention of policy makers, especially by prioritizing MSKC in healthcare budgets.

Table 1. Association of type (or combination) and number of morbidities with costs of health care utilization during a 3 month period

Morbidity or combination of morbidities†	exp(β) [95% CI]†	Raw costs (€), mean (SD) ♂/♀	Predicted costs (€)* ♂/♀
Musculoskeletal condition when occurring alone	2.2 [1.8–2.5]	575 (2169)/488 (1904)	328/483
Any other chronic morbidity when occurring alone	1.5 [1.4–1.7]	388 (1906)/401 (2801)	220/323
Any combination of 2 morbidities when MSK is one of them	3.0 [2.7–3.7]	664 (1863)/1094 (4895)	483/711
Any combination of 2 morbidities when MSK is not one of them	2.2 [2.0–2.7]	595 (1835)/626 (1928)	355/522
Any combination of ≥3 morbidities when MSK is one of them	6.1 [5.5–7.4]	2028 (6647)/2468 (7461)	955/1406
Any combination of ≥3 morbidities when MSK is not one of them	5.5 [5.0–6.7]	1314 (3503)/2786 (7599)	919/1353
Number of morbidities†			
1	1.8 [1.7–2.0]	437 (1979)/429 (2548)	256/380
2	3.0 [2.7–3.3]	622 (1844)/875 (3814)	423/627
3	5.5 [4.5–6.1]	1208 (3518)/2032 (7326)	746/1107
4	8.2 [6.7–11.0]	1864 (4244)/3465 (8680)	1208/1794
≥5	12.2 [8.2–16.5]	4429 (12384)/3328 (5918)	1692/2513

† Reference category: healthy/absence of disease
+ Estimates derived from zero-inflated negative binomial regression models adjusted for age, gender, BMI, education and smoking-status
*Predicted costs are presented for men and women with median age (54 yrs), normal BMI (18.5–25 kg/m2), non-smokers, middle or secondary professional education and western origin

2114

Comorbidity Characteristics of Patients Starting First-Line Acute Gout Agents - Colchicine, NSAID, and Corticosteroids. Alfonso Perez[1], Robert Jackson[1], Jiao Yang[1], Aki Shiozawa[1], Shawn Yu[1], Yimin Qin[1], Huifang Liang[1] and Hyon K Choi[2]. [1]Takeda Pharmaceuticals International, Inc, Deerfield, IL, [2]Boston University School of Medicine, Boston, MA.

Comorbidity Characteristics of Patients Starting First-Line Acute Gout Agents - Colchicine, NSAID, and Corticosteroids

Background/Purpose: There is a remarkable, increasing disease burden of gout and its associated comorbidities in the US. The 2012 ACR gout management guidelines endorsed the use of colchicine, NSAIDs, and corticosteroids as appropriate first-line options for the treatment of acute gout. Cardiovascular-metabolic-renal comorbidities of gout should dictate the choice among these agents, but relevant data are scarce. To address this issue, we examined and compared the prevalence of major cardiovascular-metabolic-renal comorbidities in gout patients who were newly prescribed these three agents.

Methods: We used US insurance claims data (2009–2012) to conduct a population-based study. Subjects aged ≥18 years who had at least 1 visit coded with the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes 274.xx for gout were identified. Patients diagnosed with cancer (ICD-9-CM codes: 140.xx-208.xx, 230.xx-234.xx) any time before or after the index date were excluded. Acute gout attacks were identified by an outpatient visit coded for gout, followed by a new dispensing of colchicine, NSAIDs, or oral or injectable corticosteroids. We assessed the comorbidity status during the 180 days prior to initiation of these acute gout care agents.

Results: There were 2,181 colchicine, 10,773 NSAID, and 2,364 corticosteroid initiators for acute gout attacks. The mean ages were 52, 49, and 51 years and 85, 85, 80% were men, respectively. Compared with NSAID initiators, colchicine initiators had more comorbidities, including hypertension, hyperlipidemia, coronary heart disease, stroke, congestive heart failure, type 2 diabetes, and chronic kidney disease at the time of initiation (**Table 1**). Compared with corticosteroid initiators, colchicine initiators had higher prevalences of hypertension, coronary heart disease, stroke, and type 2 diabetes, although the difference was less (**Table 1**).

Conclusion: This large US insurance claims-based study indicates that patients who initiated colchicine for acute gout had more cardiovascular-metabolic comorbidities than those who initiated NSAIDs or corticosteroids. While some of these findings confirm expected prescription patterns, given the known adverse effects of these agents, the overall comorbidity profile of colchicine initiators was noteworthy. These prescription patterns and pre-existing comorbidities should be appropriately taken into account for comparative effectiveness studies of these agents.

Table 1. Comorbid Medical Conditions during the 180 Days Prior to Initiation of the First Line Acute Gout Agents

Comorbid Medical Conditions	Colchicine (N=2181) n (%)	NSAIDs (N=10773) n (%)	Corticosteroids† (N=2364) n (%)

Inflammatory Arthritis Treatment Outcomes at a First Nations Reserve Rheumatology Specialty Clinic. Erin Bell[1], Sharon Leclercq[1], Dianne P. Mosher[1], Hani El-Gabalawy[2], Tyler White[3], Marvin Fritzler[1] and Cheryl Barnabe[1]. [1]University of Calgary, Calgary, AB, [2]University of Manitoba, Winnipeg, MB, [3]Siksika Health Services, Siksika, AB.

Background/Purpose: Inflammatory arthritis (IA: rheumatoid arthritis, systemic lupus erythematosus, and spondyloarthritis) disproportionately affects Canada's First Nations population. Treatment outcomes may be ameliorated by health service models that mitigate logistical barriers to care and provide specialty services embedded in the primary care context. This study assessed the effectiveness of a specialized care model, delivered in a First Nations primary care setting, in achieving IA activity targets.

Methods: Consenting participants were recruited to an arthritis screening program held in a First Nations community between June 2011 and August 2012. Those determined to have IA (n=47) received ongoing follow-up with collection of disease activity measures and patient-reported outcomes, as well as treatment recommendations, at each visit. Repeated measures ANOVA was used to describe changes in disease activity measures over a 24 month period. The frequency with which a treatment change was recommended, based on moderate or high disease activity state determined from the DAS28, was calculated.

Results: A total of 131 visits by 47 participants (79% female, mean age 47 years, diagnosis of rheumatoid arthritis n=34) occurred over the 24 month study period. At the baseline visit, 70.6% of participants had moderate or high disease activity (DAS28>3.2). Significant decreases in joint counts (/28) were achieved (mean swollen joint count decrease of 7.0, 95% CI 3.5–10.4, p=0.0061; mean tender joint decrease of 7.2, 95% CI 4.1–10.3, p=0.0116). Patient-reported outcomes for pain, global assessment and physical function were not significantly improved during treatment. A recommendation for treatment change was made at 67% of visits where patients were classified in moderate or high disease activity.

Conclusion: Although the program adequately addressed physician-derived disease activity targets, patient-reported outcomes were not significantly improved during follow-up. This suggests that the program should be modified to include a multi-disciplinary team that can address holistic aspects of First Nations health and reduce loss to follow-up from specialty care. A quality improvement initiative will be introduced to document reasons for deviation from the treat-to-target protocol.

Hospitalization Rates and Utilization Among Rheumatoid Arthritis Patients: A Population-Based Study from 1987 to 2012. C. John Michet III[1], Katrina Strobova[2], Sara J. Achenbach[3], Cynthia S. Crowson[3] and Eric L. Matteson[3]. [1]Mayo Clinic College of Medicine, Rochester, MN, [2]Charles University, Prague, Czech Republic, [3]Mayo Clinic, Rochester, MN.

Background/Purpose: Patients with rheumatoid arthritis (RA) experience chronic management issues and are at risk for complex comorbidities. It is unknown, however, to what extent the complications of the disease may lead to hospitalization. The goal of this study is to discern whether patients with RA are at greater risk for all-cause hospitalizations when compared to the general population.

Methods: This retrospective, population-based cohort study utilized patients who were 18 years or older and diagnosed with RA (as defined by the 1987 ACR criteria) between 1/1/1980 and 12/31/2007, and a reference cohort of patients without RA matched on age, sex, and calendar year. Each patient's medical record was examined for hospitalizations from 1987 through 2012. For this analysis, follow-up began with the latter of index date or 1/1/1987 and ended at the earlier of death, last follow-up or 12/31/2012. Discharge diagnoses were grouped together using the Clinical Classifications Software for ICD-9-CM from Healthcare Cost and Utilization Project. Data were analyzed using person-year methods and rate ratios comparing RA to non-RA.

Results: The 799 RA and 797 non-RA cohorts each consist of patients with a mean age of 56 years (68% female) and a mean follow-up of 12 years and 13 years respectively. The patients with RA had 2968 hospitalizations and the non-RA patients had 2069 hospitalizations. RA patients proved to be at greater risk for all causes of hospitalization (Table 1). Increased risk for all-cause hospitalizations for patients with RA also held true for both sexes and all age groups.

Two discharge diagnoses are of interest. First, hospitalization for depression is a greater risk for male patients with RA (23 hospitalizations) than for the general male population (3 hospitalizations) (Rate Ratio [RR] 7.16, 95% Confidence Interval [CI] 2.78, 30.67). Second, patients with RA are at greater risk of hospitalization for diabetes (31 hospitalizations) than patients without RA (13 hospitalizations) (RR 2.45, CI 1.34, 4.89). Female patients with RA are at a significantly increased risk of hospitalization for diabetes (16 hospitalizations) when compared to the general female population (6 hospitalizations) (RR 2.65, CI 1.14, 7.45). An increased risk of hospitalization for diabetes is especially true for all RA patients age 45–64 (22 hospitalizations) when compared to the general population (0 hospitalizations) (RR 44.76, CI 8.32, 45072.3).

Conclusion: In this first ever analysis of all-cause hospitalizations in a population-based cohort, patients with RA appear to be at greater risk for hospitalization than patients without RA. This risk is true for both sexes and all age groups. RA patients are also markedly more likely to be hospitalized for depression if they are male. Furthermore, hospitalization for diabetes is prevalent among patients with RA, especially among females and patients in the 45–64 age group.

		RA Rate*	Non-RA Rate*	Rate Ratio	Confidence Interval
Overall		30.4	20.2	1.51	1.42,1.59
Sex	Female	29.0	19.2	1.51	1.41,1.62
	Male	33.6	22.4	1.50	1.36,1.65
Ages	18-44	12.4	8.6	1.44	1.14,1.84
	45-64	22.4	10.8	2.07	1.86,2.32
	65-84	41.1	28.1	1.46	1.36,1.58
	85+	70.3	55.6	1.26	1.09,1.46

Association Between Depression and High Utilization of Emergency Department in Patients with Systemic Lupus Erythematosus from the Southeastern United States: The Goal Cohort. Alfredo Aguirre[1], S. Sam Lim[2], Gaobin Bao[1], Charles T. Molta[3], Hong Kan[4] and Cristina Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Division of Rheumatology, Atlanta, GA, [3]GlaxoSmithKline, King of Prussia, PA, [4]GSK, Durham, NC.

Background/Purpose: Frequent visitors of the emergency department (ED) among the general population share several demographic, health system and disease characteristics, including older age, poverty, government-financed insurance and poorer health. The burden of depression is also high among frequent ED visitors. Depression strikes up to 75% of SLE patients and is more severe among blacks compared to whites. Previous reports among predominantly white SLE samples suggest that there is an association between depression and ED usage. We sought to examine whether the severity of depressive symptoms increases the risk of being a frequent user of the ED in a predominantly black SLE cohort in the Southeastern US.

Methods: Georgians Organized Against Lupus (GOAL) is a longitudinal cohort largely drawn from a population-based registry of people with SLE, which has been established in Atlanta, GA. Annual surveys furnish self-administered data on demographics, disease outcomes and healthcare utilization. Over 75% of participants are black, and 35% live under the poverty

level. We used the 9-item Patient Health Questionnaire (PHQ-9) to assess severity of depressive symptoms. PHQ-9 can be assessed as a continuous (score range 0–27) or categorical (5 categories from minimal to severe depressive symptoms) variable. Individuals who visited the ED ≥ 3 times in the past year were considered frequent ED users. We conducted logistic regression analyses to test the effect of depression severity on being a frequent ED user, after controlling for potential confounders.

Results: Of 566 SLE participants, 96 (17%) visited the ED at least 3 times in the past year. Frequent usage of the ED was found in 10%, 17%, 26%, 24%, and 28% of patients with minimal, mild, moderate, moderately severe, and severe symptoms of depression, respectively. Severity of depressive symptoms, demographic factors, type of insurance, disease activity, and organ damage were associated with frequent ED utilization (Table 1). The PHQ-9 score remained positively associated with the outcome after controlling for major confounders. PHQ-9 and self-reported disease activity (SLAQ) scores were highly correlated (rho=0.65). The association between the PHQ-9 score and frequent ED usage was not longer significant when SLAQ was included in the model (OR=0.98; p=0.85).

Conclusion: Our data suggest that the severity of depressive symptoms may modulate healthcare-seeking behavior in SLE. However, other factors often disproportionately prevalent among socioeconomically disadvantaged subgroups with SLE, such as severe organ damage, greater disease activity and being on Medicaid showed stronger association with the outcome. Longitudinal studies are needed to tease out the complex pathways implicated in the usage of avoidable healthcare resources among minorities with SLE, particularly among those stricken by depressive symptoms.

Table 1. Association of Depressive Symptoms with Frequent Usage of the Emergency Department

Characteristics	Univariable LR		Multivariable LR (stepwise)	
	Odds Ratio	P Value	Odds Ratio	P Value
Depressive symptoms (5-unit increase in PHQ-9 score)	1.43 (1.21–1.70)	<0.0001	1.30 (1.07–1.59)	0.009
Age at diagnosis (5 year increase)	0.91 (0.83–1.00)	0.051	0.85 (0.75–0.95)	0.006
Gender (female)	0.79 (0.35–1.79)	0.58		
Race (non-white)	2.68 (1.31–5.52)	0.0073	2.22 (0.95–5.19)	0.07
Disease duration (1 year increase)	0.99 (0.96–1.01)	0.29	0.96 (0.93–0.99)	0.009
Educational attainment (3 year increase)	0.80 (0.63–1.00)	0.051		
Household income below poverty level	2.90 (1.81–4.63)	<0.0001		
Insurance type (ref: Private)	2.83 (1.17–6.84)	0.021		
No Insurance			1.83 (0.71–4.75)	0.80
Medicare	3.29 (1.65–6.55)	0.0007	2.30 (1.08–4.90)	0.50
Medicaid	6.27 (3.22–12.23)	<0.0001	3.63 (1.76–7.47)	0.003
Married or living with partner	0.59 (0.37–0.94)	0.028		
Disease activity (5-unit increase in SLAQ score)	1.65 (1.44–1.88)	<0.0001	Not included*	
Organ damage (SA-BILD score)	2.07 (0.95–4.51)	0.067	1.89 (0.82–4.34)	0.76
Mild damage (1–2) vs. no damage (0)				
Severe damage (≥3) vs. no damage (0)	4.91 (2.34–10.33)	<0.0001	4.26 (1.84–9.86)	0.0001

Abbreviations: LR: logistic regression; PHQ-9: 9-item Patient Health Questionnaire; SA-BILD: Self-administered Brief Index Lupus Damage; SLAQ: Systemic Lupus Activity Questionnaire. * Because SLAQ was highly correlated with PHQ-9 (Pearson correlation coefficient =0.65; p<0.0001), it was not included in the multivariate model.

2118

Lower Socioeconomic Status at Disease Onset Is Associated with Higher Health Care Costs in Patients with Systemic Lupus Erythematosus: A General Population-Based Cohort Study. Natalie McCormick[1], Mohsen Sadatsafavi[2], Wenjia Chen[2], Carlo A. Marra[3] and J. Antonio Avina-Zubieta[4]. [1]University of British Columbia/Arthritis Research Centre of Canada, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Univ of British Columbia, Vancouver, BC, [4]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Low socioeconomic status (SES) negatively impacts health outcomes in the general population, as well as in systemic lupus erythematosus (SLE), but the impact on healthcare costs is unknown. In addition, there are little data on the long term costs of SLE cases beginning from diagnosis. To address these knowledge gaps, we examined the relationship between SES at diagnosis, and direct medical costs for 10 years following, in a general population-based context.

Methods: Data Source: Our administrative data captured *all* provincially-funded outpatient encounters and hospitalizations (1990–2010), and *all* dispensed medications (1996–2010) regardless of funding source, in British Columbia, Canada. Sample: We assembled a population-based cohort of all incident cases of SLE who received care from 1996–2010, based on the following validated algorithm: **a)** two ICD-9-CM codes for SLE at least 2 months apart but within a 2 year period by a non-rheumatologist physician; or **b)** one ICD code by a rheumatologist or hospitalization. Statistics Canada neighborhood income quintile data for the year of SLE diagnosis was used to define SES. Cost Calculation: Costs for outpatient services and prescriptions were summed directly from billing data. Case-mix methodology was used for hospitalizations. Statistical Analysis: While most cases (87%) had less than 10 years follow-up, estimating long-term costs exclusively from cases with complete follow-up can introduce survival bias, and underestimate costs. Thus, costs were predicted using data from *all* cases. To account for censoring, follow-up was divided into 90-day periods, and costs per-period were weighted by the person-specific inverse probability of being alive in each period. A generalized linear model was used to predict the cumulative 10-year costs (adjusted for censoring) for cases in each SES group. Parametric bootstrapping was used to obtain 95% confidence intervals (CI). Costs are reported in 2010 Canadian dollars.

Results: We identified 4,209 incident SLE cases (86% female, mean age 49 years) contributing 18,028 person-years. The 10-year costs from all cases totaled $132,762,777 with 30% from outpatient, 41% from hospitalizations and 30% from medications.

After adjusting for sex, age and baseline Charlson's comorbidity index, predicted costs were significantly greater (21%, p=0.01) for the lowest SES cases compared to the highest, and averaged $12,489 more per-patient over 10 years.

Hospitalization costs over 10 years were 64% greater for the lowest-SES cases versus the highest ($13,097 vs. $8,001, p=0.05), with most hospitalizations (85%) occurring within 12 months of SLE diagnosis. Medication costs were 18% greater for the lowest SES than the highest, but unlike hospitalization costs, these costs continued over time.

Conclusion: Lower SES at SLE diagnosis is associated with higher healthcare costs, with medication costs driving this disparity over the long term.

Socioeconomic Quintile at Diagnosis	N Cases	N Female (%)	Mean Age at Diagnosis (SD)	Median Baseline Charlson Comorbidity Score (IQR)	N Months of Follow-Up	N 90-Day Costing Periods	N Ever-Hospitalized (%)	Unadjusted Overall Costs	Covariate-Adjusted Mean Per-Person Predicted Costs (95% CI)

Off Work Days Decreased RATE in Muskuloeskeletal Disease Patients: Usefulness of the EARLY Intervention Program. Francisco Miguel Ortiz Sanjuan, Isabel Martinez-Cordellat, Jose Ivorra, Jose Luis Valero, Inmaculada Chalmeta, Elena Grau, Carlos Feced, Rosa Negueroles, Luis Gonzalez-Puig, Cristobal Nuñez-Cornejo Piquer, Cristina Alcañiz, Eztizen Labrador and Jose Andres Roman Ivorra.Department of Rheumatology, Hospital Universitario y Politécnico La Fe., Valencia, Spain.

Background/Purpose: In March 2012, a new project was started at HUP La Fe following the pilot project carried out at San Carlos Clinical Hospital in Madrid, where patients who were off work for musculoskeletal causes were referred to us from Primary Care. The aim of the study is to analyze the variation in days off work in those individuals included in this program with respect to the normal average of days off.

Methods: Cohort, observational, cross-sectional study from April 2012 to December 2013, which included patients from the HUP La Fe area, referred for the first time to the Rheumatology Early Intervention consultation program because of temporary disability due to musculoskeletal problems. These patients are referred to a medical appointment with a maximum waiting time of one week and were provided medical treatment, ultrasound, joint injections and directed exercises if

needed. The patient is reviewed continuously until discharge. We excluded patients whose disabilities were due to trauma or surgery or if their situation could cause permanent disability.

Results: We included a total of 250 patients with a mean age of 48 years and 53% were women. The most frequently reported diseases were: back pain (33%), neck pain (16%), shoulder pain syndrome (13%) and other tendinopathies (10%). 100% of patients received medical treatment, 39% underwent articular ultrasound, 35% of them underwent injections and 82% were trained to perform physical therapy exercises at home. The pathology that had a higher average number of days from the first visit to the medical discharge was lumbar/sciatic pain (38 days), neck pain (30 days), and painful shoulder syndrome (34 days). Comparing our data with the control population in the San Carlos Hospital study, there was a decrease of the days off, being in the control group lumbociatalgia (57.6 days), neck (37.4 days) and neck pain (37.4 days).

Conclusion: Results obtained in our study show that early intervention by rheumatologists in patients with temporary disability of musculoskeletal origin decreases the number of days off work compared to patients who receive routine treatment and they can be incorporated in work early. Consequently, it saves all costs resulting from such temporary disability.

Societal Preferences for Rheumatoid Arthritis Treatments. Evidence from a Discrete Choice Experiment. Mark Harrison[1], Carlo Marra[2], Kam Shojania[2] and Nick Bansback[2]. [1]University of Manchester, Manchester, United Kingdom, [2]University of British Columbia, Vancouver, BC.

Background/Purpose: The cost-effectiveness of new interventions is increasingly assessed using the cost per quality-adjusted life year (QALY). QALYs are calculated by multiplying the length of time spent in a health state by the value of that health state, usually representative of the general public and estimated using a generic preference-based measure such as the EQ-5D. A limitation of generic preference based instruments is that they may fail to describe benefits of a treatment that patients experience and that society might value such as the method or convenience of treatment. The aim of this study was to determine the value society places on aspects of rheumatoid arthritis treatment, including mode of administration

Methods: A discrete choice experiment (DCE) was administered using a web survey in a representative sample of the Canadian general population using an online panel. Focus groups led to the development of a DCE with 7 attributes (route and frequency of administration, chance of benefit, chance of serious and minor side-effects, confidence in benefit and side-effect estimates (based on GRADE definitions), and life expectancy. An experimental design led to the development of 120 choice sets. Each respondent was randomized to complete 10 of these. A conditional logit regression model was used to estimate the significance and relative importance of attributes in influencing preferences. The life years attribute enables the DCE to estimate values on the health utility scale for use in QALY calculations.

Results: Responses from 733 respondents who provided rational responses to the choices in the experiment were included in the analysis. They were recruited from all provinces and territories in Canada, and their mean age (44), gender (55% female) and education (45% had up to a high school education) were representative of the general population. Six attribute levels within four attributes significantly influenced preferences for treatments. Respondents were willing to give up to a year of life expectancy over a 10 year period to increase the probability of benefitting from treatment, or two thirds of a year to reduce minor or serious side-effects to the lowest level or improve the confidence in benefit/side-effect estimates. There was some evidence of a preference for oral drug delivery and sub-group analysis suggested this preference was restricted to injection naive respondents.

Conclusion: As expected, our study found society values the benefits and side-effects of treatments. However, our study also found that people also value the degree of confidence in the estimates of risks and benefits of treatments, and to a lesser extent, the route of administration. Since economic evaluations typically focus only on the health outcomes of treatments, they may miss process aspects of treatment that are valued by society. This study provides important evidence to policy makers determining the cost-effectiveness of treatments in arthritis.

2121

Real-World Cost Comparison of Urate Lowering Therapies in Patients with Gout and Moderate to Severe Chronic Kidney Disease. Ghaith Mitri[1], Eric Wittbrodt[1], Robin Turpin[1], Beni Tidwell[2] and Kathy Schulman[2]. [1]Takeda Pharmaceuticals International, Deerfield, IL, [2]Outcomes Research Solutions, Inc., Waltham, MA.

Background/Purpose: Gout flare prevention relies heavily on urate-lowering therapies (ULT) such as allopurinol (ALP) and febuxostat (FBX) but clinical decision-making in patients with moderate to severe chronic kidney disease (CKD) is complicated by significant comorbidity. This study compared healthcare expenditure in ALP and FBX initiators after diagnosis with gout and CKD.

Methods: Gout patients (ICD-9-CM 274.xx), aged >18, with concurrent CKD (stage 3, 4), were selected from the MarketScan® databases (January 2009-June 2012) upon ALP or FBX initiation. Patients were followed until disenrollment, discontinuation of the qualifying ULT or use of the alternate study agent. Patients initiating on ALP were subsequently propensity score (PS) matched (1:1) to patients initiating on FBX. Mean monthly healthcare cost (2012 US$) was calculated in aggregate and for 4 disease specific conditions: gout, renal, diabetes (DM) and cardiovascular (CV). Five generalized linear models (GLM) were developed, each controlling for PS, to identify the incremental costs (vs ALP) associated with initiation on FBX after prior exposure to ALP and without prior exposure to ALP.

Results: PS matching yielded two cohorts, each with 1,486 patients (65% male, mean (SD) age 67.4 (12.8)). Post-match, 75% of patients had stage 3 CKD, 83% CV disease and 42% DM. The post-match sample was well-balanced on numerous comorbidities and medication exposures with the following exception. Fifty percent of FBX initiators had baseline exposure to ALP while only 3% of ALP initiators had baseline exposure to FBX. There were no differences ($p=0.27$) in follow-up gout flare frequency. There were no significant differences in mean monthly per patient expenditure, unadjusted, ($1,490 ALP, $1,525 FBX, $p=0.8$). CV, renal, DM and gout specific costs represented, respectively, 31%, 14.3%, 13% and 10.9% of total cost.

GLM model results suggest that FBX users with recent ALP exposure incurred significantly ($p<0.01$) more cost than ALP users while FBX users without recent exposure to ALP incurred significantly ($p<0.01$) less cost than ALP users. Multivariate models also found that both FBX cohorts, with and without recent exposure to ALP, had significantly ($p<0.0001$) higher gout-specific cost, due almost entirely to higher FBX acquisition cost. However, increased gout-specific expenditure in the FBX cohort without recent ALP exposure was offset by significantly lower CV ($p<0.0001$) and renal- ($p<0.0001$) related cost. There were no significant differences, adjusted, in either renal or CV costs between the ALP cohort and FBX patients with baseline exposure to ALP. Similarly, there was no significant difference in DM-related expenses between any of the cohorts.

Conclusion: The use of FBX in first- and second-line settings may confound outcome evaluation since FBX use after ALP failure may suggest more aggressive disease. Gout patients with concurrent CKD, initiating on FBX in a first-line setting incurred significantly less total cost than patients initiating on ALP. Higher acquisition cost for treatment with FBX should not be a barrier to appropriate treatment, especially in patients with co-morbid CV and renal conditions.

2122

Variation in the Prescribing Practices of Biologic Dmards. Heather O. Tory[1], Josephine A. Awosogba[2], Amish J. Dave[2], Jonathan S. Coblyn[2], Daniel H. Solomon[2] and Sonali P. Desai[2]. [1]Boston Children's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Biologic DMARDs (bDMARDs) are effective yet expensive treatments for RA. Variability in the prescribing practices of rheumatologists using these agents may be attributable to patient-specific clinical factors. We performed a quality improvement project to better

understand this variability, comparing practice to an adapted standardized treatment pathway.

Methods: A standardized treatment pathway was developed based on the 2012 ACR guidelines for treatment of patients with early moderate to severe RA (Singh JA et al., 2012) and was endorsed by the rheumatologists in our practice (**Figure 1**). This pathway differed from the ACR guidelines primarily by liberalizing the duration required for each treatment step.

We reviewed charts of 224 patients with ≥ 3 ICD 9 codes for RA (714.0) seen at our single center academic practice who initiated a new bDMARD (first time use or a change from prior bDMARD) from January through December 2013. Data were abstracted using a standardized form, including demographics, RA characteristics, complete available medication history and reasons for medication choices. Each patient was included only once. We categorized patients as having treatment courses that did or did not follow the treatment pathway. Inter-rater reliability (kappa), assessed by re-review of charts of patients with treatment courses that varied from the pathway, was 0.82, $p < 0.001$. When reviewers disagreed, final adjudication occurred through a consensus process.

Results: 224 patients initiated a new bDMARD during the study period. Mean age was 53 (range 20–84) and 183 (82%) were female. 197 (88%) had disease duration of over 2 years. Erosive disease was seen in 99 (44%) and 116 (52%) were seropositive. Only 13 patients (6%) had treatment courses that did not follow the treatment pathway (**Table 1**). The reasons for these variations included co-morbidities (n = 8), disease severity (n = 1) and initial care at other institutions (n = 4). None of the included patients had failed oral triple therapy prior to initiation of a biologic.

Conclusion: We examined practice patterns for the prescription of bDMARDs at our institution and found little variability based on an adapted standardized treatment pathway. Variations from the pathway were justified by patient co-morbidities and disease characteristics, suggesting that existing variability may be appropriate.

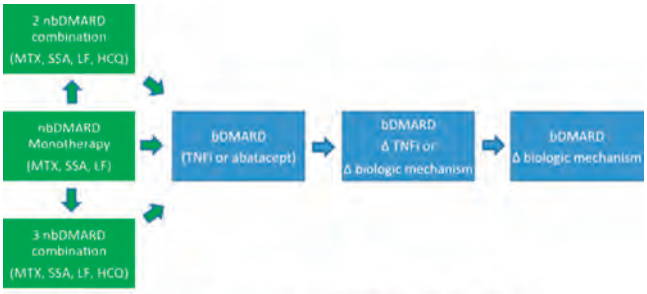

Figure 1: Adapted standardized treatment pathway for patients with RA.
nbDMARD: Non-biologic DMARD; MTX: Methotrexate; SSA: Sulfasalazine; LF: Leflunomide; HCQ: Hydroxychloroquine; bDMARD: Biologic DMARD; TNFi: Tumor necrosis factor inhibitor

Table 1: Reasons for patient treatment not following suggested pathway (N=13 out of 224)

2123

Significant State-Level Variation in Source of Biologic Drug Coverage Among Beneficiaries with Rheumatoid Arthritis. Chris Tonner, Gabriela Schmajuk and Jinoos Yazdany.University of California, San Francisco, San Francisco, CA.

Background/Purpose: Biologic drugs can be obtained both through Medicare's Part B medical benefit (physician administered drugs) or Part D pharmacy benefit (self-administered drugs). Coverage for biologics is additionally complicated by the low-income subsidy (LIS), whereby Medicare beneficiaries with low socioeconomic status face minimal costs for Part D biologics (while non-LIS beneficiaries pay less out of pocket for Part B drugs). Despite the complexity of biologic benefit design, variation in biologic use and coverage in the Medicare program has not been adequately studied. We performed a nationwide study of Medicare beneficiaries with rheumatoid arthritis (RA) to investigate geographic variations in payment source for biologic drugs. We hypothesized that there would be consistent use of Part D biologics among LIS patients.

Methods: We used data from nationwide Medicare fee-for-service claims files for 2009 for a 5% random sample of beneficiaries, including all medical and pharmacy claims. Included beneficiaries had RA (2 face-to-face visits coded as 714.xx within the calendar year), were continuously enrolled in a pharmacy plan, and had at least one prescription for a disease-modifying drug. Source of biologic coverage (Part B or Part D) was tabulated for all biologic users according to LIS status and stratified by state. We calculated the proportion of LIS vs. non-LIS beneficiaries receiving Part B biologics in each state and examined the correlation between these variables within states. Individuals residing in states with fewer than 50 eligible beneficiaries were censored from this analysis to increase the precision of our estimates.

Results: 7190 beneficiaries received a DMARD for RA; 1901 (26%) received biologic drugs. 25% of biologic users received a low-income subsidy (LIS). Among LIS recipients, 8% received their biologic through Part B and 20% through Part D. Conversely, among non-LIS patients, 18% received their biologic through Part B and 8% through Part D. Across states, Part B biologic use ranged from 5–26% for non-LIS patients (median 9, IQR 14–22) and 0–5% (median 2, IQR 1–3) for LIS patients (Figure). Proportions of non-LIS and LIS patients using Part B biologics within a state were modestly correlated (r^2=0.15).

Conclusion: We found substantial variations between states in the proportion of patients with RA receiving biologics, and whether patients received biologics through Medicare Part B or Part D. Variations were even observed for those receiving LIS, suggesting that factors other than cost-sharing influence biologic drug selection. Further studies should examine how both insurance coverage policies and physician practice variation impact the choices available to patients.

Characteristics of Medicare Beneficiaries Travelling Long Distances to Visit a Rheumatologist. Gabriela Schmajuk[1], Chris Tonner[2] and Jinoos Yazdany[2]. [1]UCSF/San Francisco VA, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Studies of the distribution of rheumatologists across the United States suggest that a significant number of patients travel long distances to visit a rheumatologist. The geographic, health care market, and patient factors associated with travel distances have not been described. We examined individual and area-level predictors of travelling long distances to see a rheumatologist.

Methods: Data derive from nationwide Medicare fee-for-service medical claims for 2009 for a 5% random sample of beneficiaries. All patients ≥ age 18 with 12 months of continuous enrollment in Medicare Parts A and B who had at least 1 visit to a rheumatologist were included. We calculated distance

between the center of the patient's 5-digit ZIP code and the center of the rheumatologist's office 5-digit ZIP code for the first rheumatologist seen during the calendar year. We compared the characteristics of patients travelling ≥ 50 miles to see a rheumatologist to all others based on sociodemographic (age, sex, race, dual Medicare/Medicaid eligibility, and state buy-in, a measure of personal income) and area-level variables (ZIP-code level socioeconomic status, state-level supply of rheumatologists per 100,000 residents, state-level price-adjusted total Medicare spending per person). Two percent of observations were censored due to missing data. Included variables were tested for noncolinearity. We used general estimating equations to adjust for individual and area level characteristics in a single multivariate model.

Results: We studied 42,571 Medicare patients who had at least one visit to a rheumatologist during 2009. Median distance traveled was 9.3 miles (IQR 4–22); 9% of patients travelled ≥50 miles to see a rheumatologist. Patients who travelled ≥50 miles were more likely to be younger (age 70.7 vs. 73.3) male (25% vs 20%), White (92% vs. 88%), and live in a low-SES ZIP code (40% vs. 21%). They were also more likely to reside in regions with the lowest supply of rheumatologists (34% vs. 23%). In the adjusted model, the effects of age, sex, race, area-level SES, and rheumatologist supply remained significant although area-level SES had the strongest effect (Table).

Conclusion: Patients travelling very long distances to visit a rheumatologist are more likely to be male, White, and live in lower-SES areas compared to patients travelling less far. Sociodemographic effects are at least as strong as the effect of low rheumatologist supply. These findings suggest that interventions beyond increasing the number of rheumatologists in low supply areas will be necessary to reduce travel distances and improve access to rheumatology care in the U.S.

Table Individual and Area-level Predictors of Traveling ≥ 50 Miles to See a Rheumatologist.

Variable	Adjusted odds ratio (95% Confidence Interval)*

Burden of Illness in Refractory Gouty Arthritis: A One-Year Prospective Multinational, Observational Study. Louis Bessette[1], Frédéric Lioté[2], Carmen Moragues[3], Rüdiger Moericke[4], Zhang Zhiyi[5], Alberto Ferreira[6], Pascal Lecomte[6], Sophia Kessabi[6], Haijun Tian[7] and Jasvinder Singh[8]. [1]CHUL, Quebec, QC, [2]Hôpital Lariboisière & University Paris Diderot, Paris, France, [3]Hospital Platón, Barcelona, Italy, [4]Institut für Präventive Medizin & Klinische Forschung GbR, Magdeburg, Germany, [5]The First Affiliated Hospital of Haerbin Medical University, Haerbin, China, [6]Novartis Pharma AG, Basel, Switzerland, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [8]Mayo Clinic, Rochester, MN.

Background/Purpose: Refractory gouty arthritis (RGA) is a condition characterized by appearance of recurrent flares and contraindication, intolerance, or lack of efficacy to first-line anti-inflammatory therapy (NSAIDs/colchicine/steroids) and conventional uric acid lowering therapies (ULT). The objective of the study was to assess the humanistic and economic burden of RGA over 1 year during presence or absence of a flare.

Methods: This 12-month, multinational (6 countries), prospective, observational study investigated the disease impact in patients suffering from RGA who had experienced 3 or more flares in past 12 months. Patients who were enrolled were also refractory to first-line anti-inflammatory therapy (NSAIDs, colchicine, or steroids) or to ULTs. Patients were divided in two groups as per the presence or absence of gout flares. Summary statistics pooled for all visits are presented as mean and SD for continuous variables, and proportions for categorical variables. The utility score derived from the combinations of responses to the five questions of the EuroQol Health Status Questionnaire 5D (EQ-5D) was used as the primary outcome measure. Secondary outcomes included Gout Assessment Questionnaire–Gout Impact Scale (GAQ-GIS) and Healthcare resource utilization (ER visit, hospitalization, physician visit and home care).

Results: A total of 454 eligible patients were enrolled in the study (mean age: 56, males: 86.1%). Patients who were having a flare experienced greater difficulty on all 5 dimensions of the EQ-5D descriptive system and mean EQ-5D utility scores pooled across all the visits were worse for patients having a flare [0.614; 95%CI 0.600, 0.628] as compared to patients without a flare [0.867; 95%CI 0.861, 0.872]. The results for mean EQ-5D VAS scores were lower in patients having a flare [60.7; 95%CI 59.3, 62.1] than patients without a flare [79.5; 95%CI 78.9, 80.1]. The mean GAQ-GIS scores for patients with a gout flare vs. those without a gout flare were higher for various parameters such as overall gout concern [81.27 vs 70.06], medication side effects [59.12 vs 51.26], unmet treatment needs [48.26 vs 37.19], wellbeing during attack [57.32 vs 45.23], and gout concern during attack [63.58 vs 54.09]. Furthermore, higher healthcare utilization was observed in patients experiencing a flare (table 1).

Conclusion: RGA imposes a considerable humanistic and economic and burden. Gout flares were associated with increased healthcare resource utilization and diminished quality of life. These findings suggest unmet medical needs in refractory gout patient population.

Table 1. Healthcare resource utilization survey over 12 months' observation period (All locations)

	Patients having a gout flare N = 334	Patients not having a gout flare N = 119
Percent of patients visited emergency unit for gout in the last year	21.3%	6.7%
Percent of patients admitted to the hospital for gout in the last year	15.0%	5.9%
Percent of patients who visited their doctor or another physician for gout in the last year	62.0%	49.6%
Percent of patients who needed help at home due to gout in the last year	43.7%	21.8%

The Utility of Digital Activity Fluorescence Optical Imaging in Quantifying Hand and Wrist Inflammation in Rheumatic Diseases. Yogan Kisten[1], Noémi Györi[1], Hamed Rezaei[2], Adrian Levitsky[1], Anna Karlsson[1], Erik af Klint[2] and Ronald van Vollenhoven[2]. [1]The Karolinska Institute,Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Stockholm, Sweden, [2]The rheumatology clinic of the Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: The objective detection and quantification of disease activity in its earliest pathophysiological stage is critical for achieving optimal therapy results. Fluorescence optical imaging (FOI) is a novel imaging modality for the hands & wrists, and automated quantification of the ensuing images using DACT (Disease ACTivity)-FOI as a novel algorithm representing activity. This study was designed to determine the utility of FOI as a diagnostic tool, and whether it could be used in lieu of color/power Doppler ultrasound (US) to quantify and ascertain apparent & non-apparent active synovitis.

Methods: A total of 872 hand/wrist joints in 26 patients (18 female, 8 male, average age 51.5 years) with various rheumatic diseases (RA: 12, JIA, SLE, DM, FM, PsA & polyarthritis 1–2 each) were examined by standard clinical assessment, US and DACT-FOI. Joints swollen & tender or swollen only were considered clinically inflamed. Active synovitis was defined as having synovial thickening & Doppler activity on US. Joints positive by FOI displayed abnormal focal optical intensities by visual inspection. Silent synovitis was defined as showing synovitis by US but not clinically. The DACT value was digitally quantified per patient by an automated computer-based algorithm of the composite image (240 frames). After clinical, US and FOI positive joints for each hand were calculated, the sensitivity, specificity & kappa statistics computed & compared with the mean DACT values for all patients.

Results: Out of 872 joints, 242 (16%) were inflamed clinically, 241 (28%) by US, and 229 (26%) by FOI. There was moderate agreement for synovitis detection between clinical examination & US (kappa 0.524 ± 0.033; 95% CI: 0.459 – 0.589) and between clinical examination & FOI (kappa 0.450 ± 0.035; 95% CI: 0.381 – 0.519). Of the 241 inflamed joints by US, 196 (81%) were also inflamed by FOI, while only 119 (49%) were inflamed clinically. Agreement between US and FOI in synovitis detection was good (kappa 0.773 ± 0.024; 95% CI: 0.725 – 0.821). Depending on the gold standard used to define inflammation, FOI was 73–83% sensitive and 86–95% specific for detecting synovitis.

Out of 730 non-inflamed joints by clinical examination, 608 (83%) were non-inflamed by US and 605 (83%) were non-inflamed by FOI. Of these clinically non-inflamed joints, 122 (17%) were inflamed by US. For detecting silent synovitis, FOI was 80% (98/122) sensitive and 96% (581/608) specific.

The number (mean ±SD) of active joints detected by clinical, US and FOI was 5.4 ±7.6; 9.4 ±9.8; and 9.3 ±9.7 respectively, and the overall automated disease activity DACT-FOI was 4.3 ±2.1. There was a strong positive correlation (r = 0.556; p=0.003) between the clinical detection of synovitis & DACT-FOI. The mean DACT values also correlated significantly with US (r = 0.479; p=0.013) and semi-quantitative FOI (r = 0.515; p=0.007).

Conclusion: FOI and the automated analysis DACT-FOI were technically feasible with high reproducibility and agreement with clinical scoring & US. For detecting synovitis semi-quantitatively, FOI had a lower sensitivity but similar specificity compared to US. FOI may be particularly useful in identifying patients with clinically non-apparent hand/wrist inflammation (silent synovitis).

Subclinical Arthritis Is Detected By Macrophage Targeting and Positron Emission Tomography (PET) in Early RA Patients in Clinical Remission. Y.Y.J. Gent[1], M.M. ter Wee[1], D den Uyl[1], N. Ahmadi[1], W.F. Lems[2], O.S. Hoekstra[2], A.E. Voskuyl[1] and C.J. Van der Laken[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]VU Medical Center, Amsterdam, Netherlands.

Background/Purpose: Recurrent flares in RA patients in complete remission (CR) are not an uncommon phenomenon. Studies with advanced imaging techniques have suggested that residual subclinical synovitis can still be present despite clinical remission and has been linked to ongoing radiological damage. Our group has shown that positron emission tomography with macrophage targeting (^{11}C-*(R)*-PK11195 PET) is a highly sensitive and specific technique to visualize (subclinical) arthritis activity. In the current study we investigated if ^{11}C-*(R)*-PK11195 PET can depict residual disease activity in early RA patients who reached CR and whether the inflammatory activity on the scans was associated with the development of a flare (as compared to MRI).

Methods: ^{11}C-*(R)*-PK11195 PET (HRRT, CTI/Siemens) of hands/wrists was performed in 25 RA patients that had no tender or swollen joints after treatment with combined DMARD therapy (DAS44<1.6). *(R)*-^{11}C-PK11195 uptake (visual score: 0 (low)-3 (high)) in metacarpophalangeal, proximal interphalangeal and wrist joints (n=22 joints/patient) was scored and corrected for background uptake. Individual joint scores were summed to obtain a cumulative PET score (range 0–66). Follow-up duration was 1 year after PET. Flare of clinical disease activity was defined as ≥ 1 swollen joint.

Results: Of the included patients, 14 out of 25 (56%) developed a clinical flare of arthritis anywhere within 1 year of follow-up. *(R)*-^{11}C-PK11195 PET showed enhanced tracer uptake in at least one scanned joint in 11/25 (44%) patients. Cumulative PET scores of patients developing a flare tended to be higher than that of patients without a flare (median (IQR) 1 (0–4) vs 0 (0–1), p=ns) (Fig left). Within the flare subgroup, patients with a flare in hands/wrists (n=6), had significantly higher cumulative PET scores than patients without a flare (n=11)(p=0.04). Patients with a cumulative PET score of 4 and higher, all developed arthritis in hands/wrists within 6 months. As comparison, MRI scans of all included patients were positive regardless of flaring, not distinguishing between subgroups of flare and no flare (Fig right).

Conclusion: Macrophage targeting by *(R)*-^{11}C-PK11195 PET can visualize subclinical synovitis in hand/wrist joints of drug-induced remission in early RA. Uptake of *(R)*-^{11}C-PK11195 was higher in patients with with a flare compared to those without a flare. High cumulative PET scores seem to be associated with short-term development of flare. In comparison to MRI, PET may have superior diagnostic value with respect to specificity. Larger cohort studies are needed to confirm these data.

Effectiveness of ^{18}f-Fluoro-Dexoxyglucose Positron Emission Tomography for the Diagnosis of Polymyalgia-like Illness. Hideyuki Horikoshi, Takashi Nakanishi, Reiko Takahashi, Fumihiko Kimura and Kenji Itoh.National Defense Medical College, Tokorozawa, Japan.

Background/Purpose: Polymyalgia rheumatica (PMR) is an inflammatory condition that affects the elderly. It is characterized by pain and stiffness in the shoulder and pelvic girdles. Various inflammatory conditions such as infection, vasculitis, and neoplasms can mimic PMR. Owing to the low specificity of the diagnostic criteria of PMR, it is often difficult to distinguish PMR from the so-called 'polymyalgia-like illness.' In previous reports of PMR imaging studies, rheumatic diseases such as rheumatoid arthritis were used as controls. Therefore, the differentiation of PMR from polymyalgia-like illness including paraneoplastic syndrome has not been discussed yet. Herein we performed ^{18}f-Fluoro-Dexoxyglucose Positron Emission Tomography (FDG-PET/CT) in polymyalgia-like illness, and report on the findings.

Methods: Twenty-five cases of polymyalgia-like illness (PMR, 17 cases; paraneoplastic syndrome, 3; infection, 2; vasculitis, 1; others, 2) were analyzed using FDG-PET/CT.

Results: All patients met the diagnostic criteria of Bird et al. and the 2012 ACR/EULAR criteria. The average scores of PMR and non-PMR cases using

these criteria were 4.35 and 4.13, respectively, and no differences were observed between these two groups in clinical presentations. FDG-PET/CT revealed that all PMR cases showed a high FDG uptake in PMR-specific accumulation sites, including the shoulder joints, sternoclavicular joints, hip joints, spinous processes, ischial tuberosities, and greater trochanters. However, non-PMR cases showed various patterns of accumulation. Furthermore, no non-PMR case showed a high FDG uptake in the PMR-specific accumulation sites.

Conclusion: These results indicate the usefulness of FDG-PET/CT for the differential diagnosis of polymyalgia-like illness including paraneoplastic syndrome. Together with the current diagnostic criteria, accumulation of FDG in PMR-specific sites is useful to more accurately diagnose PMR. Various patterns of FDG uptake on FDG-PET/CT in patients with polymyalgia-like illness reveal the diversity of pathogenesis in similar clinical presentations.

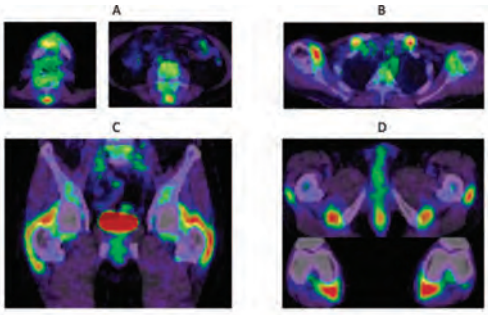

Figure 1. Typical FDG-PET/CT findings in a patient with PMR. PMR case showed a high FDG uptake in PMR-specific accumulation sites, including cervical and lumbar spinous processes (A), shoulder joints and sternoclavicular joints (B), hip joints and greater trochanters (C) ischial tuberosities, and knee joints (D).

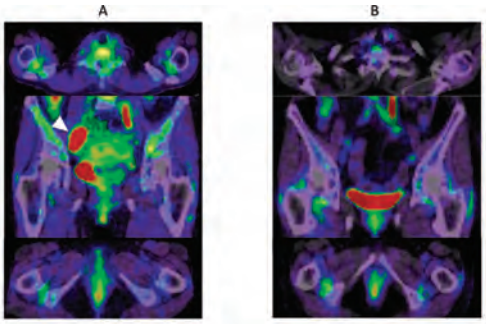

Figure 2. FDG-PET/CT findings in non-PMR cases.
A, A 50-year-old woman with Polymyalgia-like Illness (ovarian cancer). Strong FDG uptake was seen in the ovary (arrowhead). Weak FDG uptake was seen in the shoulder joints, however, an accumulation was not observed in other joints.
B, A 59-year-old woman with Polymyalgia-like Illness (coxsackie virus). FDG uptake was not observed in PMR-specific accumulation sites.

Sensitivity and Specificity of the "Green Nail" Sign in Fluorescence Optical Imaging in Psoriatic Arthritis. Oliver Wiemann[1], Stephanie G. Werner[1], Hannah Röver[1], Gudrun Lind-Albrecht[1], Sabine Mettler[1], Marina Backhaus[2] and Hans-Eckhard Langer[1]. [1]RHIO (Rheumatology, Immunology, Osteology), Duesseldorf, Germany, [2]Charite University Hospital, Berlin, Germany.

Background/Purpose: ICG-enhanced fluorescence optical imaging (FOI) is a novel technology for the assessment of inflammation in arthritis [1,2]. Recent work suggested that a "green nail" sign in a FOI sequence could possibly be diagnostic for psoriatic arthritis (PsA) [3]. The objective of this study was to determine the sensitivity and specificity of this finding.

Methods: 215 consecutive FOI sequences (n=54 PsA, n=29 RF+ RA, n=67 RF- RA, n=19 uA, n=16 SpA, n=30 other) were read for PVM, P1, P2 and P3 [1] separately. "Green nail" was defined as a caldera-like configuration with a larger rounded green area in the center of the nail and a smaller surrounding of circular or semicircular red or white FOI signals (fig).

Results: The green nail sign was observed in 18/54 subjects with PsA (33%), 2/29 RF+ RA (7%), 10/67 RF- RA (15%), 4/19 uA (21%) and 5/46 other diagnoses (11%) (sensitivity of 0.33, specificity of 0.87). In 9 subjects with green nails and diagnoses different from PsA clinical findings (e.g. nail changes, enthesitis, dactylitis) were suspicious to PsA. After exclusion of those cases specificity increased to 0.93. In PsA green nails were observed predominantly in FOI phase 1 or in early phase 2. The finding was observed more frequently in advanced (> 24 months, 13/36, 36%) than in early arthritis (5/18, 28%). The green nail sign has to be distinguished from a green dot phenomenon that was observed in some cases with RA (small green dot at the borderline between nail and nail fold) and from signs of impaired perfusion in connective tissue diseases and vasculitis that are typically located in the distal, acral regions of the fingers.

Conclusion: While the prevalence of the green nail sign in FOI sequences is relatively low the high specificity for psoriatic arthritis suggests that this finding could provide important additional information for differential diagnosis.

Bone Microstructure in Patients with Cutaneous Psoriasis and No History of Psoriatic Arthritis Shows Bone Anabolic Changes at a Greater Extent Than in Healthy Controls. David Simon[1], Francesca Faustini[1], Matthias Englbrecht[1], Arnd Kleyer[1], Roland Kocijan[2], Judith Haschka[1], Stephanie Finzel[1], Sebastian Kraus[1], Axel J. Hueber[1], Michael Sticherling[1], Georg Schett[1] and Jürgen Rech[1]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]St. Vincent Hospital, Vienna, Austria.

Background/Purpose: Psoriasis (PSO) is a frequent disease which affects about 1–2% of the population and can be associated to arthritis (PsA). Skin disease often predates the onset of PsA and the transition from skin to joint pathology has been not yet fully elucidated. PsA bone changes include erosions and new bone formation. Aim of the present study was to investigate whether patients with PSO, without clinical history of synovitis, dactylitis or enthesitis at any time and no fulfillment of CASPAR criteria show early changes of the periarticular bone that are typical of PsA.

Methods: PSO patients and healthy subjects (HS) underwent HR-pQCT (XtremeCT, Scanco Medical, Switzerland) scans of the dominant hand which focused on the metacarpal head and phalangeal base of the MCP joints 2 and 3. Erosions, defined as cortical breaks within the joint and visible in two planes, were assessed by frequency and volume (mm^3). Bony spurs, defined as bony projections emerging from the cortical shell and located in the periarticular region were assessed by frequency and maximal height (mm) i.e.

the distance between the highest surface of the lesion and the original cortical surface). Patients participated after signing informed consent. The study was conducted upon approval by the local ethic committee and the National Radiation Safety Agency (BfS).

Results: Images were acquired from 55 PSO patients (mean age 49.5±11.5 y, 36.4% females) and 47 HS (mean age 45.8±13.0 y, 48.9% females). Mean age and sex distribution were comparable. PSO patients had mean disease duration of 15.2±15.4 y, a mean PASI score of 6.2±8.0, while the most prevalent subtype was psoriasis vulgaris (73%). Nail psoriasis was present in 51 % and scalp involvement in 29%. Erosions were identified in PSO and HS (27 vs 18). The most frequent location of the erosions was the radial aspect of the metacarpal head 2 in both groups. The volume of the erosion was not significantly different between the groups. An average number of 6 bony spurs was found in the PSO patients while this accounted for 3 in the HS (total number 306 vs 138). A similar trend of distribution of bony spurs was found in both groups with the majority of them locating in the metacarpal head 2 (palmar and dorsal aspect). PSO patients showed larger bony spurs compared to the HS in each region of interest. For the metacarpal head 2 the mean size accounted for 1.7±0.8 vs. 1.2±0.5 mm respectively, *p=0.001;* metacarpal head 3: 1.2±0.6 and 0.8±0.3 mm, *p=0.001*. In the phalangeal base 2 the PSO patients showed a mean size of 1.3±0.7 mm, and the HS of 0.7±0.3 mm, *p<0.001*. In the phalangeal base 3 mean values accounted for 1.2±0.7 mm and 0.8±0.2 respectively, *p=0.003*.

Conclusion: Analysis of the bone microstructure indicates that patients with PSO without PsA show more pronounced anabolic changes than healthy subjects. Periarticular new bone formation could be an early expression of altered bone remodeling previous to the onset of PsA.

The Impact of Patient-Reported Flares on Radiographic Progression in Rheumatoid Arthritis Patients with Low-Disease Activity: Secondary Analyses from a Randomized Trial. Dorota Kuettel[1], Jette Primdahl[2], Lykke Midtbøll Ørnbjerg[3], Hans Christian Horn[4], Robin Christensen[5] and Kim Hørslev-Petersen[6]. [1]King Christian X's Hospital for Rheumatic Diseases, Graasten, Denmark, [2]Danbio Registry, Glostrup, Denmark, [3]Copenhagen Center for Arthritis Reasearch, Center for Rheumatology and Spine diseases, Glostrup Hospital, Copenhagen, Denmark, [4]Odense University Hospital, Odense, Denmark, [5]MSU, The Parker Institute, Copenhagen University Hospital, Frederiksberg, Denmark, [6]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark.

Background/Purpose: Flares, potentially disabling and disease worsening even when a patient is in low disease activity, are common features in patients with rheumatoid arthritis (RA) that may escape the routine clinical control. Consequently the current treat-to-target goal to achieve remission or low disease activity fails to take into account the potential of flares to represent the persistence of disease activity and it remains unknown whether these flares can worsen radiographic joint damage. The aim of this study was to see whether transient flares increase the risk for radiographic progression.

Methods: From 287 patients included in the AMBRA trial, 276 RA patients with low disease activity (DAS28-CRP < 3.2, and no swollen joints at baseline) with radiographs available at baseline and data about flares, were followed for two years. An annual clinical evaluation was performed by a senior rheumatologist and at the same occasion the patients were asked to recall the occurrence of flares during the past year, according to: No flares, transient flares or persistent joint complaints with tender and swollen joints. X-rays of hands and feet were performed at baseline and after two years and scored according to the Sharp/van der Heijde method. The change in Total Sharp Score (TSS) and its components (Joint Space Narrowing (JSN) and Erosions (E)) were calculated. The proportion of patients who progressed (ΔTSS/ ΔJSN/ ΔE > 0 units) across the three groups were compared using Chi-square test and interpreted based on Relative Risks (RR).

Results: 70% of patients were women, median age [IQR] was 63 years [55;70], 73% were rheumatoid factor positive, 71% anti-CCP positive and all had established RA (median [IQR] 7 years [4;13]). In total 268 out of the 276 patients had two year radiographic scores: Radiographic progression depicted by either ΔTSS, Δ JSN, or ΔE, respectively, was seen in 33%, 7%, and 28% of no-flares group (n=82); 36%, 17%, and 31% of patients with transient flares (n=144) and in 46%, 24%, and 34% of patients with persistent joint complaints (n=50). Only differences in worsening of JSN (Figure 1) were statistically significant (P=0.026): RR was 2.37 for the transient flares group and 3.28 for the group with persistent joint complaints compared to the no flares group. Worsening of TSS and E showed some tendencies according to the flare phenotype, but they were not statistically significant.

Conclusion: RA patients with established low active disease, who report transient flares or persistent joint complaints with tender and swollen joints, have more radiographic damage on JSN (which has recently been reported as the main driver of physical disability) in comparison to no-flares patients.

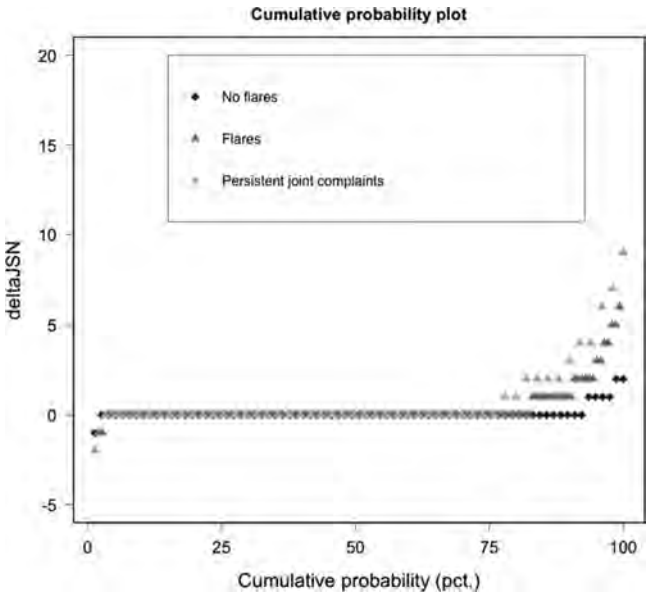

Figure 1: Cumulative probability plot of the three flare phenotypes (no flares; flares; persistent joint complaints) for delta JSN

What Is Associated with X- Ray Progression at 5 Years in Rheumatoid Arthritis (RA) Patients in Low Disease Activity? Violaine Foltz[1], Lisa Biale[2], Frederique Gandjbakhch[1], Laure Gossec[1], Pierre Bourgeois[1], Benjamin Granger[1] and Bruno Fautrel[1]. [1]UPMC Paris 06 University, GRC 08, Paris France and Pitié Salpétrière Hospital Paris France, Paris, France, [2]Instruction des Armées Begin hospital, Saint-mande, France.

Background/Purpose: Persistent inflammation on Power Doppler (PD) by ultrasound (US) was associated with relapse and structural progression after one year of follow up in a cohort of RA patients in low disease activity (LDA).

Methods: Patients with RA (1987 ACR criteria) were included in 2007–2008 in one centre if their diagnosis of RA was recent (≤ 2.4). All patients underwent clinical and biological assessments every year. Hands and forefeet X-ray were performed at baseline and at 5 years and evaluated blindly by two investigators (van der Heijde Sharp score: mTSS). Progression was defined as a variation of the mTSS superior to the smallest detectable difference (SDD) of 6.6 points. The metacarpophalangeal (MCPs) joints 2–5 and wrist of the dominant hand were examined with a 0.2T dedicated MRI (ESAOTE C-scan); and bilateral wrists, MCPs 2, 3, 5 and metatarsophalangeal 2, 3, 5 were studied with high resolution US (ESAOTE Technos) at baseline and evaluated blindly using validated acquisition and OMERACT scoring systems (Skuldarek for US and RAMRIS for MRI). The association between the structural progression at 5 years and MRI/US covariates was measured by Wilcoxon Mann-Whitney tests or Fisher's exact test, then by a multivariate logistic regression (forward and backward procedure) to explain a progression $>$ SDD.

Results: 85 patients were included: mean age 50.7 (±13.5) yrs; mean disease duration 35 (±20.7) months, 63.5% patients were anti-CCP positive and mean DAS44 was 1.5 (± 0.54). At baseline the median score [interquartiles] of the grade of synovitis for US and MRI was respectively 3 [1;5] and

3 [4;7]. The median of the number and the grade of synovitis PD positive were 0 [0;1]. The median of the number and the grade of bone marrow edema (BME) were 0 [0;0]. 17 patients (20%) and 8 patients (9%) had respectively score of PD or BME above the median. At 5 years, 13 patients of 70 followed up, were considered in progression. In bivariate analysis X-ray progression at 5 years was associated with baseline number of synovitis PD >0 (p= 0.0001), grade of synovitis DP>0 (p= 0.0001), and total RAMRIS>14 (p=0.03). In multivariate analysis the number of synovitis PD>0 (adjusted OR 9.8 [95% CI 1.7–4.1] was associated with X-ray progression.

Conclusion: Persistence of Doppler signal on US was the best predictor of structural progression on X-ray at short and long term, in a cohort of patients in LDA. Further studies should assess whether patient management guided by US may decrease relapses and X-ray progression.

Efficacy of Tocilizumab Therapy in Patients with Rheumatoid Arthritis Based on FDG-PET/CT. Koichi Okamura[1], Yukio Yonemoto[1], Chisa Okura[2] and Kenji Takagishi[1]. [1]Gunma University, Maebashi, Japan, [2]Gunma University Graduate School of Medicine, Maebashi, Japan.

Background/Purpose: A humanized anti-interleukin-6 receptor (anti-IL-6R) antibody, tocilizumab (TCZ), is one of the biologics and the C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) immediately decrease after the initiation of TCZ therapy. Therefore, it has been proposed that the Disease Activity Score in 28 Joints (DAS28) is an inappropriate marker for assessing the effectiveness of TCZ therapy for RA patients. In fact, clinical physicians are sometimes confused as to how to judge the efficacy of TCZ therapy. Positron emission tomography (PET) with 2-[18F]-fluoro-2-deoxy-D-glucose (18F-FDG) can be used to precisely recognize an increase in synovitis in affected joints, imaging studies with ^{18}F-FDG PET have been performed to assess the metabolic activity of synovitis in RA patients and evaluate the disease activity of RA. Hence, in the present study, we evaluated whether TCZ suppresses synovitis in RA patients after three or six months of treatment and whether conventional assessments of the DAS 28, DAS28-CRP, simplified disease activity index (SDAI) and clinical disease activity index (CDAI) for patients treated with TCZ reflect the improvements in inflammation observed on ^{18}F-FDG PET.

Methods: Seventeen patients (5 males, 12 females; average age: 59.9 ± 11.7 (30–82) years) were enrolled in this study. All patients were diagnosed according to the American College of Rheumatology (ACR) criteria revised in 1987 and had a history of a clinically inadequate response to previous treatment with non-biologic disease modifying antirheumatic drugs (DMARDs), including methotrexate (MTX) and biologic agents, including TNF inhibitors only. ^{18}F-FDG PET was performed at baseline and three and six months after the therapy. The maximum SUV (SUVmax) of the bilateral shoulder, elbow, wrist, hip, knee and ankle joints were totaled (total SUV) and used to assess the degree of FDG uptake as a representative parameter. Wilcoxon's signed-rank sum test was used to assess differences in the effects of treatment. Spearman's rank correlation test was applied to test for correlations between the different parameters recorded in this study.

Results: The disease activity scores of the DAS 28, DAS28-CRP, SDAI and CDAI, and total SUV were significantly decreased at three months after the initiation of TCZ. The disease activity and total SUV scores were also found to be further decreased at six months compared to baseline. The ΔSUV, the differences in the total SUV at baseline and three/ six months after treatment, positively correlated with the ΔDAS28 (r = 0.615 p = 0.009/ r = 0.775 p < 0.001), ΔDAS28-CRP (r = 0.696, p = 0.002/ r = 0.828, p < 0.001), ΔSDAI (r = 0.652, p = 0.005/ r = 0.686, p = 0.002) and ΔCDAI (r = 0.662, p = 0.004/ r = 0.711, p = 0.001) for each period.

Conclusion: A reduction in the FDG uptake was observed at three months after the initiation of TCZ therapy. Our results indicate that conventional parameters of TCZ efficacy in RA patients match the disease activity estimated on ^{18}F-FDG PET. ^{18}F-FDG PET can be used to evaluate the response of RA patients to TCZ therapy.

Baseline Scintigraphic Detection of TNFá As a Predictor of Therapy Response after Treatment with Certolizumab Pegol in Rheumatoid Arthritis and Spondyloarthritis Patients. Philippe Carron[1], Bieke Lambert[2], Filip De Vos[3], Gust Verbruggen[1], Dirk Elewaut[1] and Filip van Den Bosch[1]. [1]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [2]Department of Nuclear Medicine Ghent University Hospital, Ghent, Belgium, [3]Department of Radiopharmacy Ghent University, Ghent, Belgium.

Background/Purpose: A major challenge in the biologic era is to predict clinical response. A large variability in the level of TNFα expression has been recognized which may influence the outcome of TNF antagonism. Thus far, treatment decisions are solely based on clinical disease activity. In this way, only 40% of rheumatoid arthritis (RA) and spondyloarthritis (SpA) patients achieve a clinically important response (ACR50 or ASAS40). We hypothesized that *in vivo* assessment of TNFα by scintigraphy with 99mTc-radiolabeled anti-TNFα antibodies may be helpful to optimize and monitor the effect of TNFα blockade. This technique may facilitate 'evidence-based biological therapy' by *in vivo* measurement in inflamed joints of a target cytokine, prior to therapeutic administration of a biologic.

Objective: Predict response to therapy by baseline immunoscintigraphy before starting anti-TNF treatment in active RA and SpA patients.

Methods: Certolizumab pegol (CZP)was radiolabeled with Tc99m. Whole body images and static images of hands and feet were acquired immediately following administration, 4–6 hours and 24 hours post injection. Immunoscintigraphic findings were scored as either negative (no or faint uptake) or positive (clear uptake). All patients were treated with CZP for 6 months and standard clinical assessments were performed. Statistical analysis for the joint based response (tender and swollen) was based on a logistic regression model including patient as random effect to accommodate for clustering of the joints in the patient and using the odds ratio (OR) as summary statistic.

Results: 20 patients were included (RA n=5, SpA n=15), scanned and treated according to the protocol. Images 4–6 hours post-injection yielded the best discriminatory results of radiolabeled uptake. Immunoscintigraphy was a good predictor for a joint being swollen at baseline as only 2.2% of the scintigraphic negative joints were swollen compared to 63.5% of the scintigraphic positive joints.The mid scintigraphic evaluation had a significant predictive value on the tender (OR=18.7, P<0.0001) and swollen joint count (OR=44.4, P<0.0001) at baseline, implying that clear uptake increases the odds of having a problematic joint. After 24 weeks, the odds of joints remaining painful was significantly smaller in joints with a positive scintigraphic result as compared to joints with a negative scintigraphic result (OR=0.41, P=0.04):32 out of 114 (28.1%) painful negative scintigraphic joints at baseline remained painful at week 24, whereas only 18 out of 58 (13.8%) painful positive scintigraphic joints at baseline remained painful at week 24. No significant results were found for the swollen joints.

Conclusion: Baseline scintigraphic detection of TNFα with radiolabeled anti-TNFα has a significant predictive value at baseline and after 24 weeks treatment with CZP on the tender joint count. Tender joints not identified by immunoscintigraphy respond to a lesser degree to anti-TNF treatment, potentially indicating another biological reason for a painful joint. Therefore TNF-immunoscintigraphy could offer a new tool to identify good clinical responders to biological treatment.

Patients with Moderate Disease Activity in the First 5 Years of Rheumatoid Arthritis Still Progress Radiographically Despite Conventional Disease Modifying Therapy. Lewis Carpenter[1], Elena Nikiphorou[1], Sam Norton[2], Keeranur Jayakumar[3], Josh Dixey[4] and Adam Young[5]. [1]University of Hertfordshire, Hatfield, United Kingdom, [2]King's College London, London, United Kingdom, [3]Heart of England NHS Foundation Trust, Birmingham, United Kingdom, [4]New Cross Hospital, Wolverhampton, United Kingdom, [5]ERAS, St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: Patients with moderate disease are an important, and often poorly studied, patient subgroup. The extent to which traditional DMARD therapies adequately control the disease is an important research question. Radiographic damage is a crucial indicator of the success or failure of treatment to adequately control the disease.

Methods: The Early Rheumatoid Arthritis Study (ERAS) is an inception cohort that recruited 1,465 recent onset, DMARD naïve, RA patients from 9 hospitals in England between 1986 and 1998, with follow up for up to 25 years. Data collected included demographics, disease activity (DAS), functional disability (HAQ) and radiographs of hands and feet (Larsen). A total of 1,409 (96%) patients had at least one DAS score over the first 5 years of follow-up. Patients mean DAS score over the first 5 years was calculated, and patients were split into three categories based on this score. Patients with a mean score of 5.2 as severe (n=304), in accordance with the EULAR definitions. A mixed effects negative binomial regression was conducted to analyse the rate of Larsen progression over the first 5 years of disease. Follow-up year, age at onset, sex, treatment at 5 years, baseline HAQ and baseline HB were controlled for in the model.

Results: Patients in the severe group were older, more likely to be female, Rheumatoid Factor positive, higher baseline HAQ, lower baseline HB and shorter mean follow-up. Patients in the moderate group had the highest mean time from symptom onset to first secondary care visit. Patients in the mild and moderate groups were more likely to be on mono-therapy DMARD and steroids, while those patients in the severe group were more likely to be on DMARD step up or add-on treatment. Larsen significantly increased over the first 5 years of disease ($P<0.001$). Those patients in the moderate group had a significantly higher progression of Larsen over the 5 years compared to those patients in the mild group ($P<0.001$). There was no significant difference in 5 year Larsen progression between the moderate and severe groups.

Conclusion: Patients with moderate disease had similar radiographic progression to severe disease, whilst controlling for treatment. Similarly, patients with moderate disease had significantly higher Larsen progression compared to those with mild disease. Results highlight that targeting this group and aiming for remission, or at least better disease control, is as important as for those with high disease.

Rheumatoid Arthritis Erosion Detection and Measurement in Longitudinal Datasets Using High-Resolution Peripheral Quantitative Computed Tomography.

Stephanie Finzel[1], Cheryl Barnabe[2], Kathryn Stok[3], A. Scharmga[4], Andrew J. Burghardt[5], Ellen-Margrethe Hauge[6], Hubert Marotte[7], Stephanie Boutroy[8], Klaus Engelke[9], Dominique Toepfer[1], Sebastian Kraus[1], Roland Kocijan[10], Xiaojuan Li[5] and J. de Jong[4]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Calgary, Calgary, AB, [3]ETH Zurich Institute for Biomechanics, Zurich, Switzerland, [4]Maastricht University Medical Center, Maastricht, Netherlands, [5]Musculoskeletal Quantitative Imaging Research, UCSF, San Francisco, CA, [6]Aarhus Universitetshospital, Aarhus C, Denmark, [7]University Hospital of Saint Etienne, Saint Etienne, France, [8]INSERM U1033 and University of Lyon, Hôpital Edouard Herriot, Lyon, France, [9]Institute of Medcial Physics Synarc, Hamburg, Germany, [10]St. Vincent Hospital, Vienna, Austria.

Background/Purpose: An operational case definition for identification of erosions imaged by HR-pQCT was achieved and tested in a first reliability exercise (RELEX-1) using cross-sectional data. Aim of the study: oo test the case definition and define landmarks for measurement of erosion size in 2D in a longitudinal dataset.

Methods: Patients meeting the new ACR/EULAR classification criteria for RA at various stages of disease duration and severity received a HR-pQCT scan of the 2nd and 3rd MCP joints at 0 and 12 months. Standard image acquisition and segmentation was performed for a 2.7 cm scan area. Images were evaluated for erosions at 8 surfaces per joint (ulnar, radial, dorsal, palmar surfaces of the proximal phalanx and metacarpal head). The erosion case definition requires the presence of a definite interruption in the cortical bone extending over at least 2 consecutive slices, visualized in 2 orthogonal planes, with loss of underlying trabecular bone and being non-linear in shape. The maximal width of the cortical break is identified and measured in the axial multiplanar resolution (MPR), with the maximal depth recorded perpendicular to this line. This same method is repeated in the corresponding MPR. Five readers blinded to patient identity and time sequence of the scan scored 36 baseline and follow-up images (18 joints from 9 patients). Percent agreement and a kappa score for erosion detection (minimum of 2 readers in agreement) was calculated. The variation in width and depth measurements of erosions in axial and perpendicular planes between readers was calculated using the root-mean-square coefficient of variance (RMSCV). McNemar's test was used to test for a significant change in the number of erosions identified from 0 to 12 months. Paired t-tests were used to calculate the average width and depth changes from 0 to 12 months.

Results: Agreement for the presence or absence of an erosion was 92.9% (k=0.711, 95%CI 0.539–0.839). Mean (SD) dimensions of the erosions were: axial width 1.66 (SD 0.99) mm, perpendicular width 1.60 (SD 0.78) mm, axial depth 1.16 (SD 0.66) mm, and perpendicular depth 1.17 (SD 0.57) mm. The respective RMSCV were 36.4%, 30.3%, 15.7% and 27.3%. Seven erosions were detected at both 0 and 12 month timepoints (k=0.755, 95%CI 0.616–0.895) and all readers agreed on a single new erosion developing between 0 and 12 months for 1 subject (McNemar's test p=1.00). Erosion dimensions did not significantly change over 1 year but a trend to reduction in mean size was observed, with an axial width decrease of 0.171 mm (95%CI -0.168, 0.509, p=0.310), perpendicular width decrease of 0.014 mm (95%CI -0.202, 0.230, p=0.898), axial depth increase of 0.007 mm (95%CI -0.147, 0.133, p=0.917), perpendicular depth decrease of 0.133 mm (95%CI -0.075, 0.340, p=0.201).

Conclusion: The case definition for erosions imaged by HR-pQCT is valid in longitudinal datasets. Despite variability in measurements, a trend towards changes in erosion size is demonstrated.

Linear Extrapolation of Missing Radiographic Progression Scores Does Not Spuriously overestimate overall Radiographic Progression in Rheumatoid Arthritis.

Iris Markusse[1], Robert Landewé[2], Meilien Ho[3], Martin Jenkins[3] and Desiree van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom.

Background/Purpose: Linear Extrapolation (LE) is a frequently applied method to impute missing radiographic data in trials. However, there is frequent critique that LE overestimates overall progression. Therefore, 'Last Observation Carried Forward' (LOCF) has been suggested by regulatory bodies as a more conservative method. In the OSKIRA-1 trial (NCT01197521), radiographs were taken at the 12 week (wk) time point, where early escape was possible, in all patients thus providing an excellent opportunity to compare extrapolations based upon LOCF and LE to the truly observed radiographic progression.

Methods: The phase 3 OSKIRA-1 trial enrolled rheumatoid arthritis patients (pts) with an inadequate response to methotrexate. Films of hands and feet were obtained at baseline, wk 12 and 24 in those pts still on study, and were assessed by two readers in random time order using the van der Heijde modified total Sharp score (mTSS). Ten datasets with an artificially, randomly selected sample of 20% missing wk 24 data were created, based upon pts with complete sets of films. First, these missing data were imputed using LE as (mTSS at wk 12 + progression wk 0 – 12, corrected for the actual days between films). Second, the missing data were imputed using LOCF. This approach was iterated for 10 random samples with 50% missing data and 10 random samples with 80% missing data. The datasets obtained with LE and LOCF were compared to the dataset with truly observed data at week 24.

Results: Complete sets of films were available for 579 pts. All our analyses were essentially similar in the 3 treatment arms, so here we present the analysis on pooled data. Mean (SD) observed progression from baseline to wk 24 was 0.33 (2.42). Table 1 shows the average (SD) and range of the mean radiographic progression in the 10 random samples. Using LE, the mean progression estimates were close to the observed data, and not affected by the proportion of missing data. The SD however increased by increasing proportions of missing data. Using LOCF, the mean progression estimates were consistently lower than the observed progression. LOCF increasingly underestimated observed progression by increasing proportions of missing data. As expected, the SD of the LOCF estimates remained stable by increasing proportions of missing data.

Conclusion: In contrast to LOCF, linear extrapolation gives a more accurate impression of true mean radiographic progression at a group level and is less influenced by the proportion of missing data. Since LE inflates the standard deviation of progression scores, the statistical power to detect a significant difference between active treatment and placebo may decrease by increasing proportions of missingness. LE does therefore not overestimate mean treatment effects and is a more robust method than LOCF in this respect.

Table 1: Change in the van der Heijde modified total Sharp score (mTSS) from baseline to week 24.

		Observed change in mTSS in patients completing 24 weeks, mean (SD): 0.33 (2.42)					
	Method	*Mean of the mean**	*Mean of the SD**	*Minimum mean**	*Maximum mean**	*Minimum SD**	*Maximum SD**
20% missing data	LOCF	0.29	2.43	0.28	0.32	2.38	2.48
	LE	0.32	3.02	0.27	0.39	2.60	4.44
50% missing data	LOCF	0.25	2.41	0.21	0.29	2.32	2.49
	LE	0.34	3.83	0.22	0.42	2.73	4.61
80% missing data	LOCF	0.19	2.41	0.18	0.21	2.37	2.44
	LE	0.30	4.19	0.21	0.36	3.05	4.74

Radiological Outcomes after Two Years of Remission Steered Treatment in Early Arthritis Patients. G. Akdemir[1], L. Heimans[1], K.V.C. Wevers-de Boer[1], M.K. Verheul[1], A.a. Schouffoer[2], M. van Oosterhout[3], J.B. Harbers[4], C. Bijkerk[5], G.M. Steup-Beekman[6], L.R. Lard[7], T. W. J. Huizinga[1], L.a. Trouw[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]GHZ Hospital, Gouda, Netherlands, [4]Franciscus Hospital, Roosendaal, Netherlands, [5]Reinier de Graaf Gasthuis, Delft, Netherlands, [6]Bronovo Hospital, The Hague, Netherlands, [7]MCH Antoniushove Hospital, Leidschendam, Netherlands.

Background/Purpose: We investigated whether early, remission steered treatment can prevent damage progression in patients with early rheumatoid arthritis (RA) or undifferentiated arthritis (UA), and aimed to identify potential predictive factors for damage progression.

Methods: 610 patients with early RA (2010 criteria) or UA suspected to be early RA started treatment with methotrexate (MTX) and a tapered high dose prednisone in the IMPROVED study. After four months patients achieving a Disease Activity Score (DAS) <1.6 (early remission) tapered prednisone to zero. If remission was maintained at eight months MTX was tapered to zero. Patients not in early remission were randomized to MTX plus hydroxychloroquine, sulphasalazine and prednisone (arm 1) or to MTX plus adalimumab (arm 2). Every four months medication was tapered and next stopped in case of remission but increased or switched in case of no remission. Radiological joint damage was assessed on radiographs of hands and feet at baseline and yearly in random order by two independent readers using the Sharp/van der Heijde score (SHS). Progression scores were compared between treatment arms and between RA and UA patients. Potential predictors of radiological progression were assessed using logistic regression analysis.

Results: Progression scores were available for 488 patients with a median (IQR) SHS progression of 0 (0-0) point. There was no difference in median SHS progression score between RA and UA patients nor between treatment arms. In only 10% (50/488 patients) radiological progression (≥0.5 SHS) was seen: 33/50 (66%) were in the early remission group, 9 (18%) in arm 1, 5 (10%) in arm 2 and 3 (6%) were treated outside the protocol. In 98 patients (7 in the early remission group and 1 in arm 2) the progression score was ≥5 points (minimal clinically important difference) after two years. Age (OR (95% CI) 1.03 (1.00–1.06)) and the combination of anti-CarP (anti-carbamylated protein antibodies) positivity and ACPA (anti-citrullinated protein antibodies) positivity (2.54 (1.16–5.58)) were independent significant predictors for radiological progression.

Conclusion: After 2 years of remission steered treatment in early arthritis patients radiological progression in the majority of patients was practically zero, regardless of diagnosis RA or UA and regardless of treatment arm following initial combination therapy with methotrexate and a tapered high dose of prednisone. Predictors for radiological progression were age and the combination of anti-CarP positivity and ACPA positivity.

2139

Predictors of Radiologic Disease Progression during the Rheumatoid Arthritis Comparison of Active Therapies Trial. Alan Erickson[1], Denis Rybin[2], Mary Brophy[2], Robert Lew[2], Ted R. Mikuls[1], Timothy Moore[3], Keri Hannagan[2], Edward Keystone[4] and James O' Dell[1]. [1]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [2]VA Boston Heathcare System, Boston, MA, [3]University of Nebraska Medical Center, Omaha, NE, [4]University of Toronto and Mount Sinai Hospital, Toronto, ON.

Background/Purpose: Halting joint damage is a central goal in the treatment of rheumatoid arthritis. Much research has been conducted to identify factors associated with progressive radiographic damage typically measured by the Sharp/van der Heijde score (SHS). Trials have also suggested that treatment choices impact disease course including the development of rapid radiographic progression, defined as a threshold change in SHS ≥ 5U/year. In the 48-week, double-blind, noninferiority RACAT trial, 353 patients with suboptimal methotrexate response were randomized to two treatment strategies, either first adding sulfasalazine and hydroxychloroquine (triple therapy or T) or first adding etanercept (E). After 24 weeks of treatment patients not achieving a DAS28 improvement of 1.2 were switched in a blinded fashion to the other therapy. We explored the associations of strategy and baseline factors with SHS progression.

Methods: Two expert readers provided SHS for patients at baseline and 48 weeks. Using the mean value of the two readers, SHS change was categorized as a an increase ≤ 0.5 U or > 0.5U. Possible baseline predictors of change evaluated included swollen and tender joint count, ESR, Global Health Assessment, DAS28, gender, smoking, RF status, disease duration and baseline SHS. From logistic regression models we obtained odds ratios (OR) for each predictor alone and in multivariable models with all factors. We analyzed all participants, the two strategy subgroups (T and E) and the four treatment subgroups (T-only, E-only, T switch to E, and E switch to T).

Results: Of 304 participants with week-48 Sharp scores, only 4.3% (13 of 304) had increases in SHS ≥5U evenly spread over the four treatment groups, while 23% demonstrated increases >0.5 units again evenly spread over treatments. Approximately 60% demonstrated changes of −0.5, 0, or 0.5U, and 17% showed improvement (<−0.5 change).

Baseline SHS values were significantly different for increases ≤ 0.5U compared to increases >0.5U (15.3 vs. 26.4, p=0.006). In multivariable analyses, only baseline SHS consistently predicted disease progression (see Table). Other measures, including treatment strategy, were not predictive of radiographic progression. No evidence suggested that any of the four treatments was associated with change defined either as >0.5U or as ≥5U. Only 4% had changes ≥5U.

Table: Univariate and multivariable associations of patient factors with SHS progression (increase >0.5U) over 48 weeks (same results obtained using stepwise up or down selection to detect intercorrelation); *model includes all variables shown

	Univariate		Multivariable*	
Baseline Characteristic	**OR (95% CI)**	**p value**	**OR (95% CI)**	**p value**
Sharp Score at Baseline	1.02 (1.01,1.03)	0.002	1.02 (1.01,1.03)	0.007
Male Gender	1.04 (0.61,1.78)	0.881	1.18 (0.66,2.11)	0.584
Ever Smoked	0.58 (0.34,1.01)	0.052	0.60 (0.33,1.08)	0.090
DAS28	1.22 (0.91,1.65)	0.185	1.23 (0.49,3.10)	0.660
Swollen Joint Count	1.02 (0.97,1.07)	0.487	1.00 (0.93,1.07)	0.950
Tender Joint Count	1.00 (0.96,1.04)	0.986	0.99 (0.91,1.08)	0.861
Erythrocyte Sedimentation Rate	1.01 (1.00,1.02)	0.042	1.00 (0.98,1.03)	0.862
Patient Global Health Assessment	1.00 (0.99,1.01)	0.779	1.00 (0.98,1.02)	0.771

Disease Duration	1.01 (0.98,1.04)	0.524	0.98 (0.94,1.02)	0.304
RF Status	1.59 (0.87,2.89)	0.131	1.46 (0.78,2.74)	0.240

Conclusion: Similar to other trials, we found that radiologic progression is most strongly associated with baseline SHS. A weak and non-significant association with positive RF status was observed. We found no significant radiographic advantage with either of the two treatment strategies or among the 4 treatment groups. Rapid radiographic progression, an increase in SHS≥5U, was uncommon (less than 4.3%) regardless of strategy.

Agreement Among FDG-PET/CT, Ultrasound and Physical Examination in Patients with Inflammatory Arthritis. Alexis Ogdie[1], Shiv Sehra[1], Viviane Khoury[1], Yihui Jiang[1], Shawn Rose[2], Nehal N. Mehta[1], Sally W. Pullman-Mooar[3], Abass Alavi[1], Joel Gelfand[4] and Joshua Baker[5]. [1]University of Pennsylvania, Philadelphia, PA, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [3]University of Pennsylvania and Philadelphia Veterans Hospital, Philadelphia, PA, [4]University of Pennsylvania., Philadelphia, PA, [5]University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: The lack of tools to accurately measure and quantify joint inflammation is a challenging problem in the study of inflammatory arthritis. No gold standard method for identifying and quantifying the presence of inflammation exists. The joint examination has relatively poor inter-rater reliability and ultrasound (US) can identify inflammation but is operator-dependent. Joint inflammation can also be seen on 18F-Flurorodeoxyglucose (FDG) Positron Emission Tomography/Computed Tomography (PET/CT) but little is known about how this compares to other modalities. The objective of this study was to examine the agreement among three methods of assessing joint inflammation: physical examination (swelling/tenderness), US (grayscale/Doppler), and FDG-PET/CT visual assessment. We hypothesized that there would be good agreement among the measures.

Methods: Ten patients with active inflammatory arthritis underwent physical examination, US and FDG-PET/CT. Exclusion criteria included pregnancy, elevated fasting glucose (>150) or diabetes. The examination was performed by an attending rheumatologist. US was performed by an US-trained rheumatology fellow or a trained ultrasonography technician. US images were read by a US-trained rheumatologist or musculoskeletal radiologist blinded to the clinical examination. PET/CTs were read by a rheumatology fellow blinded to the examination and US results. Previously reported grading scales for US synovitis, doppler and PET/CT were used but for analysis these variables were converted to binary measures (yes/no inflammation) for analysis. Agreement among the modalities was examined using Cohen's kappa. Confidence intervals were generated using a bootstrapping method to account for clustering by individual.

Results: Four patients with rheumatoid arthritis and 6 with psoriatic arthritis were enrolled with mean age 52.7 years and 80% male. All patients were on therapy at the time of the assessments and had relatively mild disease activity. Among the 10 patients, 300 joints were included in the analysis (340 examined, 300 PET/CT, 180 US). Of these, 46 were swollen, 50 were tender, 56 had FDG uptake on PET/CT, 26 had signs of inflammation on US grayscale and 14 were Doppler positive. Agreement among the imaging modalities and examination was low (**Table**), with κ ranging from 0.01–0.22. Restricting the analysis to only large peripheral joints did not substantially change agreement.

Conclusion: This is the first study to examine agreement among PET/CT, US and physical examination in the assessment of joint inflammation. In this small pilot study, we found low agreement among PET/CT with US and both PET/CT and US with physical examination findings among patients on therapy with mild disease activity. It may be that each modality measures a distinct property of inflammation, all equally valuable in measuring the construct of inflammation.

	All joints				Large Peripheral Joints*			
	PET	Grayscale	Doppler	Tenderness	PET	Grayscale	Doppler	Tenderness
US-Grayscale†	0.18 (−0.03–0.39)				0.15 (−0.10–0.40)			
US-Doppler†	0.11 (−0.08–0.31)	0.49 (0.22–0.75)			0.10 (−0.13–0.32)	0.47 (0.08–0.86)		
Tenderness	0.01 (−0.16–0.18)	0.10 (−0.16–0.35)	0.18 (−0.07–0.42)		0.09 (−0.14–0.31)	0.10 (−0.28–0.48)	0.25 (−0.15–0.64)	
Swelling	0.22 (−0.06–0.51)	0.07 (−0.13–0.27)	−0.02 (−0.20–0.16)	0.44 (0.10–0.79)	0.18 (−0.14–0.50)	0.13 (−0.17–0.44)	−0.01 (−0.25–0.23)	0.58 (0.22–0.94)

Cohen's kappa values and confidence intervals are presented in this table. Kappa ranges from -1 to 1 where positive values suggest systematic agreement and negative values suggest systematic disagreement. Confidence intervals were generated based on a cluster bootstrap method. †Ultrasound was performed on ankles, knees, elbows, wrists, shoulders second and third MCPs, and second and third PIPs bilaterally. FDG uptake was assessed for ankles, knees, elbows, wrists, shoulders, MCPs, and PIPs. In patients with psoriatic arthritis, DIPs, hips, and SI joints were also assessed. *Large peripheral joints included ankles, knees, wrists, elbows and shoulders.

Sensitivity to Change of Joint Space Width Measurements in Hand Osteoarthritis in a Two Year Follow-up Study. W. Damman, S.E. de Bruin, B.C. Stoel, R. van 't Klooster and M. Kloppenburg. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Cartilage loss, represented by joint space width (JSW) on radiographs, is an important outcome measure in hand OA disease course. JSW can be assessed quantitatively in a valid, reliable and feasible way. However, it is not known whether this method is sensitive over time and was therefore subject of this 2-year follow-up study.

Methods: We used data of 276 participants (mean age 61 yrs, 88% women, mean BMI 27 kg/m^2, 93% fulfilled ACR criteria, median number of joints with pain 2 (range 0–24)) in the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) study, including consecutive primary hand OA patients diagnosed by their treating rheumatologist.

During physical examination (PE) in the 2nd to 5th DIP and PIP joints the number of joints painful upon palpation, with bony swellings, soft-tissue swelling, limited Range Of Motion (ROM) and deformity was assessed (all 0–16). Digital hand radiographs (dorsal-volar views) were taken at baseline and after two years.

JSW was measured in 2nd to 5th DIP, PIP and MCP joints (n=24) with a semi-automatic quantification method (van 't Klooster Osteoarthritis Cartilage 2008; 16: 18–25. Openly available through www.lkeb.nl (software downloads)). ICC were calculated based on repeat measurement in 40 radiographs to determine reliability. Smallest Detectable Differences (SDDs) of all joints and per joint group were calculated by measuring two radiographs from 21 patients acquired within a 6-months (max 196 days) time-interval, assuming no progression over such short time.

Progression was defined as a change more than the SDD. Progression on patient level was defined when at least 1 joint had progressed.

Generalized Estimating Equations (GEE) were used to test on joint level in 2nd to 5th DIP and PIP joints which factors associate with progression. Adjustments were made for patient (age, sex, BMI) and joint characteristics (all five PE assessments and baseline JSW).

Results: After two years, of 192 patients both baseline and follow-up radiographs were available to assess progression. Of the 4570 joints measured, 8.8% progressed, which was seen most often in the DIP joints. On patient-level, 76.6% progressed. The results are depicted in table 1. The reliability was high with ICC 0.97.

Variables at joint level associated with progression are JSW at baseline OR 9.9 (95%CI 5.1;19.0), pain upon palpation dichotomized to present/absent 1.4 (1.02;1.9) and limited ROM 1.9 (1.4;2.5). All the other variables had no significant association.

Conclusion: Semi-automated JSW measurement is sensitive to change over 2 years. Risk factors for progression on joint level are: a relatively large JSW on baseline, pain upon palpation and limited ROM.

Table 1: JSW, SDD and progression in 195 patients with hand osteoarthritis

	JSW at baseline, mean (SD)	JSW at two years, mean (SD)	SDD, mm	Progression, %
Total (n=4570)	0.92 (0.17)	0.91 (0.17)		
DIP joints (n=1524)	0.63 (0.18)	0.63 (0.18)	0.116	10.8
PIP joints (n=1522)	0.78 (0.19)	0.77 (0.18)	0.135	6.9
MCP joints (n=1524)	1.34 (0.25)	1.32 (0.25)	0.202	8.7

Sensitivity and Precision of Automated Osteophyte Volumetric Measurement in Knee Osteoarthritis over Four Years. Michael Hakky[1], Charles Ratzlaff[2], Mohamed Jarraya[3], Ali Guermazi[3] and Jeffrey Duryea[4]. [1]Lahey Clinic, Burlington, MA, [2]Harvard Medical School / Brigham and Women's Hospital, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Brigham & Women, Boston, MA.

Background/Purpose: Osteophyte formation and evolution is a hallmark of knee OA, and their radiographic identification and progression is fundamental in clinical practice, observational research and randomized clinical trials. The most commonly used grading scales are ordinal, requiring subjective judgment and expert reading time potentially hampering precision and responsiveness. We have developed a semi-automated method for osteophyte volumetric analysis on MRI. Our objective was to evaluate the sensitivity and precision of this method to osteophyte volume change over four years in subjects with established knee OA according to Kellgren and Lawrence (KL) grade.

Methods: Ninety subjects (51 KL 2 and 39 KL 3) were selected from the Osteoarthritis Initiative (OAI) Progression Cohort. Double echo steady state 3D sagittal images were obtained on a 3T Siemens Trio MR system. Measurements were performed on coronal reformatted series. A reader (MH) used software to segment marginal femoral and tibial osteophytes of all 90 knees at baseline and 48 months, blinded to order of visit. The first and last slice of the central weight bearing region were identified and an edge detection algorithm demarcated the bone margins. The reader then 'closed off' each osteophyte by marking the expected normal bone contour. The software calculated the total volume (V) for each compartment, bone and knee. Reliability was assessed using an experienced MSK radiologist (MJ) on a random sub-sample of 20 subjects.

The primary outcome was change in osteophyte volume (ΔV). Statistics used were the average change (ΔV), the standard deviation of ΔV (SD), the standardized response mean of (SRM, defined as ΔV/SD), and the percentage of subjects with net increase in V. Intraclass correlation coefficient (ICC) and root mean square of the standard deviation (RMSSD) were used to assess reliability.

Results: The average change in osteophyte volume (ΔV) was 196 mm^3(272), and the SRM was 0.72. A net increase in osteophyte volume from baseline to 48 months was observed for 84% (76/90, 40 KL 2 and 36 KL 3) of the subjects. The average reading time was approximately 10 minutes per knee.

Table 1 – Responsiveness to change over 48 months

Baseline KL grade (n)	Net Increase	Mean ΔV	SD ΔV	SRM
KL 2 + KL 3 (90)	76 (84%)	196 mm^3	272 mm^3	0.72
KL 2 (51)	40 (78%)	155 mm^3	233 mm^3	0.67
KL 3 (39)	36 (92%)	250 mm^3	309 mm^3	0.81

Table 2 — Responsiveness to change by compartment

	Mean ΔV	SD ΔV	SRM
Medial Compartment	53mm^3	88 mm^3	0.60
Lateral Compartment	45 mm^3	95 mm^3	0.48
Medial Femur	72 mm^3	99 mm^3	0.72
Lateral Femur	60 mm^3	115 mm^3	0.52
Medial Tibia	34 mm^3	72 mm^3	0.47
Lateral Tibia	30 mm^3	66 mm^3	0.45

The intra- reader ICC was 0.98, and RMSSD 82 mm^3, while inter- reader ICC was 0.97 and RMSSD 91 mm^3.

Conclusion: A new computer-assisted method of osteophyte volume measurement is reliable and sensitive. It may provide a more responsive and rapid method for osteophyte change than traditional ordinal methods, making it feasible to assess a large number of knees in a short period of time.

Cortical Breaks and Bone Erosions in the Hand Joints: A Cadaver Study Comparing Conventional Radiography with High-Resolution and Micro-Computed Tomography. A. Scharmga[1], A. van Tubergen[1], J. van den Bergh[1], J. de Jong[1], M. Peters[1], B. van Rietbergen[2] and P. Geusens[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Eindhoven University of Technology, Eindhoven, Netherlands.

Background/Purpose: Conventional radiography (CR) is considered the gold standard for diagnosing bone erosions in rheumatic diseases. However, High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) and microCT (μCT) allow analysis of bone erosions in finger joints at micro level. This study aimed to quantify cortical breaks and erosions in hand joints assessed from CR, HR-pQCT and μCT images.

Methods: Eight metacarpal phalangeal and four proximal interphalangeal joints from eight female human cadaveric index fingers with unknown medical history were scanned by HR-pQCT (82 μm, Scanco XtremeCT) and μCT (18μm, Scanco μCT 80). Also radiographs were taken. A modified SPECTRA (Study grouP for xtrEme Computed Tomography in Rheumatoid Arthritis) algorithm was used by one reader to assess all cortical breaks and erosions. A cortical break was defined as an interruption of cortical bone on two consecutive slices on two orthogonal planes for HR-pQCT, and similarly, but on eight consecutive slices, on μCT. An erosion was defined as a definite cortical break, with irregular shape, and loss of underlying trabecular bone on two consecutive slices on two orthogonal planes on HR-pQCT, and eight consecutive slices on two orthogonal planes on μCT. CRs were independently scored for erosions by two rheumatologists. Descriptives, paired samples t-test, Wilcoxon signed-rank test, kappa and intraclass correlation coefficients (ICC) were calculated ($p<.05$ was considered significant).

Results: Figure 1 shows a picture obtained from the three imaging modalities used in this study. In total, twelve joints (mean± SD age 82.6±9.1 years) were imaged by HR-pQCT and μCT. In total, 79 cortical breaks were detected on HR-pQCT (6.5±2.5 per joint) and 163 on μCT (13.5±4.9 per joint). A total of 11 erosions were detected on HR-pQCT (0.9±0.9 per joint) and 47 on μCT (3.9±3.0 per joint). The ICC for number of cortical breaks was. 122 ($p=.150$), and for number of erosions -.090 ($p=.699$). On CR, the total number of erosions scored was four by Reader 1, and two by Reader 2. Kappa was fair ($\kappa=.250$).

Conclusion: Three times more erosions were detected on HR-pQCT than CR and four times more erosions were detected on μCT than HR-pQCT. Furthermore, twice the number of cortical breaks was scored on μCT compared to HR-pQCT. These results indicate that further research, such as histological and longitudinal studies, will be necessary to reveal the prevalence, incidence and significance of cortical breaks and erosions as found by HR-pQCT and μCT of hand joints.

Cuantification of Hand Bone Mineral Density By Radiogrammetry and Dual X-Ray Absorptiometry in Early Arthritis Patients. Irene Llorente Cubas*[1], Leticia Merino-Meléndez*[1], Saturnino González Ortega[2], Ana M. Ortiz-García[1], Eugenio Escolano[2], Esther Vicente-Rabaneda[1], Rosario Garcia-Vicuña[3], Isidoro González-Alvaro[3] and Santos Castañeda-Sanz[4].

[1]Hospital Universitario de La Princesa, Madrid, Spain, [2]Hospital Universitario de la Princesa, Madrid, Spain, [3]Hospital Universitario de La Princesa. IIS La Princesa, Madrid, Spain, [4]Hospital Universitario de La Princesa. Madrid. Spain, Madrid, Spain.

Background/Purpose: The evaluation of cortical bone mineral density (BMD) on metacarpal bones by digital radiogrammetry (DXR) has been proven to be a simple, reliable and predictive method to evaluate the severity of the disease in patients with early arthritis (EA). However, DXR is a tool that is not usually available in our environment. By contrast, dual X-ray absorptiometry (DXA) is a more familiar and accessible technique in our clinical practice.

Purpose: The aim of this study was to compare the association between BMD measurements of the hand by DXR and DXA with parameters of activity and severity at two years of follow-up in a cohort of patients with EA.

Methods: A prospective longitudinal study of patients with EA was done. DXR was performed in a total of 111 patients (87.4% women) and DXA was implemented in a total of 378 (82% women). Mean age at disease onset was 57 years [46 – 65 (p25 - p50)] in the DXR group and 54 years [44 – 66 (p25 - p50)] in the DXA group. Anthropometric and clinical data were collected per protocol during 2 years of follow-up. Forty-two percent of patients in the DXR group presented citrullinated peptide antibodies and 41.3% in the DXA group. In both, the 57% fulfilled RA 2010 criteria at the start of follow up (43% undifferentiated arthropathy). Each patient underwent a digital radiograph of both hands (GE © DX Definium 8000) at 0, 3, 12 and 24 months, determining BMD of each hand and the mean of both measures by DXR (Sectra, Linköping, Sweden). Also, DXA of global hand and metacarpophalangeal joints (MCPs) of the nondominant hand were performed and analyzed using a Hologic QDR -4500 Elite© densitometer at 0, 6, 12 and 24 months. In addition, a variable that measures the intensity of cumulative treatment received during the 2 year follow-up was specifically generated as a marker of severity. Statistical analysis was performed using the statistical package STATA 12.

Results: Our data show a good correlation between values of BMD obtained by DXR and DXA in the different locations studied (global hand and MCPs: $r=0.830$ and 0.718, respectively, $p=0.0001$), both at the baseline visit and along the two years of monitoring. In the bivariate analysis, a negative association is observed between baseline BMD values measured by DXA and disease activity by DAS28 at 2 yrs, which disappears when adjusting for other variables (age and sex). However, we found an inverse relationship between the intensity of cumulative treatment at two years and baseline BMD measured by DXA, both at global hand ($r = -2.51$, $p=0.041$, $n=220$) and MCPs ($r = -3.45$, $p=0.007$, $n=221$). The DXR association was not significant, probably due to the small sample size of the population ($n=32$).

Conclusion: BMD of the global hand and MCPs of the nondominant hand assessed by DXA predicts disease severity and the intensity of cumulative treatment at two years of follow-up in a population of patients with EA. By contrast, the predictive value of the hand DXR was not significant. Further studies with a larger population are needed to obtain more consistent conclusions.

Diagnostic Performance and Disease Activity Assessment By FDG-PET in Large-Vessel Vasculitis: A Systematic Literature Review and Meta-Analysis. Michael Soussan[1], Patrick Nicolas[2], Catherine Schramm[3], Sandrine Katsahian[3], Veronique Eder[4], Olivier Fain[5] and Arsene Mekinian[6]. [1]Nuclear Medicine, Avicennes Hospital, Bobigny, France, [2]Avicenne Hospital, 93000, France, [3]Centre de Recherche des Cordeliers, Equipe 22, Paris 5, Paris 6, Paris, France, paris, France, [4]Avicenne Hospital, Bobigny, France, [5]Hôpital Saint Antoine, DHU i2B, Service de Médecine Interne, paris, France, [6]Internal Medicine, DHUi2B Saint Antoine Hospital, paris, France.

Background/Purpose: FDG-PET is increasingly used in the work up of large-vessel vasculitis (LVV)**.** The purpose of this study is to perform a systematic review and meta-analysis of the value of FDG-PET for the diagnosis of LVV.

Methods: MEDLINE and Cochrane Library were searched for articles that evaluated the value of FDG-PET in LVV, from 01/2000 to 12/2013. Inclusion criteria were: American College of Rheumatology (ACR) criteria for the diagnosis of Giant Cell Arteritis (GCA) or Takayasu Arteritis (TA), definition of PET positivity threshold, and > 4 cases included. Data were pooled to compare clinical/biological data and PET results. Sensitivity and specificity of FDG-PET for the diagnosis of LVV were calculated from each included individual study, then pooled for meta-analyses with a random effects model.

Results: Were included 21 studies with a total of 413 patients and 299 controls. Pooled sensitivity and specificity of FDG-PET for the diagnosis of LVV were 0.77 (95% CI,0.69– 0.83) and 0.95 (95% CI,0.92–0.95), respectively. When GCA subgroup was considered, sensitivity increased to 0.9 (95% CI,0.79–0.96) and specificity to 0.98 (95% CI,0.94–0.99), with a decrease in inconsistency (I-square). Pooled sensitivity and specificity of FDG-PET to assess TA disease activity were 0.87 (95% CI,0.78– 0.93) and 0.73 (95% CI,0.63– 0.81), respectively. Sub-analysis of studies using NIH criteria for disease activity assessment, showed that the specificity increased to 0.84 [0.73; 0.92], with a decrease in inconsistency. High vascular uptake ($>$ liver uptake) was the most reliable PET threshold for the diagnosis of aortitis. As a limitation, PET technology and threshold used to define the presence of vascular inflammation varied among the studies. Furthermore, no systematic comparison with conventional cross imaging was available.

Conclusion: FDG-PET has an overall valuable performance for the diagnosis of LVV, especially for GCA, and for the assessment of the activity in TA. Further studies are needed to better determine the utility of PET for management of LVV.

Optimal Hand Position for Reliable Volumetric Joint Space Width Measurements Using High-Resolution Peripheral Quantitative Computed Tomography. Cheryl Barnabe, Sarah Manske, Britta Jorgenson and Steven K. Boyd. University of Calgary, Calgary, AB.

Background/Purpose: Joint space narrowing is an important outcome measure in rheumatoid arthritis, linked tightly to function and disability. High-resolution peripheral quantitative computed tomography (HR-pQCT) allows detection of bone margins with high precision. Based on this capability, we have devised a software script to quantify volumetric joint space width based on the method of 'fitting maximal spheres'. The reproducibility of this method may be affected by the angular positioning of the joint. Our study assesses variability of 3D volumetric joint space measurements with variations in joint flexion between 0 and 30 degrees.

Methods: The 2nd and 3rd MCP joints of six cadaver hands were imaged with HR-pQCT ($n=12$ joints). Using a positioning device, the MCPs were placed at 7 different angles of flexion (0, 5, 10, 15, 20, 25 and 30 degrees). Actual angles of acquisition were verified in the sagittal plane post-hoc. Descriptive statistics were used to calculate the mean, median, minimum, and maximum joint space widths and total volume measurements, by degree of angulation. The coefficient of variation (root-mean-square deviation), CV(RMSD), was calculated to determine the variability caused by angulation.

Results: There was little variation in positioned angle and post-hoc angle measurement up to 15 degrees of flexion (measured angle mean 2.1, 5.7, 10.7, 15.3 vs positioned angle 0, 5, 10 and 15 respectively). At greater degrees of flexion, positioning error was significant, with the post-hoc angle measurement ranging from 20.8 to 32.5 at 30 degrees. Mean, median, maximum and minimum joint space increased linearly between 5 and 30 degrees (Figure 1). The CV(RMSD) was optimized between 5 and 15 degrees of flexion (Table 1). Minimum joint space measurements were highly variable at all degrees of flexion.

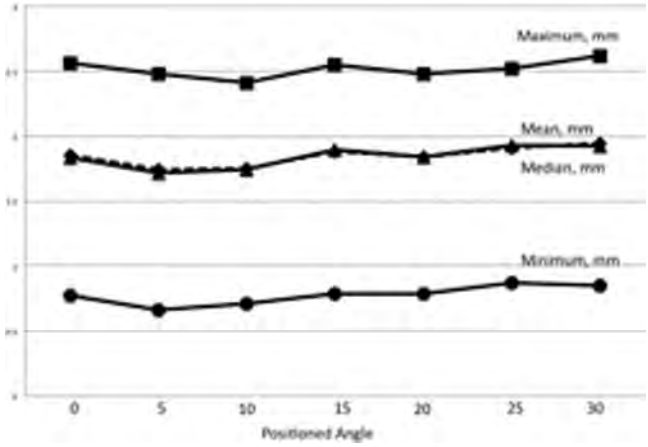

Figure 1. Plot of Obtained Measurements by Degree of Angulation.

Table 1. Coefficient of Variation (Root-Mean Square Deviation) for Joint Space Measurements by Angle of Flexion of the MCP Joints

Angles	Mean	Median	Minimum	Maximum	Volume
0-10	4.8%	5.2%	14.6%	4.0%	3.2%
0-15	5.0%	5.9%	20.2%	4.5%	3.8%
5-15	4.4%	5.5%	18.0%	4.3%	3.4%
0-20	5.4%	6.7%	22.4%	5.0%	4.2%
0-25	6.1%	7.3%	35.8%	5.3%	5.2%
0-30	6.7%	7.5%	35.9%	5.7%	5.2%

Conclusion: Our 3D volumetric measurement method of joint space width for images acquired with HR-pQCT technology is reliable for MCP flexion angles of 0 to 20 degrees. Reproducibility metrics are optimized between 5 and 15 degrees. Care should be given to remaining in this parameter for longitudinal or repeated measures studies using this technology for joint space width assessment.

Automatically Extracted Quantitative Biomarkers for Assessing Connective Tissue Disease Using Nailfold Capillaroscopy. Michael Berks[1], Graham Dinsdale[2], Andrea Murray[2], Tonia Moore[3], Chris Taylor[1] and Ariane Herrick[2]. [1]Centre for Imaging Sciences, University of Manchester, Institute of Population Health, Manchester, United Kingdom, [2]Centre for Musculoskeletal Research, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Salford Royal Hospital NHS Foundation Trust, Salford, United Kingdom.

Background/Purpose: Videomicroscopy can capture high-magnification images of nailfold capillaries, allowing non-invasive assessment of microvasculature change indicative of connective tissue disease. Whilst images may be qualitatively graded visually, quantitative biomarkers are required for detailed analysis and tracking disease progression. To overcome the problems of manual measurements (time consuming, subjective), we have developed fully automated software to measure the spatial density, width and tortuosity of capillaries[1]. Our objective was to assess how well these automated biomarkers differentiate between healthy controls (HC), subjects with primary Raynaud's phenomenon (PRP), patients with systemic sclerosis (SSc), and patients with an undifferentiated connective tissue disease (UCTD).

Methods: Our software was used to analyze 577 nailfold images (85 HC; 46 PRP; 402 SSc, 44 UCTD). Analysis is performed in four stages: the software 1) detects all vessels, measuring the orientation and width for each 2) locates the apex of each capillary and determines which belong to the distal row 3) extracts measures that characterize the size and shape of each distal capillary 4) combines these measurements to compute a single value of density, width and tortuosity for each image. For each biomarker one-way ANOVA, followed by Tukey's range test, was used to check for differences between the means of each subject group.

Results: ANOVA tests showed significant group-wise differences for all biomarkers (all $p < 0.001$). The group mean and 95% confidence interval of each biomarker are shown in Table 1, along with the pairs of groups that showed significantly different means under Tukey's test.

Table 1: Group-wise means and confidence intervals for each automatically measured capillaroscopy biomarker. Pairs of groups with significantly different means are listed in the rightmost column.

	Subject group means (95% confidence intervals)				Groups with significantly different means under Tukey's test
Biomarker type	HC (n=85)	PRP (n=46)	SSc (n=402)	UD (n=44)	
Capillary density (per mm)	12.6 (12, 13.3)	13.4 (12.5, 14.2)	9.02 (8.74, 9.3)	11.5 (10.6, 12.3)	HC v SSc (p< 0.001); PR v SSc (p< 0.001); UD v SSc (<0.001 PR v UD (p=0.011);
Mean apical width (mm)	10.5 (11, 10.1)	11.2 (11.9, 10.5)	14.3 (14.7, 14)	12.5 (13.4, 11.7)	HC v SSc (p<0.001); PR v SSc (p<0.001); UD v SSc (p =0.0017); HC v UD (p<0.001);
Mean capillary tortuosity (no units)	4.42 (4.38, 4.46)	4.33 (4.27, 4.39)	4.55 (4.53, 4.57)	4.41 (4.35, 4.47)	HC v SSc (p<0.001); PR vSSc (p<0.001); UD v SSc (p<0.001);

Conclusion: Images from patients with SSc had significantly lower capillary density and higher width and tortuosity than all other subject groups (including UCTD), matching findings from earlier studies using manual or semi-automated analysis[2]. No significant differences were observed between healthy controls and PRP, again, matching clinical expectations. Images from patients with UCTD generated biomarkers that lay in between healthy controls/PRP and SSc. These highly promising results suggest our software produces clinically useful biomarkers of connective tissue disease. Automatic analysis is potentially a major step forward, enabling large datasets of images to be assessed quickly and efficiently, and obviating the inherent subjectivity of manual assessment.

Dual Energy CT Scanning: Variable Sensitivity for Gout in Non-Tophaceous and Tophaceous Disease and in Individual Erosions. Tracie Kurano[1], Uma Thakur[1], Gaurav Thawait[1], Elliot Fishman[1], Mara McAdams-DeMarco[1], Janet W. Maynard[1], Matthew Fuld[2], John A. Carrino[3] and Alan N. Baer[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Siemens Medical Solutions USA, Inc., Baltimore, MD, [3]Hospital for Special Surgery, New York, NY.

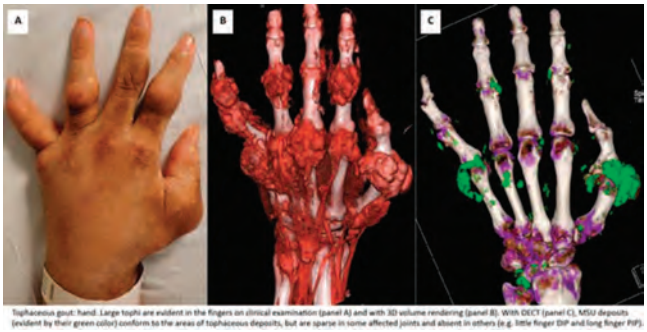
Background/Purpose: Dual energy computed tomography (DECT) is emerging as a diagnostic tool for gout, but its sensitivity has not been established. We assessed the sensitivity of DECT for the detection of monosodium urate (MSU) deposits in both non-tophaceous and tophaceous gout.

Methods: Twenty-one patients with gout (per Wallace criteria) agreed to participate in this study funded by Siemens Medical Solutions and underwent DECT of their hands, wrists, elbows, knees, ankles, and feet. Eleven had non-tophaceous gout confirmed by the demonstration of MSU crystals in a joint aspirate. Ten patients had tophaceous gout (crystal-proven in 7), defined by the presence of palpable tophi (n=5), the presence of erosions of the first metatarsal head on radiograph (n=3), or gross MSU deposits in a surgical specimen (n=2). Scans were performed using a SOMATOM Definition Flash Dual Source CT scanner (Siemens Healthcare) with simultaneous acquisition of images at 80 and 140 kV. Post-processing was performed using Siemens software with predefined standard parameters; the threshold ratio parameter was set at 1.36. Sensitivity was defined as the percentage of gout patients who were correctly identified by DECT.

Results: The 21 patients included 17 men, with a mean age of 61 years (range, 43 – 83). Among the 11 patients with non-tophaceous gout, MSU deposits were only detected by DECT in the joint proven to be affected by aspiration in 2 (sensitivity=18%). However, the MSU deposits were evident in ≥1 joint area evaluated by DECT in 7 patients (overall sensitivity=64%), ≥1 clinically affected joint in 4 (57%) patients and ≥1 clinically unaffected joint in 6 (86%) patients. The number of MSU deposits correlated with the

maximum recorded serum urate (r^2=0.502, p=.022) but not with gout duration. Among the 10 patients with tophaceous gout, 9 had MSU deposits evident by DECT (sensitivity=90%). In an index case of tophaceous gout (Figure), we were surprised to see tophi evident by clinical examination (panel A), 3D volume rendering (Panel B), and bony erosion (panel C-little finger DIP), that were negative by DECT (panel C-lack of green deposits). This prompted us to evaluate the sensitivity of DECT for individual gouty erosions (defined by the presence of an overhanging edge in a joint not affected by severe joint space loss). In 3 patients with extensive foot involvement, MSU deposits were detected by DECT within or immediately adjacent to 13/26 (50%) erosions.

Conclusion: DECT detected MSU deposits in non-tophaceous gout, with 65% sensitivity on scanning of both upper and lower extremity joints and only 18% on scanning of the crystal-proven joint. The sensitivity was 90% in tophaceous gout, but remained inadequate when evaluated on the basis of individual erosive lesions. The detection of MSU deposits by DECT may relate to their density and this could potentially be improved with an adjustment of algorithm input parameters.



Tophaceous gout: hand. Large tophi are evident in the fingers on clinical examination (panel A) and with 3D volume rendering (panel B). With DECT (panel C), MSU deposits (evident by their green color) conform to the areas of tophaceous deposits, but are sparse in some affected joints and absent in others (e.g. little finger DIP and long finger PIP).

Relationship Between the Magnitude of Bone Formation in the Anterior Vertebral Corners, As Assessed through 18F-Fluoride Uptake, and Lumbar Spine Bone Mineral Density in Patients with Ankylosing Spondylitis.

Seung-Geun Lee[1], Eun-Kyoung Park[1], Geun-Tae Kim[2], Sang-Yeob Lee[3] and Joung-Wokk Lee[4]. [1]Divsion of Rheumatology, Department of Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Kosin University College of Medicine, Busan, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Dong-A University College of Medicine, Busan, South Korea, [4]Divsion of Rheumatology, Department of Internal Medicine, Busan St. Marys center, Busan, South Korea.

Background/Purpose: 18F-fluoride uptake represents active osteoblastic bone synthesis. We investigated the relationship between the magnitude of bone formation in anterior vertebral corners, as assessed through 18F-fluoride uptake on positron emission tomography (PET) and lumbar spine bone mineral density (BMD) in patients with ankylosing spondylitis (AS).

Methods: Twelve male patients with AS who was biologics-naïve underwent whole body 18F-fluodride PET and dual energy X-ray absorptiometry (DXA). The maximum standardized uptake value (SUVmax) of 18F-fluoride uptake at the anterior vertebral corner (L1 upper to L4 lower) was analyzed to determine the degree of active bone formation; the BMD of the lumbar spine in the AP (L1 to L4) and lateral (L2 to L4) projections was measured using DXA (Figure 1). At each lumbar vertebra level, the relationship between the sum of the SUVmax in the upper and lower anterior vertebral corners and the BMD of the corresponding lumbar vertebral body was assessed using a generalized estimating equation (GEE) to adjust within-patient correlation.

Results: A total of 48 lumbar vertebrae were analyzed. In correlation analyses, the sum of SUVmax in upper and lower anterior vertebral corners positively correlated with in both the lumbar AP (Spearman correlation coefficient=0.273, p=0.039) and lateral spine BMD (Spearman correlation coefficient=0.206, p=0.04). In the GEE model, the sum of SUVmax in upper and lower anterior vertebral corners was significantly associated with the both lumbar AP (β=0.012, p=0.002) and lateral spine BMD (β=0.013, p<0.001). This association remained significant after adjusting for disease duration and the presence of syndesmophytes.

Conclusion: Active bone formation in the anterior vertebral corners, as assessed through 18F-fluoride uptake on PET was associated with increased BMD of corresponding vertebral bodies in patients with AS. This finding suggests that the precise measurement of lumbar spine BMD using DXA can be hampered by active bone formation in AS.

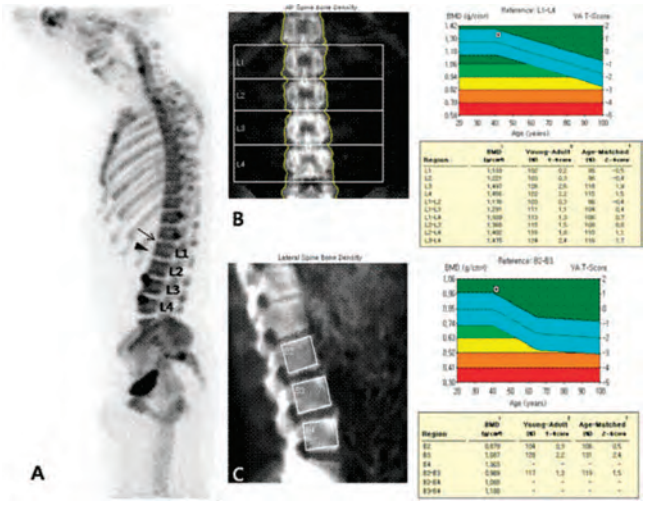

Figure 1. 18F-fluoride positron emission tomography (PET) scan (A) and dual energy X-ray absorptiometry evaluating bone mineral density in the AP (B) and lateral (C) projection of a 42-year-old man with ankylosing spondylitis. On PET scan, the maximum standardized uptake value of 18F-fluoride uptake in the upper (arrow in A) and lower (arrowhead in A) parts of the anterior vertebral corner was measured from L1 to L4.

The Craniocervical Junction in Ankylosing Spondylitis: A Computed Tomography Based Study.

Gleb Slobodin[1], Arsen Shpigelman[1], Hanna Dawood[1], Doron Rimar[2], Simona Croitoru[1], Nina Boulman[2], Michael Rozenbaum[2], Lisa Kaly[1], Itzhak Rosner[1] and Majed Odeh[1]. [1]Bnai Zion Medical Center, Haifa, Israel, [2]Bnai Zion Medical Center / Technion Faculty of Medicine, Haifa, Israel.

Background/Purpose: Available studies of craniocervical junction (CCJ) involvement in ankylosing spondylitis (AS) are based on conventional radiography, which has limited ability in the definition of many elements of the CCJ. The goal of the present study was to describe the spectrum of computed tomography (CT) findings in the CCJ in a cohort of patients with AS.

Methods: CT scans of the cervical spine of 11 patients with AS were reviewed and imaging findings related to the CCJ assessed. The standard anatomic intervals describing the CCJ were measured and compared to accepted normal standards. Findings, representing pathology were described, categorized by localization and relation to joints or ligaments of the CCJ.

Results: All patients were males with median age of 48 years and median disease duration of 20 years. The calculated median modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) for the cervical spine was 8.5, ranging from 0 to 27. Disease-related changes in one or more elements of the CCJ were detected in all patients. Patients with AS had a strong tendency to the narrowing of the atlanto-occipital joints and atlanto-dental interval, with some patients demonstrating complete fusion of these articulations. Atlanto-occipital joints were involved in 8 patients, while 3 patients had disease of the atlanto-dental articulation. Enthesopathy of the CCJ was observed in 7 patients. Significant changes of CCJ were observed also in patients with very low mSASS.

Conclusion: The CCJ is frequently involved in AS patients with advanced disease and may be independent on the mSASSS. Both articulations and ligaments of CCJ may be affected in AS patients.

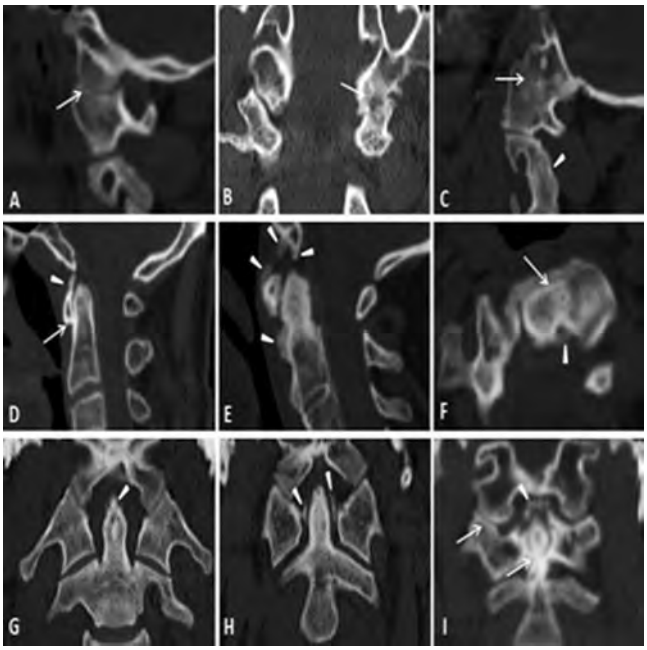

Fig 1. Ankylosing spondylitis of craniocervical junction.

1. Mild atlanto-occipital joint space narrowing (arrow), saggital view
2. Significant narrowing of the left atlanto-occipital joint with erosion (arrow) and osseous sclerosis; right atlanto-occipital joint looks normal
3. Total ankylosis of the atlanto-occipital joint (arrow) with secondary osteopenia. Fusion of C2 and C3 parts is also seen (arrowhead)
4. Anterior atlanto-dental interval shortening (arrow) and ossification of the anterior atlanto-occipital ligament (arrowhead)
5. Severe osseous sclerosis of the dens and C1 arch. Rude proliferative enthesopathy of the anterior longitudinal ligament and ossification of the occipital attachment of the apical ligament (arrowheads)
6. Ankylosis of the atlanto-axial joint (arrow), axial view; ossification of the left part of the transverse ligament (arrowhead)
7. Apical ligament enthesopathy (arrowhead), coronal view
8. Transverse ligament ossification (arrowheads), coronal view
9. Alar ligament ossification (arrowhead), coronal view. Narrowing of the right atlanto-occipital and atlanto-axial joints are seen (arrows)

Abatacept Related Infections: No Association with Gammaglobulin Reduction. Valquiria Dinis, Vilma S. T. Viana, Elaine P. Leon, Clovis A Silva, Carla G.S. Saad, Julio C. B. Moraes, Eloisa Bonfá and Ana C.M. Ribeiro. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: A recent study reported that abatacept (ABA) reduces rheumatoid arthritis (RA) related autoantibodies and gammaglobulins levels. However, the possible association of these findings with infections was not assessed. The aim of this study was, therefore, to evaluate immunoglobulins levels and infections in RA patients treated with ABA compared to anti-TNF agents, biological agents without any effect in immunoglobulin production.

Methods: Eighteen RA (ACR criteria) patients undergoing abatacept (ABA-RA) were selected and compared to 18 patients treated with anti-TNF (aTNF-RA) agents. Total and specific (IgG, IgM and IgA) gammaglobulin levels were assessed before and 6 months after biological treatment. Before entry, all patients were vaccinated for influenza/ pneumococcus and they were evaluated for tuberculosis. A systematic clinical screening protocol for infection was performed before each dose and at least monthly and when indicated virus, bacteria and fungus etiologies were investigated. Central nervous system, upper/lower respiratory tracts, cutaneous, gastrointestinal and genitourinary infections were classified in mild/moderate or severe (hospitalization). Demographic, clinical and laboratory data were also collected. Exclusion criteria were: low gammaglobulin level at baseline (<0.7) and previous abatacept or rituximab treatments.

Results: At baseline, median current age (55 vs. vs. 53 years, $p=0.96$), frequencies of female gender (78 vs. 78%, $p=1.0$), DAS28 (5.73 vs. 5.67, $p=0.34$), ESR (21.5 vs. 22mm/1sth, $p=0.84$.), CRP (15.5 vs. 12mg/dL, $p=0.37$) and lymphocyte counts (2,200 vs. 1,800/mm^3, $p=0.42$) were comparable in ABA-RA and aTNF-RA groups. Medians of gammaglobulin (1.4 vs. 1.35 g/dL, $p=0.71$), IgG (1167.5 vs. 1078.5 mg/dL, $p=0.84$), IgM (107.2 vs. 112.6 mg/dL, $p=0.38$) and IgA (333 vs. 322 mg/dL, $p=0.74$) were also alike in both groups. At 6 months, median percentage variations of gammaglobulin levels from baseline were distinct with a significant reduction for ABA-RA compared to aTNF-RA: total (−20 vs. +4%, $p<0.001$), IgG (−11 vs. +8 %, $p<0.001$), IgM (−15 vs+26%, $p<0.001$), IgA (−13 vs. +2%, $p=0.002$). Frequency of infections was similar in both groups (61 vs. 67%, $p=0.73$) with only one severe infection in ABA–RA and no death. Respiratory tract was the most frequent site in both groups (33 vs. 50%, $p=0.34$) followed by skin (29%) in aTNF-RA and urinary tract (28%) in ABA-RA. Of note, antibiotics or antifungal therapy were indicated less often for ABA than aTNF (44 vs. 85%, $p= 0.028$). ABA patients with and without infections had comparable levels at baseline and 6 months of IgG ($p=0.28$ and $p=0.08$) and IgM ($p=0.78$ and $p=0.83$).

Conclusion: The present work provides novel data demonstrating that infection in ABA-RA patients is not associated with the observed reduction in gammaglobulins induced by this co-stimulatory agent. Infections seems, however, to be less severe with this agent than with aTNF agents.

2152

Frequency of Postoperative Deep Infection in Patients with Rheumatoid Arthritis. Masayuki Azukizawa and Hiromu Ito. Kyoto University, Kyoto, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is known to be associated with an increased risk of serious infection. It has been discussed about the risk of the surgical site infection in the RA patients. However there are few reports about the postoperative deep infection in those patients. The aims of the study were to investigate the postoperative deep infection in RA patients treated in our institution and to clarify the frequency of the postoperative deep infection.

Methods: We reviewed a total of 696 orthopaedic surgeries for RA patients underwent between January 2004 and December 2013. We investigated the cases of deep infection after surgery, the sites of infection, and surgical techniques. We researched the postoperative deep infection free rate for the RA patients.

Results: The mean follow-up period was 4.7 years. 27.3% of all RA patients used Biological DMARDs. Twenty-five cases (3.6%) were suffered from the postoperative deep infection. Infection sites (surgical procedures) are 5 hips (bipolar hemiarthroplasty and total hip arthroplasty), 6 knees (total knee arthroplasty), 6 elbows (total elbow arthroplasty), one shoulder (total shoulder arthroplasty), 2 hands (metacarpophalangeal joint arthroplasty and proximal interpharangeal joint arthroplasty), one ankle (ankle arthrodesis) and 4 spines (Magerl technique, cervical posterior fixation, transforaminal lumbar interbody fusion). According to the Kaplan-Meier survival analysis, the cumulative deep infection free rate of all patients in 3 months, in 2 years and in 5 years was 98.7%, 97.8%, and 97.0%, respectively. That of the patient treated with biologic DMARDs was significantly lower than that of without biologic DMARDs. (Log-rank Test: $p = 0.0068$)

Conclusion: These results suggest that the postoperative deep infection is likely to occur within the first 3 months after surgery in the RA patients, and that the use of biological DMARDs is a risk factor for postoperative deep infection. We should pay more attention to the postoperative deep infection within 3 months of a procedure.

Clinical Characteristics and Outcomes in Synovial Fluid Culture-Negative Septic Arthritis. Sarah B. Lieber, Ziv Paz and Robert H. Shmerling. Beth Israel Deaconess Medical Center, Boston, MA.

Background/Purpose: Delays in diagnosis and treatment of septic arthritis may be associated with significant morbidity. While many patients with suspected or proven septic arthritis are treated surgically, aggressive surgical intervention may be unnecessary when the diagnosis is not secure. This includes patients with negative synovial fluid cultures, representing up to 40% of patients with clinically suspected septic arthritis. We aim to characterize patients with presumed septic arthritis who were treated surgically, but who had negative synovial fluid cultures. This may help predict which patients could be treated safely without surgical intervention.

Methods: We conducted a restrospective cohort study of patients 18 years and older admitted to a single tertiary care center from January 2010 to May 2014 with a presumptive diagnosis of septic arthritis leading to operative management. Patients were stratified into culture-positive and culture-negative groups based on synovial fluid testing. Length of hospital stay (LOHS) was designated as the primary outcome. Secondary outcomes included 60-day readmission rate and establishment of an alternative diagnosis to explain the index admission within a year of discharge.

Results: Of 208 patients with clinically suspected septic arthritis who underwent surgical intervention, 90 (43.3%) were synovial fluid culture-positive. The culture-positive and culture-negative groups were similar with respect to gender (approximately half were female), age (mean of 63 years), frequency of prosthetic joint involvement (about 60%), and frequency of knee involvement (about 60%). For the culture-positive group, mean LOHS and 60-day readmission rate were 11.4 days and 26.7%, respectively; in the culture-negative group, mean LOHS and 60-day readmission rate were 9.9 days and 36.4%, respectively ($p = 0.09$ for LOHS; $p = 0.18$ for 60-day readmission rate). An alternative diagnosis to explain the index admission was made in 3 (3.3%) cases in the culture-positive group and in 10 (9.3%) cases in the culture-negative group ($p = 0.16$). Among patients with native joints, mean LOHS, 60-day readmission rate, and frequency of alternative diagnosis did not differ significantly between the culture-negative groups.

Conclusion: In our medical center, the majority of patients with clinically suspected septic arthritis managed operatively had negative synovial fluid cultures at the time of diagnosis. While those with positive and negative synovial fluid cultures had similar baseline features, we observed a trend toward shorter length of hospital stay and more alternative diagnoses in the culture-negative group. The inclusion of additional presenting features (currently underway), including the presence of comorbidities, prior use of antibiotics, systemic signs of infection, and synovial fluid characteristics, may identify a subset of patients with suspected septic arthritis who may be managed safely without surgery.

Risk for Developing Adult T-Cell Leukemia in Patients with Human T Lymphotropic Virus Type-I Carrier Receiving Immunosuppressive Therapy. Kensuke Nakanishi[1], Rita Mcgill[2] and Mitsuyo Kinjo[1]. [1]Okinawa Chubu Hospital, Uruma City Okinawa, Japan, [2]AGH Nephrology Associates, Pittsburgh, PA.

Background/Purpose: Human T-lymphotropic virus type-I (HTLV-1) is a retrovirus associated with Adult T-cell leukemia (ATL) that is commonly seen in endemic areas. Several case reports suggest that immunosuppressants, including biologic agents, may be related to development of ATL in HTLV-I carriers. The purpose of this study was to evaluate the risk for developing ATL in HTLV-1 carriers who received immunosuppressive therapy for rheumatic or inflammatory bowel diseases, or cancer.

Methods: Medical records were reviewed at Okinawa Chubu Hospital to locate all HTLV-1+ patients from 2010 to 2013. After excluding 8 renal transplant patients, there were 727 HTLV-1+ patients. Incidence and progression of ATL were compared between subjects with and without immunosuppressive therapy. Data were collected on clinical features, medications and peripheral smears.

Results: We identified 83 HTLV-1+ subjects who received immunosuppressive therapy, including prednisolone, disease-modifying anti-rheumatic drugs (DMARDs) or biologic agents: 52/83 (64%) had rheumatic diseases. 90 subjects (12%) had non-ATL malignancy including solid cancer and hematological malignancy with or without chemotherapy (Table). Median observation period was 26 months (2–50) in patients receiving immunosuppressive therapy, and 26 months (2–50) in controls. Incidence of ATL did not differ between subjects on and off immunosuppressive therapy (P=0.6). In 7 patients on biological agents (5 etanercept, 1 infliximab and 1 abatacept), no ATL occurred during the observation period (median 22 months, range 9–50).

Conclusion: No cases of ATL developed among HTLV-1+ patients on immunosuppressants over an observation period of 26 months. Immunosuppressive therapy may not promote development of ATL in HTLV-1+ patients with rheumatic diseases.

	Immunosuppressive therapy (n=83)	P	Non-ATL malignancy (n=90)	P	Control (N=542)
Age + SD years	64 + 14	0.002	73 + 12	0.12	70 + 17

Chikungunya Fever in Patients Under Biologics. Lauren Brunier[1], Katleen Polomat[2], Christophe Deligny[2], Veronique Dehlinger[3], Patrick Numeric[3], Georges Jean-Baptiste[3], Serge Arfi[2] and Michel De Bandt[4]. [1]Unit of rheumatology, CHUM, 97200 Fort de France, France, [2]unit of internal medicine, Fort de France, France, [3]Unit of rheumatology, CHUM, Fort de France, France, [4]Hopital Zobda-Quitman. CHU La Meynard., Fort de FRance, France.

Background/Purpose: Chick is an epidemic disease due to an arthropod-borne virus (*Alphavirus*) transmitted by *Aedes* mosquitoes. CHIKV causes an acute illness with a febrile phase, followed by a period of severe polyarthritis that can persist for long time. There is no specific treatment, the best prevention is mosquito control and avoidance of bites. Martinique (French West Indies) is currently experiencing an outbreak of CHIK with 40 000 reported cases (June 1st). No data is available regarding the prognosis of Chikungunya in patients under biologics. We have observed 22 patients with Chik infection while on biotherapy and DMARDS for rheumatic diseases, between January and May 2014.

Methods: Physicians prescribing biologics were asked to declare patients under biologics experiencing Chik. For each patient we collected diseases characteristics and course, current treatment (steroids, immunosuppressant, biologics. . .), changes in the treatment during infection, and outcome. 22 patients were included, all with a diagnosis confirmed by PCR (20/22) or serology.

Results: Among these patients were 19 women and 3 men, 3 Caucasians and 19 Afro-Caribbean's. There were 5 spondyloarthritis (3 associated with Crohn), 1 psoriatic rheumatism, 2 systemic lupus, 1 antisynthetase syndrome and 13 RA. 17 had methotrexate (mean dose 21.6 mg), 3 Plaquenil, 2 Imuran, 1 cellcept, 2 cyclophosphamide. 11/22 were under steroids (mean dose of 8.6 mg / d). All experienced fever (mean duration 1.7 day), skin rash (15/22, mean duration 1.3 d), and acute disabling polyarthritis (mean pain VAS 8.4, mean SJC 9.6, mean TJC 6.8) for a mean 11.5 days duration. Nine had back pain and 4 tenosynovitis. None of them showed any organ failure, one single episode of transient thrombopenia was noted. None of them was hospitalized for Chik. Analgesic treatment (alone 4/22), associated with NSAIDs (17/22) or prednisone (1/22) and rest were sufficient to overcome the crisis. All but one patient maintained their previous treatment (DMARDS, Biologic, steroids. . .) without specific complication. All patients were able to differentiate between Chik related complains and those related to their preexisting condition. Mean clinical disease scores before and after Chik (DAS, BASDAI, SLEDAI) remained unchanged.

Conclusion: This is the first report of the occurrence of Chik in patients under biologics. Patients under biologics are at increased risk for serious infections either viral or bacterial, but no data has been published regarding Chik. This study was not conducted to discover all cases of Chik among patients under biologic. Chik does not seem to be deleterious in patients under biologics who do not exhibit more severe or prolonged disease than common forms. Chik does not seem to aggravate pre-existing disease. It does not seem necessary to modify the basic treatment of rheumatism in the announcement of a Chik as the clinical pictures observed in these patients are quite benign. NSAIDs and best rest are mostly effective. Chik does not seem harmful in patients receiving biological and this issue should be given to travellers.

Persistent Arthralgia Following Chikungunya Fever. Anna Kristina Gutierrez-Rubio and Ester Penserga. Philippine General Hospital, Manila, Philippines.

Background/Purpose: Chikungunya fever is a reemerging viral infection in the Philippines and neighboring countries. Persistent arthralgia following Chikungunya infection has been observed during previous epidemics, but few studies have discussed this aspect of the disease.

Methods: Adult patients who were diagnosed to have Chikungunya fever were included in this study. Patients were assessed at the time of acute infection and were followed-up at least 12 months after the acute disease occurred. Patients were asked questions regarding musculoskeletal symptoms and were examined on follow-up.

Results: Fourteen patients were included in this study. Ten (71%) were female, and the mean age was 31.67± 14.23 years. Mean duration of follow-up was 13.9 months. None of these patients reported a history of preexisting arthralgia. Eight (57%) had arthritis lasting at least 6 weeks following the acute infection, with a mean duration of 13.6 ± 5.72 weeks. Seven of the 14 patients (50%) had persistent arthralgia, with five (71%) having intermittent arthralgia, and 2 (29%) having continuous arthralgia. Two patients had recurrent chronic arthritis. One patient had a traumatic fracture of the third right metatarsal on the third month of illness. Arthralgia was symmetric and polyarticular in all cases, with the ankles being the most commonly affecred joint area (71%).

Conclusion: Chikungunya can result in severe, debilitating arthralgia that affects daily activities, and may persist for as long as a year. Further studies are needed to determine the prevalence of persistent arthralgia, identify risk factors, and establish the real burden of disease.

Disclosure: A. K. Gutierrez-Rubio, None; **E. Penserga**, None.

Background/Purpose: Tumor necrosis factor alpha inhibitors (anti-TNF) are a breakthrough for the treatment of inflammatory rheumatic diseases and tuberculosis (TB) is the prevailing and vitally important infectious complication. This retrospective data analyzes the risk of tuberculosis reactivation and demographic features of patients treated with anti-TNF drugs in Turkey, where TB is still a widespread endemic disease.

Methods: The study is held by **Tu**rkish Mul**t**i-centered **I**nvestigators **P**latform in Rheumatology (TULIP).10.434 patients treated with anti-TNF drugs, 73 (0.69%) patients were diagnosed with TB (M/F: 39/34), 7.695 patients with accurate and complete data of laboratory and clinical history were enrolled as control group.

Results: Among 73 patients diagnosed with TB, 38 patients were diagnosed with ankylosing spondylitis, 25 with rheumatoid arthritis, 4 with psoriatic arthritis, 5 with Behcet's syndrome, and a patient with vasculitis. TB frequency in patients using infliximab (1.27%) was significantly higher than patients using etanercept (0.3%) and adalimumab (0.57%) ($p < 0.001$ and 0.008, respectively). Six patients out of 73 TB cases (8.2%) died under follow-up. Thirty-four cases (46.6%) out of 73 TB patients had pulmonary tuberculosis. In the logistic regression model, type of anti-TNF (infliximab) (OR: 3.4, 95%CI: 1.88–6.1, $p=0.001$) and insufficient prophylaxis (<9 months) (OR: 3.15, 95%CI: 1.43– 6.9, $p=0.004$) were independent predictors of TB development among anti-TNF treated patients.

Conclusion: Our results suggest that TB is an important complication of anti-TNF therapies in Turkey, where the disease is still endemic. TB chemoprophylaxis less than nine months and the use infliximab therapy were independent risk factors for TB development.

Severe Neutropenia in Patients with Rheumatic Diseases at a Tertiary Care Hospital in South Korea. Chang-Nam Son[1], Ji-Min Kim[1], Sang-Hyon Kim[1], Soo-Kyung Cho[2], Yoon-Kyoung Sung[2], Tae-Hwan Kim[2], Jae-Bum Jun[2], Sang-Cheol Bae[3] and Dae-Hyun Yoo[2]. [1]Keimyung University School of Medicine, Daegu, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: Neutropenia is relatively common in patients with rheumatic diseases. Neutropenia is characterized by an absolute neutrophil count (ANC) of less than 1,500/μL. It is associated with diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) or it may be caused by the side effects of medications or accompanying infection. The risk of neutropenia-related infection increases with an ANC near 1,000/μL (moderate neutropenia) and rises dramatically as ANC falls below 500/μL (severe). Some patients with neutropenia require hospitalization in an isolation ward and are administered recombinant human granulocyte colony stimulating factor (rhG-CSF) or antibiotics to treat neutropenic fever. Our aim was to investigate the possible causes and clinical characteristics of severe neutropenia in Korean patients with rheumatic diseases.

Methods: The study participants (n=64) were enrolled from September 2003 to August 2013 from a population of patients with rheumatic diseases who were admitted to a tertiary care center. These subjects had severe neutropenia and received rhG-CSF at least once during hospitalization. We retrospectively examined data of the subjects including age, gender, initial diagnosis, concomitant medications, serial complete blood count, and bone marrow biopsy.

Results: The most frequent initial diagnoses were SLE (n = 35; 55%), RA (n = 13; 20%), and inflammatory myositis (n = 6; 9%). The possible causes of severe neutropenia were therapeutic drugs (n = 31; 48%), association with lupus (n = 17; 27%), infection (n= 12; 19%), and hemophagocytic syndrome (n = 4; 6%). During hospitalization, nine deaths occurred (14%, 9/64). Mortality was higher in patients with sepsis than in patients with neutropenia associated with other causes (Table). Pneumonia was the most common cause of sepsis in patients with neutropenia (58.3%, 7/12). The frequency of sepsis and death was higher in the long-term recovery group (≥ 28 days) than in the other groups (< 7 days and 7–27 days).

Possible cause	Drug Toxicity (n = 31)	Disease activity of SLE (n = 17)	Sepsis (n = 12)	*P*-value
Age (yrs, Mean±SD)	41.7 ± 17.4	28.6 ± 8.8	50.1±15.3	0.001
Women, no. (%)	24 (77.4)	15 (88.2)	10 (83.3)	0.647
Disease duration (yrs, Mean±SD)	7.7 ± 8.8	4.2 ± 3.7	9.7 ± 12.9	0.552
Any immunosuppressive drug	23 (74.2)	9 (52.9)	9 (75.0)	0.238
Leucocytes (Mean±SD, /μL)	1258.1 ± 653.6	1117.6 ± 304.6	1058.3 ± 550.1	0.581
Hemoglobin (Mean±SD, g/dL)	9.1 ± 2.2	9.6 ± 1.5	8.6 ± 1.5	0.401
Platelets (Mean±SD, X 10^3/μL)	118.9 ± 82.5	132.9 ± 77.4	115.9 ± 70.7	0.688
Neutrophils (Mean±SD, /μL)	262.9 ± 462.7	376.2 ± 313.0	366.3 ± 471.1	0.301
Pancytopenia, no. (%)	22 (71.0)	11 (64.7)	9 (75.0)	0.828
Recovery time of neutropenia	5.3 ± 5.3	8.1 ± 13.9	19.3 ± 37.1	0.515
Death, no. (%)	4 (10.5)	1 (5.6)	4 (50)	0.033

Conclusion: In patients with rheumatic diseases, drug toxicity was the most common cause of severe neutropenia. Among the causes of neutropenia, sepsis is of greatest concern; therefore, physicians need to pay attention to the early detection of infection.

Human T-Lymphotropic Virus Type 1 Biomarkers in Patients with Rheumatoid Arthritis. Akihiko Okayama[1], Masako Iwanaga[2], Yasuko Sagara[3], Toshihiko Hidaka[4], Kunihiko Umekita[1], Kazumi Nakano[5], Toshiki Watanabe[5], Yoshihisa Yamano[6], Yoshiro Horai[7], Hideki Nakamura[8] and Atsushi Kawakami[8]. [1]University of Miyazaki, Miyazaki, Japan, [2]The Jikei University of School of Medicine, Tokyo, Japan, [3]Japanese Red Cross Kyushu Block Blood Center, Fukuoka, Japan, [4]Zenjinkai Shimin-No-Mori Hospital, Miyazaki, Japan, [5]Graduate School of Frontier Sciences, The University of Tokyo, Tokyo, Japan, [6]St. Marianna University School of Medicine, Kanagawa, Japan, [7]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [8]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background/Purpose: Human T-lymphotropic virus type 1 (HTLV-1) is the causative agent of adult T-cell leukemia (ATL). It has been debated recently whether or not immunosuppressive agents for HTLV-1 carriers with a variety of inflammatory/immunological conditions can increase the risk of developing ATL, which is of important in terms of the pros and cons of anti-rheumatic treatment for HTLV-1 positive patients with RA. Through HTLV-1 biomarkers, whether the immunosuppressive medicines or biologics for HTLV-1 positive rheumatoid arthritis (RA) patients may affect adversely to the risk of ATL was speculated.

Methods: HTLV-1 antibody was screened for 808 patients with RA diagnosed in two regions in Japan, Nagasaki and Miyazaki prefectures, endemic areas of HTLV-1 infection. Among those, HTLV-1 positive RA patients treated with anti-rheumatic medicines including biologics (anti-TNFs, tocilizumab, and abatacept) were selected to be subjects for this study and evaluated about the levels in blood samples of HTLV-1 proviral load (PVL) by real-time PCR, antibody titer by particle agglutination assay, and soluble IL-2 receptor (sIL-2R) by enzyme immunoassay. The levels of the biomarkers were compared with those of age and sex matched asymptomatic HTLV-1 carriers (ACs) using Wilcoxon rank sum test.

Results: The HTLV-1 seroprevalence in patients with RA was 8.2% (66/808). Blood samples were available in 33 among the 66 HTLV-1 positive RA patients. The median HTLV-1 PVL of the 33 patients was 0.52 copies per 100 peripheral blood mononuclear cells (PBMCs), which was lower than that of age and sex matched 99 ACs (1.0 copy per 100 PBMCs) (p=0.08). The median antibody titer of the 33 patients was $2^{8.9}$, which was lower than that of age and sex matched 99 ACs ($2^{9.7}$) (p=0.03). The level of sIL-2R was not different between 2 groups (p=0.10).

Conclusion: The HTLV-1 seroprevalence in patients with RA in the endemic area in Japan was higher than we expected. Both HTLV-1 PVL and antibody titer in HTLV-1 positive RA patients treated with anti-rheumatic medicines showed lower values comparing with those in ACs. These findings, when viewed in light of a previous report that high HTLV-1 PVL is considered as the risk factor for developing ATL, suggest that treatment by anti-rheumatic medicines including biologics may not necessarily increase the risk for ATL development in HTLV-1 positive patients with RA. Further long-term follow-up study can determine the safety of anti-rheumatic treatment in HTLV-1 positive patients with RA.

2161

Interest of Systematic Lyme Serology in Context of Recent Onset Arthritis. Dewi Guellec[1], Valérie Narbonne[1], Divi Cornec[2], Thierry Marhadour[3], Maxime Dougados[4], Jean-Pierre Daures[5], Sandrine Jousse-Joulin[1], Valerie Devauchelle[6] and Alain Saraux[7]. [1]CHU Brest, Brest, France, [2]Brest Occidentale University, Brest, France, [3]CHU de la Cavale Blanche, Brest, France, [4]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [5]INSERM, Montpellier, France, [6]Brest university medical school, EA 2216, Lab Ex, INSERM, IGO,UBO and CHU de la Cavale Blanche,, Brest, France, [7]CHU Brest and EA 2216, UBO, Brest, France.

Background/Purpose: Lyme arthritis is a late manifestation of a tick-transmitted spirotechal infection, mainly caused by *Borrelia burdorgferi*. Lyme arthritis typically presents as a mono- or oligoarticular arthritis primarily affecting the large joints. However, various presentations including polyarthritis and polyarthralgias are possible (*Puius et al.*). It results that spirotechal infection is sometimes evoked by the rheumatologist in context of recent-onset arthritis, even in non-endemic regions.

The aim of this study was to determine the utility of systematic Lyme serology in a French cohort of patients with recent-onset arthritis, by determining the seroprevalence of Lyme antibodies according to the region of inclusion, the prevalence of Lyme arthritis and the diagnostic accuracy of serological testing.

Methods: The present study is an ancillary project from a French prospective and multicentric cohort study monitoring clinical, biologic, and radiographic data for patients with inflammatory arthritis lasting 6 weeks to 6 months (*Combe et al.*). Patients were included during the period of December 2002 to March 2005 in 14 regional centers. Antibodies against *Borrelia* at baseline were detected in 2006, using an IgG and IgM Immune Assay, from blood samples collected at baseline, without Western blot confirmation. This procedure was conducted independantly of the physician's strategy to detect

a possible spirotechal infection. The final diagnosis was recorded after two years of follow-up. Global and regional seroprevalence of Lyme antibodies were determined. The proportion of patients with a final diagnosis of Lyme arthritis and the diagnostic accuracy of Lyme serology in context of recent-onset arthritis were recorded. The clinical and biological characteristics of patients according to the results of Lyme serology were analyzed in detail.

Results: Among the 814 patients included in the ESPOIR cohort, 810 were tested for the presence of *Borrelia* antibodies (99.5%). Of these patients, 7,6% had positive serology (62/810) and 2,6% had equivocal results (21/810). Average positivity of Lyme serology varied significantly by region of inclusion (2.4% - 14.9%), the highest value being found in an endemic area. After two-years of follow-up, no cases of definite Lyme arthritis were identified, although it was the main diagnostic hypothesis at baseline for 2 patients. Thus, diagnostic accuracy of lyme serology in context of recent-onset arthritis seems very low despite a relatively high proportion of patients having an IgG positive serology. Additional analyzes revealed an association between the positivity of the immune assay and renal failure (p: 0.0005).

Conclusion: In France, where there is an heterogeneous risk of borrelia infection by region, the diagnosis of polyarthritis linked to borrelia was never considered by the clinician. In contrast, serology, even IgM with positivity, is not rare. This study does not support the routine use of Lyme serology and highlight the risk of difficulty to interpret the results in a context of recent-onset arthritis and confirm the results previously obtained by other authors, in France and in the Netherlands (*van Burgel et al*, *Muller et al*.).

2162

Immunological Abnormalities in Adult Patients with Parvovirus B19 Infection: A study of 23 Cases. Edouard Pertuiset, Farid Kemiche, Mehdi Yahia and Isabelle Cerf-Payrastre. Centre Hospitalier René Dubos, Pontoise, France.

Background/Purpose: In adults, parvovirus B19 infection can induce joint symptoms and cutaneous manifestations which are known to be transient most of the time. It has been associated with the production of various antibodies directed against various autoantigens. In this study we report the immunological results in 23 adult patients with parvovirus B19 infection.

Methods: Between 1996 and 2014, 23 adult patients (mean age 35.4 ± 8.9 years; 19 women and 4 men) have been diagnosed with parvovirus B19 infection in our rheumatology department. All patients have been examined by a rheumatologist with a mean delay of 2 weeks after the onset of symptoms and had biological tests including autoimmunity in most cases. In all cases anti-parvovirus B19 IgM were present at a level greater than anti-parvovirus B19 IgG. All patients had arthralgias, 52% of them had mild arthritis and/or tenosynovitis. Cutaneous manifestations were observed in 65% of patients. In all patients, acute joint symptoms resolved in two months, except in one who developed a HLA-B27 negative spondyloarthropathy. Autoimmune tests included search for antinuclear antibodies (ANA) in all patients, rheumatoid factor (RF) in 19 patients, anti-keratine or anti-CCP antibodies in 11 patients, anticardiolipin antibodies (ACL) in 11 patients. Furthermore, C3 and C4 were evaluated in 19 patients and cryoglobulinemia was search in 13 cases.

Results: ESR was 29 ± 17 mm/1sth. Two patients had thrombocytopenia. Five patients (22%) had ANA at moderate levels (160 in 4 cases, 320 in one case) without any specificity (no case of anti-ENA or anti-DNA antibodies). RF was positive in 2 patients (10%) and no patient had anti-CCP antibodies. ACL antibodies were detected in seven cases (63%). In three cases diagnosed before 2009, they were IgG anti-ACL at low levels (20–28 U). Since 2009, our laboratory tests both IgG and IgM ACL antibodies: 4 patients had IgM ACL at levels ranged from 22 to 51 U (normal 0–19), without IgG ACL antibody. A decrease of C3 was observed in one patient (5%) and a decrease of C4 was present in 5 patients (26%). Search for cryoglobulinemia was positive in 6 cases (46%). In five cases it was a type III cryoglobulinemia at low level and in one case these level was too small for identification.

Conclusion: Some immunological abnormalities including ANA, RF, ACL antibodies, low C4 level and cryoglobulinamia are quite often encountered in parvovirus B19 infection in adults with rheumatologic symptoms. The presence of IgM ACL antibodies and mixed type III cryoglobulinemia appears frequent in our most recent experience. These abnormalities are asymptomatic and transient, but can lead to misdiagnosis and highlight some relationships between innate immunity activation and autoimmune response.

2163

Genetic Variants of *TNFAIP3* in Patients with HCV Related Lymphoma Are Associated with the Presence of Rheumatoid Factor (RF). Gaetane Nocturne[1], Saida Boudaoud[2], Caroline Besson[3], Frederic Davi[4], Danielle Canioni[5], Patrice Cacoub[6], Olivier Hermine[7] and Xavier Mariette[8]. [1]Paris sud university, Le Kremlin Bicetre, France, [2]INSERM U1012, Le Kremlin Bicêtre, France, [3]Paris Sud University, Le Kremlin Bicêtre, France, [4]Department of Pathology, Hôpital de la Pitié Salepetrière, Paris, France, [5]Service d'anatomo-pathologie, Hôpital Necker,, Paris, France, [6]Groupe Hospitalier Pitié Salpétrière, Service de Médecine Interne, DHU i2B, Paris, France, [7]Service d'hématologie, Centre de référence des mastocytoses, Hôpital Necker Enfants malades, Université Paris V, IFR Necker,, Paris, France, [8]Université Paris-Sud, Le Kremlin Bicêtre, France.

Background/Purpose: HCV chronic infection is associated with an increased risk of non-Hodgkin lymphoma (NHL) occurrence. HCV-associated NHL share homologies with primary Sjögren Syndrome (pSS)-associated NHL, and especially an association with chronic antigenic stimulation. *TNFAIP3* encodes the A20 protein that plays a key role in controlling NF-kB activation. We have previously demonstrated that genetic impairment of A20 plays a key role in lymphomagenesis in the context of pSS. The aim of this study was to assess the role of variants of *TNFAIP3* in patients with HCV related NHL.

Methods: Sixty-one cases with available germline DNA were drawn from the 116 patients included in the LymphoC study. Total exon sequencing of *TNFAIP3* was performed in a discovery set of 31 cases. Then 30 additional cases and 53 controls (HCV patients without NHL) were used for extension (ie genotyping of the rs2230926 and the TT>A dinucleotide). All our cases and controls were European. Case-only associations were tested with Fischer's exact test. Differences in lymphoma histologic type and immunological status were assessed using Fisher's exact test.

Results: Among the 61 cases, histology subsets were 23 diffuse large B cells lymphomas (DLBCL), 17 marginal zone lymphomas (MZL), 6 splenic marginal zone lymphoma (SMZL), 5 mantle cells lymphomas, 8 follicular lymphomas, 1 chronic lymphoid leukemia and 1 chronic EBV-related lymphoproliferation. RF and mixed cryoglobulinémie (MC) were present in 30/61 (49.2%) and 25/43 (58.1%) of the patients respectively. Among the 53 controls, RF and MC were present in 31/53 (58.5%) and 28/53 (52.8%) of the patients respectively. We found the rs2230926G variant in 6/61 (9.8%) patients with NHL and in 7/53 (13.2%) patients without NHL meaning that there was no association between this SNP and HCV-associated NHL (OR=0.72 [95%CI 0.22– 2.28] p=0.77). We did not find any association between the variant and the marginal zone subtype of the lymphoma. However, we found that, among NHL patients, the rs2230926G allele was associated with the positivity of RF (6/30 (20%) in RF+ patients compared to 0/31 (0%) in RF- patients, OR=16.7 [95%CI 0.9 – 311.5], p=0.01). We did not find any association between the rs2230926 variant and the presence of MC patients probably due to the amount missing data and the variability of the technic of detection.

Conclusion: Again in situation of chronic stimulation of RF+ B cells, a coding mutation of *TNFAIP3* leading to a small functional defect of A20 function and of control of activation of NK-kB, is enough for favoring the lymphomatous escape of these autoimmune B cells.

Self-Phospholipids Regulate Inflammation Via Activation of CD1d-Restricted T-cells and Induction of 'anti-inflammatory' Myeloid-Derived Suppressor Cells (MDSC). Ram Raj Singh[1], Cynthia Tran[1], Priti Prasad[1], Jing Wang[2], Dirk Zajonc[2] and Ramesh Halder[1]. [1]UCLA, Los Angeles, CA, [2]La Jolla Institute of Allergy and Immunology, La Jolla, CA.

Background/Purpose: Self-lipids play an increasingly appreciated role in immunity and inflammation. Lipid antigens are presented by CD1d and CD1a-d molecules in mouse and human, respectively, to T cells. Glycolipids (GL) such as βGluCer, and phospholipids (PL) such as phosphatidic acid (PA), phosphatidylcholine (PC), phosphatidylethanoloamine (PE), phosphatidylinositol (PI), and phosphatidylserine (PS), have been eluted and identified by mass spectrometry as natural human CD1d ligands, and PC and PE have been eluted from murine CD1d. Crystallography shows that complexes of CD1d bound to PL can exist. Diverse subsets of T cells that recognize self lipids have been reported, including invariant natural killer T cells (iNKT). Extensive work shows protective or pathogenic roles of GL αGalCer-reactive iNKT cells in a wide range of diseases. However, the functions of T cells that recognize abundant self PL are not known. Here, we identified and characterized self PL-reactive T cells (PLT), investigated their in vivo functions, and elucidated the cellular and molecular participants in PL mediated immune homeostasis.

Methods: CD1d tetramers were loaded with 8 PL or GL antigens, and cells analyzed by flow cytometry. Chemical binding of PL to CD1d was assessed by isoelectric focusing/gel shift analysis. CD1d-PA complex was crystallized by sitting drop vapour diffusion. Autoimmune hepatitis that is mediated by iNKT cells was induced by injecting concanavalin A (ConA), and assessed by serum ALT, morphology, and histology.

Results: CD1d tetramers loaded with PL, namely PA, PC, PE, PI, PS and BMP (bismonoacylglycerophosphate), identify 0.4–4% T cells in the lymphoid organs of wild-type and iNKT–deficient $J\alpha18^{-/-}$ mice but not in $CD1d^{-/-}$ mice. PLT cells don't recognize GL-loaded tetramers and don't respond to αGalCer, suggesting that PLT cells are distinct from iNKT cells. PLT cells expand, express CD69, and produce cytokines upon in vivo priming. Chemical binding and crystal structure show that PA binds CD1d in the absence of lipid transfer proteins, and is centrally located in the CD1d-binding groove opening for TCR recognition. Although PA bound slightly weaker to CD1d than a self GL, it competed with αGalCer to load onto CD1d. All PL tested profoundly inhibited the proliferation and cytokine production by iNKT cells. Such PL-induced inhibition of iNKT cells was abrogated upon depletion of granulocytes by gemcitabine that preferentially depleted the MDSC subset called monocyte-MDSC (mMDSC). Furthermore, PL induced IL-10 producing mMDSC that inhibited iNKT cell proliferation in an IL-10-dependent manner. Finally, treatment with a PL ameliorated ConA–hepatitis, reduced pro-inflammatory cytokines, granulocyte accumulation and $IFN\gamma^+$ mMDSC, but promoted $IL\text{-}10^+$ mMDSC that upon adoptive transfer reduced the incidence/severity of ConA–hepatitis.

Conclusion: We identified a new role for self PL that activate a distinct subset of CD1d-restricted T cells that inhibit iNKT cells by competitive inhibition and via induction of $IFN\gamma^-IL10^+$ mMDSC that ameliorate autoimmune hepatitis. These results have important implications for conditions with altered lipid metabolism and inflammation such as atherosclerosis and autoimmune disease.

Myeloid-Derived Suppressor Cells in Rheumatoid Arthritis: Friend or Foe? Fanlei Hu[1], Chunqing Guo[2], Xiang-Yang Wang[2] and Zhanguo Li[1]. [1]Peking University People's Hospital, Beijing, China, [2]Virginia Commonwealth University School of Medicine, Richmond, VA.

Background/Purpose: Although myeloid-derived suppressor cells (MDSCs) have been linked to T-cell tolerance, their role in rheumatoid arthritis (RA) remains exclusive. Here, we investigated the potential association of MDSCs with the disease pathogenesis using specimen collected from RA patients and the experimental model of collagen-induced arthritis (CIA).

Methods: The frequency of MDSCs in the peripheral blood and the synovial fluids of RA patients (n = 59), osteoarthritis patients (OA, n = 15), and healthy individuals (n = 20) was detected by flow cytometry. And their association with the disease severity and the levels of IL-17A was analyzed. Similarly, MDSCs in the peripheral blood, lymphoid tissues, inflamed paws, or synovial fluid and their association with disease severity, tissue inflammation, and the levels of pathogenic T-helper (Th) 17 cells was examined in CIA mice. The MDSCs in arthritic mice were also characterized for their phenotype, inflammation status, T-cell suppressive activity, and their capacity of pro-Th17 cell differentiation. The contribution of MDSCs to Th17 response was examined by co-culturing MDSCs with naïve $CD4^+$ T cells under Th17-polarizing conditions both in RA patients and mice. Moreover, their pathogenic role in RA was further revealed by antibody depletion of MDSCs in CIA mice.

Results: MDSCs expanded significantly in RA patients and in CIA mice, which were correlated positively with disease severity and an inflammatory Th17 response. While displaying T-cell suppressive activity, MDSCs from arthritic mice produced high levels of inflammatory cytokines (e.g., IL-1β, and TNF-a). Both human MDSCs ($CD11b^+CD33^+$) and mouse MDSCs ($CD11b^+Gr\text{-}1^+$) efficiently promoted Th17 cell polarization *ex vivo*. Elimination of MDSCs in CIA mice markedly ameliorated disease symptoms concomitant with reduced levels of Th17 cells.

Conclusion: Our studies revealed the unrecognized pathogenic role of MDSCs in RA with the capacity of driving Th17 cell differentiation. This cell population might be served as novel therapeutic target for RA.

Bim Suppresses the Development of Glomerulonephritis By Inhibiting M2 Polarization. Fu-Nien Tsai Northwestern University, Chicago, IL.

Background/Purpose: Only recently have monocytes and macrophages been accepted as critical players in the pathogenesis of SLE. However.very little is known regarding the molecular rheostats that control the actions of monocytes and macrophages and their state of polarization. Previous studies have shown that loss of Bim, a pro-apoptotic protein, in all cells leads to SLE-like disease and early mortality. We have shown that reduction of Bim alters macrophage function independent of its role in apoptosis. Thus, we hypothesize that Bim is essential in monocytes and macrophages to limit the development of SLE-like disease.

Methods: We generated mice lacking Bim specifically in myeloid cells ($Cre^{LysM}Bim^{flox/flox}$) and assessed mice at 8, 16, 24, 36 and 48 weeks of age for characterization of SLE-like disease. Macrophage turnover, activation, and polarization were examined *in vivo* and *in vitro*using flow cytometric analyses and luminex based assays.

Results: $Cre^{LysM}Bim^{flox/flox}$ mice displayed splenomegaly, lymphadenopathy, heightened amounts of serum pro-inflammatory cytokines, hypergammaglobulinemia, IC deposition in the kidney, proteinuria, GN, and early mortality as compared to $Bim^{flox/flox}$ and mice lacking Bim in either lymphocyte compartments. Bim functions independently of its role in apoptosis in macrophages and monocytes, since macrophages from $Cre^{LysM}Bim^{flox/flox}$ and from $Bim^{flox/flox}$ mice had equal BrdU uptake. Moreover, MyD88 is not necessary as $Cre^{LysM}Bim^{flox/flox}MyD88^{flox/flox}$ mice also developed SLE-like disease. The protein kinase Akt was increased in macrophages from $Cre^{LysM}Bim^{flox/flox}$ mice and was co-immunoprecipatated with Bim in wild type cells. Additionally, the BH3 domain, which is essential for its apoptotic function is necessary for suppressing inflammatory response in macrophages. Mixed bone marrow chimeras were sufficient to reduce development of SLE-like disease in $Cre^{LysM}Bim^{flox/flox}$ mice, which suggests that Bim may affect macrophage development or polarization. To this end, we show that Bim is necessary to prevent the skewing of macrophages towards M2, pro-fibrotic phenotype.

Conclusion: The expression of Bim in monocytes and macrophages is sufficient to inhibit SLE-like pathogenesis. These data suggest that Bim acts through its BH3 domain to reduce the intensity of inflammation and polarization status in macrophages through suppression the activity of Akt. These studies are crucial for understanding the development and the persistence of SLE, as well as for translational studies leading to the development of new targets for SLE.

Snapin Is Critical for Cathepsin D Activation and the Normal Lysosomal Function. Bo Shi, Qi Quan Huang, Robert Birkett, Renee E. Koessler, Andrea Dorfleutner, Christian Stehlik and Richard M. Pope. Northwestern University Feinberg school of Medicine, Chicago, IL.

Background/Purpose: Our recent data indicates that Snapin, a SNAP associated protein, is critical for maintaining healthy autophagy and monocytes to macrophage (MFs) differentiation which requires functional autophagy. Snapin and autophagosomes are increased in MFs from the joints of patients with rheumatoid arthritis. Reduction of Snapin hindered the maturation of autophagosomes, resulting in autolysosome accumulation and delayed bacterial clearance in macrophages. Failure to digest the sequestered cargos in

these vacuoles might have resulted from deficient capacity of lysosomal hydrolysis. Here, we examined cathepsin D activity, a major hydrolase in lysosomes, in macrophages following the forced reduction of Snapin.

Methods: The reduction of Snapin in primary human MFs was performed using siRNA, while in the J774A murine MF cell line it was reduced by infection with a lentiviral vector expressing Snapin shRNA. Cell fractions enriched with lysosomes were isolated using a density gradient separation method. The protein levels of non-active pro-form and active cathepsin D were detected by Western blot analysis. The active cathepsin D in cells was also detected by staining with bodipy-pepstatin A which binds to catalytic portion of cathepsin D. Autophagosomes were identified by the accumulation of LC3 punctae. Acidification of autophagosomes was assessed by transfection of tandem fluorescent LC3 plasmid expressing a tandem red (not pH dependent) and green (quenched at low pH) fluorescence-tagged LC3. **Results:** Following the reduction of Snapin, bodipy-pepstatin A staining was greatly reduced in lysosomes in primary human MFs, suggesting a reduction of active cathepsin D. The forced reduction of Snapin in MFs resulted in 30% reduction in the active form of cathepsin D, identified by immunoblot analysis, in whole cell lysates, compared to control MFs, while the pro-form of cathepsin D was slightly increased. Cathepsin D extracted from lysosome enriched fractions from Snapin reduced J774A MF cells showed a 40% reduction in the active form, but no reduction of the pro-form, indicating the cathepsin D activation was disturbed, rather than the delivery of hydrolases to lysosomes. Interestingly, cathepsin B activation was unchanged in both whole cell lysates and in lysosome enriched fractions. Cathepsin D is activated in a low pH environment. Disrupting the acidification process in lysosomes or in autophagosomes will reduce cathepsin D activation. The forced reduction of Snapin in HEK293 cells increased green LC3 punctae, indicative of an increased pH in the autophagosomes/autolysosomes.

Conclusion: Snapin in macrophages is necessary for cathepsin D activation in lysosomes and autophagosomes, preventing the maturation of autolysosomes, by limiting the degradation of cargo within the autophagosomes. Snapin may contribute to the pathogenesis of rheumatoid arthritis by maintaining healthy autophagy and monocyte to MF differentiation.

Extramedullary Myelopoiesis Drives Persistent Toll-like Receptor-Mediated Inflammation. Lehn K. Weaver[1] and Edward M. Behrens[2]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Many rheumatic diseases are driven by chronic, repeated activation of Toll-like receptors (TLR) causing the initiation and perpetuation of disease. However, TLR-activated innate immune cells undergo the well-known immunoregulatory phenomenon of TLR tolerance, whereby the initial activation of TLRs results in impaired proinflammatory responses to subsequent TLR stimuli. Therefore, it is unclear how TLR-driven inflammation persists *in vivo*. Our well-characterized model of repeated TLR9-driven inflammation demonstrates that repeated activation of TLR9 results in a feed-forward, interleukin (IL)-12-mediated inflammatory response culminating in systemic immunopathology rather than tolerance. Using this model, we dissect the cellular mechanisms utilized to bypass TLR9 tolerance *in vivo*.

Methods: *In vitro* mixed TLR9 sufficient and deficient cell cultures were stimulated with CpG1826, a TLR9 agonist, to demonstrate that IL-12 is a readout of cell-intrinsic TLR9 activation. Yet40 IL-12-reporter mice were treated with 4 doses of CpG1826 before tissue leukocytes were isolated and analyzed by flow cytometry to identify the IL-12-producing cells. Bone marrow, peripheral blood, and tissue leukocytes from CpG-treated mice were stained for myeloid progentor cell markers to determine if myelopoiesis is altered during TLR9-mediated systemic inflammation.

Results: We demonstrate that inflammatory monocyte-derived dendritic cells increase in frequency and total numbers during TLR9-mediated systemic inflammation, and are the key IL-12-producing cell in this model. To determine the origin of these inflammatory tissue-invading cells, we tested peripheral blood and bone marrow of CpG-treated mice to enumerate the number of inflammatory monocytes and myeloid progenitor cells. To our surprise, the total number of peripheral blood inflammatory monocytes and bone marrow myeloid precursors was unchanged during TLR9-induced systemic inflammation. In contrast, extramedullary myeloid precursors were markedly increased in peripherally inflamed tissues of CpG-treated mice.

Conclusion: Our data highlight an important mechanism whereby persistent TLR9 activation bypasses TLR tolerance *in vivo* by increasing extramedullary myelopoiesis. Increased extramedullary myelopoiesis provides a continuous source of new TLR9-responsive cells that perpetuates TLR-driven inflammation. These new insights into the mechanisms driving persistent TLR-mediated inflammation may lead to novel therapeutic targets to ameliorate TLR9-mediated rheumatic diseases by intervening to suppress TLR-driven extramedullary myelopoiesis.

Targeting ITGAM+ Cells Successfully Treats a Model of Anti-RNP-Associated Pulmonary Hypertension. Vineet Gupta[1], Yunjuan Zang[2], Karen Young[2], Jian Huang[2], Irina Fernandez[2] and Eric L. Greidinger[2]. [1]Rush University Medical Center, Chicago, IL, [2]University of Miami, Miami, FL.

Background/Purpose: Aggressive immunotherapy has shown modest effectiveness for pulmonary hypertension in anti-RNP Autoimmunity, but with high morbidity. We studied the ability of an ITGAM-targeted therapy that has been previously reported to have immunomodulatory properties to treat a model of this condition.

Methods: Following IACUC-approved protocols, study mice were adoptively transferred with splenic dendritic cells from anti-RNP-immunized syngeneic donor mice, and screened for elevations in serum Brain Naturietic Peptide (BNP) levels. Mice developing increased BNP levels received a single IV dose of the ITGAM-specific small molecule agonist Leukadherin-1 (LA-1), a chemically similar compound without ITGAM specificity (LA-C), or sterile PBS. Mice were then followed for BNP levels and/or underwent right heart catheterization to directly assess pulmonary circulation hemodynamics.

Results: The majority of splenic CD11c+ dendritic cells from anti-RNP+ donor mice express ITGAM by FACS. Treatment of these cells in vitro induces massive dendritic cell death, and prevents the development of adoptive transfer-induced lung disease. Mice receiving intact CD11c+ dendritic cells from anti-RNP donor mice develop substantial elevations in serum BNP levels, that correlate with increases in pulmonary pressures on right heart catheterization. Treatment of mice with established high serum BNP levels with LA-1 (but not controls) leads to rapid normalization of serum BNP levels and hemodynamic indices in 80% of study mice. No LA-1-induced toxicity was observed.

Conclusion: Adoptive transfer of ITGAM+ dendritic cells can induce pulmonary hypertension and ITGAM-targeted therapy can treat established pulmonary hypertension in a model of anti-RNP autoimmunity. These findings emphasize the potential importance of dendritic cells as mediators of tissue damage in anti-RNP autoimmunity, and raise the question whether the genetic associations of ITGAM with autoimmune disease risk could be mediated through effects on dendritic cells. LA-1 is a promising compound to develop for potential human trials.

Human Tolerogenic Dendritic Cells Generated with Protein Kinase C Inhibitor Are Optimal for Regulatory T Cell Induction-a Comparative Study. Endy Adnan, Hitoshi Hasegawa, Takuya Matsumoto, Jun Ishizaki, Sachiko Onishi, Koichiro Suemori and Masaki Yasukawa. Ehime University Graduate School of Medicine, Toon, Japan.

Background/Purpose: Tolerogenic dendritic cells (tDCs) are a promising tool for autoimmune diseases, transplantation and allergy. Actually, tDCs have been tried for the therapy of rheumatoid arthritis and type 1 diabetes. To date, immunomodulatory DCs are prepared from monocytes for in vitro experiments by using various agents. Previously, we generated stable tDCs with protein kinase C inhibitor (PKCI) in human and mouse and PKCI-tDCs prevented graft-versus-host disease in a murine model (J Immunol 191: 2247, 2013). The following functional characteristics are required for clinically applicable tDCs: efficient induction of functional regulatory T cells (Treg); CCR7-dependent migration; and stability under proinflammatory conditions. In this study, to select the optimal agent for clinically applicable tDCs, we compared the clinical-grade tDCs generated with various agents.

Methods: We compared tDCs generated with the following agents; vitamin D3 (Vit D3), dexamethasone (Dexa), bisindolylmaleimide I (PKCI), PPAR gamma plus retinoic acid (PPAR+RA), rapamicin (Rapa), IL-10, and TGF-beta. tDCs were prepared by adding these agents prior to the induction of maturation using TNF-alpha, IL-1beta and PGE2. We evaluated the effects of each agent on phenotype, CCR7-dependent migration, cytokine produc-

tion, phagocytosis, stability, T-cell suppression, and induction of IL-10-producing T cells and functional Foxp3^{+} Treg cells.

Results: All tDCs except Rapa-tDCs showed an immature or semi-mature phenotype, whereas the phenotype of Rapa-tDCs resembled that of mature DCs. PKCI-tDCs, TGF-tDCs and Rapa-tDCs had moderate and high CCR7 expression, whereas tDCs generated with PPAR+RA, Vit D3, Dexa or IL-10 had very low CCR7 expression. IL-10 production by IL-10-tDCs and PKCI-tDCs was high. Immature DCs (iDCs) and PKCI-tDCs showed high production of TGF-beta. Functionally, iDCs, PKCI-tDCs, PPAR+RA-tDCs, Vit D3-tDCs and IL-10-tDCs strongly suppressed T-cell activation, whereas Dexa-tDCs, TGF-tDCs and Rapa-tDCs weakly suppressed. All tDCs showed phagocytic ability and stable tolerogenic properties under proinflammatory conditions. From these findings, PKCI-tDCs showed moderate expression of CCR7, leading to migrate toward CCR7 ligands, maintained stability, and strongly suppressed T-cell activation by generating IL-10-producing T cells and functional Foxp3^{+} Treg cells.

Conclusion: PKCI-tDCs appear to be optimal for clinically applicable tDCs. We expect that PKCI-tDCs are useful for tolerance-inducing therapies.

Polymorphisms in the *FCN1* Gene Coding for M-Ficolin Are Associated with Disease Activity, Radiographic Damage and Are the Strongest Predictors of DAS28 Remission in 180 DMARD naïve Early Rheumatoid Arthritis Patients.

Christian G. Ammitzbøll[1], Rudi Steffensen[2], Steffen Thiel[3], Jens Christian Jensenius[3], Kim Horslev-Petersen[4], Torkell Ellingsen[5], Merete Lund Hetland[6], Peter Junker[7], Mikkel Ostergaard[8] and Kristian Stengaard-Pedersen[1]. [1]Arhus University Hospital, Aarhus, Denmark, [2]Aalborg University Hospital, Aalborg, Denmark, [3]Aarhus University, Aarhus, Denmark, [4]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Graasten, Denmark, [5]Odense University Hospital, Odense, Denmark, [6]DANBIO, Department of Rheumatology, Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [7]Department of Rheumatology, Odense University Hospital, Odense, Denmark, [8]Copenhagen University Hospital, Glostrup, Denmark.

Background/Purpose: M-ficolin is a pattern recognition molecule that collaborates with associated serine proteases as an activator of the complement system. High M-ficolin levels are strongly associated with high disease activity in early RA and low levels at baseline are strong predictors of both remission and low disease activity after one year(1). Single nucleotide polymorphisms (SNPs) in the M-ficolin gene *FCN1* have been shown to influence the concentration and function of M-ficolin(2) and are associated with outcome in patients with systemic inflammation. We have now investigated associations of 7 *FCN1* SNPs with DAS28, modified Total Sharp Score (mTSS), low disease activity (LDA, DAS28<3.2), and remission (DAS28≤2.6) in a cohort of 180 early RA patients.

Methods: 180 DMARD naïve RA patients with disease duration <6 months were included in a randomized double blind placebo-controlled trial (OPERA-study,NCT00660647) of methotrexate, intra-articular glucucorticoids plus either adalimumab or placebo. SNPs were analyzed with TaqMan OpenArray system (2). The associations between SNPs and endpoints were evaluated using linear or logistic regression analysis adjusted for age, sex, anti-CCP and treatment with the common allele homozygous genotype selected as reference.

Results: Baseline characteristics were similar in the two groups, Table 1. Table 2 states the four SNPs of which the minor allele was previously shown to be associated with higher plasma M-ficolin levels in healthy adults(2). Homozygosity of the minor allele in any of these 4 SNPs was associated with higher DAS28 at both baseline ($p<0.005$) and after one year of aggressive treatment ($p<0.009$), while no effect was observed in the heterozygote state. Homozygosity of the minor allele in the 4 SNPs was further associated with increased mTSS at both baseline ($p<0.02$) and at year one ($p<0.04$), except for rs7657015 ($p=0.06$). The four SNPs were, in multivariate logistic regression analyses, the only variables able to predict LDA at year one (OR between 0.16 to 0.18) and the strongest predictors of remission (OR between 0.24 to 0.26) followed by treatment with adalimumab (OR between 2.49 to 2.66).

Conclusion: Homozygosity of the minor allele of 4 *FCN1* SNPs is associated with higher DAS28 levels and modified Total Sharp Score in early RA. The four SNPs were the only variables capable of predicting LDA and the strongest predictors of DAS28 remission. These data consolidate our previous findings that M-ficolin, a molecule of the innate immune system, is a strong prognostic marker at both the protein and gene level.

***PTPN22* Promotes TLR-Induced Amelioration of Arthritis.**

David Ewart, Erik J. Peterson and Yaya Wang, University of Minnesota, Minneapolis, MN.

Background/Purpose: Rheumatoid arthritis (RA) synovial fluid exhibits high levels of type 1 interferons (IFN). Type 1 IFN may exert potent anti-inflammatory effects, since a TLR3 agonist suppresses inflammatory arthritis in a type 1 IFN-dependent manner. *PTPN22*, encoding Lymphoid Tyrosine Phosphatase (Lyp), is a "risk" gene for RA. A *PTPN22* disease-associated variant encodes an R620W substitution-bearing protein "LypW". We showed previously that *PTPN22* promotes Toll-like receptor (TLR) signaling and type 1 IFN production. Further, we found that LypW exhibits reduced function in poly(I:C)-mediated suppression of inflammatory arthritis in the K/BxN "serum-transfer" arthritis model. TLR9 agonists can also suppress arthritis through an unknown mechanism. We tested the hypothesis that *PTPN22* is required for TLR9 agonist-driven amelioration of arthritis.

Methods: Serum-transfer arthritis was induced in control or *Ptpn22*$^{-/-}$ mice by intraperitoneal injection of K/BxN mouse serum. Mice were then injected with ODN 1668 (10 nmol), a CpG oligonucleotide agonist of TLR9.

Arthritis scores were monitored. Synovial RNA was assayed for type 1 interferon and interferon-dependent gene expression via RT-qPCR.

Results: Confirming previous reports, ODN 1668 treatment ameliorated serum-transfer arthritis in control mice. However, *Ptpn22*$^{-/-}$ mice exhibited diminished suppressive response to ODN 1668. Reduced arthritis amelioration in *Ptpn22*$^{-/-}$ mice correlated with impaired TLR9 induction of *Ifna4* and *Cxcl10* (type 1 IFN-dependent chemokines) in synovium (Figure 1).

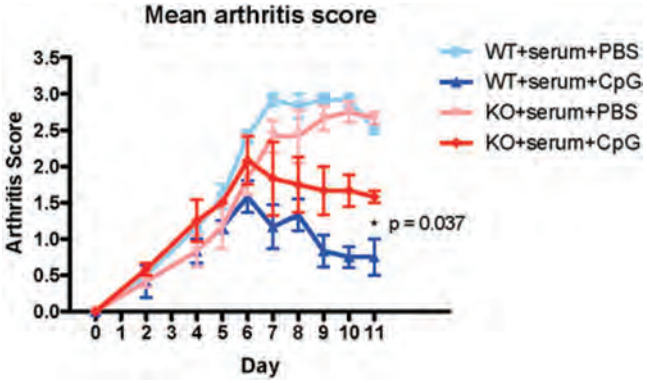

Figure 1: Mice (n = 3 per group) were injected with K/BxN serum together with ODN 1668 or vehicle alone. Arthritis severity scores (mean± SEM) are shown. WT, wild-type; KO, *Ptpn22*$^{-/-}$.

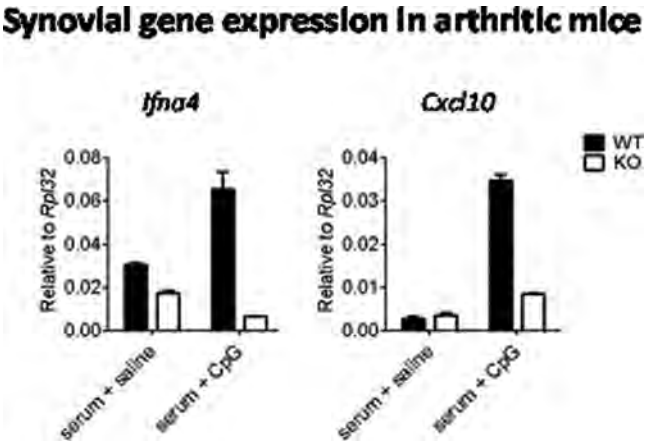

Figure 2: Expression of *Ifna4* and the IFN-inducible gene *Cxcl10* in synovium at day 11 post injection of serum was determined by qPCR.

Conclusion: *Ptpn22* is required for CpG-induced amelioration of inflammatory arthritis, and for upregulation of type 1 IFN-dependent genes in synovium. These data support a model wherein Ptpn22 exerts anti-inflammatory effects by promoting TLR signals that induce type 1 IFN and type I IFN-dependent genes.

Role of Natural Killer Cells and Gamma Delta T Cells in Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis. Priyanka Gaur, Ramnath Misra and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Enthesitis Related Arthritis (ERA) is the most common form of Juvenile Idiopathic Arthritis (JIA) in India. ERA is associated with increased frequency of Th17 cells and synovial fluid (SF) IL-17 levels. Recently innate immune cells like Natural Killer (NK) cells, γδ T cells have been reported to produce IL-17 and contribute to disease pathogenesis in Ankylosing spondylitis. Thus we have studied the frequency and effector functions of innate cells in ERA.

Methods: Fifty JIA-ERA, 21 other JIA patients (disease controls) and 25 healthy controls were enrolled in the study and peripheral blood (PB) was collected.19 paired synovial fluids were also studied. Frequency of NK cells, NKT cells, γδ T cells, expression of perforin in NK cells and KIR3DL1/2 on NK cell and T cells were measured by flow cytometry. Frequency of IL-17 producing T cells, NK cells and γδ T cells were quantified by Flow cytometry.

Results: Patients with ERA as compared with healthy controls had normal frequency of NK cells (9.52% ± 4.67 v/s 9.62% ± 2.65) and NKT cells (2.93% ± 1.96 v/s 2.42% ± 1.78) but had increased frequency of γδ T cells (9.31% ± 4.61 v/s 5.12% ± 2.61; p<0.001). Further NK cells in ERA patients had low expression of perforin (56.19% ± 15.67) and high KIR3DL1/2 expression (31.33% ± 12.13) as compared to controls (82.79% ± 9.43; p < 0.001, 21.32% ± 11.05, p=0.001 respectively). Frequency of IL-17 producing NK cells were increased in PB of JIA-ERA patients (n=10, 3.69% ± 2.72) as compared to healthy controls (n= 6, 0.83% ± 0.80; p = 0.01). Also the IL-17 producing γδ T cells were high in JIA-ERA (2.22% ± 2.20) than healthy controls (0.35% ± 0.56, p=0.02). In paired samples the frequencies of these cells were similar but as compared to PB,SF NK cells had reduced expression of perforin (56.64% ± 17.08 v/s 1.55% ± 2.5, p=0.001)and KIR3DL (31.39 ± 9.66 v/s 10.89% ± 10.84, p < 0.001).

Conclusion: NK cells in ERA patients have CD56 bright phenotype with low perforin expression suggestive of cytokine producing cells. Further increase in KIR3DL1/2 expression on NK cells suggests that they may interact with HLA B27 and have enhanced survival. Increased frequency of IL-17 producing NK cells and γδ T cells in ERA suggests that in addition to Th17 cells they may also contribute to IL-17 in ERA.

MicroRNA-146a in Salivary Gland Epithelial Cells Inhibits Co-Stimulatory Molecule CD80 Expression and Increases Autoreactive T Cell Activation in Sjögren's Syndrome. Adrienne Gauna[1], Jun-O Jin[2], Qing Yu[3], Carol Stewart[1] and Seunghee Cha[1]. [1]University of Florida, Gainesville, FL, [2]Fudan University Shanghai Medical College, Shanghai, China, [3]The Forsyth Institute, Cambridge, MA.

Background/Purpose: Sjögren's syndrome (SS) causes severe dry mouth and eyes. The presence of immune cell infiltration in the salivary (SG) and lacrimal glands suggests a response to local antigens, presumably from resident antigen presenting cells (APCs) and exocrine epithelium stimulation of autoreactive CD4+ T cells. Recent studies in our lab identified co-stimulatory molecule CD80 as a target of microRNA (miR)-146a and showed reduced CD80 in the SG cells of SS-prone mice (C57BL/6.NOD-*Aec1Aec2*, B6DC). Co-stimulatory molecule CD80 is presumed to promote T cell regulatory phenotypes by binding to CTLA-4 or PD-L1. Therefore, we sought to identify which cell subsets were contributing to the reduced CD80 in SGs and whether there were alterations in regulatory (Treg) and conventional (Tconv) T cell functional markers in B6DC mice.

Methods: Single cell suspension of submandibular SGs and draining lymph nodes (dLNs) of 20–24-week-old B6DC and C57BL/6 (B6) mice (n = 5–9 per group) were evaluated by flow cytometry. To identify potential APC subsets, cells were assessed for CD19, CD11c, CD11b, and F4/80. SG epithelial cells (SGECs) were negatively selected using anti-CD45 microbeads and identified using CD326. APCs and SGECs were evaluated for co-stimulatory molecules CD80 and CD86. In addition, Treg (CD4+Foxp3+) and Tconv (CD4+Foxp3-) cells were assessed for cell surface proteins CD25, CTLA-4, PD-L1, and intracellular IL-10 and TGF-β1. Quantitative real-time-PCR was used to evaluate the expression of miR-146a in SGECs relative to RNU6b. Data were analyzed by two-tailed-unpaired t-test or linear regression where $P < 0.05$ was considered significant.

Results: SG APCs contributed to less than 5% of total SG cells. The CD19+CD11c- B cells, CD11c+CD11b+F4/80+CD19+ macrophages, CD11c+CD11b+F4/80-CD19- dendritic cells and CD11c+CD11b+F4/80+CD19- macrophages showed reduced percentages of CD86+CD80+ cells. Analyses of B6DC SGECs revealed a 29% reduction in CD80 mean fluorescence intensity (MFI), but no alteration in CD86 MFI in comparison to B6 mice. The ratio of CD86:CD80 MFI was increased and the relative expression level of miR-146a was elevated by 2.09-fold in B6DC SGECs. Furthermore, CD80 MFI showed a negative relationship to the relative expression level of miR-146a (slope = −0.376, r^2 = 0.511). Also, B6DC SG Tregs were increased (+56%) and had increased CTLA-4 (+81%) and PD-L1 (+37%) positive cells; while Tconv had increased PD-L1 (+43%) and decreased IL-10 (−60%) positive cells. The dLN Tregs had increased CTLA-4 (45+%) or PD-L1 (+8.7%) positive cells along with 28% decrease in IL-10 positive cells; whereas Tconv cells showed 8.8% increase in PD-L1 positive cells.

Conclusion: SGECs are major contributors to reduced total CD80 expression in the SG since contributions of resident APCs were minimal. Therefore, it is presumed that the imbalance of CD86:CD80 in SGECs, due

to aberrantly expressed miR-146a, could contribute to the abnormal activation of T cells in the affected tissues of SS. This is supported by the observed reduction in regulatory cytokine IL-10 in SG T cells despite elevated expression of regulatory CTLA-4, PD-L1, and the number of Foxp3+ Tregs.

Macrophages from the Synovium of Active Rheumatoid Arthritis Exhibit an Activin a- Dependent Pro-Inflammatory Profile. Elena Izquierdo[1], Blanca Soler Palacios[2], Lizbeth Estrada-Capetillo[2], Gabriel Criado[3], Concha Nieto[1], Cristina Municio[2], Isidoro González-Álvaro[4], Paloma Sánchez-Mateos[2], Jose L. Pablos[5], Ángel L. Corbí[1] and Amaya Puig-Kröger[2]. [1]Centro de Investigaciones Biologicas (CSIC), Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, [3]Instituto de Investigación Hospital 12 de Octubre (i+12), Madrid, Spain, [4]Hospital Universitario La Princesa, Instituto de Investigación Sanitaria Hospital Universitario La Princesa, Madrid, Spain, [5]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain.

Background/Purpose: Synovial macrophages are key effector cells in rheumatoid arthritis (RA), where they are a major source of pro-inflammatory cytokines and contribute to the cartilage and bone destruction. Macrophages are phagocytic cells present in all tissues and show a remarkable plasticity in response to environmental signals. However, the polarization state of macrophages in RA has not been fully uncovered. To dissect the molecular basis for the tissue-damaging effects of macrophages in RA joints, we have characterized the phenotype and transcriptome of RA synovial macrophages. Moreover, we have studied the macrophage polarizing ability of the synovial fluid of RA (RA-SF) patients.

Methods: Human monocytes (obtained from buffy coats from normal donors) and macrophages from RA-SF (RA-SF MØ) were isolated by Ficoll gradient and subsequent magnetic cell sorting using anti-CD14 microbeads. Monocytes were cultured for 7 days in RPMI containing GM-CSF or M-CSF to generate GM-CSF-polarized macrophages (GM-MØ) or M-CSF-polarized macrophages (M-MØ). The phenotypic and transcriptomic characterization of ex-vivo isolated CD14+ RA-SF macrophages was accomplished by flow cytometry and quantitative real time PCR. In normal and synovial tissues, the expression of macrophage-polarization markers was analyzed by immunofluorescence labeling. To assess the RA-SF polarizing ability, RA-SF was added onto monocytes or M-MØ (ratio 1:1 in culture medium) in the presence or absence of a blocking anti-activin A antibody for 72 hours and the expression of macrophage-polarization markers was analyzed by qRT-PCR and Western Blot.

Results: Flow cytometry and gene profiling indicated that RA-SF macrophages express pro-inflammatory polarization markers (MMP12, EGLN3, CCR2), lack expression of markers associated to homeostatic and anti-inflammatory polarization (IGF1, HTR2B), and exhibit a transcriptomic profile that resembles the activin A-dependent gene signature of pro-inflammatory *in vitro* generated macrophages. *In vitro* experiments on monocytes and macrophages indicated that RA-SF promote the acquisition of pro-inflammatory markers (INHBA, MMP12, EGLN3, CCR2), but led to a significant reduction in the expression genes associated to homeostasis and inflammation resolution (FOLR2, SERPINB2, IGF1, CD36), thus confirming pro-inflammatory polarization ability of RA-SF. Importantly, the macrophage polarizing ability of RA-SF was inhibited by an anti-activin A neutralizing antibody, thus demonstrating that activin A mediates the pro-inflammatory macrophage polarizing ability of RA-SF. Moreover, and in line with these findings, multicolor immunofluorescence evidenced that macrophages within RA synovial membranes (RA-SM) express pro-inflammatory polarization markers whose expression is activin A-dependent.

Conclusion: Altogether, our results demonstrate that macrophages from RA synovial fluid and membrane exhibit an MMP12+ EGLN3+ CCR2+ pro-inflammatory polarization state whose acquisition is partly dependent on activin A from the synovial fluid.

Macrophages-Mediated Response to Uric Acid Crystals Is Modulated By Their Functional Polarization. Emma Garcia-Melchor[1], Monica Guma[2], Jordi Yagüe[1], Manel Juan[1] and Jacquie Harper[3]. [1]Hospital Clinic Barcelona, Barcelona, Spain, [2]University of California, San Diego, La Jolla, CA, [3]Malaghan Institute of Medical Research, Wellington, New Zealand.

Background/Purpose: Macrophages have been involved in both initiation and resolution of gout flares. Accordingly, these cells are characterized by their plasticity as the environment modulates their phenotype exerting inflammatory or anti-inflammatory functions depending on their activation or polarization state. Macrophages in the presence of interferon-γ and lipopolysaccharide (LPS), what is known as classical activation, acquire an inflammatory phenotype and are also termed M1 macrophages. On the other hand, M2 or alternatively activated macrophages with IL-4 have anti-inflammatory and homeostatic functions. Equivalently, in the presence of granulocyte macrophage colony-stimulating factor (GM-CSF) and macrophage colony-stimulating factor (M-CSF) macrophages become M1 or M2 respectively. As M-CSF is present in the blood stream at steady state some authors propose that M2 macrophages polarized with M-CSF could represent the population of resident macrophages. In this work we investigated M2 macrophages response to monosodium urate (MSU) crystals *in vitro*.

Methods: Macrophages were derived from peripheral blood monocytes of healthy donors after informed consent. Peripheral blood mononuclear cells were separated from whole blood by centrifugation with a density gradient. Monocytes were then isolated by negative selection with magnetic beads and cultured for 1 week with GM-CSF (1000 I.U./ml) or M-CSF (20 ng/ml) to obtain M1 or M2 macrophages respectively. Macrophages were then stimulated with MSU (200 μg/ml), LPS (100 ng/ml) or both for 18 hours and quantification of IL-1β and IL-10 in supernatants was performed by ELISA. Activation of caspase-1 in M1 and M2 macrophages was analyzed by flow cytometry with the Caspase-1 FLICA™ Detection Kit (Immunochemistry Technologies). Cytoplasmic pro-caspase-1 and pro-IL-1β were analyzed by western blot. Flow cytometry and statistics analysis were performed with the FACSDiva and GraphPad Prism 5 respectively.

Results: As expected, M1 macrophages produced inflammatory cytokines in response to LPS, whereas M2 macrophages were unable. Both M1 and M2 failed to produce IL-1β after MSU stimulation. However, when challenged with MSU and LPS, M2 macrophages produced IL-1β (mean+/−SEM, LPS 2.59+/−1.37 pg/ml, MSU+LPS 111.4+/−30.44 pg/ml, p= 0.0078) and reduced IL-10 production (mean+/−SEM, LPS 3738+/−230 pg/ml, MSU+LPS 1587+/−386.4 pg/ml, p= 0.0039). Resting M2 macrophages exhibited lower levels of active caspase-1 and pro-caspase-1. MSU stimulation increased active caspase-1 levels in both M1 and M2 macrophages and the presence of MSU and LPS had a synergic effect in pro-IL-1β.

Conclusion: M1 and M2 macrophages failed to produce inflammatory cytokines after MSU challenging, according with the fact that MSU crystals can be found in asymptomatic joints. However, after MSU phagocytosis, M2 macrophages were able to produce IL-1β after LPS stimulation, explaining the requirement of a trigger, such as a copious meal or alcohol intake, for the initiation of an acute flare in gout. M2 macrophages also had lower levels of caspase-1 and pro-caspase-1, than M1 macrophages.

Class a Scavenger Receptor (SR-a) Exacerbated Synovial Fibroblasts-Mediated Inflammation in Rheumatoid Arthritis. Yingni Li[1], Fanlei Hu[1], Li Zheng[1], Linchong Su[2], Lianjie Shi[1], Pei Song[1] and Zhanguo Li[1]. [1]Peking University People's Hospital, Beijing, China, [2]Hubei Minzu University, Enshi, China.

Background/Purpose: Class A scavenger receptor (SR-A/CD204), mainly expressed on macrophages, plays an important role in the pathogenesis of atherosclerosis and in the pattern recognition of pathogen infection. However, its role in rheumatoid arthritis (RA) has not been defined. The aim of this study was to reveal the expression of SR-A in synovial fibroblasts (RASF) and its impact on synovial inflammation.

Methods: Immunohistochemistry (IHC) was performed to detect the expression of SR-A in the synovial tissues from RA and osteoarthritis (OA) patients. The expression of SR-A in RASF was demonstrated by both qPCR and western blot. To reveal the effects of SR-A on synovial inflammation, RASF were treated with either recombinant SR-A protein or SR-A specific

siRNA. Then, the expression of pro-inflammatory cytokines (TNF-α, IL-6, and IL-8) and MMPs (MMP-1, MMP-3, and MMP-9) were determined by real-time PCR and ELISA. Accordingly, the activation of the MAPKs and NF-κB signaling pathways was evaluated by western blot when SR-A was silenced.

Results: The level of SR-A was higher in the synovial tissues from RA patients than those from OA patients. Moreover, we for the first time demonstrated that SR-A was expressed in RASF. SR-A protein stimulated pro-inflammatory cytokine and MMP expression in RASF. On the contrary, knocking down SR-A by specific siRNA suppressed the expression of these factors, with dampened activation of the ERK, JNK, p38 and NF-κB signaling pathways.

Conclusion: SR-A exacerbated synovial inflammation and cartilage erosion in RA. Targeting SR-A might provide novel therapeutic strategies for overcoming this stubborn disease.

Extensive Natural Killer Cell Receptor Phenotyping on NK and T Cells Discloses Differences in RA and Psa, Potentially Mirroring Diverse Immunoregulatory Functions. Marta Cossu[1], Sandra TA van Bijnen[2], Mieke Roeven[2], Tim Jansen[2], Frank Preijers[2], Harry Dolstra[2] and Timothy Radstake[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are immune-mediated diseases, which share clinical features, but differ in the mechanisms, leading to aberrant immune responses. Natural killer (NK) cells tune the innate immune response depending on the integration of signals coming from a complex network of activating and inhibitory surface receptors. Here, we aim to elucidate the potential role of NK and T cells in inflammation and autoimmunity in RA and PsA and we focused on extensive characterization of the NK cell receptor (NKR) (co-) expression patterns on their surface.

Methods: The frequency of T and NK cells expressing Killer like immunoglobulin Receptors (KIR), NKG2 and Natural Cytotoxicity receptors was assessed by 10-color flow cytometry (FCM) in peripheral blood of 23 RA patients (ACR 1987 revised criteria), 12 PsA patients (Taylor et Al, 2006 Classification of Psoriatic Arthritis Study Group criteria for PsA) and 18 healthy controls (HC). Cytotoxicity of NK cells against K562 cells before and after stimulation with IL-12 and IL-18 as broad activating signals was assessed in a FCM-based cytotoxicity assay in 8 additional RA patients and 8 additional HC; during co-culture, NK degranulation was measured by cell surface expression of CD107a and IFNγ intracellular expression was also assessed in parallel.

Results: RA patients, but not PsA patients, had an increased frequency of NK cells expressing the inhibitory receptor NKG2A compared to HC, particularly in patients with rheumatoid factor positivity. The NKG2A+ NK population was predominantly $CD56^{dim}$and lacked expression of KIRs and activating NKG2C. No differences were observed in the expression of the other NKRs between HC and RA nor PsA patients.

RA patients showed decreased cytotoxicity against K562 cells in the 10:1 Effector:Target ratio, when compared to HC, but the capability of killing in RA NK cells was restored after IL-12/IL-18 stimulation. Degranulation and IFNγ expression were similar in HC and RA patients.

T cells expressing the Fcγ receptor CD16 were more frequent in RA than in HC. Compared to HC, we found higher frequencies of T cells expressing the KIRs CD158ah in both RA and PsA, and CD158e1e2 in RA. $CD4^{+}$T cells expressing the KIRs CD158ah, CD158b1b2j and CD158e1e2, although present at low frequency, were also significantly elevated compared to HC.

Conclusion: The differences in NKR expression on NK and T cells in RA and PsA could mirror the diverse pathogenic mechanisms implicated in these diseases; in particular, the immature phenotype (NKG2A+/KIR-) of circulating NK cells in RA and the reversible impairment in their cytotoxic ability could reflect the activation status of the NK population described in RA synovial fluid and provide growing evidence for the potential of the exploitation of NKG2A blockade in this disease.

The Monocyte-Phagocyte System in Gout: Enhanced Inflammasome Activity and Expansion of CD14++CD16+ Monocytes in Patients with Gout. Emma Garcia-Melchor[1], Cesar Diaz-Torne[2], Monica Guma[3], Europa Azucena Gonzalez-Navarro[1], Francesc Xavier Alemany[1], Jordi Yagüe[1] and Manel Juan[1]. [1]Hospital Clinic Barcelona, Barcelona, Spain, [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]University of California, San Diego, La Jolla, CA.

Background/Purpose: The central role of the monocyte-macrophage system in gout has been highlighted during the last years. Macrophages initiate the inflammatory response to monosodium urate (MSU) crystals and produce inflammatory cytokines and chemokines that induce migration of blood monocytes to further amplify the inflammatory response. Different subpopulations of blood monocytes have been recognised: classical (CD14++CD16-), intermediate (CD14++CD16+) and non-classical (CD14+CD16++); characteristically intermediate monocytes are expanded in infectious and inflammatory diseases. One of the questions that remain unanswered is why some patients with hyperuricemia, and even with MSU deposits, remain clinically asymptomatic. We investigated the possibility that it could be due to a greater inflammasome reactivity to MSU crystals in patients who develop gout. Moreover, we analyzed the distribution of monocyte subpopulations in patients with gout.

Methods: Seventeen patients with gout were selected, 13 asymptomatic and in 4 patients samples were obtained during an acute flare. Nineteen healthy donors were selected for comparison. Inflammasome activity was assessed by the increase of active caspase-1 after stimulation with MSU in peripheral blood mononuclear cells (PBMCs) by flow cytometry using Caspase-1 FLICA™ Detection Kit (Immunochemistry Technologies). Phagocytosis of MSU crystals was quantified by flow cytometry, as cells that phagocyte crystals increase their side scatter (SSC) values. PBMCs were cultured for 24 hours in the presence of MSU (200 μg/ml), LPS (100 ng/ml) or both and IL-1β was quantified by ELISA. Samples of peripheral blood were stained with CD45, HLA-DR, CD16, and CD14 antibodies and analyzed by flow cytometry. Uric acid, creatinine and C-reactive protein (CRP) were quantified in sera. Flow cytometry and statistics analysis were performed with the FACSDiva and GraphPad Prism 5 respectively.

Results: No differences were observed in active caspase-1 at baseline between patients and controls. However, when stimulated with MSU, monocytes from gout patients exhibited a higher increase of active caspase-1 (mean+/−SEM, gout 2.20+/−0.15, controls 1.66+/−0.18, p= 0.0419). Differences in phagocytosis of MSU crystals were excluded, as in both groups monocytes exhibited equivalent phagocytic capability. PBMCs of patients with gout exhibited diminished IL-1β production when challenged with LPS and MSU (p=0.0473). Regarding monocyte subpopulations, the intermediate phenotype was expanded in patients with gout during an acute flare and a weak correlation between intermediate monocytes and CRP was observed.

Conclusion: Monocytes of patients with gout exhibited an enhanced inflammasome activation with MSU crystals, suggesting that the reduced threshold in the inflammatory response could be involved in the development of clinical gout. The expansion of intermediate monocytes was observed during gout flares and, although it cannot be excluded that intermediate monocytes could be "innocent bystanders" in the context of inflammation, it could suggest that these monocytes participate in the inflammatory response to MSU crystals.

Macrophage Depletion Ameliorates Nephritis Induced By Pathogenic Antibodies. Samantha Chalmers[1], Leal Herlitz[2], Violeta Chitu[1], Richard Stanley[3] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Columbia-Presbyterian Medical Center, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NJ.

Background/Purpose: Kidney involvement affects up to 60% of lupus patients, and is responsible for significant morbidity and mortality. Previous studies using a variety of methods to reduce the number of macrophages have reached conflicting conclusions regarding the role of macrophages in lupus nephritis (LN). Moreover, "off target" effects occur in mice congenitally deficient in macrophages. In this study we investigated the role of macrophages in an inducible model of LN, using a novel depletion method that minimized the confounding factors seen in previous studies.

Methods: To determine the role of macrophages in the antibody mediated nephritis associated with lupus, we utilized the nephrotoxic serum nephritis model. This is an inducible model of nephritis which closely mimics LN, and which is often used to model immune complex mediated renal disease. Mice received nephrotoxic serum (NTS) containing rabbit anti-mouse glomerular antibodies which deposited within the kidney to initiate nephritis. GW2580, an oral kinase inhibitor monospecific for the CSF-1 receptor, was used as a novel and highly selective method for macrophage depletion. GW2580 was delivered via oral gavage over a 10 day period (n=18). A second group of mice received a control gavage of PBS in addition to the NTS transfer (n=18). A third group was neither gavaged nor given NTS, and served as a healthy control population (n=9).

Results: We found that NTS challenged mice, when treated with GW2580 from day 0, did not develop the significant increases in proteinuria, serum creatinine or BUN seen in control treated mice. Furthermore, GW2580 treated mice were protected from the robust kidney expression of inflammatory cytokines associated with LN seen in control treated mice, including RANTES, IP-10, VCAM-1, MCP-1 and IL-6. Flow cytometry analysis of kidney single cell suspensions revealed a significant decrease in inflammatory macrophages ($CD11b^{+}F480^{lo}$) in GW2580 treated mice. Furthermore, IBA-1 staining confirmed profound depletion of macrophages within glomeruli of treated mice. There was no significant change in circulating monocyte numbers with GW2580 treatment; however, there was a significant decrease in the number of macrophages in the spleen. Importantly, GW2580 did not interfere with the induction of the disease model. Finally, treatment with GW2580 at a later time point in the disease model (beginning day 5) was also effective at attenuating nephritis.

Conclusion: Our results support an important role of macrophages in LN pathogenesis, and suggest targeting this cell type as a promising approach to the treatment of LN.

Investigating Myeloid and Plasmacytoid Dendritic Cell Activation within the Synovium and Peripheral Blood of Rheumatoid Arthritis Patients. Mary Canavan, Michael Anthony O'Rourke, Douglas J. Veale and Ursula Fearon. Translational Rheumatology Research Group, Dublin, Ireland.

Background/Purpose: Dendritic cells (DC) are a heterogeneous population of professional antigen presenting cells which link both the innate and adaptive arms of the immune system. Myeloid and plasmacytoid DC represent the two major DC subsets and can be distinguished based on their morphology, expression of surface markers and gene expression profiles. In this study we compared the percentage and activation status of myeloid versus plasmacytoid DC at the site of inflammation in RA compared to systemic circulation.

Methods: DC whole blood phenotyping was assessed using multicolour flow cytometry on the Beckman Coulter Cyan system using FlowJo software for subsequent analysis. DC were defined as $HLADR^{+}$, $Lineage^{-}$, and further subdivided as either myeloid ($CD11c^{+}$, $CD1^{+}$ or $CD141^{+}$) or plasmacytoid DC ($CD123^{+}$). Cell surface expression of CD80, CD83 and CD40 was used to assess the activation and maturation status of each subtype. For characterisation of synovial tissue DC, biopsies were digested using the GentleMACs mechanical and enzymatic digestion system. Viable CD45 cells were gated and subsequently assessed for DC pan markers in addition to maturation and activation markers. In parallel, synovial fluid and peripheral blood were comparatively assessed to profile DC from blood, fluid and tissue. To assess the effect of the synovial environment on DC maturation, immature DC were derived from CD14+ monocytes in the presence of GM-CSF (70ng/ml) and IL-4 (50ng/ml). Synovial tissue explants were cultured for 24hr allowing the spontaneous release of cytokines and soluble mediators into the culture medium. Monocyte derived dendritic cells (MoDC) were cultured in the presence of this explant conditioned media for 24hr after which the expression of maturation markers was analysed on $CD11c^{+}$ $CD14^{-}$DC.

Results: RA patients have a decreased percentage of CD11c mDC circulating in peripheral blood compared to that of healthy controls. The percentage of CD123 pDC between RA and healthy controls is not significantly different however the expression of CD40 on pDC in RA patients is significantly increased compared to healthy control ($p<0.001$). A comparative analysis of mDC and pDC in peripheral blood, synovial fluid and synovial tissue highlighted an increase in DC maturation as DC migrate from blood, to fluid and finally tissue. CD40 and CD83 expression on mDC is increased in tissue compared to that of fluid or blood. Similarly an increase in CD40 and CD83 on pDC was found in synovial tissue compared to that of fluid or peripheral blood. Finally immature monocyte derived DC cultured in the presence of explant conditioned media have increased expression of CD80 and CD83 compared to basal DC medium.

Conclusion: DC have a more mature and activated phenotype in the synovial tissue compared to that in synovial fluid or peripheral blood. Given that there are also lower circulating levels of DC in RA patients compared to controls our data suggest that peripheral blood DC are recruited to the joint where they undergo a programme of maturation. Ongoing studies aim to elucidate the mechanisms in which these subsets are activated and matured.

Investigating the Roles of Factor H-Related Proteins in Systemic Lupus Erythematosus (SLE) and Other Autoimmune Diseases. Alexandra Antonioli, Brandon Renner, Joshua Thurman, V. Michael Holers and Jonathan Hannan. University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Complement plays a central role in the pathogenesis of systemic lupus erythematosus (SLE) wherein inappropriate activation of complement leads to substantial tissue damage, especially in the kidney. Factor H is a complement regulatory protein that controls activation of the alternative pathway in the fluid phase and on cell surfaces. Recent human linkage data implicate a role for a group of genes, encoding a family designated Factor H-Related (FHR) proteins, in the pathogenesis of SLE. Specifically, a FHR3-1Δ deletion is associated with a higher risk for the development of SLE, while also demonstrating a protective association in age-related macular degeneration. To date, few functional studies have been carried out on the mouse FHR proteins, and these molecules have not been studied in any *in vivo* models of inflammatory or autoimmune disease. Our central hypothesis is that FHR proteins act as antagonists of FH function and increase complement deposition which exacerbates inflammation and injury.

Methods: To test our hypothesis that FHR proteins compete with FH-mediated complement regulation we: **1)** Generated recombinant forms of the murine FHR proteins (mFHR-A and mFHR-B) using transiently transfected 293-F cells grown in serum free media. **2)** Evaluated the capacity of each of these molecules to inhibit FH function using a hemolysis protection assay. **3)** Performed ELISA assays to detect cross-species reactivity between murine FHRs and human complement components. **4)** Used flow cytometry to evaluate C3b deposition on the surface of nucleated cells (Retinal Pigment Epithelial (ARPE-19) and/or murine tubular epithelial cells (TEC)) upon addition of mFHRs under both oxidatively stressed and non-stressed conditions. We are also producing antibodies directed to the murine FHRs in order to better understand how the FHRs may be involved in SLE and other autoimmune diseases and whether FHR levels are altered during different disease activity states (i.e. during SLE disease flares).

Results: Addition of 1uM of mFHR-A or mFHR-B results in 100% and 50% hemolysis, respectively, of sheep red blood cells which are normally resistant to complement mediated lysis due to their lack of membrane associated complement regulators. We also observe a significant increase in C3b deposition under both stressed and non-stressed conditions on the surface of at least one type of nucleated cell (ARPE-19) upon addition of mFHR-A (mean fluorescence intensity is two-fold greater than serum only control). These results suggest that the murine FHRs are excellent surrogates by which to interrogate the underlying mechanisms linking variations within the human *CFH* gene family to complement deregulation in tissues such as the kidney or eye.

Conclusion: Our preliminary work supports recent studies which have shown that the FHR proteins modulate complement by competing with FH for binding to its major ligand, complement component C3b, likely disrupting FH-driven complement regulation on specific biological surfaces. The long-term objective of this work is to determine whether the FHR proteins are suitable therapeutic targets for the treatment of complement-driven inflammatory diseases such as SLE.

Release of Enzymatically Active Peptidyl Arginine Deiminases (PADs) By Neutrophils Allows Generation of Citrullinated Extracellular Autoantigens in the Synovial Fluid of Patients with Rheumatoid Arthritis. Julia Spengler[1], Bozo Lugonja[1], Andrew Creese[1], Jimmy Ytterberg[2], Karin Lundberg[3], Michael Milward[1], Mark Pearson[4], Christopher Buckley[1], Andrew Filer[1], Karim Raza[1], Paul Cooper[1], Iain Chapple[1] and Dagmar Scheel-Toellner[1]. [1]University of Birmingham, Birmingham, United Kingdom, [2]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [4]University of Birmihgham, Birmingham, United Kingdom.

Background/Purpose: Citrullinated proteins are important autoantigens in the inflamed joints of patients with rheumatoid arthritis (RA). Several of these proteins are derived from proteins generally found in the extracellular space, such as fibrinogen and type II collagen. It is therefore important to understand the source of extracellular peptidyl deiminases, (PAD) the enzymes responsible for citrullination. After entering the joints of RA patients, neutrophils are activated and release DNA in an active process termed NETosis. As this process involves histone citrullination by PAD4 we hypothesized that neutrophils undergoing NETosis in the rheumatoid joint release enzymatically active peptidyl arginine deiminases.

Methods: Extracellular DNA was quantified in the synovial fluid (SF) of patients with RA (n=27) and osteoarthritis (OA) (n=15). Presence of decondensed DNA in association with neutrophil elastase was studied on smear preparations of RA SF and synovial tissue. Release of PAD2 and PAD4 was examined during in vitro induced NETosis using Western Blotting and verified by mass spectrometry and immunofluorescence. NETS isolated from in vivo and in vitro activated neutrophils were isolated and probed on western blots. PAD activity in the supernatant of in vitro stimulated neutrophils and in the SF of patients with RA (n=7) and OA (n=9) was determined by a conversion assay involving citrullination of target peptides.

Results: Extracellular DNA was detected in the SF from RA patients at significantly higher levels than in OA SF ($p<0.001$) and correlated with SF neutrophil cell counts (n=15, $R^2=0.68$, $p=0.002$) and with PAD activity (n=14, $R^2=0.32$, $p=0.03$) in the SF. Immunofluorescence revealed the co-localization of neutrophil elastase with decondensed DNA in RA SF and within neutrophil precipitates on the surface of the synovial lining layer. Furthermore, PAD activity was detected at significantly higher levels in the SF of RA patients when compared to SF from OA patients ($p<0.001$) and the isoenzymes PAD2 and PAD4 were both found to be present in the SF of RA patients. Significantly higher PAD activity could also be detected in the supernatant of in vitro stimulated neutrophils when compared to unstimulated cells ($p<0.05$). Western blotting revealed the release of free PAD2 and PAD4 into the supernatant and also the association of both isoenzymes with isolated NETs. The loss of nuclear PAD4 signal during NETosis was confirmed by immunofluorescence staining.

Conclusion: These results demonstrate the enzymatic activity of PADs in the synovial fluid of RA patients. Combined with our findings from in vitro stimulated neutrophils the data suggest that neutrophils undergoing NETosis are a source of this extracellular activity. The correlation of the measured PAD activity with DNA levels and neutrophil cell counts in the synovial fluid of RA patients are in line with this hypothesis. This study highlights the possibility that activated neutrophils recruited into the joints could continuously release enzymatically active PADs which contribute to the continuous generation of citrullinated autoantigens and thus drive an inflammatory response in the joint.

Selective Consumption of C2 Component in HCV Patients. Atila Granados Afonso de Faria[1], Luis Eduardo C. Andrade[2] and Maria Lucia Gomes Ferraz[3]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Hepatitis C virus (HCV) causes immunologic disorders (vasculitis, myositis, arthritis) and high frequency of autoantibodies and mixed cryoglobulinemia (CRYO). Recently, we observed that some HCV patients present absent serum C2 hemolytic activity without consumption of other components of the Complement System (CS). Liver enzyme (AST/ALT) serum levels were registered as the times the upper limit of normal (ULN). This study characterizes this phenomenon in a large series of consecutive HCV patients.

Methods: 1021 samples from 716 consecutive HCV patients were analyzed for CS parameters: functional assessment of C2 (radial immune-hemolysis); C2, C3 and C4 protein concentration (immune-precipitation). Clinical and laboratory data were obtained from a structured medical form.

Results: Samples were classified into three groups according to C2 hemolytic activity: 1) Absent activity (n=154; 15.1%); 2) Decreased activity (n=154; 15.1%); 3) Normal activity (n=713; 69.8%). Most samples with decreased/absent C2 activity had decreased serum C2 protein concentration. Serum C3 and C4 was normal in 89 (82%) and 82 (72%), respectively, of samples with absent C2 activity. Analysis of multiple sequential samples from 192 patients showed that the selective decrease in C2 activity is a transient phenomenon with variable duration in time. Patients with absent C2 activity had higher serum liver enzymes (AST/ALT) (2,46±1,25 ULN and 2,29±2,15 ULN) and lower serum albumin (4,0±0,6mg/dL) than those with normal C2 activity (AST 1.46±1,25 ULN $p<0.001$; ALT 1.62±1.47 ULN; $p=0.03$; albumin 4,3±0,5; $p=0.01$). Samples with absent C2 activity had higher frequency of CRYO (13%) than those with normal C2 activity (0.8%) ($p<0.001$). In vitro exposure of normal to CRYO induced selective decrease in C2 activity in a dose-dependent manner. C2 activity status was not associated with other clinical and laboratory parameters.

Conclusion: Selective decreased C2 activity is transiently observed in 30% of HCV patients. This phenomenon was associated with liver biochemical abnormalities and CRYO. Further studies are warranted to define the role of these and other yet unknown factors on selective C2 deficiency in HCV patients.

Alterations in B Cell Complement Processing Related to a Lupus-Associated Variant in Complement Receptor 2. Brendan M. Giles and Susan A. Boackle. University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: We have recently identified a variant in intron 1 of complement receptor 2 (CR2/CD21) that is associated with decreased risk of lupus (rs1876453; $P_{meta}=4.2\times10^{-4}$, OR=0.85). Its effect was strongest in subjects with anti-dsDNA antibodies ($P_{meta}=7.6\times10^{-7}$, OR=0.71), suggesting a preferential association with this B cell-driven endophenotype. Peripheral blood B cells from healthy subjects with the rs1876453 minor allele had increased levels of complement receptor 1 (CR1/CD35) resulting in an altered CR1:CR2 ratio on the cell surface. CR1 binds the C3b and iC3b fragments of C3 and is a required cofactor for the degradation of C3b to the CR2-specific ligand C3dg. While crosslinking of CR2 and the B cell antigen receptor is known to lower the activation threshold, the role of CR1 during complement-dependent B cell activation remains unclear. We hypothesize that increased CR1 levels associated with the protective allele facilitate complement processing and modify B cell activation.

Methods: A novel CR1 ligand (biot-C3b) was developed by biotinylating C3b in the thioester domain, the site of antigen attachment. The biotin orientation enables multimers of biot-C3b to be formed that mimic the natural C3b-coated immune complexes that are targets for CR1-mediated processing. Multimeric and monomeric CR1 ligands were generated by incubating biot-C3b with and without streptavidin, respectively. For analysis of CR1-mediated processing, ligand binding was evaluated by flow cytometry using primary B cells and cofactor activity was determined by incubating CR1 (soluble or cell bound) with biot-C3b and factor I followed by SDS-PAGE.

Results: Multimers of biot-C3b were processed by CR1 more efficiently than monomers as demonstrated by increased B cell binding and more complete degradation to C3dg. In solution, higher CR1 concentrations resulted in more rapid conversion of biot-C3b to its degradation products. On primary B cells, elevated levels of CR1 associated with the protective allele enhanced biot-C3b processing with increased binding capacity ($p<0.05$) and hastened degradation kinetics.

Conclusion: Here, we show that increases in CR1 levels, both in solution and on primary cells, enhance the processing of biot-C3b multimers. These data suggest that the elevated B cell CR1 levels associated with the protective minor allele at rs1876453 will result in increased generation of C3dg-coated complexes that bind CR2. Further characterization of the downstream effects of these augmented signals through CR1 and CR2 are likely to provide mechanistic insights into the protective effect of rs1876453 as well as enhance the understanding of how the complement system modulates B cell activation.

Clinical and Immunologic Correlates in Cocaine Users with Serum Anti-Neutrophil Cytoplasmic Antibodies. Christian Lood and Grant C. Hughes. University of Washington, Seattle, WA.

Background/Purpose: Illicit cocaine use is associated with the development of serum anti-neutrophil cytoplasmic autoantibodies (ANCA) and a variety of clinical manifestations. However, the mechanisms linking cocaine use and autoimmunity remain obscure. A causal link between cocaine use and ANCA is suggested by known immunostimulatory properties of cocaine, and its frequent contamination with levamisole, an immunomodulatory chemical. Here, we describe the immunologic and clinical characteristics of a series of cocaine users found to have extremely high-titer serum ANCA. The purpose of this report is to generate testable hypotheses regarding possible links between cocaine use and autoimmunity.

Methods: Chart review of 12 consecutive patients referred for rheumatologic evaluation at 2 tertiary referral centers from 2008 and 2013 for active cocaine use and high-titer serum ANCA. Clinical and immunologic parameters with complete or near-complete data sets were chosen.

Results: Results are summarized in the table below. The majority of subjects were female users of crack cocaine. Half presented with hematologic abnormalities, but only a minority (2) presented with purpura, a frequently reported manifestation. Interestingly, 2 patients presented with diffuse alveolar hemorrhage (DAH) not readily explained by vasculitis or cryoglobulinemia. 3 patients presented glomerular disease. One presented with supraglottic inflammation, and another with ischemic bowel. Arthralgia/arthritis was common.

All patients had high-titer P-ANCA reactivity with variable MPO and PR reactivity, suggesting reactivity against unmeasured neutrophil antigens (Ags). High-titer ANA was not observed in any patient, although some displayed reactivity against select ANA-associated Ags. Most patients showed serum IgM (but not IgG) cardiolipin and/or b2-glycoprotein reactivity, along with frequent lupus inhibitor positivity, again consistent with previous reports. Hypocomplementemia was frequent among those patients with active HCV infection. Finally, there were no clear correlations between route/nature of cocaine exposure and either clinical or immunologic features.

Conclusion: We observed a wide variety of clinical manifestations in cocaine users with high-titer serum ANCA reactivity. Immunologically, patients were more homogeneous, showing near-exclusive P-ANCA reactivity, frequent IgM (but not IgG) cardiolipin/b2-glycoprotein reactivity and a complete absence of significant titer ANA – suggesting loss of immune tolerance to a limited set of self-Ags. That MPO reactivity was variably present further suggests P-ANCA reactivity was directed against other perinuclear neutrophil cytoplasmic Ags. The nature of these Ags in cocaine-users, as well as the effects of cocaine and levamisole on neutrophils, are the subjects of ongoing investigation.

Revisiting RS3PE after Twenty Five Years: A Systematic Review of 250 Cases. Paras Karmacharya[1], Anthony Donato[2], Madan Aryal[1], Sushil Ghimire[1], Ranjan Pathak[1], Kalpana Shah[3], Pragya Shrestha[4], Ananta Subedi[5], Smith Giri[6], Leena Jalota[1], Dilli Poudel[1] and David George[2]. [1]Reading Health System, West Reading, PA, [2]Reading Health System, Reading, PA, [3]Mymensingh Medical College, Mymensingh, Bangladesh, [4]Nanjing Medical University, Nanjing, China, [5]Good Samaritan Hospital, Baltimore, MD, [6]University of Tennessee Health Science Center, Memphis, TN.

Background/Purpose: Remitting seronegative symmetrical synovitis with pitting oedema (RS3PE) syndrome is a rare inflammatory arthritis, first described by McCarty *et al* in 1985 characterised by abrupt onset of symmetrical distal synovitis, marked pitting edema of the dorsum of the hands and/or feet, absence of rheumatoid factor (RF), and favorable response to corticosteroids. The aim of our study is to further delineate the clinical and laboratory features, their correlation with various rheumatologic diseases and malignancies; and response to treatment.

Methods: A systematic electronic search of Medline, PubMed, and EMBASE for case reports, case series, and related articles of RS3PE published from 1985 till Feb 2014 was carried out. Statistical analysis was done using EXCEL and SPSS version 20.0, comparing categorical variables with Chi-square tests and frequencies of means via t-tests.

Results: Two hundred fifty cases of RS3PE were identified from 91 articles. RS3PE was found predominantly in males (70%) and the age at onset was 69±11 years. It was symmetrical in most cases (98%) and majority involved dorsum of the hands. Patients had a mean white cell count of 8,800/mm3 and elevated erythrocyte sedimentation rate (63±35mm/hr) and C-reactive protein (569±2687mg/dl). RF was negative in most cases (97%). Vascular endothelial growth factor (VEGF) was found to be significantly elevated (2–3 times above normal) in the 5 cases reporting it. Radiographic joint erosions were found in 2%. Most patients responded to low dose prednisone (16.39±10 mg/day). Prednisone dose was not associated with reported presence of malignancy (16 vs 18 mg, p=not significant). NSAIDs were useful in the acute setting in addition to the steroids. Other therapies such as hydroxychloroquine and methotrexate were used with variable efficacy. Concurrent malignancy was present in 13.6% (3.6% hematological, 10% solid organ malignancies). These patients were found to have more severe disease requiring higher dose of prednisone (16 vs. 22 mg). Other rheumatological diseases were present in 2.8%. CRP was significantly higher in those with underlying malignancy (3293 vs. 374, $p<0.001$), but ESR was not (65 vs 62 mm, $p=0.4$).

Conclusion: RS3PE seems to be a distinct entity rather than a subset of other rheumatologic diseases or a paraneoplastic syndrome. Although we cannot establish an association between malignancy and RS3PE from this study, clinicians should be aware that patients with concurrent cancer tend to have more severe presentation and resistance to low-dose steroids. The cost effectiveness of aggressive cancer screening for patients with RS3PE compared to age-appropriate screening will need further research. Serum VEGF levels may be associated with its pathogenesis and it might be useful for the diagnosis and monitoring of disease activity. Uncomplicated cases of RS3PE usually have an excellent prognosis.

Incidence and Mortality of Relapsing Polychondritis in the United Kingdom: A Population-Based Cohort Study. Nisha Hazra[1], Alex Dregan[1], Judith Charlton[1], Martin C Gulliford[1] and David P. D'Cruz[2]. [1]King's College London, London, United Kingdom, [2]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom.

Background/Purpose: To estimate the incidence, prevalence and mortality of Relapsing Polychondritis (RP), and to describe the clinical features of RP, in a large population.

Methods: All participants diagnosed with RP were sampled from the Clinical Practice Research Datalink (CPRD). Prevalence and incidence rates for 1990–2012 were estimated. Relative mortality of RP cases was estimated in a time-to-event framework using UK life tables for reference. A questionnaire validation study was performed.

Results: There were 117 participants with RP ever recorded. In the validation study, 47/58 (81%) of cases were confirmed by a physician and unconfirmed cases were excluded. The analysis included 106 participants (42 men, 64 women) diagnosed with RP. The mean age (range) at diagnosis in men was 55 (17 to 81) years and in women 51 (11 to 79) years. There was a median interval of 1.9 years from first symptom consultation to diagnosis. The incidence of RP between 1990 and 2012 was 0.71 (0.55 to 0.91) per million population per year. There were 19 deaths from any cause. There were 16 observed deaths eligible for survival analysis and 7.4 deaths expected for the UK population of the same age, sex and period. The standardised mortality ratio was 2.16 (1.24 to 3.51), $p<0.01$. Respiratory disease, cardiac conditions and cancer were the most frequent causes of death.

Conclusion: The incidence of RP may be lower than previously estimated and diagnostic misclassification and delay may be frequent. Mortality in RP is more than twice that of the general population.

Multicentric Reticulohistiocytosis- Case Series from a Tertiary Care Center. Namrata Singh[1], Karolyn A Wanat[1], Mary Stone[1], Zuhair K. Ballas[2] and Jacob W. Ijdo[1]. [1]University of Iowa, Iowa City, IA, [2]Iowa City VA and the University of Iowa, Iowa City, IA.

Background/Purpose: Multicentric Reticulohistiocytosis (MRH) is a rare systemic inflammatory disease with skin nodules and arthritis. On skin or joint biopsy the hallmark is the presence of multinucleated giant cells and histiocytes with a ground glass appearance of the cytoplasm secondary to lipid inclusions. In the past solitary or multiple cutaneous reticulohistiocytoma without joint involvement were thought to be a separate entity because it only affects the skin, albeit the histopathology is identical. Due to the rarity of the disease little is known about pathophysiology or treatment. Anecdotal reports suggest that the use of TNF inhibitors and bisphosphonates may be beneficial. We wished to review the combined experience of this rare condition at a tertiary care institution.

Methods: After obtaining IRB approval, we searched the electronic medical records at the University of Iowa Hospital and Clinics (UIHC) to identify all patients with MRH or cutaneous reticulohistiocytoma seen between January 2000 and December 2013. The aims of this retrospective study are to describe the different treatments and outcomes and concomitant diagnoses in patients with MRH/cutaneous reticulohistiocytoma with or without joint involvement.

Results: We have identified 16 patients of which 4 had both skin and joint involvement and 12 cases with cutaneous involvement only that were diagnosed and treated at UIHC. All cases had a skin biopsy consistent with non-Langerhans reticulohistiocytosis. The age of patients with MRH ranged from 48–66 years old. Hands, wrists and knees were the most commonly affected joints. Treatments varied from intravenous infusions of zoledronic acid to TNF-inhibitors (adalimumab and etanercept) with varying responses. Two patients were treated with cyclophosphamide with improvement of disease. None of the patients were diagnosed with a malignancy.

Conclusion: Multicentric reticulohistiocytosis and cutaneous reticulohistiocytoma share identical histopathology but have different distribution and organ involvement. The pathogenesis and mechanism for different organ distribution of this systemic inflammatory disease is unknown. We report here the largest case series to date (16 cases) from a single academic institution in the last 13 years. It seems that MRH includes a wide spectrum ranging from no joint involvement to severe destructive arthritis. Follow up of patients with solitary and multiple cutaneous reticulohistiocytoma is warranted as joint involvement may develop with time.

Features of Interstitial Lung Disease Associated with Connective Tissue Disease in a Spanish Southwest Cohort. Adela Gallego Flores[1], Carmen Carrasco Cubero[2], Raul Veroz Gonzalez[1], Luz Maria Mellado Narciso[1], Tamara Libertad Rodriguez Araya[1], Juan Jose Aznar Sánchez[1] and Eugenio Chamizo Carmona[1]. [1]Hospital de Mérida, Mérida, Spain, [2]Hospital de Merida, Mérida, Spain.

Background/Purpose: Diffuse interstitial lung disease (ILD) can be associated with connective tissue diseases (CTD), and can increase morbidity and mortality significantly. The predominant patterns of ILD associated with CTD are often nonspecific interstitial pneumonia (NSIP) and usual interstitial pneumonia (UIP). UIP is more common in rheumatoid arthritis (RA). Pulmonary involvement in rheumatic diseases can be the first manifestation of these pathologies, preceding the onset of extrapulmonary symptoms. The presentation, clinical features and evolution of ILD associated with CTD can be variable, and therefore, it's important to improve the prognosis by early diagnosis and treatment. The aim of this study is to describe the clinical features, treatments and outcome of patients with ILD associated with CTD found in the General Hospital of Mérida.

Methods: We systematically collected all cases of ILD associated with CTD reported in the Rheumatology Department from January 2008 to January 2014. We included patients over 18 years old, who had a CTD and radiological diagnosis of ILD.

Results: We found 36 patients with ILD associated with CTD: 17 rheumatoid arthritis (RA), 10 scleroderma (ES), 6 antisynthetase syndromes (SAS) and 3 Sjögren's syndrome (SS). The mean age was 66.08 years, with a female predominance (2-1). History of smoking was present in 33.3% of the sample, and previous lung pathology in 18.7%. The diagnosis of CTD preceded the diagnosis of ILD in 58,3 % (21). The ILD patterns were: 17 NSIP (47,2 %), more frequent in ES (6 pac) and SAS (5 pac); and 19 UIP (52,8%), predominantly in RA. Thirty patients were treated with IV cyclophosphamide (CF) and 14 with rituximab (RTX). We observed a sustained response in 13 patients (10 NSIP and 3 UIP): 2 patients had received CF, 6 RTX, 4 CF+RTX, and 1 antiTNF. All RA patients were rheumatoid factor (RF) positive, 33,3 % with a title over 100. The predominant pattern was UIP (73,2 %). Methotrexate was used in 64.2% of patients and it was suspended at the diagnosis of ILD, although no cases of pneumonitis were found by this drug. Patients with ES, SAS and SS were younger at diagnosis (63.7, 62 and 64.3 years respectively) than RA patients (69,23 years) and a predominance of NSIP pattern (66.7, 80 and 66.6 % respectively). All these patients had negative RF. ANAs were positive in 100 % of SAS, with a predominance of anti Ro 52 and anti JO1 (3 and 4 patients) and 77.8% of ES and 66.6 % of SS. Two patients presented with poor responses to CF, one with UIP (ES) and 1 with NSIP (SAS), who died from infectious complications.

Conclusion: Usually the first manifestation of an ETC is due to the ILD, so it is advisable to maintain close cooperation with pneumologist. According to the literature, all patients with RA and ILD in our sample had RF+, as it usually occurs in rheumatoid extraarticular involvement. Otherwise, the UIP was the predominant pulmonary pattern. Rest of ETC associated ILD had a predominance of NSIP pattern and positive ANAs, especially anti Ro, and anti Jo1 in SAS. The RF was negative in all cases. Nine patients treated with RTX or sequentially with CF + RTX achieved better response. However, more studies need to be undertaken to reach better conclusions on the ways forward in treatment.

Intravenous Sodium Thiosulfate for Treatment of Refractory Calcinosis in Rheumatic Disease. Ross Thibodaux, Bahnsen Miller and Stephen Lindsey. Louisiana State University Health Science Center, Baton Rouge, LA.

Background/Purpose: Calcinosis, or dystrophic calcification, is a poorly understood, debilitating condition commonly manifested in connective tissue diseases such as scleroderma and polymyositis. Despite treatment of the rheumatologic disease, patients typically endure pain, infections, and decreased joint mobility. Therapeutic options for calcinosis, including coumadin, corticosteroids, diltiazem, probenecid, and colchicine, have shown little success, and treatment failure is common. Intravenous sodium thiosulfate (IV STS) is commonly used to treat calciphylaxis, and several mechanisms are proposed for its effects. Intriguingly, the chelating properties of IV STS form water soluble calcium-thiosulfate, which aids in dissolving deposited calcium

salts. Additionally, STS increases production of glutathione and nitric oxide, which improve endothelial function, vasodilate blood vessels, and decrease tissue ischemia. Physiologically, it is feasible to hypothesize that IV STS may treat refractory calcinosis, but data is not available regarding its use. The following patient chart reviews illustrate this hypothesis:

Methods: Patients #1, a 63 yo Caucasian female with limited scleroderma, and #2, a 46 yo Black female with polymyositis, suffer with recurrent calcinosis deposits of the skin and soft tissue causing pain and functional loss. Patient #1 reported severe pain and decreased mobility of her hands, and patient #2 reported deposits in her posterior thigh causing severe pain on sitting down and standing up. Aggressive therapy, including corticosteroids, colchicine, calcium channel blockers, and surgical interventions, yielded little improvement in pain and function. Each patient regularly reported pain scores of 8–9/10. After discussing IV STS therapy and obtaining consents, infusions were started at 12.5 grams over one hour weekly and advanced as tolerated. The maximum doses achieved in patients #1 and #2 were 15 gm/week and 25 gm/week, respectively. Infusions were continued weekly for approximately seven months. The infusions were tolerated well, and the most common patient reported side effects were nausea and blurry vision. The most common laboratory abnormality was a non-gap metabolic acidosis.

Results: As early as two weeks after starting the infusions, improvements in pain scores and softening of calcinosis deposits were observed. Both patients reported improved pain scores of 3–4/10 at two weeks and 0–1/10 at four weeks, and this persisted throughout therapy. At four weeks, functional status improved; specifically, patient #1 was able to grip a drinking glass without difficulty, and patient #2 was able to sit and stand with ease.

Conclusion: The clinical improvements observed may be attributed to the inherent properties of IV STS. Intravenous STS therapy is approved for calciphylaxis as well as cyanide and chemo-related toxicities. Although calcinosis is pathologically different from calciphylaxis, the physiologic properties of IV STS may contribute to the clinical improvements outlined above. These findings illustrate the potential of IV STS to treat painful calcinosis and the need for further studies of its use in rheumatic disease.

Successful Therapy with Intravenous Sodium Thiosulfate for Adult Dermatomyositis Associated Calcinosis. Maria Constanza Florestano[1] and Mauricio Álamo[2]. [1]University of Valparaiso, Chile, Santiago de Chile, Chile, [2]Clinica Dávila, Santiago of Chile, Santiago of Chile, Chile.

Background/Purpose: Calcinosis cutis is the deposition of insoluble calcium salts in skin or subcutaneous tissue. In cases related to CTD, presents with normal calcium/phosphorus metabolism, and is frequently associated with SSc and DM. Despite therapies available, treatment response is often poor.

Methods: The subject is a 38-year-old male that presented with classic DM in 2007. Secondary causes were ruled out. He was treated with corticosteroids and methrotrexate, with recovery of muscle strength and normalization of creatinkinase. In May 2008 without DM activity, he presented progressive painful subcutaneous calcifications in the axillary, gluteal and popliteal region, hands and back, confirmed by x-ray. Metabolic studies were normal.

Infliximab was initiated (200mg tid every 8 weeks totaling 5 doses), with poor response and progression of calcinosis.

Results: In August 2009 therapy with sodium thiosulfate was initiated: 50ml at 25% (12,5gr) in prolonged infusion over 60 minutes qid, with 10 doses per session. He received 17 monthly sessions, with a slow but significant regression of pain and calcinosis. Adverse effects were nausea, headache and infusion site pain, all mild. The patient has remained asymptomatic, without new calcinosis.

Conclusion: Sodium thiosulfate is a calcium chelating agent, with unknown mechanisms of action, such as the formation of soluble complexes, antioxidant, protector of the endothelium, vasodilator, antithrombotic, antimetaloproteases and increases endogenous calcification inhibiting proteins. Recent studies show benefit in dialysis-associated calcification. Its systemic use in the treatment of CTD associated calcinosis has been only communicated through case reports. Our patient presented with favorable outcome, with clinically significant reduction of calcifications and reduction of pain without major adverse effects, which might lead to a more effective therapy than available options.

Prevalence of Raynaud's Phenomenon and Nailfold Capillaroscopic Abnormalities in Fabry's Disease: A Cross-Sectional Study. Samuel Deshayes[1], Roland Jaussaud[2], Bernard Imbert[3], Olivier Lidove[4], Jean-Jacques Parienti[1], Nathalie Triclin[5], Laurent Auboire[6] and Boris Bienvenu[1]. [1]CHU Côte de Nacre, CAEN, France, [2]CHU de Reims, REIMS, France, [3]CHU, Grenoble, Grenoble, France, [4]Hôpital Croix-Saint-Simon, PARIS, France, [5]Association des Patients de la Maladie de Fabry, VENDRESSE, France, [6]UMR Imagerie et Cerveau, TOURS, France.

Background/Purpose: Fabry's disease (FD) is a lysosomal disorder leading to progressive systemic involvement, including neurologic and vascular. We hypothesize that the microangiopathy observed in FD could be documented, including at an early stage, by using nailfold capillaroscopy and assessing the presence of Raynaud's phenomenon (RP). The objective of this study was to measure the prevalence of RP and nailfold capillaroscopic abnormalities in FD.

Methods: This cross-sectional study included a standardized questionnaire and a nailfold capillaroscopy assessing previous reported patterns in FD (dystrophic and giant capillaries, avascular fields, irregular architecture, dilatation and density of capillaries, hemorrhage), and was conducted on 32 Fabry patients and 39 controls. Two independent blinded reviewers carried out the analysis of capillaroscopic photographs.

Results:

Table 1: Demographic and clinical characteristics of Fabry patients and controls

	Fabry patients	Control group	p value
n	32	39	
Age, mean ± SD	45,5 ± 13,8	48,2 ± 11,5	0.38
Sex-ratio (males/females)	0,46 (10/22)	1,6 (24/15)	**0.02**
Smoking, n (%)	1 (3)	4 (10)	0.37
Cannabis, n (%)	0 (0)	0 (0)	1
Hypertension, n (%)	8 (25)	4 (10)	0.1
Hyperlipidemia, n (%)	4 (13)	4 (10)	1
Diabetes, n (%)	1 (3)	3 (8)	0.63
Pain in the extremities, n (%)	28 (88)	0 (0)	**<0.001**
Enzyme replacement therapy, n (%)	25 (78)	0 (0)	**<0.001**

Table 2: Characteristics of patients suffering from Raynaud's phenomenon (RP)

	Fabry patients	Control group	p value
Males with RP, n (%)	5/10 (50)	0/24 (0)	**<0.001**
Females with RP, n (%)	7/22 (32)	2/15 (13)	0.27
Total with RP, n (%)	12/32 (38)	2/39 (5)	**<0.001**

Patients with FD and RP all suffered from pain in the extremities, whereas none in the control group did ($p = 0.011$). RP was concomitant or prior to the occurrence of pain in the extremities in 42% of Fabry patients. Significantly more ramified capillaries were observed in Fabry patients (12/32, 38%) than in controls (5/39, 15%, $p = 0.016$). No other statistically significant difference was observed by nailfold capillaroscopy.

Conclusion: This study is, to the best of our knowledge, the largest one assessing nailfold capillaroscopy and the presence of RP in FD. RP was highly prevalent in our series of Fabry patients (38%) and involved 50% of males. FD should thus be considered as a cause of secondary RP. RP was concomitant or prior to the occurrence of pain in the extremities in almost 50% of Fabry patients. It could be, at least in part, a causal factor of these pains. Secondary RP should lead to a screening for FD, especially in men. By extension, in high-risk populations (i.e. hypertrophic cardiomyopathy, dialysis patients, stroke in young people), the presence of ramified capillaries and RP should also be assessed.

Blue Digit Syndrome: The Rheumatologist's Perspective. Helena Borrell[1], Javier Narváez[2], Eulalia Armengol[1], Milagros Ricse[1], Gloria Albert[1], Sergi Heredia[1], Andrea Zacarias[1], Carmen Gomez Vaquero[1] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Blue or purple digit syndrome (or sign) is a cutaneous manifestation of multiple diseases that produce acute or subacute ischemic compromise in one or more fingers or toes. The most frequent cause of this syndrome is a reduction in arterial blood flow due to compromise or occlusion of small peripheral vessels, with preservation of the distal pulses.

The finger or toe affected by ischemia turns blue or violet and may develop necrosis. Whatever the cause, blue digit syndrome is a medical emergency requiring rapid diagnosis and specific treatment, given the risk of progression to irreversible necrosis. Only a very small percentage of cases need surgical intervention; the great majority of patients can be safely managed by medical therapy. Given their nature, medical cases should be managed by rheumatology services. Our aim was to evaluate the frequency, etiology and outcome in a series of patients admitted with blue digit syndrome in the Department of Rheumatology of the University Hospital of Bellvitge, a tertiary care teaching institution in Barcelona, Spain.

Methods: Ambispective cohort study of all patients admitted to our department with blue digit syndrome between 1990 and the first quarter of 2014.

Results: 41 patients (12 women and 19 men) were identified, with a mean age at diagnosis of 55 ± 18.8 years (range: 23–86 years). In 75% (31/41) of patients showed ischemic compromise of one or more fingers (being the second and third fingers most commonly affected), in 15% (6/41) were affected one or several fingers feet, and in 10% (4/41) remaining fingers and toes are affected simultaneously. The main etiologies are summarized in Table 1.

	Number of cases
Autoimmune diseases	11
Buerger's disease	3
Crioglobulinemia related to Sjogren's syndrome or HCV infection	7
Other primary systemic vasculitis or Vasculitis Associated with Systemic Disease (RA, SLE)	10
Systemic sclerosis (scleroderma)	1
Mixed connective tissue disease (MCTD)	
Pseudovasculitis	2
Cholesterol crystal embolism	2
Antiphospholipid syndrome	2
Paraneoplastic acral vascular síndrome	1
Hypothenar hammer syndrome	
Myeloproliferative síndromes (essential thrombocythemia)	1
Arteriosclerosis	1

Sixty per cent of patients (24/41) also had cardiovascular risk factors, the most common being active smoking and high blood pressure. Three of the patients with Buerger's disease were cannabis smokers.

Ninety per cent of patients (37/41) progressed well with conservative medical treatment and only 10% (4/41) required amputation (one case with arteriosclerosis and three patients with scleroderma).

Conclusion: In our experience, the most common causes of blue digit syndrome are systemic sclerosis and vasculitis. Differential diagnosis should also include pseudovasculitis, observed in a considerable percentage (17%) of these patients. Despite its severity, the ischemia usually responds to conservative medical treatment and amputation is unnecessary in most cases.

Eculizumab Treatment of Malignant Atrophic Papulosis (Köhlmeier-Degos Disease): World Experience to Date. Aixa Toledo-Garcia, Lee S. Shapiro and Jessica F. Farrell. The Center for Rheumatology, Albany, NY.

Background/Purpose: Malignant atrophic papulosis (MAP) is an obliterative vasculopathy which presents with distinctive cutaneous lesions but can progress over months to years to systemic disease with a rapidly fatal course. Pathologic findings of involved tissues reveal dense deposition of membrane attack complex (MAC). Eculizumab is a monoclonal antibody which prevents activation of C5 to C5b and C5a. Within the past five years, based on immunopathology of the disease, eculizumab has been used in MAP. The relative importance of inhibition of formation of C5a and of inhibition of formation of MAC has not been determined.

Methods: A literature review and personal communication with physicians treating MAP patients throughout the World identified survivors and treatment failures (deaths). We attempted to identify those characteristics which distinguished the survivors from those who died.

Results: We identified eight patients who were treated with eculizumab at different stages of disease and in different circumstances. Among those eight patients, only three are alive, two for nearly five years since initiation of eculizumab. Two out of the three survivors presented with GI perforations and cardiovascular decompensation and were placed on eculizumab with an immediate and dramatic response. They did not receive systemic steroids. The third live patient presented with CNS involvement affecting the right eye requiring enucleation. Treprostinil was started after that event, temporarily suppressing cutaneous lesions, but because of gastrointestinal disease progression, eculizumab was later added. All other patients had received high doses of systemic steroids and may have had bacteremia at the time of treatment with eculizumab. In addition, one patient had very aggressive dermatomyositis overlap.

Conclusion: Our results suggest that eculizumab is a vital treatment option for patients with rapidly progressive systemic MAP. These individuals have a life expectancy of less than one year if left untreated. Treatment benefits likely arise both from the inhibition of C5a formation and from inhibition of formation of membrane attack complex. Treatment experience to date has been associated with high mortality, which we feel most likely is the consequence of increased risk of bowel perforation and septicemia in those who had already received systemic steroids. The avoidance of systemic steroid therapy is essential for a good outcome. Also, earlier identification of those at high risk for bowel perforation should improve outcome by reducing risk of bacteremia developing during treatment. We report long term survival of several individuals, but in none was eculizumab effective long-term as monotherapy.

2196

Treprostinil Use in Malignant Atrophic Papulosis (Köhlmeier-Degos Disease): Review of Worldwide Experience to Date. Lee S. Shapiro[1], Aixa Toledo-Garcia[2] and Jessica F. Farrell[2]. [1]Steffens Scleroderma Center, Saratoga Springs, NY, [2]The Center for Rheumatology, Albany, NY.

Background/Purpose: Malignant atrophic papulosis (MAP) is a rare thrombo-occlusive vasculopathy that presents with cutaneous only lesions but can progress after months or years to rapidly fatal systemic involvement. Until the very recent past, there were no reports of effective treatment of the systemic disease. A recent publication described successful use of treprostinil, a prostacyclin analog, in treatment of systemic MAP and in MAP-scleroderma-SLE overlap.

Methods: We performed a retrospective analysis of six patients using data collected from treating physicians worldwide through personal communications and our own experience. We also employed PUBMED for a literature search, which yielded 200 articles, using the keywords malignant atrophic papulosis and Degos disease. We evaluated outcomes of six MAP patients who were treated with treprostinil to identify discriminating factors between survivors and non-survivors.

Results: Among the six treprostinil MAP treated patients we know four are alive. Our first treprostinil treated patient was a female with scleroderma/SLE overlap who developed MAP lesions without systemic MAP involvement. As a result of pulmonary hypertension she was started on treprostinil. Cutaneous lesions subsequently resolved. We then treated a primary MAP male who had progressive CNS disease despite ongoing therapy with eculizumab. Within months after treprostinil was started MRI showed resolution of the lesions. Another male on eculizumab with disease progression was started on treprostinil with resolution of symptoms. The fourth patient was a female with biopsy proven MAP who already had CNS involvement with loss of vision in the right eye that led to enucleation. Treprostinil was started with temporary stabilization of symptoms. In the fifth patient, treprostinil was started after severe systemic involvement had taken place. She had GI perforations and CNS involvement which led to death. Eculizumab was not the first line therapy in patients four and five. Lastly, through a literature search we found a sixth patient who was a female on treprostinil for pulmonary hypertension related to systemic sclerosis. She then developed a restricted form of MAP while on treprostinil and is possibly alive, making a total of five patients alive today.

Conclusion: MAP is a rapidly fatal systemic disorder with a life expectancy of less than one year after development of visceral involvement. After comprehensive review of treprostinil use for MAP, we found the majority of patients treated (4/5) are still alive up to 42 months after initiation of therapy. All survivors with systemic disease are on dual therapy with eculizumab. The first patient with cutaneous MAP and scleroderma/SLE overlap had resolution of skin lesions on treprostinil alone. Patient six developed a restricted form of MAP while on treprostinil leading the authors to believe treprostinil limited the MAP vasculopathic process. The efficacy of treprostinil in MAP may be related not only to antithrombotic and vasodilatory effects but also to its reported ability to increase the number of endothelial progenitor cells.

2197

Malignant Atrophic Papulosis (MAP) Complicating Connective Tissue Diseases (CTDs). Aixa Toledo-Garcia, Lee S. Shapiro and Jessica F. Farrell. The Center for Rheumatology, Albany, NY.

Background/Purpose: Malignant Atrophic Papulosis (MAP) is a rare vasculopathy of unknown etiology commonly presenting with cutaneous lesions, but can progress to multisystem disease with a fatal outcome. MAP has been reported in the setting of other CTDs. Currently, there is a limited understanding of the association between CTDs and overlapping MAP. We theorize that MAP can present independent or complicating a vasculopathic CTD.

Methods: We performed a retrospective review on approximately 200 MAP cases obtained through a PubMed literature search, personal experience and communications with treating physicians worldwide. Cases were then analyzed for overlapping CTDs and further stratified for factors associated with disease outcomes.

Results: Of the 200 MAP cases, we identified 33 with an overlapping CTD diagnosis. These included: 11 SLE, 1 chronic cutaneous lupus erythematosus (CCLE), 3 SSc, 8 DM, 1 amyopathic DM, 6 APL syndrome (including patients positive for antibodies) 1 undifferentiated CTD, 1 granulomatous polyangiitis, and 1 RA. Patients with systemic MAP had fatal outcomes. Patients positive for APL antibodies with cutaneous MAP have survived but patients with APL syndrome and MAP have died. DM patients given steroids have died. In the setting of SSc there are two females who are alive and one male who died of fulminant SSc. Both females were on treprostinil for pulmonary hypertension.

Conclusion: MAP complicating CTD represents a challenging picture diagnostically and therapeutically. The presence of MAP may be a marker of more severe microvascular disease in those with SSc and DM and may be associated with worse prognosis because of concurrent steroid use. Steroids have been associated with increase risk of GI perforations and death. We believe MAP can present in the setting of a CTD in both cutaneous only and systemic forms. Histologically lupus and MAP can have similar findings but are not the same disease. MAP is not a systemic vasculitis but in its initial stages can present with an inflammatory infiltrate that later changes to the characteristic dermal necrosis and atrophic dermis with non-inflammatory endarterial thrombotic occlusion, leading to wedge-shaped skin necrosis, sclerosis and mucinosis. When MAP affects the CNS, the CNS pathology could have a perivascular lymphocytic infiltrate like a vasculitis, but MAP is not a vasculitis and seems to respond very poorly to steroids. Early intervention of systemic MAP can be lifesaving.

2198

The Aromatase Inhibitor Induced Musculoskeletal Syndrome: Is There a Potential Role of Osteoporosis Therapy and Menopause Timing? Zsolt Kulcsar[1], Clinton Morgan[2], Peter Kaufman[1], Jonathan Jones[3] and William Rigby[4]. [1]Dartmouth Hitchcock Medical Center, lebanon, NH, [2]Dartmouth Hitchcock Medical Center, Lebanon, NH, [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [4]Dartmouth-Hitchcock Medical Center and Dartmouth Medical School, Lebanon, NH.

Background/Purpose: Aromatase Inhibitor (AI) therapy is the most effective hormonal treatment in post-menopausal estrogen receptor (ER) positive breast cancer. These patients may be seen by rheumatologists due to the side effects of arthralgias, termed aromatase inhibitor induced musculoskeletal syndrome (AIMSS), which limit their use in some patients. We evaluated factors associated with AIMSS and explored possible therapeutic options in a large cohort of patients.

Methods: We performed an IRB-approved retrospective review of breast cancer patients seen in the Norris Cotton Cancer Center clinics from April 2011 to January 2013. 378 patients were included in our chart review on the basis of taking an AI for breast cancer with follow up documented in the electronic health record. Statistical analysis was performed by chi squared test for dichotomous variables and students t-test for continuous variables.

Results: In our cohort 91% of patients were taking an AI as adjuvant therapy (9% for metastatic disease) with 41% (n=153) reporting new or worsening arthralgias after initiation of an AI. AIMSS was 42.5%(95%CI: 0.375 to 0.478) in the adjuvant and 22.7%(95%CI: 0.101 to 0.434) in the metastatic groups. The median time to symptom onset was 120 days. 2.1% (n=8) discontinued AI therapy due to AIMSS. There was no association with prior chemotherapy, baseline arthralgia, BMI, or statin use. We found an apparent increased risk of developing AIMSS with more recent menopause ($p=0.055$), and therapy in the adjuvant setting ($p=0.067$). We also note a potential association with baseline osteoporosis and osteoporosis therapies with lower rates of AIMSS ($p<0.05$; Table 2). Management options included temporary discontinuation of AI, switching between AI, and non-steroidal anti-inflammatory therapy (NSAIDs). Nearly all had improvement with temporary discontinuation, 24.5% improved after AI switch, and 84% had symptomatic benefit on NSAIDs.

Conclusion: The incidence of AIMSS in our review was 41%. Patients treated for metastatic disease may have a lower rate of AIMSS. Our cohort revealed that more recent menopause did seem to be a risk factor. Baseline osteoporosis and osteoporosis treatments have a potential association to be explored. Management options included switching between AIs, temporary discontinuation, and NSAID treatment. Updated analysis will be presented.

Table 1. Baseline patient characteristics

Characteristic	*N* (%)
Patients on AI therapy	375
Type of Aromatase Inhibitor Used	
Anastrazole	206 (54.9)
Letrazole	132 (35.2)
Exemestane	37 (9.9)
Baseline T-score by Dexa Scan	316
Normal (T-score 0 to −1.499)	101 (26.9)
Osteopenia (T-score−1.499 to −2.5)	173 (46.1)
Osteoporosis (T-score < −2.5)	41 (10.9)
Total patients experiencing AIMSS	153 (40.8)

Median time from start of AI to AIMSS in days	120
Average age at AI initiation [SD]	61.8[±10]
Attempted an AI switch	38 (24.8)
Reported improved symptoms after switch	27 (24.5)
Needed to stop drug temporarily due to AIMSS	52 (17.0)
Needed to stop drug permanently due to AIMSS	8 (2.1)

AIMSS = Aromatase Inhibitor Induced Musculoskeletal Syndrome, DEXA = Dual-energy x-ray absorptiometry

Table 2. Potential risk factors for the development of AIMSS.

Characteristic	N	(−)*Arthralgia* N (%)	(+)*Arthralgia* N(%)	p-value
Type of AI Used				
Anastrazole	204	112 (55.9)	92 (45.1)	0.19
Letrazole	131	83 (63.4)	48 (36.6)	
Exemestane	36	23 (64.9)	13 (36.1)	
Menopause timing				
LMP <5 years prior to AI start	151	79 (52.3)	72 (47.7)	0.055

Intravenous Immunoglobulin Therapy for Secondary Hemophagocytic Lymphohistiocytosis: A Retrospective Study of 46 Patients. Bertrand Dunogué[1], Magdalena Gerin[2], Claire Larroche[3], Catherine Montagnier-Petrissans[4], Loïc Guillevin[1] and Luc Mouthon[1]. [1]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [2]Hôpital Jean Verdier, Bondy, France, [3]Hôpital Avicenne, Bobigny, France, [4]Groupe d'Expert AP-HP, Paris, France.

Background/Purpose: Intravenous Immunoglobulins (IVIg) have been reported as giving good results in infectious, but also auto-immune related forms of hemophagocytic lymphohistiocytosis (HLH), but only in case reports and small retrospective studies.

The objective of this study was to evaluate the use of IVIg as a treatment of secondary HLH in a wide hospital-based population.

Methods: A multicenter retrospective study of all cases of secondary HLH treated with IVIg in Parisian hospitals between January 2000 and December 2006.

Results: Of the 162 IVIg-treated patients for declared secondary HLH, 46 met the HLH-2004 criteria (29 male (63%), median age 47.5 yr (min 15; max 87)). Thirty-three (72%) had a history of immunodepression (AIDS (15/46), hemopathy (12/46), systemic disease (5/46)). Causes of HLH were: infection (18/46, 39.1%), malignant hemopathy (20/46, 43.5%), systemic disease (3/46, 6.5%), or undetermined (5/46, 10.8%). IVIg were administered mostly at 2 g/kg (25/46, 52%), with a median delay of 2 days (−12; 253) after diagnosis. One adverse event to IVIg administration occurred (shock). Other therapies included: corticosteroids (32/46, 70%), etoposide (10/46, 21.7%), chemotherapy (9/20 of the hemopathy group), anti-infectious agents (41/46, 89%), red blood cell (38/46, 82.6%) and platelet (30/46, 65%) transfusions. Twenty-nine patients (63%) required intensive care (respectively 10 (55.5%), 14 (70%), and 4 (80%) in the infection, hemopathy, and undetermined groups). Twenty-five patients (54.3%) died of HLH (respectively 6 (33.3%), 13 (65%), 2 (66.6%), and 4 (80%) in the infection, hemopathy, systemic disease, and undetermined groups), with a median time to death of 12 days (1; 142). While long-term survival was better in the infection group, short-term survival (at 20 and 60 days) and evolution of cytopenias did not vary significantly among the different etiological groups.

Conclusion: Short-term evolution of IVIg-treated HLH patients seems to be equally severe in all etiological groups, despite IVIg treatment. The impact of IVIg treatment on lower long-term mortality in the infectious-related group is hard to establish, owing to a higher long-term mortality related to the underlying cause in the hemopathy group.

Elevated Serum Ferritin Levels in Adult Inpatients As a Predictor of in-Hospital Mortality and Association with Macrophage Activation Syndrome. Matthew Mullen, Marcin Trojanowski, W. Winn Chatham and Bita Shakoory. University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Macrophage Activation Syndrome (MAS) is a syndrome similar to Familial Hemophagocytic Lymphohistiocytosis (HLH) characterized by increased proliferation and activity of T-cells and macrophages leading to massive systemic inflammation, multi-organ system failure, and often significant morbidity/mortality. Elevated serum ferritin is part of the diagnostic criteria for MAS/HLH and studies have shown that extremely elevated levels of serum ferritin have a high specificity for MAS. We sought to determine the correlation between significantly elevated ferritin levels (>2000) and in-hospital mortality as well as associated presence of MAS among adult inpatients.

Methods: Using Cerner EHR, patients were selected for study inclusion based on serum ferritin levels >2000 obtained during hospital admissions. Patients with hemoglobinopathy associated ferritin elevation were excluded. Patient charts during hospitalizations corresponding to the elevated serum ferritin were reviewed for mortality, diagnostic criteria for MAS, and treatment interventions. Patients were determined to have likely MAS based on either 1) whether current case definition criteria for HLH were met with at least 5 of the following: fever >100.4 degrees F, splenomegaly, two or more cytopenias (Hgb ^{9}/L, ANC $<1.0\times10^{9}$/L), hypertriglyceridemia (fasting >265 mg/dl), hypofibrinogenemia (meters checked, if they met 4 out of the 5 clinical/laboratory criteria: fever, splenomegaly, two or more cytopenias, hypertriglyceridemia, and hypofibrinogenemia or new coagulopathy defined as INR >1.5 if no fibrinogen level available.

Results: Patients were stratified into groups by peak serum ferritin levels: 2–5,000, 5–10,000, 10–20,000, and >20,000. Mortality rates were 70/370 (19%) in the 2–5000 group, 28/78 (36%) in the 5–10,000 group 11/40 (28%) in the 10–20,000 group, 15/39 (39%) in the >20,000 group. A total of 48 patients met the designated criteria for MAS, comprising 2% of patients in the 2–5,000 group; 6% of the 5–10,000 group; 30% of the 10–20,000 group and 61% of the >20,000 group. In addition to treatment with corticosteroids, 29 of these 48 patients received treatment with the IL-1 inhibitor anakinra, 10 of whom died during the hospitalization (in-hospital mortality of 34.5%); among the 19 patients with identified MAS who did not receive anakinra as part of their treatment there were 15 in-hospital deaths (in-hospital mortality of 79%).

Conclusion: Our results demonstrate a correlation between elevations in serum ferritin levels and increased in-hospital mortality in adult patients. Furthermore, our results suggest that at least part of the increased mortality observed in patients with extremely elevated serum ferritin is attributable to unrecognized or undertreated MAS.

Haematological Complications in Rheumatic Diseases: Not Only Lymphomas. Elena Elefante[1], Chiara Baldini[1], Alice Parma[1], Elisa Cioffi[1], Francesco Ferro[1], Roberta Vagelli[1], Martina Rousseau[2], Rosaria Talarico[1], Sara Galimberti[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Hematology Unit, Pisa, Italy.

Background/Purpose: Several immunological abnormalities have been reported among patients affected by myelodisplastic syndrome (MDS). On

the other hand, a relatively limited number of studies have explored the occurrence of MDS during the course of systemic autoimmune diseases (AD) Aim of the study: to estimate characteristics and frequency of MDS among patients with systemic autoimmune diseases (AD).

Methods: A retrospective systematic search through the electronic health records of the patients admitted at our Rheumatology University Medical center from 2009 and 2014 was performed to select those patients with systemic AD and MDS. To refine the search the ICD-9-CM diagnosis code for MDS was utilized. Medical charts of eligible patients were retrieved and data were collected with regard to demographics, type of AD, AD duration, prior treatments, serum haematologic indices, bone marrow aspiration and biopsy data. Categorical variables were compared using chi square test and Fisher's test; continuous variables were compared using Student's t-test. A 2-tailed value of $p < 0.05$ was taken to indicate statistical significance.

Results: Out of the medical records of 3800 patients, we identified 23 patients with AD and MDS. Patients' mean (SD) age at the diagnosis of MDS was 65.3±12.6 years with a 1.09:1 female to male ratio. Rheumatoid arthritis and seronegative arthritis were the most frequent underlying AD condition (7/23, 30%) followed by large and small vessel vasculitis (7/23, 30%), Systemic Lupus Erythematosus (3/23, 13%), Sjogren's syndrome and myositis (2/23, 8%). Moreover, one patient was affected by Systemic Sclerosis and one by Behçet's syndrome. Anaemia (21/23, 91%) was the most common haematologic presenting abnormality followed by thrombocytopenia (9/23, 39%) and neutropenia (8/23, 35%). Three patients out of 23 presented with a trilineage cytopenia (13%). In the majority of the patients the diagnosis of MDS was subsequent to that of AD with a mean period between the two diagnosis of 4±6.3 yrs. Prior to MDS diagnosis, about one third of the patients received cytotoxic drugs, among which MTX was the most commonly prescribed (5/23, 22%) followed by azathioprine and cyclophosphamide (2/23, 8%). Regarding MDS, the most common diagnosis was refractory anemia with excess of blasts (RAEB I and II) (4/16, 25%) followed by sideroblastic anemia (2/16, 12%) and refractory anemia (2/16, 12%). A progression to leukemia was documented in 2 patients.

Conclusion: Our study is limited by its retrospective design. However, our results documented that the frequency of MDS in AD is not negligible and might be suspected especially in older patients presenting with "unexplained" cytopenias.

Pilot Study of Tocilizumab in Patients with Erdheim-Chester Disease. Giulio Cavalli[1], Alvise Berti[1], Barbara Gulgielmi[1], Marco Gelpi[1], Riccardo Biavasco[1], Corrado Campochiaro[1], Alessandro Tomelleri[1], Marina Ferrarini[2], Maria Grazia Sabbadini[1] and Lorenzo Dagna[1]. [1]Vita-Salute San Raffaele University, Milan, Italy, [2]Department of Oncology, San Raffaele Scientific Institute, MIlan, Italy.

Background/Purpose: Erdheim-Chester disease (ECD) is a rare, systemic disorder of unknown etiology, characterized by tissue infiltration with CD68+, CD1a- foamy histiocytes. ECD is a chronic, debilitating disease without a gold-standard treatment. Growing evidence suggests that inflammatory cytokines and chemokines are responsible for histiocytes recruitment and activation. In particular, IL-6 is strongly expressed in ECD lesions and increased serum levels of IL-6 have been implicated in the systemic manifestations observed in ECD. We intended to assess the efficacy and safety of IL-6 blockade in the management of ECD.

Methods: We are conducting an open-label, single-arm, phase II, prospective, pilot study of tocilizumab (TCZ) in ECD (ClinicalTrials.gov NCT01727206; Eudra-CT 2012–003151–11). We planned to treat 6 patients (with contraindications or unresponsive to IFN-α) with the IL-6 receptor inhibitor TCZ 8 mg/kg monthly. We are collecting clinical, laboratory and radiological data, by means of total-body computed tomography (CT) scan, Technetium-99m methylene diphosphonate (99mTc-MDP) bone-scan, fluorine-18-2-fluoro-d-glucose positron emission tomography (FDG-PET), brain and cardiac Magnetic Resonance Imaging (MRI).We are also evaluating the levels of pro-inflammatory cytokines and chemokines before, during and after therapy, in order to evaluate whether TCZ treatment modulates the network of soluble factors involved in ECD pathogenesis. The Mann-Whitney U test for unpaired was chosen to compare data obtained from ECD patients and controls. The significance level was set at 0.05 (two-tailed p distribution).

Results: We present data from per protocol interim analysis on the first three patients who completed the protocol so far. All patients achieved significant improvement of all the clinical manifestations and laboratory findings (follow up at 12 months). Repeated whole-body CT scans, FDG-PET imaging and 99mTc-MDP bone scans confirmed the clinical and biochemical improvement in all patients. Cardiac MRI of the patient who had cardiovascular involvement showed an improvement of the diastolic function. However, the single patient who had CNS involvement had neurological progression, albeit showing improvement of other disease sites. During follow-up, we demonstrated a progressive reduction of circulating pro-inflammatory cytochemokines levels found to be increased before treatment. Plasma levels of IL-6 increased in all patients after the first infusion, as already shown in patients with other diseases treated with TCZ.

Conclusion: Although data must be completed with the final analysis and possibly by larger studies, the interim analysis of the trial support the efficacy and safety of IL-6 targeting with TCZ in ECD patients, in particular when CNS is not involved. Of interest, TCZ showed beneficial effects on ECD cardiovascular involvement, which has been shown to be poorly responsive to most currently available treatments.

Adalimumab Therapy Improves Insulin Sensitivity in Non-Diabetic Psoriatic Patients: A 6-Month Prospective Study. Trinitario Pina Murcia[1], Raquel López-Mejías[1], Fernanda Genre[1], Begoña Ubilla[1], Susana Armesto[2], Marcos A. González-López[2], María del Carmen Gonzalez-Vela[3], Javier Llorca[4], Ricardo Blanco[5] and MA González-Gay[1]. [1]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain, [2]Dermatology Division, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain, [3]Dept. of Pathology, Hospital Universitario Marqués de Valdecilla, Universidad de Cantabria, Santander, Spain, [4]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain, [5]Hospital Marques de Valdecilla, Santander, Spain.

Background/Purpose: psoriasis is a systemic inflammatory condition that shares similarities with other inflammatory immune disorders. In this context, patients with psoriasis are at an increased risk of cardiovascular death, as it has also been reported in patients with rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis. Accelerated atherosclerosis plays an important role in this regard. Several studies have reported a beneficial effect of anti-TNF-α therapy on the mechanisms associated with accelerated atherogenesis in inflammatory arthritis, including a beneficial effect on insulin resistance. In the present study, we aimed to prospectively evaluate for the first time whether the anti-TNF-α monoclonal antibody adalimumab may improve insulin sensitivity in patients with moderate-to-severe psoriasis.

Methods: A 6-month prospective study of adult patients (>18 years old) diagnosed with moderate-to-severe psoriasis who were put on treatment with adalimumab 40 mg every other week as a subcutaneous injection based on clinical indication (Spanish guidelines). Patients with history of cardiovascular or cerebrovascular disease, hypertension, diabetes, high body mass index (>35) or treatment during the previous 6 months before recruitment with corticosteroids or biologic therapies were excluded. At the time of enrollment and after six months of treatment, all patients were assessed for insulin sensitivity using the Quantitative Insulin Sensitivity Check Index (QUICKI). Laboratory tests including glucose, insulin, serum creatinine, ultra sensitive C-reactive protein [usCRP] and erythrocyte sedimentation rate [ESR], and data regarding disease activity (percent of body surface area affected [BSA], Psoriasis Area and Severity Index [PASI], Psoriatic Arthritis Screening and Evaluation questionnaire [PASE], Nail Psoriasis Severity Index [NAPSI] and physician′s global assessment of disease severity [PGA]) were also collected at the onset of the treatment (time 0) and at month 6.

Results: thirty-three consecutive patients (52% women), with moderate-to-severe psoriasis (mean BSA 37.2±16.4%, mean PASI 18±7.9) were recruited from the Dermatology outpatient clinics of the Hospital Universitario Marques de Valdecilla (Santander, Northern Spain). The mean age was 38.6±10.7 years. A statistically significant improvement (p-value 0.008) of insulin sensitivity (QUICKI) was observed after six months of treatment with adalimumab (QUICKI at time 0: 0.35±0.04 versus 0.37±0.04 at month 6).

Also a significant improvement ($p<0.05$) of ESR, usCRP, BSA, PASI, NAPSI, PGA and PASE was found at month 6.

Conclusion: in keeping with previous results on patients with chronic inflammatory rheumatic diseases, our findings show an improvement of insulin sensitivity following treatment with adalimumab. Therefore, adalimumab could have a beneficial effect on the mechanisms associated with accelerated atherogenesis in patients with psoriasis.

AbbVie Inc. funded this study.

New Onset Vitiligo Under Biological Agents: A Case Series. Laure Mery-Bossard[1], Emmanuelle Mahé[2], Guillaume Charby[3], François Maccari[4], Nathalie Quilès[5], Ziad Reguiai[6], Abdallah Khemis[7], Anne Grasland[8], Morgane Guerin[9], Denis Jullien[10], Kelly Bagny[11], Jean Sibilia[12], Eric Toussirot[13] and Resopso Le CRI[14]. [1]Centre hospitalier, Mantes la Jolie, France, [2]Centre hospitalier, Argenteuil, France, [3]University hospital, Amiens, France, [4]Centre hospitalier, Saint Mandé, France, [5]University hospital, Marseille, France, [6]Uniersity hospital, Reims, France, [7]University hospital, Nice, France, [8]University hospital, Colombe, France, [9]University hospital, Lyon, France, [10]Hopital Edouard Herriot, Lyon, France, [11]University hospital, La Réunion, France, [12]University Hospital of Strasbourg, Strasbourg, France, [13]Rheumatology Department, Univesity Hospital, besancon, France, [14]University Hospital, Paris, France.

Background/Purpose: biological agents are now widely used in clinical practice for the treatment of chronic cutaneous, rheumatic and gastrointestinal inflammatory diseases. Various cutaneous lesions have been described in the patients receiving biologics (including infections, paradoxical psoriasis or tumoral lesion). The development of depigmenting disorders is an unusual event under these treatments.

Objectives: to describe the characteristics of patients developing a depigmenting skin disorder while receiving a biological agent for the treatment of psoriasis, inflammatory bowel disease (Crohn's disease or ulcerative disease-UC-) or inflammatory rheumatic disease (rheumatoid arthritis-RA-, ankylosing spondylitis-AS- or psoriatic arthritis).

Methods: a call for observations of new cases of vitiligo following biological (anti-TNFa, rituximab, tocilizumab, abatacept, anakinra, ustekinumab) treatment was sent to the members of the French specialist networks "Resopso" (dermatologist), "Club Rhumatismes & Inflammation" (CRI) (rheumatologist and internal medicine). The skin lesion has to be confirmed by a dermatologist. The current and previous biological agents were recorded.

Results: 12 cases were reported over a one year period: 9 M, 3 F, mean age 42 $\pm$13.5 years. The underlying condition requiring a biological agent was plaque psoriasis in 5 cases, AS in 3 cases, RA in 3 cases and an UC in 1 case. They all had new onset non segmental vitiligo (achromic patches involving the face, hands, chest or back), excepting leucotrichia (lashes and brows) in one case. 7 patients received adalimumab, 1 infliximab, 2 ustekinumab, 1 abatacept and 1 secukinumab. The mean delay between biologic agent initiation and development of hypopigmentated lesions was 15.9 $\pm$ 15.8 months (range 1–72). This was the first line of biologics in 10 cases. Laboratory testing ruled out thyroid disease. The biological agent was maintained in 7 cases, without worsening of hypopigmentated lesions while it was stopped or switched for the other cases. Excepting dermocorticosteroids, no specific treatment was given for the hypopigmentation.

Conclusion: experimental evidences have shown that TNF-α may play a role in the pathogenesis of non segmental vitiligo, and successful cases of vitiligo treated with TNFα inhibitors have been reported. However, a vitiligo may occur during a biological treatment. In this series, anti TNFα was the main (but not exclusive) biologic class associated with this event. Only non segmental vitiligo was observed allowing the maintenance of the treatment. Concomitant occurrence of vitiligo and inflammatory disease such as RA, AS or UC, although rare, has been described. On the other hand, the depigmentation may be related to the biological agent and could represent a new paradoxical side effect.

2205

Management of Asymptomatic Coccidioidomycosis in Patients with Rheumatic Disease. Dominick Sudano[1], Varun Bhalla[1], Neil M. Ampel[2] and Jeffrey R. Lisse[1]. [1]University of Arizona, Tucson, AZ, [2]Southern Arizona Veteran's Affairs Medical Center, Tucson, AZ.

Background/Purpose: In the Southwestern United States, coccidioidomycosis (valley fever) is an endemic fungal infection which typically causes a self-limited pulmonary illness. Immunosuppressed patients, including those with rheumatic disease on disease-modifying antirheumatic drugs (DMARD) or biologic response modifiers (BRM), are at higher risk of more severe infection. The routine practice at our institution is to screen patients for coccidioidomycosis before initiating BRM therapy, and then annually thereafter. Through this process, patients have been identified with asymptomatic positive serologies. This is concerning as it indicates recent active infection in these patients. There are currently no guidelines regarding the management of these patients; however, a recent retrospective study proposed continuing antirheumatic therapy rather than stopping it.

Methods: A prospective chart review at two centers in Tucson, Arizona identified patients who developed coccidioidomycosis while on DMARD or BRM therapy. Several of those patient had asymptomatic illness as defined as a positive serology found on surveillance labs, not ordered in response to symptoms, and no concurrent signs or symptoms of active disease. Patients were seen at least once between 2007 and 2014. Review emphasized management of BRM/DMARD therapy, as well as antifungal therapy and duration.

Results: Seventy one patients with rheumatic disease were diagnosed with coccidioidomycosis, and 18 of them had positive serologies and no symptoms. Most (16/18) had rheumatoid arthritis, 1 had psoriatic arthritis, and 1 had dermatomyositis. Fifteen patients were identified during routine annual surveillance, and three were identified during pre-BRM therapy screening. Six patients were on BRM alone, 10 on BRM with a DMARD, and 2 on a DMARD alone. Three patients were also on prednisone. All but 6 patients continued their antirheumatic therapy. BRM therapy was restarted in 5 of these patients, most resuming therapy within 1 month of infection (range 0.5 – 12 mos). One did not resume therapy due to osteonecrosis of the jaw. Six patients received fluconazole, duration ranging from 6 to 73 months (median 30.5 mos). One of these patients remains on fluconazole for persistently positive serologies (42 mos.). Eight patients neither reduced antirheumatic therapy, nor started antifungal treatment. The median follow up is 31.5 months, and no patients have developed symptomatic illness. Three patients have been lost to follow up.

Conclusion: Positive coccidioidomycosis serologies are concerning in asymptomatic patient as they indicate a recent active infection. At present, the optimal screening interval and management in patients with rheumatic disease remains unclear. This series supports the management strategy of continuing BRM therapy in patients with asymptomatic disease. It also suggests that antifungal therapy may be reserved for those with persistently positive serologies. Future studies are needed to determine the significance of positive serologies in immunosuppressed patients with rheumatic disease, and the safest management strategy.

The Incidence of Zoster in Patients with Cutaneous Lupus Erythematosus and Dermatomyositis Is Increased Compared to the Average U.S. Population. Elizabeth S. Robinson[1], Joyce Okawa[2], Rui Feng[2], Aimee S. Payne[2] and Victoria P. Werth[1]. [1]Veteran Affairs Medical Center, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Herpes zoster is a common condition that causes significant pain and, often, post-herpetic neuralgia. In the United States the incidence of zoster per 1,000 person-years is 6 for people 60 years old and increases with age to nearly 11 for people above 80 years old. The incidence of zoster may be increased in autoimmune diseases, but few studies have looked specifically at cutaneous autoimmune diseases. Prior studies have found that the incidence of zoster in systemic lupus erythematosus is up to 32.5 per 1,000 person-years (n=303).

Methods: This retrospective chart review examined the incidence of zoster in patients with cutaneous lupus erythematosus (CLE) (n=105), dermatomyositis (DM) (n=66) and pemphigus vulgaris (PV) (n=55) seen in the practices of two dermatologists between April 1, 2013 and September 31, 2013. An incidence of zoster was determined according to a matched text search for "zoster" or "shingles" in all available electronic medical records.

The date of the zoster episode, if known, and the medications that the patient was taking at the time of the episode were recorded. The date of each patient's earliest visit with his dermatologist recorded in the electronic medical record until the most recent visit through September 31, 2013 or an episode of zoster, whichever was earlier, was used to estimate the time that the person had been at risk. The total number of incidences of zoster divided by the total number of person-years at risk was used to determine the incidence rate. Patients with a known history of zoster prior to the start of their electronic medical records and patients whose date of zoster was unknown were excluded from the incidence rate calculations.

Results: The incidence rate of zoster per 1,000 person-years was 23 for CLE, 54 for DM, and 7 for PV. The incidence rates were based on 6 episodes of zoster per 257.9 person-years for CLE, 8 episodes of zoster per 149.5 person-years for DM and 1 episode of zoster per 145.4 person-years for PV. Six CLE, 7 DM and 3 PV subjects had an unknown date of zoster. One CLE, 5 DM and 2 PV patients had zoster prior to the start of their electronic medical records. The mean (SD) duration of follow-up was 2.7 (1.7) years for CLE, 2.8 (1.7) years for DM and 3.0 (1.8) years for PV. The mean age (standard deviation) of each group was: 46.2 (14.1) for CLE, 55.9 (14.2) for DM and 56.1 (13.8) for PV. Fourteen of the 16 patients who had zoster were on immunosuppressive medications at the time of the zoster episode. Some patients were on more than one immunosuppressive therapy at the time of their zoster episode. The immunosuppressive medications were: mycophenolate mofetil (n=7), prednisone (n=6), methotrexate (n=1) and azathioprine (n=1). The majority of patients in each disease group were Caucasian women.

Conclusion: The incidence rate of zoster in CLE and DM is higher than in the average U.S. population at or above 80 years old. The incidence of zoster in PV is close to that of the average U.S. population of a similar age. The use of immunosuppressive therapies may play a role in the increased incidence of zoster in CLE and DM.

2207

Decreased Bone Mineral Density in Patients with Ehler-Danlos Syndrome. Narender Annapureddy, Joel A. Block and Sonali Khandelwal. Rush University Medical Center, Chicago, IL.

Background/Purpose: Ehler-Danlos Syndrome (EDS) constitutes a heterogeneous group of inherited connective tissue disorders characterized by abnormalities of collagen I, III, V, or fibronectin, and primarily affects the joints, skin and blood vessel walls. Other "true connective tissue diseases", such as osteogenesis imperfecta, a disease of collagen I, are characterized by severe osteoporosis and fractures; however these are not commonly described in EDS. Two case-series have examined bone mineral density in EDS: seven EDS patients with early onset osteoporosis were described by Deodhar et al., and Coelho et al. described 4 young Portuguese EDS patients who had osteopenia/osteoporosis primarily of the lumbar spine. Here, we have examined bone mineral density in a cohort of EDS patients followed at the Rush Connective Tissue diseases clinic.

Methods: Patients with a diagnosis of EDS where identified from the Rush Inherited connective tissue disease repository from 2010- June 2014. The study was approved by the Institution's IRB and informed consent was obtained from each participant prior to inclusion in the study. Demographics were recorded and areal bone mineral density (BMD) was assessed by dual photon X-ray absorptiometry (DEXA).

Results: 14 subjects with a diagnosis of EDS underwent bone mineral densitometry. Baseline demographics are described in the table. Of the 14 patients, two were male. None had prior exposure to glucocorticoids, though two did receive such treatment after having undergone DEXA (one for mast cell degranulation syndrome and one for possible undifferentiated inflammatory arthritis). Of the 14 participants, 6 had osteopenia and 1 had osteoporosis. Those with low bone mineral density were older than those with normal density (43.0± 10.9 vs. 28.7± 10.8, p=0.03, mean ±S.D.). Mean T-score at the femoral neck in the patients with decreased BMD was -1.44 (−2.8 to -1.1) and the mean T-score at the Lumbar spine was – 0.97 (−2.7 to +1.2). 5 out of the 7 patients had both their femoral neck and Lumbar spine T-scores < -1.0 and the remaining 2 patients had femoral neck T-score < -1.0.

Table

Patient Characteristics (N=14)

Age, years (mean, S.D.)	35.9 (12.8) Range: 20–58
Female	12 (85 %)
Current Smokers	3 (21 %)
Patients with decreased bone mineral density	7 (50 %)
Osteopenia	6
Osteoporosis	1
Subtypes of EDS	2
Type 1	8
Type 3	1
Type 4	3
Non-characterized	
Mean T-score at the femoral neck in patients with decreased BMD	−1.44 (Range: −2.8 to −1.1)
Mean T-score at the Lumbar spine in patients with decreased BMD	−0.97 (Range: −2.7 to +1.2)

Conclusion: Our data suggest that EDS may be associated with decreased BMD. Patients with EDS with decreased BMD were more likely to be older than EDS patients with normal BMD. Nevertheless, the mean age of those patients is still lower than when traditional screening for osteoporosis is considered. If these findings are replicated in other cohorts, then it would suggest that EDS should be considered an indication for early BMD screening. Nonetheless, the clinical significance of these findings remains unclear, as does the role of potential therapy to prevent or treat such low BMD.

Ovarian Reserve Alterations in Premenopausal Women with Rheumatoid Arthritis, Behcet's Disease and Spondyloarthritis – Impact on Anti-Muellerian Hormone Levels. Joerg C. Henes[1], Julia Froeschlin[2], Andre Taran[3], Theodoros Xenitidis[1] and Melanie Henes[4]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]University Tuebingen, Tuebingen, Germany, [3]University Hospital for Women Tuebingen, Tuebingen, Germany, [4]University Hospital for Women, Tuebingen, Germany.

Background/Purpose: Recent publications showed a negative influence of systemic lupus erythematosus and antiphospholipid antibody syndrome on female ovarian reserve (OR). Other authors did not find a significant impact of Crohn's disease or early rheumatoid arthritis (RA) on anti-Muellerian hormone (AMH) levels. This study aimed to investigate the potential effect of Behcet's disease (BD), RA and spondyloarthritis (SpA) on OR, as reflected by serum AMH levels.

Methods: Serum samples of 33 RA, 32 SpA and 30 BD patients without previous cytotoxic – especially cyclophosphamide – treatment were analyzed and compared to age matched, healthy controls. AMH was quantified using a standard ELISA with standard value 1–8μg/l; values $< 1\mu$g/l defined as reduced, $< 0.4\mu$g/l as severely reduced fertility. All patients gave written informed consent and filled out a questionnaire on menstrual irregularities, lifestyle, pregnancy outcomes and contraception. For statistical analysis SPSS 19.0 was used and $p<0.05$ considered statistically significant.

Results: The median age was 26, 28.5 and 33 years and the disease duration was 6, 5.9 and 7 years for RA, SpA and BD patients, respectively. Compared to healthy controls the patients had significant reduced AMH levels with a median value for RA of 1.83 (control. 2.44; p=0.009), SpA 1.46 (control: 2.3; p=0.013) and for BD of 1.08 (control; 1.93; p=0.007). The mean number of children was 0.4 for RA, 0.5 for SpA and 1.0 for BD patients. The HLAB51 status and origin in BD patients were not associated with significant reduced AMH levels.

Conclusion: This is the first study to show the reduced OR in patients with RA, SpA and BD. Together with the findings in SLE we conclude a negative influence of chronic rheumatic diseases on OR.

Novel Biomarkers of Extracellular Matrix Remodeling in Inflammatory Bowel Disease: Different Patterns of Gut Injury in UC and CD. Joachim Høg Mortensen[1], Line Elberg Godskesen[2], Michael Dam Jensen[2], Lone Gabriels Klinge[2], Jens Kjeldsen[2], Aleksander Krag[2], Morten Karsdal[3] and Anne C. Bay-Jensen[4]. [1]Cartilage Biomarkers and Research, Nordic Bioscience, Købehavn, Denmark, [2]Odense University Hospital, Odense, Denmark, [3]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [4]Cartilage Biomarkers and Research, Nordic Bioscience, Herlev, Denmark.

Background/Purpose: About 10 % of patients with IBD have symptoms that match both Crohn's disease (CD) and ulcerative colitis (UC), termed

inflammatory bowel disease unclassified (IBDU). The hallmark of both diseases is inflammation, which leads to excessive extracellular matrix (ECM) remodeling and release of specific protein fragments, called neoepitopes. However, the pathophysiology, clinical manifestations and treatment is still different among the two diseases. Consequently, to ensure the best possible patient care, accurate diagnosis is essential. Therefore, we speculate that the biomarker profile panel of UC and CD represents a heterogeneous expression pattern, and thus these biomarkers will be a valuable non-invasive diagnostic tool to aid the diagnosis of UC and CD.

Methods: 37 patients with active CD (>150 CDAI) of which 24 had inflammation in colon or colon/ileum, and 56 patients with active UC (St. Marks score >2) were included in this study. All patients had standardized work-up at inclusion, including medical history, physical examination, endoscopy, C-reactive protein. Biomarkers of degraded collagens I, III-IV (C1M, C3M, and C4M), collagen type 1 formation (PINP) and citrullinated and MMP-degraded vimentin (VICM) secreted by activated macrophages were evaluated by a competitive ELISA assay system. Receiver operator characteristics (ROC) curve analysis was carried out to evaluate the discriminative power of the biomarkers. The combination of biomarkers was investigated by a backward logistic regression model.

Results: The serum level of the biomarkers, C3M and VICM, was significantly different between patients with either active UC or CD. C3M was significantly elevated in patients with UC compared to CD ($P=0.039$). In contrast, VICM was highly elevated in patients with CD compared to UC ($P<0.0001$). The biomarkers C3M and VICM showed the highest discriminative value were seen (ROC analysis). The biomarkers were adjusted for demographic variations (age, gender, BMI, and smoking). VICM showed an AUC of 0.76 ($P<0.0001$) (CD vs. UC), while C3M showed a more modest AUC of 0.62 ($P=0.039$) (CD vs. UC) (table 1). Furthermore a logistic regression model was developed to find the best combination of the biomarkers. The best combination of biomarkers was VCIM, C3M, and C4M with an AUC of 0.85 ($P<0.0001$) (table 1). When including only the patients with colon and ileocolonic inflammation the AUC was improved to 0.92 ($P<0.0001$) (table 1).

Conclusion: These data provide new insights into differences in mechanisms of gut injury in CD and UC. We observed a clinical relevant potential of VICM and C3M as novel biomarkers to differentiate between UC and CD. This suggest that activated macrophages (VICM) and MMP mediated destruction of type III collagen (C3M) are essential disease drivers in IBD, and may discriminate these pathologies.

Table 1: The AUC, sensitivity, specificity, and percentage of cases correctly classified of each ROC-analysis

	AUC (CI)	Sensitivity	Specificity	Percent of cases correctly classified
Biomarkers: CD vs. UC				
C3M	0.63 (0.52–0.73)	23.6%	80.0 %	66.3%
C3M*Adjusted*	0.69 (0.57–0.78)	48.9%	80.0 %	63.0%
VICM	0.76 (0.66–0.85)	64.9%	83.6 %	69.6%
VICM*Adjusted*	0.77 (0.66-0.86)	64.9%	86.67%	76.8%
[C3M, VICM, C4M]	0.85 (0.75–0.91)	78.4	87.3	83.7%
[C3M, VICM, C4M] *Adjusted*	0.85 (0.75–0.92)	73.0	91.1	80.5%
[C3M, VICM, C4M-) *Adjusted* (colon and ileocolonic inflammation)	0.92 (0.83–0.97)	79.2	93.3	88.4%

CI: Confidence interval
*: The logistic regression model was adjusted for age, BMI, tobacco smoking, and gender

Redefining Dermatomyositis: Description of New Diagnostic Criteria That Differentiate Pure Dermatomyositis from Overlap Myositis with Dermatomyositis Features. Marie-Pier Payette[1], Yves Troyanov[1], Ira N. Targoff[2], Jean-Pierre Raynauld[1], Suzanne Chartier[3], Jean-Richard Goulet[1], Josiane Bourré-Tessier[1], Eric Rich[1], Tamara Grodzicky[1], Marvin J. Fritzler[4], France Joyal[5], Martial Koenig[5] and Jean-Luc Senécal[1]. [1]Division of Rheumatology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, [2]Veterans Affairs Medical Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Division of Dermatology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, [4]Mitogen Advanced Diagnostics Laboratory, Faculty of Medicine, University of Calgary, Calgary, AB, [5]Division of Internal Medicine, Centre Hospitalier de l'Université de Montréal, Montreal, QC.

Background/Purpose: Dermatomyositis (DM) is a major form of autoimmune myositis (AIM). The characteristic DM rash (Gottron's papules, heliotrope rash) and perifascicular atrophy (PFA) at muscle biopsy are regarded as diagnostic. However, new concepts are challenging the definition of DM. A modified Bohan and Peter clinical classification (mcBP) of AIM was proposed. In the mcBP, overlap features in presence of myositis allow a diagnosis of overlap myositis (OM), irrespective of the presence or absence of the DM rash or PFA. Therefore, our objective was to further differentiate DM from OM.

Methods: Using the mcBP, we performed a longitudinal study of 100 AIM patients, including 44 patients with a DM phenotype, defined as DM rash, and/or DM-type calcinosis and/or PFA at biopsy. Overlap features, DM rash course, adermatopathic DM (aDM), cancer and survival were evaluated, as well as DM-specific and overlap autoantibodies by protein A immunoprecipitation.

Results: Two subsets were identified in patients with a DM phenotype: *pure DM* (n=24) and OM with DM features, or *OMDM* (n=20). In pure DM, the rash of DM was the first disease manifestation, was always present at the time of myositis diagnosis, and was chronic and associated with a high cutaneous score. Concurrent heliotrope rash and Gottron papules (PPV 91%), as well as the V-sign and/or shawl sign (PPV 100%), were diagnostic of pure DM. Anti-Mi-2, anti-MJ and anti-p155 autoantibodies were restricted to pure DM (PPV 100%) and present in 50% of patients. 21% of patients had cancer. Fifteen-year survival was high (92%).

In contrast, in OMDM the first manifestation was proximal muscle weakness or other skeletal muscle-related complaints. The DM rash appeared at diagnosis or followup and was associated with a low cutaneous score. aDM, absent in pure DM, predicted OMDM (PPV 100%). Autoantibodies, found in 70% of patients, included anti-Jo-1, anti-PL-7, anti-PM-Scl, anti-U1RNP and anti-U5-RNP. OMDM was not associated with cancer but 15-year survival was only 65%.

PFA occurred as commonly in OMDM (n=6/20 patients, 30%) as in pure DM (n=4/24, 17%). These 6 OMDM patients had aDM at the time of myositis diagnosis. Only one of them developed a DM rash at follow-up, emphasizing the lack of specificity of PFA for pure DM.

Conclusion: Using the mcBP allowed identification of OMDM, a new clinical subset of OM. Furthermore, identification of OMDM allowed in turn recognition of pure DM as a new entity, distinct from OMDM or from OM without DM features. However, the absolute specificity of a DM rash and PFA for the diagnosis of pure DM was lost.

Epidemiologic and Clinical Features of Patients with Adult and Juvenile Dermatomyositis, Polymyositis and Inclusion Body Myositis from Myovision, a National Myositis Patient Registry. Abdullah Faiq[1], Payam Noroozi Farhadi[1], Nastaran Bayat[1], Mikaela Chase[1], Anna Jansen[1], Karen Malley[2], Jesse Wilkerson[3], Kathryn Rose[4], Caroll Co[4], Lukasz Itert[5], Anne Johnson[5], Richard Morris[4], Christine Parks[6], Edward H. Giannini[5], Hermine I. Brunner[5], Frederick W. Miller[1], Bob Goldberg[7] and Lisa G. Rider[1]. [1]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD, [2]Malley Research Programming, Inc, Bethesda, MD, [3]Social and Scientific Systems, Inc., Research Triangle Park, NC, [4]Social and Scientific Systems, Inc., Durham, NC, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [6]NIEHS, NIH, Research Triangle Park, NC, [7]The Myositis Association, Alexandria, VA.

Background/Purpose: The myositis syndromes are rare systemic autoimmune diseases, little is known about their epidemiology. We describe the demographics and comorbidities of patients in a large myositis patient registry.

Methods: Between December 2010 and July 2012, nine thousand two hundred eleven questionnaires were mailed to patients with adult and juvenile dermatomyositis (DM, JDM), polymyositis (PM, JPM), inclusion body myositis (IBM), and other forms of myositis in the US and Canada that had registered with The Myositis Association or learned of the survey from other sources. The questionnaire queried demographics, clinical features, environmental exposures, and quality of life. The response rate was 24.2% (N=2209). One thousand two hundred sixty six participants were re-contacted to resolve missing and discrepant responses.

Results: One thousand eight hundred six patients (708 DM, 483 PM, 466 IBM, 139 JDM, 10 JPM) met probable or definite Bohan and Peter criteria or possible Griggs criteria and were included in the analyses. The median date of diagnosis was March 2002 with a median disease duration of 9.2 yrs. IBM patients were older at diagnosis (median 62.3 years) than PM and DM (47.8 and 46.4 years, p=0.009). Most patients were female (84% DM, 75% PM, 78% JDM), except for IBM (41%, p<0.0001). Most patients were non-Hispanic Caucasian (86% DM, 82% PM, 94% IBM, and 88% JDM); blacks were more frequent among PM patients (12%) than DM (5%), IBM (3%), or JDM (0.7%, P<0.003 for all). Twenty-two percent of patients reported having a graduate degree and 28% had a college degree. The majority of DM and PM patients were diagnosed by an adult rheumatologist (59% and 52%), whereas IBM patients were more often diagnosed by a neurologist (76%, p<0.005) and JDM patients by a pediatric rheumatologist (48%, p<0.016). DM and JDM frequently had skin rashes as a major clinical manifestation (85% vs. 14% PM, 6% IBM, p<0.0001 for all); DM most often had arthritis (49% vs. 34% PM, 21% IBM, p< 0.0001); DM and PM were more likely to have lung disease (31% vs. 15% IBM, p < 0.0001); and DM most often had fever (23% vs. 17% PM, 5% IBM, p<0.008 for all). The overall age-, gender-and race-adjusted prevalence rate of self-reported diagnosis with another autoimmune disease was 23%, with an increased odds of RA (OR 2.1) and autoimmune thyroid disease (OR 2.5) in DM and PM vs. IBM. The odds of SLE were higher in DM vs. IBM (OR 4.4). Multivariable modeling showed female gender (OR 2.5), arthritis (OR 1.7) and rashes (OR 1.5) to be risk factors for an associated autoimmune disease in DM. The age-, gender- and race-adjusted self-reported prevalence of malignancy, excluding skin cancers, within 2 years of myositis diagnosis was 3.8% of DM, 2.1% of PM and 2.5% of IBM patients. Age was a risk factor for malignancy in DM (OR 1.1) and dysphagia was protective in IBM (OR 0.39).

Conclusion: A nationwide registry of myositis patients has been established with similar demographic and clinical features to other myositis cohorts. Our results suggest that there is considerable variation in the demographic and comorbidity profiles of patients by myositis subtype. MYOVISION registry data will be useful in further clinical and epidemiological studies.

Serum Adipokines in Dermatomyositis: Correlation with Risk Factors Associated to Cardiovascular Diseases and Metabolic Syndrome. Marilda Guimarães Silva, Suzana Beatriz Veríssimo de Mello and Samuel Katsuyuki Shinjo. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Adipokines are a group of cytokines produced by adipose tissue, which include adiponectin, resistin and leptin. The adiponectin has anti-diabetic, anti-inflammatory and anti-atherogenic effects, whereas leptin and resistin are considered atherogenic and pro-inflammatory associated with peripheral insulin resistance. Adipokines have been evaluated in many systemic autoimmune diseases, such as systemic lupus erythematosus and rheumatoid arthritis. However, there is no description of these cytokines in patients with dermatomyositis (DM), who have a high prevalence of risk factors to cardiovascular diseases and metabolic syndrome.

Methods: This one-center and cross-sectional study included 78 adult patients with DM (Bohan and Peter criteria, 1975), in the period of 2011 to 2013. As a control group, 120 healthy individuals were included in the same period. Metabolic syndrome was defined according to the criteria of the National Cholesterol Education Program - Adult Treatment Panel III (NCEP/ATP III). Blood samples were collected in fasting and processed immediately for further adipokines analysis, basing on the multiplex assay according to the manufacturer's protocol Millipore.

Results: Age, gender and ethnicity were comparable between patients with DM and control (*P*0.05). The mean duration of DM was 4.9±5.6 years. DM patients compared to the control group, showed a high prevalence of risk factors for cardiovascular disease: hypertension, diabetes mellitus, family history of cardiovascular disease, increased body mass index, waist circumference, serum triglycerides, insulin and glucose levels, lower serum levels of HDL cholesterol, and higher frequency of metabolic syndrome ($P<0.05$). Moreover, we noted higher serum adiponectin concentration [73.5 (56.1 to 101.9) pg/mL *vs.* 60.4 (43.2 to 81.2) pg/mL, $P=0.009$] and lower leptin [3.7 (0.2 to 25.5) pg/mL *vs.* 15.4 (6.9 to 29.0) pg/mL, $P<0.001$] in patients with DM compared to control group. Serum resistin was similar in both groups. Further analysis showed that adiponectin was significantly correlated with serum levels of HDL cholesterol (rho=0.307, $P=0.006$) and negatively correlated with serum creatine kinase (rho=-0.223, $P=0.050$), aldolase (rho=-0.271, $P=0.016$), triglycerides (rho=−0.313, $P=0.005$) and metabolic syndrome (rho=−0.238, $P=0.036$) in patients with DM. Leptin correlated positively with serum insulin level (rho=0.305, $P=0.010$), interleukin-6 (rho=0.24, $P=0.040$) and C-reactive protein (rho=0.282, $P=0.010$).

Conclusion: The results of this study showed high serum adiponectin and low serum leptin in patients with DM which may mitigate the inflammatory response. Further studies are necessary to assess the possible role of these adipokines in patients with DM.

Gene Expression Profiling of T Helper Subsets in Blood and Affected Muscle Tissues Reveals Differential Activation Pathways in Patients with Juvenile and Adult Dermatomyositis. Consuelo Lopez de Padilla[1], Molly S. Hein[1], Cynthia S. Crowson[1], Richard S. Pendegraft[2], Erik J. Peterson[3], Emily Baechler[3] and Ann M. Reed[1]. [1]Mayo Clinic, Rochester, MN, [2]Biomedical Statistics and informatics, Rochester, MN, [3]University of Minnesota, Minneapolis, MN.

Background/Purpose: The molecular and cellular basis for juvenile and adult dermatomyositis (JDM and ADM) presumably is similar. However, important differences in the clinical features, outcome and associated disorders suggest that different mechanisms, at least partially, may be involved. The aim of this study was to identify shared and differential molecular pathways in peripheral blood and affected muscle between JDM and ADM, and examine their association with disease activity.

Methods: Cytokine mRNA expression profiles were analyzed in paired PBMCs and muscle specimens in 7 JDM and 5 ADM. In addition, cytokine mRNA expression in blood in 21 ADM and 26 JDM subjects over 2 study visits (baseline and 6 months visit). Disease activity was also measured by IMACS core set measures and other validated tools. Expressions of type 1 helper (Th1)-related genes (*IL-2, IL-12β, IFN-γ, TBX21, STAT4, TNFα, TNFSF1*), Th2 (*IL-4, IL-5, IL-9, IL-10, IL-13, IL-12p70, STAT6, GATA3, IRF4*), Th17 (*IL-1β, IL-6, IL-21, IL-23A, IL-17A, IL-17D, IL-17F, IL-27, TGF-β1, STAT3, RORC*), Tregs (*FoxP3+, STAT5β*), Th22 (*AHR, IL-22*) and Tfh (*BCL6*), and of innate-related genes (MIP-1α/CCL3, CCL8/MCP2, IFNα2, IFN-β and IL-8) were examined using a custom RT2 Profiler PCR Array. Wilcoxon tests, Spearman correlations and paired t-tests were used for analysis. All reported p-values were adjusted for multiple comparisons using the Bonferroni method.

Results: Expressions of cytokine mRNAs for *IL-23A* (p<0.001), *IL-6* (p<0.001), *IL-17F* (p=0.022), *IRF4* (p<0.001), and *BCL6* (p=0.014) were significantly up-regulated in blood of JDM compared to ADM. In the muscle, however, there were no significant differences between JDM and ADM, probably due to the small sample sizes. We also compared the gene expression profiles in paired blood samples and muscle biopsies among 12 patients (7 JDM and 5 ADM). Expressions of *AHR* (p=0.007), *IFN-γ* (p=0.054), *IL-23A* (p=0.050), *STAT5β* (p=0.022), *TBX21* (p=0.047), *TGF-β1* (p=0.036), *TNFSF1* (p=0.011), CCL3 (p=0.022) were found at higher levels in muscle compared to blood of JDM/ADM patients, the majority of these genes were Th1 and Th17 pathway-associated genes. Finally, among 16 patients with samples tested at baseline and 6 months visits, there were no significant correlations between changes in gene expression profiles in blood and disease activity measures over time.

Conclusion: We observed differences in gene expression profiling in blood between new onset JDM and ADM, many of the overexpressed genes in JDM were Th17-cytokine genes. The upregulation of Th1 and Th17-related genes was apparent in muscle compared to blood in JDM/ADM patients and may reflect activation of different Th pathways between muscle and blood.

Power Doppler Ultrasonography for Detection of Abnormal Fascial Vascularity: A Potential Early Diagnostic Tool in Fasciitis of Dermatomyositis. Ken Yoshida[1], Makiko Nishioka[1], Satoshi Matsushima[1], Kensuke Joh[2], Yosuke Oto[1], Yoshiga Masayuki[1], Kazuhiro Otani[1], Haruyash Ito[1], Kenichiro Hirai[1], Kazuhiro Furuya[1], Taro Ukichi[1], Kentaro Noda[1], Isamu Kingetsu[1] and Daitaro Kurosaka[1]. [1]Jikei University School of Medicine, Tokyo, Japan, [2]Tohoku University Graduate School of Medicine, Sendai, Japan.

Background/Purpose: We have previously demonstrated that fasciitis is a common lesion of dermatomyositis (DM) detectable early after disease onset by *en bloc* biopsy combined with magnetic resonance imaging (MRI). Furthermore, we have shown by *en bloc* biopsy that the fascial microvasculature, rather than intramascular microvasculature, is one of the primary sites for inflammatory cell infiltration. Serial MRI findings showed that inflammation progresses from the fascia into the muscle. These facts indicate that fasciitis may cause muscle symptoms such as myalgia even when the muscle biopsy reveals a lack of evidence of myositis. Therefore, the detection of fasciitis plays an important role in the diagnosis of DM especially in its early stage. Power Doppler ultrasonography (PDUS) is useful method for detection of inflammation and vascularity in rheumatic diseases. We examined whether fasciitis is also detectable by PDUS in patients with DM.

Methods: Five patients newly diagnosed with DM and 5 patients newly diagnosed with polymiositis (PM), who fulfilled the Bohan and Peter criteria, were recruited from the Division of Rheumatology of Jikei University Hospital in Tokyo, Japan. In this study, all patients underwent MRI, PDUS, and *en bloc* biopsy before treatment with prednisolone and immunosuppressive agents. The muscles were resected *en bloc* with the skin, subcutaneous tissue, and fascia on the site at which patients were conscious of muscle pain, weakness, or stretched a feeling and/or in which STIR and gadolinium-enhanced fat-suppressed T1-weighted MR images showed an abnormal hyperintense area as described previously (Arthritis Rheum. 2010;62:3751–9). Hematoxylin and eosin staining and immunohistochemical staining for CD31 were performed on paraffin-embedded sections.

Results: MRI showed significant fasciitis findings in 3 patients with DM, while in no patients with PM. PDUS showed abnormal stippled blood flow signals along the fascia in all patients with DM, but in no patients with PM. Fasciitis was histologically detected in 4 patients with DM, while in no patients with PM. Although fasciitis was not detected histologically in only the fifth patient with DM, there were mild perivascular inflammatory infiltrates and neovascularization along the fascia. Immunohistochemical staining for CD31 showed abnormal growth of capillaries and venules along the fascia in all patients with DM, not in any patients with PM. This suggests that PDUS did show the blood flow of neovascularity along the fascia in patients with DM.

Conclusion: Fasciitis, demonstrated histologically by *en bloc* biopsy, was detected by PDUS in patients with DM. Mild fasciitis undetectable by MRI can also be detected by PDUS. Our data suggests that PDUS allows early diagnosis of fasciitis associated with DM.

2215

Clinical Characteristics and Prognosis of Malignancies Associated with Active Myositis. Sang Jin Lee[1], Eun Ha Kang[2], Yun Jong Lee[2], Eun Young Lee[3] and Yeong Wook Song[4]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine,Seoul National University Bundang Hospital, Seongnam, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea, [4]Department of Molecular Medicine and Biopharmaceutical Sciences, BK 21 plus Graduate School of Convergence Science and Technology, and College of Medicine, Seoul National University, Seoul, South Korea.

Background/Purpose: To examine the clinical features and prognosis of cancers associated with active myositis and to compare them with cancers found in patients with myositis but unrelated to myositis activity.

Methods: Medical records of 289 patients who had been diagnosed as having polymyositis or dermatomyositis according to Bohan and Peter criteria were reviewed to identify fifty two cancer cases. Patients were screened for malignancies at the diagnosis of myositis but active cancer screening was not done during follow-up unless suspicious symptoms developed or their myositis worsened. Cancers were defined to be associated with active myositis if they were present during active phase of myositis (group A). If cancers were not detectable during active phase of myositis, they were defined to be unrelated to myositis activity (group B).

Results: Thirty patients were included in group A consisting of those who developed myositis and cancer together (n =25), whose myositis recurred with cancer development (n=2), or who developed myositis when their cancers progressed/recurred (n=3). Twenty two patients in group B were comprised of those who developed myositis during remission state of cancers with no further relapse of cancer (n=6) or whose cancers were detected during remission state of myositis with no further relapse of myositis (n=16). Group A tended to be male (14/30 vs 5/22, p=0.077) and had an older age at myositis diagnosis compared with group B (60.5±11.1 vs 49.3±16.6 years, p=0.022). Group A patients had shorter intervals between the diagnoses of myopathy and cancer (5.4±9.0 vs 71.6±46.6 months, p<0.001); 90% of cancers in group A developed within 1 year of myositis diagnosis whereas 90% in group B beyond 1 year. Muscle power grades and enzyme levels were not significantly different between the two groups at baseline. Dysphagia was more frequent (p=0.002) and interstitial lung disease less frequent (p=0.001) in group A. Notably, stages at cancer diagnosis were far advanced in group A (stage 3 and 4, 24/29 vs 7/22, p<0.001). Fewer patients in group A achieved normal muscle power during their course of myositis than in group B (p=0.036). The recovery to normal muscle power was associated with induction of cancer remission (p=0.036). Group A patients showed poor survival compared to group B patients (hazard ratio for mortality [95% confidence interval], 7.4 [2.6–21.2], p<0.001), which was still significant when adjusted for age and gender (4.3 [1.5–12.7], p=0.008 by Cox regression model).

Conclusion: In patients with myositis, clinical features of cancers associated with active myositis were distinctive from those of cancers unrelated to myositis activity. The former were found to develop within 1 year of myositis in contrast to the latter, and to be more advanced at diagnosis. The outcome of associated myositis in the former cases was worse in terms of muscle power recovery. Successful cancer treatment was associated with better outcome of myositis. Patients who had cancers associated with active myositis showed poor survival compared to those who had cancers unrelated to myositis activity.

Muscle Type I Interferon Gene Expression May Predict Therapeutic Responses to Rituximab in Myositis Patients. Kanneboyina Nagaraju[1], Svetlana Ghimbovschi[2], Sree Rayavarapu[3], Aditi Phadke[3], Lisa G Rider[4], Eric Hoffman[3] and Frederick W. Miller[5]. [1]Children's National Medical Center, Washington DC, DC, [2]Children's National Medical Center, Washington DC, WA, [3]Children's National Medical Center, Washington, DC, [4]Environmental Autoimmunity Group, Program of Clinical Research, National Institute of Environmental Health Sciences, National Institutes of Health, US Department of Health and Human Services, Bethesda, MD, [5]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD.

Background/Purpose: To identify muscle gene expression patterns that predict rituximab responses and assess the effects of rituximab on muscle gene expression in polymyositis (PM) and dermatomyositis (DM).

Methods: In an attempt to understand the molecular mechanism of response and non-response to rituximab therapy, we performed Affymetrix gene expression array analyses on muscle biopsies taken before and after rituximab therapy from eight PM and two DM patients in the Rituximab in Myositis study. We also analyzed selected muscle-infiltrating cell phenotypes in these biopsies by immunohistochemical staining. Partek and Ingenuity pathway analyses were used to identify gene pathways and networks.

Results: Microarray analysis of gene expression changes in the skeletal muscle of myositis patients before and after rituximab treatment showed differential expression of innate immune and inflammatory genes. Supervised hierarchical clustering analysis of these genes resulted in myeloid clusters (clusters 1 and 2) and non-myeloid clusters (cluster 3–5). Myeloid clusters include cluster 1(STAT4, SDC1, ITGB8, MAVS, RFX3, IFNAR2, IRF4, UBA7, and IFRD1) cluster 2 (ICAM1, IRF1, CASP2, SIGLEC1, CD68, and

IFI44). Non-myeloid clusters include predominantly type 1IFN genes (cluster 3 (CD19, IFI35, IFNA1, MX2, UBE2L6, LY6E, XAF1, SP110), cluster 4 (OAS1, USP18, ISG15, IFIT5, MEG3, RTP4, MX1, OAS3, and IFNA2), and cluster 5 (OAS2, OASL, IFIT3, IFIT2 and IFNB1). Type 1 Interferon (IFN) signature genes were expressed at higher levels at baseline in the skeletal muscle of rituximab responders than in non-responders. These genes are known to have immunomodulatory effects on the infiltrating immune cells as well as skeletal muscle. Also, IFN signature genes were significantly down-regulated post-treatment in patients who had a clinical response when compared to non-responder patients. The decrease in the type I IFN signature following administration of rituximab may be associated with the decreases in muscle-infiltrating CD19+ B cells and CD68+ macrophages in responders. Further, analysis of muscle-infiltrating CD138-positive plasma cells showed an increase in non-responder patients.

Conclusion: Our study confirms that myeloid and type 1 IFN signatures are important in myositis pathogenesis and rituximab treatment alters these signatures. Our findings also suggest that high levels of muscle type I IFN gene expression predict responses to rituximab in PM/DM and that rituximab responders also have a greater decrease in the expression of these genes. These data add further evidence to recent studies defining the type I IFN signature as both a predictor of therapeutic responses and a biomarker of myositis disease activity.

Ultrasonography Analysis of Carotid Parameters in Patients with Idiopathic Inflammatory Myopaties: Correlation with Demographic Profile and Disease Activity. Simone Barsotti[1], Maria Aurora Morales[2], Rosaria Talarico[3], Claudia Ferrari[1], Nicole Di Lascio[2], Anna d'Ascanio[1], Elisabetta Bianchini[2], Stefano Bombardieri[3] and Rossella Neri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Institute of Clinical Physiology, CNR, Pisa, Italy, [3]Rheumatology Unit, Pisa, Italy.

Background/Purpose: Subclinical cardiovascular (CV) involvement is frequent in patients with idiopathic inflammatory myositis (IIM). Growing interest exists on the role of markers of subclinical CV involvement including vascular parameters assessed at carotid artery. The primary aim of our study was to explore Intima-Media-Thickness (IMT), mean arterial diameter (mAD) and distensibility coefficent (DC) in consecutive IIM patients; the secondary aim was to correlate these parameters with demographic and clinical profile.

Methods: Twenty-one IIM patients (F/M 15/6; mean age 55.9±8.7; mean disease duration 8.7±7.5 years) fulfilling the Bohan and Peter criteria were prospective enrolled. We collected demographic data and disease activity parameters according to IMACS criteria. CV risk factors were collected: smoking habits, diabetes mellitus, hypertension, family history of CV disease, body mass index (BMI).

Each patient underwent a B-mode ultrasonography sampling of right common carotid artery, 1 cm beneath the bifurcation; the images were automatically analyzed (Carotid Studio, Quipu) for the measurement of IMT and mAD. Cross-sectional DC was computed as $DC=\Delta A/(PP*A)$ where A is the diastolic lumen area, ΔA the stroke change in lumen area and PP the local pulse pressure estimated by tonometry (Pulsepen, Diatecne). The results were compared with 17 healthy subjects, comparable for sex, age and CV risk factors.

Results: The patients presented mean CK and aldolase levels respectively of 175±159 UI/ML (NV <175) and 8.6±3.2 UI/L (NV <7). MMT8 mean values were 72.5±7.8, HAQ 0.6±0.58, patient and physician VAS respectively 4±2.7 cm and 2±2.1 cm. Three patient were smokers, 4 ex-smoker, 9 hypertensive, 4 affected by diabetes mellitus, 15 had familiar history of CV disease. BMI mean values were 25.5±3.39.

Mean IMT, mAD and DC data in patients and healthy subject were reported in table 1; mAD was significantly higher in IIM patients. In IIM group the association between mAD and hypertension (p=0.02) and BMI (p=0.022) was found. Elevation of IMT positively correlate with age (p=0.02). No correlation was found between the other parameters studied.

Conclusion: Our data have shown that IIM patients presented higher mAD than healthy subjects; ultrasonographic data seem to be influenced by hypertension, BMI and age but not with activity and duration of the disease. Further data are necessary to confirm our observation.

Table 1: Carotid parameters in IIM patients and healthy subjects

	IIM patients	Healthy subjects	p
Intima media thickness – IMT (mean±SD)	0.62 ± 0.1	0.65 ± 0.16	ns
Mean arterial diameters – mAD (mean±SD)	7.5 ± 1	6.9 ± 0.7	**0.04**
Distensibility coefficient – DC (mean±SD)	25 ± 8.2	30 ± 12	ns

Endoplasmic Reticulum (ER) Stress-Induced Mitochondrial Dysfunction and Atrophy Can be Prevented By Pharmacological Upregulation of Heat Shock Protein 70 (HSP) in Cultured Murine Myotubes. Adam P. Lightfoot, Malcolm J. Jackson, Anne McArdle and Robert G. Cooper. University of Liverpool, Liverpool, United Kingdom.

Background/Purpose: The symmetrical proximal muscle weakness typical of myositis often fails to improve completely with any treatment, due to irreversible muscle fibre degeneration. Although inflammatory cell infiltration is a primary feature of myositis, increasing evidence suggests that muscle weakness correlates poorly with the degree of infiltration (Englund et al. 2001; Li et al. 2004), and in fact may precede inflammatory cell infiltrates (Nagaraju et al. 2001). Research suggests that non-immune cell-mediated mechanisms contribute to muscle weakness, including activation of the ER stress response which is associated with muscle fibre dysfunction and damage (Nagaraju et al. 2005; Yoshida 2007). The mechanisms which mediate ER stress-induced muscle dysfunction in myositis remain unelucidated. However, studies suggest that interplay between the ER stress response, mitochondrial dysfunction and oxidative damage may be involved(Yuzefovych et al. 2013; Cao et al. 2014). Targeted transgenic up-regulation of molecular chaperones, termed Heat Shock Proteins (HSPs), specifically HSP70, attenuates muscle dysfunction and oxidative damage in muscle of old rodents (McArdle et al. 2004; Broome et al. 2006). Similarly, pharmacological increases in HSP70 content of muscle using 17-N-allylamino-17-demethoxygeldanamycin (17AAG), provided an enhanced functional recovery of muscle following exercise-induced damage (Kayani et al. 2008). We hypothesised that, in myositis, ER stress induces mitochondrial dysfunction and oxidative damage, which is a major non-immune cell mediated factor contributing to muscle weakness. We further hypothesised that targeted pharmacological up-regulation of HSP70 could provide a therapeutic strategy to protect muscle fibres in myositis.

Methods: C2C12 myoblasts were grown in standard cell culture conditions (5% CO_2, 37°C) and differentiated to myotubes in growth media (DMEM) supplemented with 2% horse serum. Myotubes were treated with 1mg/ml Tunicamycin to induce ER stress, in the prescence and abscence of 17AAG (0.1mg/ml) for a period of 24 hours. Cells were harvested and oxygen consumption assessed using a clark electrode (Hansatech Instruments), in the presence of electron transport chain (ETC) substrates and inhibitors: Succintate/Rotenone and Glutamate/Malate to determine the respiratory control ratio (RCR) and Phosphate/Oxygen (P:O) ratio. ATP generation was quantified using bioluminescence assay (Roche). Specific ER stress markers were measured using SDS-PAGE/western blotting and qPCR. Myotube morphology changes were assessed using light microscopy.

Results: Activation of the ER stress response in C2C12 myotubes resulted in mitochondrial dysfunction, evidenced by declines in RCR, P:O ratio and in ATP generation. Cells treated with Tunicamycin in the presence of 17AAG showed full preservation of mitochondrial function and ATP generation. ER stress-induced atrophy of C2C12 myotubes was prevented by the presence of 17AAG.

Conclusion: Data demonstrate that pharmacological up-regulation of HSP70 provides protection against ER stress-induced mitochondrial dysfunction and atrophy in C2C12 myotubes.

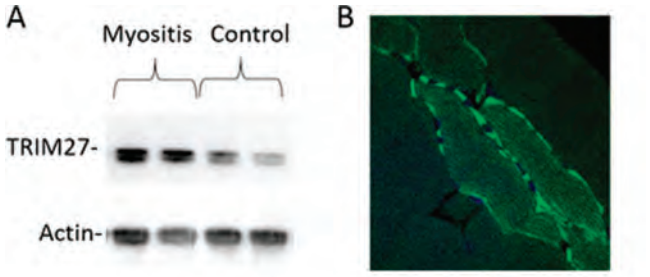
Contribution of Tripartite Motif Proteins Modulating Membrane Repair to the Pathogenesis of Autoimmune-Mediated Myositis. Jenna Alloush[1], Nicholas A. Young[2], Kevin McElhanon[1], Wael N. Jarjour[2] and Noah Weisleder[1]. [1]The Ohio State University College of Medicine, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH.

Background/Purpose: The idiopathic inflammatory myopathies are a heterogeneous group of diseases that result in autoimmunity toward muscles and lead to tissue destruction, but the pathogenesis remains largely unknown. Synaptotagmin VII-knockout (Syt $VII^{-/-}$) mice display mild myositis and we have previously demonstrated that combining this genetic defect with

regulatory T-cell deficiency (FoxP3$^{-/Y}$) results in a robust inflammatory myositis when adoptively transferred into immunodeficient (RAG1$^{-/-}$) recipients. Interestingly, Syt VII$^{-/-}$ mice have impaired sarcolemmal membrane resealing capacity, which allows exposure of intracellular antigens. Tripartite motif (TRIM) proteins have also been linked to membrane repair capacity and are associated with myopathy in human patients. Here, we examined protein expression levels and subcellular localization of several novel TRIM proteins linked to membrane repair capacity in muscle tissue from mice using the Syt VII$^{-/-}$/FoxP3$^{-/Y}$ model of myositis.

Methods: Membrane repair was monitored *in vitro* in cells using an established assay where the membrane of cultured cells is physically disrupted by glass microbeads. Mouse skeletal muscle was collected from wild type mice exercised on a treadmill or RAG1$^{-/-}$ mice adoptively transferred with lymph node preparations from Syt VII$^{-/-}$/FoxP3$^{-/Y}$ mice. Tissue was analyzed by standard Western immunoblotting and by immunohistochemistry.

Results: We identified multiple TRIM family proteins that can modulate membrane repair capacity in cultured cells. Our results show that TRIM27 translocates to the membrane of injured muscle cells *in vivo*, as shown by immunohistochemistry. Similarly, when mice were exposed to membrane disruption due to eccentric contractions during treadmill running, there was translocation of TRIM27 from a diffuse pattern to the damaged membrane. In skeletal muscle of RAG1$^{-/-}$ mice, expression of several TRIM proteins, including TRIM27, was altered and displayed differential subcellular localization.



Increased TRIM27 expression and membrane localization in muscle tissue of mice with myositis. Skeletal muscle from RAG1 deficient mice adoptively transferred with lymph node preparations from synaptotagmin VII / FOXP3 double knockout mice was collected and processed for (A) immunoblotting of whole muscle extract or (B) immunofluroesence microscopy.

Conclusion: We have identified altered expression and localization of TRIM proteins in muscle in this mouse model of myositis. These results highlight an association of decreased sarcolemmal membrane integrity in the development of myositis and suggest a mechanism that could be targeted for diagnostics and therapeutics in these diseases.

Overexpression of Ankyrin Repeat Domain Containing Protein 1 Gene (*ANKRD1*) in Polymyositis Muscle Biopsies Is Correlated to Hypoxia. Samuel Katsuyuki Shinjo, Sueli Mieko Oba-Shinjo, Miyuki Uno and Suely Kazue Nagahashi Marie. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: *ANKRD1* codes for ankyrin repeat domain containing protein 1, which belongs to the muscle ankyrin repeat protein family involved in a mechano-signaling pathway that links myofibrillar stress response to muscle gene expression. In addition, *ANKRD1* has an important role in transcriptional regulation, myofibrillar assembly, cardiogenesis and myogenesis. Recently, at first time, our group had demonstrated that *ANKRD1* was overexpressed in dermatomyositis muscle specimens. Herein, we analyzed *ANKRD1* expression in muscle biopsies of patients with polymyositis (PM).

Methods: RNA was extracted from frozen muscle biopsies samples of 33 untreated adult with PM (Bohan and Peter's criteria, 1975). As a control group, we analyzed 20 muscle biopsies with no histological change from untreated adult patients with non-inflammatory myopathy diseases. Additional to *ANKRD1*, the gene coding for hypoxia-inducible factor 1, alpha subunit (*HIF1A*) was also analyzed to estimate hypoxia degree. The *ANKRD1* and *HIF1A* transcript expression levels were determined by quantitative real time PCR using Sybr Green method. Muscle biopsies were analyzed histologically by semi-quantitative method of HE stained biopsies. Expression and localization of ANKRD1 and HIF1a in muscle biopsies was accessed by immunohistochemistry.

Results: Higher *ANKRD1* and *HIF1A* expressions levels were observed in PM samples relative to control group ($p<0.001$ and $p<0.001$). In addition, the expression levels of both genes were correlated ($r=0.380$, $P=0.029$). We also observed a positive correlation of both genes to degree of muscle impairment and inflammatory infiltration. However, *ANKRD1* and *HIF1A* expression levels did not correlate to demographic, clinical and laboratory features ($p0.05$). Immunohistochemistry showed that *ANKRD1* and *HIF1*a were expressed mainly by affected muscle fibers.

Conclusion: Our results demonstrated *ANKRD1* is overexpressed and correlated to *HIF1A* and to infiltrate inflammation found in PM muscle specimens. *ANKRD1* involvement in myogenesis and angiogenesis mechanism will be further investigated.

Reduction of Ovarian Reserve in Adult Patients with Dermatomyositis. Fernando Henrique Carlos de Souza[1], Samuel Katsuyuki Shinjo[1], Lucas Yugo Shiguehara Yamakami[2], Vilma dos Santos Trindade Viana[1], Edmund Chada Baracat[1], Eloisa Bonfa[2] and Clovis Artur Almeida Silva[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil.

Background/Purpose: Dermatomyositis (DM) affects female gender during reproductive age, in which ovarian reserve and future fertility are major topics of interest. However, there is no systematic study assessing these abnormalities in patients with DM. Therefore, the aim of the present study was to evaluate ovarian reserve markers and anti-corpus luteum (anti-CoL) antibodies in patients with DM.

Methods: All 40 female patients with DM (Bohan e Peter criteria, 1975), aged between 18 and 42 years, followed at our tertiary center, from March 2011 to December 2012, were invited to participate. Exclusion criteria were hormonal contraceptive use in the last six months (n=13), neoplasia (n=3), overlap systemic autoimmune diseases (n=3), pregnancy (n=2), gynecological surgery (n=1) and did not agree to participate (n=2). The remaining sixteen DM patients and 23 healthy controls were evaluated at early follicular phase of menstrual cycle. IgG anti-CoL (immunoblotting), follicle stimulating hormone (FSH), estradiol, inhibin B, anti-Müllerian hormone (AMH) serum levels (ELISA) and sonographic antral follicle count (AFC) were determined.

Results: DM patients and controls had comparable mean age (33.4±6.8 *vs.* 31.4±6.8 years, $P=0.337$), ethnicity and socioeconomic class ($P0.05$). DM mean age of onset was 29.1±4.7 years and disease duration of 5.6±3.2 years. Comorbidities and life style were similar in both groups ($P0.05$). Menstrual cycles were alike in both groups with a similar frequency of age at menarche, gynecological age, duration and length of menstrual cycle ($P0.05$). Of note, AMH ≤ 1 ng/mL (50% *vs.* 13%, $P=0.027$) and number of the AFC (10.5±5.6 *vs.* 17.3±0.7, $P=0.017$) were significantly reduced in DM patients compared to controls. Serum FSH (6.2±2.0 *vs.* 6.6±3.8 IU/L, $P=0.617$) and inhibin B levels (49.8±31.5 *vs.* 45.2±29.0 ng/mL, $P=0.616$) were comparable to controls whereas serum estradiol level [45.0 (29–126) *vs.* 34 (24–128) pg/mL, $P<0.001$] was higher in DM patients. Ovarian volumes [6.2 (4.7–8.2) *vs.* 5.5 (1.4–15.8) mm^3, $P=0.214$], and the frequency of anti-CoL antibody (6.5% *vs.* 0%, $P=0.398$) were also alike in both groups ($P0.05$).

Conclusion: The present study was the first to identify that patients with DM may have a shortened reproductive lifespan. Further studies are necessary to assess the possible role of disease and treatment related factors underlying ovarian impairment in these patients.

Predictors of Myositis Treatments Received and Associated Treatment Responses in Myovision, a National Myositis Patient Registry. Abdullah Faiq[1], Payam Noroozi Farhadi[1], Jesse Wilkerson[2], Nastaran Bayat[1], Anna Jansen[3], Kathryn Rose[4], Lukasz Itert[5], Anne Johnson[5], Christine Parks[6], Edward H. Giannini[5], Hermine I. Brunner[7], Bob Goldberg[8], Richard Morris[4], Frederick W. Miller[1] and Lisa G. Rider[1]. [1]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD, [2]Social and Scientific Systems, Inc., Research Triangle Park, NC, [3]NIEHS / EAG, Bethesda, MD, [4]Social and Scientific Systems, Inc., Durham, NC, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [6]NIEHS, NIH, Research Triangle Park, NC, [7]PRCSG, Cincinnati, OH, [8]The Myositis Association, Alexandria, VA.

Background/Purpose: Little is known about medications received for myositis and patients' responses to therapies. We present information on self-reported myositis therapy use and responses from a national patient registry.

Methods: MYOVISION consists of 1796 patients who met probable or definite Bohan and Peter criteria for DM/PM (708 DM, 483 PM, 139 JDM) or possible Griggs criteria for IBM (466 IBM) with a median diagnosis date of March 2002. Enrolled patients were queried about myositis treatments received and treatment effectiveness. Logistic regression modeling, using a backwards elimination approach, was used to determine demographic and clinical covariates; a significance level of <0.1 was required to retain variables in the model.

Results: Most DM, PM and JDM patients reported receiving prednisone (96–98%) and methotrexate (MTX) (70–84%); these treatments were reported less commonly in IBM patients (54% and 28%, $p<0.0001$ respectively). Use of azathioprine (41%, 47%) and rituximab (ritux) (14%, 16%) were reported more frequently in DM and PM, in contrast to IBM and JDM (11%, 15%, $p<0.012$ and 9%, 10% $p<0.007$, respectively). JDM patients reported receiving hydroxychloroquine (60%), IV methylprednisolone (54%), IVIG (48%), and cyclosporine (19%) more frequently than other subgroups (2–10% $p<0.021$ for all). Overall, ritux was the most common biologic therapy (13%), and anti-TNFs were received by 10% of patients. Factors associated with MTX treatment among DM, PM and IBM patients included younger age, geographic region, absence of lung disease, and type of treating physician (rheumatologist) ($p=0.022$ - < 0.0001). Younger age, SES, and being treated by a neurologist were factors associated with receipt of IVIG in DM and PM, and presence of dysphagia, fever, and lung disease were additional factors for DM.

Overall, prednisone was reported to be the most helpful medication (39% $p<0.007$), followed by IVIG (35%, $p<0.005$), mycophenolate mofetil (31%) and ritux (24%, $p<0.029$). Some patients (17%) did not find any treatments helpful, and 46% of these had IBM. Absence of dysphagia in DM (OR 0.66), presence of fever in IBM (OR 5.66), and fewer myositis therapies (OR 0.68 – 0.76) were factors associated with a response to prednisone in DM, PM and JDM. Absence of an overlapping autoimmune disease in PM (OR 0.35) and fewer myositis therapies in DM (OR 0.67) were associated with response to IVIG. IBM patients reported physical therapy as the most effective treatment (38%). Older age (OR 1.03), overlapping autoimmune diseases (OR 2.6), absence of fever (OR 0.13), lung disease (OR 2.1) and receipt of fewer myositis therapies (OR 0.48) predicted a positive response to physical therapy in IBM.

Conclusion: Prednisone and MTX are the most frequently prescribed medications in DM, PM, IBM and JDM. Patients vary substantially in their assessment of the effectiveness of these and other treatment approaches. Demographics, clinical features and the specialty of the treating physician appear to influence which therapies are received by myositis patients and the perception of their effectiveness. In the absence of controlled clinical trials, prospective registries of inception cohorts may aid in identifying effective therapies in rare disorders.

High Prevalence of Hepatitis C Virus Infection in a Japanese Inclusion Body Myositis Cohort.

Akinori Uruha[1], Satoru Noguchi[1], Yukiko K. Hayashi[2], Ikuya Nonaka[1] and Ichizo Nishino[1]. [1]National Center of Neurology and Psychiatry, Tokyo, Japan, [2]Tokyo Medical University, Tokyo, Japan.

Background/Purpose: There have been several case reports of inclusion body myositis (IBM) that appeared after chronic hepatitis C virus (HCV) infection. However, the relationship between HCV infection and IBM remains unclear. In this study, we assessed the prevalence of HCV infection in IBM patients and re-evaluated the clinicopathological aspects of HCV-positive IBM by using our cohort.

Methods: We analyzed the presence/ absence of anti-HCV antibodies of 118 patients (mean age 69.0 ± 8.1y) who were pathologically diagnosed as IBM in 2002 to 2012. As a control, we analyzed likewise 44 age-matched patients (69.0 ± 7.5y) who were pathologically diagnosed as polymyositis in the same period. Then we compared HCV-positive IBM group with HCV-negative group in terms of clinicopathological features including intervals in years from first symptom onset to each onset of symptoms characteristic for IBM and frequencies of fibers with rimmed vacuoles and ragged-red fibers.

Results: In IBM group, anti-HCV antibodies were detected in 34 patients (28.8%). This rate was higher than that of the polymyositis group and of the Japanese general population in the sixties (4.5% and 3.4%, respectively) ($p < 0.001$). No significant difference was seen between HCV-positive and -negative IBM groups, in terms of age at onset (66.6 ± 8.0 vs. 64.1 ± 8.6 years of age), sex ratio (1.4: 1 vs. 1.4: 1), periods after onset showing inability to squat (3.8 ± 3.6 vs. 3.9 ± 2.5 years), inability to open a bottle (4.2 ± 3.2 vs. 4.1 ± 2.3 years), dysphagia (4.9 ± 4.8 vs. 4.5 ± 2.3 years), non-ambulatory (6.1 ± 4.0 vs. 7.1 ± 3.2 years), and pathological findings including the frequency of fibers with rimmed vacuoles [1.7 (0.17–8.1) vs. 2.2 (0.2–23.6)%] and that of ragged-red fibers [0.5 (0.1–5.7) vs. 0.4 (0–4.8)%].

Conclusion: Our results confirm the association between HCV infection and IBM, and suggest a possible causal role of HCV infection in the pathogenesis of IBM.

Increased Immune Complex Levels in Children with Juvenile Dermatomyositis Are Not Associated with Levels of Von Willebrand Factor Antigen, C4, Duration of Illness, Disease Activity Score, or the Absolute NK Count.

Lauren M. Pachman[1], Akadia Kachaochana[2], Gabrielle A. Morgan[3], Dong Xu[2], Chiang-Ching Huang[4] and Anil K. Chauhan[5]. [1]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Stanley Manne Children's Research Institute, affiliated with Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Stanley Manne Children's Research Institute, affiliated with Ann & Robert H. Lurie Children's Hospital of Chicago, Cure JM Myositis Center, Chicago, IL, [4]Zilber School of Public Health, University of Wisconsin at Milwaukee, Milwaukee, WI, [5]Saint Louis University, St. Louis, MO.

Background/Purpose: A potential mechanism for the vasculopathy of Juvenile Dermatomyositis (JDM), the most common pediatric inflammatory myopathy, has been attributed to complement mediated immune complex damage to endothelial cells with subsequent release of von Willebrand Factor Antigen (vWF:Ag). Although we previously reported that JDM C4 levels were decreased in 30% patients, associated with decreased gene copy number [Arthritis Rheum, 2012; 64(S10):S826], the role of C4 in this process has not been documented. The purpose of this cross-sectional study was to determine the concentration of immune complexes in JDM sera compared with healthy controls and their association with levels of C4, duration of illness, disease activity scores, vWF:Ag, and absolute number of natural killer cells (NKs)– previously found to be decreased in active disease in 55.7% of JDM.

Methods: 62 children with definite JDM and 20 healthy controls were enrolled and their sera were obtained for immune complex measurement. Among the JDM patients, 29 had normal levels of C4 (21 girls and 8 boys; mean age 14.7 ± 6.8 years) and 32 had low C4 (22 girls and 10 boys, mean age 15.0 ± 3.8 years). The healthy control group was composed of 11 girls and 9 boys, mean age 12.5 ± 3.5 years. Immune complex level, measured as an aggregated human γ-globulin equivalent, was determined by ELISA. The association of immune complex levels with clinical variables was determined: disease activity scores (DAS, skin, muscle, total score), duration of untreated disease (DUD), and vWF:Ag**.** ANOVA was used to test the difference of immune complex levels among low, normal C4, and control groups. The Tukey post-hoc was used to test the pair-wise mean difference.

Results: The immune complex level in pediatric healthy controls was 317 ± 332.4 μg/mL (n=20) (AHG equivalent), 506 ± 347 μg/mL in JDM with low C4 (n=32) and 534 ± 350 μg/mL in JDM with normal C4 (n=29). The immune complex levels in JDM with low or normal C4 was significantly higher than that in healthy controls ($p=0.01$). However, there was no difference in the immune complex levels between children with JDM with low C4 and JDM with normal C4 levels ($p=0.99$). Furthermore, no significant correlation was observed between immune complex levels and a range of clinical features, including duration between disease onset and first treatment ($p=0.99$), DAS skin ($p=0.14$), DAS muscle ($p=0.15$), DAS total ($p=0.25$), level of vWF:Ag ($p=0.86$), or between immune complex level and the absolute NK count ($p=0.29$) among the patients with JDM.

Conclusion: We conclude that that immune complex levels are increased in children with JDM irrespective of C4 levels and are not associated with disease duration, activity or evidence of vascular damage. It is not known if these immune complexes are antigenic, or if they play a role in the initiation or perpetuation of disease.

Does Previous Corticosteroid Treatment Affect the Inflammatory Infiltrate Found in Polymyositis Muscle Biopsies? Mayara Mendes Pinhata, Juliana Jesus do Nascimento, Suely Kazue Nagahashi Marie and Samuel Katsuyuki Shinjo. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: We conducted this study because there have been no studies evaluating the effect of the use of corticosteroids (CE) on the presence of inflammatory infiltrates in muscle biopsies of patients with polymyositis (PM).

Methods: This single-center retrospective study, conducted from 2002 to 2013, evaluated 60 patients with defined-PM (Bohan & Peter criteria, 1975) with clinical and laboratory disease activity. Two researchers systematically and independently evaluated muscle biopsy samples that had been obtained at the time of the investigation and diagnosis of PM. The patients were divided into three groups according to the degree of the inflammatory infiltrate (semi-quantitative) present in the muscle biopsies: (a) minimal inflammatory infiltrate present only in an interstitial area of the muscle biopsy (endomysium, perimysium) or in a perivascular area; (B) moderate inflammatory infiltrate in one or two areas of the interstitium of the muscle biopsy or of the perivascular area; and (C) moderate inflammatory infiltrate throughout the interstitium or intense inflammation in at least one area of the interstitium of the muscle biopsy or of the perivascular area.

Results: The three groups (A=10, B=23 and C=27 patients) were comparable regarding the age at the time of the muscle biopsy, gender, ethnicity distributions, interval time between the muscle biopsy and the symptom onset, clinical manifestations, degree of muscle weakness and serum muscle enzyme measurements (P0.05). Approximately half of the patients in each group were using CE at the time of the muscle biopsy. The median (interquartile) duration of CE use [4 (0–38), 4 (0–60) and 5 (0–60) days: groups A, B and C, respectively] and the median cumulative CE dose used [70 (0–1200), 300 (0–1470) and 300 (0–1800) mg] were similar between the groups (P0.05).

Conclusion: Previous CE use did not influence the presence or the degree of inflammatory infiltrates found in muscle biopsies in PM with clinical and laboratory disease activity. Our study showed that muscle biopsies should be performed this population, even in individuals who have already been taking CEs.

Systemic Treatment for Clinically Amyopathic Dermatomyositis. Janice Lin[1], Alisa Femia[2], Mital Patel[1], Joseph Merola[1] and Ruth Ann Vleugels[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]NYU Langone Medical Center, New York, NY.

Background/Purpose: Clinically amyopathic dermatomyositis (CADM) is an important subset and accounts for approximately 20% of patients with dermatomyositis (DM). CADM is characterized by the presence of pathognomonic cutaneous findings without symptoms of muscle weakness. Cutaneous DM can be difficult to treat and is often refractory to photoprotection and topical therapy, frequently requiring additional systemic treatment even in the absence of muscle involvement. In our series, we investigate the use of systemic medications for treating CADM in our tertiary care center.

Methods: Retrospective chart review was conducted using the Partners Healthcare Research Patient Data Registry, which includes over 1.8 million outpatient visits in a university setting. Patients with CADM (including amyopathic and hypomyopathic DM) diagnosed and treated by any dermatology provider between January 2010 and January 2014 were identified. Data collected included demographics, referral type, diagnosis, medications used for DM, medication side effects, and laboratory tests including anti-nuclear antibody (ANA) and anti-Jo-1 (Jo-1).

Results: We identified 36 patients with CADM (6 hypomyopathic and 30 amyopathic). 47% of patients were referred from dermatology providers, 38.8% from rheumatology, 8.3% from primary care, and 5.5% were self-referred. Only one male patient was identified. One patient was Asian, the remainder Caucasian. Mean age of diagnosis was 50 years (±17.1, range 21–86). 41% of patients were diagnosed within 6 months from the onset of their rash. 36.1% were treated with hydroxychloroquine and topical corticosteroids alone, while 63.9% required at least one additional immunosuppressive therapy. Medications used for control of cutaneous disease included, methotrexate (47.2%), IVIG (30.6%), prednisone (30.5%), mycophenolate mofetil (16.7%), azathioprine (5.6%), rituximab (8.3%), and others including but not limited to dapsone and thalidomide (13.9%). Notably, 25% of patients developed a cutaneous hypersensitivity reaction to hydroxychloroquine. Of the 31 patients with laboratory data available, most (64.5%) had a positive ANA, while no patient had a detectable Jo-1 antibody.

Conclusion: Our series demonstrates that photoprotection, topical therapy, and hydroxychloroquine control disease in only a third of patients with CADM, thus underscoring the frequently refractory nature of skin disease and the need to treat with additional systemic therapy. Methotrexate and IVIG were the most commonly used additional therapies to treat CADM. Furthermore, the risk of cutaneous hypersensitivity reaction to hydroxychloroquine in this series of patients with CADM was similar to that reported in the literature for patients with DM.

Physical Impairment in Patients with Idiopathic Inflammatory Myopathies Is Predicted By the American College of Rheumatology Functional Status Measure. Laura Cleary[1], Leslie J. Crofford[2], Archana Srinivas[1], Heather Bush[1], Catherine Starnes[1], Qian Fan[1], Jidan Duan[1], Kirk Jenkins[1], Natasha Fraser[1], Matthew Rutledge[1] and Beatriz Hanaoka[1]. [1]University of Kentucky, Lexington, KY, [2]Vanderbilt University, Nashville, TN.

Background/Purpose: The American College of Rheumatology classification criteria of functional status (ACR-FS) in Rheumatoid Arthritis is used as a measure of the consequences of impairment in patients with IIMs. However, studies on the utility of applying the ACR-FS on data derived from chart review of patients with IIMs, as well as the relationships among ACR-FS, patient-reported outcome measures of health and physical activity, and objective measures of muscle strength, endurance and fatigability in IIMs are unknown. The goals of this study were to evaluate the predictive value of ACR-FS with known and suspected risk factors of disability, and to relate it with measures of muscle function in IIMs.

Methods: Demographic and clinical data on 118 patients with IIMs were obtained through retrospective chart review. Current ACR-FS was obtained by chart abstraction and direct patient report. Clinical and functional status evaluation, IPAQ, SF-36v2, muscle strength [manual muscle testing (MMT-8) and knee extensor maximal voluntary isometric contraction (MVIC)], muscle fatigability (percent loss of MVIC immediately following a fatigue protocol and after 12 minutes of recovery), muscle endurance (functional index-2) and body composition (Dual x-ray absorptiometry) measures were performed on a subset of 21 patients. Spearman's correlations were used to examine the relationships between ACR-FS derived from chart abstraction and direct patient report; as well as between physical function, body composition measurements and ACR-FS assessments.

Results: Older age at diagnosis was associated with lower functional status (p=0.045). There was strong correlation between ACR-FS derived from chart abstraction and direct patient report (r=0.782, p=0.0001). There were strong to moderate correlations between ACR-FS assessments and measures of general health, physical function, physical activity, muscle strength and endurance ($p<$ 0.05). ACR-FS correlated best with lower extremity portions of the FI-2. Previous research has shown that performance tests of lower extremity function alone can accurately predict disability across diverse populations. **Figure 1** shows pre, post and recovery MVIC normalized to total lean mass by ACR-FS by patient report. Pre, post and recovery MVICs clearly distinguished patients with no disability, mild to moderate disability, and severe disability. Pre, post and recovery MVICs were largely reduced in patients with severe functional status impairment, although this was not statistically significant.

Conclusion: Age related frailty is likely an important contributor of functional impairment in older IIM patients. The ACR-FS is a simple measure of disability that can be used in chart abstraction studies involving IIM patients. We have demonstrated that ACR-FS correlates well with muscle performance tests of strength, endurance

and fatigue, in general.

Has MRI an Added Value over Serum Creatine Kinase Measurement in Myositis? Nicolo Pipitone[1], Antonella Notarnicola[2], Giulio Zuccoli[3], Lucia Spaggiari[1], Gabriele Levrini[1], Arnaldo Scardapane[4], Florenzo Iannone[2], Giovanni Lapadula[2] and Carlo Salvarani[1]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]D.I.M.I.M.P, Rheumatology Unit - University of Bari, Bari, Italy, [3]Children's Hospital of Pittsburgh, Pittsburgh, PA, [4]University of Bari, Bari, Italy.

Background/Purpose: MRI is widely used to assess inflammation in myositis. Muscle edema on short tau inversion recovery (STIR) sequences is thought to reflect active inflammation. However, it is unclear whether MRI has an added value over the cheaper, easier-to-obtain measurement of serum creatine kinase (sCK) levels. Our aim was to assess the concordance between sCK and MRI edema in a cohort of patients with myositis at their first presentation to our centers.

Methods: We enrolled in 2 Rheumatology centers 73 patients, 34 with dermatomyositis (DM) and 39 with polymyositis (PM) diagnosed according to Bohan and Peter criteria. In all patients, sCK were measured and MRI sequences were acquired at the same time. MRI edema (1= present, 0= absent) was assessed bilaterally in 17 thigh and pelvic floor muscles. An MRI composite edema score (0–17) was calculated by adding the separate scores bilaterally and dividing them by two as described elsewhere (1). sCK was considered positive if values were above the upper limit of normal (190 U/l), while MRI was considered positive if the edema score was at least 1. The (single measures) intraclass correlation coefficient (ICC) between the Radiologists involved was 0.78. Muscle strength was measured by MMT (manual muscle testing) and graded according to the Medical Research Council extended scale (0–5). The ICC between the 2 physicians performing the MMT was 0.8.

Results: sCK and MRI were discordant in 47% of patients with myositis, more frequently in DM (59%) than in PM (39%). 56% of patients with DM, but only 15% of those with PM had a positive MRI with normal sCK.

	All patients (=73)	DM (=34)	PM (=39)
sCK+ MRI+	32	11	21
sCK- MRI-	7	3	4
sCK + MRI-	9	1	8
sCK- MRI+	25	19	6

There was a significant correlation between MRI score and muscle strength of the hip flexors (Spearman's rho 0.26, p 0.028) but not between MRI score and overall muscle strength.

Conclusion: MRI is a useful tool to assess disease activity in myositis, especially in DM, where it can be identify a sizeable number of patients who have normal sCK. Further studies of larger cohorts are warranted to confirm our findings.

2229

How Often Are Clinically Amyopathic Dermatomyositis Patients Truly Amyopathic? Edward J. Oberle[1], Michelle Bayer[2], Dominic O. Co[1] and Yvonne Chiu[2]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]Children's Hospital of Wisconsin, Milwaukee, WI.

Background/Purpose: Juvenile dermatomyositis (JDM) is a chronic inflammatory disorder primarily involving the skin and striated muscle. Classic JDM presents with rash, proximal muscle weakness, and objective evidence of muscle inflammation. A subset of patients presenting with cutaneous manifestations in the absence of muscle weakness have been variably termed dermatomyositis sine myositis or amyopathic dermatomyositis. The prevalence in adult populations has been reported up to 20% while the prevalence in children is unclear. The extent of the evaluation for myositis in pediatric patients varies between individual practitioners. Given the variability in evaluation, we hypothesized that truly amyopathic JDM is rare when a comprehensive evaluation for myopathy is performed.

Methods: A chart review of the initial evaluation was performed on all patients with the diagnosis code for dermatomyositis (ICD-9 code 710.3) seen at the Children's Hospital of Wisconsin between January 2000 and April 2013. Patients with disease onset after age 18 years or those previously treated with systemic anti-inflammatory therapy were excluded. Data collected included patient demographics, presenting symptoms and exam findings, muscle enzyme panel (AST, ALT, LDH, CK, and aldolase), muscle biopsy, electromyography (EMG), and magnetic resonance imaging (MRI).

Results: Forty-six patients were evaluated for JDM and met study criteria. All presented with typical cutaneous features of JDM. Twenty-six patients (57%) reported weakness as a symptom, while thirty-six (78%) demonstrated weakness on exam. Therefore, ten patients (22%) were classified as clinically amyopathic. The sensitivity of detecting myositis in the entire study population was 95% when all five enzymes were checked. All ten clinically amyopathic patients had a full muscle enzyme panel, nine had an MRI of the thigh to assess for myositis, one had an EMG, and one had a muscle biopsy. Six amyopathic patients had at least one abnormal muscle enzyme. Of the four amyopathic patients with normal enzymes, two had an abnormal MRI consistent with myositis while the other two were normal. The two with normal MRIs and enzymes did not have any additional testing and were labeled as amyopathic based on these studies alone. The one muscle biopsy was done in a patient with abnormal MRI and elevated enzymes; however it did not demonstrate pathologic features consistent with JDM. The EMG was performed on a patient with elevated enzymes and normal MRI; the EMG was normal.

Conclusion: In children, true clinically amyopathic dermatomyositis is rare when a full panel of muscle enzymes and other ancillary studies are performed. In our series, EMG and muscle biopsy were not consistently done, and it is not clear how much these studies contribute to the diagnosis. In patients with negative evaluation (enzymes and MRI), a muscle biopsy should be considered to confirm that the disease is truly amyopathic. Further research is necessary to define the natural history of true clinical amyopathic patients to determine if such a comprehensive evaluation is necessary and to help identify the appropriate therapy to initiate at time of diagnosis.

Treatment of Symptomatic Knee Osteoarthritis with Oral Salmon Calcitonin: Results from Two Phase 3 Randomized Clinical Trials. Morten Asser Karsdal[1], Anne C. Bay-Jensen[2], Asger Bihlet[3], Peter Alexandersen[4], Inger Byrjalsen[3], Jeppe Andersen[3], Bente J. Riis[3] and Claus Christiansen[3]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Cartilage Biomarkers and Research, Nordic Bioscience, Herlev, Denmark, [3]Nordic Bioscience, Herlev, Denmark, [4]Center for Clinical and Basic Research, Vejle, Denmark.

Background/Purpose: To evaluate the structure-modifying and symptom efficacy, as well as safety and tolerability of oral salmon calcitonin (sCT) formulated with a 5-CNAC carrier (a molecule based on Eligen® technology), in osteoarthritis (OA) patients with moderate to severe knee pain and joint structural damage classified as Kellgren-Lawrence 2–3.

Methods: This is the combined reporting of two randomized, double-blind, multi-center, placebo-controlled trials (CSMC021C2301 and CSMC021C2302), evaluating the efficacy and safety of oral salmon calcitonin in patients with painful knee OA, enrolling 1,176 and 1,030 patients, respectively. The subjects had painful knee OA with structural manifestations. Study subjects were randomized (1:1) to oral sCT 0.8 mg twice daily or placebo (PBO) for 24 months. The primary efficacy objectives were to examine the treatment effect compared to placebo on change over 24 months in joint space width (JSW) in the signal knee measured by X-ray, and to examine the change in pain and function using the WOMAC questionnaire. Other study parameters included patient and physician global assessment, cartilage volume measured by MRI technology, and biochemical markers of bone resorption (CTX-I) and cartilage degradation (CTX-II). The primary safety objective was to characterize the safety and tolerability profile based on adverse events incidence and changes in laboratory profiles.

Results: At the 24 month endpoint there was no statistically significant treatment effect on JSN in any of the two studies. In CSMC021C2301 there was a statistically significant ($p<0.0001$) treatment effect on WOMAC (sum of pain, function, stiffness, and total scores) as well as on the biomarkers of bone and joint metabolism ($p=0.0003$). None of the WOMAC scores or the biomarkers achieved a statistically significant treatment effect in the CSMC021C2302 study.

Conclusion: The present formulation of oral calcitonin did not provide reproducible clinical benefits in patients with symptomatic knee OA. (NCT00486434, NCT00704847).

Background/Purpose: The Multicentre Osteoarthritis interVEntion trial with Sysadoa (MOVES) compared efficacy and safety of Chondroitin sulfate (CS) and Glucosamine Hydrochloride (GH) with that of Celecoxib (CE) in patients with knee osteoarthritis (OA) and severe knee pain.

Methods: 606 patients with knee OA (Kellgren-Lawrence grade 2 or 3) and moderate to severe pain (WOMAC pain >300) were randomized to 400 mg CS + 500 mg GH tid or 200 mg CE qd for 6 months.

Methods: Primary outcome was decrease in WOMAC pain (0–500 scale) from baseline to 6 months; non-inferiority margin was set at 40 (corresponding to 8 mm on a 0–100 mm scale). Secondary outcomes included WOMAC function/stiffness, VAS pain, joint swelling/effusion, use of rescue medication, OMERACT-OARSI Responder Index and EuroQoL-5D.

Patients were excluded if they had a history of known cardiovascular or gastrointestinal disease.

The main study analyses were performed using PP population. Primary efficacy analysis was also performed according to ITT to test the robustness of results.

Results: Mean age at baseline was 62.7 years, 83.9% were women, WOMAC pain was 371.3 (41.6) and 62.6% had KL grade 2. There were no differences between treatment groups.

Adjusted mean change (95% CI) from baseline to 6 months in WOMAC pain was –185.7 (–200.3; –171.1) (50.1% decrease) in CS+GH group and –186.8 (–201.7; –171.9) (50.2% decrease) in CE group (Figure 1). The mean difference at 6 months met non-inferiority margin: –1.11 (–22.0; 19.8). All sensitivity analyses confirmed the non-inferiority conclusion.

There were no differences at 6 months between treatment groups in the secondary outcomes, including WOMAC stiffness, with a decrease of 46.9% and 49.2% ($P=0.434$); WOMAC function, 45.5% and 46.0% ($P=0.530$); and VAS, 48.0% and 48.8% ($P=0.924$); in GH+CS and CE groups respectively. Similarly, there were no significant differences in patient and physician global assessments of disease activity or response to therapy. Over 70% of patients in both groups fulfilled OMERACT-OARSI responder criteria at 120 days with ~ 80% response rate at 6 months. Both groups had a reduction (>50%) in joint swelling from baseline, from 12.5% to 5.9% for CS+GH, and from 14.0% to 4.5% for CE. Use of rescue medication was low and similar between treatments. There was no difference in proportion of patients with treatment-emergent or SAEs between groups; no deaths occurred in this study.

Finally, there were no significant subgroup by treatment interactions for either efficacy or safety confirming consistence of non-inferiority of CS+GH across clinically relevant subgroups.

Conclusion: The MOVES trial confirms that CS+GH is comparable to CE in reducing pain in patients with knee OA and extends results from GAIT. This fixed-dose CS+GH combination should offer a safe and effective alternative for those patients with cardiovascular or gastrointestinal conditions who have contraindications to celecoxib.

Cost-Effectiveness of Glucosamine, Chondroitin Sulfate, Their Combination, Celecoxib,Non-Selective Non-Steroidal Anti-Inflammatory Drugs, and Placebo in Treating Knee Osteoarthritis. Vishvas Garg[1], Dennis Raisch[2], Ning Yan Gu[2], Matthew E Borrego[2] and Daniel O. Clegg[3]. [1]University of New Mexico (at the time of research), Grayslake, IL, [2]University of New Mexico, Albuquerque, NM, [3]George Wahlen VA Medical Center/University of Utah, Salt Lake City, UT.

Background/Purpose: Knee osteoarthritis (KOA) affects 13.8% of the US population aged ≥26, causing significant burden-of-illness. We compared the cost-effectiveness of conventional medicines such as non-steroidal anti-inflammatory drugs (NSAIDs) and celecoxib (CXB) with complementary and alternative medicines (CAM) therapies to treat KOA from the US health care payers' and patients' perspectives, with 24-week, 2-year, and 10-year time-horizons.

Methods: We constructed a Markov cohort model (10-year analysis) and a decision-tree model (24-week and 2-year analyses). All costs were obtained from

the published literature (converted to 2012 USD) and included both direct and indirect health care costs of medications, drug-associated adverse events, and total knee replacement surgery. Clinical efficacies for treatment strategies were obtained from the Glucosamine/CS Arthritis Intervention Trial (GAIT). Effectiveness was measured using quality-adjusted life-years (QALYs) gained, estimated from the SF-6D data collected during GAIT. Patients were stratified into mild pain only and moderate-to-severe pain groups based on their severity of knee pain. Published literature was used to obtain the rest of the modeling parameters. Base-case results were varied in both one-way and probabilistic sensitivity analyses.

Results: We found that, among the mild, moderate, and severe patients together (from time-horizon of 24 weeks and years 2 and 10), CAM therapies were cost-effective versus conventional medicines to treat KOA in the US, with CS being the most cost-effective treatment ($1,332 per QALY gained) and glucosamine the next most cost-effective ($ 120,367 per additional QALY gained). However, in a 24 week time-horizon among KOA patients with mild pain CXB was also incrementally cost-effective versus CS ($49,988 per QALY gained). Among moderate-to-severe pain patients from 24-week time-horizon, the combination of glucosamine and CS was the most cost-effective ($3,279 per QALY gained). A major driver of cost-effectiveness of CAM therapies over conventional medicines in the 10 year time horizon was the lack of evidence of adverse events (AEs), compared to NSAIDS and CXB which have extensively-documented AEs.

Conclusion: Our analysis indicates CAM therapies to be more cost-effective than conventional medicines in treating KOA, due to lack of known adverse events rates and lower drug utilization costs from CAM. Prescribers may want to consider the findings of our study; however, future research is needed regarding the long-term effectiveness and safety of CAM therapies in treating KOA.

A PHASE 2, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group, Efficacy Study of Apremilast (CC-10004) in Subjects with Erosive Hand Osteoarthritis.

Juergen Rech[1], Francesca Faustini[1], Axel J. Hueber[1], Wolfgang Ochs[2], Wolfgang Spieler[3], Herbert Kellner[4], Ulf Muller-Ladner[5], Mathias Grünke[6], Matthias Schneider[7] and Georg Schett[1]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Rheumatologist in private practice, Bayreuth, Germany, [3]ZeFOR GmbH Zentrum für Forschung, Zerbst, Germany, [4]Centre for Inflammatory Joint Diseases, Munich, Germany, [5]Univ Giessen/Kerckhoff-Clinic, Bad Nauheim, Germany, [6]University of Munich, Munich, Germany, [7]Heinrich-Heine-University, Düsseldorf, Germany.

Background/Purpose: We report on a phase II, multicenter, randomized, double-blind, placebo-controlled, efficacy and safety study in subjects with erosive hand osteoarthritis. Subjects must have had a minimum of 6 months' history of EHOA immediately prior to enrolment to this study.

Methods: Subjects must have had a diagnosis of erosive hand osteoarthritis (EHOA), fulfilling the classification criteria of the American College of Rheumatology (ACR) with a disease duration for at least 6 months. The study included four phases: a pre-randomization phase for up to 35 days, a 91-days double-blind treatment phase, a 77-days open-label treatment phase, and a 28-days observational follow-up phase (to monitor worsening of EHOA). Subjects meeting eligibility criteria at the baseline visit (Visit 2/Day 1) were randomized in parallel 2:1 to either 20 mg PO BID of apremilast or placebo. The primary objective of the study was to evaluate the 84-day efficacy of apremilast 20 mg twice per day [BID], subsequent to a 7-day dose titration, compared with placebo, on the symptoms of erosive hand osteoarthritis.

Results: Until day 85 no patient achieved a 70% improve in AUSCAN and only 2 (7%) achieved a 50% improvement (1 in the apremilast and 1 in the placebo group). 44% of the patients achieved a 20% improve in AUSCAN at day 85 (42% in the apremilast and 50% in the placebo group) and 81% of the patient ended at day 85 with an AUSCAN below the baseline value (89% in the apremilast and 63% in the placebo group). None of the response rates showed a significant difference between apremilast treatment and placebo in the double blind treatment phase. There were small to modest correlations between AUSCAN and HOAMRIS scores (Table 78 and Figure 45) with a correlation coefficient of 0.30 for the linear correlation of the sum of HOAMRIS scores and the total AUSCAN score.

Conclusion: Given the lack of treatment options for patients with EHOA there is unmet need for effective treatment for this disease. Considering the pathophysiology of PDE4 inhibitors we initially considered apremilast as an interesting treatment option for patients with EHOA. However, regarding our pre-limary results we have to conclude that due to the high placebo response rate apremilast failed to meet the primary and secondary objectives in our study. Detailed MRI sub-analyses of responders and non-responders with respect to HOAMRIS scores may allow to define responder profiles in patientes with EHOA.

2234

Safety and Efficacy of Liposome Intra-Articular Injection in Moderate Knee Osteoarthritis. a Prospective Randomized Double-Blinded Study.

Leonid Kandel[1], Yaniv Dolev[2], Rachel Shimonov[1], Gurion Rivkin[1], Meir Liebergall[1], Yoav Mattan[1] and Xavier Chevalier[3]. [1]Hadassah Medical Center, Jerusalem, Israel, [2]Moebius Medical Ltd., Tel Aviv, Israel, [3]Department of Rheumatology Hopital Henri Mondor, Créteil, France.

Background/Purpose: Bio-lubrication is a prerequisite for proper joint mobility and is crucial for prevention of degradative changes of the joint. Phospholipids are components of the synovial fluid and are known to serve as natural lubricants of cartilage surfaces. MM-II is a novel intra-articular bio-lubricant made of liposomes suspended in aqueous solution.

Purpose: to test the safety and effectiveness of intra-articular injection of MM-II in osteoarthritic patients compared with intra-articular hyaluronic acid (HA) up to 3 months of follow-up in a double-blind, randomized clinical study.

Methods: Patients with symptomatic unilateral knee OA with baseline pain on VAS of more than 40 mm and a stage 2–3 Kellgren Lawrence score on X-ray, were recruited. 40 patients were randomized into two groups of 20, to receive a single intra-articular injection of either MM-II or HA (Durolane®). Effectiveness measures included maximal global pain in the target knee, recorded by a 100mm VAS; WOMAC subscales; OMERACT OARSI responder criteria; PGA, PASS, PAE questions and consumption of paracetamol/acetaminophen, which was the only authorized rescue medication. Tolerability was assessed by local manifestation defined by an increase of at least 3 cm in knee circumference, measured at 2 cm above the upper border of the patella or local pain increase of more than 30 mm on a 100 mm VAS. Adverse events were recorded through 90-days of follow-up.

The study was FIM Exploratory non-powered, with descriptive statistics.

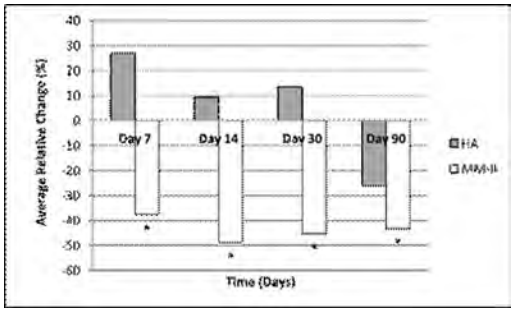
Results: All patients completed the study. **Results:** relating to WOMAC A pain, summarized in Figure 1, show a faster response with MM-II, with maximal effect observed on day 14, which was maintained over time and was associated with a statistically significant difference from baseline pain from day 7. In the HA group, the onset of pain relief was slower, with an improvement statistically significant change from baseline observed only on day 90.

Daily acetaminophen intake was lower in the MM-II group, with a reduction of more than 50% in the number of days and total dose of rescue medication consumption seen following MM-II administration, compared with HA injection.

The percent of responders to treatment according to the OMERAC-OARSI response criteria was 52.6, 66.7, 70 & 60 at the day 7, 14, 30 & 90 respectively compared to 30, 36.8, 25, 45 at the HA group (data not shown).

Local adverse events (inflammatory flare) were observed in one patient at day 3 in the MM-II group and in 4 pts at day 1, 1 pt at day 3, and 1 pt at day 7 in the HA group.

Patient's Relative Change in WOMAC A in Target Knee over Time



*statistically significant difference from baseline

Conclusion: Intra-articular injections of MM-II were found to be safe and effective. The pain-reduction action was more rapid and sustained up to 3 months compared with HA. Larger randomized controlled trials are needed to confirm these encouraging results.

Disclosure: L. Kandel, MM-II, 2; **Y. Dolev**, Stock options, 1; **R. Shimonov**, None; **G. Rivkin**, None; **M. Liebergall**, None; **Y. Mattan**, None; **X. Chevalier**, MM-II, 6.

2235

Cost-Effectiveness of Long-Term Opioid Use in the Treatment of Knee Osteoarthritis in Older Patients with Multiple Comorbidities. Jeffrey N. Katz[1], Savannah Smith[1], Jamie E. Collins[1], Joanne M. Jordan[2], David J. Hunter[3], Edward H. Yelin[4], Lisa Suter[5], A. David Paltiel[6] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [3]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, [4]University of California, San Francisco, San Francisco, CA, [5]Yale University, New Haven, CT, [6]Yale School of Public Health, New Haven, CT.

Background/Purpose: Because older patients with osteoarthritis (OA) and multiple comorbidities face high risk of toxicity from nonselective non-steroidal antiinflammatory drugs (NSAIDs) and Cox-2 inhibitors, opiates (including tramadol) have been proposed as an analgesic strategy. We evaluated clinical and economic outcomes of using prototypic medications (tramadol, naproxen, and celecoxib) in such patients.

Methods: We used the Osteoarthritis Policy Model, a validated computer simulation of knee OA, to project long-term clinical outcomes, costs and incremental cost-effectiveness ratios (ICERs) of OA treatment strategies in patients with mean age 70, knee OA, diabetes and coronary heart disease whose pain persists after initial therapy with acetaminophen, steroid injections and physical therapy (PT). We examined four treatment strategies: 1) continuing PRN acetaminophen; 2) tramadol; 3) naproxen and 4) celecoxib. Pain was the primary determinant of quality of life and its relief was assessed with the Western Ontario McMaster (WOMAC) Pain Scale. Treatment efficacies and toxicities were estimated from published literature and influenced time on regimen. Mean WOMAC change was 22 points for tramadol; 15 for naproxen and celecoxib. Annual medication costs and major toxicities for the first and subsequent years are shown in the Table. Toxicities included CVD and – for tramadol – fractures. We adopted a societal perspective, discounting outcomes at 3%, and assumed a willingness to pay (WTP) of $100,000 per quality adjusted life year (QALY) gained. ICERs below this threshold defined cost-effective strategies.

Results: Patients remained on tramadol for 1.98 years and the other regimens for 2.36 years. Twice as many experienced major toxicity with tramadol as with the other agents. The Table lists the cost-effectiveness results. The ICER for tramadol exceeded that for naproxen; thus, we compared naproxen directly to PRN acetaminophen and observed that naproxen had an ICER of $78,848/QALY. However, tramadol cost effectiveness was highly sensitive to its toxicity. When tramadol toxicity was reduced by just 10% it became cost-effective (ICER $53,968/QALY), and ICERs for the naproxen-based strategy then exceeded the WTP threshold (ICER=$102,000/QALY) compared to the tramadol-based strategy.

Conclusion: In patients with OA and multiple comorbidities who have pain despite acetaminophen, steroid injection and PT, naproxen was cost-effective at a WTP=$100,000. Tramadol became cost effective following a 10% reduction in its overall toxicity. The cost of celecoxib precluded its offering acceptable value. The impact of tramadol toxicity on these estimates underscores the need for further research on toxicity of opiates in frail patients; the limited number of years on regimen highlights the need for therapies with better efficacy and toxicity profiles.

Table: Cost-effectiveness, toxicity and years on regimen among individuals treated with acetaminophen, tramadol, naproxen and celecoxib

	Inputs			Results			
Regimen	Toxicity (first yr, subseq yrs)	Costs	QALE	COST	ICERs	Average Years on Regimen	Proportion Experiencing Major Toxicity attributable to treatment
Acetaminophen PRN		$71	6.328	$131,558			
Tramadol	21%, 6.0%	$755	6.363	$133,817	Dominated	1.98	33.7%
Naproxen	9.3%, 4.8%	$2,642	6.410	$137,983	$78,848	2.36	15.3%
Celecoxib	9.5%, 4.9%	$4,750	6.406	$142,610	Dominated	2.36	15.5%

PRN = as needed; Toxicity=coronary heart disease, gastrointestinal, fracture
QALE=quality adjusted life expectancy; ICER = incremental cost effectiveness ratio.
Dominated = Agent costs more and provides less benefit than some other agent or combination of agents

Plant–Derived Products Are Effective for Treatment of OA Pain and Safer Than Other Active Therapies. Laura Laslett, Xingzhong Jin and Graeme Jones. University of Tasmania, HOBART, Australia.

Background/Purpose: Osteoarthritis (OA) is a leading cause of chronic disability. There are no approved treatments for modifying the disease course, therefore disease management consists of symptom control, with patients often eventually requiring joint replacement. The controversy surrounding use of the COX–2 inhibitor class of NSAIDs and heightened cardiovascular risk highlights the importance of finding safer treatment options to minimise adverse side effects, such as natural therapies. Plant–derived therapies are traditionally used as medicines. However, such therapies have not typically been studied with the same rigour as pharmaceutical agents. This review summarises use of plant–derived products compared to placebo and active comparator for the treatment of OA pain and function.

Methods: 62 RCT's of plant–based therapy for OA were identified from literature databases (PubMed, EMBASE), and summarized for pain (assessed using visual analog scores (VAS), numeric rating scales (NRS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) or Knee Injury and Osteoarthritis Outcome Score (KOOS) pain scales, function and safety outcomes using standardised mean differences (SMDs) and relative risks (RR), with trials grouped by class where possible.

Results: Overall, plant–derived therapies are effective for treating pain compared to placebo, assessed using VAS and NRS scores (SMD 1.08; 95% CI 0.72 – 1.44), or WOMAC/KOOS pain scales (SMD 0.98; 95% CI 0.62 – 1.35). Classes demonstrating overall efficacy in more than one trial for either VAS or WOMAC pain included *Boswellia serrata*, capsaicin, and ginger; there was single trial evidence of efficacy for another 9 agents (pine bark, willow bark, NR–INF–02, UP446, E–OA–07, passion fruit peel, phytalgic, Aquamin–F, SKI306X). Plant–derived therapies have similar efficacy to active comparator (most commonly NSAIDs), assessed using VAS and NRS scores (SMD 0.32, p=0.08) or WOMAC/KOOS pain scales (−0.08, p=0.14). Therapies are also effective for functional outcomes compared to placebo (SMD 0.92, p<0.001). However, significant heterogeneity remains for all pain and function outcomes, indicating results need to be interpreted with caution. Risk of adverse events was similar to placebo (RR 1.13, p=0.1), but reduced compared to active comparator (RR 0.75, p<0.001).

Conclusion: Plant–derived therapies may be efficacious in treating osteoarthritic pain and functional limitation and appear safer than other active therapies. However, quality trials and long term data are lacking, and the number of trials for each therapy is limited. Comparison of efficacy would be assisted by trial standardisation.

Interleukin-1 Dual-Variable Domain Immunoglobulin Reduces Multiple Inflammatory Markers in Knee Osteoarthritis Patients. Susanne X. Wang[1], Jeroen Medema[1], Matthew Kosloski[1], Wei Liu[1], Mary Saltarelli[1] and Morten Asser Karsdal[2]. [1]AbbVie Inc., North Chicago, IL, [2]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark.

Background/Purpose: Osteoarthritis (OA) may comprise multiple phenotypes, one of which is inflammation-driven OA. Consequently, a selected subpopulation of OA patients may benefit from optimally targeted anti-inflammatory treatment. Interleukin-1 (IL-1) is a potent catabolic cytokine thought to play a major role in the development and progression of OA both in terms of disease (structural progression) and symptoms (pain and functional deterioration). The anti-inflammatory effects of a novel human DVD-Ig targeting IL-1α and IL-1β (ABT-981) were evaluated in knee OA patients using a panel of biomarkers that are elevated in the presence of tissue degradation secondary to joint inflammation.

Methods: This was a randomized, double-blind, placebo-controlled trial of the safety, pharmacokinetics, and pharmacodynamics of multiple subcutaneous injections of ABT-981 in knee OA patients (N=36). Three groups of patients (n=27) received 4 doses of ABT-981 or matching placebo (7:2) every other week (EOW) at 0.3, 1, and 3 mg/kg. Serum samples were collected on days 1, 5, 15, 19, 29, 33, 43, 47, and 57. The panel of inflammation and joint-degradation biomarkers included high-sensitivity C-reactive protein (hsCRP); matrix metallopeptidase (MMP)-9; vascular endothelial growth factor (VEGF); MMP degradation products of type I, II, and III collagen (C1M, C2M, and C3M) and CRP (CRPM); and circulating levels of citrullinated and MMP-degraded vimentin (VICM). Biomarker response for patients on active drug in each group was compared with the pooled placebo response across groups. Statistical analysis was performed on least-square means using SAS 9.2.

Results: Mean serum hsCRP levels in all ABT-981 groups were significantly decreased vs placebo (p value range, 0.003–0.031). Mean serum C1M levels decreased in a dose-dependent manner (p=0.062, 0.027, and 0.015 for 0.3, 1, and

3 mg/kg groups, respectively). Mean serum C3M levels exhibited a nonsignificant decreasing trend in the 1 and 3 mg/kg groups (p=0.062 and 0.090, respectively). Mean serum CRPM levels were decreased with ABT-981; however, a statistical difference was only established from day 33 on (p value range, 0.097–0.025; Figure). No other markers showed significant changes or trends.

Conclusion: Through inhibition of IL-1α and IL-1β, ABT-981 significantly reduced serum hsCRP and markers of joint metabolism that are elevated in inflammation-driven joint destruction diseases, suggesting a reduction in systemic inflammation. ABT-981 significantly decreased C1M, suggesting a dampening of inflammation-mediated joint destruction by reducing connective tissue turnover. The observed serum C3M and CRPM decreases suggest the potential of ABT-981 to ameliorate inflammation-mediated tissue destruction and chronic tissue inflammation. Thus, ABT-981 may provide clinical benefit to a selected subpopulation of patients with inflammation-driven OA.

2238

Exploratory Six Month Phase IIa Study of a Potential Disease Modifying Drug in Patients with OA of the Knee. Ketan Desai Voltarra Pharma, Easton, PA.

Background/Purpose: No disease modifying drugs exists to treat osteoarthritis. Recently, a phase II study from Tasmania showed that Zoledronic Acid, a bisphosphonate, has an effect on decreasing bone marrow lesions in patients with osteoarthritis of the knee. However, this was associated with post-dose syndrome with the once-a-year infusion. A new combination of Zoledronic Acid and an established drug. Volt01, was devised to decrease the post-dose syndrome.

Methods: In a single blind study (patients were blinded), 36 subjects with knee OA were given a single intravenous infusion of either Zoledronic Acid or Volt01 in a 1:1 ratio. Patients who had bilateral knee OA had the worse joint selected as the index joint. No patient with knee OA was rejected based on severity of OA. Patients with concomitant diseases were excluded. Patients were evaluated at baseline with the visual analogue pain score (VAS) and bone mineral density with a DEXA scan. VAS was evaluated at 1 month, 3 months, and six months. DEXA scan was repeated at six months to confirm no decrease in BMD.

Results: At six months, after a single infusion, there was no difference in bone mineral density in either cohort. The number of patients complaining of post-dose syndrome in the cohort treated with Zoledronic Acid was significantly worse that in those treated with Volt01 (9/16 versus 2/16). The improvement in pain as measured by VAS at six months was also significantly better in the Volt01 cohort than the Zoledronic Acid cohort (−35mm versus -10mm)

Cohort	PDS (# reporting/total)	ΔBMD	Δ Mean VAS
ZA=16	9/16	0	−10mm
VOLT01 =16	2/16	0	−35mm

Conclusion: Zoledronic Acid has been recently shown to have disease modifying properties in a large phase II study in patients with OA of the knee. In the study presented in this abstract, Volt01, a new combination with Zoledronic Acid, was both safer and more effective than Zoledronic acid after a single infusion in patients with knee OA for at least six months. Volt01 thus has the potential to be a disease modifying drug for knee OA. Larger studies using MRI will need to be undertaken to confirm this observation.

Efficacy of Ketoprofen Lysine Salt in Reducing Inflammation and Pain in Primary Osteoarthritis of the Hand: Preliminary Results of a Retrospective and Prospective Clinical Trial. Maurizio Muratore[1], Laura Quarta[1], Antonella Grimaldi[1], Daniela Costanza[1], Luigi Lanata[2], Michela Bagnasco[2], Alessandra Monguzzi[2] and Eugenio Quarta[1]. [1]Department of Rheumatology, Hospital Galateo, San Cesario di Lecce, Italy, [2]Dompé SpA, Milan, Italy.

Background/Purpose: Osteoarthritis (OA) is a common progressive joint disease and a leading cause of musculoskeletal pain and functional disability worldwide. Despite various interventional treatment approaches such as non-steroidal antinflammatory drugs (NSAIDs), pain management of OA remains suboptimal. Among NSAIDs, ketoprofen lysine salt (KSL) has a marked analgesic effect, through both its anti-inflammatory action and a central action. The primary aim of our study was to evaluate the efficacy of KSL in reducing the severity of osteoarticular pain. Secondary aims were grip strength assessment, duration and severity of swelling, acute exacerbations frequency and inflammation grade.

Methods: This was a retrospective and prospective clinical trial, including 58 post-menopausal women (>50 years) affected by primary osteoarthritis of the hand. All patients (pz) reported pain and swelling at least in 3 interphalangeal joints (IF) of the hands. Pz were randomized into 2 groups: Group A (30 pz, 105 IF) took KSL (160 mg/die) for 10 days plus glucosamine (500 mg) and chondroitin sulphate (400 mg) for 20 days. Group B (28 pz, 95 IF) received only glucosamine (500 mg) and chondroitin sulphate (400 mg) for 20 days. Pulsed wave (PW) *Doppler (Esaote Mylab 25 Gold equipped with a 12–18 MHz multi-frequency transducer)* was performed on the dorsal and palmar side of IF, with longitudinal and transverse scans, assessing synovitis/effusion and PW-Doppler signal (OMERACT scale: 0–3). *Clinical assessments of pz were performed at day 1 (T0)* and after 5,10,15,20 days (T1,T2,T3,T4). At each visit *Visual Analog Scale* for *Pain* (*VAS Pain)* and grip strength were recorded.

Results: Pain improved in 24 Group A pz (mean VAS score decreased from 70 to 16) and 70/105 IF showed an improvement in PW Doppler. None of these pz reported exacerbations. Also grip strength improved by an average of 50%. On the contrary, only 10/28 Group B pz obtained an improvement of pain (mean VAS score decreased from 70 to 55). PW Doppler improved in 20/95 IF, ≥1 exacerbations were reported by 12 pz and grip strength remained unchanged.

Conclusion: These results demonstrate that the addition of KSL is highly effective in reducing joint inflammation and pain in women with primary osteoarthritis of the hand. The reduction in the number of exacerbations in the group of patients treated with KSL also suggests that the use of this NSAID may reduce relapses lessening the bone and cartilage damage and joint deformities.

An Exploratory 4-Week Study of a P2X3 Antagonist AF-219 in the Treatment of Patients with Osteoarthritis (OA) of the Knee. Vibeke Strand[1], Michael Kitt[2], Alan Kivitz[3], Anthony Ford[2], Peter Butera[2] and Bruce McCarthy[2]. [1]Stanford University, Portola Valley, CA, [2]Afferent Pharmaceuticals, Inc., San Mateo, CA, [3]Altoona Center for Clinical Research, Duncansville, PA.

Background/Purpose: Targeting P2X3 receptors that mediate the sensitizing effects of ATP released from inflamed and damaged tissues on the primary afferent neurons (PAN) of musculoskeletal structures may interrupt processes that drive hyperalgesia and allodynia. P2X3 blockade in a range of rodent hyperalgesia models has demonstrated efficacy. Recently, AF-219, a selective P2X3 antagonist, has shown efficacy in patients with refractory chronic cough. This was a multicenter phase 2 study to assess safety and efficacy of AF-219 versus placebo in patients with moderate to severe pain due to OA of the knee over 4

weeks. Secondary objectives assessed changes in physical function, stiffness, global assessment of OA, and health related quality of life.

Methods: Eligible patients, 40–80 years with Kellgren-Lawrence grade ≥2 and OA of ≥6 months duration required baseline average daily pain between 5 and 9 on the Numeric Pain Rating Scale (NPRS) following pain medication washout. Primary endpoint analysis of change from Baseline (Week 4) of weekly average daily NPRS used a mixed effects model with repeated measures yielding an overall 1-sided α=0.0225.

Results: The Full Analysis Population included 164 patients (AF-219 n=78, placebo n=86) who received ≥ one dose of study medication and completed ≥50% of week 1 daily NPRS scores. 134 patients completed 4 weeks treatment (AF-219 n=56, placebo n=78) due to early discontinuations for taste-related adverse events (AEs) with active treatment and lack of efficacy in placebo. Reduction in weekly average daily NPRS in AF-219 treated patients was numerically greater than placebo at each week. This difference was greatest in week 2 (p=0.0436).

Normalized pain, stiffness, physical function, and total WOMAC scores revealed larger numeric mean reductions at all end of treatment analyses; the Week 1 normalized total WOMAC score was significantly better in AF-219 treated patients (p=0.0176). Patient (PGIC) and Clinician Global Impression of Change (CGIC) and Short Form-36 physical component summary and role physical and bodily pain domains at end of treatment were significantly improved compared with placebo. Placebo patients took significantly more rescue medication over all 4 weeks.

There were no deaths or SAEs during the treatment phase. AEs were generally mild. 88% AF-219 treated patients reported dysgeusia/hypogeusia and 19% discontinued treatment due to dysgeusia.

Conclusion: In patients with OA of the knee, treatment with the P2X3 antagonist AF-219 resulted in improvement in pain and symptoms compared with placebo.

Intermittent Analgesic Use and Risk of Pain Exacerbation in Knee Osteoarthritis: A Web Based Case-Crossover Study. Tahereh Erfani[1], Yuqing Zhang[2], Joanna Makovey[1], Ben Metcalf[3], Lyn March[1], Kim Bennell[3] and David J. Hunter[1]. [1]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, [2]Boston University School of Medicine, Boston, MA, [3]University of Melbourne, Melbourne, Australia.

Background/Purpose: The pain experienced by osteoarthritis (OA) patients is neither constant nor stable and most patients experience episodes of pain exacerbations or flares. A number of factors have been hypothesized that could increase the risk of pain exacerbations in people with knee OA. Using a web based case-crossover study design, we evaluated whether intermittent use of analgesics is a risk factor for pain exacerbations in people with knee OA.

Methods: Participants with a diagnosis of symptomatic knee OA were recruited and followed for 3 months at 10-day intervals (control periods). Participants were also instructed to log on to the study website if they experienced a knee pain exacerbation during the follow-up period (case periods). Via the internet, we collected data on triggers occurring during "control periods" as well as "case periods". Pain exacerbation was defined as an increase of 20 mm in a participant's VAS knee pain score (VAS 0–100) over the follow-up period from his/her mildest pain score reported at the baseline visit. We collected data on analgesic use type and pattern during 7 days prior to the exacerbation dates. We asked participants whether they have taken analgesic over a specific time span (1 day, 2 days, 3–7 days prior). We assessed the effect of intermittent analgesic use on the risk of pain exacerbation compared with regular use using the conditional logistic regression model. Intermittent use was defined as taking analgesic in one of the three time spans only. Regular use was defined as taking analgesic daily over the prior 7 days.

Results: Of 268 participants (women: 61%, mean age: 62 years, mean BMI: 29.4 kg/m^2) recruited in the study, 153 participants experienced at least one episode of knee pain exacerbation. Intermittent use of any analgesic during the prior 7 days was associated with an increased risk of flares with OR of 1.57 (95% CI 0.92, 2.67) (Table). This odds ratio differed greatly amongst different categories of analgesics; intermittent use of Meloxicam (COX 2-Selective) had the highest effect on pain exacerbation with OR of 7.02 (95% CI 1.70, 29.1).

Conclusion: This study suggests that intermittent use of analgesics (compared with regular use) is associated with an increased risk of pain exacerbation in persons with symptomatic knee OA. The relationship was strongest for Meloxicam. Further work to better elucidate this connection will be important, as this may represent an important target for efforts designed to prevent and treat OA pain exacerbations.

Table Association of Intermittent Analgesic Use and Risk of Pain Exacerbation

			95 % CI

Effects of Intraarticular (IA) Corticosteroid Injections on Bone Markers and Endogenous Cortisol in Patients with Knee Osteoarthritis (OA): A Randomized, Double-Blind, Placebo Controlled Trial. Muhammad Imran[1], Aruna Baratham[2], Jo Wick[3], Barbara Lukert[4] and Herbert Lindsley[3]. [1]University of Kansas Medical Center, Kansas City, KS, [2]Private Community Practice, Kansas city, KS, [3]Kansas University Med Ctr, Kansas City, KS, [4]Kansas University Medical Center, kansas city, KS.

Background/Purpose: IA steroids are used to treat knee OA. Little is known about the systemic effect of intraarticular steroid injections on bone or the hypothalamic-pituitary- adrenal axis (HPA).

Methods: We describe a 2:2:1 randomized, double blind, placebo controlled study. 25 subjects (20 females, 5 males) with knee OA, age range 45–83 years were identified from our clinical practice. Ten subjects (Group 1) were injected with Depo-methylprednisolone 80 mg plus lidocaine 20 mg, 10 additional subjects (Group 2) were injected with Depo-methylprednisolone 16 mg plus lidocaine 20 mg and 5 subjects (Group 3) were given normal saline with lidocaine 20 mg. Blood draws were performed 5 times (Days 0, 2–3, 7, 14 and 28). Means and 95% CI were reported by time and group. All plots show mean (+/− SEM). Between and within-group comparison *p*-values were generated by *t*-tests. All parametric assumptions were verified.

Results: Mean levels of serum osteocalcin, a bone formation marker, reached a nadir (10.2 ng/ml (95% CI 9.3–11.2) from baseline of 15.5 ng/ml (95% CI 14.4–16.7) by Days 2–3 with recovery by Day 7 (14.9 ng/ml (95% CI 13.8–16.1)) after IA corticosteroids only for Group 1, with mean change of 5.3 ng/ml (95% CI 2.4–8.2) (p = 0.01). No change was seen in Groups 2, 3 (Fig 1, p> 0.05). In contrast, the bone catabolic marker Tartrate-resistant Acid Phosphatase Form 5b (TRACP-5b) showed no consistent change for any of the three groups over 28 days (range 1.7–2.7 U/L) (Fig 2). Mean baseline endogenous cortisol level reached a nadir by Days 2–3 for Group 1 (8.9 mcg/mL (95% CI 8.0–9.8)) and by Day 7 for Group 2 (8.9 mcg/ml (95% CI 8.0–9.7). Both returned at least to baseline by day 14. Baseline vitamin D levels did not differ significantly between groups (p > 0.05), though Group 1 levels were not as low (range 22–47 ng/mL) as Group 2 (range 8.3–51.5 ng/mL) or Group 3 (range 8.6–38.5 ng/mL). In control subjects, lower baseline levels of vitamin D were associated with greater decreases in

osteocalcin at Day 2 – 3 ($r = 0.9$, $p < 0.05$). Low levels of vitamin D were associated with greater levels of suppression of osteocalcin at Day 7 in Group 2 ($r = -0.7$, $p = 0.03$).

Conclusion: IA corticosteroids have a transient adverse effect on bone formation with significant recovery of osteocalcin levels by one week and no change in bone catabolism. Cortisol levels decrease slightly at one week of IA administration and rebound above baseline by two weeks. In contrast to daily oral corticosteroids, single doses of IA steroids have no persistent adverse effect on bone or the HPA axis.

Comparison Between Two Diclofenac Diethylamine Gel Formulations, 1.16% Vs 2.32%: Is It Only Increasing the Strength of the Active Ingredient Enough? Giuseppa Quartarone[1] and Nathalie Hasler-Nguyen[2]. [1]Novartis CH R&D OU Italy Greece, Milan, Italy, [2]Novartis CH Global R&D, Nyon, Switzerland.

Background/Purpose: Topically applied non-steroidal anti-inflammatory drugs (NSAIDs) can produce clinically effective drug concentrations at a peripheral site, but with low systemic concentrations and thus a lower risk of AEs. Various factors influence penetration and absorption of topical NSAIDs such as chemical properties of adjuvants included in the formulation and inter-individual variability in skin absorption. Modulating skin permeation is a pivotal factor in the development of new formulations as well as their posology and duration of therapeutic effect. Diclofenac diethylamine (DDEA) 1.16% gel (Voltaren® Emulgel™ [VEG 1%], Novartis Consumer Health, Nyon Switzerland) is used topically to relief pain and inflammation; it is applied to the affected site 3 or 4 times daily. We compared the *in vitro* skin permeation of VEG 1% with a new double-strength formulation of DDEA 2.32% [VEG 2%] including different doses of a permeation enhancer (PE) to assess the hypothesis of increased skin permeation that may result in delivering higher drug amounts to target tissues when applied every 12h.

Methods: *In vitro* skin penetration studies were performed at 35°C in glass Franz static diffusion cells (Bernard Gallas, Antibes, F; 1.54 cm^2) using human skin. Samples of donor abdomens were obtained from the NDRI Institute (USA) and the WHRTB Institute (HU) and kept frozen at –80°C until use. The comparison of *in vitro* skin permeation of VEG 1% vs VEG 2% was performed. Then VEG 1% was tested against VEG 2% containing low (0.5%), medium (0.75%) and high (1.0%) amounts of a permeation enhancer. All samples were applied at 20 mg/cm^2 in a single dose, equivalent to the maximum daily dose of 4 applications of 5 mg/cm^2 under *in use* conditions.

Results: Addition of the PE at the VEG 2% gel resulted at a dose-dependent (up to 3-fold) increase in diclofenac's skin permeation (Fig. 1). Medium and high PE concentration resulted in similar cumulative permeation.

Conclusion: Addition of PE to VEG 2% resulted in an up to 3-fold increased diclofenac skin permeation which correlated with the PE dose concentrations. The new gel is expected to have a lasting effect, e.g. up to 12h, potentially attributed to the release of a higher amount of drug at the application site as confirmed in a RCT (Predel 2012), where 2 daily doses significantly reduced pain and improved joint function vs placebo. This could be useful when treating flares of peripheral joint conditions such as OA.

Fig. 1 In vitro Skin permeation of diclofenac from VEG 2% with various amounts of PE vs VEG 1%

Multimedia Patient Education Tool for Patients with Osteoarthritis. Aparna Ingleshwar[1], Maria A. Lopez-Olivo[1], Robert Volk[1], Andrea Barbo[1], Maria Jibaja-Weiss[2], Heather Lin[1] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: The use of video modelling in patient education can result in positive patient outcomes including informed decision-making and improved self-management. The purpose of our study was to test the efficacy of a multimedia patient education tool (MM-PtET) for patients with knee osteoarthritis (OA).

Methods: We randomized 219 participants to receive a MM-PtET including storylines and testimonials n=109), and 110 to receive a written booklet with the same content (n=210). Inclusion criteria were: (i) age ≥50, (ii) prior diagnosis of knee OA (unilateral or bilateral) by a physician, (iii) adequate cognitive status, and (iv) ability to communicate in English or Spanish language. Upon completion of the baseline questionnaire, participants reviewed the materials (MM-PtET or written booklet) to which they were allocated, and then completed a post-questionnaire. Primary outcome measures included: a) Disease knowledge and, b) Decisional Conflict Scale (DCS). Secondary outcomes included: a) Ottawa Acceptability Instrument, and b) Evaluation of the educational materials. Demographics and health literacy (Adequate vs Inadequate) were also collected at baseline. We compared difference in knowledge scores (pre-post randomization) between the intervention and control groups, and within the groups themselves. Linear regression was employed to assess the influence of the intervention and patient characteristics on the knowledge score adjusting by age, sex and pre-randomization knowledge score.

Results: Mean age was 65±8 years, 76% were female, 82% had adequate health literacy, and 17(%) spoke Spanish. Mean difference in knowledge scores was higher in the MM-PtET group compared to controls (p=0.03). No statistically significant difference was observed in DCS scores between groups (p0.05, for both scales). However, significant improvement in DCS scores was observed in both groups after the intervention; patients perceived being more informed (p<0.001) with higher values clarity (p<0.001). Regression analysis indicated that intervention group, female gender, and higher level of educational attainment were predictive of higher knowledge improvement scores (p<0.05 for all, Adjusted R^2=0.11). Compared to control group, MM-PtET group participants were more likely to answer "Yes" to the following questions: (1) Did the video/booklet meet your needs for information about knee osteoarthritis? (94% vs 81%, p<0.01), and (2) Did you like the explanation of the medical facts in the video/booklet? (100% vs 95%, p=0.04). Compared to the control group, intervention group participants were more likely to rate the presentation of information about impact of OA and, self-care options as "Excellent" (47% vs 27% and 47% vs 32%, respectively; p<0.05 for both questions).

Conclusion: The results of our study support the efficacy of the MM-PtET over written booklets in improving disease knowledge in patients with knee OA.

Characteristics of Conventional Footwear and Their Association with Reductions in Knee Loading with a Flexible Footwear Intervention. Najia Shakoor[1], Roy H. Lidtke[1], Chris Ferrigno[2], Anjali Nair[1], Markus A. Wimmer[1], Laura E. Thorp[1], K. Douglas Gross[3] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University, Chicago, IL, [3]Boston Univ School Medicine, Boston, MA.

Background/Purpose: The peak external knee adduction moment (KAM) as measured through gait analyses has been associated with severity, progression and pain in medial knee osteoarthritis (OA); thus, biomechanical approaches to knee OA aim to reduce the KAM. We previously reported that flat flexible footwear may reduce the KAM compared to wearing conventional footwear. However, the characteristics of conventional footwear that influence the magnitude of this reduction remain unclear. Here we evaluate the footwear of participants with knee OA to identify the properties associated with response to a flexible footwear intervention.

Methods: Participants with medial compartment knee OA were provided with a flexible study shoe (previously described "mobility shoe") and were asked to bring their own conventional shoes that they used most often for walking activities. Their own shoes were evaluated for stability/flexibility with the following 3 tests: 1) Sagittal stability: the shoe was held perpendicular to a flat surface with the tip of the toe on the ground and approximately 5 pounds of load was applied vertically on the heel; 2) Torsional stability: the shoe was held parallel to the ground with a hand at the heel and the toe and about 5 pounds of torque was applied; 3) Heel counter stability: about 5 pounds of force was applied to the medial and lateral heel counter using the thumb and index finger. With all three tests, the resistance to deformation was classified on a 3-point grading scale (0: rigid, 1:supportive, 2: flexible). The heel height of the shoes was also measured. Gait analyses were performed while walking in subjects' own shoes and the flexible study shoes. Paired t-tests were used to evaluate overall percent reduction in the KAM with the flexible footwear compared to participants' own shoes, and the association between reduction in the KAM and measures of their own shoe flexibility/stability was evaluated using Spearman's coefficient.

Results: 22 participants (15 women, mean age (SD) of 62±11 yrs) were evaluated. Overall, the use of the flexible study shoes was associated with a significant 6% reduction in the KAM (2.55±1.00 vs 2.40±1.00 %BW*ht, p=0.007). The percent reduction demonstrated in the KAM was significantly associated with the sagittal (rho=−0.470, p=0.027), torsional (rho=−0.470, p=0.027), and heel counter stability (rho=−0.551, p=0.008) of the participant's own shoe, with more rigid footwear being associated with greater KAM reduction. The assessments for sagittal and torsional stability did not appear to provide unique information since they were strongly correlated (rho = 1.0) with one another. Interestingly, heel height was not associated the extent of KAM reduction (rho=0.181, p=0.488).

Conclusion: Footwear has been associated with knee joint loading and choice of footwear may be an important consideration in knee OA. This study suggests that those wearing more rigid footwear may expect the greatest benefit in medial knee load reduction with transition to flexible footwear and supports the concept that flexibility is an important load-reducing feature of footwear. Simple protocols to evaluate footwear such as those used in this study may be beneficial in helping patients make choices regarding footwear.

Reduction of Knee Osteoarthritis Symptoms in a Cohort of Bariatric Surgery Patients. Andrea Leyton-Mange, Janice Lin, Ryan Flanagan, Evan Wilder, Jay Bhatia, Farah Taufiq, Lauren Browne, Mukundan Attur, Renata La Rocca Vieira, Manish Parikh, Christine Ren-Fielding, Steven B. Abramson and Jonathan Samuels. NYU Langone Medical Center, New York, NY.

Background/Purpose: Obesity is a modifiable risk factor of knee osteoarthritis (KOA). While medical treatments can have limited beneficial effects, an alternative strategy would target weight loss to delay or avoid joint replacement. Limited retrospective data have shown improvement in KOA pain after bariatric surgery. We initiated a prospective study to evaluate painful KOA in the obese population, and track whether weight loss after bariatric surgery affects KOA-related pain and physical function.

Methods: We screened consecutive patients (N=537) prior to laparoscopic adjustable gastric banding (LAGB), sleeve gastrectomy, or gastric bypass (RYGB). Patients age ≥21 with knee pain for ≥1 month and a visual analog scale pain score ≥30mm were enrolled, excluding lupus, inflammatory arthritis, or psoriasis. Baseline pre-op assessments included x-rays for OA severity by Kellgren-Lawrence (KL) grade, the Knee Injury and Osteoarthritis Outcome Score (KOOS), and the Western Ontario McMasters Universities Osteoarthritis Index (WOMAC) with a Likert scale calculated from the KOOS. Patients are completing the questionnaires and being measured for BMI and % excess weight loss (%EWL) at intervals through 12 months post-op.

Results: In total, 307 patients reported knee pain, and of those, 175 met criteria and consented (89.7% female, mean BMI 43 kg/m^2±7, range: 32–60, mean age 42 ±11, range: 18–73). X-rays were completed on 160 patients: KL0=38, KL1=31, KL2=33, KL3=33, KL4=25. The mean pre-op KOOS scores were 46 (0=worst, 100=best) for both pain and ADLs, the mean WOMAC pain score was 11 (0=best, 20=worst), and the mean overall WOMAC index was 52 (0=best, 96=worst). Higher KL correlated with symptoms; mean KOOS pain was 54, 49 and 37 for KL0, KL1–2, and KL3–4 (p=0.0006 for KL1–2 vs 3–4), with similar trends across other KOOS and WOMAC scores. Higher BMI also correlated with worse pre-op knee symptoms, as the quartiles with the lowest and highest BMIs (32–38 and 49–61) had mean KOOS pain scores of 48 and 43. Thus far, 117 patients have had surgery (31 RYGB, 64 sleeve, 22 LAGB). Improvement in average KOOS and WOMAC scores over baseline has been observed at all intervals (46, 36, 31 and 7 responses at 1,3,6,12 month visits), with more improvement farther after surgery. At 6

months post-op, mean KOOS scores improved 29 points for pain, with mean WOMAC pain and index improving by 6 and 22 points. The %EWL correlated with knee symptoms at each interval and for all followups combined, as the smallest and largest %EWL quartiles (4–29%, 54–92%) showed mean improvements of 18 and 31 points ($p=0.03$) in KOOS pain - mirrored across KOOS and WOMAC scores. RYGB and sleeve yielded higher %EWL than LAGB (44%, 43% vs. 37%) across all intervals, and greater improvement in mean KOOS and WOMAC scores (e.g. mean KOOS pain increased by 28, 29 and 8). Neither presence nor severity of KOA severity affected knee pain improvement from weight loss.

Conclusion: These data suggest that bariatric surgery improves patients' KOA pain proportional to weight loss, with durability over time. RYGB and sleeve gastrectomy have more impact on knee symptoms than LAGB. While patients with worse KL grades report more baseline pain and disability, x-ray severity did not impact the response to weight loss.

Bariatric Surgery Improves Quality of Life in Patients with Osteoarthritis and Obesity Compared to Non-Surgical Weight Loss. Christopher Chong[1], Sangeeta Kashyap[1], Philip Schauer[1], Colin O'Rourke[1] and M. Elaine Husni[2]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Numerous studies support obesity as a strong risk factor for development and progression of knee osteoarthritis (OA). The potential benefits of massive weight loss, as seen after bariatric surgery, have not been well studied. The study objective is to examine if massive weight loss after bariatric surgery is associated with improved OA symptoms and quality of life (QoL) compared with medical management alone in obese patients.

Methods: A total of 150 patients were screened for clinical and radiographic evidence of OA within the STAMPEDE trial (March 2007 – Jan 2011). The STAMPEDE trial examined the effects of bariatric surgery vs. medical management alone in obese patients with diabetes. 100 patients received bariatric surgery (50 sleeve gastrectomy and 50 Roux-en-Y gastric bypass) and 50 patients were medically managed. Clinical data, medication usage, and QoL scores were collected before and 12 months after intervention. OA was defined by physician diagnosis at an office visit and/or radiographic evidence of OA (joint space narrowing and osteophytes) of the hip, knee, ankle, or foot. The change in 12 month post-intervention SF-36 scores between the surgical group and medically managed group were compared. Scores were compared using linear regression models, adjusting for baseline score. Baseline scores were centered at their median value.

Results: 67 patients with OA had baseline and follow up data available for review. Demographics between the bariatric surgery and medical group were similar (mean age 51, female gender 44/67, mean BMI 36.6). 49 patients were in the surgery group and 18 in the medical group. There was a statistically significant difference in BMI change, over 12 months, between the surgical group and medical group (BMI −9.12 and −2.24 respectively). The surgical group improved in each of the SF-36 physical health scales (Figure 1). There was a significant improvement in the surgical group compared to the medical group in the physical functioning (P 0.03), general health ($P<0.001$), and overall physical health scores (P 0.004) (Table 1). There was no significant difference between the groups in pain or role-physical scores.

Conclusion: Patients with OA who underwent massive weight loss after bariatric surgery had significant improvement in SF 36 physical functioning and general health scores when compared to patients treated with medical management of weight loss alone. There was also a trend suggesting improvement in bodily pain and role-physical.

Table 1: Adjusted SF-36 improvement in surgical compared to medical group at 12 months

SF-36 Scale	SF-36 difference	95% CI	p-value
Physical Functioning	11.47	1.15–21.79	0.03
Role Physical	8.55	−7.12–24.21	0.28
Bodily Pain	9.44	−2.77–21.65	0.13
General Health	19.24	12.25–26.23	<0.001

Clinical Outcomes, Neuropathic Pain and Patient Satisfaction over a 15 Year Period Following Primary Tka: A Repeat-Cross-Sectional Analysis. Anne Lübbeke, Matthieu Zingg, Daniel Fritschy, Pierre Hoffmeyer and Hermes Miozzari. Geneva University Hospitals, Geneva, Switzerland.

Background/Purpose: Studies evaluating patient-reported long term outcomes (>10 years) after primary TKA are lacking. Moreover, variability in patient satisfaction after TKA has been reported for the short and mid term, but has not been investigated over the long term and in relation to presence or absence of neuropathic pain.

Our objective was to assess pain, function, general health, and patient satisfaction at short, mid and long term following primary TKA.

Methods: Patients eligible for this study were part of a prospective hospital-based cohort of all primary TKAs operated upon since March 1998. All patients operated in 2012, 2010, 2007, and 2004–1998, who were alive and still living in the area, received a postoperative questionnaire by mail between 2012 and 2013. We performed repeat cross-sectional analyses of pain, function, general health and patient satisfaction at the following time-points: prior to surgery, and 1, 2, 5, 9–11 and 12–15 years postoperative. Pain was evaluated with use of WOMAC and VAS score, neuropathic pain with DN4 (=neuropathic pain diagnostic questionnaire), function with WOMAC, general health with the SF-12, and satisfaction was evaluated with use of a five-item satisfaction rating.

Results: 1451 TKAs were eligible (68.4% women, mean age 71 (±9) years, mean BMI 29.6 kg/m^2). Of those, 1021 returned the questionnaire (response rate 70.4%). Their mean age was 71 years, mean BMI was 29.5 kg/m^2 and 67.8% were women. Mean values of pain, function and general health were clinically significantly higher (effect sizes 0.22–1.71) one year postoperative as compared to prior to surgery (see Table). For pain and satisfaction there was an ongoing clinically significant "improvement" between 1 and 2 years postoperative. Results remained similar between 2 and 10 years with minimally lower (effect size <0.2) outcomes between 10 and 15 years. Neuropathic pain was reported in 12.4% preoperative, 14% at 1 year, 10% at 2 years and 5–7% 5–15 years after surgery. Its presence was significantly ($p<0.001$) associated with dissatisfaction.

Conclusion: Clinical outcomes and patient satisfaction were similar between 2 and 15 years after primary TKA. Neuropathic pain when present was strongly associated with dissatisfaction.

Criteria for Clinically Important Worsening in Knee and Hip Osteoarthritis. Elien A.M. Mahler[1], Alfons A. den Broeder[1], Vincent J.J.F. Busch[1], Johannes W.J. Bijlsma[2] and Els van den Ende[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Clinically important worsening in OA has not been well defined. Validated worsening criteria are important for research but also clinical practice to make informed treatment choices. The goals of this study are 1) to select candidate clinical worsening criteria and 2) to validate criteria for clinically important worsening.

Methods: Data were used from a cohort of knee and hip OA outpatients visiting our department who received standardised evidence-based tailored conservative treatment in a stepped-care format for 3 months. The development cohort comprised 218 patients with three-months follow up and the validation cohort consisted of 296 patients with two-years follow up. For this study baseline and three month data were used.

In the first round, an expert group (methodologists, orthopaedic surgeon, physical therapists, psychologist, rheumatologists) reviewed previously proposed criteria for clinical worsening and selected on the basis of consensus and face-validity the criteria that should be tested. Furthermore, the expert group decided that newly defined criteria of worsening should contain both pain and function and optional PGA and embed both an absolute and a relative change. Then, 15 new criteria of worsening criteria were constructed. In the second round, first we examined the sensitivity and specificity of the newly developed criteria of worsening in development cohort using an anchor-based 7-point Likert transition scale (much worse-much better). Second, we evaluated all the selected criteria from the literature and newly developed criteria of worsening criteria in the validation cohort using the transition scale.

Results: The expert group's review of existing criteria yielded five criteria that were included in the validation round and the sensitivity of these previously proposed criteria for clinical worsening was low while specificity was high. Of the expert group's proposed criteria, the sensitivity and specificity of the newly developed worsening criteria ranged from 1 to 65% and 60 to 97% respectively. The three newly defined sets of criteria that performed best incorporated smaller relative and absolute changes compared with improvement criteria. Set 1 and 3 performed best, with sensitivity and specificity ranging between 50 and 75% in both the development and the validation cohort (Table 1).

Conclusion: Previously proposed criteria for clinical worsening in knee or hip OA are specific but lack sensitivity. Our results suggest that, compared with improvement criteria, criteria for worsening should incorporate relatively small absolute and relative changes. Our newly developed criteria pairs acceptable sensitivity with acceptable specificity and can be used to measure clinically important worsening in knee/hip OA studies and clinical care.

Table 1. Sensitivity and specificity of newly developed worsening criteria, in the development and validation cohort

	Newly developed criteria	Development cohort Sensitivity %	Development cohort Specificity %	Validation cohort Sensitivity %	Validation cohort Specificity %
Set 1	Set 1: worsening in ● pain ≥20% and absolute change ≥20 or ● function ≥10% and absolute change ≥10 or ● PGA ≥10% and absolute change ≥10				
	with NRSpain	53	70	58	75
	With WOMACpain	50	71	55	69
Set 2	Set 2: worsening in ● pain ≥20% and absolute change ≥ 20 or ● function ≥10% and absolute change ≥5 or ● PGA ≥10% and absolute change ≥5 or				
	with NRSpain	55	65	65	70
	With WOMACpain	58	62	63	65
Set 3	Set 3: worsening in ● pain ≥10 % and absolute change ≥ 10 or ● function ≥10 % and absolute change ≥ 10 or ● PGA ≥10 % and absolute change ≥ 10				
	with NRSpain	65	60	64	69

The Effects of Treatment on Disease Symptoms and Progression of Structural Changes in Knee Osteoarthritis Participants from the Osteoarthritis Initiative Progression Cohort. Jean-Pierre Pelletier[1], Camille Roubille[1], François Abram[2], Marc Dorais[3], Philippe Delorme[1], Jean-Pierre Raynauld[1] and Johanne Martel-Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Medical Imaging Research & Development, ArthroLab Inc., Montreal, QC, [3]StatSciences Inc., Notre-Dame de l'Île-Perrot, QC.

Background/Purpose: In the perspective of personalized management of osteoarthritis (OA), a clinically relevant concern is the impact of meniscal extrusion on response to treatment. This study evaluated the role of meniscal extrusion on the effects of conventional OA pharmacological treatments and of the combination of glucosamine and chondroitin sulfate (Glu/CS) on knee structural changes.

Methods: Participants (n=600) from the OAI progression cohort were stratified based on whether or not they received conventional OA pharmacological treatment (analgesics/NSAIDs), the presence/absence of medial meniscal extrusion at baseline, and whether or not they received Glu/CS for 24 consecutive months (T24). The main outcomes were knee structural changes including cartilage volume measured by quantitative MRI and loss of joint space width (JSW).

Results: In both - and + analgesics/NSAIDs groups (n=300 each), participants with meniscal extrusion had more severe disease at baseline, more JSW loss ($p \leq 0.0001$) and cartilage volume loss in the medial compartment ($p=0.003$) compared to those without meniscal extrusion. In both analgesics/NSAIDs groups, no significant effect on JSW loss was found at T24 between groups regardless of the presence or absence of meniscal extrusion and of the consumption or not of Glu/CS, whereas significant differences emerged for cartilage volume loss. In the –analgesics/NSAIDs group, at T24, while no difference was found within the participants without meniscal extrusion (mild disease), in participants with meniscal extrusion (more progressive disease), Glu/CS had a protective effect on cartilage volume loss in the medial plateau ($p=0.01$, univariate analysis; $p=0.009$, multivariate analysis). In the +analgesics/NSAIDs group, in participants without meniscal extrusion (moderate disease), Glu/CS protected the cartilage volume in the lateral plateau($p=0.007$, univariate analysis; $p=0.013$, multivariate analysis). No effect was found in participants from the +analgesics/NSAIDs group with meniscal extrusion (severe disease).

Conclusion: This study is the first to demonstrate, using qMRI, the response to conventional and Glu/CS treatments in subjects with meniscal extrusion. Data first revealed that Glu/CS prevented cartilage volume loss in patients with mild to moderate disease, i.e., subjects with meniscal extrusion not taking analgesics/NSAIDs and those without meniscal extrusion but taking analgesics/NSAIDs. The non-effect on patients without meniscal extrusion not taking analgesics/NSAIDs, representing very mild disease, probably reflects that the cartilage volume loss was small and unlikely to provide an accurate estimate. Moreover, in subjects with meniscal extrusion who took analgesics/NSAIDs (severe disease), the non-effect observed likely reflects irreversible cartilage damage. The present data argue for MRI based diagnosis of meniscal extrusion in clinical practice to help physicians identify knee OA patients more susceptible to benefit from DMOAD treatment. These data also support the added benefit of using

qMRI as an alternative to X-ray for the evaluation of DMOAD agents, especially in patients with less advanced disease.

Kneeling Disability Associated with the Treatment of Osteoarthritis: Analysis of a Copcord Study in Mexico. Alexia Hernández-Cáceres[1], Jacqueline Rodríguez-Amado[1], Ingris Peláez-Ballestas[2], David Vega-Morales[3], Mario Garza-Elizondo[1], Roberto Negrete-López[1], Lorena Pérez-Barbosa[1] and Janett Riega-Torres[1]. [1]Servicio de Reumatología, Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico, [2]Departamento de Reumatología Hospital General de México "Dr. Eduardo Liceaga", Distrito Federal, Mexico, [3]Hospital Universitario UANL, Monterrey, Mexico.

Background/Purpose: Osteoarthritis (OA) is the most prevalent rheumatic disease in Mexico. The core treatment, a combination of pharmacological and non-pharmacological modalities, is mainly performed in primary care.

Objective: To describe which are the most employed therapeutic resources for osteoarthritis and their associated factors in the urban and rural population of Nuevo León.

Methods: Analysis of a cross-sectional study of patients with OA from a COPCORD study database that included the adult population ≥ 18 years of a representative sample of the State of Nuevo León who met the diagnosis of clinical OA and had information about the anatomical location of the disease. All variables in the COPCORD questionnaire were included and performed a descriptive analysis. For the univariate analysis, the population was divided between those who did and those who didn't receive treatment. For the multivariate analysis, a regression logistic analysis of all the variables with statistical significance was performed.

Results: There were 696 patients with OA with an average age of 58yr (SD 14.1), 484 (69.5%) women and 579 (83.2%) patients were living in urban areas. Five hundred and two patients (85.1%) had pain in the last 7 days, with a mean VAS pain of 6 (IQR 3); 507 (72.8%) patients had a VAS pain ≥4. Functional disability was present in 133 (19%) patients and a mean HAQ of 0.37 (IQR 0.75) was found. The most common places of OA where knee (356, 51.5%), hand (224, 37%) and generalized OA (93, 13%); 259 (37%) patients already knew their diagnosis by the time of the examination. Four hundred and ninety four (71%) patients reported having treatment for OA, being the most frequently prescribed NSAIDS (289, 58.5%), mostly diclofenac (198, 68.5%). Analgesics were used by 100 (20.2%) patients, mostly acetaminophen (73, 77%). There was more utilization of NSAIDS by physicians (231/289, 79.9%) and of analgesics by self-prescribers (35/100, 35%). In the univariate analysis, the variables associated with treatment where age >58yr (OR 1.3, 95% CI 1.0–1.5), female gender (OR 1.17, 95% CI 1.0–1.3), VAS pain ≥ 4 (OR 1.3, 95% CI 1.1–1.4), functional disability (OR 2.6, 95% CI 1.6–4.1), HAQ > 0.375 (OR 1.9, 95% CI 1.5–2.4), and past diagnosis of OA (OR 5.1, 95% CI 3.3–8.0). In a multivariate analysis, VAS pain ≥ 4 (OR 1.9, 95% CI 1.2–2.8), kneeling disability (OR 3.15, 95% CI 1.3–7.4) and previous diagnosis of OA (OR 7.6, 95% CI 4.5–12.9) had statistical significance.

Conclusion: Associated factors with treatment of OA are VAS pain ≥ 4, kneeling disability and previous diagnosis of OA.

Autoimmune Thyroid Disease Is Associated with a Higher Frequency of Spinal Degenerative Disc Disease. Asha Shrestha, Hillel Cohen and Clement Tagoe. Albert Einstein College of Medicine, Bronx, NY, Bronx, NY.

Background/Purpose: Autoimmune thyroid disease (AITD) has been linked to a number of rheumatic syndromes including arthritis and generalized pain. Although AITD has been associated with back pain, the relationship with spinal degenerative disc disease (DDD) in particular is unknown. We therefore investigated the association between AITD and spinal DDD.

Methods: We identified adult patients with anti-thyroglobulin (anti-TG) and anti-thyroid peroxidase (anti-TPO) antibodies tested from January 1997 through January 2014 in the Clinical Looking Glass database at the Montefiore Medical Center. We performed a cross-sectional analysis of patients with and without AITD. Main variable of interest was AITD, defined as abnormal levels of anti-TPO and/or anti-TG antibodies. Main outcome measure was spinal DDD confirmed by radiological evidence of disc disease. Adjusted odds ratios were estimated with multivariate logistic regression model. The model was adjusted for covariates including age, gender, race, ethnicity, smoking, diabetes (DM), and body mass index (BMI). We did sub-analysis by stratifying patients according to BMI, thyroid stimulating hormone (TSH) levels, and by excluding patients with known connective tissue diseases.

Results: Out of 7094 patients with anti-TG and anti-TPO levels, we included 4383 patients with complete data on thyroid autoantibodies, spinal DDD, and the covariates. Of those, 1557 (35.5%) patients had AITD. Compared to patients without AITD, patients with AITD were more likely to be women (86% vs 81%, $p < 0.001$); more likely to be hypothyroid (24% vs 8%, $p<0.001$); more likely to be on levothyroxine (31% vs 9%, $p<0.001$); less likely to be euthyroid (50% vs 73%, $p<0.001$); less likely to have DM (21% vs 27%, $p=0.02$); and less likely to be black (25% vs 37%, $p<0.001$). BMI in the 2 groups were comparable. There were no significant differences for age, smoking, and known connective tissue diseases between the 2 groups.

The unadjusted odds ratio (OR) with 95% confidence interval (CI) for AITD of having spinal DDD was 1.5 (1.3,1.7), $p<0.001$. After adjustment for the covariates, the association of AITD with spinal DDD was stronger with an OR of 1.8 (1.5 2.1), $p<0.001$, table 1. When stratifying by BMI and TSH levels, the results were similar within the strata. Further sub-analysis by excluding patients with known connective tissue diseases showed a similar positive association.

Conclusion: AITD is significantly associated with a higher frequency of spinal DDD, both in patients with and without known connective tissue diseases, independent of BMI and TSH levels. This finding is novel and suggests a possible important link between thyroid autoimmunity and spinal DDD. Further studies are needed to determine if AITD has a causal link with spinal DDD.

Table 1: Adjusted odds ratio for AITD and spinal DDD

	Outcome = Spinal degenerative disc disease	
Variables	**Adjusted OR (95%CI)**	**P-value**
AITD	**1.75 (1.49, 2.05)**	**<0.001**

Effect of Teriparatide in Patients with Osteoporosis with Prior Vertebral Fracture. Guillermo Valenzuela[1], Douglas Yim[2], Douglas Beall[3], Michael Gordon[4], John H. Krege[5] and Kelly D. Krohn[5]. [1]Integral Rheumatology and Immunology Specialists, Plantation, FL, [2]Division of Vascular & Interventional Radiology, University of California, Irvine Medical Center, Orange, California, Orange, CA, [3]Clinical Radiology of Oklahoma, Edmond, Oklahoma, Edmonda, OK, [4]Newport Orthopedic Institute, Newport Beach, California, Newport Beach, CA, [5]Eli Lilly and Company, LLC, Indianapolis, Indiana, Indianapolis, IN.

Background/Purpose: The Direct Assessment of Nonvertebral Fracture in Community Experience (DANCE) study was an open-label, prospective, observational study that examined occurrence of nonvertebral fragility fractures in osteoporotic men and women

treated with teriparatide for ≤2 yr. and followed for up to 2 more yr. in a community based setting. In DANCE, teriparatide decreased the incidence of nonvertebral fragility fractures in patients treated for >6 mo. (6–24 mo.) vs. ≤6 mo. of therapy (2.12% vs. 3.70%, p=0.002). This retrospective analysis assessed the effects of teriparatide in patients who entered DANCE with prior vertebral fractures, including those with previous vertebral augmentation, vs. those without.

Methods: We compared baseline demographics, safety, and teriparatide effectiveness in patients with or without prior vertebral fractures. Patients with previous vertebral fractures included those that did or did not have vertebral augmentation before study enrollment. Incident rates of nonvertebral fracture following 6–24 vs. 0–6 mo. of teriparatide therapy were compared using a Poisson regression model.

Results: Of 4085 patients who received ≥1 dose of teriparatide 20 μg/day, 715 had documented prior vertebral fractures of which 202 had previous vertebral augmentation. Patients with prior vertebral fractures vs. those without were older (mean [SD] age, 71.85 [10.66] vs. 67.07 [11.92] yr., respectively), more likely to have had prior fragility fractures (95.2% vs. 47.8%), had higher L1-L4 T-scores (−2.35 [1.47] vs. −2.50 [1.35]), had more baseline clinical conditions (2.21 [1.58] vs. 1.72 [1.37]), and a higher proportion had comorbid conditions (88.4% vs. 81.6%) (all p-values <0.04). Mean teriparatide exposure was similar for both groups (541.8 [283.1] vs. 542.3 [292.2] days). Bone density in the spine, total hip, and femoral neck increased similarly in patients with or without prior vertebral fracture (all p-values ≥0.06), with similar results in patients who did or did not have vertebral augmentation (all p-values ≥0.08). Compared with the first 6 mo., the incidence of nonvertebral fractures during months 6–24 was 52% lower (absolute difference 3.76%) in patients with and 37% lower (absolute difference 1.08%) in those without prior vertebral fractures. The reduced incidence of nonvertebral fracture over time was statistically consistent in both groups (effect of time by subgroup interaction p=0.38). Reduction in nonvertebral fracture during months 6–24 vs. the first 6 mo. of treatment was 62% lower (absolute difference 4.33%) for patients with prior vertebral augmentation and 41% (absolute difference 1.44%) for those without. Teriparatide was well tolerated.

Conclusion: Patients with prior vertebral fractures were older and had more fragility fractures and comorbid conditions at baseline than patients without previous vertebral fracture. In this post-hoc analysis, teriparatide improved bone density and reduced the incidence of nonvertebral fractures with >6 mo. vs. ≤6 mo. of therapy in osteoporosis patients with and without prior vertebral fracture, including those with prior vertebral augmentation.

Changes in Subject Characteristics in the Denosumab Pivotal Fracture Trial and Its Extension for up to 8 Years. JD Adachi[1], CJF Lin[2], PR Ho[2], MA Bolognese[3], HG Bone[4], P Hadji[5], S Papapoulos[6], C Recknor[7], NS Daizadeh[2], P Dakin[2], RB Wagman[2] and S Ferrari[8]. [1]McMaster University, Hamilton, ON, [2]Amgen Inc., Thousand Oaks, CA, [3]Bethesda Health Research Center, Bethesda, MD, [4]Michigan Bone and Mineral Clinic, Detroit, MI, [5]Philipps-University of Marburg, Marburg, Germany, [6]Leiden University Medical Center, Leiden, Netherlands, [7]United Osteoporosis Centers, Gainesville, GA, [8]Geneva University Hospital, Geneva, Switzerland.

Background/Purpose: Changes in demographics of study population enrolled in long-term osteoporosis clinical trials may affect interpretation of efficacy/safety outcomes. Denosumab is being evaluated for up to 10 years in the 3-year FREEDOM trial and 7-year Extension. Denosumab for up to 8 years is associated with low fracture incidence, continued BMD increases, and adverse event profile similar to what has previously been reported (Papapoulos et al., *JBMR.* 2013;28:S1). We compared the FREEDOM and Extension populations at baseline and in the Extension to assess potential selection bias that might influence long-term treatment outcomes.

Methods: In FREEDOM, women were randomized to placebo or denosumab 60 mg every 6 months. All FREEDOM subjects who had not missed >1 dose of investigational product, completed the 3-year visit, and consented to enroll were eligible to receive open-label denosumab in the Extension. We assessed whether older age and incident fractures contributed to attrition at Year 5 of the Extension, representing 8 years of follow-up.

Results: In FREEDOM, 6478/7808 (83%) subjects completed the trial. Of 5928 subjects eligible for the Extension, 4550 (77%) enrolled. Through Year 5 of the Extension, 3004 (66%) remained on study. While baseline characteristics were similar in FREEDOM and Extension, all subjects were 3 years older at Extension baseline, prevalent vertebral fracture rate in placebo-treated subjects was higher at Extension baseline compared with FREEDOM baseline (25% vs 22%), and denosumab-treated subjects had higher mean BMD at Extension baseline. Age distribution after 5 years of Extension remained consistent with the antecedent 3 years in FREEDOM, with no preponderance of younger subjects (Figure). As expected, older subjects were more likely to discontinue, however, 62% of subjects who were ≥75 years at Extension baseline remained on study through Year 5. While subjects who fractured were more likely to discontinue in FREEDOM and in the Extension, 88% and 83% of placebo and denosumab fractured subjects, respectively, completed the 3-year FREEDOM trial, and 72% of fractured subjects in the Extension remained enrolled through Year 5.

Conclusion: In this large-scale, long-term study of denosumab, Extension population maintained similar characteristics to the original FREEDOM cohort. During Extension, a high percentage of subjects at increased risk for fractures due to older age and incident fracture remain on study. This suggests that the low fracture incidence and consistent safety profile reflect the long-term denosumab treatment effect.

Figure. Age Distribution at FREEDOM Baseline (A) and Year 5 of FREEDOM Extension (B)

Vertebral Cortical Bone Mass and Structure Significantly Improved with Romosozumab Compared with Teriparatide: HR-QCT Analyses of Postmenopausal Women with Low BMD from a Phase 2 Study. T Damm[1], C Libanati[2], J Peña[1], G Campbell[1], R Barkmann[1], DA Hanley[3], S Goemaere[4], MA Bolognese[5], C Recknor[6], C Mautalen[7], YC Yang[2] and CC Glüer[1]. [1]Christian-Albrechts-Universität zu Kiel, Kiel, Germany, [2]Amgen Inc., Thousand Oaks, CA, [3]University of Calgary, Calgary, AB, [4]Ghent University Hospital, Ghent, Belgium, [5]Bethesda Health Research Center, Bethesda, MD, [6]United Osteoporosis Centers, Gainesville, GA, [7]Centro de Osteopatias Medicas, Buenos Aires, Argentina.

Background/Purpose: Understanding the effect of therapies in the vertebral compartments is relevant to bone biology and clinical practice. We developed an improved technique using cortical shell segmentation-based layering of high resolution quantitative computed tomography (HR-QCT) scans of T12 vertebral bodies to evaluate compartment-specific changes in BMD and microstructure.

Methods: In an international, randomized, phase 2 study (McClung et al., *N Engl J Med.* 2014), postmenopausal women with low BMD supplemented with calcium and vitamin D received subcutaneous (SC) romosozumab (210 mg monthly), teriparatide (20 mcg SC daily), or placebo (PBO). A subset of these women underwent HR-QCT scanning of T12 (N=11 romosozumab, 12 teriparatide, 8 PBO) at baseline and month 12. For cortical HR-QCT analysis (blinded to treatment assignment), adjacent 200 micron thin films of the cortical shell were evaluated to determine changes from the outer soft tissue bordering the vertebrae to the medullary spongiosa (Figure). In addition to the standard cancellous compartment variables previously described (Graeff et al., *J Bone Miner Res.* 2007), this improved method allows accurate determination of cortical variables in the subregions, including apparent and corrected (deconvolved) cortical thickness, bone mineral content (BMC), and BMD. Changes in cortical thickness are modeled assuming an average 50% mineralization of newly added matrix.

Results: At baseline, mean (SD) apparent cortical thickness of 1.37 (0.13) mm was corrected to a cortical thickness of 0.29 (0.05) mm. At month 12, romosozumab significantly improved cortical BMC and BMD from baseline and in comparison to teriparatide or PBO (all $P \leq 0.0003$; Table). These gains were attained by both endosteal and periosteal bone matrix apposition. Improvements in cancellous BMD were similar between romosozumab and teriparatide.

Conclusion: Using HR-QCT scans of the spine, it is possible to evaluate changes across the cortical shell of the vertebral bodies and determine alterations in the endosteal and periosteal regions. The anatomical location and magnitude of these changes could impact changes in bone strength and thus affect fracture risk. Romosozumab administration was associated with significant increases in cortical thickness and improvement in all measured cortical parameters at 12 months compared with teriparatide or PBO. The clinical effect of romosozumab to reduce fractures is being evaluated in an ongoing phase 3 clinical program.

Figure. 3D Visualization of Vertebral Cortex (left) and Schematic Drawing of Bone Apposition (right)

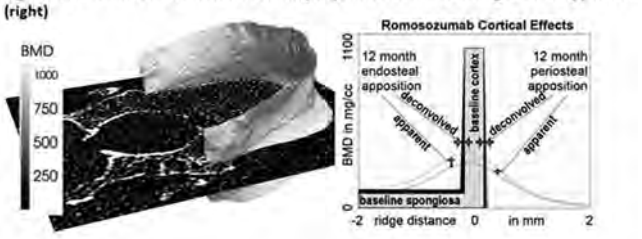

Table. Changes From Baseline in Cortical Thickness, BMC, and BMD at Month 12

Region	Romosozumab N = 11	Teriparatide N = 12	Placebo N = 8
Deconvolved cortical thickness (microns)	157 (12)*†	61 (12)‡	10 (14)
Cortical BMC (% of baseline)	22 (2)*†	11 (2)‡	−1 (2)
Apparent cortical BMD (mg/cm³)			
Periosteal apposition at 0.2 to 0. 6 mm from ridge	37 (4)*†	16 (4)‡	0 (5)
Endosteal apposition at −0.2 to −0.6 mm from ridge	59 (6)*†	19 (6)	0 (7)
Subcortical apparent BMD (mg/cm³)	28 (3)†	22 (3)‡	1 (4)
Spongiosa apparent BMD (mg/cm³)	20 (3)†	19 (3)†	−4 (3)

Values are mean (SD).
*P value ≤ 0.0003 compared with teriparatide.
†P value < 0.0001 compared with placebo.
‡P value < 0.05 compared with placebo.

Effects of Pre-Dosage Alendronate Treatment on Bone Metabolic Indices and Bone Mineral Density in Patients Treated with Glucocorticoids: A Prospective Study. Yasuo Kuroki[1], Hiroshi Kaji[2], Mika Yamauchi[3] and Toshitsugu Sugimoto[4]. [1]Kobe Century Memorial Hospital, Kobe, Japan, [2]Kinki University Faculty of Medicine, Osakasayama, Japan, [3]Shimane University Faculty of Medicine, Izmo, Japan, [4]Shimane University Faculty of Medicine, Izumo, Japan.

Background/Purpose: Glucocorticoids (GCs) treatment induces secondary osteoporosis characterized by rapid bone loss and an increase in fracture risk, although GCs are used to treat a wide variety of rheumatic and autoimmune diseases. We have ever investigated the effects of GC therapy on bone metabolic indices and bone mineral density (BMD) in a prospective study. Our previous study indicated that the biochemical markers of bone metabolisim are affected from the early term of GC therapy (day3), and that the simultaneous treatment of alendronate (ALN) with GC therapy (co-dosage group) suppresses the changes of bone turnover markers at the early stage of GC therapy. Moreover, ALN was effective to suppress a reduction in BMD induced by GC. However, the simultaneous treatment of ALN was not effective to suppress an increase in bone resorption markers on day 7 of GC therapy and a reduction in BMD on 1 month. In the present study, we investigated the effects of pre-dosage ALN treatment before GC therapy on rapid bone loss in GC-treated patients prospectively.

Methods: Twenty-one patients (62.0±9.9 y.o.) treated with prednisolone (PSL) at the dose of over 20 mg received weekly 35mg ALN one day or several days before the initiation of GC therapy (pre-dosage group), and serum Ca, intact parathyroid hormone (PTH), osteocalcin (OC), bone-type alkaline phosphatase (BAP) and urinary levels of type I collagen cross-linked N-telopeptide (NTx) were measured on 7 days, 1, 3 and 6 months after the initiation of GC therapy. BMD values were measured by dual-energy X-ray absorptiometory at the lumbar spine (L2–4) and femoral neck on 1,3,6 and12 months. The subjects were divided into the following two groups; 10 patients receiving PSL at doses[3]a40mg/day (H) and 11 patients receiving PSL at doses [3]a20mg/day (M).

Results: The pre-dosage ALN treatment caused decreases in serum Ca levels and urinary Ca excretion as well as a significant increase in serum PTH levels ($p<0.05$) on day 7 of GC treatment, which were not observed in the co-dosage group of our previous study. As for bone-formation indices, serum BAP levels were significantly decreased after 1 month only in the pre-dosage group, although serum OC levels were decreased on day 7 of GC administration in both co-dosage and pre-dosage groups. Although ALN was not effective to suppress an increase in bone resorption markers on day 7 of GC therapy in the co-dosage group, ALN decreased urinary NTx levels in the pre-dosage group. Moreover, BMD at lumbar spine were not decreased at 1 month and significantly increased 6 months after the initiation of GC therapy in the pre-dosage group, although ALN was not effective to suppress a reduction in BMD at 1 month in the co-dosage group. No significant reduction of BMD at femoral neck was observed in the pre-dose group. These results were similar in the subgroup analysis dividing into H and M groups.

Conclusion: The present study suggests that pre-dosage ALN treatment before GC therapy is more effective for the preservation of GC-induced osteoporosis, which might be attributed by early suppression of GC-stimulated bone resorption.

How Does Non-Compliance to Prolia® (DENOSUMAB) Impact the Change in Bone Mineral Density (BMD) in Osteoporotic Patients? Aashish Kalani[1], Matt Wong-Pack[1], Jacob Hordyk[2], Arthur N. Lau[3], George Ioannidis[4], Robert Bensen[5], William G. Bensen[1] and Jonathan D. Adachi[1]. [1]McMaster University, Hamilton, ON, [2]University of Ottawa, Hamilton, ON, [3]Division of Rheumatology, McMaster University, Hamilton, ON, [4]St Joseph's Healthcare Hamilton, Hamilton, ON, [5]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON.

Background/Purpose: Denosumab (Prolia®) has shown to be a safe and efficacious therapy for osteoporotic patients in many clinical trials. Unfortunately, few studies have explored its effectiveness in clinical practice. Currently, best practice guidelines suggest that denosumab should be administered subcutaneously every six months. However, in clinical practice, patients do not always receive subsequent denosumab as prescribed. This non-compliance may have a significant impact on the effectiveness of the drug. The objective of this study is to assess the impact that noncompliance with the regular dosing regimen has on bone mineral density (measured at the lumbar spine [LS] and femoral neck [FN]) compared to patients who receive their scheduled dosing regimen.

Methods: A retrospective cohort study was conducted from August 2012 to August 2013. We included all osteoporotic patients from a single academic center who received a minimum of two injections of denosumab with a follow-up BMD measurement since May 2010 for analysis. Patients who have only received their first subcutaneous injection and patients without a corresponding BMD score were excluded from the study. Patients were classified into 3 categories and analyzed in these groups: 1) subsequent injection less than five months, 2) between five to seven months, 3) more than seven months after their initial subcutaneous injection. Interval changes in BMD (at the LS and FN) over a 1-year follow-up period was analyzed between these three groups.

Results: Of the 924 charts examined, 436 patients met eligibility criteria. Multi-variable regression analysis was conducted comparing the change in BMD after one year of denosumab therapy at both the LS and FN for the three pre-specified groups. The group receiving an injection 7 months after their initial injection was used as a reference. The change in BMD (95% confidence interval) after one year was −0.00008 (−0.01335 to 0.01168) and 0.02073 (−0.00697 to 0.04843) for patients receiving a subsequent injection between 5–7 months later, at LS and FN respectively. The change in BMD (95% confidence interval) after one year was 0.00515 (−0.00619 to 0.01649) and 0.01474 (−0.01042 to 0.03990) for patients receiving a subsequent injection less than 5 months later, at LS and FN respectively. The relationship between the timing of drug administration and change in BMD over 1 year was not statistically significant ($p>0.05$).

Conclusion: This observational study proposes that the efficacy of denosumab (as measured by BMD measurements at the lumbar spine and femoral neck) has great efficacy in the treatment of osteoporosis especially when patient compliance was maintained. This emphasizes the importance of patient compliance and the need for programs available to patients to help ensure this compliance. However, in the small subset of patients who were unable to receive their subsequent denosumab injection within the 5 to 7 month window, there was no difference in BMD measurements. This suggests that although compliance is essential, a delay in a subsequent injection may be acceptable in extenuating circumstances. A follow-up study with a larger sample size and longer follow-up duration is required to further characterize this relationship.

Changes in serum Soluble RANKL and Osteoprotegerin Levels after Teriparatide Administration in Rheumatic Disease Patients with Glucocorticoid-Induced Osteoporosis. Makoto Kaburaki, Kaichi Kaneko, Kotaro Shikano, Mai Kawazoe, Emiko Shindo, Hiroshi Sato, Natsuki Fujio, Sei Muraoka, Nahoko Tanaka, Tatsuhiro Yamamoto, Natsuko Kusunoki, Tomoko Hasunuma, Shinichi Kawai and Shotaro Masuoka. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Osteoporosis is one of the serious complications of systemic glucocorticoid therapy. Reduced bone formation is the key process in patients with glucocorticoid-induced osteoporosis (GIOP), however, the significance of increased bone resorption in these patients is still under consideration. We reported that serum soluble receptor activator for nuclear factor-κB ligand (sRANKL) level might be a predictive factor in patients under glucocorticoid therapy (J Clin Endocrinol Metab. 97: E1909-917, 2012). Teriparatide, a recombinant form of parathyroid hormone, is an option of treatment for GIOP, especially to the severe cases. Its daily injection stimulates bone formation, resulting increase of bone volume and reduction of bone fracture. Thus, we observed the effect of teriparatide on serum sRANKL and osteoprotegerin (OPG) levels as bone resorption markers in patients with rheumatic disease under glucocorticoid therapy. The aim of this study is to evaluate the effect of teriparatide on serum sRANKL and OPG levels in patients under glucocorticoid therapy.

Methods: Patients were recruited at Toho University Omori Medical Center. This study was approved by the Ethics Committees at Toho University Omori Medical Center (approval number; 24–97). Twenty postmenopausal women (71±6 yr [mean ± SD]) with rheumatic diseases (rheumatoid arthritis 9, vasculitis syndrome 6, polymyalgia rheumatica 3, polymyositis 1, and systemic lupus erythematosus 1) were included in this study. All the patients were changed from oral bisphosphonates to daily s.c. injections of teriparatide (20 μg) for treatment of GIOP. Patients who received mean prednisolone at doses of 6.7±5.4 (SD) mg daily were eligible for this study. We measured serum sRANKL, OPG, bone formation markers (OC, ucOC, BAP, and P1NP), and bone resorption markers (TRACP-5b and NTX) during teriparatide treatment. The bone mineral density (BMD) was measured before and 6 months after start of teriparatide treatment. Data were expressed as the median with the interquartile range.

Results: Serum sRANKL levels were significantly decreased after teriparatide treatment (0.066 [0.0–0.188] to 0.0 [0.0–0.008] pmol/L, $p < 0.05$). In contrast, serum OPG levels were not changed after the treatment (6.71 [5.79–8.13] to 7.17 [5.69–8.92] pmol/L, $p = 0.584$). All of serum bone formation markers (OC; 3.6 [2.9–5.8] to 10.0 [8.2–18.0] ng/mL, ucOC; 1.4 [0.9–4.6] to 5.2 [3.4–9.1] ng/mL, BAP; 10.9[8.8–16.0] to 15.5 [11.6–22.3] U/L, and P1NP; 26.8 [12.5–43.2] to 88.8 [48.1–196.0] ng/L) and resorption markers (TRACP-5b; 227 [171–506] to 353 [269–506] mU/L and NTX; 12.7 [10.7–22.4] to 21.9 [16.9–26.6] nmolBCE/L) were significantly ($p < 0.05$) increased after teriparatide treatment. Mean BMD was significantly increased when compared to that of pretreatment value (0.65 [0.59–0.71] to 0.72 [0.65–0.84], $p < 0.05$).

Conclusion: It is suggested that the improvement of bone density by teriparatide might be explained not only by activation of bone formation but also by decreased bone resorption due to reduction of sRANKL in patients under glucocorticoid therapy.

Effects of Daily Teriparatide on the Spine and Femoral Strength Assessed By Finite Element Analysis of Clinical Computed Tomography in Rheumatoid Arthritis Patients. Kumiko Ono[1], Satoru Ohashi[2], Hiroyuki Oka[3], Yuho Kadono[1], Tetsuro Yasui[1], Yasunori Omata[1], Naoko Shoda[1] and Sakae Tanaka[1]. [1]The University of Tokyo Hospital, Tokyo, Japan, [2]Sagamihara Hospital,National Hospital Organization, Kanagawa, Japan, [3]22nd Century Medical & Research Center, faculty of medicine, the university of Tokyo, Tokyo, Japan.

Background/Purpose: Rheumatoid arthritis (RA) decreases bone mineral density and bone quality, and exposes patients to an increased risk of fracture. In RA treatment, improvement of systemic osteoporosis using anti-osteoporotic agents is important, as is suppression of fracture risk by controlling inflammation with a combination of disease-modifying anti-rheumatic drugs or biological agents. However, few studies have examined the effects of anti-osteoporosis drugs on patients with RA. Therefore, this study quantitatively evaluated the effects of daily teriparatide (TPTD) in RA patients at high risk of fracture after 6 months using several methods.

Methods: A total of 30 RA patients were enrolled in this prospective study. All patients receiving TPTD were evaluated according to changes in two bone turnover markers from baseline to 1, 3, and 6 months. The markers used were serum procollagen type 1 N-terminal propeptide (P1NP) and

tartrate-resistant acid phosphatase-5b (TRACP-5b). Assessments were also made according to bone mineral density (BMD) by dual x-ray absorptiometry (DXA) and bone strength by quantitative computed tomography (CT) at baseline. Reevaluation was performed after 6 months. Nonlinear finite element analysis (FEA) was performed on CT to estimate spinal and femoral predicted bone strength (PBS). We adopted two loading conditions, stance and fall configurations, on femoral PBS.

Results: Patients were 67.7±8.2 years old and the duration of symptoms was 12.2±10.7 years. The majority of subjects showed moderate disease activity (mean baseline 28-joint Disease Activity Score, 3.0±1.3). Mean values at baseline and at 1, 3, and 6 months were 42 μg/L, 141 μg/L, 144 μg/L and 153 μg/L for PINP, and 423 mU/dL, 527 mU/dL, 583 mU/dL and 601 mU/dL for TRACP-5b. Patients had significantly greater levels of serum PINP and TRACP-5b ($p<0.05$ compared with baseline) at all points measured. Mean values at baseline and at 6 months were 0.89 g/cm^2 and 0.94 g/cm^2 ($p<0.01$) for BMD-spine (median change 6.1%), 0.62 g/cm^2 and 0.63 g/cm^2 ($p=0.31$) for BMD-femoral neck (median change, 1.1%), 3584 N and 3971 N ($p<0.01$) for PBS-spine (mean change 12.1%), 4146 N and 4194 N ($p=0.3$) for femoral PBS-stance (mean change 1.9%) and 1485 N and 1504 N ($p=0.2$) for femoral PBS-fall (mean change, 1.9%) (Fig. 1).

Conclusion: Our results show that TPTD can increase BMD and FEA on RA patients, and bone loss in patients with RA can be prevented by TPTD. FEA appears to detect the effects of TPTD more sensitively than DXA. We will have to follow these effects in the longer term.

A Meta-Anlaysis of Bisphosphonate and Parathyroid Hormone (PTH) Use in Osteoporosis. Zsolt Kulcsar[1], Lena Saleh[2], Shravani Gangidi[3] and Poonam Khadka[1]. [1]Dartmouth Hitchcock Medical Center, lebanon, NH, [2]The Dartmouth Institute For Healthcare Policy and Clinical Practice, Lebanon, NH, [3]The Dartmouth Institute For Healthcare Policy and Clinical Practice, lebanon, NH.

Background/Purpose: Bisphosphonates are currently the drug of choice for treatment of osteoporosis. While anabolic agents like parathyroid hormone (PTH) have shown greater improvements in bone mineral density (BMD) in severe osteoporosis, their use is limited to a maximum of 2 years due to risk of osteosarcoma with rapid loss of gained BMD after cessation of treatment. Given the limits of both agents, we want to assess the effects of PTH and bisphosphonate combination therapy versus monotherapy with either agent on BMD in patients with osteoporosis.

Methods: We searched MEDLINE, the Cochrane Library, and Clinical-Trials.gov from inception to October 2013. We also reviewed reference lists of included studies and searched the abstracts of the last four years of relevant scientific meetings. We included randomized trials comparing combination therapy with bisphosphonate and PTH versus monotherapy with either agent in men and post-menopausal women with osteoporosis followed for at least 3 months. Studies had to report mean change in BMD as measured by dual-energy X-ray absorptiometry (DEXA) at either the total hip or lumbar spine. Data collection and analysis was done by at least two reviewers independently collected data from each study using a standardized form. We used random effects models to calculate pooled weighted mean differences (WMD) and relative risks (RR).

Results: Of 332 studies identified, six met all inclusion criteria. Combination therapy led to small increases in % change in BMD at the total hip compared to PTH alone (WMD 0.38, 95% CI -1.41 to 2.18, $I^2=80\%$, 5 studies) and bisphosphonate alone (WMD 0.15, 95% CI −0.82 to 1.12, $I^2=38\%$, 5 studies). Similarly, combination therapy resulted in larger increases in % change in BMD at the spine compared to bisphosphonate alone (WMD 3.65, 95% CI 1.82 to 5.47, $I^2=67\%$, 5 studies), however PTH alone was superior to combination therapy at the lumbar spine (WMD −0.54, 95% CI −2.15 to 1.07, $I^2=46\%$, 5 studies). Based on 6 studies, there was a significant risk in developing hypercalcemia with combination therapy compared to monotherapy (11.83% vs. 7.04%, RR 1.68, 95% CI 1.18 to 2.41).

Conclusion: Combination therapy with PTH and bisphosphonates leads to greater improvements in BMD only at the lumbar spine compared to bisphosphonate therapy alone, however at the cost of increased risk of hypercalcemia.

Figure 1. Mean percent change in BMD by DXA at [total] hip and lumbar spine.

Raloxifene for Osteoporosis in Postmenopausal Women with Rheumatic Diseases. Won Seok Lee[1], Yun Jung Choi[2], Yun-Hong Cheon[1], Myong-Joo Hong[3], Chang-Hoon Lee[4], Myeung Su Lee[4], Sang-Il Lee[5] and Wan-Hee Yoo[1]. [1]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, JeonJu, South Korea, [3]Department of internal Medicine, Presbyterian Medical center, Jeonju, South Korea, [4]Department of Internal Medicine, School of Medicine, Wonkwang University, Iksan, Chonbuk, South Korea, [5]Gyeongsang National University School of Medicine, Jinju, South Korea.

Background/Purpose: Raloxifen is a selective estrogen receptor modulator that has been extensively studied. We studied the efficacy of raloxifene on disease activity and bone mineral density (BMD) in postmenopausal women with rheumatic diseases receiving long-term glucocorticoids (GC).

Methods: Postmenopausal women with rheumatic diseases and osteoporosis were included. Patients with a history of thromboembolism or antiphospholipid antibody positivity were excluded. They were managed with raloxifene (60 mg/day) plus elemental calcium (1,200 mg/day). BMD of the hip and spine (primary outcome) was measured initially and at month 12, and disease activity (secondary outcome) was serially assessed using DAS28 and SELENA-SLEDAI.

Results: Between January 2010 and December 2013, 130 patients (86 assigned to receive GC and 44 patients not receiving GC, mean ± SD age 60.1 ± 9.0 vs. 59.3 ± 7.0 years) were recruited. 81 rheumatoid arthritis, 15 Sjogren's syndrome, 11 scleroderma, 11 Behcet's disease, 7 lupus and 5 other rheumatic diseases were included. Demographic data, osteoporotic risk factors and BMD at various sites were similar between the two groups of patients. The duration and dose of prednisolone received was 72.5 ± 24 months and 3.3 ± 1.6 mg/day. At month 12, a significant gain in the lumbar spine (+0.9 ± 0.7%; p = 0.04 vs. +0.4 ± 0.1%; p=0.05) and total hip BMD (+1.1 ± 0.5%; p = 0.03vs. 1.5 ± 0.7%; p = 0.04) was observed in patients receiving GC or not. However, femoral neck BMD was decreased in both groups. No patient had a major flare of lupus and rheumatoid arthritis. No fracture and thromboembolic events were reported.

Conclusion: Raloxifene was well tolerated in postmenopausal female patients with rheumatic diseases who had inactive disease and in whom hypercoagulability was not identified. Raloxifene increased total hip and lumbar spinal BMD in patients receiving corticosteroids or not.

2263

Continued Zoledronic Acid Use in a Large Healthcare System. Robert A. Overman[1], Julie C. Lauffenburger[1], Margaret L. Gourlay[1] and Chad L. Deal[2]. [1]University of North Carolina, Chapel Hill, NC, [2]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Oral bisphosphonates adherence has been reported as less than 50% at one year. With patients frequently having refill gaps greater than 30 days. Zoledronic acid (ZA) is a once yearly injectable bisphosphonate anti-osteoporosis medication (AOM) with 100% adherence for 12 months. We evaluated what proportion of patients who continued ZA after the first infusion and for those receiving a second dose how close to 365 days that dose was administered.

Methods: We identified new ZA users using billing data between January 1, 2010 and December 2012 from a large healthcare system based on healthcare procedure codes J3488 and Q2051 and linked to electronic medical record data. Included patients had at least two rheumatology office visits and first receipt of ZA was in or after 2010. We excluded patients who had received ZA before the study period but not other AOM. **Results:** are presented as mean (standard deviation [SD]) or %.

Results: There were 771 patients who met inclusion criteria. A second ZA infusion was given to 489 patients (63.4%) and 6.5% not continuing ZA were prescribed another AOM. Women (89.5%) and Caucasian (89.0%) race were the majority of the cohort with a mean age of 68.1 (10.9). The mean number of AOMs used prior to ZA was 1.7 (1.3) with 18.7% not having an AOM prescribed within the health system. Previous fractures were present in 20.4%, mean Charlson Comorbidity score of 1.9 (2.5), and 29.7% had GERD or gastric ulcers at first ZA administration. Persistence of ZA is presented in Table 1. Of the 489 patients who received a second ZA infusion 307 (63%) were within 365 ±30 days (a care gap of >30 days is defined as lack of persistence with oral agents). By 180 days 445/489 (91%) and 365 days 486 (99%) had received a second ZA infusion.

Conclusion: Although ZA adherence is by definition superior to oral BPs at one year, 36.6% of patients in our cohort did not receive a second infusion. Of those receiving a second infusion only 63% do so within the first 30 days although 99% had a second infusion at 365 days. Considering recent data suggesting that a single dose of ZA may reduce fracture for longer than one year, a gap of >30 days may be too strict a criterion for lack of persistence. ZA is approved for use at 24 month intervals for prevention. Since 36% of patient did not receive a second ZA dose, reasons for discontinuation and delay in a second infusion should be further investigated. Additionally, physician offices should have a method for scheduling yearly ZA infusions as a quality metric.

Table 1 Zoledronic Acid Treatment Gaps

Treatment Gap	% Treated
±30 days	62.8%
+60 days	77.7%
+90 days	85.7%
+120 days	87.5%
+150 days	90.0%
+180 days	91.0%
+365 days	99.4%

ZA: Zoledronic Acid; 2nd ZA administration was assessed at 365 days after first administration

2264

Denosumab for Long-Term Glucocorticoid Users Who Have Inadequate Response to the Bisphosphonates: A 12-Month Randomized Control Trial. Chi Chiu Mok, Ling Yin Ho and Kwok Man Ma. Tuen Mun Hospital, Hong Kong, Hong Kong.

Background/Purpose: To evaluate the efficacy of denosumab on bone mineral density (BMD) in long-term glucocorticoid users who have inadequate response to oral bisphosphonate treatment.

Methods: Patients who were receiving long-term prednisolone treatment for their underlying medical illnesses were recruited. The inclusion criteria were: (1) adult patients >=18 years of age; (2) Daily dose of prednisolone >2.5mg within 3 months of study entry; (3) Inadequate BMD response (<2% increase in BMD or remaining osteoporotic) or the development of new fracture despite oral bisphosphonates for >=2 years. Participants were randomized to receive either: (1) Denosumab (60mg subcutaneously every 6 months) + discontinuation of bisphosphonates; or (2) Continuation of oral bisphosphonates (control group). Calcium (3g/day of caltrate), vitamin D (rocaltrol 0.25ug/day) and other medications were continued. Baseline and follow-up BMD (femoral neck, femoral trochanter, total hip, lumbar spine and whole body) at 6 and 12 months were performed. Markers of bone turnover (serum osteocalcin, P1NP and CTX) were also assayed at the same time points. The primary outcome was the difference of lumbar spine BMD at month 12 between the two groups.

Results: 42 women were recruited (age 54.7±12.9 years)- 21 shifted to denosumab and 21 continued on bisphosphonates. Underlying medical diseases were: SLE (76%) and RA (24%). The duration of prednisolone therapy was 101±66.3 months and the daily dose was 4.4±2.1mg. 30 (71%) patients were postmenopausal and the mean duration of menopause was 12.3±7.2 years. The mean body mass index (BMI) was 22.3±4.1kg/m^2 (21% patients had BMI^2). The bisphosphonates being used by the patients were alendronate (79%), risedronate (12%) and ibandronate (10%). Pre-existing vertebral fracture was present in 7 (17%) patients and 3 patients (7%) had a family history of fragility fractures. Baseline demographic data, osteoporotic risk factors, and BMD at various sites were not significantly different between the two groups. At month 12, a significant gain in BMD at the lumbar spine (+3.4±0.9%; p=0.002) and the hip (+1.4±0.6%; p=0.03) was observed in denosumab-treated patients, whereas the corresponding change was +1.5±0.4% (p=0.001) and +0.80±0.5% (p=0.12) in the bisphosphonate group. The spinal BMD at month 12 was significantly higher in the denosumab than bisphosphonate group after adjustment for baseline BMD values, age and other parameters (p=0.03). No new fractures occurred in any participants at month 12. Minor upper respiratory tract infection was more commonly reported with denosumab treatment (33% vs 5%; p=0.045) while other adverse events occurred at similar frequency between the two groups. One patient of each group was withdrawn from the study because of non-compliance. None of the patients withdrew from study because of adverse events.

Conclusion: In patients receiving long-term glucocorticoids but not having adequate response to bisphosphonates, shifting to denosumab was more effective in raising the BMD at the spine after 12 months' therapy. Denosumab was well tolerated.

Comparative Effects of Raloxifene and Bisphosphonate on Bone Mineral Density and Osteoporotic Fracture Outcomes in Rheumatoid Arthritis Patients. Kowoon Joo, Won Park, Seong-Ryul Kwon, Mie-Jin Lim and Kyong-Hee Jung. Inha University Hospital, Incheon, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) accelerates bone loss, increasing the risk of osteoporosis and osteoporotic fractures. We evaluated the effect of raloxifene and bisphosphonate on bone mineral density (BMD) and osteoporotic fractures in RA patients.

Methods: We retrospectively examined data of 112 seropositive RA patients who were diagnosed with osteoporosis and started on either raloxifene or bisphosphonate from January 2006 to December 2010 with no prior history of either medication. Patients with baseline BMD and at least one follow up BMD were included. The patients were examined for maximum of 3 years with mean follow up period of 2.1 years. Bisphosphonates consisted of risendronate, alendronate or oral ibandronate. Vertebral fractures were defined using Genant's semiquantitative classification.

Results: Forty-four patients were in the raloxifene group and 68 patients were in the bisphosphonate group. The patients in the raloxifene group were older and lighter in weight compared to the bisphosphonate group (Table 1). The patients in the bisphosphonate group consumed higher doses of calcium and vitamin D through medication compared to the raloxifene group. There was no significant difference in duration of RA, the daily dosage of prednisolone and medication possession ratio between the 2 groups. Thirty-six patients in the raloxifene group and 67 patients in the bisphosphonate group had follow up BMD at 1 year of treatment (Table 2). Nineteen patients in the raloxifene group and 40 patients in the bisphosphonate group had follow up BMD at 2 years of treatment. There was no significant difference in the yearly change of lumbar, total hip and femoral neck BMD from baseline and the number of vertebral fractures between the 2 groups at 1 year and at 2 years of treatment. Eighteen patients in the raloxifene group and 29 patients in the bisphosphonate group had follow up BMD at 3 years of

treatment. There was no significant difference in the mean change of lumbar and femoral neck BMD from baseline and the number of vertebral and non-vertebral fractures between the 2 groups at 3 years of treatment. However the mean change of total hip BMD was higher in the bisphosphonate group compared to the raloxifene group.

Conclusion: There was no significant difference in BMD changes and osteoporotic fractures in RA patients treated with raloxifene and bisphosphonate.

Table 1. Baseline characteristics

		Raloxifene (n = 44)	Bisphosphonate (n = 68)	*P* value
Female (%)		45 (100)	46 (68)	< 0.001

Risk Factors for Treatment Failure in Osteoporotic Patients with Rheumatoid Arthritis.

Kyung-Eun Lee, Lihui Wen, Dong-Jin Park and Shin-Seok Lee. Chonnam National University Medical School, Gwangju, South Korea.

Background/Purpose: No available anti-osteoporotic medication has been shown to completely prevent declines in bone mineral density (BMD) and the resulting increased risk of fracture. The objective of this study was to investigate the risk factors associated with treatment failure in osteoporotic patients with rheumatoid arthritis (RA).

Methods: A retrospective cohort study of 103 patients with RA and osteoporosis was conducted. Subjects were selected from patients who visited the Rheumatology Department of Chonnam National University Hospital between January 2002 and December 2012. All participants fulfilled the 1987 American College of Rheumatology revised criteria for RA and the World Health Organization criteria for osteoporosis. Baseline demographics, clinical characteristics, bone mineral density (BMD), laboratory results and treatment-related data were collected from the patients' chart review. Patients were divided into two groups for comparison: those whose osteoporosis treatment was effective and those whose treatment failed. Risk factors for treatment failure were identified by univariate and multivariate logistic regression using variables that differed significantly between the groups.

Results: Osteoporosis treatment failed in 66 of 103 patients (64.1%). During 14.01 months of (SD: 1.89 months) follow-up, non-adherence to bisphosphonate use (OR = 12.997; $p = 0.006$) was the most powerful risk factor for treatment failure. Daily glucocorticoid dosage ≥ 7.5 mg/day before the first BMD measurement (OR = 6.230; $p = 0.015$), immobilization > 3 months (OR = 4.773; $p = 0.006$), and DAS28 ≥ 3.2 (OR = 4.428; $p = 0.009$) were also significantly related to treatment failure.

Conclusion: Our findings indicate that osteoporosis treatment fails frequently in RA patients and adherence to bisphosphonate use, daily glucocorticoid dosage, immobilization, and DAS28 score should be taken into consideration when treating osteoporotic patients with RA.

Percentage of Women Achieving Non-Osteoporotic BMD T-Scores at the Spine and Hip over 8 Years of Denosumab Treatment.

S. Ferrari[1], C. Libanati[2], C.J.F Lin[2], S. Adami[3], J.P. Brown[4], F. Cosman[5], E. Czerwinski[6], L.H. de Gregório[7], J. Malouf[8], J.-Y. Reginster[9], N.S. Daizadeh[2], A. Wang[2], R.B. Wagman[2], E.M. Lewiecki[10] and S. Cummings[11]. [1]Geneva University Hospital, Geneva, Switzerland, [2]Amgen Inc., Thousand Oaks, CA, [3]University of Verona, Verona, Italy, [4]Laval University and CHU de Québec Research Centre, Quebec City, QC, [5]Helen Hayes Hospital, West Haverstraw, NY, [6]Krakow Medical Center, Krakow, Poland, [7]CCBR, Rio de Janeiro, Brazil, [8]Universitat Autònoma de Barcelona, Barcelona, Spain, [9]University of Liège, Liège, Belgium, [10]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, [11]San Francisco Coordinating Center, CPMC Research Institute, and UCSF, San Francisco, CA.

Background/Purpose: Guidelines for the treatment of chronic conditions such as hypertension and diabetes include specific biomarker targets. This differs from osteoporosis treatment guidelines, which currently do not define treatment targets or goals. In general, absence of BMD loss and absence of fracture are considered treatment successes. This is far from ideal because success defined by the lack of a negative outcome does not set a real goal for therapy. Potential goals for osteoporosis treatment might include reaching a BMD T-score value somewhere above –2.5 which represents an acceptable level of fracture risk. To provide insight into T-score values achieved over time with denosumab (DMAb), we report on the percentage of women who achieved a range of possible target BMD T-scores at both the lumbar spine and total hip over 8 years of treatment.

Methods: For these analyses, women received 3 years of DMAb (60 mg subcutaneously every 6 months) during FREEDOM and 5 years of DMAb during the Extension for a total of 8 years of continued treatment. The percentage of women with T-scores > −2.5, > −2.2, > −2.0, and > −1.8 at both the lumbar spine and total hip, and T-scores > −2.5 at either the lumbar spine or total hip at baseline and over 8 years of DMAb treatment were determined. The influence of baseline T-score on subsequent T-score improvement was also explored.

Results: At FREEDOM baseline, mean (standard deviation) lumbar spine and total hip T-scores were −2.83 (0.67) and −1.85 (0.79), respectively, for the DMAb Extension participants (N = 2,343). The percentage of women with T-scores > −2.5, > −2.2, > −2.0, and > −1.8 at both the lumbar spine and total hip progressively increased from baseline over 8 years of DMAb treatment as follows: 11% to 82% (> −2.5), 4% to 65% (> −2.2), 2% to 53% (> −2.0), and 1% to 39% (> −1.8) (Fig. 1). At individual sites, the percentage of women with a T-score > –2.5 increased from baseline over 8 years of DMAb treatment from 19% to 86% (lumbar spine) and from 75% to 94% (total hip). Baseline T-scores by quartile remained largely consistent throughout the 8 years of DMAb treatment, which showed similar trajectory in BMD across subjects regardless of initial BMD (not shown).

Conclusion: DMAb enables a substantial proportion of women with osteoporosis to achieve non-osteoporotic T-scores. The data reported here contribute insightful information to discussions on the topic of treatment goals for osteoporosis.

Background/Purpose: Odanacatib (ODN), a selective oral inhibitor of cathepsin K, is in development for the treatment of osteoporosis. The Phase III Long-Term Odanacatib Fracture Trial (LOFT; NCT00529373) and its pre-planned blinded extension in which patients continue on their originally assigned treatment, evaluated the efficacy and safety of ODN in reducing the risk of fractures in postmenopausal women with osteoporosis.

Methods: This randomized, double-blind, placebo-controlled, event-driven study enrolled women ≥65 years of age with a BMD T-score ≤−2.5 at the total hip (TH) or femoral neck (FN) or with a radiographic vertebral fracture (VFx) and a T-score ≤−1.5 at the TH or FN. Participants were randomized to either ODN 50 mg once-weekly or placebo (1:1) and received weekly vitamin D_3(5600IU) and daily calcium supplements to ensure a total daily calcium intake of ~1200 mg. Primary efficacy endpoints of the trial were new morphometric vertebral, clinical hip, and clinical non-vertebral fractures. Secondary endpoints included safety and tolerability, clinical VFx, spine and hip BMD, and bone turnover markers.

Results: A total of 16,713 participants were randomized at 387 centers in 40 countries, with 16,071 included in the analyses, and 642 excluded from all analyses due to study site closure (n=483), duplicate randomization (n=3), or failure to take any study drug (n=156). At baseline, mean (SD) age was 72.8 (5.3) years, 57% were Caucasian, 46.5% had a VFx prior to study entry, and mean BMD T-scores were: lumbar spine −2.7, TH −2.4, and FN −2.7. A total of 237 patients with hip fracture were estimated to provide statistical power. A prespecified interim analysis was performed when ~70% of targeted events had accrued. An external Data Monitoring Committee (DMC) reviewed these data and recommended that the base study be closed early due to robust efficacy and a favorable benefit/risk profile. The DMC noted that safety issues remained in certain selected areas. Both safety and efficacy continue to be monitored in the ongoing blinded extension trial. Data from an average follow-up of 40.8 months have been accrued from the base and extension studies, with 7,081 patients completing at least 4 years of follow-up. At the time this abstract was written, final data analyses were not complete.

Conclusion: The blinded, placebo-controlled base and extension study periods of LOFT will provide data on the efficacy of ODN on fractures and BMD and general safety. A separate presentation will discuss in depth the safety profile for ODN from this trial.

Efficacy and Safety of High Dose Infliximab in the Treatment of Uveitis in Pediatric Patients. Liza Mariel Bermudez[1], Patricia Irigoyen[1], Anca Askanase[1], Michael Weiss[2], Joyce Hui-Yuen[1], Amy J. Starr[1], Lisa F. Imundo[3], Andrew H. Eichenfield[1] and Josephine Isgro[1]. [1]Columbia University Medical Center, New York, NY, [2]Division of Ophthalmology Uveitis Service College of Physician And Surgeons of Columbia University, New York, NY, [3]Pediatric and Adult Rheumatology Columbia University Medical Center, New York, NY.

Background/Purpose: Chronic uveitis, an inflammatory eye disease, is a leading causes of childhood blindness and often has a chronic recurrent course. This study reviews the efficacy and safety of high dose (≥10–20 mg/kg) infliximab (IFX) in children with uveitis.

Methods: Retrospective chart review of 125 children and young adults with uveitis requiring systemic treatment. Data were collected on demographics, disease characteristics, infliximab dose, concomitant medications, treatment outcomes and side effects. Remission was defined as inactive eye disease ≥ 3 months after discontinuing all treatment; with 'inactive disease' was defined as grade 0 inflammatory cells. Descriptive statistics and Fisher's exact were employed.

Results: Of 125 patients with uveitis, 33 (26.4%) were treated with high-dose IFX (≥10–20 mg/kg). An additional 19 patients received alternate TNF inhibitors (adalimumab 17(13.6%), etanercept 2 (1.6%)). The median age at diagnosis was 10 years (IQR 2,22), 76 (61%) were female. The ethnic distribution was 78 (62%) Caucasian, 26 (21%) Hispanic, 4 (4%) African American, 3 (1%) Asian, and 14 (11%) not specified. Uveitis was associated with JIA (JIA-U) in 62 (50%); 56 (45%) oligoarticular-JIA, 4 (4%) poly-JIA and 2 (2%) systemic-JIA. Forty-nine (40%) patients had idiopathic uveitis; other causes included sarcoidosis 6 (5%), tuberculosis 1 (1%), Behcet's 1 (1%), Vogt-Koyanagi-Harada 1 (1%).

For the 33 patients on high-dose IFX, the median length of follow-up after initiation of treatment was 6 years, with a mean cumulative dose of 23 grams ± 16.7 (mean 7.2 mg/kg/dose ± 20.4). Fourteen were first started on methotrexate (MTX) and topical steroids (TS) with a median time to initiation of IFX of 17 months (IQR 7, 26), 12 were started on MTX and IFX simultaneously, and 7 received IFX monotherapy. Twenty-one (64%) achieved inactive eye disease, while 12 (36%) had persistently active disease. Of 73 patients treated with MTX/TS alone, 23 (32%) had inactive disease while 50 (68%) were active at last visit, showing increased inflammatory ophthalmic disease in patients not on IFX ($p<0.0013$). This difference was maintained when comparing all 52 patients on TNF inhibitors to those on MTX alone, 33 (63%) of patients on TNF inhibitiors had inactive disease compared to 23 (32%) on MTX ($p<0.0005$).

Ophthalmologic complications of uveitis included band keratopathy in 13 (10%), cataracts in 9 (7%), posterior synechiae in 8 (6%), and glaucoma in 4 (3%). The majority of complications were seen prior to starting IFX. No significant differences were seen between patients on IFX and those on MTX.

No malignancies or serious infections requiring hospitalization were seen in these patients. One patient on adalimumab developed dilated cardiomyopathy and 1 herpes zoster. At the end of study, 28 (85%) patients remain on IFX and 3 on adalimumab, 1 on etanercept and 1 on leflunomide/rituximab.

Conclusion: This is the largest study assessing the efficacy and safety of high-dose infliximab in the treatment of pediatric uveitis. Our data demonstrate favorable outcomes in patients on IFX, with 64% achieving inactive disease vs 32% on MTX. Extended use of high-dose infliximab did not appear to be associated with increased risk of serious infection or malignancy.

Changes in Cerebral Blood Flow Velocity in Patients with Familial Mediterranean Fever. Gozde Yildirim Cetin[1], Uygar Utku[2], Nurhan Atilla[3], Kadir Gisi[3] and Mehmet Sayarlioglu[4]. [1]Sutcu Imam University, School of Medicine, Department of Internal Medicine, Division of Rheumatology, Kahramanmaras, Turkey, [2]Kahramanmaras Sutcu Imam University, Medical Faculty, Kahramanmaras, Turkey, [3]Sutcu Imam University, School of Medicine, Kahramanmaras, Turkey, [4]Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Background/Purpose: Familial Mediterranean fever (FMF) is a hereditary and an auto-inflammatory disease predominantly characterized by repeated attacks of fever, abdominal pain, pleuritic chest pain, arthritis and erysipelas-like erythema. The MEditerranean FeVer (MEFV) gene mutations altering the structure and function of pyrin protein play a significant role in the pathophysiology of the disease. Mutated pyrin is associated with the loss of delicate control of the inflammatory pathways, which results in a prolonged or augmented inflammation that predisposes these patients to a pro-inflammatory state. This increased inflammation might lead to susceptibility to vascular comorbidities in FMF patients. The aim of this study was to assess the effects of this increased inflammation on cerebral blood flow velocity with transcranial Doppler (TCD) ultrasonography.

Methods: In this study, 30 subjects were enrolled for FMF and healthy control groups. All patients with FMF were under colchicine treatment and they were in an attack free period. Bilateral middle cerebral artery (MCA) peak-systolic, end-diastolic, and mean blood flow velocities; Gosling's pulsatility index values; and Pourcelot's resistance index values were recorded and compared with each other.

Results: There were 30 subjects in each group. Men/women ratio and mean age in FMF and control groups were 4/3, 26/27 and 34,7±5,9 *vs.*32,3±4,7 respectively. Peak-systolic, end-diastolic, and mean blood flow velocities of bilateral MCA were significantly higher in FMF group when compared with the control group (Table 1).

Table 1 Transcranial Doppler data of FMF group compared with control group.

	FMF group (mean±SD)	Control group (mean±SD)	p-value
L-peak-systolic BFV	143,3 ± 19,5	104,5 ± 13	**<0,001**
L-end-diastolic BFV	56,4 ± 13,5	38,4 ± 6,2	**<0,001**
L-mean BFV	90,9 ± 13,8	61,8 ± 8,2	**<0,001**
L-PI	0,85 ± 0,07	0,9±0, 09	0,02
L-RI	0,59 ± 0, 03	0,6±0,05	0,57
R-peak-systolic BFV	145,2 ± 22,3	103,5 ± 17,05	**<0,001**
R-end-diastolic BFV	59,5 ± 13	36,7 ± 12,36	**<0,001**
R-mean BFV	90,7 ± 15,47	63,2 ± 10,5	**<0,001**
R-PI	0,8 ± 0,08	0,85 ± 0, 09	0,89
R-RI	0,56 ± 0,04	0,63 ± 0, 06	**0,002**

L, left; R, right; PI, pulsatility index; RI, resistance index; BFV; blood flow velocity.

Conclusion: There has been recently considerable attention concerning the possible causal role of systemic inflammation in the development of atherosclerosis in patients with rheumatic diseases. The attacks of FMF with clinical inflammation is only the tip of the iceberg, inflammation maintains in attack-free remission periods in 30% of patients with FMF. This maintaining subclinical inflammation induces endothelial dysfunction, and increases the risk of developing significant complications such as atherothrombosis, anemia, splenomegaly, decreased bone mineral density, heart disease, and life-threatening secondary systemic amyloidosis. In this study, we investigated the effects of clinical and subclinical inflammation regarding FMF disease on cerebral blood flow parameters. In our study, the mechanisms that underlie significantly increased blood flow velocities of the FMF group is most likely to be due to mild diffuse subclinical atherosclerosis. Consequently, our results suggest that persistent clinical and subclinical inflammation in FMF patients causes increased cerebral blood flow velocities.

Symptom and Treatment Characteristics of Juvenile Primary Fibromyalgia Syndrome: Are Males and Females Created Equal? Jennifer E. Weiss[1], Kenneth N. Schikler[2], Alexis Boneparth[3], Cara Hoffart[4], Mark Connelly[4] and The CARRA Registry Investigators[5]. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Univ of Louisville Schl of Med, Louisville, KY, [3]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, [4]Children's Mercy Hospital, Kansas City, MO, [5]Childhood Arthritis and Rheumatology Research Alliance, Durham, NC.

Background/Purpose: Children and adolescents with persistent widespread musculoskeletal pain frequently present to pediatric rheumatologists for evaluation. Limited data are available on the characteristics and treatments used for these patients, particularly for males. Using the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry, we sought to evaluate the overall demographic, symptom, and treatment characteristics of patients diagnosed with juvenile primary fibromyalgia syndrome (JPFS) and to compare these characteristics as a function of gender.

Methods: Deidentified data on demographics, symptoms, functional measures and treatment characteristics were extracted from the baseline visits of JPFS patients in the CARRA registry between May 2010 and May 2014.

Results: There were 181 patients (28 males), ages 8–21 years (M = 15.4 +/− 2.3) included. Patients were symptomatic for a mean of 1.7 +/− 2.2 years prior to their first visit to a pediatric rheumatologist, with no significant difference between males and females (M = 2.1 versus 1.6 respectively, $t(173)=1.06$, $p=.29$). The most commonly reported symptoms at baseline included widespread pain (91%), fatigue (84%), disordered sleep (82%), headaches (68%), and extremity numbness/tingling (32%). Females were more likely to report numbness/tingling (36% versus 13% respectively, $\chi^2 = 5.09$, $p = 0.02$). Table 1 lists treatments tried and recommended. Males were significantly more likely to have used gabapentin (25% versus 8%, $\chi^2 = 7.41$, $p < 0.01$). Of the 64 patients using non-pharmacologic treatment, the most commonly used treatment was physical therapy (59%), with females significantly more likely to have used massage and yoga (Table 1). Less then 10% of patients tried opioids, serotonin norepinephrine reuptake inhibitors, craniosacral therapy, hypnosis, and biofeedback.

Mean pain scores at baseline were moderate to severe (6.3+/− 2.5/10) and were significantly positively related to CHAQ functional impairment scores ($r = .35$, $p < .01$), patient ratings of impairments in health-related quality of life (HRQOL) ($r = .42$, $p < .01$), and patient ratings of impairments in overall well-being ($r = .64$, $p < .01$). Males were found to be reliably more disabled based on *subjective* (patient/parent report) functioning measures (HRQOL and CHAQ), although no differences were observed on physician report measures (physician global assessment and ACR functional class).

Table 1. Treatments tried and recommended for JPFS patients (N=181)

Treatment	Percent of Patients: Females (N=154)	Males (N=27)	Total
Medical treatments tried (N=117)			
Daily non-steroidal anti-inflammatory drugs	42%	48%	43%
Selective serotonin reuptake inhibitors	29%	14%	26%
Tri-cyclic antidepressants	27%	24%	26%
Gabapentin	12%	33%*	16%
Non-pharmacological treatments tried (N=64)			
Physical therapy	59%	62%	59%
Dietary supplements	22%	46%	27%
Therapeutic massage	29%*	8%	25%
Mindfulness/meditation	18%	23%	19%
Chiropractic	18%	8%	16%
Acupuncture/acupressure	16%	8%	14%
Yoga	14%*	0%	11%
Treatments recommended/started at baseline visit (N=181)			
Pain education	92%	89%	91%
Graded aerobic activity	78%	67%	76%
Sleep hygiene	72%	57%	70%
General counseling	52%	54%	52%
Physical therapy	56%	57%	56%
Medications	50%	57%	51%
Referral to pain clinic	46%	43%	46%
Cognitive-behavioral therapy	41%	50%	42%
Biofeedback	7%	14%	8%

*Significant gender difference, $p<.05$.

Conclusion: Based on data from the largest known cohort of JPFS patients, there appear to be few significant gender differences in disease characteristics and treatment. However, higher levels of disability are reported by male patients despite no comparable differences observed on physician severity measures, suggesting the need to consider gender on evaluation and treatment of JPFS.

Assessment of Transition Readiness in Adolescents and Young Adults with Rheumatic and Other Chronic Health Conditions. Gabrielle Paul[1], Stephanie LaCount[1], Charles H. Spencer[2], Gloria C. Higgins[3], Karla Jones[4], Brendan Boyle[5], Manmohan K. Kamboj[5], Christopher Smallwood[6] and Stacy P. Ardoin[7]. [1]Ohio State University, Columbus, OH, [2]Nationwide Childrens Hospital, Columbus, OH, [3]Nationwide Childrens Hosp, Columbus, OH, [4]Nationwide Children's Hospital, Ohio, OH, [5]Nationwide Children's Hospital, Columbus, OH, [6]Ohio State Univeristy, Columbus, OH, [7]Ohio State University College of Medicine, Columbus, OH.

Background/Purpose: The transition from pediatric to adult care is a vulnerable period. The lack of objective measures of transition readiness is a barrier to improving care. The Transition Readiness Assessment Questionnaire (TRAQ) is a disease-neutral, patient-reported tool with 33 questions across 2 domains (self-management and self-advocacy). Items are scored on a 1 to 5 ordinal scale representing stages of change model (precontemplation, contemplation, preparation, action and maintenance). The TRAQ has not previously been assessed in adolescents and children with rheumatic or gastroenterologic (GI) conditions.

Methods: 89 adolescents and young adults (16 – 25 years) with chronic rheumatic, endocrine or GI conditions at a single pediatric center were enrolled. Participants completed surveys including demographics, transition experience, TRAQ. Clinical information was obtained via chart review. Data were analyzed with descriptive statistics. Mean TRAQ scores were compared across specialty and age groups using one way ANOVA.

Results: The 89 participants were 65% female, 18.3 years, 72% Caucasian, 86% non-Hispanic and had rheumatic (54%), GI (21%) or endocrine (23%) conditions (Table 1). The 50 participants with rheumatic diseases had JIA/RA (25), SLE or MCTD (13), vasculitis (6), overlap or other disease (6). Only 40% of participants reported discussing with current provider seeing an adult subspecialty provider in the future. Participants reported seeing subspecialist independently for part of visit never (31%), rarely (15%), sometimes (20%), often (24%) or always (8%). TRAQ self-management and advocacy scores did not differ significantly by specialty but the TRAQ self-advocacy score increased with age (Tables 2 and 3).

Conclusion: Despite guidelines that transition processes begin at age 14, fewer than half of these 16–25 year old respondents reported ever discussing future transition to adult providers and almost 1/3 had never seen provider independently for portion of clinic visit. Mean TRAQ scores for this group represented the preparation stage of change. The TRAQ is a promising tool for measuring transition readiness and can be used clinically and to assess intervention efficacy. These results underscore the need for improved transition processes for adolescents and young adults with chronic disease.

Does a Standardized Multidisciplinary Approach Improve Outcomes for Children with NMDA Receptor Antibody Encephalitis?: A Preliminary Assessment of a Single Center Experience.

Mered Parnes[1], Amber Stocco[2], Trung Nguyen[1], Jun Teruya[1], Jeanine Graf[1] and Eyal Muscal[1]. [1]Baylor College of Medicine, Houston, TX, [2]Integris Pediatric Neurology, Oklahoma City, OK.

Background/Purpose: NMDA receptor antibody encephalitis (NMDAR) is a potentially devastating isolated autoimmune condition affecting children and young adults that was mostly unrecognized prior to 2007. The clinical phenotype includes encephalopathy, neurocognitive deficits, seizures, and abnormal movements. The largest published observational study to include children suggests that earlier diagnosis, and utilization of immunotherapy (rituximab or cyclophosphamide) in refractory cases may decrease relapse rates and neurologic morbidity (Titulaer MJ et al. Lancet neurology 2013: 12;157–165). Yet, best care practices regarding multi-disciplinary care, the role of pediatric rheumatologists, and timing of immunotherapy modalities have not been validated for children.

Methods: A standardized multidisciplinary approach to NMDAR care was designed at our institution after struggling with initial cases during 2009–2011. A task force composed of physicians from neurology, rheumatology, intensive care, and transfusion medicine services reviewed the literature and approaches of other pediatric hospitals. Institutional criteria were developed regarding the use of therapeutic plasma exchange (TPE) and early B-cell depletion with rituximab. In our algorithm, patients remaining at a moderate disability level one week after first-line therapy (corticosteroids + IVIG or TPE) received rituximab. We assessed initial presentations, interventions, and neurologic outcomes for all children diagnosed with NMDAR during the period of 2009–2013 after obtaining IRB approval. Only descriptive statistics were analyzed due to the small sample size of our cohort.

Results: We identified 13 patients with the appropriate clinical phenotype and NMDA receptor antibodies in serum and/or CSF. There were 9 females (70%), median age at presentation was 10 (range 3–17), and median time from symptom onset to diagnosis and initial treatment was 16 days (range 2–90 days). Of the first six children treated at our institution (median follow-up time 20.5 months) without a standardized approach (2009-July 2012) only 1 received rituximab, and 4 had relapses (66.6%; 3 children within the first year and one child at 19 months). Since July 2012, 7 children have been treated according to a standardized approach. Six of these children (86%) received rituximab and there have been no relapses during the first year of follow-up (median 10 months). Median time to diagnosis was similar in both cohorts (15 vs. 24 days). A greater percentage of children in the standardized cohort (71% vs. 33%) achieved a modified Rankin score of 0 (no deficits) OR 1 (mild deficits, no impairment).

Conclusion: Preliminary analyses of children presenting with NMDAR since 2009 reveal lower relapse rates and disability scores in the recent cohort receiving standardized care and early utilization of rituximab. It is not apparent whether low relapse rates status post rituximab will be sustained with longer follow up. The institutional task force aims to address best care practices for psychiatric, neuropsychological, and rehabilitation services.

2274

TNF Inhibitors Provide Long-Term Clinical Benefits in 6 Patients with Early-Onset Sarcoidosis.

Tomokazu Nagakura[1], Tsuyoshi Yamatou[2], Tomohiro Kubota[2], Hiroyuki Wakiguchi[2], Yuichi Yamasaki[2], Yukiko Nonaka[2], Tomoko Takezaki[2], Harumi Akaike[2], Yasuhito Nerome[2], Hiroyuki Imanaka[2] and Syuji Takei[3]. [1]House of Meguminoseibo, Usuki, Japan, [2]Kagoshima University Hospital, Kagoshima, Japan, [3]Kagoshima University, Kagoshima, Japan.

Background/Purpose: Early-onset sarcoidosis (EOS) is a NOD2 gene-associated chronic autoinflammatory disease, characterized by the triad of arthritis, rash, and uveitis, which usually occurs in children younger than 4 years of age. The aim of this study was to evaluate the clinical benefits of TNF inhibitors (TNFi) in EOS.

Patients and Methods: Six EOS patients treated with biologic agents at our hospital were reviewed. To evaluate the benefits of biologic agents, patients were retrospectively assessed at baseline, 3, 6, 12 and 36 months and the last visit after initiating the therapy. Severity of each clinical symptom such as arthritis, camptodactyly, uveitis, and skin rash was assigned by scoring from 0 (none) to 3 (severe). Laboratory findings such as CRP, ESR, or matrix metalloproteinase-3 (MMP-3) were also evaluated. In addition, the accumulated continuation rate of each biologic agent was analyzed by Kaplan-Meier method.

Results: The biologic agents were initiated after 10.9 years from onset (0.8–18.1y). The 1st biologic agents (1st Bio) used were infliximab (IFX) in 2, etanercept (ETA) in 2, adalimumab in 1, and IL-6 inhibitor (IL-6i) tocilizumab (TCZ) in 1. Four patients maintained clinical remission with the 1st biologic agents. The rest of 2 had switched to the 2nd biologic agents due to the lack of efficacy, and one of the 2 had switched to the 3rd one. One of the 2 cases treated with ETA showed refractory arthritis; subsequently required to switch to the 2nd Bio (TCZ) followed by the 3rd Bio (IFX) to achieve a clinical remission. A case treated with TCZ showed no clinical improvements; she finally attained clinical remission after switching to the 2nd Bio, IFX. During the TNFi therapy, clinical improvement was observed in joint pain/swelling (6/7), cystic swelling (2/7), uveitis (3/4), and skin rash (4/7), except in camptodactyly (0/7) (Fig.1). On the other hand, patients treated with IL-6i showed poor clinical response. The accumulated continuation rate after 3 years of each biologic therapy was 85.7% in TNFi and 0% in IL-6i ($p=0.022$, the log-rank test) (Fig.2). Of 4 patients with uveitis at initiating biologic agents, 3 patients treated with IFX attained substantial improvement of uveitis, while one treated with TCZ did not. The other 2

patients who had started biologic therapy without uveitis kept uveits free by the age of 14.6 or 15.3 years old at their last visit.

Conclusion: TNF inhibitors appear to be more effective than IL-6 inhibitor in the treatment of EOS, and may have a potential to prevent the onset of uveitis.

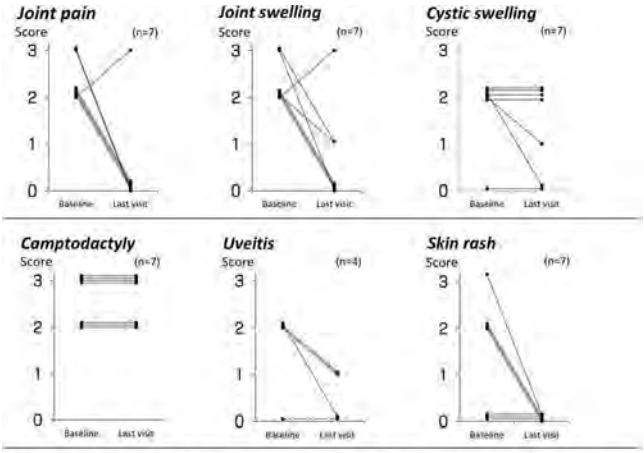

Figure.1 Changes in clinical score during TNF inhibitor therapy.

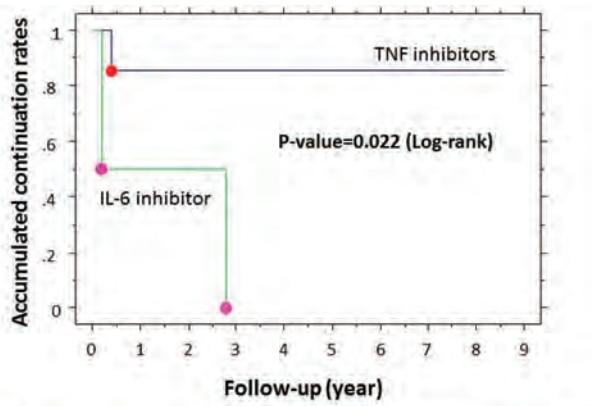

Figure.2 The accumulated continuation rates of TNF/IL-6 inhibitors in the treatment of EOS.

2275

Immunization Status and Barriers in Childhood Rheumatic Diseases. Shine Vazhappilly[1], Otto Vanderkooi[2], Susanne Benseler[3], Tommy Gerschman[4], Nicole Johnson[3], Nadia Luca[3], Paivi Miettunen[3], Dwaraka Veeramreddy[1] and Heinrike Schmeling[3]. [1]University of Calgary, Calgary, AB, [2]Department of Pathology and Laboratory Medicine & Microbiology Immunology & Infectious Diseases/University of Calgary, Calgary, AB, [3]Department of Pediatrics/University of Calgary, Calgary, AB, [4]Alberta Children's Hospital, Calgary, AB.

Background/Purpose: To determine the vaccination status of children with rheumatic diseases, and identify immunization knowledge of families and potential barriers to vaccination.

Methods: A cross-sectional study of children with rheumatic diseases followed at a tertiary care center outpatient clinic was performed between October 2013 and March 2014. Demographics, diagnosis and current treatments were obtained from health records. Children were considered immunosuppressed, if they were currently received corticosteroids, non-biologic or biologic disease-modifying agents. A unique provincial electronic database that records accurate vaccine history was used to obtain actual patient vaccination history. Perceived immunization barriers, concerns and knowledge regarding contraindications to vaccination, and sources of immunization information were captured from a patient/parent questionnaire. Descriptive statistical methods were used to analyze the data.

Results: A total of 82 children were recruited into the study. The median age was 11.7 years. The most common diagnoses were juvenile idiopathic arthritis (65%), systemic lupus erythematosus (9%), and juvenile dermatomyositis (5%). Fifty eight (71%) children were considered immunosuppressed.

Vaccination database: Patients received most recommended vaccines, with the exception of the Influenza (2013/2014) and Hepatitis B vaccines (recommended for age of 10 [grade 5] in Canada). Influenza was missed 40% of the time in the 1 – 3 years old group, 18% of the time in the 4 – 9 years old group, and 27% of the time in the 10 – 17 years old group. Hepatitis B was missed at a rate of 4% in the 10 – 17 years old group.

Patient/parent questionnaire: Nine patients reported previous adverse reactions to vaccination (Influenza [5], Measles, Mumps, and Rubella (MMR) [2], Hepatitis B [2] and Varicella [2]). In 38% at least one vaccination was withheld, most commonly for active disease (26%), recommendation against receiving vaccinations by health care provider (23%), uncertainty about whether or not a vaccine should be given (19%), concerns about disease flare (13%) and/or side effects post vaccination (5%). Several sources of information were utilized by patients and families for vaccination information, and satisfaction with this information was fairly high. Patients and parents identified the following information gaps: 1) risks and contraindications of vaccinations in childhood rheumatic diseases, 2) age-appropriate vaccination schedules and modalities, 3) best practice of vaccination documentation. Vaccination reminders were identified as useful, with several comments indicating that e-mail alerts, reminders, and a method to track this information would be useful.

Conclusion: The majority of children with rheumatic illnesses received the recommended vaccines. Immunization gaps were identified for Influenza and Hepatitis B. Knowledge regarding contraindications to vaccination is good. Concerns about perceived safety limit vaccination completeness.

Consensus Statement on the Transition Process from Pediatric Care to Adult Care in Patients with Chronic Inflammatory Rheumatic Diseases with Childhood-Onset. Maria Inmaculada Calvo-Penedes[1], Jordi Anton Lopez[2], Sagrario Bustabad-Reyes[3], Marisol Camacho[4], Jaime De Inocencio[5], Maria Luz Gamir Gamir[6], Genaro Graña[7], Lucía La Cruz[8], Juan Carlos Lopez-Robledillo[9], Marta Medrano[10], Rosa Merino[11], Consuelo Modesto[12], Esmeralda Nuñez[13], Maria Jesus Rua Elorduy[14],Vicente Torrente[15], Carmen Vargas-Lebrón[16] and Estibaliz Loza[17]. [1]H. de la Fe, Valencia, Spain, [2]University Childrenxs Hospital, Barcelona, Spain, [3]Hospital Universitario de Canarias, La Laguna, Spain, [4]Hospital Universitario Virgen del Rocío, Sevilla, Spain, [5]Hospital 12 de Octubre, Madrid, Spain, [6]Hospital Universitario Ramón y Cajal, Madrid, Spain, [7]Complejo Hospitalario Universitario A Coruña, La Coruña, Spain, [8]Hospital Universitari Son Dureta, Mallorca, Spain, [9]Hospital Niño Jesus, Madrid, Spain, [10]Hospital Universitario Miguel Servet, Zaragoza, Spain, [11]Hospital Universitario La Paz, Madrid, Spain, [12]Hospital Valle de Hebron, Barcelona, Spain, [13]Hospital Regional Universitario Carlos Haya, Málaga, Spain, [14]Hospital de Cruces, Barakaldo, Spain, [15]Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain, [16]Hospital Virgen Macarena, Seville, Spain, [17]Institu, Madrid, Spain.

Background/Purpose: many young people with childhood-onset diseases, including rheumatic diseases, continue to require medical care into adult life. There are many differences between pediatric and adult health care. Although there is an extensive evidence base for the need of transitional care, there is a paucity of robust outcome data and a great variability on the models of transitional care. The aim of this study was to develop recommendations on the transition from pediatric care to adult care in patients with chronic inflammatory rheumatic diseases with childhood-onset based on the best evidence and experience.

Methods: recommendations were generated following nominal group methodology and Delphi technique. A panel of experts was established (8 pediatricians, 8 rheumatologists). A systematic literature review (on transitional care) and a narrative review (websites, clinical guidelines and other relevant documentation) were performed and presented to the panel in the 1st panel meeting to be

discussed and to help define recommendations. A first draft of recommendations was generated and circulated for comments and wording refinements. Focal groups with adolescents, young adults and parents were separately. In a 2nd panel meeting the focus group results along with the input from invited psychologist was used to established definitive recommendations. Then, a Delphi process (2 rounds) was carried out. A large group of 70 pediatricians and rheumatologists took part. Recommendations were voted from 1 (total disagreement) to 10 (total agreement). We defined agreement if at least 70% voted ≥7. The level of evidence and grade or recommendation was assessed using the Oxford Centre for Evidence-based Medicine Levels of Evidence.

Results: transition care was defined as a purposeful, planned process that addresses the medical, psychosocial and educational/vocational needs of adolescents and young adults with chronic inflammatory rheumatic diseases with childhood-onset as they move from child-centred to adult-oriented health care systems. The consensus covers: transition needs, barriers and facilitators, transitional issues (objectives, participants, content, phases, timing, plans, documentation, and responsibilities), physicians and other health professionals knowledge and skills requirements, models/programs, strategies and guideline for implementation. Preliminary recommendations and agreement grade are shown in the table (1st Delphi round).

Conclusion: these recommendations are intended to provide pediatricians, rheumatologists, patients, families and other stakeholders with a consensus on the transition process from pediatric care to adult care in patients with chronic inflammatory rheumatic diseases with childhood-onset.

#	RECOMMENDATIONS	% ≥7
1	Transition in pediatric rheumatology should be considered as a continuous, natural and flexible process	92%
2	To standardize, plan ahead, and to define specific protocols related to transitional care	94%
3	To promote outpatient care during transition	47%
4	To endorse specialized nursing care during transition	88%
5	During transitional care, health professionals should convey to patients and parents normality, optimism, sincerity, and should listen to and dialog with them efficiently	97%
6	To support and reinforce patients autonomy and participation adapted to the age/maturity of them during transition	99%
7	To facilitate (evidence based) useful written information (electronic, paper) about disease most relevant issues, management and other aspects for patients and parents	91%
8	To actively involve patients and parents in all of the processes of the transitional care	94%
9	To inform patients and parents about the disease and transitional processes including adult care	99%
10	To monitor adherence (to treatments, visits, etc)	90%
11	To endurance effective communication, collaboration and coordination, among all health professionals involved in the transitional care	78%
12	To endurance effective communication, collaboration and coordination, between health professionals involved in the transitional care and patients educators	64%
13	To develop clinical sessions between pediatric rheumatologists and adult rheumatologists and with other specialists involved in transitional care	90%
14	Adaptations to patients academic needs should be considered	34%
15	An specific training on transitional care as a part of the pediatric training	58%
16	To promote multidisciplinary care by implementing a transitional care model based on each center characteristics, resources and needs	97%
17	The implementation of a transition care model should be planned carefully as well as the strategies to assure the implementation	94%
18	When transferring a patient to the adult care, a full report on the disease course, impact, treatments, and other relevant aspects should be delivered	100%
19	To set up reference units of transitional care	37%

Inpatient Pediatric Rheumatic Diseases: Characteristics, Cost and Trends. Monica Mahajan, Mohammad Shah, Mary Toth, Neil McNinch and Moussa El-Hallak. Akron Children's Hospital, Akron, OH.

Background/Purpose: Childhood rheumatic diseases (cRD) have wide spectrum of complexity and disease course from mild disease to acute fulminate disease and even sudden death. Physicians and policy makers are increasingly interested in admission rates and resource utilization of chronic illnesses. We aimed to describe temporal trends in inpatient hospitalizations and service costs for patients with cRD.

Methods: Pediatric Health Information System database was used to query children with rheumatic conditions between 2004 and 2012. Clinical variables, including age, gender, ethnicity, diagnoses, length of stay (LOS), payer type, admission costs (adjusted for hospital location then rescaled to 2012 dollar), chronic condition indicator and co-morbidity were determined. We excluded patients with LOS ≤1 day as these patients may not represent unplanned admissions.

Results: This study comprised 24,291 discharges from pediatric hospital inpatient units. There were more female (53%) than male (47%) patients. Mean age (±SD) was 7 years (±5.76 years). There was an increase in the total number of admissions and inpatient adjusted service cost during the 9 year study period (Figure 1). Linear trend for admissions and adjusted costs were significant at $p=0.01$ and <0.001 respectively. Lupus, vasculitis and scleroderma admissions were associated with more chronic co-morbidities and chronic diagnoses than the rest of cRD groups.

Kawasaki disease accounted for nearly half of the admissions, lupus for 21.7%, Henoch-Schonlein Purpura for 10.2%, juvenile idiopathic arthritis (JIA) for 7%, vasculitis for 5%, inflammatory myositis for 5% and scleroderma for $p<0.001$) and increased with number of chronic co-morbidities ($p<0.001$).

During the 9-year study period, the total number of inpatient admissions increased by 24% from 2,194 in 2004 to 2,715 in 2012. After rescaling to 2012 dollar, the median adjusted inpatient services cost of cRD increased by 53% and the total costs increased by 61.5% from 78 million in 2004 to 127 million in 2012. Patients with government supported insurance had higher median adjusted admission cost $25,344 compared to patients with commercial insurance $24,284.

Conclusion: Both, rate of hospitalization and cost of admission for cRD increased over the study period of 2004 to 2012. The observed trends highlight the burden of cRD on patients, families and payers. Further research and development of management strategies to support high-value pediatric care and resource targeting is warranted to ensure patients with cRD are cared for in the most efficient manner without compromising quality. This study also reinforces the need for pediatric rheumatologists in the United States.

Orbital Pseudotumor As the Presenting Symptom of Pediatric ANCA-Associated Vasculitis. Amanda Schlefman[1], Maureen Leffler[2], AnneMarie C. Brescia[3] and Carlos D. Rose[4]. [1]A.I. DuPont Hospital for Children, Wilmington, DE, [2]AI duPont Hospital for Children, Wilmington, DE, [3]Thomas Jefferson University/ AI duPont Hospital for Children, Wilmington, DE, [4]Division of Rheumatology, Nemours A.I. duPont Hospital for Children, Thomas Jefferson University, Wilmington, DE.

Background/Purpose: Ocular involvement, particularly orbital pseudotumor, has been reported as the initial manifestation of ANCA-

associated vasculitis (AAV) in the adult population, predominantly in granulomatosis with polyangiitis (GPA) with less frequency in Churg-Strauss syndrome (CSS) and microscopic polyangiitis (MPA). There are several cases in the literature of pediatric patients with GPA presenting with orbital pseudotumor, however to our knowledge there are no published cases of this type of presentation in childhood CSS or MPA.

Methods: During the period between 2009 and 2014 three cases of orbital pseudotumor were diagnosed in our Pediatric Rheumatology Division. A thorough chart review was conducted on these patients regarding clinical presentation, laboratory data, imaging studies and pathology. A literature review was then completed in PubMed looking for individual reports of pediatric ANCA-associated vasculitis, as well as previously reported cases of orbital pseudotumor in both adults and children.

Results: Four reports in PubMed were published regarding orbital pseudotumor and ANCA-associated vasculitis in pediatrics. Within these studies there were 15 cases of pediatric AAV presenting as orbital pseudotumor, all of which were limited to GPA. There was no published evidence of this initial presentation in either CSS or MPA in the pediatric population. The characteristics of our patients are listed below:

Table 1.

Case	Age (years), Gender	Serology	Diagnosis	Diagnostic Modality	Disease Course	Treatment	Outcome
1	11, Female	+p-ANCA	Churg-Strauss Syndrome	Biopsy of flank lesions	- Erythema Induratum-like flank lesions	Steroids Cyclophosphamide	Remission
		+MPO Antibody			- Glomerulonephritis		
					-Hashimoto's thyroiditis		
2	6, Female	+p-ANCA	Microscopic Polyangiitis	Renal biopsy	- Glomerulonephritis	Steroids Cyclophosphamide Rituximab	Remission
		+MPO Antibody			-Dialysis complicated by peritonitis		
					- Kidney transplant		
3	3, Female	+p-ANCA	ANCA-vasculitis, Not otherwise specified	Biopsy of orbital mass	No systemic involvement at this time	Steroids	Remission
		+MPO Antibody					

MRI Brain/Orbit of one patient revealing an enhancing mass within the superolateral post-septal soft tissues of the right orbit, as well as signal abnormality along the pre-septal soft tissues involving the superior eyelid.

Conclusion: When pediatric patients present with orbital pseudotumor the differential should be widened regarding types of ANCA-associated vasculitides to include CSS and MPA. Recognizing these possibilities would allow for early screening and monitoring for potential multi-organ involvement.

[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [3]Hopital Tenon, Paris, France, [4]Pediatric Rheumatology Unit. Hospital Sant Joan de Déu. Universitat de Barcelona, Barcelona, Spain, [5]NIH, Bethesda, MD, [6]University of Siena, Siena, Italy, [7]Bicêtre Hospital, University of Paris SUD, Paris, France, [8]Versailles Hospital, Le Chesnay Cedex, France, [9]Centre Multisite Romand de Rhumatologie Pediatrique, Lausanne, Switzerland, [10]Charite, University Medicine Berlin, Berlin, Germany, [11]University Hospital Tuebingen, Tuebingen, Germany, [12]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [13]Deptartment. of Pediatric Rheumatology, Hacettepe University, Ankara, Turkey, [14]Hospital De Pediatria, Buenos Aires, Argentina, [15]Radboudumc, Nijmegen, Netherlands, [16]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel, [17]University of Leuven, Laboratory of Pediatric Immunology, University Hospital Leuven, Leuven, Belgium, [18]The Hospital for Sick Children, Toronto, ON, [19]Wilhelmina Children's Hospital/ UMC Utrecht, Utrecht, Netherlands, [20]University College London Medical School, London, United Kingdom, [21]Istituto Giannina Gaslini, Genova, Italy.

Background/Purpose: Tumor necrosis factor receptor-1 associated periodic syndrome (TRAPS) is a rare hereditary autoinflammatory syndrome that can lead to significant morbidity. Evidence-based guidelines are lacking and management is mostly based on physician's experience. Consequently, treatment regimens differ throughout Europe. In 2012, a European initiative called SHARE *(Single Hub and Access point for pediatric Rheumatology in Europe)* was launched to optimize and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. One of the aims of SHARE was to provide evidence based recommendations for diagnosis and treatment of TRAPS.

Methods: Evidence based recommendations were developed using the European League Against Rheumatism (EULAR) standard operating procedure. An expert committee was instituted, consisting of pediatric and adult rheumatologists. The expert committee defined search terms for the systematic literature review. Two independent experts scored articles for validity and level of evidence. Recommendations derived from the literature were evaluated by an online survey. Those with less than 80% agreement on the online survey or with relevant comments of the experts were reformulated. Subsequently, all recommendations were discussed at a consensus meeting using the nominal group technique. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 523 articles, of which 22 were considered relevant and therefore scored for validity and level of evidence. Eighteen were scored valid and used in the formulation of the recommendations. Seventeen recommendations were suggested in the online survey and discussed during the consensus meeting. Five general recommendations on management, two recommendations for diagnosis, seven for monitoring and eight for treatment were accepted with more than 80% agreement. Topics covered are the following:

- *general recommendations:* use of the multidisciplinary team, treatment goals and vaccinations
- *diagnosis:* TNFRSF1A screening, interpretation of R92Q and P46L variants
- *monitoring:* monitoring frequency and minimal assessments in TRAPS patients, the use of AIDAI score in clinical studies and risk assessment of amyloidosis

● *treatment:* NSAIDS and/or glucocorticoids during attacks, IL-1 blockade, etanercept, anti-TNF monoclonal antibodies, switching between biologicals

Conclusion: The SHARE initiative provides recommendations for diagnosis and treatment for TRAPS and thereby facilitates improvement and uniformity of care throughout Europe.

Background/Purpose: Cryopyrin-associated periodic syndromes (CAPS) is a group of rare monogenetic autoinflammatory disorders. Evidence-based guidelines are lacking and management is mostly based on physician's experience. Consequently, treatment regimens differ throughout Europe. In 2012, a European initiative called SHARE *(Single Hub and Access point for pediatric Rheumatology in Europe)*was launched to optimize and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. One of the aims of SHARE was to provide evidence based recommendations for management (treatment and monitoring) of CAPS.

Methods: Evidence based recommendations were developed using the European League Against Rheumatism (EULAR) standard operating procedure. An expert committee was instituted, consisting of pediatric and adult rheumatologists. The expert committee defined search terms for the systematic literature review. Two independent experts scored articles for validity and level of evidence. Recommendations derived from the literature were evaluated by an online survey. Those with less than 80% agreement on the online survey or with relevant comments of the experts were reformulated. Subsequently, all recommendations were discussed at a consensus meeting using Nominal Group Technique. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 1698 articles, of which 25 papers on treatment were considered relevant and therefore scored for validity and level of evidence. Seventeen were scored valid and used in the formulation of the recommendations. Fifteen recommendations were suggested in the online survey and discussed during the consensus meeting. Six general recommendations on management, five for monitoring and four for treatment were accepted with more than 80% agreement. Topics covered are the following:

● *General recommendations*: use of the multidisciplinary team, treatment goals, adjunctive therapies, psychosocial support and vaccinations

● *Monitoring*: monitoring frequency, minimal assessments in all CAPS patients and monitoring of severe phenotypes

● *Treatment*: IL-1 blockade, NSAIDs and/or glucocorticoids during attacks and DMARDS/biologicals other than IL-1 blockade

Conclusion: The SHARE initiative provides recommendations for the management of CAPS and thereby facilitates improvement and uniformity of care throughout Europe.

Iashvili Children's Central Clinic, Tbilisi, Georgia, [20]Stanford University, Stanford, CA, [21]Children's Hospital Zagreb, Zagreb, Croatia, [22]Steven and Alexandra Cohen Children's Hospital of New York, New York, NY, [23]Ospedale Pediatrico Bambino Gesù, Roma, Italy, [24]Hospital das Clínicas da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [25]University of Latvia, Riga, Latvia, [26]Botucatu Medical School, Botucatu, Brazil, [27]King Faisal Specialist H.,Riyadh, Riyadh, Saudi Arabia, [28]King AbdulAziz Medical City, Riyadh, Saudi Arabia, [29]Arkansas Children's Hospital, Little Rock, AR, [30]P. A. Kyriakou Childrens Hospital of Athens University, Athens, Greece, [31]Children's Hospital of Philadelphia, Philadelphia, PA, [32]Istituto Giannina Gaslini, Genoa, Italy, [33]University of Alabama at Birmingham, Birmingham, AL, [34]University of Genova, Genova, Italy.

Background/Purpose: Macrophage activations syndrome (MAS) occurring in the context of systemic juvenile idiopathic arthritis (sJIA) can pursue a rapidly fatal course. However, the diagnosis of the syndrome is often challenging as its features may be mimicked by those of confusable conditions, such as flares of the underlying disease or systemic infections. In addition, the clinical spectrum of MAS is known to be heterogeneous. The aim of this study is to seek insights into the heterogeneity of MAS by comparing the characteristics of patients enrolled in a large multinational survey in relation to geographic origin of patients, specialty of attending physician, demonstration of hemophagocytosis (HP), and outcome.

Methods: Patient data were collected retrospectively by pediatric rheumatologists (PR) or pediatric hemato-oncologists (PHO) and entered in a web-based database. Clinical and laboratory features, therapeutic interventions and outcome were compared between subgroups by means of Mann-Whitney U test or chi-square/Fisher exact test, as appropriate. "Severe course" was defined as the occurrence of ICU admission or death.

Results: A total of 362 patients with sJIA-associated MAS were collected by 95 investigators from 33 countries. 179 patients (49.4%) were enrolled in Europe (EU), 72 (19.9%) in North America (NA) and 111 (30.7%) in other continents (OC). 283 (88.2%) patients were included by PR and 79 (21.8%) patients by PHO. Bone marrow HP was detected in 160 (44.2%) patients and was not detected or looked for in 202 (55.8%) patients. Severe course was reported in 92 (25.4%) patients. Comparison by geographic origin showed a lower frequency of CNS disease and higher levels of liver transaminases in EU patients. NA physicians used more frequently iv Ig and biologics than did physicians from EU and OC. Patients entered by PHO had a greater frequency of multiorgan failure and were given more commonly biologics and etoposide, whereas patients seen by PR received more frequently cyclosporine. Patients with demonstration of HP had shorter duration of sJIA at MAS onset, higher prevalence of hepatosplenomegaly, lower levels of platelets and fibrinogen and higher levels of triglycerides, and were given more frequently cyclosporine, iv Ig and etoposide. Patients with severe course were older, had a longer duration of sJIA at MAS onset and had a greater frequency of haemorrhages and CNS dysfunction, lower levels of ESR, albumin and fibrinogen, higher levels of LDH, triglycerides and D-dimer, and were treated more commonly with cyclosporine, iv Ig and etoposide.

Conclusion: Clinical, laboratory and histopathologic features of sJIA-associated MAS were overall comparable among patients from different continents, whereas there was a disparity in the therapeutic choices made by specialists practicing in different geographic areas or fields. Patients with demonstration of HP or severe course presented with a more acute clinical and laboratory picture and were treated more aggressively.

Background/Purpose: Mevalonate kinase deficiency (MKD) is a rare hereditary autoinflammatory syndrome that can lead to significant morbidity. Evidence-based guidelines are lacking and management is mostly based on physician's experience. Consequently, treatment regimens differ throughout Europe. In 2012, a European initiative called SHARE (*Single Hub and Access point for pediatric Rheumatology in Europe*) was launched to optimize and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. One of the aims of SHARE was to provide evidence based recommendations for diagnosis and treatment of MKD.

Methods: Evidence based recommendations were developed using the *European League Against Rheumatism* (EULAR) standard operating procedure. An expert committee was instituted, consisting of pediatric and adult rheumatologists. The expert committee defined search terms for the systematic literature review. Two independent experts scored articles for validity and level of evidence. Recommendations derived from the literature were evaluated by an online survey. Those with less than 80% agreement on the online survey or with relevant comments of the experts were reformulated. Subsequently, all recommendations were discussed at a consensus meeting using the nominal group technique. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 618 articles, of which 28 were considered relevant and therefore scored for validity and level of evidence. Fourteen were scored valid and used in the formulation of the recommendations. Sixteen recommendations were suggested in the online survey and discussed during the consensus meeting. Six general recommendations on management, three recommendations for diagnosis, six for monitoring and seven for treatment were accepted with more than 80% agreement. Topics covered are following:

- *general recommendations:* the use of the multidisciplinary team, treatment goals, and vaccinations
- *diagnosis:* diagnostic value of Gaslini diagnostic score, IgD and urinary mevalonic acid excretion
- *monitoring:* the use of AIDAI in clinical studies, monitor frequency, minimal assessments in all MKD and additional assessments in severe MKD patients, risk of infection and macrophage activation syndrome
- *treatment:* NSAIDs, glucocorticoids, IL-1 blockade, etanercept, switching biologicals, colchicine, statins and hematopoietic stem cell transplantation

Conclusion: The SHARE initiative provides recommendations for diagnosis and treatment for MKD and thereby facilitates improvement and uniformity of care throughout Europe.

Steroid-Sparing Effect of Anakinra (Kineret®) in the Treatment of Patients with Severe Cryopyrin-Associated Periodic Syndrome. Bengt Hallén, Mika Leinonen, Torbjörn Kullenberg and Hans Olivecrona. Swedish Orphan Biovitrum, Stockholm, Sweden.

Background/Purpose: Cryopyrin-Associated Periodic Syndromes (CAPS) include a group of rare inherited autoinflammatory diseases consisting of FCAS, Muckle-Wells Syndrome and the most severe form, NOMID. Reduction in the use of steroids as concomitant medication is a treatment goal for anakinra-treated CAPS patients, since inappropriate use of steroids could lead to increased toxicity. Adverse events (AEs) related to the cardiovascular system are along with infections most frequently reported in steroid-treated patients with rheumatic diseases (Hoes et al Ann Rheum Dis. 2007;66,1560–67). Among 16 patients with severe CAPS treated with anakinra and taking steroids at baseline, the mean daily prednisone-equivalent dosage has been reported to decrease from 0.80 mg/kg/day at baseline to 0.033 mg/kg/day after 60 months (Sibley et al. Arthritis Rheum. 2012;64:2375–86). The objective of the present analysis is to further evaluate the steroid-sparing potential and its consequences in an expanded cohort of patients with severe CAPS treated with anakinra.

Methods: A prospective, open-label withdrawal design study of anakinra treatment with long-term extension including 43 patients was conducted at the National Institutes of Health (Goldbach-Mansky et al. NEJM. 2006;355:581–92). The primary efficacy endpoint, Diary Symptom Sum Score (DSSS), collected daily up to 60 months, included 5 symptoms (fever, rash, joint pain, vomiting, headache); each scored from 0 (no symptoms) to 4 (severe symptoms). Use of steroid medication was obtained from the patient diary.

The prednisone dose was to be decreased by 20% at each study visit in which the subject's disease activity was "moderately" or "significantly" improved. Different types of steroids were converted into prednisone-equivalent doses to enable comparisons. The AEs were analyzed with the infection rate (number of infections per patient years of treatment).

Results: During the study, the proportion of patients in the ITT population on steroids decreased from 47.1% at baseline to 33.3% at Month 60. Among the patients using steroids at baseline the mean (SEM) prednisone-equivalent dose was 0.76 (0.31) mg/kg at baseline, but a prompt tapering of their doses during the first 6 months to 0.15 (0.03) mg/kg was seen. At Month 36 and Month 60 there was a further decline in the prednisone-equivalent dose to 0.08 (0.02) and 0.05 (0.02) mg/kg, respectively. There was a rapid significant decrease of DSSS both in patients not using steroids at all and in patients reducing the steroids dose. The decrease was maintained up to Month 60 ($p<0.001$ in both subgroups at each follow-up visit). Among the patients reducing the steroid dose, the rate of infections was reduced from 3.4 events/patient year (Year 1) to 1.4 (Year 5).

Conclusion: The use of steroids expressed as mean prednisone equivalent dose decreased from 0.76 mg/kg to 0.05 mg/kg after 5 years of treatment with anakinra. The treatment effect evaluated by DSSS was maintained at the same low level throughout the study.

2284

Joint Involvement in Pediatric Crohn's Disease Is Related to Higher Disease Activity and Worse Quality of Life. Beata Derfalvi, Gabor Bozsaki, Doloresz Szabo, Aron Cseh, Katalin Eszter Muller, Andras Arato and Gabor Veres. Semmelweis University, Budapest, Hungary.

Background/Purpose: The incidence of arthritis and arthralgia in pediatric patients with Crohn's disease (CD) is reported to be 2–15% and 22%, respectively. The aim of our study was to assess joint involvement with Pediatric CD Activity Index (PCDAI) and to assess quality of life (IMPACT-III). While arthritis in pediatric Crohn's disease is associated with the enthesitis-related JIA subgroup, subclinical sacroiliitis and HLA-B27-association may also be found.

Methods: A cross-sectional study was conducted in 82 pediatric patients with CD (age: 13.7±3.2 years, male:female ratio = 1.2:1, disease duration: 21.6±21, median: 15 months) to assess the prevalence of arthritis, lower extremity enthesitis and arthralgia. Detailed joint physical examination and a modified JAMAR (Juvenile Arthritis Multidimensional Assessment Report) were performed by a pediatric rheumatologist. Regarding disease activity, a PCDAI, IMPACT-III questionnaire and basic laboratory parameters including CRP and platelet count were determined, as well as sacroiliac MRI (n=62) and molecular genetic testing for HLA-B27 (n=72) were assessed.

Results: Altogether 35% (29/82) of the patients had arthritis. At the time of the examination, only 1 child had active enthesitis, 8/29 children had active arthritis indicated by swollen joint(s) - including 4 patients with also restricted range of motion in one or more other joints, suggestive of previous arthritis. Another 15/29 children had evidence of previous arthritis on joint examination. Another 5 patients had a remote history of documented active arthritis. Hip (12/29) and knee (11/29) joints were most commonly affected. Cumulative incidence of arthralgia during the entire course of the disease was 48% (39/82), of whom 22% (18/39) had arthralgia, without arthritis, usually affecting the knee. There was a significant association between arthritis and lower quality of life (IMPACT-III score, $p < 0.01$). In addition, incidence of arthritis and arthralgia correlated with higher CRP and PCDAI independent of age and sex. Arthritis was significantly more common in patients requiring infliximab treatment. None of the patients had sacroiliitis based on MRI, and HLA-B27 positivity was not related to arthritis.

Conclusion: The prevalence of joint involvement such as arthritis and arthralgia in pediatric CD was higher than previously reported when assessment is done by a pediatric rheumatologist. Arthritis was associated with more severe disease, as reflected by higher CRP, PCDAI score, as well as lower quality of life. Enthesitis was uncommon and sacroiliitis and HLA-B27 positivity were not significant associations in our pediatric CD cohort.

Safety and Efficacy of Rilonacept in Patients with Deficiency of Interleukin-1 Receptor Antagonist (DIRA). Dawn C. Chapelle Neal[1], Adriana Almeida de Jesus[1], Yan Huang[2], Yin Liu[2], Raphaela Goldbach-Mansky[2] and Gina Montealegre[1]. [1]NIAMS/NIH, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD.

Background/Purpose: Deficiency of interleukin-1 receptor antagonist (DIRA) is a neonatal-onset autoinflammatory syndrome caused by recessive mutations in *IL1RN* gene, the gene encoding the interleukin-1-receptor antagonist. It is clinically characterized by a perinatal-onset of pustular dermatosis, aseptic multifocal osteomyelitis, and marked elevation of acute phase reactants. In our treated patients, IL-1 blockade with daily anakinra leads to rapid and complete resolution of symptoms and normalization of the acute phase reactants. There is a need, however, for longer acting IL-1 blocking agents that are more convenient to administer and are less likely to cause injection site reactions.

Objectives: The primary objective of this study is to assess the ability of rilonacept to achieve/maintain remission in patients with DIRA who have shown response to anakinra. The secondary objective is to assess the safety of rilonacept in DIRA patients, and to assess its ability to prevent new organ damage.

Methods: Patients with a genetically confirmed diagnosis of DIRA and an adequate response to anakinra are eligible for the study. Per protocol, anakinra was discontinued 24 hours prior to first dose of study medication. A loading dose of rilonacept of 4.4 mg/kg/ week was given and then decreased to a maintenance dose of 2.2 mg/kg/week. Patients who met flare criteria were subsequently escalated to 4.4 mg/kg/week with the option to increase to 6.6 mg/kg/week if needed. Diary and Dermatology scores in addition to ESR and CRP were collected at each visit. Paired t-test analyses were used to compare baseline and the most recent clinic visit data.

Results: Six Caucasian patients have been enrolled**,** 50% male, with a mean age of 4.8 years SD (±1.3). All patients were in remission on anakinra (diary score 0) with a mean dosage of 3.21 mg/kg/day SD (±0.48). The mean follow-up time has been 4.5 months. The diary scores have increased to 0.09 at the last visit, reflecting the onset of nail changes in one patient. All patients (except one) required an escalation in dosage from 2.2 mg/kg/week to 4.4 mg/kg/week due to a transient increase in micropustular lesions mostly in hyperkeratotic areas of the skin (elbow and knee). The micropustular lesions lead to the increase in dermatology scores from 1.3 to 3.2. Despite the mild skin lesions, no new bone lesions were detected and the acute phase reactants have decreased from baseline. No SAE's have occurred and four adverse events have been reported.

Conclusion: Preliminary data in six DIRA patients suggest that doses of rilonacept at 4.4 mg/kg/week are required to achieve remission. Rilonacept treatment provides increased quality of life due to weekly injections. Long acting IL-1 inhibition with rilonacept seems to be a viable option in the treatment of DIRA.

Food Allergy and Celiac Disease in Children with Juvenile Idiopathic Arthritis. Trevor E. Davis[1], Mei-Sing Ong[2], Diana Milojevic[3], Jyoti Ramakrishna[3] and Marc D. Natter[4]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]University of New South Wales, Sydney, Australia, [3]Floating Hospital for Children at Tufts Medical Center, Boston, MA, [4]Children's Hospital Boston, Boston, MA.

Background/Purpose: There are multiple strong associations between gut pathology and rheumatologic diseases. This connection, between primary GI disease and rheumatologic diseases, is manifest in both autoimmune and infectious GI diseases. For example, arthritis is a component of several GI infections (Reactive arthritis following *Salmonella, Shigella, Yersinia, or Campylobacter* species, Whipples disease, and multiple parasitic infections) as well as inflammatory bowel disease and behcet's. Arthritis is also a known extra-intestinal manifestation of celiac disease. There is controversy regarding the prevalence of celiac in adult arthritis and to date only a few small studies exist in children. Additionally, both in children and adults, little is known regarding possible association of food allergies and arthritis. With this study, we endeavored to assess the risk of food allergy and celiac disease in a large population of children with juvenile idiopathic arthritis (JIA).

Methods: We analyzed electronic medical records from Boston Children's Hospital, between the years 1993 and 2014. Children with JIA, food allergy and celiac disease were identified, using tools of the National Center for Biomedical Computing "Informatics for Integrating Biology to the Bedside" (i2b2). We assessed the risk of food allergy and celiac disease in JIA patients, in comparison with the children without JIA.

Results: A total of 1,933,719 children were included in our study. Of this total population 0.21% (n=4,128) had documented JIA, 1.14% had food allergy, and 0.18% had celiac disease (Table 1). Of the subjects with JIA 1.99% had documented food allergy and 1.02% had celiac disease. Children with JIA had an elevated risk of developing food allergy (OR 1.75; 95% CI 1.41 – 2.18; $p<0.0001$), and celiac disease (OR 5.58; 95% CI 4.11 – 7.58; $p<0.0001$).

Table 1.

Disease	Number of patients (%)
Study population (n=1,933,719)	
JIA	4,128 (0.21)
Food allergy	21,953 (1.14)
Celiac disease	3,559 (0.18)
JIA population (n=4,128)	
Food allergy	82 (1.99)
Celiac disease	42 (1.02)

Conclusion: We again find evidence of an association between the gut and rheumatologic disease. We clearly demonstrate an increased risk of celiac in JIA, consistent with the limited data on the subject. We also find a statistically significant increased risk of food allergies in JIA. In celiac evidence supports improvement or resolution of the associated arthritis with the removal of the trigger food, gluten. We do not yet know if the same holds true for food allergies. It is possible food allergies can exacerbate JIA but further work must be done to answer this question.

2287

Cartilage Thickness and Bone Health in Children with Juvenile Idiopathic Arthritis. Marinka Twilt, Dan Pradsgaard, Anne Helene Spannow, Arne Horlyck, Carsten Heuck and Troels Herlin. Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Although treatment options have increased and morbidity has decreased in the last decade Juvenile Idiopathic Arthritis (JIA) may still result in disability. Increasingly ultrasonography (US) has been used to measure cartilage thickness in children with JIA and normal values have been established. Although treatment of JIA has moved away from the use of long term steroids bone health remains a consistent worry in patients with JIA. The relation between cartilage thickness and bone health in patients with JIA has not been studied before. The aim of this study is to determine if there is a correlation between cartilage thickness and bone health index in children with JIA.

Methods: We clinically examine joint activity in 68 children with JIA. Joint cartilage thickness was assessed by greyscale USin knee, ankle, wrist, metacarpophalangeal, and proximal interphalangeal (PIP) joints. Measurements were compared to reference values of a healthy cohort of a previous study. Medical records were reviewed for JIA subtype, treatment and disease duration. Automated determination of bone health index and bone age was made by using BoneXpert (Visiana) software implying digital programmetry (DXR) and conventional hand radiographs.

Results: In total 68 patients (17 males, 51 females) with a median age at investigation of 11 years (range 5–15 years) and median disease duration of 42 months were included. Subtypes represented were; 26 oligoarticular persistent; 13 oligoarticular extended; 17 polyarticular rheumatoid factor (RF) negative; 4 polyarticular RF positive; 8 systemic onset. In total 680 joints were examined for cartilage thickness. Decreased cartilage thickness was present in 27% of the examined joints (181 joints). Most common joint with decreased cartilage thickness was the PIP, followed by the wrist, the least common was the ankle joint. 34 patients had a decreased bone health index and 23 patients a decreased bone age; only 14 patients examined showed a combined decreased bone health index and decreased bone age. Decreased cartilage thickness of the left wrist is found in 29 patients; 48% of these patients also have a decreased bone health index but only 17% have a decreased bone age.

Conclusion: Decreased cartilage thickness is a prominent and frequent feature in JIA. Decreased bone health and bone age is found in approximately half of the patients. Cartilage thickness seems to be correlated with decreased bone health, but less with decreased bone age. Further studies are necessary to study these correlations as decreased cartilage thickness might be an indicator for future bone health and steer treatment decisions.

The Research in Arthritis in Canadian Children Emphasizing Outcomes (ReACCh Out) Cohort: Independent Risk Factors and Medication Use in New Onset Uveitis in Juvenile Idiopathic Arthritis. Jennifer JY Lee[1], Ciarán M. Duffy[1], Jaime Guzman[2], Nick Barrowman[3], Deepti Reddy[3], Kimberly Morishita[2], Lynn R. Spiegel[4], Elizabeth Stringer[5], Michele Gibbon[1], Rae S.M. Yeung[4], Lori B. Tucker[2], Kiem Oen[6], Karen N Watanabe Duffy[1] and ReACChOut Investigators[1]. [1]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON, [2]BC Children's Hospital and University of British Columbia, Vancouver, BC, [3]Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, [4]The Hospital for Sick Children and University of Toronto, Toronto, ON, [5]IWK Health Centre, Halifax, NS, [6]University of Manitoba, Winnipeg, MB.

Background/Purpose: The Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh Out) cohort is a multi-centre prospective inception cohort of newly diagnosed Juvenile Idiopathic Arthritis (JIA) patients. From our analysis of JIA associated new onset uveitis, we reported the first true incidence of uveitis of 2.9% per year and prevalence of 6.9%, the latter considerably lower than previously reported. We identified a positive ANA and young age at diagnosis of JIA (< 7 years) as independent risk factors for uveitis. In this study, we examined the association between medications, uveitis and these independent risk factors.

Objectives: 1) to assess medications administered prior to uveitis and after diagnosis 2) to determine the association between the independent risk factors for uveitis and specific medication use and 3) their association with asymptomatic versus symptomatic presentation.

Methods: The ReACCh Out cohort recruited newly diagnosed JIA patients from 16 Canadian centres between January 2005 and December 2010. Prospective data was collected every 6 months for 2 years, then yearly. Clinical and laboratory data, medications, the presence of uveitis and complications determined by an ophthalmologist, was documented at each visit. Descriptive statistics characterize the uveitis cohort and frequencies were obtained for the medications used. We calculated the relative risk for certain medications, controlled for by the presence or absence of independent risk factors.

Results: 1104 newly diagnosed (≤ 6 months) JIA patients with ≥1 follow-up visit were included. Patients were predominantly female (63%), median age at diagnosis of 9.3 (3.9, 13.0) years. Time from diagnosis to enrollment was 0.3 (0, 1.6) months. Follow-up to last visit was 34.2 (21.5, 48) months. 23 patients, uveitis status not available, were excluded. 77 patients with new onset uveitis were identified. Patients were on the following systemic medications prior to uveitis diagnosis: NSAIDs (71; 92.2%), Methotrexate (34; 44.2%), other DMARDs (7; 9.1%), systemic glucocorticoids (20; 26%), biologics (12; 15.6%). Following diagnosis: NSAIDs (45; 58.4%), Methotrexate (56; 72.7%), other DMARDs (10; 13%), systemic glucocorticoids (23; 30%), biologics (11; 14.3%).

58 (75.3%) patients had asymptomatic uveitis: 43 (74.1%) ANA positive compared to 13 (22.4%) ANA negative. ANA positive uveitis patients were 2.48 and 1.10 times more likely to be placed on methotrexate and biologics respectively, compared to those who were ANA negative. 52 (90%) of the asymptomatic uveitis patients were < 7 years old, compared to 6 (10%) of patients ≥ 7 years old and were 1.29 and 1.32 times more likely to be on methotrexate and biologics respectively, compared to the older group.

Conclusion: In a large inception cohort of newly diagnosed JIA patients followed prospectively, we evaluated medications administered prior to and after the diagnosis, uveitis presentation and independent risk factors for uveitis. The majority of ANA positive patients and of a younger age (< 7 years) at diagnosis of JIA, presented with asymptomatic uveitis, highlighting the important role of these independent risk factors for uveitis screening.

2289

Accuracy of the Use of Administrative Diagnostic Codes to Identify Pediatric in-Patient Musculoskeletal Conditions in an African Tertiary Hospital.

Rosie Scuccimarri[1], Carol Hitchon[2], Sasha Bernatsky[3], Eugene Were[4], Thomas Ngwiri[4] and Ines Colmegna[3]. [1]Montreal Children's Hospital, Montreal, QC, [2]University of Manitoba, Winnipeg, MB, [3]McGill University Health Centre, Montreal, QC, [4]Gertrude's Children's Hospital, Nairobi, Kenya.

Background/Purpose: The spectrum and frequency of pediatric rheumatic conditions in East Africa are unknown. Administrative data that is systematically collected using International Classification of Disease (ICD) codes can provide insight into this issue. The aim of this study was to assess the accuracy of using ICD-10 diagnostic codes in identifying either inflammatory or infectious musculoskeletal conditions requiring hospitalization at the largest pediatric center in East-Africa.

Methods: We reviewed the hospital records of all patients identified as having diseases of the musculoskeletal (MSK) system and connective tissues (CT) by ICD-10 diagnostic codes (M-codes) at discharge from Gertrude's Children's Hospital in Kenya, during a one year period from January to December 2011. ICD coding at this center is performed by medical records personnel based on the diagnosis provided by the treating physician. We evaluated the concordance rate between the physician's diagnosis at discharge and the ICD-10 code assigned.

Results: The total number of admissions during 2011 was 8,011. Among these, 42 patients had an "M-code" diagnosis at discharge (0.5%) and 39 of these had charts available for review. Among those with M-code diagnoses, concordance rates between the ICD-10 code assigned by an administrator and the treating physician's discharge diagnosis was 66.7% (26/39). Specifically, when only the infectious and inflammatory categories of M-codes were included (26 cases), concordance improved to 76.9% (20/26). The specific diagnosis in those with musculoskeletal infections (n=10) included septic arthritis (7/10), pyomyositis (2/10) and infective bursitis (1/10). Seven of these cases were coded correctly (70%). The diagnoses for those with inflammatory conditions (n=16) included 4 with Kawasaki disease; 2 with inflammatory arthropathies; and 10 with non-specific inflammatory M-codes such as unspecified arthritis, arthralgia or joint effusion. The concordance among the inflammatory M-codes was 81.3% (13/16 were coded correctly including all KD cases).

Conclusion: Overall, the concordance of ICD-10 codes assigned in comparison to the physician's discharge diagnosis for categories of inflammatory and infectious musculoskeletal conditions is acceptable. Inflammatory conditions are coded less specifically due to the physicians' use of descriptive terms instead of definitive diagnoses at discharge. Therefore, administrative diagnostic codes could be used to estimate overall frequencies of rheumatic diseases in in-patients in East Africa however, their utility in estimating the frequency of specific inflammatory conditions is limited.

Race and Other Risk Markers of Uveitis in a Prospective Cohort of Children with Juvenile Idiopathic Arthritis.

Sheila T. Angeles-Han[1], Courtney McCracken[1], Steven Yeh[1], Kirsten Jenkins[2], Erica Myoung[3], Daneka Stryker[3], Kelly A. Rouster-Stevens[1], Larry B. Vogler[1], Christine Kennedy[4], Sampath Prahalad[1] and Carolyn Drews-Botsch[5]. [1]Emory University School of Medicine, Atlanta, GA, [2]Children's Healthcare of Atlanta, Atlanta, GA, [3]Emory University, Atlanta, GA, [4]Emory Children's Center, Atlanta, GA, [5]Emory University School of Public Health, Atlanta, GA.

Background/Purpose: Juvenile idiopathic arthritis-associated uveitis (JIA-U) can lead to poor visual outcomes. American Academy of Pediatric guidelines recommend screening every 3 months in children with oligoarticular (oligo) or polyarticular (poly) rheumatoid factor (RF) (−) subtype, ANA positivity, <4 years of arthritis, and onset <7 years old. Identification of other risk markers could help modify current screening and improve outcomes.

Methods: In our prospective cohort of 250 JIA patients, rheumatology and ophthalmology medical record reviews and parent/patient based questionnaires were completed every 3–6 months (2011–2014). We collected data on demographics, arthritis and uveitis, and quality of life/function. We compared children with JIA and JIA-U, and African American (AA) and Caucasians (W) with uveitis.

Results: Our cohort was primarily W females with oligo persistent and poly RF (−) JIA. There were 45/250 (18%) with uveitis of whom 15.6% were AA (Table 1). Compared to JIA alone, JIA-U were more frequently of the oligo persistent JIA subtype (p = <0.001), younger at arthritis diagnosis (p = <0.001), ANA positive (p = 0.029), anti-CCP negative (p = 0.018) and had reduced vision related quality of life and function (p = < 0.001). No children with JIA-U had psoriatic (p = 0.030), systemic (p=0.029) or poly RF (+) (p=0.133) JIA.

On regression analysis, young age at diagnosis (OR = 0.88, (95% CI 0.81–0.98), p <0.001) and oligo persistent JIA (OR 3.15, (95% CI 1.42–6.98), p = 0.011) were predictors for uveitis. AA race approached significance (OR = 2.56, (95% CI = 0.93–7.02), p = 0.068). ANA was not significant after adjustment.

Comparing JIA-U by race, there were fewer AA children then W overall (7/40 (17.5%) vs. 33/40 (82%)) (Table 2). However, there was no significant difference in the frequency of uveitis between AA and W (7/33 (21%) vs. 33/190 (17%), p=0.624). They were similar in age at arthritis diagnosis, JIA subtype, ANA positivity, arthritis characteristics, and treatment. AA were older at uveitis diagnosis (p = 0.018) with more ocular complications –synechiae (p<0.027) and band keratopathy (p<0.011).

Conclusion: In our cohort, uveitis was less frequent in AA children overall. However, we found a similar likelihood of uveitis in AA compared to W (21% vs 17%). AA were older when diagnosed and suffered more ocular complications. We also confirmed known uveitis risk factors (young age at JIA diagnosis and JIA subtype). Further investigation into the role of race should be conducted as uveitis may be more common in AA but diagnosed later leading to increased visual complications, or may be more severe in AA.

Table 1 Characteristics of children with JIA and JIA-associated uveitis

Characteristics N (%)[1]	Group JIA N=205	Group JIA-U N=45	p-value

Canakinumab in Biologic-naïve Versus Previously Biologic-Exposed Systemic Juvenile Idiopathic Arthritis Patients: Efficacy Results from a 12 Week Pooled Post Hoc Analysis. A Grom[1], P Quartier[2], N Ruperto[3], H.I Brunner[1], K Schikler[1], M Erguven[3], L Goffin[3], M Hofer[3], T Kallinich[3], K Marzan[1], C Gaillez[4], K Lheritier[4], K Abrams[5], A Martini[3] and D.J Lovell[1]. [1]PRCSG, Cincinnati, OH, [2]Hôpital Necker-Enfants Malades, Paris, France, [3]PRINTO-Istituto Gaslini, Genova, Italy, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceutical Corporation, East Hanover, NJ.

Background/Purpose: Efficacy and safety of canakinumab (CAN), a selective, human, anti-IL-1β monoclonal antibody, was previously demonstrated in 2 phase III trials.[1] Out of these trials ≥60% of the patients (pts) received a previous biologic and were switched to CAN due to lack of efficacy or for safety reasons, and may be more refractory to another biologic therapy. Efficacy of CAN in biologic-naïve (BN) pts and those previously exposed to biologics (BE) during the first 12-weeks are evaluated.

Methods: Pooled data from CAN naïve pts, enrolled in two phase III trials[1] and an extension phase (up to interim data lock 10 August 2012) were considered. Pts (2–19 yrs) with active SJIA were enrolled and received CAN 4 mg/kg for 12 weeks. CAN naïve pts who entered the trials and received at least one dose of CAN were included in this analysis (N=178 CAN naïve pts). Descriptive efficacy analyses of adapted ACR-JIA responses at Week 12 are provided for the BN and BE pts groups.

Results: At baseline, there were 66 (37%) BN pts whereas anakinra (ANA), tocilizumab (TCZ), etanercept (ETN) and adalimumab (ADA), were the biologics received by 78 (44%), 10 (6%), 58 (33 %) and 9 (5%) pts, respectively. The main reasons for discontinuation of biologics in BE group (n=112) was lack of efficacy (ANA, n=32; TCZ, n=7; ETN, n=56; ADA, n=9) or safety/tolerability (ANA, n=20; TCZ, n=4, ETN, n=0). At Week 12, the BN and BE groups were similar in aACR-JIA 30 and 50 response rates. Numerically higher aACR-JIA 70 and 90 response rates were achieved in BN vs BE pts (Table). aACR-JIA 70 and 90 response rates were similar in pts previously exposed to ANA vs those not exposed to ANA at 12 weeks (aACR-JIA70: 58% vs 63% and aACR-JIA 90:47% vs 50%). Compared to pts who discontinued ANA due to lack of efficacy, there was a trend towards numerically higher aACR-JIA 70 and 90 response rates at Week 12 in pts who stopped ANA for other reasons (aACR-JIA70: 34% vs74%; aACR-JIA90: 25% vs 63%). A numerically higher aACR-JIA 30, 50, 70 and 90 response rates were observed in TCZ naïve pts vs. those pts exposed to TCZ (n=10) at week 12 [aACR-JIA30: 71% vs 50%; aACR-JIA50: 70% vs 50%; aACR-JIA70: 61% vs 50%; aACR-JIA90: 49% vs 40%]. Numerically higher aACR-JIA 70 and 90 responses were observed for ETN naïve pts vs those exposed to ETN at week 12 [aACR-JIA70: 67% vs 48%; aACR-JIA90: 58% vs 31%]; while ADA- naïve pts had similar responses to CAN as ADA-exposed pt (aACR-JIA 70: 61% vs 56%) and they had higher aACR-JIA 90 response (aACR-JIA90: 50% vs 22%) at week 12.

Table. Percentage of patients with adapted JIA ACR (aACR) response* at Week 2, 4 & 12

	Previous exposure to biologics					
	Week 2		Week 4		Week 12	
Total patients N=178	No (n=66)	Yes (n=112)	No (n=66)	Yes (n=112)	No (n=66)	Yes (n=112)
aACR50	75.8%	67.0%	77.3%	69.6%	74.2%	65.2%
aACR70	66.7%	51.8%	72.7%	53.6%	69.7%	55.4%
aACR90	36.4%	36.6%	54.5%	34.8%	60.6%	42.0%

*aACR response= ACR response level plus absence of fever

Conclusion: In general, BE pts achieved aACR-JIA 50,70 and 90 responses to CAN quickly in the first 2 weeks, and maintained their response up to Week 12; albeit at a numerically lower level than BN pts. These data support the consistent efficacy of CAN across different subgroups of pts.

Demographic, Clinical and Treatment Characteristics of the Childhood Arthritis and Rheumatology Research Alliance Registry Systemic JIA Cohort. Ginger L. Janow[1], Laura Schanberg[2], Soko Setoguchi[3], Elizabeth D. Mellins[4], Rayfel Schneider[5], Yukiko Kimura[6] and The CARRA Registry Investigators[7]. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Duke University, Durham, NC, [3]Duke Clinical Research Institute, Durham, NC, [4]Stanford University Medical Center, Stanford, CA, [5]The Hospital for Sick Children, Toronto, ON, [6]Hackensack Univ Medical Ctr, Hackensack, NJ, [7]Childhood Arthritis and Rheumatology Research Alliance, Durham, NC.

Background/Purpose: Systemic JIA (sJIA) is a rare disease whose treatment has changed in the past 10 yrs. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry contains a large cohort of sJIA pts. We aimed to: (1) describe the characteristics of the CARRA Registry sJIA cohort; (2) identify medication usage trends; and (3) identify subgroups at increased risk for poor outcomes.

Methods: 54 US/Canadian sites enrolled 528 sJIA pts as a cross-sectional convenience sample from 2010–2013. Only pts with complete datasets were included in this analysis. We tested binary and continuous variables for subgroup differences among or across groups, using a chi-square or ANOVA, respectively.

Results: 435 pts were included (Table 1). Disease activity was low: 15% had rash, 7% fever, median joint count 0, and median physician global assessment 1. Significant changes in medication usage occurred over the study period: DMARD and TNF inhibitor use decreased while IL-6 inhibitor (IL-6i) use increased (Fig 1). 29% were on corticosteroids at enrollment. African Americans (AA) had higher CHAQ, worse quality of life and poorer ACR functional class (p 0.0004). Pts diagnosed at a younger age (< 2 yrs) had more frequent biologic use and lower overall well being. Joint damage on imaging increased with younger age at diagnosis (p 0.0003). 259 pts had follow-up visits at least 3 mos from enrollment, and disease activity measures improved in these pts. Of 234 pts without active systemic features, 91 had active arthritis (median active joints=4). There were no other disease or demographic differences in the subset with persistent arthritis, but there was increased current IL-6i, steroid and NSAID use and past biologic use compared to those without persistent arthritis.

Conclusion: This study describes the largest sJIA cohort reported to date. Significant changes occurred in medication usage over the study period, but corticosteroids are still frequently used. AA pts had more severe disease, as did pts diagnosed at a younger age. A significant proportion has persistent arthritis despite new treatments. Predictors of persistent arthritis are needed to improve treatment and outcomes in this subgroup.

Lurie Children's Hospital of Chicago, Chicago, IL, [9]University of Chicago, Chicago, IL, [10]Emory University School of Medicine, Atlanta, GA, [11]University of Texas Southwestern Medical Center, Dallas, TX, [12]Seattle Children's Hospital, Seattle, WA, [13]St. Christopher's Hospital for Children, Philadelphia, PA, [14]Duke University Medical Center, Hillsborough, NC, [15]The Children's Hospital of Philadelphia, Philadelphia, PA, [16]Duke University, Durham, NC.

Background/Purpose: Treatment options for systemic JIA (sJIA) have recently expanded to include IL1 and IL6 inhibitors in addition to traditional treatments such as glucocorticoids (GC) and methotrexate (MTX). The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed standardized consensus treatment plans (CTPs) for new onset sJIA to study comparative effectiveness of these treatments using an observational registry. A pilot study was conducted to assess the feasibility of using the CTPs for this purpose.

Methods: New onset untreated sJIA patients (pts) enrolled in the CARRA Registry are treated according to the CTP selected by the treating physician (GC alone; MTX ± GC; IL1 inhibitor (IL1i) ± GC; IL6 inhibitor (IL6i) ± GC). Data is collected at standard intervals for 9 mos from baseline. Physicians could deviate from the chosen CTP for inadequate response at any time. If GC is started, the CTPs suggest an aggressive taper (<50% of the starting dose by 3 mos). Biospecimens are being collected from consenting pts for future use.

Results: 13 of 15 CARRA study sites enrolled at least 1 pt (total 30, range 1–6 pts/site) (Table 1). As of 6/2014, 8 (27%) of 30 pts had reported completing the study. The GC-only CTP was used in only 2 pts (7%) and a biologic was used as initial therapy in 22 (73%). The chosen CTP varied by site, especially with regard to use of biologics vs non-biologics (Table 2). Most common reasons cited for choosing non-biologic CTPs were: usual treatment at site (63%), perceived safer treatment (63%), and pt preference (38%); most common reasons for choosing biologic CTPs: will likely work best (77%), better tolerated (59%), and perceived safer (45%). As of 6/2014, 13 pts (43%) had changed or deviated from the starting CTP. 67% of patients did not consent for specimen collection.

Conclusion: The CARRA sJIA CTP pilot study successfully reached its target enrollment. The study is ongoing for most patients. Despite the absence of randomization, CTP choice is reasonably balanced aside from the GC CTP and appears to be based on physician/center preference. Most providers found the CTPs acceptable to use, and enrollment of additional patients at more CARRA sites to study comparative effectiveness of the CTPs appears feasible. Exploring barriers and improving processes for biospecimen collection consent may increase participation in future studies.

The Presentation and Initial Treatment of Systemic Juvenile Idiopathic Arthritis According to Observational Data from the United States and the United Kingdom. Timothy Beukelman[1], Roberto Carrasco[2], Yukiko Kimura[3], Laura Schanberg[4], Wendy Thomson[5], Kimme L. Hyrich[6], For the CARRA Registry Investigators[7] and For the CAPS Investigators Group[8]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]The University of Manchester, Manchester, United Kingdom, [3]Hackensack Univ Medical Ctr, Hackensack, NJ, [4]Duke University, Durham, NC, [5]Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [6]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [7]CARRA, Durham, NC, [8]CAPS, Manchester, United Kingdom.

Background/Purpose: Systemic JIA (sJIA) treatment has changed dramatically with the introduction of biologic agents, although treatment approaches may differ between countries. We characterized and compared presenting features and initial treatment of sJIA at pediatric rheumatology (PR) centers in the United States (US) and United Kingdom (UK).

Methods: The US data source was the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, an observational registry established in 2010 that collects clinical data on children with incident or prevalent rheumatic disease from >55 clinical sites throughout the US. Children with sJIA who were enrolled in the Registry within 9 weeks of their first encounter with PR were included in the analysis of presenting features and children with clinical data available from 9 to 15 months following their first encounter with PR were included in the analysis of initial treatment. The UK data source was the Childhood Arthritis Prospective Study (CAPS), an observational study established in 2001 that collects clinical data at regular intervals from a cohort of children with newly diagnosed JIA from 7 UK PR centers. All children with sJIA were included in the analysis of presenting features and children with clinical data available from the 12 month visit were included in the analysis of initial treatment. We also evaluated a subset of CAPS children enrolled since 2009 to match the CARRA enrollment period. Presenting features and initial treatments were compared using chi-square, Fisher's exact, and Wilcoxon ranksum tests.

Results: Presenting features are shown in Table 1 and medication use in the first 12 months is shown in Table 2. Disease manifestations were similar between the US and UK except hepatosplenomegaly was more frequent in the US ($p=0.01$). Elapsed time from first symptom to evaluation by PR was similar but slightly shorter in the US ($p=0.01$), and overall most children were evaluated within 2 months. Differences in enrollment procedures precluded valid comparisons of disease activity measures. US patients were more likely to receive biologic agents (specifically anakinra) and systemic glucocorticoids in the first 12 months of disease compared to UK patients.

Conclusion: Presenting features of children with sJIA were generally similar in the two countries. Compared to the UK, initial treatment of sJIA in the US more frequently included anakinra and, to a lesser extent, systemic glucocorticoids, which may represent differences in medication coverage.

Table 1. Presenting Features.

Characteristic	CARRA Registry (US) (N = 64)	CAPS (UK) (N = 90)	CAPS (UK) enrolled since 2009 (N = 21)
Age at first encounter with pediatric rheumatologist (years) (median, IQR)	5.8 (3.2-10.7)	6.7 (3.5-10.6)	7.8 (3.6-10.6)
Female (n, %)	43 (67%)	58 (64%)	12 (57%)
Caucasian race (n, %)	53 (83%)	76 (88%)	17 (90%)
Elapsed time from symptom onset to first encounter with pediatric rheumatologist (months) (median, IQR)	1.0 (0.5-2.4)	1.5 (0.75-3.5)	1.8 (1.2-3.5)
Active joint count (median, IQR)	3 (1-7)	3 (1-6)	5 (2-8)
Physician global assessment (median, IQR)	4 (2-6)	5.6 (3.6-7.2)	6.1 (5.2-6.9)
Parent global assessment (median, IQR)	5 (2-7)	3.4 (0.7-6.2)	5.5 (3.4-8.5)
Pain score	5 (2-7)	4.8 (1.1-7.1)	7.2 (3.8-8.0)
CHAQ score	0.6875 (0.25-1.75)	1.25 (0.375-2.06)	1.43 (0.625-2.125)
Evanescent rash (n, %)	52 (81%)	75 (83%)	16 (76%)
Lymphadenopathy (n, %)	20 (31%)	26 (29%)	7 (33%)
Hepatosplenomegaly (n, %)	15 (23%)	8 (9%)	3 (14%)
Serositis (n, %)	6 (9%)	3 (3%)	0 (0%)

Table 2. Initial Medication Use in the First 12 Months of Disease

Medication	CARRA Registry (US) (N=75)	CAPS (UK) (N=74)	CAPS (UK) enrolled since 2009 (N=21)	P value for comparison between CAPS enrolled since 2009 and CARRA

A Pharmacometric Based Analysis of the Occurrence of Selected Safety Events of Special Interest and Canakinumab Exposure in Systemic Juvenile Idiopathic Arthritis Patients. Micha Levi[1], Thomas Dumortier[2], Nicolino Ruperto[3], Hermine H. Brunner[4] and Olivier Luttringer[2]. [1]Novartis Pharmaceutical Corporation, East Hanover, NJ, [2]Novartis Pharma AG, Basel, Switzerland, [3]Istituto Giannina Gaslini, Genoa, Italy, [4]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Canakinumab (CAN), a human, selective anti-interleukin-1β monoclonal antibody, has demonstrated rapid and sustained efficacy in systemic juvenile idiopathic arthritis (SJIA) patients,[1]and is approved in >30 countries including USA, EU, Canada, UK and Russia. Given the nature of the disease (pediatric

population, rare condition), the phase III program only included limited placebo data. In such a context, the safety profile of CAN has been characterized via a model-based analysis of the dose-exposure-safety event relationship. The purpose of the study is to explore the relationship between CAN concentration and the occurrence of adverse events of special interest (ESI) and related laboratory abnormalities.

Methods: The analysis considered the open-label, part I of phase III trial wherein SJIA patients received CAN 4mg/kg (300 mg max.) every 4 weeks for a maximum of 8 consecutive doses (n=188). Individual CAN concentration time-profiles have been predicted for those patients, by combining the patients' CAN and IL-1β concentration-time data and an established population PK model. This model is a PK-binding model parameterized in terms of clearance of drug and ligand (IL-1β), central and peripheral volume for the drug, interstitial flow rate, ligand production rate and binding affinity which has been developed using all the data available from the entire CAN program. The average serum CAN concentration (Cavg) was calculated from the concentration time profiles for each patient and dosing interval. In each dosing interval, Cavg were compared between patients with and without the following safety events of special interest: AEs of abdominal pain, cough, headache, infection, serious AE infection, pyrexia, and vomiting, as well as lab abnormalities of thrombocytopenia (>3XULN [upper limit normal]), leucopenia (≤0.8 XLLN [lower limit normal]), >20g/L decrease from baseline hemoglobin, neutropenia (<0.9 X LLN), transaminases elevation (>3XLLN), elevated total cholesterol (≥1.5XULN), triglycerides (≥5.7 mmol/L), and >25% decrease from baseline estimated glomerular filtration rate for 2 consecutive visits.

Results: For all adverse ESIs and related laboratory abnormalities, except neutropenia, Cavg was not different for patients who experienced an event compared with those who did not. The mean Cavg for patients with neutropenia was comparable to the 74thpercentile of those patients without neutropenia, however this higher Cavg was not found to be associated with more infection.

Conclusion: A pharmacometric based analysis in SJIA patients treated with a therapeutic dose of CAN, did not find, in the range of CAN exposure observed, any relationship between average CAN exposure and the occurrence of any safety ESI, except for neutropenia. This increased Cavg in patients with neutropenia was not associated with increased infections. These data support the effective and safe use of CAN4mg/kg every 4 week for the treatment of SJIA in patients >2 years old.

Tocilizumab Therapy in Children with Systemic Juvenile Idiopathic Arthritis. DATA from Russian Register of Sjia. Ekaterina Alexeeva[1], Saniya Valieva[1], Rina Denisova[1], Tatyana Bzarova[1], Kseniya Isayeva[1], Tatyana Sleptsova[1], Elena Mitenko[1], Evgeniya Chistyakova[2], Anna Fetisova[1] and Olga Lomakina[1]. [1]Scientific Center of Children's Health of RAMS, Moscow, Russia, [2]I.M.Sechenov First Moscow State Medical University, Moscow, Russia.

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (sJIA) is classified as an acquired autoinflammatory disease. The interleukin-1 and interleukin-6 play a pivotal role in pathogenesis of this disease. The systemic manifestations as well as arthritis in sJIA are related to interleukin-6 action. Tocilizumab is effective drug for the treatment of systemic arthritis refractory to immunosuppressive drugs.

Objectives: To evaluate safety and efficacy of tocilizumab treatment in children with systemic juvenile idiopathic arthritis.

Methods: 829 patients with sJIA were included in the register. 212 received tocilizumab. Analysis of efficacy and safety tocilizumab therapy was performed in 75 patients, whom follow up period was 2 years. Median age was 7,5 years (range; 0,9 to 15 years) and median disease duration was 2,5 years (range; 0.3 to 12 years). Tocilizumab was administrated intravenously at a dose of 8–12 mg/kg every 2 weeks during 2 months then every 4 weeks. All patients received DMARDs, 38 patients received prednisolone at dose 9.5 (6.5; 12) mg/day. Efficacy end points included the American College of Rheumatology (ACR) Pediatric criteria for improvement 30 (ACR30), ACR50, ACR70, ACR90 and criteria of inactive disease and remission. During the follow-up period, significant side-effects were sought and the reduction in oral prednisolone was recorded too.

Results: The ACR Pedi 30, 50, 70 and 90 improvement were achieved by 100%, 75%, 58% and 30% of patients at Week 12 (n=73), by 100%, 90%, 80% and 55% of patients at Week 24 (n=72) and by 100%, 100%, 95% and 70% of patients at Week 52 (n=60), by 100%, 98%, 98% and 85% of patients at Week 104 (n=52), respectively. Inactive disease was achieved by 18/75 of patients at week 12, by 36/75 of patients at week 24, by 42/75 of patients at week 52, by 44/75 of patients at week 104. Remission was achieved by 44/75 of patients at Week 104. The mean dose of oral glucocorticoid was decreased from 0,5 (0,4; 0,7) to 0,1 (0,04; 0,2) mg/kg/day at week 52 ($p<0.001$), was dicontinued in 5 patients by Week 104. The frequently observed non-severe adverse events were nasopharyngitis, upper respiratory tract infections and gastroenteritis. No cases of opportunistic infections, malignancies or death were reported. There were three cases of pneumonia and cellulitis. 30 patients had incidences of neutropenia, 2 – trombocytopenia, 15 – high level of ALT and AST. Tocilizumab treatment was discontinued in 23 patients during the follow-up 52 weeks period. The causes for cancellation were relapse of disease (n=9), lack of efficacy (n=8), self-cancellation by parents because of remission (n=2), parent's refusal (n=1), infusion reaction (n=2) and Crohn's disease (n=1). 7 patients were switched to canakinumab, 3- to rituximab and 4 – to antiTNF blockers. Survival of tocilizumab treatment was 96% at Week 24, 81% - at Week 52, 69% - at Week 104.

Conclusion: Tocilizumab induced remission of extra-articular manifestations, arthritis and normalized laboratory parameters of the disease activity without initiation of treatment with oral prednisolone and increase its dose, thus avoiding severe irreversible complications of glucocorticoid therapy.

Efficacy of Canakinumab in Patients with Systemic Juvenile Idiopathic Arthritis (SJIA) using JADAS Criteria - an Analysis of 12-Week Pooled Data. A. Ravelli[1], H. I. Brunner[2], N. Ruperto[1], P. Quartier[3], A. Consolaro[1], N.M. Wulffraat[4], K. Lheritier[5], C. Gaillez[5], A. Martini[1] and D.J. Lovell[2]. [1]PRINTO-Istituto Gaslini, Genova, Italy, [2]PRCSG, Cincinnati, OH, [3]Necker-Enfants Malades Hospital, Paris, France, [4]UMC Utrecht, Utrecht, Netherlands, [5]Novartis Pharma AG, Basel, Switzerland.

Background/Purpose: Chronic active disease and persistent synovial inflammation can lead to structural damage, joint destruction and impairment of physical function in patients with systemic juvenile idiopathic arthritis (SJIA). The JADAS score[1, 2] 27-CRP (J27), 10-CRP (J10), and cut-off values for inactive (ID), low (LDA), moderate (MDA) and high disease activity (HDA) were designed to monitor the level of disease activity in all JIA subtypes[1]. The efficacy of canakinumab (CAN), a selective, human, anti-IL-1β monoclonal antibody, was previously demonstrated in SJIA in phase III trials using aACR-JIA response criteria. The level of disease activity in CAN-treated SJIA patients, using J10 and J27 in a 12-week pooled (phase III studies) data set is presented.

Methods: Patients (2–19 years of age) with active SJIA were enrolled and received sc CAN 4 mg/kg. This post-hoc analysis focused on a 12-week pooled dataset (from three phase III studies) in a total of 178 CAN-naïve patients, assessing the J10 and J27 scores at Days (D) 15, 29, 57, 85, and applies the appropriate cut-off values for ID, LDA, MDA, and HDA.

Results: The median [Q1, Q3] J10 for completer patients (i.e. patients who complete 12 weeks treatment) was 29.1 [23.1, 33.2] at baseline. The median change [Q1, Q3] from baseline at D15 and D85 was −19.4 [−25.7, −13.4] and −21.2 [−27.7, −16.7], respectively. Results for J27 were very similar. The disease status at all-time points for J10 and J27 is reported in Table 1. Median change from baseline at each time point was consistent between the completers and the full analysis dataset for J10 and J27 (data not shown).

Table 1. J10 and J27-related disease criteria applied to the full analysis dataset (%)

%	Disease state*	Baseline N=178	D15 N=172	D29 N=157	D57 N=131	D85 N=125
J10	ID	0.0	18.0	26.8	34.4	33.6
	LDA	0.0	14.0	11.5	16.8	24.8
	MDA	0.6	19.2	19.7	20.6	16.8
	HDA	99.4	48.8	42.0	28.2	24.8

J27	ID	0.0	18.0	26.8	34.4	33.6
	LDA	0.0	14.0	11.5	16.8	25.6
	MDA	0.6	15.1	16.6	17.6	12.8
	HDA	99.4	52.9	45.2	31.3	28.0

*Cut-off values for ID, LDA, MDA, and HDA, respectively for J10: ≤1, >1–≤3.8, >3.8–≤10.5, >10.5; and for J27: ≤1, >1–≤3.8, >3.8–≤8.5, >8.5

Conclusion: There was a dramatic reduction in disease activity from baseline to D85, with much of the reduction taking place by D15 onwards in both completers and in the full analysis dataset. An increasing proportion of CAN patients achieved ID or LDA - according to J10 and J27 — in the first 12 weeks of treatment, despite corticosteroid tapering, consistent with the previous ID definition from the phase III trials. These data confirm the early onset of effect as well as the short-term and sustained efficacy over 12 weeks of CAN, and suggest that JADAS may represent a useful tool to monitor treatment response.

Canakinumab Treatment Shows Maintained Efficacy in Systemic Juvenile Idiopathic Arthritis (SJIA) Patients at Individual Patient Level: An Analysis of 12 Week Pooled Data. A. Ravelli[1], H.I. Brunner[2], N. Ruperto[1], P. Quartier[3], A. Consolaro[1], N.M. Wulffraat[4], K. Lheritier[5], C. Gaillez[5], A. Martini[1] and D.J. Lovell[2]. [1]Istituto Gaslini-PRINTO, Genova, Italy, [2]PRCSG, Cincinnati, OH, [3]Necker-Enfant Malades Hospital, Paris, France, [4]UMC Utrecht, Utrecht, Netherlands, [5]Novartis Pharma AG, Basel, Switzerland.

Background/Purpose: Key objectives of biologic therapies in systemic juvenile idiopathic arthritis (SJIA) are to induce and maintain inactive disease, according to the ACR 2011 definition. Recent advances in the management of SJIA consider the induction or maintenance of inactive disease according to the JADAS 10-CRP (J10) or 27-CRP (J27) scoring system[1, 2]. The efficacy of canakinumab (CAN), a selective, human, anti-IL-1β monoclonal antibody, was demonstrated in the withdrawal phase of 2 phase III trials[3], but was not evaluated at the individual level. Here, we assessed the maintenance of efficacy at individual level from Week 2 to 12, using the adapted ACRJIA response criteria (aACR) as well as J10 and J27 on the 12-week pooled data set (3 phase III studies).

Methods: For this post-hoc analysis of the CAN Phase III program in SJIA, the change in disease states between Day (D) 15 and D85 for a total of 178 CAN-naïve patients was assessed. Subjects were 2–19 years of age and had active SJIA at enrollment. This shift analysis considered the aACR response and disease activity states related to J10 and J27: Inactive Disease (ID), Low Disease Activity (LDA), Moderate Disease Activity (MDA); High Disease Activity (HDA).

Results: J10 changes during the study period are provided in Table 1. Results for the J27 were very similar to the J10 observations. The D15-D85 aACR shift analyses, including only patients who had a D15 and a D85 value, likewise indicated that the majority of patients maintained or improved their response: NR (n=32): 12.5% of patients improved; aACR30 (n=14): 0.0% were maintained/78.6% improved; aACR50 (n=21): 33.3% were maintained/42.9% improved; aACR70 (n=36): 25.0% were maintained/58.3% improved; aACR90 (n=26): 30.8% were maintained/57.7% improved; aACR100 (n=34): 82.4% were maintained.

Table 1 J10 shift analysis table from D15 to D85*

N (%)	Disease state at Day 15*	Disease state at Day 85* ID	LDA	MDA	HDA
ID	28 (100)	24 (85.7)	1 (3.6)	3 (10.7)	0 (0.0)
LDA	20 (100)	10 (50.0)	10 (50.0)	0 (0.0)	0 (0.0)
MDA	30 (100)	5 (16.7)	12 (40.0)	10 (33.3)	3 (10.0)
HDA	44 (100)	2 (4.5)	6 (13.6)	8 (18.2)	28 (63.6)

*Only patients with both a Day 15 and a Day 85 value are included.

Conclusion: A majority of SJIA patients treated with CAN either maintained or improved their JADAS status or aACR response level from Week 2 to 12. These data confirm the consistent maintenance of efficacy of CAN at the individual level in the first 3 months, irrespective of the measure of treatment response, that is aACR criteria or JADAS-derived criteria, and extend previous findings at group level.

M-Ficolin and Masp-2 As Inflammatory Markers in Oligoarticular and Systemic Juvenile Idiopathic Arthritis. Christine Petri[1], Steffen Thiel[2], Jens Christian Jensenius[2] and Troels Herlin[1]. [1]Aarhus University Hospital, Aarhus, Denmark, [2]Aarhus University, Aarhus, Denmark.

Background/Purpose: The lectin pathway of the complement plays a crucial role in the pathogenesis of various inflammatory processes. The lectin pathway proteins are activated through the recognition of pathogens by the pattern recognition molecules (PRMs), which include the mannan-binding lectin (MBL), and H- and M-ficolin in collaboration with MBL-associated serine proteases (MASPs). PRMs reportedly play a role in rheumatoid arthritis (RA) indicating a correlation between the concentration of these proteins and RA disease activity. The aim was to evaluate the possible pathogenic role of the PRMs in Juvenile Idiopathic Arthritis (JIA).

Methods: We measured MBL, M-ficolin, H-ficolin, MASP-1, -2, -3, and the two alternative splice products, MAp44 and MAp19, in plasma and synovial fluid (SF) of 109 children with persistent oligoarticular JIA and 19 children with systemic JIA. The concentrations of the eight proteins were measured by in-house time-resolved immunoflurometric assays (TRIFMA) using monoclonal antibodies.

Results: We observed significantly higher levels of M-ficolin and MBL-associated serine proteases in plasma from patients with systemic JIA compared to persistent oligoarticular JIA ($p<0.001$). Notably higher levels of M-ficolin and MASP-2 were also found in synovial fluid from patients with systemic JIA (n=11) compared to SF from patients with oligoarticular JIA (n=36). Plasma/SF ratio of the lectin pathway proteins were calculated in paired samples for oligoarticular JIA (n=36) and systemic onset JIA (n=11). We observed significantly high plasma/SF for both subtypes for M- and H-ficolin, MASP-1 and

-2, MAp44 and MAp19, but the MASP-3 levels was significantly higher in SF than in plasma for both subtypes. M-ficolin and MASP-2 was significantly related to erythrocyte sedimentation rate (ESR), C-reactive protein, white blood cell count, platelet count ($p<0.001$). In addition M-ficolin was significantly related to the number of active joints ($p=0.008$) and conversely related to hemoglobin levels ($p=0.017$).

Conclusion: Our results suggest plasma M-ficolin and MASP-2 as inflammatory markers in juvenile idiopathic arthritis. The level of the proteins is higher in plasma than in SF, except for MASP-3, indicating that MASP-3 may be secreted into or produced locally in the joint.

Biologic Treatment in Systemic Juvenile Idiopathic Arthritis: Single Center Experience. Buthaina Al adba[1], Rayfel Schneider[2] and Earl Silverman[3]. [1]sickkids hospital, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]Hosp for Sick Children, Toronto, ON.

Background/Purpose: The prevalence of juvenile idiopathic arthritis (JIA) is approximately 3.3/1000 children and 10– 15% have the systemic form (SJIA). Biologics, specifically anti-IL -1 and anti-IL-6 agents have been introduced to decrease the need for corticosteroids and therefore ameliorate the associated morbidity including growth failure, cataracts, fractures and body image problems.

Methods:

Study design:

Retrospective chart review of 306 patients diagnosed with SJIA at Hospital of sick children from January 1980 to December 2012. Exclusion criteria: Diagnosis not confirmed, <1 year follow-up, <1 visit per year and unable to obtain complete medical record.

Data analysis:

1) Number of patients treated with biologics.

2) Response of: i) Systemic features (fever or rash) and ii) Arthritis.

3) Definition of response for systemic features i) Complete response: no symptoms off steroids. ii) Partial response: no symptoms but on steroids.

4) Definition of response for arthritis: i) Complete response: no active arthritis ii) Partial response: >50% improvement in active joint count.

Results: The cohort consisted of 306 SJIA patients which 58 of them (18%) have received biologic. 28/58 (48%) Since 2009. The main biologic used are anti-IL-1, anti-IL-6 and anti TNF. 41/58 needs one biologic, 10/58 two biologic and 7/58 three or more. Some patients used same biologic more than once. Anti IL-1 was used 47 times in the 58 patients (81%), anti IL-6 used 14 times (24%) and anti TNF used 38 times (65%). The complete response of systemic features was about 70% in both anti IL-1 and anti IL-6 group, however it was 20% in anti TNF group. The complete response of arthritis was 64%, 48% and 31% in anti IL-6, anti IL-1 and anti TNF respectively.

SUMMARY: 1) 58/306 received biologic during the study- 28/58 (48%) since 2009. 2)The main biologics used were: anti-IL-1, anti-IL-6 and anti-TNF agents.3) A complete response of systemic features was found in about 70% for both anti-IL-1 and anti- IL-6 groups but only 20% in the anti-TNF group. 4)A complete response of arthritis was seen in 64%, 48% and 31% in the anti-IL-6, anti-IL-1 and anti-TNF groups respectively.

Conclusion: 1) Since 2009 there was a significant increase in the use of biologic therapies in SJIA. 2) Systemic features responded well to anti- IL-1 and anti- IL-6 but not anti-TNF treatment.3) Arthritis improved by >66% with anti-IL-1 and anti-IL-6 in all patients but not with anti-TNF treatment.4) Further studies with large number of patients are needed to evaluate anti-IL-1 and anti-IL-6. 5) With anti-IL-1 and anti-IL-6 agents, a substantial proportion of patients were able to discontinue steroid.

The New Proposal Classification Criteria for Juvenile Spondyloarthropaties. Ozgur Kasapcopur[1], Metin Sezen[1], Kenan Barut[1] and Cengizhan Acikel[2]. [1]Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]Gulhane Military Medical Academy, Ankara, Turkey.

Background/Purpose: Juvenile spondyloarthropathies (JSpA) are a group of rheumatologic diseases with a disease onset before 16 years of age and are characterized with enthesitis, lower extremity oligoarthritis, involvement of the axial skeleton and HLA B27 positivity. The main problem in the classification of this group of diseases is the difficulty of diagnosis at disease onset and the difficulty to differentiate them from juvenile idiopathic arthritis. The aim of our study was to evaluate the pre-determined classification criteria for children with JSpA and to develop new classification criteria.

Methods: The study group consisted of 113 patients with the diagnosis of JSpA and 150 patients with juvenile idiopathic arthritis (JIA). Enthesitis related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) were included into the JSpA group. Eligible criterion of atypical spondyloarthropathy criteria which can also be used for children, SEA syndrome, ERA, Garmisch- Partenkirchen, ESSG, Amor, ASAS peripheral SpA, ASAS axial SpA criteria were applied to all of the enrolled patients. Odds ratios were determined for the variables of these criteria and for clinical findings in the classification of JSpA and JIA cases. Variables of the major findings of JSpA disease were determined by using probability analysis and clinical characteristics, Specificity, sensitivity and kappa values were determined for the new set diagnostic criteria proposed by us and for the pre-determined criteria in order to evaluate which diagnostic criteria were superior for the diagnosis of JSpA.

Results: Major clinical variables of JSpA group of diseases by using pre-existing criteria are; oligoarthritis, enthesopathies, onset of disease after 6 or 10 years of age, inflammatory lumbar pain, hip arthritis, tarsometatarsal joint arthritis, male sex, rapid response to nonsteroidal antiinflammatory drugs, sacroiliitis (MRI or radiography confirmed), HLA B27 positivity, limitation in lumber mobility test (below 4 cm), family history of SpA group of disease, dactylitis, psoriasis or presence of inflammatory bowel disease. All the variables had a kappa value over 0,8. The usefullness of all of the pre-determined criteria in children was low. The variables of the new set criteria that were determined in our study were summarized below:

Major criterion: Oligoarthritis, enhesopathy, disease onset after 6 years of age, inflammatory lumbar pain.

Minor criterion: Hip arthritis, tarsometatarsal arthrtitis, male sex**,** NSAID response**,** sacroiliitis (in MR or radiography), HLA B27 positivity, limitation in schober test **(,** psoriasis or presence of IBD.

Diagnosis: 2 major+3 minor or 3 major variables. The sensitivity, specificity and kappa value of this criteria were found as 90.3%, 90.7% and 0.807, respectively.

Conclusion: We found that the pre-determined criteria were inadequate for the classification and diagnosis of juvenile spondyloarthropathies. We suggest that new set criteria proposed by us could be used in the diagnosis and classification of JSpA. However, neither the pre-determined criteria nor the new set criteria are adequate and efficacious for the classification and diagnosis of this disease.

Classification of Juvenile Spondyloarthropathies According to ASAS Criteria. Marìa M. Katsicas[1] and Ricardo A. G. Russo[2]. [1]Hospital de Pediatrìa Garrahan, Buenos Aires, Argentina, [2]Hospital de Pediatria Garrahan, Buenos Aires, Argentina.

Background/Purpose: The juvenile spondyloarthropathies (JSpA) are a group of related seronegative rheumatic diseases characterized by involvement of the axial, peripheral large joints and entheses. Sets of classification have been developed in adult patients with SpA. The ASAS classification criteria for axial and peripheral SpA have not been validated in pediatric populations.

Objectives: To assess the sensibility[sen] and specificity[sp] of the ASAS criteria for patients with JSpA. To compare the performance of the ASAS criteria with that of ESSG classification criteria. To identify associations between criteria fulfillment and disease features.

Methods: Consecutive patients with JSpA (defined as ERA, JPsA or UA according to ILAR) followed in our center with complete records were included. Clinical charts and databases were retrospectively reviewed. Randomly selected patients with oligoarthritis, systemic arthritis and polyarthritis RF negative served as controls. Demographic and clinical characteristics, disease duration at first visit and follow up time were recorded. Items corresponding to the ASAS, ESSG, AMOR, seronegative enthesopathy and arthropathy (SEA) syndrome and Modified New York (NY) criteria for SpA and Ankylosing Spondylitis were obtained from first visit and during disease course. Descriptive, summary statistics ([sen], [sp], positive predictive value [PPV],

negative predictive value [NPV]) and Wilcoxon Rank Sum test were used.

Results: 109 patients with JSpA (104 ERA, 2 JPsA, 3UA) were included (M:93), age at onset: 10 (1–15) years, disease duration at first visit 10 (1–15) months, follow-up time 4(1–12)years. Controls: 69 patients with JIA (25 oligoarthritis, 24 polyarthritis RF negative, 20 systemic)**.** At first visit cases showed: 106 (97%) arthritis, 89 (82%) asymetrical oligoarthritis, 69 (63%) elevated CRP, 53 (49%) limitation of lumbar spine motion, 53 (49%) HLA-B27, 46 (42%) enthesitis, 44 (40%) tarsitis, 40 (37%) low back pain (LBP), 32 (29%) good response to NSAIDS, 27 (25%) positive family history, 21 (19%) radiographic bilateral sacroiliitis grade 2–4, 14 (13%) dactylitis, 8 (7%) uveitis, 7 (6%) unilateral sacroiliitis grade 3–4, 7 (6%) diarrhea, 5 (4%) infectious previous disease, 2 (2%) urethritis, 2 (2%) inflammatory bowel disease, 2 (2%) buttock pain, 1 (1%) psoriasis. At first visit (109 patients): 81(74%) patients fulfilled ASAS criteria, 81 (74%) peripheral (p)ASAS, 80 (73%) ESSG criteria, 71 (65%) Amor, 33 (30%) SEA, 26 (24%) NY(23 definite, 3 probable), 26 (24%) axial ASAS. Disease course (102 patients): 100 (98%) fulfilled ESSG criteria, 97 (95%) ASAS, 97 (95%) pASAS, 94 (92%) Amor,75 (74%) NY (63, 12), 42 (41%) SEA, 41 (40%) axial ASAS. ASAS sen 74%, sp 97%, PPV 97%, NPV 71%. ESSG sen 73% sp 94% PPV 95%, NPV 69 %. When tarsisis was added to the ASAS and ESSG criteria, sen increased to 82 and 84% respectively. Fulfillment of pASAS was associated with HLA-B27 (p=0,0022). Axial ASAS with LBP (p=0,00001), sacroiliitis (p=0,0007),HLA-B27 (p=0,0012).

Conclusion: In our cohort ASAS criteria performed as well as ESSG for classification of JSpA. The addition of tarsitis as a clinical criterion would improve the performance of these criteria sets.

Clinical Observation on Ankylosing Spondylitis Patients with Different Phenotypes. Zhiming Lin[1], Jun Qi[2], Jieruo Gu[1] and Pingping Zhang[3]. [1]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China, [2]The Third Affiliated Hospital of Sun Yat-sen University, guangzhou, China, [3]Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background/Purpose: Juvenile and adult forms of ankylosing spondylitis (AS) have been shown different in initial symptoms, clinical presentation, imaging manifestations and prognosis. So, according to the diagnostic criteria of adult ankylosing spondylitis (AAS),it is difficult to diagnose early and treat timely for the Juvenile ankylosing spondylitis(JAS).Meanwhile, the JAS mostly will progress to adulthood, the delayed diagnosis and treatment may seriously affect the prognosis and the quality of life in adulthood, We did this retrospective analysis to compare the similarities and differences between the two phenotypes of AS in southern Chinese Han patients, so as to provide foundation for the early diagnosis and treatment for JAS.

Methods: Case records of 576 patients diagnosed as AS according to modified New York criteria(1984) were reviewed. All the patients satisfied the ACR classification criteria for AS.They were grouped according to age: those with onset of symptoms before the age of 16 years were classified as JAS, and patients older than 16 at onset were classified as AAS. Data on age at disease onset, initial symptoms, clinical features, uveitis and imaging manifestations were recorded.

Results: There were 165 patients with JAS and 411 with AAS. The former had higher male preponderance(10.8:1 VS 4.3:1, P<0.01) and more frequent onset with peripheral arthritis(P<0.001), while most AAS with initial symptoms of lumbosacral pain. Peripheral joints involved in JAS include lower extremity joints such as the hip, knee, ankle and heel, followed by the upper limb joints, such as the shoulder, elbow and wrist. Positive family history was present in 28 JAS patients (16.97%) and 84 (28.44%) in JAS(p0.05).JAS patients also had greater involvement of hip joints than AAS(P<0.001).The incidence of spinal involvement was significantly lower in JAS than that in AAS(P<0.001).Through the x - ray examination, the spinal lesions in JAS were characterized by osteoporosis and blurred articular surface, but in AAS were sclerosis of spine bone, formation of syndesmophyte and bony bridge, bone loss and osteoporosis. The incidence of anterior uveitis was also comparable: 4.91% (8 patients) in JAS and 11.44%(47 patients) in AAS(P<0.05).BMD T-score at the femoral neck was significantly lower in JAS than that in AAS(p<0.05). In addition, the mean time from onset to final diagnosis was much longer in JAS than in AAS (P < 0.01);for those patients with the onset symptoms of Peripheral joints, the mean time from onset to symptoms of axial joints much longer in JAS than in AAS (P < 0.001).

Conclusion: Gender advantage in JAS was more obvious, and JAS had onset more often with peripheral arthritis than with Spinal symptoms. Hip joint involvement was more common in JAS than AAS. The femoral neck BMD was reduced much seriously in JAS compared with that in AAS, while there was lower incidence of ophthalmia in JAS than AAS, clinicians should focus on the different manifestations in JAS and AAS,so as to make early diagnosis, provide aggressive treatment and prevent complications.

2304

Positive HLA-B27 in Juvenile Spondyloarthritis Is Associated to Early Sacroiliitis and Progression to Ankylosing Spondylitis. Mariana O Perez[1], Nadia E Aikawa[1], Solange Carrasco[1], Percival D Sampaio-Barros[2], Celio R. Gonçalves[2], Carla G.S. Saad[2], Julio C. B. Moraes[2] and Cláudia Goldeinstein-Schainberg[2]. [1]University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Juvenile spondyloarthritis (JSpA) manifests with axial and peripheral involvement, enthesitis and HLAB27+ in 60–90% children. Radiological sacroiliitis may occur within 10 years, representing an important prognostic factor. To determine initial and long term clinical profiles of JSpA patients from a single tertiary university center; HLAB27 prevalence and relationship with disease progression to ankylosing spondylitis (AS), according to ASAS criteria.

Methods: Descriptive cross-sectional study of a cohort of JSpA subjects. Demographic, clinical and radiological data were obtained by chart review and HLA-B27 tested by flow cytometry (Becton Dickinson). Fisher and McNemar′s tests were used for statistical analyses and p<0.05 considered significant.

Results: Fifty patients with JSpA were evaluated, mean age=31.5±11.1yrs (15–60), mean age at onset=12.2±2.73yrs (7–16), mean age at diagnosis=19.8±9.0yrs (7–44), mean disease duration=18.9±11.4yrs (3–44). Most were males (44M:6F,88%) and whites (n=42,84%). Eleven (22%) children had a 1st-degree relative with SpA and 87% (34/39) were HLAB27+. At diagnosis (Table), peripheral manifestations prevailed, particularly asymmetric oligoarthritis while axial involvement was mainly inflammatory back and buttocks pain; 21 (42%) had enthesitis, all at the Achilles insertion; major extra-articular manifestation was anterior uveitis. After a mean follow up period of 12.8±9.13yrs (1–45), 5 patients were lost, axial involvement was predominant, none had uveitis and enthesitis remained in 13/21 (Table). Radiological sacroiliitis developed in 96% (n=48) patients: 41.7% (n=20) ≤5yrs, 16.7% (n=8) within 6–10yrs and 41.7% (n=20) >10yrs of initial symptoms. Remarkably, HLA-B27+ children had earlier sacroiliitis ≤5yrs of diagnosis (p=0.02), high ESR at diagnosis (p=0.04) and developed AS (p=0.02). Sacroiliitis progression was not prevented (p0.05) despite daily NSAIDs therapy intake by all patients. Sulfasalazine was used by 86% and MTX by 72%. Currently 49% are receiving anti-TNF drugs.

Table: Clinical manifestations of patients with JSpA

Manifestations	At Diagnosis (n=50), n (%)	Currently (n=45), n (%)	p values
Peripheral	35 (70)	13 (28.8)	0.0001
Asymmetry oligoarhritis	24 (68.5)	8 (61.5)	0.19
Symmetry oligoarthritis	1 (2.8)	1 (7.6)	0.002
Polyarthritis	10 (28.5)	5 (38.4)	0.008
Axial	29 (58)	43 (95.5)	0.001
Pain in buttocks	22 (75.8)	0	0.0001
Inflammatory back pain	25 (86.2)	18 (41.8)	0.001
Extra-articular	14 (28)	1 (2.2)	0.03
Anterior uveitis	12 (85.7)	0	0.01
Gastrointestinal	2 (14.3)	1 (100)	0.009
Oral ulcers	1 (7)	0	0.009
Enthesitis	21 (42)	13 (28.8)	0.26
Calcaneus	21 (100)	11 (84.6)	0.02
Hips	0	1 (7.7)	0.12
Spinous process L5	0	2 (15.3)	0.05

Conclusion: Brazilian JSpA patients are typically white males with initial peripheral joint and enthesitic involvement that progress to axial disease. The high prevalence of HLAB27+ in JSpA associated to early sacroiliitis, elevated ESR at diagnosis and development of AS strengthen its role as a genetic marker of disease severity in children.

Improving Screening for Hyperlipidemia in Patients with Rheumatoid Arthritis at an Academic Rheumatology Practice. Ashwini Komarla and Alexis Ogdie. University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Cardiovascular disease is the leading cause of mortality in the rheumatoid arthritis (RA) population. However, cardiovascular risk factors such as hyperlipidemia are undertreated in patients with RA compared to other high risk groups like diabetics. We examined the effectiveness of two interventions to increase screening for hyperlipidemia among patients with RA within the rheumatology practice of an academic medical center.

Methods: Interventions included a web-based survey regarding attitudes towards lipid screening in patients with RA sent to physicians in the division of rheumatology at the University of Pennsylvania on 1/6/14 and posters and flyers about cardiovascular risk in inflammatory arthritis posted in each clinic's check-in area and exam rooms between 2/1–2/28/14. A query of our electronic health record was used to generate a list of patient visits with an ICD-9 code for RA seen in the practice between 7/1/13 - 4/15/14. Charts were reviewed for a random sample of 100 patient visits for the periods before and after the interventions (7/1 - 1/5/14 and 2/1 – 4/15/14 respectively). Patients were excluded if the rheumatologist had not documented a diagnosis of RA in the encounter note. If multiple visits for the same patient were found in the sample, the last visit in that period was used. The outcome was achieved if lipid screening was documented as performed in the encounter note or if results were recorded in the encounter note or in the laboratory section within 3 years of the visit date. The prevalence of up to date lipid screening in each period was assessed, and the groups were compared using the chi-squared test.

Results: Seventy-eight patients in the pre-intervention group and 82 in the post-intervention group satisfied inclusion criteria. Demographics are listed in the Table. Lipid screening was considered up to date in 39 of the 78 patients (50.0%) in the pre-intervention group and 57 out of the 82 patients (69.5 %) in the post-intervention group ($p=0.01$).

Conclusion: Among patients with RA, the management of traditional cardiovascular risk factors, including lipid screening, is suboptimal. Flyers and posters increased the prevalence of documented lipid screening in the short term. The survey of physician attitudes towards lipid screening likely also increased awareness of practice patterns among rheumatologists. Further quality improvement initiatives are needed to identify long term solutions to improve the recognition and management of traditional cardiovascular risk factors among patients with RA.

Table. Demographics of the Pre and Post Intervention Groups

		Before N= 78	After N=82

Quality of Care for Cardiovascular Prevention in RA: Compliance with Diabetes Screening Guidelines. Timothy J Schmidt[1], J Antonio Avina-Zubieta[1], Eric C. Sayre[2], Michal Abrahamowicz[3], John M. Esdaile[4] and Diane Lacaille[5]. [1]University of British Columbia, Department of Experimental Medicine, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]McGill University, Montreal, QC, [4]University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, BC, [5]Arthritis Research Centre of Canada, Vancouver, BC.

Background/Purpose: Comorbidities are increasingly recognized as significant contributors of decreased quality of life, and increased mortality in RA. RA is associated with an increased risk of diabetes and cardiovascular mortality. Previous research suggests that RA populations receive sub-optimal care for their non-RA health related issues.

Our aim was to evaluate the quality of care for cardiovascular disease prevention in RA by measuring compliance with general population diabetes screening guidelines in RA compared to the general population.

Methods: We conducted a retrospective matched cohort study among patients with RA who received care between Jan 1996 and Mar 2006 and followed-up until Dec 2010. RA cases were selected if they had ≥2 MD visits more than 2 mos apart with an RA code. Cases were excluded if they had ≥2 subsequent MD visits for other inflammatory arthritis; if they saw a rheumatologist and RA diagnosis was never confirmed; or if there were no subsequent RA diagnoses over a follow-up > 5 yrs (N=36,458). Controls were selected from the general population and matched 1:1 to RA cases on gender, age, and calendar year. Administrative data was obtained on all physician visits, hospital admissions, tests ordered and medications.

Outcome: Compliance with current screening guidelines for diabetes defined as testing for plasma glucose (PG) at least once every 3 years for individuals ≥ 45years, excluding individuals with previous diabetes. Individuals' follow-up was divided into 3-year eligibility windows, when they were eligible for the screening guideline. Each individual could contribute up to four three-year eligibility windows. Compliance was measured as the proportion of eligibility windows with at least one PG test performed within the time period. Compliance rates between RA and controls, using eligibility windows as the unit of analysis, were compared via a GEE model to account for the lack of independence of observations obtained from the same patient, adjusting for age and gender. Compliance rate per patient was also calculated, as the proportion of eligible windows per patient during follow-up when screening was performed. Mean compliance rates in the RA sample were compared to controls using a Mann-Whitney U test.

Results: We identified 27,650 individuals with RA (68.8% female, mean [SD] age 62.5 [12.9] yrs), contributing 49,515 three-year eligibility windows; and 30,486 controls (68.6% female, age 62.3 [12.9] yrs), contributing 62,942 three-year eligibility windows. Overall, PG was measured in 71.2% of the eligible time windows in the RA sample and in 74.4% for controls (OR=0.89 [95% CI; 0.86, 0.92], $p<.0001$). RA individuals met the recommended screening guidelines in 72.1% (SD=37.1%) of their eligible time windows, compared to 74.1% (SD=35.3%) for controls ($p<.001$).

Conclusion: Compliance with screening guidelines for diabetes was slightly lower in our RA cohort than the general population. Although the difference was statistically significant, it may not be a clinically relevant difference. Regardless, given the increased prevalence and burden of cardiovascular diseases in RA, diabetes screening is sub-optimal for RA individuals.

Cardiovascular Disease Prevention in Rheumatologic Disease: Assessing Screening in a Primary Care Setting. Micaela Bayard[1] and Magdalena Cadet[2]. [1]New York Hospital of Queens/ Weill Cornell Medical Center, New York, NY, [2]Duke University School of Medicine, Durham, NC.

Background/Purpose: To determine the proportion of patients diagnosed with rheumatologic disease receiving preventive health care according to US Preventive Services Task Force recommendations with emphasis on hypertension, dyslipidemia, and glucose tolerance screening. Cardiovascular disease is the most prevalent co-morbidity for patients with Rheumatoid Arthritis, specifically ischemic cardiac disease. Studies have shown that more than half of premature deaths in people living with Rheumatoid Arthritis are attributable to cardiovascular disease. Studies also demonstrate a significantly increased risk of coronary artery disease in other inflammatory diseases including Systemic Lupus Erythematous, Gout, and Psoriatic Arthritis. Enhanced atherosclerosis in rheumatic disease is a result of higher rates of systemic inflammation. Despite the recognized risk of cardiovascular disease in rheumatologic disease, little is known about cardiovascular risk management in these patients.

Methods: Clinical data from June 2013 to November 2013 was abstracted from outpatient electronic medical records of patients seen in rheumatology clinic with primary care follow-up with one of the following International Classification of Diseases, Ninth Revision (ICD-9) codes: Rheumatoid Arthritis (714.0), Systemic Lupus Erythematous (710.0), Psoriatic Arthritis (696.0), and Gout (274.0). 69% had Rheumatoid Arthritis, 13% had Systemic Lupus Erythematous, 18% had Psoriatic Arthritis, and 13% had Gout, this included patients with more than one of the 4 ICD-9 codes. Charts were reviewed for blood pressure testing at the most recent primary care visit, a lipid profile within the last year, and glucose or Hemoglobin A1C testing within the last year. These probabilities were summarized and compared between disease categories using Pearson's chi-square test.

Results: A total of 46 men and 121 women, with a mean age of 55.2 years, were identified. 79 were identified by having at least one of the four target ICD-9 codes. In this cohort, 100% were screened for hypertension, 24% for hyperlipidemia, and 27% for diabetes. Of the women, 100% were screened for hypertension, 24% for hyperlipidemia, and 29% for diabetes. There was no significant difference in screening between men and women. Rheumatoid Arthritis patients were more likely to be screened for diabetes, when compared to patients with Systemic Lupus Erythematous, Gout, or Psoriatic Arthritis (43% vs 12%, $p < .05$).

Conclusion: This data suggests that patients with rheumatologic diseases known to accelerate risk for cardiovascular disease are not being consistently screened in primary care settings. The data also suggests that physicians may be more aware of recommendations for cardiovascular screening in rheumatoid arthritis and less in other rheumatologic diseases. Although traditional cardiovascular risk factors may be suboptimal screening tools for patients with rheumatologic disease, studies must first identify gaps in existing screening and intervention. Further research is needed to develop cardiovascular screening guidelines and risk stratification models, as seen in diabetes, which are specific to rheumatologic disease.

Quality of Care for Cardiovascular Disease Prevention in RA: Compliance Lipid Screening Guidelines. Timothy J Schmidt[1], J Antonio Avina-Zubieta[2], Eric C. Sayre[3], Michal Abrahamowicz[4], John M. Esdaile[5] and Diane Lacaille[6]. [1]University of British Columbia, Department of Experimental Medicine, Richmond, BC, [2]University of British Columbia, Department of Experimental Medicine, Vancouver, BC, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]McGill University, Montreal, QC, [5]University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, BC, [6]Arthritis Research Centre of Canada, Vancouver, BC.

Background/Purpose: Comorbidities are increasingly recognized as significant contributors of reduced quality of life and increased mortality in RA. Cardiovascular diseases are the leading cause of premature death in RA. Previous research suggests that RA populations may receive sub-optimal care for their non-RA health related issues.

Our aim was to evaluate the quality of care for cardiovascular disease prevention in RA by measuring compliance with general population hyperlipidemia screening guidelines in RA compared to the general population.

Methods: We conducted a retrospective matched cohort study among patients with RA who received care between Jan 1996 and Mar 2006 and followed-up until Dec 2010. RA cases were selected if they had ≥2 MD visits more than 2 mos apart with an RA code. Cases were excluded if they had ≥2 subsequent MD visits for other inflammatory arthritis; if they saw a rheumatologist and RA diagnosis was never confirmed; or if there were no subsequent RA diagnoses over a follow-up > 5 yrs (N=36,458). Controls were selected from the general population and matched 1:1 to RA cases on gender, age, and calendar year. Administrative data was obtained on all physician visits, hospital admissions, tests ordered and medications.

Outcome: Compliance with current screening guidelines for hyperlipidemia defined as testing for lipids at least once every 5 years for women ≥ 50 and men ≥ 40, excluding individuals with previous diabetes, coronary artery disease, or hyperlipidemia. Individuals' follow-up was divided into 5-year eligibility windows, when they were eligible for the screening guideline. Each individual could contribute up to two five-year eligibility windows. Compliance was measured as the proportion of eligibility windows with at least one lipid test performed within the time period. Compliance rate between RA and controls, using eligibility windows as the unit of analysis, were compared via a GEE models to account for the lack of independence of observations obtained from the same patient, adjusting for age and gender. Compliance rate per patient was also calculated, by measuring the proportion of eligible windows per patient during follow-up when screening was performed. Mean compliance rates in the RA sample were compared to controls using a Mann-Whitney U test.

Results: We identified 13,117 individuals with RA (64.5% female, mean [SD] age 59.0 [11.3] years), contributing 5,273 five-year eligibility windows; and 14,694 controls (65.0% female, age 59.0 [11.4] years), contributing 7,228 five-year windows. Overall, lipids were measured in 75.4% of the eligible time windows in the RA sample and in 76.7% for the control sample (OR[95% CI]=0.94 [0.86, 1.02], p=0.12). RA individuals met the recommended screening guidelines in 77.6% (SD= 37.5%) of their eligible time windows, compared to 78.5% (37.0%) for controls (p=0.22).

Conclusion: In our population-based RA cohort, compliance with general population guidelines for diabetes and hyperlipidemia screening was similar in people with RA and the general population. However, given the increased prevalence and burden of cardiovascular disease, plasma glucose and lipid screening was sub-optimal for RA individuals.

A Novel Approach to Assess Wait-Times to Rheumatologists. Jessica Widdifield[1], Claire Bombardier[2], J. Carter Thorne[3], R. Liisa Jaakkimainen[4], J. Michael Paterson[1], Sasha Bernatsky[5], Jacqueline Young[1], Laura Wing[1], Noah Ivers[2], Debra Butt[1], Vivian Poon[1], Vandana Ahluwalia[6] and Karen Tu[1]. [1]Institute for Clinical Evaluative Sciences, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [4]Sunnybrook Health Sciences Centre, Toronto, ON, [5]McGill University Health Centre, Montreal, QC, [6]William Osler Health Center, Brampton, ON.

Background/Purpose: Previous studies quantifying delays in assessment of patients by rheumatologists have studied patients from rheumatology clinics and thus include all patients who ultimately had access to rheumatologists. Our study estimates overall wait times for initial rheumatology consultations for patients referred by their primary care physician.

Methods: We employed a novel approach to identify first-time rheumatology referrals from the primary care Electronic Medical Record Administrative data Linked Database (EMRALD), representing comprehensive EMR data from 168 primary care physicians across Ontario, Canada (32 rural, 39 suburban and 97 urban physicians). We randomly sampled patients with rheumatology referral letters and performed linkage with administrative data to retrospectively confirm that patients had no prior rheumatologist assessments. Using a standardized data abstraction tool, the entire patient medical record was reviewed to categorize each patient according to their diagnosis: systemic inflammatory conditions, mechanical/degenerative/arthritic conditions, chronic pain, regional musculoskeletal (MSK) syndromes, osteoporosis/osteopathies, and other (e.g., abnormal diagnostic tests). Administrative data were then used to identify the date of the first rheumatologist visit subsequent to the date recorded on the referral identified in the EMR. The time in days from the date the first referral letter was sent to the date of the first rheumatologist visit was determined overall and for each diagnostic category.

Results: Among 1086 patients with first-time referrals, 99% of referrals analyzed occurred between 2006 and 2013. The majority of referrals were for mechanical/degenerative conditions (34%) and systemic inflammatory conditions (30%). Overall, 36% of patients were seen by a rheumatologist within 6 weeks from referral and 67% within 3 months. 68 (6%) patients were waiting longer than 12 months to be seen (Table). The average wait time to

see a rheumatologist for any condition was 142 days (median 61) post-referral. For patients with systemic inflammatory conditions, the median time to be seen was 47 days (interquartile range 18–97). The median wait times for individuals with conditions deemed non-urgent (osteoarthritis, chronic pain) were roughly 2 weeks longer.

Conclusion: Using EMRs from a representative sample of Ontario primary care practices revealed longer wait times to see a rheumatologist than previous Canadian reports that sampled patients from urban rheumatology clinics. 33% of patients were still waiting >3 months to be seen, exceeding current Canadian recommendations. Individuals with systemic inflammatory conditions were seen earlier compared to other types of referrals. An analysis of wait times along each component of the care pathway is currently underway.

Improving Access to Health Care in Rheumatology Practices through Initiation of an Outpatient Urgent Care Clinic, a Paradigm Shift. Ruchi Jain, Meenakshi Jolly, Theodore Pincus, Isabel Castrejón, Annie Huang and Joel A. Block. Rush University Medical Center, Chicago, IL.

Background/Purpose: Urgent care clinics are built into some primary care practices, but no reports are available of urgent care clinics in rheumatology settings. Many rheumatologists currently reserve slots in their schedules to accommodate patients with urgent needs. However, this practice may be inadequate as the slots may become filled by waitlisted, follow-up, or new patients, particularly in academic practices where providers may see patients only a few days per week. A survey of patients with rheumatic diseases indicated that 50% reported inadequate provider access for urgent concerns, which was greater among patients of providers whose clinical activities involved fewer rather than 5 days per week. We studied patients seen at an academic rheumatology urgent care clinic to analyze possible reduction in emergency room (ER) visits, and possible improved patient confidence that timely care by their rheumatologist is available.

Methods: A weekly urgent care clinic was initiated for established patients under care at an academic rheumatology setting who had issues that could not wait until their next appointment, as well as for recently discharged inpatients with need of early outpatient follow up. A control group of 100 patients seen sequentially in routine care was identified, and compared to the urgent care group using t tests and chi square tests. Each patient in the control and urgent care group completed a multidimensional health assessment questionnaire (MD-HAQ) at each visit as part of routine care, with scores for physical function, pain, patient global assessment, RAPID3 (routine assessment of patient index data), and demographic data. Each physician scored a contemporaneous physician global assessment. An additional survey for urgent care clinic patients queried if patients would have gone to the ER if not seen today (Yes or No) and the level of the patients' confidence that future urgent concerns would be met (0=no confidence - 10=great confidence).

Results: Demographics of the 42 patients and 100 controls are in Table 1. Those seen in the urgent care clinic were older, less likely to work full time, and more likely to have osteoarthritis than the controls. MDHAQ scores were significantly higher in the urgent care clinic vs controls (Table 1**).** 61% of urgent care patients reported that they would have gone to the ER if the urgent care clinic were not available, and mean confidence score of patients in the urgent care clinic group was 9.75 on a 0–10 scale.

	Control Group N=100	Urgent Care Group N=42	P
Female, n (%)	81 (81.0%)	34 (80.9%)	0.99
Age, mean (SD)	51.8 (16.8)	59.9 (15.8)	0.01
Ethnicity, n (%)	–	–	–
Caucasian	48 (48%)	13 (31.7%)	0.11
Afro-American	36 (36%)	22 (53%)	
Hispanic	8 (8%)	5 (12.2%)	
Others	8 (8%)	2 (3.1%)	
Education, mean (SD)	14.6 (2.9)	14.1 (2.7)	0.45
Work Full time, n (%)	34 (40%)	5 (19%)	0.05
Diagnosis, n (%):	–	–	–
RA	29 (29%)	9 (21.9%)	0.037
OA	9 (9%)	10 (24.4%)	
SLE	16 (16%)	2 (4.8%)	
Crystal Diseases	3 (3%)	5 (5.7%)	
Other Diseases	43 (43%)	16 (43.2%)	
Physician Global (0-10), mean (SD)	3.6 (2.2)	5.4 (1.0)	<0.001
Patient Global (0-10), mean (SD)	4.3 (2.9)	7.2 (1.6)	<0.001
PAIN (0-10), mean (SD)	4.6 (3.3)	7.3 (2.2)	<0.001
FUNCTION (0-10), mean (SD)	2.3 (2.2)	4.5 (2.9)	<0.001
RAPID3 (0-30), mean (SD)	10.9 (7.4)	17.7 (4.3)	<0.001
Anxiety (0-3.3)	0.57 (0.77)	0.91 (0.16)	0.03
Depression (0-3.3)	0.44 (0.73)	0.82 (0.97)	0.018

All scores are mean (standard deviation=SD)

Conclusion: Patients seen in the urgent care clinic had poorer clinical status than control patients, with higher patient and physician scores. 61% would have gone to the ER had they not been seen in the urgent care clinic. These patients also expressed high confidence that timely access would be available in the future. Improved patient access for urgent needs may be met by a dedicated urgent care clinic.

Tele-Rheumatology: Despite Improved Access Could There be a Potential Delay in Care without a Skilled "Presenter"? Zsolt Kulcsar[1], Daniel A. Albert[2], Krista Merrihew[3] and John Mecchella[4]. [1]Dartmouth Hitchcock Medical Center, lebanon, NH, [2]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH, [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [4]Giesel school of medicine and Dartmouth Hitchcock Medical Center, Lebanon, NH.

Background/Purpose: Arthritis treatment in New Hampshire (NH) is complicated by the fact that a large proportion of the population lives in rural areas (60%) with limited resources and access to care. Tele-rheumatology services developed at Dartmouth-Hitchcock Medical Center (DHMC) in partnership with Weeks Memorial Hospital (Critical Access Hospital in Northern NH) bring arthritis care to these rural regions, thus improving access. In addition to the providers and patients tele-medicine utilizes a "presenter," an individual who sits with patients at the remote site (medical assistant, nurse, etc.) to facilitate the visit. We sought to learn what challenges and accomplishments our early tele-medicine program has encountered since inception.

Methods: As part of a quality improvement initiative we performed an IRB-exempt retrospective review of the charts for patients seen in the tele-rheumatology clinic at DHMC from October 2011 to January 2013. We also interviewed the participants: including providers, presenters and patients regarding their experience of care. We used descriptive statistics to summarize our findings.

Results: In our cohort of 22 patients there were 63 encounters (18 initial consults and 45 follow-up visits) with either of the two participating rheumatologists. 27% (n=6) of the patients seen initially by tele-rheumatology needed to be seen in-person for clarification of the joint exam. 83% (n=5) of the patients seen in-person had findings of synovitis not seen via telemedicine. The average time from initial consult to in-person evaluation was 81 days. These patients went without aggressive anti-inflammatory therapy for longer than the recommended 42 days (6 weeks) according to current guidelines. Providers expressed concern about not being able to lay hands on patients, and the inability of the "presenter" to perform and convey the findings of the joint exam which may have contributed to the delay in care. The top two diagnosis that patients presented with during the tele-rheumatology visits were inflammatory arthritis (n=10) and fibromyalgia (n=9). 40% of the patients seen by tele-rheumatology were ultimately started

on high risk medications such as high dose steroids (prednisone>20mg/daily), biologics, and DMARDs (Table 1).

Conclusion: The use of tele-rheumatology has successfully increased access to arthritis care in rural regions of NH allowing for shorter travel and intense anti-inflammatory therapy. The lack of musculoskeletal training for the presenter and inability of providers to lay hands on patients could lead to increased delay in initiation of this therapy for inflammatory arthritis. Initial strategies are being developed to improve the training of the presenters and to shorten this interval to meet current guidelines.

Table 1. Dartmouth-Hitchcock Medical Center Tele-rheumatology Services Patient Characteristics

Characteristic	N (%)
Providers	
Patients seen by Provider #1	5 (22.7)
Patients seen by Provider #2	17 (77.3)
Total # of Patients seen since inception	22
Total # of visits	63
Patients	
Age (avg. in years)	56.8
Sex (% female)	12 (54.5)
Avg. Distance from home to DHMC one way (miles)[1]	99.6
Avg. Distance from home to Weeks Memorial (miles)[1]	10.7
Visit Type (# of encounters)	
Consult	18 (28.6)
Follow-up	45 (71.4)
Required in-person follow up for joint exam	6 (27.3)
Avg. time from initial visit to in-person follow-up (days)	80.8
Discrepancy in joint exam after in person visit[2]	5 (83.3)
Started on high risk medication[3]	9 (40.9)
Diagnosis Seen in Clinic[4]	
Fibromyalgia	9 (40.9)
Inflammatory Arthritis (RA, PsA, Ank Spon)	10 (45.5)
Osteoarthritis (DJD)	2 (9.0)
Crystal Arthropathy (Gout, CPPD)	1 (4.5)
Osteoporosis	1 (4.5)
Other	1 (4.5)

RA = Rheumatoid Arthritis, PsA = Psoriatic Arthritis, Ank Spon = Anylosing Spondylitis, CPPD = Calcium Pyrophosphate Dihydrate Crystal Deposition Disease, DHMC = Dartmouth- Hitchcock Medical Center
1. Miles calculated using zipcodes.com calculator
2. Synovitis appreciated on exam which was not seen initially via tele-medicine
3. DMARDs (i.e.: methotrexate), colchicine, high dose steroids (equivalent of prednisone >20 mg daily), denosumab.
4. Diagnosis is greater than 100% as some patients had overlapping diagnosis (ie: both rheumatoid arthritis and fibromyalgia).

Use of Physician Extenders to Improve Quality and Efficiency of Clinical Visits. Carl Orr[1], Francis Young[1], Lorraine O' Neill[1], Mairead Murray[1], Phil Gallagher[2] and Douglas J. Veale[3]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: Logistical difficulties associated with managing a large, publically funded secondary service, means that service delivery is costly in terms of physician time. Patients frequently do not have medication lists with them when they attend clinic. Recent results are not available to the physician at the time of clinic visit. Disease activity scores to assist in informing clinical decisions with a treat-to-target approach, are not calculated. Patient reported outcome measures (PROM) are rarely formally assessed and recorded, because these too are often time consuming.

Physician Extenders (PE) have been used to improve efficiency in out-patient clinics.(1) In this action-research endeavour(2), we introduced changes both to the structure and process of how return patients are assessed, making use of a PE to prepare for patient visits.

The specific aims were:

1. To decrease the time physicians spend with inflammatory arthropathy (IA) return patients.
2. To perform a standardised and validated measurement of disease activity for all patients.
3. To increase the proportion of patients acquiring staging hands and feet plain film radiographs every two years in compliance with the consensus of rheumatologists at the hospital.

Methods: The PE recorded the results of the last inflammatory markers and plain film radiographs of hands and feet in a pro-forma. Where these results were not recent (2 weeks for blood results and 2 years for radiographs), the PE liaised with a physician, on a scheduled basis, to arrange for the latter to complete the required ordering forms.

The PE assembled and mailed the pro-forma and ordering forms to returning IA patients 2 weeks in advance of their clinic visit. The pro-forma included a patient global assessment; other PROMs, e.g. HAQ-DI, SF-36; as well as an accurate current medication list. Patients were asked to complete the pro-forma, and to have the bloods and radiographs taken a few days before their appointment.

Patients presented to clinic with a self-completed pro-forma as well up to date results.

Results: 125 patients (85 female) with IA were sent pro-formas before their clinic visit.

Mean time a physician spent at clinic per patient was decreased from 23 minutes to 15 minutes.

120 (96.0%), patients had DAS28-CRP scores calculated, 5 (4%) did not have scores calculated because of a piece of missing data.

68/125 (54.4%) had no radiographs in the three 3 years before their clinic visit. Of the 68 who had no radiographs taken during this time, 49 (72.1%) had radiographs directly as a result of this action-research.

Conclusion: The use of a PE in preparation for clinic visits decreases the time physicians need to spend reviewing patients, and increases the quality of the visit as measured by the collection of DAS scores, and PROMs, and relevant radiological investigations. A cost analysis needs to be done to demonstrate that this approach is cost effective.

Best Practices for Best Practice Alerts: Evaluation of a Best Practice Alert to Detect Chronic Glucocorticoid Use. Mingyuan Zhang[1], Catherine Staes[1], Lara Kapp[2] and Karla L. Miller[3]. [1]University of Utah, Salt Lake City, UT, [2]University of Utah School of Medicine, Salt Lake City, UT, [3]University of Utah School of Medicine, SLC, UT.

Background/Purpose: Chronic glucocorticoid (GC) use is a known risk factor for osteoporosis and fracture. Patients with chronic GC use often receive suboptimal osteoporosis prevention, diagnosis, and treatment. We sought to create a best practice alert (BPA) to identify chronic GC users in our electronic health records (EHR) to recommend bone density testing. Daily dosage and duration of prescription data were not uniformly available for building the BPA. To improve identification of these patients, our objectives were to 1) describe the quality of medication data available for triggering a BPA to prompt bone density screening for patients on chronic GCs, and 2) assess alternative criteria using existing data.

Methods: Our target population was patients ≥50 years of age on chronic GCs defined as taking ≥7.5mg of prednisone daily or equivalent, for 30 days or more. We extracted medication orders from the University of Utah Healthcare clinical data warehouse for all GCs ordered between July 1 and December 31, 2013 for patients ≥ 50 years. The extract included refill number, quantity dispensed, difference between order start and end date, frequency, signature, and dosage per episode. We manually reviewed and classified each order as 'yes', 'no', or 'unable to determine' for chronic GC use. We assessed the frequency of data available for each data field, and stratified by records created using the structured versus free-text order template. We assumed that records without the paired dosage and frequency information were entered using the free text template. Finally, we assessed sensitivity and positive predict value (PPV) of selected medication data elements to identify the target population.

Results: Among the 1,699 GC prescriptions identified, 17% (292) were determined to be chronic GC use; 52% (881) were entered using a structured

template. The structured and free-text templates resulted in similar rates of data populating Refills (97% vs 98%), Quantity dispensed (97% vs 98%), Order start date (99.7% vs 99.9%), and 'Sig' (99.9% vs 99.8%), respectively. In contrast, rate of data availability differed between structured verses free-text templates: Order end date (90.5% vs 71%), Frequency (99.9% vs 0%) and Dosage (100% vs 0%), respectively.

Data Field	Structure of Data	% of Records with Computable Data	Criteria	Sensitivity	PPV
Refill	Structured	97.3%	1 or more refill	72%	41%
	Free text	97.7%		72%	42%
Quantity Dispensed	Structured	97.5%	dispensed >=30 tablets	97%	44%
	Free text	98.5%		93%	44%
	Structured	97.5%	dispensed >=45 tablets	79%	48%
	Free text	98.5%		84%	64%
	Structured	97.5%	dispensed >=60 tablets	75%	50%
	Free text	98.5%		79%	68%
Difference Between Order Start and End Date	Structured	90.2%	Date difference between order start and end date	67%	43%
	Free text	71.1%		50%	19%
Refill and Quantity Data	Structured	97.0%	Refill >0 and quantity data >=30	71%	46%
	Free text	97.6%		72%	64%

In the absence of daily dosage and duration information, quantity dispensed ≥ 30 tablets performed best with the highest sensitivity, and mid-range PPV (Table 1).

Conclusion: Medication data in the EHR are subject to variability and detecting chronic medication use requires adequate evaluation of medication data quality, available data fields, and clinician practice patterns. This is particularly challenging with GCs given their widespread use both chronically and in short-term tapers. Successful alert designers must evaluate both the accuracy of data used to generate an alert, and triggering criteria, to improve identification of the desired population.

Dexa Testing in Long-Term Steroid Use. Beth Scholz University of Texas Health Science Center at Houston, Houston, TX.

Background/Purpose: Risk stratification in the ACR glucocorticoid-induced osteoporosis guidelines includes DEXA testing, which is not universally implemented at our rheumatology clinic. DEXA utilization should be increased to screen for this effect of long-term glucocorticoid use.

Methods: As a quality improvement project, institutional policy exempted this study from IRB review. As a baseline, charts were reviewed from 50 patients on steroids (equivalent to prednisone ≥5 mg/day, ≥ 3 months) seen in rheumatology clinic in August 2013. DEXA status was categorized as never, current, or out-of-date (>2 years ago). Patient gender, menopausal status, steroid dose, and duration of steroid use were also recorded. Then a medication monitoring questionnaire (see Figure 1) was administered to all patients at the time of visit during the intervention pilot period in January 2014 with the intention of triggering more DEXA orders by providers. Other drugs and monitoring tests were included on the form for clinical utility but were not measured for this project. Charts from the 44 patients on qualifying steroid therapy seen during the pilot period were reviewed.

Results: During the baseline period.32% of patients had a current DEXA. Status distribution was similar regardless of menopausal status or prednisone dose (>5 versus ≤5 mg/day). Of 9 male patients, 7 (78%) had current DEXA as opposed to 10 of 41 female patients (24%). During the intervention period, current DEXAs (including DEXAs ordered at the visit) increased to 48% (see Figure 2). The number of patients with "never" status was similar; most of the gain to "current" status resulted from updating DEXA testing.

Conclusion: A medication monitoring questionnaire at routine clinic visits can serve as a reminder to trigger appropriate DEXA orders in patients on long-term steroids. This intervention could be modified for other chronic medication monitoring parameters as well. Future interventions will target increasing FRAX calculation and documentation.

UTPB Rheumatology Medication Monitoring Questionnaire

Please answer the following questions with respect to medications you are CURRENTLY taking.

Steroids
(prednisone, methylprednisolone)
Not taking – skip to next section

When was your last bone density (also called DEXA) test? _____ (mo/yr)

Plaquenil (hydroxychloroquine)
Not taking – skip to next section

When was your last eye exam? _____ (mo/yr)

Biologic agent
(Humira, Enbrel, Cimzia, Simponi, Remicade, Rituxan)
Not taking – skip to next section

Have you ever had an abnormal (positive) tuberculosis test? Yes No Unsure

If YES, when was your last chest x-ray? _____ (mo/yr) N/A

If NO, when was your last tuberculosis test? _____ (mo/yr) N/A

What kind of test was it? PPD (skin test) quantiferon (blood test)

Immunizations:

When was your last influenza (flu) shot? _____ (mo/yr)

Figure 1. Medication monitoring questionnaire

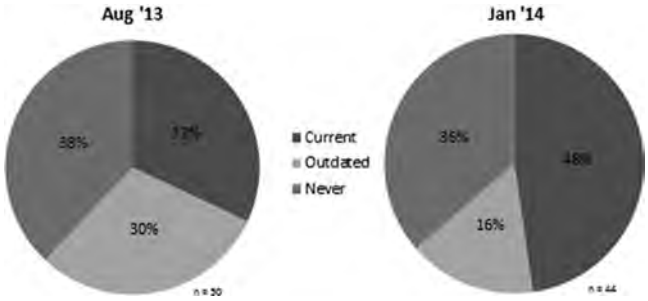

Figure 2. DEXA status during baseline and pilot periods

Glucocorticoid Induced Osteoporosis Screening and Treatment in a Cohort of Male Patients with Underlying Rheumatologic Diagnosis in a Tertiary Care Setting. Hajra Shah, Narender Annapureddy, Joel A. Block and Ruchi Jain. Rush University Medical Center, Chicago, IL.

Background/Purpose: One-fourth of hip fractures occur in men. Three groups of men are at high risk for fracture: those who have already suffered a fragility fracture, those treated with androgen deprivation therapy for prostate cancer, and men treated with oral glucocorticoids for at least 3 months. Rapid bone loss occurs in the first 3 months of steroid use, peaks at 6 months and slows with continued use. In addition hypogonadism in chronic disease also may contribute to fracture risk. Men with rheumatic diseases taking glucocorticoids may not receive adequate screening or treatment compared to females. The American College of Rheumatology recommends that males over age 50 who take chronic glucocorticoids be screened for treatment and prevention of osteoporosis (OP). We assessed adherence to these guidelines in a busy academic practice.

Methods: A retrospective chart review identified male patients 50 years or older with a rheumatic diagnosis seen from 2010 to 2013. Inclusion criteria were 1. Patients who received any dose of prednisone

for at least 3 months; and 2. Seen for at least 3 clinic visits. Exclusion criteria were 1. Recognized osteoporosis; and 2.Prior bisphosphonate use. Most patients had incident prednisone use. We collected demographic data, dose and length of steroid use, timing of DXA from initiation of prednisone use, T-score and calcium and vitamin D supplementation use. We defined appropriate care as screening with a baseline DXA within 6 months of initiation of prednisone, calcium and vitamin D supplementation and bisphosphonates use when indicated. Patients not meeting these criteria were defined as receiving sub-optimal care. Fisher's exact test was used to compare categorical variables.

Results: 100 patients met inclusion criteria; 50% were Caucasians with a mean age of 63.4 (SD 8.4 (51 – 85)) and had rheumatoid arthritis. 76% were taking 7.5 mg of prednisone or higher for at least 3 months and 62% for greater than 12 months. T-scores were available for 57 patients. 61% of T-Scores were found to be abnormal. 53% were treated with calcium and vitamin D and only 31% with bisphosphonates when indicated. 78% of the patients received sub-optimal care for glucocorticoid induced osteoporosis (GIOP) management. 35% of junior faculty (< 5 years out of fellowship) compared with 13% of senior faculty (> 5 years from fellowship) managed patients appropriately (P= 0.014). OP screening for Vasculitis and PMR was more likely compared to other diseases (Figure 1).

Conclusion: The majority of patients who took significant amounts of prednisone for > 3 months received sub-optimal osteoporosis care. To our knowledge, this study is the first to analyze this problem, and identifies a potential gender gap in management of OP in a vulnerable population with inflammatory diseases taking steroids. More vigilance appears needed to managing GIOP, a potentially modifiable risk factor in male patients with rheumatic diseases.

2316

Adherence to Denosumab in a Large Healthcare System. Robert A. Overman[1], Julie C. Lauffenburger[1], Margaret L. Gourlay[1] and Chad L. Deal[2]. [1]University of North Carolina, Chapel Hill, NC, [2]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Oral bisphosphonates adherence has been reported as less than 50% at one year. Adherence to denosumab has been reported to be higher than alendronate in several clinical trials. We evaluated adherence rates for denosumab, an anti-osteoporosis medication (AOM) administered in office as an injection every six months, by rheumatologists in a large healthcare system.

Methods: We identified new denosumab users using billing data between June 2010 and October 2013 based on HCPCS code J0897 or J3590 with denosumab as the listed biologic. Patients had at least 183 days (6 months) follow-up and were administratively censored at two years post-denosumab initiation, for death, or on 6/1/2014 (end of study period). These data were linked to electronic medical record data and only included patients who had at least two office visits in a rheumatology clinic. Patient characteristics were assessed prior to first administration. Adherence to denosumab was assessed with proportion of days covered (PDC) based on a 183 day coverage period (dosing interval for denosumab). After initiation, PDC was calculated at a maximum of one and two years or censored at study end. We defined a patient as adherent if they had ≥80% of days covered. **Results** are presented as mean (standard deviation [SD]) or %.

Results: Five hundred patients met inclusion criteria. Included patients had a mean age of 71.9 (SD 11.0), 92.6% were women, and 88.8% Caucasian. Denosumab was the first AOM in 9.8% of patients. In those with a history of previous therapy, a mean of 2.3 (SD 1.5) AOMs were prescribed. Prevalent fractures were present in 32.8%, mean Charlson Comorbidity score of 2.0 (SD 2.7), and 25% had diagnoses for either gastric ulcers or GERD at first denosumab administration. Eighty-three percent of patients had 12 months follow-up and 26% had 24 months of follow-up. Two denosumab injections were given in 82.3% of patients, 3 in 53% and 4 in 30% of patients. Of those who didn't receive a second administration 2.6% were prescribed another AOM. Mean 1 year PDC, 85.5% (SD 19.0), and 80.7% (SD 21.6) at 2 years. PDC ≥80% was achieved in 72.8% and 62.0% of patients at 1 and 2 years, respectively.

Conclusion: In patients treated with denosumab 72.8% of patients were adherent at 12 months and 62.0% were adherent at 24 months. Only 9.8% of patients started on denosumab were treatment naïve. Adherence rates were higher than those reported for oral bisphosphonates. Other studies have suggested that higher adherence rates for denosumab may be related to in office administration, patient preference and convenience, and a favorable side effect profile. Since studies have suggested that adherence rates <50% are associated with little anti-fracture effect, the greater adherence with denosumab may have important implications for fracture prevention.

Towards Reliable Implementation and Optimal Use of Medication Decision Aid Cards for Shared Decision Making in Juvenile Idiopathic Arthritis. Esi Morgan DeWitt[1], Janalee Taylor[1], Karla B. Jones[2], Murray H. Passo[3], Catherine C. Mims[3], Jesse Pratt[1], Ellen A. Lipstein[1], Nancy Griffin[1], Sheetal S. Vora[4], Beth S. Gottlieb[5], Elizabeth Roth-Wojcicki[6] and William B. Brinkman[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Medical University of South Carolina, Charleston, SC, [4]University of North Carolina Chapel Hill, Chapel Hill, NC, [5]Cohen Children's Medical Center of New York, New Hyde Park, NY, [6]Medical College of Wisconsin, Milwaukee, WI.

Background/Purpose: The purpose of the study was to improve communication and shared decision-making (SDM) between clinicians and parents of patients with juvenile idiopathic arthritis (JIA), and patients with JIA, regarding the choice of medication. SDM aims to ensure medication choices match families' goals and preferences. A treatment plan that is a good fit may be more reliably implemented at home, leading to better health outcomes. This project aimed to develop reliable care processes within a subset of centers in the Pediatric Rheumatology Care & Outcomes Improvement Network (PR-COIN) to 1) identify patients with JIA facing a decision to start or switch medicine, 2) provide SDM support during visits with our JIA 'medication discussion cards' that we developed and 3) measure the outcomes that accrue. Tests of implementation strategies across sites followed the Model for Improvement.

Methods: Volunteer PR-COIN sites employed iterative Plan-Do- Study-Act cycles to reliably implement the materials. To track the quality of interaction and the fidelity of use with the SDM cards, sites collected a short, voluntary, anonymous survey from parents after the visit. The post-visit survey contained information from two validated scales: 1) CollaboRATE is a 3-item measure of SDM (scale range 0 –100). 2) SURE is a 4-item measure of unmet decision support needs (scale range 0–4). The survey also contained 3 parent-report items that we developed with yes/no response options to assess the extent to which the decision aid cards were used as intended during the visit, or "fidelity of use." The first fidelity item asks parents "Did you discuss starting or switching medicine to treat your child's arthritis?" The

second item shows a picture of the cards and asks "Did your clinician show you the tool (pictured) during your visit?" The third item asks, "If "yes", did your clinician ask you to pick the first topic to discuss?" Outcomes were tracked on run charts including: proportion of eligible patient visits where 'JIA medication discussion cards' were used, percent of card use visits with cards used as intended. Separate run charts depict the weekly mean score for each proximal decisional outcome measure.

Results: 78 surveys were collected from 3 sites from March – June 2014. Decision aid cards were used in 33% of visits where a parent reported a medication start/switch. Cards were used as intended during 71% of visits. There was a ceiling effect with both outcome measures. CollaboRATE scores were 100 for all but 3 parents, one who reported card use and two who did not. 75 of 78 parents had maximal SURE scores; the two parents with the greatest number of unmet decisional needs did not report use of the cards.

Conclusion: Uptake of decision aid cards was achieved in approximately 1/3 of visits where a parent reported a medication start or switch. When cards were used, there was moderate fidelity (71%) to intended use. Due to ceiling effects it was difficult to estimate if the use of cards was associated with improved proximal decisional outcomes. Next steps are to collect a different measure of decisional quality and expand the number of sites assessing outcomes, including a control site. We will develop and test new approaches with PDSAs to increase reliability and fidelity of use.

Increasing Rates of Remission in Juvenile Idiopathic Arthritis through a Quality Improvement Learning Network – the Pediatric Rheumatology Care and Outcomes Improvement Network.

Esi Morgan DeWitt[1], Stacy P. Ardoin[2], C. April Bingham[3], Beth S. Gottlieb[4], Ronald M. Laxer[5], Nancy Griffin[1], Jesse Pratt[1], Anne Paul[1], Daniel Lovell[6], Judyann C. Olson[7], Murray H. Passo[8], Jennifer E. Weiss[9], Tzielan C. Lee[10], Sheetal S. Vora[11], Melissa M. Hazen[12] and Peter Margolis[13]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Ohio State University College of Medicine, Columbus, OH, [3]Penn State Hershey Children's Hospital, Hershey, PA, [4]Cohen Children's Medical Center of New York, New Hyde Park, NY, [5]The Hospital for Sick Children, University of Toronto, Toronto, ON, [6]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Department of Pediatrics, University of Cincinnati, Cincinnati, OH, [7]Medical College of Wisconsin, Milwaukee, WI, [8]Medical University of South Carolina, Charleston, SC, [9]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [10]Stanford University School of Medicine, Stanford, CA, [11]University of North Carolina Chapel Hill, Chapel Hill, NC, [12]Boston Children's Hospital, Boston, MA, [13]Cincinnati Children's Hospital, Cincinnati, OH.

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) since 2011 has used quality improvement (QI) methods, chronic illness care model interventions, and a modified, sustainable, Breakthrough Series Collaborative approach to operations. As the network matures in use of population management and pre-visit planning interventions measureable improvements in remission outcomes for children with juvenile idiopathic arthritis (JIA) are being realized.

Methods: Teams conduct Plan-Do-Study-Act cycles using the Model for Improvement. Sites contribute data to a shared registry. Informed consent is obtained from patients for research uses. Data is displayed in run charts, funnel charts, and Pareto charts. Strategies for use of the Population Management Tool include peer review of patients with more than mild disease activity assessed by Physician Global Assessment >3 with decision support treatment algorithms. Pre-visit planning increases reliability of completion of process measures of care (medication safety lab tests, uveitis eye screening) and flags patients for needed services such as PT, OT, or if there is inadequate disease control. Patients are being engaged at network and local levels to inform priorities and contribute to improvement work. Teams share resources, materials and best practices on monthly webinars, "Learning Labs", and semi-annual face-to-face "learning sessions".

Results: 8 of 11 participant sites submit data to the registry (ACR Rheumatology Clinical Registry). 1,457 patients contribute 7,040 encounters. Rates of clinical remission on medication for 6 months were statistically increased from baseline of 37.2% to 48.4% in the aggregate. There is variability in current site performance by >20%, with remission rates for May 2014 ranging from 39.4% – 62.7% at individual sites.

Conclusion: PR-COIN has marked a turning point from early improvement in process measures of care to demonstrable improvement in outcomes as teams are more experienced in QI methods and more reliably implementing pre-visit planning and using population management approaches. Variability in site performance provides opportunity for shared best practices. Challenges to growth have included delays in regulatory approval, and currently a single IRB model is being implemented. Double data entry is a barrier to efficient participation and teams are jointly developing "SmartForms" for electronic health records to facilitate standardized data collection and electronic data transfer. Patient engagement is a new direction expected to support enrollment and influence self-management initiatives.

Standardizing and Documenting Patient Education and Disease Indices in Childhood-Onset Systemic Lupus Erythematosus.

Julia G. Harris[1], Elizabeth Roth-Wojcicki[1], Marsha Malloy[1], Kristyn I. Maletta[2], Dominic O. Co[1] and Judyann C. Olson[1]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]National Outcomes Center, Children's Hospital of Wisconsin, Milwaukee, WI.

Background/Purpose: Systemic lupus erythematosus (SLE) can affect many organ systems and lead to significant morbidities. **Methods** to standardize and improve care in this patient population have recently been established with development of quality indicators. Education is a common theme throughout many of the quality domains addressed. Our project sought to create a standard process for providers to educate SLE patients and their families and document its occurrence, in addition to collecting data pertaining to disease activity and damage. This pilot study will also establish baseline performance of these parameters that can lead to future quality improvement work.

Methods: Patient education materials were compiled pertaining to certain quality indicators: sun precautions, eye exams, vitamin D and calcium recommendations, smoking avoidance and cessation, risk of hypertension, risk of diabetes, weight management, exercise, and vaccination against influenza, pneumococcus, meningococcus, and *Haemophilus influenzae*. Previsit planning identified SLE patients and what educational topics they were in need of. Teaching materials pertaining to the identified educational topics were given to the patient at each routine visit and education was provided. A SLE-specific flow sheet was created and incorporated into our electronic medical record where education was documented and tracked. Additional information including provider global assessment, parent/patient global assessment, disease activity score, and disease damage score were recorded in the flow sheet as well.

Results: Preliminary results have been recorded on 45 SLE patients during 99 clinic visits in a 15-week period from February to May 2014. A total of 162 separate educational variables (range 0–10 per person) were discussed in 88.9% of patients. The most common educational topics discussed (Table 1) and documented include: sun precautions (53.3% of patients), annual eye exams (51.1%), vitamin D recommendation (48.9%), calcium recommendation (46.7%), and pneumococcal vaccination (31.1%). Provider global assessment was recorded at least once in 93.3% of patients and patient/parent global assessment in 66.7%. Disease activity and disease damage scores were calculated in 64.4% of patients.

Conclusion: Our pilot study has been successful in developing an educational curriculum for our SLE patients, establishing a process for documenting and tracking educational topics, and creating a method for recording disease activity and disease damage parameters. Baseline performance on these measures is helpful to target areas for future quality improvement efforts.

Table 1 Educational variables from select SLE quality indicators (n = 45)

Educational topics	Number of times discussed (range per person)	Number of patients (%)
Sun precautions	36 (0–4)	24 (53.3%)
Annual eye exams	30 (0–4)	23 (51.1%)
Vitamin D recommendation	26 (0–3)	22 (48.9%)
Calcium recommendation	24 (0–3)	21 (46.7%)
Pneumococcal vaccination	17 (0–3)	14 (31.3%)
Weight management	15 (0–2)	13 (28.9%)
Exercise	26 (0–4)	17 (28.9%)
Smoking avoidance and cessation	15 (0–2)	12 (26.7%)
Hypertension risk	7 (0–2)	5 (11.1%)

Diabetes risk	5 (0–1)	5 (11.1%)
Influenza vaccination	9 (0–4)	5 (11.1%)
Meningococcal vaccination	2 (0–2)	1 (2.2%)
Haemophilus influenzae vaccination	0	0 (0%)

Initial Benchmarking of the Quality of Medical Care of Childhood-Onset Systemic Lupus Erythematosus. Ahmad I. Zaal[1], Rina Mina[1], Simone Appenzeller[2], Julia Harris[3], Marco F. Silva[4], Jiha Lee[5], Prachi Khandekar[6], Maraisa Centeville[2], HaiMei Liu[1], Joshua D. Pendl[1], Anne Johnson[1], Jennifer L. Huggins[1], Raju Khubchandani[6], Stacy P. Ardoin[7], Marisa S. Klein-Gitelman[8], Clovis A. Silva[4] and Hermine I. Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil, [3]Children's Hospital of Wisconsin, Milwaukee, WI, [4]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [5]University of Cincinnati Medical Center, Cincinnati, OH, [6]Jaslok Hospital and Research Center, Mumbai, India, [7]Ohio State University College of Medicine, Columbus, OH, [8]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.

Background/Purpose: Quality indicators (QI) are minimum standards of medical care in support of optimal disease outcomes. In childhood-onset systemic lupus erythematous (cSLE), 26 QI's, which are categorized into nine domains, have recently been developed based on international consensus and scientific evidence. The current level at which these QI's are followed has not been well documented. Hence, the objective of this study is to assess the current quality of medical care received by patients with cSLE at tertiary pediatric rheumatology centers.

Methods: Cross-sectional data pertaining to the QI's were acquired via chart review and analyzed collectively in 483 cSLE patients followed at seven international tertiary pediatric rheumatology centers – four in the United States, two in Brazil, and one in India. All cSLE patients followed in the participating centers were enrolled. The QI's were adjudicated to be satisfactorily met if they were performed and documented for[3] 80% cSLE patients they were applicable for.

Results: Adherence to the QI's varied widely, ranging from 61 to 100%. The QI with the highest adherence (100%) fell under the *Pregnancy* domain. Most of the QI's were satisfactorily met while six QI's were not (Table 1). These six QI's were classified under the following domains: *Medication Management, General Prevention, Lupus Nephritis and Hypertension Management, Bone Health, and Education on Cardiovascular Risk Factors*. Adherence to the QI's was similar across centers, supporting the suitability and appropriateness of the current cSLE QI's for international use.

Conclusion: Based on this benchmarking effort, the medical care of patients with cSLE at the participating international tertiary pediatric rheumatology centers is very good. Further efforts are warranted to improve the performance of several QI's especially those pertaining to *Education on Cardiovascular Risk Factors*.

Table 1 Adherence to the Quality Indicators

Quality Indicators by Domain	Results (%)
Laboratory Testing at Diagnosis and Screening	
Obtained diagnostic/confirmatory labs within first two visits	96
Obtained lab surveillance of complete blood count, renal, liver function test every 12 months	99
General Prevention	
Prescribed influenza and/or encapsulated organisms vaccination, unless contraindicated	85
Discussed and documented education on sun avoidance at least once in the medical record (e.g., wearing protective clothing, applying sunscreens whenever outdoors, and avoiding sunbathing)	82
Discussed transition plan to appropriate adult healthcare providers with patient age $\geq$ 14 years	62
Lupus Nephritis (LN) and Hypertension Management	
Kidney biopsy discussed/ordered/performed if developed proteinuria $>$ 500 mg/day, or worsening glomerular filtration rate (GFR), or urinary sediment	86
Evaluated by a nephrologist in the last year for LN and of hypertension	67
Evaluated by rheumatologist every 3 months in last year if a patient has known LN regardless of disease activity	97
Received kidney biopsy when diagnosed with LN	80
If LN Class III/IV, treated with immunosuppressive and glucocorticoids within 1 month	96
Angiotensin receptor blocker or Angiotensin-converting enzyme inhibitor were prescribed if ongoing proteinuria $>$ 500 mg/day or worsening GFR in last year of care.	94
Check assessments (kidney function, urine sediment, and proteinuria) every three months	89
Medication Management	
If started new medications, discussed risk vs. benefit of therapy	96
Currently prescribed any antimalarial therapy	91
Attempted to taper a dose of steroids not acceptable for chronic use	90
Attempted to taper and unable to decrease steroid; added/ increased steroid sparing agent	61
Surveillance for medication safety done at regular intervals	99
Bone Health	
Received at least one bone mineral density testing DEXA scan	68
Repeat bone mineral density testing if baseline testing outside normal limits (Z score ≤ -2)	80
Prescribed calcium/vitamin D if a patient is on any steroid therapy	88
Ophthalmological Surveillance	
Receives eye exams annually while on anti-malarial therapy	81
Receives eye exams annually while on glucocorticoids	82
Education on Cardiovascular Risk Factors	
Education on cardiovascular risk factors (smoking, hypertension, high body mass index) every 1 year with patient and parent if patient is 13 years or older	68
Discussed lifestyle modifications (smoking cessation, weight control, exercise) every 2 years with parent and patient 13 years or older	70
Pregnancy	
Anti-SSA, anti-SSB and anti-phospholipid antibodies have been assessed during pregnancy	100
Neuropsychiatric Manifestations	
Prescribed Immunosuppressive therapy if patient has major neuropsychiatric manifestations in the last year of care (optic neuritis, coma, psychosis, etc.)	94

Quality Improvement in the Identification of Crystals from Synovial Fluid: Hospital Laboratory Versus Rheumatology Department Evaluation. Joanne Szczygiel Cunha[1], Anthony Reginato[2] and Stuart Schwartz[2]. [1]The Warren Alpert School of Medicine at Brown Univeristy, Providence, RI, [2]The Warren Alpert School of Medicine at Brown University, Providence, RI.

Background/Purpose: It has been well studied and accepted that the best method for evaluating joint disease is examination of synovial fluid. Synovial fluid analysis is critical to establish a definite diagnosis, whether the patient has a septic joint or a crystal arthropathy. Our study aims at studying the consistency of crystal identification between the Rheumatology department and the hospital laboratories as well as identifying the factors contributing to the misidentification of crystals.

Methods: A retrospective study of synovial fluid analysis performed by the Rheumatology Department and the Rhode Island Hospital (RIH) laboratories was done over a year. Synovial fluid was gathered by arthrocentesis performed by the Rheumatology faculty for anyone with suspected crystal induced arthritis. Synovial fluid samples were analyzed by an attending physician with a compensated polarized microscope in the office and reviewed by another attending and/or fellow. Synovial fluid sent to the RIH lab was analyzed within the hour. A standard protocol was used for each sample which included cell count and differential. For this analysis the fluid was diluted with normal saline. Afterwards, part of the sample was dry centrifuged to examine for crystals. Both the wet prep of the sample as well as the dry centrifuged slides were examined by laboratory technicians for crystals. Within 24 hours, all dry centrifuged samples were reviewed by a pathologist. **Results** from the Rheumatology department were compared to the laboratory results on the same sample fluids.

Results: A total of 64 synovial fluid samples were examined. 18 discrepancies were found between the Rheumatology Department and the

hospital laboratories. 14 of the samples reviewed by the faculty were found to have crystals, while the laboratory reported these to be negative. A McNemar's test was used to evaluate the data set. For each type of crystal, the p-value was not statistically significant (p-value MSU = 0.45, CPP = 0.07) but the p-value for both crystals was statistically significant at 0.02. Sensitivity for each was calculated, with specificity being 100%, and compared between the faculty and the laboratory. The sensitivity for the detection of any crystals by the faculty was found to be 0.92, while for the laboratory it was 0.66. The sensitivity of MSU crystal detection by the faculty was 0.89 and by the laboratory, 0.74. Similar results were seen for the detection of CPP crystals by the Rheumatologists with the sensitivity being 0.90, while the laboratory's sensitivity was much less, only at 0.57.

Conclusion: The results of our study are consistent with previous studies showing that there are still discrepancies in synovial fluid analysis. Many factors may be contributing to these variations including observer error, differences in time spent examining the fluid, technician training and crystal concentration. When analyzed separately, not all of our findings reached statistical significance, but when examined together, statistical significance was met. We believe that this study has profound clinical significance. Errors in crystal detection can have serious impacts on disease management and patient care.

Disclosure: J. Szczygiel Cunha, None; **A. Reginato**, None; **S. Schwartz**, None.

Aim for Better Gout Control: A Retrospective Analysis of Preventable Hospital Admissions for Gout. Tarun S. Sharma[1], Thomas M. Harrington[2] and Thomas P. Olenginski[2]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA.

Background/Purpose: ACR/EULAR guidelines have been published on the management of gout. Despite these guidelines, many patients with gout suffer recurrent flares and hospitalizations resulting in poor disease control and increased health care utilization. We aim to analyze the hospitalizations related to gout, determine whether these admissions were preventable and calculate imputed hospitalization costs.

Methods: A retrospective cohort of adult patients hospitalized at our institution with a primary discharge diagnosis of gout (defined as ICD-9 274, 275 or 712) from 01/01/2009 to 12/31/2013 was constructed (n=79). The primary diagnoses were validated and preventable admissions ascertained on chart review. A preventable admission was defined as an admission where the primary admitting diagnosis was a mono or polyarthritis subsequently diagnosed as gout on hospitalization and without any concomitant illness on presentation warranting admission. We reported demographic characteristics, including clinical diagnosis on admission, prior history of gout, possible risk factors for gout (Diabetes, Cardiovascular disease, chronic kidney disease, diuretic or low dose aspirin use), gout medications, serum uric acid levels within 1 year prior to admission, timing of arthrocentesis, if done, surgical procedures performed and hospitalization costs.

Results: Fifty six (56) of 79 patients were found to have adjudicated primary diagnosis of gout. Of these 56 gout admissions, 50 (89%) met the definition of preventable admission. On admission, the clinical diagnosis was septic arthritis (76%), inflammatory polyarthritis (14%) or cellulitis (8%). Of the 50 preventable admissions, 33 patients underwent arthrocentesis, 24 of which were performed in the Emergency Room. Thirty-five (35) patients (70%) had a previous history of gout and 21 (42%) had ≥3 risk factors for gout. Of the 35 patients with a prior history of gout, 74% were managed by primary care, whereas 26% were being managed by rheumatology. Of the 26 patients managed by family physicians, 8 (31%) were on urate lowering therapy (ULT) and 5 (19%) were on colchicine prophylaxis. Twenty three serum uric acid levels within 1 year of the date of hospitalization were recorded of which 18 (78%) were not at goal of <6 mg/dL. Of 15 patients on long term gout treatment, 33% were non-compliant. Three (3) patients underwent orthopedic procedures: toe amputation (1), arthroscopic debridement (2) and were subsequently diagnosed as gout.

Total additive length of stay for the preventable admissions was 171 days (mean 3.42 days). Total hospitalization-related-costs were $208,000 with average cost per admission of $4160.

Conclusion: We conclude that 89% of the hospitalizations with primary diagnosis of gout were preventable. Defined gaps in clinical care include: ACR/EULAR guidelines not followed, lack of crystal-confirmed diagnoses, patients presenting to emergency room for care, and medication non-compliance. Consequently, this population incurred unnecessary health care costs in the emergency room and costly and preventable admission care expenditures. Steps to reassess the care of gout at our institution have begun as a direct result of these study findings.

Only 30% Rheumatologists Collect Basdai in Patients with Axial Spa in Daily Practice: The Potential Role of a Consensual Meeting to Improve It. Hélène Che[1], Adrien Etcheto[1], Emmanuelle Dernis Labous[2], Henri Nataf[2], Patrick Boumier[2], Philippe Breuillard[2], Marianne Durandin-Truffinet[2], Jacques Fechtenbaum[1], Veronique Gaud-Listrat[1], Bernard Giraud[2], Christophe Hudry[2], Sylvain La Batide Alanore[2], Patricia Le Devic[2], Patrick Le Goux[2], Agnes Lebrun[1], Emmanuel Maheu[2], Bertrand Moura[2], Minh Nguyen[2], Antoinette Sacchi[2], Xavier Ayral[2], Anne Blanchais[1], Severine Neveu[1], Maxime Dougados[3] and Anna Molto[3]. [1]Université Paris René Descartes and Hôpital Cochin, Paris, France, [2]Réseau Hôpital et Ville en Rhumatologie (RHEVER) Network, Paris, France, [3]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France.

Background/Purpose: The current recommendations for optimal monitoring of axial spondyloarthritis (SpA) are to assess regularly disease activity. The two proposed tools comprise clinical aspects as well as laboratory abnormalities, e.g. BASDAI and C-Reactive Protein, or ASDAS [1].

To evaluate the tools used by rheumatologists in axial SpA patients in their daily practice and the potential interest of a meeting during which rheumatologists achieved a consensus on the tools to be used for such monitoring after a presentation of a systematic literature review (consensual meeting).

Methods: The medical chart of out-patients seen by rheumatologists (office-based or hospital-based) have been checked by an independent investigator. The patients had to have visited twice the same rheumatologist within one year (within six months before and after the consensual meeting) to be retained for this analysis For each visit, the existence of the following informations in the medical chart (BASDAI score, CRP, ASDAS score) were collected.

Results: In total, 456 medical charts issued from 228 patients (mean age: 44.6 (±12.6) years old, 147 (64.5%) males, mean disease duration: 11.7 (±10.7) years) who visited 23 rheumatologists (9 (39.1%) hospital-based and 14 (60.9%) office-based, mean age 51.6 (±10.3) years old and with 22.2 (±10.1) median years of practice of rheumatology), visiting a mean of 62 (±37.1) patients per week of whom 17.8% were diagnosed with axial spondyloarthritis) were reviewed.

Before the consensual meeting, the frequency of reported tools in the medical chart was 65 (28.5%), 117 (51.3%), 38 (16.7%) and 2 (0.9%) for BASDAI, CRP, BASDAI and CRP and ASDAS respectively. After the consensual meeting, these frequencies changed to 118 (51.7%), 119 (52.2%), 72 (31.6%) and 14 (6.1%) respectively.

An increase in the frequency of the reported tools, was more frequently observed in office-base rheumatologists (e.g. BASDAI score from 32 (23.2%) to 70 (50.8%) medical charts, before and after the consensual meeting, respectively).

Conclusion: This study suggests that 1) despite existing recommendations, tools permitting the evaluation of disease activity are not frequently collected in daily-practice and 2) a reminder through regular meetings could be considered in order to improve this situation.

A Systematic Review of the Educational Approach of Occupational Therapy for Rheumatoid Arthritis. Kristine Carandang and Elizabeth Pyatak. University of Southern California, Los Angeles, CA.

Background/Purpose: In order to enhance daily functioning for patients with chronic conditions, occupational therapists employ a range of techniques and strategies. Among these strategies, interventions within the educational approach have been reported as having limited to no evidence despite being used regularly in clinical practice (Steultjens, et al. 2002). Over a decade later, this study seeks to provide an update of current literature through the following aims: (1) to identify occupational therapy interventions that target patients with rheumatoid arthritis (RA) and (2) to systematically review the effectiveness of the identified interventions that utilize an educational approach.

Methods: To fulfill the first aim, a list of the most commonly used occupational therapy textbooks was obtained, and textbooks were searched for interventions targeting patients with RA. Data were grouped and categorized into specific intervention domains. To fulfill the second aim, MedLine, CINAHL, and select occupational therapy journals, were searched utilizing designated medical subject headings. Inclusion criteria were randomized control trials of educational interventions determined within the first aim, published between 2002 and 2013, and included adult participants (over 18 years old) diagnosed with RA. Study characteristics were extracted, and individual studies were reviewed for 6 criteria to determine methodological risk of bias. Studies lacked sufficient construct and assessment agreement to conduct a meta-analysis; therefore, a between-studies qualitative synthesis was conducted to determine levels of evidence for primary outcomes designated within individual trials.

Results: Twelve intervention categories emerged within the occupational therapy scope of practice, including four within the educational approach. 375 articles were screened and 21 studies (2478 participants) were included for data extraction (see Table for overview of characteristics). The identified studies evaluated a wide range of outcomes using diverse measures (over 30 assessments of pain, fatigue, disease activity, functional status, and psychosocial constructs). Interventions that utilized a combination of educational techniques demonstrated strong evidence to improve disease knowledge and disease activity, as well as psychosocial interventions to improve pain and disease activity. Moderate evidence was found for the effectiveness of joint protection/energy conservation on joint protection behaviors. Limited or no evidence existed for the remaining outcomes.

Conclusion: Although the number and quality of studies evaluating educational interventions have increased, there continues to be limited evidence that these approaches impact meaningful outcomes for patients with RA.

Investigation of Parameters Used to Test Quadriceps Muscle Power Using Isokinetic Dynamometer in Arthritis. Maria Beatriz Catelani, Samannaaz S. Khoja, Gustavo J. Almeida and Sara R. Piva. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Muscle power (MP) plays an important role in daily activities that require force generated at fast speeds such as climbing stairs. MP is decreased in individuals with arthritis and its contribution to disability has been suggested to be above that of muscle weakness. Yet, there is no consensus on testing parameters such as angular speed and muscle contraction curve to assess MP using isokinetic dynamometers. The purpose of this study was to investigate testing parameters used to assess quadriceps MP in subjects with arthritis. Aim 1 tested the associations of angular speed (or slope of angular speeds) and muscle contraction curve with a well-accepted performance-based measure of MP – the stair climbing test (SCT). Aim 2 investigated whether MP explains variability in SCT beyond that of demographic variables related to muscle performance and muscle strength.

Methods: Adults diagnosed with rheumatoid arthritis were invited to participate. This cross-sectional study used an isokinetic dynamometer to measure quadriceps maximal voluntary isometric contraction (MVIC) and MP. MP was measured using four angular speeds of contraction (240, 180, 120, and 60 degrees per second). Then, values of MP were retrieved from the dynamometer using 3 methods: 1) MP of the whole muscle contraction curve (maximum knee flexion to knee extension); 2) MP of partial curve up to peak torque (maximum knee flexion to peak torque), and 3) MP of partial curve deleting 10° of acceleration and deceleration from whole curve. We also calculated power slopes using MP of the 4 speeds for each curve method. SCT was measured in seconds as the time to go up 11 steps. Bivariate correlations were calculated to determine the associations between SCT and MP at the 4 angular speeds and power slope for each curve method. Separate hierarchical regression models were built to determine the contribution of each method to measure MP on SCT after controlling for age, gender, BMI, and MVIC.

Results: Sixty one subjects participated (age 59 $\pm$ 1 years, 82% female, BMI 31 $\pm$ 0.9 kg/m^2). All bivariate correlations coefficients between MP and SCT were significant and ranged from -.35 to -.54 ($p < 0.001$). Hierarchical regression analyses demonstrated that age, gender, and BMI explained 46% of variability in SCT. After adjusting for these variables, MP explained significant variability in SCT regardless of the angular speed or curve method used (7% to 17%). In separate regression models, after adjusting for demographics, MVIC was added and explained additional 15% of variability. Then, MP measures were added to the models. The only variable that contributed significantly to SCT in this model was the MP slope measured by the curve method that excluded acceleration/deceleration (Beta -.326; $p=0.027$).

Conclusion: The contribution of MP to SCT was beyond demographics and muscle strength only when measured as MP slope (combining all angular speeds) and used the curve method that discarded acceleration/deceleration. When measuring MP, utilization of MP slope rather than a single speed of contraction and carefully selection of the curve method are encouraged.

Delivering *ESCAPE-Pain (Enabling Self-Management and Coping of Arthritic Pain through Exercise)* - an Online Guide for Healthcare Professionals. Michael V. Hurley[1], Andrea Carter[1], Des Carter[1], Lonan Hughes[2], Aoife Ni Mhuiri[2] and Nicola E. Walsh[3]. [1]Health Innovation Network South London, London, United Kingdom, [2]Salaso Health Solutions, Tralee, Ireland, [3]University of the West of England Bristol, Bristol, United Kingdom.

Background/Purpose: Worldwide, chronic joint pain is a major cause of suffering, impaired mobility, physical and psychosocial function, quality of life, dependency and healthcare expenditure. *Enabling Self-management and Coping of Arthritic Pain through Exercise (ESCAPE-pain)* is a programme that integrates the core interventions recommended by clinical management guidelines - patient education, self-management, coping strategies and exercise. Robust evaluation shows ESCAPE-*pain* is more effective and cost-effective than usual care, has sustained benefits, is popular with patients and therapists and reduces healthcare costs. Wide implementation would enable many more people to benefit from the *ESCAPE-pain*programme.

Objective: To facilitate implementation of *ESCAPE-pain*by developing a "free to access" website that encapsulates the programme's ethos, description, content and format for healthcare professionals (HCP) who want to deliver the programme.

Methods: Focus groups and interviews were held with approximately 30 HCPs to determine what information they required in order to deliver *ESCAPE-pain*. Using this information a clinical web and multimedia content development team constructed a prototype website describing the content, format and practicalities of delivering *ESCAPE-pain*. "Think aloud" interviews were conducted with 10 HCPs experienced in delivering *ESCAPE-pain*

and 10 HCPs with no experience of delivering the programme. Field notes of user's likes, dislikes, preferences, difficulties and opinions of the website were recorded, analysed, summarised and feedback to the web-developers who revised the to incorporate this feedback. The users re-evaluated the revised website and from their comments an updated website produced.

Results: The opinions of HCPs guided the content and aesthetic format of a website describing delivery of the *ESCAPE-pain* programme. HCPs experienced in delivering *ESCAPE-pain* determined the information they considered needed to encapsulate the ethos of ESCAPE-pain, detail the essential content and format. The final website contains videos of the programme in action (exercise and education sessions), contains the resources required to deliver the programme (downloadable therapist and patient handbooks), PDFs of research evidence-base. Users can feedback the experiences of patients and therapists to improve the programme and website. The opinions of clinicians who had never delivered *ESCAPE-pain* tested the website to ensure it contained and conveyed the information necessary to enable "naïve" clinicians to set up and deliver *ESCAPE-pain*.

Conclusion: Through an iterative process, clinicians and a clinical web and multimedia development team collaborated to produce a website describing the content, format and resources required to implement *ESCAPE-pain*. Making access to the website, the downloadable resources and permission to deliver the *ESCAPE-pain*programme completely free available will facilitate implementation of the programme enabling many more people to benefit.

The website is available at www.escape-pain.org.

The Physical and Psychosocial Effects of Exercise on Chronic Hip and Knee Pain: A Cochrane Review with Meta-Analysis. Professor Mike Hurley[1], Dr Nicola E. Walsh[2], Sandy Oliver[3], Hanan Hauari[3], Kelly Dickson[4], Robert Grant[1] and Jo Cumming[5]. [1]St George's University of London and Kingston University, London, United Kingdom, [2]University of the West of England, Bristol, United Kingdom, [3]Institute of Education University of London, London, United Kingdom, [4]Institute of education University of London, London, United Kingdom, [5]Arthritis Care, London, United Kingdom.

Background/Purpose: Chronic peripheral joint pain is extremely prevalent and a major cause of physical and psychosocial problems. Exercise improves pain and physical function, but the effect of exercise on psychosocial function (health beliefs, depression, anxiety and quality of life) is unknown. To improve our understanding of the inter-relationship between pain, physical and psychosocial function and exercise we conducted a Cochrane Review with meta-analysis of clinical trials that reported the effect of exercise interventions on psychosocial variables.

Methods: Twenty three clinical, public health, psychology, social care databases and 25 other relevant resources were searched. References of included studies were checked for relevant studies. Key experts were asked about unpublished studies. Quantitative synthesis of randomised controlled clinical trials of exercise-based rehabilitation programmes for chronic peripheral joint pain was conducted. Four of the authors independently assessed studies against inclusion/exclusion criteria and methodological quality, and entered extracted data into a database.

Results: Twenty four trials (with 2640 participants) met criteria for inclusion in the quantitative synthesis. There were large variations in the exercise programme's content, mode of delivery, frequency and duration, participant's symptoms, duration of symptoms, outcomes measured, methodological quality and reporting. Design and reporting of the trials was moderate/good, though some were ambiguous, complex and difficult to understand. Many of the trials small (less than 50 participants per group) with low power to detect medium effect size. Outcome measures were heterogeneous, often self-reported, subject to recall and socially desirable biases. Most of the trials reported changes immediately after completing an exercise programme, or had short (less than 6 months) follow-up.

Exercise reduced pain (SMD, 95% CI: −0.22, −0.36 to −0.08), improved physical function (−0.20, −0.31 to −0.09), self-efficacy (0.41, 0.24 to 0.57) and depression (−0.16, −0.28 to −0.03) but not anxiety (−0.38, −1.13 to 0.36). The effect of exercise on health-related quality of life measured in few studies using the SF-36 with significant benefit on social function (6.58, 2.78 to 10.38), borderline significance in mental health (2.90, 0.15 to 5.65), non-significant effect on role emotional (1.20, −4.12 to 6.53) and vitality (3.90, 0.55 to 7.25).

Conclusion: Exercise not only improves pain and physical function, but also has moderate benefits on psychosocial functioning and quality of life. Heterogeneity in the programmes and lack of well-designed trials with psychosocial variables as the primary outcome impedes our understanding. In addition, whether and how to enhance moderate treatment effects, and sustain improvements needs to be determined.

Course and Outcome of Rehabilitation Care in Different Rheumatological Diagnosis Groups. a Descriptive Study Using the STAR-Etic Registry. Elisabet Lindqvist[1], Margreth Grotle[2], Kim Hoerslev-Petersen[3], Theodora P.M. Vliet Vlieland[4] and Ann B. I. Bremander[5]. [1]Lund University and Skåne University Hospital, Lund, Sweden, [2]National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital, N-0319 Oslo, Norway, [3]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Spenshult Research and Development Center, Halmstad, Sweden.

Background/Purpose: The frequency of admission to rehabilitation varies among countries but also among diagnosis groups. So far research describing and comparing the rehabilitation in various diagnosis groups using a similar set of endpoint measures is missing.

Aim: To describe the course and outcome of rehabilitation care in different rheumatological diagnosis groups.

Methods: Multicenter prospective observational study in 4 North-European countries (18 study sites) including patients with various rheumatic diseases admitted for rehabilitation. Assessments were done at admission, discharge and after 6 and 12 months. Assessments included pain, fatigue (numeric rating scales, NRS, 0–10), physical functioning (Health Assessment Questionnaire, HAQ, 0–3), Quality of Life (EQ-5D and SF-36). In addition, at baseline sociodemographic and health characteristics were recorded. Moreover, the setting and duration of the rehabilitation were registered. Comparisons of baseline characteristics among diagnosis groups were made using multivariate or logistic regression analysis. Changes over time were analysed within diagnosis groups using analysis of variance, including all available data.

Results: 1215 patients were evaluated. The different diagnosis groups were Rheumatoid arthritis, 418 patients, Spondylarthropathies, 300 patients, systemic rheumatic diseases, 104 patients, unspecified arthritis, 22 patients, fibromyalgia/chronic pain 45 patients, non-inflammatory back pain, 26 patients and osteoarthritis 119 patients. 181 patients participated in rehabilitation post large joint surgery of which 171 patients were diagnosed with osteoarthritis and the 10 remaining patients had an inflammatory arthritis.

In all diagnosis groups, patients improved significantly between baseline and the discharge assessments in pain, fatigue, HAQ. The mean change in pain was -1.7 (confidence interval (CI) −1.8 - −1.6), in fatigue −1.6 (CI −1.7 - −1.5) and in HAQ −0,18 (CI −0.21 - −0.16). After 6 months the mean change from baseline in pain was −1.1 (CI −1.2 - −0.9), in fatigue −0.7 (CI −0.9 - −0.5) and in HAQ −0.22 (CI −0.26 - −0.19). The improvements were similar in all diagnosis groups except for the post-surgery osteoarthritis patients where the improvements were remarkably higher.

Conclusion: Using a standardized framework across diagnosis groups we were able to demonstrate improvement after rehabilitation within 10 rheumatological diagnosis groups. The use of similar endpoint measures in national registries is advocated. It is of importance to register all treatments apart from drugs.

Construct Validity of the Adult Myopathy Assessment Tool in Individuals with Inclusion Body Myositis. Michael Harris-Love[1], Galen Joe[2], Todd Davenport[3], Joseph Shrader[2], Beverly McElroy[2], Goran Rakocevic[4], Olavo Vasconcelos[5] and Marinos Dalakas[4]. [1]VA Medical Ctr, Washington, DC, [2]National Institutes of Health, Bethesda, MD, [3]University of the Pacific, Stockton, CA, [4]Thomas Jefferson University, Philadelphia, PA, [5]Richmond Veterans Affairs Medical Center, Richmond, VA.

Background/Purpose: The Adult Myopathy Assessment Tool (AMAT) is a 13-item performance-based battery developed to assess function and anaerobic endurance in adults with muscle disease. The AMAT has been shown to be a valid assessment of physical status in people with neuromuscular disease, and has demonstrated intrarater and interrater reliability among clinicians rating patients with idiopathic inflammatory myopathy. The purpose of this study was to determine the construct validity of the AMAT in patients with sporadic inclusion body myositis (sIBM).

Methods: The AMAT was administered to 43 participants with sIBM (31 men, 12 women; age: 66.0 ±7.5 years; disease duration: 9.9 ±4.3 years) by a single practitioner at a Federal hospital. Peak isometric force measurements were obtained using quantitative muscle testing, and temporal characteristics of gait during habitual and fast walking conditions were measured using a portable gait analysis system. The participants also completed assessments for depression (Beck Depression Inventory), psychosocial fatigue (Fatigue Severity Scale), physical activity levels (Human Activity Profile), and self-reported physical status (36-item Short Form Health Survey, Ver. 2, Physical Component Summary).

Results: The participants attained a mean AMAT score of 30.1 (±5.7; range, 18–44). AMAT scores were significantly associated with strength ($r = 0.40$–0.43, $p < 0.01$), gait speed ($r = 0.69$–0.73, $p < 0.001$), physical activity levels ($r = 0.67$, $p < 0.001$) and self-reported physical status ($r = 0.50$, $p < 0.005$), but not depression or psychosocial fatigue (p 0.05). These relationships were independent of age, disease duration, and age of onset. No floor or ceiling effects were observed as no participant attained the minimum or maximum score (0–45).

Conclusion: The construct validity of the AMAT is supported by its significant associations with muscle strength, functional performance, physical activity, and self-reported physical status. However, anaerobic endurance as measured by the AMAT differs from estimates of psychosocial fatigue in our sample. The AMAT is a standardized, performance-based tool that may be used to assess functional limitations and anaerobic endurance in patients with sIBM.

People's Views, Beliefs and Experiences of Exercise for Chronic Hip and Knee Pain: Cochrane Review with Qualitative Synthesis. Professor Mike Hurley[1], Kelly Dickson[2], Hanan Hauari[3], Dr Nicola E. Walsh[4], Robert Grant[1], Jo Cumming[5] and Sandy Oliver[3]. [1]St George's University of London and Kingston University, London, United Kingdom, [2]Institute of education University of London, London, United Kingdom, [3]Institute of Education University of London, London, United Kingdom, [4]University of the West of England, Bristol, United Kingdom, [5]Arthritis Care, London, United Kingdom.

Background/Purpose: Chronic peripheral joint pain is extremely prevalent and a major cause of physical and psychosocial dysfunction. Exercise improves pain and physical function, but the effect of exercise on psychosocial function (health beliefs, depression, anxiety and quality of life) is unknown. To improve our understanding of the inter-relationship between pain, physical and psychosocial function and exercise we conducted a Cochrane Review of qualitative studies that reported people's views, beliefs, feelings and experiences of exercise.

Methods: Twenty three clinical, public health, psychology, social care databases and 25 other relevant resources were searched for relevant studies. Two reviewers independently read and extracted data and used a thematic analysis to match the data against a conceptual framework and identify broad themes and sub-themes. Reviewers compared their individual coding, considered the extent to which each sub-theme was mutually exclusive and how they understood the data in relation to their individual coding. They reached a consensus on which *a priori* themes were supported by the data, and whether new themes identified by the reviewers did actually map to the pre-existing broad theme. This approach has provided a clear path from the original research data, to individual study author's descriptions and analyses to the findings of the qualitative review synthesis.

Results: Nine studies met the inclusion criteria. Their design, methodological rigor and reporting was good. Most of the studies gave clear descriptions of their methodology, clearly reported their findings, and took steps to ensure transparency and minimise the bias arising from researcher's values and opinions in their reporting, interpretation and conclusions.

Chronic hip and knee pain affects all domains of people's lives. Beliefs about chronic pain shaped people's attitudes and behaviors about how to manage their pain. With little information or advice from healthcare professionals people attributed joint pain to "wear and tear", ageing processes and/or familial disposition. Physical activity was often associated with onset or increase in pain and interpreted as causing additional joint damage, so people avoided activity for fear of causing additional harm.

People's views about their symptoms, health beliefs and psychosocial experiences revealed implications for practice which included: providing people with more and better information and advice about the safety and benefits of exercise; tailoring exercise to ensure they are enjoyable and seen by people as being relevant; challenging unhelpful health beliefs; providing practical support.

Conclusion: The uptake and effectiveness of exercise might be improved by challenging inappropriate health beliefs, providing better information and advice about the safety and value of exercise, tailoring exercise programmes to individual's preferences, abilities and needs and provide better support.

Use of Wrist Hand Orthoses during Hand Function Skills and Functional Tasks By Adults with and without Rheumatoid Arthritis. Janet L. Poole[1], Kelly Nunez[2] and Patricia Burtner[3]. [1]University of New Mexico, Albuquerque, NM, [2]Veteran's Administration Medical Center, Albuquerque, NM, [3]University of New Mexico, Greenbank, WA.

Background/Purpose: To determine changes in muscle activation in the upper extremity using electromyography (EMG) when static and dynamic orthoses are worn by adults with and without rheumatoid arthritis (RA) during hand function skills and functional tasks.

Methods: Ten adults with Rheumatoid Arthritis and five controls were tested in four orthosis conditions (no, static, hinged, spiral) during hand function measures of grip, pinch and dexterity as well as functional tasks of drinking from a 12 ounce soda can, pouring from a 1 liter pitcher, turning a knob on a simulated door, and inserting a coin in a slot. Each participant completed three trials for the strength, dexterity and functional tasks. The order in which the orthoses were worn and was counterbalanced to control for effects of practice and fatigue. Muscle activity of eight muscles involved with reach and grasp were recorded in the dominant upper extremity using surface electromyography (EMG) during execution of the hand function measures and functional tasks. Computer software calculated average integrated EMG of muscles for each participant in each orthosis condition for each measure and functional task which were converted to percentage of maximum voluntary contraction (%MVC). EMGs by shoulder, elbow and wrist muscle groupings were expressed as combined %MVC during grip, pinch, dexterity and functional tasks and were compared across orthotic conditions using multivariate analyses of variance (MANOVAs).

Results: Orthosis use on individuals with RA and controls did not increase or hinder grip or pinch strength or increase speed in dexterity tasks.

Compared to the controls, adults with RA demonstrated lower strength on grip and pinch measures and took longer to complete the dexterity task in all orthosis conditions ($p < .05$). Other group differences were noted in muscle activation (% MVC in shoulder, elbow and wrist muscles) with individuals with RA having less muscle recruitment than controls in all strength, dexterity and functional tasks and in all orthosis conditions ($p < .05$). EMG differences varied when individuals wore orthoses. During grip, wrist and elbow muscle recruitment was greater than shoulder muscles in both groups in all orthosis conditions. Increased muscle activation in all muscles was noted during two point pinch in both groups when orthoses were worn ($p < .05$). When all subjects wore orthoses, muscle activation decreased at the wrist during drinking ($p < .01$). Similarly, individuals used more muscle activation in all muscles during pouring when no orthosis was worn ($p < .05$). There were no differences in EMG activity between the groups or orthosis conditions for turning the door knob or inserting a coin.

Conclusion: Adults with RA showed less muscle activation than controls during all strength, dexterity, and functional tasks. Both groups had greater EMG activity in the elbow and wrist as compared to the shoulder muscles in all orthosis conditions. Our findings suggest therapists might want to consider the type of tasks their patients need to perform when recommending orthoses as muscle activation may vary depending on the tasks.

The Natural Use of Activity Pacing in Daily Life Does Not Result in Lower Symptoms in Osteoarthritis. Susan L. Murphy[1], Anna Kratz[1] and Mark P. Jensen[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Washington, Seattle, WA.

Background/Purpose: To examine the how individuals naturally use the behavioral strategy of activity pacing in daily life and how its usage relates to pain and fatigue within days among older adults with knee or hip osteoarthritis. Specifically, we hypothesized that pain and fatigue increases would precede increased natural use of pacing (i.e., pacing behavior would be symptom-contingent) and that individuals would experience a "pay-off" from pacing in that pain and fatigue would decrease after using pacing.

Methods: Participants ($N=147$) were community-living adults 65 years and older who reported mild to moderate pain severity with evidence of osteoarthritis in a corresponding hip or knee joint. Participants wore a wrist-worn accelerometer for five days and were asked to report frequency of activity pacing behaviors (modified from the activity pacing scale of the Chronic Pain Coping Inventory), pain severity, and fatigue severity five times per day. Physical performance and survey data were also collected.

Results: Multi-linear mixed models ($N = 147$), including key demographic and clinical variables, showed that both pain and fatigue increases were associated with subsequent increased use of natural pacing. The increased use of pacing was associated with subsequent increases in both pain and fatigue.

Conclusion: The natural use of pacing appears to be symptom-contingent which is different from how pacing is taught as part of behavioral treatment. Natural use of pacing was not shown to be adaptive in terms of short-term symptom reduction; rather self-reported pacing behaviors were related to increased symptoms. Future studies are warranted to further examine these relationships by capturing more complex contextual issues such as medication effects, social context, and momentary mood.

Understanding the Experiences of Rural Community-Dwelling Older Adults in Using a New DVD-Delivered Otago Exercise Programme. Arun Agha, Teresa Liu-Ambrose, Catherine Backman and Linda C. Li. University of British Columbia, Vancouver, BC.

Background/Purpose: Arthritis is known to increase the risk of injurious falls. The home-based Otago Exercise Programme (OEP) has been shown to reduce the occurrence of falls in community-dwelling seniors. We recently developed a new OEP DVD that was designed to be delivered with minimal coaching by a physiotherapist (PT), for people living in rural communities. The current study aimed to: 1) understand older adults' experiences in using the DVD-delivered OEP, and 2) explore barriers and facilitators to implementing the DVD-delivered OEP from the participants' perspectives.

Methods: Thirty-two rural community-dwelling older adults (≥75 years old) who participated in a 6-month DVD-delivered OEP study were invited to participate in this qualitative study. Two small group interviews were initially conducted to explore the breadth of participants' experiences with the program. These were followed by semi-structured individual interviews to gain an in-depth understanding of these experiences. An inductive constant comparison analysis involving coding of transcripts was performed. Methodological rigour was ensured through field note taking, journaling and maintaining an audit trail. Further, peer-review was performed to detect issues in the analysis such as overemphasized or underemphasized points, vague descriptions, and assumptions made by the researcher.

Results: Five participants partook in group interviews and 16 in individual interviews. Fifteen participants were female; eight participants received at least some university education. Participants' ages ranged from 74 to 97 years. Three themes emerged. Theme 1, 'The OEP DVD: Useful training tool but in need of more pep', reflected participants' experiences that the DVD provided important guidance at program onset, but was too slow and low-energy for longer-term use. Theme 2, 'Providing greater control over one's exercise regimen, but sometimes life gets in the way of staying active', described participants' appreciation of the program's flexibility, but personal health concerns and everyday lives imposed challenges for adhering to the program. Theme 3, 'Social creatures: Wanting greater human connection during exercise', described how some participants desired further social interactions for enhancing motivation and sense of guidance.

Conclusion: In general, participants were positive about the OEP DVD, but it might not be needed once they are familiar with the program. Our findings also suggest that the program should be prescribed with strategies to address barriers to exercising and tips to increase adherence, such as encouraging older adults to exercise with family members or peers.

Reliability and Validity of the Arthritis Helplessness Index in Systemic Sclerosis. Shadi Gholizadeh[1], Sarah D. Mills[1], Rina S. Fox[1], Philip J. Clements[2], Suzanne Kafaja[2], Vanessa L. Malcarne[3], Daniel E. Furst[2] and Dinesh Khanna[4]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [3]SDSU/UCSD Joint Doctoral Program in Clinical Psychology; Department of Psychology, San Diego State University, San Diego, CA, [4]University of Michigan Health System, Ann Arbor, MI.

Background/Purpose: The unpredictable and uncontrollable course of rheumatic diseases has made them an interesting area of study in the learned helplessness and health outcomes literature. The Arthritis Helplessness Index (AHI), a 15-item self-report measure of helplessness, was developed to address a gap in the understanding of psychological correlates of rheumatoid arthritis (RA). The AHI was initially conceptualized as a unidimensional measure, however subsequent factor analytic studies identified two subscales: Helplessness and Internality. Though developed and validated in RA patients, the AHI and its adaptation, the Rheumatology Attitudes Index (RAI), have been used across rheumatic conditions, including among patients with systemic sclerosis (SSc). The present study examines the reliability and validity of the AHI among SSc patients.

Methods: A sample of patients ($N= 208$) with physician-confirmed SSc completed the AHI as part of participation in the University of California Los Angeles (UCLA) Scleroderma Quality of Life Study. Baseline data from the study were used to explore the structural validity of the measure via confirmatory and exploratory factor analytic methods. Internal consistency reliability was evaluated with Cronbach's alpha, and convergent validity was explored via Pearson product-moment correlations with measures of depression (CES-D), mental and physical functioning (SF-36v2 Physical and Mental Component Scores, HAQ-DI) and pain (SF-36v2 Bodily Pain).

Results: Because confirmatory factor analysis failed to demonstrate a tenable one or two factor solution, exploratory factor analysis using a geomin-rotated matrix was undertaken to examine the structure of the AHI among SSc patients. A revised two-factor model fit well both statistically (c^2 [19, $N = 208$] = 22.32, $p = .269$), and descriptively (CFI = .985, RMSEA = .029, SRMR = .032). Nine items were retained in the final solution, with the original five Helplessness items comprising Factor 1,

Helplessness, and four of the original seven Internality items comprising Factor 2, Internality. Internal consistency reliability was marginal for both subscales (five-item Helplessness factor: a =. 634; four-item Internality Subscale a =. 634), and convergent validity was supported by significant correlations of AHI scores in the expected directions with the CES-D, SF-36v2 relevant subscale scores, and the HAQ-DI.

Conclusion: The present study derived a revised version of the AHI for use among patients with SSc. Several items that were appropriate for RA patients (e.g., regarding flares) dropped out of the revised version of the measure, suggesting that helplessness is not identical between the two conditions. Although the updated two-factor structure of the shortened nine-item measure fit the data well, it is unlikely that the present measure fully captures the construct of helplessness in SSc. Until future revisions of the measure incorporating patient involvement and input are completed, it is recommended that research examining helplessness in SSc use the updated 9-item, two-factor structure identified in the Arthritis Helplessness Index-Scleroderma version (AHI-SSc).

Evaluating the Use of Video-Stimulated Recall to Research the Osteoarthritis Consultation in Primary Care: Reaching Parts Other Methods don't Reach. Zoe Paskins, Tom Sanders, Peter Croft and Andrew Hassell. Keele University, Keele, United Kingdom.

Background/Purpose: Video-stimulated recall (VSR) is a method of enhancing participants' accounts of a consultation using a video recording of the event to encourage and prompt participant recall in a post-consultation interview. VSR is used in education and education research, and to a lesser extent in medical and nursing research, although little is known about the validity, utility and acceptability of the method. This abstract describes an evaluation of the use of VSR in a study of the Osteoarthritis (OA) consultation in primary care in the UK.

Methods: With ethical approval and informed consent, 195 doctor-patient consultations were video-recorded with patients aged ≥ 45. Seventeen consultations in which OA was discussed were the subject of post-consultation interviews using VSR. VSR interviews were conducted with 17 patients and 13 General Practitioners (GPs). Evaluation of the method was achieved by thematic analysis of comments made during video playback, in addition to analysis of observations, field notes, consultation and interview transcripts. Empirical quotes will be presented to illustrate the findings.

Results:

Validity

There was evidence of the video altering both GPs' and patients' behaviour in the consultation with GPs particularly keen to demonstrate 'desirable' behaviours. However, GPs frequently expressed surprise that their actions did not reflect what they felt was best practice, and so we conclude that any altered behaviour would not bias study findings and would likely help interpretation of clinical behaviour during VSR.

Utility

The method was useful to explore meanings behind specific sections of talk in the consultation and both patients and clinicians often adopted a more critical stance to the consultation following playback. VSR resulted in subtly different 'added value' to interviews with patients and doctors. Patients were more empowered to reveal emotional narratives following video playback. VSR gently challenged GPs' descriptions of their "normal" consultations.

Acceptability

Both GPs and patients reported finding the method broadly acceptable with some reporting enjoyment and educational value. However, occasional distress and anxiety occurred in interviews, to which the video playback may have contributed.

Conclusion: This study adds to the existing literature on VSR by describing specifically how this method enables a more critical, specific and in-depth response from participants to events of interest during clinical encounters, and in doing so, generates multiple perspectives on such encounters. The benefits of VSR for clinical and educational research need to be considered in conjunction with the important ethical considerations and the potential for this method to be intrusive.

The Cost and Effectiveness of Various Recruitment Strategies in a Mind Body Clinical Trial Among Older Adults with Knee Osteoarthritis. Jade V. Goldsmith, Lori Lyn Price, Jeffrey B. Driban, William F. Harvey and Chenchen Wang. Tufts Medical Center, Boston, MA.

Background/Purpose: Recruitment and adherence are important and challenging factors that can determine the success of a clinical trial. Mind body therapies are an emerging and controversial field; therefore, recruiting people to these types of trials can be difficult. The primary objective of this study was to compare the costs and effectiveness of recruitment strategies employed in a clinical trial of older adults with knee osteoarthritis (KOA). We also sought to determine which recruitment strategies provided the most adherent participants. The aim of these analyses was to identify successful strategies to improve recruitment for future studies.

Methods: We assessed recruitment strategies, cost, and adherence from a clinical trial of Tai Chi and physical therapy among older adults with KOA in the Boston area. All participants met ACR criteria for symptomatic KOA and were recruited between Dec. 2010 and May 2013. Recruitment strategies included: 1) clinical referrals, 2) other referrals (studies, staff, and class members), 3) electronic ads (Patientslikeme, Facebook, Clinicalconnections, clinicaltrials.gov, Craigslist, employee newsletter) and 4) paper ads (local newspapers, flyers). Costs were calculated by adding printing, posting, and personnel expenses. We calculated the percent of participants screened (# screened/prescreen), randomized (# randomized/screen), and able to complete their 12-week evaluation (# 12 week/randomized). We also calculated the yield (# randomized/ total prescreened), cost per randomized participant as well as median adherence to class schedule (# classes attended/total classes).

Results: 1195 people were phone prescreened, 282 were screened in person (mean age 59.7 years) and of these 72% were randomized; the cost per randomized participant was $178.43 (See Table). Sixteen participants were randomized who did not report recruitment source. Paper ads resulted in the highest number of prescreens and randomized participants. Clinical referrals and the senior expo generated the lowest number randomized. The yields for paper, electronic, and other referrals were highest. Clinical referrals resulted in the lowest yield. With the exception of clinical referrals, adherence was high for all recruitment methods as measured by attendance (>79%) and completion of a 12-week evaluation (>76%). Cost per participant was $253.51 for paper and $7.62 for electronic ads. There were no costs associated with referral methods.

Conclusion: Electronic ads are an effective tool in this older population and had minimal cost. Their effectiveness is likely to further increase with time. Paper ads still play a prominent role in effective recruitment. There were no costs associated with clinical referrals but this strategy was not the most effective given the low yield. Additional educational material for clinicians may encourage more referrals.

Table 1. Yield and Cost of Recruitment Strategies in a TaiChi and Physical Therapy Study for Older Adults with Knee Osteoarthritis

	Paper[a]	Electronic[b]	Clinical Referrals	Other Referrals[c]	Senior Expo	Unknown[g]	Total
Telephone Prescreens Completed	695	90	38	87	4	281	1195
In Person Screens Completed	189	29	4	30	2	28	282
Randomized (# randomized/screens completed)	140 (74%)	21 (72%)	3 (75%)	23 (77%)	1 (50%)	16 (57%)	204 (72%)
Attendance (Median)	83.3	87.5	25.0	83.3	79.2	83.3	83.3
12-week evaluation Completed (# 12 week/randomized)	114 (81%)	16 (76%)	2 (66%)	21 (91%)	1 (100%)	13 (81%)	167 (81%)
Cost per Randomized participant	$253.51[d]	$7.62[e]	$0.00	$0.00	$749.00[f]	NA	$178.43
Total Cost	$35,491.50[d]	$160.00[e]	$0.00	$0.00	$749.00[f]	NA	$36,400.50

Cost-Effectiveness and Yield of Different Recruitment Strategies Utilized in an Exercise Trial of Fibromyalgia Patients. Anna Schmid, William F. Harvey, Lori Lyn Price and Chenchen Wang. Tufts Medical Center, Boston, MA.

Background/Purpose: In a large-scale clinical trial with a long-term outcome, it is essential to use recruitment strategies that are both cost-

effective and likely to yield eligible participants. The objective of this study is to evaluate the different recruitment methods utilized to date in the Tai Chi and Aerobic Exercise for Fibromyalgia study in terms of a.) yield (% prescreened, % screened, and % randomized) and b.) cost-effectiveness.

Methods: All participants were recruited within a 20-month time period between January 2012 and September 2013. Recruitment strategies included 1.) clinical referrals; 2.) word of mouth; 3.) ads posted in electronic sources (Craigslist, Google, NIH website, clinicalconnection.com, clinicaltrials.gov, and Tufts website); 4.) ads placed in a local newspaper, the Boston Metro; 5.) flyers posted in the hospital and in the surrounding neighborhood; and 6.) direct mailings to patients. Recruitment costs were calculated by summing advertising, printing, and personnel costs. Percentages were calculated for prescreened, screened, randomized into an intervention arm, and yield (#randomized/#participants contacted). We compared the strategies in terms of yield and cost-effectiveness.

Results: 492 participants were prescreened, 195 were screened at baseline (40% of prescreened) and 165 (85% of screened) were randomized. Ads placed in the Boston Metro yielded the most randomized participants (76) and second highest percentage of randomized participants per prescreen (38.38%) but also had highest associated costs ($273.65/participant). Mailings to patients produced the second highest number of randomized participants (27) and the highest percentage of randomized participants/prescreen (38.57%) and had much lower associated costs ($23.44/participant). Flyers posted within the hospital and in the surrounding neighborhood generated 32.69% of randomized participants/prescreen, 17 participants, and had associated costs of $17.50/participant. Clinical referrals produced 18 randomized participants (29.03% randomized/prescreen) and had no associated costs. Other referrals generated 2 randomized participants and 12.50% of those prescreened. Electronic ads produced 15 randomized participants, 32.61% of those prescreened by this method, and had no associated costs.

Table 1 Yield and cost of clinical referrals, word of mouth, electronic advertising, advertising in local newspaper, flyers posted in hospital, and direct mailings to patients.

	Clinical referral	Word of Mouth	Electronic ad	Newspaper/ magazine	Flyer	Direct mailing
Participants prescreened	62	16	46	198	52	70
Screened	24	2	18	90	21	30
Randomized	18	2	15	76	17	27
Yield	29.03%	12.50%	32.61%	38.38%	32.69%	38.57%
Cost per enrolled	$0	$0	$0	$273.65	$17.50	$23.44
Total Costs	$0	$0	$0	$20800[a]	$297.45[b]	$632.90[c]

[a]Advertising
[b]Printing, personnel
[c]Printing, personnel, postage

Conclusion: Ads placed in the Metro were significantly more costly than any of the other strategies, but yielded 46.06% of participants randomized in the study. Clinical referrals, word of mouth, and electronic ads were the most cost-effective strategies; however, they yielded the fewest randomized participants. In future studies conducted with this population in this location, a strong recruitment strategy would include placing Metro ads and expanding the patient mailing list and number of referring physicians through the mechanism of educating more physicians about the study.

Detecting Inflammation *in Vivo* Using Activatable Fluorescence Contrast Agents in Inflammatory Arthritis. Monica Guma[1], Beatrix Bartok[1], Viet Anh Nguyen Huu[1], Mathieu L. Viger[1], Jacques Lux[1], Shivanjali Joshi-Barr[1], Adah Almutairi[1] and Gary S. Firestein[2]. [1]University of California, San Diego, La Jolla, CA, [2]University of California at San Diego School of Medicine, La Jolla, CA.

Background/Purpose: Current medical imaging technology detects structural rather than functional manifestations of disease. Imaging agents designed to enhance signal based on molecular mechanisms might permit earlier diagnosis and personalized treatment. We examined whether optical contrast agents whose fluorescence properties may be switched from OFF to ON in response to specific biological stimuli can identify inflammation *in vivo* in the murine serum transfer-induced arthritis model.

Methods: Mice were injected with 150 ml of K/BxN sera on day 0. At day 5, mice were injected intravenously with an imaging agent and visualized by IVIS® in vivo imaging system. Clinical arthritis scores were assessed. The imaging agent consists of H_2O_2- and acid-responsive polymeric particles (size: 250 nm) packed with a high concentration of near infrared (NIR) dyes. The close proximity of the dye molecules quenches their fluorescence, thus creating an "off-state". The signal of this agent is "turned on" through the cleavage of protecting moieties on the polymer backbones upon exposure to either H_2O_2 or acidic pH, which reveals hydroxyl groups and thus increases the material's hydrophilicity. After the hydrophobicity switch, dye molecules diffuse out of the polymer matrix, relieving the particle from fluorescence quenching ("on-state") (Figure 1).

Results: After injecting particles (dose: 100 mL of 0.7 mg/mL Hy-Dex-IR780 in DPBS) intravenously on day 5 after arthritis induction, mice were imaged by IVIS®. Regions of inflammation exhibited significantly higher fluorescence intensity measured as an average of radiant efficiency of paws between non-arthritic and arthritic joints (1.91E+07±1.5E+06 vs 4.44E+07±1.85E+07; $p<0.05$). This activation results from inflammation-triggered release of dye molecules, as fluorescence was insignificant in healthy animals, and a non-responsive control version poly(lactic-co-glycolic acid)-IR780 was not activated by inflammation. Radiant efficiency in each paw significantly correlated with their clinical score. For example, a paw with a clinical score of 4 had radiant efficiency of 6.95E+07 while a paw with clinical score of 1 had 2.58E+07.

Conclusion: These results suggest that a novel activatable bioimaging agent can detect inflammation *in vivo* for clinical diagnosis of inflammatory conditions or to assess inflammation in animal models.

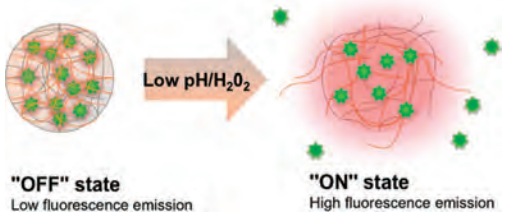

Figure 1. Particles composed of H_2O_2- and acid-responsive polymers partially disassemble upon exposure to either stimulus, activating fluorescence by relieving the particle from self-quenching. Since the NIR dye is not fluorescent in aqueous environments, only the particles light up.

Human Osteoclasts Are Mobilized in Erosive Arthritis of Epstein-Barr Virus-Infected Humanized NOD/Shi-*Scid*/IL-2Rγ^{null} Mice. Yosuke Nagasawa[1], Natsumi Ikumi[1], Takamasa Nozaki[1], Hirotake Inomata[1], Kenichi Imadome[2], Noboru Kitamura[1], Mitsuhiro Iwata[1], Shigeyoshi Fujiwara[2] and Masami Takei[1]. [1]Nihon University School of Medicine, Tokyo, Japan, [2]National Research Institute for Child Health and Development, Tokyo, Japan.

Background/Purpose: Various studies of the relationship between Epstein-Barr virus (EBV) and rheumatoid arthritis (RA) have not produced convincing evidence. Many human viruses do not infect mice; thus, it is difficult to conduct biomedical research. At this congress, we previously reported that EBV infection induces erosive arthritis that resembles RA in humanized NOD/Shi-*scid*/IL-2Rγ^{null} (NOG) mice. However, the mechanisms underlying arthritis in this mouse model are unknown.

In this mouse model, osteoclast-like cells are observed during bone erosion. To determine whether the human or mouse immune system activates bone erosion, we analyzed the origin of osteoclasts in this mouse model.

Methods: The NOG mouse is a highly immunodeficient mouse strain. Seven-week-old female NOG mice were intravenously injected with human CD34$^+$ stem cells from cord blood (1.0×10^5 cells/mouse). Characterization of human hematoimmune system reconstitution (we termed it humanization) was then performed. Human CD4$^+$, CD8$^+$, and CD45$^+$ cells in peripheral blood of these humanized mice were quantified every week using flow cytometery. The engraftment rate of human cells and characteristics of lymphocytes were determined. After 3 months of humanization, these mice were intravenously infected with EBV (1.0×10^1 TD50/mouse). EBV was purified from EBV-producing cells (AKATA or B95-8). After 8–10 weeks of EBV infection, these mice were sacrificed. The joint tissue samples were stained with hematoxylin-eosin, stained for tartrate-resistant acid phosphatase (TRAP) with an immunoenzyme method,

and immunostained for human cathepsin K (specific to humans and dogs). To let osteoclasts differentiate with progenitor cells, bone marrow cells from EBV-infected humanized NOG mice were cultured with human receptor activator of nuclear factor κB ligand (RANKL) and human macrophage colony-stimulating factor (M-CSF) in slide chambers. These stimulated multinucleated cells were subjected to TRAP staining and immunostaining for human cathepsin K and human mitochondria.

Results: After humanization, >40% of peripheral-blood lymphocytes in these mice were human $CD45^+$ cells. When the number of human $CD8^+$ T-cells increased and surpassed the number of human $CD4^+$ T-cells in peripheral blood, erosive arthritis was observed histologically at a high rate (approximately 90%). Multinucleated cells present in the bone erosion zone were positive for human cathepsin K and TRAP staining. Multinucleated giant cells resembling osteoclasts were observed among cultured bone marrow cells stimulated with human RANKL and M-CSF. Human cathepsin K, mitochondrial, and TRAP staining were all positive in these multinucleated cells.

Conclusion: In this mouse model, we achieved a high engraftment rate. The relationship between the degree of arthritis and the ratio of $CD4^+$ to $CD8^+$ T-cell numbers in peripheral blood was evident. Osteoclasts present in the bone erosion zone originated from human cells. In addition, observed that multinucleated giant cells among bone marrow cells cultured with human RANKL and M-CSF were osteoclasts and originated from human cells.

The Combination Therapy of Cell Cycle Regulation Therapy Combined and TNF Blockade Ameliorated the Established Arthritis. Tadashi Hosoya[1], Kimito Kawahata[2], Hideyuki Iwai[2] and Hitoshi Kohsaka[1]. [1]Japan Science and Technology Agency–CREST Program, Tokyo, Japan, [2]Tokyo Medical and Dental University (TMDU), Tokyo, Japan.

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is characterized by infiltration of inflammatory cells to the synovial tissues and their hyperplasia. Activated synovial fibroblasts become another source of inflammatory cytokines and a platform inducing further recruitment of inflammatory cells.

Cyclin-dependent kinases (CDK) are known to be key regulators of the cell cycle progression and targets in cancer treatment. We have revealed that a highly selective small-molecule CDK4/6 inhibitor (CDKI) ameliorated an animal model of RA, even with a dose one-fifth lower than the dose used in a cancer treatment model. Furthermore, CDKI combined with a cytokine blocker ameliorated early stage of arthritis additively without inhibiting antigen-specific immune responses.

In the clinical setting, we often treat RA patients with high disease activity. However, few agents were proven effective in treating established arthritis models. The drug effectiveness is usually estimated with early stage of arthritis in the pre-clinical study and is sometimes discrepant between animal models of arthritis and human RA. Therefore, it is difficult to predict which drug is promising in the patients with RA based on the results of arthritis models. However, the drug would be promising if it could ameliorate the established arthritis model. The present studies were carried out to discern if combination of CDKI and TNF blocker is effective in treating established arthritis.

Methods: DBA/1J mice immunized with bovine type II collagen emulsified in complete Freund's adjuvant twice and evaluated for arthritis score and the joint deformity. Mice with collagen-induced arthritis (CIA) were divided into 4 groups equated the mean arthritis score of individual groups 30 days after the initial immunization and were treated with 20 mg/kg of CDKI, 3 mg/kg of (ETN), a combination of both, or a vehicle solution from 30 days until 42 days after the initial immunization.

Results: The arthritis became established with 9.1 of the mean arthritis score 30 days after the initial immunization. Mice with CIA were treated with a vehicle solution or CDKI or ETN - separately or together. The mean arthritis score changed from 9.1 to 10.4, 8.4, 8.1, and 6.4 respectively 42 days after the initial immunization. The percentage of deformed limbs was observed at 25%, 18%, 7%, and 4% respectively. Both monotherapies inhibited further development of arthritis and decreased the arthritis score, but their efficacies were not statistically significant. Combination therapy decreased the arthritis score significantly and inhibited the joint deformity.

Conclusion: The combination therapy of CDKI and TNF blocker is effective on established arthritis and could prevent joint deformity. Because TNF blockade disturbs the proliferative signaling and CDKI directly prohibits cell cycle progression, the combination of the two might act synergistically based on their mechanisms. We expect that the combination therapy of CDKI with cytokine blockers should help to increase the remission induction rate in RA patients even with high disease activity.

Redox Regulation of a New Autoimmune Mouse Model, Glucose-6-Phosphate Isomerase Peptide Induced Arthritis in Mice. Min Yang[1] and Rikard Holmdahl[2]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is a perpetuating disease, which affects approximately 1% of the population. Until now, the pathogenic mechanisms of RA remain elusive and currently no cure for the disease. Animal models of arthritis have provided valuable platforms to investigate the potential mechanisms of RA and test new therapeutic principles before initiating clinical trials in humans. Based on the well-known K/BxN model, a spontaneous arthritis mouse model, we have established glucose-6-phosphate isomerase (G6PI) peptide induced arthritis in mice. Since the G6PI peptide used in this model has two cysteines inside, therefore, we focus on how redox balance could affect antigen recognition and thereby affect the pathogenesis of autoimmunity.

Methods: G6PI peptide-induced arthritis is established by immunizing C57Bl/6N.Q (B6N.Q) mice or Ncf1*/* mice with single injection of G6PI peptide emulsified in complete freund's adjuvant. Cysteine(s) in the peptide is substituted with serine to test whether redox can influence peptide itself. APCs from both wild type and Ncf1*/* mice are isolated, loaded with G6PI peptide or substituted peptide and cocultured with peptide-specific T cell hybridoma for 24hr. Supernatants are collected then to compare the IL-2 secretion level.

Results: Immunized B6N.Q mice start to develop arthritis on day 10–12, reach to the peak value of severity on day 14–20 and then recover during following 7–10 days. Moreover, both female and male B6N.Q mice could be induced arthritic diseases by G6PI peptide and the incidence is over 80%. Obviously, this peptide-induced arthritis mouse model represents an acute arthritic disease progression. To establish a chronic mouse model with this peptide, we inject pertussis toxin together with G6PI emulsion. It turns out that pertussis toxin not only increases the severity of the disease but also prolong the disease progression over two months. To investigate whether cysteine inside of the peptide is regulated by redox, Ncf1 mutant mice were used. N*cf1* encodes $p47^{phox}$ subunit, which is an essential cytosolic subunit of NADPH oxidase 2 (Nox2). The mutation of Ncf1 results in the deficiency of ROS production. The in vitro assay suggest that APCs from Ncf1*/* mice show higher capability to present G6PI peptide. However, when either one or both of the cysteine substituted with serine, there is no difference at all in antigen presenting between wild type and Ncf1*/* mice. Furthermore, peptide immunized Ncf1*/* mice exhibit more severe and chronic disease comparing with immunized wild type mice.

Conclusion: Taken together, we have established a peptide-induced arthritis mouse model. The model is induced with a defined peptide, leading to a high reproducibility and allowing a more precise investigation of the pathogenicity. Since the peptide per se is sensitive to ROS level, therefore, this model provides unique possibility to investigate redox regulation in autoimmune disease including RA.

Therapeutic Effects of Mesenchymal Stem Cells, Anti-Tumor Necrosis Factor and Anti-CD20 Treatment on Collagen Induced Arthritis. Yue Sun, Xuebing Feng and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background/Purpose: Tremendous progress has been made in the development of non-conventional therapies for rheumatoid arthritis (RA). In this study, the effects of mesenchymal stem cells (MSCs) transplantation on established

collagen-induced arthritis (CIA) were evaluated and compared with two kinds of biologic agents, anti-tumor necrosis factor (TNF) and anti-CD20 antibody.

Methods: CIA was induced with the immunization of type II collagen (CII) and CFA in DBA/1J mice. Human umbilical cord derived MSCs (5×10^6), anti-TNF antibody (100ug) and anti-CD20 antibody (200ug) were intraperitoneally injected into 3 groups of mice on day 28 after the immunization. The control group was treated with human fibroblasts (5×10^6). All mice were sacrificed 3 weeks later and arthritis severity was assessed by clinical and histology scoring. The frequency of CD4+ T cell subsets, B cells and plasma cells in spleen was analyzed by flow cytometry. Serum levels of autoantibody to mouse CII were determined by ELISA. The ability of MSCs to modulate Treg/Th17 cell percentages in CD3/CD28 stimulated DBA/1J T cells was assessed in vitro.

Results: MSCs treatment significantly decreased the severity of arthritis and pathology scores, which was comparable to anti-TNF or anti-CD20 treatment. Anti-CD20 treatment depleted nearly half of B220+ cells, and markedly reduced the frequency of plasma cells and serum levels of autoantibody compared to the control group (738±187 *vs.* 1817±447 U/ml, $p<0.001$). The decrease of autoantibody level was also detectable in those with anti-TNF treatment (663±336 U/ml) and MSCs treatment (1057±362 U/ml), but neither of these two treatments had an impact on the percentage of B cells or plasma cells. All of the three treatments resulted in a decrease in Th1 subset, but none of them altered the percentage of Th2 subset. Except anti-CD20 treatment, both MSCs and anti-TNF treatment significantly decreased the percentages of Th17 cells. Notably, only MSCs treatment increased the percentages of regulatory T cells (11.39±0.85 % *vs* 7.37±1.82 % in the control group, $p<0.01$). In vitro study confirmed that MSCs could induce the generation of Foxp3+ T cells but reduce the percentages of pathogenic IL-17+Foxp3+ T cells.

Conclusion: MSCs exerted comparable therapeutic effects as biological agents on CIA through different mechanisms. MSCs may provide a promising approach for the treatment of RA.

Amelioration of Collagen-Induced Arthritis By Water-Soluble Fullerene $C60(OH)_{36}$ Nanoparticles through the Inhibition of Angiogenesis. Chia-Tse Weng[1], Shih-Yao Chen[2], Yu-Hung Chen[2], Chao-Liang Wu[2], Ming-Fei Liu[2], Ai-Li Shiau[2] and Chrong-Reen Wang[2]. [1]National Cheng Kung University Hospital, Tainan, Taiwan, [2]National Cheng Kung University Medical College, Tainan, Taiwan.

Background/Purpose: Our previous study has shown that injection of 13-nm gold nanoparticles ameliorates collagen-induced arthritis (CIA) through the inhibition of angiogenesis by binding to VEGF. Fullerene derivatives, strong scavengers of superoxide radicals, have been recently identified as potential therapeutic agents for arthritis, with the ability to inhibit proinflammatory mediators. In this study, we demonstrate amelioration of CIA by treatment with $C60(OH)_{36}$nanoparticles through the suppression of proinflammatory cytokine production, bone/cartilage erosion and synovial angiogenesis.

Methods: Physical properties of newly synthesized $C60(OH)_{36}$ nanoparticles were characterized by X-ray photoelectron spectrometer, infra-red spectroscopy, fast-atom bombardment and matrix-assisted laser desorption/ionization mass spectroscopy, transmission electron microscope and dynamic light scattering analysis. Their ability to remove superoxide radicals was confirmed by the electron paramagnetic resonance spectrometer and the inhibition of intracellular reactive oxygen species formation in RAW 264.7 cells. Eight-week-old male Sprague-Dawley rats were immunized with bovine type II collagen emulsified in complete Freund's adjuvant on day 0 and 7. Articular index was used to evaluate the therapeutic effect of the nanoparticles on arthritic joints receiving intra-articular injection of 10 mg nanoparticles or PBS as control (16 joints per group) on day 7. Histological and radiographic scores of arthritic joints were calculated upon sacrifice on day 21. Proinflammatory cytokines (IL-1b and TNF-a) and VEGF concentrations in homogenized synovium extracts were measured by enzyme-linked immunosorbent assay. Synovial angiogenesis was examined by counting microvessel numbers after immunohistochemical staining. The ability of nanoparticles to suppress endothelial cell proliferation was tested by using VEGF-treated human dermal microvascular endothelial cells-1 (HMVEC-1).

Results: Articular indexes of nanoparticles-injected joints were reduced as compared with PBS-treated counterparts. There were lower histological and radiographic scores with less pannus formation and erosion of cartilage/bone in nanoparticles-treated synovium. Reduced IL-1b concentrations were identified in the treatment group. Notably, nanoparticles-treated synovium had decreased microvessel density without reduction of VEGF levels, and nanoparticle treatment inhibited VEGF-induced HMVEC-1 proliferation in a dose-dependent manner, suggesting that the mechanism of angiogenesis inhibition was through the interference in the signal transduction pathway rather than physical adsorption of the growth factor.

Conclusion: This study demonstrates first that intra-articular injection of $C60(OH)_{36}$ nanoparticles ameliorates CIA through anti-angiogenesis effect, further implicating a novel mechanism in application of certain fullerene derivatives as potential therapeutic agents in rheumatoid joints.

Anti-IL-6 Receptor Antibody Prevents Deterioration in Bone Structure in a Mouse Model of Collagen-Induced Arthritis. Hiroto Yoshida, Mika Yagoto, Miho Suzuki, Keisuke Tanaka, Misato Hashizume and Yoshihiro Matsumoto. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a disease that typically induces secondary osteoporosis, which increases the risk of bone fractures and, consequently, mortality. Bone fracture is induced not only by lower BMD but also by deterioration in bone structure. It is not clear whether anti–human IL-6 receptor antibody (tocilizumab) affects bone structure in RA patients, and the purpose of this study is to examine the changes in bone structure that occur when arthritis develops and the effects of anti-IL-6 receptor antibody on those changes, using a mouse model of collagen-induced arthritis (CIA).

Methods: CIA was triggered in DBA/1J mice by an intradermal injection of bovine type II collagen on Days 0 and 21. Mice were injected intraperitoneally either with anti-mouse IL-6 receptor antibody (MR16-1) on Days 0 and 21 or with TNF receptor-Fc (TNFR-Fc) 3 times per week from Day 0 to Day 56. Urine and serum were sampled on Day 35, the peak of swelling. Urinary CTX, a bone resorption marker, and serum P1NP, a bone formation marker, were measured by ELISA. Femurs and lumbar spine were excised on Day 56, after swelling subsided. In the distal femur and L5 lumbar spine, the bone structure of trabecular bone and cortical bone was analysed by micro-computed tomography (μCT).

Results: In CIA mice, urinary CTX and serum P1NP were significantly higher and lower, respectively, than in non-immunized mice. Trabecular bone volume (BV/TV), trabecular number (Tb. N), trabecular thickness (Tb. Th), and cortical bone thickness (Ct) of the distal femur, and BV/TV and Tb. N of the L5 lumbar spine in CIA mice were significantly lower than in non-immunized mice. Both MR16-1 and TNFR-Fc suppressed the development of arthritis. An increase in urinary CTX during development of CIA was prevented by MR16-1 and TNFR-Fc. On the other hand, a decrease in serum P1NP was prevented by only MR16-1. MR16-1 treatment significantly suppressed the deterioration in bone structure (BV/TV, Tb. N, Tb. Th, and Ct in the distal femur, and BV/TV and Ct in the L5 lumbar spine). TNFR-Fc treatment significantly suppressed the decrease of BV/TV and Tb. N in the distal femur.

Conclusion: We demonstrated that CIA induced severe deterioration in bone structure through an imbalance of bone turnover that was a result of not only increased bone resorption but also decreased bone formation. Moreover, our results indicated that proinflammatory cytokines such as IL-6 and TNF play an important role in bone structure deterioration. Our findings indicate that anti-IL-6 receptor antibody improves the imbalance in bone turnover by suppressing both the increase in bone resorption and the decrease in bone formation and thus prevents the deterioration in bone structure.

Specific Overexpression of FPR2 (FPRL-1) on Th1 Cells in GPI-Induced Arthritis and Patients with Rheumatoid Arthritis. Yuki Tanaka[1], Isao Matsumoto[2], Asuka Inoue[1], Naoto Umeda[3], Chinatsu Takai[4], Yuko Kurashima[5], Hoshimi Kawaguchi[5] and Takayuki Sumida[2]. [1]University of Tsukuba, Tsukuba city, Ibaraki, Japan, [2]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [3]University of Tsukuba, Tsukuba City, Japan, [4]University of Tsukuba, Ibaraki, Japan, [5]University of Tsukuba, Tsukuba, Japan.

Background/Purpose: $CD4^+$T cell are critical to the pathogenesis of rheumatoid arthritis (RA). In glucose-6-phosphate isomerase (GPI) induced-arthritis (GIA), Th1 and Th17 cells are indispensable for both the induction and the effector phase. We recently identified the highly expression of formyl

peptide receptor 2 (FPR2) in splenic $CD4^+$T cells from GIA mice by DNA microarray. The FPR2 (human homologue: FPRL-1) is a G-protein coupled receptor showing pro- and anti-inflammatory effect. To clarify the function of FPR2 in CD4+ T cells in the generation of arthritis, we investigated the expression of FPR2 in GIA and FPRL-1 in patients with RA.

Methods:

(1) To confirm the results of DNA microarray, we analyzed the fluctuated expression of FPR2 mRNA on $CD4^+$T cells in GIA (day0, day 7: induction phase, day 14: effector phase, day 28: contraction phase) by real-time PCR.

(2) To determine the Th subsets expressing FPR2, we sorted $FPR2^+$ or $FPR2^-$ $CD4^+$T cells from lymph nodes of GIA (on day7), and the mRNA expression of various markers on $CD4^+$T cell subsets (Th1, 2, 17, Tfh and Treg) was examined.

(3) We analyzed the expression of FPR2 on Th1 or Th17 cells in the polarized condition in vitro.

(4) In human, we analyzed the expression of FPRL-1 mRNA on peripheral blood mononuclear cells (PBMC) and $CD4^+$T cells from healthy subjects (HS), patients with Sjogren's syndrome (SS), and RA patients.

(5) We assessed the expression of FPRL-1 on human Th1 cells in the polarized condition in vitro.

Results:

(1) The FPR2 mRNA was significantly highly expressed on $CD4^+$T cells in GIA on day7 ($p<0.05$).

(2) The T-bet and IFNγ were higher expressed on $FPR2^+CD4^+$T cells than those on $FPR2^-CD4^+$T cells, whereas each marker for Th2, Th17, Tfh and Treg cells were not.

(3) The expression of FPR2 was frequently detected on Th1 polarized cells, but not on Th17 polarized cells.

(4) The expression of FPRL-1 on PBMC and $CD4^+$ cells was significantly higher in RA compared with HS and SS ($p<0.05$).

(5) FPRL-1 expression was significantly increased on human Th1 polarized cells.

Conclusion: We identified that $FPR2^+$T cells showed Th1 phenotype in mice and FPRL-1 was highly detected on $CD4^+$T cells in patients with RA. Th1 polarized cells in mice and humans also expressed FPR2 and FPRL-1, respectively, suggesting $FPR2^+$ ($FPRL\text{-}1^+$) T cells might play a crucial role in the pathogenesis of RA.

Therapeutic Effect of a Novel Histone Deacetylase 6 Inhibitor, CKD-L, on Collagen Induced Arthritis and Peripheral Blood Mononuclear Cells from Patients with Rheumatoid Arthritis. Bo Ram Oh[1], Hyojin Lim[2], Daekwon Bae[2], Nina Ha[2], Young il Choi[2], Hyun Jung Yoo[1], Jin Kyun Park[3], Eun Young Lee[4], Eun Bong Lee[3] and Yeong Wook Song[1]. [1]Department of Molecular Medicine and Biophamaceutical Sciences, BK 21 plus Graduate School of Convergence Science Technology, Colleage of Medicine, Seoul National University, Seoul, South Korea, [2]Department of Pharmacology and Toxicology, CKD Research Institute, CKD Pharmaceutical Company, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea, [4]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Epigenetic regulation plays an important role in inflammatory arthritis, including rheumatoid arthritis (RA). Histone deacetylase inhibitor (HDACi) has been recently reported to have therapeutic effect in collagen induced arthritis (CIA). CKD-L is a new HDAC6i developed by Chong Kun Dang Pharmaceutical Corporation. We investigated the therapeutic effect of selective HDAC6 inhibitors (CKD-L and Tubastatin A) on CIA, peripheral blood mononuclear cells (PBMCs) and regulatory T (Treg) cells.

Methods: CIA was induced by bovine type II collagen (CII) in DBA/1 mouse. Mice were treated with vehicle (n=10), CKD-L (15, 30 mg/kg, n=10, respectively) or Tubastatin A (30 mg/kg, n=10) by subcutaneous injection every day for 18 days. Arthritis score was assessed twice weekly after the onset of arthritis. Histological analysis was performed by H&E stain. $CD4^+CD25^-$ cells were isolated from C57BL/6 mice spleen and activated with anti-CD3/CD28 beads, TGF-β and HDAC6i (1~10 μM) for 6 days. Cytotoxic T lymphocyte associated protein 4 (CTLA-4) expression in induced Treg (iTreg) cells was analysed by flow cytometry. Natural Treg (nTreg) cells and $CD4^+CD25^-$ (Teff) cells were isolated from C57BL/6 mice spleen. nTreg cells were incubated with anti-CD3/CD28 bead, HDAC6i (200~2000 nM) and carboxyfluorescein succinimidyl ester (CFSE)-labeled Teff cells for 3 days (Treg:Teff ratio=1:2). Proliferation of Teff cells was analysed by flow cytometry. RA PBMCs were stimulated with lipopolysaccharide 100 ng/ml and HDAC6i (10–5000 nM) for 24 hours. Multiplex cytokine assay was performed with supernatant. RA $CD4^+CD25^-$ cells were cultured with anti-CD3 Ab, anti-CD28 Ab, IL-2, TGF-β and $1,25(OH)_2VD_3$ for 5 days. iTreg cells were incubated for 3 days with CFSE-stained Teff cells in the presence of anti-CD3/CD28 beads and HDAC6i (10–5000 nM). Proliferation of Teff cells was analysed by flow cytometry.

Results: In CIA, CKD-L and Tubastatin A significantly reduced arthritis score and histological score. CTLA-4 expression in mouse iTreg cells was increased after treatment of CKD-L ($P<0.001$) and Tubastatin A ($P<0.05$). And mouse nTreg cells inhibited the proliferation of Teff cells after treatment with CKD-L (67.8 %) and Tubastatin A (68.3 %) compared to no treatment (80.1 %). In RA PBMC, TNF-α was decreased after treatment with CKD-L ($P<0.001$) and Tubastatin A ($P<0.001$). IL-10 was increased after treatment CKD-L ($P=0.051$) and Tubastatin A ($P=0.083$). In co-culture with iTreg cells and Teff cells, CKD-L efficiently inhibited the proliferation of Teff cells (13.9 %) compared to no treatment (32.6 %). Tubastatin A had no effect on proliferation of Teff cells (30.1%).

Conclusion: CKD-L was effective on the suppression of arthritis in CIA. CKD-L increased CTLA-4 expression and function of Treg cells. These results suggest that CKD have beneficial effect in the treatment of RA.

Activatory Fc Gamma Receptor IV Plays a Crucial Role in Pathogenesis of Experimental Immune Complex Mediated Chronic Arthritis. Irene Di Ceglie[1], Arjen Blom[1], Sjef Verbeek[2], Peter van der Kraan[1], Wim van den Berg[1] and Peter L. van Lent[1]. [1]Experimental Rheumatology, Radboud University, Nijmegen, Netherlands, [2]Human Genetic, Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Rheumatoid arthritis is characterized by Immune complex dependent chronic joint inflammation and severe cartilage and bone destruction. Earlier we found that in the absence of activatory FcγRI and III, joint destruction during the early murine phase of antigen-induced arthritis (AIA) was protected (1) but the role of FcγRIV has not yet been elucidated.

Methods: AIA was induced by injection of mBSA into the knee joint of $Fc\gamma RI,II,III^{-/-}$, $Fc\gamma I,II,III,IV^{-/-}$and wild type (WT) control mice previously immunized with mBSA/CFA. Histology of total knee joints was taken at day 7 and 21 after arthritis induction. Joint inflammation was scored using an arbitrary scale. Cartilage damage was measured as proteoglycan (PG) depletion. Bone destruction was determined using an arbitrary score. mBSA antibody titers were determined using ELISA.

Results: Both KO strains showed antibody titers against mBSA comparable to immunized control mice. In the early phase of AIA (day 7), joint inflammation was significantly higher in $Fc\gamma RI,II,III^{-/-}$ (infiltrate 47% and exudate 107% higher) when compared to WT controls. In $Fc\gamma RI,II,III,IV^{-/-}$however, although comparable antibody titers, inflammation was significantly lower (infiltrate 30% and exudate 46% lower) than in WT controls. Early cartilage destruction was protected in both strains reflected by significantly lower PG depletion (34% and 20% lower respectively) when compared to their WT controls.

During the chronic phase at day 21, joint inflammation in $Fc\gamma I/II/III^{-/-}$ was still significantly higher (infiltrate 450% and exudate 170% higher) when compared to WT controls. Protection of cartilage damage seen in early AIA was lost and PG depletion significantly increased in $Fc\gamma RI,II,III^{-/-}$by 260 %. Bone erosion also increased by 150%. These results suggest that FcγRI and III regulate destruction in the early phase whereas FcγRIV may be more important in chronic stages of arthritis.

In line with this we found that joint inflammation in $Fc\gamma RI,II,III,IV^{-/-}$ was much lower when compared with $Fc\gamma I/II/III^{-/-}$ and remained at the same level as their WT controls, implying an active role of FcγRIV in inflammation during the chronic phase. The amount of PG depletion in $Fc\gamma RI,II,III,IV^{-/-}$was comparable to that observed in WT. In contrast erosion of cartilage matrix but also bone were found to be significantly lower when compared to WT controls (76% and 34% lower respectively).

Conclusion: Activatory FcγRIV is crucial in regulating joint inflammation during acute and chronic phase of AIA and became crucial in mediating cartilage and bone destruction during the chronic phase of the disease.

Early Sympathectomy Inhibits Egress of Lymphocytes in Control and Arthritic Animals and Ameliorates Arthritic Disease. Susanne Klatt and Rainer Straub. University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: The sympathetic nervous system (SNS) plays an important role in course and development of autoimmune diseases like arthritis. In type II collagen- induced arthritis (CIA), early activation of the SNS is proinflammatory, but the SNS is anti-inflammatory in later stages of disease. Early sympathectomy (SYX) prior to immunization ameliorates disease severity, but beneficial mechanisms of early SYX are not completely understood. The aim of this study was to determine how the SNS influences energy expenditure in lymph nodes / spleen and, in parallel, egress of lymphocytes from draining lymph nodes / spleen of control and arthritic animals.

Methods: A new technique termed "spatial energy expenditure configuration (SEEC)" was developed to demonstrate bodily areas of high energy demand. SEEC is based on removal of tissue during the course of arthritis in DBA/1 mice, and subsequent determination of oxygen consumption *in vitro* as a measure of local energy expenditure (immune cell activation). SEEC was applied to healthy control animals, arthritic animals, and animals that underwent early SYX. We evaluated homing behaviour of labelled donor splenocytes, expression of CCR7 on lymphocytes by flow cytometry, concentration of CCL21 in lymphocyte cell culture supernatants, and levels of sphingosine-1-phosphate (S1P) in serum of arthritic, sympathectomized arthritic, and control animals.

Results: In draining lymph nodes and spleens of arthritic mice, we observed a marked increase in oxygen consumption and organ weight during the course of arthritis. Although early SYX ameliorated later CIA, early SYX increased energy consumption and cell numbers in arthritic but also in control lymph nodes. This was interpreted as a probable sign of lymphocyte retention in lymphoid organs in healthy and arthritic animals. Splenocyte migration to the spleen was enhanced in early SYX compared to control mice. After early SYX, we observed an elevated expression of CCR7 on lymph node cells and a higher level of CCL21 in lymphocyte cell culture supernatants. This probably contributes to retention of T cells and dendritic cells within lymph nodes. Egress of lymphocytes requires an S1P gradient, low in the lymph node parenchyma and high at the exit site in the vascular lumen. The measurement of S1P in mouse serum revealed a significant higher concentration in CIA animals when compared to controls. Importantly, early SYX decreased S1P concentration in arthritic animals to control levels.

Conclusion: By using the SEEC technique, we identified draining lymph nodes as target organs of the sympathetic nervous system. SYX-induced disease amelioration is probably exerted by sequestration of lymphocytes in secondary lymphoid organs. This might prevent recirculation of immune cells to peripheral sites of inflammation.

A Humanized Monoclonal Antibody Raised Against a Heat Shock Protein Epitope Suppresses Autoimmune Inflammatory Diseases By Skewing the Immune System Selectively Towards an Anti-Inflammatory Response. Yaakov Naparstek[1], Rina Ulmansky[1], Galia Katzavian[2], Ronit Meyuhas[2], Eli Moallem[1], Shira Yair[2], Dorit Landstein[2] and Virginie Loeb[2]. [1]Hadassah - Hebrew University Medical Center, Jerusalem, Israel, [2]ProtAb Ltd., Jerusalem, Israel.

Background/Purpose: We have previously shown that resistance to Adjuvant Arthritis (AA) is due to the presence of anti-heat shock protein (HSP) antibodies, directed at peptide-6, a 16 amino acid epitope of Mycobacterium Tuberculosis (MT) HSP65. Furthermore, we have shown that polyclonal rat anti-peptide-6 antibodies suppress AA and bind to the whole MT HSP65 molecule as well as its mammalian homolog, HSP60. In this work, we have studied the effect of a humanized anti-peptide-6 monoclonal antibody, termed Prozumab, on various models of autoimmune arthritis and colitis and the mechanism of its anti-inflammatory effect.

Methods: We have recently developed a humanized anti-peptide-6 antibody, termed Prozumab, and evaluated its potential as a therapeutic immunomodulatory drug. We tested its binding to MT HSP65 and mammalian HSP60, its effect on cytokine modulation from human PBMCs, and its therapeutic effects in acute and chronic animal models of arthritis and colitis.

Results: Prozumab bound similarly to recombinant MT HSP65 and mammalian HSP60. Its ability to modulate cytokine balance was established as it induced IL-10 secretion from human PBMC. Moreover, in the presence of Prozumab, a reduction in secretion of IFNg and IL-6 from anti-CD3 activated human PBMC was observed. Administration of this antibody to mice and rats with collagen induced arthritis, adjuvant arthritis and TNBS colitis, induced a change in the cytokine balance and suppression of disease. Treatment with this antibody suppressed disease severity in spontaneous IL-10 knock-out colitis in mice as well. The level of natural anti-peptide-6 antibodies in the serum of patients with rheumatoid arthritis was significantly lower than in healthy controls.

Conclusion: We conclude that HSP65 contains protective B-cell epitopes exposed on its surface, and that natural and acquired resistance to autoimmune arthritis is associated with the ability to develop an antibody response to these epitopes. These antibodies cross react with the human HSP60, modulate cytokine production from human PBMCs and ameliorate disease in experimental autoimmune inflammatory disease models. The high homology between the peptide-6 region in MT HSP65 and the mammalian HSP60 and the similarity of the in vitro binding suggest that HSP60 is its target on mammalian cells. Presence of HSP60 on various mammalian cells has been shown previously. Lower levels of anti-peptide-6 antibodies in patients with RA suggest that they play a role in protection against human autoimmune diseases as well. The monoclonal humanized anti-peptide-6 antibody may serve as a new therapeutic tool for suppression of human arthritis and inflammatory bowel diseases by skewing the immune system selectively towards an anti-inflammatory response.

Ligand of Glucocorticoid-Induced Tumor Necrosis Factor Receptor Enhances Th17 Cells Response in Collagen-Induced Arthritis Via P38 MAPK and STAT3 Pathway. Xinyi Tang[1] and Shengjun Wang[2]. [1]Jiangsu University Affiliated People's Hospital, Zhenjiang, China, [2]Jiangsu University Affiliated People's Hospital, Zhenjiang, China.

Background/Purpose: Helper T lymphocyte-17 (Th17) has recognized to be an important factor in rheumatoid arthritis (RA) pathogenesis. The natural ligand of glucocorticoid-induced tumor necrosis factor receptor (GITRL) could exacerbate autoimmune arthritis via the enhancement of Th17 cells expansion. It has reported that GITRL/GITR could trigger phosphorylation of p38 mitogen-activated protein kinase in T cell. The purpose of this study is to investigate the role of p38 signaling during the enhancement of Th17 expansion and exacerbation of autoimmune arthritis by GITRL stimulation.

Methods: We used mouse GITRL (mGITRL) protein as a co-stimulatory factor for Th17 differentiation in presence or absence of p38 inhibitor and detected ability of Th17 differentiation. Activated naïve $CD4^+$T cells were pretreated with or without p38 inhibitor before stimulated with mGITRL and phosphorylation of p38 and STAT3 were examined by western blot. And we injected mGITRL protein into collagen induced arthritis (CIA) mice alone or combine with the p38 inhibitor, and observed development of arthritis.

Results: In previous study, we have certificated a function of GITRL in exacerbating autoimmune arthritis via the enhancement of Th17 cells expansion. In this study, naïve $CD4^+$T cells could differentiate into higher frequency of Th17 cells under the mGITRL co-stimulated and be attenuated in a concentration dependent manner by p38 inhibitor treatment. Also, the relative expression of RORγt and IL-17 mRNA was impaired with p38 inhibitor in a concentration dependent manner. Phosphorylation of p38 was reinforced in activated naïve $CD4^+$T cells after stimulated with GITRL protein. STAT3 has two important phosphorylation sites, tyrosine705 (Tyr705) and serine727 (Ser727). An enhancement of STAT3Ser727 phosphorylation by mGITRL stimulate was observed and been attenuated in activated naïve $CD4^+$T cells with p38 inhibitor pretreated. CIA models were established for investigate the function of p38 in the process of arthritis. Compared with the group treated by mGITRL protein (mGITRL-CIA group), the group injected with mGITRL and p38 inhibitor (mGITRL-SB203580-CIA group) had a later onset of symptoms and reached the peak score gently. There were more serious inflammatory changes in the mGITRL-CIA group. Th17 cells and the level of IL-17 in serum of the mGITRL-group increased significantly compared with the mGITRL-SB203580-CIA group.

Conclusion: Our results suggested that the enhancement of Th17 cells differentiation with mGITRL stimulation was influenced by p38-STAT3 singnaling pathway activation; the exacerbation of CIA development in mice by mGITRL can be released with p38 inhibitor treatment and correlate with

the attenuation of Th17 cells. This phenomenon may provide a new insight in the study of RA pathopoiesis and clinical treatment.

RORγt Expressing Foxp3$^+$ Regulatory T Cells Regulates the Development of Autoimmune Arthritis in Mice. Yuya Kondo[1], Masahiro Tahara[1], Mana Iizuka[1], Masahiro Yokosawa[1], Shunta Kaneko[1], Hiroto Tsuboi[1], Satoru Takahashi[2], Isao Matsumoto[1] and Takayuki Sumida[1]. [1]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Laboratory Animal Resource Center, University of Tsukuba, Tsukuba, Japan.

Background/Purpose: To determine the effect of RORγt overexpression in T cells on the development of collagen induced arthritis (CIA).

Methods: Arthritis was induced with chicken type II collagen (CII) in both C57BL/6 (B6) and CD2 T cell-specific RORγt Transgenic (RORγt Tg) mice. Anti-CII antibody in sera was measured by ELISA. At 10 days after the first immunization of CII, lymph node (LN) cells were cultured with or without CII, and then the expression level of cytokine, transcription factor and chemokine receptor on CD4$^+$ T cells were analyzed by flow cytometer and RT-PCR. Cytokine levels in culture supernatants were measured by ELISA. Joint infiltrating cells were also examined by flow cytometer. Cytokine production and suppressive function of Foxp3$^+$ regulatory T cells was analyzed in vitro. Total draining lymph nodes cells or CD4$^+$cells were harvested from B6 mice or RORγt Tg mice at 10 days after the first immunization of CII, and cells were injected into B6 mice intravenously at 10 days after the immunization of CII. Mice were also immunized with CII in CFA intradermally on 11 days after the cell transfer.

Results: CIA was significantly suppressed in RORγt Tg mice compared with B6 mice. Anti-CII antibody in sera was also reduced in RORγt Tg mice. RORγt expression and IL-17 production in CII reactive CD4$^+$ T cells was significantly increased in RORγt Tg mice. Although there was no difference in IFNγ production and T-bet and Foxp3 expression between B6 mice and RORγt Tg mice, RORγt expression in Foxp3$^+$ regulatory T cells were significantly higher in RORγt Tg mice than B6 mice. Most of Foxp3$^+$ regulatory T cells expressed chemokine receptor 6, and which highly infiltrated in joints after the induction of CIA in RORγt Tg mice. Moreover, Foxp3$^+$ regulatory T cells in RORγt Tg mice retain the expression of CD25, the suppressive function of effector CD4$^+$ T cells in vitro, and IL-10 production as well as Foxp3$^+$ regulatory T cells in B6 mice. In adoptive transfer of draining LN cells or CD4$^+$cells from immunized mice, arthritis was significantly attenuated in recipient B6 mice transferred with cells from RORγt Tg mice.

Conclusion: CIA was significantly suppressed in RORγt Tg mice, although IL-17 production and RORγt expression in CII reactive T cells was markedly higher than that of B6 mice. In vitro analyses and cell transfer experiments proposed the possibility that RORγt induced expression of CCR6 in Foxp3$^+$ regulatory T cells, and these cells might regulate the development of CIA.

The Nitric Oxide Receptor Soluble Guanylyl Cyclase Is Found in Lymphatic Vessels of Arthritic Mice and Inhibition Alters Lymphatic Pulse. Homaira Rahimi[1], Yawen Ju[2], Echoe M. Bouta[3], Ronald Wood[4], Christopher T. Ritchlin[4] and Edward M. Schwarz[2]. [1]University of Rochester/Golisano Children's Hospit, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester School of Medicine and Dentistry, Rochester, NY, [4]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic erosive inflammatory condition that is characterized by episodes of "flare" due to synovitis of an affected joint. It has been shown in the tumor necrosis factor transgenic (TNF-Tg) mouse model of RA that the popliteal lymph node (PLN) can serve as a biomarker of arthritic flare. Prior to onset of knee flare, the PLN is expanded and an intrinsic lymphatic pulse is maintained. However, at some point following chronic ankle arthritis, the PLN suddenly collapses, the lymphatic pulse is lost, and knee arthritis occurs. Here, we show that the nitric oxide (NO) signaling pathway, known to be involved in blood vasculature contractility, is involved in lymphatic vessel contractility, and that the NO receptor soluble guanylyl cyclase (sGC) may be a key regulator.

Methods: Immunofluorescent microscopy was performed on fresh frozen histology sections of PLN from wild type (WT) and TNF-Tg mice stained for alpha (a1, a2) and beta (b1) subunits of sGC and co-localized with smooth muscle actin. In WT mice, near infrared indocyanine green (NIR-ICG) imaging was performed to determine and quantify lymphatic pulse. The sGC inhibitor NS2028 or control vehicle was injected into the footpads of mice, and lymphatic pulse was measured with NIR-ICG imaging 30 minutes later.

Results: Immunohistochemistry confirmed the presence of all sGC subunits in PLN from both WT and TNF-Tg mice. Of the six footpads injected with sGC inhibitor NS2028, a clear alteration in the lymphatic pulse with more frequent doublet and triplet spikes compared to control was observed (Figure 1). Quantification of the pulse showed an increased lymphatic pulse in the drug treated limb compared to control (2.66 vs 1.39 pulse per minute, respectively, $p<0.05$).

Conclusion: The presence of sGC receptor subunits in the lymphatic tissue of WT and TNF-Tg mice strongly supports a role for nitric oxide signaling in lymphatic contractility. Furthermore, local injection of sGC inhibitor in WT mice results in a dysregulated lymphatic pulse with an increased rate. This novel finding of increased lymphatic pulse rate with sGC inhibition suggests resumption of the lymphatic pulse in arthritic flare in mice via specific targeting of the sGC receptor may ameliorate flare in inflammatory arthritis.

Efficacy of a Novel Orally Bioavailable JAK1 Selective Compound in a Preclinical Rat Collagen-Induced Arthritis Model. Lily Y. Moy, Chi-Sung Chiu, Robert Faltus, Mark Zielstorff, Kalyan Chakravarthy, Sujal Deshmukh, Ilona Kariv, Joel Klappenbach, Jason Brubaker, Duan Liu, Tony Siu, Jonathan Young, Hongshi Yu, Fiona Elwood and Milenko Cicmil. Merck Research Laboratories, Boston, MA.

Background/Purpose: Janus kinase (JAK) is a family of four tyrosine kinases that play a critical role in cytokine signaling and downstream lymphocyte activation and function. Inhibition of JAK enzymes as therapeutic targets in rheumatoid arthritis (RA) has been validated by multi-JAK inhibitors that modify disease in clinical studies. However, there is also evidence from these trials that JAK inhibition with Tofacitinib increases the risk of infections as well as highlighting other potential toxicity concerns. These side effects are thought to be attributable to JAK2 inhibition, suggesting that better therapeutic ratios might be achieved with selective JAK inhibitors that spare JAK2 activity. Here we report the *in vitro* and *in vivo* preclinical characterization of a highly selective JAK1 inhibitor (Compound B) as compared to the effects of a multi-JAK inhibitor (Compound A).

Methods: Biochemical assays were used to determine JAK family kinase potencies. Cellular assays included: 1) IL-6 induced pSTAT3 driven gene expression in ME-180 cells and 2) erythropoietin induced pSTAT5 driven gene expression in TF1 cells. Collagen-induced arthritis (CIA) in female Lewis rats was performed with a subcutaneous injection of bovine collagen on Days 1 and 8. Inflammation was monitored by measuring paw thickness; μCT imaging and histopathological evaluation were also performed in the ankle joint at the end of the study. Inhibition of baseline hematological parameters was assessed separately in naïve female Lewis rats following compound administration.

Results: Compounds A and B are reversible ATP competitive inhibitors of JAK1 and JAK2. Compound A has comparable activity in both enzymatic and cellular assays, whereas Compound B displays ~10X selectivity for JAK1 to JAK2 in the same assays. Therapeutic administration of both compounds dose-dependently inhibited the inflammation resulting from CIA in rats *in vivo*. Compound exposure levels corresponding to 50% inhibition were approximately 70μM*hr and 12μM*hr for Compounds A and B,

respectively. Inhibition of hematological parameters (reticulocytes, hemoglobin and hematocrit levels) in naïve rats was observed with compound administration at exposures comparable to that required for efficacy in the rat CIA model for the non-selective JAK inhibitor, Compound A. In contrast, for the JAK1 selective Compound B, changes in these parameters were not observed until >10X exposures of that required for efficacy in the rat CIA model were achieved. Furthermore, Compound B inhibited bone mineral density loss by μCT and attenuated inflammation, pannus formation, and cartilage damage by histopathology.

Conclusion: We identified a JAK1 selective compound using enzymatic and cellular assays where selectivity translated to *in vivo* selectivity in rats. These data demonstrate that a similar degree of preclinical efficacy is achievable with a JAK1 selective inhibitor as compared to a multi-JAK inhibitor. Importantly, the JAK1 selective inhibitor provided ~10X therapeutic window to adverse events. The optimal JAK selectivity profile to achieve maximal clinical efficacy with minimal side effects in patients remains to be determined.

Apremilast, a Novel Phosphodiesterase 4 Inhibitor, and Methotrexate Independently Prevent Inflammation *in Vivo* and *in Vitro*. Miguel Perez-Aso[1], M. Carmen Montesinos[2], Aranzazu Mediero[3], Peter H. Schafer[4] and Bruce N. Cronstein[5]. [1]New York University, New York City, NY, [2]Universitat de València, Valencia, Spain, [3]NYU School of Medicine, New York, NY, [4]Celgene Corporation, Summit, NJ, [5]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Phosphodiesterase 4 (PDE4) inhibitors have clear immunoregulatory effects in laboratory studies, and the clinical application of this class of drug in the field of rheumatology is now beginning with the introduction of the novel PDE4 inhibitor apremilast, which was recently approved by the FDA for the treatment of psoriatic arthritis. Although apremilast is known to increase intracellular cAMP levels, less is known about its downstream signaling mediators. We therefore undertook this work to delineate intracellular signaling pathways for apremilast and to examine interactions between apremilast, methotrexate (MTX), and adenosine A2A receptors ($A_{2A}R$).

Methods: After apremilast and lipopolysaccharide incubation, intracellular cAMP, TNF-α, IL-10, IL-6, and IL-1α were measured in the Raw264.7 mouse monocytic cell line. PKA, Epac1/2 (signaling intermediates for cAMP), and A_2R knockdowns were performed by shRNA transfection and interactions with $A_{2A}R$ and $A_{2B}R$. Apremilast and MTX were tested *in vivo* in the murine air pouch model.

Results: *In vitro*, apremilast increased intracellular cAMP (apremilast 1 μM: 240.0±57.7% of control, n=3, $P<0.001$) and reduced TNF-α release ($pIC_{50}=6.98\pm0.20$, n=8), and MTX reduced TNF-α release (maximum inhibition 50.9±10.2% of vehicle, n=3). The specific $A_{2A}R$-agonist CGS21680 (1 μM) increased apremilast potency ($pIC_{50}=7.59\pm0.20$, n=8), suggesting that apremilast-mediated TNF-α inhibition can be enhanced by signaling through $A_{2A}R$. In this mouse-derived cell line, apremilast increased IL-10 (apremilast 100 nM: 576.3±32.8% of control, n=3, $P<0.001$) and IL-6 (apremilast 100 nM: 257±53.1% of control, n=3, $P<0.05$). PKA, Epac1, and Epac2 knockdowns reduced TNF-α inhibition and IL-10 stimulation by apremilast. In the murine air pouch model, both apremilast and MTX significantly inhibited leukocyte infiltration, while apremilast, but not MTX, significantly inhibited TNF-α release (apremilast 5 mg/kg: leukocyte accumulation 72.5±11.6% of vehicle, n=6, $P<0.05$; TNF-α release 65.5±7.7% of vehicle, n=6, $P<0.001$; MTX 1 mg/kg: leukocyte accumulation 54.6±3.9% of vehicle, n=20, $P<0.001$; TNF-α release 83.7±8.9% of vehicle, n=5, $P>0.05$). The addition of MTX (1 mg/kg) to apremilast (5 mg/kg) yielded no more inhibition of leukocyte infiltration or TNF-α release than that of apremilast alone.

Conclusion: The immunoregulatory effects of apremilast appear to be mediated by cAMP through the downstream effectors PKA, Epac1, and Epac2. $A_{2A}R$ agonism potentiated TNF-α inhibition by apremilast, consistent with the cAMP-elevating effects of that receptor. Because $A_{2A}R$ is also involved in the anti-inflammatory effects of MTX, the mechanism of action of both drugs involves cAMP-dependent pathways and is therefore partially overlapping in nature.

Toluenesulfonylamido-Chalcone, 4-(p-toluenesulfonylamido)-4-Hydroxychalcone (TSAHC) Suppresses Inflammatory Response and Joint Destruction in an Experimental Arthritic Mice and Fibroblast-like Synoviocytes. Yun-Hong Cheon[1], Wan-Hee Yoo[2], Young Sun Suh[3], Min-Gyu Jeon[3], Hyun-Ok Kim[3] and Sang-Il Lee[3]. [1]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Chonbuk National University School of Medicine, Jeonju, South Korea, [3]Gyeongsang National University School of Medicine, Jinju, South Korea.

Background/Purpose: TSAHC, a toluenesulfonylamido-chalcone, 4-(p-toluenesulfonylamido)-4-hydroxychalcone is a compound to block proliferation and metastatic potential of cancer cells. Fibroblast-like synoviocytes of rheumatoid arthritis (RA-FLS) have inflammatory phenotypes and tumor-like characteristics such as abnormal proliferation, apoptotic resistance, migration, and invasion. Thus, this study was performed to determine whether TSAHC suppress inflammation and joint destruction in K/BxN serum transfer arthritic mice and RA-FLS.

Methods: TSAHC was synthesized with a purity > 99.0%. Treatment included intravenous injections of PBS, vehicle, or TSAHC (5mg/kg once every other day, n=9–10 for each group) for 10 days in K/BxN serum transfer model. Arthritis severity and ankle histology was evaluated using a semi-quantitative scoring system. The levels of inflammatory cytokines in the joints and serum were measured by ELISA and quantitative PCR. The NF-kB activation and cytokine expression were assessed by Western blotting and quantitative PCR using RA-FLS.

Results: The mice injected with TSAHC showed less severe arthritis than vehicle group in clinical score (5.4 ± 0.39 vs. 3.9 ± 0.79, mean ± SE, $p < 0.05$) and the change of ankle thickness (0.49 ± 0.04 vs. 0.29 ± 0.04 mm, $p < 0.01$). The pathologic analysis also showed decreased inflammation and bone erosion in TSAHC group. The levels of TNF-α, IL1-β, and sRANKL were decreased in serum and ankle tissue of TSAHC group than vehicle. In addition, IL-10 was increased nearly by 51% in TSAHC group than vehicle ($p<o.o5$). 20uM of TSAHC, which observed as the highest non-toxic concentration on the cell viability, decreased IL-6 production with reduction of nearly 40% than vehicle ($p<0.05$) and inhibit nuclear translocation of NF-κB in TNF-α-stimulated RA-FLS.

Conclusion: This study indicates that TSAHC inhibit inflammation and bone destruction in arthritic mice and decrease IL- 6 production in RA-FLS via inhibition of NF-κB activation. Therefore, TSAHC may have therapeutic potential for the treatment of RA.

Vascular Adhesion Molecule-1 Overexpression in Collagen-Induced Arthritis: Modeling Vascular Dysfunction in Rheumatoid Arthritis. Luca Semerano[1], Gaelle Clavel[2], Delphine Lemeiter[3], Marie-Christophe Boissier[4] and Anne Denys[5]. [1]Avicenne Teaching Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP),, Bobigny, France, [2]Fondation Ophtalmologique A. De Rothschild, Paris cedex 19, France, [3]INSERM UMR 1125, Li2P, University Paris 13, Sorbonne Paris Cité, Bobigny, France, [4]AvicenneTeaching Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), Bobigny, France, [5]INSERM UMR U1125, University Paris 13, Sorbonne Paris Cité, Bobigny, France.

Background/Purpose: Rheumatoid Arthritis (RA) patients are at risk of developing primary coronary heart disease earlier than general population. Increased cardiovascular risk in RA is attributed to both traditional Framingham risk factors and systemic inflammation over a long period.

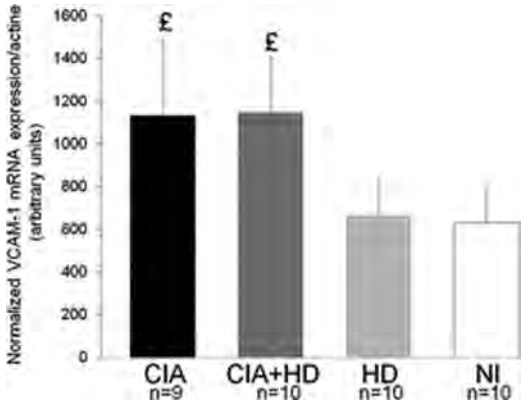
Limited experimental data exist on vascular involvement in arthritis models.

The aim of our study was to model vascular dysfunctions and inflammation in RA using CIA. We focused on VCAM-1, IL-17 and iNOS expression in aorta removed 15 weeks after arthritis induction.

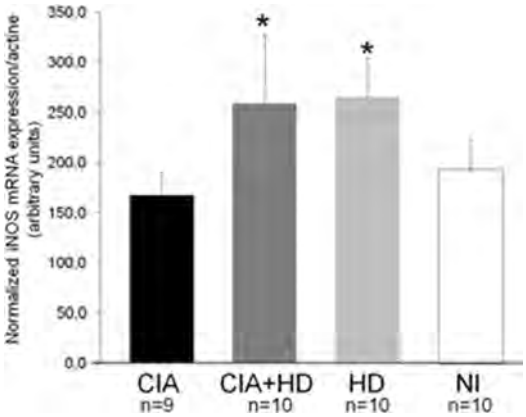
Methods: Arthritis was induced in C57BL mice (11 week old) by 2 injections within 21 days of chicken CII (cCII) emulsioned in Adjuvant (CFA). Half of these mice (n=12) were fed with a hyperlipidic diet (HD and the other half (n=12) with a standard diet. The control mice were not immunized (NI) but were fed either the standard diet (n=12) or HD (n=12). Aorta and synovial membranes were removed 15 weeks after the first immunization. We analysed VCAM-1, iNOS and IL-17 mRNA level in aorta by real time quantitative PCR (qRT-PCR). VCAM-1 localisation in the aortic sinus layers (intima, media and adventitia) was determined by immunohistochemistry (IHC).

Results: VCAM-1 expression was increased in aorta from CIA mice compared to NI mice, regardless of the fed diet (fig.1). Conversely, iNOS expression was increased in aorta from HD fed mice, whether immunized or not (fig.2). The expression of IL-17 in the aorta was not affected by collagen immunization or diet

Conclusion: CIA in C57BL6 mice is accompanied by large vessel inflammation. Collagen immunization induced vascular dysfunctions marked by VCAM-1 overexpression independently of the diet. Conversely, HD diet induced a distinct profile of vessel inflammation characterized by high iNOS expression. CIA may be a pertinent model to study cardiovascular disease in RA.



≤: p<0.05 vs.HD and NI



*: p<0.05 vs. CIA and NI

The Role of Dendritic Cells during Inflammatory Arthritis. Antonia Puchner[1], Victoria Saferding[1], Eliana Goncalves-Alves[1], Josef S. Smolen[2], Kurt Redlich[1] and Stephan Blüml[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Dendritic cells (DCs) play an important role in bridging the innate and the adaptive immune response by serving as antigen presenting cells and are therefore implicated in the initiation of chronic autoimmune diseases, including rheumatoid arthritis. Using two different models of inflammatory arthritis, K/BxN serum transfer arthritis as well as hTNFtg arthritis, both depending only on the innate immune system, we investigated the innate role of dendritic cells in inflammatory arthritis.

Methods: We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of $CD11c^+$ cells by immunohistochemistry. We also performed synovial biopsies and analyzed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphteria toxin receptor (DTR) transgenic mice, which express the human diphtheria-toxin receptor under the CD11c promoter, allowing for specific depletion of $CD11c^+$ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

Results: We show that $Cd11c^+$ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both myeloid dendritic subsets, $CD8^+$ $CD11c^+$ and $CD11b^+$ $CD11c^+$, can be found in synovial tissue. In K/BxN serum transfer arthritis, clinical scores showed that CD11c-DTR transgenic mice that received DT had significantly reduced paw swelling and loss of grip strength compared to PBS treated animals. Histological analysis found reduced inflammation after the depletion of $CD11c^+$ cells in K/BxN arthritis. In addition local bone destruction and the number of osteoclasts was significantly reduced. Also in TNF-driven arthritis in CD11c-DTR/hTNFtg mice, depletion of $CD11c^+$ cells led to a significant reduction of synovial inflammation, as well as local bone erosions. To exclude unspecific effects of DT in mice, wild type animals received DT showed identical clinical and histological signs of arthritis as PBS treated animals.

Conclusion: These data show that $CD11c^+$ cells are involved in innate reactions leading to inflammatory arthritis and suggest that dendritic cells could be an important therapeutic target for patients suffering from rheumatoid arthritis.

CGEN-15001, a Novel Immunomodulatory Fusion Protein of the B7 Family Induces Immune Tolerance and Shows Efficacy in Mouse Models of Rheumatoid Arthritis and Psoriasis. Iris Hecht[1], Kay McNamee[2], Aviad Keren[3], Joseph R. Podojil[4], Ilan Vaknin[1], Anat Oren[1], Galit Rotman[1], Eyal Neria[1], Stephen D. Miller[4], Amos Gilhar[3] and Richard O. Williams[2]. [1]Compugen Ltd., Tel Aviv, Israel, [2]Oxford University, Oxford, United Kingdom, [3]Technion Institute of Technology, Haifa, Israel, [4]Northwestern University, Chicago, IL.

Background/Purpose: CGEN-15001 is an Fc-fusion protein consisting of the extracellular domain of a novel B7-like protein, discovered based on shared family characteristics. CGEN-15001 inhibits T cell activation and demonstrates immunomodulatory activity by inhibiting Th1 and Th17 responses while promoting Th2 responses and IL-10 secretion. Potential re-establishment of immune tolerance by CGEN-15001 is suggested by durable long term efficacy observed following short course therapeutic treatment in the EAE model of multiple sclerosis and in the NOD mouse model of type 1 diabetes. Tolerance induction is further supported by prevention of graft rejection in the H-Y minor Ag mismatch bone marrow transplantation model and by enhancement of Tregs. CGEN-15001 is also efficacious in a CIA model of rheumatoid arthritis (RA) and we sought to further study its mode of action in this model. Furthermore, the efficacy of CGEN-15001 was tested in a humanized psoriasis mouse model to elucidate its therapeutic potential for this disease.

Methods: CIA was induced by immunizing DBA/1 mice with type II collagen (CII) in CFA. Efficacy was evaluated following therapeutic treatment starting at onset of arthritis symptoms. On day 10 of arthritis paws and sera were collected for analysis. For mode of action studies, treatment was given from the day of disease induction, and *ex-vivo* recall responses were tested on draining lymph nodes (dLN) cells harvested on day 10 and re-stimulated with CII or anti-CD3. Proliferation and cytokine secretion were evaluated.

Psoriasis was induced in normal human skin grafted onto SCID mice by intradermal injection of activated PBMCs from psoriatic patients. Treatment began at time of disease induction.

Results: CGEN-15001 demonstrated a potent therapeutic effect in the CIA model with significant reduction of clinical score and joint swelling. Reduced inflammation and joint erosion were observed by histological analysis of the arthritic joints. In addition, CGEN-15001 treatment resulted in increase of the CII-specific IgG1/IgG2a ratio in the serum, which is in line with a Th1/Th17 to Th2 shift observed previously in vitro and in vivo.

Recall responses of dLN cells from CGEN-15001 treated mice results in inhibition of proliferation and secretion of IL-17 and GM-CSF in cultures reactivated with the inducing antigen, CII.

In the psoriasis model, CGEN-15001 treatment resulted in prevention of psoriasiform features in 55% of grafts, and in significant reduction in epidermal thickness. In addition, decrease in hallmark pathologic and inflammatory features of psoriatic skin were shown by IHC.

Conclusion: The therapeutic effect of CGEN-15001 in the CIA model of RA and in the humanized mouse model of psoriasis support its therapeutic potential for these diseases. These findings might also indicate a potential clinical value for psoriatic arthritis, a disease which combines both skin and joint pathologies and is underserved by current therapies. Its effect on key pathologic mechanisms of these and other autoimmune diseases, including downregulation of Th1 and Th17 inflammatory responses, induction of regulatory T cells and restoration of immune tolerance suggest a broad therapeutic potential with durable long-term effect.

Glucocorticoids and Vascular Function in Arthritis: Benefic or Deleterious Effects? Study in Rat. Frank Verhoeven[1], Katy Maguin-Gaté[2], Perle Totoson[3], Daniel Wendling[4] and Céline Demougeot[5]. [1]CHU jean Minjoz, Besançon, France, [2]EA 4267 « Fonctions et Dysfonctions Epithéliales », Faculté de Médecine-Pharmacie, Besançon, France, [3]EA 4267 "Fonctions et Dysfonctions Epithéliales", besançon, France, [4]CHU J Minjoz, Besancon, France, [5]EA 4267 "Fonctions et Dysfonctions Epithéliales", Besançon, France.

Background/Purpose: Rheumatoid Arthritis (RA) is associated to an increase of cardiovascular (CV) risk explained in part by an accelerated atherosclerosis as a consequence of endothelial dysfunction. Glucocorticoids (GCs) are widely prescribed in RA patients. Surprisingly, despite the commonly held belief that glucocorticoids worsen the CV risk, data concerning their impact on endothelial function in RA are lacking. The present study investigate the effect of prednisolone on vascular function in arthritic rats and identified the underlying mechanisms.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6 weeks old male Lewis rats by injection of *Mycobacterium butyricum* in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated (i.p) with prednisolone at 10 (high dose) or 0.1 mg / kg (Low dose) or saline (Vehicle) for 21 days. Arthritis score and tarsus diameter were daily monitored. At the end of treatment, thoracic aortas were harvested to measure the relaxation to acetylcholine on pre-constricted aortic rings in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), arginase (nor-NOHA), COX-2 (NS-398), EDHF (Apamin/Charybdotoxin), or a superoxide dismutase analog (Tempol). The relaxing effect of a NO donor (sodium nitroprussiate, SNP) was studied on endothelium-denuded aortic rings. Blood pressure and heart rate, glycaemia, triglyceride and total cholesterol levels and radiological score of hind paws were also assessed.

Results: Compared to "Vehicle", AIA "High dose" exhibited reduced ($p<0.05$) arthritic score, paw diameters and radiological damage. This dose of GC significantly ($p<0.05$) improved Ach-induced relaxation through increased NO synthase activity and EDHF production, decreased arginase and COX-2 activities and decreased superoxide anions production. Blood pressure and triglyceride level were significantly ($p<0.05$) higher in AIA "high dose". By contrast, the low dose of prednisolone modified nor arthritis severity neither blood pressure, glycaemia and triglycerides levels. On the vascular side, this dose decreased the production of superoxide anions and increased EDHF, but failed to improve endothelial function in AIA rats. The response of rings to the NO donor was unchanged after GC treatment whatever the dose.

Conclusion: Our study demonstrates for the first time that a high dose of prednisolone during a short time is beneficial for endothelial function in case of arthritis, even though it induced deleterious cardio-metabolic effects. From a clinical perspective, these results raise the question of the use of high doses of GC during a short period to reverse endothelial dysfunction along with a rapid disease control. Whether this beneficial vascular effect of GC depends on the reduction of disease activity or not deserves further investigations.

Disclosure: F. Verhoeven, None; **K. Maguin-Gaté**, None; **P. Totoson**, None; **D. Wendling**, None; **C. Demougeot**, None.

the Role of CD146 in the Therapeutic Potential of Mesenchymal Stem Cells in Favor of CD146$^+$ Cells for Experimental Arthritis. Deh-Ming Chang[1] and Cheng-Chi Wu[2]. [1]Taipei Veteran's General Hospital, Taipei, Taiwan, [2]National Defense Medical Center, Taipei, Taiwan.

Background/Purpose: To illustrate whether the subtypes of mesenchymal stem cells (MSCs) have different cellular characteristics and therapeutic potentials, we separated CD146+/− mesenchymal stem cells and investigated their effects on chondrogenesis, osteogenesis, the Treg/TH17 cells expression and arthritis model.

Methods: We isolated CD146+ cells from human umbilical cords mesenchymal stem cells by beads sorting and then investigated the chondrogenesis and osteogenesis in a conditioned medium. The cytokine levels of IL-6 and TGFβ1 in CD146$^{+/-}$ cells and the effects of CD146$^{+/-}$ cells on Treg/Th17 cell population were analyzed by flow cytometry. CD146+/− cells were injected intraarticularly (IA) in experimental mice model, and then analyzed the clinical scores and the histological findings.

Results: CD146$^+$ cells showed significant higher chondrogenesis than CD146$^-$ cells. CD146$^+$ cells also expressed lower levels of IL-6 than CD146$^-$ cells. Furthermore, TH17 cells were significantly induced post addition of CD146$^-$ cells *in vitro* and *in vivo*. Our data also showed that the intraarticular injection of CD146$^+$ cells attenuated the disease progress *in vivo*. The immunohistological stains showed that only HLA-A$^+$ CD146$^+$ cells could be detected in the cartilage of CIA mice, and may preserve proteoglycans expression.

Conclusion: We firstly demonstrated that CD146$^+$ cells have higher multilineage potency and can suppress the activation of TH17 cells *in vitro* and suppress disease activities *in vivo*. These data suggest that CD146$^+$ cells have more therapeutic potentials than CD146$^-$ cells for inflammatory arthritis.

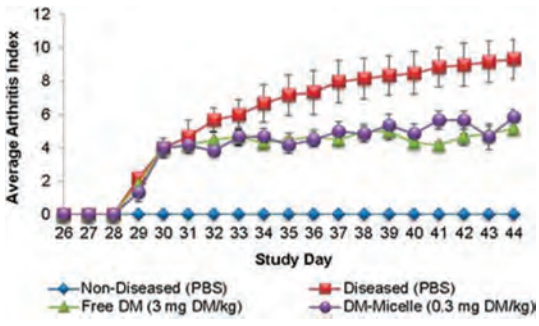
Enhanced Efficacy of Dexamethose with Synovial Fibroblast Targeted Micelles in a Collagen-Induced Arthritis Mouse Model. Rebecca A. Bader, David R. Wilson, Arundhati Ramani and Patricia R. Wardwell. Syracuse University, Syracuse, NY.

Background/Purpose: A number of conventional, disease modifying anti-rheumatic drugs (DMARDs) are associated with severe side effects due to non-specific targeting and impaired immune function. To improve therapeutic efficacy and reduce negative consequences, our research group has developed a platform for site-specific delivery to the synovial tissue based upon the self-assembly of polycaprolactone modified polysialic acid (PSA-PCL) into micelles. Hydrophobic DMARDs, such as dexamethasone (DM), can be entrapped within the micelles at a loading capacity of 0.1 mg DMARD/mg of PSA-PCL. To further enhance specificity, targeting of the overexpressed CD44 receptor on RA synovial fibroblasts was achieved by modifying the PSA-PCL with hyaluronic acid (HA) oligomers to yield PSA-PCL-HA micelles. The goal of this study was to establish the *in vivo* therapeutic efficacy of DM-loaded, PSA-PCL-HA micelles using a collagen-induced arthritis (CIA) mouse model.

Methods: 24 male, DBA/1J mice were divided into four treatment groups: non-diseased, diseased (with no drug therapy), free DM (3.0 mg DM/kg), and DM-loaded micelle (3.0 mg PSA-PCL-HA/kg ~ 0.3 mg DM/kg). At day 28 following induction of collagen-induced arthritis (CIA) in 18 of the 24 mice, each mouse was scored for arthritis index (AI). Treatments were administered via tail-vein injection starting on day 32. Subsequently, the mice received IV doses every 3 days until completion of the study on day 44. Treatment groups designated as diseased and non-diseased received tail vein injections of PBS alone (10 mL/kg).

Results: Based upon the average AI, DM, alone and when entrapped within the PSA-PCL-HA micelles, reduced the symptoms of RA. Mice that were administered treatments of DM-loaded micelles were provided with 1/10th the DM dose received by mice within the free DM treatment group. Despite the significantly reduced dose, the DM-loaded micelles yielded a decrease in average AI that was comparable to that obtained with free DM.



Conclusion: This study demonstrated that our targeted, drug delivery platform can be used to enhance the therapeutic efficacy of hydrophobic DMARDS. DM loaded into the PSA-PCL-HA micelles was as effective as free DM when administered at 1/10th the dose to mice with CIA.

Leucine-Rich Alpha-2 Glycoprotein Is a Potential Disease Activity Marker Under IL-6 Suppression in Autoimmune Arthritis. Yusuke Takahashi[1], Minoru Fujimoto[2], Satoshi Serada[3] and Tetsuji Naka[2]. [1]Osaka university, Suita city, Japan, [2]National Institute of Biomedical Innovation, Ibaraki, Japan, [3]National Institute of Biomedical Innovation, Laboratory for immune signal, Japan, Ibaraki, Japan.

Background/Purpose: C-reactive protein (CRP) is frequently used to evaluate inflammation in patients with rheumatoid arthritis (RA). However, CRP is normalized when IL-6 function is potently suppressed by anti-cytokine biologics such as tocilizumab. Therefore, novel biomarkers are required for accurate and sensitive assessment of the inflammation during anti-cytokine therapy. By proteomic screening of sera from patients with rheumatoid arthritis (RA), we previously identified serum leucine-rich alpha-2 glycoprotein (LRG)as a potential biomarker that reflects disease activity in RA better than CRP.

This study is aimed to investigate the clinical significance of LRG as a biomarker of RA disease activity during anti-IL6 therapy.

Methods: As a preclinical testing, cynpmolgus monkeys with collagen induced arthritis (CIA) were treated with anti-IL-6 receptor antibody (anti-IL-6-R mAb) and joint sewelling and rigidity were scored for clinical assessment of arthritis throughout the experiment. At the time of sacrifice, blood samples were collected to be subjected to the measurement LRG and CRP were evaluated.

Results: In CIA monkeys with anti-IL-6R mAb treatment, plasma LRG levels correlated better with disease activity than plasma CRP levels, presumably due to the fact that LRG levels were elevated in some animals with negative CRP in spite of high arthritis scores. Furthermore, among tocilizumab-treated patients for 6months with normalized CRP levels ($<$0.2mg/dL), serum LRG levels were significantly higher in patients with active RA (defined by CDAI$>$10) than those with RA with low disease activity (CDAI$\leq$10).

Conclusion: Our study indicates that LRG is a promising biomarker for monitoring disease activity in RA, even when CRP levels are reduced or normalized by anti-cytokine therapy.

PET-CT Imaging of Joints: A Quantitative Tool for Developing Novel Anti-Inflammatory Drugs. Siba Raychaudhuri[1], Anupam Mitra[2], Smriti K. Raychaudhuri[2] and Abhijit Chaudhari[3]. [1]Univ California Davis/VA Sac, Davis, CA, [2]VA Sacramento Medical Center, Mather, CA, [3]UC Davis School of Medicine, Sacramento, CA.

Background/Purpose: Mouse collagen induced arthritis (CIA) is the most commonly used preclinical model to screen new drug candidates for inflammatory arthritis. The conventional read out of this model are clinical score and histopathology. These read outs have several limitations including (i) longitudinal studies using the same mouse cannot be performed; (ii) clinical and histopathological scores are subjected to observer bias; (iii) *in vivo* cellular events cannot be captured in its native environment. Thus, an *in vivo* drug screening tool is the unmet need of the day. Herein, we validated ^{18}F-FDG PET as an *in vivo* drug screening tool for new anti-inflammatory drugs using the mouse CIA model.

Methods: Animal handling was performed in accordance with the approved UC Davis IACUC protocol. Arthritis was induced using bovine type II collagen in 8–12 week old male DBA/1J mice (n=20), out of which 15 mice showed clinical signs of arthritis on day 28. After the disease progressed, on the day 42 to identify the pre-treatment histopathology 5 mice were sacrificed. In the remaining 10 mice, 5 mice received I.P 300 μg of anti-mouse TNF-α antibody (CNTO5048, Janssen Biotech, PA, USA) every alternate day for next 10 days, and 5 mice remained untreated (negative control). Mice were scored clinically and had ^{18}F-FDG PET scan on day 42 and 52. Histological score (HS) of the joint tissues were performed in all the mice.

Results: The pre-treatment mean clinical score (CS), histopathological score (HS), and ^{18}F-FDG uptake were 3.8$\pm$1.1, 9$\pm$1 and 340$\pm$22 kBq/cc (Mean$\pm$SD), respectively. In the untreated group, the CS, HS and ^{18}F-FDG uptake progressed on day 52 to 5.4$\pm$1.2 ($p<0.05$), 13.4$\pm$1.3 ($p<0.05$) and 480$\pm$32 KB1/cc ($p<0.05$), respectively. Anti-TNF therapy successfully arrested the disease progression as evident by CS and HS at day 52, 0.75$\pm$0.06 ($p<0.01$) and 2.5$\pm$1.1 ($p<0.01$), respectively compared to untreated group. ^{18}F-FDG PET uptake in this group was also significantly decreased at day 52 to 200$\pm$12 KBq/cc ($p<0.01$) (Figure 1). The PET uptake significantly correlated with changes in CS ($r^2=0.74$, $p<0.01$) and HS ($r^2=0.9$, $p<0.01$). Among CS and HS, the correlation of ^{18}F-FDG PET with HS was higher than that observed with CS.

Conclusion: Our observation strongly suggest that ^{18}F-FDG PET scan can be considered as an *in vivo* preclinical drug screening tool for anti-inflammatory drugs of autoimmune arthritis. PET-CT imaging will reduce the number of animals required for a study and also the same animal can be studied at different stages of the disease, which will eventually reduce the effect of intra-species biological variations. The use of this *in vivo* imaging tool will allow longitudinal quantitative evaluation of the degree of joint inflammation in the same mouse.

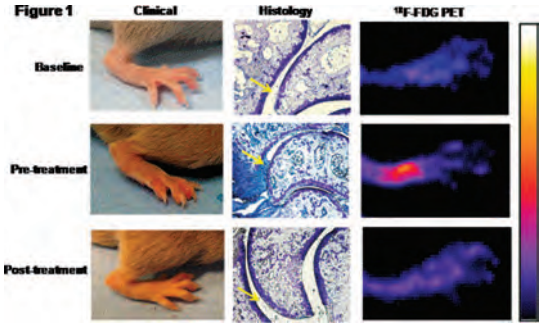

Figure 1: ^{18}F-FDG PET is an useful i*n vivo* tool to assess therapeutic potential of antiinflammatory drugs (representative image).

Comparison of the Effects of a Pharmaceutical Industry Decision Guide and Decision Aids on Patient Choice to Intensify Rheumatoid Arthritis Therapy with Etanercept. Richard Martin[1], Ryan Enck[2], Andrew J. Head[3], James Birmingham[1] and Aaron T. Eggebeen[2]. [1]Michigan State University, College of Human Medicine, Grand Rapids, MI, [2]Michigan State University College of Human Medicine, Grand Rapids, MI, [3]College of Human Medicine, Michigan State University, Grand Rapids, MI.

Background/Purpose: To evaluate the comparative effects of a pharmaceutical industry decision guide (Pharm Booklet) and International Patient Decision Aids Standard (IPDAS) compliant patient decision aids (PtDA) on patient choice to intensify rheumatoid arthritis (RA) therapy.

Methods: We conducted a mail survey of 797 biologic naïve RA patients in a community rheumatology practice. Patients were presented with a hypothetical decision scenario where they were asked to consider adding Enbrel™ (etanercept) to their current regimen. Each was randomized to review 1 of 3 forms of etanercept specific decision support: a long 24 page PtDA (LONG DA), a short 2 page PtDA (SHORT DA), or the manufacture's Enbrel™ decision guide (Pharm Booklet). Each subject was evaluated for: their decision to intensify therapy, beliefs about etanercept viewed through the Integrated Model of Behavioral Prediction, pre and post intervention etanercept related knowledge and decisional conflict.

Results: 402 anti-TNF naïve RA patients participated (response rate 52%). 30.6% of patients randomized to Pharm Booklet elected to initiate etanercept. Only 14.6% and 14.0% of patients who reviewed the LONG DA or SHORT DA choose to take etanercept ($\chi^2=15.7$; $P<.001$). A binary logistic regression model explained 44.2% ($R^2=$.

442) of patient choice to intensify therapy by initiating etanercept. The strongest predictor of choice to intensify therapy were beliefs about etanercept: Improve Symptoms (OR = 2.55), Social Normative Beliefs about intensifying therapy with etanercept (OR = 2.24), and likelihood of Adverse Event (AE) (OR= 0.59). LONG and SHORT DA produced greater increase of relevant knowledge, but greater knowledge and feeling of being informed did not impact patient beliefs about etanercept, decisional conflict or their choice to intensify therapy. After controlling for other co-variates, gender, low income, minority status, HAQ and CDAI did not add to the predictive power of the model. The brief 2 page PtDA was acceptable to patients, and lead to similar knowledge gains and decisional conflict as a 24 page IPDAS compliant PtDA.

Conclusion: PHARM Booklet may nudge patients towards adopting a proposed commercial product without critical consideration of the drug attributes. Patient decision aids offer a balanced alternative that clinicians could use to structure complex medication discussions and support more informed patient choice. We believe patients would benefit if they used them more.

Effectiveness, Tolerability, and Safety of Subcutaneous Methotrexate in Early Rheumatoid Arthritis: Clinical Data from the St. Gallen Cohort. Ruediger Mueller[1], Johannes von Kempis[1], Michael H Schiff[2] and Sarah Haile[3]. [1]St. Gallen Hospital, CH- 9007 St.Gallen, Switzerland, [2]University of Colorado, Denver, CO, [3]University of Zurich, Switzerland, Zurich, Switzerland.

Background/Purpose: MTX is the cornerstone of RA treatment, although limitations of systemic exposure of oral MTX may affect its efficacy. Subcutaneous (SC) MTX has greater bioavailability than oral MTX, which may result in better efficacy and tolerability. Few clinical studies have assessed the efficacy and tolerability of SC MTX. We assess the clinical effectiveness and tolerability of SC MTX among pts with RA naïve at baseline to both conventional and biologic DMARDs at our center.

Methods: DMARD-naïve RA pts fulfilling the ACR/EULAR-2010 criteria and had ≥ 1 follow-up visit were selected through sequential chart review until 70 were identified using a prospectively designed retrospective analysis. Pts received SC MTX at varying doses (10–25 mg/week, mean 18.2 mg) w/ 5 mg folic acid/wk. The primary endpoint was a change in DAS28 (ESR); secondary endpoints included time to employment of the first biologic agent and cumulative MTX doses. Pts were followed until SC MTX administration was terminated or their last clinical visit. Decision for adding biologic agents was at the discretion of the treating physician.

Results: 70 pts remained in follow-up for a mean ± SD of 1.8 ± 1.6 years (range, 0.13–7.1) after initiating SC MTX treatment. During this time 33 (47%) required the addition of a biologic therapy (BIO+MTX), and 37 (53%) remained on SC MTX without any biologics (SC MTX). Mean weekly MTX doses were 19.1 mg for BIO+MTX pts and 17.4 mg for SC MTX pts. Compared to SC MTX pts, BIO+MTX pts were more frequently female (63.6% vs 51.4%), and less frequently ACPA-positive at baseline (33.3% vs 51.4%). Mean baseline DAS28 scores were 4.9 (range 2.42–7.4) for BIO+MTX pts and 4.7 (range 1.6–7.7) for SC MTX pts. During follow-up, BIO+MTX pts had a higher DAS28 score (mean ± 95% CI) than SC MTX pts (see figure). Both LDAS and remission were achieved by slightly fewer BIO+MTX than SC MTX pts (LDAS, 78.8% vs 81.1%; remission, 69.7% vs 75.7%). Among BIO+MTX pts, biologic therapy was required after a mean ± SD of 387 ± 404 days (range 54–2164). Over the the study period, SC MTX was discontinued in 32 pts (46%). Most common discontinuation reasons were gastrointestinal discomfort (n=7), inefficacy (n=7), disease remission (n=3), patient's decision (n=3), interstitial lung disease (n=1), and cough (n=1). Severe infections occurred in 3/33 (9%) of BIO+MTX pts and in 3/37 (8%) of SC MTX pts.

Conclusion: SC MTX is an effective, well-tolerated option for pts with RA in real life. Remission was achieved by a majority of pts following the initiation of SC MTX, and the addition of biologics was not needed throughout the study period for about half of pts. SC MTX delayed need for biologic therapy for about 1 year for almost half of the pts.

Physician Awareness of Suboptimal Patient Adherence to MTX: Results from a Large U.S. Rheumatoid Arthritis Registry. Jeffrey R. Curtis[1], Aseem Bharat[1], Lang Chen[1], Jeffrey D. Greenberg[2], Joel M. Kremer[3] and Dimitrios A. Pappas[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Corrona, LLC., Southborough, MA, [3]Albany Medical College and the Center for Rheumatology, Albany, NY.

Background/Purpose: Most rheumatoid arthritis (RA) registries capture information about medication use using data captured at office visits. The extent to which this information may be misclassified or over-estimated for RA medications, including methotrexate (MTX), is unknown.

Methods: In 1Q and 2Q 2014, we conducted an Internet-based survey of RA patients participating in the comparative effectiveness CERTAIN substudy (n= 2485 unique biologic initiations as of April 2014) nested within the Corrona RA registry. Patients were eligible if they had valid email addresses (n=991 unique patients).. Patients were asked whether they were taking methotrexate and if so, how many MTX doses in the last 4 weeks they had taken. Patient report from the survey was used as the gold standard and compared to the use of MTX routinely recorded in the registry at the previous and next office visits. A subgroup analysis was conducted for the additional patients who had not yet had a follow-up visit in the registry. A sensitivity analysis restricted the interval of time between the survey and the previous registry visit to <=6 months to assess whether misclassification of MTX use was related to the interval of time between registry visits.

Results: A total of 433 patients answered the survey, a 44% response rate. Overall, survey respondents had mean (SD) age 53.5 (12.5) age, were 80.8% women, and 78.9% RF+ or CCP+. Mean (SD) disease activity measured at the previous visit using CDAI was 17.4 (14.7). Of the subgroup of patients who were recorded at the prior and next registry visit as consistently being on MTX (n=88), only 1 (1%) of patients indicated that they were not actually taking MTX. However, 10% of the remaining patients indicated that they had missed one or more doses in the last 4 weeks. Results were similar for the 111 additional patients who had not yet had a follow-up registry visit; 15% indicated that they had missed one or more doses in the last 4 weeks. Of the patients who missed one or more doses in the last 4 weeks, approximately one-third to one-half missed more than 1 dose. Results were robust in sensitivity analysis.

Conclusion: In this large U.S. registry, MTX use was generally ascertained accurately at office visits. However, up to 15% of patients recorded by their rheumatologist to be on MTX had missed doses in the last month. Clinicians need to be aware of potentially suboptimal adherence when assessing response to MTX. Further efforts to detect low adherence to MTX and identify reversible barriers to adherence are needed.

Impact of Physicians' Adherence to Treat-to-Target Strategy on Outcomes in Early Rheumatoid Arthritis. Laura Kuusalo[1], Kari Puolakka[2], Hannu Kautiainen[3], Marjatta Leirisalo-Repo[4] and Vappu Rantalaiho[5]. [1]Turku University Hospital, Turku, Finland, [2]South Karelia Central Hospital, Lappeenranta, Finland, [3]Medcare Oy, Äänekoski, Finland, [4]Helsinki University Central Hospital, Helsinki, Finland, [5]Tampere University Hospital, Tampere, Finland.

Background/Purpose: We have previously shown that in early rheumatoid arthritis (RA) remission targeted, intensive combination treatment, regardless of initial infliximab, results in remission in most patients. Still, patients' adherence to medication in RA is often poor and difficult to improve. Little attention, however, has been focused on the effect of physicians' adherence.

Methods: In the Neo-RACo study 99 patients with early, active RA were treated with methotrexate, sulfasalazine, hydroxychloroquine and low-dose prednisolone for 2 years. Patients were randomized to receive either infliximab or placebo for 6 months from week 4. All swollen joints had to be injected with intra-articular glucocorticoids. After 2 years, medication could be tapered down in the case of remission. In non-remission, treatments were unrestricted, including the use of biologics. At all times, treatment aimed at strict Neo-RACo remission defined as no swollen or tender joints and presence of 5 out of the 6 following criteria: morning stiffness <15 minutes; no fatigue; no joint pain; no tender joints; no swelling in joints or tendons; and ESR <30 mm/h in women and <20 mm/h in men. During a 5-year follow-up, strict remission rates, disease activity score 28 (DAS28) levels, radiological changes, anti-rheumatic medication after 2 years, and cumulative days off work were assessed. Physicians' ($n=30$) adherence during 15 study visits between 0 and 24 months was evaluated with a scoring system. On every visit, lack of glucocorticoid injections (0.2–0.4 points), lack of medication adjustments (0.4 points), and poor filling of the study forms (0.2 points) were assessed. Also, 0.5–1.0 points were given if a study visit was cancelled. The patients were divided into tertiles by the sum of the points for inactivity between 0 and 24 months. Factors contributing to remission rates at 3 and 24 months were evaluated.

Results: Follow-up data were available on 93 patients. Mean of the sum of the points for inactivity was higher in the placebo group (2.67 ± 2.25) than in the infliximab group (2.09 ± 1.71, $p=0.032$). Physicians' adherence ($p<0.001$), duration of symptoms ($p=0.037$) and the use of infliximab ($p=0.016$) predicted strict remissions in a multivariable model at 3 months, whereas at 24 months physicians' adherence ($p<0.001$) was the sole independent predictor. We found a relationship favoring active treatment on strict Neo-RACo remission rates, which were 77.4%, 62.7% and 46.7% ($p=0.018$) in the actively treated, the intermediately treated, and the inactively treated at 2 years. The respective figures at 3 years were 80.0%, 56.3% and 53.3% ($p=0.048$), at 4 years 73.3%, 75.0% and 41.4% ($p=0.025$), and at 5 years 63.6%, 65.6% and 51.7% ($p=0.40$). In addition, the DAS28 levels were lower in the actively treated than in the intermediately and the inactively treated at all time points. There were no significant differences in radiological progression and cumulative days off work between tertiles of treatment activity. After the first 24 months, biologics were used more often among the inactively treated compared with the intermediately and the actively treated ($p=0.024$).

Conclusion: Physicians' active stance is crucial for the targeted treatment of RA to work.

Management of Perioperative Tumor Necrosis -á Inhibitors in Rheumatoid Arthritis Undergoing Arthroplasty: A Systematic Review and Meta-Analysis. Susan M. Goodman[1], Indu Menon[2], Rie Smethurst[2], Paul Christos[3] and Vivian P. Bykerk[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, NY, NY, [3]Weill Cornell Medical College, NY, NY.

Background/Purpose: Tumor Necrosis Factor α inhibitors (TNFi) are widely used in patients with RA (Rheumatoid Arthritis) undergoing orthopedic surgery, yet its optimal perioperative management is unknown. The objective of this study is to systematically review the available literature regarding perioperative TNFi management and post-operative infections and to formulate clinical practice recommendations for the optimum perioperative use of TNFi.

Methods: A librarian assisted search was conducted in PUBMED, EMBASE, and the Cochrane Central Register of Controlled Trials, with defaulted date range of each database using the following key terms: Rheumatoid Arthritis, TNF- α, antirheumatic agent, surgical site infections (SSI), surgery/infection, arthroplasty, anti-TNF- α, infliximab, etanercept, adalimumab, risk factor, perioperative, postoperative. Studies were included if most patients had RA, age ≥ 18, and were undergoing orthopedic surgery. The intervention was use of TNFi. The comparison group was patients not treated with TNFi. The outcome of interest was surgical site infection. Study quality was assessed using Oxford Center for Evidence Based Medicine Levels of Evidence. No randomized controlled trials were available; high quality cohort studies (2b) and case control studies (3b) were included.

Results: A total of 2,004 studies were found. After abstract review, 30 studies met inclusion criteria. After detailed quality assessment, 11 studies met criteria with low risk of bias, representing 3730 RA patients with recent exposure to TNFi's (TNF+) and 4,307 with no recent exposure to TNFi's at the time of surgery (TNFi-). These studies were included in the final analysis. There was no consistent reporting of corticosteroid use. If the non-combinability p-value was greater than 0.20, a fixed-effects model was used to estimate the pooled odds ratio (OR); if $p\leq0.20$, a random effects model was used to estimate the pooled odds ratio (a forest plot is presented).

Patients in the TNF+ group for all orthopedic surgeries had a 2.39-times greater likelihood of developing SSI compared to patients in the TNF- group (pooled fixed-effects OR=2.39; 95% CI=1.72, 3.31; $p<0.0001$). A smaller group of cases with only total hip and total knee replacement were also meta-analyzed; here patients in the TNF+ group had a 3.08-times greater likelihood of developing SSI compared to patients in the TNF- group (pooled random-effects OR=3.08; 95% CI=0.87, 10.95; $p=0.08$). The Begg-Mazumdar test and Egger test did not reveal any evidence of publication bias ($p = 0.88$ and $p=0.91$, respectively).

Conclusion: Perioperative exposure to TNFi is associated with a higher risk of infection in all orthopedic surgery, although the risk in total hip and knee replacement is less clear. These data support withholding TNFi prior to orthopedic surgery.

Efficacy of First Line Biological Monotherapy in RA: Data from the Czech Registry Attra. Herman F. Mann[1], Sarka Forejtova[2], Katerina Jarosova[2], Ladislav Senolt[3], Jakub Zavada[4], Michal Uher[5], Karel Hejduk[5] and Karel Pavelka[6]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Revmatologicky ustav, Prague, Czech Republic, [4]Charles University, Prague, Czech Republic, [5]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic, [6]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Background/Purpose: The biological disease-modifying anti-rheumatic drugs (bDMARDs) should be used for the treatment of rheumatoid arthritis (RA) in combination with conventional synthetic DMARDs (csDMARDs). However a significant proportion of patients receive bDMARDs in monotherapy.

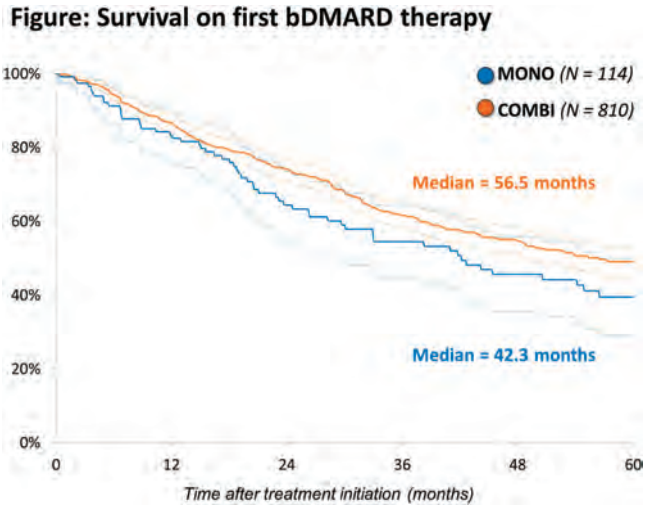
Methods: Baseline demographic data and efficacy parameters of the first bDMARD treatment of RA patients initiating bDMARD monotherapy (MONO) or combination (COMBI) therapy between 2007 and 2012 were retrieved from the national registry ATTRA. ATTRA is a centralized prospective computerized registry of patients receiving bDMARD therapy collecting data on efficacy, safety and quality of life of all patients treated with bDMARDs. bDMARD therapy was indicated after failure of at least 1 csDMARD (DAS28 $\geq$5.1).

Results: 1378 patients initiated bDMARD treatment after 2007, prospective data regarding disease activity were available for 924 of them and this subgroup was further analyzed. The 114 patients (12%) who were started on bDMARD monotherapy were older (58 versus 52 years; P<0.001) with longer disease duration (10.1 versus 6.8 years; P=0.001) and more failed csDMARDs in the past (4 versus 3; P=0.002). The baseline DAS28 scores were similar in both groups (5.9 versus 5.8; P=0.083). The most commonly used first line bDMARDs in both groups were antiTNFα drugs (93.9% vs 94.4%; p=0.8). 61.4% MONO patients remained on the same therapy after 12 months, further 21.1% had a csDMARD added to their initial bDMARD. 75.3% COMBI patients remained on the original therapy, 9.7% more were on monotherapy with the first bDMARD. Remission (DAS28<2.6) was reached by 37.8% MONO patients and 41.6% COMBI patients after 12 months. Longitudinal binary logistic regression model was used to calculate the likelihood of reaching remission for both groups at various time points.

Month		Crude estimate		Adjusted estimate*	
		OR (95% IS)	P value	OR (95% IS)	P value
3	COMBI	*reference*		*reference*	
	MONO	**0.59** (0.35; 0.98)	**0,041**	**0.60** (0.36; 1.02)	0.059
6	COMBI	*reference*		*reference*	
	MONO	**0.60** (0.37; 0.98)	**0,040**	**0.61** (0.37; 1.01)	0.055
12	COMBI	*reference*		*reference*	
	MONO	**0.68** (0.44; 1.07)	0,093	**0.67** (0.42; 1.07)	0.093

*Adjusted for gender, age, disease duration, number of previous csDMARDs, glucocorticoid use and baseline DAS28.

The median survival on the first bDMARD was 42.3 months in the MONO and 56.5 months in the COMBI group (HR 1.29; P=0.073) (Figure).



Conclusion: The results of this observational study suggest that bDMARD efficacy and retention is lower when used as monotherapy, however most observed differences did not reach statistical significance.

Fatigue and Related Factors in Patients with Rheumatoid Arthritis Treated with Tocilizumab in Daily Clinical. H Corominas[1], C Alegre de Miguel[2], M Rodríguez-Gómez[3], C Marras Fernández-Cid[4], F Maceiras Pan[5] and ACT-AXIS Study Group. [1]Hospital de Sant Joan Despí Moisès Broggi, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [3]Complejo Hospitalario Cristal Piñor, Ourense, Spain, [4]Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, [5]Complejo Hospitalario Arquitecto Marcide-Profesor Novoa Santos, A Coruña, Spain.

Background/Purpose: Fatigue in RA possibly resulting from alterations in the HPA axis like occurs with others RA symptoms as morning stiffness, and mood and sleep alterations. In addition, improvement of IL-6-induced anemia noted in RA patients appears to be associated with disease activity, even with fatigue. This, together with the effect of tocilizumab (TCZ) in reducing morning stiffness, pain and fatigue, and improving Hb levels, has led us to investigate the correlation between the change in fatigue and related factors as serum Hb levels, SJC, morning stiffness, pain, sleepiness and depression.

Methods: A prospective, observational and multicenter study in patients with moderate to severe RA, non-responders or intolerants to DMARDs or TNF-inhibitors who initiated treatment with TCZ. Data were collected at the time of TCZ-beginning (baseline visit) and at 2 routine follow-up visits closest to the weeks 12 and 24. The variance of fatigue outcomes relative to associated factors was calculated by multiple regression analysis.

Results: Of 122 patients included, 120 were evaluable (87% female; mean age: 52.2±12.6 years; mean disease duration: 9.1±7.8 years). At baseline: Hb (g/dL), 12.4±1.4; CRP (mg/L), 12.5±16.9; DAS28 score, 5.6±1.0; TJC, 8.6±6.3; SJC, 5.9±4.2; pain (visual analogue scale, cm), 6.7±2.3; morning stiffness duration (hours), 1.3±2.4; FACIT_F fatigue outcome, 23.7±11.1; Beck depression score, 18.5±13.0; Epworth sleepiness score, 6.1±4.5. At 12 and 24 weeks, DAS28 had significantly decreased 2.5±1.1 and 2.7±1.4 points, respectively, fatigue scores had significantly fallen to 19.2±10.6 and 18.8±10.7, and 51% and 61% of patients were good EULAR responders. Significant improvements were also observed in the other RA-related factors evaluated (Table). Sleepiness and depression were significant correlates in the multivariate model explained 35% of the variance in fatigue scores.

Mean changes (SEM) in fatigue outcomes and related factors from baseline

Variable	Week 12	*p*-value*	Week 24	*p*-value*
FACIT_F fatigue	−4.7 (0.9)	*<0.001*	−5.2 (1.0)	*<0.001*
Serum Hb levels (g/dL)	0.6 (0.1)	*<0.001*	0.6 (0.1)	*<0.001*
CRP levels (mg/L)	−10.7 (0.9)	*<0.001*	−11.2 (2.1)	*<0.001*
SJC	−3.7 (0.5)	*<0.001*	−4.1 (0.4)	*<0.001*
Morning stiffness (hours)	−0.9 (0.3)	*<0.001*	−1.0 (0.2)	*<0.001*
Pain VAS (cm)	−2.6 (0.2)	*<0.001*	−2.7 (0.3)	*<0.001*
Epworth sleepiness score	−0.6 (0.4)	*0.162*	−1.0 (0.3)	*<0.001*
Beck depression score	−3.6 (0.9)	*<0.001*	−3.9 (1.1)	*<0.005*

*Based on paired samples t-test. No multiple comparison adjustment was made.
Abbreviations: SEM, standard error mean.

Conclusion: Tocilizumab improves fatigue outcomes in patients with RA, a benefit that may be mediated by its effect on disease activity as shown by the reduction of DAS28. Tocilizumab reduces the concentration of acute-phase reactants and improves Hb levels, which can also contribute to decreasing fatigue experienced by RA patients. However, if the improvements observed in morning stiffness duration, pain, and sleepiness and depression scores are the result of the improvement in patient's fatigue cannot be concluded. Fatigue highly correlates with sleepiness and depression, having these RA-symptoms a significant role in explaining fatigue in RA.

Compliance in the Rheumatoid Arthritis Comparison of Active Therapies Trial: Triple Vs Etanercept. Sarah Leatherman[1], Hongsheng Wu[2], Edward Keystone[3], Mary Brophy[1] and James O'Dell[4]. [1]VA Boston Healthcare System, Boston, MA, [2]Wentworth Institute of Technology, Boston, MA, [3]Mount Sinai Hospital, Toronto, ON, [4]University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: In the 48-week, double-blinded, noninferiority RACAT trial, 353 methotrexate suboptimal responders were randomized to two treatment strategies, either the addition of sulfasalazine and hydroxychloroquine (triple therapy) or the addition of etanercept. If subjects showed no clinical improvement in DAS28 at 24 weeks, their treatment strategy was switched. Compliance to the study medications as well as placebo is an important aspect for any clinical outcome and an important consideration for the application of results to treatment of patients. This is particularly relevant since many have questioned the tolerability of triple therapy.

Methods: Compliance with placebo and study medications was calculated using returned pill counts. Participants were defined as medication compliant if they took 80% or more of dispensed study medication. Baseline characteristics were compared between active drug compliant and non-compliant subjects for both the 24-week and 48-week follow-up periods. Administration method (pills versus injection) compliance, treatment strategy (active drug versus placebo) compliance, and the association between compliance and treatment response were also explored.

Results: Within active drug group, there were no significant differences at 24 or 48 weeks between compliant and non-compliant subjects for any of the baseline variables except that the Physician Global Assessment score for compliant was significantly better than that of non-compliant ($p=0.01$ and $p=0.01$, respectively). Injection compliance was significantly higher than pill compliance at both 24 weeks (94.6% versus 86.4%, $p = 0.0003$) and 48 weeks (96.4% versus 90.6%, $p = 0.0034$). There were no differences in compliance of active and placebo medications at 24 weeks (90.0% versus 90.9%) and 48 weeks (93.9% versus 93.8%). Unlike some other studies, we found no relationship between compliance and treatment response. Other factors previously found to be associated with good compliance, such as demographic variables, treatment assignment, and treatment response, were not significantly related.

Conclusion: Subjects taking pills were less likely to be compliant than those having injections. Patients were equally likely to take active therapy and placebo therapy. Despite differences in compliance, treatment strategies were comparable and both strategies were well tolerated.

Use of Hydroxychloroquine Associated with Improved Lipid Profile in Rheumatoid Arthritis Patients. Jose Felix Restrepo[1], Inmaculada del Rincon[2], Emily Molina[3], Daniel Battafarano[4] and Agustin Escalante[1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]UTHSCSA, San Antonio, TX, [3]University of Texas Health Science Center, San Antonio, TX, [4]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX.

Background/Purpose: Cardiovascular disease (CVD) is one of the leading causes of morbidity and mortality in rheumatoid arthritis (RA). CVD risk factor reduction, such as reducing cholesterol and plasma glucose may be beneficial for preventing CVD. Hydroxychloroquine (HCQ), a DMARD with a good safety profile and low cost, has been reported to improve lipid profiles and glucose level in RA. We aimed to examine the association between HCQ with plasma lipid and glucose levels in a large RA cohort.

Patients and Methods: We recruited RA patients from public, private, military and Veterans Administration rheumatology clinics, and invited them for yearly follow up evaluations in which we assessed demographic and laboratory features, as well as hydroxychloroquine use.

We performed cross sectional analyses at baseline comparing fasting lipid profiles and plasma glucose between patients that were currently taking HCQ and those that were not. We subsequently used cross-sectional time- series regression models including all follow up visits, dividing patients into three groups based on hydroxychloroquine exposure: Those who had never taken HCQ during the time of our study, those who took it intermittently, and those who took it continuously.

Results: We studied 1261 patients (938 female, 323 male) with a mean ± SD age of 59.6±11.5 years. At baseline 254 patients were on HCQ. After adjusting for age, sex, ethnicity and lipid lowering medications, patients taking HCQ had significantly lower total cholesterol (TC) (P-value= 0.001), LDL (P-value≤0.001), triglycerides (TG) (P-value=0.013), and lipid profile ratios TC/HDL (P-value ≤0.001) and LDL/HDL (P-value ≤0.001). Furthermore, HDL was significantly higher in patients taking HCQ (P-value≤0.001). Plasma glucose level was not significantly associated with HCQ.

Patients were followed for a total of 4,646 visits between 1996 and 2014, and each patient was classified by HCQ exposure. After adjusting for confounders, patients that were continuously exposed to HCQ showed significantly lower lipid levels in TC, LDL, TG, TC/HDL, LDL/HDL, and higher HDL compared to the other two groups (P-value ≤ 0.01). Plasma glucose levels were only significantly different only when comparing patients never exposed to HCQ with those that were taking it at all visits (P-value = 0.003) (Table 1).

Table 1. Pooled follow-up visits of 1,261 RA patients divided by HCQ exposure

	None	Intermittent	Continuous	P_{adj}*
No of patients/No of visits	836/2935	316/1411	109/301	------
Female, n(%)	2,134 (73)	1,055 (75)	239 (79)	------
Non-Hispanic White, n(%)	1,059 (36)	372 (26)	123 (40)	------
Duration of RA, mean ± SD	15.3 ± 10.9	13.3 ± 9.3	11.9 ± 9.5	≤0.001, ’0.001
Laboratory				
TC mg/dl, mean (SD)	185.6 ± 40.4	182.0 ± 38.0	181.2 ± 35.6	0.005, 0.006
LDL mg/dl, mean (SD)	106.5 ± 33.6	102.9 ± 30.7	97.5 ± 29.7	≤0.001, ≤0.001
HDL mg/dl, mean (SD)	52.7 ± 16.3	54.6 ± 17.2	60.4 ± 18.4	≤0.001, ≤0.001
TG mg/dl, mean (SD)	132.2 ± 81.2	122.9 ± 62.7	115.1 ± 56.9	≤0.001, ≤0.001
TC/HDL, mean (SD)	3.8 ± 1.5	3.6 ± 1.3	3.2 ± 1.1	≤0.001, ’0.001
LDL/HDL, mean (SD)	2.21 ± 1.1	2.08 ± 1.1	1.8 ± 0.8	≤0.001, ’0.001
Glucose mg/dl, mean (SD)	103.0 ± 39.5	101.9 ± 37.6	95.1 ± 30.4	0.4, 0.003

**P-values were adjusted (P_{adj}) for age, sex, ethnicity and if the patients were currently on lipid lowering medications.*

Conclusion: HCQ use was associated with significantly lower TC, LDL, TG, and TC/HDL and LDL/HDL ratios, and with higher HDL. The association of HCQ with plasma glucose was not as strong as that with lipids. These findings support the need for a randomized trial to establish the role of HCQ in CVD prevention in RA patients.

Should Physician Reduce patients’ Glucocorticoids to Offset the Risk of Serious Infection Event Among RA Patients Who Switched from Non-Biologic Dmards and Glucocorticoid to Biologics? Huifeng Yun[1], Lang Chen[2], George W. Reed[3], Joel M. Kremer[4], Jeffrey D. Greenberg[5] and Jeffrey R. Curtis[2]. [1]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Corrona, LLC., Southborough, MA, [4]Albany Medical College and the Center for Rheumatology, Albany, NY, [5]New York University School of Medicine, New York, NY.

Background/Purpose: Glucocorticoids (GCs) and biologic disease-modifying antirheumatic drugs (DMARDs) have previously been associated with serious infection events (SIEs) among rheumatoid arthritis (RA) patients. For patients on non-biologic DMARDs (nbDMARD) and GCs,, it is unclear whether any increased risk for SIEs associated with adding a biologic might be offset if patients are able to reduce their GC exposure.

Methods: Using 2002–2013 Corrona RA registry data contributed by U.S rheumatologists and their RA patients, we identified eligible index visits where patients were on a nbDMARD and GCs, but not on biologics. Biologic DMARDs include etanercept, adalimumab, certolizumab, golimumab, infliximab, abatacept, rituximab and tocilizumab. Patients with psoriasis arthritis and malignancy were excluded. Follow up started at this time (i.e. index date), and ended at the earliest date of: a hospitalized infection, a visit when patient was on nbDMARDs only without GC, GCs without nbDMARD or no RA treatment, death, an 18-month gap between CORRONA visits, or 6/30/13. As a time-varying exposure, we categorized each person day into the following five exposure categories: nbDMARDs + GC (prednisone <5mg/day), nbDMARDs + GC (≥5mg/day), biologic DMARD + GC (<5mg/day), biologic DMARDs + GC (≥5mg/day), and biologic DMARD without GCs. Biologic exposure could have included concomitant nbDMARD use. At each visit, physicians reported the occurrence of SIEs. Events were confirmed in two stages, both by reporting physicians and with medical records. We calculated the incidence rate of SIEs for each exposure and compared risks using Cox regression adjusting for age, gender and clinical disease activity index (CDAI) at the index date.

Results: Of 12,851 eligible index visits where patients initiated nbDMARDs and GCs, 23% were with GC <5mg/day and 77% with GC ≥5mg. For patients were treated with nbDMARDs and GCs <5mg/day at the start of follow-up, 14.4% subsequently initiated biologics. For these individuals, 45.9% were able to discontinue GCs, 32.6% were on GC <5mg/day and 12.5 were on GC ≥5mg at the end of follow-up. Of 1,779 (20%) patients starting on nbDMARDs and GCs ≥5mg and then initiated biologics, 41.7% were able to discontinue glucocorticoids, and 9.8% were able to reduce GC dose to < 5mg by end of follow-up. After excluding 7% of SIEs that could not be confirmed, we identified 293SIEs yielding an incidence rate for SIEs of 1.8 per 100 person years across all exposures. After adjustment and compared to exposure of nbDMARDs + GCs (≥5mg/day), patients on biologic DMARDs without steroid use were less likely to have a SIE (Table). Both age and CDAI at the index date were positively associated with SIEs (not shown).

Conclusion: Many RA patients treated with nbDMARDs and glucocorticoids who initiate biologics are subsequently able to discontinue glucocorticoids. These individuals are at reduced risk for serious infections.

Table: Events, absolute incidence rate and adjusted hazard ratio of serious infections by DMARD, biologic, and glucocorticoid exposure

Biologic Exposures	Events	Incidence rate per 100 person years	Adjusted Hazard Ratio (95% CI)
nbDMARDs + GCs (≥5mg/day)	162	2.10	1.0 (referent)
Biologic DMARDs + GCs (≥5mg/day)	47	2.71	1.34 (0.94–1.91)
nbDMARDs + GCs(<5mg/day)	55	1.63	0.79 (0.58–1.08)
Biologic DMARDs + GCs (<5mg/day)	12	1.56	0.76 (0.41–1.40)
Biologic DMARDs without GC	17	0.75	0.41 (0.24–0.70)

* Adjusted for age, gender and CDAI at the index date
DMARD = disease-modifying antirheumatic drugs
NbDMARDs = non biologic disease-modifying antirheumatic drugs
GC = glucocorticoid; CI = confidence interval;

Safety of Rapid Rituximab Infusion in Rheumatoid Arthritis in a Single Community Practice. Rafat Faraawi[1], Kelly Roth[2] and Sameeka Malik[3]. [1]K-W Musculoskeletal Research Inc, Kitchener, ON, [2]K-W Musculoskeletal Research Inc., Kitchener, ON, [3]KW Musculoskeletal Research Inc., Kitchener, ON.

Background/Purpose: Rituximab, a chimeric monoclonal anti-CD20 antibody, is approved to be infused over 4 hours and 15 minutes (first infusion), and 3 hours and 15 minutes (second infusion) due to the potential for infusion reactions. The risk of infusion reactions has been shown to be the greatest with the first infusion. Previously we reported our experience with rapid rituximab infusion in 10 rheumatoid arthritis patients, receiving a total of 26 rapid infusions. We now report a current safety analysis of 28 patients receiving a total of 132 rapid infusions in a single rheumatology practice. The objective is to evaluate the safety, tolerability, and practicality of a rapid infusion protocol for rituximab in RA patients (n=28) in a single community setting.

Methods: Patients, who were prescribed rituximab for the treatment of moderate to severe RA, were recruited from October 2006 to November 2013 and given the opportunity to participate in the rapid infusion protocol. All patients provided written informed consent. Each treatment course consisted of 2 rituximab 1000 mg infusions given 2 weeks apart. The first infusion followed the conventional infusion schedule. Rapid infusion protocol was administered on the second and/or all subsequent infusions over 2 hours. All patients received premedication. Vital signs were recorded at baseline and at 15, 30, 60, 90, and 120 minutes.

Results: A total of 57 patients received rituximab infusions (280 infusions) from October 2006 to November 2013. Out of these, 50 patients with a diagnosis of rheumatoid arthritis met the criteria to be followed on the short infusion protocol. A total of 28 patients agreed to be followed on rapid rituximab protocol. 132 infusions were included in this analysis with the mean treatment interval of 9.4 months. 93% of the patient population had failed or were intolerant to prior TNF-alpha inhibitors and 7% were biologic naïve. A total of 7 infusion reactions were reported over 132 rapid rituximab infusions (28 patients), as compared to 8 infusion reactions over 148 conventional infusions (22 patients). There was no significant difference in the incidence of infusion reactions between rapid and conventional infusions (p=0.97). In both rapid and conventional infusions, no patients discontinued rituximab due to infusion related symptoms or reactions. Overall, all symptoms reported were mild and resolved within 24 hours after the infusion. No serious infections or serious adverse events were reported in either rapid or conventional infusion groups.

Conclusion: The current analysis provides reassurance that rapid rituximab infusion is safe and well tolerated. Our experience of administering this protocol over 7 years proves that rapid infusion is as safe as the conventional infusion. In addition to safety, patients reported greater satisfaction with the short infusion duration. This data and previously reported data on rapid infusion in rheumatoid arthritis patients assures physicians that this strategy can be safely implemented in a single community practice setting.

A Pilot Randomized Controlled Trial of a Tailored Smoking Cessation Intervention for Rheumatoid Arthritis Patients. Pip Aimer[1], Gareth Treharne[2], Simon Stebbings[2], Christopher Frampton[1], Vicky Cameron[1], Sandra Kirby[3] and Lisa K. Stamp[1]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]Arthritis New Zealand, Wellington, New Zealand.

Background/Purpose: Smoking adversely influences comorbidities in rheumatoid arthritis (RA) and may affect progression of RA. The combination of negative health effects makes a compelling case for smoking cessation in RA. The aim of this pilot was to determine whether a targeted 3-month smoking cessation intervention for RA patients increases smoking cessation.

Methods: Thirty-eight RA patients who were currently smoking were recruited and randomized on a 1:1 ratio. All participants were given the current local standard of care for smoking cessation (brief advice and subsidised nicotine replacement therapy: ABC). Participants randomized to the intervention arm (ABC+) received additional advice from trained Arthritis New Zealand educators for 3 months. Advice was tailored to participants' specific needs from a range of intervention tools developed from previous qualitative consultation and focused on education about the relationship between smoking and RA, pain control, exercise, coping, and support. The primary outcome measure was smoking cessation at 6 months. The secondary outcome was sustained reduction in smoking at 6 months. The assessor was blind to intervention allocation. Disease and psychosocial characteristics of quitters and non-quitters were examined statistically.

Results: Thirty-five participants completed the 6 month trial; the 3 who withdrew were in the intervention arm. The overall smoking cessation rate was 24%. There was no significant difference in smoking cessation rate between the ABC+ and ABC groups (26% vs 21%; P=0.70). The mean number of cigarettes smoked per day reduced by 56% (P<0.001) but did not differ between ABC+ and ABC groups (mean reduction 59% vs 53%; P=0.72). There was no difference in smoking cessation rates between participants with disease duration 2 years (27% vs 22%; P=0.74). Successful quitters had a greater number of years in education beyond high school and had smoked less across their lifetime, but these differences were not statistically significant. The successful quitters did appear to have less severe disability and pain, and better psychosocial factors including less depression, perceived stress, and an enhanced quality of life but these did not reach statistical significance (*Table 1*). No other demographic, disease, or psychosocial variables predicted quitting.

Conclusion: This pilot randomized controlled trial evaluated the effects of an individually tailored smoking cessation programme in patients with RA. The smoking cessation rate and reduction in number of cigarettes smoked were high compared to previous smoking cessation studies. The lack of added benefit of the tailored intervention suggests brief advice is the best practice supporting RA patients who wish to quit smoking. RA patients with fewer years of education or longer history of smoking may require particular cessation support.

Table 1: Baseline disease and psychosocial factors associated with smoking cessation. All data are presented as mean (SD)

Baseline disease and psychosocial factors*	Successful Quitters (n=9)	Non-quitters (n=29)	Total (n=38)	P
Education (years)	12.56 (1.88)	11.48 (1.33)	11.74 (1.52)	0.06

Ethnic Minorities with Rheumatoid Arthritis Achieve a Meaningful Clinical Response at 12 Months Despite Infrequent Use of Biologic Therapies. Gail S. Kerr[1], Yusuf Yazici[2], Christopher Swearingen[3], Sharon Dowell[4], Luis R. Espinoza[5], Edward Treadwell[6], Theresa Lawrence-Ford[7], Yvonne Sherrer[8], Angelia Mosley-WIlliams[9], Rodolfo Perez Alamino[10], Ignacio Garcia-Valladares[11], Akgun Ince[12], Mercedes Quinones[13], Chunqiao Luo[3], Adrian Godoy[4] and John Amatruda[4]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]New York University School of Medicine, New York, NY, [3]University of Arkansas, Little Rock, AR, [4]Howard University, Washington, DC, [5]LSU Medical Center, New Orleans, LA, [6]E Carolina Univ Sch of Med, Greenville, NC, [7]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [8]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [9]Detroit VAMC, Detroit, MI, [10]LSUHSC, New Orleans, LA, [11]Hospital General de Occidente, Zapopan, Jal., Mexico, [12]St. Louis University, St. Louis, MO, [13]Howard University Hospital, Washington, DC.

Background/Purpose: Ethnic minorities with rheumatoid arthritis (RA) often, for varied reasons, receive less biologic therapies despite more severe disease. Yet, data in this patient subset regarding time to meaningful clinical response and the clinical determinants are lacking. We examined the prevalence of meaningful clinical response (MCR) and its clinical associations in RA ethnic minority patients.

Methods: Ethnic Minority RA Consortium (EMRAC) patients with at least one follow up visit were evaluated. Comparisons of demographic (age, gender, race, education, smoking), RA disease status (RF, ACPA, nodules/erosions), RA treatment (prednisone, DMARD, biologics) variables amongst ethnic subsets were made as well as frequencies of MCR (DRAPID3 [-3.6]) at 3, 6, and 12 months from enrollment. Baseline differences between ethnic subsets were compared using Chi-square for categorical and Kruskal-Wallis for continuous variables. Logistic regression associating outcome at 3, 6 and 12 months with ethnic subset were estimated adjusting for age, gender, education, disease duration, baseline RAPID3, DMARD and biologic use.

Results: EMRAC analysis is shown in (Table). African Americans (AA) and Hispanics had fewer years of education, but had longer follow up periods and more frequent clinic visits. Despite higher ACPA and RF titers, frequencies of erosions and baseline RAPID3 scores, both ethnic minority subsets received less biologic but more frequent DMARD therapies. A MCR was more prevalent in AA and Hispanics. While the frequency of a MCR in Hispanics was significant at 3 months (p<0.001) compared to other ethnic subsets, it was similar in AA and Caucasians. However at 6 and 12 months – achievement of a MCR was more frequent in both AA and Hispanic patients.

Conclusion: Despite more severe RA disease and infrequent biologic use, frequent follow up visits in ethnic minority patients result in the achievement of a meaningful clinical response within 6 months of disease management. The long term outcome of these variations in RA therapies among ethnic subsets, particularly with regards to cardiovascular disease, requires further study.

Table: Clinical Characteristics of EMRAC cohort and Frequencies of Meaningful Clinical (RAPID3) Response

	Total	Caucasian	African-American	Hispanic	P
N	671	299	225	147	
# of Followup visits	3.0 (2.7)	2.7 (2.7)	2.9 (2.4)	3.6 (3.0)	**<0.001**

Minimal Radiographic Progression in RA Patients Receiving Routine Care in the Espoir Early Arthritis Cohort: Similar Prognosis According to 6 Different Remission Criteria. Isabel Castrejón[1], Maxime Dougados[2], Bernard Combe[3], Francis Guillemin[4], Bruno Fautrel[5] and Theodore Pincus[1]. [1]Rush University Medical Center, Chicago, IL, [2]Université Paris René Descartes and Hôpital Cochin, Paris, France, [3]Hôpital Lapeyronie, Montpellier, France, [4]Nancy University Hospital, Nancy, France, [5]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Remission has become a more achievable goal in rheumatoid arthritis (RA). Several criteria for remission are available in RA, including one based on RAPID3 (routine assessment of patient index data 3) with <1 swollen joint (RAPID3≤3+SJ≤1), which identifies remission similarly to Boolean and SDAI criteria [1]. It would be of value to know if any remission criteria predict radiographic progression more effectively than others. We analyzed radiographic progression according to remission status in the ESPOIR French early arthritis cohort, in which only 18.3% of patients received a biological DMARD over a 5 year follow-up as part of their routine care [2].

Methods: Radiographic progression over 1 year was analyzed in the ESPOIR cohort, which includes early arthritis patients who received routine care. Remission was assessed 12 months after baseline, according to 6 different criteria: ACR Boolean criteria; simplified disease activity index (SDAI) ≤3.3; clinical disease activity index (CDAI) ≤2.8; disease activity score (DAS28) <2.6; RAPID3 ≤3; and RAPID3≤3+SJ≤1.The numbers of patients whose radiographic progression according to the Sharp van der Heijde score was ≥5 -the smallest detectable difference (SDD) [3], ≥10 or ≥20 units at 24 months (12 months after the remission assessment) were analyzed, according to whether patients had been in remission 12 months earlier for each of the 6 criteria, using chi-square tests for statistical significance.

Results: Radiographic progression ≥5 units (SDD) was seen in 10.1%-11.8% of patients in remission compared to 13.0%-13.8% of patients not in remission; differences were not statistically significant (p>0.3) (Table). Progression ≥10 units was seen in 1.4–4.3% of patients in remission versus 6.5–7.6% of those not in remission, a 2-fold difference; only differences by DAS28 and RAPID3≤3+SJ≤1 were statistically significant (p<0.05). Progression ≥20 units was seen in 0.1–1.1% of those in remission versus 2.6–3.1% of those not in remission, a 3-fold difference, statistically significant for SDAI, CDAI, DAS28 and RAPID3≤3+SJ≤1. A sub analysis including 179 patients with radiographic damage at baseline and rheumatoid factor positivity was performed, with similar results.

		Radiographic progression (%) over 1 year according to remission status					
		≥ 5 units		≥ 10 units		≥ 20 units	
Remission Criteria	Remission vs Non remission	Remission	No Remission	Remission	No Remission	Remission	No Remission
Boolean	140 vs 492	10.9%	13.0%	3.6%	6.5%	0%	2.6%
SDAI ≤ 3.3	135 vs 467	10.4%	13.3%	3.0%	6.9%	0%	2.8%*
CDAI ≤ 2.8	135 vs 467	10.4%	13.3%	3.0%	6.9%	0%	2.8%*
DAS28 ≤ 2.6	247 vs 355	10.9%	13.8%	3.6%	7.6%*	0.8%	3.1%*
RAPID3 ≤ 3	187 vs 415	11.8%	13.0%	4.3%	6.8%	1.1%	2.7%
RAPID3≤3+SJ≤1	139 vs 463	10.1%	13.4%	1.4%	7.3%*	0%	2.8%*

$p \leq 0.05$

Conclusion: Very little radiographic progression was seen in patients receiving routine care in recent years although only 18.3% of patients received a biological agent. Differences between patients in remission or non become apparent when applying higher cut-off points to define radiographic progression.

Durability of First Biologic Is Not Influenced By Initial/Early DAS28. Gina Rohekar[1], Binu Jacob[2], Janet E. Pope[3] and Claire Bombardier[4]. [1]St. Joseph's Hospital, London, ON, [2]University Health Network, Toronto General Research Institute, Toronto, ON, [3]Western University, London, ON, [4]University of Toronto, Toronto, ON.

Background/Purpose: The Ontario Best Practices Research Initiative (OBRI) collects data on RA treatment in a real-world setting. Patients are enrolled and prospectively followed to assess response to biologic and DMARD therapy as well as to collect data on other factors. The objective of this study is to look at a real-world population and determine if initial disease activity influences the durability of the first used biologic in RA treatment.

Methods: Biologic-naïve RA patients were included if they started a biologic at baseline or at any time after entry into OBRI. For initial DAS, we used the DAS28 value when it was measured between 6 months before and 3 months after the start of the first biologic, whichever was closer to the date of biologic use. This was done so as the initial DAS28 would best reflect the patient's DAS at start of biologic. Patients were censored at treatment stop date or discontinuation date, date of death, or up to 18 months after initiation of biologic, whichever occurred first. Persistence was defined as the length of time the patients continued to receive the drug, irrespective of change in dose, route, or addition of any other DMARD, steroids, etc. If the drug was stopped for <60 days after which the patient restarted the same medication, it was considered a continuation and the duration was calculated accordingly. Survival was first compared using KM curves and then again using Cox-regression analysis. Analysis was performed for all years and also censored at 1.5 years.

Results: 471 patients were included. At 1 year, the survival probability was 0.76 (95% CI 0.68–0.81). Median survival was 5.005 years (95% CI 3.466–8.337). Patients who were on biologic monotherapy, with no concomitant DMARD use, has worse persistence of their initial biologic.

Patients were divided into three groups for analysis based on initial DAS28 score: remission (≤ 2.60), medium to high DAS28 (2.61–5.10) and severe (>5.10). Figure 1 shows the KM Plot of survival on biologic stratified by DAS28.

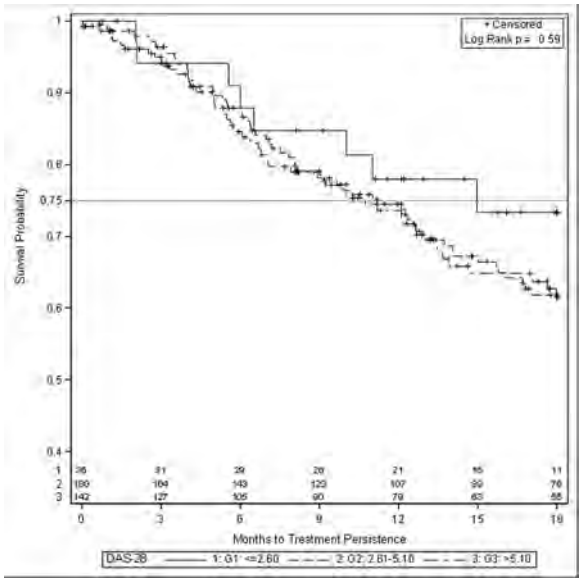

Figure 1: Despite the initial trend towards better survival associated with lower initial DAS, this was not statistically significant. Similarly, type of insurance (public/private) did not impact survival. As seen in other studies, the only significant factor to impact survival on initial biologic was use of DMARD with the biologic.

Conclusion: Early/initial DAS28 score did not impact persistence on their initial biologic, nor did insurance type. This suggests that initial DAS28 score does not influence the durability of the initial biologic Combination of DMARD and biologic was more durable than biologic monotherapy.

Background/Purpose: The treat-to-target (T2T) strategy has become the new paradigm for the treatment of Rheumatoid Arthritis (RA); however the question is whether this strategy is feasible in daily clinical practice. The purpose of the study was to evaluate the adherence to a T2T strategy aiming at remission in a cohort of DMARD naïve patients with early RA.

Methods: We included DMARDs naïve patients with diagnosis of early RA belonging to a prospective cohort of patients with diagnosis of early arthritis (<2 years of disease duration). Data was collected every 3 months, including sociodemographic characteristics, functional status (HAQ), disease activity (DAS28) and medication. Clinical remission was defined as DAS28 < 2.6. The primary outcome measure was the proportion of cohort visits in which therapy was adapted according to disease activity, stratified by remission state. Compliance with the T2T recommendations was defined as a change in drug treatment in patients failing to achieve clinical remission. Treatment strategies were stratified in seven groups: i) addition or dose escalation of NSAIDs, ii) addition/change of DMARDs, iii) dose escalation of DMARDs, iv) addition/change of biologic agents, v) addition or dose escalation of oral prednisone, vi) administration of parenteral corticosteroids, vii) administration of intra-articular corticosteroids. Compliance with T2T and treatment strategy was evaluated on each visit. The statistical analysis was carried out using STATA 12.

Results: We included 535 DMARDs naïve patients with early RA. Mean age was 51 ± 14 years, 82% were female and disease duration was 7 ± 6 months. The patients contributed to a total of 3022 visits (mean follow-up = 24 ± 16 months). Mean HAQ and DAS28 score during follow-up were 0.9 ± 0.6 and 3.9 ± 1.2, respectively. Patients did not achieved remission in 2063 (68%) of the visits. A change in drug treatment was registered in 42% of these visits. The most frequent strategy was addition/change of DMARDs (31%), followed by addition/dose escalation of oral prednisone, addition/dose escalation of NSAIDs, dose escalation of DMARDs, intra-articular corticosteroids, parenteral corticosteroids and addition/change of biologic agents (9%, 9%, 8%, 3%, 3% and <1%; respectively).

Conclusion: In our cohort, including patients with early rheumatoid arthritis in "real world", the compliance with the T2T treatment recommendations were low. A change in drug treatment was registered in less than half of the visits where patients were not in remission.

Adherence to Dmards in the First Six Months of Treatment in Early Arthritis Patients; Comparing Three Adherence Measures. Annelieke Pasma[1], Ethan den Boer[1], Adriaan van 't Spijker[1], Reinier Timman[1], Jan van Busschbach[1] and J.M.W. Hazes[2]. [1]Erasmus MC University Medical Center, Rotterdam, Netherlands, [2]Erasmus University Medical Center, Rotterdam, Netherlands.

Background/Purpose: Non-adherence to DMARDs is an important indicator for the effectiveness of treatment in early arthritis patients. Reported non-adherence rates differ widely, because studies use different adherence measures. Electronic measurement is considered as a 'gold standard', but other measures have other attractive features. This study compared three methods to ascertain how non-adherence should be measured: the Compliance Questionnaire Rheumatology (CQR), the intracellular uptake of methotrexate (MTX) in the form of methotrexate-polyglutamates (MTX-PGs) and Medication Event Monitoring Systems (MEMS).

Methods: Adult patients diagnosed with arthritis who started DMARDs were included in a cohort study. MTX-PGs were collected and the CQR was filled out after three and six months of treatment. Non-adherence was continuously measured with MEMS. When there was a discordance between the observed opening and the expected opening of the MEMS cap, this was assigned as a non-adherence event. The CQR and MEMS were compared with Pearson correlations. Sensitivity and specificity of adherence measured with MEMS against a CQR discriminant cut-off score was calculated at three and six months. To assess the influence of adherence measured with MEMS on MTX-PGs, a multivariate linear regression (backward selection) with MTX-PGs as dependent variable and with non-adherence measured with MEMS the 12 weeks before MTX-PG measurement (continuous score), age, gender, time of treatment and dosage as independent variables was performed.

Results: Two hundred and one patients entered the study. As measured with MEMS, non-adherence rates varied over time and between different DMARDs (figure 1). For sulfasalazine and hydroxychloroquine, the non-adherence rates were highest. For all medicines, except for prednisone, the non-adherence rate rose over time. The CQR did not correlate with MEMS at any of the time points of therapy. At both time points, the ROC curves showed no discrimination between non-adherence measured with MEMS against the CQR cut-off score. Non-adherence (B 0.548, p=0.035), time of treatment (B 0.947, p=0.006) and age (B 2.052, p<0.000) significantly contributed to MTX-PGs, but only accounted for 18.8% of explained variance.

Conclusion: Non-adherence rates for prednisone are lowest and stable. This might be explained by the fact that patients immediately experience the effect of prednisone, and that most patients tapered prednisone. The non-adherence rate for MTX was low, probably because rheumatologists emphasize the necessity of MTX. The CQR is not associated with MEMS, but MTX-PGs are weakly associated with MEMS. This can be due to several reasons, such as individual differences in the uptake of MTX. We have to learn more about the uptake of MTX over time per patient, before we can use MTX-PGs in daily practice as a non-adherence measure.

Figure 1. Non-adherence rates measured with MEMS per medicine per month

The 12-Years Retention Rate of the First-Line TNF-Inhibitor in the Treatment of Rheumatoid Arthritis: Real-Life Data from a Local Registry. Ennio Giulio Favalli[1], Martina Biggioggero[2], Francesca Pregnolato[3], Andrea Becciolini[2], Alessandra Emiliana Penatti[2], Antonio Marchesoni[1] and Pier Luigi Meroni[2]. [1]Department of Rheumatology, Gaetano Pini Institute, Milan, Italy, [2]Chair and Division of Rheumatology, Gaetano Pini Institute, University of Milan, Milan, Italy, [3]Experimental Laboratory of Immunological and Rheumatologic Researches, IRCCS, Istituto Auxologico Italiano, Milan, Italy.

Background/Purpose: Data on over-10-years drug survival of TNF inhibitors (TNFi) are still lacking. The aim of the study is to analysed the long-term retention rate of the first TNFi and to compare the drug survival of infliximab (IFX), etanercept (ETN) and adalimumab (ADA) for the treatment of rheumatoid arthritis (RA) in a setting of real-life.

Methods: We extracted data from a local registry that includes all RA patients (all fulfilling ACR/EULAR 2010 classification criteria) treated with biologic therapies between October 1999 and May 2014 in our Rheumatology Unit, limiting the analysis to patients treated with IFX, ETN, or ADA as first-line biologic drug. Data were collected through 31 May 2014. Drug survival up to 12-year follow-up was evaluated overall by the Kaplan-Meier method and compared according to anti-TNF agent after matching for propensity scores (based on age, sex, health assessment questionnaire [HAQ], disease duration, concomitant DMARDs therapy, concomitant corticosteroids, Disease Activity Score 28 [DAS28], ESR and CRP) by a stratified logrank test.

Results: The analysis included 583 patients (mean age [±SD]=54 [±12.4] years, mean disease duration 8.6 [±18.9] years), treated with IFX (n=222), ADA (n=182), or ETN (n=179). The median time of receiving TNFi was 44.3 months and the overall 5-years and 12-years TNFi retention rates were 44.1% and 19.39%, respectively. Drug inefficacy (51.1%) and toxicity (41.2%) represented the main causes of treatment discontinuation. Combination with MTX was significantly associated with a higher TNFi retention rate ($p<0.01$). ETN showed a significant lower probability of discontinuation compared with both IFX ($z=6.52$, $p<0.0001$) and ADA ($z=5.66$, $p<0.0001$). No significant differences emerged between IFX and ADA ($z=0.19$, $p=0.85$).

Conclusion: In a real-life setting, the 12-years retention rate of the first TNFi was lower than 20% and the most frequent reason for discontinuation was inefficacy (51.1%). The drug survival of ETN was significantly higher compared with anti-TNF monoclonal antibodies.

Factors Associated with Methotrexate Treatment Duration, Including Subcutaneous Use, in Patients with Rheumatoid Arthritis: Observations from the VA Database. Bernard Ng. U.S. Department of Veterans' Affairs- Puget Sound Healthsystem, Seattle, WA.

Background/Purpose: A previous analysis of RA patients in national administrative databases of the Department of Veterans Affairs (VA) suggested that injectable MTX was associated with a higher likelihood to remain on MTX monotherapy. We seek to determine whether RA patients in the VA database treated with injectable MTX after being unable to tolerate or having inadequate response to oral MTX remain on MTX monotherapy longer than those treated only with oral MTX. We also compare the rates of liver enzyme abnormalities between patients using injectable MTX monotherapy and those using oral MTX monotherapy.

Methods: The duration of MTX monotherapy before a therapeutic change was required (defined as switching to or adding another DMARD or biologic agent) was compared between patients treated with injectable MTX for at least 30 days and those who were treated only with oral MTX using a Wilcoxon-Matt-Whitney test. Factors that could potentially influence the duration of MTX monotherapy in subjects with therapeutic change included the use of injectable MTX.gender, age, race, starting MTX dose, maximum MTX dose, and modified Charlson comorbidity score. These factors were assessed using a log-rank test and Kaplan-Meier curves; in order to correct for patient variables, linear regression models were also run. Liver enzyme abnormalities were compared between patients on injectable and oral MTX who received MTX monotherapy for >90 days; abnormal alanine aminotransferase (ALT) levels and aspartate aminotransferase (AST) levels were defined as exceeding twice the upper limit of normal.

Results: Of the 7107 patients who were treated with MTX monotherapy for >90 days, 3910 required a therapeutic change (3808 were treated with oral MTX, 102 with injectable MTX). Patients treated with oral MTX remained on MTX monotherapy for a mean (SD) of 627 (636.5) days compared with 962 (786.6) days for patients treated with injectable MTX monotherapy ($P<0.001$). Based on log-rank tests (see figure) and linear regression models, the use of injectable MTX was significantly associated with longer duration of MTX monotherapy ($P=0.0018$ and $P<0.001$, respectively). When adjusted for patient variables, the duration of MTX monotherapy was also significantly associated with age, race, starting MTX dose, and maximum MTX dose. Of the patients treated with MTX who also had ALT and/or AST levels assessed, the rates of abnormal ALT and AST levels were not significantly different between those receiving oral and injectable MTX ($P=0.870$ and $P=0.056$, respectively).

Conclusion: Among patients identified in the VA database, the use of injectable MTX was associated with a significantly longer duration of MTX monotherapy compared with oral MTX. No significant differences in liver enzyme abnormalities were found between patients treated with injectable MTX and oral MTX.

Reasons for Non-Vaccination in Rheumatoid Arthritis and Spondyloarthritis Patients. Charlotte Hua[1], Jacques Morel[1], Bernard Combe[1] and Cédric Lukas[2]. [1]Hôpital Lapeyronie, Montpellier, France, [2]Hopital Lapeyronie, Montpellier, France.

Background/Purpose: Patients with inflammatory rheumatic diseases are at increased risk of infections when compared to healthy controls. Despite the fact that part of these infections could easily be prevented by available vaccines, vaccination coverage remains very low in France. The aim of this study was to evaluate the reasons why rheumatoid arthritis (RA) and spondyloarthritis (Sp) patients had not been vaccinated against influenza and streptococcus infections.

Methods: In this French observational multicenter study, questionnaires were completed by RA and Sp patients referred to rheumatology departments from December 2012 to November 2013. The questionnaires consisted of questions about pneumococcal or influenza vaccinations, about the prescribing physician and, if applicable, about the reasons of non-vaccination. Clinical and demographic data were also collected.

Results: 268 RA patients and 189 Sp patients from 4 centers were included. Vaccination coverage was respectively 53% and 54.5% for pneumococcal vaccine and 59.7% and 47.1% for influenza vaccine. Lack of proposal was the main reason for non vaccination for pneumococcal (78.2% for RA and 78.9% for Sp patients- Figure 1) and influenza vaccine (48.1% and 61.1%- Figure 2). For pneumococcal vaccine, predictive factors for proposal were: history of RTX treatment (p= 0,0001) for RA patients and treatment with anti-TNFα (p=0.006) for Sp patients. For influenza vaccine, predictive factors for proposal were: increased age (p= 0.01) and current biologic treatment (p=0.002) in RA patients and presence of co-morbidities (p=0.004) in Sp patients.

Conclusion: Despite the recognized usefulness of vaccination among patients with inflammatory rheumatic diseases and the current international recommendations, we found that the vaccination coverage of patients from 4 French centers is low, mainly due to the lack of vaccine proposal by the practitioners. These findings are consistent with data from other countries and highlight the need of pursuing information of the patients and their doctors.

Patients' Interpretations of Rheumatoid Arthritis Model Disease States in a Safety-Net Rheumatology Clinic. Carol Bledsoe[1], Lisa A. Davis[2], Vivian Tran[3], Angela Keniston[3], Liron Caplan[4], Itziar Quinzanos[5] and Joel M. Hirsh[3]. [1]The Brody School of Medicine - East Carolina University, Greenville, NC, [2]Denver VAMC and Univ of Colorado School of Medicine, Aurora, CO, [3]Denver Health and Hospital Authority, Denver, CO, [4]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [5]University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Patient assessment of disease activity (PtGA) measured by visual analog scale (VAS) is often a barrier to patients achieving remission in rheumatoid arthritis (RA). The Boolean and Simplified Disease Activity Index (SDAI) criteria for remission mandate a PtGA of ≤10mm and ≤33mm, respectively. For this reason, it is critical to understand the patient perspective on model disease states, including remission. The objective of our study was to determine how a diverse cohort of RA patients interprets case scenarios of disease states, and to identify variables that were associated with rating the remission model disease state at ≤10mm and ≤33mm.

Methods: We enrolled English- and Spanish-speaking patients at our clinic who met American College of Rheumatology 2010 criteria for RA. We asked subjects to rate their health on a VAS if their arthritis were like that described in each of four case scenarios ranging from remission to severe RA disease activity. These scenarios included the domains: engagement in activities of daily living; personal care; anxiety related to the course of disease; leisure activity; pain; and side effects of treatment. Responses were classified according to **Figure 1**. We performed multivariate logistic regression to identify predictors of: 1) scorable responses with the remission disease state rated lower than the severe disease state (category 4 [Cat 4]); 2) rating the remission model disease state ≤10mm; or ≤33mm.

Results: We enrolled 300 subjects. Only 128 subjects were grouped into Cat 4, indicating understanding of the scenarios. By multivariate regression, higher health literacy (HL) (OR 1.20) and increasing education (OR 2.02) were associated with being grouped in Cat 4. The mean score for the remission scenario for Cat 4 was 17 mm. Of the Cat 4 subjects, 70% and 79% assigned the remission model scenario a score that would satisfy the Boolean and SDAI remission criteria, respectively. No socio-demographic variable predicted responses ≤10mm. Increasing income (OR 5.37) and decreasing pain scores (OR 0.79) predicted classification of the remission model scenario at a level of ≤33mm (**Table 1**).

Conclusion: Limited HL and education are associated with responses to the remission scenario that are inconsistent with understanding the VAS line or question content. Approximately 30% of the patients in Cat 4 rated the remission model disease state at a level that would preclude them from being judged in remission by the Boolean criteria. These results expand what is known about patient perspectives of remission and the challenges of meeting remission criteria in clinics caring for diverse and disadvantaged populations.

Figure 1: Responses to rheumatoid arthritis case scenarios of remission and severe rheumatoid arthritis disease activity, grouped into categories according to completion, scorability, and appropriateness of responses

Cat 1 No response n=31	Cat 2 Unscorable responses such as writing along VAS line, circling anchor, etc. n=45
Cat 3 Scorable responses, but remission scenario not rated lower than severe scenario n=95	Cat 4 Scorable responses and remission scenario rated lower than severe scenario n=128

Cat: category; RA: Rheumatoid arthritis

Relation Between Disease Activity Indices and Their Individual Components and Radiographic Progression in Rheumatoid Arthritis: A Systematic Literature Review. Victoria Navarro-Compán[1], Ana Maria Gherghe[2], Josef S. Smolen[3], Daniel Aletaha[4], Robert B. M. Landewé[5] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Carol Davila University of Medicine and Pharmacy & Cantacuzino Hospital, Bucharest, Romania, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [4]Medical University of Vienna, Vienna, Austria, [5]Amsterdam Rheumatology Center, Amsterdam, Netherlands.

Background/Purpose: Composite indices and single items are available to monitor disease activity in rheumatoid arthritis (RA). Their relation to radiographic progression is an important aspect to select the most appropriate as target. The objective of this study was to investigate the relationship between different disease activity indices (DAIs) and their individual components and radiographic progression in patients with RA.

Methods: A systematic literature review until July 2013 was performed by two independent reviewers using Medline and EMBASE databases. The research question was formulated according to the PICO method: Population (RA patients); Intervention (DAI including DAS, DAS28, SDAI, CDAI, RADAI and RAPID and individual items or scales including patientxs global health (GH), patientxs global disease activity, pain, evaluatorxs global disease activity (EGA), all on a VAS, CRP, ESR, SJC and TJC); Outcome (radiographic progression). Longitudinal studies with ≥ 12 months of follow up assessing the relation between DAIs and single items and radiographic progression were included. Risk of bias of the studies was evaluated according to Hayden tool (range 1–6). The results were grouped based on the means of measuring (baseline versus time-integrated) and analysis (univariable or multivariable).

Results: Fifty five studies from 1232 citations were included. Most of the studies were prospective cohorts and had an overall quality score ≥ 4 points. Radiographic progression was mainly assessed using the modified Sharp van der Heijde or Larsen scoring methods and the period to evaluate progression ranged between 12 and 240 months. The table shows a summary of the studies included in the SLR. All published studies that assessed the relationship between any time-integrated DAI and radiographic progression reached a statistically significant association. Among the single items, only SJC and ESR were associated with radiographic progression, while no significant association was found for TJC. Data with respect to CRP is conflicting. Data on patientxs GH, pain assessment and EGA is limited and does not support a positive association with progression of joint damage.

Conclusion: Published data indicates that composite disease activity scores including swollen joints are more related to radiographic progression than their individual components. Therefore, these are the optimal tools to monitor disease activity in patients with RA. The best performing single items are SJC and ESR.

Table: Summary of studies evaluating the relationship between disease activity indices and their individual components and radiographic progression; Data show total number of studies and the percentage of studies that reached statistically significance (% sig) based on the type of measure and analysis employed.

DMARD Use after an Initial Acute MI Is Associated with Reduced Risk of a Recurrent Event and Mortality. Jie Zhang[1], Fenglong Xie[2], Lang Chen[2], Huifeng Yun[3], Paul M. Muntner[2], Emily Levitan[2], Monica Safford[2], Kenneth G. Saag[4], Jasvinder Singh[2] and Jeffrey R. Curtis[2]. [1]Univ. of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [4]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Previous studies have suggested that disease modifying anti-rheumatic drugs (DMARDs) may reduce cardiovascular risk among patients with rheumatoid arthritis (RA). This analysis examined whether DMARD use after an initial acute myocardial infarction (MI) was associated with reduced risk of having a recurrent MI and mortality among older RA patients.

Methods: We identified RA patients who were enrolled in Medicare (which covers more than 90% of all individuals 65 or older in the U.S.) and had an acute MI from 2006 to 2011. Eligibility criteria included the following: 1) had ≥2 rheumatologist visits with a diagnosis code for RA during a baseline period of at least 365 days prior to follow-up start; 2) had an acute MI defined as having an inpatient hospital claim with a discharge ICD-9 diagnosis code 410.X (excluding 410.x2) in any position and at least one overnight inpatient stay, unless the patient died. Follow-up started at time of discharge from the hospital after the initial MI. We used multivariable proportional hazard regression to examine the association between DMARD use after the initial MI and risk of having a recurrent MI and mortality, adjusting for factors ascertained during baseline (socio-demographics and CHD risk factors [diabetes, hypertension, chronic kidney disease, abdominal aortic aneurism, peripheral arterial disease, atrial fibrillation, hyperlipidemia, tobacco use, overweight/obese, heart failure, chronic obstructive pulmonary disease]), and after MI (medications for hypertension, hyperlipidemia, and RA). Exposure to DMARDs after MI was categorized into the following exclusive hierarchical groups: 1) any anti-TNF biologic DMARD use; 2) any non-anti-TNF biologic DMARD use; 3) any methotrexate (MTX) use; 4) any non-MTX non-biologic DMARDs use (reference group, mostly hydroxychloroquine, sulfasalazine, and leflunomide use); and 5) no DMARD use.

Results: We identified 13,985 eligible RA patients with mean age 74 (SD 11) years, 74% of whom were women. Compared to the reference group of any non-biologic and non-MTX DMARD use, non-TNF biologic DMARD use was associated with reduced mortality (hazard ratio [HR] 0.30 and ; 95% confidence interval [CI] 0.14–0.68]) and recurrent MI (HR: 0.22, 95% CI: 0.07–0.69). Compared to the same reference group, any MTX use was associated with reduced mortality (HR: 0.71, 95% CI: 0.62–0.81) but not with recurrent MI. Oral glucocorticoid use (compared to no use) was significantly associated with increased mortality at low (≤ 7.5mg/d [HR: 1.26, 95% CI: 1.18–1.34]) and high doses (> 7.5mg/d [HR: 1.73, 95% CI: 1.60–1.87]) and with recurrent MI at doses > 7.5 mg/d (HR: 1.29, 95% CI: 1.12–1.48).

Conclusion: Our findings suggest that among older RA patients, non-TNF biologic use and MTX use after an acute MI were associated with reduced risk of having a recurrent MI and mortality compared to non-biologic and non-MTX DMARD use, where glucocorticoid use was associated with increased risk of both outcomes. These results should be interpreted with caution given the possibility of residual confounding in observational studies.

MRI Osteitis at Baseline Predicts the Development of Rapid Radiographic Progression at 1 Year Toward Patients with Early-Stage Rheumatoid Arthritis. Yoshikazu Nakashima[1], Mami Tamai[2], Junko Kita[3], Sousuke Tsuji[1], Shoichi

Fukui[1], Masataka Umeda[1], Ayako Nishino[1], Takahisa Suzuki[1], Yoshiro Horai[1], Akitomo Okada[4], Tomohiro Koga[1], Shinya Kawashiri[5], Naoki Iwamoto[1], Kunihiro Ichinose[1], Yasuko Hirai[1], Kazuhiko Arima[5], Hideki Nakamura[1], Tomoki Origuchi[6], Masataka Uetani[7], Kiyoshi Aoyagi[5], Katsumi Eguchi[8] and Atsushi Kawakami[1]. [1]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Departments of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [4]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan, [5]Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [6]Department of Health Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [7]Department of Radiological Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [8]Sasebo City General Hospital, Sasebo, Japan.

Background/Purpose: EULAR recommendations for the use of imaging of the joints in the clinical management of rheumatoid arthritis (RA) states that magnetic resonance imaging (MRI) bone oedema (osteitis) is a strong independent predictor of subsequent radiographic progression in early RA and should be considered for use as a prognostic indicator. The development of rapid radiographic progression (RRP) is considered as a representative poor outcome in patients with RA.We have tried to examine whether MRI osteitis predict the further development of RRP in patients with early-stage RA from Nagasaki University Early Arthritis Cohort.

Methods: This is a 1-year observational study from seventy-six early-stage RA patients recruited consecutively from Nagasaki University Early Arthritis Cohort in which the subjects received Gd-enhanced MRI of both wrists and finger joints. All of the patients had been received DMARDs during 1 year after entry. Synovitis, osteitis and bone erosion determined by Gd-enhanced MRI was scored by Rheumatoid Arthritis Magnetic Resonance Imaging score (RAMRIS). Plain radiographic outcome of both wrists and finger joints was scored by Genant-modified Sharp score and the development of rapid radiographic progression (RRP) at 1 year in this study was identified as a score $>$ 3/year. The clinical response toward introduction of DMARDs at each point (every 3 months) was defined according to DAS28-EULAR response criteria. Variables with a *p* value less than 0.20 were selected for the following multivariate logistic regression analyses. Starting with a full model, the most appropriate model was selected on the basis of Akaike's information criteria in the SAS system®, version 9.2.

Results: Median age and disease duration at entry were 54.5 y.o and 3 months, respectively. Median RAMRIS synovitis score, RAMRIS osteitis score, RAMRIS bone erosion score and Genant-modified Sharp score at entry were 9, 1, 0, 0, respectively. RRP was developed in 12 patients at 1 year. Fifteen variables including gender, age, disease duration, DAS28-CRP, CRP (mg/dl), matrix metalloproteinase-3 (ng/dl), presence of RF, presence of ACPA, initial therapy with MTX, use of biologic DMARDs within the first 6 months, HAQ, RAMRIS synovitis score, RAMRIS osteitis score, RAMRIS bone erosion score and mTSS were evaluated to explore the development of RRP at 1 year. Multivariate logistic regression analyses have identified that RAMRIS osteitis score at baseline (1 increase, Odds ratio: 1.12, 95% C.I.: 1.06–1.19, p = 0.0002) is the only independent predictor toward the development of RRP at 1 year.

Conclusion: Present data suggest that MRI osteitis is closely associated with poor radiographic outcome in patients with early-stage RA. Physicians should especially consider the tight control of disease activity if MRI osteitis is obvious in early RA patients.

Determinants and Impact of Early Initiation of Disease-Modifying Anti-Rheumatic Drug Therapy in Rheumatoid Arthritis. Chandana Keshavamurthy[1], Kevin Kuriakose[1], Deepak Chandra[1], Aneet Kaur[1], Horace Spencer[1] and Nasim A. Khan[2]. [1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR.

Background/Purpose: Early initiation of disease-modifying anti-rheumatic drug (DMARD) therapy is recommended to improve rheumatoid arthritis (RA) outcomes. The aim of this study was to determine a) characteristics associated with early DMARD initiation ($<$ 6 month of RA symptom) and b) impact of early DMARD therapy on outcomes at one year.

Methods: This is a retrospective study of newly diagnosed RA patients at a single academic center. Eligibility criteria were RA diagnosis made by a board-certified rheumatologist, follow-up of at least 12 months and no prior history of DMARD use (except corticosteroids). Data on socio-demographics; dates of symptom onset, visit to referring healthcare provider (PCP), receipt of referral, Rheumatologist appointment and DMARD therapy initiation; functional status by Multi-Dimensional Health Assessment Questionnaires (MDHAQ) & disease activity by Routine Assessment of Patient Index Data 3 (RAPID3); and initial and one year DMARD(s) therapy were extracted in standardized manner from medical records.

Results:103 patients [71 (68.9%) females, 73 (70.9%) white; median (interquartile range, IQR) age of 50 (43–58) years, 74% anti-cyclic citrullinated peptide antibody positive] were found eligible. 50 (48.5%) were uninsured, 37 (35.9%) had Medicaid or Medicare and 16 (15.5%) had private insurance. Median (IQR) time from RA symptom onset to DMARD initiation was 51 (26–83) weeks. 25 (24.3%) patients had early DMARD therapy initiation. The delay from symptom onset to PCP visit contributed most to non-early DMARD therapy initiation followed by duration for receipt of PCP referral to Rheumatology appointment (Table). Uninsured patients were significantly less likely to receive early DMARD therapy, and were more likely to present with longer symptom duration to the PCP (p =. 029), and have longer wait before getting Rheumatology appointment (p =. 015). No other socio-demographic factor was associated with early DMARD initiation. There were no differences in MDHAQ, RAPID3, or initial DMARD agent among the early and late DMARD therapy groups. However, early DMARD therapy group had better functional status and lesser requirement of traditional and biological DMARDs after 12 month.

Conclusion: Only about one-fourth of RA patients received early DMARD therapy. Lack of insurance was associated with late DMARD therapy. Improved outcome and lesser need for intensive therapies were associated with early DMARD therapy. Our results supports need for improved insurance coverage as well improving awareness of early RA symptoms in general population and improving access to Rheumatology services.

Table: Comparison of patients who received early and late DMARD therapy.

Sustained Rheumatoid Arthritis Remission and Low Disease Activity: Analysis of 13 Years of Follow up in Clinical Practice. G. Avila[1], Arnald Alonso[1], María América López-Lasanta[1], Andrea Pluma-Sanjurjo[2], C. Diaz[2] and Sara Marsal[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]University Hospital Vall d'Hebron, Barcelona, Spain.

Background/Purpose: Biological therapies (BTs) have greatly improved the outcomes in RA patients and nowadays clinical remission (REM) and low disease activity (LDA) have become realistic goals. Only few studies have examined sustained REM and LDA in clinical practice during large periods of time. Our objective was to analyze the duration of clinical REM and LDA in RA patients in clinical practice in a university hospital.

Methods: RA patients treated with ≥ 1 anti-TNF (infliximab, etanercept, adalimumab) during the period December'99-March'13 were included. Only those treatments with ≥ 12 weeks of follow-up were analyzed. A large number of data were collected (gender, erosions, nodules, RF, ACPA, disease duration, previous BTs and concomitant corticosteroids/DMARDs...etc). DAS28 score was recorded every 3 months in all patients.

DAS28 records for each patient were interpolated to increase time resolution on the disease activity variations. We performed a parametric survival analysis in order to analyze the time until each patient reaches the first sustained period of low activity (LDA and REM). Survival curves were analyzed according to (i) DAS28 threshold that determines a low activity, (ii) minimum period of time in which one patient must be below DAS28 threshold to be considered as sustained low activity. DAS28 thresholds were 2.6 for REM and 3.2 for LDA. The periods to consider sustained low activity were 12, 24, 48 and 96 wks. The Cox regression model was used to evaluate differences in survival times. To analyze the differences between anti-TNFs, the model included DAS28 at baseline, gender and disease duration.

Results: 222 RA patients were included (87% female, 78% erosive, 75% RF (+), 77% ACPA (+)). 452 BTs met the inclusion criteria and were analyzed. In the global survival analysis we found that 44%, 20% and 10% of patients started a sustained REM period of at least 12, 24 and 96 wks during the first year of treatment. The analysis stratified by clinical variables showed that the absence of erosions was associated with sustained REM for periods longer than 48 weeks (*P*-value=7.94e-03; HR=0.49[0.32–0.76]). The differential analysis between anti-TNFs showed higher clinical remission rates in patients treated with Etanercept (ETN) compared to infliximab when longer periods were analyzed. Large periods of sustained LDA were also associated to ETN (*P*-value=8.1e-04; HR=2.42 [1.57–3.73]). Figure 1 shows heat maps representing (1) DAS28 for each treatment and time in low activity (external columns), (2) comparative analysis between treatments (central columns).

Conclusion: In our series of RA patients treated with anti-TNF therapies it was observed that 20% of patients initiate sustained clinical remission for at least 24 weeks during the first year of treatment. Patients treated with ETN are more likely to reach large periods of clinical remission and low disease activity measured by DAS28 score.

Anti-Carbamylated Antibodies (anti-CarPA) Are Associated with Long Term Disability and Increased Disease Activity in Patients with Early Inflammatory Arthritis: Results from the Norfolk Arthritis Register (NOAR). Jenny H. Humphreys[1], Marije K Verheul[2], Anne Barton[3], Tarnya Marshall[4], Bo Fu[5], René E.M. Toes[2], Deborah PM Symmons[1], Leendert A. Trouw[2] and Suzanne MM Verstappen[1]. [1]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Arthritis Research UK Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom, [4]Norfolk and Norwich University Hospitals Trust, Norwich, United Kingdom, [5]The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Anti-CarPA have been shown to predict development of rheumatoid arthritis (RA) in patients with arthralgia. However, little is known about their association with disease activity and long term outcomes such as disability; or whether they provide additional prognostic information to anti-citrullinated protein antibodies (ACPA). The aims of this study were (i)to investigate the association between anti-CarPA status, disability and disease activity over 20 years follow up in patients with early inflammatory arthritis (EIA), and (ii)to examine these associations in the subgroups of patients with and without ACPA.

Methods: Adults presenting to primary care with recent onset swelling of ≥2 joints for ≥4 weeks were recruited to NOAR since 1990. Baseline assessment included joint examination, smoking status and patient recording of the HAQ. CRP, rheumatoid factor (RF), ACPA and anti-CarPA were measured on stored sera obtained at baseline or in the first year of follow up. DAS28-CRP was calculated and 2010 ACR/EULAR classification criteria for RA were applied. Further HAQ scores were obtained at 1, 2, 3, 5, 7, 10, 12, 15 and 20 years follow up, and DAS28-CRP every 5 years. Generalized estimating equations (GEE) were used to test the association between anti-CarPA status and longitudinal HAQ and DAS28 scores including a time interaction term; then additionally adjusting for age, gender, smoking status, year of inclusion and ACPA status. The analyses were repeated in the ACPA negative and positive subgroups and in patients who fulfilled RA classification criteria without adjustment for ACPA.

Results: 1995 patients were included; 1310 (66%) were female, median age at onset (IQR) was 55 years (43–66) and median symptom duration (IQR) was 33 weeks (17–68). Anti-CarPA were positive in 460 (23%) patients and 1221 (61%) satisfied the 2010 ACR/EULAR classification criteria for RA. 539 (26%) were current smokers. ACPA were tested in 1465 patients, 373 (25%) were positive. Median follow up time (IQR) was 7 years (5–11). Baseline median HAQ and DAS28 were higher in anti-CarPA positive vs negative patients (1.125 vs 0.875 and 4.23 vs 3.73 respectively). In the GEE analysis, patients who were anti-CarPA positive had significantly more disability over time and higher levels of disease activity than those who were negative; multivariate model for the HAQ including adjustment for ACPA gave a β coefficient (95% confidence interval) 0.13 (0.03–0.23) (Table 1). Statistically significant associations were also seen in the ACPA negative subgroups. In the ACPA positive and RA subgroups there were significant associations with DAS28 and trends approaching statistical significance with HAQ scores.

Conclusion: The presence of anti-CarPA is associated with increased burden of disability and higher disease activity over time in patients with EIA. Our results suggest anti-CarPA may be useful in identifying ACPA negative patients with poor prognosis.

Similar Improvements in Physical Function, Quality of Life and Work Productivity Among Rheumatoid Arthritis Patients Treated with 2 Different Doses of Methotrexate in Combination with Adalimumab. Gurjit S. Kaeley[1], Midori Jane Nishio[2], Daryl MacCarter[3], Jenny Griffith[4],

Hartmut Kupper[5], Vishvas Garg[6] and Jasmina Kalabic[5]. [1]University of Florida, Jacksonville, FL, [2]Diablo Clinical Research, Walnut Creek, CA, [3]Coeur d'Alene Arthritis Clinic, Coeur d'Alene, ID, [4]AbbVie, Inc., North Chicago, IL, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [6]AbbVie Inc., North Chicago, IL.

Background/Purpose: Methotrexate (MTX) is used in monotherapy or in combination with other DMARDs in the treatment of patients (pts) with rheumatoid arthritis (RA). We evaluated the effects of low and high MTX doses in combination with initiation of ADA on patient-reported outcomes (PROs), in MTX-inadequate responders (MTX-IR) with moderate-to-severe RA.

Methods: MUSICA (NCT01185288) was a double-blind, randomized, controlled trial evaluating the efficacy of 2 different dosages of MTX, 7.5 or 20 mg/week (wk) in combination with ADA (40 mg every other wk) for 24 wks in MTX-IR RA pts. Pts entering the study had been receiving ≥15 mg/wk MTX for at least 12 wks. At each study visit, from baseline (BL) to wk 24, the following PROs were recorded: physical functioning, work productivity and activity impairment, and health-related quality-of-life (HRQoL), using the health assessment questionnaire-disability index (HAQ-DI), work productivity and impairment (WPAI), and the short-form 36 (SF-36) questionnaires, respectively. Last observation carried forward (LOCF) was used to account for missing values.

Results: 154 pts were enrolled in the 7.5 mg/wk MTX+ADA arm, and 155 pts in the 20 mg/wk MTX+ADA arm. Both arms were similar for BL demographics (mean age 54.8, mean disease duration 5.3 years) and disease characteristics (mean DAS28(CRP) of 5.8). In the low and high MTX dosage groups respectively, mean BL HAQ-DI scores were 1.5, mean percentages (%) of time in absenteeism at BL were 9.2 and 10.1; mean % of time in presenteeism at BL were 45.0 and 47.6; mean % of activity impairment at BL were 57.0 and 61.9. BL SF-36 (physical component) scores were 31.5 for both groups, and BL SF-36 (mental component) scores were 44.7 and 41.9 for the low and high-dosage groups respectively. After 24 wks, significant improvements from BL were observed for both MTX dosage groups, in the WPAI (except for absenteeism), HAQ-DI and the physical and mental components of the SF-36 (table). Differences in physical function, QoL and work productivity observed between the low and high dosage MTX groups were not statistically significant.

Table 1 Effect of treatment with ADA + low or high dose MTX on patient outcomes at week 24

Outcome measure	n	Change from BL to wk 24, mean (95% CI)	*P*-value (BL and wk 24 mean scores)	wk 24, mean score (95% CI)	*P*-value (between wk 24 mean scores of dosage groups)

SF-36-mental component					
7.5mg/wk MTX+ADA	150	3.7 (1.9, 5.6)	<.001	48.8 (47.0, 50.5)	0.759
20mg/wk MTX+ADA	152	4.8 (2.9, 6.7)	<.001	46.5 (44.7, 48.3)	

P-values between dosage groups at wk 24 determined by ANCOVA

Conclusion: Similar to observations in pts with early RA,[1]the addition of ADA to MTX in pts with moderate to severe disease and insufficient MTX response, led to improvements in physical function, work productivity and quality of life after 24 wks. The improvements were observed regardless of the MTX dosage. Similar improvements in the two MTX dosage groups support the idea that MTX dose could be reduced in some MTX-IR pts while initiating ADA therapy.

Sustained Remission Improves Physical Function in RA Patients Treated with Tumor Necrosis Factor Inhibitor. Jon T. Einarsson[1], Meliha C. Kapetanovic[1] and Pierre Geborek[2]. [1]Lund University, Lund, Sweden, [2]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden.

Background/Purpose: Remission is increasingly becoming a treatment goal in rheumatoid arthritis (RA) patients. Despite their limitations DAS28 remission criteria are widely used. It is not clear whether achieving remission is sufficient or weather the goal should be sustained remission. Physical function measured by health assessment questionnaire (HAQ) is a major outcome in RA. HAQ is shown to be one of the strongest predictors of long-term outcomes including quality of life, work disability and mortality.

The purpose of this study was to investigate the physical function over a long time period in RA patients treated with Tumor Necrosis Factor inhibitors (aTNF) who achieved sustained remission (SR) compared to that of patients occasionally achieving remission (non-sustained remission, nonSR).

Methods: Anti-TNF treated RA patients included in the observational South Swedish Arthritis Group register were eligible for this study. We identified patients with DAS28<2.6 at some point and those that achieved sustained remission in consecutive visits for at least 6 months. The course of functional status was assessed using HAQ at each visit.

Results: Of 2416 patients included, 1194 (49.4%) reached DAS28 remission at some point. Of those fulfilled 382 (15.8 %) the criteria for SR with median duration of 5.25 years while 812 (33.6%) had non-sustained remission. The nonSR group had mean disease duration of 11.5 years at treatment start compared to 10.1 years in the SR group, and mean HAQ of 1.3 compared to 1.0 in the SR group. Figure1 show the mean HAQ in each year after remission start with the 95% confidence interval of mean. In the first year the mean HAQ in the SR group was 0.48(95%CI of mean 0.026) and then continued to improve in every year for 7 years. The HAQ is significantly lower in year 4 (0.32; 95%CI 0.050) and again in year 7 compared to year 4 (0.167; 95%CI 0.058). In the nonSR group the mean HAQ in the first year was 0.701 and did not change significantly over 8 years.

Conclusion: Physical function measured by HAQ improves in patients with established RA reaching sustained remission and continues to improve while in remission. This suggests that treatment should be aimed at maintaining sustained remission.

Understanding Patient Preferences Associated with the Use of Therapies for Rheumatoid Arthritis: Results of a Conjoint Analysis. K. Saverno[1], A. Louder[1], A. Singh[2], J. Cappelleri[3], A. Aten[4], A. Koenig[5] and M. Pasquale[1]. [1]Comprehensive Health Insights Inc, Louisville, KY, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, New York, NY, [4]Humana Inc, Louisville, KY, [5]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Tofacitinib provides patients with a new oral alternative to biologic therapies; however, little is known about the

patient preference of modern treatments for RA. Here, we determined patient preferences for attributes associated with therapies used in the treatment of RA.

Methods: A choice-based conjoint survey was mailed to 1400 randomly selected Humana adult (21–80 years old) members diagnosed with RA (continuously enrolled and had ≥2 medical claims with an ICD-9-CM diagnosis code of RA [714.0] between 5/1/2012 and 4/30/2013) and no prior use of a biologic indicated for RA. Attributes included route of administration (ROA); monthly out-of-pocket cost; frequency of administration (FOA); ability to reduce daily joint pain and swelling; likelihood of serious side effects (SAE); improvement in the ability to perform daily tasks and activities; and medication burden (methotrexate co-administration). Mean attribute importance scores (AIS) were calculated after adjusting for various member demographics (e.g. age, gender, region, years since RA diagnosis). Mean AIS scores were used to rank order patient preferences for the attributes. An aggregate logit analysis was implemented to estimate average utilities & preference shares for two treatments – a twice daily oral and every other week self- injection.

Results: A total of 380 commercially enrolled members (response rate of 27.1%) in Humana returned the survey (mean ± standard deviation [SD] age 54.9 ± 9.3 years, 9.7% had a history of joint surgery due to RA, 81.6% female). After an adjustment for demographic and clinical characteristics, commercial members' ranking of attribute importance was as follows in decreasing order (mean AIS ± SD): ROA 34.08 ± 15.53; FOA 16.43 ± 6.82; SAE 12.01 ± 9.32; cost 10.12 ± 6.21; medication burden 9.75 ± 8.15; joint pain reduction 8.86 ± 3.82; and improvement in daily tasks 8.76 ± 4.70. Within the route of administration attribute, the oral formulation was the level with the highest part-worth utility (preference score) compared with subcutaneous and intravenous routes of administration. Based on the part-worth utility, it was estimated that 62% of RA patients included in the sample would prefer oral therapy.

Conclusion: Route of administration is an important consideration for those diagnosed with RA and naïve to biologic therapy. Given the variety of RA therapies available, gaining a better understanding of the attributes considered important to patients in their treatment may help inform payer and prescriber decisions in selecting therapies that will lead to higher patient satisfaction and improved medication adherence.

2396

Treat to Target in Routine Clinical Practice. Mohammad Solaiman[1], Olga Semenova[1], Helen Thompson[1], Joanne Cunnington[1], Elaine Baguley[1], Sathish Kallankara[2], Olanbambo Ogunbambi[1] and Yusuf Patel[3]. [1]Hull Royal Infirmary, Hull, United Kingdom, [2]Hull Yoyal Infirmary, Hull, United Kingdom, [3]Hull and East Yorkshire NHS Trust, Hull East Yorkshire, United Kingdom.

Background/Purpose: In order to overcome obstacles with overbooked outpatient clinics and lack of capacity to see rheumatoid patients frequently for treatment escalation, we established a protocol-driven clinic run by a speciality doctor and nurse in 2010. All newly diagnosed patients with Rheumatoid Arthritis were seen on a 4–6 weekly basis by the team to escalate DMARD treatment according to disease activity as measured by DAS28-CRP. To assess DAS28-CRP remission rate in this cohort of patients (after 1, 2 and 3 years of therapy). We also looked at rates of low disease activity (LDA) - DAS 28 CRP≥2.6 but≤3.2 and categorisation by DMARD monotherapy, combination therapy, or Biologic therapy.

Methods: Treatment escalation was done by agreed departmental protocol which included oral Methotrexate (up to 25mg/week, followed by S/C injections if necessary). This was followed by addition of Hydroxychloroquine and then either Leflunomide or sulphasalazine if DAS28-CRP indicated activity. UK NICE guidelines allow use of Biologics if the DAS > 5.1 at 6 months, hence this was the next step followed on the protocol. We collected additional outcome data for HAQ score, work stability data, and radiological erosion data. We have 331 patients through the clinic to date and present outcome data for those completing 1year (127), 2years (75) and 3years (36).

Results: 127 patients have completed 1year, of which 20% achieved DAS28 scores <3.2 (LDA) and 60% <2.6 (remission). 64% needed combination DMARD therapy and 7 patients (5.5%) needed biologics, 30% remaining on DMARD monotherapy at 1 year. Mean HAQ scores reduced from 1.1 (+−0.01) to 0.32 (+−0.07) and radiological erosions progressed in only 10%. Job retention at one year was 90%.

75 patients completed 2 years of follow-up, 68% in DAS-remission and 16% LDA. 8% are on Biologics at end of year 2, 32% on DMARD monotherapy.

36 patients completed 3 years follow-up, with LDA in 25% and remission 61%. At year 3, Biologics use is 5.5%, with DMARD monotherapy in 20%.

DAS28 remission is maintained at 60% over the course of the 3years, with LDA increasing from 20% to 25% at year3. The active group (>3.2 DAS <5.1) who do not satisfy NICE criteria for Biologics reduced from 20% (year1) to 14% (year 3) on combination DMARD therapy.

Conclusion: Targeted protocol-driven treatment of early RA with rapid escalation of therapy using conventional DMARDs/biologics resulted in remission of 60% at 1 year and maintained remission of 68% and 61% at 2 and 3 years. The DAS28 remission rates and other outcomes achieved in this relatively 'routine' clinic are comparable to results achieved in controlled clinical trials. The innovative use of limited human resources and clinic appointments has provided good outcomes for patients with potential savings in expenditure on Biologic therapy.

Table: Comparison between Disease activity and therapy on consecutive 3 years

			YEAR 1 (2011)	YEAR 2 (2012)	YEAR 3 (2013)

Improvement of Fatigue in Patients with Rheumatoid Arthritis Treated with Biologics: Relationship with Sleep Disorders, Depression and Clinical Efficacy. A Prospective, Multicenter Study. Marlène Genty[1], Marie Kostine[2], Elodie Ardouin[3], Bernard Combe[4] and Cédric Lukas[5]. [1]CHU Lapeyronie, Montpellier, France, [2]Rheumatology, CHU Pellegrin, Bordeaux, France, [3]Rheumatology, Limoges University Hospital, Limoges, France, [4]Hôpital Lapeyronie, Montpellier, France, [5]Hopital Lapeyronie, Montpellier, France.

Background/Purpose: The functional burden of disease in Rheumatoid arthritis (RA) patients, mainly caused by inflamed joints, is often worsened by extra-articular manifestations, among which asthenia remains the most frequently reported. Most biologics have shown overall efficacy on fatigue, but whether this is due to overall improvement of disease or to more specific aspects of the disease like sleep disorders due to overnight pain and awakenings remains unknown. The aim of this study was to evaluate potential predictive factors of improvement in related fatigue in RA patients newly receiving biologic therapy, and more specifically the potential influence of the improvement in sleep disorders.

Methods: We conducted a multicenter prospective study in RA patients (100% fulfilling ACR/EULAR classification criteria) requiring initiation or change of biologic therapy. The improvement in fatigue was assessed by the FACIT fatigue scale at inclusion (M0) and after 3 months (M3). Sleep disorders and evaluation of depression were respectively measured by Spiegel scale and Beck Depression Inventory. Potential confounders like presence of anemia, thyroid dysfunctions, iron deficiency, psychotropic or corticosteroids medications were adjusted for. The association between evolution of fatigue (improvement/no improvement according to predefined validated cutoffs) and

other characteristics were evaluated by univariate (Chi2) then multivariate (logistic regression) analyses.

Results: We included and followed-up 99 patients (72,7% women, aged 58,2±12,1 with initially active disease (DAS28 5,1±1,4). FACIT scores at inclusion revealed frequently reported fatigue: 89% with scores more severe than expected in general population, high prevalence of sleep disorders (95%: abnormal 68%, pathologic 27%) and depression (67%: mild 33%, moderate 24%, severe 11%). Anti-TNF drugs were started in 50 patients, other biologics in 49 patients (tocilizumab N=19, abatacept N=16, rituximab N=14). Clinical response was beneficial in most patients: 36% good EULAR response, 40% moderate, 24% no response. Improvement of fatigue, sleep quality and depression according to predefined cutoffs was observed in respectively 58.6%, 26.3% and 34.3% of cases. Factors associated with an improvement in fatigue at M3 were an elevated sedimentation rate at M0 (OR=5.7[2.0–16.0], p=0.001) and a favorable EULAR response at M3 (OR=4.8[1.6–14.8], p=0.006). Furthermore, a number of swollen joints >5 at baseline (OR=0.3 [0.1–0.8]) and the use of psychotropic drugs (OR=0.2[0.04–0.9]) were predictive of an absence of improvement in fatigue. No significant association with the improvement in sleep disorders could be demonstrated: of 29 patients with improvement in sleep quality, 17 (58.6%) considered their level of fatigue had decreased, while 41/70 (58.6%) did so among those without correction of sleep disorders (p=0.9).

Conclusion:. Our study confirmed that fatigue in RA is frequent, as well as depression and sleep disorders, and is usually improved by effective treatment (i.e. via decrease in disease activity). Our results indicate that improvement of sleep disorders is more likely a surrogate of therapeutic efficiency rather than an independent outcome.

Continued Participation in a 10-Year Tight Control Treat-to-Target Study in Rheumatoid Arthritis: Why Keep Patients Doing Their BeSt?
I.M. Markusse[1], L. Dirven[1], T.H.E. Molenaar[2], N. Riyazi[3], P.B.J. de Sonnaville[4], P.J.S.M. Kerstens[5], W.F. Lems[6], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Groene Hart Hospital, Gouda, Netherlands, [3]Haga Hospital, The Hague, Netherlands, [4]Admiraal de Ruyter Ziekenhuis, Goes, Netherlands, [5]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [6]VU Medical Center, Amsterdam, Netherlands.

Background/Purpose: To identify risk factors for premature study termination and patients' motives for adherence to a long term follow-up clinical trial in rheumatoid arthritis (RA).

Methods: In 508 patients with early RA enrolled in the BeSt study, risk factors for premature study discontinuation were identified through univariable and then multivariable logistic regression analysis. In this analysis, for every patient ten endpoints were generated (still under follow-up at the end of a year, yes/no), and baseline characteristics and clinical characteristics as present in the preceding year of follow-up were entered as determinants. Patients who completed 10-year follow-up were asked to fill in a questionnaire on study experiences and possible motives for study adherence.

Results: In total, 313/508 patients (62%) attended the final visit, and 288 (92%) filled in the questionnaire. Mean age of completers was 61 years and 67% were female. Based on 508 included patients, risk factors for early termination were a higher age (odds ratio, OR 1.04, 95% confidence interval, CI 1.03 – 1.06), worse functional ability during the preceding year (measured with the health assessment questionnaire, OR 1.63, 95% CI 1.27 – 2.08), having achieved drug-free remission during the preceding year (OR 1.85, 95% CI 1.38 – 2.47) and suffering a severe adverse event during the preceding year (OR 1.71, 95% CI 1.18 – 2.49). In the first part of the questionnaire, the majority of patients mentioned contributing to scientific research (97% of patients agreed), helping other patients (91%), 'I have nothing to lose' (80%), gaining understanding of new treatment strategies (84%) and of their disease (85%) as reasons to continue participation. Next, patients were asked to mark one or more possible reasons to continue participation. In total, 278 patients marked 912 reasons: tight disease control (202/278 patients), good treatment strategy (128/278), good medication prescribed by the protocol (117/278) and good half-time results (102/278) were most often mentioned. Over 95% of patients experienced participation 'as expected' or 'better than expected'. In particular care by the study nurses was appreciated: 55 – 75% answered 'better than expected' to 4 questions regarding this issue. Additional examinations during the yearly visits (additional questionnaires, imaging techniques) were mentioned 'worse than expected' (10% of patients) as was filling in the 3-monthly questionnaires (7%). Most patients (74%) would participate in another trial and 94% would recommend participation to friends and family.

Conclusion: Continued participation during 10 year follow-up in the BeSt study was relatively high (62%), although impaired functional ability, higher age, experiencing severe adverse events and achieving drug-free remission in the previous year were predictors for early termination. Motivators to continue participation were a wish to contribute to scientific research, to learn more about their disease and its treatment, personal benefit of available therapies, and a good rapport with the study nurse. By cultivating these motivators, early termination in future long-term follow-up studies might be reduced.

Non-Adherence to Disease-Modifying Anti-Rheumatic Drugs in Patients with Rheumatoid Arthritis: An Italian Survey.
Gerolamo Bianchi[1], Antonio Carletto[2], Oscar Massimiliano Epis[3], Crescenzio Scioscia[4], Angelo Semeraro[5], Laura Bianchino[6], Laura Bazzichi[7], Giovanni Lapadula[8], Luigi Sinigaglia[9] and Andrea Lo Monaco[10]. [1]ASL3 Genovese, Genoa, Italy, [2]Dipartimento di Medicina,U.O. Complessa di Reumatologia, Azienda Ospedaliera Universitaria di Verona, Verona, Italy, [3]Rheumatology Unit, Niguarda Ca' Granda Hospital, Milan, Italy, [4]University of Bari, Bari, Italy, [5]P.O. "Valle d'Itria, Martina Franca, Italy, [6]Roche Spa., Monza, Italy, [7]Rheumatology Unit, Pisa, Italy, [8]Rheumatology Unit, Bari, Italy, [9]Department of Rheumatology, Gaetano Pini Institute, Milan, Italy, [10]Azienda ospedaliero-universitaria Sant'Anna, Ferrara, Italy.

Background/Purpose: Approximately 50% of patients (pts) with chronic diseases are non-adherent to the therapeutic regimen assigned. In pts with rheumatoid arthritis (RA), the non-adherence to therapy may impair the efficacy of treatment and is often associated with the disease flare and increased disability; moreover, non-adherence is a dynamic feature, unpredictable, because pts initially compliant to treatment may become non-adherent. The objectives of this survey were to evaluate the presence, to quantify the extent and to identify reasons for non-adherence to treatment with conventional disease-modifying anti-rheumatic drugs alone (cDMARDs) or with biological DMARDs (bDMARDs) in RA pts in Italy.

Methods: This was a self-reported survey performed in RA pts treated with cDMARDs in Italy. In the hospital waiting room, pts were asked to fill out an anonymous paper based questionnaire, without either nurses or physicians support. Fieldwork: December 3rd 2013 - February 24th 2014.

Results: A total of 1,000 RA pts treated with cDMARDs were recruited from 25 Italian centers (females: 76.3%; mean age: 57 years; mean time since RA diagnosis: 9 years): 360 pts were treated with cDMARDs alone and 640 pts were treated in combination with a biologic drug.

Overall, the proportion of pts reporting non-adherence to cDMARDs was 37.2% (n=372): 28.9% (n=104) treated with cDMARDs alone and 41.9% (n=268) treated in combination cDMARDs + biologic drug. cDMARDs non-adherent pts were asked to report how often they do not take the cDMARDs treatment: the frequency of non-adherence was reported as "sometimes" by 55.38% of pts, "seldom" by 34.14%, "often" by 9.68% and "always" by 0.8%.

The main reason given for cDMARDs pts non-adherence was forgetfulness (54.8%); other reasons reported were: side effects fear (15.1%), the feeling they were taking too many drugs (14.2%), the thought of feeling better (9.4%) and the difficulty to remember drug dose and frequency of administration (6.5%). Interestingly, pts who did not mention cDMARDs non-adherence to their physician were 37.6% of the total 372 cDMARDs non-adherent pts, particularly younger pts (aged ≤ 40 years). More details are shown in Figures 1 and 2.

Conclusion: This extensive research about non-adherence to cDMARDs treatment, carried out in a large sample of RA pts, allowed to obtain an extensive local real life data set, representing Italian clinical practice. Results show that non-adherence to cDMARDs is fairly widespread (37.2%) among RA pts; furthermore, a considerable proportion of non-adherent pts (37.6%) find difficult to talk to their physician about this issue.

Comparing a Tapering Strategy to the Standard Dosing Regimen of TNF Inhibitors in Patients with Rheumatoid Arthritis in Remission or with Low Disease Activity.

Chamaida Plasencia-Rodriguez[1], G. J. Wolbink[2], Charlotte L. M. Krieckaert[2], Eva L. Kneepkens[3], Samina Turk[4], Maria Gema Bonilla[5], Alejandro Villalba[1], Diana Peiteado[1], Laura Nuño[6], Mike T. Nurmohamed[2], Theo Rispens[7], Desiree van der Kleij[8], Teresa Jurado[9], Emilio Martín-Mola[10], Dora Pascual-Salcedo[5] and Alejandro Balsa[6]. [1]Hospital La Paz - IdiPaz, Madrid, Spain, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [3]Reade, centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands, [4]Reade, Amsterdam, Netherlands, [5]La Paz University Hospital, Madrid, Spain, [6]Hospital La Paz-IdiPaz, Madrid, Spain, [7]Sanquin Research, Amsterdam, Netherlands, [8]Sanquin Diagnostic Services, Amsterdam, Netherlands, [9]La Paz University Hospital-Idipaz, Madrid, Spain, [10]Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: There is a growing interest about optimization of biological therapies but for now no strong evidence is available to support a tapering strategy in clinical practice.

Our aim was to compare the clinical outcomes of a tapering strategy to the standard dosing regimen of TNF inhibitors (TNFi) in patients with rheumatoid arthritis (RA) and low disease activity during long-term follow-up.

Methods: In this retrospective observational study, two groups of RA patients on TNFi with DAS28<3.2 were compared: the tapering group (TG: 67 pts from Spain) and the control group with the standard therapy regimen (CG: 77 pts from the Netherlands). DAS28 was measured at different time points: visit 0 (prior starting TNFi), visit 1 (prior to starting tapering in TG and at least 6 months with DAS28<3.2 after starting TNFi in the TG and CG), visit 2 (6 months after visit 1), visit 3 (1 year after visit 1) and visit 4 (the last visit available after visit 1).

Results: The demographic characteristics are summarized in Table 1. Despite an overall reduction of administered drug at visit 4 in the TG (an interval elongation of 32.8% in infliximab, 52.9% in adalimumab and 52.6% in etanercept), no significant differences were found in the clinical activity between the groups at the end of the study (DAS28: 2.7±0.9 in TG vs. 2.5±1 in CG, p=0.1) (Figure 2). The number of patients with flares was similar in both groups [28/67 (42%) in TG vs. 36/75 (48%) in CG, p=0.5]. No significant differences were seen in the proportions of patients who dropped out [10/67 (15%) in TG vs. 6/77 (8%) in CG, p=0.17].

Conclusion: The tapering strategy of TNFi in RA patients with low disease activity results in an important reduction in the amount of drug administered, while the disease control remains similar to that of patients on the standard dosing regimen.

Interrupted and Delayed Care in First Nation Patients with Rheumatoid Arthritis: The Best Target for Therapy?

Liam O'Neil[1], Carol A. Hitchon[1], David B. Robinson[1], Navjot Dhindsa[1], Hani El-Gabalawy[1] and Christine A. Peschken[2]. [1]University of Manitoba, Winnipeg, MB, [2]University of Manitoba, Canada, Winnipeg, MB.

Background/Purpose: Severe disease and poor outcomes have been described in First Nation (FN) patients with Rheumatoid Arthritis (RA). We examined the contributions of interrupted and delayed care to the outcomes of FN RA patients compared with Caucasian (CA) patients with RA.

Methods: Our academic Arthritis Centre maintains a prospective database on all patients seen since 1990, with records of more than 10,000 patients. The database includes patients' diagnoses, demographics, year of disease onset, and date of first and subsequent clinic visits, and self-reported ethnicity. At each visit, patients complete a modified health assessment score (mHAQ), disease activity visual analogue scales (VAS), while physicians complete joint counts, physician global VAS, and current treatment information. A Lansbury Index (LBI), a weighted joint count, is calculated each visit. After excluding patients if disease duration was >15 or <1 year, or if there were <2 clinic visits, records of the most recently assessed 150 FN and 150 CA RA patients were abstracted. The database was supplemented with search of the provincial electronic imaging and laboratory databases for each patient, to determine serology, acute phase reactants, and radiologic damage or documented joint deformities.

Results: Records of 154 CA and 150 FN patients were abstracted**.** Disease duration and gender distribution were similar in CA compared to FN (9 ±4 vs 8 ±5 years; and 79% vs. 85% female respectively). Mean distance from care was 73 km for CA and 408 km for FN, with 35% of FN living >500 km away compared to 1% of CA, (p <0.001). FN patients were younger at disease onset than CA, (40 ±13 vs 49 ±17 years; p < 0.001). At clinical presentation, FN were more likely to be seropositive for both RF and ACPA compared to CA, (59% vs 46%; p = 0.02) and had higher RF titers (405 ±551 vs 236 ±485; p = 0.005), and ACPA titres (114 ±88 vs 68 ±82; p < 0.001) The two groups did not differ in mHAQ, ESR, CRP, VAS, tender, or swollen joint counts at first visit, but FN had higher LBI scores (40 ±36 vs 28 ±33; p = 0.012). FN had greater delays from symptom onset to first DMARD (19 months ±26 vs 15 ±35; p = 0.2), and first biologic (57 months ±34 vs 46 45; p = 0.06), but had more total DMARD trials over their disease course (5.1 ±3.2 vs 3.7 ±2.5; p = <0.001), and were off DMARD therapy for longer periods in total (36 months ±30 vs 25 ±40; p = 0.009), had fewer clinic visits/year (5 ±12 vs 3 ±7; p = 0.072, and received more frequent intramuscular steroid injections (IMS) for flares: 21% of FN had received 3–5 IMS vs. 12% of CA, and 11% had received ≥ 6 IMS vs 3% of CA; p<0.001. At the last visit, FN had higher mHAQ scores (.71 ±.47 vs. 42 ±.52; p <0.001), higher LBI (34 ±37 vs 20 ±30; p = 0.003), and more frequent joint damage/deformity, (85% vs 74%; p = 0.02).

Conclusion: The younger onset age, more frequent seropositivity, and higher LBI suggest biologically more severe disease, but our data suggests differential care delivery with modifiable factors over the disease course that likely impact outcomes, including treatment delays, missed appointments, and interrupted treatment. Improved care delivery models, particularly incorporating outreach care, have the potential to improve outcomes substantially for this population.

Evaluation of Perceived Self-Efficacy, Learned Helplessness and Functional Capacity in Patients with Rheumatoid Arthritis. Facundo Vergara[1], Emmanuel Bertiller[2], Celeste Orozco[3], Javier Rosa[1], Erika Catay[1], Maria de los Angeles Gallardo[4], Emilce Schneeberger[5], Maria Victoria Garcia[1], Gustavo Citera[6], Marcos G. Rosemffet[6], Mirtha Sabelli[1] and Enrique R. Soriano[7]. [1]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Instituto Rehabilitacion Psicofisica, Buenos Aires, Argentina, [4]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, BUENOS AIRES, Argentina, [5]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [6]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [7]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Rheumatoid Arthritis (RA) is an inflammatory chronic disease that involves cognitive and emotional aspects of patients, from the beginning of diagnosis. One relevant cognitive factor is perceived self-efficacy, which is defined as the individual's abilities to cope with the disease. Another important cognitive factor in the perception of RA control is the learned helplessness. We could define it as an inadequate perception of the disease generating feeling of defenselessness, behaviors of passivity, loss of self-esteem and belief that nothing you do can improve your situation.

It has been reported that petients with high levels of self-efficacy have less pain, learned helplessness and functional disability. On the other hand patients with higher learned helplessness, have more pain and functional disability.

Our objective was to assess the association between perceived SE and LH with disease activity, functional disability, and educational level.

Methods: Consecutive patients, older than 18 years, with definite diagnosis of RA according to 2010 ACR/EULAR criteria, seen at the outpatient rheumatology unit between March and April 2014, were included. During the inclusion visit the following data were collected: Demographics; socioeconomic status (Graffar scale); educational level; disease duration; swollen and tender joint counts (28 joints); CDAI (Clinical Disease Activity Index); HAQ-A (Health Auto Questionnaire-simplified Argentinean validation); pain by visual analogue scale (VAS); fatigue (VAS); patient and physician global assessment of disease activity (VAS); morning stiffness (VAS), depression screening measured by CES D-7; perceived SE measured by Arthritis Self-auto-efficacy Scale; LH measured from Rheumatology Attitudes Index (RAI) (spanish validation).

Descriptive statistics were calculated. Correlations were calculated using Pearson test. SE and LH were compared between patients in remission and with active disease.

Results: One hundred and two patients were included. Patient's characteristics are shown in table 1.There was a significant positive correlation between LH and pain (r=0.67; p<0.001); HAQ (r=0.64; p<0.001), and CDAI (0.41; p<0.001); and a negative correlation between SE and pain (r= − 0.43; p<0.001); HAQ (r= − 0.41; p<0.001); and CDAI (r= -0.34; p<0.001). Patients on remission (n=30) according to CDAI, had significantly higher SE (70.3 vs. 56.8; p<0.001) and lower LH (7.2 vs. 11.6; p<0.001) than patients not in remission. There was a poor correlation between LH and SE with educational level (years of education) (r = 0.39 and −0.19, respectively).

From Early Arthritis Clinic to Remission Clinic: Short-Term Outcome and Ultrasonographic-Synovitis Dynamics in Rheumatoid Arthritis Patients in DMARD-Induced SDAI-Remission during Drug-Free Follow-up. Antonio Manzo, Francesca Benaglio, Garifallia Sakellariou, Martina Scarabelli, Elisa Binda, Barbara Vitolo, Serena Bugatti, Roberto Caporali and Carlomaurizio Montecucco. Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico S.Matteo Foundation/University of Pavia, Pavia, Italy.

Background/Purpose: The introduction of DAS-driven intensive treatment strategies in early rheumatoid arthritis (RA) has considerably improved outcome and patients' quality of life. Previous studies have also suggested the possibility, in selected cases, of maintenance of an acceptable clinical status for prolonged periods following treatment suspension. Despite these observations, three critical issues remain partly unsolved: 1) whether systemic

suppression of inflammation can coincide with reversal of the pathogenic process, 2) the possibility to define exploitable parameters able to predict in which patients treatment can be suspended, 3) the primary dynamics as well as the anatomic-biologic substrate of relapse. The aim of the current study was to investigate the clinical-radiographic-functional outcome and ultrasonographic-synovitis dynamics of RA patients in DMARDs-induced SDAI remission, during 12 months drug-free follow-up.

Methods: From December 2011, all RA patients followed at our Early Arthritis Clinic achieving stable clinical remission and candidate to treatment suspension are referred to a dedicated Remission Clinic. Referral criteria: 1) introduction of DMARDs treatment within 12 months from symptoms' onset, 2) ≥24 months DMARDs treatment with a DAS28-driven intensive protocol, 3) stable DAS28 remission (DAS28steroids. All patients allowed to drug-free follow-up are monitored at three months' intervals through complete clinical, ultrasonographic (hands-feet-axillary lymph nodes' PD-US) and immunologic screenings. Hands-feet radiographs are performed at baseline and every 12 months. Treatment is re-introduced in case of moderate disease activity (DAS283.2) or radiographic progression.

Results: 40 consecutive RA patients in DAS28 and SDAI remission (SDAI≤3.3) at the baseline visit have been followed-up for 12 months in drug-free regimen and monitored every 3 months. Maintenance of stable DAS28 remission (T0-T12) was observed in 18/40 patients (45%), while treatment re-introduction due to disease relapse was required in 13/40 patients (32.5%). No significant radiographic progression (SHS) and functional impairment (HAQ) was detected at a group level during drug-free follow-up. Ultrasonographic stratification at baseline showed the absence of power Doppler signal (hands-wrists) in 29/40 (72.5%) (SDAI≤3.3-PD=0). Despite stringent remission and absence of sub-clinical signs of synovitis at recruitment, 8/29 (27.5%) patients relapsed, while in 12/21 (57.1%) a transient or persistent reappearance of defined PD signal (PD>1) was detected during follow-up despite the lack of requirement of DMARDs re-introduction according to study criteria.

Conclusion: Suspension of DMARDs with short term maintenance of good clinical status is an achievable goal after treat-to-target and tight control strategies in early RA. However, despite stringent clinical and ultrasonographic remission, relapse or signs of disease reactivation can occur early after drug withdrawal, supporting the requirement of additional patho-biologic insights for a more specific stratification of RA remission phase.

RA Patients with Inadequate Response to Oral MTX Maintain Satisfactory Disease Control and Durable Long-Term Response When Switched to SC MTX Monotherapy. Anthony Hammond[1] and Michael Batley[2]. [1]Maidstone and Tunbridge Wells NHS Trust, Kent TN13 2JD, United Kingdom, [2]Maidstone and Tunbridge Wells Hospital, Kent, United Kingdom.

Background/Purpose: Methotrexate (MTX) is the cornerstone of rheumatoid arthritis (RA) therapy, but many patients do not achieve adequate response to oral therapy for reasons of tolerability or efficacy.[1,2] Subcutaneous (SC) MTX should be considered for RA patients who have an unsatisfactory response to oral MTX.[3] In this analysis, RA patients switched from oral MTX to SC MTX monotherapy were evaluated to understand durability of response and disease control.

Methods: A prospective analysis of retrospective RA patient data collected from 2003–2011 at single site in the U.K.[4] was performed. Per institutional practice, incremental oral MTX dose increase was followed by a switch to SC MTX. Folic acid (5–15 mg) was given 1 day after SC MTX treatment as a matter of routine practice. Mean duration on SC MTX monotherapy following switch from oral MTX was documented via patient record review.

Results: 112 RA patients were eligible for analysis. Mean age was 60.9 yrs (range 26–83 yrs) and mean disease duration was 8.3 years (range 0.5–46 yrs). 49 (44%) patients with an inadequate response to oral MTX for reasons of tolerability or efficacy were switched to SC MTX monotherapy and included in this analysis. (Table 1) 20 patients (41%) switched from oral MTX to SC MTX for reasons of tolerability. Amongst these: Mean DAS28 improved by 18% (−1.05), patients remained on SC MTX monotherapy for a mean of 28.6 months before additional treatment was added and 40% (8) achieved low disease activity (LDA) of DAS28 ≤3.2; 29 patients (59%) switched for reasons of efficacy. Amongst these: Mean DAS28 scores improved 25% (−1.26), patients remained on SC MTX monotherapy for a mean of 34.58 months before addition of other therapies and 24% (7) achieved LDA.

Conclusion: In this single-center analysis, RA patients with an inadequate response to oral MTX for reasons of efficacy and/or tolerability maintained satisfactory disease control and durable, long-term response when switched to SC MTX monotherapy.

Table 1.

Evaluable (n=49)	n	Pre-Switch DAS 28	Post-Switch DAS 28	DAS28 Change (Value, %)	Mean Duration on SC MTX monotherapy (months)	LDA (≤3.2) (n,%)	Remission (≤2.6) (n,%)
Inadequate Response to Oral MTX (Tolerability)	20	4.46	3.65	−1.05 (18%)	28.6	8 (40%)	6 (30%)
Inadequate Response to Oral MTX (Efficacy)	29	5.34	4.08	−1.26 (25%)	34.58	7 (24%)	2 (7%)

Quality of Patient- Clinician Communication in a Diverse Cohort of Adults with Rheumatoid Arthritis. Jennifer Barton[1], Chris Tonner[1], Laura Trupin[1], Patricia P. Katz[2] and Edward H. Yelin[1]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, CA.

Background/Purpose: To assess correlates of the quality of patient-clinician communication in a diverse cohort of adults with rheumatoid arthritis (RA).

Methods: Data were obtained through structured 30-minute telephone interviews conducted in English or Spanish. Subjects were enrollees of the Rheumatoid Arthritis Outcomes Study (RA OS), a longitudinal cohort of adults with RA. Two questions from the Consumer Assessment of Healthcare Providers and System (CAHPS) were used to assess RA patients' experience of communication with their rheumatologist: "How often did this doctor check to make sure you understood everything?" and "How often did this doctor spend enough time with you?" Responses options consisted of 5 choices ranging from "never" to "always." We report the proportion of subjects who responded "always" which is considered by CAHPS as the "Top-box" score. Logistic regression was used to model the quality of communication as a function of demographics (age, gender, race/ethnicity), education, health literacy (single-item literacy screener), English language proficiency, disease characteristics (duration, fatigue, disease activity), depression (score ≥10 on the Patient Health Questionnaire 9), and insurance.

Results: 395 adults with RA were surveyed with a mean age of 61 years, 89% were female, 46% white, 31% Latino. Nearly one-third (31%) had limited health literacy (LHL) and 17% had limited English language proficiency (LEP). Mean disease duration was 23 ± 12 years, 39% reported moderate fatigue and 18% severe, and 17% had a PHQ-9 score ≥10. In multivariate models controlling for disease activity, fatigue, and depression (see table), RA patients with LHL and LEP were more likely to report that their rheumatologist always checked for understanding. However, patients with LEP were less likely to report that their doctor always spent enough time with them, as were Latinos (compared to all other race/ethnic groups)..

Conclusion: Despite the finding that over 90% of RA patients with limited English language proficiency perceive that rheumatologists always check for understanding, only 38% of these same patients and 40% of Latinos report that doctors spend enough time with them. These results were independent of disease activity and depression. Providing high quality, patient-centered care in RA is important for all patients, especially those with barriers to communication. Awareness and interventions to enhance quality of communication and that address cultural expectations for care are needed for vulnerable populations.

Table Proportion of subjects who responded "always" to communication questions about rheumatologists among 395 adults with rheumatoid arthritis, from multivariate models^

	Overall percent (95% CI)	
	Check to be sure you understood	Spend enough time with you
Sociodemographics	74 (69, 78)	59 (54, 63)
Race/ethnicity		
Latino	74 (64, 84)	**40 (29, 50)**
Asian/Pacific Islander	71 (52, 89)	**69 (51, 87)**
African American	75 (61, 89)	**76 (64, 90)**

Mixed/Other/ Unknown	85 (71, 94)	**72 (60, 85)**
White	71 (65, 78)	**61 (54, 69)**
Limited English language proficiency	*	*
No	**70 (65, 76)**	**61 (56, 67)**
Yes	**93 (83, 99)**	**38 (18, 57)**
Limited health literacy		*
No	**70 (65, 76)**	58 (52, 64)
Yes	**84 (74, 90)**	60 (52, 69)

Ĉontrolled for age, gender, education, insurance, disease activity, disease duration, fatigue, depression (PHQ-9≥10), and all variables listed in table.

Primary Non-Adherence, Associated Clinical Outcomes and Healthcare Resource Utilization Among Rheumatoid Arthritis Patients Prescribed Injectable Biologics. J. Harnett[1], D. Wiederkehr[1], R. Gerber[2], D. Gruben[2], J. Bourret[3] and A. Koenig[3]. [1]Pfizer Inc, New York, NY, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Injectable biologics are commonly used to treat patients (pts) with moderate to severe rheumatoid arthritis (RA); the frequency with which they are prescribed but not filled is unknown. This exploratory analysis aimed to evaluate filling of newly prescribed injectable biologics for RA and characterize pt outcomes.

Methods: In a retrospective cohort design, pts (age ≥18 years during study period) with an RA diagnosis (ICD9: 714.XX) in 2007–2013 were selected from a de-identified database of clinical information from electronic health records (EHR; Humedica) linked to healthcare claims (Optum) from commercial and Medicare Advantage health plans. First injectable biologic prescription date in EHR was the index date. Pts without continuous pharmacy coverage for ≥6 months pre- and post- index, with evidence of pre-index injectable biologic administration in EHR or claims, or with hospitalization within 30 days post-index were excluded. Pts were categorized as filling the biologic prescription within 30 days (early fillers), 31–180 days (late fillers), or not at all within 180 days (non-fillers) of index. Pt baseline characteristics, including claims-based index of RA severity, RA prescribing patterns, and pt-reported pain scores (0–10; provider-determined scales) from EHR were assessed across all pts; 6-month post-index healthcare resource utilization (including biologic fills) and costs as identified within claims were assessed in pts with continuous medical and pharmacy coverage.

Results: Of 381 pts meeting inclusion criteria, 171 (45%) and 60 (16%) filled an injectable biologic prescription within 30 days and 31–180 days of index, respectively; 90% of prescriptions were written for TNF inhibitors (TNFi). Early fillers were younger, more likely to be female, had higher baseline RA severity, and filled more prescriptions for any reason pre-index. Of non-fillers, 65% were Medicare pts vs 18 and 37% of early and late fillers, respectively. Filling of nonbiologic DMARD prescriptions within 30 days of index was highest in early biologic fillers (45.6%) and lowest among non-fillers (23.3%); however, during days 31–180, the rate was 5.9% in early biologic fillers vs 34.0% in non-fillers. Of early fillers, 14% did not have another biologic prescription filled after 30 days. In the small subgroup of pts with both pre- and post-index pain scores, mean pain scores decreased in early fillers (−1.6; n=11), but increased in late fillers (0.5; n=6) and non-fillers (1.1; n=7). In pts with pharmacy and medical coverage for 180 days post-index (n=375), early fillers had greater RA-related pharmacy (84% of cost difference) and medical resource use and costs than late and non-fillers combined.

Conclusion: Over half (55%) of pts prescribed injectable biologics (90% TNFi) did not fill the prescription within 30 days; 40% had not filled by 180 days. For evaluation of clinical outcomes, documentation of pain scores in the EHR was limited for structured analysis. As expected, healthcare resource use/costs were higher in early fillers over short-term observation. Future research will need to focus on long-term consequences of under-treatment on clinical and economic outcomes.

Early Treatment in Rheumatoid Arthritis and Its Effect on Patient Outcomes. Laurent Chanroux and Joan Casellas. The Research Partnership, London, United Kingdom.

Background/Purpose: It is generally thought that the early treatment of patients with rheumatoid arthritis (RA) leads to improved patient outcomes over time. Our study aims to better understand if early treatment alone is sufficient to achieve these goals and assess whether measures such as DAS, joint count and perceived severity are sufficiently sensitive for this purpose.

Methods: We used data collected as part of an online treatment survey conducted among a panel of 500 European rheumatologists between April 2008 and May 2014 across EU5 (Fr, Ge, It, Sp, UK). In order to assess whether earlier treatment has an effect on patients current disease status we ran a linear regression using patients' current DAS, current disease severity (as perceived by their physicians) and the number of joints affected by their disease as dependent variables (DV) and included the following as independent variables (IV):

- Time from cDMARDs initiation until first bDMARDs initiation (β_1)
- Time from diagnosis until cDMARDs initiation(β_2)
- Time from diagnosis until bDMARDs initiation(β_3)
- Severity at diagnosis(β_4)
- Number of cDMARDs before bDMARDs initiation(β_5)
- Current bDMARDs (Brand) (β_6)

We focused our analyses on patients diagnosed post 1998 to ensure patients had access to bDMARDs and only considered those currently prescribed their first line of bDMARD therapy to avoid any confounding effects caused by patients' treatment history. We also accounted for possible differences in patients' disease severity, both at diagnosis and at the time of their first bDMARD treatment, as well as the length of time they had been on their current bDMARD treatment.

Results: We considered data from a sample of 43,769 patient record forms and on average, our patients had a DAS of 2.9 with 85.8% classified as having moderate to severe RA. In addition, the mean time from diagnosis to cDMARD initiation and bDMARD initiation was 12.1 and 45.5 months, respectively.

Preliminary results from the regression analysis show that we can explain very little of the variability in our DV with an adjusted R square of just 5% for DAS, 2% for current severity and 5% for the number of affected joints. Therefore, we considered the coefficients of each model to measure the effect of our IV.

β_1 and β_2 have a low positive effect on DAS and current disease severity however, the choice of Enbrel, Humira and RoActemra as a first bDMARD has a strong negative effect on these two DV. In addition, β_2 and β_5 both have a strong positive effect on patients' number of affected joints, while $\beta_1$has a low positive effect.

Finally, we see that patients who have been on their first bDMARD for a shorter period of time (up to 2 years) better explained the variation seen in our DV.

Conclusion: Our analyses demonstrate that simply initiating treatment with cDMARDs and bDMARDs early on in patients' disease is not enough to optimise patient outcomes. Instead, early treatment must be combined with close monitoring and aggressive step-up treatment strategies such a treat-to-target to maximise patients' response to treatment and control their disease. In addition, our data also suggest that the impact that early treatment may have could be limited in time with disease statuses becoming more similar as the duration of bDMARD therapy increases.

Frequency of Rheumatoid Arthritis Flares in Clinical Practice: Analysis of a Monocentric Cohort of Patients in Stable Remission or Low Disease Activity. Francesca Ometto[1], Costantino Botsios[2], Livio Bernardi[1], Bernd Raffeiner[2], Leonardo Punzi[2] and Andrea Doria[2]. [1]University of Padova, PADOVA, Italy, [2]University of Padova, Padova, Italy.

Background/Purpose: Rheumatoid arthritis (RA) flares are predictive of structural damage even in case of stable disease course. No definition for flare has been validated to date. The objective of our study was to determine the rate of flares in RA patients on stable LDA or remission. We considered flares assessed at each visit (FV), self-reported flares (SRF), and major flares (MF) defined as flares requiring a change in the DMARD or in the biologic dose or

lasting more than 30 days. We investigated the relationships between flare rate and baseline characteristics of patients or treatments. We further investigated whether flare rate could be related to survival of remission or LDA.

Methods: We conducted an observational study on RA patients, treated with subcutaneous anti-TNF-alpha, on stable (> 6 months) LDA or remission, with a minimum follow up of one year. We investigated associations of flare rates with age, sex, disease duration, baseline activity indices, positive ACPA and RF, concurrent fibromyalgia, smoking, previous biologic failures, treatment with methotrexate (MTX), prednisone (PDN) dose, and dose of biologics. Survival of remission or LDA according to flare rate was calculated with Kaplan-Meier curves.

Results: Out of 86 patients, 11 patients were excluded because of pregnancy or little reliability in recalling events, and 55 patients achieved a stable LDA or remission. We observed 237 flares in 55 patients with a mean follow up of 70.72 ± 30.41 months: 91 FV, 146 SRF, and 18 MF. Overall flare rate was 0.80 ± 0.79 flares/year, rate of FV was 0.26 ± 0.28, rate of SRF was 0.54 ± 0.70 and rate of MF was 0.05 ± 0.10. Flare rates on remission or LDA were not significantly different (0.67 ± 0.75 and 1.08 ± 1.29 flares/year, respectively). Mean time to flare was 23.62 ± 21.21 months and was inversely correlated with flare rate on LDA periods (Spearman's correlation, $R^2 = -0.405$, p 0.024). Overall flare rate and SRF rate were higher in patients with concurrent fibromyalgia and active smokers (Table). No significant differences were seen between full dose and low dose biologic, between different PDN doses or between combination with and without MTX, although fewer flares were observed on MTX (Table). Patients naive to biologics had many fewer flares than those who had a failure of one biologic or specifically of one anti-TNF-alpha (Table). PDN was the most used medication in case of flare (138/237, 58.2% of flares). Mean increase of PDN compared with previous dose was 3.66 ± 5.81 mg daily. Flare rate < 1 flare/year or a SRF rate < 0.5 flares/year were associated with a longer survival of LDA/remission (p 0.029 and p 0.037 respectively).

Conclusion: Flares are frequent on LDA or remission. Patients that have already failed a biologic treatment, active smokers and with concurrent fibromyalgia patients seem to be more prone to experience flares. SRF account for most of the flares and have the greatest impact on survival of remission.

Table. Flare rate

	N	Flare rate*	p value**
Concurrent fibromyalgia	11 (20.0%)	1.12 ± 0.72	p 0.037
No fibromyalgia	44 (80.0%)	0.72 ± 0.80	
Active smokers	9 (16.4%)	1.38 ± 1.31	p 0.049
Non smokers	46 (83.6%)	0.64 ± 0.55	
Naive patients	32 (58.2%)	0.49 ± 0.48	p 0.000
Patients that failed one previous anti-TNFα failure	23 (41.8%)	1.23 ± 0.93	
Combination therapy with methotrexate		0.38 ± 0.75 74 flares over 119.8 years	p 0.073
Combination therapy without methotrexate		0.79 ± 1.19 163 flares over 204.7 years

Omega-3 Fatty Acids and Mediterranean Diet As Complimentary Therapies for Rheumatoid Arthritis. Ana Carolina Araújo[1], Maria Francisca Moraes-Fontes[1], Lèlita Santos[2] and Nuno Riso[1]. [1]Hospital de Curry Cabral, Centro Hospitalar Lisboa Central, Lisbon, Portugal, [2]Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting the synovial joints, often with a progressive and destructive course, leading to disability. Nowadays, there are several drugs available to treat this condition. However, in some patients the disease can be quite difficult to manage, due to refractoriness and expense of therapy. Complimentary therapies to manage RA may contribute to this unmet need. The anti-inflammatory effect of the Mediterranean diet (MedDiet) has been increasingly recognized in the last forty years together with the anti-inflammatory properties of omega-3 fatty acids (n-3 FA) [1,2].

This study aimed to evaluate the effects of n-3 FA supplements and MedDiet upon disease activity and laboratory measures of a cohort of RA patients.

Methods: This is a prospective randomized controlled trial including 37 RA patients (fulfilling ACR 1987 classification criteria). Patients were assigned to n-3 FA supplements (n=11) or MedDiet (n=8) and compared to a control group (n=15), during a 6 month follow-up period. Demographic characteristics, number of tender and swollen joints, global health status, ESR, CRP, and DAS-28 were obtained before and after the intervention. The analysis of dietary intake was performed with a semi-quantitative food frequency questionnaire. Patients were further stratified according to biological therapy. The statistical analysis was performed by Wilcoxon and Kruskal-Wallis tests with a significance level of 0,05.

Results: A significant reduction in ESR was noted after 6 months of n-3 FA but there was no significant variation in the remaining measures after 6 months, independently of the study group and the ongoing therapy for RA. However, a trend towards a reduction in DAS-28 and VAS was noted (table 1).

Table 1 Evaluated parameters at the beginning and after 6 months of intervention

	n-3 FA				MedDiet				Control Group				
Parameter	Beginning	6 months	n	p	Beginning	6 months	n	p	Beginning	6 months	n	p	p
ESR	32,18 ± 19,42	19,64 ± 13,27	11	0,01	21,75 ± 17,32	24,75 ± 13,72	8	0,58	28,00 ± 21,03	22,13 ± 12,02	15	0,12	>0,05
DAS-28	3,65 ± 1,26	3,41 ± 1,10	11	0,76	3,30 ± 1,02	3,53 ± 1,65	8	0,55	3,58 ± 0,91	3,94 ± 1,13	15	0,36	>0,05
EVA GH	39,09 ± 26,16	38,18 ± 29,17	11	0,84	46,25 ± 17,68	43,75 ± 22,80	8	0,94	46,67 ± 26,10	51,00 ± 28,55	15	0,36	>0,05
Tender Joints	3,54 ± 6,29	3,82 ± 5,51	11	0,73	3,00 ± 5,24	4,12 ± 5,03	8	0,13	2,33 ± 3,27	4,40 ± 5,18	15	0,10	>0,05
Swollen Joints	1,45 ± 2,50	1,00 ± 1,79	11	0,44	0,25 ± 0,46	1,12 ± 1,88	8	0,25	0,53 ± 0,83	1,13 ± 2,06	15	0,25	>0,05
CRP	0,14 ± 0,10	0,31 ± 0,40	6	1,00	0,45 ± 0,45	1,50 ± 2,35	5	0,13	0,82 ± 1,21	0,70 ± 0,41	9	0,16	>0,05

Mean ± standard deviation; n,number of patients.

Conclusion: Omega-3 fatty acids supplements were associated with a reduction in the ESR after 6 months in accordance to other studies. The trend towards a reduction in DAS-28 observed in this study encourages the need for further studies in larger samples.

Working Status and Improvements in Work Productivity over Time in an Early Rheumatoid Arthritis (ERA) Cohort. Bindee Kuriya[1], Daming Lin[2], Cheryl Barnabe[3], Gilles Boire[4], Boulos Haraoui[5], Carol Hitchon[6], Shahin Jamal[7], J. Carter Thorne[8], Diane Tin[9], Janet E. Pope[10], Edward Keystone[11] and Vivian P. Bykerk[12]. [1]University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]University of Calgary, Calgary, AB, [4]CHUS - Sherbrooke University, Sherbrooke, QC, [5]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [6]University of Manitoba, Winnipeg, MB, [7]Vancouver Coastal Health, Vancouver, BC, [8]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [9]Southlake Regional Health Centre, Newmarket, ON, [10]Western University, London, ON, [11]University of Toronto and Mount Sinai Hospital, Toronto, ON, [12]Hospital for Special Surgery, New York, NY.

Background/Purpose: To describe working status in an ERA population in the first year of disease, and factors associated with improved work productivity.

Methods: Patients in the Canadian Early Arthritis Cohort who completed the Work Productivity and Activity Impairment (WPAI) questionnaire at baseline and month 12 (commencing in 2010) were included. Differences in working status at baseline were compared using chi-square or student's t-tests. A change in employment status and overall activity impairment was calculated as change from baseline to month 12. A change in absenteeism (work hours missed) and presenteeism (impact of RA on work productivity) was only calculated for those working at baseline. Multivariate logistic regression analyses tested whether age, sex, symptom duration, DAS28 score, HAQ-DI or treatment at month 6 were associated with improvements in WPAI domains.

Results: Of 2524 patients in the cohort, 729 had completed at least one WPAI questionnaire. Of these, 190 were eligible (423 did not have serial WPAI and 306 were missing month 6 variables for analysis). At baseline, the 190 patients had mean age 56 years, symptom duration 5.6 months, baseline DAS28 score 4.85; 110 were in paid employment at baseline. Individuals not in paid employment at baseline less frequently had high school or college education, had lower income, were older, had moderate-to-high DAS28

scores, and demonstrated higher HAQ-DI scores. Improvements in WPAI domains are shown (Table). Among working individuals, by 12 months, 78% had an improvement in working hours missed, 67% reported improved productivity and 72% had reduced activity impairments. The largest change occurred for absenteeism (9.57 fewer hours/week missed). Younger age (OR 0.93, CI 0.89–0.98), DAS28 remission (OR 10.52, CI 1.4–79) and higher HAQ-DI at month 6 (OR 4.01, CI 1.2–13.1) were associated with gaining employment by month 12. DMARD or biologic use at month 6 was not associated with change in WPAI domains but corticosteroid use was negatively associated with presenteeism (OR 0.23, CI 0.06–0.89).

Conclusion: Differences in demographic and disease-related variables exist between ERA patients who are working versus those who are not. The majority of working individuals show improvements in WPAI domains over time but establishing the minimum clinically important difference for these domains is needed to help guide clinical interpretability. The impact of disease activity and functional ability on work productivity warrants further exploration in larger samples.

Table. Mean (SD) in WPAI domain scores at baseline, month 12 and change from baseline to month 12

		Working hours missed due to RA in past 7 days? (0-100 hours)		In past 7 days, how much did RA affect productivity while working? (0-10 scale)		In past 7 days, how much did RA affect daily activities? (0-10 scale)	
		Improved	Not Improved	Improved	Not Improved	Improved	Not Improved
Working at baseline (N=110)	N (%)	76 (78)	21 (22)	55 (67)	27 (33)	80 (72)	30 (28)
	Baseline score	9.95 (8.51)	0.58 (4.61)	4.69 (2.43)	0.81 (1.49)	4.95 (2.38)	2.47 (2.91)
	Month 12 score	0.38 (1.75)	1.71 (7.17)	1.51 (1.83)	1.74 (2.40)	1.19 (1.42)	3.70 (3.10)
	Change in score	−9.57 (8.45)	1.13 (5.58)	−3.18 (1.87)	0.93 (1.44)	−3.76 (2.08)	1.23 (1.61)
Not working at baseline (N=80)		-	-	-	-	53 (66)	27 (34)
						5.66 (2.53)	2.44 (2.69)

Sampalis[12], Francois Nantel[13], Susan Otawa[13], May Shawi[13] and Allen J Lehman[13]. [1]The Mary Pack Arthritis Centre, Vancouver, BC, [2]University of Ottawa, Ottawa, ON, [3]Memorial University of Newfoundland, St. John's, NF, [4]University of Alberta, Edmonton, AB, [5]McGill University Health Centre, Montreal, QC, [6]St Josephs Hospital and McMaster University, Hamilton, ON, [7]Nanaimo Regional General Hospital, Nanaimo, BC, [8]University of Saskatchewan, Saskatoon, SK, [9]Université de Montréal, Montreal, QC, [10]McMaster University, Hamilton, ON, [11]McMaster University, Hamilton and Credit Valley Hospital, Mississauga, ON, [12]JSS Medical Research, Montreal, QC, [13]Janssen Inc., Toronto, ON.

Background/Purpose: The efficacy of anti-TNF in the management of psoriatic arthritis (PsA) and rheumatoid arthritis (RA) has been demonstrated in numerous controlled clinical trials. The objective of this analysis was to assess in Canadian routine clinical practice the durability of treatment with infliximab (IFX) in PsA and RA and the determinants associated with sustainability of IFX.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. Patients with PsA or RA treated with IFX who were enrolled between 2002 (2005 for PsA patients) and 2012 were included in this analysis. Dose optimization was defined as an increase in the frequency and/or dosing of IFX. Kaplan Meier (KM) estimates and Cox proportional models were used in the analysis.

Results: A total of 92 PsA and 830 RA patients were included in the analysis. Mean (SD) age of the PsA and RA patient cohorts was 48.7 (9.9) and 55.8 (13.4) years, respectively, and mean (SD) duration since diagnosis was 6.8 (9.1) and 10.2 (10.1) years, respectively. Twenty seven (29.3%) PsA patients and 407 (49.0%) RA patients had discontinued treatment. Overall KM-based mean (SE) duration of treatment was 41.4 (3.6) months and 61.3 (2.2) months for PsA and RA patients, respectively. Longer treatment duration was associated with significantly greater improvements in pain (parameter estimate PsA: -0.21, P=0.020; RA: -0.27, P<0.001), patient global (PsA: -0.35, P<0.001; RA: -0.28, P<0.001) and HAQ-DI (PsA: -0.01, P<0.001; RA: -0.01, P<0.001). Significant associations with duration of treatment in PsA patients were observed for disease duration (HR=1.04), previous biologic (HR=2.10), baseline TJC28 (HR=1.10), baseline PASI (HR=0.86) and concomitant use of traditional DMARD(s) (HR=0.16) or NSAID(s) (HR=0.38). For RA patients, IFX dose optimization (HR=0.72) and concomitant use of steroids (HR=1.78) were identified as significant predictors of treatment durability.

Conclusion: The results of this observational study have shown a high durability of treatment with IFX for patients with PsA or RA in a real-world setting. Concomitant medication use significantly impacts treatment durability. Furthermore, longer disease duration, higher TJC, less severe skin disease at initiation and previous biologic use in PsA, and absence of IFX dose optimization in RA, may be associated with reduced treatment durability.

Regime of Use of Rituximab in Patients with Rheumatoid Arthritis in Daily Clinical Practice. Leticia Merino-Meléndez[1], Irene Llorente[1], Santos Castañeda[2], Teresa Velasco[1], Luis Sala-Icardo[3], Rosario Garcia-Vicuña[3], Alberto Garcia-Vadillo[1], Juan P. López-Bote[3], Jorge López-López[1], Federico Herrera[1], Cecilia Muñoz-Calleja[1], JM Álvaro-Gracia[1] and Isidoro González-Alvaro[3]. [1]Hospital Universitario de La Princesa, Madrid, Spain, [2]Hospital Universitario de La Princesa, IISP, Madrid, Spain, [3]Hospital Universitario de La Princesa. IIS La Princesa, Madrid, Spain.

Background/Purpose: The recommended therapeutic regime for Rituximab (RTX) in Rheumatoid Arthritis (RA), according to prescribing information, includes two 1000-milligram infusions given two weeks apart, every 6 months. However, this is often not the case in clinical practice, since both consensus documents and information from clinical trials consider other alternatives. Our objective in this study was to analyze the pattern of use of RTX in RA in daily clinical practice.

Methods: This is a retrospective study that includes patients treated with RTX between 1998 and 2013 in a single university hospital. We reviewed medical records and collected demographic data, number of cycles, doses and intervals of RTX administered to the patients, response duration, as well as frequency and reasons of treatment discontinuation. Descriptive analysis was performed using the statistical package Stata v. 12.

Results: Ninety-three patients were studied, of which 83% were women. Median age at disease onset was 51 years with an interquartile range (IQR) of 39 to 60 years. Median age at the start of treatment with RTX was 60 [IQR: 51–70] years. Out of the 93 patients, 11 had negative rheumatoid factor. The number of cycles of RTX administered to each patient ranged from one to nine. Treatment was discontinued in 33% of the patients. The reasons for discontinuation were inefficacy (16%), adverse effects (7%) and others (10%). RTX was most commonly withdrawn during the first two cycles. The main data related to use of RTX in our study are summarized in the following table.

CYCLE OF RTX	1	2	3	4	5	6	7	8	9	TOTAL
Patients (N)	93	78	53	45	35	25	12	10	5	356
Fixed regime [1](%)	16	10	13	11	6	0	0	0	0	11.2
Dose (mg)/cycle[2]	1956	1736	1711	1704	1735	1708	1727	1444	1250	1663
Response duration (months)	10	10	10	11	11	10	12.5	9.5	8	10.2
Administration interval (months)	10	11.6	10.3	11.4	13	14.8	13.6	9.9	–	11.8
ADMINISTRATION YEAR	1998-2005	2006	2007	2008	2009	2010	2011	2012	2013	
Patients (N)	7	12	25	36	50	56	44	44	35	
Fixed regime[1](%)	36	33	13	16	17	6	4	0	0	
Dose (mg)/cycle[2]	2000	1944	1946	1953	1733	1716	1652	1818	1485	
Response duration (months)	15	10	11	10	9	10	10	12	7	
Administration interval (months)	16	11.2	12	10.4	9.4	10.3	11.5	13.1	–	
Cost Savings compared to fixed regime[3] (%)	60	42	47	41	42	48.5	50	54.5	–	

[1] Fixed regime: administration of two 1000-milligram infusions given 2 weeks apart, every 6 months.
[2] Mean value.
[3] Calculated percent saving in direct yearly drug cost compared to the fixed regime.
* All unspecified data are given in median value.

Response duration in males tended to be longer [12 months; IQR: 8–13] than in females [10 months; IQR: 7–12], but this didn't reach statistical significance (p = 0'11, Mann-Whitney's test). Longer response duration was observed in patients with a longer RA history (r = 0.24, P = 0.001, Pearson's test). RTX dose per cycle did not modify the response duration (1 vs 2 grams, 9.5 and 10 months respectively).

Conclusion: Our data show that, in daily clinical practice, RTX is more frequently used on demand, tending to abandon the fixed regime of 2 grams every six months. In addition we observe a tendency to an increased use of 1 gram cycles with time. This results in cost savings without apparent decrease in healthcare quality.

Similar Response Rates to Anti-Tumor Necrosis Factor and Non-Anti-Tumor Necrosis Factor Biologic Therapies in Ethnic Minority Patients at 6 Months.

Gail S. Kerr[1], Yusuf Yazici[2], Christopher Swearingen[3], Luis R. Espinoza[4], Edward L. Treadwell[5], Yvonne Sherrer[6], Angelia Mosley-WIlliams[7], Ignacio Garcia-Valladares[8], Rodolfo Perez Alamino[9], Sharon Dowell[10], Mercedes Quinones[11], Akgun Ince[12], Theresa Lawrence Ford[13], Chunqiao Luo[14], Adrian Godoy[10] and John Amatruda[10]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]New York University School of Medicine, New York, NY, [3]University of Arkansas, Little Rock, AR, [4]LSU Medical Center, New Orleans, LA, [5]East Carolina University, Greenville, NC, [6]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [7]Detroit VAMC, Detroit, MI, [8]Hospital General de Occidente, Zapopan, Jal., Mexico, [9]LSUHSC, New Orleans, LA, [10]Howard University, Washington, DC, [11]Howard University Hospital, Washington, DC, [12]St. Louis University, St. Louis, MO, [13]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [14]University of Arkansas for Medical Sciences, Little Rock, AR.

Background/Purpose: Biologic therapies have expanded the treatment options and strategies for rheumatoid arthritis (RA). While anti-tumor necrosis factor (anti-TNF) biologic response rates are well established, in multi-ethnic populations, the response to anti-TNF and non- anti-TNF agents is unknown. Hence, we evaluated the response rates to RA biologic therapies in a diverse ethnic cohort.

Methods: Ethnic Minority RA Consortium (EMRAC) patients with follow up data were evaluated. Comparisons of patient socio-demographic (age, gender, race, education, smoking), RA disease status (disease duration, RF, ACPA, nodules/erosions), DMARD use, and disease activity (RAPID3) were made between anti-TNF and non-anti-TNF therapies using chi-square test of categorical variables and Wilcoxon-Mann-Whitney test for continuous variables. A logistic regression analysis associating RAPID3 outcome (low/moderate disease vs severe disease) at last follow-up encounter with anti-TNF and non-anti-TNF therapies adjusting for age, disease duration, gender, smoking, race and baseline RAPID3 was performed.

Results: EMRAC analysis of biologic responses in 350 subjects with an average followup of 8 months was performed (Table) More Caucasians received biologic therapies and anti-TNF use was most common. Anti-TNF patients were similar to non-anti-TNF patients in all demographic and clinical characteristics, including use of DMARD therapy. While, baseline RAPID3 was significantly higher in non-anti-TNF than anti-TNF patients, there was no significant difference in proportions of patients achieving RAPID3 outcome between biologic groups (P=0.969), adjusting for age, duration, gender, smoking, and baseline RAPID3. Moreover, no differences between races were observed in achieving RAPID3 outcome (P=0.688, regression).

Conclusion: There is a similar prevalence of use and response to anti-TNF and non-anti-TNF biologic agents in ethnic minority RA patients in routine clinical care. Follow up analyses are needed to assess sustained clinical response and outcomes to the varied biologic armamentaria, inclusive of ethnic subsets.

Etanercept in Mono Therapy or in Combination with MTX: Results from a Sub Analysis of a German Non-Interventional Study.

Karl Heinz Goettl[1], Markus Gaubitz[2], Andreas Krause[3], Udo Lendl[4], Ralph Lippe[4], Thomas Meng[4] and Peter-Andreas Loeschmann[5]. [1]Joint practice for internal medicine, Passau, Germany, [2]Academy of manual diagnostic at University of Münster, Münster, Germany, [3]Immanuel Krankenhaus Berlin, Berlin, Germany, [4]Pfizer Pharma GmbH, Berlin, Germany, [5]Loeschmann, Berlin, Germany.

Background/Purpose: Although a combination with MTX is recommended for all biologics, data from different registries around the world show that in real life around 30% of all RA patients are treated in mono therapy. However, data on safety and efficacy of Etanercept (ETN) as mono therapy in dally practice are rare.

Methods: Adults with RA newly initiating ETN have been included into this non-interventional study.

Due to the non-interventional nature of the study, no specific requirements were specified with regard to the management of treatment. The physician could decide on dosing and the duration of treatment according to the treatment needs of each individual patient. At seven data collection points the course of the disease was documented for up to 52 weeks. Safety, efficacy as well as health outcome parameters have been assessed.

Results: 4871 patients have been included into this study. 1090 of these have continuously been treated with ETN and 1441 with ETN + MTX. There have been no statistically differences regarding all baseline characteristics. The mean disease duration was 10.6±10.3 years in the ETN and 9.7±8.9 years in the ETN + MTX group. They have been pretreated with 2.9±1.6 and 2.7±1.2 DMARDs respectively. From a mean baseline value of 5.5±1.3

and 5.3±1.3 score points, the DAS28 continually decreased to 3.4±1.4 and 3.2±1.3 at visit 7. At week 52 slightly less patients with ETN reached DAS28 remission (DAS28<2,6) as with ETN+MTX (32.5% [29.0–36.1%] vs. 35.4% [32.5–38.3%]). Concurrently with the DAS28 also the mean disease activity (patient global assessment, visual analogue scale VAS), pain (VAS) and fatigue (VAS) improved in both treatment groups. Duration of morning stiffness decreased in the ETN group from 78.7±88.1 to 26.2±50.6 min and in the ETN + MTX group from 72.6±81.1 to 21.8±50.6 min. 38.4 % [35.1 – 41.7%] of patients with ETN reached a functional remission (FFbH) at week 52 (vs. 44.3 % [41.5 – 47.2%] under ETN+MTX therapy). In both groups the treatment was well tolerated and no new safety signals have been observed.

Conclusion: Etanercept rapidly reduces diseases activity in combination with MTX as well as in mono therapy. Abaout half of the patients stay on their initial treatment regime (mono or combination with MTX) in daily practice over 52 weeks. Within this study no new safety signals occurred and Etanercept was well tolerated in mono and combination therapy.

Characteristics of Rheumatoid Arthritis Patients Not Receiving Early Initiation of Disease Modifying Therapy. Dimitrios A. Pappas[1], Jeffery D. Kent[2], Jeffrey D. Greenberg[3], Marc Mason[4], Joel M. Kremer[5], Amy Y. Grahn[2] and Robert J. Holt[6]. [1]Columbia University, New York, NY, [2]Horizon Pharma, Inc., Deerfield, IL, [3]New York University School of Medicine, New York, NY, [4]Corrona, LLC., Southborough, MA, [5]Albany Medical College and the Center for Rheumatology, Albany, NY, [6]University of Illinois - Chicago, Chicago, IL.

Background/Purpose: Early and aggressive therapy of Rheumatoid Arthritis (RA) with Disease Modifying Anti-Rheumatic Agents (DMARDs), glucocorticoids, and biologic agents is recommended by current treatment guidelines and supported by interventional studies with treat to target principles.(1) However, delays in initiation of therapy might be observed in real life. The objective of this analysis was to evaluate how frequently RA therapy is instituted promptly and to describe the characteristics of patients who are not treated early upon diagnosis.

Methods: The percentage of patients who at the time of enrollment in the Corrona Registry were not receiving any RA directed therapy was evaluated and their characteristics were summarized. The time to subsequent initiation of any RA directed therapy was also estimated.

Results: Out of the 35,485 patients enrolled in CORRONA, 20,317 (57.3%) had no prior use of prednisone, 18,299 (51.6%) had no prior biologic use, 16,930 (47.7%) had no prior DMARD use (excluding MTX), 15,335 (43.2%) had no prior MTX use. 2,166 (6.1%) had no prior nbDMARD use, and 750 (1.2%) had no history of receiving any RA directed therapy at the time of enrollment. For the patients without any history of RA directed therapy: age at the time of enrollment (mean ± SD) was 57.5±14.7 and age at RA onset was 52.3 ± 15.4 years. 69.4% were seropositive for RF and 60.6% for CCP antibodies. Patients had an overall established disease duration of 5.5 ± 9.0 years with only half (50.7%) having early disease (duration ≤1 year). CDAI was 18.3 ± 15.0; 34% of the patients had high and 27.6% moderate disease activity by CDAI. Subjects graded their fatigue as 35.6 ± 31.4 on a visual analog scale (0–100). Patients with no history of directed RA therapy did not have lower disease activity at enrollment compared with those receiving directed therapy. These patients were followed for a median (95% CI) time of 29.5 months (24.6–33.8). During the follow-up period, only 372 out of 750 (49.6%) patients initiated any RA directed therapy. The median time to initiation of any DMARD was 15.9 months (12.2–18.4) and to initiation of any RA directed therapy was 12.1 months (9.3–14.8). The Kaplan Meier survival estimates of RA therapies are shown in Figure 1.

Conclusion: In this registry analysis, a high percentage of patients with RA did not have a history of receiving directed therapy within a mean of approximately 5 years of RA onset. In those patients that had not received any RA directed therapy previously, approximately 50% did not initiate any therapy in 12 months of registry follow-up.

Do Patterns of Joint Swelling or Tenderness in Rheumatoid Arthritis Patients Impact Disease Activity Outcomes and Pain? Implications for Clinical Practice. Regan Arendse[1], John Kelsall[2], J. Antonio Avina-Zubieta[3], Philip Baer[4], Erica Weinberg[4], Jude Rodrigues[5], Algis Jovaisas[6], Isabelle Fortin[7], Maqbool Sheriff[8], Majed M. Khraishi[9], Emmanouil Rampakakis[10], John S. Sampalis[10], Francois Nantel[11], Susan Otawa[11] and Allen J Lehman[11]. [1]University of Saskatchewan, Saskatoon, SK, [2]The Mary Pack Arthritis Centre, Vancouver, BC, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]Private Practice, Scarborough, ON, [5]Clinical Research and Arthritis Centre, Windsor, ON, [6]University of Ottawa, Ottawa, ON, [7]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [8]Nanaimo Regional General Hospital, Nanaimo, BC, [9]Memorial University of Newfoundland, St Johns, NF, [10]JSS Medical Research, Montreal, QC, [11]Janssen Inc., Toronto, ON.

Background/Purpose: This analysis aimed to describe the pattern of specific joint involvement (tender and/or swollen) pre- and post-TNFi treatment and the impact of specific joint pattern involvement on composite score outcomes and pain.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab (IFX) or golimumab (GLM). In this analysis, RA patients included those treated with IFX between 2002–2014 or with GLM between 2010–2014. Based on joint involvement 7 groups were created: shoulder(s), elbow(s), metacarpophalangeal (MCP(s)), wrist(s), proximal interphalangeal (PIP(s)), knee(s), and thumb(s). The impact of specific joints on disease activity indices and pain was assessed with the independent-samples t-test; linear regression produced adjusted estimates.

Results: A total of 1030 RA patients were included with 5177 assessments. At baseline, MCP(s) (84.8%) and wrist(s) (66.1%) were the most commonly swollen joints. Tenderness was most frequent at baseline in these two joint types (81.1% and 70.9% of patients, respectively). Swelling/tenderness rates in all joint groups were significantly lower (Table 1) among patients enrolled in 2010–2013 vs. those enrolled in 2002–2005; no significant differences, however, were observed in joint involvement pattern.

Swelling and tenderness in all joint groups were associated with significantly (P<0.001) higher pain. Upon adjusting for age, gender and the total number of swollen (SJC28) or tender (TJC28) joints, swollen shoulder(s) and knee(s), and tender shoulder(s) and elbow(s) had the biggest impact on pain. Swollen MCP(s), knee(s) and thumb(s) had the greatest impact on DAS28, while for CDAI and SDAI swollen thumb(s) and swollen thumb(s) and

knee(s), respectively, showed the highest association. Tender wrist(s), shoulder(s), and knee(s) showed the highest association with DAS28, while tender MCP(s) had the greatest impact on CDAI and SDAI. However, all indices were significantly higher among cases with swollen thumb(s) (unstandardized coefficient (B): B_{DAS28}=0.25, P=0.006; B_{CDAI}=2.09, P=0.001; B_{SDAI}=2.66, P=0.001).

Conclusion: Although joint swelling/tenderness documented at anti-TNF initiation has decreased over time, the profile of affected joints has remained stable. Swelling/tenderness in specific joint groups was differentially associated with pain, with larger joints having the greatest impact. Furthermore, differences were observed in levels of disease activity based on the type of affected joint which could be attributed to their impact on patient global assessment. These results suggest that location of joint involvement, in addition to the number of affected joints, has an independent impact on pain.

Table 1: Pattern of Swelling or Tenderness by Enrolment Period

Swelling/Tenderness by Joint Type	Enrolment Period 2002-2005 (N=412)	2010-2014 (N=278)	P-value

Is Remission Really Achievable in EARLY Rheumatoid Arthritis? Olga Addimanda[1], Pierluigi Macchioni[2], Andrea Caruso[1], Niccolò Possemato[1], Mariagrazia Catanoso[1] and Carlo Salvarani[2]. [1]Arcispedale Santa Maria Nuova, I.R.C.C.S., Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova, Reggio Emilia, Italy.

Background/Purpose: To stress the need of routine use of US imaging in treat to target strategies aiming to achieve remission in early rheumatoid arthritis.

Methods: 54 patients with early rheumatoid arthritis (ERA) or undifferentiated arthritis (UA) diagnosed according to 2010 ACR/EULAR criteria were enrolled. Demographic (age, gender, disease duration,BMI), clinical (total SJC and TJC, DAS28, CDAI, SDAI, HAQ, EULAR response), serological (ESR, CRP, RF, anti-CCP) data has been collected. Ultrasonographic hand (MCP, PIP and DIP joints), wrists (intercarpic and radiocarpic joints) and feet (MTP, PIP, DIP as well as ankle joints) evaluation was performed according to OMERACT recommendations. The patients were evaluated at baseline, after three and six months:all 54 patients have complete 3rd month follow-up data, only 38 have already completed 6th month follow-up.

Results: 11 UA (20,4%) and 43 RA (79,6%) were enrolled from November 2012 to January 2014.Mean disease duration was 15,5 ± 7,8 weeks (min – max 4 – 24). 26 (48,1%) were RF positive (Mean ± sd values 121.7 ± 90.5) and 25 (46,3%) were CCP positive (Mean ± sd values 361,0 ± 448,2). Only 8 (14,8%) showed radiographic erosions at baseline. We observed a progressive reduction in all clinical and clinimetric features not associated with statistically significant improvement in US findings (Table). When analyzing for predictive factors of good response only increased values of ESR and CRP at baseline were found to be associated with better clinical response altough not always reaching statistically significant value (ESR t0-t3 p = 0,024; ESR t0-t6 p = 0,766; CRP t0-t3 p = 0,822; CRP t0-t6 p = 0,071). Baseline number of joints with US synovitis or power-Doppler (PD) signal were not different between responder and not responder at 3 and 6 months. The number of joints with US synovitis or US presence of PD were not statistical different between moderate or good responder at 6 months.

Conclusion: Clinical remission could not be considered enough to avoid erosive progression in rheumatoid arthritis and US remission is needed in order to avoid structural damage.

Treatment Pattern and Direct Cost of Biologics for Rheumatoid Arthritis Patients: A Real-World Analysis of Nationwide Japanese Claims Data. Naonobu Sugiyama M.D., Ph.D.[1], Tatsunori Murata, M.S.[2], Yosuke Morishima[1], Yuri Fukuma[1], Yoshiyuki Shibasaki[1] and Lisa Marshall[3]. [1]Pfizer Japan Inc. RA & Inflammation Area Medical Affairs Department, Tokyo, Japan, [2]Health Economics Research Group, CRECON Research and Consulting Inc., Tokyo, Japan, [3]Pfizer Inc. Inflammation Immunology Disease Group, Collegeville, PA.

Background/Purpose: Biologics such as etanercept (ETN), adalimumab (ADA), infliximab (IFX) and tocilizumab (TCZ) have led dramatic improvement in the treatment of rheumatoid arthritis (RA), but the impact of their high drug costs on medical expenditure remains a concern. The aim of this study is to characterize the treatment patterns of patients with RA treated with biologics and evaluate the direct biologics cost and medical cost using Japanese claims data provided by Japan Medical Data Center Co., Ltd.

Methods: Patients with RA (defined by ICD10 code) treated with ETN, IFX, ADA, and TCZ between Jan, 2005 and Mar, 2013 were included. Annual costs of the biologics per patient, based on average daily dose and NHI drug price, were calculated from 2009 to 2012 for ETN, IFX, ADA, and TCZ. Patients were grouped based upon their initial prescription for either ETN, IFX, ADA, or TCZ. One year biologics cost including all biologics (including second or more, e.g. golimumab) and total medical cost following initial prescription were compared between ETN and the other treatment groups. Discontinuation and switching event rates to other biologics in each group were estimated using Kaplan-Meier survival analysis. Dose changes, based on +/−50% change in average dose per administration, at 3 month intervals were also evaluated up to 4 years following initial prescription.

Results: A total of 524 patients were identified for longitudinal analysis, with 45% (n=238) initiating ETN, 41% (n=217) initiating TFX, and 13% (n=69) initiating. The cross-sectional annual biologics cost was $8,000 in 2009 and $7,200 in 2012 in patients with ETN, $10,000 both in 2009 and in 2012 in patients with ADA, $12,000 in 2009 and $16,000 in 2012 in patients with IFX, $9,000 in 2009 and $8,000 in 2012 in patients with TCZ (Fig.1). The one year total medical costs from the initial prescription in ETN, IFX and ADA groups were approximately $19,000, $26,000 and $23,000, respectively (ETN: IFX p<0.001, ETN: ADA p<0.001). A similar trend was also observed in the biologics cost. The discontinuation event rates at 36 months was 48.6%, 58.0% and 75.8% in ETN, IFX and ADA group, respectively (ETN: IFX p=0.052, ETN: ADA p=0.004) (Fig.2). The switching event rate to other biologics at 36 months was 9.9%, 17.4% and 27.7% in ETN, IFX and ADA group, respectively (ETN: IFX p=0.042, ETN: ADA p=0.052) (Fig.3). The longitudinal dose changing trend in IFX was different from ETN and ADA group.

Conclusion: The biologic and total medical costs, along with discontinuation and switching event rates were lowest in ETN group. Although there are limitations such as channeling bias, these findings might imply the clinical cost reductive benefits in ETN first line treated group.

Efficacy of Biologic Medications in Active Rheumatoid Arthritis: A Systematic Review. Lynden Roberts[1], Kathleen Tymms[2], Julien de Jager[3], Geoffrey Littlejohn[4], Hedley Griffiths[5], David Nicholls[6], Paul Bird[7], Jennifer Young[8] and Jane Zochling[9]. [1]JCU Clinical School, Townsville, QLD, Australia, [2]Canberra Rheumatology, Canberra, ACT, Australia, [3]Olser House, Southport, QLD, Australia, [4]Monash Medical Centre and Monash University, Clayton, VIC, Australia, [5]Barwon Rheumatology Service, Geelong, VIC, Australia, [6]Coast Joint Care, Maroochydore, QLD, Australia, [7]Combined Rheumatology Practice, Sydney, NSW, Australia, [8]Roche Products Pty Limited, Sydney, NSW, Australia, [9]Menzies Research Institute Tasmania, Hobart, TAS, Australia.

Background/Purpose: In the last decade, biologic medications have transformed the management of RA. The effectiveness of these medications has been reported in numerous randomized controlled trials and cohort studies. A summary of the effect size for biologic medications would be useful to inform expectations of rheumatologists and patients when considering and commencing these medications. Further, with an increased interest in real-life effectiveness data from clinical registries, comparisons between controlled trial and registry effectiveness outcomes would be of interest.

Methods: Using PRISMA methodology, a pre-specified search and review strategy was devised to answer the question "what are the EULAR response rates for biologic medications in adults with active RA?" MEDLINE and EMBASE were searched for Rheumatoid Arthritis (Both Mesh term and free text) in Title/Abstract AND Name of biologic drug (free text) in Title/Abstract OR Biologic Therapy (Mesh term) OR 'Biologic' (free text) in Title/Abstract AND EULAR response (free text) in Entire Document AND Adult (free text) Entire Document. All articles were reviewed independently by 2 experts; duplicates and non-primary research articles were removed along with those using medication doses outside of the approved Australian indications, and only patients with ≥ moderate DAS or tender/swollen joint count ≥ 4 were included. Whether the patients were naïve to biologic DMARD and whether the response assessment was at 3 (2.0 – 4.5) months or 6 (4.5 – 7.0) months was recorded. The percentage of patients achieving a moderate, good, or either EULAR response was calculated overall and for subgroups.

Results: Overall, 27,280 patients were included representing 62 studies. Mean baseline DAS28 was 6.0 (SD=0.6). Good (G) and moderate (M) EULAR responses were achieved in 25.8% and 47.3% respectively, with 28.1% failing to achieve a Good or Moderate EULAR response when all patients were pooled. Response rates were similar for patients who were naïve to biologics (G-24.0% & M-47.5%), those who had failed to respond to at least 1 biologic (G-28.1% & M-47.1%) and at both 3 months (G-27.1% & M-50.4%) and 6 months (G-25.2% & M- 46.3). Sufficient data was present for separate analyses of adalimumab (ADA), etanercept (ETN) and tocilizumab (TCZ) and EULAR response rates were similar, however tocilizumab had a higher rate of good EULAR response [37.4% (TCZ), 28.2% (ADA), 27.6% (ETN)].

Conclusion: A systematic review of studies reporting EULAR response rates for biologic medications in active RA showed that only 28.1% of patients fail to achieve at least a moderate EULAR response. Response rates were similar for patients who were naïve or had previous exposure to biologics, for 3 and 6 months assessment time points, and for different biologic medications. Comparison of these controlled trial data with real life response rates reported in clinical registries will be of interest.

Quality Assessment of Controlled Trials Evaluating Chinese Herbal Medicine in Patients with Rheumatoid Arthritis: a Systematic Review. Xin Pan, Maria A. Lopez-Olivo, Pratibha Nayak and Maria E. Suarez-Almazor. The University of Texas, MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Chinese herbal medicine (CHM) is a mainstay in the treatment of rheumatoid arthritis (RA) in China. We conducted a systematic review to appraise the methodological quality of controlled clinical trials evaluating the efficacy and safety of CHM in patients with RA.

Methods: We searched electronic databases (Medline, EMBASE, The Cochrane Library, and Web of Science) from inception until May 2014 for controlled trials (randomized or not) evaluating the use of CHM including herbals and decoctions (i.e., "tang"), in patients with RA. The search was not limited by language, year of publication or type of publication. Study selection was performed by 2 independent reviewers. Data extraction and the methodological quality of the trials was assessed using the Cochrane risk of bias tool for randomized trials and Newcastle Ottawa Scale for controlled non-randomized studies. Descriptive statistics were used to report on risk of selection, performance, detection, attrition, reporting biases and others (i.e., conflict of interests) for randomized trials and selection, comparability and outcome biases for cohort studies.

Results: Out of 2,125 unique citations only 54 studies were included (51 randomized trials and 3 non-randomized studies) including 7,792 patients. Only one study was conducted in the US, the remaining in China. There were 3,446 patients receiving CHM. In the control groups 2,283 patients received a disease modifying anti-rheumatic drug (DMARD) (i.e., methotrexate, leflunomide, sulfasalazine, and etanercept), 182 non-steroidal anti-inflammatory drugs (NSAIDs), and 164 inert placebo. Additionally, 1,717 received combined CHM + either DMARD or NSAIDs. In 23 studies patients were described as having active disease, 13 included patients with more than 1 year disease duration, 1 included patients with RA and anemia, and 17 included patients with one or two traditional Chinese medicine (TCM) 'pathological factors' (i.e., *feng*, *shi*, and/or *han*). Discontinuations were not reported in 31 studies, but ranged from 0 to 55% in the remaining studies. For the randomized studies, when evaluating selection bias 54% of the studies were judged to have an adequate random sequence generation, but 77% had inadequate allocation concealment. 79% had a high risk of performance bias (not blinding participants and/or personnel) and detection bias was unclear in 56% of the studies; 62% of the studies reported how missing data was handled, therefore attrition bias was judged to be low. In 87% no disclosure of interest or source of founding was reported. For non-randomized studies, all the studies were representative of RA patients, had an adequate ascertainment of intervention with comparable groups, but only one demonstrated that the outcome of interest was not present at start of study or provided the rate of lost to follow-up.

Conclusion: Studies evaluating CHM often fail to meet expected methodological criteria, and high quality evidence is lacking. Future studies of CHM should be methodologically robust and adhere to reporting guidelines such as the CONSORT statement for TCM.

Patient Treatment Goals in Rheumatoid Arthritis: Results of Focus Groups Among Rheumatologists, English and Spanish-Speaking Patients. Jennifer Barton[1], Christopher J. Koenig[2], Diana Martinez[3], Gina Evans-Young[2], Patricia P. Katz[1] and Edward H. Yelin[1]. [1]University of

California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]UCSF/San Francisco General Hospital, San Francisco, CA.

Background/Purpose: Treatment guidelines in rheumatoid arthritis (RA) frame provider's therapeutic goal as disease remission. Although goal concordance between providers and patients has been shown to positively impact outcomes in other chronic diseases, like diabetes, patient-provider goal sharing has not been well-studied in RA. We performed a literature review and conducted focus groups to identify goals important to RA patients.

Methods: A systematic review using PubMed from 1966 to 2013 included terms for RA and patient goals. The results were used to inform domains discussed in focus groups. We conducted 2 patient focus groups (1 in English, 1 in Spanish), and one with rheumatologists. A professional qualitative researcher conducted the English-language patient and physician groups and trained a bilingual moderator who conducted the Spanish group. We used a two-phase structured process where participants first reflected on personal functional and treatment goals as a way to discuss a wide range of goals. The physician group used a similar process, and included a presentation of goals from patient focus groups. We used Grounded Theory to organize goals thematically and combined patient results with goals identified in the literature review.

Results: 865 papers were identified and after review, 28 articles remained; from these, 110 goals were abstracted. Patient goals from focus groups and literature review fell into one of six categories: symptoms, function/quality of life, treatment, research/policy, social support, and system-level goals. Goals identified by both Spanish and English-speaking patients (Table 1) included symptom goals (less pain), function (ability to open jars), and social support (help family understand severity of disease and what to expect), and treatment (more affordable medications). Areas of difference included goals of improved mood (Spanish), more time with providers (Spanish), more coordination among multiple providers (English), sex and intimacy without shame (English). Providers' goals included remission, cheap and simple medications, and holistic treatments. Physicians expressed surprise with many of the patient-generated goals, including desire for complementary and alternative medication, and felt overwhelmed and ill-supported to manage mood-related issues.

Conclusion: The elicitation of patient goals and goal setting in RA is an important, understudied area especially among vulnerable populations. More research to study the role of eliciting goals, goal concordance, and its impact on outcomes in diverse populations is needed. Interventions to improve goal concordance may improve self-efficacy, adherence, and outcomes in RA.

Table. Patient-reported goals organized by themes from focus groups in English (n=7, all female) and Spanish (n=4, 3 females, 1 male)

Themes and individual goals	Both groups	English only	Spanish only
Symptom goals			
Less pain	X		
Less mobility limitations	X		
Improved mood			X
Function/quality of life goals			
Ability to open cans and jars (easily)	X		
Ability to work consistently/meet expectations	X		
Have flare interfere less with activities	X		
Being able to exercise safely	X		
Transportation/take public transit vs. paratransit/be able to drive		X	
Sex and intimacy without shame and/or fear		X	
Be able to do housework without "paying the price"			X
Social support goals			
Help family understand the severity of the disease and what to expect	X		
Social support: Access to support groups/ counseling/social workers		X	
Would like doctor to ask about emotional well-being, not just physical			X
System-level goals			
To find a cure	X		
Want more doctor communication around drug treatments and condition	X		
More coordination of care between provider types		X	
Be understood by their doctor(s)			X
Would like to be able to drink safely (and have more doctor input on subject)			X
Research/policy goals			
More access to drugs/more affordable drugs	X		
Develop a more sensitive/functional Visual Analog Scale for pain		X	
Longer visits to allow for full discussion of RA			X
Treatment goals			
More information around nutrition	X		
Less surgeries		X

A Tailored Approach to Reduce Dose of TNF Inhibitors Is Equally Effective, but Substantially Less Costly Than Standard Dosing in Patients with Rheumatoid Arthritis over One and Two Years: A Prospective Cohort Study. Jakub Zavada[1], Michal Uher[2], Katarina Sisol[3], Sarka Forejtova[3], Katerina Jarosova[3], Liliana Sedova[3], Zuzana Urbanova[3], Olga Sleglova[3], Jiri Vencovsky[4] and Karel Pavelka[5]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic, [2]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [5]Charles University, Prague, Czech Republic, Prague, Czech Republic.

Background/Purpose: To compare effectiveness and costs of standard versus individually tailored reduced doses of TNF inhibitors (TNFi) in patients with Rheumatoid Arthritis (RA) after achieving low disease activity.

Methods: This was a single center prospective observational study performed within the national biologics registry. The TNFi dose tapering strategy was chosen by treating physicians, without pre-specified protocol. Patients with RA treated for at least 6 months by TNFi who reached low disease activity (LDA) were eligible for this analysis. LDA was defined as DAS28≤3.2. Firstly, we selected one "baseline" visit for each patient in the standard dosing group, which would be most comparable to baseline visits in the reduced dosing group (=start of dose reduction) using 3 parameters (duration of TNFi treatment, DAS28 and HAQ) to find the best match. Secondly, a propensity score (PS) was used to control for all other confounders associated with starting TNFi dose reduction. The co-primary outcomes were change (D) in HAQ and loss of LDA (defined as DAS28 $>$ 3.2 & DDAS28 $\geq$ 0.6). Secondary outcomes were DAS28 area under the curve (AUC), HAQ AUC, and annual cost of anti-TNF therapy. The outcomes after one and two years of treatment (since baseline visit) by standard vs reduced doses of TNFi were assessed by generalized linear regression after adjustment on PS.

Results: In the reduced dosing group the mean dose of TNFi corresponded to 0.64, 0.66 and 0.69 of the standard dose initially, at 12 and 24 months resp. After PS adjustment, baseline demographic and clinical characteristics between the groups were well balanced (table 1). 48 (32) and 136 (76) patients in the reduced vs standard dosing group after 1 year (2 years) resp. were available for analysis. Both co-primary outcomes were similar between both groups after one and two years since baseline (table 2 and 3). Annual cost of TNFis per patient was lower by ~4,000 € in the reduced dosing group.

Conclusion: In RA patients after reaching LDA, a tailored approach to reduce doses of TNFi produced similar clinical outcomes at 1 and 2 years resp., but was substantially less costly.

2423

Prevalence of Subclinical Synovitis Detected By Ultrasound in Rheumatoid Arthritis and Psoriatic Arthritis Patients Receiving Anti-TNF-α Therapy with Extended Interval of Administration. José M. Senabre-Gallego[1], José Rosas-Gómez de Salazar[1], Esteban Salas-Heredia[1], Gregorio Santos-Soler[1], Francisca Llinares-Tello[1], Carlos Santos-Ramirez[2], Mabel Sánchez-Barrioluengo[3], Xavier Barber-Vallés[4], Rafaela Ortega[2], Ana Pons[1], Catalina Cano[1] and Maria Luisa Lorente-Betoret[1]. [1]Hospital Marina Baixa, Villajoyosa, Spain, [2]Hospital Marina Salud, Denia, Spain, [3]Universitat Politècnica de València, Valencia, Spain, [4]University Miguel Hernández, Elche, Spain.

Background/Purpose: To estimate the prevalence of subclinical synovitis detected by ultrasound in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients in clinical remission receiving anti-TNFα therapy with extended interval of administration (EIA).

Methods: Prospective observational study. Population: Patients diagnosed with RA and PsA, being in clinical remission and receiving anti-TNFα therapy with EIA. 12-joint ultrasound assessment (elbows, wrists, 2nd and 3rd metacarpo-phalangeal, knees and ankles) (Naredo E. Arthritis Rheum 2008,59:515-22) was performed (MyLab 25 Esaote s.p.a, Firenze, Italy), evaluating synovitis through B-mode (BM) and Color Doppler signal (CD), both by semiquantitative scale from 0 to 3 points. Subsequently, a BM and CD score was calculated, summing the highest score obtained from any one of the synovial sites evaluated at each joint to a maximum of 36 points. The sonographer was blinded to the clinical and laboratory data.

Results: 26 patients were included in the study, 76.9% were women, mean age was 59 years [31–79] and mean duration of disease was 14 years [3–46]. The diagnosis was RA in 24 patients (92%) and APs in 2 (7%). In 83% of RA patients rheumatoid factor was positive, and in 79% the citrullinated protein antibody was positive. Ultrasound assessment prior to EIA was available in 17 patients. Clinical activity and ultrasound scores are summarized in Table 1. Ultrasound detects some synovitis by CD in 50% of EIA patients, and by BM in 96% of EIA patients. Nevertheless most of them had a low CD score (average 1.42 out of 36 points). No statistically significant differences were found when comparing prior and after EIA clinical and ultrasound scores (data not shown). The mean time from the beginning of EIA was 15 months (range 1 to 48 months). The EIA treatments were etanercept (ETN) in 14 patients and adalimumab (ADA) in 12 patients, with the following patterns: ETN/10 days (11 pat.), ETN/14 days (3 pat.), ADA/18 days (1 pat.), ADA/21 days (10 pat.), ADA/30 days (1 pat.). 10 patients (not included in the study) never began EIA due to clinical decision, and 7 (27%) had to return to the standard administration pattern due to worsening of disease activity.

Table 1 Clinical and ultrasound scores

	Prior to EIA ultrasound	After EIA ultrasound
n	17	26
DAS28-VSG, mean [range]	1.55 [0.63–2.64]	1.74 [0.51–4.06]
DAS28-PCR, mean [range]	1.69 [1.13–2.89]	1.75 [1.13–3.38]
SDAI, mean [range]	3.58 [2.10–10.10]	4.05 [2.10–16.1]
CDAI, mean [range]	3.35 [2–10]	3.92 [2–16]
Color Doppler score >0, n (%)	12 (70.6%)	13 (50.0%)
Color Doppler score, mean [range]	1.06 [0–3]	1.42 [0–5]
B-mode SH score >0, n (%)	14 (82.4%)	25 (96.2%)
B-mode SH score, mean [range]	4.18 [0–19]	4.46 [0–17]

EIA: Extended interval of administration of anti-TNFα; DAS28: Disease Activity Score in 28 joints; SDAI: Simplified Disease Activity Index; CDAI: Clinical Disease Activity Index; SH: synovial hypertrophy.

Conclusion: Some synovitis was detected by Color Doppler ultrasound in 50% of patients in clinical remission receiving anti-TNFα therapy with extended interval of administration. Most of them had a low Color Doppler ultrasound score. Synovial hypertrophy was detected by B-mode ultrasound in 96% of them. No statistically significant differences were found when comparing prior and after EIA clinical and ultrasound scores.

Comparison of Medication Use in Rheumatoid Arthritis Patients Between University and Private Settings – Results from Ontario Best Practice Research Initiative. Thomas McKeown[1], Binu Jacob[1], Xiuying Li[1], Sandra Couto[1], William Bensen[2], Vandana Ahluwalia[3], Arthur Karasik[4] and Claire Bombardier[5]. [1]University Health Network, Toronto General Research Institute, Toronto, ON, [2]St Josephs Hospital and McMaster University, Hamilton, ON, [3]William Osler Health Center, Brampton, ON, [4]Courtesy Staff Appointment St. Joseph's Health Centre, Toronto, ON, [5]University of Toronto, Toronto, ON.

Background/Purpose: The objective of this study was to compare the characteristics and patterns of medication use among rheumatoid arthritis (RA) patients in university and community settings.

Methods: Descriptive analyses were performed using data collected from the Ontario Best Practice Research Initiative (OBRI), a clinical registry of RA patients followed in routine care. Patients were categorized as university if their rheumatologist worked in a teaching hospital, mentored medical students and/or had their Research Ethics Board (REB) located at a hospital. The patients of a community rheumatologist worked at a community center and/or had their REB at a location other than a hospital. A group of mixed Physicians (n=12), who were affiliated with an academic site, but practiced at a community site were excluded from the analysis. Patient baseline demographics, clinical characteristics, socioeconomic features and treatment regimens were compared between university and community patients using chi-square and t-tests.

Results: Among 1583 RA patients, 512 (32%) were from university and 1071 (67%) from community sites. Compared to community patients, university patients were younger (55.5 ± 12.9 vs. 57.9 ± 13.3 yrs, p=0.004), had longer RA disease duration (11.3 ± 10.9 vs. 6.9 ± 8.5yrs, p<0.0001), and were highly educated with higher household incomes. Prevalence of depression was higher among community patients (26%) compared to university (21%), p=0.04. The disease activity measures and functional status at baseline were similar between the two groups. The use of Biologics was more in university patients (31% vs. 17%, P<.0001) with fewer use of DMARDS (61% vs. 73%, P<.0001).

Conclusion: RA patients in community settings appeared to be older with longer disease duration, had lower socio-economic status and a lower utilization of biologics. The results does not represent the clinician practice patterns as the referral criteria might have biased the patients enrolled in the study. Further analysis is required to evaluate whether the care gap due to differential utilization of biologics have an impact on disease severity in subsequent years.

Rheumatoid Arthritis Stable Follow up Visits – 3 Month Versus 6 Month Intervals. Mark C. Fisher and Deborah S. Collier. Massachusetts General Hospital, Boston, MA.

Background/Purpose: Specialist visits are a contributing factor to the rising cost of healthcare and payment models increasingly encourage decreased outpatient specialty visits.

Due to monitoring of methotrexate, sulfasalazine, or leflunamide, many rheumatologists see patients with stable Rheumatoid Arthritis (RA) every 3 months for routine follow up. We hypothesized that decrease in utilization and cost of outpatient specialty services can be achieved without compromising patient care or safety by seeing these patients every 6 months, with a lab check every 3 months.

Methods: Patients with RA on either methotrexate or sulfasalazine in stable remission or low disease activity were offered visits every 6 months instead of every 3 months, with labwork done at 3 months. This was part of a Quality Improvement initiative to decrease healthcare costs.

Outcomes included number of eligible patients for two full time providers over a 6 month period, percent of total established RA patients for these providers deemed appropriate for inclusion, percent of patients who had their labs done, percent of patients with new cytopenia or liver function test (LFT) abnormality, percent of patients who had problems requiring a follow up visit during the 6 month interval, and estimated cost savings.

Results: Over 6 months, 21 eligible patients were identified. Clinical features are noted in Table 1. Overall, 14/21 patients were seropositive, either for RF or CCP antibodies, and 12 were positive for both. 10 patients were on combination therapy with a biologic. The 21 RA patients were out of 184 established RA patients seen for followup visits by two full time providers (11.4%) during the study period (Table 2). 14 of 21 patients (66.7%) had their labs drawn at 3 months. There were no new cytopenias or LFT abnormalities. No patients required additional follow up for RA. One patient required a follow up visit during the 6 month interval for new diagnosis of Giant Cell Arteritis. Each saved visit equaled an estimated cost savings of between $92 and $356, depending on the insuror, with an average of $161 saved per visit and $362 per patient annually.

Conclusion: Patients with RA in stable remission or low disease activity can safely and cost effectively be seen at 6 month intervals with labs drawn at 3 months. There were no new RA issues between visits, and no new laboratory abnormalities. Patient compliance was good, but could be improved. This intervention saved an average of $362 per patient annually.

Table 1: Clinical Characteristics

Age	56.8
Gender (female)	82.3%
Ethnicity	
White	15
Hispanic	6

Comparison of Patient Self-Reported and Physician Reported Rheumatoid Arthritis Medication Use - Results from the Ontario Best Practices Research Initiative. Binu Jacob[1], Xiuying Li[1], Angela Cesta[2], Bindee Kuriya[3], Edward Keystone[4] and Claire Bombardier[3]. [1]University Health Network, Toronto General Research Institute, Toronto, ON, [2]University Health Network, Toronto, ON, [3]University of Toronto, Toronto, ON, [4]Mount Sinai Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Patient self-reported medication histories may be prone to misclassification and recall bias. We aimed to assess the agreement between patient (Pt) and physician (MD) reported medication use in a cohort of RA patients.

Methods: Patients enrolled in the Ontario Best Practices Research Initiative (OBRI), a clinical registry of RA patients followed in routine care, were included. Following patient consent, data were extracted from physician charts using a structured questionnaire on patient demographics, comorbidities, disease activity and use of RA medications. Patients are assessed every 3 months through telephone interviews according to a standardized protocol to collect additional socio-economic characteristics, disease activities measures, and medication use. We examined the concordance of reporting

medication names and the level of agreement between Pt and MD reported RA medications. RA medications (only DMARDs and BIOLOGICS) were categorized as (yes/no) for both self-reported and physician reported data and kappa statistics with 95% confidence intervals were computed at baseline and 12 month period to assess chance-corrected agreement between the two sources of data. Percent agreement was also calculated as a measure of agreement. In addition, dose reported for various drugs were compared at baseline and one year. Wilcoxon signed rank test was used to compare the mean difference of doses reported.

Results: Of the 2347 patients included in the study, 77% of patients were female with a mean (SD) age of 57.4 (12.9) years, and the majority (85%) were Caucasian. Patients had moderate disease activity according to both mean (SD) DAS28 scores 4.5 (1.5) and CDAI scores 21(14). At baseline, substantial agreement was found between Pt and MD reported medication use (kappa =0.78, 95% confidence interval (CI), 0.77–0.79); agreement=97.4%), and use of specific BIOLOGIC and DMARDS with agreement ranged from 88 to 100% (Figure, kappa range 0.50–0.85). The degree of agreement was lowest for methotrexate (kappa=88%). The MD reported mean dose was significantly higher than Pt except for MTX. At one year, the overall agreement of reported medication name increased with kappa=0.84 (95% CI 0.83–0.85) and there was no significant difference in reported dose between Pt and MD.

Conclusion: Similar level of agreement between patients and physicians suggest that differential misclassification is unlikely in the reporting of RA medication use. Furthermore, the accurate reporting of doses at one year suggests that patient's ability to report their medications improves over time.

2427

Attainment of Low Disease Activity Is Predictive of Maintenance of Disease Control upon Adalimumab Discontinuation for Two Years Following Combination Therapy in Japanese Patients with Early Rheumatoid Arthritis. Yoshiya Tanaka[1], Hisashi Yamanaka[2], Naoki Ishiguro[3], Nobuyuki Miyasaka[4], Katsuyoshi Kawana[5], Katsutoshi Hiramatsu[5], Aki Kuroki[5] and Tsutomu Takeuchi[6]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [3]Nagoya University Graduate School of Medicine, Nagoya, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]Abbvie, Tokyo, Japan, [6]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Although available data has suggested successful withdrawal of a monoclonal antibody TNF blocker after achieving low disease activity (LDA) or remission over the short-term for a large proportion of patients with early rheumatoid arthritis (RA), longer term follow-up data are needed to predict maintenance of biologic-free disease control. The purpose of this study was to identify the factors associated with maintenance of disease control for 2 years of adalimumab (ADA) discontinuation after treatment with ADA plus methotrexate (MTX) in patients with early RA.

Methods: In the HOPEFUL-1 study, patients with early RA were randomized to receive ADA 40 mg every other week (EOW) plus weekly MTX 6–8 mg, or only MTX 6–8 mg every week for 26 weeks. Thereafter, all patients received open-label ADA 40 mg EOW plus weekly MTX for 26 weeks. At week 52, patients could enroll in HOPEFUL-2, an observational follow-up study, where they received ADA plus MTX (ADA-continued group) or MTX alone (ADA-withdrawn group) for 52 weeks based on investigator and/or patient decision. At week 104, patients could enroll in HOPEFUL-3, a 104-week follow-up extension. Data at week 156 were used in this interim analysis. Using multivariate analysis, factors associated with remaining in ADA-withdrawn group as well as sustaining LDA in the ADA-withdrawn group at week 156, were analyzed. The 28-joint disease activity score based on erythrocyte sedimentation rate (DAS28-ESR), Health Assessment Questionnaire Disability Index (HAQ-DI), and modified total Sharp score (mTSS) were also examined.

Results: Among the 220 HOPEFUL-2 patients, 172 were enrolled in the HOPEFUL-3 study, 79 from ADA-continued and 93 from ADA-withdrawn. Patient characteristics at the baseline of HOPEFUL-2 were similar in the ADA-continued and -withdrawn groups, except for SJC, which was significantly higher in the former group. At week 156, 73 patients out of 93 (78%) remained in the ADA-withdrawn group, with the remainder of patients either discontinuing from the study or continuing/restarting treatment with ADA. At week 156, there were no differences in clinical, functional, and structural outcomes between the patients in ADA-withdrawn group and the remainder of patients. (table). The predictive factors for remaining in the ADA-withdrawn group at week 156 were level of CRP at week 0, as well as SJC, CRP, and titer of rheumatoid factor at week 52 (cut-offs =week 0 CRP, 2.04; week 52 CRP, 0.21; week 52 SJC, 0). Moreover, DAS28-ESR 2.6 at week 52 distinguished 44 patients, those who were able to sustain LDA without using ADA at week 156.

Conclusion: The attainment of low disease activity based on serological markers at the onset and at the time of ADA withdrawal was the key determinant for maintenance of biologic-free disease control for up to 2 years in early RA patients.

Table 1.

	ADA-withdrawn (n = 73)	Others (n = 99)	P
DAS28-ESR[a]	2.83 ± 0.97	2.91 ± 1.43	p=0.473[b]
HAQ-DI[a]	0.26 ± 0.45	0.25 ± 0.41	p=0.605[b]
Percentage of patients with ΔmTSS ≤ 0.5	67.1%	71.2%	p=0.717[c]
Percentage of patient in LDA	62.0%	71.3%	p=0.245[c]
Percentage of patient in remission	42.3%	52.6%	p=0.212[c]

Comparative Study of Rheumatoid Arthritis Disease Activity Indices in Two Populations of Meteor Database. Helena Canhão[1], Fernando Magalhaes Martins[2], Jose Antonio Melo Gomes[3], Maria Jose Santos[4], Augusto Faustino[5], José Antonio Costa[6], Cornelia Allaart[7], E. Gvozdenovic[8], Pedro

Machado[9], Jaime C. Branco[10], João E. Fonseca[11] and José Pereira Da-Silva[12]. [1]Hospital Santa Maria, Lisboa, Portugal, [2]Portuguese Society of Rheumatology, Lisbon, Portugal, [3]Instituto Português de Reumatologia, Lisbon, Portugal, [4]Hospital Garcia de Orta, Almada, Portugal, [5]Clínica de Reumatologia de Lisboa, Lisbon, Portugal, [6]Centro Hospitalar do Alto Minho, Hospital de Ponte de Lima, Ponte de Lima, Portugal, [7]Leiden Univ Med Ctr, Leiden, Netherlands, [8]Leiden University Medical Center, Leiden, Netherlands, [9]University College London, London, United Kingdom, [10]Centro Hospitalar de Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, [11]Lisbon Academic Medical Center, Lisbon, Portugal, [12]Hospitais da Universidade de Coimbra, Coimbra, Portugal.

Background/Purpose: Our aims were to assess disease activity states using DAS28ESR, CDAI and SDAI and to compare their outcomes in two rheumatoid arthritis (RA) populations of METEOR database.

Methods: A total of 24605 visits from 5870 Dutch patients and 20120 visits from 3185 Portuguese patients were analyzed. We also selected and replicated the same analyses in a subset of one random visit per patient. K-statistics and z-tests were applied to assess agreement and differences between groups. The relative contribution of each RA core set measure was determined for the three indices.

Results: We found significant differences in the distribution of RA disease activity states between Dutch and Portuguese populations when DAS28ESR was used. SDAI and CDAI attenuated those differences. The percentage of Dutch and Portuguese visits classified as "in remission" was very similar with CDAI, SDAI and ACR/EULAR remission criteria. Contrary, using DAS28ESR, a significant higher proportion of Dutch visits was classified in remission. ESR was lower in Dutch visits and this component was determinant for lowering DAS28 scores in this group of patients.

Conclusion: CDAI and SDAI assigned distinct RA activity states when compared to DAS28 in our two populations from METEOR database.

Table – Comparing means of the components of the disease activity indices within each disease activity state between Dutch and Portuguese populations

	Remission		Low		Moderate		High	
	z	p-value	Z	p-value	z	p-value	z	p-value
A. DAS28 original

Seasonal Changes May Influence Activity of Rheumatoid Arthritis. Ryuji Nagamine. Sugioka Memorial Hospital, Fukuoka, Japan.

Background/Purpose: RA activity during the year was assessed to investigate whether seasonal changes influenced parameters of RA activity.

Methods: This study was performed in Fukuoka, a Japanese city with four distinct seasons. From September 1, 2009 to August 31, 2011, parameters of RA activity were assessed in a total of 3811 visits by 348 patients (mean age, 62.1 years; mean duration of RA, 10.8 years), including 2174 visits by 140 patients treated with biologics (mean age, 63.0 years; mean duration of RA, 11.9 years). The following parameters were assessed: C-reactive protein (CRP); erythrocyte sedimentation ratio (ESR); matrix metalloproteinase (MMP)-3; rheumatoid factor; DAS28-CRP and DAS28-ESR. All parameters in each month in the first and second years were assessed and results were compared among months. Monthly mean temperature and mean atmospheric pressure in Fukuoka in the 2 years of the study are shown in Figure 1.

Results: For all cases, mean CRP level was 0.65 mg/dl from October to December, and 0.53 mg/dl from July to September. In cases treated using biologics, mean CRP level was 0.67 mg/dl from October to December and 0.50 mg/dl from January to March. These differences were significant ($p<0.05$). CRP level from April to June (mean, 0.70 mg/dl) was also significantly higher than that from January to March ($p<0.01$). CRP was significantly higher in autumn and spring than in summer and winter, even in patients treated with biologics. Seasonal changes thus clearly influenced CRP levels. No significant differences in other parameters were found, although MMP-3 levels were also higher from October to December and from April to May compared to other months (Fig. 2).

Conclusion: The results clearly show that seasonal changes significantly influence CRP levels. In the city, the temperature rapidly fell and atmospheric pressure rose in autumn to early winter, and the reverse occurred in spring. RA activity may correlate with changes in temperature and atmospheric pressure.

Serological and Clinical Characteristics of a Large Collection of Incomplete Lupus Erythematosus Patients. Teresa Aberle[1], Virginia C. Roberts[1], Julie M. Robertson[1], Joel M. Guthridge[1], Kathy L. Sivils[1], Astrid Rasmussen[1], David R. Karp[2] and Judith James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: Incomplete lupus (ILE) is defined as a condition in which patients present with signs of systemic autoimmunity and clinical manifestations compatible with systemic lupus erythematosus (SLE) but do not fulfill the American College of Rheumatology (ACR) classification

criteria. Some of these individuals may transition to classified SLE or another systemic autoimmune rheumatic disease; however, many will remain ILE patients without major organ involvement. Differentiating between these groups is clinically challenging and better clinical, demographic and molecular biomarkers which define ILE patients would be clinically helpful and would also allow better identification of high-risk individuals for prevention trials or for closer monitoring.

Methods: For this analysis, we examined participants enrolled to the Lupus Family Registry and Repository (LFRR). Medical records were reviewed to assess for ACR SLE classification criteria and medications; individuals who met only 3 ACR classification criteria were designated as ILE for this study (n=443). Additionally, each participant completed connective tissue screening questionnaires (CSQ), detailed clinical questionnaires, demographic and therapeutic information. Autoantibody testing for ANA with titer/pattern, anti-dsDNA by IIF, anti-cardiolipin (aCL), and autoantibodies against Ro, La, Sm, nRNP and ribosomal P by precipitin, ELISA or by multiplexed assay were also measured.

Results: In this cohort, individuals with ILE (n=443) were most commonly European-American or African-American females on average 46.0 ± 13.9 years of age with an average CSQ score of 6.03 ± 2.39. Among the 443 individuals meeting 3 ACR classification criteria, 311 (70%) never took an immunomodulating drug (methotrexate, azathioprine, hydroxychloroquine/chloroquine, corticosteroids) and 375 (85%) never took a major immunosuppressant (cyclophosphamide, mycophenolate mofetil, cyclosporine, biologic). The most prevalent ACR classification criteria that ILE individuals presented with were ANA (97.2%), immunologic criteria (62.3%), arthritis (44.2%), photosensitivity (24.6%), and hematologic criteria (25.3%). aCL (46.5%), anti-dsDNA antibodies (27.3%), leukopenia (14.6%), and lymphopenia (12.4%) were the most prevalent ACR sub-criteria present. When 13 autoantibodies were examined using a high-throughput multiplex assay, anti-chromatin (34.5%), anti-Ro (27.7%), anti-RNP (24.3%), anti-Sm/RNP (20.9%), anti-dsDNA (14.9%), and anti-Sm antibodies (11.5%) were the most prevalent autoantibodies.

Conclusion: Large numbers of individuals with ILE can be identified and their clinical presentation is characterized by immunologic and hematologic findings, as well as arthritis and cutaneous disease. Multiple lupus-associated autoantibodies are enriched in these patients. Longitudinal studies are warranted to better understand the individuals at the highest risk of transition to systemic autoimmune rheumatic disease, as well as to understand the biologic processes which help prevent individuals from progressing to major organ involvement.

Tai Chi and Yoga Are Effective for Improving Physical Function in Adults with Rheumatoid Arthritis- a Meta-Analysis. Heather Greysen and Kathy Lee. School of Nursing, University of California San Francisco, San Francisco, CA.

Background/Purpose: Recent research suggests that mind-body physical activity such as yoga and tai chi can significantly improve physical function in rheumatoid arthritis (RA). Yoga and Tai Chi are gentle physical activities that promote strength, flexibility, balance and positive mental health. However, it is difficult to assess the effectiveness of these activities given that prior studies have small sample sizes. Therefore we conducted a systematic meta-analysis to assess the effectiveness of these exercises on improvement of physical function in adults with RA.

Methods: Medline was searched using the keywords: Yoga, Tai Chi, Physical Function, and Rheumatoid Arthritis. Included articles were those which measured the pre-intervention and post-intervention physical function scores using a validated physical function measurement tool for adults with a clinical diagnosis of RA who participated in a yoga or Tai Chi intervention lasting at least 6 weeks. Articles were excluded if the population was younger than 18, if the physical function measure was not a validated tool and if the reported results combined disease conditions such as RA and lupus. Effect sizes with confidence intervals were calculated using a fixed effects model for each intervention study by comparing the mean pre-intervention physical function score to the mean post-intervention score.

Results: The Medline search retrieved 219 English articles. The final analysis included 6 articles. There were 3 tai chi studies, 1 RCT and 2 pre/post intervention assessments, with a total of 22 participants. There were 3 yoga studies, 2 controlled clinical trials and 1 pre/post intervention assessment, with a total of 30 participants. There is strong evidence for the effectiveness of Tai Chi (standardized mean difference (SMD) = 1.20, 95% confidence interval (CI) = 0.13, 2.31) and for yoga (SMD = 1.22, 95% CI = 0.10, 2.27) on improving physical function in adults with RA who have participated in a physical activity program for at least 6 weeks. See Forrest plot.

Conclusion: Our data suggest that Tai Chi and Yoga are largely effective in improving physical function in adults with RA. Providers may be able to assist in improving the physical function of this population by discussing health promotion strategies such as yoga or tai chi physical activity programs.

Nutritional Assessment in Patients with Systemic Lupus Erythematosus and Systemic Sclerosis. Sabrina Vagnani[1], Chiara Tani[1], Linda Carli[1], Francesca Querci[1], Alessandra Della Rossa[1], Anna d'Ascanio[1], Ilaria Ermini[2], Marco Ceroti[2], Saverio Caini[2], Domenico Palli[2], Stefano Bombardieri[3] and Marta Mosca[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Molecular and Nutritional Epidemiology Unit, Cancer Research and Prevention Institute, ISPO, Florence, Itay., Florence, Italy, [3]Rheumatology Unit, Pisa, Italy.

Background/Purpose: Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc) can be both associated with various degrees and types of malnutrition, with different pathogenetic mechanisms. It's well known that a balance between nutritional needs, energy intake and nutrients can contribute to the control of the inflammatory processes and can have a beneficial effect on osteoporosis, metabolic syndrome, hypertension, cardiovascular disease and neoplasia. Nutritional therapy is a promising way to approach SLE and SSc, indeed, a diet rich in vitamins, minerals and mono/polyunsaturated fatty acids could promote a beneficial protective effect against inflammatory activity and tissue damage as well as comorbidities. The aim of this study was to assess the nutritional status and food intake of a cohort of SLE and SSc patients in comparison to healthy subjects.

Methods: Twenty patients with SLE and 20 patients with SSc were included in the nutritional assessment. Twenty healthy age and sex matched subjects (H) were used as controls. Food intake was assessed using a Food Frequency Questionnaire, validated in the European Prospective Investigation into Cancer (EPIC) Cohort Study. All individual questionnaires were checked and coded by trained dieticians, computerized and then transformed into estimates of intake for a series of over 30 nutrients. At enrollment, weight, height, waist and hip circumferences were measured for each participant.

Results: The average age of SLE, SSc patients and controls was 36 ± 10, 40 ± 9 e 35 ± 10 years respectively (p=n.s.). The majority of SLE patients (90%) resulted normal weight: the body index mass (BMI) ranged between 18,5 and 24,99 kg/m^2. The rest of the group was overweight (25 ≤ BMI ≤ 29,99 kg/m^2). No obesity or underweight was observed. No differences in BMI were observed between SLE patients and H.

More than half of the SSc patients (66%) was normal weight; the rest of the group was underweight (89% slightly underweight with 17 ≤ BMI ≤ 18,49 kg/m^2 and 13% moderately underweight with 16 ≤ BMI ≤ 16,99 kg/m^2). SSc patients showed a lower mean value of BMI if compared with both SLE patients and H.

The annual frequency consumption of fruit, leafy vegetables, legumes, vegetables, milk, pasta, meat, and fish was similar in all the groups. On the contrary, the annual energy intake (kcal) was significantly lower in SSc patients if compared to SLE patients and H (p<0.02).

Conclusion: In this study we investigated the nutritional status of patients affected by two systemic autoimmune diseases. Our preliminary data showed an inadequate consumption of nutrients in SSc patients if compared to SLE patients and controls, probably due to a more severe gastro-enteric involvement. These results highlight the importance of an individualized nutrition approach in these patients according to disease-related specificities and pharmacological therapies.

Efficacy of Ketoprofen Vs Ibuprofen and Diclofenac for Treating Pain in Patients with Rheumatoid Arthritis: A Systematic Review and Meta-Analysis. Fabiola Atzeni[1], Alessandra Monguzzi[2], Elisabetta Grillo[2], Luigi Lanata[2] and Piercarlo Sarzi-Puttini[1]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]Dompé SpA, Milan, Italy.

Background/Purpose: Patients with rheumatic diseases, including rheumatoid arthritis (RA), describe symptoms such as pain and stiffness as important factors affecting their quality of life. The most widely used drugs to decrease inflammation and manage mild-to-moderate pain in RA patients are NSAIDs. In our previous meta-analysis, we demonstrated that ketoprofen was superior to ibuprofen and/or diclofenac in relieving different kinds of moderate-to-severe pain conditions, and so the aim of this systematic review of the literature and meta-analysis of randomised controlled trials (RCTs) was to compare the clinical efficacy of these drugs in patients with the specific pain associated with RA.

Methods: We made a systematic search of the Medline and Embase databases from their inception to March 2014 in accordance with the Cochrane Collaboration guideline in order to identify RCTs directly comparing the recommended therapeutic doses of oral ketoprofen (50–200 mg/day), ibuprofen (600–1800 mg/day) and diclofenac (75–150 mg/day) for RA pain relief. The meta-analysis was made using the standardized mean difference (SMD) of each included RCT and a fixed effects model.

Results: Five RCTs, involving a total of 456 patients met the inclusion criteria. The meta-analysis showed a statistically significant difference in clinical efficacy in favour of ketoprofen (SMD= 0.34; CI 95% 0.16–0.52; p=0.0002). The heterogeneity test for the efficacy outcome was not statistically significant and equal to zero (χ^2=3.67 - df=4 - P=0.45 - I^2=0%), thus demonstrating the homogeneity of the trials and the validity of the meta-analysis findings. The meta-analysis did not reveal any significant differences between drugs in terms of tolerability (the percentage of patients developing adverse events) or safety (withdrawn patients).

Conclusion: The result of this meta-analysis shows that therapeutic doses of ketoprofen are more efficacious than ibuprofen and diclofenac in managing RA-related pain, thus supporting its use in clinical practice.

Gait Instability in the Elderly: A New Dedicated out-Patients Consultation. Vincent Goeb[1], Bernard Auvinet[2] and Claude Touzard[3]. [1]University Hospital, AMIENS, France, [2]Polyclinic, LAVAL, France, [3]Hospital of Laval, LAVAL, France.

Background/Purpose: Gait instability which represents a common but non-specific complaint, mainly in the elderly, is of major interest in PubMed (6038 references). Gait Instability can be the first step towards risk of falling, exposure to dementia, and disability [1]. Despite the frequency of this symptom and its major devastating consequences, few dedicated out-patients consultations have been initiated, in order to provide a practical management approach. A two year study will highlight the interest and perspectives of such an out-patients consultation.

Methods: Patients were recommended either by their general practitioner for gait abnormalities, or following an out-patients memory consultation. The assessment included six steps: self-questionnaires (*Dizziness Handicap Inventory*, *Hospital Anxiety and Depression Scale*), nurse evaluation, balance tests (one leg balance, Timed Up and Go score, Timed chair rise test), Mini Mental Score, clinical examination, and ambulatory Gait Analysis under simple and dual task conditions (counting backwards). We measured, using a validated ambulatory gait analysis system (Locometrix®), 3 main gait variables: walking speed, cadence, and stride regularity index. According to the results, additional specialized out-patients consultation and tests can be carried out (geriatrician, neurologist, otolaryngologist, brain magnetic resonance imaging. . .).

Results: - 80 patients were included (M=41, F=39, age: 68±14 y, BMI: 25±5 kg/m^2).

- 3 main subgroups of patients with gait complaints were identified (gait instability and cautious gait (n=38), recurrent falls (n=24) and memory impairment (n=18),

- Gait analysis was found with no abnormality in thirteen patients under simple task, in these cases gait abnormalities occurred only during the dual task test

- A broad diversity of diagnosis and syndromes were identified as the main pathology (Mild Cognitive Impairment (n=23), dementia (n=9), leukoaraiosis (n=9),vestibular disease (n=7), frail people (n=9), musculoskeletal disorders including spinal stenosis (n=7), brain stroke attack sequel (n=6), hydrocephaly (n=2), peripheral neuropathy (n=1), Charcot Marie Tooth disease (n=1), myopathy (Facio-scapulo-humeral dystrophy) (n=1), brain haemosiderosis (n=1), and patients without any diagnosis (n=4).

Conclusion: The complaint of gait instability has to be taken into account by the clinician, and necessitates a multi-disciplinary network. Clinical examination remains a key point, but gait analysis provides a measurement of gait instability, which can sometimes occur only under dual task conditions. A decrease in gait variability under the dual task test may explain the mechanism of an unexplained fall. Moreover a large decrease in one or more of the gait variables highlights for the clinician about a decrease in the cognitive reserve of the patient. Thus this condition provides key information to the clinician who has to look for brain pathology in addition to musculoskeletal deterioration.

'It's like the Worst Toothache You've Ever Had' – How Persons with Rheumatoid Arthritis Describe and Manage Pain in Daily Life. Maria Bergström[1], Inger Ahlstrand[2], Ingrid Thyberg[3], Torbjörn Falkmer[4], Björn Börsbo[5] and Mathilda Björk[6]. [1]School of Health Sciences, Jönköping University, Jönköping, Sweden, [2]School of Health Sciences Jönköping University, Jönköping, Sweden, [3]Linköping University Hospital, Linkoping, Sweden, [4]School of Occupational Therapy and Social Work, CHIRI, Curtin University, Perth, WA, Australia, Perth, Australia, [5]Linköping University, Linköping, Sweden, [6]Rehabilitation Center and Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden.

Background/Purpose: Although it is reported that biological treatment has a positive effect on Rheumatoid arthritis (RA), pain intensity is still moderate to high in the majority of those affected, causing activity limitations and thus participation restrictions. Indeed, persons with RA have identified pain as the predominant health status impairment most important to reduce. However, pain in RA is commonly assessed using a visual analogue scale (VAS), which does not capture the complexity of pain and certainly does not address the management of it in daily activities. The purpose was to describe how persons with RA experience and manage pain in their daily life.

Methods: A focus group study was conducted. The participants were recruited with a purposive sample from three Rheumatology Units in Sweden. The inclusion criteria were seropositive RA, ≥4 years duration and pain intensity >40 mm as reported by VAS over the last two clinical visits. Of 77 eligible patients, 33 agreed to participate (34 to 73 years old). Seven semi-structured focus groups discussions were conducted and analyzed using content analysis. A RA-patient research partner was involved in the study confirming the interview guide and the results from a patient perspective. The study protocol was approved by the Regional Ethical Committee.

Results: The analysis revealed four categories: (1) *Pain expresses itself in different ways;* referring to descriptions of RA pain as overwhelming, painful

and as a feeling of stiffness in joints. While pain was described as closely related to fatigue and stress, sometimes it was invisible to others in the participants' social environment. (2) *Managing by easing the pain;* referring to the use of heat and/or cold treatments, medications and activities as distractions. (3) *Managing by adapting to pain;* referring to the strategies of learning to live with the pain, to plan activities in daily life to reduce pain, to use assistive devices or to sometimes simply stop doing some activities. (4) *Managing pain in a social context;* referring to the social environment as being both supportive and uncomprehending, the latter causing the participants to sometimes hide their pain.

Conclusion: Pain in RA was described as complex and multifaceted. To manage pain the participants used a wide range of strategies, ranging from personal strategies to those applied in their social context. This wide range of strategies could possibly complement the traditional methods used in clinical settings to manage pain. These findings further suggest that assessment of pain needs to be extended beyond the linear VAS measurement to cover its complexity.

Analytical and Clinical Evaluation of an Immunoassay for Estimating Immunogenicity of Infliximab and Etanercept in Indian Population. Canna Ghia[1], Shashank Akerkar[2], Shailaja Sabnis[3], Rao RK Uppuluri[4] and Gautam Rambhad[5]. [1]Medical Advisor, Pfizer Limited, India, Mumbai, India, [2]Mumbai Arthritis Clinic and Research Centre, Mumbai, India, [3]Sneh Nursing Home,, mumbai, India, [4]Sri Deepti Rheumatology Centre, Hyderabad, India, [5]Associate Director Medical Services, Pfizer Limited, India, Mumbai, India.

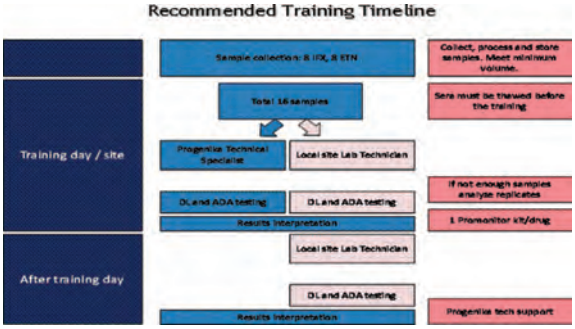
Background/Purpose: Biologic anti-TNFs in India have improved the patient management. Significant proportions of patients lose response over time or do not respond. Possible explanations are suboptimal trough anti-TNF*a* concentrations or antibodies to anti-TNFs[1].

Anti-infliximab antibodies are found in 12%-44% of patients[2] vis-à-vis anti-etanercept antibodies (0%-18%). Anti-etanercept antibodies are without apparent effect on effectiveness or adverse events[2]. Clinicians should have access to immunogenicity testing facility in India.

The aim of this project was to set up and standardize an independent laboratory to test immunogenicity of anti-TNF biologics (infliximab and etanercept) with the help of pharmaceutical partnership.

Methods: Three rheumatologists piloted this project approved by independent ethics committee and carried out in compliance with ICH/GCP guidelines. Pfizer supplied the immunogenicity kits to the independent laboratory (SRL labs). After informed consent, blood (5 mL) was collected before infusion of infliximab (n=8) or injection of etanercept (n=8). Following all precautions, the blood samples were transported to the laboratory. Promonitor® was the ELISA test used for testing of biological levels and anti-TNF*a* antibodies in patients samples. Laboratory staff was trained by Progenika specialist from Spain (Table I).

Table I



DL – Drug level; ADA – Anti-drug antibody

Results: Mean age of 16 patients was 42.06 ± 12.89 years. Table II represents the assay cut points and Table III lists the drug and antibody concentrations for patients.

Table II

	Cut-point	Interpretation
Infliximab	0.035 ug/mL	1) ≤ 0.035 ug/mL – Negative 2) 0.035-1.5 ug/mL – Low positive 3) ≥ 1.5 ug/mL – Positive
Anti-Infliximab antibodies	2 AU/mL	1) > 2 AU/mL – Positive 2) ≤ 2 AU/mL – Negative
Etanercept	0.035 ug/mL	1) ≤ 0.035 ug/mL – Negative 2) ≥ 0.035 ug/mL – Positive
Anti-Etanercept antibodies	142 AU/mL	1) ≤ 142 AU/mL – Negative 2) ≥ 142 AU/mL – Positive

Table III

	Drug level	Interpretation
Infliximab	<0.035 ug/mL (n=4)	Negative
	0.8217 ug/mL (n=1)	Low positive
	Range 2.706 to 8.079 ug/mL (n=3)	Positive
Anti-Infliximab antibodies	>2 AU/mL (n=1; 12.5%)	Positive
Etanercept	4.20 ± 3.23 ug/mL (n=8) (Range 2.000–9.712 ug/mL)	All patients positive
Anti-Etanercept antibodies	<142 AU/mL (n=8)	Negative for all patients

While 4 patients tested negative for infliximab, one patient tested low positive and 3 patients were positive. Anti-infliximab antibody was detected in 1/8 patient (12.5%) and the blood level of infliximab was negligible. When anti-TNF*a* are used, thereapeutic drug monitoring is of help for optimal clinical outcomes. It might be more cost effective to adjust anti-TNFα dosages according to serum drug concentrations[1,3,4]

Conclusion: This study met its objective of setting up and standardizing an independent laboratory for immunogenicity testing of anti-TNF biologics in India.

Why Doesn't Participation in Activity Increase Following Hip or Knee Replacement? Aileen Davis[1], Viji Venkataramanan[1], Jessica Bytautas[2], Rose Wong[1], Lisa Carlesso[1], Anthony Perruccio[3] and Fiona Webster[2]. [1]Division of Health Care & Outcomes Research, Toronto Western Research Institute, University Health Network, Toronto, ON, [2]Department of Family and Community Medicine, University of Toronto, Toronto, ON, [3]Toronto Western Hospital, University Health Network, Toronto, ON.

Background/Purpose: Activity is critical for healthy aging. Our prior work demonstrated that despite improved pain and function, people did not increase their participation in activity post total hip or knee replacement (TJR). Our subsequent qualitative work identified that not only had people given up many activities prior to TJR, they experienced new comorbidity or symptomatic joints that limited their engagement. They also described significant life changes that impacted participation. This study evaluated if these health and social contextual factors were associated with change in participation.

Methods: We conducted a retrospective analysis of our TJR cohort. The primary outcome was change in participation frequency (Late Life Disability Index (LLDI) frequency subscale) pre- to 1 year post-surgery. Predictors were: surgical complication, new comorbidity, another primary TJR, and positive and negative life events (Life Experience Survey) in the year following TJR. Analyses included multivariable regression for the TKR and THR cohorts, adjusting for age, sex, education, pre-surgery BMI, comorbidity, and frequency, and change pre- to 1 year post-TJR in depression, WOMAC pain and function and LLDI limitations.

Results: The 418 TKR patients (mean age=65, 36% male, 69% >high school education) had a mean BMI of 30 and 49%, 6%, 13%, 12% had hypertension, CVD, diabetes, lung disease respectively. 74 episodes of new comorbidity (29 hypertension, 27 CVD, 8 diabetes, 10 lung disease) occurred. 38 (12%) had a complication, 39 another TJR, 151 (36%) reported a positive life event and 273 (65%) a negative life event. In adjusted analyses, pre-operative frequency, having a complication and negative life events were associated with less change in frequency.

The 376 THR patients (mean age=64, 46% male, 77% >high school education) had a mean BMI of 28 pre-surgery. 157 (42%) had hypertension, 28 (7%) had CVD, 31 (8%) had diabetes and 19 (5%) had lung disease. 34 (9%) had a complication and 33 (9%) another TJR. 54 episodes of a new comorbidity were reported (19 hypertension, 19 CVD, 4 diabetes, 12 lung disease). In adjusted analysis, lower pre-surgery frequency was associated with less change and positive life events were associated with greater change in frequency.

Conclusion: Low activity pre-TJR coupled with social context influenced changes in engagement in activity post TJR. Although additional health issues occurred, other than complications of TKR, none were associated with change in frequency. To promote healthy aging in people having TJR, appropriate timing of surgery, pre-surgical interventions to maintain activity and targeted programs post-surgery considering social context are required to enhance activity.

A Multi-Centre Survey of Tolerability Problems for Patients on Regular Methotrexate. David Walker[1], Emmanuel George[2], Sarah Gibson[3], Una Martin[4], Hilary Wrightson[5], Peta S. Heslop[6], Peter Prowse[7], Matthew Kalinowski[7], Adewale O. Adebajo[8], David Marshall[9], Michael Reed[9] and Sandra M. Robinson[6]. [1]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [2]Wirral University Teaching Hospital NHS Foundation Trust, The Wirral, United Kingdom, [3]Wirral University Teaching Hospital NHS Foundation Trust, The Wirral, United Kingdom, [4]Waterford Regional Hospital, Waterford, United Kingdom, [5]Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom, [6]North Tyneside General Hospital, North Shields, United Kingdom, [7]Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom, [8]University of Sheffield, Sheffield, United Kingdom, [9]Inverclyde Royal Hospital, Greenock, United Kingdom.

Background/Purpose: Methotrexate has become the core DMARD for the treatment of Rheumatoid Arthritis. It has also found utility in treating other forms of inflammatory arthritis including Psoriatic, and can be used to reduce corticosteroid therapy. We were struck by the number of patients who complain of side effects that interfere with their lives but are not sufficiently serious to need withdrawal. We surveyed our own patients and found that 57% had at least 1 side effect. We were interested to see if this pattern was repeated in other places in the UK and to determine whether patients reported side effects and adherence differently to Doctors and Nurses.

Methods: A steering group of participants was organised to reflect a wide geographical spread throughout England Scotland and Ireland and included nurses and consultants. The questionnaire was slightly modified to include questions about adherence. 50 consecutive patients on Methotrexate for any reason, who were on a stable dose and planning to continue, were surveyed from each site, 100 patients were surveyed from Glasgow in Scotland.

Results: The patient report rate of any side effect was higher in all of the new centres compared to our first survey ranging between 67% to 86%. The biggest report rate difference was fatigue where there was an increase of up to 3.5 fold of patients reporting this side effect. Up to twice as many patients were reporting other side effects than were reported in the original survey.

Adherence was explored with questions about choosing not to take and forgetting to take. Choosing not to take ranged from 2% to 8%, with high VAS scores for severity of side effects which suggests that the decision to choose not to take Methotrexate was related to severity of side effects. Patient response to forgetting to take Methotrexate showed more variation, ranging from 0 to 18% and they rated lower VAS scores for severity of side effects. It is interesting to note that the survey completed by the nurse produced the highest disclosure of non-adherence by the patients; this may reflect on the way nurses communicate with patients. Numbers of missed weeks ranged between 2 and 4.

Conclusion: These surveys have shown a very high rate of side effects that patients are prepared to put up with for the benefits they get from Methotrexate. The main variation is in the complaint of Fatigue which is very subjective. The variation in admission of non adherence is interesting and merits further study as it may be an underestimate.

Knee Joint Pathology in Patients with Rheumatoid Arthritis and Osteoarthritis Using a Validated Ultrasound Scoring System: A Cross Sectional Study. Karen Ellegaard[1], Marius Henriksen[2], Birgit Falk Riecke[3], Søren Just[4], Jakob Espesen[5], Mohammed Yusuf Naderi[6] and Henning Bliddal[3]. [1]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiksberg, Denmark, [2]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Copenhagen F, Denmark, [3]The Parker Institute, Copenhagen, Denmark, [4]Svenborg Sygehus, Svendbotg, Denmark, [5]Odense Universitetshospital, Odense, Denmark, [6]Esbjerg Sygehus, Esbjerg, Denmark.

Background/Purpose: Ultrasound (US) signs of inflammation in joints are synovial hypertrophy, effusion, and Doppler activity (increased perfusion), which have been demonstrated in both osteoarthritis (OA) and rheumatoid arthritis (RA). It might be expected that inflammatory signs are more pronounced in patients with RA however, a comparison of RA and OA with respect to US changes remains to be performed.

Methods: A standardized US examination and scoring technique in patients with OA has been developed and validated in a group of patients with knee OA. This validated technique was applied on a group of RA patients and a group of OA patients – both with knee involvement. The diagnoses of OA and RA were according to the ACR criteria. RA and OA patients were examined by US according to the standardized procedure at baseline before onset of biologics. In the present study the validated US scoring were performed in all patients (RA and OA). All US images were scored by the same person (KE). The amount of synovial hypertrophy (mm) and Doppler (+/− scored as 1/0) were measured in five positions (supra patellar; medial and lateral joint space and recess). Synovial hypertrophy measures for all 5 positions were summed and Doppler presence was summed for the medial and lateral joint space and recess (4 positions). Presence and size of Baker's cyst were registered and any Doppler activity in or around the cyst was registered. Statistics: The difference between US findings in the two diseases was evaluated with both non-parametric and parametric statistics. The level of significance was $2\alpha=0.05$.

Results: Eighteen RA patients were included, the percentage of women was 66% and mean age was 66 years (range26.3–73). The mean DAS28 was 4.9 (range 3.5–7.0). The OA group consisted of 99 patients the percentage of women was 59 and the mean age was 64 (range42.3–84.4). See table.

Conclusion: On US examination statistically significantly more synovial hypertrophy and more Baker's cysts were seen in the OA knees as compared to the RA knees. Little Doppler activity (increased blood flow) was found with no difference between the two patient groups. These results support that inflammation is an important pathological feature in OA.

Factors Influencing Health Related Quality of Life (HR-QOL) for Korean Patients with Rheumatoid Arthritis. SeungIn Paek[1], Kyeong Yae Sohng[2] and Sung-Hwan Park[3]. [1]ST Mary's Hospital, Seoul, South Korea, [2]The Catholic Univ of Korea, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: The purpose of this study was to identify factors influencing the Health-related quality of life (HR-QOL) for Korean patients with rheumatoid arthritis and factors associated with each domain of the Health-related quality of life(SF-36).

Methods: A total of 299 patients with rheumatoid arthritis were recruited from one University Hospital in Seoul, Korea. Their clinical and socio-demographic data were widely collected by means of interviews, self-administered questionnaires and clinical examinations. Disease activity score in 28 joints (DAS28), patient visual analogue pain scale (100mm), functional disability measured with Korean Health assessment questionnaire (KHAQ), The Functional Assessment of Chronic Illness Therapy-Fatigue, (FACIT-Fatigue), Centers for Epidemiologic Studies Depression (CES-D), sleep scale were assessed. The HR-QOL was assessed by Short Form Health Survey-36 (SF-36). Pearson's correlation coefficient, stepwise multiple regression analyses were performed to determine the factors influencing HR-QOL and associated with each domain of the SF-36.

Results: Of the 299 subjects with RA, 272 (91%) were women and mean age was 49.5±10.5 years. The mean disease duration was 117 ± 91.2 months. The mean scores of SF-36 physical component summary (PCS) and mental component summary (MCS) were 42.5 ± 7.9, 45.8 ± 10.9.The mean scores of DAS 28, functional disability (KHAQ), visual analog pain scale were 3.83±1.41, 0.57±0.63, 34.95±24.43 and FACIT-Fatigue was 36.25±10.43, depression (CES-D) was 15.28±10.07 and sleep quality scale was 44.58±8.46.

On the socio-demographic features, educational level, occupation state, exercise were associated with HR-QOL (SF-36).History of hospitalization within 2 years, ESR(mm/hr), CRP(mg/dl), DAS28 score, visual analog pain, KHAQ, disability index, FACIT-Fatigue, depression (CES-D) and sleep quality scale were associated with all domains of HR-QOL (SF-36). Visual analog pain was strong association with HR-QOL(SF-36) domain of bodily pain (BP) (r=−0.74,p=<.0001) and depression(CES-D) was also strong association with mental component summary (MCS)(r=−0.73,p=<.0001).

In multiple stepwise regression model, KHAQ disability index (p=<.0001) was significant predicting variable of the physical component summary (PCS) and depression (CES-D) (p=<.0001) was significant predicting variable of the mental component summary (MCS) of HR-QOL (SF-36).KHAQ disability index (p=<.0001) was significant predicting variable on the domain of PF(Physical Functioning), RP(Role-Physical), SF(Social Functioning) and the FACIT-Fatigue (p=<.0001) was significant predicting variable on the domain of GH(General Health), RE(Role-Emotional), VT(Vitality) of HR-QOL (SF-36).

Conclusion: The factors influencing HR-QOL were functional disability, fatigue, depression and pain. However various factors are influencing the quality of life for patient with rheumatoid arthritis. It suggests that all healthcare professionals should pay more attention to improve fatigue, depression, pain and prevent progressing disability of patient with rheumatoid arthritis.

Prevalence and Determinants of Treatment Adherence Among Patients with Rheumatoid Arthritis. Maria Celeste Orozco[1], Maria Florencia Marengo[1], Christian A. Waimann[1], Ana Inés Marcos[2], Amelia Granel[2], Sofia Velez[3], Federico Zazzetti[3], Juan C. Barreira[4], Paula Kohan[5], Oscar L. Rillo[6], María Victoria Collado[7], Graciela Gómez[8], Ricardo V. Juárez[9], Veronica Lencina[9], Andrea D'Orazio[10], Gustavo Rodriguez Gil[10], Mariana Salcedo[11] and Gustavo Citera[1]. [1]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Hospital San Roque de Gonnet, La Plata, La Plata, Argentina, [3]Hospital Britanico, Buenos Aires, Argentina, [4]British Hospital, Buenos Aires, Argentina, [5]Hospital Gral. de agudos Dr. E. Tornú, Buenos Aires, Argentina, [6]Hospital General de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [7]Instituto de Investigaciones Medicas Alfredo Lanari, Buenos Aires, Argentina, [8]Insituto de Investigaciones Medicas de la UBA, Capital Federal, Argentina, [9]Hospital Señor del Milagro, Salta, Argentina, [10]Hospital Municipal de agudos Dr. Leonidas Lucero, Bahía Blanca, Argentina, [11]Consultorio Privado, San Nicolás, Argentina.

Background/Purpose: Treatment adherence is a crucial part of successfully managing rheumatic diseases such as Rheumatoid Arthritis (RA). Low adherence to treatment has been related to poor radiographic and clinical outcomes in these patients. The aim of our study was to determine the prevalence and factors associated with non-adherence in patients with RA.

Methods: We designed a multicenter cross sectional study. Consecutive patients with RA (ACR'87 and or ACR/EULAR 2010) were recruited from 7 rheumatology clinics. Data collected included comorbidities, demographic and clinical variables. Patient-reported clinical outcomes included the Clinical Disease Activity Index (CDAI) and the Health Assessment Questionnaire (HAQ). Adherence to treatment was assessed using the Compliance Questionnaire Rheumatology (CQR; 0 – 100, 0 low adherence). Patients were categorized as having low or acceptable adherence using the traditional cutoff (≤80). Frequencies and distribution of adherence were calculated. The association between adherence and clinical/demographic variables were assessed using univariate and multivariate models.

Results: Three hundred and thirty-eight patients were included, 84 % were female, mean age was 53 ± 12 years, disease duration 13 ± 10 years, CDAI 13 ± 11 and HAQ 1.00 ± 0.75. Mean adherence to the treatment regimen as determined by CQR score was 86 ± 10. Two hundred and sixty-two patients (81%) had acceptable level of adherence. These patients had significantly higher age (p=0.03), higher level of education (p=<0.01), were more frequently unemployment (p=0.03), and had longer disease duration (p=<0.01). After adjusting for multiple confounders, only longer disease duration (OR= 1.1, CI95%=1.01–1.08, p =0.04) and live alone (OR= 0.3, CI95%=0.1–0.6, p = <0.01) remained significantly associated with acceptable adherence (Table 1).

Conclusion: In our population, only one fifth of patients with RA showed low self-reported adherence to treatment. These patients had shorter disease duration and more frequently live alone. Physicians must be aware of patients at high risk of low treatment adherence in order to avoid long-term consequences.

Table 1 Logistic regression using level of adherence as dependent variable (CQR ≥80 =1; CQR <80 =0)

	OR	95% Confidence interval	p-value
Age (years)	1.02	0.99–1.05	0.10
Female	0.90	0.39–2.09	0.81
Disease duration (years)	**1.04**	**1.00–1.08**	**0.04**
Years of education	1.02	0.95–1.11	0.54
Number of comorbidities	1.2	0.81–1.89	0.33
Live alone	**0.26**	**0.11–0.61**	**0.002**

Aligning Ethics with Digital Health Technologies and Shared Decision-Making: Interview Accounts of Patients and Clinicians. Anne F. Townsend[1], Paul Adam[2], Jenny Leese[1], Linda C. Li[1], Michael McDonald[3], Sheila Kerr[4], Gordon Whitehead[4] and Catherine Backman[3]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]University of British Columbia, Vancouver, BC, [4]Arthritis Patient Advisory Board, Richmond, BC.

Background/Purpose: Medical ethics evolves as health care develops. Digital health technologies are transforming health care delivery and patient and clinician relationships. Ethical approaches are shifting from a clinician focus on beneficence and improving patient health as emphasized in the Hippocratic oath, to patient-centered models of care, which emphasize patient autonomy in medical decision-making and patients as partners in their care. We have little understanding however, of how digital technologies promote a more patient-centered model of decision-making. Specifically we know little about how clinicians are altering their practices to support patients in making informed choices, and how patients are making treatment decisions. The study aimed to examine the role of various digital technologies in supporting patient choice and informed shared decision-making.

Methods: We present preliminary findings of a qualitative interview study, informed by narrative and phenomenology to understand patient and clinicians' experiences of new technologies and shared decision-making. Eligible participants were: adults with multi-morbidity including arthritis; clinicians with relevant caseloads. Recruitment was via online ads, notices, and word of mouth. The interview guides were consistent for both groups and explored broadly: 1) Use of a range of digital technologies e.g. apps, devices, Internet information, social media; 2) How use influenced illness management and patient-clinician interactions and relationships. An iterative, con-

stant comparative analysis with independent open coding of transcribed data by 2 researchers is ongoing.

Results: We purposively sampled 18 participants for maximum variation (11 patients, 7 clinicians) to take part in 2 in-depth interviews. Three emerging themes have been identified. First, participants described how digital health technologies were changing their roles and responsibilities, involving new types of 'work' for both patients and clinicians. Second, patients and clinicians emphasized the benefits of the Internet in preparing patients for discussions in consultations, while identifying the potential burdens of accessing extensive and unreliable sources. Third, mutual trust and respect was integral to effective patient-clinician discussions, sharing online information and informed, shared decision-making.

Conclusion: Preliminary findings imply that new technologies support autonomy in terms of informed patient choice and shared decision-making, but only when mutual trust and respect underpin patient-clinician interactions. Understanding how patient-clinician relationships are changing in the era of digital health is critical for ethical, clinical practice.

A New Meta-Analysis on Safety of Ketoprofen Vs Ibuprofen and Diclofenac: Risk and Benefit of Nsaids Beyond Efficacy Meta-Analysis. P. Sarzi-Puttini[1], F. Atzeni[1], Luigi Lanata[2], Alessandra Monguzzi[2] and Michela Bagnasco[2]. [1]Rheumatology Unit, L. Sacco University Hospital of Milan, Milan, Italy, [2]Dompé SpA, Milan, Italy.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are widely used for management of mild-to-moderate pain, chronic inflammatory and degenerative joint diseases. Among NSAIDs, ketoprofen, ibuprofen and diclofenac have been widely used for the last 30 years and particular attention should be taken into account when choosing a NSAIDs in order to achieve the best risk/benefit ratio for patients. Recent publication of our comparative meta-analysis demonstrating that efficacy of oral ketoprofen is greater than ibuprofen and/or diclofenac, raised many questions about safety profile of these molecules. For this reason we performed this meta-analysis of randomised controlled trials (RCTs) in order to compare the safety of orally administered ketoprofen vs ibuprofen and diclofenac and to obtain a complete comparative assessment of risk/benefit profile of these NSAIDs.

Methods: A systematic literature search was performed on main databases (Medline, Cochrane Central and Embase) until July 2013 to identify RCTs comparing directly therapeutic doses of oral ketoprofen (50–200 mg/day) vs ibuprofen (600–1800 mg/day) or diclofenac (75–150 mg/day). In accordance with the Cochrane Collaboration guideline, two rheumatologists carried out independently study selection.

Results: A total of 10 RCTs involving 826 patients met the inclusion criteria. Five of the 10 RCTs included patients with systemic rheumatic diseases. Findings from this meta-analysis did not reveal any difference in safety for ketoprofen compared to ibuprofen and/or diclofenac. The difference between ketoprofen and the pooled ibuprofen/diclofenac data was not statistically significant (risk ratio; RR=1.02, 95% CI 0.78–1.33; P=0.92) at all point-estimates of the mean weighted size effect. Further sub-analysis also confirmed that ketoprofen was not significantly different to either diclofenac (RR=0.86; 95% CI 0.51–1.45; P=0.58) or ibuprofen (RR=1.08; 95% CI 0.79–1.48; P=0.65) at all point-estimates. Heterogeneity for the safety measures analysed were not statistically significant for all meta-analyses.

Conclusion: Findings of this meta-analysis show that ketoprofen is well tolerated, with a safety profile at least comparable to ibuprofen and diclofenac, and no serious AEs. In light of superior efficacy demonstrated in our previous meta-analysis, these further safety results support recommendation that oral ketoprofen has the best risk/benefit profile vs ibuprofen and diclofenac.

Pharmacist-Developed Letters May Enhance Success in Obtaining Insurer Approval for Off-Label Use of Biologics. Jessica F. Farrell[1], Lee S. Shapiro[1], Joel M. Kremer[2] and Aixa Toledo-Garcia[1]. [1]The Center for Rheumatology, Albany, NY, [2]Albany Medical College and the Center for Rheumatology, Albany, NY.

Background/Purpose: A growing number of publications suggest that biological DMARDs, predominantly approved for RA, can be efficacious treatment options for several rare rheumatic diseases. These potentially efficacious treatments are often "out of reach" because of inability to obtain insurance coverage. Insurers routinely deny coverage of "off-label use" because of the absence of double-blind placebo controlled studies demonstrating efficacy. This type of evidence is only infrequently available for these rare rheumatic diseases. The medical director for the insurer often has no familiarity with the disease, the potential consequences of non-treatment or the inadequacy of more accessible therapies. The addition of a pharmacist as part of a multidisciplinary team can provide an effective resource in successfully navigating the medication prior authorization process.

Methods: Our approach involves the use of a clinical pharmacist in development of comprehensive, evidence-based appeal letters. These letters are drafted by a clinical pharmacist (PharmD.) and pharmacy interns who perform extensive literature searches including all relevant case reports and clinical data related to disease state and drug therapy. The PharmD's then summarize that data as justification for use of therapy. Appeal letters are then drafted to include an explanation of the patient's circumstances, disease manifestations, progression, prognosis, as well as the treatment history, and the comprehensive review of current literature on the rationale for and experience with the proposed therapy.

Results: Since January 2009, our pharmacist has drafted and submitted approximately 141 letters. We have decreased the rate of initial "denials" for off-label use to near zero. We estimate that we have saved the physicians and support staff approximately 100 hours while achieving the desired outcome for both patients and physicians. We estimate that the average rheumatologist will have a need for between 5– 15 of these letters per quarter. If we calculate the value of physician time based upon billable dollars, we would estimate a net saving for individual physicians of between $1000 and $4000 hours per quarter. Additionally, we have decreased the time associated with the approval process from an average of 4–6 weeks to less than 4 weeks.

Conclusion: The issuance of an evidence based approach to the off-label appeal process has decreased the time associated with approvals and prevented the need for mention of litigation or liability. Due to time constraints, the ability to provide this level of patient care would not be possible without the assistance of the clinical pharmacist. The practice of pharmacy has expanded its scope to include extensive clinical training beyond the preparation and dispensing of medication. Pharmacists have the capacity to provide a wide range of patient-oriented services. As part of their education, PharmD's have extensive training in scientific literature evaluation and drug information. Based on our experience and success, it is clear that PharmD's are an underutilized resource in the ambulatory care setting and can greatly improve patient-care outcomes.

2445

A Distinct Profile of Circulating Microparticles Is Associated with Disease Features in Rheumatoid Arthritis Patients and Impairs Endothelial Functionality in Vitro. Javier Rodríguez-Carrio[1], Mercedes Alperi-López[2], Patricia López[1], Sara Alonso-Castro[2], Santiago Rubén Carro-Esteban[1], Javier Ballina-García[2] and Ana Suárez[1]. [1]University of Oviedo, Oviedo, Spain, [2]Rheumatology Department, Hospital Universitario Central de Asturias, Oviedo, Spain.

Background/Purpose: Cell-derived microparticles (MPs) could be considered biomarkers of cell damage and activation and they are thought to have a role in cardiovascular (CV) and inflammatory diseases. Since Rheumatoid Arthritis (RA) is characterized by immune and endothelial activation, the main aim of this study was to evaluate MP counts in RA patients.

Methods: MPs were analyzed by flow cytometry following a total-labelling procedure in platelet-poor plasma from 33 healthy controls (HC), 72 individuals with marked CV risk (CVR: diabetes, n=24; dyslipidemia, n=27; and hypertension, n=41) and 114 RA patients (61.4% RF, 61.4% αCCP, DAS28: 3.61(1.97), 42.1% erosive disease). Different subsets were identified by their surface markers: platelet- ($CD41^+$, PMPs), endothelial- ($CD146^+$, EMPs), granulocyte- ($CD66^+$, GMPs), monocyte- ($CD14^+$, MoMPs) and Tang-derived ($CD3^+CD31^+$, Tang-MPs). TNFα serum levels were quantified by ELISA. In vitro assays on Matrigel with HMEC-I cells were performed to assess the effect of MPs on endothelial functionality. Clinical and immunological parameters as well as traditional CV risk factors (diabetes, hypertension, dyslipidemia, obesity and smoking) were registered from clinical records and all data were analyzed by Principal Component Analysis (PCA).

Results: Total MPs count was increased in RA compared to both HC ($p<0.0001$) and CVR ($p=0.0009$) and was positively correlated with traditional CV risk factors (BMI, TC/HDL ratio, triglycerides and number of risk factors). Additionally, specific MPs subsets were increased in RA (EMPs $p<0.0001$, GMPs $p<0.0001$, Tang-MPs $p=0.006$ and MoMPs $p=0.028$). Clinical data were integrated with PCA and 4 components were identified. Notably, different MP subsets correlated with different components (table 1), thereby involving specific disease features in MPs profile. Interestingly, TNFα correlated with Tang-MPs in RA after adjusting by traditional risk factors ($r=0.218$, $p=0.036$). Finally, MPs from RA patients were able to impair endothelial cell functionality (measure as tube formation and number of branching points) in vitro in a dose-dependent manner, linked to an upregulation of endothelial activation markers (CD62E, CD144 and VEGFR2). This effect appeared even within the physiological range and it was not present with HC or CVR MPs.

Conclusion: MPs analysis in RA patients revealed an increased damage in several cell types. Circulating MPs from RA patients displayed a unique quantitative and qualitative profile as the result of both disease-specific and traditional CV risk factors. These differences are independent of comorbidities. Accordingly, this MP profile could underlie the detrimental effects on endothelial cells in vitro, thus supporting their role as biomarkers of endothelial damage and vascular repair failure.

DNA Methylation Profiles That Distinguish Rheumatoid Arthritis from Osteoarthritis in Fibroblast-like Synoviocytes Can be Detected in Immune Cells from Peripheral Blood. Brooke Rhead[1], Calliope Holingue[1], Michael Cole[1], Xiaorong Shao[1], Hong L. Quach[1], Diana Quach[1], Lisa F. Barcellos[1] and Lindsey A. Criswell[2]. [1]University of California, Berkeley, Berkeley, CA, [2]University of California, San Francisco, Rosalind Russell/Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease with potential to cause substantial disability, primarily due to the erosive and deforming process in joints. RA etiology is complex, with contributions from genetic and non-genetic factors. Epigenetic changes, such as altered patterns of DNA methylation, are also present in RA. Recent work by Firestein and colleagues (Nakano, 2013) compared genome-wide DNA methylation profiles in synovium-derived fibroblast-like synoviocytes (FLS) from RA patients and osteoarthritis controls and identified a set of differentially methylated genes that appear to distinguish these two forms of arthritis. Given the greater accessibility of peripheral blood compared to synovium-derived FLS, we set out to determine whether similar methylome signatures were present in immune cell subsets in peripheral blood.

Methods: We generated over 400 genome-wide DNA methylation profiles for 101 women (70 cases and 31 controls) using Illumina HumanMethylation450 BeadChips. Four FACS-sorted immune cell types were assayed for each individual: CD14+ monocytes, CD19+ B cells, CD4+ memory T cells, and CD4+ naive T cells. All samples were background subtracted using the lumi Bioconductor package and normalized using all sample mean normalization (ASMN) followed by beta-mixture quantile normalization (BMIQ). All study individuals were fully characterized for whole genome SNP profiles using the Illumina OmniExpress BeadChip. We excluded CpG sites near SNPs known to be common (>1%) from analysis, as well as sites with a low detection p-value, leaving 367,704 sites for analysis.

Results: We examined the top differentially hypo- and hypermethylated (n = 17 and 18, respectively) loci from the Firestein study in each immune cell type and found strong evidence for overlapping RA methylome signatures between FLS and immune cells. The most significantly differentially methylated genes in cases vs. controls include STK24, ADAMTS2, CABLES1, CD55, COL4A1, COL4A2, CYFIP1, FOXO1, ITGB8, ITGBL1, MAP3K1, PHLPP1, PTPN14, RXRA, TGFBR2, and TIMP2. The strongest evidence for replication of differential methylation in candidate gene regions was observed for naive CD4+ T cells; more than 20% of CpG sites tested were hypermethylated in cases compared to controls.

Conclusion: Methylation patterns that distinguish RA cases from controls in FLS are also present in immune cells from peripheral blood. Our investigation of DNA methylation underscores the importance of epigenetic mechanisms in RA pathogenesis and represents the largest study, to date, of methylome profiles derived from immune cells.

The Role of TET3-Mediated DNA Demethylation By Pro-Inflammatory Cytokines in Rheumatoid Arthritis. Kazuhisa Nakano, Kunihiro Yamaoka, Akira Kurozumi, Akio Kawabe, Kaoru Yamagata and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: In the pathogenesis of Rheumatoid arthritis (RA) RA fibroblast-like synoviocytes (RA FLS) exhibit a unique aggressive phenotype that contributes to the cytokine milieu and joint destruction. We previously revealed that persistent exposure of pro-inflammatory cytokines contribute to passive DNA demethylation through decreased expression of DNMT in FLS. We here assessed the involvement of a novel active DNA demethylation enzyme, Ten-eleven-translocation (TET), in cytokine-mediated activation of RA-FLS.

Methods: FLS were obtained from patients with RA and osteoarthritis (OA) synovium at total joint replacement and studied in the 4th through 6th passage. The study was approved by the ethical committee of the university and informed consents were obtained by each patient. cDNA, Nuclear extracts and genomic DNA were purified from control or stimulated FLS. Gene expression was determined by qPCR and protein expression by Western blot and immunostaining. 5-hmC was determined by dot blot. Secretion of cytokines and MMPs was measured by Cytometric Bead Array and latex agglutination method. Cell migration was assessed using a wound healing scratch assay.

Results: TET3 and its product, 5-hydroxymethylcytosine (5-hmC), are detected in the intimal lining layer of synovium in patients with active RA, while TET1 and TET2 were observed marginally there. TET3 was characteristically expressed in both cytoplasm and nuclear of FLS, whereas TET1 and TET2 were not detected in nucleus. Although unstimulated RA and OA FLS expressed similar amounts of TET3 mRNA (n=6 each; n.s.), stimulation with TNFα (10 ng/ml) and IL-1β (1 ng/ml) for 2 hrs significantly increased TET3 mRNA expression in FLS (>3-fold and >4-fold respectively). Western blot analysis showed expression levels of TET3 protein in nucleus in RA FLS were significantly increased by stimulation with TNFα within 48 hrs and were maintained for 96 hrs. Dot blot analysis showed that 5-hmC was also increased by TNFα when FLS were cultured continuously for 96 hrs with TNFα. TET3-knockdown of FLS with siRNA not only inhibited TNF-induced expression of key migratory genes, including CCL2 and ICAM-1, but also reduced TNF-induced FLS-migration completely.

Conclusion: We initially report that a novel DNA methylation enzyme TET3 is characteristically induced in RA FLS through TNF/IL-1 stimulation.

Taken together with our previous report, persistent exposure to pro-inflammatory cytokines in the synovium not only decreases DNMT expression but also increases TET3 expression, resulting in promotion of DNA demethylation. In addition to demonstrating a critical role for TET3 in FLS in cytokine milieu, our study suggests that targeting the TET3–5-hmC pathway may be a therapeutic strategy for preventing FLS from TNF-mediated imprinting in RA.

DNA Methylation Analysis of Lymph Node Stromal Cells of Rheumatoid Arthritis Patients. Emmanuel Karouzakis[1], Caroline Ospelt[1], Janine Hähnlein[2], Renate E. Gay[3], Paul Peter Tak[4], Danielle Marie Gerlag[5], Michel Neidhart[1], Steffen Gay[1] and Lisa G.M. van Baarsen[2]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Zurich University Hospital, Zurich, Switzerland, [4]University of Cambridge,Cambridge and GlaxoSmithKline, Stevenage, United Kingdom, [5]GSK,Clinical Unit Cambridge,R&D Projects Clinical Platforms & Sciences, Cambridge, United Kingdom.

Background/Purpose: Lymph node stromal cells (LNSC) build the scaffold that enables migration and interaction of lymphocytes in the lymph node. More recently, it has been shown that during inflammation LNSC play a crucial role in shaping the immune response and maintaining tolerance. Since DNA methylation changes have been reported in autoimmune diseases, we analysed the DNA methylation profile of LNSC from healthy individuals and rheumatoid arthritis (RA) patients.

Methods: Needle biopsies of inguinal lymph nodes were strained through a 70μm nylon mesh and the resulting stromal part was cultured in DMEM with 10% FCS. Adherent cells were passaged 4 times before total genomic DNA was isolated. DNA samples (healthy n=4 and ACPA+ RA n=5) were subjected to the Illumina HumanMethylation 450 array, which allows the analysis of 485.000 methylation sites per sample. It covers the promoters, 5-UTR, 3-UTR, gene body, first exon of 99% RefSeq genes and 96% of CpG islands. After strict quality control analyses we calculated the differential methylated regions using the COHCAP bioinformatics package in R (version 3.0.1). The results obtained by array analyses were validated for a selected number of probe sequences by pyrosequencing.

Results: The bioinformatics analysis between healthy and RA LNSC revealed 557 significantly differential methylated CpG sites (delta β-value >0.25, $p<0.05$. We found 57% of the differentially methylated CpG sites to be hypomethylated and 43% hypermethylated. 374 genes were found to be associated with the differential methylated sites. Functional annotation clustering was performed using the hypermethylated (167 genes) and hypomethylated (207) genes. For the hypermethylated genes, the highest enrichment was associated with homophylic cell adhesion and positive regulation of cell death pathways. For the hypomethylated genes, pathways associated with cell adhesion, cell projection, regulation of cell growth and cell motion were significantly differentially methylated. Next, we analysed for specific genes with differentially methylated CpG islands. Interestingly, we identified the hypermethylated genes CXCL4 (RA β-value=0.46 - healthy β-value=0.20, p=0.008) and Lactotransferin (RA β-value=0.52 – healthy β-value=0.25 p=0.016) that have previously associated with RA. In addition, other gene targets were found to be strongly hypomethylated such as NTGN1 (RA β-value =0.13 - healthy β-value=0.40, p=0.016) and KCNE1 (RA β-value=0.09-healthy β-value=0.35, p=0.010).

Conclusion: This the first study reporting epigenetic modifications in LNSC of RA patients. Specifically, DNA methylation analysis identified interesting known and novel gene targets altered in the LNSC of RA patients.

Microrna-346 Regulation of Follicular Helper T Cells Is Involved in the Pathogenesis of rheumatoid Arthritis Disease. Xinyi Tang[1], Jie Ma[2] and Shengjun Wang[3]. [1]Jiangsu University Affiliated People's Hospital, Zhenjiang, China, [2]Jiangsu University Affiliated People's Hospital, Zhenjiang, China, [3]Jiangsu University Affiliated People's Hospital, Zhenjiang, China.

Background/Purpose: Follicular helper T (Tfh) cells have been identified as a new subset of effector helper T cells that are essential in regulating the development of antigen-specific B-cell immunity. Tfh differentiation is regulated by specific transcription factor Bcl-6. Several studies have certified the vital role of Tfh cells in the pathogenesis of autoimmune diseases. MicroRNAs (miRNAs) could negatively regulate gene expression post-transcriptionally and participate in the development of autoimmunity. The purpose of this study is to investigate the function of miR-346 in enhancement of Tfh cells during the pathogenesis of RA.

Methods: We detected the proportion of Tfh cells, concentration of IL-21, relative expression of Bcl-6 and IL-21 mRNA as well as miR-346 in RA patients and healthy donors. A Luciferase reporter assay was undertaken for directly proves that Bcl-6 is the functional target of miR-346.The level of Bcl-6 protein in Jurkat cells which were transfected with the miR-346 mimics was detected. Percentage of $CD4^+CXCR5^+$ T cells in circulating $CD4^+$ Tcells from healthy donor transfected with miR-346 mimics was examined.

Results: A significantly increased frequency of $CD4^+CXCR5^+$ and $CD4^+CXCR5^+ICOS^{high}$ circulating Tfh cells was detected in RA patients, compared with that in healthy controls. Frequency of the circulating Tfh cells showed a positive correlation with anti-CCP antibody in plasma from RA Patients. It has reported that Tfh differentiation is regulated by specific transcription factor Bcl-6. IL-21 is derived from activated Tfh cells and could enhance B cells to produce antibodies. In this study, Bcl-6 and IL-21 mRNA expression in $CD4^+$T cells of RA patients was higher than that in control. Also, a higher IL-21 concentration was found in RA Patients.

A sequence motif of the 3'UTR of Bcl-6 matches with miR-346. And level of miR-346 expression in circulating $CD4^+$T cells from RA patients was significantly downregulated. We found that miR-346 inhibited the luciferase activity of reporters containing the wild-type UTR1 or UTR2 but not that of the reporter with a mutated 3'UTR unable to bind miR-346.

As Bcl-6 is also expressed in Jurkat cells, miR-346 suppressed the expression of Bcl-6 mRNA in a dose-dependent manner. Manipulation of miR-346 in Jurkat cells also regulated the amount of endogenous Bcl-6 protein.

The percentage of $CD4^+CXCR5^+$ T cells in miR-346-transfected group was decreased than that in control group. It could certify the negative function of miR-346 in the differentiation of Tfh cells.

Conclusion: In summary, we found that miR-346 could regulate Tfh cells differentiation by targeting Bcl-6, and in RA patients, miR-346 expression was downregulated, which correlated with increased proportion of Tfh cells and disease severity. Collectively, our results may facilitate the validation of miR-346 as a new therapeutic target for the treatment of patients with rheumatoid arthritis.

Downregulation of Mirna-196a and Its Downstream HOXC8 Target Gene in Rheumatoid Arthritis Synovial Fibroblasts. Maria Filkova[1], Michelle Trenkmann[1], Borbala Aradi-Vegh[1], Lenka Pleštilová[1], Joanna Stanczyk[1], Beat A. Michel[2], Ladislav Senolt[3], Renate Gay[1], Steffen Gay[4] and Astrid Juengel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich Schlieren, Switzerland, [2]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [3]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [4]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Comprehensive analysis of 260 miRNAs suggested a downregulation of miR-196a in rheumatoid arthritis (RA) synovial fibroblasts (SF) compared with osteoarthritis (OA) SF. Mature miR-196a originates from 2 regions in human genome: MIR-196-A1 (chromosome 17) and MIR-196-A2 (chromosome 12) both located in HOX- gene clusters. The altered expression of miR-196a has been reported in multiple conditions, such as cancer. Our aim is to analyze the expression and regulation of miR-196a in cells from patients with RA.

Methods: Expression of pri-miRNA precursor and mature miR-196a was analyzed in RA/OA synovial tissue, SF under proinflammatory and hypoxic conditions, peripheral blood mononuclear cells (PBMC), synovial fluids and sera using TaqMan RealTime-PCR. Chromatin immunoprecipitation (ChIP) was used to analyze histone methylation and acetylation within both promoters MIR-196A1 and MIR-196A2 in SF. Ilumina sequencing with subsequent single assay verification was performed following Lipofectamine transfection with pre-miR-196a or anti-miR-196a to identify miR-196a targets genes.

Results: Expression of miR-196a is significantly lower in RA synovial tissues (n=6) compared with OA (n=4, p=0.01) as well as RASF (n=19) compared with OASF (n=15, p<0.0001). No difference was observed in PBMC or synovial fluids while a lack of cell-free miR-196a was detected in RA and OA sera. The precursor pri-miR-196A1 was expressed neither in RA nor OA SF while pri-miR-196A2 was significantly downregulated in RASF vs. OASF (n=4 each, p<0.05). Expression of miR-196a in SF was not affected by proinflammatory cytokines (TNFα, IL-1β), TLR ligands (LPS), 1% hypoxia or 5'AZA mediated DNA demethylation. ChIP of MIR-196A2 promoter revealed significantly higher methylation of repressive H3K27me3 (p=0.005), lower methylation of activating H3K4me3 (p=0.001) and hypoacetylation of H3 (p=0.008) in RASF (n=13) compared to OASF (n=10) explaining the downregulation of the mature miR-196a in RASF. Using Ilumina sequencing after pre-miR transfection of RASF (n=2) HOXC8 and HOXA7 were identified as most likely direct miR-196a targets. Downregulation HOXC8 (p=0.01) as well as HOXA7 (p<0.0001) pre-miR-196a transfection (n=5), and upregulation of HOXC8 (p=0.11) and HOXA7 (p=0.56) and upon anti-miR-196a transfection (n=5) suggest these HOX genes as direct targets. However, unexpectedly, significant downregulation of HOXC8 was observed in RASF (n=17) vs. OASF (n=18, p=0.004) while the expression HOXA7 was not significantly different between RASF and OASF (p=0.91).

Conclusion: MiR-196a is one of the few miRNA showing a significant dowregulation in resident cells of synovial tissue in RA patients regulated by histone modifications. Although HOXC8 and HOXA7 are suggestive of being direct targets of miR-196a, their distinctive role in unique RASF behavior remains to be investigated. Given low expression of miR-196a in RASF and location within HOXC cluster, we hypothesize that expression of HOXC8, except regulation by miR-196a, may be influenced by additional epigenetic features similar to those regulating miR-196a.

Mir-155 Expression Correlates with Clinical Disease Activity and Has Effector Function in Rheumatoid Arthritis. Aziza Elmesmari[1], Derek G. Gilchrist[2], Mariola Kurowska-Stolarska[2] and Iain B. McInnes[2]. [1]Institute of Infection,Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom.

Background/Purpose: MicroRNAs are fine tuners of biological pathways that function via post-transcriptional regulation of target mRNA life span. MicroRNA 155 (miR155) is particularly implicated in Rheumatoid Arthritis (RA) pathology through regulation of synovial macrophage cytokine and chemokine production. Thus far miR155 expression across disease activity status has not been examined – to this end we have developed a novel assay of absolute copy number to facilitate such investigation.

Methods: Peripheral blood (PB) was obtained from healthy controls and RA patients who met the 2010 ACR/EULAR diagnostic criteria. CD14+ cells (monocytes) were isolated using micro-beads. The absolute copy numbers of miR-155 transcripts and housekeeping short RNA (U1) in peripheral blood (PB) and synovial fluid (SF) macrophages of RA and healthy controls were assessed using a novel qPCR methodology**.**

Results: RA PB (n=24) and SF $CD14^+$ monocytes (n=11) expressed higher copy numbers of miR-155 compared with healthy controls (n=22). As expected, RA SF macrophages exhibited the highest expression levels of miR-155 ($75318.2/10^6$ copies of RNU1A). In PB monocytes, miR-155 levels were higher when derived from patients with high or moderate disease activity (according to DAS28; p<0.05) than those in remission or healthy controls. The copy number of miR-155 expression was significantly increased in anti-citrullinated protein antibody (ACPA) positive RA (n=17) compared with ACPA negative RA (n=7). The RA PB monocyte miR-155 copy number correlated positively and significantly with DAS28 as a continual variable. There was no correlation between observed increase in miR-155 copy number and patients' age, disease duration or medication.

Conclusion: Our data demonstrate that miR-155 levels may reflect RA disease activity and could be a potential clinical disease activity biomarker for RA. Moreover our data suggest that circulating monocytes in RA patients exhibit an early activation signature, which is primed for subsequent cytokine release.

Protective Effect of the *IL33* rs3939286 Gene Polymorphism in the Development of Subclinical Atherosclerosis in Patients with Rheumatoid Arthritis. Raquel López-Mejías[1], Fernanda Genre[1], Mercedes García-Bermúdez[2], Alfonso Corrales[1], Carlos González-Juanatey[3], Begoña Ubilla[1], J. Llorca[4], Encarnación Amigo[5], Jose A. Miranda-Filloy[6], Trinitario Pina Murcia[1], Ricardo Blanco[7], Santos Castañeda[8], Javier Martin[9] and Miguel A González-Gay[1]. [1]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain, [2]Instituto de Parasitologia y Biomedicina López-Neyra, IPBLN-CSIC, Granada, Spain, [3]Hospital Universitario Lucus Augusti. Cardiology Division, Lugo, Spain, [4]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain, [5]Hospital Universitario Lucus Augusti, Rheumatology Division, Lugo, Spain, [6]Division of Rheumatology, Hospital Lucus Augusti, Lugo, Spain, [7]Hospital Marques de Valdecilla, Santander, Spain, [8]Hospital Universitario de La Princesa, IISP, Madrid, Spain, [9]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain.

Background/Purpose: Rheumatoid arthritis (RA) is a complex inflammatory disease characterized by chronic inflammation, accelerated atherosclerosis and increased cardiovascular (CV) mortality. Interleukin 33 (IL-33) is a cytokine with a pathogenic role in some autoimmune diseases and a potential protective effect on atherosclerosis. Recently, an association between the *IL33* rs3939826 polymorphism and inflammatory bowel disease (a well-established chronic inflammatory disorder) has been described in Caucasian individuals. In the present study, we aimed to establish for first time whether this gene polymorphism influences the development of subclinical atherosclerosis in patients for RA.

Methods: 567 patients with RA from Northern Spain without a previous history of CV events were assessed by carotid ultrasonography (US) to determine the carotid intima-media wall thickness (cIMT). Also, the *IL33* rs3939286 polymorphism was genotyped in these patients by TaqMan single-nucleotide polymorphism genotyping assays in a 7900 HT real-time polymerase chain reaction system.

Results: Patients with RA carrying the TT genotype had lower cIMT values than those homozygous for the CC genotype (mean ± standard deviation [SD]: 0.71 ± 0.14 mm in TT versus 0.76 ± 0.14 mm in CC carriers). Moreover, patients carrying the CT genotype had intermediate cIMT values (mean ± SD: 0.73 ± 0.17 mm). In keeping with these observations, patients with RA carrying the mutant allele T exhibited significantly lower cIMT values than those carrying the wild allele C (mean ± SD: 0.72 ± 0.16 mm versus 0.75 ± 0.18 mm, respectively; p=0.04). The association of allele T with lower values of cIMT in patients with RA remained statistically significant after adjusting the results for sex, age at the time of the carotid US study, follow-up time and traditional CV risk factors (p=0.02).

Conclusion: Our results indicate a protective effect of the *IL33* rs3939286 gene polymorphism in the susceptibility to subclinical atherosclerosis in patients with RA.

High-Density Genotyping of Risk Loci in African Americans with RA. Maria I. Danila[1], Richard Reynolds[1], Qi Yan[1], Nianjun Liu[1], Peter K. Gregersen[2], CLEAR Investigators[1], Donna K. Arnett[1] and S. Louis Bridges Jr.[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: Genetic studies have identified 101 risk loci for RA in individuals of Caucasian and Asian descent. However, to date the genetic determinants of RA in African Americans, an admixed population, are poorly understood. We sought to determine whether genetic markers of autoimmunity validated in European and Asian population influence the occurrence of RA in African Americans.

Methods: Using the ImmunoChip custom array, which contains 196,525 single nucleotide polymorphisms (SNPs) from 186 autoimmune disease associated loci, a total of 814 African Americans with RA and 933 African American healthy controls were genotyped. After quality control procedures (related samples, sex inconsistency, marker call rate >98.5% and sample call rate >90%,), 100,268 SNPs with minor allele frequency (MAF) greater than 5% were available for analysis in 601 cases and 830 controls. Set-based association analysis using the sequence kernel association test (SKAT) was also performed in the autoantibody-positive and the autoantibody-negative subsets. Fine mapping of loci identified from the Caucasian RA ImmunoChip study was performed by association testing all markers +/− 500 kB conditionally on the top Caucasian SNP for each RA locus.

Results: Among the 601 cases, 479 (80%) individuals were autoantibody-positive. In the single marker association analysis adjusted for global European admixture, the strongest statistical associations with seropositive RA were found in the MHC region in chromosome 6. However, when the analysis was restricted to the 122 cases with autoantibody-negative RA, no statistical significant association for the MHC region was found. Since many of the markers were weakly associated with RA, we also performed set-based analysis using SKAT. SNPs were assigned to 17,529 genes if they were located within 100 kb 5' or 3' of the coding region. We found that *AP1*, transporter 1 ATP-binding cassette, subfamily B, a gene on chromosome 6 in the MHC region, previously associated with primary immunodeficiency, was associated with seropositive RA ($p = 3.5 \times 10^{-7}$). Conditional analyses indicated no ethnic specific SNPs refined the top association observed from the Caucasian RA Immunochip study.

Conclusion: The present study provides further evidence to support the importance of MHC region in African-Americans with RA.

Background/Purpose: Rheumatoid arthritis (RA) affects 0.5–1% of the population worldwide. The genetics of RA has been analyzed in large European and Asian studies, but much less is known about RA in African-Americans. Trans-ethnic analysis has found similarities and differences in RA genetics, making both validation and novel gene association important goals in African-Americans (AA). We present genome-wide association (GWA) data on African-Americans with RA alongside analysis of whole genome sequencing (WGS) data on a subset of the population. These data were analyzed in the context of publically available datasets on RA.

Methods: 535 AA cases (from the CLEAR Registry and the VARA Registry) and 1,506 AA controls (from CLEAR and SLEGEN) were genotyped using Illumina Omni 1M and 1S platforms. Inclusion thresholds were: sample call rate > 98.5%, SNP call rate > 98%, HWE p-value > 1×10^{-7}, MAF >0.05. The top principal component was included as a covariate. Imputation was carried out using IMPUTE2 with 1000 Genomes. The number of SNPs after merging was 1,790,756, and the total number of pruned SNPs after imputation was 8,380,261. After this, genomic inflation was 1.031. Associated and suggestive loci were defined as 500kB on either side of lead SNPs with a p-value of $<10^{-8}$, or $< 10^{-5}$, respectively. We gathered available GWAS, transcriptomic, methylomic data, and other data in RA for these loci. Next, we integrated this with analysis of copy number, structural, and rare variation (CNV, SV and RV) from WGS of 62 AA RA patients who were also genotyped on the Illumina platform and, 80 Yoruban (YRI), and 96 Northern European (CEU) genomes sequenced by CGI. We annotated rare variants with Combined Annotated Dependent Depletion (CADD) scores as well as according to 27 other ontologies to aid interpretation.

Results: One associated and 44 suggestive loci were identified among African-Americans with RA through GWA analysis. Two of these loci were previously associated with RA and another ten have been identified in other GWAS on autoimmune diseases or immunologic conditions. Multiple CNV were identified in the regions circumscribed by GWAS, some of which were several times more common in genomes of cases than controls. We found neither large deletions nor insertions unique to the RA population in the loci. Gene Burden Testing (GBT) reaffirms prior associations (e.g. *SYNGR1* displays 2.71 times more RV per genome than a weighted average of the CEU and YRI genomes). GBT appears particularly effective at enabling identification of associated antisenseRNAs and microRNAs. Most importantly, integrated analysis of our data displays internal consistency; for instance *SEMA6D* is in a locus defined by GWAS, is differentially methylated in RA, and is identified by GBT using WGS.

Conclusion: This co-analysis of GWAS, WGS, and publically available data allows refinement of gene and variant-level associations. This study re-confirms the importance of CNV in RA, but in loci not yet reported to have such. Finally, our results show that GBT enables confirmation and refinement of associations as well as the identification of RV likely to be deleterious in the context of RA.

IL-6 Proximal Promoter SNP rs18000795 Genotype Strongly Correlates with Synovial Fibroblast IL-6 Expression. Erika Noss, Sook Kyung Chang, Gerald Watts and Michael Brenner. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Interleukin (IL)-6 is an important driver of rheumatoid arthritis (RA) pathology, and synovial fibroblasts are a major source of IL-6 in the RA synovium. We noted large differences in IL-6 expression across several human synovial fibroblast lines. Our objective was to better define the variation in IL-6 expression between synovial fibroblasts and identify mechanisms mediating these differences.

Methods: Human synovial fibroblast lines were derived from discarded surgical specimens by serial passage from ten RA or osteoarthritis (OA) donors. Human CD14+ monocytes were isolated from healthy donor peripheral blood mononuclear cells by magnetic bead positive selection. IL-6 was measured in cell culture media by ELISA. IL-6 mRNA expression was measured by quantitative reverse transcription polymerase chain reaction (qRT-PCR). IL-6 transcript stability was determined by measuring IL-6 mRNA decay after actinomycin D inhibition of transcription. Cell genotype at the IL-6 proximal promoter single nucleotide polymorphism (SNP) rs18000795 (otherwise known as IL-6 –174 G/C) was determined by restriction fragment length polymorphism analysis.

Results: Human synovial fibroblast lines reproducibly segregated into low, medium, and high IL-6 producers after tumor necrosis factor-alpha (TNF-α) stimulation, independent of cell passage and disease state. The IL-6 expression pattern after TNF-α stimulation correlated significantly with the expression pattern observed in unstimulated cells or cells stimulated with IL-1 or lipopolysaccharide (LPS), indicating that this pattern was not secondary to differences in TNF-α signaling pathways. The IL-6 expression pattern also correlated strongly with total mRNA expression, but not with differences in IL-6 mRNA stability, suggesting it was driven by transcriptional rather than post-transcriptional mechanisms. Given that the proximal promoter SNP rs18000795 has been associated with diverse effects on IL-6 levels and disease expression in many systems, we analyzed synovial fibroblast IL-6 production as a function of rs18000795 genotype. We found that high IL-6 expression was significantly associated with the homozygous minor allele (CC) genotype. We then tested if a similar genotype effect was seen in stimulated CD14+ monocytes, since macrophage lineage cells are another major IL-6 producer in the RA synovium. We found, in contrast to synovial fibroblasts, that the rs18000795 genotype had a modest and opposite effect on CD14+ monocyte IL-6 expression, with a trend toward higher production in the major allele (GG) homozygotes.

Conclusion: This study reports that synovial fibroblast IL-6 expression is significantly influenced by genetic differences in linkage with the IL-6 proximal promoter SNP, rs18000795. In contrast, little association between

rs18000795 and monocyte IL-6 expression was found in this study, showing that SNP associations may have divergent effect when analyzed in different cell types. These results highlight that analysis of the role of disease-associated SNPs on gene expression and pathologic processes must consider the effect of that genetic variation in different cell types.

Associations of Toll-like Receptor (TLR)-4 Single Nucleotide Polymorphisms and Rheumatoid Arthritis Disease Progression. Marshall Davis[1], Tricia LeVan[2], Fang Yu[1], Harlan Sayles[3], Jeremy Sokolove[4], William H. Robinson[5], Kaleb Michaud[6], Geoffrey M Thiele[7] and Ted R. Mikuls[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Med Ctr, Omaha, NE, [3]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [4]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA, [5]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [6]National Data Bank for Rheumatic Diseases, Wichita, KS, [7]Omaha VA and the University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Toll-like receptor (TLR)-4 signaling pathways have been implicated in both the innate and adaptive immune responses that characterize rheumatoid arthritis (RA). In this study, we examined the associations between TLR-4 single nucleotide polymorphisms (SNPs) and RA using a large well-characterized RA cohort.

Methods: A total of 1,559 patients were genotyped for three TLR4 SNPs (rs1927911, rs11536878, and rs4986790), which were selected using a haplotype tagging strategy. Measures of disease severity included the Disease Activity Score-28 (DAS28), Multidimensional Health Assessment Questionnaire (MD-HAQ), Clinical Disease Activity Index (CDAI), and Simplified Diseases Activity Index (SDAI). Associations of TLR4 SNPs with these measures were examined longitudinally (mean of 10 visits, range: 0–60) using generalized estimating equations in both univariate and multivariate analyses, adjusting for age, sex, race, comorbidity, body mass index, smoking, erythrocyte sedimentation rate (ESR), rheumatoid factor (RF) and anti-CCP positivity, methotrexate and anti-tumor necrosis factor use. Based on existing data showing that anti-citrullinated protein antibody (ACPA)-containing immune complexes may drive TLR4 signaling in RA, analyses were also stratified by ACPA positivity including antibody positivity to anti-CCP and anti-citrullinated fibrinogen (cFb) antibody.

Results: RA patients homozygous for the minor allele of TLR4 rs1927911 demonstrated lower disease activity over follow-up including lower DAS28 ($p<0.001$), CDAI ($p=0.002$), and SDAI ($p=0.010$) in univariate analysis and lower DAS28 ($p<0.001$) and CDAI ($p=0.007$) in multivariate analysis (Table). Disease activity among those homozygous for the minor allele tended to be numerically lower in groups with elevated anti-CCP and anti-cFb antibody though no significant differences by ACPA status were identified. There were no associations of TLR4 rs11536878 and rs4986790 SNPs with any of the RA disease activity measures.

Conclusion: We found TLR4 rs1927911 genotypes are associated with the rate of disease progression over time independent of other factors. Although further studies are needed to identify mechanisms by which variation in rs1927911 impacts inflammatory burden, these data are consistent with reports in other disease states suggesting that this SNP is associated with a meaningful anti-inflammatory effect and support the concept of TLR4 as a potential therapeutic target in RA.

Table: Associations of TLR-4 rs1927911 genotype with RA disease progression (DAS28, HAQ, CDAI, and SDAI differences per year of follow up); p-values < 0.0167 (Bonferroni correction) considered to be statistically significant

Anti-Major Histocompatibility Complex Class I-Related Chain a (MICA) Antibodies in Rheumatoid Arthritis Patients with Interstitial Lung Disease. Hiroshi Furukawa[1], Shomi Oka[1], Kota Shimada[2], Akiko Komiya[1], Naoshi Fukui[1], Naoyuki Tsuchiya[3] and Shigeto Tohma[1]. [1]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [2]Tokyo Metropolitan Tama Medical Center, Tokyo, Japan, [3]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan.

Background/Purpose: Interstitial lung disease (ILD) is frequently associated with rheumatoid arthritis (RA), and is designated RA-associated ILD (RA-ILD) that influences the prognosis of the disease. Transfusion related acute lung injury is defined as an acute lung injury associated with blood transfusion; one of its causes is thought to be anti-HLA antibody. Here, we investigated the anti-HLA antibody profiles to determine whether they may be useful for diagnosing RA-ILD.

Methods: Anti-HLA antibody levels were analyzed using the Lambda Array Beads Multi-Analyte System (LABScreen Mixed Assay, One Lambda, Canoga Park, CA), using a LabScan 100 system (Luminex, Austin, TX), in 34 RA patients with or without RA-ILD. This study was reviewed and approved by the ethics committees of each participating institute. Informed consent was provided by all subjects.

Results: Average anti-major histocompatibility complex class I-related chain A (MICA) antibody levels were higher in RA patients with ILD than in those without ($P=0.0013$, Mann-Whitney's U test). Average anti-HLA class I or class II antibody levels were not significantly different between RA patients with or without ILD ($P=0.6419$ and 0.2486, respectively). The ratio of (average anti-MICA antibody levels) / (average anti-HLA class I antibody levels) was increased in RA patients with ILD than in those without ($P=4.47\times10^{-5}$). The area under the curve value of receiver operating characteristic curves of the ratio was 0.912. The optimized cut-off level of the ratio was determined for RA-ILD, and the specificity and the sensitivity were 88.2% and 82.4%, respectively.

Conclusion: To the best of our knowledge, this is the first report of anti-HLA antibody profiles in RA-ILD. The ratio of (average anti-MICA antibody levels) / (average anti-HLA class I antibody levels) could be a better marker for diagnosing RA-ILD. Further large-scale studies would provide a possibility of generating better markers for RA-ILD.

Targeting IL-6, JAK or SYK? : An Analysis of Transcriptome Alteration in Peripheral Blood By RA Treatments. Yoshinobu Koyama[1], Motohiko Tanino[2], Shuji Nagano[3], Toshiyuki Ota[3] and Toshie Higuchi[1]. [1]Japan Red Cross Okayama Hospital, Okayama, Japan, [2]DNA Chip Research Inc., Yokohama, Japan, [3]Iizuka Hospital, Iizuka, Japan.

Background/Purpose: The advances in understanding of the molecular nature of immune cell receptors enabled to offer new oral, targeted therapies. Tofacitinib (TOF) is the first selective kinase inhibitor to be approved to treat rheumatoid arthritis (RA). TOF inhibits Janus kinase (JAK) 1, JAK3 and, to a lesser extent, JAK2, which is known to lead inhibition of cytokine signaling including interleukin (IL)-6. Tocilizumab (TCZ), an anti-IL6 receptor monoclonal antibody, also block IL-6 signaling by preventing IL-6 from binding to both membrane-bound and soluble receptors. IL-6 is known to have a wide range of biological activities including B cell and T cell differentiation. As Spleen tyrosine kinase (SYK) participates in the activation of B cells and T cells, a Syk kinase inhibitor, fostamatinib (FOS) have been a candidate for RA

treatment. Although the targets of these three treatments are specific, the downstream biological activities seem to be wide. In order to investigate whether the effect of these treatments share common biological process or are disparate, we conducted transcriptome analysis with using next-generation sequencing.

Methods: The study includes a total of 30 RA patients treated by these three medications (TOF 6–20mg/d:15, FOS 100–200mg/d:4, TCZ 8mg/kg/4w:11). Peripheral blood was drawn at just before (pre) and 3 months after (post) these treatments. Total RNAs were then extracted with using PAXgene miRNA kit. After constructing single-stranded, strand-specific libraries (length 50bp), multiplex sequencing was done. After quantifying the expressions of transcripts, hierarchical clustering analysis was performed. And then, differentialy expressed genes (DEGs) were selected by paired comparison (post vs. pre), setting thresholds at 2-fold change up/down and less than P=0.05 in corrected paired T-test.

Results: In total, 57571 genes/transcripts including 976 newly predicted genes were quantified. By a hierarchical clustering analysis, the pre and the post of FOS or TOF treatment were segregated each other while those of TCZ treatment were nearest neighbors, indicating that TCZ has the least influence over the transcriptome. The 118, 344 and 121 genes were selected as DEGs from the comparison of post vs. pre treatment of TOF, FOS or TCZ, respectively. Disparate gene ontology (GO) terms were enriched in each DEGs group. Terms relevant to immunity including 'JAK-STAT cascade' were enriched in the down-regulated genes in the TOF group. Of 344 DEGs from the FOS group, 30 were related to "ribosomal proteins" and 29 of them were up-regulated. In the TCZ group, terms related to "extra cellular matrix", such as "extracellular matrix binding" and "wound healing" were detected.

Conclusion: Although some of downstream biological cascade for JAK, SYK or IL-6 appear to share, the influence of these treatments over the transcriptome in the peripheral blood seems to be disparate. The hierarchical clustering shows TCZ treatment has the least influence on transcriptome. On the other hand, it is noteworthy that FOS treatment seems to have much greater influence upon transcriptome as compare with others. Enrichment analysis using GO terms indicated that different biological processes were involved in the effect of each treatment.

IIS La Princesa, Madrid, Spain, [14]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain.

Background/Purpose: Rheumatoid arthritis is an inflammatory disease with a high incidence of cardiovascular disease due to accelerated atherosclerosis. Osteoprotegerin (OPG) has been associated with an increased risk of atherosclerotic disease in the general population. Several polymorphisms in the *OPG* gene with functional effects on cardiovascular disease in non-rheumatic individuals have been described. Therefore, we aimed to analyze the effect of three of these functional *OPG* polymorphisms on the risk of cardiovascular disease in a large and well-characterized cohort of Spanish patients with rheumatoid arthritis.

Methods: Three *OPG* gene variants (rs3134063, rs2073618 and rs3134069) were genotyped by TaqMan assays in 2,027 Spanish patients with rheumatoid arthritis. All the patients fulfilled the 1987 American College of Rheumatology (ACR) and also the 2010 classification criteria for RA. Anti-cyclic citrullinated peptide (anti-CCP) antibody testing was positive in 997 out of the 1,714 tested. Also, 18.3% of the whole series had experienced cardiovascular events, including 5.4% with cerebrovascular accidents. The relationship between *OPG* variants and cardiovascular events was assessed using Cox regression.

Results: No association between *OPG* gene variants and cardiovascular disease was observed in the whole group of rheumatoid arthritis patients or in anti-CCP positive patients. Nevertheless, a protective effect of CGA haplotype on the risk of cardiovascular disease in general, and specifically in the risk of cerebrovascular complications after adjusting for sex, age at disease diagnosis and traditional cardiovascular risk factors was disclosed in anti-CCP negative patients (HR=0.54; 95%CI: 0.31–0.95; p=0.032 and HR=0.17; 95%CI: 0.04–0.78; p=0.022, respectively). These results were in accordance with a reduced risk of developing cerebrovascular complications observed in those anti-CCP negative patients who carried the *OPG* rs2073618 GG genotype after adjusting for potential confounder factors (HR=0.17; 95% CI: 0.03–0.89; p=0.035).

Conclusion: Our results indicate a protective effect of the *OPG* CGA haplotype on cardiovascular risk, mainly due to a protective effect against cerebrovascular events in anti-CCP negative rheumatoid arthritis patients.

This study was supported by European Union FEDER funds and "Fondo de Investigación Sanitaria" (grants PI06/0024, PS09/00748 and PI12/00060) (Spain). Phospho-STAT1/3 and Gene Expression Measurement in Circulating CD4$^+$ T Cells As Diagnostic Tools in Early Autoantibody-Negative Rheumatoid Arthritis. Amy E. Anderson[1], Arthur G Pratt[1], Mamdouh Sedhom[2], Nisha Nair[3], Jonathan Massey[3], Christine Routledge[1], Ben Hargreaves[1], Philip Brown[1], Anne Barton[4], John D Isaacs[1] and Ranjeny Thomas[2]. [1]NIHR Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom, [2]The University of Queensland Diamantina Institute, Queensland, Australia, [3]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academy of Health Sciences, Manchester, United Kingdom, [4]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/Purpose: Early diagnosis of rheumatoid arthritis (RA) improves outcomes but is challenging, particularly amongst anti-citrullinated peptide auto-antibody (ACPA) negative individuals. Previously we identified an IL-6 mediated CD4$^+$T cell transcriptional signature, enriched for signal transduction and activation of transcription-3 (STAT3) target genes, which had discriminatory value for this purpose. In the present work we sought a more readily applicable diagnostic assay, and insight into mechanisms of disease induction.

Methods: Amongst early arthritis patients and controls naïve to immunomodulatory treatment, constitutive and IL-6-induced expression of phosphorylated STAT1 and 3 (pSTAT1/3) were determined in circulating lymphocytes using flow cytometry. Contemporaneous serum cytokine levels were measured using a validated, highly sensitive immuno-assay, and normalised CD4$^+$T cell gene expression of the previously described STAT3 target gene-enriched signature was determined using microarray.

Results: In 187 early arthritis patients, constitutive pSTAT3 correlated with serum IL-6 levels maximally in $CD4^+$ T cells, compared with other circulating leukocyte subsets. Increased constitutive pSTAT3, but not pSTAT1, was observed in circulating $CD4^+$ T cells of early ACPA negative RA patients compared with disease controls. Amongst patients presenting with undifferentiated arthritis (UA) the ratio of constitutive pSTAT3:pSTAT1 in $CD4^+$ T cells could be incorporated into an algorithm for predicting progression to classifiable RA with high accuracy (area under ROC curve = 0.91; $p<0.001$). The comparable utility of the previously described $CD4^+$T cell gene signature as a discriminatory tool, and the accuracy of pSTAT3: pSTAT1 as a surrogate for target gene expression, are the subject of on-going analyses.

Conclusion: Our findings support a particular role for IL-6-driven $CD4^+$ T cell activation via STAT3 during the induction of RA, which may be of particular importance in the pathogenesis of ACPA-negative disease. $CD4^+$ pSTAT measurements show promise as biomarkers of progression to RA in sero-negative UA.

Hospital Universitario de Canarias, Tenerife, Spain, [4]Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [5]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain, [6]Hospital Marques de Valdecilla, Santander, Spain, [7]Hospital Universitario Lucus Augusti. Cardiology Division, Lugo, Spain.

Background/Purpose: We determined whether osteoprotegerin (OPG) concentrations are associated with established cardiovascular disease (CVD) amongst patients with rheumatoid arthritis (RA).

Methods: OPG concentrations were measured by an enzyme-linked immunosorbant assay in 151 (54 with CVD) RA patients and 62 age and sex matched control subjects without CVD. Concentrations of the endothelial activation marker angiopoietin 2 were also evaluated in a subgroup of 85 RA participants.

Results: In RA patients, age, body mass index (BMI), rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibody positivity, and joint erosion status were associated with OPG concentrations (partial R (p)=0.175 (0.03), -0.277 (0.0009), 0.323 (<0.0001), 0.217 (0.008) and 0.159 (0.05)), respectively. Median (interquartile range) OPG concentrations increased from 6.38 (3.46–9.31) to 7.07 (5.04–10.65) and 8.64 (6.00–11.52) pmol/l in controls and RA patients without and with CVD, respectively (p=0.0002). Upon adjustment for age, sex, traditional risk factors and BMI in mixed regression models, OPG concentrations remained lower in controls compared to RA patients without CVD (p=0.05) and in the latter compared to those with CVD (p=0.03); the association of OPG concentrations with CVD amongst RA patients also persisted after additional adjustment for RF and anti-CCP antibody positivity, and erosion status (p=0.04). OPG concentrations related independently to those of angiopoietin 2 in RA patients with but not without CVD (partial R (p)=0.545 (0.003) and 0.076 (0.6)).

Conclusion: OPG concentrations are associated with disease severity and CVD prevalence in RA patients. Whether consideration of OPG concentrations can improve CVD risk stratification in RA merits future longitudinal investigation.

This study was supported by European Union FEDER funds and "Fondo de Investigación Sanitaria" (grants PI06/0024, PS09/00748 and PI12/00060) (Spain). Centrosomal Protein 70kDa Is Down-Regulated By Decoy Receptor 3 in Specifically Rheumatoid Synovial Fibroblasts. Koji Fukuda[1], Yasushi Miura[2], Toshihisa Maeda[2], Shinya Hayashi[2] and Masahiro Kurosaka[2]. [1]Kakogawa City Hospital, Kakogawa, Japan, [2]Kobe University Graduate School of Medicine, Kobe, Japan.

Background/Purpose: Decoy receptor 3 (DcR3) is a secreted decoy tumor necrosis factor receptor and competitively binds and inhibits the TNF family including Fas-ligand, LIGHT, and TL1A. DcR3 is overexpressed in tumor cells and might benefit tumors by helping them to avoid cytotoxic and regulatory effects of the ligands. We previously reported that DcR3 overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNFα protects the cells from Fas-induced apoptosis [1]. We recently reported that DcR3 binds to TL1A expressed on RA-FLS resulting in the negative regulation of cell proliferation induced by inflammatory cytokines [2]. Further, we newly revealed the gene expression profiles in RA-FLS regulated by DcR3 by using microarray data analysis. The profiles indicated centrosomal protein 70kDa (Cep70) was down-regulated by DcR3 (fold change 1.87) [3]. Centrosome forms the backbone of cell cycle progression mechanism. Further, CEP family protein is the active component of centrosome and plays a vital role in centriole biogenesis and cell cycle progression control [4]. In this study, we studied Cep70 as one of the key molecules in DcR3-TL1A signaling in RA-FLS based on the genes expression profiles regulated by DcR3.

Methods: *Real-time polymerase chain reaction (real-time PCR).* RA and osteroarthritis (OA) -FLS were stimulated with 1ng/ml of recombinant human TNFα or IgG1 for 24 hours, or with various concentration of DcR3-Fc or control IgG1 for 12 hours. Further, RA-FLS were incubated with DcR3-Fc for 12 hours after overnight pre-incubation with anti-TL1A antibody. The relative expression levels of Cep70 mRNA were quantified by real-time PCR.

Immunohistochemistry. Anti-Cep70 antibody was applied to frozen sections of synovial tissues from patients with RA or OA for over night. Sections were stained with HistoFine simple stain Kit and DAB chromogen, followed by counterstaining with hematoxylin.

Results: Real-time PCR revealed that the expression of Cep70 mRNA in RA-FLS was higher than that in OA-FLS and that TNFα significantly decreased the expression of Cep70 mRNA in RA and OA-FLS (RA, 51%; OA, 59%). DcR3-Fc also significantly decreased the expression of Cep70 mRNA in RA-FLS in a dose dependent manner (81% with 10ng/ml, 73% with 100ng/ml, and 57% with 1000ng/ml). In contrast, DcR3-Fc did not decrease Cep70 mRNA in OA-FLS. Anti-TL1A antibody inhibited the down-regulation of Cep70 expression in RA-FLS induced by DcR3-Fc. Immunohistochemistry revealed that Cep70 protein was expressed more in superficial lining layer of rheumatoid synovium than that of OA synovium.

Conclusion: In this study, we revealed that Cep70 was increased in RA-FLS and that the expression of Cep70 in RA-FLS was decreased by DcR3 by binding to membrane-bound TL1A in a disease-specific fashion. DcR3 may affect the pathogenesis of RA through Cep70.

Stromal Cell Markers Are Differentially Expressed in the Synovial Tissue of Patients with Early Arthritis. Ivy Y.K. Choi[1], Olga N. Karpus[2], Jason D. Turner[3], Debbie L. Hardie[3], Maria J. H. de Hair[1], Karen I. Maijer[1], Paul-Peter Tak[1], Karim Raza[3], Jörg Hamann[2], Christopher Buckley[3], Danielle Marie Gerlag[1] and Andrew Filer[3]. [1]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Department of Experimental Immunology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Rheumatology Research Group, MRC Centre for Immune Regulation, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom.

Background/Purpose: Previous studies have shown increased expression of stromal markers in synovial tissue (ST) of patients with established rheumatoid arthritis (RA). Here, the expression of tissue expressed stromal markers in early arthritis in relationship to diagnosis and outcome was studied.

Methods: ST from 67 patients included in two different early arthritis cohorts (Birmingham and Amsterdam) and seven non-inflammatory controls was analysed using immunofluorescence to detect the stromal markers CD55, CD248, fibroblast activation protein (FAP) and podoplanin. Diagnostic classification (gout, psoriatic arthritis, unclassified arthritis (UA), parvovirus associated arthritis, reactive arthritis and RA) and outcome (resolving or persistent) was determined at baseline and after follow-up. The relationship between the expression of the stromal markers and diagnosis and outcome was determined.

Results: We observed expression of all stromal markers in ST of early arthritis patients, independent of diagnosis or prognostic outcome. Expression of FAP and podoplanin was significantly higher in patients with early RA compared to non-inflammatory controls ($p=0.003$ and $p=0.021$, respectively). Significantly greater expression of FAP was found in anti-citrullinated peptide antibody (ACPA)-negative RA patients and in patients with UA fulfilling classification criteria for RA after follow-up compared to patients with resolving disease and patients with persistent disease who did not fulfil classification criteria for RA after follow-up ($p=0.030$ and $p=0.020$, respectively for ACPA-negative RA patients and $p=0.045$ and $p=0.024$, respectively for UA patients fulfilling classification criteria for RA after follow-up).

Conclusion: The stromal cell markers CD55, CD248, FAP and podoplanin, are expressed in the synovium in the earliest stage of arthritis. Expression of FAP is higher in early unclassified arthritis patients who fulfil classification criteria for RA over time and in ACPA-negative RA compared to resolving or non-RA arthritides. These results suggest that significant fibroblast activation occurs in RA in the early window of disease.

Anti-Arthritic Effect of Tubastatin A, a Novel Histone Deacetylases-6 Inhibitor, Is Mediated By Stabilization of IkB Via Suppression of Ubiquitin-Proteasome Pathway. Eun Chung Hong[1], Hemin Jeong[2], Jiwon Hwang[2], Eun-Kyung Bae[1], Hyungjin Kim[2], Joong Kyong Ahn[3], Hoon-Suk Cha[2], Eun-mi Koh[2] and Jaejoon Lee[2]. [1]Samsung Biomedical Research Institute, Seoul, South Korea, [2]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Sungkyunkwan univ. school of medicine, Seoul, South Korea.

Background/Purpose: Histone deacetylase-6 (HDAC-6) functions as a non-epigenetic deacetylase for non-histone substrates and regulates microtubule-mediates processes such as cell migration, cell cycle arrest, and angiogenesis. We have previously demonstrated that Tubastatin A suppresses synovial inflammation and joint destruction in a collagen antibody-induced arthritis mouse model. However, the exact mechanism through which Tubastatin A exerts its anti-arthritic effect is not fully understood. The aim of the study is to investigate whether ubiquitin-proteasome pathway is involved in the anti-arthritic mechanism of Tubastatin A.

Methods: Fibroblast-like synoviocytes (FLS) were treated with TNF-α in a time-dependent manner (control, 5, 15, 30 minutes) and the phosphorylation activity of NF-κB and IκB was measured using Western blot analysis. FLS were stimulated with TNF-α after treatment with different doses of proteasome inhibitor (MG-132) or Tubastatin A, and the expression of IL-6 were measured using ELISA. FLS were stimulated with TNF-α after treatment with different doses of Tubastatin A and phosphorylation of nuclear NF-κB and of cytosolic IκB were measured using Western blot analysis. FLS were stimulated with TNF-α in a time dependent manner (15, 30, 45, 60 min) after pretreatment with Tubastatin A or control and expression of phosphorylated IκB was measured using Western blot analysis. FLS were treated with TNF-α after treatment with different doses of Tubastatin A, and cytosolic proteasome activity was measured using 20S Proteasome Activity Assay Kit.

Results: The phosphorylation of NF-κB and IκB were increased after stimulation of TNF-α at 5 minutes. After stimulation with TNF-α, the expression of IL-6 was attenuated in FLS treated with Tubastatin A or MG-132 compared with controls. At 3μM of Tubastatin A, the phosphorylation of NF-κB induced by TNF-α was suppressed, and phosphorylated IκB in cytosol was increased. Furthermore, the total cytosolic IκB remained the same. Phosphorylated IκB appeared in the cytosol 30 min after incubation with TNF-α after treatment with Tubastatin A, but no effect was seen when treated with TNF-α alone. After stimulation with TNF-α, the cytosolic proteasome activity was significantly decreased after treatment of Tubastatin A or MG-132 compared with controls.

Conclusion: Our study demonstrates that Tubastatin A exerts its anti-arthritic effect, at least in part, through preventing degradation of IκB by attenuating ubiquitin-proteasome pathway, and thus inactivating nuclear translocation of NF-κB.

Cyclic Phosphatidic Acid (cPA) Suppresses MMP-3, a Disintegrin and Metalloproteinase with Thrombospondin Motifs(ADAMTS)-4, -5 and Stimulates HAS2 Expression in Inflammatory Rheumatoid Synovial Fibroblasts Induced with IL-1β and/or TNF-α. Ikuko Masuda[1], Kodo Okada[2], Hisashi Yamanaka[3] and Shigeki Momohara[3]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]SANSHO, Co. Ltd., Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Cyclic phosphatidic acid (cPA) is one of bioactive lipid, has been implicated as an mediator of various biological effects including i) antiproliferative effect on eukaryotic cell cycle, ii) regulation of Ca^{2+} release, iii) regulation of actin rearrangement, iv) inhibition of tumor cell invasion. Furthermore, on human skin fibroblasts, cPA stimulates high molecular hyaluronic acid (HA) production through up-regulating HA synthase (HAS). cPA also has shown to have antinociceptive effect on animal models of acute and chronic pain. We have previously confirmed that cPA also stimulated HAS2 production on human osteoarthritic chondrocytes and synovial fibroblasts in vitro. Furthermore, we have shown that intra-articular administration of cPA suppressed pain, swelling, and articular cartilage degeneration in rabbit experimental osteoarthritis. These compelling results lead to a hypothesis that cPA may have direct role on anti-inflammation and protection of cartilage in arthritic condition. The aim of this study was to evaluate the effects of cPA on rheumatoid synovial fibroblasts which are under more severe inflammatory condition than osteoarthritis.

Methods: In vitro studies were performed using synovial fibroblasts obtained from rheumatoid arthritis patients at joint replacement surgery. cPA 0–25 μM was added to synovial fibroblasts cultures and effects of cPA on synovial fibroblasts on HAS, HYAL, ADAMTS-4, ADAMTS-5, MMP-3, TIMP-3 expression were assessed at 24 and 48hrs by real time PCR using specific primers to corresponding genes. Synovial fibroblasts were also cultured with IL-1β and/or TNF-α, to study attenuated effect of cPA. Beta-actin was used as endogenous expression control.

Results: cPA stimulated endogenous HA synthesis from synovial fibroblasts as time and dose-dependent manner in vitro. HAS2 gene was up-regulated as dose–dependent manner. IL-1β and/or TNF-α addition didn't effect much on HAS2 expression, however addition of cPA stimulated HAS2 on synovial fibroblast with cytokines. On the other hand, cPA repressed HYAL-1 and HYAL-2 expression, and IL-1β (and/or TNF-α) stimulated HYAL-1 and -2, and cPA further repressed HYAL expression stimulated by cytokines. Not only with HYAL, cartilage degenerating enzymes, ADAMTS-4, ADAMTS-5, MMP-3 in synovial fibroblasts were all repressed by cPA, even after stimulated by cytokines.

Conclusion: The in vitro results confirmed that cPA had stimulatory effects on HA synthesis by rheumatoid synovial fibroblasts. The suppressing effect of HYAL, ADAMTS-4, ADAMTS-5, and MMP-3 on rheumatoid synovial fibroblasts by cPA shown here, might have played direct role to suppressing inflammation and also protecting articular cartilage of arthritic condition. Molecular mechanism of cPA to prevent cartilage degeneration remains to be elucidated, however, further study should be warranted for cPA as a novel candidate for therapeutic agent of arthritis.

Increased Risk of Rheumatoid Arthritis (RA) Among Shared Epitope-Negative (SE-) Mothers with Shared Epitope-Positive (SE+) Children.

Giovanna Cruz[1], Lindsey A. Criswell[2], Xiaorong Shao[1], Hong L. Quach[1], Janelle Noble[3], Nikolaos Patsopoulos[4], Michael Busch[5] and Lisa F. Barcellos[1]. [1]University of California, Berkeley, Berkeley, CA, [2]University of California, San Francisco, Rosalind Russell / Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA, [3]Children's Hospital Oakland Research Institute (CHORI), Oakland, CA, [4]Harvard Medical School, Boston, MA, [5]Blood Systems Research Institute, San Francisco, CA.

Background/Purpose: RA (RA [MIM 180300]) disproportionately affects women of reproductive age, implicating pregnancy-related factors. Fetal microchimerism (FMC), or the persistence of a small population of cells in the mother, is a natural consequence of pregnancy. FMC is present more often in RA cases than in controls. Mother-child histocompatibility could determine long-term FMC, possibly increasing risk of RA through exposure to fetal HLA-antigens. We hypothesized that RA cases are more likely to have histocompatible (HC) children compared to controls.

Methods: The MCIS included 5,000+ individuals; mothers with RA or SLE and controls (n=750), their children and fathers. RA cases with 1+ birth before diagnosis were recruited at UC San Francisco. Controls were primarily recruited from blood donors. Mothers provided information on their reproductive history, history of transfusion, transplant and infections. Comprehensive MHC region SNP genotyping was conducted using the Illumina MHC panel (n=1,783), ImmunoChip (n=8,842), and 660K (n=1,991) arrays. Four-digit genotype data for *HLA-A, B, C, DPA1, DPB1, DQA1, DQB1* and *DRB1* were imputed using the T1DGC reference panel and BEAGLE. We estimated ancestry proportions from 384 markers using STRUCTURE. A child was HC from the mother's perspective if the paternal allele did not differ from the non-inherited maternal allele. Carrier status (+ or −) of any *DRB1* allele associated with RA risk (Raychaudhuri, 2012) and corresponding to SE amino acid sequences QKRAA and QRRAA (*01:01, 04:01, 04:04, 04:05, 04:08)* and DERAA *(01:03, 04:02, 11:02, 13:01, 13:02)* was determined for mothers and children. We used logistic regression models to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between RA and a) HC at each HLA locus and b) exposure to any SE+ and DERAA+ children, stratifying on maternal carrier status.

Results: Increased HC among cases was only evident at *DQB1* (25.3% vs. 17.4%, $p=0.03$). Having any SE+ children significantly increased risk of RA for SE- mothers (n=218) (OR 2.56; 95% CI, 1.43–4.58) but not SE+ mothers (n=248) (OR 1.48; 95% CI, 0.83–2.62). No association was found with DERAA+ children, regardless of maternal carrier status. Ancestry, parity, and history of transfusion did not impact results.

Conclusion: Exposure to SE+ children and *DQB1* HC may contribute to RA etiology and could contribute to RA's female-predominance. This is the largest study confirming the association between RA and SE+ children in SE− mothers.

Effectiveness and Safety of Tocilizumab in Biologics Naïve RA Patients - Interim Analysis of PMS for Investigating Success in Achieving Clinical and Functional Remission and Sustaining Efficacy with Tocilizumab in Biologics-Naïve RA Patients Study.

Naoki Ishiguro[1], Tatsuya Atsumi[2], Masayoshi Harigai[3], Tsuneyo Mimori[4], Norihiro Nishimoto[5], Takayuki Sumida[6], Tsutomu Takeuchi[7], Yoshiya Tanaka[8], Nobuhiro Takagi[9], Kunihiko Tanaka[9] and Hisashi Yamanaka[10]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Hokkaido University, Sapporo, Japan, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]Kyoto Univ Grad Schl of Med, Kyoto, Japan, [5]Tokyo Medical University, Osaka, Japan, [6]Univ of Tsukuba/Inst Clin Med, Tsukuba City, Japan, [7]School of Medicine, Keio University, Tokyo, Japan, [8]U Occupa & Environ Hlth, Kitakyushu, Japan, [9]Chugai Pharmaceutical, Tokyo, Japan, [10]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: The all-patient PMS study of tocilizumab (TCZ) followed 7901 RA patients for 28 wks. That study (hereafter, PMS7901) showed patients with a high probability of remission and a low probability of developing serious infection to be those most likely to have early and less advanced RA and to have not received biologics previously. The FIRST Bio study is designed to investigate effectiveness and safety of TCZ in RA patients who had not received any biologics (i.e. bio-naïve) in a real clinical setting.

Methods: FIRST Bio is a 52-wk observational postmarketing surveillance study which enrolled bio-naïve RA patients who met the ACR/EULAR 2010 classification criteria for RA, experienced inadequate response or were intolerant to one or more DMARDs, and had DAS28-ESR > 3.2. Patients received 8 mg/kg TCZ every 4 wks intravenously with or without DMARDs at the investigators' discretion. Patient characteristics and safety and effectiveness data were collected. This interim analysis reports the results of 24 wks' observation. A paired t-test was used to detect statistically significant differences in disease activity (CDAI, DAS28-ESR) and Health Assessment Questionnaire (HAQ) score compared to baseline.

Results: This report analyzes 551 of 855 patients enrolled. Mean disease duration and percentage of patients who had less advanced Steinbrocker's stage and class and had comorbidities were lower in the FIRST Bio study than in PMS7901 (Table 1). At Wk 24, 87.2% of patients were continuing TCZ treatment. Mean CDAI improved from 23.4 at baseline to 7.5 at Wk 24 ($p < 0.0001$). DAS28-ESR also improved from 5.2 at baseline to 2.2 at Wk 24 ($p < 0.0001$). At Wk 24, rate of CDAI remission (CDAI ≤ 2.8) was 30.9%, DAS28-ESR remission (DAS28-ESR < 2.6) was 66.5%, and Boolean remission was 27.8%. The Boolean remission rate in the FIRST Bio study was almost twice that in PMS7901 (15.1%) (Table 2). The mean HAQ score improved from 1.0 at baseline to 0.5 at Wk 24 ($p < 0.0001$), and in 59.8% of patients the HAQ score decreased to <0.5 (i.e. HAQ remission). The incidence rates of total and serious AEs were 25.2% and 6.4%, respectively. Infections were the most frequent AEs (6.4%) and the most frequent serious AEs (2.0%). Malignancies were reported in 2 patients (0.4%). Gastrointestinal disorders were reported in 19 patients (3.4%), including 1 (0.2%) gastrointestinal tract perforation. One patient died (0.2%). The incidence rates of serious AEs and serious infections were lower in the FIRST Bio study than in PMS7901 (Table 2). Mean dose of concomitant MTX decreased from 9.1 mg/wk at baseline to 7.3 mg/wk at Wk 24. Mean dose of concomitant corticosteroid also decreased from 5.7 mg/day at baseline to 3.6 mg/day at Wk 24.

Conclusion: The FIRST Bio study revealed that in the real clinical setting TCZ showed high effectiveness and safety in those patients who have less advanced RA and who have not previously received biologics.

Table 1 Patient background

	FIRST Bio study	PMS7901
Mean age (SD), years	59.4 (13.7)	58.7 (12.9)
Mean disease duration (SD), years	7.2 (8.7)	10.4 (9.2)
% of patients (pts) whose Steinbrocker's stage was I or II	63.5	35.2
% of pts whose Steinbrocker's class was 1 or 2	81.5	73.8

% of pts who had any comorbidities (% of pts who had respiratory disease as comorbidity)	56.8 (11.3)	70.6 (14.5)
% of pts with prior use of biologics	0	62.8
% of pts with concomitant use of MTX (mean dose in pts using MTX)	60.8 (9.1mg/wk)	55.8 (7.0mg/wk)
% of pts with concomitant use of corticosteroids (mean dose in pts using corticosteroids)	55.4 (5.7mg/day)	74.0 (5.3mg/day)

Table 2. Comparing safety and effectiveness

	FIRST Bio study At Wk 24	PMS7901 At Wk 28
Boolean remission rate, %	27.8	15.1
Incidence rate of AEs (serious AEs), %	25.2 (6.4)	43.9 (9.6)
Incidence rate of infections (serious infections), %	6.4 (2.0)	11.0 (3.7)

Stringent Criteria for Low Disease Activity and Remission after 12 Months of Treatment, and after Treatment Withdrawal, with Abatacept Monotherapy, Abatacept with Methotrexate or Methotrexate Alone in Early Rheumatoid Arthritis. Gerd Burmester[1], D E Furst[2], B G Combe[3], T W J Huizinga[4], Vivian P. Bykerk[5], D Wong[6], C S Karyekar[6] and P Emery[7]. [1]Charité – University Medicine Berlin, Berlin, Germany, [2]University of California at Los Angeles, Los Angeles, CA, [3]Montpellier University Hospital, Montpellier, France, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [6]Bristol-Myers Squibb, Princeton, NJ, [7]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Clinical remission is associated with better long-term outcomes[1,2] and should be the goal of therapy in RA. In the Assessing Very Early Rheumatoid arthritis Treatment (AVERT) trial, greater percentages of patients (pts) achieved DAS28 (CRP) <2.6 following 12 mths of treatment with SC abatacept + MTX and 6 mths after withdrawal of all RA therapy, compared with MTX alone. At most time points, abatacept monotherapy was more effective than MTX alone.[1] Here, we report clinical efficacy and remission rates from AVERT, using stringent criteria at Mth 12 and after treatment withdrawal (Mth 18).

Methods: AVERT enrolled pts who were MTX-naïve, anti-cyclic citrullinated peptide 2 seropositive (CCP2+), aged ≥18 yrs, with active synovitis ≥2 joints for ≥8 wks, DAS28 (CRP) ≥3.2, and disease onset of ≤2 yrs. Pts were randomized to 12 mths of weekly SC abatacept (125 mg) + MTX, SC abatacept (125 mg) or MTX. All RA treatment was withdrawn after 12 mths (abatacept immediately, MTX and steroids over 1 mth) in pts with DAS28 (CRP) <3.2. Percentages (%) of pts achieving DAS28 (CRP) <2.6 or <2.4, Major Clinical Response (MCR: ACR70 response for ≥6 consecutive mths), or remission (CDAI ≤2.8, SDAI ≤3.3, Boolean criteria) at Mth 12, and the % who maintained these reduced disease activity states at Mth 18 were analyzed.

Results: 351 pts with early RA were enrolled (n=119, abatacept + MTX; n=116, abatacept monotherapy; n=116, MTX alone). Mean characteristics at baseline were: disease duration 0.6 yrs, DAS28 (CRP) 5.4, HAQ-DI 1.4, 95.2% RF+ and anti-CCP2+). At Mth 12, higher % of pts in the abatacept + MTX group achieved DAS28 (CRP) <2.6 (primary analysis) as well as the more stringent clinical endpoint DAS28 (CRP) <2.4 or remission (CDAI, SDAI, Boolean), compared with MTX alone (Table). Rates of low disease activity and remission with abatacept monotherapy were intermediate between abatacept + MTX and MTX alone (Table). Higher % (95% CI) of abatacept-treated pts achieved MCR at Mth 12, compared with MTX alone (abatacept + MTX and abatacept monotherapy vs MTX alone: 31.9% [23.6, 40.3] and 17.2% [10.4, 24.1] vs 8.6% [3.5, 13.7]). Following treatment withdrawal, a small but higher % of abatacept-treated pts (with MTX or monotherapy) sustained low disease activity or remission than in the MTX group (Table).

Criteria	Reduced disease activity at Mth 12: Abatacept + MTX (n=119)	Reduced disease activity at Mth 12: Abatacept monotherapy (n=116)	Reduced disease activity at Mth 12: MTX (n=116)	Sustained levels of reduced disease activity (at both Mth 12 and 18): Abatacept + MTX (n=84)	Sustained levels of reduced disease activity (at both Mth 12 and 18): Abatacept monotherapy (n=66)	Sustained levels of reduced disease activity (at both Mth 12 and 18): MTX (n=73)
Primary analysis						
DAS28 (CRP) <2.6*	60.9% (52.0, 70.0)	42.5% (33.4, 51.6)	45.2% (36.1, 54.3)	14.8% (8.3, 21.3)	12.4% (6.3, 18.5)	7.8% (2.9, 12.7)

OR, odds ratio
Percentages calculated using all randomized patients (N=351), unless otherwise stated. Data given as % (95% CIs).
*Percentages from adjusted logistic regression analysis.
†Percentages calculated using 115 (abatacept plus MTX) or 116 (abatacept monotherapy and MTX-alone treatment arms) patients.
‡p<0.05 for treatment difference vs MTX (95% CI for the estimate of treatment difference did not cross 0)

Conclusion: In early RA, abatacept + MTX for 12 mths resulted in higher rates of low disease activity and remission according to stringent criteria, than MTX alone. Few pts who achieved these stringent clinical measures at 12 mths could maintain them 6 mths after all RA treatment had been withdrawn. These findings indicate that treatment with abatacept + MTX early in the course of RA can achieve high remission rates at 12 mths, which may be sustained on withdrawal of all RA therapy in a small but higher proportion of pts than using MTX alone.

The Efficacy and Safety of Tocilizumab Subcutaneous Q2W and Following Escalation from Q2W to QW Therapy in Combination with Traditional Dmards in Patients with Moderate to Severe Rheumatoid Arthritis at 96 Weeks. Alan Kivitz[1], Ewa Olech[2], Michael A. Borofsky[3], Beatriz M. Zazueta[4], Federico Navarro-Sarabia[5], S. C. Radominski[6], Joan T. Merrill[7], Jinglan Pei[8], Lucy Rowell[9], Clare Nasmyth-Miller[9], Sunethra Wimalasundera[9] and Janet E. Pope[10]. [1]Altoona Arthritis & Osteoporosis Center, Duncansville, PA, [2]University of Nevada School of Medicine, Las Vegas, NV, [3]Clinical Research Center of Reading, Reading, PA, [4]Centro de Investigacion en Enfermedades Reumaticas, Mexicali, Mexico, [5]University Hospital Virgen Macarena, Sevilla, Spain, [6]Universidade Federal do Paraná, Curitiba, Brazil, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]Genentech, South San Francisco, CA, [9]Roche, Welwyn Garden City, United Kingdom, [10]St Joseph Health Care, London, ON.

Background/Purpose: The BREVACTA study assessed the efficacy and safety of subcutaneous tocilizumab (TCZ SC) in patients (pts) with RA who had an inadequate response to ≥ 1 DMARD (21% previously failed aTNF therapy). The primary objective assessed efficacy and safety to Week 24. Superiority over placebo (PBO) was observed, with a safety profile comparable to intravenous (IV) TCZ. We now report the efficacy and safety data for TCZ SC every 2 weeks (q2w) and TCZ weekly (qw) following escalation from either TCZ q2w or PBO q2w to Week 96.

Methods: This phase 3, randomized, multicenter, parallel arm study included a 24 week double blind, PBO controlled period followed by a 72 week open label phase and a further 8 weeks of safety follow up. Pts were initially randomized 2:1 to receive TCZ SC 162 mg q2w (n=437) or PBO SC q2w (n=219) via prefilled syringe (PFS) with prestudy DMARD(s). At Week 24, pts in both arms were rerandomized 1:1 to receive open label TCZ SC q2w via PFS or autoinjector pen. These data focus on pts who were rerandomised at Week 24 and received TCZ SC regardless of injection device. Escape therapy with TCZ SC qw was available for pts with an inadequate efficacy response from Week 12. At the first dose on escape therapy pts were rebaselined; efficacy is from time of escape up to Week 84 and safety is from time of escape to the end of the study.

Results: In the open label phase, 338 pts (77%) were maintained on TCZ SC q2w and 119 (54%) switched from the PBO to TCZ SC q2w. For the escape pts, in the double blind phase, 72 (16.5%) escaped from the TCZ arm and 90 (41.3%) from the PBO arm, while in the open label phase 27 (5.9%) escaped from the TCZ SC q2w arm. In the TCZ q2w arm, the proportion of pts who achieved ACR20/50/70 responses increased up to Week 96. In the TCZ q2w arm, the rates of AEs and SAEs, including serious infections, remained stable or decreased up to Week 96. No anaphylaxis or serious hypersensitivity occurred. By Week 96, 31 pts (7.1%) withdrew due to AEs and 7 pts (1.6%) died. Nine pts (2.1%) developed antiTCZ antibodies postbaseline without loss of efficacy or clinically significant hypersensitivity. For escape pts, the proportion of pts who achieved an ACR20 response increased after escape in both the TCZ or PBO arms; although there was a higher ACR20 response in escape pts from the PBO arm than the TCZ q2w arm (86.4% and 63%, respectively) at Week 84. The rate of AEs per 100 pt years, following escape therapy was similar between pts who previously received TCZ or PBO (331.9 and 360.5, respectively) and comparable to the TCZ q2w arm (332.8).

Conclusion: TCZ SC q2w demonstrated long term efficacy, including sustained ACR responses over 96 weeks. The AE profile for TCZ SC at 96 weeks was comparable to 24 weeks. For escape pts, there were improvements in ACR20 response rates in pts who previously received PBO and escalated from q2w to qw. TCZ SC will offer an alternative route of administration and the possibility of self administration for pts with RA.

	TCZ SC q2w + DMARD Week 24 (N = 437)		TCZ SC q2w + DMARD Week 96 (N = 437)

Treatment Strategy for Maximizating the Effect of Adalimumab in Japanese Patients with Rheumatoid Arthritis : Retrospective Analyses of Data Collected from the Patient Treated with Adalimumab in Routine Clinical Practice in Hamamatsu Area. Toshiaki Miyamoto. Seirei Hamamatsu General Hospital, Hamamatsu, Japan.

Background/Purpose: Adalimumab (ADA) showed highly efficacious in rheumatoid arthritis (RA) in the clinical trials, although there is little evidence in daily clinical practice. The clinical usefulness and treatment continuation rate of 52 weeks of a ADA treatment in rheumatoid arthritis (RA) patients were investigated over time.

Methods: The subjects were 124 analyzable patients that had been introduced to ADA treatment at this institution from May 2009 to October 2012. In patients' background, mean age was 53 years, mean duration of illness 7.2 years, rate of concomitant MTX treatment 96% (116 patients), mean MTX dose 11.4 mg/week, and rate of concomitant PSL treatment 16.1%. Of these patients, 35 had a duration of illness below 2 years (<2 group), 89 a duration of at least 2 years (≥ 2 group), 85 were Bio Naive (N group), 39 were Switch (S group), 95 received MTX ≥10 mg/week (≥10 group), and 24 received MTX<10 mg/week (<10 group). There was no significant difference in baseline disease activity between the groups. Treatment efficacy up to 52 weeks after ADA treatment in each group was investigated comparatively.

Results: The DAS28 (CRP) remission rate for all the patients at 4, 24, and 52 weeks was 36%,62%,and 70%, respectively, showing that from 4 weeks, about 40% of the patients achieved clinical remission. Changes in DAS 28 (CRP) remission rates for the <2 and ≥2 groups at 4, 24, and 52 weeks were 29% vs. 39%, 69% vs. 60%, and 83% vs. 65%, respectively. Similarly, changes in DAS 28 (CRP) in the N and S groups were 34% *vs* 41%, 67% *vs* 51%, and 74% *vs* 62%, respectively; in the ≥10 and < 10 mg groups, they were 43% *vs* 13%, 72% *vs* 25%, and 77% *vs* 46%, respectively, showing that the values were significantly high in the ≥ 10 group at all the time points. Moreover, HAQ remission rate for the overall patients at 52 weeks was 82%, and treatment continuation rate was 72%. Excluding the patients that discontinued treatment for reasons such as hospital transfer, of the 82% on concomitant MTX treatment, response was good in 90%.

Conclusion: With ADA, remission could be induced from very early on in the treatment at 4 weeks in about 40% of the patients. The best way to apply ADA treatment is to use it concomitantly with an adequate dose of MTX in early-stage RA and Bio Naïve patients. By so doing, the potential of ADA can be exploited maximally.

Effect of Teriparatide in Patients with Osteoporosis and Rheumatoid Arthritis. Robin Dore[1], Kenneth G. Saag[2], Guillermo Valenzuela[3], Kathleen Taylor[4], Qiu He[4], Jahangir Alam[4] and Kelly D. Krohn[5]. [1]University of California, Los Angeles, CA, [2]The University of Alabama at Birmingham, Birmingham, AL, [3]Integral Rheumatology and Immunology Specialists, Plantation, FL, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly and Company, LLC, Indianapolis, Indiana, Indianapolis, IN.

Background/Purpose: A common complication in rheumatoid arthritis (RA) is osteoporosis (OP) with increased incidence of fragility fractures. RA is the only disease specifically included in the World Health Organization fracture prediction algorithm, FRAX®. The effect of teriparatide (TPTD) on the incidence of clinical vertebral (VERT) and nonvertebral (NV) fragility fractures, bone mineral density

(BMD), and safety was examined in the subgroup of OP patients with RA enrolled in the DANCE trial.

Methods: This was a post hoc analysis of patients with RA enrolled in the DANCE open-label, prospective, observational study, treated with TPTD 20 mg/day for ≤2 years (treatment phase), and followed for up to 2 more years (cessation phase). Mixed model repeated measures analysis was used to evaluate BMD changes over 18 months (mo). Incident rates of new clinical VERT or NV fragility fractures (traumatic fractures excluded) after 6–24 mo vs 0–6 mo of TPTD therapy were compared using a Poisson regression model. Time to new NV fragility fracture was compared using Kaplan-Meier analysis. Rates of incident NV fractures were assessed at intervals over treatment and cessation phases vs the first 6-mo treatment (reference) period.

Results: Of 4085 patients who received ≥1 dose of TPTD, 544 had documented RA. Patients with vs without RA at baseline had similar age (mean [SD] age, 68.6 [11.5] vs 67.8 [11.9] years), but significantly more history of prior NV fractures (60.8% vs 55.4%, p=0.017), higher L1-L4 T-scores (−2.21 [1.44] vs -2.51 [1.36], p<0.001), more baseline clinical conditions (3.1 [1.4] vs 1.6 [1.3], p<0.001), and more glucocorticoid use (32.5% vs 7.1%, p<0.001). Mean TPTD exposure was similar (523.0 [303.9] vs 545.4 [288.4] days). Over 18 mo, bone density in the spine, femoral neck, and total hip increased similarly in patients with vs without RA (all p-values>0.1). Incident rates of new VERT with or without back pain or NV fragility fractures decreased in mo 6–24 vs the first 6 mo. There was no significant difference in the decrease in fracture incidence in mo 6–24 vs the first 6 mo in the patients with RA compared with those without, regardless of the type of fracture (all interaction p>0.15). There was no difference in the time to a new NV fragility fracture (log-rank p>0.2) by RA status. NV fracture incidence rates/100 patient years decreased vs reference baseline during treatment and stayed down during cessation phase vs reference baseline (Figure 1). In the overall DANCE study, TPTD was well tolerated and no new significant safety findings were observed.

Conclusion: Patients with rheumatoid arthritis receiving teriparatide showed similar increases in BMD at the spine, femoral neck, and total hip and similar reduction over time in the incidence of NV fractures compared with osteoporosis patients without RA. Compared to baseline, the incidence of NV fractures remained down after drug cessation.

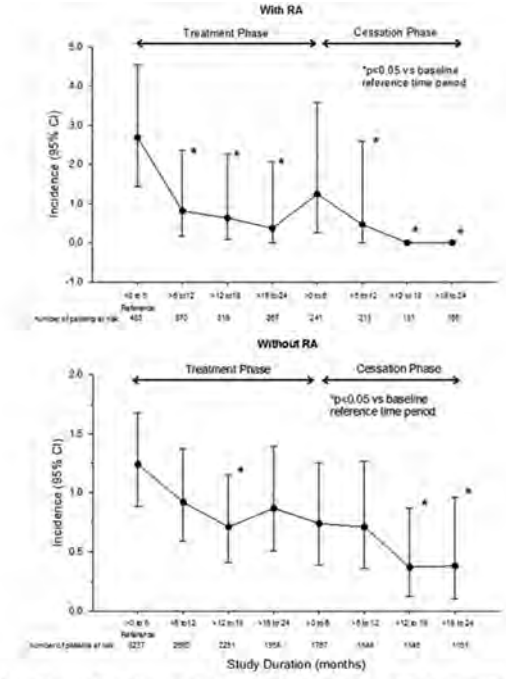

Figure 1. Incidence of New Nonvertebral Fracture During Treatment With Teriparatide and After Treatment Cessation in Patients with Rheumatoid Arthritis and without Rheumatoid Arthritis. Incidence = Number of patients with new nonvertebral fractures/Number of patients at risk × 100. CIs were derived from Clopper Pearson method; *p* value was derived from a one-sample binomial proportion test vs. the first period incidence rate

The First, Multicenter, Double-Blind, Randomized, Parallel-Group Study of Certolizumab Pegol in Early Rheumatoid Arthritis Demonstrates Inhibition of Joint Damage Progression.

Tatsuya Atsumi[1], Kazuhiko Yamamoto[2], Tsutomu Takeuchi[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Yoshiya Tanaka[6], Katsumi Eguchi[7], Akira Watanabe[8], Hideki Origasa[9], Toshiharu Shoji[10], Osamu Togo[10], Toshiyuki Okada[11], Désirée M. van der Heijde[12], Nobuyuki Miyasaka[13] and Takao Koike[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]Keio University School of Medicine, Kitakyushu, Japan, [4]Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University Graduate School and Faculty of Medicine, Nagoya, Japan, [6]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [7]Sasebo City General Hospital, Nagasaki, Japan, [8]Tohoku University, Tokyo, Japan, [9]University of Toyama School of Medicine, Toyama, Japan, [10]UCB Pharma, Tokyo, Japan, [11]Astellas Pharma Inc, Tokyo, Japan, [12]Leiden University Medical Center, Leiden, Netherlands, [13]Tokyo Medical and Dental University, Tokyo, Japan.

Background/Purpose: The efficacy and safety of certolizumab pegol (CZP)+methotrexate (MTX) therapy compared to MTX alone, in Japanese MTX-naïve early rheumatoid arthritis (RA) patients (pts) with poor prognostic factors from the C-OPERA trial, have not been previously reported.

Methods: Pts with ≤12 months persistent arthritis fulfilling 2010 ACR/EULAR classification criteria[1] were enrolled in this multicenter, double-blind, randomized study (NCT01451203). Eligible pts were MTX-naïve, with at least moderate disease activity (DAS28[ESR]≥3.2), high-positive anti-CCP (>3xULN), and were either rheumatoid factor positive or had bone erosion on radiographs of hands/feet. Pts were randomized 1:1 to CZP+MTX or placebo (PBO)+MTX. Unless precluded by tolerability, MTX dose was rapidly escalated to 16mg by Week (Wk) 8. The primary endpoint was change from baseline (CFB) in van der Heijde modified total Sharp score (mTSS) at Wk52. Secondary endpoints were CFB in mTSS at Wk24, and clinical remission rates by DAS28[ESR], ACR/EULAR (SDAI), and ACR/EULAR (Boolean) at Wk24 and 52. Post-hoc analyses assessed whether higher radiographic progression amongst PBO+MTX treated pts occurred within certain categories of baseline (BL) factors (eg. CRP, HAQ-DI, MMP-3).

Results: A total of 316 pts (CZP+MTX: n=159, PBO+MTX: n=157) were randomized and received ≥1 dose of study drug. Groups were well-balanced at BL, with mean (±SD) age: 49.2±10.5 yrs, symptom duration: 4.1±2.9 months, DAS28[ESR]: 5.45±1.15 and mTSS: 5.55±12.43. Average MTX dose was 11.6±2.8 mg/wk. CFB in mTSS at Wk52 and 24 for CZP+MTX were, on average, 0.36 and 0.26, and for PBO+MTX were 1.58 and 0.86, respectively (Figure). Statistical comparison of CFB in mTSS by nonparametric approach (ANCOVA on ranks) was significantly greater for CZP+MTX than PBO+MTX at Wk52 (p<0.001) and Wk24 (p=0.003) (Figure). CZP+MTX remission rates were significantly greater than for PBO+MTX at Wk52 (SDAI: 57.9% vs 33.8% [p<0.001]; Boolean: 45.3% vs 28.0% [p=0.002]; DAS28[ESR]: 57.2% vs 36.9% [p<0.001]) and at Wk24 (SDAI: 48.4% vs 29.3% [p<0.001]; Boolean: 36.5% vs 22.3% [p=0.007]; DAS28[ESR]: 52.8% vs 30.6% [p<0.001] Fisher's Exact test). Higher BL DAS28[ESR], CRP, mTSS, HAQ-DI and serum MMP-3 seemed associated with more radiographic progression in the PBO+MTX group, whereas CZP+MTX still inhibited progression of structural damage in these pts despite this higher risk of progression (Table). CZP+MTX was well tolerated, with no unexpected safety signals observed.

Conclusion: CZP+MTX was significantly more effective than PBO+MTX in inhibiting disease progression, as well as in achieving clinical remission, in MTX-naïve Japanese early RA pts with poor prognostic factors.

Post-Marketing Surveillance of Efficacy and Safety of Tacrolimus Add-on Therapy in Japanese Rheumatoid Arthritis Patients Who Failed to Show an Adequate Response to Biological Dmards : Interim Analysis.

Tsutomu Takeuchi[1] and Kota Ishida[2]. [1]School of Medicine, Keio University, Tokyo, Japan, [2]Astellas Pharma Inc., Tokyo, Japan.

Background/Purpose: Tacrolimus (TAC) is an immunosuppressive macrolide that blocks T cell activation by specifically inhibiting calcineurin, and it is widely administered following organ transplantation. TAC was approved in Japan for the treatment of rheumatoid arthritis (RA) in 2005. We report here the interim results of Post-marketing surveillance we have been conducting to evaluate the safety and efficacy of TAC adding on to biological disease-modifying anti-rheumatic drugs (DMARDs) in Japanese RA patients who failed to show an adequate response to biological DMARDs in a real clinical setting.

Methods: The observation period of this study was 24 weeks. One hundred and seventy-two patients were included in the safety population and 165 patients were included in the efficacy population. An inadequate response to biological DMARDs was defined as that all of the following conditions were met: Simplified Disease Activity Index (SDAI) >3.3 when TAC was started; Both tender joint count and swollen joint count were the same or increased compared to those at four to eight weeks prior to TAC; Biological DMARDs were used for at least eight weeks prior to TAC. Efficacy was evaluated using the SDAI, DAS28-CRP (Disease Activity Score 28-C-reactive protein), EULAR (European League Against Rheumatism) response criteria. SDAI improvement was defined as SDAI≤11. DAS28-CRP improvement was defined as DAS28-CRP <2.7.

Results: Mean age was 61.9 years and the mean disease duration was 11.0 years. The mean TAC dose was 1.3 mg during the observation period. Adverse drug reactions (ADRs) occurred in 18 patients and serious ADRs was observed in two patients (Herpes zoster, Myocardial infarction). One patient (age 76) who developed herpes zoster was resolved during the observation period. One patient (age 89) who developed myocardial infarction died on the day when it occurred. SDAI remission rate was 13.3% at week 24, SDAI improvement rate was 58.5% at week 24 and the mean SDAI was decreased from 20.1 at baseline to 11.7 at week 24. DAS28-CRP remission rate was 33.3% at week 24, DAS28-CRP improvement rate was 48.9% at week 24 and the mean DAS28-CRP was decreased from 4.0 at baseline to 2.9 at week 24. Based on EULAR response criteria, moderate or good response rate was 69.8% at week 24.

Conclusion: TAC is well tolerated and effective when added on to the biological DMARDs in Japanese RA patients who failed to achieve an adequate response to biological DMARDs in a real clinical setting.

Efficacy and Tolerability of Subcutaneous Methotrexate for Inflammatory Arthritis: A Retrospective Observational Cohort Study.

Jessica Gunn, Aikaterina Panopolou and Alan Steuer. Wexham Park Hospital, Slough, United Kingdom.

Background/Purpose: Methotrexate (MTX) monotherapy or MTX in combination with other conventional and biologic disease-modifying anti-rheumatic drugs (DMARDs) is standard treatment for patients with inflammatory arthritis. A significant number of patients discontinue therapy with oral (PO) MTX because of intolerance or a lack of efficacy. Standard practice at our institution involves switching such patients to subcutaneous (SC) MTX prior to the addition of other agents. This study was designed to assess the therapeutic outcomes of this approach in the outpatient setting.

Methods: We retrospectively reviewed electronic medical records within our patient cohort from 2001 to the present, and included patients who switched from PO to SC MTX. Records were analyzed for baseline demographics, reasons for switching to SC MTX, doses of PO and SC MTX at the time of the switch, duration of SC MTX use, reasons for discontinuation of SC MTX (if applicable), and whether the addition of biologic agents was required.

Results: The records of 240 patients who switched to SC MTX were examined. Fifty-eight patients were excluded because of incomplete data. Of the 182 patients included, 125 (68%) were female, and the average age at starting SC MTX was 52.5 years (range 17–82). Underlying diagnoses included rheumatoid arthritis (n=144), psoriatic arthritis (n=20), juvenile idiopathic arthritis (n=7), ankylosing spondylitis (n=2), undifferentiated inflammatory arthritis (n=6), systemic lupus erythematosus (n=1), and vasculitis (n=2). Reasons for switching from PO to SC MTX included intolerance (n=55), inefficacy (n=118) and unknown (n=9). One hundred ten patients (60%) were receiving no other DMARDs at the time of the switch. In the majority of the remaining patients (n=60), MTX was used in combination with sulfasalazine (n=21), hydroxychloroquine (n=21), prednisolone (n=11), leflunomide (n=4), or anti-tumor necrosis factor-α therapies (n=3). At the time of switching patients were taking an average dose of 20mg/week PO MTX and were switched to an average dose of 15mg/week SC MTX (range for both 5–25mg/week). One hundred thirty-three (73%) patients remain on SC MTX to date; 49 patients discontinued SC MTX because of intolerance (n=26), adverse drug reaction (n=10), inefficacy (n=6), disease remission (n=2), or undocumented reasons (n=5). Thirty-nine percent of those who discontinued SC MTX required the addition of a biologic, compared with 28% of those who continued with SC MTX. Sixty-five percent of those who switched to SC MTX because of intolerance were able to continue with this drug, for an average duration of 46 months (range 2–144 months) to date; 40 to 45% of those who switched to SC MTX because of intolerance or inefficacy, respectively, did not require the addition of another DMARD or biologic agent.

Conclusion: This evidence strongly supports the use of SC MTX as a tolerable and efficacious alternative after failure of PO MTX. After the switch to SC MTX, 65% of patients who were intolerant of PO MTX continued with MTX, either as monotherapy or in combination with other DMARDs or biologic agents. Furthermore, patients who continued with SC MTX were less likely to require biologic agents. Further evaluation of this approach may be warranted.

Multiple Approaches for Implementation of Long-Term Efficacy: Interpretation of Certolizumab Pegol Data in Rheumatoid Arthritis Case Study. Edward C. Keystone[1], Josef S. Smolen[2], Vibeke Strand[3], Thomas Kumke[4], Irina Mountian[5], Susan Walker[6] and Robert B. M. Landewé[7]. [1]Mount Sinai Hospital, Toronto, ON, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [3]Biopharmaceutical Consultant, Portola Valley, CA, [4]UCB Pharma, Monheim, Germany, [5]UCB Pharma, Brussels, Belgium, [6]UCB Pharma, Raleigh, NC, [7]Amsterdam Rheumatology Center, Amsterdam, Netherlands.

Background/Purpose: Use of imputed or observed data, as well as the patient (pt) population evaluated (eg. intention-to-treat [ITT], completer), affects the interpretation of long-term efficacy data. Statistical analysis of data from long-term studies must consider the impact of missing values, which result from pt drop-out due to various reasons. Imputation methods should link such reasons with assumptions made for missingness. Missing completely at random (MCAR) approaches (eg. last observation carried forward [LOCF], non-responder imputation [NRI]), assume that missingness is independent of observed and unobserved outcomes. In contrast, missing at random (MAR) methods (eg. mixed models with repeated measures [MMRM]) assume that missingness is dependent on observed outcome.

Methods: Data from pooled analysis of Rheumatoid Arthritis Prevention of Structural Damage (RAPID) 1 and 2 RCTs and open-label extensions (OLE) (NCT00152386[1], NCT00175877[2], NCT00160602[3] and NCT00160641[4]) were used. RAPID1[1] and 2[3] evaluated safety and efficacy of certolizumab pegol (CZP) with methotrexate. Efficacy data were collected up to 256 weeks (wks) of CZP exposure for clinical measures, including DAS28(ESR) (LOCF), HAQ-DI (LOCF) and ACR20/50/70 (modified NRI [mNRI]). Observed and imputed (MCAR, MAR) data are presented for CZP ITT (all pts randomized to CZP in RCT) and CZP Completer (CZP ITT pts who completed RCT and reconsented into OLE) populations.

Results: Improvements from baseline in DAS28(ESR) and HAQ-DI were evident in CZP Completer and ITT populations at 256 wks. The use of LOCF and MMRM imputation gave results consistent with observed data (Table). Long-term CZP exposure resulted in sustained ACR response. mNRI determined rates were, per definition, lower than observed data (Table), but were in line with data observed in blinded periods.[1,3] MMRM imputation followed long-term mean treatment response more closely and was more homogeneous between patient populations compared to LOCF/mNRI. Different reasons for discontinuation lead to distinct differences in imputed results. Imputed mean response was more homogeneous in the completer population.

Conclusion: Considering multiple populations and imputation approaches enables more reliable long-term efficacy data interpretation. Pooled RAPID1 and 2 results revealed similar patterns between observed and imputed data, although differences were observed between different imputation methods and reasons for withdrawal. Analysis of the ITT population gives a less biased estimate of efficacy compared with CZP Completers. Nonetheless, results were consistent with maintained improvements in RA signs and symptoms following 256 wks of exposure to CZP.

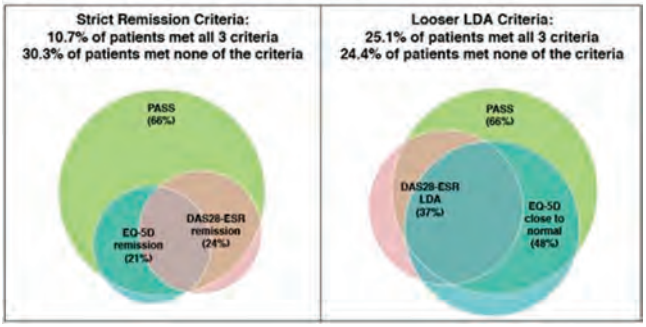
Integrating Treatment Goals of Physicians, Patients, and Payers during Treatment with Golimumab in Patients with Rheumatoid Arthritis. B Combe[1], DJ Veale[2], R Burgos-Vargas[3], G Sz″ucs[4], M Leirisalo-Repo[5], R Yao[6], S Huyck[6], R Lyu[6], M Govoni[7], N Vastesaeger[8] and HH Weng[6]. [1]Monpellier University Hospital, Montpellier, France, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]Cliditer S.A. de C.V. and Hospital General de Mexico, Mexico City, Mexico, [4]University of Debrecen Faculty of Medicine, Debrecen, Hungary, [5]Helsinki University Central Hospital, Helsinki, Finland, [6]Merck & Co., Inc., Whitehouse Station, NJ, [7]MSD Italy, Rome, Italy, [8]MSD Belgium, Brussels, Belgium.

Background/Purpose: Physicians, patients, and payers may have different ideas about what constitutes successful treatment and how treatment goals should be defined for rheumatoid arthritis (RA). This analysis was designed to evaluate overlap between attained treatment goals that are important to physicians, patients, and payers after 6 months of add-on golimumab (GLM) in patients with active RA, and to determine baseline predictors of patients who achieve all 3 goals.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients with active RA (28-joint disease activity score using erythrocyte sedimentation rate [DAS28-ESR] ≥3.2) despite disease-modifying antirheumatic drug (DMARD) treatment. Patients received 50-mg subcutaneous (SC) GLM once monthly for 6 months. Efficacy outcomes including DAS28-ESR, patient-acceptable symptom state (PASS; 1 yes/no question of patient satisfaction with their current disease state), and EuroQol 5-dimension (EQ-5D) were evaluated at month 6. The overlap in achievement of strict remission treatment goals was evaluated (DAS28-ESR remission, normal EQ-5D [≥.8], and met PASS); looser low disease activity (LDA) goals were also evaluated (DAS28-ESR LDA, EQ-5D near normal [≥.7], and met PASS). A multivariate regression analysis identified baseline predictors of patients who achieved the intersection of the 3 criteria.

Results: In 3280 efficacy-evaluable patients, mean disease duration was 7.6 years; mean DAS28–ESR was 5.97 (SD=1.095). As previously reported, 23.9% of 3280 efficacy-evaluable patients achieved remission, and 37.4% achieved LDA (based on DAS28-ESR) at month 6.[1] 21% of patients achieved normal QoL, and 48% achieved close-to-normal QoL (EQ-5D ≥.7). 66.0% of patients achieved PASS. Overlap in patients who achieved each goal is shown (figure). 10.7% of patients (350/3280) met all 3 strict criteria, and 25.1% (823/3280) met all 3 looser criteria. Significant baseline predictors of achieving all 3 strict remission criteria were absence of comorbidities; lower DAS28, Health Assessment Questionnaire (HAQ), and swollen joint count scores; and greater anti-cyclic citrullinated peptide levels and EQ-5D Index scores. When PASS was replaced with HAQ ≤.5 (minimal or no functional impairment, achieved by 37.4% of patients) in either the set of strict or looser criteria, the percentage of patients who met all 3 criteria was similar to when PASS was used.

Figure. Overlap in Achieving Strict and Looser Treatment Goals



Conclusion: In patients with active RA who failed ≥1 DMARD and received add-on GLM for 6 months, overlap in achievement of LDA goals of physicians, patients, and payers was attained in 25.1% of patients. Overlap was smaller when strict remission goals were evaluated. Several measures of lower disease activity at baseline predicted achievement of all 3 strict remission criteria.

Analysis of the Clinical Sustained Response after Retreatment with a Lower Dose of Rituximab in Patients with Chronic Inflammatory Arthropathies. M. Victoria Hernández[1], Andrea Cuervo[1], Sonia Cabrera[1], Jose Inciarte-Mundo[1], Julio Ramirez[1], Virginia Ruiz-Esquide[1], Juan D. Cañete[2] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clinic, Barcelona, Spain.

Background/Purpose: The dosage of rituximab (RTX) approved for the treatment of active rheumatoid arthritis (RA) is two intravenous (iv.) 1 g infusions, separated by two weeks. However, it has recently been reported that, after initial treatment with the standard dosage, RTX retreatment at a lower dose may have comparable efficacy and be more cost-effective[1]. Our objective was to analyse whether retreatment with RTX at a lower dose (1 g total dose) is equally effective in maintaining the clinical response as the standard dosage of cycles of 2g.

Methods: Observational, descriptive, retrospective study. We analysed the long-term efficacy of RTX retreatment with 1 g (total dose) cycles (2 iv. 500 mg infusions separated by 2 weeks; or 1 g iv single infusion) in routine clinical practise. All patients had initially been treated with at least one 2g (total dose) cycle, with a good response according to clinical judgment. The main efficacy variables were: mean DAS-28 score at the last follow-up visit and at the follow-up visit previous to RTX dose reduction; need to increase the RTX dose to the standard 2g dose; treatment withdrawal due to inefficacy. Secondary variables were: erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) values after retreatment in order to analyse variations between the last follow-up visit (dosage of 1g total dose) and the follow-up visit previous to RTX dose reduction (2g total dose).

Results: From 2006 to 2013, 53 patients (86.8% RA) attended by our Department received at least, one cycle of 2g RTX (standard dosage); 41 out of 53 (77.3%) had a good response. Since September 2011, RTX retreatment was administered at a reduced 1g (total dose)/ cycle in 29 patients (mean age: 59.5±10.4 years; 86.2% female; disease duration 11.7±7.9 years; 79.3% positive for rheumatoid factor/anti-cyclic citrullinated peptides). 79.3% of patients received concomitant disease-modifying antirheumatic drugs (DMARD) and 86.2% glucocorticoids. The mean number of RTX cycles received per patient before RTX dose reduction was 2.03±1.35. No increase in the DAS-28 score was found at the last follow-up visit (2.85±0.98) compared to the follow-up visit previous to RTX dose reduction (3.66±1.17) ($p<0.0001$). After a follow-up of 20.7±9.3 months, none of the 29 patients required a RTX dose increase or treatment withdrawal due to loss of efficacy. No significant differences were observed in ESR and CRP values between the last follow-up visit and the follow-up visit previous to the RTX dose reduction (mean ESR: 18.1±12.3 vs 18.4±13.1 mm/h, respectively; $p=0.50$; mean CRP: 0.6±0.8 vs 0.9±1.2 mg/dl, respectively; $p=0.07$). We observed no increase in the frequency of RTX cycles required after dose reduction (8.5±3.2 (1g total dose) vs 8.2±2.8 (2g total dose) months).

Conclusion: After an initial favourable response to the standard dose of RTX, posterior retreatment with a total dose of 1g/cycle maintained the clinical response over time and was more cost-effective.

Utility of Adjustment of Administration Interval in Tocilizumab in Rheumatoid Arthritis. Shuntaro Saito, Keisuke Izumi, Yuko Kaneko, Katsuya Suzuki and Tsutomu Takeuchi. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Interleukin-6 (IL-6) is considered a key cytokine in the pathogenesis of rheumatoid arthritis (RA). Tocilizumab (TCZ) is a monoclonal antibody which binds to membrane-bound and soluble forms of human IL-6 receptor, and has proved to be effective in the treatment of RA. In the standard protocol for RA, TCZ is administered intravenously every four weeks. However, given that the impact of IL-6 presumably differs among patients, treatment might be optimized by shortening or prolonging the administration interval of TCZ. Here, we evaluated the usefulness of modifying the protocol based on the treat-to-target concept in daily practice.

Methods: We retrospectively surveyed all 453 patients treated with TCZ (8mg/kg) at our institution between 2008 and 2014. Patients administered TCZ at an interval of ≤ 3 weeks or ≥ 5 weeks were analyzed as the shortened or prolonged interval group, respectively. Clinical information, including disease activity, was collected and statistically analyzed.

Results: A) Patients administered TCZ at a shortened interval (administration interval ≤ 3 weeks).

Among 453 patients, 25 (5.5%) were administered TCZ at a shorter interval due to insufficient effectiveness after administration at a 4-week interval for a median of 33.8 weeks. Disease activity was significantly improved after two administrations at this shortened interval, with disease activity score (DAS) 28 changing from 5.10 to 3.40 ($p<0.05$). Among these

25 cases, interval could be returned to 4 weeks in 15. In contrast, the remaining 10 required continuous administration at a shortened interval for more than 1 year due to exacerbation of RA activity on return to a 4-week interval.

B) Patients administered TCZ at a prolonged interval (administration interval ≥ 5 weeks).

Sixty-three patients (13.9%) were administered TCZ at a prolonged interval, after having achieved remission after a median of 70.0 weeks at a 4-week interval. The prolonged interval ranged from 5 to 8 weeks. Of these 63 patients, 48 (76.2%) were able to continue TCZ administration at a prolonged interval for more than 1 year, while 15 (24.8%) required returning to a 4-week interval due to exacerbation of RA activity after a median of 51.1 weeks at a prolonged interval. All 15 cases achieved low disease activity equivalent to the original level before interval prolongation.

Conclusion: Our study highlighted the importance of administration interval in the effectiveness of TCZ in RA. Adjustment of interval according to disease activity in individual patients is a promising way to optimize treatment.

Is there a Difference in the Effectiveness in the Treatment of Rheumatoid Arthritis with Rituximab when Using a Dose of 1 or 2 Grams per Cycle? a Systematic Review. Ana M. Ortiz[1], María Piedad Rosario[2], Carmen Martínez[2] and Isidoro González-Alvaro[1]. [1]Hospital Universitario de La Princesa. IIS La Princesa, Madrid, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain.

Background/Purpose: Since the description of the efficacy of rituximab (RTX) in treating patients with rheumatoid arthritis (RA), the use of this drug has been extended. The recommendation in fact sheet is the administration of two infusions of 1 g in each cycle but some studies have used two infusions of 500 mg. Currently the most suitable pattern for its use is not established. The purpose of this work was to systematically review the published evidence to date regarding on the difference in efficacy in the treatment of RA with RTX when used at a dose of 2 × 500 mg (1 g) or 2 × 1000 mg (2 g) per cycle.

Methods: A sensitive search of all published studies on the difference in the efficacy of RTX in RA patients used at a dose of 1 and 2 g per cycle was performed in Medline, Embase and Cochrane Central databases since its inception until July 2013. We selected all studies involving adult patients with RA treated with RTX in which intervention was described as treatment with RTX at a dose of 1 g per cycle and comparator as the administration of RTX at a dose of 2 g per cycle. Any standardized measure of efficacy in RA was considered as outcome measure at two years of follow-up. Although meta analysis, systematic reviews, clinical trials and cohorts well designed were preferably selected, finally we also included open studies and all studies that showed a methodologically correct subanalysis related to the question even if it had not been his main objective. After removing duplicates, an initial selection by reading titles, a second selection after reading abstracts and, finally, full reading of selected studies, assessing the methodological quality by levels of the Oxford Centre for Evidence Based Medicine Evidence (2001 update) where applicable, was carried out. A manual search of the references of included studies was also performed.

Results: A total of 451 citations about the treatment of RA patients with RTX used at a dose of 1 and 2 g per cycle were identified, which were reduced to 46 after removing duplicates and selection by reading titles and abstracts. Of the 46 articles selected, finally 14 were included in the review, 3 reviews, 2 of them systematic and one not systematic, 5 corresponding to 4 clinical trials, 3 open studies and 3 abstracts, two of them about the same retrospective cohort and, the third one, an open study previously included as a publication. Although published outside the period included in this review, an article about a systematic review and meta-analysis was included because it provides valuable information for the same.

Conclusion: RTX shows an equivalent overall clinical efficacy administered at doses of 1 and 2 g per cycle in the treatment of RA patients (level of evidence 1a, grade of recommendation A). However, there may be differences in extreme efficacy parameters with trend, not statistically significant, to a more ACR70 response or EULAR good response at the dose of 2 g per cycle.

This work has been funded by the Spanish Society of Rheumatology.

Which Factors Influence the Prescription of Tocilizumab Alone or in Combination with DMARDs in Rheumatoid Arthritis Patients in a Real Life Setting? An Interim Analysis of Safety and Efficacy at 6 Months. Jacques Tebib[1], Isabelle Idier[2], Mathieu Coudert[3], David Pau[4], Rene-Marc Flipo[5] and Jean-Francis Maillefert[6]. [1]University Hospital Lyon, Lyon, France, [2]Chugai Pharma, La Defense, France, [3]Experis IT, Nanterre, France, [4]Roche, Boulogne-Billancourt, France, [5]University Hospital Lille, Lille, France, [6]University Hospital Dijon, Dijon, France.

Background/Purpose: Baseline factors influencing the use of tocilizumab (TCZ) in monotherapy (Mono) instead of combination with DMARDs (Combo) in real-life practice in RA patients (pts) as described previously in the Act Solo study were: no MTX treatment over the past 2 years, past-history of severe infection, age ≥ 65 years and an increased DAS28-ESR[1].

Objective: To describe drug retention rate, efficacy and tolerance of TCZ in real life in RA patients at 6 months.

Methods: *Study design*: prospective, multicenter, longitudinal, non interventional 12-month study. *Patients*: RA requiring TCZ treatment according to their physician. *Treatment:* TCZ as prescribed in real life. *Primary endpoint*[1]: Baseline factors influencing the use of TCZ in Mono or in Combo. *Secondary endpoints*: drug retention rate, premature withdrawals, safety and efficacy. *Data collected*: pts' characteristics at baseline and after TCZ initiation, monthly disease activity components, RA treatments. *Statistical analysis*: pts fulfilling inclusion and non-inclusion criteria and with ≥1 TCZ infusion were analyzed.

We herein present only the results at 6 months.

Results: 608 patients were recruited of whom 603 were analysed for safety and 577 (Total) for other endpoints. Baseline characteristics: mean age 57±13 years, 454 (79%) females, at least 1 co-morbidity: 409 (71%), mean RA duration 11±9 years, RF or ACPA positive: 479 (86%), erosive disease: 435 (77 %), mean DAS28-ESR 5.2±1.3. Past RA treatments included DMARDs in 98% and biologics in 75%. MTX was previously prescribed in 94% of pts and in 69% within the last 2 years. TCZ Mono was initiated in 229 (40%) pts and TCZ Combo in 348 (60%) pts of whom 74% received MTX (mean dose 16±5mg). Steroids were used in 385 (67%) pts (mean dose 10±7mg). 386 pts completed M6. 86 pts had no M6 visit. 105 pts withdrew for: AE 38 pts, inefficacy 28, patient's wish 6, lost to follow-up 15, remission 1, wish of pregnancy 1, unknown 14. 2 pts died: stroke 1, inhalation pneumopathy 1. At M6, drug retention rate was 78% in Total, 75% in Mono, 79% in Combo. Among the 577 pts, 211 (37%) pts remained without DMARD, 366 (63%) received TCZ+DMARD. DMARD was added in 18 TCZ Mono pts (twice on a temporary way) and definitely stopped in 23 TCZ Combo pts. 199 (34%) pts experienced at least 1 dose modification (temporary or definitive stop, dose changing) in TCZ infusions, 90 (39%) pts in TCZ Mono and 109 (31%) in TCZ Combo group. During the period 362 (63%) pts received steroids; at M6, 235 (41%) pts remained on steroids. Mean DAS28-ESR in Total, Mono and Combo were 2.80±1.49, 2.89±1.50 and 2.74±1.49 respectively. DAS28-ESR remission was 31% in Total, 28% in Mono, 33% in Combo. DAS 28-ESR LDA was 40% in Total, 38% in Mono, 42% in Combo. No new safety signal was reported. 264 (44%) patients had at least one AE, 46 (8%) had at least one serious AE.

Conclusion: In this 6-month interim analysis, drug retention rate was 78% in pts receiving TCZ in real life. In Total mean DAS 28-ESR decreased from 5.2±1.3 to 2.80±1.5 No new safety signal occurred. Both TCZ Mono and TCZ Combo groups were comparable for drug retention, efficacy and safety.

This study was conducted thanks to an unrestricted grant from Roche Chugai France.

Use of Biologic Therapy As Monotherapy in Patients with Rheumatoid Arthritis. Antonio Gómez-Centeno[1], Olga Martínez[2], Francisco Javier Ballina[3], José Manuel Rodríguez[4], Jenaro Graña[5], Manuel Brito[6], Juana Sampedro[7], Gerardo Iglesias[8], Concepción Delgado[9] and Indalecio Monteagudo[10]. [1]Hospital Parc Taulí, Sabadell, Spain, [2]Hospital Virgen de la Concha, Zamora, Spain, [3]Hospital Central de Asturias, Oviedo, Spain, [4]Hospital Getafe, Getafe, Spain, [5]Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [6]Hospital Nuestra Señora Candelaria, Santa Cruz de Tenerife, Spain, [7]Hospital Virgen de la Salud, Toledo, Spain, [8]Complejo Hospitalario Palencia, Palencia, Spain, [9]Hospital Clínico Lozano Blesa, Zaragoza, Spain, [10]Hospital Gregorio Marañón, Madrid, Spain.

Background/Purpose: The treatment for Rheumatoid Arthritis (RA) is based on synthetic or biological disease-modifying drugs (DMARDs). Current guidelines recommend biologics in combination with methotrexate as this shows better control of disease progression. However several studies show that up to 30% of patients are treated with biologic monotherapy for different reasons. The aim of the study was to know the characteristics of patients receiving biologic monotherapy, including previous treatments and reasons for treatment change.

Methods: Observational, cross-sectional, retrospective and multicentric study with the participation of 38 rheumatology units in Spain. Patients were consecutively included if they were >18, with moderate to severe RA with an inadequate response or intolerance to synthetic or biologic DMARD (as recommended by the Spanish Rheumatology Society, SER), treated with biologic DMARD in monotherapy for >6 months and gave informed consent.

Collected variables included sociodemographic (age, gender), clinical (RA diagnosis date, extra-articular manifestations, DAS28, CDAI and SDAI, presence of joint damage), and treatment (prior treatments with DMARD and reasons for change).

Results: Two hundred and nine patients were included, 82.8% were women, mean (SD) age was 57.6 (13.6). Mean (SD) time since RA diagnosis was 13.5 (8.8) years. Most had RF (59.8%), 38.3% anti-CCP antibodies, 73.7% joint damage; 28.5% had extra-articular manifestations.

At study visit, 58.4% of patients were receiving tocilizumab, 18.7% etanercept, 12.4% adalimumab, and 10.5% other biologics. Mean (SD) number of tender joints was 1.9 (3.0), of swollen joints was 0.84 (2.1); mean (SD) CRP level was 4.0 (7.7), and ESR was 14.6 (13.4). Mean (SD) DAS28 score was 2.7 (1.1), CDAI index was 8.4 (6.9), and SDAI index was 8.8 (7.1), with 49.8%, 15.8%, and 20.1% of patients on in remission, respectively.

28 of the 122 patients (23.0%) receiving monotherapy with tocilizumab were on first-line treatment, while 70.4% of patients with anti-TNF on monotherapy were on first-line.

The first synthetic DMARD prescribed was methotrexate (62.3%), followed by gold salts (17.9%). Mean time (months) since first DMARD prescription was 19.5 (52.8) [mean (SD)] and 89.8 (86.4) since the first biologic use.

Patients had received a mean (SD) of 2.6 (1.4) synthetic DMARDs and 1.7 (0.9) biologics.

Just before initiating monotherapy, 45.5% of patients had received synthetic+biologic DMARD, 30.6% synthetic DMARD as monotherapy, and 23.9% another biologic as monotherapy (30.0% adalimumab and 28.0% etanercept).

The most frequent reason for treatment withdrawal before monotherapy was lack of effectiveness (61.2%), intolerance (10.5%), adverse events (10.0%), and lack of adherence (1.5%).

Conclusion: The clinical control with biologics as monotherapy was good, with a mean DAS28 of 2.7. Patients with RA treated with biologic DMARD as monotherapy had previously received more than 2 synthetic DMARD. The withdrawal of the DMARD was mainly due to lack of effectiveness, intolerance, or adverse event. Treatment with biologics as monotherapy is a therapeutic alternative for patients who do not tolerate or cannot receive synthetic DMARD.

Treatment Adjustment Strategy after Achieving Remission or Low Disease Activity in Rheumatoid Arthritis : A Systematic Review and Meta-Analysis. Sophie Henaux[1], Thomas Barnetche[2], Adeline Ruyssen Witrand[3], Bruno Fautrel[4], Alain G. Cantagrel[5] and Arnaud Constantin[3]. [1]Hopital Purpan, Toulouse, France, [2]Bordeaux University Hospital, Bordeaux, France, [3]CHU Purpan - Hôpital Pierre-Paul Riquet, Toulouse, France, [4]GRC-UPMC 08; AP-HP, Rheumatology dépt, Pitié Salpêtrière Hospital, Paris, France, [5]Centre Hospitalier Universitaire de Toulouse, Toulouse, France.

Conflict of interest:[r] NONE.

Background/Purpose: Attaining remission or at least low-disease activity (LDA) is a goal achieved in a significant proportion of rheumatoid arthritis (RA) patients thanks to the development of TNF blockers. In these patients, reduction or withdrawal of anti-TNF represent the main adjustment strategies in view to decrease the use of TNF blockers for safety and economic concerns.

Our aim was to 1) compare the maintenance of remission or LDA after anti-TNF withdrawal in comparison to anti-TNF continuation 2) compare the maintenance of remission or LDA after anti-TNF dose reduction in comparison to anti-TNF continuation.

Methods: A systematic literature review searching for controlled trials comparing anti-TNF withdrawal or anti-TNF dose reduction and anti-TNF continuation in RA patients achieving LDA or remission was conducted using the Embase, PubMed, Cochrane library, and ACR/EULAR meeting databases, updated until June 2014. The two primary endpoints were 1) maintenance of remission or LDA after anti-TNF withdrawal 2) maintenance of remission or LDA after anti-TNF dose reduction. Meta-analysis was performed using the inverse variance approach and statistical heterogeneity was assessed with the Cochran Q-test and I^2 values.

Results: After systematic literature review, 6 controlled trials comparing anti-TNF withdrawal (725 RA patients in 4 trials) or anti-TNF dose reduction (694 RA patients in 4 trials) and anti-TNF continuation in RA patients achieving LDA or remission were selected for meta-analysis. For the comparison of anti-TNF withdrawal versus anti-TNF continuation, meta-analysis indicates ORs (95% CI) of 4.29 (3.04–6.07) for maintenance of remission ($p<0.00001$) and 5.33 (3.65–7.79) for maintenance of LDA ($p<0.00001$) (Figure 1), in favour of anti-TNF continuation. For the comparison of anti-TNF dose reduction versus anti-TNF continuation, meta-analysis indicates ORs (95% CI) of 1.60 (1.15–2.24) for maintenance of remission ($p=0.006$) and 1.31 (0.88–1.95) for maintenance of LDA (not significant) (Figure 2), in favour of anti-TNF continuation.

Conclusion: Anti-TNF dose reduction appears as a possible strategy for maintenance of LDA or even remission, while anti-TNF withdrawal appears as a risky strategy in RA patients who achieved LDA or remission.

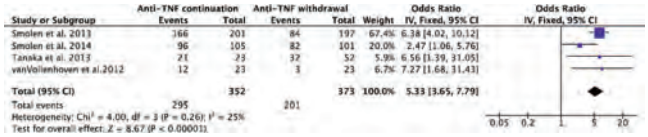

Fig 1 – Meta-analysis of controlled trials assessing the maintenance of LDA after anti-TNF withdrawal in comparison to anti-TNF continuation in RA.

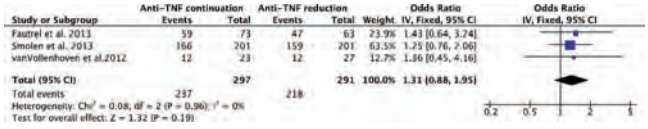

Fig 2 – Meta-analysis of controlled trials assessing the maintenance of LDA after anti-TNF dose reduction in comparison to anti-TNF continuation in RA.

Adding an Initial Six-Month Course of Infliximab to an Active Combination Treatment Is Cost Saving in Working-Aged Early Rheumatoid Arthritis Patients. Vappu Rantalaiho[1], Kari Puolakka[2], Janne Martikainen[3], Hannu Kautiainen[4] and Marjatta Leirisalo-Repo[5]. [1]Tampere University Hospital, Tampere, Finland, [2]South Karelia Central Hospital, Lappeenranta, Finland, [3]University of Eastern Finland, Kuopio, Finland, [4]Turku University Hospital, Turku, Finland, [5]University of Helsinki, Helsinki, Finland.

Background/Purpose: To study the cost-effectiveness of adding initial infliximab to a remission-targeted combination treatment with disease modifying antirheumatic drugs (DMARDs) in early rheumatoid arthritis (RA).

Methods: Economic evaluation was conducted alongside the NEO-RACo trial with a 2-year follow-up. A total of 99 patients with early, DMARD-naïve RA, receiving a triple combination of DMARDs and prednisolone, were randomized to double-blindly receive either added-on infliximab (FIN-RACo+INFL) or placebo (FIN-RACo+PLA) infusions during the first 6 months. All the patients fulfilled the ACR 1987 classification criteria for RA, were 18 to 60 years of age, and available for the workforce.

Direct costs during the 2-year follow-up were estimated on a micro-costing level. The consumed resources were collected from the study forms including all RA-related visits, medications, intraarticular injections, physiotherapy, splints and aids, as well as another person's help. The unit costs were obtained from the national list of health care costs and other public sources. In addition, data about the lost workdays due to RA were gathered, and the monetary value of lost productivity was estimated by the human capital method. The quality-adjusted life-years (QALYs) gained were calculated on the basis of SF-6D utilities. Both the costs and the QALYs were discounted by 3%.

Results: Over the 2-year follow-up, the average direct costs were 13,574 Euro for the patients in FIN-RACo+INFL group and 6,160 Euro for those in FIN-RACo+PLA group. In FIN-RACo+INFL the patients lost 51 workdays and in FIN-RACo+PLA 101 workdays. The respective lost productivity was 8,841 Euro and 17,387 Euro, while the total costs amounted 22,415 Euro and 23,548 Euro. In FIN-RACo+INFL group the patients gained on average 1.5533 QALYs and in FIN-RACo+PLA group 1.5267 QALYs with difference of 0.0266 (95% CI: – 0.065 to 0.1139, by bias-corrected and accelerated bootstrapping). Based on the direct costs only, the 2-year incremental cost-effectiveness ratio of adding an initial 6-month course of INFL on the FIN-RACo combination was 278,918 Euro. However, when taking also the indirect costs into account, the FIN-RACo-INFL treatment was a dominant option (i.e., less costly and more effective).

Conclusion: From the societal point of view, the induction treatment of early RA by adding a six-month course of infliximab on a targeted treatment with combination DMARDs and prednisolone is cost saving in working-aged patients.

Predictors of Drug-Free Remission Following Treatment with Abatacept (in Combination with Methotrexate or as Monotherapy) in Early Rheumatoid Arthritis. P Emery[1], Gerd Burmester[2], Vivian P. Bykerk[3], B Combe[4], D E Furst[5], E Barre[6], C S Karyekar[7], D Wong[7] and T W J Huizinga[8]. [1]University of Leeds, Leeds, United Kingdom, [2]Charité – University Medicine Berlin, Berlin, Germany, [3]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [4]Monpellier University Hospital, Montpellier, France, [5]University of California at Los Angeles, Los Angeles, CA, [6]Bristol-Myers Squibb, Braine-L'Alleud, Belgium, [7]Bristol-Myers Squibb, Princeton, NJ, [8]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: In the Phase IIIb, randomized, double-blind, active-controlled AVERT study, abatacept (ABA) + MTX and ABA monotherapy induced protocol-defined DAS remission (DAS28 [CRP] <2.6) in 60.9% and 42.5% of pts with early RA after 12 months (mths) on treatment (vs 45.2% with MTX alone); DAS-defined remission was also maintained in 14.8% and 12.4% of pts 6 mths after rapid withdrawal of all RA treatment (vs 7.8% with MTX alone).[1] We further investigated predictors of drug-free DAS-defined remission at 6 mths after ABA withdrawal.

Methods: Pts with early RA (active synovitis in ≥2 joints, onset of symptoms ≤2 years) and DAS28 (CRP) ≥3.2, who were anti-CCP2 positive and MTX-naïve, were randomized to weekly SC ABA 125 mg + MTX, ABA monotherapy or MTX alone for 12 mths. At 12 mths, pts with DAS28 (CRP) <3.2 stopped all RA treatment (ABA immediately and MTX and steroids tapered over 1 mth). Co-primary endpoints were the proportion of pts with DAS-defined remission at (i) Mth 12 and at (ii) both Mths 12 and 18, for ABA + MTX versus MTX alone. To assess predictive characteristics of drug-free DAS-defined remission, *post hoc* analyses were performed in all treatment groups: (i) descriptive analysis of the proportion of pts with DAS-defined remission at both Mths 12 and 18 by baseline characteristic subgroups and (ii) clinical variables were tested individually by logistic regression in a univariate analysis and variables with p<0.20 were entered into a multivariate model.

Results: Descriptive analysis showed that in both ABA treatment arms, the proportion of pts with DAS28 (CRP) <2.6 at both Mths 12 and 18 was numerically higher in pts with lower baseline DAS28 (CRP), lower baseline HAQ-DI and shorter symptom duration; these factors were not associated with remission at Mths 12 and 18 in the MTX-alone group). Predictive factors for DAS28 (CRP) <2.6 at both Mths 12 and 18 identified in the univariate analysis are shown in the figure. In the multivariate model, adjusted for corticosteroid use and restricted to pts with DAS28 (CRP) <2.6 at Mth 12, baseline DAS28 (CRP) (OR [95% CI] = 1.676 [1.176, 2.387], p=0.0043) and duration of remission in the first 12 mths while on treatment (0.913 [0.807, 1.033], p=0.1484) were identified as predictors of DA28 (CRP) <2.6 at both Mths 12 and 18.

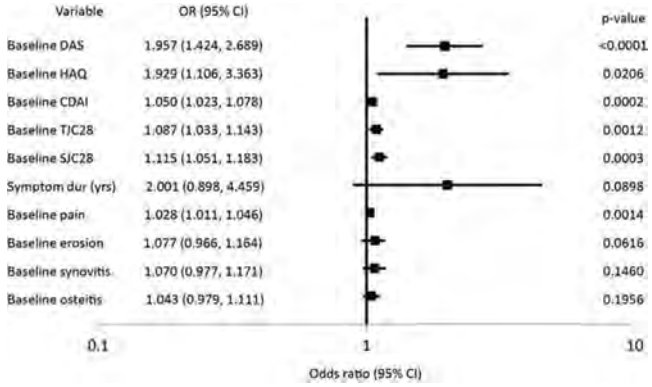

Figure. Predictors of DAS28 (CRP) <2.6 at both Mths 12 and 18 identified by univariate analysis

Conclusion: A small but significant number of patients treated with abatacept plus MTX achieved drug-free remission 6 months after drug withdrawal. According to descriptive and multivariate analyses, less severe disease activity at baseline and longer duration in DAS-defined remission on treatment were predictors for drug-free remission following abatacept withdrawal.

2486

Patient-Reported Outcomes Following 12 Months of Therapy with Abatacept (Plus Methotrexate or as Monotherapy) or Methotrexate and up to 6 Months after Treatment Withdrawal in Patients with Early Rheumatoid Arthritis. D E Furst[1], Vivian P. Bykerk[2], Gerd Burmester[3], B Combe[4], T W J Huizinga[5], E Alemao[6], D Wong[6], C S Karyekar[6] and P Emery[7]. [1]University of California at Los Angeles, Los Angeles, CA, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [3]Charité – University Medicine Berlin, Berlin, Germany, [4]Monpellier University Hospital, Montpellier, France, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Bristol-Myers Squibb, Princeton, NJ, [7]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Early biologic use can improve long-term control of RA,[1,2] potentially leading to improved physical function and reduced pain. Recent EULAR recommendations support shared decisions between the patient (pt) and rheumatologist,[3] emphasizing the need for more pt-focused outcomes to assess treatment targets. In the Assessing Very Early Rheumatoid arthritis Treatment (AVERT) trial, greater % of pts achieved DAS28 (CRP) <2.6 after 12 mths of treatment with SC abatacept (ABA) + MTX and 6 mths after withdrawal of all RA therapy, compared with MTX alone. At most time points, ABA monotherapy was more effective than MTX alone in controlling signs and symptoms of RA.[4] Here, pt-reported outcomes (PROs)

are presented over 18 mths (12 mths of treatment and 6 mths after withdrawal of all RA therapy) in the AVERT trial.

Methods: AVERT enrolled pts who were MTX naïve, anti-cyclic citrullinated peptide 2 seropositive (CCP2+), aged ≥18 yrs, with active synovitis ≥2 joints for ≥8 wks, DAS28 (CRP) ≥3.2, and a disease onset of ≤2 yrs. Pts were randomized to 12 mths of weekly SC ABA (125 mg) + MTX, SC ABA (125 mg) + placebo or MTX + placebo. All RA treatment was removed after 12 mths (ABA immediately and MTX and steroids tapered over 1 mth) in pts with DAS28 (CRP) <3.2. Fatigue was measured by 100-mm visual analog scale, physical function by HAQ-DI, and health-related quality of life by Short Form-36 (SF-36; Bodily Pain, Physical and Mental Component Summary subscores [PCS and MCS] presented). Improvement in activity limitation and work productivity/activity were estimated using the Activity Limitation Questionnaire (APaQ) and Work Productivity Activity Impairment Questionnaire (WPAI:RA). Adjusted mean change from baseline in PROs was calculated using a longitudinal repeated measures model.

Results: 351 pts with early RA were enrolled (n=119, ABA + MTX; n=116, ABA monotherapy; n=116, MTX monotherapy; at baseline: mean disease duration 0.6 yrs, mean DAS28 (CRP) 5.4, mean HAQ-DI 1.4, 95.2% RF+ and anti-CCP2+). Adjusted mean changes in PROs during treatment (baseline to Mth 12) and treatment withdrawal (Mth 12 to Mth 18) are presented (Table).

MCS, Mental Component Summary subscore; PCS, Physical Component Summary subscore; SF-36, Short Form-36;
VAS, visual analog scale; WPAI, Work Productivity Activity Impairment Questionnaire.
*Pts with assessments available at both Mth 12 and Mth 18.
†$p<0.05$ for treatment difference vs MTX (95% CI for the estimate of treatment difference did not cross 0).

Conclusion: In pts with early RA, abatacept + MTX, abatacept monotherapy and MTX alone showed improvements in PROs, with greater improvements seen for abatacept + MTX at 12 mths, compared with MTX alone. PROs worsened in all groups after treatment withdrawal but remained below baseline values. These results indicate that treatment with abatacept + MTX early in the course of RA leads to notable improvements in outcomes that are important to pts, such as fatigue, physical function, pain and participation in daily activities, and that some improvement may be maintained up to 6 mths following treatment withdrawal.

Effects of Tofacitinib on Health Care Resource Utilization and Work Productivity in US Patients with Rheumatoid Arthritis.

V. Strand[1], R. Riese[2], R. Gerber[2], D. Gruben[2], A.G. Bushmakin[2], E.Y. Mahgoub[3] and G. Wallenstein[2]. [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Here we describe health care resource utilization (HCRU) and work productivity in RA patients from the US treated with tofacitinib.

Methods: Data for US patients enrolled in two global, Phase 3, randomized, controlled trials of 6 months' (ORAL Step, NCT00960440) and 24 months' (ORAL Scan, NCT00847613) duration were reviewed: these two Phase 3 trials were chosen as, for both trials, the patient populations reflected how tofacitinib is mainly prescribed in the US. Tofacitinib was dosed at 5 or 10 mg twice daily (BID) in combination with non-biologic disease-modifying antirheumatic drugs (DMARDs) (mainly methotrexate) in patients with inadequate responses to ≥1 non-biologic or biologic DMARDs. Patients receiving placebo (in combination with DMARDs) were advanced to tofacitinib at Month 3 (ORAL Step) or by Month 6 (ORAL Scan). Analysis of endpoints for both studies occurred at Month 3, before patients receiving placebo were advanced to tofacitinib. The 17-item RA HCRU Questionnaire (v1.1) assessed the impact of RA across three domains: health care resource use, work-related activities, and daily activities. The composite Work Loss Index assessed work productivity in US patients; work productivity for the entire study population was assessed with the 25-item Work Limitations Questionnaire.

Results: Representative questions from each domain of the HCRU questionnaire are shown (Table). With the exception of doctor office visits, there was generally infrequent use of health care resources by patients receiving tofacitinib (both doses) at Month 3 in both studies, and was comparable to placebo. In ORAL Step and ORAL Scan, patients treated with both tofacitinib doses reported numerically lower impact on daily and work-related activities vs placebo at Month 3. The work productivity results reflect those of the entire study population, where US patients in ORAL Step receiving either tofacitinib 5 or 10 mg BID reported significant improvements in least squares mean (LSM) changes in work loss index from baseline vs placebo at Month 3: -1.73 ($p<0.05$) and -2.10 ($p<0.01$), respectively, vs placebo (1.36). In ORAL Scan, only US patients treated with tofacitinib 10 mg BID had significant improvements in LSM changes from baseline: -2.38 ($p<0.05$) vs -0.33 for placebo. Overall, the tofacitinib responses reported at Month 3 were maintained up to Month 6 (ORAL Step) and Month 24 (ORAL Scan).

Conclusion: At Month 3, US patients receiving tofacitinib in these two Phase 3 studies reported similar use of health care resources as placebo. At Month 3, patients receiving tofacitinib reported numerically less impact of RA on daily and work-related activities compared with patients receiving placebo.

Relationship Between Different Clinical Measurements and Patient-Reported Outcomes. Roy Fleischmann[1], V Strand[2], B Wilkinson[3], K Kwok[4] and E Bananis[3]. [1]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Department of Medicine, Dallas, TX, [2]Biopharmaceutical Consultant, Portola Valley, CA, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Here we compare the relationship between clinical measures and patient-reported outcomes (PROs) in patients (pts) with RA treated with tofacitinib or methotrexate (MTX).

Methods: MTX-naïve pts with RA from a double-blind, parallel group, Phase 3 trial (ORAL Start; NCT01039688) were randomized (2:2:1) and treated with tofacitinib 5 mg twice daily (BID) monotherapy (N=373), tofacitinib 10 mg BID monotherapy (N=397), or MTX titrated from 10 to 20 mg/week (N=186). Clinical measures included: the proportion of pts achieving ACR50 and ACR70 responses, the proportion achieving low disease activity (LDA) measured by Clinical Disease Activity Index (CDAI LDA, CDAI≤10), and Simplified Disease Activity Index (SDAI LDA, SDAI≤11), and the proportion achieving remission (REM) measured by CDAI REM (CDAI≤2.8) and SDAI REM (SDAI≤3.3). PROs included: proportion of pts achieving improvements in physical function measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI, to normative values <0.5).

Results: At Month 6, a greater proportion of pts achieved ACR responses, LDA, and REM with tofacitinib 5 mg or 10 mg BID than with MTX (Tables). Most pts who achieved LDA and REM by one measure also achieved LDA and REM by other measures (Tables); however, discordance was observed between different measures of LDA and REM, and appeared greater with MTX vs either tofacitinib dose (Tables). As expected there was a high degree of concordance between CDAI LDA and SDAI LDA (Table 1) and CDAI REM and SDAI REM (Table 2). Overall, pts achieving LDA or ACR50 showed less improvement from baseline in patient-reported pain, and patient global assessment of disease compared with tender joints, swollen joints, physician global assessment of disease, and HAQ-DI: pts receiving MTX showed an overall lower improvement in these PROs compared with tofacitinib 5 mg or 10 mg BID. In general, better improvements and consistency in PROs were observed in ACR50 responders compared with measures of LDA. Pts achieving ACR70, CDAI REM, and SDAI REM showed similar improvements across PROs and similarly between MTX and tofacitinib.

Conclusion: A higher proportion of MTX-naïve pts receiving tofacitinib 5 or 10 mg BID achieved a clinical response compared with pts receiving MTX. While most pts achieve similar responses across different clinical measures, many may achieve a response in one measure but not the other. Variability of responses with clinical.

Table 1 ACR50 and LDA clinical disease activity outcomes at Month 6

	Treatment	ACR50	CDAI LDA	SDAI LDA	HAQ-DI (<0.5)

Analysis of Early Neutropenia, Clinical Response, and Serious Infection Events in Patients Receiving Tofacitinib for Rheumatoid Arthritis. V. Strand[1], A. Dikranian[2], J. Beal[3], K. Kwok[3], S. Krishnaswami[4], S. Wood[4] and C. Nduaka[4]. [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]San Diego Arthritis Medical Clinic, San Diego, CA, [3]Pfizer Inc, New York, NY, [4]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Post-baseline (BL) decreases in mean peripheral neutrophil count were observed in Phase (P) 3 trials, although no association between neutropenia and serious infection events (SIEs) was observed.[1] Given the role of neutrophils in initiation and progression of RA,[2] we further evaluated early post-treatment neutrophil changes to identify any trends with early clinical responses (ER) or SIEs in patients (pts) receiving tofacitinib 5 or 10 mg twice daily (BID).

Methods: Data were pooled from 6 P3 studies. Pts recruited to 4 of these received stable doses of background DMARDs, mainly methotrexate (MTX). Decreases from BL in neutrophil counts were evaluated at Week (W) 4.

Quartile categories (Q): 0 to <650 (Q1); 650 to <1410 (Q2); 1410 to <2500 (Q3); ≥2500 (Q4) were defined by quartiles obtained from pts with a mean decrease from BL in neutrophil counts (cells/μL) at W4. ER: decrease from BL in DAS28-4 ESR ≥1.2 at W4. Incidence rates (IRs) for SIEs were compared between categories. Pts receiving tofacitinib (all 6 trials) were included in the analysis presented for tofacitinib 5 and 10 mg BID.

Results: At BL and W4, 1488, 1506, 622 and 179 pts were evaluable for neutrophil counts for tofacitinib 5, 10 mg BID, placebo (PBO), and MTX, respectively. The proportions of pts with any decrease from BL in neutrophil counts were 69%, 73%, 52% and 56% with tofacitinib 5, 10 mg BID, PBO, and MTX, respectively. At W4, pts with neutrophil decreases in the tofacitinib 5 mg BID group were evenly distributed between categories. With tofacitinib 10 mg BID, a higher proportion of pts had neutrophil decreases within Q3 and Q4 than within Q1 and Q2 (Table). Neutrophil decreases with PBO and MTX were mostly within Q1 and Q2 (Table). In general the proportion of pts per category with an ER was slightly higher with tofacitinib 10 vs 5 mg BID. With tofacitinib, a higher proportion of pts with an ER was observed in categories with greater reductions in neutrophil counts (Table). SIEs occurred in 30 and 27 pts in the tofacitinib 5 and 10 mg BID groups, respectively. The distribution of pts with SIEs across categories was variable and there were no consistent trends to indicate an association between SIEs and decreases in neutrophil counts (Table), reflecting studies that did not find associations between SIEs and neutropenia.[3,4]

Conclusion: A trend was observed between decreases in neutrophils and ER with tofacitinib. ERs were most commonly seen in pts with the largest category decreases in neutrophil count at W4. No differences were noted between categories with respect to decreases in neutrophil counts and SIEs.

Assessment of Structural Benefits of SC Abatacept Using MRI in Patients with RA Who Have Failed 1 or 2 TNFs and Correlated with Clinical Outcomes As Measured By DAS28(ESR). Norman B. Gaylis[1], Steven Needell[2] and Joanne Sagliani[1]. [1]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [2]Boca Radiology, Boca Raton, FL.

Background/Purpose: Previous studies[1–2] suggest the structural benefit of IV abatacept in patients with RA who have previously failed MTX, TNF therapy or both.

Objectives: This study evaluates the structural benefit of SC abatacept in a cohort of patients with RA, comparing the structural findings with clinical outcomes and measuring any difference between 1 or 2 TNF failure cohorts on stable MTX. average 17 mg/wk.

Methods: 34 patients were enrolled over 18-months into an open-label 1-year trial. Patients received SC abatacept 125 mg/week on background MTX. Patients on prednisone remained on a stable dose <10 mg. daily. MRIs of the hands/wrists were performed on a 0.3T Esaote S-Scan and scored blinded using a modified OMERACT/RAMRIS scoring system at Baseline, Wks. 12, 24 and 48. A global response of progression, regression, or no change was calculated for each time point. Clinical outcomes were measured by a DAS28(ESR) at similar time points.

Results: 27 patients completed; 7 patients discontinued including 3 treatment failures. Of the 27 patients who completed the trial, 15 patients had prior exposure to 1 TNF and 12 patients had prior exposure to 2 TNFs. The clinical and structural findings of each group were analyzed independently since individual clinical responses did not directly correlate with the structural response due to disease duration, disease activity at the time of trial entry, and prior drug exposure. Structurally, there were patients in both groups who showed improvement in synovitis and osteitis by MRI, however, the patients who had only 1 prior TNF exposure had a more robust response overall for both synovitis and osteitis. Of the 27 completed patients, 25 were positive DAS28 responders. 2 patients were non-responders. Clinical remission was achieved in 4 patients, low disease activity in 6 patients, moderate disease activity in 8 patients, and high disease activity remained in 7 patients. Clinically, there was no clear trend to distinguish any difference between the two groups. Both clinical and structural responses occurred within 6-months. 2 patients who had a clinical response at 6 months failed to sustain a response at 12 months. No adverse events were noted.

Conclusion: Overall, this small cohort of patients suggests that SC abatacept has clinical and structural benefit in patients who have had treatment with either 1 or 2 TNFs and is a viable choice of therapy. The structural findings were comparable to the benefits of IV abatacept which have been previously published.[1] The group that had 1 TNF exposure showed a greater improvement with respect to synovitis and osteitis than the population with 2 TNF exposure. It is possible that the structural benefit may be more robust when a switch from TNF therapy to an alternative mechanism of action such as abatacept is made after only 1 TNF failure. Further analysis is needed to determine if 6 months can be used as a cut-off point that prognosticates the value of continuing further therapy in the face of a lack of clinical and/or structural response. In addition, a better understanding of the clinical/structural disconnect demonstrated is necessary to provide optimal management of RA patients.

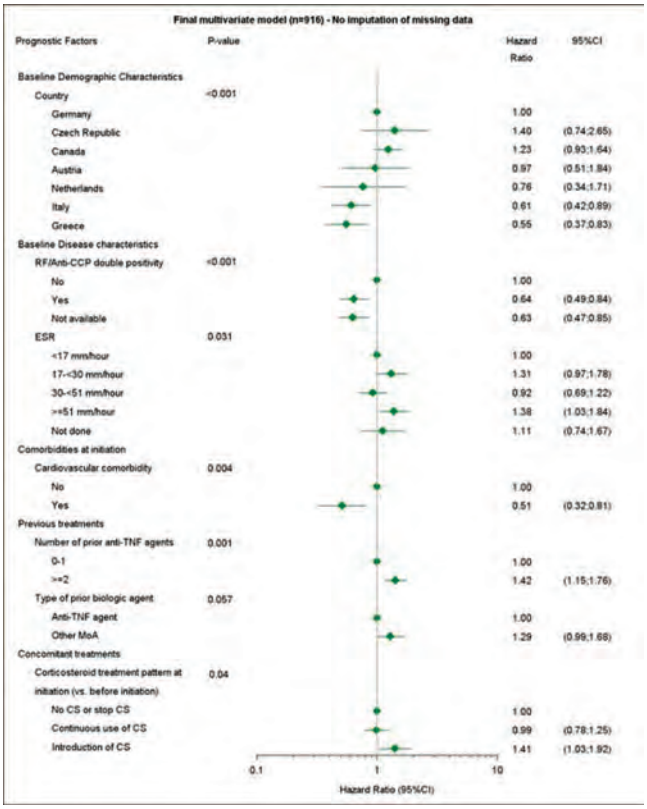
Prognostic Factors for IV Abatacept Retention in Patients Who Have Received at Least One Prior Biologic Agent: 2-Year Results from a Prospective, International, Real-World Study. H Nüβlein[1], R Alten[2], M Galeazzi[3], HM Lorenz[4], MT Nurmohamed[5], WG Bensen[6], Gerd Burmester[7], H-H Peter[8], P Peichl[9], K Pavelka[10], M Chartier[11], C Poncet[12], C Rauch[13] and M Le Bars[14]. [1]Internistische Schwerpunktpraxis, Nürnberg, Germany, [2]Schlosspark-Klinik University Medicine, Berlin, Germany, [3]University of Siena, Siena, Italy, [4]University Hospital, Heidelberg, Germany, [5]VU Univ Medical Center/Jan van Breeman Research Institute, Amsterdam, Netherlands, [6]St Josephs Hospital and McMaster University, Hamilton, ON, [7]Charité-Universitätsmedizin, Berlin, Germany, [8]University of Freiburg, Freiburg, Germany, [9]Evangelisches Krankenhaus, Vienna, Austria, [10]Institute of Rheumatology, Prague, Czech Republic, [11]Chiltern International, Neuilly, France, [12]Docs International, Nanterre, France, [13]Bristol-Myers Squibb, Munich, Germany, [14]Bristol-Myers Squibb, Rueil-Malmaison, France.

Background/Purpose: To identify prognostic factors of retention for abatacept (ABA) treatment in patients (pts) with moderate-to-severe RA, using final results from the real-world ACTION study.

Methods: ACTION was a 2-year follow-up, non-interventional, international, multicenter, cohort study that evaluated retention and effectiveness of

IV ABA in adults with moderate-to-severe RA in Europe and Canada (May 2008–Jan 2011). Socio-demographics, disease characteristics, previous/concomitant therapies, and comorbidities at ABA initiation were considered potential prognostic variables of retention. Pts who had received ≥1 prior biologic agent in countries with sufficient pt numbers to explore between-country effects were included. Clinically relevant variables, known risk factors and prognostic factors with a p≤0.10 (univariate analysis) were entered into a multivariate Cox proportional hazards regression model, with clustered data adjusted for one investigator. Factors with p≤0.10 after backward selection were retained in the final model. Co-linearity and interactions were assessed. Additional analysis to account for missing data in covariates was performed using multiple imputation by chained equations.

Results: 1009/1131 (89.2%) evaluable pts had failed ≥1 prior biologic agent. The crude retention rate (95% CI) at 24 months (Kaplan–Meier method) for pts exposed to ≥1 prior biologic agent was 53.4% (50.1, 56.6%).[1] 995 of 1009 pts were included in the analysis of prognostic factors. Final multivariate model results (n=916) are shown in the Figure. Pts had significantly higher likelihood of ABA retention if they were both RF and ACPA positive or had cardiovascular comorbidity at initiation. Prior anti-TNF agents, high baseline ESR and corticosteroid (CS) use were also prognostic factors for discontinuation. Despite showing borderline significance in the first model (Figure), use of a non-anti-TNF biologic agent before ABA (n=143, 15.6%) was an additional prognostic factor of lower retention (1.29 [1.00, 1.66]; p=0.049) in the model with imputation of missing data (not shown). Disease duration, ABA monotherapy and BMI were not identified as prognostic factors.



Conclusion: ACTION is one of the first studies to identify and report prognostic factors of long-term abatacept retention in a real-world setting. Double ACPA and RF positivity and cardiovascular comorbidity at initiation were prognostic of higher retention. Consistent with other reports,[2,3] higher number of prior anti-TNFs, country and more severe disease (suggested by higher baseline ESR and introduction of CS) were identified as prognostic factors of lower retention. These results will support individualized biologic treatment strategies in pts with moderate-to-severe RA.

Does Body Mass Index Impact Long-Term Retention with Abatacept in Patients with RA Who Have Received at Least One Prior Biologic Agent? 2-Year Results from a Real-World, International, Prospective Study.

H Nüβlein[1], R Alten[2], M Galeazzi[3], HM Lorenz[4], MT Nurmohamed[5], WG Bensen[6], Gerd Burmester[7], H-H Peter[8], P Peichl[9], K Pavelka[10], M Chartier[11], C Poncet[12], C Rauch[13] and M Le Bars[14]. [1]Internistische Schwerpunktpraxis, Nürnberg, Germany, [2]Schlosspark-Klinik University Medicine, Berlin, Germany, [3]University of Siena, Siena, Italy, [4]University Hospital, Heidelberg, Germany, [5]VU Univ Medical Center/Jan van Breeman Research Institute, Amsterdam, Netherlands, [6]St Josephs Hospital and McMaster University, Hamilton, ON, [7]Charité-Universitätsmedizin, Berlin, Germany, [8]University of Freiburg, Freiburg, Germany, [9]Evangelisches Krankenhaus, Vienna, Austria, [10]Institute of Rheumatology, Charles University, Prague, Czech Republic, [11]Chiltern International, Neuilly, France, [12]Docs International, Nanterre, France, [13]Bristol-Myers Squibb, Munich, Germany, [14]Bristol-Myers Squibb, Rueil-Malmaison, France.

Background/Purpose: In RA, reduced efficacy with anti-TNF therapy[1] and dose escalation[2] have been reported for obese patients (pts) compared with non-obese pts. Clinical trials have shown that BMI does not affect abatacept (ABA) efficacy or pharmacodynamics[3] and real-world data show that short-term ABA retention, dosing and treatment outcomes are unaffected by BMI.[4–6] We assessed the impact of BMI on the long-term retention of pts using IV ABA who had previously failed ≥1 biologic in clinical practice across Europe and Canada.

Methods: ACTION was a 2-year, non-interventional, international, multicenter, cohort study that evaluated the retention and effectiveness of IV ABA in adults with moderate-to-severe RA. Pts who received ≥1 prior biologic and enrolled in countries with sufficient pt numbers to explore between-country effects were included in this analysis. Pts were stratified by their baseline BMI.[7] Crude 2-year retention rate was estimated using the Kaplan–Meier method. The effect of BMI was analyzed through a multivariate Cox proportional hazard model clustered for site effects with conditional imputation of missing data for covariates. Hazard ratios and corresponding 95% CI were adjusted for socio-demographic variables, disease characteristics, comorbidities at initiation and treatment characteristics. Pts were considered adherent to ABA if the ratio of the number of infusions received to the number expected was between 80 and 120%.

Results: 1009/1131 (89.2%) evaluable pts had received ≥1 prior biologic; 995 were included in the analysis. Pts with higher BMI had shorter disease duration, more severe disease (assessed by TJC, DAS28, HAQ-DI), were more likely to have comorbidities, but were less likely to be RF or anti-cyclic citrullinated peptide positive. Crude retention rates and adjusted HR are shown in Table 1. Similar proportions of pts were considered adherent to ABA therapy in all BMI groups as follows: BMI <25 kg/m^2 = 82.8%, BMI 25–<30 kg/m^2 = 79.5%, BMI 30–<35 kg/m^2 = 85.0%, BMI ≥35 kg/m^2 = 84.1%.

Table 1

BMI class[7]	n (%)	Crude retention rate, % (95% CI)	Adjusted hazard ratio	95% CI	p-value
Underweight/normal <25 kg/m^2	359 (36.1)	53.8 (48.3, 59.0)	1		
Overweight 25–<30 kg/m^2	324 (32.5)	57.4 (51.5, 62.8)	0.90	0.72, 1.13	0.365
Obese class I 30–<35 kg/m^2	168 (16.9)	50.5 (42.4, 58.1)	0.96	0.71, 1.31	0.815
Obese class II/III ≥35 kg/m^2	85 (8.5)	53.2 (41.3, 63.7)	0.86	0.58, 1.26	0.437

Conclusion: In this analysis of the real-world ACTION study, BMI did not impact long-term retention of IV abatacept in pts who had previously received ≥1 biologic, when adjusted on differences in disease severity and comorbidities between BMI classes. Increased BMI was not associated with an increased number of infusions, indicating that IV abatacept can be an effective treatment option irrespective of BMI, without need for dose adjustment.

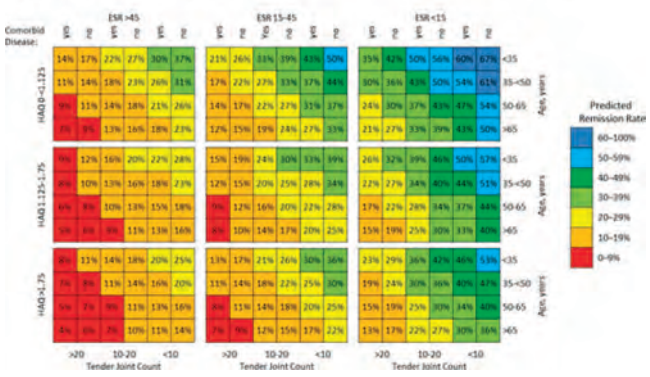
Prediction of Remission and Low Disease Activity in DMARD-Refractory Patients with RA Treated with Golimumab. N Vastesaeger[1], P Durez[2], B Dasgupta[3], B Combe[4], H Schulze-Koops[5], I Louw[6], J Wollenhaupt[7], CAF Zerbini[8], A Beaulieu[9], K Pavelka[10], M Lazaro[11], A Garcia Kutzbach[12], RJ Moots[13], H Amital[14], S Huyck[15], B Fu[15], M Govoni[16] and HH Weng[15]. [1]MSD Belgium, Brussels, Belgium, [2]Université Catholique de Louvain, Bruxelles, Belgium, [3]Southend University Hospital, Essex, United Kingdom, [4]Monpellier University Hospital, Montpellier, France, [5]University of Munich, Munich, Germany, [6]Panorama Medical Centre, Cape Town, South Africa, [7]Schön Klinik Hamburg-Eilbek, Hamburg, Germany, [8]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [9]Centre de Rhumatologie, St-Louis, QC, [10]Revmatologicky Ustav, Praha, Czech Republic, [11]IARI Instituto de Asistencia Reumatologica Integral, Buenos Aires, Argentina, [12]AGAR Francisco Marroquin University, Guatemala City, Guatemala, [13]University Hospital Aintree, Liverpool, United Kingdom, [14]Sheba Medical Center, Tel-Hashomer, Israel, [15]Merck & Co., Inc., Whitehouse Station, NJ, [16]MSD Italy, Rome, Italy.

Background/Purpose: EULAR recommendations for RA therapy suggest addition of a biologic only if poor prognostic factors such as high disease activity are present. However, low baseline disease activity is associated with better biologic treatment outcomes. Better tools to predict remission/low disease activity (LDA) and aid in selection of patients for anti-TNF treatment are important.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients (pts) with active RA despite DMARD therapy. Pts received 50-mg subcutaneous golimumab (GLM) once monthly for 6 months in addition to their background DMARDs. The following baseline characteristics were first evaluated in univariable models predicting 28-joint disease activity score based on ESR (DAS28-ESR) LDA and remission at 1 and 6 months: age, sex, smoking history, comorbidities, number of failed DMARDs, methotrexate dose, disease duration, tender joint count-28 (TJC28), swollen joint count-28 (SJC28), ESR, patient global assessment of disease activity (PGA), and HAQ. Factors were evaluated in a stepwise fashion. Those with significant associations ($P<.10$) were included in a final multivariable model. Factors that predicted both LDA and remission at 1 and 6 months were used in the final model. The ability of the models to predict LDA and remission at month 6 was investigated using receiver operating characteristic (ROC) analyses.

Results: 3280 pts were included in the analysis: 82.8% female, mean age 52.3 years, mean disease duration 7.6 years, mean baseline DAS28–ESR 5.97 (standard deviation=1.095). DAS28-ESR remission and LDA were achieved by 7.7% and 16.6% of pts, respectively, after 1 month of GLM treatment (1 injection), and by 23.9% and 37.4%, respectively, after 6 months of treatment. In multiple regression models, LDA at 1 month was associated with male sex; absence of comorbidities; and lower age, TJC28, SJC28, PGA, HAQ, and ESR. Remission at 6 months was associated with male sex; absence of comorbidities; and lower age, HAQ, ESR, and TJC28. The final model included sex, comorbidities, age, HAQ, ESR, and TJC28 as continuous variables and had an area under the ROC curve (AUC) of 0.81, 0.74, and 0.71 to predict remission at 1, 3, and 6 months, respectively, and an AUC of 0.80, 0.73, and 0.71 to predict LDA at 1, 3, and 6 months, respectively. When CRP replaced ESR or SJC replaced TJC, predictive ability was slightly reduced. The model for remission at 6 months had an AUC of 0.71 and showed remission rates from 4% to 67% in females (figure) and from 7% to 76% in males.

Figure. Prediction model estimates of 6-month DAS28-ESR remission in female patients using categorical variables as predictors.



Conclusion: Sex, age, ESR, HAQ, absence of comorbidities, and TJC28 at baseline allow accurate prediction of remission and LDA in the first 6 months of GLM therapy in patients failing DMARDs. This prediction model allows better selection of anti-TNF candidates.

Mikuls[3], Gail Kerr[4] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Dallas VA and Univ of TX Southwestern Med Ct, Dallas, TX, [3]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [4]Washington DC VA and Georgetown and Howard University, Washington, DC.

Background/Purpose: Few rheumatoid arthritis (RA) patients are managed successfully with a single disease modifying anti-rheumatic drug (DMARD). This investigation determined the prevalence and clinical characteristics of US veterans with RA treated with a single DMARD in comparison to patients receiving multiple DMARDs.

Methods: Patients in the Veterans Affairs RA (VARA) registry, a long-term observational cohort, enrolled at or before four years of disease onset (to allow at least one year of VA-based observation) had DMARD exposures recorded during their first five years of RA. DMARD exposure was determined by chart annotation for DMARD use occurring prior to VA enrollment and VA pharmacy databases for DMARD exposure after VA enrollment. Patients who had died within five years of RA diagnosis were excluded. Patients who received only a single DMARD during the first five years were classified as monotherapy persistent (MONO) and patients receiving more than one DMARD either alone or in combination during the first five years were classified as polytherapy (POLY). Demographic information, serologic status, smoking history, disease characteristics at the time of

VARA enrollment, HLA-DR1 genotyping for shared epitope status, mean multidimensional health assessment questionnaire (MDHAQ), and mean disease activity score (DAS28) during observation were compared in the two groups. Chart review was conducted on all MONO patients to determine status of RA disease control and if specific reasons were present for not using additional DMARD therapy.

Results: Of 2,079 enrolled VARA patients, 486 met enrollment criteria with 50 (10.3%) MONO patients and 436 (89.7%) POLY patients. MONO DMARDs were methotrexate 36 (72%), hydroxychloroquine 11 (22%), and one (2%) each for leflunomide, sulfasalazine, and etanercept. Reasons documented for MONO persistence included adequate disease control (n=46; 92%), poor medication adherence (n=3; 6%), and contraindications to other DMARDs because of frequent infections (n=1; 2%). MONO were older at diagnosis ($p<0.02$), and were less likely to be seropositive for anti-CCP ($p<0.01$), less likely to have rheumatoid nodules ($p<0.03$), and less likely to have DRB1 shared epitope ($p<0.05$). MONO patients had lower average DAS28 scores ($p<0.05$) (Table).

Table: RA patient characteristics among those using persistent MONO compared to POLY during the first five years of disease; *chi-square test for categorical variables, t-test for continuous variables

	Monotherapy N=50	Polytherapy N=436	p-value*
Age at Diagnosis	64.7±13.5	58.8±11.8	<0.02
Gender (Male)	45 (90%)	382 (88%)	NS
Smoking Status			
Never	7 (14%)	93 (21.3%)	NS
Former	31 (62%)	190 (43.6%)	
Current	12 (24%)	153 (35.1%)	
Rheumatoid Factor Positive	32 (65.3%)	326 (77.8%)	NS
Anti-CCP Positive	27 (56.3%)	310 (74.2%)	<0.01
Rheumatoid Nodules	6 (12.5%)	116 (28.5%)	<0.03
X-ray Changes at Enrollment	11 (22%)	139 (32.7%)	NS
HLA-DRB1 Shared Epitope Status			
SE positive – 2 copies	4 (8%)	66 (15%)	<0.05
SE positive – 1 copy	16 (32%)	205 (47%)	
No Copies	26 (42%)	118 (27%)	
Average MDHAQ	0.8±0.5	0.9±0.5	NS
Average DAS28 Score	3.0±1.0	3.8±1.2	<0.05

Conclusion: While sustained treatment with a single DMARD during the first five years of RA treatment in US veterans is rare, most of these patients have adequate disease control. Patients on persistent monotherapy were older at disease onset, less likely to be seropositive, less likely to have rheumatoid nodules, and less likely to carry the DRB1 shared epitope in comparison to patients receiving multiple DMARDs.

Impact of Golimumab on Physical Function and Employability of Patients with Rheumatoid Arthritis: 5-Year Data from 3 Phase III Clinical Trials.

Chenglong Han[1], Edward C. Keystone[2], Roy Fleischmann[3], Josef S. Smolen[4], Eric L. Matteson[5], Paul Emery[6], Mark C Genovese[7], Timothy A. Gathany[1] and Elizabeth C. Hsia[8]. [1]Janssen Global Services, LLC., Malvern, PA, [2]Mount Sinai Hospital, Toronto, ON, [3]Metroplex Clinical Research Center, University of Texas, Dallas, TX, [4]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [5]Mayo Clinic, Rochester, MN, [6]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [7]Stanford University Medical Center, Palo Alto, CA, [8]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: To assess the impact of golimumab (GLM) on physical function and employability in patients with rheumatoid arthritis (RA) with various prior treatment histories, after 5 years of therapy.

Methods: The efficacy and safety of GLM were assessed in methotrexate (MTX)-naïve RA patients (GO-BEFORE, N=637), patients with inadequate response to MTX (GO-FORWARD, N=444), and patients previously treated with TNF-inhibitors (TNFi, GO-AFTER, N=445). Patients with active RA were randomized to placebo (PBO), GLM 100mg+PBO (GO-BEFORE and GO-FORWARD), or GLM (50 or 100mg), q4w. Patients in GO-BEFORE and GO-FORWARD could receive concomitant MTX or no MTX and crossed-over to GLM after wk24 (GO-FORWARD) OR wk52 (GO-BEFORE), while patients in GO-AFTER were on background (with or without) MTX and crossed-over to GLM after wk24. Clinical remission was defined as DAS28 (ESR) <2.6. Physical function was measured using Health Assessment Questionnaire (HAQ) and employability was defined as being employed or being able to work if job was available (Yes/No). 5 year data were presented by 3 patient populations.

Results: At baseline, the percent of patients with disability (HAQ-DI score >0.5) in each of 3 RA populations were 90.9% in patients who were MTX-naïve, 87.6% in patients who were MTX-inadequate responders and 92.3% in patients who were TNFi-experienced. Among the analyzed patient population for employability (not retired and age<65 years), the percent of patients unemployable due to their RA at baseline were 9% in MTX-naïve patients, 8.1% in MTX-inadequate responders and 13.1% in TNF-experienced patients. After treatment with GLM, among those who had disability at baseline, 46.8% of MTX-naive patients, 37.5% of MTX-inadequate responders and 27.5% of TNFi-experienced patients had no disability (HAQ-DI score≤0.5) at wk256; among patients unemployable at baseline, 29.5% of MTX-naive patients, 28.6% of MTX-inadequate responders and 5.4% of TNFi-experienced patients regained employability at wk256. Similar trends of better outcomes on disability and employability of MTX-naïve patients were observed among those who achieved remission at wk256: 65.1% in MTX- naive patients, 54.4% in MTX-inadequate responders and 53.1% in TNFi-experienced patients achieved no disability; and 73.3% in MTX-naive patients, 50% in MTX-inadequate responders and 50.0% in TNFi-experienced patients regained employability.

Conclusion: This analysis indicates that effective treatment at an early stage may result in reduction in disability and improvement in employability over the long-term.

Predictors of ACR/EULAR Boolean and SDAI Remission in Patients with Established Rheumatoid Arthritis Treated with Anti-TNF: An Analysis from the Prospective, Observational, Biological Treatment Registry Across Canada.

Boulos Haraoui[1], Maqbool Sheriff[2], Majed Khraishi[3], Michael Starr[4], John Kelsall[5], Milton Baker[6], Regan Arendse[7], Sanjay Dixit[8], William Bensen[8], Philip Baer[9], Rafat Faraawi[8], Emmanouil Rampakakis[10], John S. Sampalis[10], Susan Otawa[11], Allen J Lehman[11], Francois Nantel[11] and May Shawi[11]. [1]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [2]Nanaimo Regional General Hospital, Nanaimo, BC, [3]Nexus Clinical Research, St John's, NF, [4]Montreal General Hospital, Montreal, QC, [5]The Mary Pack Arthritis Centre, Vancouver, BC, [6]University of Victoria, Victoria, BC, [7]University of Saskatchewan, Saskatoon, SK, [8]McMaster University, Hamilton, ON, [9]Private Practice, Scarborough, ON, [10]JSS Medical Research, Montreal, QC, [11]Janssen Inc., Toronto, ON.

Background/Purpose: Early achievement of remission is associated with improved clinical, functional and radiographic outcomes1. Recent recommendations of the Canadian Rheumatology Association dictate that treatment target should be remission or, when not possible, low disease activity. The aim of this analysis was to define the predictive factors of time to disease remission in established rheumatoid arthritis (RA) patients treated with infliximab.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after having been treated with a biologic for <6 months. RA patients treated with infliximab

who were enrolled between 2002–2012 and had ≥1 follow-up assessment were included. Remission was defined according to the ACR/EULAR Boolean criteria (TJC28≤1, SJC28≤1, CRP≤1 mg/dL, and PtGA≤1) or CDAI≤2.8. Independent predictors of remission were identified by multivariate Cox regression considering as potential confounders parameters showing a statistical trend (P<0.150) in univariate analyses.

Results: A total of 671 patients were included of whom 494 (73.6%) were female. At baseline, mean (SD) age was 56.0 (13.5) years and mean (SD) disease duration was 10.3 (10.1) years. Median time to CDAI and Boolean remission was 47.3 and 54.1 months, respectively. In univariate analysis, the following factors showed a statistical trend in their association with longer time to CDAI remission: earlier enrolment period (P=0.117), increased age (P=0.070), longer disease duration (P=0.008), female gender (P=0.143), and increased baseline disease activity as indicated by TJC28 (P<0.001), SJC28 (P<0.001), morning stiffness (P=0.003), pain (P<0.001), PtGA (P<0.001), MDGA (P<0.001), HAQ-DI (P<0.001), and CDAI (P<0.001). Rheumatoid factor (RF) status, number of previous DMARDs, and initial (first 6 months) treatment with DMARD(s), NSAID(s) or steroid(s) did not predict achievement of remission. In multivariate analysis, baseline CDAI [HR (95%CI): 0.97 (0.96,0.98); P<0.001] and disease duration [0.98 (0.97,1.00); P=0.018] were identified as independent predictors of time to CDAI remission. Similarly, multivariate survival analysis showed that increased disease duration [0.98 (0.96,1.00); P=0.047] and increased pain [0.98 (0.98,0.99); P<0.001] at baseline were associated with a lower chance of achieving ACR/EULAR Boolean remission.

Conclusion: Upon adjusting for potential confounders, increased disease duration before anti-TNF initiation is an independent predictor of longer time to remission. The results of these real-world Canadian data support findings that earlier initiation of anti-TNF agents may be associated with increased remission rates when stringent definitions of remission are considered.

Correlation Between Time to Switch and Clinical Response Amplitude to Rituximab in Second Line Treatment in Rheumatoid Arthritis Patients with Treatment Failure to Tumor Necrosis Factor Inhibitors: 3-Year Data from Repeat Observational Study.

Ioan Ancuta[1], Ruxandra Ionescu[2], Catalin Codreanu[3], Andra Balanescu[2], Elena Rezus[4], Maria Suta[5], Paulina Ciurea[6], Mihaela Milicescu[7], Dan Nemes[8], Codrina Ancuta[9], Mihai Bojinca[1], Magda Parvu[10] and Horatiu Popoviciu[11]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania, [3]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [4]Recovering Clinical Hospital, Iasi, Romania, [5]Constanta Municipal Hospital, Constanta, Romania, [6]Clinical County Hospital,Craiova, Craiova, Romania, [7]"Dr. I. Cantacuzino" Clinical Hospital, Bucharest, Romania, [8]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [9]G.T.Popa Center for Biomedical Research, Iasi, Romania, [10]Colentina Clinical Hospital, Bucuresti, Romania, [11]Clinical County Hospital, Tg Mures, Romania.

Background/Purpose: In recent years we assist to an increasing interest to get more clinical data to improve the control of disease course in rheumatoid arthritis (RA) patients. According to treat to target principle, best practice still needs to be better defined in patients that encounter inadequate response after a variable period of time to anti-TNF treatment.

To investigate the clinical impact of switching to rituximab (RTX) according to the length of previous anti-TNF treatment in routine practice setting in patients suffering from RA and failure to TNF inhibitors.

Methods: REPEAT is an open-label, multicenter, prospective observational local study, 1087 patients with active RA and inadequate response to at least one TNF inhibitor received initial RTX (2×1000 mg IV, at 2 weeks apart) and subsequent RTX courses have been enrolled from 2010 to 2013. The patients were stratified according to the length of anti-TNF treatment before switch: <12 months (group A=260), 12–24 months (group B=278) and >24 months (group C=526). Clinical assessments including 28-joint disease activity score (DAS-28) were performed at baseline (switch moment) and after each retreatment course at 6, 12, 18, 24, 30 and 36 months. For the purpose of this analysis, median DAS-28 values were calculated for each group (A,B and C)and followed by median Delta Δ DAS-28 values calculation, as differences between values found at two successive evaluations and also from baseline to each evaluation. Statistical analyses were performed with STATA SE 11.0 software. Comparison between all previous treatments and evaluations for disease activity were performed using Nptrend and ANOVA tests.

Results: Median values for Δ DAS-28 obtained for group A, group B and group C from baseline to 6 months were -1,65;-1,35;-1,33 (P=0.01), from baseline to 12 months: -2,43;-2,05;-2,17 (P=0.02), from baseline to 18 months: -2,96;-2,59;-2,49 (P=0.009), from baseline to 24 months: -3,26;-2,83;-2,57 (P=0.01), from baseline to 30 months: -2,58;-2,7;-2,66 (P=0.15) and from baseline to 36 months: -2,56;-2,54;-2,83 (P=0.9). The median Δ DAS-28 achieved in group A at 1 year (−2.43) is comparable with Δ DAS-28 obtained at 18 month in group B (−2.59) and group C (−2.49). Across evaluations Nptrend test was P<0.0001 and ANOVA was P<0.0001.

Conclusion: 1. The median values of Δ DAS-28 as a measure of the amplitude of response to RTX show robust data that support the sustained clinical response to RTX across all 3 groups of patients over the 36 months treatment observation.

2. It is a significant difference between median values of Δ DAS-28 for group A and group B and C, showing a deeper and faster clinical response achieved in patients who were switched earlier to RTX in second line after anti-TNF treatment failure, with a pick at 24 months.

2498

Characteristics of Responding Versus Non-Responding Moderate Rheumatoid Arthritis Patients Treated with Etanercept Plus Methotrexate.

Josef S. Smolen[1], David Collier[2], Annette Szumski[3], Heather Jones[3] and Lisa Marshall[3]. [1]PsAID taskforce, EULAR, Zurich, Switzerland, [2]Amgen, Inc., Thousand Oaks, CA, [3]Pfizer Inc., Collegeville, PA.

Background/Purpose: While synthetic or biologic disease-modifying antirheumatic drugs (DMARDs) are often effective, treatment with such agents does not adequately control disease activity in all patients. Early identification of those unlikely to achieve long-term therapeutic goals is a clinically relevant strategy that may allow for appropriate modification in patient management to achieve optimal outcomes. The objective of this subanalysis was to determine disease characteristics of patients with moderately active RA responsive (defined by achievement of DAS28<2.6) and non-responsive to treatment with etanercept (ETN) plus methotrexate (MTX) after 36 weeks in the PRESERVE study.

Methods: In the induction phase of PRESERVE, subjects with moderately active RA (DAS28 >3.2 and ≤5.1) despite stable doses of oral MTX received open-label ETN 50 mg QW plus MTX (titrated to ≤25 mg/week as needed through week 28) for 36 weeks. Baseline demographic and disease characteristics and treatment response (DAS28, CDAI, HAQ) were compared in responders (defined as patients with DAS28<2.6) and non-responders (DAS28 ≥2.6) at week 36. Analyses using observed cases (OC) were conducted in all patients who received ≥1 ETN/MTX dose (mITT population).

Results: Of 764 patients receiving ETN50/MTX, 515 (67.4%) were classified as responders and 249 (32.6%) as non-responders at week 36. At baseline, responders were significantly younger (46.9 vs 50.9 years, P<0.001) with a lower BMI (25.4 vs 26.4, P=0.008) compared with non-responders. Responders also had significantly lower ESR (21.2 vs 24.7, P<0.001), CRP (11.4 vs 14.4, P=0.02), DAS28 (4.3 vs 4.5, P<0.001), CDAI (17.5 vs 18.3, P<0.001) and HAQ (1.1 vs 1.3, P<0.001) values than non-responders at baseline. Among responders and non-responders, significant changes from baseline in DAS28, CDAI and HAQ were observed at Week 4 and at all time-points up to Week 36 (all P<0.0001). Reductions in DAS28, CDAI, and HAQ were significantly greater among responders than non-responders after 4 weeks and this difference between groups was maintained for all clinical outcomes for the duration of the study period (Table).

Table: Differences in disease characteristics at baseline (BL) and week 36 in responders and non-responders to ETN50/MTX at week 36 (OC)

Characteristic	Mean (SD)/Adjusted Mean Change (SE) Responders	Non-Responder	Mean Difference (95% CI)	P Value
DAS28 at BL	4.3 (0.4)	4.5 (0.4)		<0.001
Week 36	1.9 (0.5)/−2.5 (0.03)	3.4 (0.9)/−1.0 (0.04)	−1.5 (−1.6, −1.4)	<0.0001
CDAI at BL	17.5 (4.8)	18.3 (5.2)		
Week 36	3.5 (2.6)/−14.2 (0.2)	10.7 (7.5)/−7.2 (0.3)	−7.0 (−7.7, −6.3)	<0.0001
HAQ at BL	1.1 (0.6)	1.3 (0.6)		
Week 36	0.4 (0.5)/−0.7 (0.02)	0.9 (0.6)/−0.3 (0.03)	−0.4 (−0.5, −0.4)	<0.0001

Conclusion: In the PRESERVE trial, patients with moderately active RA who achieved DAS28<2.6 after treatment with ETN plus MTX showed lower disease activity and functional improvement at baseline than those patients who did not achieve treatment target. Understanding the difference between responders and non-responders may help guide treatment practices and provide the best therapeutic options to these different patient sub-types.

Early Response Indicator early Predicts Clinical Response to Certolizumab in Rheumatoid Arthritis Patients. Massimiliano Cazzato[1], Laura Bazzichi II[2], Stefano Bombardieri[1] and Camillo Giacomelli[2]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology, pisa, Italy.

Background/Purpose: In the last few years the introduction of biological agents has radically changed the clinical outcome of patients with Rheumatoid Arthritis (RA). However, no single drug is able to control all patients with RA and it is known that each drug may be poorly effective in a sizable proportion of the treated patients (1). For these reasons, the early identification of clinical responder patients would be a crucial advantage for both a clinical and socioeconomic point of view.

Certolizumab pegol (CZP), a PEGylated, Fc-free anti-TNF, demonstrated a fast response in rheumatoid arthritis (RA). The peculiarity of the clinical response to CPZ at 12 weeks is already predictive of efficacy over time (2,3). Recently, mathematic algorithms, based on classical clinical parameters, have been proposed to predict the clinical response to anti TNF (4).

In the present study we have applied a mathematic algorithm recently proposed (ERI)(4) to predict early response to anti TNF on our cohort of patients treated with CZP.

Objectives: To evaluate the ability of ERI to predict the early response to CZP in RA patients already after the first 4 weeks of treatment.

Methods: We retrospectively collected the data of 52 RA patients followed in our unit and treated with CZP. We enrolled for this study 35 patients (72% female; mean age ± SD 56.63±15.58; DAS28 at the onset: 5.77 ±0.90; DAS28 at 12 weeks: 1.99 ± 0.43). The mathematic algorithm ERI utilizing the following parameters: tender Joint, swollen Joint, Illness activity VAS by Physician and patient, pain VAS, ESR and CRP, was applied to calculate the putative responders after one month of treatment (ERI≤0.67)and this value was compared with the DAS28 responders at 3 months. The patients were classified as good responders if they had a delta DAS28≥1.2 (EULAR criteria).

Results: 35 out of a total of 52 patients treated with CZP were assessed. 17 patients were excluded because: 3 interrupted CZP due to side effects, 5 had a follow-up inferior to 12 weeks, 9 patients had insufficient data (lost or poor compliance to follow-up) to calculate ERI and/or DAS28. No one had received other biologics prior to the assessment; all had associated a synthetic DMARD to CZP, mainly MTX. Using EULAR criteria we identified 21 responders at week 12, while ERI recognized 23 responders at week 4, with a concordance of 94%. Using EULAR criteria as the gold standard with ERI analysis we observed 1 false negative and 3 false positive subjects.

Conclusion: It is very important to identify subject who are responders to anti TNF agents such as CZP. CZP-treated patients with improvement at week 12 (ΔDAS28≥1.2) have a much higher probability of low disease activity at week 52 (3,5). In our cohort, ERI is a simple formula which can early recognize the CZP-RA responders, already after the first 4 weeks of treatment. In a socio-economic context, early identification of responders could be an opportunity to reduce spending. Moreover, to take advantage of any proposals for reimbursement, even on the part of pharmaceutical companies.

Genetic Variation in the *TLR5* Locus Is Associated with Anti-TNF Response Among Rheumatoid Arthritis Patients Jacob Sode[1], Ulla Vogel[2], Steffen Bank[3], Paal Skytt Andersen[4], Merete Lund Hetland[5], Henning Locht[6], Niels H. H. Heegaard[7] and Vibeke Andersen[8]. [1]University of Southern Denmark, Odense, Denmark, [2]National Research Centre for the Working Environment, Copenhagen, Denmark, [3]University of Aarhus, Aarhus, Denmark, [4]Statens Serum Institut, Copenhagen S, Denmark, [5]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup Hospital, Glostrup, Denmark, [6]Frederiksberg Hospital, Frederiksberg, Denmark, [7]Odense University Hospital, Odense C, Denmark, [8]OPEN (Odense Patient data Explorative Network), Odense, Denmark.

Genetic Variation in the *TLR5* Locus is Associated with Anti-TNF Response among Rheumatoid Arthritis Patients

Background/Purpose: In a recent study (paper in press) of Danish rheumatoid arthritis (RA) patients we found single nucleotide polymorphisms (SNPs) in the *NLRP3* and interferon-γ genes to be associated with response to tumor necrosis factor a inhibitors (anti-TNF). The aim of this study was to extend and corroborate these associations by analyzing a new set of functional polymorphisms in the NLRP3-inflammasome and interferon-γ pathways in RA patients treated with anti-TNF.

Methods: Twenty-three functional single nucleotide polymorphisms (SNPs) in 14 genes involved in the inflammasome and interferon-gamma pathways were assessed in 538 anti-TNF naive Danish RA patients. Prospectively collected clinical data including functional status (HAQ), patient global score, smoking status, tender and swollen joint counts, treatments, rheumatoid factor (RF) status and C-reative protein (CRP) were obtained from the DANBIO registry. Multivariable logistic regression analyses adjusting for sex, age, HAQ, CRP, baseline disease-modifying anti-rheumatic drugs and RF status were performed to test associations between genotypes and EULAR response—good vs. moderate/none and good/moderate vs. none—at 3–6 months follow-up. ACR50 response was also analyzed to enable comparison with other studies. Subgroup analysis was performed for patients positive for RF (N=407).

Results: Polymorphisms in *IL12B* (rs6887695), *TLR1* (rs4833095) and *TLR5* (rs5744174) were significantly ($p<0.05$) associated with EULAR response (Table 1). *TLR1* rs4833095 was also associated with ACR50 response. None of the associations reached significance when corrected for multiple testing by false discovery rate adjustment.

TLR5 rs5744174 variant C allele is associated with an improved anti-TNF response and maps 71 bp from another polymorphism (no linkage data exists) previously found to be associated with RA anti-TNF response in a Dutch cohort (1) and it has been associated with higher PBMC IFN-γ secretion and altered CCL20 production. *TLR1* rs4833095 has been associated with high PBMC *TLR1* expression.

Subgroup associations were found for seropositive RA in *CARD8* (rs2043211), *IL18* (rs187238) and *TLR1* (rs4833095) (data not shown) but due to low power these results are preliminary.

Conclusion: Our results confirm association between a *TLR5* locus and EULAR response to anti-TNF treatment. Previous studies suggest that this polymorphism is functional and associated with a phenotype with altered cytokine expression. The associations found for other polymorphisms need validation in a new cohort.

Table 1 Associations between gene variants and anti-TNF treatment response

Indirect Comparison of Tocilizumab and Tofacitinib in Patients with Rheumatoid Arthritis. Stacey Chang[1], Laura Sawyer[1] and Fred Dejonckheere[2]. [1]Symmetron Limited, London, United Kingdom, [2]F. Hoffmann-La Roche, Basel, Switzerland.

Background/Purpose: Tocilizumab (TCZ) is a recombinant, humanized, monoclonal antibody directed against the cytokine interleukin-6 receptor, and tofacitinib (Tofa) is an oral, synthetic, disease-modifying antirheumatic drug (DMARD) inhibiting Janus kinases (JAKs). Both are licensed for use in combination with other conventional DMARDs or as monotherapy in patients with moderately to severely active rheumatoid arthritis (RA) who have had inadequate responses to ≥1 DMARDs. The purpose of this study was to evaluate the effectiveness of TCZ compared with Tofa in their licensed populations (ie, RA patients with inadequate responses to conventional nonbiologic or biologic DMARDs [cDMARD-IR or bDMARD-IR]) based on publicly available evidence to date.

Methods: Efficacy was assessed for each treatment compared with placebo using available randomized controlled trial (RCT) evidence, after which treatments were indirectly compared with each other using the Bucher method.[1] Four comparisons were performed, each developed based on similarities between TCZ and Tofa studies in terms of population characteristics and treatment type (monotherapy and combination therapy). Comparative efficacy was assessed on the proportion of patients achieving American College of Rheumatology (ACR) scores of 20, 50, and 70 and Disease Activity Score using 28 joints (DAS28)–defined remission (DAS28 <2.6). Results are presented as risk ratios. Sensitivity analyses were undertaken to test the inclusion/exclusion of studies contributing to statistical heterogeneity.

Results: Across the 4 comparisons, 6 RCTs of TCZ and 6 RCTs of Tofa were included. In both monotherapy and combination therapy in cDMARD-IR and combination therapy in methotrexate (MTX)-IR patients, TCZ was more likely to generate ACR response and DAS remission than Tofa. In bDMARD-IR patients, TCZ in combination with MTX generated more ACR20 and ACR50 responders and DAS remitters than Tofa + MTX. Treatment effects between TCZ and Tofa failed to reach statistical significance in all but 3 instances (Table 1, Figure 1). The trends observed were robust to the sensitivity analyses performed.

Conclusion: Results of the indirect comparisons suggest TCZ and Tofa have broadly similar efficacy across different RA populations. There is a consistent trend (significant in 3 instances) favoring TCZ across all licensed RA populations on the outcome of DAS remission and ACR response.

Ten Year Follow-up Results of Four Dynamic Treat to Target Strategies in Patients with ACPA Negative Rheumatoid Arthritis. I.M. Markusse[1], G. Akdemir[1], L. Dirven[1], M. van den Broek[1], K.H. Han[2], H.K Ronday[3], P.J.S.M. Kerstens[4], W.F. Lems[5], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]MCRZ hospital, Rotterdam, Netherlands, [3]Haga Hospital, The Hague, Netherlands, [4]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [5]VU Medical Center, Amsterdam, Netherlands.

Background/Purpose: To determine the optimal treatment strategy in patients with anti-citrullinated protein antibodies (ACPA) negative (−) rheumatoid arthritis (RA), as it has been suggested that these patients require a different treatment approach than ACPA positive (+)patients.

Methods: 184 ACPA− patients were randomized to 1. sequential monotherapy, 2. step-up therapy, 3. initial combination with prednisone, 4. initial combination with infliximab, as were 300 ACPA+ patients. Treatment adjustments were based on 3-monthly disease activity score (DAS) measurements, aiming at DAS ≤2.4. Functional ability (health assessment questionnaire, HAQ), radiographic progression (Sharp van der Heijde score, SHS) and (drug-free) remission (DAS <1.6) percentages over 10 years were compared between the 4 arms in ACPA− patients and between ACPA− and ACPA+ patients per randomisation arm.

Results: At 3 months, ACPA− patients achieved more often DAS ≤2.4 (52% versus 18%, p<0.001), remission (17% vs 5%, p<0.001) and improvement in functioning (mean HAQ 0.6 vs 1.0, p<0.001) on initial combination therapy than on initial monotherapy. These differences remained until year 1. After 10 years of targeted therapy, over time no differences were retrieved (p=0.551 for HAQ, p=0.851 for remission). Table 1 shows the main outcomes at year 10.

Drug survival (achieve and maintain DAS ≤2.4) on methotrexate monotherapy (1st step in arm 1 and 2) was similar in ACPA− and ACPA+ patients (median survival 10 vs 7 months, p=0.750), as also drug survival on sulphasalazine (2nd step in arm 1 and 2, median survival 3 vs 3 months, p=0.659). At year 1, in arm 3 18/55 ACPA− (33%) and 31/68 ACPA+ patients (46%) tapered to monotherapy (p=0.310). In arm 4, 17/43 ACPA− (40%) and 38/82 ACPA+ patients (46%) discontinued infliximab (p=0.466).

Drug-free remission (DFR) was more often achieved and longer sustained in ACPA− than in ACPA+ patients, in all treatment arms (26% vs 8% in arm 1, p=0.077; 24% vs 9% in arm 2, p=0.048; 30% vs 2% in arm 3, p=0.002; 28% vs 6% in arm 4, p<0.001, median DFR duration averaged in 4 arms 69 vs 32 months, p=0.073). Over time, radiographic progression (Δ≥0.5 in SHS) in ACPA− patients was not different between the 4 arms (p=0.082). SHS progression was more often observed in ACPA+ patients than in

ACPA− patients in arm 1, 2 (both p<0.001) and arm 3 (p=0.016), but not in arm 4 (p=0.849).

Conclusion: On the short term, patients with ACPA− RA benefit more from initial combination therapy with prednisone or infliximab than from monotherapy, as also ACPA+ patients. During subsequent DAS steered therapy, ACPA− patients respond similarly to treatment steps in all 4 treatment arms to ACPA+ patients, suggesting that both groups require a similar treatment approach. After 10 years of targeted therapy, ACPA− patients achieve more often sustained drug-free remission than ACPA positive patients and show less radiographic progression, except in arm 4.

Table 1: Main outcomes at year 10 for ACPA negative patients in the four treatment arms

Early Response to Full-Dose Etanercept-Plus-Methotrexate Induction Therapy Predicts Sustained Remission with Reduced-Dose Combination Therapy in Early Rheumatoid Arthritis Patients. Paul Emery[1], Ronald Pedersen[2], Jack Bukowski[2] and Lisa Marshall[3]. [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., United Kingdom, Leeds, United Kingdom, [2]Pfizer Inc, Collegeville, PA, [3]Pfizer Inc., Collegeville, PA.

Background/Purpose: In early rheumatoid arthritis (RA), achievement of clinical remission and low disease activity (LDA) limits joint damage and disability.[1] Anti-TNF agents are effective in rapidly inducing remission in early RA, which may improve the likelihood of long-term treatment success.[2] According to current EULAR guidelines, biologic withdrawal should be considered after a good clinical state is achieved,[1] but little is yet known about which patients are the best candidates for treatment reduction or withdrawal. In the PRIZE study, the impact of demographic and disease characteristics and early treatment response on the achievement of sustained remission was assessed in patients with early RA.

Methods: Methotrexate (MTX)-/biologic-naïve patients with early moderate-severe RA who achieved DAS28 ≤3.2 at week 39 and <2.6 at week 52 after open-label treatment with etanercept (ETN) 50 mg+MTX 10–25 mg (Phase 1 [P1]) were randomized to ETN 25 mg+MTX, MTX alone, or placebo (PBO) for 39 weeks in the double-blind phase (Phase 2 [P2]). With Mantel-Haenszel chi-square tests, the association between baseline (BL) characteristics and P1 treatment responses and achievement of P2 sustained remission (ie, DAS28 <2.6 at week 76 and 91, without corticosteroids for week 52–64) was analyzed. BL demographic and disease characteristics will also be analyzed in patients who achieved early P1 remission (ie, first DAS28 remission on day 0–178) vs late P1 remission (ie, first DAS28 remission after day 178).

Results: Predictors of P2 sustained remission in the ETN 25 mg+MTX group included: achievement of DAS28 sustained remission over weeks 13–52 (vs patients without this P1 response: 79% vs 54%; *P*=0.044); DAS28 LDA over weeks 13–52 (76% vs 41%; *P*=0.007); and ACR/EULAR Boolean remission at week 52 (71% vs 44%; *P*=0.049). Rapid and robust responses in P1 (ie, first DAS28 remission in days 0–179, mean DAS28 ≤1.91 at week 52) were associated with P2 sustained remission in this reduced-dose combination group (table). Predictors of P2 sustained remission in the MTX group included: achievement of DAS28 LDA over weeks 13–52 (49% vs 23%; *P*=0.044), younger age at BL, and lower levels of CRP at week 52. Predictors in the PBO group were: seronegative status at BL for anticyclic citrullinated peptide (seronegative vs seropositive: 48% vs 11%; *P*=0.001) and for rheumatoid factor (41% vs 11%; *P*=0.005) antibodies.

Table Baseline and response predictors of sustained remission for active treatment groups.

Predictor	Quartiles of Response, n/N (%)				*P* value*
	ETN 25 mg+MTX				
First DAS28 remission	**Days 0-57**	**58-179**	**180-273**	**≥274**	0.003
	12/15 (80)	16/20 (80)	8/16 (50)	4/12 (33)	
First DAS28 LDA	**Days 0-29**	**30-57**	**58-183**	**≥184**	0.041
	12/14 (86)	12/20 (60)	10/15 (67)	6/14 (43)	
Mean DAS 28, week 52	**DAS28 ≤1.55**	**>1.55–1.91**	**>1.91–2.16**	**>2.16**	0.014
	14/16 (88)	11/16 (69)	7/15 (47)	8/16 (50)	
		MTX			
Age, BL	**19-39 years**	**40-48**	**49-60**	**≥61**	0.024
	11/15 (73)	8/22 (37)	2/15 (13)	5/13 (39)	
CRP level, week 52	**0-0.5 mg/L**	**>0.5-1.09**	**>1.09-2.91**	**>2.91**	0.005
	9/16 (56)	8/14 (57)	6/18 (33)	2/16 (13)	

*Mantel-Haenszel chi-square correlation (trend) test.

Conclusion: Early onset of response to induction therapy with etanercept plus MTX predicted sustained remission with the reduced-dose combination maintenance regimen. These results are clinically important as prompt identification of patients unlikely to reach target responses may promote more timely adjustments in therapy and ultimately improved long-term outcomes.

Impact of Concomitant Methotrexate on the Enhanced Clinical Efficacy of Abatacept after 24 Weeks in Rheumatoid Arthritis Patients. Nobunori Takahashi[1], Toshihisa Kojima[1], Yuji Hirano[2], Yasuhide Kanayama[3], Koji Funahashi[1] and Naoki Ishiguro[1]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Toyohashi Municipal Hospital, Toyohashi, Japan, [3]Toyota Kosei Hospital, Toyota, Japan.

Background/Purpose: Abatacept (ABT), a selective co-stimulation modulator, is the first in a new class of biologic agents for the treatment of rheumatoid arthritis (RA) that inhibits T cell activation by binding to CD80/86, and modulating its interaction with CD28. Although some reports demonstrated that concomitant methotrexate (MTX) had little enhancing effect on short-term clinical efficacy of ABT, there have been only few long-term studies. We studied whether background MTX treatment enhanced the ABT efficacy after 24 weeks, by using data from Japanese multicenter registry system for RA patients using biological DMARDs.

Methods: All RA patients who underwent ABT treatment for at least 52 weeks (n = 254) in Nagoya University Hospital and 12 other institutes (Tsurumai Biologics Communication Registry Study Group) were enrolled in this study. Demographic data and the following parameters of disease activity were collected; tender joint count (TJC) and swollen joint count (SJC) on 28 joints, patient global assessment (VAS), ESR, and serum CRP and MMP-3 levels at baseline, 24 weeks, and 52 weeks. We compared these clinical data between the patients treated without concomitant MTX (ABT-mono, n = 130) and those treated with concomitant MTX (ABT-MTX, n = 124, mean MTX dose of 7.4 mg/week). The last observation carried forward (LOCF) method was used in each analysis.

Results: In the baseline characteristic data, the ABT-mono group had higher pulmonary comorbidity rate (21.5 vs 6.5%, p = 0.001) compared to the ABT-MTX group while no other clinical parameters showed significant difference including the proportion of patients with previous biological DMARDs history (47.7 vs 47.6, p = 0.986) or the all disease activity indices such as DAS28 (4.48 and 4.54). As shown in Figure Left and Middle panel,

the ABT-MTX group demonstrated statistically significant decreasing of DAS28 from 24 to 52 weeks while no difference in the ABT-mono group. We next studied the patients that still adhered on ABT therapy in spite of their poor clinical efficacy (moderate or high disease activity, DAS28-CRP > 2.7) at 24 weeks. Logistic regression analysis identified the concomitant MTX therapy and female as independent predictors of DAS28 category improvement (e.g. high to moderate disease activity) from 24 to 52 weeks (Figure Right panel).

Conclusion: Concomitant MTX therapy significantly decreased the disease activity after 24 weeks, while it seemed not to have enhancing effect on short-term clinical efficacy of ABT. It is true that the ABT efficacy is still significant even in the patients without MTX usage. However, it would be beneficial to use concomitant MTX in most of RA patients without serious comorbidity for MTX usage.

2505

Long-Term Treatment with Tocilizumab (TCZ) Strongly Suppresses Joint Destruction in Biologic-naïve Patients with Rheumatoid Arthritis (RA) Regardless of Inflammation Status. Akira Sagawa. Sagawa Akira Rheumatology Clinic, Sapporo, 060-0001, Japan.

Background/Purpose: It is still difficult to completely prevent the progression of joint destruction with any of the currently available biologics. It has been reported that baseline CRP may predict early improvement of synovitis and bone erosion by TCZ therapy[1]. However, only a few reports have described whether TCZ may prevent joint destruction for a long period of time in clinical settings.

TCZ was administered for 3 years to identify risk factors for the progression of joint destruction in clinical settings and utilize the data to build treatment plans in RA patients.

Methods: TCZ was administered at a dose of 8 mg/kg every 4 weeks in combination with DMARDs including methotrexate. The effect on joint destruction was assessed on the basis of X-ray findings at baseline and year 3 of treatment using the modified total Sharp score (mTSS). Statistical analysis was performed using chi-square tests and Wilcoxon tests.

Results: and **Conclusion:** Among 57 patients registered, 51 patients evaluable with X-ray were assessed. At baseline, patients were 53.5 years in average, had suffered from RA for 10.9 years, and had a DAS28-ESR of 5.31 and an mTSS of 100.6. Biologic-experienced patients at baseline accounted for 66%, and PSL users 68.6%. One patient received TCZ as monotherapy. The mean DmTCC at year 3 was 1.0, and the structural remission rate (i.e., percentage of patients with DmTCC <1.5/3y) was 75%. A comparison of patients with and without progressive joint destruction revealed significant differences in CRP and ERS at baseline. Baseline CRP was 3.6 and 1.2 in patients with and without progressive joint destruction, respectively ($p = 0.024$). Logistic regression analysis revealed that the cut-off point of baseline CRP was 2.8 (specificity 92.1%; sensitivity 46.5%; $p=0.003$). The mean DmTSS values at year 3 in patients above and below the cut-off value were compared in groups of biologic-naïve patients and biologic-experienced patients. The mean DmTSS was -0.3 for biologic-naïve patients with CRP <2.8, and 0.3 for those with CRP ³2.8, indicating that TCZ prevented joint destruction regardless of inflammation status ($P=0.739$). In biologic-experienced patients, the mean DmTSS was 0.2 for those with CRP <2.8, and 8.0 for those with CRP ³2.8, with a significant difference between the two subgroups ($p=0.011$). This significantly higher score in the latter subgroup may be explained by the presence of severe inflammation not controlled with previous treatment as well as the higher DAS28-ESR, swollen joint count and ESR at baseline ($p<0.05$).

Long-term treatment with TCZ prevented joint destruction of RA patients, and a high structural remission rate was obtained. Our findings suggest that TCZ, if given to biologic-naïve patients, may strongly prevent the progression of joint destruction regardless of inflammation status.

Decrease in the Number of Peripheral Leukocytes and Neutrophils and Increase of the Percentage of Eosinophils at 4 Week Predict the DAS28-ESR Remission at 24 Weeks after Administration of Tocilizumab. Tamao Nakashita[1], Shinji Motojima[2] and Akira Jibatake[3]. [1]Kameda Medical Center, Kamogawa-city, Japan, [2]Kameda Medical Center, Kamogawa City, Japan, [3]Kameda Medical Center, Kamogawa city, Japan.

Background/Purpose: Tocilizumab (TCZ) is a monoclonal anti-IL-6 receptor antibody, and is very effective in controlling RA activity. However we had noticed that the change in leukocyte number after the administration of TCZ is different from that of TNF-inhibitor, and the change in leukocyte number by TCZ is rapid occurring within few days of administration. We analyzed retrospectively the relationship between the change in leukocyte number at 4 week and disease activity evaluated by DAS28-ESR at 24 weeks.

Methods: Subjects were 50 patients with RA (male/ female = 10/40, mean age 56.7 +/− 12.7 years-old). The mean doses +/− SD of PSL (n = 35), MTX (n = 45), SSZ (n = 7), and bucillamine (n = 4) were 4.5 +/− 1.9 mg/day, 7.4 +/− 2.4 mg/week, 1000 +/− 0 mg/day, and 163 +/− 48 mg/day, respectively, at the introduction of TCZ. Patients were administrated with 8 mg/kg of TCZ every 4 weeks, and blood test and physical examination were done at the time of TCZ administration. Of the 50 patients, 19 were biologics naïve.

Results: The mean DAS28-ESR at week 0 and 24 were 4.72 and 2.22, respectively, and the difference was statistically significant. Thirty-one out of 50 patients reached DAS28-ESR remission at 24 weeks. The changes of leukocyte number after administration of TCZ are summarized as follows; total leukocyte number: decrease, neutrophil number: decrease, % of neutrophil: decrease, eosinophil number: no changes, % of eosinophil: increase as a result of the decrease in total leukocyte number. The changes of leukocyte number occurred at 4 weeks and did not change thereafter until 24 weeks. The change of DAS28-ESR, on the other hand,occurred gradually and reached plateau at 16 weeks. The decrease of the number of total leukocyte and neutrophil at 4 weeks significantly correlated with the decrease of DAS28-ESR at 24 weeks. The increase of % of eosinophil at the sum of 4 and 8 weeks significantly correlated with the decrease of DAS28-ESR at 24 weeks. Positive predictive values (PPV) for DAS28-ESR remission at 24 weeks were 76 %, 77 %, and 75 %, respectively, when total leukocyte and neutrophil count decreased by more than 1000 at 4 weeks, and when % of eosinophil increased by 0.5 % at 4 weeks, respectively.

Conclusion: The administration of TCZ induced significant changes of leukocyte count at 4 weeks, which is a good predictor of reaching DAS28-ESR remission at 24 weeks.

Is There an Autoinflammatory Component in Rheumatoid Arthritis Associated with Better Response to Anakinra (Kineret®)? Barbara Missler-Karger[1], Hans-Eckhard Langer[2], Mika Leinonen[3] and Björn Pilström[4]. [1]Rheumatology consultant, Cologne, Germany, [2]RHIO Research Institute, Düsseldorf, Germany, [3]4Pharma AB, Stockholm, Sweden, [4]Swedish Orphan Biovitrum AB, Stockholm, Sweden.

Background/Purpose: 458 patients with rheumatoid arthritis (RA) and inadequate response to traditional DMARDs alone and/or TNFα blocking agents were treated with the IL-1 receptor antagonist anakinra. The initial analysis showed no difference between TNFα blocker non-responders and

TNFα blocker naïve RA patients (1). In order to identify factors that could predict response to anakinra treatment we performed a *post hoc* analysis of the original study data.

Methods: Original study data including demographic parameters, concomitant diseases and other anti-rheumatic treatment were subject to multivariate statistical analysis to identify independent factors that impact on the DAS score difference and EULAR response after one year of anakinra treatment. Cohort analyses of patients leaving the study were performed to identify characteristics predictive for study dropout. Data from patients leaving the study prematurely were imputed based on the LOCF (last observation carried forward) methodology.

Results: Patients leaving the study prematurely (non-completers) were characterised by less DAS improvement and higher age than completers. Adverse events did not increase the risk of dropout. 79% of patients had high disease activity at baseline which was reduced to 48% after one month's treatment. Over the 12-month study most patients obtained moderate disease activity or better and 15–19% reached low disease activity or remission. A multivariate analysis of DAS score reduction over time concluded that the most predictive factors were disease severity (DAS28) at baseline ($p<0.001$), previous use of biologics ($p<0.05$), no or low-dose steroids ($\leq$7.5 mg prednisolone/day, $p=0.06$) and the prevalence of diabetes ($p=0.14$).

Conclusion: In a study with 458 RA patients treated with anakinra, further post hoc analysis of the raw data suggests that higher disease severity, no or low-dose steroid use or concomitant diabetes are predictive of a better response to anakinra treatment. We speculate that there may be two distinct cohorts of RA patients, one with a more autoimmune, steroid responsive disease, the other with a more autoinflammatory, steroid non-responsive disease.

Tocilizumab Serum Trough Levels and Its Relationship with Disease Activity and Drug Dosage in Rheumatoid Arthritis Patients. Virginia Ruiz-Esquide[1], Azucena Gonzalez-Navarro[2], Jordi Yagüe[3], Jose Inciarte-Mundo[1], M. Victoria Hernández[1], Julio Ramirez[1], Sonia Cabrera-Villalba[1], Juan D. Cañete[1] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clinic of Barcelona, Barcelona, Spain, [3]Hospital Clinic Barcelona, Barcelona, Spain.

Background/Purpose: Tocilizumab (TCZ) is a humanized monoclonal antibody against interleukin-6 receptor used for the treatment of active rheumatoid arthritis (RA). The response to this treatment may depend on the serum levels achieved, which depends on the interval and the total dose administered.

Purpose To analyze TCZ serum trough levels and antidrug antibodies (ADA) in a cohort of RA patients in chronic treatment with TCZ; and to evaluate its relationship with disease activity, serum levels of IL6 and CRP and drug levels.

Methods: Cross-section study including all RA patients attended in our Arthritis Unit undergoing chronic treatment with TCZ. Analysis of demographic data, disease activity IL6 and CRP serum levels together with TCZ serum levels and ADA (LISA TRACKER Tocilizumab LTT005 DuoDrug + ADAb) was done. All drug levels were measured before treatment infusion. Drug levels were correlated with different clinical and serological parameters.

Results: 33 RA patients were included (91% women, age 53 $\pm$12 years, disease duration 15.3 $\pm$ 9.7 years, anti-CCP+ 66.7%, monotherapy 22.2%, DAS28 2.9 $\pm$ 1.1). No patient showed presence of ADA. In 14 patients (42%) serum levels of TCZ were non-detectable (<1 ug/ml). Patients with detectable levels of TCZ showed higher levels of IL6 and lower levels of CRP than those with non-detectable levels (Table). 15 patients received reduced dose of TCZ (4–6 mg/Kg) due to persistent remission or low disease activity. In these patients serum levels of TCZ were lower than in those with standard dose, without differences on disease activity or CRP between groups. A significant positive correlation was found between IL6 levels and TCZ serum levels ($R2=0.268$, $p=0.005$), but not with DAS28 or CRP. In 3 patients, all of them with low disease activity, a curve of TCZ serum levels was done by TCZ dosage at baseline (before drug infusion) and 10, 20 and 28 days thereafter. In two patients, TCZ serum levels were not detectable by day 20. The third patient showed adequate levels through the entire period.

Conclusion: In a clinical setting of RA patients in treatment with TCZ no ADA were found. An important proportion of RA patients treated with TCZ had undetectable serum trough levels (42%), showing higher CRP levels, and lower IL-6, but no differences were found in disease activity measured by DAS28-ESR.

Distribution of patients according to TCZ serum trough levels

	Non detectable drug levels (< 1 ug/ml) n=14	Detectable drug levels (> 1 ug/ml) n=19	p
Dose interval (days – mean)	31.9 $\pm$ 3	29.9 $\pm$ 3	0.323
Serum IL6 levels (ug/ml)	2.8 $\pm$ 2.3	7.8 $\pm$ 2	0.012
CRP (mg/dl)	1.1 $\pm$ 1.4	0.1 $\pm$ 0.3	0.001
Hemoglobin (g/dl)	13.5 $\pm$ 15	12.8 $\pm$ 12	0.214
Reduced dose of TCZ (%)	79%	42%	0.053
DAS28-ESR	3.1 $\pm$ 1	2.8 $\pm$ 1	0.499
Remission (DAS28-ESR<2.6) (%)	29%	37%	0.956

ADAM-10 As a Tocilizumab Treatment Predictive Factor in Rheumatoid Arthritis. Takeo Isozaki, Sakiko Isojima, Takahiro Tokunaga, Masayu Umemura, Hidekazu Furuya, Ryo Yanai, Ryo Takahashi, Kuninobu Wakabayashi, Nobuyuki Yajima, Yusuke Miwa and Tsuyoshi Kasama. Showa University School of Med, Shinagawa-ku Tokyo, Japan.

Background/Purpose: A disintegrin and metalloproteinases (ADAMs) are a family of transmembrane and secreted proteins. ADAM-10 has been reported to be the enzyme responsible for the release of a number of chemokines and cytokine receptors. We have shown that ADAM-10 is overexpressed on rheumatoid arthritis (RA) synovial tissue endothelial cells (ECs) and lining cells compared with osteoarthritis and normal tissues. We also demonstrated that ADAM-10 mediates EC migration and tube formed. In this study, we examined ADAM-10 as a predictive treatment factor in RA.

Methods: The serum was collected from patients before the initial treatment with biological therapies. Fifteen patients were treated with adalimumab (ADA), and 20 patents were treated with tocilizumab (TCZ). ADAM-10 and fractalkine/CX3CL1 were measured by enzyme-linked immunosorbent assay at 0, 12, 24 and 54 weeks. Clinical disease activity was evaluated by disease activity score 28 (DAS28). Following biological therapies, we defined biologic-responders as patients whose DAS28 scores decreased by more than 1.2 at 24 weeks. ADAM-10 baseline was compared between responders and nonresponders.

Results: There were no significant differences were observed in the mean age, gender ratio, dosages of predonisolone and methotraxate between ADA and TCZ groups. In ADA group, baseline DAS28 for the 15 patients was 4.8 $\pm$ 0.3 (2.5–7.2). On the other hands, baseline DAS28 for the 20 patients was 4.8 $\pm$ 0.3 (2.5–6.8) in TCZ group. There were no differences between ADA and TCZ groups. RA patients with an insufficient response to ADA or TCZ showed highly significant improvement of DAS28 after 12 weeks (2.9$\pm$0.3 and 2.2$\pm$0.4, respectively), and 24 weeks (2.5$\pm$0.4 to 2.2$\pm$0.2, respectively). ADAM-10 highly correlates with fractalkine/CX3CL1. Serum ADAM-10 levels were no remarkable change after treatment with ADA despite decrease of disease activity of RA. On the other hand, serum ADAM-10 levels in patients who were treated with TCZ were significantly diminished following successful treatment and clinical improvement (baseline 408$\pm$88 pg/ml and 54 weeks 138$\pm$51 pg/ml, $p<0.05$). ADAM-10 baseline in TCZ responder was significantly higher than TCZ nonresponders at 24 weeks (620$\pm$134 pg/ml and 109$\pm$25 pg/ml, respectively, $p<0.05$).

Conclusion: This study indicates that ADAM-10 is correlated with RA disease activity, and is higher in TCZ responders. These results suggest that ADAM-10 may be a predictor of treatment effectiveness for RA with TCZ.

Good Response to Methotrexate (MTX) and/or MTX Plus Adallimumab (ADA): 3 Yrs Study Results in Patients with Rheumatoid Arthritis (RA).

Kazuko Shiozawa[1], Takashi Yamane[1], Miki Murata[1], Chihiro Tanaka[1], Noriaki Yo[1], Ryosuke Yoshihara[1], Yasushi Tanaka[1], Ken Tsumiyama[2] and Shunichi Shiozawa[2]. [1]Kohnan Kakogawa Hospital, Kakogawa, Japan, [2]Kyushu University Beppu Hospital, Beppu, Japan.

Background/Purpose: To achieve comprehensive disease control (CDC; defined as simultaneous achievement of DAS28 < 3.2, HAQ-DI < 0.5 and ΔmTSS ≤ 0.5) or comprehensive disease remission (CDR; defined as simultaneous achievement of DAS28 < 2.6, HAQ-DI < 0.5 and ΔmTSS ≤ 0.5) is our therapeutic goal of treating RA. Owing to 2010 ACR/EULAR recommendation for early treatment of RA (Aletaha D et al, Ann Rheum Dis 69:1580, 2010), we found, in line with the finding of O'Dell et al. (Arthritis Rheum 65:1985, 2013), that 69/137 (50.4%) of RA patients given low-dose methotrexate (MTX) monotherapy showed no radiographic progression over 3 years when the patients were treated continuously with MTX monotherapy until significant adverse events or radiographic progressions were suspected. However, it remains unclear if the CDC and/or CDR are comparable between the patients treated with MTX monotherapy and those with MTX plus biologics. We here compared the clinical efficacy of MTX monotherapy and adalimumab (ADA) + MTX: 161 patients who showed adequate responses to methotrexate (MTX) (MTX group) were compared with 96 patients treated with ADA + MTX for inadequate response to MTX (MTX-IR) (ADA group) as to the effects on functional and structural outcomes for 3 years.

Methods: Grip strength, CDR and CDC rates and patients' proportions with structural remission (ΔmTSS ≤ 0.5), clinical relevant radiographic progression (CRRP; ΔmTSS >3) and rapid radiographic progression (RRP; ΔmTSS>5) were measured in MTX group (n=161, mean disease duration: 4.4 years) or ADA group (n=96, mean disease duration: 8.5 years) every year for 3 years.

Results: There was no significant difference in clinical remission rates (DAS28-ESR<2.6) between MTX and ADA groups at 3 years (LOCF). While, CDR rates for 3 years were much higher in ADA group (43.2%) than MTX group (18.3%) as well as those of CDC (45.9% vs. 24.0%, respectively). Moreover, about the structural change, ratios of patients with RRP were decreased in both MTX and ADA group at 3 years compared to the status at first year, however the ratio of patients with RRP in MTX group was 10% whereas that of patients with RRP in ADA group was 3%. Reflecting this result about the structural change, grip strength in ADA group was improved every year, but that was gradually decreased in MTX group after 1 year, even the baseline grip strength in MTX group was much stronger than that in ADA group143 vs. 177 mmHg, p=0.0001.

Conclusion: It was demonstrated that grip strength gradually decreased from 1 year after the initiation of MTX treatment in the patients with MTX monotherapy, while ADA treatment to MTX-IR patients improved grip strength in a time dependent manner, which was supported by significantly better CDC and CDR rates over 3 years in the ADA group than those in the MTX group. Thus, the treatment in combination with biologics seems preferable for the patients with increased disease activity in face of MTX monotherapy.

Predictors of Discontinuation of Biologic DMARD Therapy Due to Remission in Patients with Rheumatoid Arthritis in a National Registry.

Jose A Gomez-Puerta[1], M. Victoria Hernández[2], Fernando Sanchez-Alonso[3], Kazuki Yoshida[4], Raimon Sanmarti[2], Daniel H Solomon[1], Juan J Gomez-Reino[5] and On behalf of BIOBADASER 2.0 study group[3]. [1]Brigham and Women's Hospital, Boston, MA, Boston, MA, [2]Hospital Clinic, Barcelona, Barcelona, Spain, [3]Spanish Society of Rheumatology, Madrid, Spain, [4]Kameda Medical Center, Kamogawa, Japan, Kamogawa, Japan, [5]Hospital Clinico Universitario at the Universidad de Santiago de Compostela, Santiago, Spain.

Background/Purpose: Remission is considered an achievable goal for many patients under biologic therapies. However, currently there is limited information about predictors of discontinuation of biologic therapy in patients with RA. Our aim was to conduct a cohort study of patients enrolled in a National Registry of Biologic therapies to clarify how often biologic DMARD are discontinued due to remission and to identify predictors of discontinuation according to baseline characteristics at the time of initiation of biologic treatment.

Methods: We conducted a retrospective, observational cohort study of previously collected data from one national registry. We included RA patients who had at least 3 consecutive months on the same first biologic DMARD. Patients receiving rituximab were excluded. The index date was defined as visit when biologic therapy was started. The study period included patients recorded in the registry from April 1998 until December 2013. The endpoint of interest was defined as discontinuation of biologic DMARD due to remission defined by treating physician. Censoring occurred administratively (end of registry data), when patients stopped the treatment for other causes (side effects, lack of efficacy or pregnancy among others) or by loss to follow up. We used multivariable proportional sub-distribution hazards (SHR) models to examine the association between several predictors with discontinuation due to remission with loss to follow-up, discontinuation due to lack of efficacy, side effects or other causes as competing events.

Results: The study included 3,516 patients with diagnosis of RA and of these 3,161 patients having received at least 3 months of biologic DMARD. 753 patients stopped treatment due to side effects, 867 patients discontinued treatment due to lack of efficacy, 101 were loss of follow-up, 143 for other reasons, 48 patients for pregnancy. In 15 cases the cause of discontinuation was not established. 1175 patients still receiving biological DMARD until the end of the study. Only 59 (1.8%) patients were able to discontinue biologic therapy due to remission. Baseline characteristics of patients at the moment of starting biologic DMARDs are in **Table.** After multivariate SHR analysis, sex (female) (SHR 2.81 95% CI 1.01–7.83), age at onset (SHR 1.04 (95% CI 1.01–1.07) and disease duration (HR 0.94, CI 95% 0.90–0.98) were significant predictors of discontinuation due to remission adjusting by methotrexate and steroids use.

Conclusion: A small proportion (<2%) of patients with RA were able to discontinue biologic DMARD therapy due to disease remission. Sex, age at onset and disease duration were predictors of such discontinuation. The prognosis of biologic-free patients after remission is still unknown and further studies are needed to elucidate their clinical course.

Table. Baseline characteristics at the moment of starting biologic DMARDs.

	No remission N=3,102	Discontinuation for remission N=59	p value
Mean age (Years, SD)	53.9 (13.2)	58.5 (12.4)	**0.007**
Sex (Female %)	79.9	88.1	0.11
Mean disease duration (years, SD)	9.3 (8.7)	7.0 (6.0)	**0.04**
Seropositive RA (%)	89.3	89.8	0.89
Current smoking	12.2	6.8	0.20
Extra-articular disease (%)	20.1	15.3	0.35
Nodular disease (%)	7.4	5.1	0.25
Mean DAS-28 (SD)	3.75 (2.85)	4.22 (2.47)	0.21
Methotrexate (ever, %)	56.7	62.7	0.35
Steroids use (at index date, %)	53.4	59.3	0.37
DMARDs use (at index date, %)	71.2	71.2	0.99
Anti-TNF therapy (as first treatment, %)	93.9	98.3	0.15

Sacco University Hospital, Milan, Italy, [5]Ospedale Mauriziano, Turin, Italy, [6]Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Turin, Italy, [7]Santa Chiara Hospital, Trento, Italy, [8]Struttura di Reumatologia A.S.O. «SS.Antonio e Biagio e C.Arrigo», Alessandria, Italy, [9]Department of Rheumatology, Gaetano Pini Institute, Milan, Italy, [10]Department of Rheumatology, Gaetano Pini Institute, Milano, Italy, [11]Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo, Pavia, Italy.

Golimumab therapy retention rates in patients with rheumatoid arthritis and seronegative spondyloarthritis: data from the Italian LORHEN registry.

Background/Purpose: The efficacy of Golimumab (GLM) treatment in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) has been widely documented. In everyday clinical practice, however, many patients discontinue therapy due to adverse events (AE), lack of efficacy or other reasons. [1] We compared first year retention rates of GLM treatment among RA, PsA and AS, using the first one as reference standard, in a multicentric observational cohort (the LORHEN Registry).

Methods: All patients in the LORHEN database who started GLM were included. All patients were treated according to current EULAR recommendations for the management of RA and spondyloarthritis. Drug survival during the first year of treatment was measured, along with specific reasons for discontinuation (inefficacy or adverse events). We compared drug retention rates using the Kaplan-Meier method. Cox regression analyses, using RA as reference category, were used to adjust for age, sex, disease duration, number of previous csDMARDs and treatment with low dose prednisone.

Results: 134 RA patients, 84 PsA patients and 108 AS patients were included. 49 (37%) RA patients, 29 (35%) PsA patients and 22 (20%) AS patients discontinued treatment during the first year. Thirty-six (27%) and 12 (9%) RA patients, 17 (20%) and 11 (13%) PsA patients, 14 (13%) and 7 (6%) AS patients discontinued GLM due to lack of efficacy or AE, respectively.

Patients with a diagnosis of AS showed a lower, but not significant, risk of discontinuation, with an adjHR (95%CI) of 0.35 (0.10 – 1.17).

Patients treated with low dose prednisone showed a reduced risk of discontinuation with an adjHR (95%CI) of 0.35 (0.14 – 0.86). Age, sex, disease duration and number of previous csDMARDs did not significantly influence the risk of discontinuation.

Conclusion: AS patients seem to have better GLM retentions rates with respect to RA and PsA patients; however this difference is significantly reduced after adjusting for confounders.

The significantly lower adjHR observed for low dose prednisone therapy might reflect a beneficial effect even in patients treated with bDMARDs.

The Monitoring of Infliximab Levels at Early Stages Can Predict the Development of Anti-Infliximab Antibodies in a Cohort of Rheumatoid Arthritis Patients Treated with Infliximab.

Chamaida Plasencia-Rodriguez[1], Dora Pascual-Salcedo[2], Maria Gema Bonilla[2], Alejandro Villalba[1], Diana Peiteado[1], Laura Nuño[3], Pilar Aguado[4], Teresa Jurado[4], Emilio Martín-Mola[5] and Alejandro Balsa[3]. [1]Hospital La Paz - IdiPaz, Madrid, Spain, [2]La Paz University Hospital, Madrid, Spain, [3]Hospital La Paz-IdiPaz, Madrid, Spain, [4]La Paz University Hospital-Idipaz, Madrid, Spain, [5]Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: There is a close association between serum Infliximab (Ifx) levels and the Antibodies To Infliximab (ATI) with the clinical activity in rheumatoid arthritis (RA) patients. Several markers have been described to predict the response to biological therapy but for now no evidence of serological markers during the TNFi therapy is available. Our aim was to analize whether Ifx drug levels at 2, 6 and 14 weeks after starting Ifx can predict the disappereance of serum Ifx levels and ATI detection at 6 months and 1 year in a cohort of RA patients treated with Ifx.

Methods: 85 RA patients were included in this is ambispective observational study. The clinical activity was measured by DAS28 at baseline, 6 months and 1 year. The serum samples were obtained before each infusion at baseline, 2, 6 and 14 weeks after starting Ifx, 6 months and 1 year. Ifx and ATI levels were measured by ELISA. Receiver-operator characteristics (ROC) analysis were used to establish a cutt-off value for Ifx levels (2, 6 and 14 w) between patients with or without detectable Ifx levels at 6 months and 1 year. Area under the curve (AUC), sensitivity (S), specificity (SP) and positive likelihood ratio (LR+) were calculated at any studied point. The Last observation was carried forward (LOCF) for patients who dropped out before 1 year.

Results: Ifx levels at early stages (2, 6 and 14 weeks) of Ifx therapy were significantly lower in RA patients without detectable Ifx levels at 6 months and 1 year (Figure 1). Ifx levels lower than 21.2μg/ml at 2 weeks, 4.4μg/ml at 6 weeks and 0.4μg/ml at 14 weeks were predictive to Ifx disappearance at 6 months (2 weeks: AUC 0.708, S 67%, SP 87%, LR+5.1; 6 weeks: AUC 0.810, S 70%, SP 88%, LR+ 6.03; 14 weeks: AUC 0.923, S 83%, SP 92%, LR+10.4) and 1 year (2 weeks: AUC 0.708, S 64%, SP 89%, LR+5.8; 6 weeks: AUC 0.800, S 63%, SP 90%, LR+ 6.3; 14 weeks: AUC 0.923, S 75%, SP 94%, LR+13.1).

Conclusion: The monitoring of Ifx levels at early stages of therapy has a high value to discriminate which RA patients will have a faster Ifx clearance with the subsequent ATI detection and poor clinical outcomes. Patients with Ifx trough levels lower than 21.2, 4.4 and 0.4 μg/ml at 2, 6 and 14 weeks, respectively, have a high probability to develop ATI in the 1st year under the therapy.

Unit, L. Sacco University Hospital, Milan, Italy, [5]Ospedale Mauriziano, Turin, Italy, [6]Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Turin, Italy, [7]Santa Chiara Hospital, Trento, Italy, [8]Struttura di Reumatologia A.S.O. «SS.Antonio e Biagio e C.Arrigo», Alessandria, Italy, [9]Department of Rheumatology, Gaetano Pini Institute, Milan, Italy, [10]Department of Rheumatology, Gaetano Pini Institute, Milano, Italy, [11]Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo, Pavia, Italy.

Background/Purpose: During the last fifteen years, the role of biologics in the management of RA, the number of available biologics, and the recommendations of use, have changed. Moreover, several observational experiences pointed out a suboptimal adherence to the principles of treat-to-target.

The aim of this study is to assess differences in baseline characteristics of patient who started a first line biologic agent over time in a multicentric observational cohort (the LORHEN Registry) from 1999 until today.

Methods: In the LORHEN Registry, we identified all adult RA patients starting a first line biologic agent between 1 January 1999 and 31 May 2014. For the purpose of our analysis, we divided the patients in three time groups, according to the date of assessment of baseline disease variables: from 1999 to 2004 [99-04], from 2005 to 2010 [05–10] and from 2011 to May 2014 [11–14]. The comparison of baseline demographics, disease characteristics and previous treatments with csDMARDs in the 3 subgroups was performed.

Results: A total of 2373 RA patients from eight different rheumatologic centers were included. Patients treated in the [11–14] time group had a statistically significant lower baseline DAS28 and HAQ compared with previous time group. DAS28 at first switch was significantly lower in [11–14] patients, shrinking to mean values of moderate disease activity from those of high disease activity observed for patients in the [05–11] group. Disease duration and time before first switch did not differed significantly between groups.

Conclusion: The disease activity status at which RA patient starts biological treatment has progressively reduced: clinicians are now aiming at tighter control of RA activity.

The vast majority of patients starts biologic treatment only after years of csDMARDs, with an established disease, in conflict with the principles of treat-to-target. The incomplete availability of biological drugs over territory and economical concerns, in addition to incomplete adherence to international recommendations, might at least in part explain this occurrence.

The observation that real life population treated with biological drugs significantly differs for duration of disease from those selected in the majority of clinical trials should be taken into account when applying inferences from randomized controlled trials to everyday clinical practice.

Serum Survivin in Early Rheumatoid Arthritis. Adrian Levitsky[1], Malin Erlandsson[2], Maria Bokarewa[2] and Ronald F. van Vollenhoven[3]. [1]The Karolinska Institute,Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Stockholm, Sweden, [2]University of Gothenburg, Gothenburg, Sweden, [3]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), the Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The proto-oncogene survivin regulates cell division and inhibits apoptosis. Elevated levels may be found in patients with rheumatoid arthritis (RA) and their presence has been associated with joint destruction. Here, we investigated if survivin may be a marker or predictor of clinical disease activity and/or response to treatment in patients with early RA.

Methods: Serum levels of survivin were measured using ELISA at baseline in 302 patients enrolled in the Swedish pharmacotherapy (SWEFOT) trial, with follow-up at 3, 12 and 24 months. After methotrexate (MTX) monotherapy for 3 months, disease non-active patients (DAS28≤3.2, NAPs) remained on MTX, while active patients (APs) were randomized to triple therapy (MTX+sulfasalazine+hydroxychloroquine) or anti-TNF (MTX+infliximab). Analyses were based on intention-to-treat and performed with respect to baseline (BL) survivin status; conversion status from BL to 3 months; or from 3 to 12 (or 24) months, (+/+) vs. (+/−) or (−/−) vs. (−/+), respectively. Values >0.45 ng/mL were considered (+). Outcome measures included the reductions from BL to 3 months or from 3 to 12 months in the DAS28 and core-set outcomes; actual values at 3, 12, or 24 months; as well as EULAR responses.

Results: Out of 302 patients, 114 (38%) were survivin (+) at BL. The survivin (+) patients were significantly more often RF (+) (81% vs. 58%, p<0.001), but no differences were found over time vs. (−) at BL in the majority of outcome measures.

Among 294 patients with 3-month status, survivin-negative patients (−/−) (n=167) had a significantly better DAS28 and swollen joint count at 12 months vs. 3-month converters (-/+) (n=14) (median 2.89 vs. 3.76, 1.0 vs. 4.5, respectively; p<0.050). Converters to negative (+/−) by 3 months (n=11) vs. non-converters (+/+) (n=28) among NAPs had significantly greater reductions at 3 months in DAS28 and patient's global visual analog scale (PG-VAS) (3.5 vs. 2.5, 40.0 vs. 23.5, respectively; p<0.010). Among APs, converters (+/−) by 3 months had improvements by 12 months.

Conversion (+/−) from 3 to 12 (or 24) months led to significant reductions among triple therapy from 3 to 12 months (n=12) vs. (+/+) (n=15) (PG-VAS, 19.5 vs. 0.0, p=0.024), which was not observed in the same interval among anti-TNF. The positive DAS28 reduction among triple therapy (+/−) vs. anti-TNF (+/−) (1.52 vs. 0.55, p=0.082) led to significantly more EULAR Good responders from 3 to 12 months (58% (7/12) vs. 0% (0/6), p=0.038).

Conclusion: Survivin status at BL did not predict the 3-month response to MTX. Non-elevated survivin (−/−) leads to better outcomes than (−/+) after 3 months' MTX treatment, whereas conversion (+/−) by 3 months is associated with greater clinical improvements than (+/+) primarily among MTX responders at 3 months, but also by 12 months among 3-month MTX non-responders. Among patients randomized to triple therapy, those whose survivin converted (+/−) from 3 to 12 months had better 12-month outcomes than non-converters (+/+). This association was not seen for patients randomized to anti-TNF, suggesting that survivin may be associated with TNF-independent inflammatory pathways.

Reasons and Risk Factor for Discontinuation of Biologic Agents in Rheumatoid Arthritis Patients. Kenya Terabe[1], Toshihisa Kojima[1], Nobunori Takahashi[1], Koji Funahashi[1], Atsushi Kaneko[2], Yuji Hirano[3], Yasuhide Kanayama[4], Yuichiro Yabe[5] and Naoki Ishiguro[1]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Nagoya Medical Center, Nagoya, Japan, [3]Toyohashi Municipal Hospital, Toyohashi, Japan, [4]Toyota Kosei Hospital, Toyota, Japan, [5]JCHO Tokyo Shinjuku Medical Center, Tokyo, Japan.

Background/Purpose: Rheumatoid arthritis (RA) patients who failed a first biologic agent due to any reasons have the option of switching to a second one along with the strategy of biologic agent treatment. Patients go

over switching to the next one at failing their biologic agent. On the other hand, there are some patients who discontinue any biologic agent treatment due to various reasons such as tolerability concern, complications, economic issue, remission and so on. The impact of this concern has been less studied.

The objective of this study was to investigate the reasons and the risk factors for discontinuation any biologic agent in RA patients.

Methods: In total patients (n=2179) who underwent biologic agent treatment between 2003 and 2011 at Nagoya University Hospital and 12 other institutes (Tsurumai Biologics Communication Study Group), 1966 patients who were confirmed continuation or discontinuation of biologic agent treatment were enrolled. We analyzed the retention rate of biologic agent treatment and the reasons for discontinuation. To identify the risks for discontinuation, baseline demographics were compared between the continuing group and the disccontinuing group using cox hazard regression analysis.

Results: In total 1966 patients, 1479 patients were administered biologics continuously, 487 patients were withdrew. Table 1 showed the demographic date in total patients. The retention rate was 72% (n=1563) at least 1 year from starting biologics treatment, 68.7% (n=866) at 3 years, 65.6% (n=360) at 5 years. In 327 patients who were confirmed the reasons of discontinuation, the reasons were adverse events in 191 patients, lack of effectiveness in 66 patients, others in 70 patients. Comparison of incidence for discontinuation using cumulative hazard function, the reason of adverse events was significantly higher than others reasons (Figure 1). To identify o the risks of discontinuation, we used cox hazard model regression in patients who discontinued treatment due to adverse events and lack of effectiveness, the risk factors were over 70 years of age (OR 1.80 [1.31–2.46]), male (OR 1.79 [1.27–2.52]), over 3 of steinblocker class (OR 1.51 [1.12–2.04]). Non concomitant with methotrexate (OR 1.47 [1.06–2.04]).

Conclusion: The most common reason for discontinuation was adverse events. In a numerically greater proportion of patients who discontinued any biologic agent treatment, timing of discontinuation was within a first year from starting treatment. In addition, the risk factors for discontinuation were similar with those of adverse events.

Long-Term Clinical, Structural, and Functional Consequences of Not Adopting Treatment in MTX Suboptimal Responders.

Josef S. Smolen[1], Ronald F. van Vollenhoven[2], Stefan Florentinus[3], Yijie Zhou[4], Benoit Guerette[4] and Arthur Kavanaugh[5]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]The Karolinska Institute, Stockholm, Sweden, [3]AbbVie, Rungis, France, [4]AbbVie, Inc., North Chicago, IL, [5]University of California San Diego, La Jolla, CA.

Background/Purpose: Methotrexate (MTX) is used as first line therapy for treatment of rheumatoid arthritis (RA). Current recommendations state that therapy should be adjusted if patients (pts) fail to attain remission or low disease activity (LDA) after 6 mo of MTX, and TNF inhibitors could be considered for pts with high risk of aggressive disease. The objective of this post hoc analysis was to identify the benefits of treatment adjustment vs no treatment adjustment in pts who did not achieve a stable LDA after 6 mo of MTX.

Methods: A post hoc analysis from OPTIMA and PREMIER was conducted in MTX-naïve, early RA pts. In OPTIMA, non-achievers (NAs) were defined as pts failing to achieve a stable LDA target of DAS28(CRP) <3.2 at weeks (wks) 22 and 26 following placebo (PBO)+MTX for 26 wks. Pts who were NAs to MTX switched to open-label (OL) ADA+MTX for an additional 52 wks. In PREMIER, following MTX monotherapy, NAs were defined as pts failing to achieve a stable LDA target at wks 20 and 24; however, these pts continued MTX monotherapy up to 104 wks. Clinical and functional outcomes were evaluated at wk 78 and 76 for OPTIMA and PREMIER, respectively, while radiographic outcomes were evaluated at wk 78 for OPTIMA and both wks 52 and 104 for PREMIER. Additionally, ANOVA and logistic regression analysis was conducted on continuous and dichotomized endpoints, respectively, with the following baseline characteristics as variables: age, sex, RA duration, RF status, previous DMARD use, tender joint count, swollen joint count, C-reactive protein, DAS28 score, HAQ-DI, mTSS, erosion score, and estimated annual TSS progression.

Results: 348 out of 517 total pts in OPTIMA and 172 out of 257 total pts in PREMIER did not achieve a stable LDA target of DAS28(CRP) <3.2 after 26 and 24 wks of MTX monotherapy. In those NAs, mean disease duration at baseline was 0.3 and 0.8 for OPTIMA and PREMIER, respectively. In OPTIMA, the mean DAS28(CRP), HAQ-DI, and mTSS at baseline for NAs were 6.1, 1.7, and 11.7, respectively. In comparison, the mean DAS28(CRP) at baseline from the NAs in the PREMIER trial was 6.4, while the HAQ-DI and mTSS were 1.6 and 23.4, respectively. There was a significant decrease compared to baseline in the clinical and functional outcomes for both pts who were given OL ADA+MTX as well as pts who remained on MTX monotherapy; however, compared with pts who continued MTX, there was a significant increase in the percentage of pts achieving LDA and remission, according to all scores used, for those who switched to combination therapy with ADA+MTX (Table). Additionally, a larger proportion of pts showed no radiographic progression in the OPTIMA trial, where pts were switched to OL ADA+MTX after 26 wks.

Table. Clinical, Functional, and Radiographic Outcomes at Week 78 and 76 for Patients who were Non-Achievers to MTX Monotherapy in OPTIMA and PREMIER

n (%)	OPTIMA[a] N=348[c]	PREMIER[b] N=172[c]	P-Value
DAS28(CRP), mean (SD)	2.9 (1.2)	3.7 (1.2)	<0.001[d]
DAS28(CRP) <2.6	138 (39.7)	23 (13.4)	<0.001[e]
DAS28(CRP) <3.2	185 (53.2)	51 (29.7)	<0.001[e]
SDAI ≤3.3	92 (26.4)	11 (6.4)	0.006[e]
CDAI ≤2.8	94 (27.0)	11 (6.4)	0.005[e]
HAQ-DI, mean (SD)	0.7 (0.6)	0.8 (0.7)	0.062[d]

HAQ-DI <0.5	125 (35.9)	49 (28.5)	0.091[e]
DHAQ-DI ≤0.22 from week 26	161 (46.3)	36 (20.9)	0.016[e]
mTSS, mean (SD)	12.6 (18.2)	29.6 (25.6)	<0.001[d]
DmTSS ≤0.5 from week 26	237 (68.1)	63 (36.6)	<0.001[e]
CDC[f] from week 26	77 (22.1)	7 (4.1)	<0.001[e]

CDAI, clinical disease activity index; CDC, comprehensive disease control; CRP, C-reactive protein; DAS28, 28-joint disease activity score; HAQ-DI, disability index of the health assessment questionnaire; mTSS, modified total Sharp score; SDAI, simplified disease activity index.
[a]Clinical, functional, and radiographic outcomes at week 78. [b]Clinical and functional outcomes at week 76 and radiographic and CDC outcomes shown for week 52. [c]N consists of patients treated with PBO+MTX who do not achieve a DAS28(CRP) <3.2 at week 24/26 or week 20/24 for OPTIMA and PREMIER, respectively. [d]p-values derived from ANCOVA model adjusted for baseline values. [e]p-values based upon the difference between the OPTIMA and PREMIER study using a logistic regression model adjusted for baseline characteristics. [f]CDC is defined as DmTSS ≤0.5, DAS28(CRP) <2.6, and HAQ-DI <0.5.

Conclusion: Not adjusting treatment in pts who did not receive a stable LDA after 6 mo of initial MTX appears to result in worse long-term clinical, functional, and structural outcomes compared to pts whose treatment was adjusted by adding ADA.

What Is the Level of Agreement Between Disease Activity Indices and Response Criteria Among Rheumatoid Arthritis Patients Treated with TNF Inhibitors? Edward C. Keystone[1], Philip Baer[2], J. Antonio Avina-Zubieta[3], Anna Jaroszynska[4], Jude Rodrigues[5], Regan Arendse[6], Dalton Sholter[7], Michael Starr[8], Ariel Masetto[9], John S. Sampalis[10], Emmanouil Rampakakis[10], Francois Nantel[11], May Shawi[11], Allen J Lehman[11] and Susan Otawa[11]. [1]University of Toronto, Toronto, ON, [2]Private Practice, Scarborough, ON, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]Private Practice, Burlington, ON, [5]Clinical Research and Arthritis Centre, Windsor, ON, [6]University of Saskatchewan, Saskatoon, SK, [7]University of Alberta, Edmonton, AB, [8]McGill University Health Centre, Montreal, QC, [9]CHUS, Fleurimont, QC, [10]JSS Medical Research, Montreal, QC, [11]Janssen Inc., Toronto, ON.

Background/Purpose: Several standardized response criteria and disease activity indices are used to assess treatment efficacy in rheumatoid arthritis (RA). These measures comprise different types and number of variables resulting in different weighting of individual variables within each of them (1). The aim of this analysis was to compare the performance of ACR, SDAI major and minor, and HAQ response criteria and to determine their level of agreement with the DAS28, SDAI, and CDAI definitions of low disease activity (LDA) and remission in RA patients treated with infliximab (IFX) or golimumab (GLM) in a real-world, Canadian, clinical practice setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with IFX or GLM. The analysis was based on RA patients treated with IFX between 2002–2014 or GLM between 2010–2014. **Response** was assessed with ACR20, ACR50, ACR70, HAQ improvement of 0.22 and 0.5, SDAI major (≥22) and minor improvement (≥10). **Disease state** was assessed with DAS28, SDAI, and CDAI definitions of LDA (<3.2, ≤11, ≤10, respectively) and remission (<2.6, ≤3.3, ≤2.8, respectively). The level of agreement was assessed with the proportion of concordant pairs over the total number of cases in each cross-tabulation and the Kappa statistic.

Results: A total of 830 RA patients with 4,100 available observations were included. The criteria for each definition of response/disease state were met for the following proportion of cases: ACR20 (66.4%), ACR50 (44.5%), ACR70 (26.4%), ΔHAQ≥0.22 (65.5%), ΔHAQ≥0.5 (53.4%), SDAI major improvement (55.8%), SDAI minor improvement (80.8%), DAS28 remission (29.4%), CDAI remission (20.4%), SDAI remission (21.8%), CDAI LDA (57.5%), SDAI LDA (58.1%), and DAS28-ESR LDA (46.0%).

Table 1 summarizes the level of agreement between different efficacy measures. Statistically significant (Kappa P<0.001) associations were observed for all combinations of variables examined. Overall, the ACR response criteria performed better than the HAQ and SDAI response criteria in their agreement with LDA and remission. In general, higher levels of response in all three measures (ACR20 vs. ACR50 vs. ACR70; ΔHAQ≥0.22 vs. ΔHAQ≥0.5; SDAI minor vs. major) showed better agreement with LDA and remission. The highest level of agreement between response criteria and disease state was observed between the strictest definitions, namely between ACR70 and CDAI / SDAI remission; whereas, SDAI minor improvement showed the lowest level of agreement with remission, irrespective of definition.

Conclusion: This analysis showed that significant variation exists in the agreement between the various efficacy outcome measures. Thus, the choice of outcome measure used to make treatment decisions could have a significant impact on patient management.

Are Patients with Rheumatoid Arthritis Initiating a TNF Biologic Comparable to Patients Initiating a Non TNF? Kaleb Michaud[1], Kunal Gandhi[2], Teresa Simon[3] and Sofia Pedro[1]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Hopewell, NJ.

Background/Purpose: Comparative research has gained attention in the field of Rheumatology. Evaluations of baseline characteristics in patients receiving similar treatments are critical in the conduct of comparative observational research to assess medication safety and effectiveness in rheumatoid arthritis (RA). Appropriate methods used in comparative research are critical. Making certain assumptions regarding the underlying distribution of baseline characteristics and the targeted population is important. Most patients receive TNF inhibitors (TNFi) as a first biologic for the treatment of RA; however, increasing numbers are starting with a non TNFi (NTNFi) biologic as an initial biologic treatment. The purpose of this analysis is to compare baseline characteristics of RA patients receiving abatacept (ABA) and other NTNFi with those taking TNFi as their first biologic.

Methods: RA patients in the National Data Bank for Rheumatic Diseases (NDB) provide treatment and other characteristics (demographics, comorbidities, and clinical status) through self-reported biannual questionnaires. Data during the period of 2005 through 2013 were used as this timeframe includes data when the first NTNFi biologics were marketed. We also limited analyses to patients who completed a questionnaire within 6-months prior to initiating their first biologic. P-values were based on ANOVA test for continuous and Chi^2 tests for categorical measures.

Results: A total of 2,125 RA patients *(1,916 TNFi; 129 NTNFi; 80 ABA)* initiated their first biologic therapy after 2005. ABA patients were significantly older and have a higher proportion of diabetes and cancer when compared to TNFi (see Table). ABA patients reported significantly higher pain, fatigue, and activity scores than TNFi initiators. When compared to the NTNFi patients, ABA patients are older and reported slightly higher baseline pain. The NTNFi patients are more likely to have diabetes and hypertension.

	ABA (N=80)	TNFi (N=1,916)	NTNFi (N=129)
Age (yrs)*	64.6 (12.5)	58.5 (12.7)	60.8 (13.4)
BMI (kg/m2)	29.2 (6.2)	28.9 (7.1)	29.1 (6.7)
Disease Duration (yrs)	13.3 (13.5)	14.2 (10.9)	14.3 (11.1)
Ever Smoked (%)	51.3	52.3	56.6
Comorbidity Index (0–9)*	2.2 (1.8)	1.6 (1.5)	2.1 (1.7)
Cancer (%)*	32.5	19.2	31.8
Hypertension (%)*	33.8	35.2	47.3
Diabetes (%)*	13.8	10.5	17.1
Hospitalized Infection (%)	0.0	1.5	2.3
Congestive Heart Disease (%)	0.0	0.6	0.0
Prednisone (%)	38.8	32.7	37.2
MTX (%)*	65.0	67.5	45.7
Other DMARD (%)	22.5	15.2	24.8
HAQ (0–3)*	1.2 (0.7)	1.0 (0.7)	1.2 (0.7)
Pain VAS (0–10)*	5.1 (3.0)	4.2 (2.8)	4.4 (2.9)
Fatigue VAS (0–10)*	5.4 (3.3)	4.6 (3.1)	5.3 (3.1)
Patient Activity Scale (0–10)*	4.2 (2.2)	3.1 (0.7)	3.4 (0.7)

*P value < 0.05

Conclusion: RA patients who receive a NTNFi as their first biologic differ from those initiating TNFi. Proper application of statistical methods and careful examination of baseline characteristics including co-morbid chronic conditions, prior/concomitant medications and biologic use is critical when performing comparative effectiveness analyses. Line of therapy should also be considered in future comparative research analyses.

Patient, Genetic and Disease Factors Influence the Response to the Disease Modifying Anti-Rheumatic Drug Leflunomide. Michael D. Wiese[1], Ashley Hopkins[1], Llew Spargo[2], Leah McWilliams[2], Catherine O'Doherty[1], Leslie G. Cleland[2] and Susanna Proudman[3]. [1]University of South Australia, Adelaide, Australia, [2]Royal Adelaide Hospital, Adelaide, Australia, [3]Royal Adelaide Hospital, SA, Australia.

Background/Purpose: Leflunomide is a disease modifying anti-rheumatic drug that is used in the treatment of rheumatoid arthritis (RA). Leflunomide is converted to teriflunomide by the Cytochrome P450 enzymes 1A2, 2C19 and 3A4, which is cleared via secretion into the gastro-intestinal tract by the transporter ABCG2. The primary mechanism of action is inhibition of di-hydroorotate dehydrogenase (DHODH) by teriflunomide. It is very effective in some patients, but treatment can be limited by intolerance and/or lack of efficacy. This study aimed to determine steady state teriflunomide concentration in a group of patients with RA and correlate steady state concentrations with response to leflunomide.

Methods: Patients with RA taking a stable dose of leflunomide according to a treat-to-target strategy were recruited from the Royal Adelaide Hospital Early Arthritis Clinic. Blood samples were taken for determination of free teriflunomide concentration and genetic differences in CYP1A2, CYP2C19, ABCG2 and DHODH. Disease activity was assessed by the 28-joint disease activity scores (DAS28). Factors associated with teriflunomide concentration and DAS28 were assessed by multivariate linear regression.

Results: 55 patients were included. The average leflunomide dose was 16.1mg/day, and the free teriflunomide concentration was 0.062mg/L - there was a 150-fold difference between maximum and minimum concentration. Leflunomide dose accounted for 10% of the variability in free teriflunomide concentration, and this increased to 38% when *CYP1A2* and *ABCG2* genotype were considered. 25 patients took leflunomide for at least 9 months (no other agents were added for treatment failure) and 76% of the variability in DAS28 was accounted for by considering baseline DAS28, shared epitope carriage, *DHODH* haplotype and free teriflunomide concentration.

Conclusion: Pharmacokinetic and pharmacogenomic variables appear to be associated with response to leflunomide in a group of RA patients treated according to a treat-to-target strategy, but this should be assessed in a prospectively recruited cohort.

Analysis on Predictors for Long-Term Clinical Efficacies of Golimumab in Patients with Rheumatoid Arthritis. Tsutomu Takeuchi[1], Yutaka Ishii[2], Kimie Tanaka[3], Yoshifumi Ukyo[4] and Hiroshi Sekine[3]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Janssen Pharmaceutical K.K, Tokyo, Japan, [3]Janssen Pharmaceutical K.K., Tokyo, Japan, [4]Janssen Pharmaceutical K.K., Japan, Tokyo, Japan.

Background/Purpose: The GO-FORTH, phase 2/3 clinical trial was conducted to examine the efficacy and safety of Golimumab (GLM) plus MTX in Japanese patients (pts) with active RA despite MTX therapy (NCT00727987). In treatment for RA, it has been recommended to assess the clinical disease activity at least every 3 months according to the treat to target (T2T) recommendation. Therefore, predictors of long-term efficacy with GLM treatment using clinical data at baseline and 3 months would seem to be extremely important.

Objective

To assess the predictability of using clinical data at baseline and week 12 (W12) after GLM treatment in GO-FORTH study, for achievement of each remission criteria after 1-year.

Methods: GO-FORTH was a multicenter, randomized, double-blind, placebo-controlled study in pts with active RA despite MTX therapy. Pts were randomized to Placebo (PBO), GLM50 mg or GLM 100 mg q4 wks combined with MTX (6–8 mg/ week). Data of all pts who were randomized to GLM 50 mg or GLM 100mg as active treatment were used for analysis. Several definitions of remission at week 52 (W52) were used and defined as: DAS remission (DAS28ESR <2.6), HAQ remission (HAQ <0.5) and radiographic remission (‡TMTSS $<=0$). Akaike Information Criteria (AIC) were calculated to assess predictability with all possible predictors using univariate logistic regression model. Area under the curves (AUC) were calculated to assess the performance of possible predictors using receiver operating characteristics (ROC) curves. Cutoff values were also calculated using Euclidean method. The correlations between possible predictors were carefully considered to determine predictor.

Results: DAS28ESR score at W12 was chosen based on the values of AIC as a possible predictor of DAS remission at W52. HAQ score at W12 was also chosen as a possible predictor of HAQ remission at W52. Similar trends were observed in the both scores at baseline. The cutoff point (AUC) of DAS28ESR for DAS remission with GLM 50 mg and GLM 100 mg at W12 were 3.0 (0.876) and 3.5 (0.863), then cutoff point of HAQ score for HAQ remission with them were 0.625 (0.880) and 0.500 (0.958), respectively (see table). The results of baseline and PPVs/ NPVs for each determined predictors were also calculated as table shown. Both potential predictors showed larger AUC and smaller cutoff values at W12 than those at the baseline. There were no noticeable differences between GLM 50mg and GLM 100mg in the potential predictors. Predictors for radiographic remission were not specified by this analysis.

Conclusion: These analyses suggest that DAS28ESR and HAQ score at baseline and W12 can be predictors for DAS remission and HAQ remission at W52 in Japanese pts treated with GLM combined with MTX individually. In particular in terms of DAS remission, it seems to be important to achieve LDA within 3 months to maintain long term clinical remission.

Table. AUC and PPV/NPV for each possible predictor calculated with GLM pts data

			Baseline		12 weeks	
Prediction (1-year)	**Group**	**Possible Predictor**	**AUC [PPV, NPV]**	**Cutoff Value**	**AUC [PPV, NPV]**	**Cutoff Value**
DAS remission	GLM 50mg	DAS (ESR)	0.736 [70.0%, 73.8%]	5.1	0.876 [85.7%, 81.8%]	3.0
	GLM 100mg	DAS (ESR)	0.748 [55.2%, 82.2%]	5.3	0.863 [63.3%, 88.6%]	3.5
HAQ remission	GLM 50mg	HAQ	0.749 [75.0%, 70.6%]	0.875	0.880 [82.9%, 83.9%]	0.625
	GLM 100mg	HAQ	0.800 [84.2%, 55.6%]	0.875	0.958 [95.2%, 75.0%]	0.500

Effect of Infliximab Dose Increase in Rheumatoid Arthritis at Different Trough Concentrations. Alejandro Balsa[1], Chamaida Plasencia-Rodriguez[2], Maria Gema Bonilla[3], Alejandro Villalba[2], Diana Peiteado[2], Sara Garcia-Carazo[4], Laura Nuño[1], Teresa Jurado[5], Emilio Martín-Mola[6] and Dora Pascual-Salcedo[3]. [1]Hospital La Paz-IdiPaz, Madrid, Spain, [2]Hospital La Paz - IdiPaz, Madrid, Spain, [3]La Paz University Hospital, Madrid, Spain, [4]Hospital La Paz-Idipaz, Madrid, Spain, [5]La Paz University Hospital-Idipaz, Madrid, Spain, [6]Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: To evaluate the effects of infliximab (Ifx) dose increase in active rheumatoid arthritis (RA) patients, presenting different serum infliximab concentrations.

Methods: Retrospective study including 42 RA patients treated with increased Ifx following insufficient response (DAS28 > 3.2). Serum concentrations of Ifx and antibodies to Ifx (ATI) were recorded together with DAS28 and EULAR clinical response parameters throughout a year prior (T1) and after increasing dose (T2: immediately post-increase, T3: 6 months after T1 and T4:1 year after T1). Analyses were carried out with three patient groups defined by Ifx serum concentration prior to treatment enhancement: no detectable levels, (NL), low levels (LL< 1.1 μg/ml) or high levels (HL≥1.1 μg/ml). This cut-off was chosen empirically, based on most patients with Ifx levels >1.1 μg/ml experienced clinical improvement in our cohort.

Results: The demographic characteristics are shown in the Table 1. Twenty patients (47.6%) were classified in NL, while 13 (30.9%) and 9 (31.4%) showed LL and HL respectively. Due to drug interference with ELISA, ATI were only detected in NL patients. DAS28 improved immediately after increasing Ifx dosage, from baseline (4.55±1.01 *vs* 3.95±1.22; p<0.05 after Bonferroni correction), but the improvement did not persist at 1 year (3.98±1.22; p=0.075 after Bonferroni correction). The change in DAS28 from baseline (deltaDAS28) followed a similar pattern (−0.63±1.18 at T2 to 1.17±1.45 at T4 (p<0.001))(Figure 1). Overall, 5 (13.2%) patients achieved a good response by EULAR response after the first dose increase, whereas 18 (47.4%) patients had no response. At T4, 3 (10.7%) patients showed a good response and 18 (64.3%) remained non-responders.

Conclusion: These results suggest that the effectiveness of Ifx dose increase after therapeutic failure is limited, independently of pre increase serum trough infliximab concentrations.

Figure 1. (A) Changes in DAS28 over time in all patients. T1 (baseline), T2 (post-infliximab dose increase), T3 (at 6 months), T4 (at 12 months). *p<0.05 *vs* DAS28 in T1 after Bonferroni correction. **(B) DAS28 and delta DAS28 from T1 in patients with No, Sub-therapeutic (ST) and High Infliximab serum concentrations.** T1 (baseline), T2 (post-infliximab dose increase), T3 (at 6 months), T4 (at 12 months)

UNV. TIP FAK. HASTANESI, ISTANBUL, Turkey, [8]Trakya University Medical Faculty, İstanbul, Turkey, [9]None, Kahramanmaras, Turkey, [10]Ege University Medical Faculty, Izmir, Turkey, [11]Cukurova University, School of Medicine, Adana, Turkey, [12]Pamukkale University School of Medicine, Denizli, Turkey, [13]Hacettepe University Faculty of Medicine, Ankara, Turkey, [14]Fatih Sultan Mehmet State Hospital, İstanbul, Turkey, [15]Gaziantep University School of Medicine, Gaziantep, Turkey, [16]Uludag University Medical Faculty, Bursa, Turkey, [17]KahramanmarasSutçü ImamUniversity School of Medicine, Kahramanmaras, Turkey.

Background/Purpose: Biologic drugs including anti-TNF agents have been used in the treatment of secondary amyloidosis, however, there is no controlled study concerning the efficacy of therapy. In this study, we retrospectively analyzed the clinical features and outcome of RA and AS patients with clinically symptomatic secondary amyloidosis who were treated with any of the biologic agents in various rheumatology centers in Turkey.

Methods: The hospital files in 10 university hospitals were examined to determine the presence of clinically apparent amyloidosis in RA and AS. Data concerning the clinical features, extraarticular involvement and biologic and other treatment response were obtained from hospital records.

Results: 27 RA (17F, 10M, mean age: 52.2), 42 AS (11F, 31M, mean age: 45.6) patients were included. Rheumatoid factor (RF) was positive in 24 (88.9%) RA patients. In 25 RA patients, the initial presentation of amyloidosis was with proteinuria; one had hematuria; and one patient prsented with renal dysfunction. Eight patients with proteinüria had also renal dysfunction.

The disease duration of RA patients before amyloidosis was 127.9 months; the duration of biologic therapy was 47.9 months. The first-line therapy was TNF-blockers in 21 RA patients; rituximab and abatacept in 2; and tociluzumab in one. Second-line biologicals were used because of side effects in 1 patient; and because of nonefficacy in 8 (2 TNF blocker, 4 rituximab, 2 tocilizumab, 1 abatacept). Third-line therapy was given to 4 patients. Renal function and/or proteinuria improved in 7 patients; however, they got worse in 7; and remained stable in 13. When patients who improved were compared to others, it was seen that there were more females (100% vs. 50%, p=0.026); and significantly longer duration of biologic therapy in this group. 2 patients using biologics developed tuberculosis; 3 patients died during follow-up because of nondrug-related causes. Renal replacement therapy was needed in 5 RA patients. 28 AS patients presented with proteinuria, 2 with hematuria, and 4 with isolated renal dysfunction. At the time of diagnosis for amyloidosis, 13 patients had also renal dysfunction. The disease duration of RA patients before amyloidosis was 101.2 months. All had been given anti-TNF agents as first-line therapy (infliximab in 13; etanercept in 19; adalimumab in 7; golimumab in 3 patients). 10 patients were switched to a second anti-TNF (because of serious side effects in 2 and nonefficacy in 8). Proteinuria and/or renal functions improved in 11 cases, got worse in 14, and remained stable in 9 after anti-TNF therapy. The results could not be evaluated in 8 patients. Initial CRP levels of patients who had any kind of improvement with anti-TNF therapy were significantly higher than others (p=0.007). There was requirement for renal replacement therapy in 11 AS patients.

Conclusion: Amyloidosis develops in RA and AS nearly 10 years after diagnosis; and it generally presents with proteiuria and/or renal dysfunction. In RA, the response to biologics was associated with a longer response to biologics and female sex. In AS patients, having a high CRP at the time of diagnosis of amyloidosis was associated with response to anti-TNF agents.

Background/Purpose: Smoking has been identified as an important negative predictor of response to antirheumatic therapy. The aim of this study was to assess whether smoking status influenced the clinical response to rituximab (RTX) in an observational patient cohort with rheumatoid arthritis (RA).

Methods: Pooled data from the Collaborating European Registries for RTX in RA (CERERRA) project were used. Patients with RA who received at least 1 cycle with RTX and had at least 2 follow-up visits were included in the analyses. Smoking status was defined as smokers (current smokers) and non-smokers (never and ex-smokers). Baseline characteristics were compared by means of descriptive statistics. Analysis of co-variance (ANCOVA) was performed with DeltaDAS28 at 6 months as the dependent variable and smoking status as well as other baseline variables (age, sex, disease duration, number of prior biologic DMARDs) as covariates. Separate analyses were made for anti-CCP positive and negative patients.

Results: A total of 2431 patients with available smoking information were included - 1916 (79%) were non-smokers and 515 (21%) were smokers. 81% were female and 80% (out of 1199 patients with available anti-CCP status) were anti-CCP positive. Smokers had shorter disease duration than non-smokers (mean±SD = 9.9±7.9 vs. 11.9±8.7, $p<0.0001$), higher number of prior biologic DMARDs (1.3±1.1 vs. 1.0±1.0, $p<0.0001$) and lower DAS28 at baseline (5.1±1.7 vs. 5.7±1.5, $p<0.0001$). 16% of females and 42% of males were smokers ($p<0.0001$). 84% of smokers and 78% of non-smokers were anti-CCP positive ($p=0.04$).

Smokers had less improvement in disease activity than non-smokers at 6 months follow-up (mean±SD DeltaDAS28 -1.5±1.7 vs. -1.8±1.7, respectively, $p=0.01$). However, the difference was no longer significant after adjustment for baseline differences (age, sex, disease duration, number of prior biologic DMARDs, concomitant corticosteroids and DMARDs; $p=0.40$). When the analysis was stratified by anti-CCP status, smoking did not influence the response to therapy in the anti-CCP negative subset ($p=0.39$) but there was a trend in the anti-CCP positive subset ($p=0.06$, see figure 1). Similar trends were observed for EULAR good/moderate response rates. For the anti-CCP negative RA patients, 63% of non-smokers and 60% of smokers achieved EULAR response ($p=0.51$), while in the anti-CCP positive subgroup the respective response rates were 73% among non-smokers and 67% among smokers ($p=0.07$).

Conclusion: Smoking was negatively associated with the clinical response to rituximab therapy in RA patients who were anti-CCP positive.

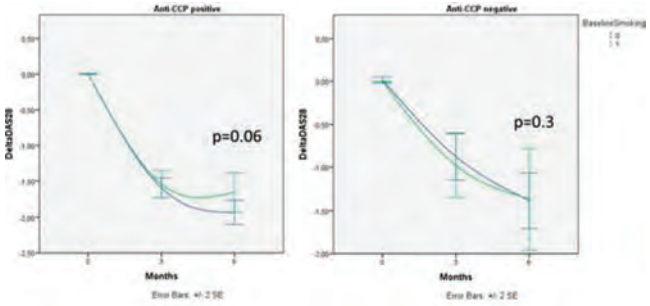

Figure 1. DeltaDAS28 during the first 6 months from baseline in anti-CCP positive and anti-CPP negative RA patients treated with rituximab according to smoking status (0=never or past smokers, 1= current smokers).

Infliximab Versus Conventional Combination Treatment and Work Loss in Early RA over 7 Years: A Randomized Trial.

Jonas K Eriksson[1], Heather Miller[2], Johan A Karlsson[3], Ingemar F Petersson[4], Sofia Ernestam[5], Pierre Geborek[3], Ronald F van Vollenhoven[2] and Martin Neovius[1]. [1]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]ClinTRID, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden, [4]Section of Orthopedics, Department of Clinical Sciences Lund, Lund University, Lund, Sweden, [5]Department of Learning, Informatics and Medical Education (LIME), Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: The introduction of TNF inhibitors has improved the treatment of RA, but at a substantial cost. The randomized Swefot trial compared the addition of infliximab vs conventional disease-modifying anti-rheumatic drugs in patients with early RA who had failed initial MTX monotherapy. From the Swefot trial we previously reported superior 2-year radiographic outcomes in the infliximab group, while disease-activity, quality of life and work loss improved similarly. Here we report work loss over 7 years after randomization.

Methods: In this multicenter, two-arm, parallel, randomized, active-controlled, open label trial RA patients with <1y symptom duration were recruited from 15 rheumatology clinics in Sweden between October 2002 and December 2005. After 3–4 months of MTX monotherapy, patients not achieving low disease-activity were randomized to addition of biologic treatment with infliximab or further conventional treatment with sulfasalazine+hydroxychloroquine. Register-based follow-up continued despite protocol breach, and treatment was thereafter decided by the responsible rheumatologist.

The main outcome measure in this study was yearly sick leave and disability pension days at 7 years after randomization, retrieved from the nationwide Swedish Social Insurance Office register. The analysis were by intention to treat, including all working age patients (<65y), and adjusted for work loss 1 year before randomization. Patients were followed for a maximum of 7 years and were excluded from the yearly average calculations if they (in the current year) had emigrated, died, or turned 65y.

Results: Of 210 patients in working age, 109 were randomized to infliximab (mean age=48.4y, [median=50.6y]; n women=80 [73%]) and 101 to conventional treatment (48.7y, [52.9y]; 78 [77%]). Seven patients in the infliximab and 4 in the conventional treatment group never received the study drug. The year before randomization the mean number of work days lost per year was 127 (median 112) in the infliximab arm and 118 (median 105) in the conventional treatment group (mean difference, 9; 95%CI, −22 to

39; **Figure**). Compared to the year before randomization, the mean changes at 7 years were −25 days in the infliximab and −26 days in the conventional treatment group (adjusted mean difference, 11; 95% CI, −24 to 46).

The cumulative work loss days over 7 years was 846 in the infliximab group and 701 in the conventional treatment group (adjusted mean difference, 105; 95% CI, −61 to 273).

Conclusion: The radiological superiority at 2 years of infliximab+MTX compared to conventional combination therapy did not translate into better long-term work loss outcomes in patients with early RA who had had an insufficient response to MTX.

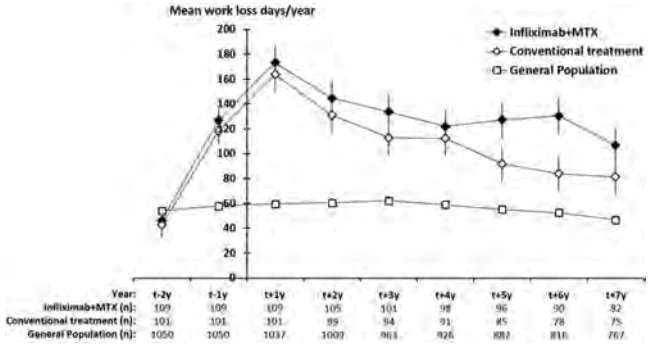

Figure Mean work loss days per year in the infliximab+MTX and the conventional treatment group in relation to randomization, as well as in general population comparators.

Efficacy of Biological Therapies in Rheumatoid Arthritis: Graphical Modeling of DAS28 Components' Evolution over Time. G. Avila[1], Arnald Alonso[1], María América López-Lasanta[1], Andrea Pluma-Sanjurjo[2], C. Diaz[2] and Sara Marsal[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]University Hospital Vall d'Hebron, Barcelona, Spain.

Background/Purpose: The wide use of biological therapies (BTs) has clearly modified the therapeutic approach in rheumatoid arthritis (RA). One of the most commonly used tools to measure the efficacy of BTs in RA is the DAS28 score. Little is known about how each of the DAS28 components varies over time. Our aim was to graphically evaluate the evolution of the DAS28 components over time for the most common anti-TNF treatments and to compare them with anti-IL6 therapy.

Methods: 222 RA patients treated with BTs during the period between Dec'99 and March'13 were included. The data on the components of DAS28 score were collected from baseline and at every 3 months of therapy. First, we visually analyzed the relative improvement of each variable for each anti-TNF (infliximab (INF), etanercept (ETN), adalimumab (ADA)). Second, we grouped the anti-TNFs and compared their combined evolution to tocilizumab (TCZ). In order to obtain a precise visualization of the changes in time of each of the DAS28 components, we used the radar charts. In this type of multivariate data visualization technique, each one of the components is represented as different circle axes and, at each time point, the mean relative improvement (i.e. percentage of reduction from baseline) for each component is connected by a line.

Results: A total of 347 BTs were analyzed (INF=100, ETN=126, ADA=79, TCZ=42). No statistically significant differences were found in the DAS28 changes between the 3 anti-TNFs. However, when comparing the graphical patterns of these therapies we found different patterns of evolution of the DAS28 components over time (Figure 1). Compared to ADA or INF, ETN had a clearly regular expanding pattern of the improvement. In ADA and INF the relative weight of each DAS28 component at each time period was variable, suggesting a different mode of action for monoclonal therapies.

When we compared the radar charts of the combined anti-TNFs against the anti-IL6 treatment (Figure 2), we found a markedly different pattern of action. While the treatment with anti-TNFs showed rapid and greater improvement in the articular component (i.e. SJC and TJC), the treatment with anti-IL6 showed a higher improvement of the ESR (Figure 2). In both treatments, the physician and patient global assessment showed a similar evolution over time.

Conclusion: Using a graphical analysis approach we have identified, for the first time, the differential time patterns of the DAS28 score components for the most commonly used anti-TNF therapies. Combining all anti-TNF therapies into a single entity and comparing to a BT targeting IL6, we have also found key differences in the temporal evolution of each of the DAS28 components. The results of this study are useful to understand the differential mechanisms of action of each treatment and could help to explain the differences observed in clinical trials, meta-analyses or observational studies.

The Effect of Biological Agents on Work in Patients with Chronic Inflammatory Arthritides: A Meta-Analysis of Randomized Controlled Trials and Controlled Cohorts. Amandine Tubery[1], Cristel Castelli[1], Florence Erny[1], Françoise Barchechath-Flaisler[1], Sabrina Dadoun[2], Bruno Fautrel[3] and Cecile Gaujoux Viala[1]. [1]Nîmes University Hospital, Rheumatology Department, Nimes, France, [2]Sorbonne Universités, UPMC Univ Paris 06, GRC-08, Institut Pierre Louis d'Epidémiologie et de Santé Publique, paris, France, [3]UPMC Paris 06 University, GRC 08, Paris France and Pitié Salpétrière Hospital Paris France, Paris, France.

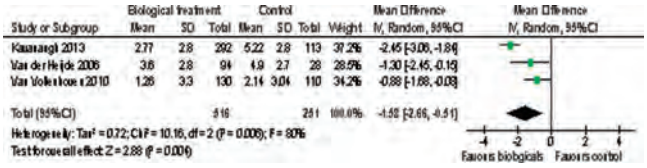
Background/Purpose: The addition of biological agents in treatment strategies in chronic inflammatory arthritides have improved the possibility of controlling disease activity and slowing the progression of joint damage. However their impact on work participation is unclear.

Objectives: To assess the effect of biological agents on work among patients with chronic inflammatory arthritides (CIAs).

Methods: A systematic review of the literature using PUBMED and the Cochrane library was performed until January 2014. All randomized controlled trials (RCTs) and controlled cohorts (CCs) reporting the effect of biological agents on work among patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) or psoriatic arthritis (PsA) were selected. Data extraction: Data were collected using a predetermined form. The outcomes were accumulated missed workdays, number of patients losing worktime du to CIAs, impact on productivity (on a visual analogue scale) and employment loss. Statistical analysis determined in each study effect size (ES) or odds-ratios (OR) as appropriate to assess the magnitude of treatment effect. Pooled ES and OR were computed by meta-analysis. A random effect model was used in case of heterogeneity.

Results: 14 RCTs and 7 CCs were analyzed i.e. 15881 patients treated by biological agents (adalimumab, etanercept, infliximab, certolizumab, golimumab and abatacept) and 9713 controls. Among those 25594 patients, 24670 suffered from RA, 319 from AS, and 605 from PsA. Pooled analyses indicated that biological agents significantly reduced accumulated missed workdays at week 24 (2 trials): ES= −0.34 [95%CI −0.60 to −0.08], the number of patients losing hours (3 trials): OR=0.54 [95%CI 0.36 to 0.79] and improved work productivity (3 trials): ES=−1.58 [95%CI −2.66 to −0.51]

(figure). The positive effect on employment loss was nearly significant (8 trials): OR=0.60 [95% CI 0.33 to 1.09].



Conclusion: Despite the heterogeneity of the data, this meta-analysis showed the beneficial effect of biologics agents on both absenteeism and presenteeism in chronic inflammatory rheumatism. Thus the high cost of biologic agents could be partly balanced with savings in indirect costs.

Efficacy Meta-Analysis of Randomized Controlled Trials (RCTs) of Biologics in Methotrexate-Naive Patients with Early Rheumatoid Arthritis. Yusuf Yazici[1], Chunqiao Luo[2] and Christopher Swearingen[3]. [1]New York University Hospital for Joint Diseases, New York, NY, [2]Biostatistics, Little Rock, AR, [3]University of Arkansas, Little Rock, AR.

Background/Purpose: NNT analysis is a useful tool for putting RCT efficacy results into perspective in patient care. For clinical decision making, the NNT is a useful measure to convey statistical and clinical significance to the doctor (i.e. number of patients needed to treat to achieve 1 additional response compared to control). The most reliable data regarding how a biologic would work comes from MTX naïve RCTs as all patients are receiving active drug for the first time and selection biases may play a lesser role in determining outcomes. We performed a NNT analysis of biologics in MTX-naive pts with early RA.

Methods: PubMed was searched for randomized double-blind, MTX-controlled studies of biologics in MTX-naive pts with early RA from Jan 1990 through Dec 2013. Response rates specified by each RCT were used to assess NNT of biologic (active) versus MTX (control) where $NNT=[1/(RR_{active}-RR_{control})]*100$. Outcomes assessed included ACR20, ACR50, and ACR70 responses as well as DAS28 remission (DAS28 <2.6).

Results: Nine published RCTs were identified.[2–5]Baseline age were similar across the studies (average age 50.2 yrs, range [47.2, 57.5]), but some variability in disease duration (average duration 3.3, range [0.7, 9.3]). All biologics achieved >50% response in ACR 20, although one adalimumab trial was outperformed by MTX only, leading to a negative estimated NNT. All biologics outperformed MTX only with ACR50, ACR90 and DAS28 outcomes.

Conclusion: In MTX-naïve pts with early RA, abatacept and anti-TNF agents have similar efficacy when RCT endpoints, such as ACR responses, are analyzed by NNT. Difference in efficacy appeared when more aggressive treatment goals, such as MCR and DAS28 remission, were evaluated and suggested that the likelihood of achieving these endpoints in patients was less with infliximab than other anti-TNFs or abatacept. In the absence of head-to-head clinical trial data, NNT analysis can be a useful tool for determining the relative efficacy of biologics in routine clinical practice.

Efficacy of Infliximab, Adalimumab, and Tocilizumab Can be Improved Under the Baseline ADAMTS5 Selection. Kensei Tsuzaka[1], Yoko Akiyama[2] and Masayoshi Nagata[1]. [1]Iruma Heart Hospital, Iruma, Saitama, Japan, [2]Kaytee Bio, Co&Ltd, Funabashi, Chiba, Japan.

Background/Purpose: We have previously (2010ACR, 2013ACR) reported that the efficacy of biologics, infliximab, adalimumab, and tocilizumab can be predictable using baseline blood a disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) mRNA level. In this study presented here, we investigated whether the efficacy of these biologics could be improved if they were administered to RA patients who were diagnosed as effective of those biologics using the baseline ADAMTS5 mRNA levels.

Methods: Whole blood was collected from 41 RA patients at baseline and total RNA was isolated. ADAMTS5 mRNA was quantified using real-time PCR (BiologicMate®) followed by the reverse transcription. ADAMTS5 mRNA was calculated as the ratio against b-actin mRNA (Index). Out of 41 patients, 12 (29.3%) have been refractory to infliximab (IFX). IFX, adalimumab (ADA), and tocilizumab (TCZ) was administered if the baseline ADAMTS5 was lower than 1.2, higher than 1.7, and higher than 1.6 Index, respectively. Efficacy of IFX at 14 weeks, ADA at 20 weeks, and TCZ at 12 weeks was estimated using EULAR response. Clinical data (Clinical remission rate, etc) of the RA patients treated with these biologics according to the baseline ADAMTS5 mRNA was compared with those of our data presented at ACR2010 (IFX and ADA) and ACR2013 (TCZ).

Results: All of 12 patients refractory to IFX revealed high level (> 1.2 Index) of the baseline ADAMTS5 mRNA. Out of 41 RA patients, 7 (5 bio-naïve and 2 bio-switch), 18 (6 bio-naïve and 12 bio-switch), and 5 patients (1 bio-naïve and 4 bio-switch), were received IFX, ADA, and TCZ according to the baseline ADAMTS5 mRNA levels (ADAMTS5 selection). As a result, the clinical remission (DAS28-ESR<2.6) rate (4/7; 57.1%) with IFX under ADAMTS5 selection was higher than that with IFX of ACR 2010 data (32/100; 32.0%). On the other hand, the clinical remission rate (12/18; 66.7%) with ADA under ADAMTS5 selection was significantly (p=0.0002) higher than that with ADA of ACR 2010 data (9/48; 18.8%). Furthermore, the clinical remission rate (4/5; 80.0%) with TCZ under ADAMTS5 selection was significantly (p=0.0083) higher than that with TCZ of ACR 2013 data (13/54; 24.0%).

Conclusion: Thus the efficacy of infliximab, adalimumab, and tocilizumab can be improved with the baseline ADAMTS5 selection.

PRE.MARK-TNF Test Based on Iga-Specific Autoantigens Predicts Therapy Response in Rheumatoid Arthritis Patients Treated with TNFα Inhibitors. Karl Skriner[1], Jörg Hollidt[2], Gerd Burmester[1] and Zoltan Konthur[3]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Drug Response DX GmbH, Berlin, Germany, [3]Drug Response DX GmbH, Hennigsdorf, Germany.

Background/Purpose: One third of rheumatoid arthritis patients treated with biologicals targeting TNFα are therapy non-responders. We have earlier investigated the difference in seroreactivity of patients being responder and non-responder to anti-TNFα therapies prior and after therapy and identified a set IgA-specific autoantigens. So far no mechanism for non-response has been described. Here we present a fist study on the diagnostic applicability of the found autoantigenic biomarkers.

Methods: Screening with >200 well defined patient sera on 5 different autoantigenic biomarker candidates, which were expressed recombinantly in *E. coli* by ELISA.

Results: Pretreatment sera from patients with diagnosis of RA based on the ACR classification criteria who were initiated on therapy with TNFα inhibitors were analyzed for the presence of autoantibodies against a set of 5 biomarker proteins (RAB11B, PPP2R1A, KPNB1, COG4, FTFT1) using ELISA assays. In total, analyses of 203 patients were carried out, of which 162 were clearly defined as Responder and 41 were clearly defined as Non-Responder after 6 month treatment. 81% of Non-responder could be clearly identified with the pre.markTNF Test. The assay has currently a specificity 94%.

Moreover, of the 203 samples, 57 samples were baseline sera from an early intervention study with Humira. In this subset, all 3 non-responder were identified and the specificity of the assay was 98 %. Only one – an intermediate responder after 6 months of treatment with Humira – gave any signal in the assay on IgA-level.

Conclusion: These data suggests that IgA-autoantibodies against a set of protein biomarkers (pre.markTNF test) might be diagnostically applied for the identification of anti-TNFα therapy non-responders prior treatment.

Risk of Venous Thromboembolism in Patients with Sjögren's Syndrome: A Systematic Review and Meta-Analysis. Patompong Ungprasert[1], Charat Thongprayoon[2], Karn Wijarnpreecha[3], Wisit Cheungpasitporn[2], Praveen Ratanasrimetha[4] and Promporn Suksaranjit[5]. [1]Bassett medical center, Cooperstown, NY, [2]Mayo clinic, Rochester, MN, [3]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, [4]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [5]University of Utah School of Medicine, Salt Lake City, UT.

Background/Purpose: Venous thromboembolism (VTE) is a common medical problem with a significant morbidity and mortality. Chronic inflammatory state, though not generally regards as a conventional risk factor for VTE, is increasingly recognized as its potential predisposing factor. In fact, several chronic inflammatory disorders, such as systemic lupus erythematosus and rheumatoid arthritis, have been shown to increase VTE in large epidemiologic studies. However, the data on Sjogren's syndrome (SS), another common chronic inflammatory disorder, remain unclear due to conflicting studies. Thus, to further investigate this possible association, we conducted a systematic review and meta-analysis of observational studies that compared the risk of VTE in patients with SS versus participants without it.

Methods: Two investigators (P.U. and C.T.) independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to March 2014 using the terms for Sjogren's syndrome in conjunction with the terms "venous thromboembolism", "pulmonary embolism" and "deep venous thrombosis". A manual search of references of retrieved articles was also performed. The inclusion criteria were as follows: (1) observational studies published as original studies to evaluate the association between SS and VTE and (2) odds ratios (OR's), relative risk (RR's) or hazard ratio (HR's) or standardized incidence ratio (SIR's) with 95% confidence intervals (CI's) were provided. Study eligibility was independently determined by the two investigators noted above. Newcastle-Ottawa scale was used to assess the quality of included studies.

RevMan 5.2 software was used for the data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran's Q test.

Results: Out of 382 potentially relevant articles, four studies (three retrospective cohort studies and one case-control study) were identified and included in our data analysis. The pooled risk ratio of VTE in patients with SS was 2.04 (95% CI, 1.85 to 2.24). The statistical heterogeneity of this meta-analysis was not significant with an I^2 of 0%.

Conclusion: Our study demonstrated a statistically significant increased VTE risk among patients with SS.

Characteristics of Primary Sjögren Syndrome in the Black Population of Martinique. Katlyne Polomat[1], Serge Arfi[2], Lauren Brunier-Agot[1], Véronique Dehlinger[3], Michel DeBandt[1], Georges Jean Baptiste[4] and Christophe Deligny[5]. [1]Centre Hospitalier universitaire de Fort de France, Fort de France, Martinique, [2]Centre hospitalier Universitaire de Fort de France, Fort de France, Martinique, [3]Centre Hospitalier universitaire de Fort de France, Fort De France - Martinique, Martinique, [4]Centre Hospitalier Universitaire de Fort de France, Fort de France, Guadeloupe, [5]CHU Fort de France, Fort de France, France.

Background/Purpose: There is very limited data on the clinical, biological characteristics and evolution of primary Sjögren syndrome (pSS) in black patients of African origin. And yet, other connective tissue diseases such as lupus have particularities in this population.

Methods: Retrospective study of all pSS patients fullfiling American-European consensus criteria followed as out and in patients in the rheumatology and internal medicine units from the academic hospital of Fort de France, Martinique.

Results: 70 patients were recruited since 1991 : 68 women, 2 men (female:male ratio, 34:1). Mean age at diagnosis was 49.5 yo (range: 17– 74). Mean follow up time was 3.5 years (range 1–17). Main characteristics were: xerostomia 82.8 % (n = 58), xerophtalmia 91.4 % (n=64). Objective ocular tests were found positive in 70.3 % (n= 45/64). The minor salivary gland biopsy was positive in 92.5 % (n = 62/67). Other characteristics were: Raynaud's phenomenon 29.8 % (n = 20/67), arthralgia 55.7 % (n=39), arthritis 21.4 % (n= 15), interstitial lung diseases 8.5 % (n= 6), peripheral neuropathy 8.5 % (n=6), central nervous system involvement 5.7 % (n = 4), pericarditis 1.4% (n=1), pleurisy 2.8 %(n =2), vasculitis 1.4 % (n =1), no pancreatitis. Some other auto-immune diseases were associated to pSS: anti-phospholipid syndrome 7.1 % (n =5), thyroiditis 7.1% (n =5), Evans syndrome 1.4 % (n =1). Antinuclear antibodies were positive for 86.9 %, anti-SSA for 62.8 % (n=44). ESR or c reactive protein were elevated in 33 patients (47.1 %). HTLV-1 positivity was present in 2 patients. In 245 patients. years of follow up, 1 patient experienced lymphoma (0.4 lymphoma for 100 patients.years of follow up). No death was to deplore.

Conclusion: This is the first series of pSS available concerning patients of African origin. Compared to the largest Caucasian pSS cohort published by Ramos Casals et al, there seems to be no major particularities, but men are less frequently suffering from pSS and vasculitis seems less frequent than in the Caucasians.

2533

Utility of the American-European Consensus Group and American College of Rheumatology Classification Criteria for Sjögren's Syndrome in Patients with Systemic Autoimmune Diseases in the Clinical Setting. Gabriela Hernandez-Molina[1], Carmen Ávila-Casado[2], Carlos Núñez-Álvarez[1], Carlos Hernández-Hernández[1], Maria Luisa Calderillo[1], Martha Marroquín[1], Claudia Recillas-Gispert[1], Juanita Romero-Díaz[1] and Jorge Sánchez-Guerrero[3]. [1]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico, [2]University Health Network, Toronto Canada., Toronto, ON, [3]Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON.

Background/Purpose: To evaluate the feasibility and performance of the AECG and ACR Classification Criteria for Sjögren's syndrome (SS) in patients with systemic autoimmune diseases.

Methods: 350 patients with primary SS (n=50), systemic lupus erythematosus (n=100), rheumatoid arthritis (n=100), or scleroderma (n=100) were randomly selected from our patients' registry. Each patient was clinically diagnosed as probable/definitive SS or non-SS by two rheumatologists following a standardized evaluation including clinical symptoms and manifestations, confirmatory tests (fluorescein staining test, non-stimulated whole salivary flow, Schirmer-I test) autoantibodies (antinuclear antibodies, anti-Ro/SSA, anti-La/SSB, rheumatoid factor), lip biopsy, and medical chart review. Using the clinical diagnosis as gold standard, the degree of agreement with each criteria set, and between both criteria sets was estimated. We estimated the sensitivity, specificity, positive predictive value, and negative predictive value with 95% CI. We used the kappa statistic.

Results: 154 (44%) patients were diagnosed with SS. The AECG criteria were incomplete in 36 (10.3%) and the ACR criteria in 96 (27.4%), P<0.001. Nevertheless, their ability in classifying patients was almost identical, sensitivity 61.6 vs. 62.3, specificity 94.3 vs. 91.3, respectively. Either criteria were met by 123 (80%); 95 (61.7%) met AECG and 96 (62.3%) ACR criteria, but only 68 (44.2%) patients met both sets. The concordance rate between clinical diagnosis and AECG or ACR criteria was moderate, k statistic 0.58 and 0.55, respectively. Among 99 patients with definitive SS the sensitivity was 83.3 vs. 77.7, and specificity 90.8 vs. 85.6, respectively. A discrepancy between clinical diagnosis and criteria was seen in 59 (17%) patients. Patients classified by the AECG criteria were older, had more sicca symptoms, parotid enlargement, positive Schirmer-I test, and lower NSWSF rate; whereas those classified through the ACR criteria had more often keratoconjunctivitis sicca, focal sialadenitis, rheumatoid factor, and the combination of rheumatoid factor plus antinuclear antibodies >1:320.

Conclusion: The feasibility applying the AECG is superior to the ACR criteria; however the performance of both sets was similar among patients with systemic autoimmune diseases. Nevertheless, a subset of patients still is missed by both criteria sets.

2534

Ocular Surface Temperature in Early Sjogren's Syndrome and Established Disease. Andreea Coca[1], Ranjini Kottaiyan[1], Mircea Coca[2], Debbie Campbell[3], Holly Hindman[1] and James Aquavella[1]. [1]University of Rochester, Rochester, NY, [2]University of Texas Medical Branch, Galveston, TX, [3]Univerity of Rochester, Rochester, NY.

Background/Purpose: Due to a variety of factors it is challenging to make a definite diagnosis in the early stages of Sjögren's syndrome (SS). The ocular examination, including fluorescein and tear break-up time (TBUT), have been a critical part of the diagnosis algorithm. Limitations of these techniques are their relative invasiveness and lack of specificity. They can also have intrinsic toxicity, including cellular morphologic changes, including loss of cellular motility, cell detachment and death. We propose ocular surface temperature (OST) measurements as a novel, non-invasive technique that can potentially overcome these limitations.

Methods: We evaluated 5 subjects with SS that fulfilled American European Consensus Group criteria (AECG SS), 5 subjects with early disease (early SS), and 5 healthy controls (HCs). The early SS was defined as presence of autoantibodies suggestive of SS, ocular dryness less than 5 years, not fulfilling the AECG criteria. OST measurements were taken on both eyes over a 5 second interval, 30 measurements per second. In addition, tear film break-up time (TBUT), Schirmer, and fluorescein staining scores were obtained for each patient and each eye. For the early SS and AECG SS subjects we also obtained SF36, visual analog scale (VAS) for dryness, ESSDAI (EULAR SS Disease Activity Index) and standard of care laboratory analysis.

For each patient, the OST measurements from both eyes were averaged to create a single observation for each individual. Receiver operating characteristic (ROC) curves were fit using the different potential metrics under two different classification scenarios: HC vs early SS and SS, and SS vs HC and early SS.

Results: Clinically, subjects with early SS had a lower SF36, VAS, ESSDAI, ESR, CRP, ANA and anti-Ro titers, and lower IgG compared with AECG SS. They also had a higher WBCs and complement levels. Although none of these differences reached statistical significance, they are suggesting that subjects with early SS had less active immunological disease and less subjective dryness than subjects with AECG SS.

An exponential transformation on OST and a log transformation on TIME produced an approximately linear relationship. The interaction was found to be statistically significant ($p < 0.0001$). This interaction indicates that early SS had a significantly less negative slope than the other two groups. The slope of the transformed linear relationship appeared to be the best metric for classifying AECG SS vs HC and early SS.

Conclusion: Using OST we showed that subjects with early SS had a slower fall in their ocular temperature (indicative of less dryness) than patients with AECG SS and clearly separated from HCs. The ocular temperature measured at each second correlated best with the tear break up time (TBUT), suggesting that it could be used in conjunction with standard of care ocular dryness measurement, potentially improving the sensitivity of ocular measurements. Although the clinical characteristics of the AECG SS vs. early SS did not reach statistical significance, the trends suggested that early SS had less dryness, and less actively immunological disease (lower level of autoantibodies, lower inflammatory markers and IgG level), consistent with early disease.

Performance of the Ocular Staining Score (OSS) *Vs.* the Van Bijsterveld Score in the Assessment of Sjögren's Syndrome-Related Keratoconjunctivitis Sicca. Astrid Rasmussen[1], Michael Brown[1], Donald U Stone[2], Keith Earley[3], Kimberly S. Hefner[4], Lida Radfar[5], David M. Lewis[5], Stephen Young[5], Nelson L. Rhodus[6], Barbara M. Segal[7], Christopher J. Lessard[1], Courtney G. Montgomery[1], R. Hal Scofield[8] and Kathy L. Sivils[5]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Dean McGee Eye Institute, Oklahoma City, OK, [3]US Air Force, Oklahoma City, OK, [4]Hefner Eye Care and Optical Center, Oklahoma City, OK, [5]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [6]University of Minnesota, Minneapolis, MN, [7]Hennepin County Medical Center, Minneapolis, MN, [8]US Department of Veterans Affairs Medical Center, Oklahoma City, OK.

Background/Purpose: Sjögren's syndrome (SS) is a complex autoimmune disorder characterized by xerostomia and xerophthalmia due to exocrine gland dysfunction. There is no single diagnostic test for SS and multiple research classification criteria have been proposed. Currently, a combined EULAR-ACR working group is dedicated to resolve discrepancies and weaknesses between two systems presently in use: the American-European Consensus Group (AECG) criteria and the SICCA (ACR) criteria, with the ultimate goal of establishing a new consensus classification. A point of contention has been the assessment of keratoconjunctivitis sicca either by the van Bijsterveld score (vBS) for AECG classification or the Ocular Staining Score (OSS) for ACR classification. We present a direct comparison of the two scoring systems to help clarify the matter.

Methods: We performed all tests for AECG and ACR classification in a multidisciplinary sicca clinic. Complete vBS and OSS evaluations were available for 716 participants; a subset of 587 were classified by AECG criteria either as pSS (n=257) or sicca (n=330). The remaining 129 had other diseases or overlap/secondary SS. Initial analysis of concordance (vBS=OSS) or discordance (vBS≠OSS) of the ocular scores was done for n=716 subjects but the correlations with classification criteria and clinical features was restricted to the pSS/sicca subset.

Results: Of the 716 subjects, 538 (75.1%) were concordant while 178 (24.9%) were discordant for vBS *vs.* OSS. The discordant subjects had significantly higher vBS (Wilcox rank sum $p<2.2\times10E\text{-}16$); the same held

true if only pSS vs. sicca were compared. ROC curves comparing the sensitivity and specificity of the vBS and OSS both in the two study groups showed that the accepted vBS cutoff of 4 has a sensitivity of 0.59–0.68 and specificity of 0.74–0.79; similar sensitivities for the OSS are observed at scores of 4 (sensitivity 0.63–0.74; specificity 0.72–0.78) and 5 (sensitivity 0.54–0.62; specificity 0.79–0.83). Discordant participants were significantly more Ro (+), La (+), and biopsy (+) than the concordant cases ($p=1.7xE10-10$; $4.3\times10-6$; $1.8\times10E-10$ respectively). The patches of confluent staining were the most common cause of discordance in the scores. When analyzing the three additional corneal staining points of the OSS, their presence was highly associated with participants meeting criteria for pSS ($p=8.4\times10E-7$ to $1.73\times10E-13$); with (+) Schirmer's ($p=3.1\times10E-6 - 6.5\times10E-10$), Ro ($p=2.7\times10E-5 - 2.9\times10E-10$), La ($p=0.01 - 8.8\times10E-6$), biopsy ($p=1.8\times10E-5 - 3.4\times10E-10$), and WUSF ($p=0.0007 - 1\times10E-6$). In all cases, the patches of confluent staining were the most highly associated with markers of disease severity while the corneal filaments were the least significant.

Conclusion: The OSS was introduced as an objective measure of KSS in the ACR classification and was considered abnormal if ≥3. However, more recent studies indicate it has poor specificity. Our results in a large sicca cohort suggest that a cutoff between 4 and 5 would maintain a good sensitivity while increasing the specificity significantly; a matter of great importance when applying the criteria for patient selection for clinical trials.

The Sjögren's Syndrome Responder Index, a Data-Driven Combined Endpoint, Could Detect Biologics Efficacy. Divi Cornec[1], Valerie Devauchelle-Pensec[2], Xavier Mariette[3], Sandrine Jousse-Joulin[4], Jean-Marie Berthelot[5], Aleth Perdriger[6], Xavier Puéchal[7], Véronique le Guern[8], Jean Sibilia[9], Jacques Gottenberg[10], Laurent Chiche[11], Eric Hachulla[12], Pierre-Yves Hatron[13], Vincent Goëb[14], Gilles Hayem[15], Jacques Morel[16], Charles Zarnitsky[17], Jean Jacques Dubost[18], Raphaèle Seror[19], Jacques-Olivier Pers[4], Emmanuel Nowak[4] and Alain Saraux[20]. [1]Brest Occidentale University, Brest, France, [2]Brest Occidentale university, Brest, France, [3]Université Paris-Sud, Le Kremlin Bicêtre, France, [4]CHU Brest, Brest, France, [5]CHU Nantes (Nantes University Hospital), Nantes, France, [6]Rhumatologie, Rennes, France, [7]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [8]Hôpital Cochin, Paris, France, [9]University Hospital of Strasbourg, Strasbourg, France, [10]Strasbourg University Hospital, Strasbourg, France, [11]CHU Marseille, Marseille, France, [12]National Scleroderma Centre, Lille CEDEX, France, [13]CHU Lille, Lille, France, [14]Amiens University Hospital, Amiens, France, [15]CHU Bichat, Paris, France, [16]Hôpital Lapeyronie, Montpellier, France, [17]Le Havre General Hospital, Le Havre, France, [18]CHU G.-Montpied, Clermont-Ferrand, France, [19]Université Paris Sud, Le Kremlin Bicêtre, France, [20]CHU de la Cavale Blanche and Université Bretagne occidentale, Brest Cedex, France.

Background/Purpose: Efficacy of rituximab remains debated in primary Sjögren's syndrome (pSS), but that could be partly due to the absence of validated endpoint. To determine which outcome measures could detect rituximab efficacy and to create an alternative combined endpoint which could be tested in future trials in pSS.

Methods: We have conducted a post-hoc analysis of the randomized, placebo-controlled, TEARS study (Rituximab versus placebo) conducted in 14 university hospitals in France and included 120 pSS patients. Several outcome measures were prospectively collected at week (W)0, W6, W16 and W24 in the TEARS study. The outcome measures which were able to detect rituximab effect were associated to create a new composite endpoint that we called the Sjögren's Syndrome Responder Index (SSRI). The SSRI was then tested in the TRIPSS study (Infliximab versus placebo).

Results: The 5 selected outcome measures were fatigue, oral dryness, ocular dryness (patient's assessment on visual analog scales), unstimulated whole salivary flow and erythrocyte sedimentation rate. In the TEARS study, the proportion of patients fulfilling at least 30% improvement of at least 2/5 outcome measures (SSRI-30 response) was, in the rituximab and placebo groups, respectively 47% vs 21% at W6; 50% vs 7% at W16; and 55% vs 20% at W24 ($p<0.01$ for all comparisons). The same analysis in the TRIPSS study (Infliximab versus placebo) confirmed that infliximab is not effective in pSS.

Conclusion: We determined a core set of outcome measures which would be able to detect rituximab efficacy in pSS, and we propose response criteria which could be tested as primary outcome measures in future trials in pSS.

Diagnostic Accuracies of Sialography and Salivary Ultrasonography in Sjogren's Syndrome Patients: A Meta-Analysis. Young Ho Lee[1] and Gwan Gyu Song[2]. [1]Korea University Medical Center, Seoul, South Korea, [2]Korea Univ College of Medicine, Seoul, South Korea.

Background/Purpose: Ultrasonography (US) may come to replace conventional invasive examinations in clinical practice. However, the diagnostic accuracy of salivary US has not been clearly compared with sialography, and there is as of yet no consensus on the use of US as an alternative method for the assessment of salivary gland involvement in Sjogren's syndrome (SS) patients. Salivary US been studied in the context of SS in comparison with sialography with respect to diagnostic accuracy. However, published results on the diagnostic accuracies of sialography and US are controversial and inconclusive. This may be due to small sample sizes, low statistical power, and/or clinical heterogeneity. The purpose of this study was to compare the diagnostic performance of sialography and salivary ultrasonography (US) for Sjogren's syndrome (SS) patients.

Methods: We searched Medline, Embase, and the Cochran library, and performed two meta-analyses on the diagnostic accuracy of sialography and salivary US in SS patients.

Results: A total of six studies including 488 patients and 447 controls from two European and four Asian studies were available for the meta-analysis. The pooled sensitivity and specificity of sialography were 80.0% (95% confidence interval [CI] 76.4–83.2) and 89.0% (85.8–91.8), respectively, and 77.4 (73.7–80.9) and 81.5 (77.6–85.0) for US, respectively. For sialography, the PLR, NLR, and DOR were 9.296 (4.200–20.57), 0.228 (0.170–0.305), and 46.51 (16.14–134.0), respectively, and for US were 4.631 (2.707–7.864), 0.302 (0.226–0.403), and 17.48 (10.03–30.45), respectively. The area under the curve (AUC) of sialography was 0.824, and the Q* index was 0.757, while the AUC of US was 0.864, and its Q* index was 0.794, indicating that the diagnostic accuracy of US is comparable with sialography in SS patients. A subgroup meta-analysis according to the diagnostic criteria did not change the overall diagnostic accuracy.

Conclusion: Our meta-analysis of published studies demonstrates that the diagnostic accuracy of salivary US is comparable with sialography in SS patients.

Ultrasound-Guided Core Needle Biopsy of the Major Salivary Glands Is a Safe and Useful Diagnostic Tool in the Evaluation of Suspected or Established Sjögren's Syndrome. Anand Narayan, Thomas Grader-Beck, Julius Birnbaum, Jean Kim, Qing Kay Li, Deborah Belchis, Joel Fradin and Alan N. Baer. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Ultrasound-guided core needle biopsy (CNB) has greater inherent risks than fine-needle aspiration for the diagnosis of major salivary gland neoplasms, but provides tissue for histologic analysis. We sought to evaluate the safety and utility of CNB in the evaluation of salivary gland abnormalities in patients with suspected or established Sjögren's syndrome (SS).

Methods: We identified 19 patients who underwent ultrasound-guided CNB of either the parotid or submandibular gland as part of a diagnostic evaluation in our SS Center between 7/2009-5/2014. CNBs of the parotids were obtained using a posterior-inferior approach from the tail of the superficial lobe to avoid injury to the facial nerve. Patients were contacted one day after the procedure to assess for complications. The patient charts were reviewed retrospectively, using a protocol approved by the institutional review board.

Results: The 5 men and 14 women had a median age of 55 years (range, 19–74). Seven patients had an established SS diagnosis and underwent the procedure to exclude lymphoma as the cause for symmetric or asymmetric salivary gland enlargement. The remaining 12 with suspected SS underwent the procedure because of bilateral salivary gland enlargement and/or induration (n=11) or an elevated serum IgG4 level (n=1), but only one was diagnosed with SS. The 19 procedures involved sampling of parotid (n=14) or submandibular (n=5) gland parenchyma and constituted CNB alone (n=9) and CNB with FNA (n=10); flow cytometry was performed on 7/10 FNA samples. None of the patients reported complications one day post-procedure or during longitudinal follow-up [median (range) duration=172 days (1–924)]. Among the established SS patients, 3/6 had a clonal B-cell population on FNA flow cytometry, but lymphoma was only diagnosed in 1 based on CNB histology. The remaining 2 patients with abnormal FNA flow cytometry had CNB histology of benign lymphoepithelial sialadenitis and did not develop signs of lymphoma during follow-up of 2.3–2.5 years. One patient with established SS underwent CNB alone and the histology showed no lymphoid aggregates. Among the 12 patients with suspected SS, final pathologic diagnoses from CNB included: eosinophilic sialadenitis (n=2), normal parotid gland tissue with/without fatty infiltration (n=8), chronic sialadenitis not related to SS (n=1), and extensive fibrosis (n=1). The utility of CNB as a diagnostic tool for salivary gland disease was supported by its identification of: 1) pathologic abnormalities (lymphoid infiltrates or >50% fibrosis) in 10/10 patients with abnormal salivary gland ultrasound echotexture and 2) lymphoid infiltrates in 5/8 patients with established SS. Three patients with enlarged parotid glands but normal ultrasound echotexture had a CNB showing fatty infiltration with normal acinar tissue.

Conclusion: Ultrasound-guided CNB of the major salivary glands can be done safely and provides useful diagnostic information about salivary gland abnormalities in the evaluation and management of SS. The evaluation of possible lymphoma should include both CNB and FNA with flow cytometric analysis of the sample since the finding of a clonal B-cell population is not sufficient to make a diagnosis of lymphoma.

Antibodies to Human Interferon-Inducible Protein-16 Are Present in Primary Sjögren's Syndrome and Systemic Lupus, but Are Rare in Dermatomyositis. Alan N. Baer[1], Michelle Petri[1], David Fiorentino[2], Tao Wang[1], Jungsan Sohn[1], Antony Rosen[1] and Livia Casciola-Rosen[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Stanford University School of Medicine, Redwood City, CA.

Background/Purpose: Interferon inducible protein-16 (IFI16) is an intracellular DNA receptor involved in innate immunity. We evaluated the frequency and clinical significance of anti-IFI16 antibodies in cohorts of primary Sjögren's syndrome (SS), systemic lupus erythematosus (SLE), and dermatomyositis (DM). Expression levels of IFI16 in relevant target tissues were quantified.
