ASSOCIATION OF RHEUMATOLOGY HEALTH PROFESSIONALS
A DIVISION OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

AMERICAN COLLEGE OF RHEUMATOLOGY
78th Annual Meeting

ASSOCIATION OF RHEUMATOLOGY HEALTH PROFESSIONALS
49th Annual Meeting

November 14–19, 2014
Boston, MA

The supplement was not financed by profit-making organizations or by organizations representing for-profit interests. The editorial and peer review processes were handled entirely by the American College of Rheumatology (ACR) according to its peer review process for abstracts submitted for presentation at the ACR Annual Meeting.

About The Annual Meeting

Participation Statement

This Annual Meeting is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather is intended to present the opinions of the authors or presenters, which may be helpful to other healthcare professionals arriving at their own conclusions and consequent application. Attendees participating in this medical education activity do so with full knowledge that they waive any claim they may have against the College for reliance on any information presented during these educational activities. The College does not guarantee, warrant or endorse any commercial products or services.

The ACR's CME purpose is to provide comprehensive education to improve the knowledge and performance of physicians, scientists and other health professionals in order to improve the quality of care in those with or at risk for arthritis and rheumatic and musculoskeletal diseases.

Conflict of Interest/Disclosure Statements

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Disclosures for invited speakers are listed in the indices by presenters' last name. Abstract author disclosures are published online and in this supplement. Disclosures for the late-breaking abstracts are published online and in the December issue of *Arthritis & Rheumatology*. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Disclosure Policy

It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias.

To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that all individuals in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content.

Permissions Policies

Copyright Materials Policy

The Annual Meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the American College of Rheumatology. Information displayed or presented at all sessions during the Annual Meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the written permission of the ACR and the presenter. Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Use of American College of Rheumatology's Name

The names, insignias, logos and acronyms of the ACR, the ARHP and the *Rheumatology Research Foundation* are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the written permission of the College.

Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special supplement of *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website. However, the ACR continues to require that information that goes beyond that contained

in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until 4:30 PM Eastern Time on Saturday, November 15, 2014. Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy.

Abstract Reprint Policy

For the purposes of this statement, the term "ACR abstracts" refers to all Annual Meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARHP sessions and the late-breaking category.

For the purposes of this statement, the term "ACR posters" refers to the accepted abstracts as presented during the Annual Meeting. All ACR posters are the property of the ACR or the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

For the purposes of this statement, the term "reproduce" includes all forms of reproduction including, but not limited to, print, electronic and photographed formats.

For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR Annual Meeting, as identified through the abstract submission process.

Approval Process

Excerpts of ACR abstracts or ACR abstracts in their entirety may not be reproduced without the prior written permission of the publisher. Permission requests and other permission inquiries should be addressed to:

Permissions Department
c/o John Wiley & Sons, Inc.
111 River Street Hoboken, NJ 07030
Fax: (201) 748-6008
wiley.com/go/permissions

IMPORTANT: Commercial entities seeking permission to reprint abstracts must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. ACR cannot provide any materials.

Reproducing ACR Abstracts and ACR Poster Presentations for Dissemination *During* the Annual Meeting

Following approval (see approval process), an exhibiting organization may:

- Disseminate copies of individual ACR abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Disseminate information summaries (title/date/time/poster number) of ACR abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstracts@rheumatology.org.

Presenting authors may disseminate individual copies of their ACR poster during their assigned poster presentation time.

Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.

Reproducing ACR Abstracts and ACR Poster Presentations for Dissemination *After* the Annual Meeting

Following approval (see approval process), the ACR permits ACR abstracts to be reprinted and disseminated following the Annual Meeting.

Booklets of abstracts (e.g., two or more) must include the following statement on the front of the booklet: *Abstracts reprinted from the ACR/ARHP Annual Meeting held November 14–19, 2014. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).*

Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the ACR and the presenting author, copies of ACR poster presentation images may be reproduced.

IMPORTANT: The ACR does not retain and cannot provide poster presentation images. Requests to reproduce individual ACR posters or booklets of posters (e.g., two or more) must be submitted via e-mail to: abstracts@rheumatology.org.

Poster reproduction requests must include the following:

- Abstract ID Number
- Abstract title
- Presenting author's name
- A copy of presenting author's written approval*
  **E-mail approval from the presenting author is acceptable.*

The following statement must be listed under each poster reprint:

Poster reprinted from the ACR/ARHP Annual Meeting held November 14–19, 2014. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).

Great Meetings Come from Great Ideas!

CALL FOR PROPOSALS: Submit your session idea or study group topic for the 2015 ACR/ARHP Annual Meeting at **ACRannualmeeting.org** TODAY!

We are looking for proposals that:

- Reflect clinical innovation and cutting edge research.
- Convey best practices.
- Present evidence-based medicine.
- Stimulate discussion and challenge mind-sets.

Tell us about learning models that:

- Address challenges in your area of practice.
- Create opportunities to share information across geographical demographics.
- Encourage collaboration between subspecialities
- Promote partnership among physicians and health professionals.

Relevant topics may include:

- Technological advances impacting practice.
- World-wide trends in patient care.
- Outcomes assessment and holistic treatment.

Visit **ACRannualmeeting.org** for submission details.

Deadline for submissions is **Friday, November 21, 2014**

2014 it's Boston!

ACR/ARHP ANNUAL MEETING

Scientific Sessions: Nov. 15-19, 2014

ACR Poster Session A
Antiphospholipid Syndrome
Sunday, November 16, 2014, 8:30 AM–4:00 PM

1

Lymphocyte Proliferation to a Cross-Reactive Gut Commensal Candidate in Antiphospholipid Syndrome. William Ruff[1], Silvio M. Vieira[1], Cassyanne Aguiar[2], John Sterpka[1], Andrew Goodman[3], Doruk Erkan[2] and Martin Kriegel[1]. [1]Yale School of Medicine, New Haven, CT, [2]New York Presbyterian/Weill Cornell Medical Center, New York, NY, [3]Yale School of Medicine, Microbial Diversity Institute, New Haven, CT.

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune clotting disorder of unknown etiology targeting a major autoantigen, β_2-glycoprotein I (β_2GPI). Infectious triggers have been implicated in transient autoantibody production, but the persistent stimuli for anti-β_2GPI antibodies remain unknown. Given the vast antigenic potential of the gut microbiota, we hypothesize that human gut commensal bacteria induce and sustain autoreactivity via cross-reactivity. To this end, we characterized APS PBMC reactivity to *in silico* candidates and determined fecal autoantibody production.

Methods: Protein BLAST and Clustal Omega were used to identify commensal protein sequences with high homology to β_2GPI-dominant epitopes. Using anaerobic cultures, we grew isolated candidate and control strains. Blood and stool samples were obtained from anti-β_2GPI-positive patients, non-autoimmune thrombophilia patients, and healthy controls. Stool DNA was isolated using the MoBio extraction kit. A novel species-specific real-time PCR strategy was developed and validated using isolated strains and defined fecal microbiomes. *In vitro* proliferation of PBMC to bacterial protein extracts was assessed by [^{3}H]-thymidine incorporation. An in-house ELISA was established with high-binding plates to analyze anti-β_2GPI levels in plasma and fecal supernatants.

Results: Systematic *in silico* searches revealed *Roseburia intestinalis* as a major candidate for cross-reactivity. *R. intestinalis* is a common colonic gram-positive, flagellated, mucus adhering commensal containing high homology to the main B and T cell epitopes of β_2GPI. *R. intestinalis* colonization load was semi-quantified in patients and controls using real-time PCR. APS PBMC proliferated significantly more to protein extracts from *R. intestinalis* versus control subjects (n=5–6; p=0.0002), and also compared to the closely phylogenetically related, but mimic-deficient gut commensal *Eubacterium rectale* (n=6, p=0.020). Importantly, we were also able to detect anti-β_2GPI IgA antibodies in APS fecal supernatants, which differed significantly compared to controls (n=14–15; p=0.0019).

Conclusion: We have identified a major cross-reactive commensal candidate *in silico* with high homology to dominant β_2GPI epitopes and developed a highly specific real-time PCR-based screening strategy. APS PBMCs proliferated significantly more to candidate protein extracts compared to controls. Furthermore, we report, to our knowledge, for the first time fecal autoantibody production in a non-gut autoimmune disease. Production of fecal anti-β_2GPI IgA in patients with peripheral blood anti-β_2GPI IgG supports our hypothesis of a gut mucosal, cross-reactive trigger in APS, which we are actively pursuing.

2

Thrombocytopenia in Primary Antiphospholipid Syndrome Is Related to Arterial Thrombosis. Ikuma Nakagawa, Kenji Oku, Olga Amengual, Ryo Hisada, Eri Sugawara, Kazumasa Ohmura, Tomoko Fukui, Sanae Shimamura, Haruki Shida, Toshiyuki Watanabe, Yuka Shimizu, Michihito Kono, Takashi Kurita, Toshiyuki Bohgaki, Tetsuya Horita, Shinsuke Yasuda and Tatsuya Atsumi. Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Background/Purpose: Antiphospholipid-associated syndrome refers to organ dysfunctions developed in the existence of antiphospholipid antibodies (aPL), apart from the typical manifestations of antiphospholipid syndrome (APS) such as thromboembolism and pregnancy morbidities. Thrombocytopenia is one of the aPL-associated manifestations and is reported in 20–40% of APS patients. Patients with thrombocytopenia and aPL are at risk of both bleeding and thrombosis. The evaluation of the coagulation status in patients with thrombocytopenia is particularly difficult and the clinical profile of APS patients with thrombocytopenia has not been fully elucidated. The purpose of this study is to analyze the clinical profile of patients with primary APS and thrombocytopenia and to examine the relation between the risk of thrombosis and thrombocytopenia.

Methods: This study comprised of 57 consecutive patients with primary APS and 72 autoimmune disease control patients (non-systemic lupus erythematosus) who visited Hokkaido University Hospital Rheumatology Clinic between January 2000 and May 2014. Thrombocytopenia was defined as a platelet count less than 100,000 per microliter, persistent on two occasions more than 12 weeks apart and without no underlying causes besides aPL. Primary APS patients were retrospectively followed-up for the incidence of thrombosis. Kaplan-Meier survival probability estimate was performed to analyze the occurrence of thrombotic events in primary APS patients with and without thrombocytopenia.

Results: The median age of patients was 41 years (IQR 32–50) in primary APS patients and 50 years (IQR 31–59) in the control group. Thrombocytopenia was more frequently diagnosed in patients with primary APS 17/57(30%) than in the control group 4/72(6%), p<0.001.

In primary APS group, arterial thrombosis was developed in 9 patients (16%) throughout the follow-up period (106 months [IQR 36–142]); 8 patients had cerebral infarctions and 1 myocardial infarction. Arterial thrombosis was more frequently developed in patients with thrombocytopenia than in those without (6/17(35%) vs. 3/40(8%), p=0.014), while no correlation was found between venous thrombosis and thrombocytopenia. There was no statistically significant difference in the rate of hemorrhagic event between APS patients with and without thrombocytopenia (1/17 (6%) vs. 0/40 (0%), p=0.298). Kaplan-Meier curve revealed that the inferior survival was associated with thrombocytopenia (6/9(67%) vs 11/48(23%), p=0.047 log-rank test: Figure1).

Conclusion: Thrombocytopenia in APS patients represents a risk factor for arterial thrombosis and not for bleeding. The risk of thrombosis associated with thrombocytopenia in primary APS must be carefully evaluated and, if necessary, appropriate antithrombotic therapy administered.

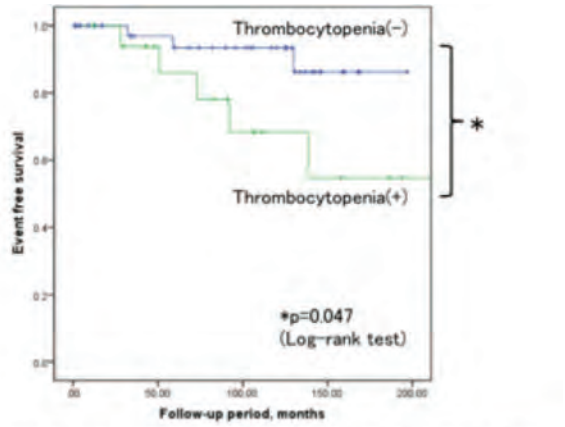

Figure1. Kaplan-Meier curves demonstrating statistically significant difference in arterial thrombosis free survival for primary APS patients with thrombocytopenia(n=17) and without thrombocytopenia(n=40).

3

Is There an Association Between Persistently High Positive Antiphospholipid Antibody Profile and Organ Damage Accrual in Lupus Patients? Doruk Erkan[1], Lisa G. Criscione-Schreiber[2], Maria Dall'era[3], Olga Dvorkina[4], Russell Griffin[5], Galina Marder[6], Maureen A. McMahon[7], Jorge Sanchez-Guerrero[8], Amit Saxena[9] and Robert Roubey[10]. [1]Hospital for Special Surgery, New York, NY, [2]Duke University School of Medicine, Durham, NC, [3]University of California, San Francisco, San Francisco, CA, [4]SUNY Health Science Center at Brooklyn, Brooklyn, NY, [5]University of Alabama at Birmingham, Birmingham, AL, [6]North Shore Long Island Health System, Great Neck, NY, [7]UCLA David Geffen School of Medicine, Los Angeles, CA, [8]UHN Toronto Western Hospital, Toronto, ON, [9]New York University School of Medicine, New York, NY, [10]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background/Purpose: Few studies assessed the impact of antiphospholipid antibodies (aPL) on organ damage in lupus with conflicting results. Our objective was to determine if persistently high positive aPL profiles are associated with organ damage in lupus patients.

Methods: The Lupus Clinical Trials Consortium Inc. (LCTC) Lupus Data Registry consists of consecutively enrolled adults with lupus from 16 US and Canada centers, each contributing ~100 patients. Patients with at least 1 follow-up (f/u) visits who were tested for aPL were analyzed. We investigated the SLICC/ACR Damage Index (SDI) (baseline [BL] and f/u) and the aPL profile (lupus anticoagulant [LA], anticardiolipin antibody [aCL] IgG/M/A, and anti-β_2Glycoprotein-I antibody [aβ_2GPI]) (historically, BL, and f/u). *"High Positive [HP] aPL"* profile was defined as positive LA, aCL IgG/M/A≥40U, and/or aβ_2GPI IgG/M/A≥40U. *"Low Positive [LP] aPL"* profile was negative LA, and aCL or aβ_2GPI IgG/M/A above the laboratory range but <40U. *"Negative aPL"* was negative LA, and aCL and aβ_2GPI IgG/M/A below the laboratory range. *"Persistent aPL"* was based on threshold levels of at least 50%, 60%, or 75% of the tests reported in HP or LP groups (based on ≥2 tests ≥12 weeks apart). A logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals for the association between an increase in SDI (first to last) and aPL-positivity adjusted for SDI at entry.

Results: Among 1506 patients, 1417 (94%) had at least 1 f/u visit, 1392/1417 (98%) had at least 1 aPL result, 1310/1392 (94%) had analyzable aPL (82 excluded; missing aCL/aβ_2GPI levels), and 816/1310 (62%) had ≥2 tests ≥12 weeks apart, or at least 1 triple negative aPL result. Tables demonstrate the crude and adjusted odds ratios for SDI increase based on different SDI accrual points and aPL profiles.

Conclusion: Our results suggest that persistently high aPL profiles, particularly those with higher thresholds for persistence, are associated with higher (≥2 or ≥3 points) SDI score accrual in lupus patients. Given the small number of patients with persistently high aPL profiles, limited analysis of potential confounders, and possibility of confounding by indication (more frequent aPL testing in patients with more severe disease/damage), further analysis of the LCTC Lupus Data Registry will clarify if aPL is a risk factor for or rather a marker of organ damage.

Detection of Anti-Beta2glycoprotein I Domain 1 Antibodies By an Automated Chemiluminescence Assay in a Cohort of 400 Clinically Characterized Consecutive Routine Samples. Laura Andreoli[1], Alessandra Zanola[1], Cecilia Nalli[1], Flavio Allegri[1], Michael Mahler[2], Gary Norman[2] and Angela Tincani[1]. [1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy, [2]INOVA Diagnostics, San Diego, CA.

Background/Purpose: Several studies suggested that antibodies to Domain 1 of beta2glycoprotein I (a-B2GPI-D1) represent a promising biomarker for the diagnosis and risk assessment of Antiphospholipid Syndrome (APS). This evidence comes from case-control studies with clinically defined APS patients and disease and healthy controls. This study aims to investigate the performance of a-B2GPI-D1 in a cohort of consecutive, clinically characterized samples derived from a routine diagnostic workup for the detection of antiphospholipid antibodies (aPL).

Methods: A total of 400 samples with a complete aPL panel (aCL IgG/IgM and a-B2GPI IgG/IgM by an in-house ELISA, Lupus Anticoagulant -LA- tested with a DRVVT and aPTT based method) were collected. All the samples were tested for aCL IgG/IgM, anti-B2GPI IgG/IgM, and anti-B2GPI-D1 IgG by QUANTA Flash CIA (INOVA). The clinical diagnosis/reason for aPL detection was retrieved from hospital records. The classification of APS was based on the Sapporo revised criteria. Systemic Lupus Erythematosus (SLE) was defined according to ACR criteria. Undifferentiated Connective Tissue Disease (UCTD) was classified upon international criteria.

Results: Out of 400 samples, 71 (14.5%) were positive for a-B2GPI IgG by either ELISA or CIA. Eighteen samples (4.5%) were positive for both a-B2GPI-D1 and a-B2GPI IgG by either ELISA or CIA assay, with the exception of 2 samples which were positive at low titer for a-B2GPI-D1 only (one positive also for aCL IgG CIA at low titer). These 2 sample derived from one patient with stroke and from one patient with recurrent pregnancy loss, both under investigation. Ten patients displayed a triple aPL positive profile (LA, aCL and anti-B2GPI positive at both ELISA and CIA). A significant association was found between the presence a-B2GPI-D1 (especially at medium-high titer) and triple aPL positivity (Chi Squared=195.468, p< 0.0001). Among 55 patients with positive a-B2GPI IgG (45 at low titer, 10 at medium-high titre) and negative a-B2GPI-D1 IgG, 47 (85.5%) had clinical features compatible with either APS (n=20) and/or systemic autoimmune rheumatic disease (SARD) (n=27).

Conclusion: In a diagnostic routine setting for aPL, medium-high titer a-B2GPI-D1 were found to cluster in patients with triple aPL positivity. a-B2GPI-D1 were present mainly in patients with APS-related clinical manifestations and in patients with SARD. Nearly 80% of sample positive for a-B2GPI IgG did not display any reactivity toward D1 and the majority of these patients had a diagnosis of APS/SARD, suggesting that clinically significant a-B2GPI IgG antibodies can also be directed against other epitopes of the B2GPI molecule.

Antiphospholipid-Associated Nephropathy Is a Risk for Developing Arterial Thromboses in Patients with Systemic Lupus Erythematosus. Tomoko Fukui, Shinsuke Yasuda, Toshiyuki Watanabe, Kazumasa Ohmura, Sanae Shimamura, Ikuma Nakagawa, Atsushi Noguchi, Haruki Shida, Yuka Shimizu, Michihito Kono, Takashi Kurita, Kenji Oku, Toshiyuki Bohgaki, Olga Amengual, Tetsuya Horita and Tatsuya Atsumi. Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Background/Purpose: Antiphospholipid-associated nephropathy (APLN) is characterized by coexistence of antiphospholipid antibodies (aPLs) and renal small-vessel vasculopathy/chronic renal ischemia. Consequences of APLN to thrombosis have yet to be known. We aimed in this study to clarify the characteristics and thrombotic risk of APLN in patients with lupus nephritis (LN).

Methods: Patients with LN proven by renal biopsy from January 2000 to February 2014 were included. A total of 90 patients were histologically diagnosed as having LN according to the ISN/RPS classification. APLN was diagnosed when both aPLs and at least one of the following pathological features were present, thrombotic microangiopathy (TMA), fibrous intimal hyperplasia (FIH), fibrocellular arterial occlusion (FAO), focal cortical atrophy (FCA) or tubular thyroidization (TUB) according to the criteria (Miyakis S *et al*. J Thromb Haemost 2006). Patients with antiphospholipid syndrome were excluded. aPLs including lupus anticoagulant, IgG/M anticardiolipin antibody, IgG/M anti-b2-glycoprotein I antibody and IgG/M phosphatidylserine dependent antiprothrombin antibody were measured. Clinical features of APLN patients were retrospectively analyzed. Development of arterial thrombosis was retrospectively observed. Log-rank test was introduced for the comparison between those with APLN and without.

Results: Among 90 patients with biopsy-proven LN, 21 were excluded (10 with APS, 5 without tests for aPLs and 6 for other reasons) and the rest 69 patients were recruited in the study. The median age and mean disease duration was 33 years old and 4.8 years, respectively. Twelve patients (17.4%) were diagnosed as APLN (9 FCA, 5 FIH, 1 FAO and 1 TUB) and 10 as APLN-like disease without aPL and with pathological features. Patients with APLN had higher frequency of hypertension (p-value by chi-square test = 0.002). APLN patients more frequently developed arterial thrombosis during the median observation period of 53 months (p-value by log-rank test = 0.018) compared with patients without APLN. Among patients positive for aPLs, patients with APLN had higher frequency of hypertension (p-value < 0.001) and developing arterial thrombosis (p-value=0.046) than patients without APLN. (Figure)

Conclusion: APLN was found in 17% of LN and associated with hypertension. APLN with LN is a possible risk for developing arterial thrombosis, although prospective study in a larger cohort would be necessary.

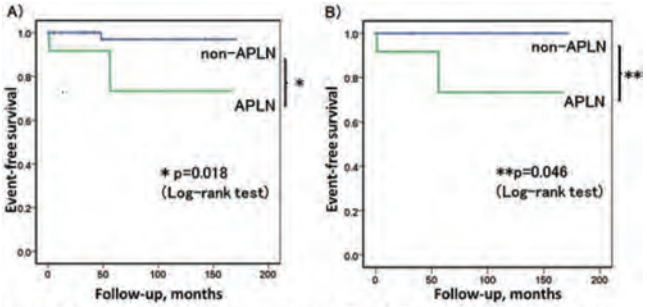

Figure. Kaplan-Meier curves demonstrating significant difference in arterial thrombosis-free survival for patients A) with APLN (n=12) and without APLN (n=57). B) with APLN (n=12) and without APLN (n=19) among patients of positive for aPLs.

Performance Evaluation and Clinical Associations of the Aphl ELISA Compared to Criteria Antiphospholipid Immunoassays in Lupus Patients. Yu Zuo[1], Rohan Willis[2], Emilio Gonzalez[3], Allan Brasier[4], Michelle A. Petri[5], Elizabeth Papalardo[6], E Nigel Harris[7], Hong Fang[8], Karel De Ceulaer[9], Monica Smikle[10], Luis M. Vila[11], John D. Reveille[12], Graciela S. Alarcon[13] and Silvia Pierangeli[14]. [1]UT Southwestern Medical Center, Dallas, TX, [2]UTMB - Galveston, Galveston, TX, [3]University of Texas Medical Branch, Galveston, TX, [4]UTMB-Galveston, Galveston, TX, [5]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [6]Louisville APL Diagnostic, seabrook, TX, [7]The University of the West Ind, Kingston, Jamaica, [8]John Hopkins University School of Medicine, Baltimore, MD, [9]Medicine, Kingston, Jamaica, [10]University of the West Indies, Kgn 7, Jamaica, [11]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [12]University of Texas Health Science Center at Houston, Houston, TX, [13]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, [14]Univ of TX Medical Branch, Galveston, TX.

Background/Purpose: Antiphospholipid Syndrome (APS) is characterized by recurrent thrombotic and obstetric manifestations in the presence of 'criteria' antiphospholipid antibodies (aPL) [anticardiolipin (aCL), anti-β2glycoproteinI (anti-β2GPI) and lupus anticoagulant (LA)]. However, aCL assays lack specificity, while anti-β2GPI assays lack sensitivity in the classification/diagnosis of APS. The APhL ® assay (Louisville APL Diagnostics), which detects antibodies against a mixture of negatively charged phospholipids, has been shown to be more specific and as sensitive as aCL in the diagnosis of APS in small observational studies. Our aim was to examine the performance of this assay in a large group of ethnically diverse lupus patients.

Methods: A total of 1178 serum samples from patients with lupus (1997 ACR criteria) from the HOPKINS (n=543), LUMINA (n=588) and Jamaican cohorts (n=47) were examined for IgG and IgM positivity in aCL (in-house), anti-β2GPI (INOVA) and APhL ELISA assays. Chi-squared or Fisher's exact test univariate analysis along with odds ratios/95% confidence intervals were used to evaluate assay correlation with clinical features (SPSS® v20.0). ROC analysis was performed to determine sensitivity, specificity, and likelihood ratios for all assays in predicting clinical features. A case series analysis was also performed of patients in whom criteria aPL assays were negative but the new APhL assay was positive.

Results: Both IgG APHL (OR2.3, 95%CI 1.5–3.7, $p<0.001$) and IgM APHL (OR1.9, 95%CI 1.1–3.4, $p=0.027$) were significantly correlated with thrombosis, while only IgG APHL (OR1.8, 95%CI 1.1–2.9, $p=0.015$) was significantly correlated with pregnancy morbidity. The IgG APHL assay had the greatest performance value as measured by positive likelihood ratio (2.2 for thrombosis and 1.7 for pregnancy morbidity), increased sensitivity as compared to anti-β2GPI, and improved specificity compared to aCL assays (tables 1 and 2). Approximately 2% (23/1178) of our patients tested positive for APHL and negative to criteria assays. Of these, 47.8% (11/23) had APS clinical manifestations, including thrombotic and pregnancy related morbidity.

Conclusion: Overall, APhL antibodies, especially IgG, represent a promising biomarker for the classification of APS patients as well as for risk

assessment in APS patients with regards to pregnancy morbidity and thrombotic manifestations. It has encouraging clinical value and potential to be part of the diagnostic criteria for APS.

Table 1: ROC Analysis: AUC, Sensitivity, Specificity and LR+ of Assays for Predicting Thrombosis

Any Thrombosis	AUC	AUC p-value	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	LR+
APHL_IgG	0.558	0.004	13.8	93.8	40.2	78.3	2.2
APHL_IgM	0.531	0.131	6.7	96.2	34.6	77.3	1.8
ACL_IgG	0.477	0.253	25.8	80.1	28.2	78.1	1.3
ACL_IgM	0.377	<0.0001	16.6	75.5	17	74.9	0.8
B2GPI_IgG	0.594	<0.0001	8.9	95.9	39.3	77.7	2.1
B2GPI_IgM	0.578	0.0001	4.1	97.5	33.3	77.1	1.7

Table 2: ROC Analysis: AUC, Sensitivity, Specificity and LR+ of Assays for Predicting Pregnancy Morbidities

Any Preg Morbidity	AUC	AUC p-value	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	LR+
APHL_IgG	0.580	<0.0001	9.8	94.2	41.7	70.9	1.7
APHL_IgM	0.523	0.244	4.9	95.7	32.6	70.2	1.1
ACL_IgG	0.456	0.024	19.2	77.9	27.1	69.3	0.9
ACL_IgM	0.417	<0.0001	17.9	73.3	22.3	67.7	0.7
B2GPI_IgG	0.573	0.0002	2.9	94.2	17.6	69.4	0.5
B2GPI_IgM	0.573	0.0002	3.3	97.1	32.3	70.2	1.1

AUC: area under the curve.
PPV: positive predicting value.
NPV: negative predicting value.
LR+: positive likelihood ratio.
Pregnancy morbidity: presence of miscarriage and/or pre-eclampsia/eclampsia.
Thrombosis: PE, DVT, TIA/CVA

Beneficial Effects of *in Vivo* Ubiquinol Supplementation on Athero-Thrombosis Prevention in Antiphospholipid Syndrome Patients. Chary Lopez-Pedrera[1], Carlos Perez-Sanchez[1], Ángeles Aguirre Zamorano[1], Nuria Barbarroja[1], Patricia Ruiz-Limon[1], Yolanda Jiménez Gómez[1], Munther A. Khamashta[2], Antonio Rodriguez-Ariza[3], Jose Antonio Gonzalez-Reyes[4], Jose Manuel Villalba[4], Eduardo Collantes-Estevez[1] and M[a] Jose Cuadrado[5]. [1]IMIBIC-Reina Sofia University Hospital, Cordoba, Spain, [2]Lupus Research Unit, The Rayne Institute, St Thomas Hospital, Kings College London School of Medicine, London, United Kingdom, [3]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [4]University of Cordoba, Agrifood Campus of International Excelence (ciA3), Cordoba, Spain, [5]The Rayne Institute, London, United Kingdom.

Background/Purpose: To investigate the beneficial effects of *in vivo* ubiquinol (Q) supplementation on athero-thrombosis prevention in APS patients.

Methods: The study was performed on 10 APS patients randomized to receive either Q (200 mg/day) or placebo for one month. Blood was drawn at time 0 and at the end of the treatment. Studies were conducted in plasma and purified leukocytes subsets. Plasma Q levels and various prothrombotic/proinflammatory parameters and oxidative stress biomarkers were evaluated. Endothelial activity analysis was performed by Laser-Doppler flowmetry measurement of post ischemic reactive hyperemia.

Results: All patients completed the intervention, which increased significantly plasma Q levels. CD14highCD16- classical monocyte count was not significantly changed after Q treatment but CD14highCD16+ intermediate monocytes and CD14dimCD16high non-classical monocytes were decreased. Q treatment decreased significantly Tissue Factor (TF) expression levels in total monocytes, and more notably in CD14highCD16+ intermediate monocytes which also displayed a more robust reduction of intracellular IKK levels. Only this monocytes subset exhibited IL-8 reduction after intervention. Q supplementation produced a significant reduction in both the levels of peroxides and the percentage of monocytes with altered mitochondrial membrane potential ($\Delta\Psi m$), and in six of the ten patients evaluated endothelial function was improved as shown by a significant amelioration in the highest perfusion value after occlusion was released, expressed as a percentage of change vs rest flow value (RF-PF). Q effects were particularly relevant in APS patients suffering from arterial thrombosis (AT) in comparison to those with venous thrombosis (VT) or obstetrical manifestations (OM) since TF expression, being particularly higher at baseline in AT patients, showed a more pronounced decline and endothelial function was better improved.

Correlation studies showed that reduced monocyte TF expression after Q treatment were related to both decreased peroxides levels and increased plasma Q levels. The decrease of CD14dimCD16high non-classical monocytes count was related to the reduction in the percentage of cells with altered $\Delta\Psi m$ as well as with the increase in RF-PF value. Improvement in endothelial function was further related to reduction of peroxide levels and to reduced TF expression on non-classical monocytes.

Conclusion: Q supplementation at 200 mg/d significantly reduced TF expression and oxidative stress markers in monocytes from APS patients, which were further related to an improvement on endothelial function. Our results support the potential impact of Q in the prevention of atherothrombosis in APS patients.

Background/Purpose: Long term anticoagulation is recommended in antiphospholipid syndrome with thrombosis in order to prevent recurrences. While the current mainstay relies on vitamin K antagonists, their long term maintenance may remain challenging. Our aim was to report on the safety and the efficacy of new oral direct inhibitors of thrombin and factor Xa (ODIs) in antiphospholipid syndrome (APS).

Methods: Descriptive analysis of patients with APS enrolled in a French multicentre observational cohort between January 2012 and March 2014 and receiving ODIs. Clinical, biological, and therapeutic data were retrospectively analyzed. The main primary outcome was the occurrence of a thrombotic recurrence. Secondary outcomes included adverse effects – notably hemorrhagic episodes, and biological tolerance. Kaplan-Meier survival analyses were performed to take into account censored data, using therapeutic interruptions/modifications as events.

Results: Twenty-four patients with APS (primary in 11) received ODIs. The median [IQR] age at APS diagnosis was 41 [23–50] years, and the median duration of disease was 3 [1–11] years at introduction of the anti-thrombotic agent. Antiphospholipid antibodies (Abs) included anticardiolipin Abs (n=21/24, IgG isotype in 20), lupus anticoagulant (n=16/22), and IgG anti-β2glycoprotein I Abs (n=6/24).

ODIs included dabigatran (n=11), and rivaroxaban (n=13). Nineteen patients had been previously treated with VKA (n=18), or fondaparinux (n=1) for a median duration of 3 years. ODIs were introduced as second-line therapy because of INR lability/therapeutic simplification (n=16), recurrent thrombosis (n=1), VKA's associated bleeding event (n=1), atrial fibrillation (n=1). Five patients received ODIs as first-line therapy. After a median follow-up of 15 [8–21] months, one relapse of arterial thrombosis, two bleeding events (hypermenorrhea and rectal bleeding under Rivaroxaban) and one recurrent migraine were reported, leading to discontinuation of therapy in these 4 patients. Overall, the event-free survival rate was of 86.6% at 12 months using Kaplan-Meier curve analysis.

Conclusion: ODIs might be an alternative therapeutic option in APS, especially for patients with INR lability. Prospective studies are warranted to evaluate their safety in this condition.

A Risk-Stratified Perioperative Management Strategy for Antiphospholipid Antibody Positive Patients Undergoing Kidney Transplantation. Vinicius Domingues[1], Darshana Dadhania[2], Choli Hartono[2], Raymond Pastore[2] and Doruk Erkan[3]. [1]New York Presbyterian Hospital, New York, NY, [2]New York Presbyterian Hospital, new york, NY, [3]Hospital for Special Surgery; Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY.

Background/Purpose: Antiphospholipid antibody (aPL) positive patients undergoing kidney transplantation (Tx) are at increased risk for perioperative complications. The objective of this study was to analyze the outcomes of aPL-positive patients who were managed by a risk-stratified perioperative "standard of care" protocol while undergoing kidney Tx.

Methods: We designed a "standard of care" protocol based on patient's *immunological* and *aPL* risk profiles. *Low Immunological Risk (IR)* was defined as negative donor flow crossmatch (T and B cell XM) with/without donor specific antibodies; *Moderate IR* was defined as positive donor flow crossmatch (T and/or B cell XM) with positive donor specific antibodies; and *High IR* defined as was ABO incompatibility OR positive donor CDC T cell crossmatch with positive donor specific antibodies. *Low aPL Risk* was defined as anticardiolipin antibody (aCL) or anti-β_2Glycoprotein-I (aβ_2GPI) IgG/M/A 20–39U at least twice $\geq$ 12w apart AND negative lupus anticoagulant (LA) test; *High aPL Risk* was aCL/aβ_2GPI IgG/M/A $\geq$40U OR a positive LA test twice $\geq$ 12w apart. We categorized patients into 6 groups and assigned different management strategies to each group (Table). For this descriptive preliminary analysis, we retrospectively reviewed the charts for perioperative and 6-month follow-up thrombosis, graft failure, and glomerular filtration rate (GFR).

Risk Stratification	Low IR Low aPL	Low IR High aPL	Moderate IR Low aPL	Moderate IR High aPL	High IR Low aPL	High IR High aPL
Pre-Tx Immunosuppressive	No	No	Rituximab	Rituximab	Rituximab	Rituximab
Regimen			MMF	MMF	MMF	MMF
Pre-Tx Antiplatelet/	Pre-Transplant Warfarin (+): Bridge Anticoagulation with Heparin					
Anticoagulation	Pre-Transplant Warfarin (−): ASA 81 mg daily for low aPL-risk					
Post-Tx Immunosuppressive	Induction Therapy*					
Regimen	MMF Tacrolimus	MMF Tacrolimus IVIG	MMF Tacrolimus Prednisone	MMF Tacrolimus Prednisone IVIG**	MMF Tacrolimus Prednisone	MMF Tacrolimus Prednisone IVIG**
Post Tx Antiplatelet/ Anticoagulation***	Aspirin 8–12w	UFH to Warfarin 8–12w	Aspirin 8–12w	UFH to Warfarin 8–12w	Aspirin 8–12w	UFH to Warfarin 8–12w

* Induction therapy consists in either Thymoglobulin 5 doses OR Basiliximab 2 doses AND pulse steroids for 4 days; ** The only immunosuppressive agent given for aPL-purposes; *** For patients who are not on long-term warfarin treatment. MMF: Mycophenolate Mofetil; UFH: Unfractionated Heparin.

Results: Eight patients (mean age: 49.2 $\pm$ 19.3; female: 4) underwent kidney transplantation (4 low IR/aPL risk; 2 low IR and high aPL risk; and 2 moderate IR and high aPL risk). Reasons for kidney Tx were lupus nephritis (5), polycystic kidney disease (2), and focal segmental glomerulosclerosis (1). No delayed graft function, thrombosis, or thrombotic microangiopathy were reported in the 6-month postoperative time. Median glomerular filtration rates at 30 days and 6-month post Tx were 70.65 (range 54–86) ml/min and 79.95 (range 36–112) ml/min, respectively. Median spot urine albumin-to-creatinine ratios at 30 days and 6-month post Tx were 53.3 mg/g (range 7–535) and 23.5 mg/g (range 5–244), respectively. One patient had perinephric hematoma on postoperative day one that was drained without further complications.

Conclusion: Our preliminary analysis suggests that a risk-stratified perioperative management strategy based on immunological and aPL risk profiles of aPL-positive patients undergoing kidney transplantation is safe. Future analysis of aPL-positive patients undergoing transplantation with and without risk-stratified management approach will determine if our approach improves clinical outcomes.

Antiphospholipid Antibodies and Neuropsychiatric Events in Pediatric Patients. Mileka Gilbert[1] and Lenore M. Buckley[2]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Yale School of Medicine, New Haven, CT.

Background/Purpose: An association between anti-phospholipid antibodies (aPL abs) and non-thrombotic neuropsychiatric events has been reported in pediatric and adult patients, including patients who do not have SLE. We reviewed the records of children with aPL abs follow at VCU Health System to assess the prevalence and type of neuropsychiatric events.

Methods: We retrospectively identified all pediatric patients with persistently positive aPLabs (two positive tests 12 weeks apart) followed in the Division of Rheumatology at VCU Health System from 1997 through 2012. Demographic, clinical, and serologic information were collected through chart review including details of clinical presentation, anti-phospholipid antibody testing over time, other autoantibodies, and information about treatment and clinical course.

Results: Twenty nine pediatric patients with aPL abs were identified. The average age at diagnosis was 13 years and average follow up was 6 years (range 1–12 years). Sixty six percent of the children were African American and 92% were female. Sixteen children (55%) met criteria for pediatric lupus (pSLE) and 13 (45%) did not. Of the children who did not meet criteria for pSLE, 4 had a positive ANA and 4 had other autoantibodies (3 with SSA, 1 with low positive DSDNA). Eight patients (28%) met criteria for antiphospholipid antibody syndrome (APS) including 4 (25%) patients with pSLE (1 CVA, 2 with pregnancy loss, 1 thrombotic skin ulcer) and 4 (31%) of those who did not meet criteria for pSLE (1 DVT, 2 with CVA, 1 with catastrophic APS). Of those children with aPL abs who did not meet criteria for pSLE, presenting symptoms included hemolytic anemia in 3 and thrombocytopenia in 7, with some children presenting with both.

Neurologic problems were common in children with aPL abs. 21 (72%) of children with aPL abs had a neurologic diagnosis and headache was the most common (12, 41%). One child had chorea and 2 had a CVA. Of note, 10 (63%) of children with pSLE and 4 (31%) of those with aPL abs alone had a psychiatric diagnosis, including major depression in 14 (with one suicide attempt), obsessive compulsive disorder (1), oppositional defiance disorder (4), schizophrenia (1), and bipolar disorder (1). Two children were in residential care for behavioral disorders (one with pSLE and one without). Among the 41 pSLE patients followed at VCUHS who did not have aPL abs, 17% had a major psychiatric disorder ($p=0.003$ compared to all children with aPL abs).

Conclusion: An association between aPL abs and neuropsychiatric events has previously been reported in adults and children but mood disorders and psychiatric diagnoses have not been consistently found in published series of children with aPL abs. In this cohort followed at VCU, children with both pSLE with aPL abs were more likely to have a psychiatric diagnoses than children with pSLE without aPL abs and children with aPL abs alone also had a high prevalence of psychiatric diagnoses. Although the personal and functional impact of these neuropsychiatric diagnoses is significant, their etiology and responsiveness to treatment is unclear.

Sustained Moderate Intensity Levels of Oral Anticoagulant Therapy and the Rate of Recurrent Thrombosis in Patients with Primary Antiphospholipid Syndrome. Alonso Turrent[1], Gabriela Hernandez-Molina[2] and Antonio R. Cabral[2]. [1]Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico.

Background/Purpose: The current recommended anti-thrombotic therapy for patients with anti-phospholipid syndrome (APS) is oral anticoagulants with an INR intensity between 2–3. This recommendation has been mostly derived from retrospective and prospective randomized studies based on INRs determined at time of thrombosis or the closest available one. The current recommended anti-thrombotic therapy for patients with anti-phospholipid syndrome (APS) is oral anticoagulants with an INR intensity between 2–3. This recommendation has been mostly derived from retrospective and prospective randomized studies based on INRs determined at time of thrombosis or the closest available one.

Objective: To evaluate the rate of re-thrombosis in patients with primary APS (PAPS) during a defined anticoagulation index period.

Methods: We studied patients attending a Tertiary Referral Care Center according to the following inclusion criteria: PAPS (Sydney Criteria), a history of one or more episodes of thrombosis, on oral anticoagulants and $\geq$2 INR determinations per year. Index period was defined as either the time elapsed between the first available INR and the next thrombotic event or the time between the first and last available INRs in rethrombosis-free patients. We also analyzed the number of thrombotic episodes before the index period.

Statistical analysis: We used X^2 test, U-Mann Whitney test and Cox survival analysis.

Results: We studied 81 PAPS patients (73% women) with a mean age of 46.8 ± 15.5 years and a median follow-up of 6.4 years (range 0.15–17). Sixty-four patients did not have an episode of re-thrombosis, while 17 had a new episode of thrombosis during follow-up. The latter by definition was longer in thrombotic-free patients (6.7 vs. 1.9 years, p= 0.003). The median INR during the anticoagulation index period was significantly higher in re-thrombosis-free patients (2.5, 1.1–3.6) compared with patients with recurrent thrombosis (1.9, 1–2.9, p=0.001). The median number of INR determinations per years of follow-up was similar in both groups (4.9 vs. 5.7). The number of thrombotic episodes in re-thrombosis-free patients before the index period (1, 1–4) was lower compared with their re-thrombosed counterparts (3, 1–5, p<0.001). Both differences remained statistically different after Cox analysis (median INR: OR 0.13, 95% CI: 0.05–0.32, p<0.001; history of rethrombosis: OR 17.4 (2.2–133.8, p=0.006). No differences were found between the two groups in the frequencies of ant-cardiolipin (IgG or IgM), anti-b_2-glycoprotein-I (IgG or IgM), lupus anticoagulant, triple marker positivity, dyslipidemia, cigarette consumption, aspirin and immunosuppressive therapy, arterial hypertension and diabetes mellitus.

Conclusion: A sustained INR of 2.5 for secondary thromboprophylaxis in patients with PAPS appears to be protective whereas a previous thrombosis confers risk. PAPS patients were more prone to develop recurrent thrombosis if their INR persistently remained beneath that threshold during follow-up.

Non-Criteria Antiphospholipid Antibodies in Obstetrical "seronegative Anti-Phospholipid syndrome". Arsene Mekinian[1], Marie Charlotte Bourrienne[2], Lionel Carbillon[3], Sabine Grootenboer[2], Luc Dechaisemartin[4], Sylvie chollet Martin[2], Olivier Fain[5] and Pascale Nicaise-Roland[6]. [1]Internal Medicine, DHUi2B Saint Antoine Hospital, paris, France, [2]Unité Fonctionnelles d'Immunologie <<Autoimmunité et Hypersensibilités>>, AP-HP, Hôpital Bichat-Claude Bernard, Paris, paris, France, [3]Service de gynécologie-obstétrique, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France., Bondy, France, [4]Unité Fonctionnelles d'Immunologie Autoimmunité et Hypersensibilités, AP-HP, Hôpital Bichat-Claude Bernard, Paris, PARIS, France, [5]Hôpital Saint Antoine, DHU i2B, Service de Médecine Interne, paris, France, [6]Unité Fonctionnelles d'Immunologie <<Autoimmunité et Hypersensibilités>>, AP-HP, Hôpital Bichat-Claude Bernard, Paris, Paris, France.

Background/Purpose: The aims of our prospective study were to determine the prevalence of non-criteria aPL and their clinical relevance in a seronegative population with pregnancy morbidity according to Sapporo criteria.

Methods: We included 118 women: 73 with history of pregnancy morbidity according to clinical Sapporo's criteria (SN-APS), 38 patients with confirmed obstetrical APS (SP-APS) and 45 with pregnancy without any obstetrical complication (Controls). Other than APS thrombophilia screening was negative in all women (protein C, S, ATIII, V and II mutations).

The IgG/ IgM anti-phosphatidylethanolamine antibodies (aPE), IgG/IgM anti-phosphatidylserin/prothrombin antibodies (aPS/PT) and IgG anti-annexin 5 antibodies (aANX) were measured by commercial ELISAs (Theradiag, Instrumentation laboratory).

Results: Among the SN-APS group, 47% women presented ≥ 3 early miscarriages, 43% mid-to-late pregnancy loss and 22% premature birth <34 weeks of gestation related to placental insufficiency.

Non-criteria aPL were detected in 32% of SN-APS and 72% SP-APS and 13% controls (p<0.05). Among the non-criteria aPL antibodies, only the aPE IgG were more frequent in SN-APS patients than controls (18% vs 2%; p<0.05) and the levels of IgG aPE and IgG aANX were higher in SN-APS patients (median titres 6 U/mL and 8 U/mL, respectively), than in controls (2 U/mL and 2 U/mL, respectively; p<0.0001)(figures 2–3). Non-criteria aPL antibodies were present in 74% SP-APS versus 33% of SN-APS (p<0.05). APS/PT antibodies were more frequent in the SP-APS group: 48% vs 4.4% in controls and 2.2% in SN-APS (p<0.001). IgA anti-β2GPI antibodies were negative in SN-APS vs 23% SP-APS. Antibodies to anti-domain I of β2GPI were absent in SN-APS vs 30% of SP-APS. None of the five aPL antibodies was associated with specific obstetrical feature in SN-APS.

Conclusion: Our results suggest that non-criteria antibodies can be detected in 33% of women with obstetrical complications suggestive of APS with negative aPL.

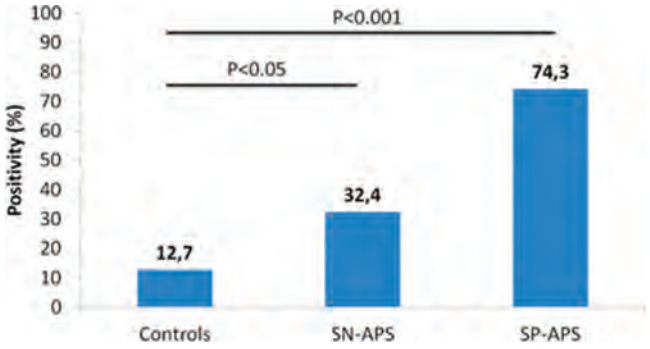

Figure 1. The prevalence of non-criteria APL in SN-APS, SP-APS and controls.

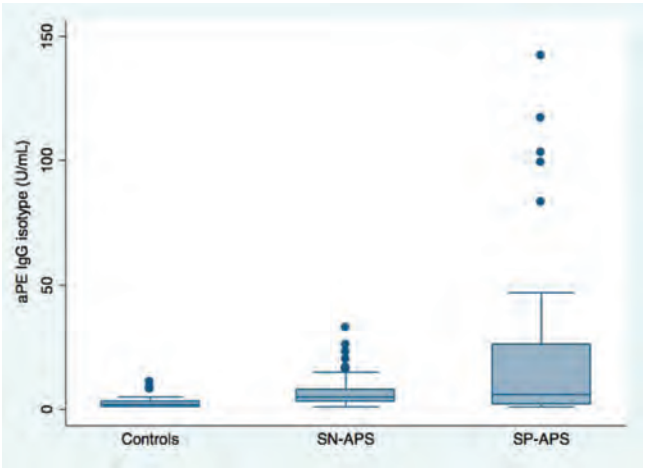

Figure 3. Anti-PE IgG titres in different groups.

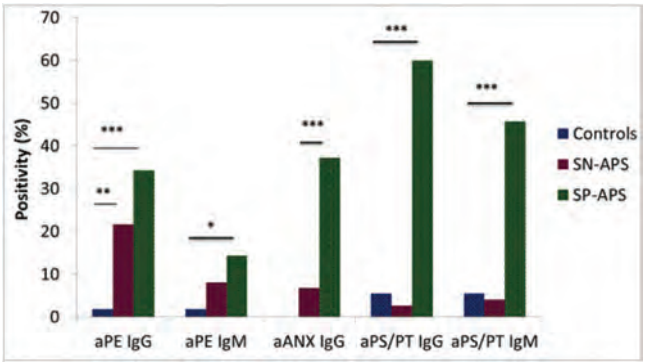

Figure 2. The frequency of different non-criteria APS prevalence in SN-APS, SP-APS and controls.

13

Eculizumab in Antiphospholipid Antibody Syndrome. Ekaterini Zapantis, Richard Furie and Diane Horowitz. North Shore - Long Island Jewish Health System, Great Neck, NY.

Background/Purpose: Antiphospholipid syndrome (APS) is defined as the occurrence of venous or arterial thrombosis and/or pregnancy morbidity, in the presence of serological evidence of antiphospholipid antibodies (including IgM and IgG anticardiolipin antibodies, IgM and IgG anti-beta2-glyoprotein I antibodies, or the lupus anticoagulant). Whereas most patients with focal thrombotic events respond to anticoagulation, occasional patients are refractory to standard therapeutic interventions and continue to have either focal or multifocal occlusive disease. For those with recalcitrant disease or those with the catastrophic antiphospholipid syndrome (CAPS), physicians resort to the addition of anti-platelet agents, steroids, immunosuppressives, IVIG, rituximab, or plasma exchange.

Complement inhibition may be an effective way to prevent thrombosis associated with APS. Eculizumab, a monoclonal antibody that binds to complement protein C5 and prevents the conversion of C5 to C5a and C5b, may potentially be an effective treatment for patients with APS. First studied in patients with systemic lupus erythematosus, rheumatoid arthritis, dermatomyositis, and idiopathic membranous nephropathy in the early 2000's, development of the drug for rheumatic diseases was abandoned in favor of paroxysmal nocturnal hemoglobinuria and atypical hemolytic uremic syndrome. Given the experience of complement inhibition in animal models of APS as well as prior use of eculizumab several years ago in one of our refractory APS patients, we administered eculizumab to three patients with severe refractory APS.

Methods: Two patients with APS, unresponsive to conventional anticoagulant therapy, were treated with a loading dose of eculizumab followed by dosing every other week (Atypical Hemolytic Uremic Syndrome dosing schedule). At the time of submission, the third patient has only received a loading dose. It has been suggested that the platelet count may be used as a surrogate marker of APS activity. During therapy, the patients' platelet counts were monitored and any new thrombotic events documented.

Results: At their lowest values, the patients had platelet counts of 35,000, 22,000 and 18,000 (K/mL). One of the patients was steroid-dependent in order to maintain her platelet count. After initiation of eculizumab, the patient was able to taper steroids as the platelet count had risen from a low of 35,000 to average counts of 100,000. The second patient's platelet count rose to over 200,000 from 22,000 within 10 days of receipt of eculizumab. After receiving one dose of eculizumab, the third patient's platelet count rose from 18,000 to 50,000 within 4 days. For the first two patients, the increases in platelet counts were sustained other than during brief periods when therapy was delayed. During the treatment period (4 and 8 months), there were no new thrombotic events. We will report additional data on the third patient as he proceeds with treatment.

Conclusion: Eculizumab has shown promising results in our patients with refractory APS. Longer follow-up of these patients will be needed in order to discern the effect on thrombosis. Controlled studies are needed to further assess the efficacy of eculizumab in this condition as are mechanistic studies.

Rivaroxaban Use in Patients with Antiphospholipid Syndrome Patients and Previous Poor Anticoagulation Control with Vitamin K Antagonists.

Savino Sciascia[1] and Beverley Hunt[2]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Thrombosis and Thrombophilia Center (St Thomas Hospital, London, UK), London, United Kingdom.

Background/Purpose: Management of antiphospholipid syndrome (APS) centres on attenuating the procoagulant state whilst balancing the bleeding risks of anticoagulant therapy. In a minority of APS patients treated with vitamin K antagonists (VKA) maintaining the INR within the target therapeutic range is still a matter of concern.

Methods: Data from consecutive APS patients attending the Thrombosis and Thrombophilia Center (St Thomas Hospital, London, UK) with poor anticoagulation control with VKA were collected. Inclusion criteria included 1) APS patients treated with VKA with INR target 2–3 for secondary prevention of venous thromboembolism (VTE) 2) Poor Anticogulation Control, defined as 'erratic' pattern (where more time is spent both above and below INR target) or unidirectional pattern (where time out of range is predominantly in one direction-low or high). Time in therapeutic range (TTR) was assed in all the included patients. Included patients were switched to rivaroxaban 20 mg od for secondary thromboprophylaxis.

Results: 18 APS patients were included (13 female, mean age 45.2 ± 10.4 yrs, mean disease duration 8.8 ± 6.7 yrs, mean age at onset of disease 35.1 ± 9.7 yrs). Thirteen had a history of deep vein thrombosis, 5 had both deep vein thrombosis and pulmonary embolism. In all the included patients TTR was 65% or lower. Indication for switching to rivaroxaban was erratic INR control (mean 15 [11–21] INR tests within the last 6 months) in 13 patients and INR constantly in sub-therapeutic range in three patients, respectively. Patients were followed for a mean of 12.9 months [6–24] after starting rivaroxaban. No further VTE or major bleeding events were observed. In two women there was a worsening of menorrhagia, which was treated with conservative management.

Conclusion: In this study, the use of rivaroxaban therapy for secondary thromboprophylaxis for VTE appears safe in APS. A larger trial RAPS (Rivaroxaban in AntiPhospholipid Syndrome, IRSCTN 68222801) is ongoing and results will be available next year. In the interim, rivaroxaban may be considered cautiously as an alternative anticoagulant in APS patients with poor anticoagulant control with VKA.

Performance of an Automated Chemiluminescence Assay for Anti-Cardiolipin and Anti-Beta2glycoprotein I Antibodies Detection in a Cohort of 400 Clinically Characterized Consecutive Routine Samples.

Alessandra Zanola[1], Laura Andreoli[1], Cecilia Nalli[1], Flavio Allegri[1], Michael Mahler[2], Gary Norman[2] and Angela Tincani[1]. [1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy, [2]INOVA Diagnostics, San Diego, CA.

Background/Purpose: Several immunoassays are available for the detection of anti-cardiolipin (aCL) and anti-beta2glycoprotein I antibodies (anti-B2GPI), but standardization and harmonization of these tests is an ongoing process. Here we aimed to comparing the performance of an automated chemiluminescence assay with a validated in-house ELISA method, using clinically characterized samples derived from a routine diagnostic workup for the detection of antiphospholipid antibodies (aPL).

Methods: A total of 400 samples with a complete aPL panel (aCL IgG/IgM and anti-B2GPI IgG/IgM determined by an in-house ELISA, Lupus Anticoagulant (LA) tested with a DRVVT and aPTT based method) were collected. All the samples were tested for aCL IgG/IgM and anti-B2GPI IgG/IgM by QUANTA Flash CIA (INOVA). The two assays were compared using a definition of aPL profile for each isotype (single vs double positive samples). The clinical diagnosis/reason for aPL detection was retrieved. Subjects were grouped upon the clinical situation: A) clinical features compatible with Antiphospholipid Syndrome (APS) and/or other systemic autoimmune rheumatic diseases (SARD) (patients considered at risk of aPL-related manifestations); B) clinical features other than A; C) unresolved clinical picture.

Results: The two assays displayed a good overall agreement for both IgG and IgM detection (81% and 84% respectively). Such agreement can be estimated to be higher after reconciliation of discrepant results using clinical features and degree of aPL positivity. The majority of discrepant results for both IgG and IgM assays were due to low titer values. No significant difference was found in the rate of group A patients in the two subgroups of discrepant samples (ELISA pos – CIA neg and *viceversa*) (Chi squared test). LA was positive in 11/75 (15%) for IgG assays and in 9/63 (15%) for IgM assays discrepant samples.

		QUANTA Flash CIA			
	IgG assays	**aCL pos and anti-B2GPI pos (double pos)**	**aCL pos or anti-B2GPI pos (single pos)**	**aCL neg and anti-B2GPI neg (double neg)**	**Total**
In-house ELISA	**aCL pos and anti-B2GPI pos (double pos)**	13 (3.3%)	0	0	13 (3.2%)
	aCL pos or anti-B2GPI pos (single pos)	6 (1.5%)	14 (3.5%)	35 (8.8%)	55 (13.8%)
	aCL neg and anti-B2GPI neg (double neg)	8 (2%)	26 (6.5%)	298 (74.5%)	332 (83%)
	Total	27 (6.8%)	40 (10%)	333 (83.2%)	400 (100%)

		QUANTA Flash CIA			
	IgM assays	**aCL pos and anti-B2GPI pos (double pos)**	**aCL pos or anti-B2GPI pos (single pos)**	**aCL neg and anti-B2GPI neg (double neg)**	**Total**
In-house ELISA	**aCL pos and anti-B2GPI pos (double pos)**	12 (3%)	5 (1.3%)	6 (1.5%)	23 (5.8%)
	aCL pos or anti-B2GPI pos (single pos)	3 (0.8%)	7 (1.8%)	46 (11.5%)	56 (14%)
	aCL neg and anti-B2GPI neg (double neg)	0	3 (0.8%)	318 (79.5%)	321 (80.2%)
	Total	15 (3.8%)	15 (3.8%)	370 (92.4%)	400 (100%)

Discrepant results	**IgG assays (n=75)**	**IgM assays (n=63)**
ELISA pos – CIA neg	Group A: 23/35 (66%)	Group A: 40/57 (70%)
IgG n=35/75 (47%)	Group B: 87/35 (23%)	Group B: 13/57 (23%)
IgM n=57/63 (90%)	Group C: 4/35 (11%)	Group C: 4/57 (7%)
Positive LA n=11 (15%)	Low titer: 27/35 (77%)	Low titer: 45/57 (79%)
ELISA neg – CIA pos	Group A: 30/40 (75%)	Group A: 5/6 (83%)
IgG n=40/75 (53%)	Group B: 7/40 (18%)	Group B: 1/6 (17%)
IgM n=6/63 (10%)	Group C: 3/40 (7%)	Group C: 0 (11%)
Positive LA n=9 (15%)	Low titer: 34/40 (85%)	Low titer: 4/6 (67%)

Conclusion: In-house ELISA assays and the CIA assays displayed a comparable performance in the detection of aCL and anti-beta2GPI. Discrepant results were mostly due to values in the low positive range. The clinical features of the subjects are crucial information to interpret results when comparing different assays for aPL detection.

Differential Assay Reactivity of IgA Anti-B_2glycoprotein I Antibodies: Implications for Clinical Interpretation of Antiphospholipid Antibody Testing. David B Hood, Karin R Snyder, Tammy R Buckner, Beth L Hurley, Kelly R Pitts and Luis R Lopez. Corgenix, Inc., Broomfield, CO.

Background/Purpose: IgA anti-β2Glycoprotein I (aβ2GPI) antibodies remain controversial in the assessment of thrombotic risk in spite of several studies indicating an association with thromboembolic events in SLE and antiphospholipid syndrome (APS) patients. In addition, recent proficiency testing revealed widely discrepant results between 2 commonly used IgA aβ2GPI ELISAs on SLE and catastrophic APS samples. This controversy may have contributed to exclusion of IgA aCL and aβ2GPI antibodies from the current classification criteria for APS. One hypothesis is that coated β2GPI of one assay displayed the open (reactive) β2GPI configuration while the other had the closed (non-reactive) configuration.

Methods: Four sera selected from positive SLE and APS patients having discrepant IgA aβ2GPI reactivity; strongly positive in assay A (144–388 A units) and negative in assay B (9.9–18.6 A units). Cut-off was <20 A units in both assays. These samples were also strong IgG aβ2GPI (143–237 G units in assay A). A negative serum was used as control. IgA antibodies were affinity purified (Peptide M, Invivogen, Inc) to investigate β2GPI reactivity. Column wash-through and eluents were tested on both IgA aβ2GPI assays.

Results: were normalized to total protein. To determine the nature of differential reactivity, assay conjugates and controls/calibrators from assay A and B were interchanged.< Results: IgA eluents from IgA aβ2GPI positive samples reacted 10× stronger on assay A compared to assay B (graph). ODs of assay B were within the negative range (<0.200). When normalized to protein content, the eluents showed no cross-reactivity for IgG or IgM aβ2GPI antibodies confirming IgA isotype specificity. IgG aβ2GPI antibodies were detected in the wash-through. Conjugate from assay A reacts with reagents from both assays. However, conjugate from assay B reacts only with assay B reagents. This confirms that β2GPI-coated plates of assay B bind IgA aβ2GPI antibodies, questioning the open/closed hypothesis. When both conjugates were compared in assay B, conjugate from assay A was 4× more reactive, suggesting that the ability of assay A to detect IgA aβ2GPI antibodies is partially dependent on the anti-IgA conjugate and calibration.

Conclusion: These results confirm not only the presence of IgA aβ2GPI antibodies in the selected patient samples but highlight an IgA conjugate reactivity issue for assay B, causing an underestimation of IgA aβ2GPI. This finding may assist in ongoing standardization efforts of APS antibody testing. In addition, conclusions from published clinical studies may need to be revised as some assays may understate IgA significance.

Antiphospholipid Syndrome Following Infection: A Systematic Review of Case Reports. Noha Abdel-Wahab[1], Maria A. Lopez-Olivo[1], Paola Patarroyo-Pinto[2] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: The occurrence of antiphospholipid syndrome (APS) following an infection has been increasingly reported in the literature. We conducted a systematic review of case reports documenting the development of primary APS, catastrophic APS (CAPS), or APS related features following infection to identify potentially putative agents, and to summarize the patients' clinical and immunologic characters, treatment administered, and patient outcomes.

Methods: We searched the Medline, EMBASE, Web of Science, and Cochrane CENTRAL databases with no language restriction from inception through October 2013 for case reports of patients with APS or CAPS related features after an infection. Study selection, data extraction, and quality appraisal were performed by 2 independent researchers. We extracted data on the related infection, clinical presentation, antiphospholipid (aPL) antibody profiles, treatment, and patient outcomes.

Results: From 2,257 unique citations, 247 publications met our inclusion criteria, reporting on 281 cases. Three different groups of patients were identified according to the clinical presentation reported: 1) patients whose symptoms met the classification criteria for definitive APS or CAPS (24.2%), 2) patients who did not meet the criteria for APS or CAPS but developed transient thromboembolic phenomena with elevated aPL antibodies during an infection and recovered completely (44.8%), and 3) patients who developed transiently elevated aPL antibodies after an infection but no clinical consequences related to APS or CAPS (31%).

The most common preceding infections across all groups was viral (55.5% of cases), including human immunodeficiency virus, hepatitis C virus, and parvovirus B19. Bacterial infections were reported in 36.7% of cases with streptococci, mycoplasma pneumonia, and coxiella burnetii infections being the most common. Parasitic infections were reported in 3.9%, fungal infections in 2.1%, and multiple types of infection in 8.9%. Infection was the sole precipitating factor in 79.7% of reported cases.

Thromboembolic manifestations were the most common presenting feature among patients in groups 1 and 2. Patients across all groups had at least 1 positive aPL antibody with persistent positive antibodies observed mainly among patients in group 1. Anticardiolipin (aCL) antibodies were the most frequently reported, often with coexisting IgG and IgM antibodies. Anticoagulation therapy was the mainstay of treatment in the majority of cases in groups 1 and 2. Clinical outcomes varied considerably and included persistent manifestations of APS or CAPS and death in Group 1. Resolution of clinical events and disappearance of aPL antibodies were most frequently reported in groups 2 and 3.

Conclusion: Development of aPL antibodies, APS, and CAPS can occur after infection with various virus, bacteria, fungus and parasites. Further longitudinal studies should be conducted to better quantify the risk and outcomes of APS or CAPS after infection.

The Effect of Clinically Significant Antiphospholipid Antibody Positivity on Organ Damage in Systemic Lupus Erythematosus. Mara Taraborelli[1], Laura Leuenberger[2], Wei Zhang[2], Angela Tincani[3], Jane Salmon[2] and Doruk Erkan[2]. [1]Spedali Civili and University of Brescia, Brescia, Italy, [2]Hospital for Special Surgery, New York, NY, [3]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy.

Background/Purpose: The effect of antiphospholipid antibodies (aPL) on organ damage in Systemic Lupus Erythematosus (SLE) patients remains unclear as there are limited number of studies with contrasting conclusions. The aim of this study was to assess the relative contribution of aPL to organ damage in SLE patients.

Methods: SLE patients (based on American College of Rheumatology [ACR] Classification Criteria) with less than 10 years of disease duration at registry entry were identified from an SLE registry. Clinical information retrieved included: demographics, disease duration, organ damage assessed by the Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI), and aPL profile. A "clinically significant" aPL profile was

defined as: positive lupus anticoagulant test, anticardiolipin antibody IgG/M/A ≥ 40U, and/or anti-β_2Glycoprotein-I IgG/M/A ≥ 40U on two or more occasions, at least 12 weeks apart, within ± 1 year of registry entry. The outcome variable was any increase of SDI at 5 years of follow-up (time 0 was defined as registry entry). For univariate analysis the demographic and clinical characteristics of patients with and without a SDI increase at 5 years were compared (Chi square or Fisher's exact test for categorical data, Student t test or Mann-Whitney for continuous data as appropriate). The Generalized Estimated Equations (GEE) model was used as multivariate analysis to detect significant factors for increased SDI at 5 years.

Results: Of 394 patients with less than 10 years of disease duration, 112 (28%) had at least 5 years of prospective follow-up and a complete aPL profile (44% Caucasian, 19% African-American, 15% Asian, and 89% female). Mean age at diagnosis was 32 years (±13) and mean age at registry entry was 35 years (±13) with mean disease duration of 3 years (±2). Twenty-one (19%) patients had clinically significant aPL profile (isolated IgA positivity only in 5 patients, 4%). Damage was present (SDI ≥ 1) in 18/112 (16%) of patients with a mean SDI of 1.9 (±1.7) at the registry entry, and in 27/112 (24%) at 5 years follow-up with a mean of 2.4 (±2.0). An increase of SDI (range: 1–5 points) after 5 years of follow-up was observed in 16/112 (14%) of patients. On a univariate analysis, no significant associations were found between any increase of SDI at 5 years and aPL profile, race, gender, age at diagnosis, and disease duration. The GEE model confirmed the lack of an association between the aPL profile and organ damage; African-American (Odds Ratio, [OR]: 7.58, 95% Confidence Interval, [CI]: 1.54–37.27, p: 0.013) and Asian (OR: 8.1, 95% CI: 1.49–44.16, p: 0.016) patients had significantly higher risk of increased SDI at 5 years.

Conclusion: Our preliminary data demonstrate that: a) approximately 15% of SLE patients have new organ damage in 5 years; b) one-fifth of SLE patients have clinically significant aPL profiles; and c) there is no association between organ damage and clinically significant aPL-profile.

Adenosine Receptors Stimulate Bone Regeneration. Aranzazu Mediero[1], Tuere Wilder[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Such orthopedic procedures as spinal fusion and repair of bone defects due to trauma, infection or metastatic disease, require formation of new bone. Adenosine, acting via stimulation of the A_{2A} receptor (A2AR), inhibits osteoclast differentiation. Here we determined whether direct A2AR stimulation or enhancing adenosine concentrations via blockade of purine transport into cells via ent1 with dipyridamole regulates bone formation in a murine calvarial model.

Methods: 6–8-wk male C57Bl/6 mice (WT) or A_{2A}KO were anesthetized; a 3mm trephine defect was formed and covered with a collagen scaffold soaked in saline or CGS21680 (A2AR agonist) or dipyridamole (1mM each) alone or in the presence of ZM241385 1mM (A2AR antagonist). Animals received appropriate treatment daily until sacrifice. Bone Morphogenetic Protein 2 (BMP-2) 200ng was used as a bone formation control. At 0, 2, 4, 6 and 8 weeks calvarias were harvested and prepared for microCT and histology. XenoLight Rediject Bone Probe 680 was injected intravenously at different time points and used to probe bone formation (fluorescence).

Results: 8 weeks after surgery microCT examination of WT mouse calvaria demonstrated that both CGS21680 and dipyridamole markedly enhanced bone regeneration as well as BMP-2 (60±2%, 79±2% and 75±1% bone regeneration, respectively, vs. 32±2% in control, $p<0.001$, n=5 mice per condition). Both CGS21680 and dipyridamole effects were abrogated by ZM241385 (20±3% and 26±4% bone regeneration, respectively, vs. 32±2% in control, p=ns, n=5 mice per condition). Neither CGS21680 nor dipyridamole enhanced bone formation in A_{2A}KO mice. In CGS21680- and dipyridamole-treated WT mice there was increased immunostaining for bone formation markers in the bony defects (Alkaline Phosphatase positive cells/hpf increased from 15±1 for control to 21±1 for CGS21680 and 24±1 for dipyridamole, $p<0.001$). TRAP staining revealed fewer osteoclasts in CGS21680- and dipyridamole-treated defects (17±1 and 16±1 osteoclast/hpf respectively vs. 24±1 Osteoclast/hpf for control, $p<0.001$) 8 weeks after defect formation, an effect blocked by ZM241385 or absent in A2AR KO mice. *In vivo* imaging with XenoLight Rediject Bone Probe 680 (a marker of bone formation) reveals a markedly increased fluorescent signal in treated animals, equivalent to BMP-2, when compared to control as soon as one week after bone defect formation and which lasts for at least 7 weeks.

Conclusion: Stimulation of A2AR increases the rate of new bone formation at sites of surgical bone defects as well as BMP2, a finding which suggests that targeting A2AR may be an effective way to increase bone formation following orthopedic procedures.

High Systemic LDL Cholesterol Levels during Experimental Osteoarthritis Lead to Increased Synovial Activation and Ectopic Bone Formation at End-Stage Osteoarthritis, While Excessive Levels Accelerate Development of Joint Pathology Already at Early-Stage Osteoarthritis. Wouter de Munter, Martijn H. van den Bosch, Annet W. Sloetjes, Peter M. van der Kraan, Wim B. van den Berg and Peter L. van Lent. Radboud university medical center, Nijmegen, Netherlands.

Background/Purpose: A relation between osteoarthritis (OA) and the metabolic syndrome has long been established. One of the characteristics of the metabolic syndrome is increased cholesterol levels. In a recent study, we showed that LDL accumulation by LDL receptor deficient mice resulted in increased ectopic bone formation during experimental osteoarthritis.

In the present study we investigate OA pathology in ApoE deficient ($ApoE^{-/-}$) mice with and without a cholesterol-rich diet, which is a model for extremely high systemic LDL cholesterol levels.

Methods: Wild type (WT) and $ApoE^{-/-}$ mice received a normal or cholesterol-rich diet for 54 days. At day 18, experimental OA was induced by intra-articular injection of collagenase and animals were sacrificed at day 28 and 54. Joint pathology was investigated by histology. LDL levels were measured in serum and synovial wash-outs.

Results: $ApoE^{-/-}$ mice on a normal diet showed markedly higher LDL levels than WT mice (8.90 mmol/L and 0.40 mmol/L, respectively; $p<0.001$). While no differences between the two groups were found at the early time point (day 28), end point OA (day 54) in $ApoE^{-/-}$ mice showed a strong increase of ectopic bone formation, mainly at the medial collateral ligament (fold increase 5.4; $p<0.001$) compared to WT mice. No significant differences in cartilage damage were found between the two groups; a slight increase in synovial thickening, however, was found in $ApoE^{-/-}$mice (arbitrary score 1.9 versus 1.1 in WT mice; $p<0.05$). Furthermore, synovial gene expression of both S100A8 and S100A9 (fold increase 1.8 and 1.4, respectively; $p<0.05$) and S100A8/S100A9 protein levels of synovial wash-outs were increased in ApoE−/− mice (fold increase 5.8; $p<0.05$), suggesting an activated status of synovial lining cells.

In addition, we investigated whether a cholesterol-rich diet could increase joint pathology after induction of OA. The diet increased LDL levels even more in $ApoE^{-/-}$ mice (fold increase 2.1, compared to $ApoE^{-/-}$ mice on a normal diet; $p<0.001$). In both $ApoE^{-/-}$ and WT mice on a cholesterol-rich diet, excessive bone formation was found in the medial collateral ligament at day 54, however, no significant difference was found between the two groups. Interestingly, at the early time point (day 28; 10 days after OA induction), histological differences between the two groups were observed. Synovial thickening was four times increased ($p<0.001$) in $ApoE^{-/-}$mice on a cholesterol-rich diet and also ectopic cartilage formation in the medial collateral ligament was strongly increased (fold increase 2.7; $p<0.01$) compared to WT mice on a cholesterol-rich diet.

Conclusion: LDL cholesterol accumulation by ApoE deficiency or a cholesterol-rich diet results in increased synovial activation and ectopic bone formation in experimental OA. Excessive LDL levels induced by a combination of ApoE deficiency and a cholesterol-rich diet did not affect joint pathology at end-stage OA, but rather accelerates synovial activation and ectopic bone formation, resulting in early pathology.

Mendelian Randomization Analysis to Examine for Causal Relationships Between Serum Urate Levels and Bone Mineral Density. Nicola Dalbeth[1], Ruth Topless[2], Tanya Flynn[2], Murray Cadzow[2], Mark Bolland[1] and Tony R. Merriman[2]. [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Dunedin, New Zealand.

Background/Purpose: In observational studies, serum urate is positively associated with bone mineral density (BMD) and reduced risk of fragility fractures. However, the possibility of unmeasured confounding means that it is uncertain whether urate is a direct mediator of bone density. Mendelian randomization analysis assumes that inherited genetic risk variants for one phenotype are naturally randomized with respect to a second unrelated phenotype, and allows disentangling of cause and effect in the presence of potential confounding. We used Mendelian randomization analysis to examine whether there is a causal relationship between serum urate and BMD.

Methods: We analysed data from the Generation 3 cohort in the Framingham Heart Study (FHS). Inclusion criteria were availability of serum urate, BMD, body mass index (BMI) and genotype data. Exclusion criteria were eGFR<30, and any of the following medications: diuretics, bisphosphonates, oral glucocorticoids and hormone replacement therapy. A weighted urate genetic risk score (GRS) was calculated using SNPs for *SLC2A9, ABCG2, SLC17A1, SLC22A11* and *SLC22A12* based on the genome wide association study by Kottgen et al[1]. Mendelian randomization analysis was done using the two-stage least squares (2SLS) method, this first calculates each individual's genetically determined predictor levels (predicts urate levels based on the urate GRS) then regresses these calculated predictor values against the outcome (BMD). The analysis was adjusted for age, sex, menopause status in women, BMI and the first two principal components from genome-wide genotype data.

Results: There were 2553 eligible participants. The urate GRS accounted for 3.3% of the variance in serum urate in the total group. A strong association between serum urate at Examination 1 and BMD at Examination 2 was observed in the unadjusted ordinary least square analysis ($p<8E-17$ for all BMD measures, Table), which was attenuated but persisted at the spine and total femur following adjustment for potential confounders. In the genetic 2SLS analysis, no significant relationship was observed between urate and BMD, either in the unadjusted or adjusted analysis. For total femur and femoral neck BMD, the effect sizes for the ordinary least square and 2SLS analysis were significantly different (Durbin-Hausman $p<0.02$). Similar findings were observed in both the male and female subgroups. Analysis of a causal role for BMD on serum urate levels using a weighted BMD GRS did not demonstrate evidence for reverse causation (data not shown).

Conclusion: Serum urate is strongly associated with BMD. However, controlling for confounders by Mendelian randomization does not provide evidence that serum urate is causal in increased BMD.

Adenosine a_{2A} Receptor (A2AR) Stimulation Inhibits Osteoclast Differentiation and Promotes Osteoblast Formation By Regulation of Axon Guidance Proteins. Aranzazu Mediero[1], Miguel Perez-Aso[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]New York University, New York City, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Semaphorins (Sema), axonal guidance proteins, play a role in communication between osteoclast and osteoblast. Thus, sema4D, secreted by osteoclasts, binds to its receptor PlexinB1 on osteoblasts to inhibit osteoblast differentiation and function whereas sema3A, produced by osteoblasts, binds to PlexinA1/Neuropilin-1 to both inhibit RANKL-induced osteoclast differentiation and stimulate osteoblast differentiation and function. Because stimulation of A2AR diminishes osteolysis we asked whether $A_{2A}R$ activation regulates bone homeostasis by regulating osteoclast and osteoblast expression of semaphorins.

Methods: Osteoclast and osteoblast differentiation were studied in primary murine bone marrow culture as the number of TRAP-positive or Alizarin Red-positive cells, respectively, after challenge in the presence/absence of CGS21680 (A_{2A} agonist) 1μM and ZM241385 ($A_{2A}R$ antagonist) 1μM together with recombinant Sema4D or Sema3A 10ng/ml each. Sema3A/PlexinA1/Neuropilin-1 and Sema4D/PlexinB1 expression were studied by RT-PCR and Western Blot in bone marrow-derived osteoclasts and osteoblasts in the presence/absence of CGS21680 and ZM241385 1μM each. RANKL and Osteoprotegerin (OPG) levels were studied by RT-PCR. β-catenin activation was studied in primary osteoblast culture. Cytoskeleton changes were studied in osteoclasts.

Results: RANKL induced a 2.5±0.1 fold increase in Sema4D mRNA ($p<0.001,n=4$) in osteoclasts which was blocked by CGS21680 (1.3±0.3 fold change, $p<0.001,n=4$). In contrast, PlexinA1 mRNA was enhanced by CGS21680 (9.3±0.7 fold increase vs 4.9±0.6 for RANKL, $p<0.001,n=4$) but Neuropilin-1 mRNA was unchanged. Sema3A mRNA increased 3.5±0.5 fold during osteoblast differentiation and CGS21680 enhanced this increase (8.7±0.2 fold, $p<0.001,n=4$); PlexinB1 mRNA was increased 2 fold during osteoblast differentiation and was not altered by CGS21680. Similar changes were observed at the protein level. CGS21680 decreased RANKL expression and increased OPG expression in osteoblasts. Total and nuclear β-catenin expression were increased in osteoblasts after CGS21680 treatment and this increase was abrogated by ZM241385. Sema4D increased RhoA phosphorylation and FAK activation in osteoclast precursors and these effectswere reversed in the presence of CGS21680.

Conclusion: A2AR activation diminishes secretion of Sema4D by osteoclasts and enhances secretion of Sema3A by osteoblasts leading to an increase in osteoblast differentiation and function, and, in combination with the suppressive effects of $A_{2A}R$ on osteoclast differentiation and function, diminishes bone osteolysis.

Activation of EPAC1/2 Is Essential for Osteoclast Formation By Modulating NFkB Nuclear Translocation and Actin Cytoskeleton Rearrangements. Aranzazu Mediero[1], Miguel Perez-Aso[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]New York University, New York City, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Bisphosphonates inhibit osteoclast differentiation/function via inhibition of Rap1A isoprenylation and cytoskeletal assembly. As Rap1 is the effector of EPAC proteins (exchange *protein* directly activated by cAMP), we determined the role of EPAC in osteoclast differentiation.

Methods: Osteoclast differentiation was studied as the number of TRAP+ multinucleated cells following M-CSF/RANKL stimulation of either primary murine or human bone marrow precursors in the presence of the EPAC-selective cAMP analog 8-CPT-cAMP (100nM) and the EPAC inhibitor BFA (10μM). Rap1 activity assay was performed. Signaling events were studied by Western Blot in EPAC1/2 knockdown (lentiviral shRNA for EPAC1 or EPAC2 or scrambled shRNA) RAW264.7 cells. Osteoclast marker

expression was studied by RT-PCR. Osteoclast morphological characterization was studied by phalloidin staining.

Results: 8-CPT-cAMP significantly increased osteoclast differentiation whereas BFA inhibited differentiation (113±3% ($p<0.05$) and 42±2% ($p<0.001$) of control, respectively, n=6). Rap1 activation was maximal 15 min after RANKL stimulation (136±3% of basal, $p<0.001$, n=4) whereas silencing of EPAC1/2 diminished activated Rap1 (43±2% and 50±5% of control respectively, $p<0.01$, n=4) and NFkB translocation. TRAP staining revealed no osteoclast differentiation in EPAC1/2 KO cells. Cathepsin K, NFATc1 and Osteopontin mRNA expression decreased in EPAC1/2 KO cells when compared to control. Activation of RhoA, cdc42, Rac1 and FAK were observed in an EPAC1/2 dependent manner and there was diminished cytoskeletal assembly in EPAC1/2 KO cells.

Conclusion: EPAC1/2 are critical signaling intermediates in osteoclast differentiation that permit RANKL-stimulated NFkB nuclear translocation and actin rearrangements. Targeting this signaling intermediate may diminish bone destruction in inflammatory arthritis.

Netrin1 Is Highly Expressed and Required in Inflammatory Infiltrates in Wear Particle-Induced Osteolysis. Aranzazu Mediero[1], Bhama Ramkhelawon[1], Ed Purdue[2], Steven R. Goldring[2], Kathryn Moore[1] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Osteoclasts play a critical role in homeostatic bone turnover and pathologic bone destruction. Netrin-1, expressed in the marrow only by osteoclast precursors, acts in an autocrine manner via its receptor Unc5b (but not its receptor DCC) to stimulate osteoclast differentiation *in vitro*. Here we tested the hypothesis that blockade of Netrin-1 or Unc5b diminishes wear particle-induced osteolysis in a mouse model.

Methods: A 1-cm midline sagittal incision was made over the anterior calvarium to the line connecting both ears in anesthetized 6–8-wk-old male C57BL/6 mice. 3mg of dried UHMWPE particles were implanted and animals were treated with either 0.9% saline, Netrin-1 antibody, Unc5b antibody or DCC antibody (Rabbit polyclonal for all). 100μg antibodies were injected intraperitonally the day of surgery and then once a week. Animals were sacrificed after 14 days and calvaria were removed, fixed, and prepared for microCT and histology. Netrin-1 immunostaining was performed in human tissue obtained following primary prosthesis implantation or after prosthesis revision for peri-implant osteolysis and aseptic implant loosening.

Results: Weekly ip injection of anti-Netrin-1 or anti-Unc5b antibodies significantly reduced the area of particle-induced bone pitting in calvaria exposed to UHMWPE (46±4 and 49±3% bone pitting, respectively, compared to control, $p<0.001$, n=5) but anti-DCC receptor antibody did not affect UHMWPE-induced pitting and resorption (80±7% bone pitting, p=ns vs control). MicroCT also revealed a significant increase in bone volume (BV) and bone volume/total volume ratio (BV/TV) in both Netrin-1 and Unc5b antibody treated mice. Anti-Netrin-1 or anti-unc5b antibody treatment markedly reduced both the inflammatory infiltrate and the number of TRAP-positive osteoclasts in affected bone (7±1 and 4±1 cells/hpf respectively vs. 12±1 for control, $p<0.001$). In contrast, treatment with anti-DCC antibody did not significantly reduce the number of osteoclasts in affected bone. There were no significant changes in Alkaline Phosphatase positive osteoblasts on bone forming surfaces in any antibody-treated group compared to control (8±1, 10±1 and 10±2 cells/hpf, vs. 10±1 for control, p=ns). The peri-implant tissues of patients undergoing prosthesis revision surgery show a similar increase in Netrin-1 expression whereas there is little Netrin-1 expression by cells in soft tissues removed at the time of primary joint replacement.

Conclusion: These results demonstrate a unique role for netrin-1 in osteoclast biology; netrin-1 is an autocrine and paracrine regulator of osteoclast differentiation and may be a novel target for prevention or treatment of inflammatory osteolysis.

Cronstein**, Canfite Pharma, 1, AstraZeneca, 2, Cellgene, 2, Gilead, 2, NIH, 2, NYU School of Medicine, 3, Bristol-Myers Squibb, 5, Pfizer Inc, 5, Eli Lilly and Company, 5, Rheumatology Reseach Foundation, 6, ACR, 6, Arthritis Foundation, 6.

25

DC-STAMP Modulates Osteoblast Differentiation and Regulates Bone Repair. Yahui Grace Chiu[1], Tzong-Ren Sheu[1], Jinbo Li[1], Dongge Li[1], Michael Thullen[1], Brendan Boyce[2], Edward Puzas[1] and Christopher T. Ritchlin[3]. [1]University of Rochester, Rochester, NY, [2]University of Rochester, Rocehster, NY, [3]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Patients with osteoporosis and the elderly have an increased risk of bone fracture. Currently, no biomarker is available to assess bone healing status in fracture patients. Although a coordinated interaction between osteoclasts (OC) and osteoblasts (OB) is required for bone repair after fracture, the molecular mechanisms underlying bone repair are not well understood. We previously demonstrated that DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a 7-pass transmembrane protein essential for cell-to-cell fusion during OC differentiation, is a biomarker of OC precursors (OCP). Intriguingly, an elevated OCP frequency was observed that correlated with an increased frequency of circulating DC-STAMP+ cells in two bone fracture patients 8-week post-fracture. Thus, we hypothesized that multinucleated OC are essential for optimal bone repair and that the frequency of DC-STAMP$^+$cells may serve as biomarkers to assess bone healing. The function of OB and OC in bone fracture and healing was dissected in the DC-STAMP knock-out (KO) mice which lack mature multinucleated OC.

Methods: OB differentiation, bone healing and bone quality were compared between gender- and age-matched wild-type and DC-STAMP KO littermates. OB differentiation was assessed by mineral nodules and ALP$^+$ cells (OB marker) quantification. Bone fracture and callus formation were examined by uCT, x-ray and histology analysis. Bone quality was tested by biomechanical assays including 3-point bending and torsion test. The presence of DC-STAMP$^+$ cells at fresh fracture sites and at healed regions was examined by immunofluorescence. The frequency of circulating DC-STAMP$^+$cells in two bone fracture patients was analyzed by flow cytometry.

Results: In mice, DC-STAMP$^+$ cells were identified at fresh fracture sites and in blood vessels traversing surrounding tissues. DC-STAMP KO mice demonstrated decreased OB differentiation (WT vs. KO: 0.6 +/− 0.1 vs. 0.1 +/− 0, p=0.05 and 0.8 +/− 0.2 vs. 0.15 +/− 0.1 cm^2/well, p=0.01 for mineral nodules and Alp+ cells, respectively) and delayed bone healing (WT and KO mice healed on wk3 and wk6, respectively, post-fracture). Tibias from KO mice have a higher stiffness as demonstrated by torsional analysis (1226 +/− 308 vs. 1762 +/− 527 N/mm for WT and KO, p=0.1). In humans, two bone fracture patients had a significant increase in the frequency of circulating DC-STAMP$^+$cells and elevated OCP frequency (healthy, 185 +/− 62; patients, 1,250 +/− 65 per 10e6 monocytes).

Conclusion: These findings suggest that (1) DC-STAMP is involved in bone healing based on the presence of DC-STAMP$^+$ cells surrounding the fracture sites; (2) Both OB and OC are required for an efficient healing of bone fractures; (3) Elevation of OCP frequency and the number of circulating DC-STAMP$^+$ cells in two patients with recent fracture suggest that an increased DC-STAMP$^+$ cell frequency might serve as a surrogate marker reflecting active ongoing bone remodeling during the course of bone repair. Our data suggest that in addition to its critical role in regulating OC development, DC-STAMP is also involved in OB differentiation and bone repair. Thus, DC-STAMP has potential to serve as a bone-repair biomarker and therapeutic target to promote fracture healing.

Functional Osteoclasts Differentiate Spontaneously from the Rheumatoid Joint. Stinne Greisen[1], Halldór Bjarki Einarsson[1], Malene Hvid[1], Ellen Margrethe Hauge[2], Bent Deleuran[3] and Tue Kragstrup[1]. [1]Aarhus University, Aarhus, Denmark, [2]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark.

Functional osteoclasts differentiate spontaneously from the rheumatoid joint

Background/Purpose: Osteoimmunology is a field of emerging interest in which bone formation and resorption are understood in the context of the immune system. In rheumatoid arthritis (RA) uncontrolled joint inflammation alters the balance between osteoclasts and osteoblasts resulting in bone resorption. The inflamed joint in RA contains multiple factors contributing to the activation of osteoclasts, among these RANKL, M-CSF, TNFα and IL-17 secreted from activated fibroblast-like cells and T-cells. In this study, we

aimed to investigate the potential of synovial fluid mononuclear cells (SFMCs) to develop into functional osteoclasts in vitro.

Methods: Synovial fluid was collected from inflamed joints of chronic RA patients at the out patient clinic at Aarhus University Hospital. SFMCs were isolated using ficoll paque and cultured in DMEM (+10% FCS + 2% penicillin/streptomycin + 1% glutamin) at a concentration of 0.5×10^6 cells/cm^2 (n=5). Following 21 days in culture, cells were TRAP stained and examined in light microscopy or lysed for qPCR for the common osteoclast genes calcitoninR, cathepsinK and beta3 integrin. To investigate functionality, SFMCs were also cultured on dentin plates for 21 days. To potentially increase the osteoclast differentiation in the SFMC cultures, culture medium was supplemented with RANKL (50ng/ml) and M-CSF (25ng/ml). As a control, conventional osteoclasts where cultured from healthy control monocytes with RANKL (50ng/ml) and M-CSF (25ng/ml).

Results: SFMCs cultured for 21 days differentiate into both multinucleated TRAP positive osteoclasts (6.7%, SD 4.8%) and mononuclear TRAP positive pre-osteoclasts (43.2%, SD 0.45%) (Fig 1). These cells expressed the common osteoclast genes calcitonin receptor, cathepsin K and beta3 integrin. Both the percentage of TRAP positive multinucleated cells (8.3%) and gene expression were comparable with conventional osteoclasts. Adding RANKL and M-CSF to SFMC cultures increased the percentage of multinucleated TRAP positive cells to 15.3% (SD 1.5%). SFMCs cultured on dentin plates finally confirmed the osteoclast phenotype of these cells, as the dentin was digested in the same manner as observed with conventional osteoclasts cultured on dentin plates.

Conclusion: Here we provide a new and simple method for generating functional osteoclasts from RA SFMCs. This spontaneous differentiation of osteoclasts from cells of the arthritic joint provides a new understanding of the inflamed joint and could explain the increased bone resorption observed in RA. Because osteoclasts are one of the ultimate effector cells in RA, this method could be a new tool to evaluate the effect of novel signaling molecules or the effectiveness of new drugs.

CD115$^+$ Osteoclast Precursors Arise before Clinical Onset of Arthritis and Are Regulated By Proinflammatory Cytokines. Antonia Puchner[1], Victoria Saferding[1], Eliana Goncalves-Alves[1], Silvia Hayer[1], Harald Leiss[1], Josef S. Smolen[2], Kurt Redlich[1] and Stephan Blüml[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Bone erosions and systemic bone loss in rheumatoid arthritis patients results from an increased activity of osteoclasts, which are derived from precursor cells of the myeloid lineage. Although there is much known about the mechanisms regulating the formation and activation of mature osteoclasts, the identity of an osteoclast precursor population in and its regulation by inflammatory cytokines during arthritis is poorly understood.

Methods: HTNFtg mice were clinically scored once per week for grip strength and swelling. In addition, blood was collected every week starting on week 4. Mice were sacrificed at week 10 - blood, spleen and bone marrow were collected for flow cytometry analysis. IL1/IL6$^{-/-}$ were crossed into hTNFtg mice and blood was also analyzed. K/BxN Arthritis was induced in wild type mice, blood and spleen were collected 14 days after disease induction. Different monocyte subsets were Facs-sorted and cultured in the presence of RANKL and MCSF to induce osteoclasts.

Results: We show that during TNF-driven arthritis CD11b$^+$ CD115$^+$ cells are elevated in blood before the onset of clinical symptoms and remain elevated throughout. In particular, a certain subset of CD11b$^+$ myeloid cells that express intermediate levels of Ly6G expand in blood, spleen and bone marrow during arthritis. Of these, 89% express CD115, the MCSF-receptor. The increase of this population is not only observed in TNF-driven arthritis, but also in K/BxN arthritis. IL-1 and/or IL-6 importantly regulate the expansion of these cells as in IL1/IL-6 double deficient hTNFtg we did not detect an elevation of this subset. After sorting this cells both subsets were able to form mature osteoclasts *in vitro*.

Conclusion: CD115$^+$ CD11b$^+$ cells with osteoclastogenic potential increase during inflammatory arthritis. This process, at least in TNF-driven arthritis is regulated by proinflammatory cytokines IL-1 and or IL-6. Elevated numbers of these cells can be detected before clinical onset of disease and therefore may provide a biomarker for inflammatory arthritis.

Evidence for Receptor Activator of NF-Kb (RANK)-Independent Bone Erosion in the Cherubism Mouse Model of Inflammatory Arthritis. William R. O'Brien, Julia F. Charles, Kelly Tsang and Antonios O. Aliprantis. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: A gain-of-function mutation in the adaptor Src Homology 3 Binding Protein 2 (SH3BP2) causes Cherubism, a rare pediatric disease marked by aggressive bone remodeling in the mandible and maxilla. Mice homozygous for the most common Cherubism mutation (*Sh3bp2$^{KI/KI}$*) display TNFa-dependent osteopenia and inflammatory arthritis with periarticular bone erosions. We sought to investigate whether bone-resorbing osteoclasts are key cellular mediators of the systemic bone loss and local inflammatory erosion observed in this model. To this end, *Sh3bp2$^{KI/KI}$* mice with an inducible mutation in *Rank*, encoding a master regulator of osteoclast differentiation, were generated.

Methods: We generated *Sh3bp2$^{KI/KI}$* RANK-deficient mice using *Mx1-Cre* driven deletion of floxed *Rank* alleles after intra-peritoneal injection of poly-IC at 10-days of age (referred to as *Sh3bp2$^{KI/KI}$ Rank$^{\Delta/\Delta}$*). Control mice, also treated with poly-IC, included *Sh3bp2$^{KI/KI}$ Rank$^{fl/fl}$* without the *Mx1-Cre* transgene, *Sh3bp2$^{+/+}$Rank$^{fl/fl}$* and *Sh3bp2$^{+/+}$ Rank$^{\Delta/\Delta}$*. Bone mass, periarticular erosions and synovitis were assessed by a combination of microcomputed tomography (mCT) and histology at 12 weeks of age.

Results: Neither *Sh3bp2$^{+/+}$Rank$^{fl/fl}$* nor *Sh3bp2$^{+/+}$ Rank$^{\Delta/\Delta}$* displayed inflammatory arthritis or bone erosion. *Sh3bp2$^{+/+}$ Rank$^{\Delta/\Delta}$* developed severe osteopetrosis, consistent with osteoclast-deficiency. As previously reported, *Sh3bp2$^{KI/KI}$* sufficient for RANK (*Sh3bp2$^{KI/KI}$ Rank$^{fl/fl}$*) developed osteopenia and inflammatory arthritis at the elbow joint with marked peri-articular erosions. Depletion of osteoclasts by genetic deletion of *Rank* reversed the systemic osteopenia observed in *Sh3bp2$^{KI/KI}$* mice but had no effect on synovitis at the elbow. Unexpectantly, peri-articular erosions at the elbow joints were not ameliorated in *Sh3bp2$^{KI/KI}$ Rank$^{\Delta/\Delta}$* mice despite a significant reduction in tartrate-resistant acid phosphatase (TRAP) positive osteoclasts.

Conclusion: Deletion of *Rank* inhibits osteoclastogenesis and reverses systemic osteopenia in *Sh3bp2$^{KI/KI}$* mice. In contrast, while the loss *Rank* reduces classic TRAP-positive osteoclasts at the inflamed elbow joints of *Sh3bp2$^{KI/KI}$* mice, it does not reduce local bone erosion. These intriguing findings suggest an alternative pathway to bone erosion exists in the *Sh3bp2$^{KI/KI}$* model of inflammatory arthritis that is independent of RANK.

Impaired Bone Healing in Patients Suffering from Rheumatoid Arthritis - Anti-Inflammatory Therapy As Confounder. Annemarie Lang[1], Sarah Fuegener[2], Paula Hoff[2], Anastasia Rakow[2], Manuela Jakstadt[3], Timo Gaber[3], Gerd Burmester[2], Carsten Perka[2] and Frank Buttgereit[2]. [1]Berlin-Brandenburg School of Regenerative Therapies (BSRT), Berlin, Germany, [2]Charité University Medicine, Berlin, Germany, [3]Berlin-Brandenburg Center of Regenerative Therapies (BCRT), Berlin, Germany.

Background/Purpose: Anti-inflammatory treatment of rheumatoid arthritis (RA) with glucocorticoids (GC) and/or non-steroidal anti-inflammatory drugs (NSAIDs) is supposed to negatively influence bone metabolism and healing. It should be noted, however, that RA itself is suspected to promote bone healing complications. However, studies addressing the number of afflicted patients and/or quantifying the negative impact of preexisting comorbidities and treatment with GC and/or NSAIDs on the bone fracture healing process are scarce. Thus, we hypothesized that both (i) suffering from RA and (ii) treatment with either GC or NSAIDs represent risk factors of bone healing disorders.

Methods: To test our hypothesis, we performed a single-center retrospective study based on the database of the Center for Musculoskeletal Surgery at Charité University Hospital Berlin to measure the impact of RA, GC and NSAID on bone healing complications. All patients who underwent surgery at our institution for treating fracture healing complications in 2012 were included. Exclusion criteria were patients with an age below 18 years at initial fracture, open fracture, and metastases close to fracture location. A control group matched for age and type of fracture at the ratio of two was considered for comparison. In parallel, we conducted *in vitro* experiments analyzing the impact of GC and NSAID on osteogenic differentiation of mesenchymal stromal cells (MSC) and the counteracting ability of hypoxia and the hypoxia-inducible factor (HIF) stabilizer deferoxamine (DFO). To this end, human bone marrow derived MSC were cultured, characterized and differentiated into osteoblasts under normoxic (37°C, 5% CO_2, 18% O_2) or hypoxic (37°C, 5% CO_2, 1% O_2) conditions using varying doses of dexamethasone (10^{-3} - 10^{-8} M), ibuprofen ($5x10^{-3}$ - $5x10^{-5}$) and desferrioxamine (DFO; 125–500μM). The calcification process during osteogenesis was analyzed using a quantifiable alizarin red staining method.

Results: Retrospective analysis included 93 patients with fracture-healing complications and 193 controls; both groups equally represented both sexes. We found a 10.6% higher probability ($p=0.036$) of fracture healing disorders in RA patients compared to the controls with a higher rate of these patients being treated with GC and NSAID, respectively. In our *in vitro* studies, we could demonstrate a concentration-dependent significant inhibitory effect of dexamethasone and ibuprofen on the osteogenetic capacity of MSC which could be considerably antagonized by either hypoxia or DFO.

Conclusion: The results we have obtained so far support the hypothesis that both RA and GC medication have a negative impact on the outcome of fracture healing. Our results also demonstrate that GC and NSAID inhibit MSC differentiation which could contribute to explain impaired fracture healing. In addition, we demonstrate a positive effect of (chemically induced) hypoxia promoting osteogenic differentiation and being a promising tool to overcome bone healing disorders which result from anti-inflammatory treatment.

Inhibiting Autocrine Interleukin-6 (IL-6) Trans-Signalling in Human CD14^{+ve} Monocultures Reduces Osteoclast Differentiation. Lauren A. Jordan[1], Fraser L. Collins[2], Simon A. Jones[1], Ernest H. Choy[1], Ann K. Harvey[1] and Anwen S. Williams[1]. [1]Cardiff University, Institute of Infection and Immunity, School of Medicine, Cardiff, United Kingdom, [2]Michigan State University, Department of Physiology, East Lansing, MI.

Background/Purpose: Interleukin-6 (IL-6) and the inflammatory CC-chemokine CCL3 are highly expressed in rheumatoid arthritis, juvenile idiopathic arthritis and multiple myeloma. While these mediators contribute to bone pain, osteoclast (OC) formation and bone resorption, the relationship of their activities to disease outcome remains unknown. For the first time, we measured the autocrine and paracrine regulation of CCL3 production by OC cultures in response to IL-6 (in combination with the soluble IL-6 receptor; termed IL-6 *trans*-signalling). Experiments identified a novel disease-activity determinant for inflammatory arthritis patients.

Methods: Human CD14^{+ve} monocytes isolated from peripheral blood were grown on ivory disks in medium containing macrophage colony stimulating factor (10 ng/mL; m-CSF) for 7 days. Cells were subsequently differentiated into OC in medium supplemented with m-CSF (5 ng/mL) and receptor activator of nuclear factor kappa-B ligand (5 ng/mL) for 17 days. Conditioned media was recovered on day 0, 3, 7, 10, 14 and 17, and levels of CCL3, IL-6 and sIL-6R were quantified with ELISA. OC formation was visualised by staining with tartrate-resistant acid phosphatase (TRAP) on ivory disks harvested at baseline (day 0), and day 7, 10, 14 and 17 of culture. Add-back studies using anti-CCL3 antibody (0–8 ng/mL) or osteoprotegerin (OPG; 100 ng/mL) were also performed. IL-6 *trans*-signalling was modulated using an engineered chimeric IL-6-sIL-6R fusion protein (HDS agonist; 10 ng/mL) and soluble gp130 (sgp130 antagonist; 500 ng/mL). Cytokine release was reported as mean±SEM and statistical significance through 2-way ANOVA, Spearman's rank co-efficient or student's t-test as appropriate.

Results: No OC or TRAP^{+ve} cells were observed in culture on day 0. OC numbers reached maximum levels after 14 days in culture (338±117 per disk; $P<0.001$). OPG supplementation potently inhibited OC formation on day 14 (8±3 per disk, $P<0.01$). A significant correlation between CCL3 levels and OC number was observed ($P<0.01$, R= 0.32). IL-6 (140±36 pg/mL and 48±28 pg/mL) and soluble IL-6 receptor (30±9 pg/mL and 19±7 pg/mL) levels were maintained throughout the culture period (day 0 and 14 reported). In add-back experiments using a neutralizing CCL3 antibody, OC numbers decreased in a concentration-dependent manner. A maximum 2.4-fold reduction in OC was noted on day 14 (anti-CCL3; 8 ng/mL). Inhibition of IL-6 *trans*-signalling with sgp130 caused a 3.6-fold reduction in OC number ($P<0.01$). Autocrine inhibition of OC differentiation by sgp130 (142±40 pg/mL) halved CCL3 production versus controls (280±86 pg/mL). OC numbers and CCL3 were comparable in control cultures to those exposed to paracrine activation of IL-6 *trans*-signalling by HDS for 14 days.

Conclusion: For the first time, we demonstrate the importance of autocrine versus paracrine regulation of IL-6 *trans*-signalling in controlling OC formation in humans and unmask a hitherto unresolved mechanism involving CCL3. These data identify soluble gp130 as a potentially important disease-modifying therapy, targeting bone destruction for inflammatory arthritis patients.

Interaction of FGF-8 and TNF-a in the Regulation of BMP-Induced Osteoblast Differentiation. Takayuki Katsuyama, Fumio Otsuka, Mariko Narazaki, Ken-ei Sada, Kenichi Inagaki, Jun Wada and Hirofumi Makino. Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background/Purpose: Osteoblasts and osteoclasts play important roles in the bone remodeling. When the balance between these cells is disrupted, bone loss or aberrant bone formation occur. In rheumatoid arthritis (RA), pro-inflammatory cytokines such as TNF-α play a predominant role in joint destruction. We earlier reported that TNF-α inhibits bone morphogenetic protein (BMP)-induced osteoblast differentiation via activation of JNK and NF-κB pathways.

The fibroblast growth factor (FGF) family constitutes of at least 25 structurally related proteins and known to be involved in various biological processes including cell migration, differentiation, growth and survival. In particular, FGF-2, -8 and -18 have been implicated as key factors for the bone and cartilage homeostasis. It has also been reported that joint destruction of RA patients is involved in the increase of endogenous FGF-2 in synovial fluids.

Among the FGF family, FGF-8 is known to be a key regulator for limb development and cranial formation. However, functional relationship between FGF-8 and BMPs in the osteoblast differentiation and the signal interaction of FGF-8 and proinflammatory cytokines remain unclear. Here we studied the effects of FGF-8 in relation to TNF-α actions on BMP-2-induced osteoblast differentiation.

Methods: Mouse myoblast cell line C2C12, osteoblast precursor cell line MC3T3-E1 and rat primary osteoblast were used to clarify the effects of FGF-8 and TNF-α on BMP-induced osteogenesis. Quantitative real-time PCR was performed to evaluate mRNA levels of osteoblast differentiation markers. Immunoblot analysis for the phosphorylation of Smads and MAPKs was performed to analyze the signal interaction induced by FGF-8, TNF-α and BMP-2.

Results: We found that FGF-8 inhibited BMP-2-induced expression of osteoblast markers in a concentration-dependent manner. The efficacy of

FGF-8 was smaller than that of TNF-α in the experiments using myoblast C2C12, MC3T3-E1 and rat osteoblasts. Of note, the inhibitory effects of FGF-8 on BMP-induced osteoblastic differentiation and Smad1/5/8 activation were enhanced under the co-treatment with TNF-α. FGF-8 also inhibited BMP-2-induced expression of Wnt5a, a non-canonical Wnt signaling, which is known to be involved in Smad-independent signaling induced by BMPs. FGF-8 had no influence on the expression levels of TNFRs, whereas FGF-8 increased the expression levels of ALK3 (BMPR1A) and reduced inhibitory Smads6/7, suggesting a possible feedback activity of FGF-8 to BMPR signaling. Moreover, a MEK inhibitor, but not JNK or NF-κB inhibitors, suppressed the FGF-8 actions on BMP-induced osteoblast differentiation.

Conclusion: Collectively, it was uncovered that FGF-8 inhibits BMP-induced osteoblast differentiation via ERK pathway and the effects were amplified by TNF-α activity. This FGF-BMP interaction may be involved in the regulatory process of inflammatory bone damages as shown in RA.

Regulation of Senescence and Inflammatory Mediators By N- and C-Terminal Parathyroid Hormone-Related Protein in Osteoarthritic Human Osteoblasts. Maria Isabel Guillén[1], Julia Platas[1], Sergio Portal-Nuñez[2], Pedro Esbrit[2] and M.J. Alcaraz[1]. [1]University of Valencia, Burjasot, Valencia, Spain, [2]Fundación Jimenez Diaz, Madrid, Spain.

Background/Purpose: In osteoarthritis (OA), there is an abnormal remodeling process in subchondral bone associated with an altered osteoblast metabolism. Inflammatory mediators participate in bone remodeling and cartilage degradation during OA progression. Parathyroid hormone (PTH) and its bone counterpart, PTH-related protein (PTHrP), increase bone turnover through interaction of their N-terminal domain with the PTH type 1 receptor in osteoblasts. PTHrP peptides may be a novel approach to treat bone metabolic alterations. The aim of this study was to investigate the effects of different PTHrP peptides, PTHrP (1–37), and the PTH-unrelated peptides, PTHrP (107–139) and PTHrP (107–111) (osteostatin), on osteoblast senescence and the production of inflammatory mediators and degradative enzymes in osteoarthritic human osteoblasts stimulated with interleukin-1β (IL-1β).

Methods: Osteoblasts were obtained from 8 patients undergoing total knee joint replacement. Subchondral bone tissue obtained from tibial plateau was minced into small portions and digested with collagenase under agitation. Collected tissue was seeded in osteogenic medium to obtain osteoblastic cells according to a standard procedure. At first passage, osteoblastic cells were treated with PTHrP (1–37), PTHrP (107–139) and osteostatin (each at 100 nM) with or without IL-1β (10 ng/ml) for 1, 3 and 6 days. Senescence-associated β-galactosidase activity (SA-β-Gal) was assessed by cytochemistry. mRNA expression of matrix metalloproteinases (MMPs) and senescence markers was determined by qPCR. Prostaglandin E_2 (PGE_2) was measured by RIA, pro-inflammatory cytokines by ELISA, and cyclooxygenase-2 (COX-2) expression was determined by immunocytochemistry.

Results: IL-1β increased senescence features and the secretion of inflammatory mediators in osteoarthritic osteoblasts. Increased production of cytokines, MMPs and PGE_2 may contribute to bone sclerosis and degradative processes in the joint. The three PTHrP peptides tested significantly downregulated SA-β-Gal and the expression of caveolin-1, p21, p53, MMP-1 and MMP-3. In addition, these peptides reduced the release of tumor necrosis factor-α into the culture medium. PGE_2 production was significantly decreased by PTHrP (1–37) on days 1, 3 and 6, and also by each C-terminal PTHrP peptide on day 6. This effect on PGE_2 was dependent on the downregulation of IL-1β-induced COX-2 overexpression.

Conclusion: These findings show that both N- and C-terminal PTHrP peptides counteract the effects of IL-1β on the induction of cell senescence and the production of inflammatory and degradative mediators in osteoarthritic human osteoblasts, suggesting a beneficial effect of these peptides in osteoarthritic subchondral bone.

Stimulation of the Adenosine a_{2A} receptor (A2AR) Regulates the Expression of Netrin1 and Their Receptors (Unc5b, DCC) and Inhibits Osteoclast Differentiation and Inflammatory Bone Destruction. Aranzazu Mediero[1], Bhama Ramkhelawon[1], Miguel Perez-Aso[2], Kathryn Moore[1] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]New York University, New York City, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: A variety of molecules mediate communication between osteoclasts and osteoblasts during bone remodeling. Netrin1 is a member of the family of axonal guidance proteins, that regulates inflammation and macrophage function. Because osteoclasts are derived from myeloid precursors we asked whether osteoclasts expressed Netrin-1 and whether A2AR activation, which diminishes osteoclast differentiation, might regulate Netrin-1 expression and inflammatory osteolysis.

Methods: 1cm midline sagittal incision was made over the calvaria in C57Bl/6 mice age 6–8 weeks. Mice received no particles (Control) or 3mg of UHMWPE with 20μl of saline 0.9% or CGS21680 (A2AR agonist, 1μM, n=4 each) at the surgical site every day up to 14 days. After sacrifice, calvaria were prepared for immunostaining for Netrin1/Unc5b/DCC. Protein and mRNA expression were studied by RT-PCR and WB in mouse and human primary bone marrow-derived OC and OB in the presence/absence of CGS21680 and ZM241385 (A_{2A}R antagonist) 1μM each.

Results: UHMWPE increased expression of Netrin1 and Unc5b, but not DCC, in periosteal inflammatory infiltrates which was reversed by the A2AR agonist CGS21680. RANKL induced 25$\pm$4 and 3$\pm$0.5 fold change, respectively, in Netrin1 and Unc5b mRNA during osteoclast differentiation, changes that were completely blocked by CGS21680 (1.17$\pm$0.1, $p<0.001$, n=4). In contrast, DCC mRNA expression did not significantly change during osteoclast differentiation and DCC expression was unaffected by CGS21680 (1.16$\pm$0.2 fold increase vs 1.9$\pm$0.2 for RANKL, p=ns, n=4). There was no change in Netrin1 or Unc5b expression during OB differentiation. Similar changes were observed in protein expression and secretion.

Conclusion: UHMWPE-induced osteolysis is regulated by Netrin1 activation. Adenosine A_{2A}R stimulation normalizes Netrin1expression and inhibits bony destruction at sites of UHMWPE-induced osteolysis. These results suggest that targeting Netrin1 directly or via stimulation of adenosine A_{2A}R may be a novel approach to preventing osteolysis and joint prosthesis loosening.

34

Pro-Nerve Growth Factor (ProNGF) Stimulates Bone Growth By Stimulating Osteoblasts and Inhibiting Osteoclast Differentiation, an Explanation for Anti-NGF-Mediated Osteonecrosis; Prongf Is a Novel Therapeutic Target for Treatment of Osteonecrosis and Charcot's Arthropathy. Aranzazu Mediero[1], Barbara Hempstead[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]Weill Cornell Medical College, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Neurotrophins (Nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF)) are initially synthesized as pro-neurotrophins (proNGF and proBDNF), which are hydrolyzed to produce the mature proteins. BDNF is reported to be a stimulus for osteoclast differentiation in multiple myeloma. Anti-NGF is currently in trials for relief of chronic pain in patients with osteoarthritis but trials are on hold due to the common occurrence of rapidly progressive osteonecrosis resembling Charcot's arthropathy. We therefore sought to determine whether pro-NGF, which stimulates different receptors than the mature protein, plays a role in bone homeostasis we examined mice that overexpressed poorly hydrolyzed pro-NGF.

Methods: Wild type C57BL/6 (WT) and proNGF/+ (mice that overexpress a poorly hydrolysable proNGF) mice were sacrificed and prepared for microCT. Osteoclast and osteoblast differentiation was studied in primary murine bone marrow precursors as number of TRAP-positive cells or Alizarin Red-positive stain after challenge with the presence/absence of recombinant neurotrophins. Neurotrophin receptors (p75, Sortilin, Sorcs2) were analyzed by Western Blot.

Results: microCT revealed an increase in cortical and trabecular bone in proNGF/+ mice when compare to WT. This change correlated with a decrease in osteoclast differentiation in cells from proNGF/+ mice (30±3% decrease, $p<0.001$, n=4) and increased osteoblast differentiation in proNGF/+ (46±5% increase, $p<0.5$, n=4). Treatment with proNGF markedly inhibits osteoclast differentiation (60±2% decrease, $p<0.001$, n=5) without affecting osteoblast differentiation (10±5% increase, p=ns, n=5). In contrast, recombinant NGF increased osteoclast differentiation (17±2% increase, $p<0.05$, n=5) with a decrease in osteoblast formation (62±3% decrease, $p<0.001$, n=5). p75, Sortilin and Sorcs2 receptors were expressed in osteoclasts and osteoblasts.

Conclusion: These results indicate that the rapid bone destruction seen in patients treated with anti-NGF antibodies is most likely due to reduction of pro-NGF levels required for maintenance of bone homeostasis. Moreover, our results suggest that administering a therapeutically effective amount of proNGF may provide a novel therapeutic approach to promote bone growth and prevent Charcot's arthropathy, a common problem in patients, such as diabetics, with peripheral neuropathy.

Disclosure: A. Mediero, None; **B. Hempstead**, None; **B. N. Cronstein**, Canfite Pharma, 1, AstraZeneca, 2, Cellgene, 2, Gilead, 2, NIH, 2, NYU School of Medicine, 3, Bristol-Myers Squibb, 5, Pfizer Inc, 5, Eli Lilly and Company, 5, Rheumatology Reseach Foundation, 6, ACR, 6, Arthritis Foundation, 6.

35

Hydrogen Sulfide Inhibits Human Osteoclast Differentiation *in Vitro* By Triggering Sustained Antioxidant Response and Inhibiting the RANKL/OPG Ratio. Francesco Grassi, Laura Gambari, Andrea Facchini and Gina Lisignoli. ISTITUTO ORTOPEDICO RIZZOLI, BOLOGNA, Italy.

Background/Purpose: Hydrogen sulfide (H_2S) has been recently appreciated as a novel gasotransmitter with an important role in the regulation of tissues and organs. H_2S is produced endogenously in mammalian cells from L-cysteine mainly by the enzymes cystathionine-β-synthase (CBS) and cystathionine-γ-lyase (CSE) Several correlations were established between low levels of plasmatic H_2S, reduced activity of H_2S-generating enzymes and diseases, including erosive bone diseases, leading to the hypotheses that disregulation of H_2S levels may be critical in the onset of specific diseases. However, the role of H_2S in the regulation of bone homeostasis has been scarcely investigated. Circulating osteoclasts (OCs) precursors are a population of clinical relevance in erosive bone diseases, such as rheumatoid arthritis or psoriatic arthritis, and a potential pharmacological target.

Our objective was to investigate the role of H_2S in the regulation of OCs differentiation and function *in vitro*, by both direct effect on OCs precursors and indirect regulation of mesenchymal stem cells (MSC).

Methods: human monocytes were isolated and differentiated into osteoclasts in the presence of M-CSF (10ng/ml) and RANKL (75ng/ml) and variable concentrations of NaHS, an H_2S donor. TRAP assay and pit assay were performed to evaluate either h-OCs differentiation or "bone" resorption. h-OCs precursors were tested for cellular apoptosis (Annexin V/ PI staining), acute toxicity (LDH assays), ROS production (DCF staining), mRNA and/or protein expression of NRF2, and NQO1 and PRDX1 (RT-PCR, IHC analyses). RANKL and OPG expression were evaluated by Real-Time PCR in human MSC stimulated with NaHS. GraphPad Prism5 software was used for statistical analysis.

Results: exogenous H_2S (100–300 μM) significantly inhibited the differentiation and function of h-OCs without affecting cell viability. H_2S inhibited RANKL-induced ROS production in OC precursors; moreover, H_2S induced significant nuclear translocation of NRF2, the master regulator of antioxidant response, and significantly increased mRNA and protein expression of PRDX-1 and NQO1, two key NRF-2-dependent antioxidant genes. Furthermore, siRNA-based inhibition of NRF2 in OC precursors completely prevented the NaHS-dependent inhibition of OCs differentiation, showing that NRF2 is critical for H_2S regulation of OCs differentiation. Finally, NaHS stimulation (100mM) significantly inhibited the RANKL/OPG mRNA ratio in human MSC, a key marker of the OCs-supporting ability of these cells.

Conclusion: Our findings show that H_2S inhibits OC differentiation by both direct and MSC-mediated mechanisms, suggesting a possible therapeutical role of H2S donors in erosive bone diseases.

The Use of Three-Dimensionally Printed β-Tricalcium Phosphate/Hydroxyapatite to Further Understand the Regulation of Adenosine Receptors in Osteoclast Formation and Promotion in Bone Regeneration. Stephanie Ishack[1], Aranzazu Mediero[1], John Ricci[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]NYU Dental School, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Bone defects resulting from trauma or infection need timely and effective treatments to restore damaged bone. Using specialized three-dimensional (3-D) printing technology, combined with bioactive molecules, we can design custom 3-D scaffolds for bone repair. The Hydroxyapatite (HA)/Beta-Tri-Calcium Phosphate (B-TCP) scaffold components provide mechanical strength, conduct bone throughout the scaffold and remodel over time. Dipyridamole (DIPY) increases local adenosine levels by blocking cellular uptake of adenosine and stimulates bone regeneration. Because DIPY, adenosine and adenosine A2A receptor-specific agonists stimulate bone regeneration in mice as well as BMP-2, a growth factor currently used to promote bone regeneration, we tested the capacity of DIPY-coated matrices could promote successful bone regeneration.

Methods: 15% HA:85% B-TCP scaffolds were designed usingRobocad software, fabricated using a 3-D Robocasting system, and sintered at 1100°C for 4h. Scanning electron microscopy (SEM), micro-computed tomography (micro-CT), x-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR) and inductive coupled plasma (ICP) were used for material characterization. Vehicle, BMP-2 and DIPY drug scaffolds (scaffold + PBS, scaffold + DIPY or BMP-2, scaffold+ collagen + DIPY or BMP-2) were implanted in C57B6 (wild type, WT) and A2AKO mice with 3mm critical size defect for 2, 4 and 8 weeks. DIPY release from scaffold was assayed spectrophotometrically over time. MicroCT and histological analysis were conducted to determine the degree of new bone formation and remodeling.

Results: Quantitative and qualitative results from microCT showed similar and significant bone formation and remodeling in HA/B-TCP- DIPY and HA/B-TCP-BMP-2 scaffolds when compared to vehicle at 2, 4 and 8 weeks in WT mice (55% bone formation for in HA/B-TCP- DIPY and HA/B-TCP-BMP-2 vs 41% for vehicle, N=5 per group; $P \leq 0.01$). Dipyridamole did not enhance bone formation in A_{2A}KO mice 4 weeks after trephination (31% for HA/B-TCP- DIPY vs 27% for vehicle, N=5, p=ns). Histological analysis of WT mice showed increased bone formation and a trend toward increased remodeling in HA/B-TCP- DIPY and HA/B-TCP-BMP-2 scaffolds. Histologic examination of Dipyridamole treated scaffold in A2AKO mice showed no significant differences in bone formation when compare to vehicle treated scaffolds. Dipyridamole release from collagen coated scaffolds, maintain a constant concentration (10-6M) for up to 10 days.

Conclusion: Dipyridanmole increases adenosine levels and targeting osteoblasts and osteoclasts via activation of the adenosine A2A receptor leads to increased bone regeneration in a murine model. Delivery of Dipyridamole in the 3-D ceramic scaffolds is a an effective approach for bone regeneration following orthopedic, dental and craniofacial procedures.

Regulation of Osteoclast and T Cell Differentiation By DC-STAMP and TRAF3. Yahui Grace Chiu[1], Jinbo Li[1], Dongge Li[1], Brendan Boyce[1] and Christopher T. Ritchlin[2]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: DC-STAMP (Dendritic Cell-Specific Transmembrane Protein) is a 7-pass transmembrane protein essential for cell-to-cell fusion during OC differentiation. We have previously shown that DC-STAMP is a specific cell surface marker of OC precursors (OCP) and the frequency of DC-STAMP$^+$cells is elevated in patients with psoriatic arthritis (PsA). Intriguingly, we found that the level of TNF receptor-associated factor 3 (TRAF3) was also significantly elevated in the OCPs of PsA patients. In addition, osteoporosis can be prevented in mice by reducing osteoclastogenesis through inhibition of TRAF3 degradation by chloroquine. Although both DC-STAMP and TRAF3 play critical roles in OC formation, it is unknown if there is an interplay between these two molecules during osteoclastogenesis. Herein, to investigate a possible mutual regulation between them, we

quantified and monitored these two proteins in DC-STAMP knock-out (KO) mice and TRAF3 conditional KO (cKO) mice.

Methods: We analyzed the expression of DC-STAMP and TRAF3 in the spleen, thymus, lymph nodes, bone marrow and skeleton by flow cytometry and Western blotting in the TRAF3 KO and DC-STAMP KO mouse strains. We also examined the effects of chloroquine on the expression of DC-STAMP and TRAF3. The TRAF3 cKO mouse line was established by conditional deletion of TRAF3 in OC lineage cells by crossing $Traf3^{fl/fl}$and CatK-Cre.

Results: In DC-STAMP KO mice, $TRAF3^+$ T cells were identified in the bone marrow, bone, spleen, lymph nodes, but not in the thymus. We showed that the DC-STAMP deficiency blocked the differentiation of $TRAF3^+CD8^+$T cells in thymus, and TRAF3 protein was not present in the thymus by Western blot analysis. In contrast, the expression level of DC-STAMP and DC-STAMP+ cell frequency was unchanged in the TRAF3 cKO mice. Chloroquine treatment increased the expression levels of extracellular DC-STAMP and intracellular TRAF3 and prevented osteoclast formation in human PBMC cell cultures.

Conclusion: The expression of DC-STAMP is normal in the TRAF3 cKO mouse cells, whereas TRAF3 expression was dramatically decreased in the thymus of DC-STAMP KO mice. Our results suggest that (1) DC-STAMP is critical for the regulation of T cell differentiation in the thymus; (2) DC-STAMP and TRAF3 are both required for osteoclastogenesis; (3) chloroquine exerts its negative osteoclastogenic effect by inhibiting the degradation of both TRAF3 and DC-STAMP. Thus, understanding the molecular events that regulate the synthesis and degradation of DC-STAMP and TRAF3 may reveal novel therapeutic targets in metabolic and inflammatory bone diseases.

Angiopoietin-like 4 Is over-Expressed in Rheumatoid Arthritis: A Potential Role in Pathological Bone Resorption. Catherine Swales[1], Nick Athanasou[2] and Helen Knowles[3]. [1]The Botnar Research Centre, Oxford, United Kingdom, [2]Department of Pathology, Oxford, United Kingdom, [3]Botnar Research Centre, Oxford, United Kingdom.

Background/Purpose: In contrast to normal synovial tissue, rheumatoid synovium is hypoxic, and expresses the hypoxia-inducible transcription factors HIF-1α and HIF-2α which allow the transcription of genes involved in angiogenesis, inflammation, apoptosis and regulation of immune function. Hypoxia also stimulates osteoclast differentiation and causes a HIF-1α-dependent 3-fold increase in bone resorption. Angiopoietin-like 4 (ANGPTL4) is a hypoxia- and HIF-inducible pro-angiogenic adipokine that is induced in fibroblast-like synoviocytes in rheumatoid arthritis. This study sought to investigate whether ANGPTL4 is expressed in osteoclasts and other cells within rheumatoid synovial tissue, and to compare serum and synovial fluid levels of ANGPTL4 with those in normal controls and patients with osteoarthritis.

Methods: Serum, synovial fluid and synovial tissue samples were derived from patients with osteoarthritis (OA) and rheumatoid arthritis (RA); serum was obtained from aged-matched normal controls. All donors were recruited from the Nuffield Orthopaedic Centre, Oxford, UK and gave written informed consent. ANGPTL4 and HIF-1α expression was assessed in OA and RA synovial sections by immunohistochemistry and immunofluorescence. Serum and synovial fluid levels of ANGPTL4 were measured by ELISA. Osteoclasts were differentiated from circulating RA monocytes using M-CSF and RANKL, and hypoxic induction of ANGPTL4 mRNA was measured by real-time PCR.

Results: Bone-apposing osteoclasts within the rheumatoid synovium expressed ANGPTL4 and its regulating transcription factor HIF-1α. ANGPTL4 was strongly expressed in synovial lining cells, endothelial cells, stromal cells, CD68+ macrophages and plasma cells within the RA synovium. Little ANGPTL4 was evident in normal synovium, mirroring the expression pattern of HIF-1α in rheumatoid versus normal synovial tissue. ANGPTL4 concentrations were higher in the serum and synovial fluid of RA patients than in OA patients or normal controls. High serum ANGPTL4 correlated with elevated levels of the serum bone resorption marker sRANKL. Finally, ANGPTL4 mRNA was induced 5.5-fold by hypoxia in monocyte-derived osteoclasts from RA patients.

Conclusion: ANGPTL4 is over-expressed in both the serum and the synovial fluid and tissue of RA patients. Expression of ANGPTL4 in bone-apposing osteoclasts and correlation of high serum ANGPTL4 with circulating sRANKL suggests ANGPTL4 as a marker for bone destruction, and a potential target for inhibition of osteoclast-mediated bone resorption in RA.

Human $CD14^+$ Monocytes Stimulated with a Combination of TNFα and IL-6 Differentiate into Osteoclast-like Cells with Bone-Resorption Activity. Kazuhiro Yokota, Kojiro Sato, Yoshimi Aizaki, Yuji Akiyama and Toshihide Mimura. Saitama Medical University, Saitama, Japan.

Background/Purpose: Proinflammatory cytokines play an important role in bone destruction in rheumatoid arthritis (RA), as inferred by the efficacy of biologics. Previously, we reported that mouse osteoclast-like cells were induced, both in vitro and in vivo, by a combination of TNFα and IL-6 from bone marrow-derived monocytes/macrophages. Herein, we examined the differentiation, function, and regulation of osteoclast-like cells that were induced by the combination of TNFα and IL-6 from human $CD14^+$monocytes.

Methods: Human $CD14^+$ monocytes were cultured with IL-6, TNFα, or TNFα plus IL-6. Pit formation assay on dentine slices was performed to assess the bone-resorbing activity. The expression of nuclear factor of activated T-cells cytoplasmic 1 (NFATc1), which is the master regulatory transcription factor for osteoclast differentiation, was detected by a western blot analysis. The effects of osteoprotegerin (OPG), a decoy receptor for RANKL, NFAT inhibitor tacrolimus, or JAK inhibitor tofacitinib were examined.

Results: The tartrate-resistant acid phosphatase positive multinucleated osteoclast-like cells were induced by the combination of TNFα and IL-6 from human $CD14^+$ monocytes in a dose-dependent manner. These osteoclast-like cells had bone resorption activity on dentin slices. The differentiation of conventional osteoclasts induced by RANKL from $CD14^+$ monocytes was inhibited by OPG, whereas that of our osteoclast-like cells was not. Expression of NFATc1 was upregulated by the combination of TNFα and IL-6 compared with TNFα or IL-6 alone. In addition, differentiation of the osteoclast-like cells from $CD14^+$monocytes was completely inhibited by tacrolimus. On the other hand, tofacitinib blocked the differentiation of the osteoclast-like cells through the JAK signaling pathway.

Conclusion: Osteoclast-like cells with bone resorption activity were induced by culturing human $CD14^+$ monocytes with the combination of TNFα and IL-6. These results indicate that not only osteoclasts, but also osteoclast-like cells may be involved in the pathogenic mechanism of inflammatory bone destruction, such as RA.

Prevalence of Spondyloarthritis (ASAS Criteria) in First-Degree Relatives of Patients with Ankylosing Spondylitis. Raúl Menor Almagro[1], Carmen Ordas[2], Carlos Montilla[3], Jose Luis Alvarez-Vega[4], Íñigo Hernández-Rodríguez[5], Montserrat Corteguera[6], Santiago MuÑoz Fernandez[7], Claudia Urrego[8], Rafael Ariza-Ariza[9], Mireia Moreno[10], Xavier Juanola[11], Maria Isabel Tévar[12], Eduardo Collantes- Estevez[13], Juan Mulero-Mendoza[14] and Ana Ruiz-Zorrilla[15]. [1]Hospital de Jerez, Jerez de la Frontera, Spain, [2]Hospital de Cabueñes, Gijón, Spain, [3]Hospital Clínico Universitario de Salamanca, Salamanca, Spain, [4]H. de Salamanca, Salamanca, Spain, [5]University Hospital Complex of Vigo, Vigo, Spain, [6]Hospital N^a S^a Sonsoles, Avila, Spain, [7]Sección de Reumatología, Hospital Universitario Infanta Sofía, San Sebastián de los Reyes, Madrid, Spain, [8]Hospital G. Segovia, Segovia, Spain, [9]University Hospital Virgen Macarena, Sevilla, Spain, [10]Hospital Universitari Parc Taulí, Sabadell, Spain, [11]University Hospital Bellvitge, Barcelona, Spain, [12]Hospital Vega Baja, Orihuela, Alicante, Spain, [13]Hospital Reina Sofía, Córdoba, Spain, [14]Hospital Puerta de Hierro, Madrid, Spain, [15]Abbvie, Madrid, Spain.

Background/Purpose: Spondyloarthritis (SpA), a group of inflammatory diseases which exhibit similar genetic background, clinical features and symptoms[1], has an estimated prevalence of 0.5–1%[2] in Spain. However, in first-degree relatives positive for the HLA-B27 antigen, this prevalence may reach up to 24%[3–7]. The ASAS (Assessment of SpondyloArthritis international Society) criteria for SpA facilitate the identification of patients throughout the SpA spectrum, helping to potentially diagnose SpA features in first-degree relatives of patients with ankylosing spondylitis (AS). The aim of this study was to determine the prevalence of axial and peripheral SpA in first-degree relatives of AS patients.

Methods: A multicentre, cross-sectional prevalence study was designed in first-degree relatives of patients with AS. Relatives agreeing to participate in the study completed a screening questionnaire to identify the presence of specific SpA characteristics. Relatives whose responses indicated the presence of SpA features were referred to a rheumatologist to collect their medical history and an assessment of disease activity, which included a blood test for the HLA-B27 antigen and C-reactive protein (CRP), a simple pelvic X-ray (Rx) and a pelvic magnetic resonance image (MRI). All the imaging tests were assessed by an expert radiologist.

Results: Of the 486 participants, 290 first-degree relatives were classified as positive for SpA features after the screening questionnaire, and 269 continued in the study. After a rheumatologist's evaluation using the ASAS criteria (table 1), 55 participants had no apparent signs of SpA and 214 were considered to be evaluable by the rheumatologist. Supplementary tests were performed in 195 relatives. Approximately 10.9% (n=53/486) of all the relatives met the criteria for SpA, of whom 60% (n=32) and 40% (n=21) were diagnosed as having? axial SpA and peripheral SpA, respectively. Of the relatives assessed for diagnosis (n=250), 21.2% (n=53) met the criteria for SpA; 12.8% (n=32) were diagnosed with axial SpA, 8.4% (n=21) with peripheral SpA (table 2).

Approximately 62.5% (n=20) of the 32 relatives with axial SpA met criteria for axial SpA through the clinical arm, 15.6% (n=5) met the imaging criteria, and 21.9% (n=7) met both the clinical and imaging criteria (table 2).

Conclusion: The incidence of SpA in first-degree relatives of Spanish patients with AS was 10.9%, which is consistent with the published literature.

Table 1: Assessed ASAS criteria rates

Relatives Screening +	n	%	N
Inflammatory back pain	193	39.70%	486
Arthritis	37	7.60%	486
Enthesitis of the heel	50	10.30%	486

The Impact of Ankylosing Spondylitis on Work Impairment: Data from the Scotland Registry for Ankylosing Spondylitis. Linda E. Dean[1], Alan G. MacDonald[2], Roger D. Sturrock[3], John Hunter[4], David Marshall[5], Gary J. Macfarlane[1] and Gareth T. Jones[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Aberdeen Royal Infirmary, Aberdeen, United Kingdom, [3]Glasgow Royal Infirmary, Glasgow, United Kingdom, [4]Gartnavel General Hospital, Glasgow, United Kingdom, [5]Inverclyde Royal Hospital, Greenock, United Kingdom.

Background/Purpose: The impact of ankylosing spondylitis (AS) on work status is substantial. While the majority of studies focus on the prevalence of absenteeism in this group, impairment (i.e. presenteeism) whilst at work is also an important factor when assessing the impact of disease on work-life yet remains relatively understudied. The aim of the current study was therefore to describe the prevalence of, and factors associated with, work impairment in AS.

Methods: SIRAS collects data on clinically diagnosed AS patients in Scotland. Clinical measures recorded from medical records include disease activity (BASDAI) and physical function (BASFI), while postal questionnaires provide patient-reported data including pain and fatigue (Chalder Fatigue Scale). Work impairment 'during the past 7days' was assessed using the *Work Productivity and Activity Impairment questionnaire – Specific Health Problem*. Logistic regression was used to identify potential clinical and patient-reported factors associated with work impairment. These were assessed further using forward stepwise logistic models to identify independent risk factors. Results: are given as odds ratios with 95% confidence intervals. Additionally, the population attributable risks associated with independent risk factors were calculated.

Results: SIRAS contains both clinical and patient-reported information on 959 patients (male 73%, mean age 52yrs). Of those who answered items on employment (n=946), 55% were currently working, and only 10% of workers had missed work (during the past 7days) due to their AS. However, 71% of workers reported some impairment during this time (any versus none). Factors independently associated with work impairment were: moderate/severe fatigue (4.8; 2.4–9.4), poor physical function (BASFI≥4: 2.6, 1.2–5.6) and chronic widespread pain (3.7, 1.9–7.3). The population attributable risks associated with these factors were 19%, 9% and 13% respectively.

Conclusion: The majority of employed AS patients did not report missing any work, in the previous week, due to their AS. However, many experienced impairment whilst working, the key identifiable drivers of which were fatigue, pain and poor physical function. Targeted, non-pharmacological treatments, such as cognitive behavioural therapy, in addition to traditional therapeutic targets, may help to improve overall work productivity. This may reduce the economic impact of the disease and, ultimately, could improve overall work retention.

42

The Prevalence of Ankylosing Spondylitis in Sweden – a Nationwide Register Study. Sofia Exarchou[1], Ulf Lindström[2], Johan Askling[3], Jonas Eriksson[4], Helena Forsblad-d'Elia[5], Lars Erik Kristensen[6], Martin Neovius[4], Carl Turesson[1] and Lennart T. Jacobsson[5]. [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [3]Clinical Epidemiology Unit, Rheumatology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [4]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [5]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [6]Lund University, Malmö, Sweden.

Background/Purpose: Reported Ankylosing Spondylitis (AS) prevalence estimates vary considerably, and there is a lack of nationwide estimates. Previous studies by our group support the validity of WHO International Classification of Disease codes (ICD-codes) for AS in the Swedish National Patient Register (NPR) and indicate that the mean diagnostic delay is about 10 years. This study aims to describe the national prevalence of diagnosed AS in

Sweden, based on data from the NPR, overall as well as stratified by age and sex, and to explore treatment, geographical variation and socio-economic factors in the Swedish AS population.

Methods: All patients given a diagnosis of AS according to ICD-codes in the NPR between 1967 and 2009 were identified. Statistics Sweden, the Swedish biologic register (ARTIS) and the national drug prescription register were used to retrieve data on demographics, drug exposure, level of education and vital status. Our case definition required at least one registered AS diagnosis in inpatient care 1967- present) or specialized outpatient care (2001-present), not including primary care and private practice. Results are presented for individuals 16–64 years old in 2009.

Results: On 31 December 2009, Sweden had a population of approximately 9.3 millions, of which 64% were in the age group 16–64 years old and 50.8% were men. Between 1967 and 2009, 20 044 patients with at least one health care registration in the NPR with a diagnosis of AS were identified. Of those, 11 030 were 16–64 years old, alive and living in Sweden on Dec 31, 2009. The overall prevalence of AS in this age group in 2009 was thus 0.18%. The prevalence increased linearly with age up to the age of 55 years, after which it leveled off. For all investigated age groups combined, men had a higher prevalence compared to women (0.23% vs 0.14%). During 2009, NSAIDs, DMARDs, corticosteroids and TNF-inhibitors had been prescribed to the AS patients in 53.4%, 20.4%, 11.7% and 14.2% respectively. Prevalence estimates by health care region revealed the highest age-/sex-standardized prevalence in the Northern Health Care Region (0.24%; 95% CI 0.23–0.25). The association between level of education and AS prevalence was explored only in those > 30 years old on Dec 31, 2009. The age-/sex-standardized prevalence of AS was lowest among those with > 12 years of education (0.20%; 95% CI 0.19–0.21), while somewhat higher prevalences were observed in the other two strata with a shorter formal education (≤ 9 years and 10–12 years) (0.24%; 95% CI 0.22–0.25 and 0.24%; 95% CI 0.23–0.24).

Conclusion: This nationwide, register-based prevalence estimate of AS in Sweden offers a unique opportunity to better understand the burden of AS to the healthcare system. Moreover, geographic and socio-economic differences in prevalence estimates suggest that genetic and possibly also environmental factors may be important for disease development and detection.

Deaths Associated with Ankylosing Spondylitis in France from 1969 to 2009. Clement Prati[1], Daniel Wendling[2] and Xavier Guillot[3]. [1]Hopital Jean Minjoz, Besancon, France, [2]CHU J Minjoz, Besancon, France, [3]rheumatology, Besançon, France.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory joint disease that can lead to chronic pain in the axial and peripheral joints and to functional impairments. AS is a systemic disease that can cause extraarticular manifestations which could participate to excess mortality. The aim of the study is to describe characteristics of deaths for which AS was mentioned on the death certificate as either the underlying cause or anywhere on the death certificate and to analyze trends in AS related mortality from 1969 to 2009 in France.

Methods: Data were obtained from the Centre of Epidemiology on the Medical Causes of Death (CépiDc) for individuals aged 18 years and over died in France. Owing to implementation of International Classification of Diseases (ICD) 8, ICD-9 and ICD-10 for recording causes of deaths, three separate periods were analyzed (1969–78; 1979–99 and 2000–09). Initial, terminal and associated causes of deaths were analyzed. Initial Causes of deaths were compared with deaths of French general population in the same periods (CIM9 and 10).

Results: In the global period (1969–2009), AS appeared in 2942 deaths certificates, 2292 men (mean age of death 68,7 years) and 650 women (mean age of 75,8), 601 between 1969-78 (ICD8), 1471 between 1979–1999 (ICD9) and 867 between 2000 and 2009 (ICD10). There is a trend that AS decreases life expectancy in men compared with general population. The number of deaths with AS on the death certificates is increasing due to change of ICD and increase of diagnosis. AS is mentioned as initial cause in 38% in 1969–1978, 33% in 1979–1999 and 5% in 2000–2009. Apart from AS, most frequent initial causes are diseases of the circulatory system (28,5 % in ICD8, 23,1% in ICD9 and 26,5% in ICD10; neoplasms (7,8%, 10,2% and 16,3%); diseases of the respiratory system (7,5%, 11,1% and 9,4%) and external causes of mortality (3,5%, 7,8% and 13,1%). Compared to general population there is less deaths caused by neoplasm, but more caused by infectious, genitourinary diseases and external causes of mortality. Most frequent associated causes are diseases of the circulatory system (22,2%, 34,4% and 23,7%).

Conclusion: The manner of death coding varies according to ICD. Our study is the first to analyze data from deaths certificate. Diseases of the circulatory system are the most frequent initial and associated causes of death. But compared to general population, infectious, genitourinary diseases and external causes of mortality are more frequent in AS.

Physical Function, Hyperuricemia and Gout in Older Adults. Mara McAdams-DeMarco[1], Bridget Burke[2], Andrew Law[3], Anna Kottgen[4], Alan N. Baer[5] and Josef Coresh[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins, Baltimore, MD, [4]University Hospital Freiburg, Freiburg, Germany, [5]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: The prevalence of gout is higher in older adults than in younger adults and these patients are at risk of physical disability. We sought to determine the prevalence of and risk factors for impaired physical function in relation to gout status and hyperuricemia.

Methods: We studied gout, hyperuricemia, and function in 5,819 older adults (age >65) using the Atherosclerosis Risk in Communities cohort, a prospective US population-based cohort study of middle-aged adults enrolled between 1987–1989 with ongoing annual follow-up through 2012. Differences in lower (Short Physical Performance Battery (SPPB) and 4 meter walk test, measured in 2011–2013) and upper extremity function (grip strength) by gout status and by hyperuricemia prevalence were estimated: adjusted ordinal logistic regression for SPPB and modified Poisson regression for 4 meter walk test and grip strength. The risk of poor physical function (lowest quartile of grip strength, lowest quartile of SPPB and highest quartile of 4 meter walk test) was estimated using modified Poison regression. Characteristics of gout participants with poor physical function were identified using modified Poisson regression.

Results: There were 595 (10.2%; women: 7.1% and men: 14.6%) participants with gout and 1,242 (21.3%; women: 16.2% and men: 28.4%) with hyperuricemia. There was no difference in grip strength by history of gout (mean difference = -0.29, 95% CI: -0.90, 0.32; P=0.36) nor risk of poor grip strength by history of gout (RR=1.07, 95% CI: 0.95–1.21; P=0.27). Participants with gout had 0.70-times (95% CI: 0.60, 0.82; P<0.001) the odds of 1-unit increase in the SPPB score, such that those with gout had worse performance on the SPPB and participants with gout were 1.28-times (95% CI: 1.15–1.42; P<0.001) more likely to have poor SPPB performance. Participants with gout had slower 4 meter walk test by history of gout (mean difference = 0.23, 95% CI: 0.12, 0.33; P<0.001) and were at 1.24-fold (95% CI: 1.10–1.41; P=0.001) increased risk of poor 4 meter walk test performance. Results were similar when comparing grip strength, SPPB and 4 meter walk test by hyperuricemia (Table). Among participants with gout, older participants (for every 5 year increase in age, RR=1.42, 95% CI: 1.28, 1.59), black participants (RR=1.58, 95% CI: 1.25, 2.00), participants with higher BMI (for every 5 kg/m^2 increase in BMI, RR=1.18, 95% CI: 1.07, 1.29), and participants who were current smokers (RR=1.65, 95% CI: 1.14, 2.38) were at highest risk of poor 4 meter walk time; similar results were observed for poor SPPB score.

Conclusion: Older adults with gout and hyperuricemia are more likely to have poor lower but not upper body function. Additionally, we identified a

group of gout participants with high risk of poor lower extremity function, namely, older age, men, with higher BMIs, and current smokers.

Table: Independent association of physical function in older adults, by gout and hyperuricemia status

	Grip strength (kg)	SPPB score	4 meter walk (seconds)

Ordinal logistic regression was used for SPPB score 5,548 with available 4 meter walk test without assistance.
Adjusted for: Age, sex, race, BMI, smoking status, education level, hypertension and alcohol intake.
Grip strength: higher scores are indicative of better function. SPPB score: higher scores are indicative of better function. 4 meter walk test: lower time is indicative of better function.
Low physical function was defined as the lowest quartile for grip strength (≤22 kg) and SPPB (≤7) as well as the highest quartile for normal walking pace (>5.2 seconds).

Body Mass Index Across the Lifespan and Lifetime Incidence of Gout in Men. Allan C. Gelber, Lucy Meoni, Michael Klag and Joseph Gallo. Johns Hopkins University, Baltimore, MD.

Background/Purpose: Gout is the leading cause of inflammatory arthritis in men and is linked to higher levels of body weight and obesity in mid-adult life. However, few, if any, observational cohorts have examined the association of body weight across the life span with incident gout. We sought to determine whether weight, assessed in young, mid and late-adult life, predicted the subsequent development of gout.

Methods: Body mass index [BMI] was first calculated at a mean age of 23 (+2) years among 1040 male former medical students who graduated from 1948–1964. Thereafter, BMI was re-assessed in each decade of adult life. Incident gout was ascertained during follow-up using self-administered questionnaires and confirmed in a subset of participants according to American College of Rheumatology criteria. Survival analysis techniques were used to examine the association of BMI in each age interval with incidence of gout, with adjustment for comorbid hypertension at time of BMI, cholesterol level and alcohol consumption at cohort entry.

Results: In this prospective cohort study, the mean weight at cohort entry was 75.6 (+9.8) kilograms, height was 1.81 (+0.06) meters, corresponding to mean BMI of 23.1 (+2.6) kg/m^2. During a median follow-up of 45 years, a total of 158 men developed gout. Notably, the youngest age at which gout first occurred was 28 years. Thereafter, 6 men developed gout by age 35 years, an additional 36 developed gout by age 50 years, 36 more between ages 50–65 years, and finally, 70 men developed gout between 65 to 88 years of age. The cumulative incidence of gout by age 45 years was 2.2%, by 55 years was 5.4%, by 65 years was 8.5%, by age 75 years was 14.4%, and the cumulative incidence of gout by 85 years was 21.0%. Further, at each period in the adult life spectrum, a dose-response association was observed between successively higher tertiles of BMI with gout incidence (Table; each logrank p<0.06). Moreover, those men in the highest tertile of BMI (at ages 35, 50 and 65) experienced a heightened risk to develop gout over the next 15–20 year period (between ages 35–50, 50–65, and 65–85, respectively,) compared to those in the lowest BMI tertile, an association largely explained in the late adult period by comorbid hypertension.

Conclusion: The incidence of gout in men rises during each decade of the lifespan. Body weight in young, mid and late adult life, each predicted gout incidence during the subsequent age period. These findings imply that across the lifespan, overweight and obesity are potential modifiable targets in the primary prevention of gout.

BMI at age 35 years	n	Incident cases of gout	Cumulative incidence at specified age (%)	P value	Unadjusted HR (95% CI)	Adjusted HR (95% CI)
Upper tertile (24.5 to 36.8 kg/m^2)	387	18	4.8		3.1 (1.2–7.7)	5.7 (1.7–19.7)
Middle tertile (22.8 to 24.4 kg/m^2)	386	12	3.3	0.04	2.1 (0.8–5.5)	3.7 (1.0–13.2)
Lowest tertile (16.6 to 22.7 kg/m^2)	387	6	1.6		1.00	1.00
BMI at age 50 years						
Upper tertile (25.2 to 41.8 kg/m^2)	347	24	7.5		2.8 (1.3–6.0)	3.1 (1.3–7.4)
Middle tertile (23.2 to 25.2 kg/m^2)	348	15	4.7	0.02	1.7 (0.7–3.8)	1.2 (0.5–3.3)
Lowest tertile (15.9 to 23.2 kg/m^2)	347	9	2.8		1.00	1.00
BMI at age 65 years						
Upper tertile (25.8 to 46.6 kg/m^2)	275	29	18.3		1.9 (1.1–3.5)	1.4 (0.8–2.7)
Middle tertile (23.4 to 25.8 kg/m^2)	276	21	12.9	0.06	1.2 (0.6–2.2)	0.8 (0.4–1.6)

Xanthine Oxidase Inhibitors and Risk of Type 2 Diabetes in Patients with Gout. Seoyoung C. Kim[1], John D. Seeger[2], Jun Liu[1] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital/Harvard Medical School, Boston, MA.

Background/Purpose: Hyperuricemia and gout are associated with an increased risk of type 2 diabetes (T2D). Xanthine oxidase inhibitors (XOI), allopurinol and febuxostat, are the main therapy to treat gout patients with hyperuricemia. Little is known whether treating hyperuricemia with a XOI has any effect on future risk of T2D. We examined the risk of T2D in gout patients initiating a XOI versus untreated patients with hyperuricemia.

Methods: We conducted a cohort study using a U.S. commercial insurance claims database. Patients aged ≥40 years with gout and hyperuricemia (≥ 6.8mg/dl) who had an enrollment period for ≥ 365 days were eligible. Propensity score (PS) matching was used to simultaneously control for baseline demographic factors, comorbidities, medications, health care utilization, and time trend. From January 2004 to December 2012, XOI initiators and non-initiators matched on a PS were identified with a 1:2 ratio in each calendar month (a total of 108 calendar months). The first day of each month was the index date for both groups. We excluded patients with diabetes, use of XOI or anti-diabetic drugs, end-stage renal disease and renal transplantation prior to the index date. Follow-up continued until the outcome occurrence, discontinuation or initiation of XOI, disenrollment, or administrative censoring. We calculated incidence rates (IR) of T2D based on a new diagnosis of T2D and a receipt of anti-diabetic medication. Due to violation of the proportional hazards assumption, Cox proportional hazards models stratified by treatment duration compared the risk of T2D in XOI initiators versus non-initiators.

Results: There were 4,045 XOI initiators and 8,090 non-initiators. Baseline characteristics were well-balanced between the matched groups. Mean age was 54 years and 89% male in both groups. Common comorbidities include hypertension (64%), hyperlipidemia (61%), CVD (10%), obesity (10%) and chronic kidney disease (8%). Use of systemic steroids at baseline was common (33%). The mean serum uric acid level at baseline was 8.9 mg/dl in XOI initiators and 8.3 mg/dl in non-initiators. The mean HgbA1c level at baseline was 5.9% in XOI initiators and 5.8% in non-initiators. The IR of T2D per 100 person-years was 1.88 (95% CI 1.41–2.51) in XOI initiators and 1.57 (95% CI 1.36–1.81) in non-initiators. XOI treatment for 0–90 days was associated with an increased risk of T2D versus non-initiators, whereas the use of XOI for longer than 360 days may be associated with a decreased risk of T2D (**Table**).

Conclusion: Nearly 2% of gout patients were newly diagnosed with T2D during follow-up. Short-term use of XOI was associated with a greater risk of T2D in gout patients compared to non-initiators, but a potential long-term beneficial effect of XOI on T2D cannot be excluded. Future research such as a randomized clinical trial ensuring treatment adherence may be needed to examine the long-term effect of XOI on T2D.

Table Risk of type 2 diabetes by the duration of xanthine oxidase inhibitor treatment in gout patients: PS-matched analysis

	Xanthine oxidase inhibitor initiators (n = 4,045)				Non-initiators (n = 8,090)

The Risk of Aplastic Anemia and Pancytopenia with Colchicine: A Retrospective Study of Integrated Health System Database. Jasvinder Singh[1], Shuo Yang[1] and Jeff Foster[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Colchicine is a commonly used medication, sometime associated with bone marrow toxicity. The objective of this study was to examine the risk of severe hematologic side effects including pancytopenia and aplastic anemia with colchicine.

Methods: This retrospective study utilized the Veterans Affairs (VA) administrative and clinical databases from fiscal year 2001 to 2012. Colchicine use was defined as at least 30-day filled prescription. Prevalent gout was defined as the presence of >=1 International classification of diseases, ninth revision (ICD-9) codes for gout during an inpatient visit or during $^{3}2$ codes during outpatient visits. Aplastic anemia was captured with an ICD-9 code of 284.9 and Pancytopenia with a code of 284.1. We used Cox proportional hazards models that assessed hazards of aplastic anemia or pancytopenia adjusted for the following factors: Model 1: drug exposure, age, gender, body mass index, race, marital status, region; Model 2: variables in model 1, plus baseline Charlson comorbidities.

Results: 198 gout patients had aplastic anemia, of which 59 occurred in patients exposed to colchicine. 2047 gout patients had pancytopenia, of which 582 occurred in patients exposed to colchicine. The incidence rate of aplastic anemia was 0.5/1000 person years and of pancytopenia was xx/ in patients taking colchicine.

Conclusion: Colchicine increases the risk of aplastic anemia 3–4 fold and pancytopenia 2–3 fold in gout patients. Predictive models that can identify coexisting conditions that increase the risk of these side effects need to be developed to screen out patients at high-risk of these severe hematologic side effects.

Table 1 Association of colchicine with severe hematologic side effects

	Model 1 (demographics)		Model 2 (demographics + comorbidity)	
	Hazard ratio (95% CI)	p-value	Hazard ratio (95% CI)	p-value
Aplastic anemia	3.72 (2.61, 5.31)	<0.0001	3.32 (2.32, 4.76)	<0.0001
Pancytopenia	2.88 (2.58, 3.22)	<0.0001	2.26 (2.02, 2.53)	<0.0001

Osteoporotic Women at High Risk for Fractures Despite Two Years of Oral Bisphosphonate Therapy: Analysis Using the Canadian Multicentre Osteoporosis Study. Jonathan D. Adachi[1], David Goltzman[2], Ankita Modi[3], Jackson Tang[4], Chun-Po S. Fan[4] and Jessica Weaver[3]. [1]Division of Rheumatology, McMaster University, Hamilton, ON, [2]McGill University, Montreal, QC, [3]Merck & Co., Inc., Whitehouse Station, NJ, [4]Asclepius Analytics, New York, NY.

Background/Purpose: Individuals with osteoporosis (OP) have an increased susceptibility to fractures. Prevention and treatment of postmenopausal OP is critical to decreasing the risk of non-traumatic bone fractures. These fractures cause medical and personal hardships, particularly among older individuals, and are a burden on health care systems (Adachi 2003). The objective of this study was to quantify the number of osteoporotic women 55 years of age or older that remain at high risk of fracture despite benefits of prior oral bisphosphonate (BIS) therapy.

Methods: This study retrospectively analyzed a subset of participants in The Canadian Multicentre Osteoporosis Study (CaMos). CaMos is a prospective cohort study of 9,423 selected from community dwelling men and women older than 25 years of age. A subset of women from the CaMos dataset were studied who were 55 years of age or older with OP, who did not have Paget's disease and who reported receiving BIS therapy for at least two consecutive years. Additionally, patients must have had at least three years of follow-up data from the index date (start of 2 years of BIS therapy), and be considered osteoporotic at baseline for inclusion. Patients with lumbar spine or hip BMD of < -2.5 at baseline, or with prior vertebral or hip fractures, were classified as osteoporotic. Two consecutive years of BIS therapy was utilized as a proxy for adherence to BIS therapy, and was based on annual self-reported patient questionnaire responses regarding BIS therapy. High risk for fracture was determined by the following three criteria: 1.) Fractures during the first year following the BIS treatment period. 2.) Any decline in BMD at the hip (femoral neck) or lumbar spine (L1-L4) from baseline BMD (the most recent BMD prior to the treatment period) to the "study BMD" (i.e. the closest BMD after the 2-year treatment period). 3.) A "study BMD" less than -2.5 at the hip (femoral neck) or lumbar (L1-L4) spine. Descriptive analysis was conducted to characterize the fracture risk profile in this patient population.

Results: 628 women with a mean age of 71.6 years met the eligibility criteria. 24 participants (3.8%) experienced fractures during the first year following the two consecutive years of BIS therapy. Of the 24 patients with fractures during this time, 3 had fractures during the two years of BIS therapy. Almost two thirds (59.2%) of participants (372) experienced a decline in BMD from baseline following two years of therapy. Additionally, 71.3% of patients (448) were classified as osteoporotic after two years of OP therapy.

Conclusion: This study demonstrates that despite the benefits of OP treatment with BIS, a considerable proportion of women represented in the CaMos database who reported taking oral BIS therapy for two years remained at high-risk for OP fractures. In light of this finding, alternative treatments should be considered for many osteoporotic women who remain at high risk for OP or non-traumatic fractures.

Long-Term Oral Bisphosphonate Use for Osteoporosis Among Older Women – US and Canadian Perspective. Nicole C. Wright[1], Wilson Smith[2], Amy H. Warriner[1], Jeff Foster[1], Ruth McConnell[2], Huifeng Yun[3], Mary H Melton[1], Jeffrey R. Curtis[1] and Kenneth G. Saag[1]. [1]The University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background/Purpose: Bisphosphonates (BPs) have been widely used for the treatment and prevention of osteoporosis for two decades. Although new parenteral preparations have been introduced, oral BPs still represent the vast majority of osteoporosis treatments. Little is known about the characteristics of or regional differences in long-term oral BP users.

Methods: We evaluated the long-term use of oral BPs in the national US Medicare and Ontario (ON) Canada data systems. The US Medicare cohort consisted of women aged ≥65 years with an osteoporosis or fracture diagnosis code, or BP prescription fill. The ON data consisted of women aged ≥66 years who were new users of oral BPs. We identified women with three years of continuous medical and pharmacy coverage. Long-term BP users were those with exposure to an oral BP (alendronate, risedronate, ibandronate, and etidronate) in each of the three most recent years of available data (2009–2011). We evaluated demographic and BP utilization data including, BP exclusivity (no exposure to another BP agent in three year period) and compliance to therapy using proportion of days covered (PDC) *(*days of drug supplied in 3 years/3*365.25). Users with a PDC of ≥*70%* were considered compliant.

Results: We identified 888,704 US and 99,530 ON women meeting the inclusion criteria with at least one oral BP prescription in the most recent data. We then identified 698,012 US and 54,656 ON long-term oral BPs users (Table). Alendronate was primarily used by Medicare patients (78.0%), whereas risedronate was the primary oral BP in ON (56%). Based on the available data, the mean duration of us among the long-term BP users was five years in both US (SD: 1.1) and ON (SD: 2.2). In the US, risedronate users were more likely to be exclusive users (83%) compared to alendronate users; whereas in ON, a higher proportion of alendronate users were considered exclusive users than risedronate users. All ibandronate users were exclusive

users in US data. Compliance was higher in ON (80% alendronate, 78% risedronate) than in US (63% alendronate, 63% risedronate).

Conclusion: Although alternative preparations of BPs and new non-BP drugs have emerged in the market, the prevalence of oral BP use is high. In the data evaluated, the prevalence of long-term use (≥3years), was also high in both countries. However, compliance differed by country. Evaluations in more recent data would determine if and how drug holidays have altered these characteristics.

Table. Characteristics of Long-term Oral Bisphosphonate Users

	US, 2009–2011 (n = 698,012)	ON, 2009–2011 (n = 54,656)
Age, mean (SD)	79.3 (7.4)	74.0 (6.4)
Mean BP duration[a], yrs (SD)	5.0 (1.1)	4.9 (2.2)
Most recent BP, (n,%)	544,656 (78.0)	24,056 (44.0)
Alendronate	96,795 (13.9)	30,600 (56.0)
Risedronate	56,561 (8.1)	–
Ibandronate		
Exclusive BP users[b]**,** (n,%)	419,496 (77.2)	22,596 (93.9)
Alendronate	80,314 (83.0)	26,981 (88.2)
Risedronate	56,561 (100.0)	–
Ibandronate		
Compliant BP users[c]**,** (n,%)	262,125 (62.5)	18,173 (80.4)
Alendronate	50,880 (63.4)	20,981 (77.8)
Risedronate	33,981 (60.1)	–
Ibandronate		

[a]Mean duration based on first BP dispensed in each data system. US = 2006–2011; ON: 2002–2011
[b]Exclusive users are those who only filled a prescription for each oral BP among most recent BP users
[c]Compliance estimated at proportion of days covered (PDC) of ≥70% among exclusive BP users

Incidence and Risk Factors for Osteoporotic Vertebral Fracture in Low-Income Community-Dwelling Elderly: A Population-Based Prospective Cohort Study in Brazil. the São Paulo Ageing & Health (SPAH) Study. Diogo S. Domiciano[1], Luana G. Machado[2], Jaqueline B. Lopes[2], Valéria Caparbo[2], Liliam Takayama[2], Ricardo M. Oliveira[3] and Rosa M. R. Pereira[1]. [1]Faculdade de Medicina, University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]RDO Diagnosticos Medicos, São Paulo, Brazil.

Background/Purpose: Vertebral fractures are associated with increased future fracture risk and mortality. No data on incidence of osteoporotic vertebral fracture have been reported in low-income countries where the population's aging has been faster. Thus, we sought to describe the incidence and predictors of radiographic vertebral fracture in a longitudinal prospective Brazilian population-based elderly cohort - the São Paulo Ageing & Health (SPAH) Study.

Methods: From 2005–2007, all residents ≥65 years living in the Butantã community, located in the Western part of the city of São Paulo, were identified through census records. In total, 1025 subjects were included in the fracture prevalence study. Until 2012, 132 individuals had died during follow-up, and 725 subjects agreed to take part in this longitudinal evaluation (response rate in surviving subjects, 81.2%). Eighteen subjects were excluded due to cancer; thus, 449 women and 258 men were evaluated. A new vertebral fracture was considered as a distinct alteration in morphology of vertebrae resulting in higher grade of deformity when the second radiograph was compared to the same vertebra on the baseline radiograph. Clinical questionnaire, bone mineral density (BMD) and laboratorial tests were performed at baseline. Multivariate Poisson regression models were used to identify independent predictors of vertebral fracture.

Results: After a mean follow-up of 4.3±0.8 years, the age-standardized incidence of vertebral fracture was 40.3/1000 person-years in women and 30.6/1000 in men. In women, three possible models of risk factors for fracture were fitted:1. age (RR:2.46, 95%CI 1.66–3.65), previous osteoporotic fracture (RR: 1.65, 95% CI 1.00–2.71) and lumbar spine BMD (RR: 1.21, 95% CI 1.03–1.41); 2. age (RR: 2.25, 95%CI 1.52–3.34) and femoral neck BMD (RR: 1.42, 95% CI 1.11–1.81); 3. age (RR: 2.11, 95% CI 1.41–3.15) and total hip BMD (RR: 1.56, 95% CI 1.21–2.0). In men, the highest quartile of serum type I collagen C-telopeptide (CTX) (RR: 1.96, 95% CI 0.98–3.91) and prior fracture (RR: 2.10, 95% CI 1.00–4.39) were predictors of new vertebral fracture.

Conclusion: This is the first population-based study to ascertain the incidence of vertebral fracture in elderly Latin Americans, confirming the high frequency of the disorder. Age, prior fracture, BMD and bone turnover were predictors of the short-term incidence of vertebral fracture.

High Incidence of Non-Vertebral Osteoporotic Fracture and Hip Fracture in Brazilian Low-Income Community-Dwelling Elderly: A Population-Based Prospective Cohort Analysis from the São Paulo Ageing & Health (SPAH) Study. Diogo S. Domiciano[1], Luana G. Machado[2], Jaqueline B. Lopes[2], Camille P. Figueiredo[2], Valéria Caparbo[2], Liliam Takayama[2], Ricardo Oliveira[3], Paulo R Menezes[1] and Rosa M. R. Pereira[1]. [1]Faculdade de Medicina, University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]RDO Diagnósticos Médicos, São Paulo, Brazil.

Background/Purpose: There is considerable variability in the incidence of hip fracture among countries, even among different geographical areas within the same country. In Brazil, population differences in occurrence of hip fracture are probably related to the huge size of the country, the substantial ethnical miscegenation and distinct lifestyle habits within the Brazilian territory. Longitudinal studies on incidence of hip fracture in the Brazilian population are scarce and the results are hampererd by incomplete capture of cases and short follow-up time. Moreover, there is no prospective study on incidence of non-vertebral fractures beyond the hip. Thus, our aim was to describe the incidence of hip and non-vertebral fracture in elderly community from a prospective population-based study.

Methods: Incidence of hip and non-vertebral fracture were determined in 707 women and men from community, aged 65 years or older. Specific questionnaire (clinical and anthropometric data), including personal history of fragility fracture in non-vertebral osteoporotic sites (hip, humerus, wrist, rib) was performed at baseline and after an average of 4.3 years. All incident fractures during the study period were confirmed by radiograph of the affected site.

Results: 449 women (mean age 72.9 ± 4.8 years) and 258 men (mean age 72.3 ± 4.7 years) were included in the study. The age-adjusted incidence of non-vertebral fracture was 1710/100.000 person-years in women and 630/100.000 person-years in men (female/male ratio: 2.6). The age-adjusted incidence of hip fracture was 420/100.000 person-years in women and 90/100.000 person-years in men (female/male ratio: 4.7). The incidence increases with age, particularly in women.

Conclusion: The incidence of non-vertebral osteoporotic fracture in the Brazilian elderly population was high, especially among women. Concerning hip fracture, these results emphasize that the incidence in the southern and southeastern regions of the country seems to be higher than the rates in the northern/northeastern population. Furthermore, our results reinforce the notion that the incidence of hip fracture in Brazilian older adults, particularly in women, is higher than in other Latin American populations, except Argentina.

Visceral Fat Measured By Dual-Energy X-Ray Absorptiometry Is Associated with Increased Risk of Non-Spine Fractures in Nonobese Elderly Women: a Population-Based Prospective Cohort Analysis from the São Paulo Ageing & Health (SPAH) Study. Luana G. Machado[1], Diogo S Domiciano[1], Camille P. Figueiredo[1], Jaqueline B. Lopes[1], Valéria Caparbo[1], Liliam Takayama[1], Ricardo M. Oliveira[2] and Rosa M R Pereira[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]RDO Diagnosticos Medicos, São Paulo, Brazil.

Background/Purpose: The protective role of obesity on bone health has currently been questioned, since it has been demonstrated that visceral fat have a deleterious effect on bone. However, there are no studies evaluating the association between visceral fat measured by DXA with fracture risk. The aim of this study was to investigate the association of visceral fat with incident non-spine fractures in community-dwelling elderly women.

Methods: This is a longitudinal prospective population-based cohort study evaluating 433 community-dwelling women aged 65 years or older. Specific questionnaire (clinical and anthropometric data), including personal history of fragility fracture in non-spine osteoporotic sites (hip, humerus, wrist, rib) was performed at baseline and after an average of 4.3 years. All incident fractures during the study period were confirmed by affected site radiography. Bone mineral density (BMD) and laboratory tests were also performed at baseline. Visceral fat was measured by a new software of dual-energy X-ray absorptiometry (DXA) in the android region of a total body DXA scan. Logistic regression models were used to estimate the relationship between visceral fat and non-spine fractures.

Results: The mean age was 72.8 ± 4.7 years and 28 incident non-spine osteoporotic fractures were identified after a mean follow-up time of 4.3 ± 0.8 years. According the Lipschitz classification for nutritional status in elderly, 61.4% of women were considered obese/overweigth (BMI > 27 kg/m^2) and 38.6% were nonobese (7.4% underweight- BMI < 22 kg/m^2 and 31.2% normal weight- BMI ≥ 22 and ≤ 27 kg/m^2). After adjusting for age, previous fracture and BMD (parameters with significance at univariate analysis), visceral fat area had a significant association with incident non-spine fractures in nonobese (BMI ≤ 27 kg/m^2) elderly women (p=0.009).

Conclusion: Higher visceral fat was associated with the risk for non-spine fractures in nonobese elderly women. This study supports a potential negative effect of visceral adiposity on bone health.

Spine-Hip Diagnostic Discordance in the United Arab Emirates. Nicholas Wilson, Lidia Sanchez Riera, Iman Hobeldin, Salman Waheeduddin, Nehad Ibrahim, Suneetha Gonuguntla, Tahir Khan, Ritu Aneja, Samer Nuhaily and Mustafa Al Maini. Mafraq Hospital, Abu Dhabi, United Arab Emirates.

Background/Purpose: Diagnostic discordance for osteoporosis is the presence of different T-scores in two skeletal sites in the same subject leading to different WHO diagnostic categories. Discordance is defined as minor when the difference between two sites is no more than one WHO diagnostic class and major when one site is osteoporotic and the other is normal[1]. This study examines to determine the percentage of minor and major diagnostic discordance and identify associated factors in patients undertaking osteoporosis screening.

Methods: Details of the first Dual-X-Ray-Absorptiometry test (DXA) during 2011–2013 were extracted, including weight, height, T score at femoral neck and total hip in the right side (RFN, RTH) and left side (LFN, LTH) and T score at lumbar spine (LS). Only complete data for individuals over 18 years old, with nationality of North Africa Middle East (as per WHO definition) were analysed. Differences in T scores and degree of discordance between sites were calculated. Age and BMI were analysed as contributing factors.

Results: One thousand, four hundred and forty four patients with complete data were identified. The mean age was 59.1 (±13.2 SD) and 86.3% were females. Diagnostic agreement among all skeletal sites was found in 415 (28.7%) patients, while 631 (43.7%) and 398 (27.6%) showed at least one major or minor discordance, respectively. Maximum concordance was found between right total hip and left total hip (86.6%) and minimum between lumbar spine and left total hip (40.7%). Minor discordance was present in about 40% of the patients when comparing spine to any hip site. Major discordance in LS compared to all hip regions ranged from 19.2 to 21.3%. All comparisons of skeletal sites, including trend of direction is shown below in table 1. A significant correlation with discordance was observed with both age and BMI (p >0.001).

Conclusion: Results show a high level of major diagnostic discordance, higher than previously reported in published studies[1–3]. This high prevalence of discordance could produce some problems for the physicians in decision-making regarding these patients. This reiterates the understanding that multiple site measurements are mandatory for osteoporosis diagnosis, including BMD measurements at both hips. High prevalence of discordance between lumbar spine and hip T-scores suggests some defects in the cut-off values for the definition of osteoporosis and osteopenia proposed by the WHO. BMD should be used as only one of the factors in making therapeutic decisions when evaluating patients with osteoporosis.

Table 1. Number (percentage) of cases categorised as normal, minor and major discordance and the directional trend and weight between the different skeletal sites

Comparison	Normal	Discordance Minor	Major	Trend	Direction	Number of comparisons
LS-RTH; n (%)	581 (41.2)	544 (38.5)	285 (20.2)	93.30%	LS lower	1410
LS-LTH; n (%)	570 (40.7)	532 (38)	298 (21.3)	93.70%	LS lower	1400
LS-RFN; n (%)	579 (40.9)	561 (39.9)	270 (19.2)	92.10%	LS lower	1407
LS-LFN; n (%)	575 (41.2)	469 (40.8)	242 (20.1)	89.50%	LS lower	1396
RTH-RFN; n (%)	1150 (80.9)	260 (18.2)	12 (0.9)	56.90%	RFN Lower	1422
LTH-LFN; n (%)	1097 (77.8)	297 (21)	16 (1.2)	67.90%	LFN Lower	1410
RTH-LTH; n (%)	1219 (86.6)	177 (12.6)	11 (0.8)	51.60%	RTH Lower	1407
RFN-LFN; n (%)	1121 (80)	261 (18.6)	19 (1.2)	64.30%	LFN Lower	1401

Concordance with the National Osteoporosis Foundation Treatment Guidelines. Nicole Wright[1], Xin Lu[2], Stephanie Edmonds[2], Fredric Wolinsky[2], Douglas Roblin[3], Peter Cram[4] and Kenneth G. Saag[5]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Iowa, Iowa City, IA, [3]Kaiser Permanente Georgia, Atlanta, GA, [4]University of Toronto, Toronto, ON, [5]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: The National Osteoporosis Foundation (NOF) published treatment guidelines to help guide clinicians on which patients should be considered for osteoporosis (OP) therapy. We examined patient factors associated with non-concordance among older adults participating in the PAADRN study.

Methods: The PAADRN study (NCT01507662) is a large, NIH funded, randomized trial currently being conducted in the Iowa City, IA, Birmingham, AL, and Atlanta, GA metro areas. Immediately following DXA, participants ≥50 years of age are recruited and randomized. We used data from the control arm, usual care group, (n=2,711 as of 6/14/14) for our analyses. We defined guideline concordant OP therapy as the report of any FDA approved OP therapy at the 12-week post-DXA survey along with one of the following criteria: 1) baseline self-report of fracture after the age of 40, 2) T-score at or below the OP threshold (<−2.5), or 3) T-score within the low bone mass range (−1.5 to -2.5) and a FRAX score ≥20%. Non-concordance was examined among participants who 1) were indicated for OP therapy who did not report OP therapy at 12 weeks (N=1,170), and 2) were not indicated for OP therapy who reported OP therapy at 12 weeks (N=1,541). We used logistic regression to assess the association of baseline demographic and comorbidity factors with non-concordance in both groups.

Results: Our study population was 85% female, 20% from minority backgrounds, and 60% ≥ 65 years of age. At baseline, 760 (28%) reported having a fracture after 40 years of age, 576 (21%) had DXA defined OP, and 188 (7%) had low bone mass with a FRAX ≥ 20%. At the 12-week survey, 38% of patients with indications for OP therapy reported medication use, and 15% of patients without indications for OP therapy reported medication use. When treatment was indicated, we found that being Black was associated with higher odds of treatment non-concordance in the crude analyses (Table). Factors associated with higher odds of non-concordance among those not indicated for treatment included: being a woman, Hispanic, having comorbidities related to secondary OP, being a pre-menopausal woman, the self-report of low bone mass and OP, calcium and multi-vitamin supplementation use, and having spoken to provider by 12-week survey (Table).

Conclusion: In this study of usual OP treatment, 38% of those indicated for OP treatment reported medication use, and 15% of those not indicated for treatment reported medication use. We found that race was associated with non-concordance when treatment was indicated. When treatment was not indicated, non-concordance was associated with conditions related to low BMD, potentially being used as preventative therapy. However, demographic and lifestyle factors were also associated with high non-concordance in this group, suggesting that additional education on the benefits and risks of OP therapies for both patients and providers is needed.

Table Factors Associated with Non-Concordant Use of Osteoporosis Medications

	Treatment Indicated but Not Received (n=723/1,170)			No Treatment Indicated But Received (n=237/1,541)		
	OR*	95% CI	p-value	OR*	95% CI	p-value
Women vs. Men	0.75	(0.52, 1.08)	0.117	4.13	(2.32, 7.34)	<0.001
Hispanic vs. Non-Hispanic	0.79	(0.29, 2.14)	0.646	2.39	(1.17, 4.91)	0.017
Black vs. White	1.71	(1.14, 2.56)	0.009	0.40	(0.27, 0.60)	<0.001
Site A vs. Site C	0.74	(0.55, 0.99)	0.044	1.39	(0.98, 1.95)	0.062
Site B vs. Site C	1.32	(0.95, 1.83)	0.099	0.55	(0.38, 0.81)	0.003
Self-report of LBM	0.45	(0.35, 0.57)	<0.001	3.35	(2.50, 4.48)	<0.001
Self-report of Osteoporosis	0.33	(0.26, 0.43)	<0.001	2.61	(1.82, 3.74)	<0.001
Pre-menopausal	0.67	(0.51, 0.89)	0.006	1.43	(1.02, 2.00)	0.038
Secondary Osteoporosis	0.74	(0.57, 0.96)	0.022	1.59	(1.17, 2.17)	0.003
Calcium Supplementation	0.53	(0.41, 0.69)	<0.001	3.07	(2.24, 4.19)	<0.001
Vitamin D Supplementation	0.52	(0.39, 0.69)	<0.001	3.02	(2.10, 4.34)	<0.001
DXA defined Low vs. Normal BMD	0.23	(0.12, 0.47)	<0.001	2.34	(1.69, 3.25)	<0.001
Spoke to Doctor by 12 week survey	0.58	(0.45, 0.73)	<0.001	1.81	(1.36, 2.41)	<0.001

Validation of the Diagnosis of Avascular Necrosis of Bone in Administrative Data. Medha Barbhaiya[1], Yan Dong[2], Jeffrey A. Sparks[1], Elena Losina[2], Karen H. Costenbader[1] and Jeffrey N. Katz[2]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Avascular necrosis (AVN) of bone is a painful, disabling condition. Studies aimed at improving the diagnosis or treatment of AVN require accurate case-finding methods. We examined the sensitivity, specificity, positive predictive value (PPV) and positive likelihood ratio (LR^+) of alternative algorithms that use claims data to identify cases of AVN of the upper and lower extremities.

Methods: Using a centralized clinical data registry from a large academic hospital, we identified all adults aged ≥18 years who underwent MRI of an upper and/or lower extremity joint for any indication between January 1, 2010 and June 1, 2011. We examined the performance characteristics (sensitivity, specificity, PPV, and LR^+) of four algorithms (A – D) using International Classification of Diseases, 9th edition (ICD-9) codes for AVN (ICD-9, 733.4X) **(Table)**. The algorithms ranged from least stringent (Algorithm A, requiring ≥1 1 ICD-9 code) to most stringent (Algorithm D, requiring ≥ 3 ICD-9 codes at least 30 days apart). Only ICD-9 codes within 6 months of MRI diagnosis were included. We compared cases identified by each algorithm to the gold standard of a clinical MRI reading by a radiologist confirming "avascular necrosis" or "osteonecrosis." We calculated 95% confidence intervals (CI) using the normal approximation of the binomial distribution.

Results: A total of 11,878 patients who underwent MRI of the upper and lower extremities during the 1.5 year period were included in this study. The prevalence of AVN using the gold standard of MRI was 0.7%, with 83 total cases of AVN. Algorithm A had a sensitivity of 81.9% (95% CI 71.9–89.5), with a PPV of 48.6% (95%CI 40.0–57.2) and a LR^+ of 134 (95% CI 104–173). The PPV of algorithm D increased to 61.4% (95% CI 47.6–74.0) with a LR^+ of 226 (95% CI 139–368), although the sensitivity decreased to 42.2% (95% CI 31.4–53.5) **(Table)**. The specificity of all four algorithms ranged from 99.0 to 99.8%.

Conclusion: In this study, we demonstrated that the PPV for AVN among patients who underwent MRI ranged from 49–61% in different ICD-9 code-based algorithms. Given its high sensitivity, Algorithm A (requiring at least 1 ICD-9 code for AVN) appears best suited for situations in which it would be problematic to miss AVN cases, and confirming cases to exclude false positives with further chart review is feasible. Algorithm B, requiring ≥2 ICD-9 codes at least 7 days apart, had the highest PPV and might be recommended when further validation is not feasible, although misclassification may occur. These algorithms provide an efficient way to identify AVN cases in administrative data, and the PPVs will be greater in populations with higher disease prevalence such as SLE or orthopedic cohorts. Of note, since all patients in this study underwent MRI, cases of asymptomatic or mild AVN that did not prompt MRI evaluation would not be detected with these methods.

Table Performance characteristics of ICD-9 code algorithms for the diagnosis of avascular necrosis (AVN) of bone

Algorithms	Sensitivity (95% CI),%	Specificity (95% CI), %	PPV (95% CI),%	LR^+ (95% CI)
A: ≥1 ICD-9 code for AVN	81.9 (71.9–89.5)	99.4 (99.2–99.5)	48.6 (40.0–57.2)	134.2 (104.4–172.6)
B: ≥2 ICD-9 codes for AVN at least 7 days apart	56.6 (45.3–67.5)	99.8 (99.7–99.8)	62.7 (50.7–73.6)	238.5 (157.5–361.3)
C: ≥2 ICD-9 codes for AVN at least 30 days apart	42.2 (31.4–53.5)	99.8 (99.7–99.9)	60.3 (46.6–80.0)	216.3 (133.9–349.4)
D: ≥3 ICD-9 codes for AVN at least 30 days apart	42.2 (31.4–53.5)	99.8 (99.7–99.9)	61.4 (47.6–74.0)	226.1 (138.8–368.2)

High Prevalence of Cervical Malignant and Premalignant Lesions Among Women with Rheumatoid and Psoriatic Arthritis. Majed Khraishi[1], Rana Aslanov[2] and Sarah Khraishi[3]. [1]Nexus Clinical Research, St John's, NF, [2]Memorial University of Newfoundland, St.John's, NF, [3]NL Research Technologies (NLRT), St. John's, NF.

Background/Purpose: Rheumatic diseases have been associated with an increased prevalence of malignancy. We aimed to examine the prevalence of precancerous lesions and malignancy in the entire cohort of patients with Inflammatory Arthritides; to compare the prevalence of malignancy between Rheumatoid (RA) and Psoriatic (PsA) Arthritis patients and to investigate correlations that may explain the high prevalence of cervical lesions that we noted.

Methods: Patients were recruited prospectively from a rheumatology clinic specializing in treating patients with arthritis and followed from January 2011 to December 2013. The prevalence of premalignant lesions and malignancy was evaluated and compared to the data provided by Statistics Canada, Canadian and Provincial Cancer Registries. Disease severity was assessed using the TJC/SJC, CRP, ESR, DAS28, and CDAI scores.

Results: A cohort of 700 (67.9% females) patients with Inflammatory Arthritis was included in this study with mean (SD) age 55.0 (12.4) years and mean (SD) duration of disease 8.4 (8.3) years. Overall, 116 (16.6%) precancerous lesions and cancers were analysed. Hundred and ten patients (15.7%) had at least one malignancy; three patients had a history of 2 malignancies. The most frequently observed cancers were: Cervical (37-7.8% of female population; OR (95%CI)=2.5 (1.0–6.2); P=0.042), Breast (20-4.2% of female population; OR (95%CI)=1.1 (1.0–1.1); p=0.001), Bowel (11-1.6%), and Lung Cancer (10-1.4%).

We identified 37 cases with cervical lesions. Of them, six females had a history of cervical cancer (SCC), 18- High Grade Squamous Intraepithelial Lesions (HSIL), 8-Low Grade SIL cannot exclude HSIL, and in 5 cases it was impossible to trace the type of cervical dysplasia. Six cases belonged to women aged 49 years and younger, 31 cases of dysplasia and cancer belonged to women aged 50 years and older. All of them underwent hysterectomy prior to enrolment in the study. Prevalence of cervical lesions was strongly correlated with: females' age (R=0.151, p=0.033), Health Assessment Questionnaire (HAQ: R=0.226, p=0.001) in PsA cohort; and with: females' age at RA diagnosis (R=0.100, p=0.026), Tender Joint Count (TJC: R=0.108, p=0.016), and Clinical Disease Activity Index (CDAI: R=0.140, p=0.002) in RA cohort. Cervical lesions were strongly correlated with the total number of comorbidities in the both cohorts (PsA: R=0.161, p=0.023 & RA: R=0.088, p=0.049). The treatment of RA women with NSAIDs showed significant association with cervical lesions (r=0.123, p=0.006). No correlation with PASI score was detected in PsA patients. No definite association with treatment with biologic disease modifiers was documented.

Conclusion: The prevalence of cervical dysplasia and cancer among affected women was higher than the tumor-based 10-year prevalence of cervicouterine cancer cases among females reported by the Canadian Cancer Registry, Statistics Canada and Provincial/ Territory Cancer Registries (7.8% vs. 3.0%, respectively). Our data suggested their possible correlation with disease activity. Closer surveillance will be warranted if the reported increased prevalence is confirmed in larger cohorts.

Risk of Hospitalized Infection in a Psoriasis/Psoriatic Arthritis Cohort. Kevin L. Winthrop[1], Lang Chen[2], John Baddley[2], Allison Taylor[2], Benjamin Chan[3], Huifeng Yun[4], Sarah Siegel[1] and Jeffrey R. Curtis[5]. [1]Oregon Health & Science University, Portland, OR, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Oregon Health and Science University, Portland, OR, [4]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [5]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Psoriasis (PsO)/Psoriatic arthritis (PsA) often requires treatment with systemic immunosuppressive agents, some of which may increase hospitalized infection risk. Few population-based studies to date have evaluated the incidence of hospitalized infections this population.

Methods: We used the US Medicare data from 2006–2011 to identify a large cohort of PsA and PsO patients. We defined PsA and PsO patients as those with >1 rheumatologist-diagnosis code for psoriatic arthritis (ICD 9 696.0), or >1 dermatologist-diagnosis code for psoriasis (ICD 9 696.1) respectively, followed by a prescription for etanercept (ETA), cyclosporine (CIC), ustekinumab (UST), adalimumab (ADA), methotrexate (MTX) or ultraviolet light (UV) therapy. Patients had at least 6 months of continuous Medicare enrollment prior to the first date of exposure to these therapies. We excluded patients with organ transplantation, human immunodeficiency virus infection, advanced kidney and liver disease, or cancer with a 183-day period prior to cohort inception. We used validated-claims based algorithms to identify hospitalized infections among all exposure groups. Patient exposures were censored at time of serious infection, death, end of study, loss of coverage, or 90 days following end of treatment exposure whichever came first. Pairwise propensity scores (PS) were calculated and used to control for potential differences between comparator treatments. We calculated crude incidence rates for exposure groups, and used Cox-proportional hazard regression models to calculate hazard ratios for hospitalized infection between exposure groups while adjusting for PS quintile.

Results: We identified 10,261 PsA individuals and 31,052 PsO individuals. Within the PsA cohort, we identified 185 hospitalized infections for an overall incidence rate of 36.2 (95% CI 31.1–41.8) per 1,000 py. The rate of hospitalized infections ranged from 13.2 (95% CI 4.3–41.0) per 1,000 py for the UV group to 38.7 (95% CI 28.8–52.0) per 1,000 py for the ETA group. In Cox modeling, incidence rates were similar between exposure groups, with the exception of patients starting ETA as compared to UV therapy (HR 3.1 [95% CI 0.9–1.9]) where a non-statistically significant trend was noted. Within the PsO cohort, there were 1,198 hospitalized infections yielding an overall incidence rate of 37.0 (95% CI 35.0–39.1) per 1,000 py. The rate of such infections ranged from 27.2 (95% CI 23.1–31.9) per 1,000 py for the UV group to 40.5 (95% CI 36.9–44.5) per 1,000 py for the MTX group. After adjustment for possible confounders, patients on ADA had higher incidence rates as compared to those on CIC (HR 1.4 [95% CI 1.0, 2.0]), or UV therapy (HR 1.4 [95% CI 1.1–1.9]), respectively. Patients on MTX were also at higher risk for infection than those using UV therapy (HR 1.3 [95% CI 1.1, 1.6]). Incidence rates between all other exposure comparisons were similar.

Conclusion: Among Medicare enrollees with PsA or PsO, rates of hospitalized infections varied across therapies but were largely similar. PsA patients were at similar risk no matter their therapy, although PsO patients starting ADA or MTX were at higher risk for infection than those using UV therapy.

What Does the Patient Global Assessment (PGA) Mean for Patients with Psoriatic Arthritis? a Post-Hoc Analysis of 223 Patients with Psoriatic Arthritis. Sandra Tälli[1], Adrien Etcheto[2], Bruno Fautrel[3], Andra Balanescu[4], Jürgen Braun[4], Juan D. Cañete[5], Kurt de Vlam[4], Maarten de Wit[4], Turid Heiberg[4], Philip S. Helliwell[4], Umut Kalyoncu[4], Uta Kiltz[6], Mara Maccarone[4], Dora Niedermayer[4], Kati Otsa[4], Rossana Scrivo[4], Josef S. Smolen[4], Tanja Alexandra Stamm[4], Douglas J. Veale[7], Tore K. Kvien[4] and Laure Gossec[3]. [1]GRC UPMC Paris 06 University, Pitie-Salpétriere hospital, Paris, France, [2]Paris Descartes University, Paris, France, [3]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France, [4]PsAID taskforce, EULAR, Zurich, Switzerland, [5]Hospital Clinic, Barcelona, Spain, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: Patient global assessment (PGA) is one of the most widely used patient reported outcomes (PROs) in psoriatic arthritis (PsA). PGA should reflect the global impact of the disease from the patient's perspective, however we lack information on the concepts encompassed in PGA. In addition the Group of Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) has proposed to use also two specific (joints, skin) patient assessments but their scope is also unclear. (1) Recently the European League Against Rheumatism (EULAR) developed the PsAID (Psoriatic Arthritis Impact of the Disease) which includes 12 domains of health important for patients. (2)

Objective: to explore PGA in PsA from the patient's point of view by comparing it to the PsAID domains of health and also to explore the two specific (joints, skin) patient assessments in relation to PGA.

Methods: Post-hoc analysis of the cross-sectional PsAID study (2) for patients with definite PsA (according to the Classification Criteria for Psoriatic Arthritis (CASPAR) criteria). Data collection included PGA ("Considering all the ways PsA has affected you during the last week, circle the number that best describes how you have been doing"), skin and joint patient assessments (patient global assessments of these 2 aspects) and PsAID questions covering physical (including joints and skin), psychological and social impact of PsA. The concepts covered by PGA were explored by univariate (Spearman correlation coefficient) and multivariate linear regression, and intra-class correlation between PGA and joint and skin patient assessments was calculated.

Results: Among 223 patients (mean age 51.0 (standard deviation, ±13.3) years, mean disease duration 9.9 (±10.1) years, mean swollen joint count 4.1 (±5.1), 84.3% with current psoriasis (mainly of less than 5% body surface area)), 51.1% were females. Mean patient assessment values were for PGA 4.8 (±2.7), joint patient assessment 5.6 (±2.5) and skin patient assessment 4.1 (±3.0). Multivariate linear regression indicated that PGA was well explained (R^2 of model 0.754) by coping (β= 0.287); pain (β= 0.240); work and/or leisure activities (β= 0.141); and anxiety (β= 0.109). Intra-class correlation between PGA and joint or skin patient assessment was respectively 0.71 [95% confidence interval, 0.64–0.77] and 0.52 [95% confidence interval, 0.42–0.60].

Conclusion: PGA in PsA is explained by coping, then as expected physical aspects of impact which may reflect joint involvement: pain and work/leisure activities; and psychological impact: anxiety. In this population, skin related issues were not additional explanatory elements of PGA in multivariate analysis. Finally, joint patient assessment may be redundant with PGA whereas skin patient assessment gives additional information in characterizing the disease and its impact.

Background/Purpose: Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) are complex diseases of unknown etiology and its pathogenesis results from the combination of genetic susceptibility and environmental factors (smoking, alcohol consumption, diet, . . .etc). Among the environmental factors, diet habits are of particular interest since they are modifiable factors. To date, information about dietary habits in this group of patients is very limited. The aim of this study was to analyze dietary habits in a large cohort of patients with RA and PsA from the Spanish population.

Methods: A multicentre cross-sectional comparative study of RA and PsA patients was performed. All patients were recruited through the *Immune-Mediated Inflammatory Diseases Consortium* (*IMIDC*) from 2007 to 2012. The *IMIDC* is a network of Spanish biomedical researchers focused in the study of the molecular basis of immune-mediated inflammatory diseases. All patients included in the present study were selected from the outpatient clinics of the Rheumatology departments at 20 different Spanish University Hospitals. An epidemiological questionnaire developed by experts at DNA National Bank was applied to obtain all data. The dietary questionnaire included the assessment of the number of days per week in which patients consumed certain foods: fresh fruit, meat, fish, legumes, vegetables, pasta, rice, bread, dairy products, sausage and sweets.

Results: From a total number of 3,941 patients surveyed n=3,229 patients were included in the present study: n=1,128 (65%) had Rheumatoid arthritis and n=1,128 (35%) Psoriatic arthritis. The proportion of women was 77% in RA patients and 47% in PsA patients. We observed that the mean number of days per week eating fish and fruit was significantly higher in RA than in PsA patients ([5.58 *vs* 5.09; *P*=8x10E-12] [2.65 *vs* 2.52; *P*=2x10E-2]). Pasta, rice and potatoes intake was also significantly increased in RA patients ([3.41 *vs* 3.22; *P*=7x10E-3]. In this group, the mean of vegetable weekly intake was 4.23 days and in PsA group was 3.97 days (*P*=6x10E-4). Dairy products consumption was also significantly higher in RA than in PsA patients (5.89 *vs* 5.62; *P*=3x10E-5). Among PsA patients the mean number of days per week of intake meat, sausage and sweets was significantly higher comparing to RA patients ([3.17 *vs* 2.72; *P*=3x10E-13], [2.02 *vs* 1.58; *P*=9x10E-10], [2.98 *vs* 2.72; *P*=5x10E-3]).

Conclusion: In our large cohort of patients we describe for the first time the dietary habits differences between rheumatoid arthritis and psoriatic arthritis patients in Spanish population. Significant differences in the consumption of several foods have been observed. Fruit, fish, pasta, rice, potatoes and vegetables were the group of aliments that RA patients intake more days per week; while meat, sausage and sweets are eaten more often in PsA patients. Our findings could provide insights about the possible implication of dietary factors in the development and prognosis of these diseases. It would be also interesting to study if these factors could contribute to disease prevention strategies.

Epidemiology of Polymyalgia Rheumatica in Korea. In young Kim[1], Seulkee Lee[1], Hemin Jeong[1], Hyungjin Kim[1], Jiwon Hwang[1], Jaejoon Lee[1], Eun-Mi Koh[2] and Hoon-Suk Cha[1]. [1]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Background/Purpose: Polymyalgia rheumatica (PMR) is a chronic inflammatory disease affecting people older than 50 years. Diagnosis is made based on clinical features and the current standard of treatment is low-dose glucocorticoids. PMR is known to be more frequent in Caucasian ethnicity and females. But up to date, there has been a scant epidemiologic study of PMR in Asian countries including Korea. We aimed to estimate incidence and prevalence rates of PMR and current treatment state in Korea.

Methods: We performed nationwide retrospective review of PMR using the Korean National Health Insurance (NHI) and Health Insurance Review and Assessment (HIRA) database from 2007 to 2012. NHI is the sole public medical insurance system in Korea, which covers 100% of the Korean population and HIRA is a government incorporated organization to build an accurate claims review and quality assessment system for the NHI. We defined PMR cases by both diagnostic codes and medication codes simultaneously, in other words, by proper ICD code (M 35.3) and concurrent appropriate prescription codes (glucocorticoids).

Results: We identified total 1,463 newly diagnosed cases of PMR for the 5 years. The annual incidence rate of PMR per 100,000 Korean individuals was estimated as 2.06 (1.45 in male, 2.59 in female), and the prevalence rate was 8.21 per 100,000 individuals in 2012 (5.60 in male, 10.42 in female). Among the 1,463 cases, 992 (67.8%) were female and 471 (32.2%) were male and the median age at the time of diagnosis was 67 years old. The incidence rate according to age appeared to increase with advancing age peaking 70 years old, as similar as previous reports of western studies. The most frequently prescribed agent was prednisolone, and the starting daily dosage of glucocorticoids as prednisolone equivalent was between 5 to 15 mg daily in 74.5 % of the patients.

Conclusion: This is the first study that evaluated epidemiologic data of PMR in Korea, and included population was the largest among those of studies published in East Asia so far. The incidence and prevalence rates of PMR are estimated considerably lower than that of Western populations. And this result supports that both genetic and environmental factor would play important roles in pathogenesis of PMR.

Advocating for Pediatric Rheumatology Care in the Mid-Canadian Provinces: Large Geographic Area, Large Pediatric Population, Low Number of Pediatric Rheumatologists and Allied Health Workers Identified As Unique Challenges. Paivi Miettunen[1], Nadia Luca[1], Susanne Benseler[1], Janet Ellsworth[2], Tommy Gerschman[3], Nicole Johnson[1], Heinrike Schmeling[1] and Natalie J. Shiff[4]. [1]Department of Pediatrics/University of Calgary, Calgary, AB, [2]University of Alberta, Edmonton, AB, [3]Alberta Children's Hospital, Calgary, AB, [4]University of Saskatchewan, Saskatoon, SK.

Background/Purpose: Advocacy for pediatric rheumatology care for Mid-Canadian (MC) provinces (Alberta, Manitoba, Northwest Territories, Nunavut and Saskatchewan) represents a challenge. Although these provinces comprise a large geographic area (>52% of Canada), patient characteristics and pediatric rheumatology workforce are not known.

Our objective was to collect and report data for pediatric population, number of pediatric rheumatologists, patient diagnoses, wait times, allied health support and pediatric rheumatologists' work-life balance in MC provinces.

Methods: Canadian 2012 Statistical data was used to identify population between 0–14 years (Defined as "children" by Statistics Canada) in MC provinces. A survey monkey was sent to each MC pediatric rheumatology center to identify 1) the number of pediatric rheumatology full time equivalents (FTEs) per province for clinical care, education, research and administration; 2) Distribution of pediatric rheumatology diagnoses and wait times, and 3) perceived work-life balance of participants.

Results: All 3 currently active pediatric rheumatology centers in MC provinces responded (2 in Alberta and 1 in Saskatchewan). Total pediatric

MC population aged 0–14 years (% of all Canadian) was 1.1 million (21.4%). There were a total of 7.7 FTE pediatric rheumatologists: 5.7 in Alberta (0.7 at one center, 5 at the other), 2 in Saskatchewan and 0 in Manitoba, Nunavut and Northwest Territories. Out of 7.7 FTEs, 4.74 were devoted to for clinical care, 1.08 for education, 3.58 for research and 0.8 for administration. Night–time on-call service frequency varied from "not mandatory" to 1:5. Allied health support was variable: nursing, physiotherapy and occupational therapy were available at 2/3 centers, 1/3 center had a social worker and a pharmacist, and 0/3 center had a psychologist. Individual outpatient data was available for Alberta and Saskatchewan and included 1225 active outpatients. The most common diagnoses (% total) were juvenile idiopathic arthritis (65–82%), systemic lupus erythematosus (4–6%), autoinflammatory disorders (3–7%) and vasculitis (2–4%). Wait time data was available for Saskatchewan and Alberta and ranged from 1 to 8 weeks for patients classified as "urgent" and from 2 weeks to 6 months for "semi-urgent". One center was not able see routine patients. Regarding wellness, 30% of responders reported their work and personal lives were "well balanced", 50% "struggled occasionally", 40% reported adverse impact on personal life and non-clinical work activities, and 60% reported their family/friends had commented on their "stress levels".

Conclusion: The MC provinces provide a unique challenge for provision of pediatric rheumatology care due to the vast geographic area and high proportion of children and low numbers of pediatric rheumatologists. Currently 3 out of 5 provinces are without a pediatric rheumatologist. The small number of rheumatologists per individual center resulted in unequal wait-times, and had an adverse impact on physician wellness. Our results underline a need for a network/collaboration to help address pediatric rheumatology care in these provinces.

Severe Spine Osteoarthritis in Older Men Is Associated with the Risk of Incident Fragility Fracture. Roland Chapurlat[1], Charline Estublier[2] and Pawel Szulc[3]. [1]Hopital Edouard Herriot, Lyon, France, [2]Hôpital Edouard Herriot, Pavillon F, Lyon, France, [3]INSERM UMR 1033, Lyon, France.

Background/Purpose: Data on the association of osteoarthritis (OA) with bone fragility are limited. In particular, data on the fracture risk in older men with spine OA are scarce. Our aim was to study the association of baseline severity of spine OA with bone mineral density (BMD), bone loss and risk of fragility fracture in a prospective study of a cohort of older men.

Methods: Men aged >50 (n=766) had lateral spine radiographs at baseline. Spine OA was assessed by Lane's score *(J Rheumatol, 1993)*. We calculated the total osteophyte score by adding up osteophyte scores for 6 intervertebral levels. We calculated total disc narrowing score (DSN) and total overall grade score similarly. BMD was measured by DXA using a HOLOGIC QDR1500 device. Abdominal aortic calcification (AAC) was assessed by Kauppila's semiquantitative score *(Atherosclerosis, 1997)*. Men were followed up for 7.5 yr to assess bone loss (every 18 mo) and incident vertebral fractures. Incident peripheral fractures were assessed for 10 yr.

Results: Moderate and severe osteophytes were found in 85% of men, 72% of men had DSN. After adjustment for age and weight, BMD (hip, forearm, whole body) was 2–7% higher ($p<0.05$ to <0.001) in men with severe spine OA in comparison with men with or without mild spine OA. For instance, men with severe DSN (total score >4, highest quartile) had 5% (0.4SD, $p<0.001$) higher total hip BMD compared with men without DSN. The rate of bone loss did not differ according to the severity of spine OA regardless of the measure of the spine OA (DSN, osteophytosis) and regardless of the skeletal site ($p>0.4$).

During the follow-up, 27 men sustained radiographic vertebral fractures. After adjustment for age, BMI, lumbar spine BMD, AAC, prior falls and fractures, risk of vertebral fracture increased with the DSN severity (HR= 1.15 per increase by 1 unit, 95%CI: 1.01–1.31, $p<0.05$). In this multivariable model, the risk of vertebral fracture was higher in the highest quartile of total DSN score vs. the three lower quartiles combined (HR= 2.47, 95%CI: 1.04–5.86, $p<0.05$).

During the follow-up, 61 men sustained non-vertebral fragility fractures. The incidence of non-vertebral fracture was lower above the median of total DSN score (4.6 vs 10.2%, $p<0.005$). After adjustment for the confounders (including hip BMD and leg disability), the risk of peripheral fracture was lower in men above the median total DSN score vs. below the median (HR= 0.44, 95%CI: 0.24–0.80, $p<0.01$).

Other measures of spine OA were not associated with the risk of fracture.

Conclusion: Men with severe spine OA have fewer non vertebral fractures but more vertebral fractures. This may be due to better bone quality but abnormal spine biomechanics.

Disclosure: R. Chapurlat, None; **C. Estublier**, None; **P. Szulc**, None.

Spine Osteoarthritis Is Associated with All Cause Mortality in Older Men. Charline Estublier[1], Roland Chapurlat[2] and Pawel Szulc[3]. [1]Hôpital Edouard Herriot, Pavillon F, Lyon, France, [2]Hopital Edouard Herriot, Lyon, France, [3]INSERM UMR 1033, Lyon, France.

Background/Purpose: Hip and knee osteoarthritis (OA) was associated with higher cardiovascular morbidity and mortality. Data on the cardiovascular status in men with spine OA are scarce. We assessed the association of spine OA with all cause mortality and with abdominal aortic calcification (AAC) severity and its progression rate in older men.

Methods: Men aged >50 (n=766) had lateral spine radiographs and blood collection and were followed up prospectively. Spine OA was assessed by Lane's score *(Lane et al., J Rheumatol, 1993)*. We calculated the total osteophyte score by adding up osteophyte scores for 6 intervertebral levels. We calculated total disc narrowing score (DSN) and total overall grade score similarly. AAC was assessed by Kauppila's semiquantitative score *(Atherosclerosis, 1997)*. We assessed the association of spine OA with all cause mortality (10 years), AAC severity and AAC progression (7.5 years).

Results: Moderate and severe osteophytes were found in 85% of men, 72% of men had DSN. During the follow-up, 176 men died. After adjustment for confounders (age, BMI, AAC, smoking, physical activity, leg disability, diabetes, pulmonary diseases, Parkinson disease, 17b-estradiol, 25OHD, GFR, fat mass, vitamin D supplementation, vitamin K antagonists), the total overall grade spine OA score predicted all cause mortality (hazard ratio [HR]= 1.20 per SD increase, 95% confidence interval [95%CI]: 1.01–1.43, $p<0.05$). After adjustment for confounders, men who had both severe AAC (AAC >2) and severe OA (total overall grade score >8, highest tertile) had higher mortality than the reference group (AAC score ≤2 and total overall grade score ≤8): 51.8 vs 10.3 /1000 person-years; HR= 2.30, 95%CI: 1.34–3.96, $p<0.005$).

After adjustment for confounders, the odds of severe AAC (AAC >5) increased with total DSN score (HR= 1.44 per SD, 95%CI: 1.11–1.87, $p<0.05$). The highest tertile of total DSN score was associated with higher odds of severe AAC (adjusted HR= 2.42 versus two lower tertiles combined, i.e. >3 vs 0–3, 95%CI: 1.24–4.73, $p<0.005$). Finally, probability of long-term AAC stability decreased with increasing total osteophyte score (adjusted HR= 0.66 per SD, 95%CI: 0.49–0.88, $p<0.05$). The highest tertile of total osteophyte score (>10) was associated with lower probability of AAC stability (adjusted HR= 0.35 versus the lowest tertile, i.e. 0–6, 95%CI: 0.18–0.71, $p<0.01$).

OA therapy (non-steroidal anti-inflammatory drugs, analgesics) had no impact on the results of all the above analyses.

Conclusion: Older men with severe spine OA have greater AAC severity, faster AAC progression and higher all-cause mortality. Higher mortality may be partly mediated by lower physical activity and metabolic abnormalities.

Disclosure: C. Estublier, None; **R. Chapurlat**, None; **P. Szulc**, None.

Effect of Family Support on Short-and Intermediate Term Pain and Function Outcomes after Knee or Hip Replacement. Jasvinder Singh[1], Kenneth G. Saag[2], Celeste Lemay[3], Jeroan Allison[4] and Patricia D. Franklin[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]The University of Alabama at Birmingham, Birmingham, AL, [3]University of Massachusetts Medical School, Worchester, MA, [4]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Patients who undergo total knee replacement (TKR) and total hip replacement (THR) need significant help in the immediate post-operative period, when discharged to home. Limited or no data are available regarding the impact of family support on short and intermediate term pain and function outcomes after THR or TKR.

Methods: A subset of patients from a national joint registry undergoing primary TJR between 5/2013 and 6/2014 were queried patients at 2- and 8-weeks regarding pain severity and level of family support, assessed with validated single-item (0–10; 10=highest family support) and dichotomized, as previously into deficient (scores 5 or less) or non-deficient family support

(6–10). Frequency distributions were used to describe the cohort; bivariate statistical tests to compare groups included the chi-square, Fisher's exact, t tests and Wilcoxon-Mann-Whitney test.

Results: There were 1,502 primary TKR or primary THR respondents at 2-weeks and 1,514 respondents at 8-weeks. 1416 patients reported good level of family support and 86 reported deficient family support (level 5 or less; 5.7%) on the 2-week survey; 1,418 reported good family support 96 reported deficient family support (6.3%) on the 8 week survey. Patients with higher family support were older (66.4 vs. 63.0), more likely to be males (41% vs. 31%), and less likely to have income <45K (25% vs. 43%).

At 2-weeks, compared to patients with non-deficient family support (scores 6–10), those with deficient family support had significantly higher levels of pain severity (3.9 vs. 3.2), pain frequency (4.6 vs. 3.2) and lower levels of satisfaction with pain control (0.68 vs. 0.83), treatment satisfaction (5.6 vs. 6.0) and participation in decision-making (6.9 vs. 8.1). At 8-weeks, similar differences were noted: significantly higher levels of pain severity (2.5 vs. 1.8), pain frequency (4.4 vs. 2.9); and lower levels of current satisfaction with pain control (0.71 vs. 0.83), treatment satisfaction (5.4 vs. 6.0) and participation in decision making (6.9 vs. 8.4).

Conclusion: To our knowledge, this is the first study examining the association of family support with pain and other outcomes after TKR and THR. A positive association of non-deficient family support with better pain and satisfaction outcomes is a novel finding. Further research into how to translate these findings into improved outcomes after TKR/THR for those with deficient family support are needed.

Impact of Dropout and Total Knee Replacement on Joint Space Narrowing Estimation: Data from Osteoarthritis Initiaive. Jamie E. Collins and Elena Losina. Brigham and Women's Hospital, Boston, MA.

Impact of dropout and TKR on Joint Space Narrowing estimation: data from Osteoarthritis Initiative

Background/Purpose: Structural progression in knee osteoarthritis (OA) is often measured by Joint Space Narrowing (JSN). In longitudinal studies, it is common for subjects to drop out before the scheduled end of follow-up. In OA, subjects might undergo total knee replacement (TKR), and consequently drop out of a study evaluating structural progression. Our objective was to estimate the impact of dropout due to TKR on estimates of structural progression in OA and investigate whether information about TKR could be used to improve these estimates.

Methods: We used data from the Osteoarthritis Initiative (OAI), a multicenter, longitudinal, observational study of knee OA. We selected knees with radiographic, symptomatic OA at baseline (KL ≥ 2, WOMAC Pain >0), selecting the knee with the worst pain for subjects with two knees with OA. We compared the estimate of change in JSN over time in persons who did and who did not undergo TKR. Further, we estimated JSN without taking into account dropout and compared to the model that took into consideration time of the dropout and timing of TKR among those that underwent TKR.

Results: We used data from 2,058 subjects with radiographic, symptomatic knee OA at baseline. 377 subjects (18%) dropped out before the 48 month visit; 231 dropped out and did not undergo TKR while 146 underwent TKR. Among those who had TKR, they were distributed evenly between 24, 36 and 48 months visits. The estimates of annual joint space narrowing ranged from 0.116 mm for those who completed the 48 month follow up to 0.28 among those who had TKR between baseline and 24 months visit (Table). Additional analyses showed that not accounting for dropout and TKRs led to underestimation of JSN (0.46 mm over 4 years) compared to the estimation of joint space narrowing using the model that took into consideration both timing of dropout and timing of TKR (0.51 mm over the course of 4 years).

Conclusion: In longitudinal studies restricting analysis to 'completers' may lead to underestimation of structural changes. Subjects with OA who drop out of the study to undergo TKR tend to have much more pronounced structural progression. Investigators studying disease progression in OA should consider the potential impact of dropout due to TKR, particularly when a large proportion of subjects undergo the procedure.

Table. Annual JSN stratified by dropout and timing of TKR

Group	Annual JSN/mm	% of cohort
No dropout/No TKR	−0.116	82.0%
Dropout/No TKR	−0.129	11.0%
TKR after 36M	−0.232	2.1%
TKR after 24M	−0.268	2.3%
TKR between BL and 24M	−0.276	2.5%

Disclosure: J. E. Collins, None; **E. Losina**, None.

Association of Knee Osteoarthritis and Limitations in Physical Function in a Rural Chinese Population: The Wuchuan OA Study. Xu Wu[1], Jingbo Niu[2], Yan Ke[3], Qiang LIU[1], Xu Tang Sr. [1], Zhengming Cao[3], Rujun Li[3], Hu Li[3], Kai Wang[3], Xin Zhi[3], Daniel White[4] and Jian Hao Lin[1]. [1]Peking University Health Science Center, Beijing, China, [2]Boston University, Boston, MA, [3]Peking University People's Hospital, Beijing, China, [4]Boston Univ School of Med, Boston, MA.

Background/Purpose: knee osteoarthritis (OA) causes more limitations in physical function than other chronic conditions in Caucasians. Knee OA is known to be more prevalent among Chinese than among Caucasians. However, little is known about the effect of knee OA on physical function among Chinese living in rural areas.

Methods: Wuchuan OA Study was a population-based cohort study conducted in the rural areas of Wuchuan, Inner Mongolia of China. Subjects completed a baseline home-interview in 2005, including knee symptoms and 8 physical function questions on daily-living activities (e.g., walking, going up or down stairs, bending or kneeling, chair standing, preparing meals, cleaning house, making beds, getting up bed) with 1: no difficulty, 2: some difficulty, 3: very difficult, and 4: unable to do. Subjects had bilateral weight-bearing posterior-anterior and patellar skyline radiographs taken. Whole radiographic knee OA (ROA) was defined as either tibiofemoral K/L score≥2 or presence of patellofemoral OA. Symptomatic OA (SxOA) was defined as presence of both ROA and knee pain for most days in the last month. We identified distinct groups of limitation in physical function based on subject's response to each of 8 physical function questions using a latent class model (SAS PROC LCA) and examined the relation of ROA and SxOA to the latent groups of limitation in physical function adjusting for potential confounders.

Results: Among 1025 subjects of Wuchuan OA study (men: 49.3%, mean age: 56.4 years, mean BMI: 22.4 kg/m^2) prevalence of knee ROA and SxOA was 17.7% and 6.2%, respectively, at baseline. For KL grading, the weighted kappa for inter-rater reliability was 0.80 (95% confidence interval (CI): 0.72–0.88) and the intra-rater reliability was 0.92 (95% CI: 0.86–0.99).We identified 4 distinct physical function groups: no limitation (n=543, 53.0%), mild limitation (n=252, 24.6%), moderate limitation (n=128, 12.5%), and severe limitation (n=102, 9.9%). Worse limitation was characterized by increasing difficulty in performing 8 daily-living activities. The mean posterior probability of subgroup assignment was 0.90, suggesting a good-fit of model Compared with those without knee ROA, multivariable adjusted odds ratios (OR) of no, mild, moderate and severe limitation in physical function among subjects with ROA was 1.6 (1.0, 2.5), 1.9 (1.1, 3.3) and 3.3(1.9, 5.7), respectively. Association of SxOA with limitation in physical function was even stronger, with ORs being 1.0, 2.7, 3.6, and 11.3, respectively, for each increasing difficulty on activity limitations.

Conclusion: Knee OA was strongly associated with limitation in physical function among people in rural areas of China. Knee OA is likely to become a major public health problem given the limitation in physical functioning associated with this disease among Chinese elderly.

	Limitations in Physical Function			
Knee OA Status	No	Mild	Moderate	Severe
No ROA (N=844)	57.2	24.2	11.6	7.0
ROA (N=181)	33.2	26.5	16.7	23.8
OR (95% CI)*	1.0	1.6 (1.0, 2.5)	1.9 (1.1, 3.3)	3.3 (1.9, 5.7)
No SxOA (N=962)	55.4	24.7	12.2	7.7
SxOA (N=63)	15.9	22.2	17.5	44.4
OR (95% CI)*	1.0	2.7 (1.2, 6.3)	3.6 (1.5, 8.9)	11.3(4.9, 25.7)

Effects of Exercise on Depressive Symptoms in Adults with Arthritis: A Systematic Review with Meta-Analysis. George A. Kelley[1], Kristi S. Kelley[1] and Jennifer Hootman[2]. [1]West Virginia University, Morgantown, WV, [2]Centers for Disease Control and Prevention, Atlanta, GA.

Background/Purpose: Previous randomized controlled trials have led to conflicting findings regarding the effects of exercise on depressive symptoms in adults with arthritis and other rheumatic diseases (AORD). The purpose of this study was to use the meta-analytic approach to try and reach some general conclusions regarding these discrepancies.

Methods: The *a priori* inclusion criteria were: (1) randomized controlled trials, (2) exercise (aerobic, strength training, or both) >/= 4 weeks, (3) comparative control group, (4) adults with osteoarthritis, rheumatoid arthritis, fibromyalgia or systemic lupus erythematosus, (5) published and unpublished studies in any language since January 1, 1981, (6) depressive symptoms assessed. Studies were located by searching 10 electronic databases, cross-referencing, hand searching and expert review. Dual selection of studies and data abstraction were performed. Hedge's standardized effect size (g) was calculated for each result and pooled using random-effects models, an approach that accounts for heterogeneity. Non-overlapping 95% confidence intervals (CI) were considered statistically significant. Heterogeneity based on fixed-effect models was estimated using Q and I^2 with alpha values </= 0.10 for Q considered statistically significant. Small-study effects were examined using funnel plots and Egger's regression test, with adjustment for statistically significant results (non-overlapping one-tailed 95% confidence intervals). In addition, the number-needed-to-treat (NNT), percentile improvement, and 95% prediction intervals (PI) were calculated. Risk of bias was assessed using the Cochrane Risk of Bias Assessment Instrument. Training program characteristics were reported as mean +/− standard deviation.

Results: Of the 500 studies screened, 2,449 participants (1,470 exercise, 979 control) from 29 studies met the criteria for inclusion. Length of training averaged 19.1 +/− 16.0 weeks, frequency 3.6 +/− 2.0 times per week and duration 33.6 +/− 16.9 minutes per session. Overall, statistically significant exercise minus control group improvements were found for depressive symptoms (g = -0.41, 95% CI, -0.58, -0.24, Q = 196.2, p<0.0001, I^2 = 82.7%). The NNT was 8 with percentile improvements of 16.0%. Overlapping 95% PI (−1.33, 0.50) were observed. When adjusted for statistically significant small-study effects, improvements were reduced by 54.7% but remained statistically significant (g= -0.19, 95% CI, -0.37, -0.003). The NNT increased to 15 while percentile improvements were reduced to 7.4%. All studies were considered to be at high risk of bias with respect to blinding of participants and personnel to group assignment. Given the lack of information provided, greater than 50% of the studies were at an unclear risk of bias with respect to (1) incomplete outcome reporting (86%), (2) allocation concealment (72%), (3) blinding of outcome assessors (62%) and (4) subjects not exercising regularly prior to enrollment (52%).

Conclusion: Exercise may improve depressive symptoms in selected adults with AORD. However, a need exists for additional, well-designed, randomized controlled trials on this topic.

Physical Inactivity to Activity Associated with Less Decline in Physical Function. Abigail Gilbert[1], Jing Song[2], Pamela A. Semanik[1], Rowland W. Chang[2] and Dorothy D. Dunlop[2]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Regular physical activity has been demonstrated to improve quality of life for adults with chronic disease including osteoarthritis. Despite these benefits, half of adults with arthritis are inactive. An inactive lifestyle is associated with disability, loss of motion, pain, and stiffness. We analyzed longitudinal data from the Osteoarthritis Initiative (OAI) to evaluate the effect of transitioning from inactivity to activity on changes in function over a 2-year follow-up to assess the benefit of increasing physical activity in persons at high risk for disability.

Methods: The Osteoarthritis Initiative enrolled adults who had or were at risk of developing knee osteoarthritis. Longitudinal physical activity accelerometer monitoring was conducted on a subgroup at baseline (48 month OAI visit) and at 2 years (72 month OAI visit). We evaluated two-year activity transitions on 565 individuals identified as being inactive at baseline (zero 10 minute bouts of moderate-to-vigorous [MV] intensity physical activity during a week). We examined the relationship of becoming active (that is, a transition from inactive to insufficient activity or inactive to meeting guideline levels [meeting DHHS Guidelines of at least 150 minutes/week MV activity]) versus remaining inactive in relationship to change in function as measured by gait speed, chair stand rate, and WOMAC function. Analyses used multiple regression analysis controlling for baseline modifiable factors (smoking, knee pain, depressive symptoms, and overweight/obesity), and descriptive factors (age, gender, race/ethnicity, education, income, arthritis severity as measured by K-L grade, knee injury, medical comorbidities, hip pain, foot or ankle pain, and chronic knee symptoms).

Results: Of the 565 adults who were inactive at baseline, 141 (25%) became active (but insufficient to meet guidelines) while 15 (2.7%) became active enough to meet activity guidelines. Over two years, this group of adults characterized by baseline inactivity on average had worse function compared to baseline levels. However, people who became more active over two years compared to those who remained inactive lost less gait speed (2.6 versus 6.1 loss in feet/second), had improved chair stand (0.6 gain versus 1.0 loss repetitions/minute) and had less decrease in WOMAC function (0.7 versus 1.0 loss). This functional benefit remained after accounting for other modifiable and descriptive covariates. (See Table.)

Conclusion: While this inactive group of individuals on average lost function over two years, those who increased their activity lost less function compared to those who remained inactive. Promoting increased physical activity, even to levels not meeting DHHS guidelines, may help inactive persons with arthritis minimize loss of function.

Table Increased activity versus remaining inactive two-year function loss among adults with/ at high risk for knee OA who were inactive at baseline

	Function measure		
	Gait speed loss feet/ minute **n = 528**	Chair Stand rate **loss** N=534	Loss in WOMAC function N=561
	Mean* ± SE		
Become more active	−2.60±26.83	0.63±8.92	−0.68±8.69
Remain inactive	−6.06±24.06	−1.01±9.85	−0.99±10.11
	More Active versus Remain Inactive difference in functional loss Regression coefficient (95% Confidence Interval)**		
Unadjusted Average Difference	3.46 (−1.23, 8.16)	1.63 (−0.17, 3.44)	0.31 (−1.50, 2.12)
Difference adjusted for descriptive + modifiable factors#	0.79 (−4.39, 5.97)	1.03 (−0.93, 3.00)	0.02 (−1.76, 1.79)

* Negative/positive values in means indicate function loss/gain.
** Negative/positive values in regression coefficient indicate better/worsening function among those who became more active compared to those who remained inactive.
# Descriptive factors: age, gender, race/ethnicity, education, income, K-L grade, knee injury, comorbidity, hip pain, foot/ankle pain, chronic knee symptoms
Modifiable factors: smoking, knee pain, depressive symptoms, overweight/obesity

Assessment of Exercise Status in Routine Care Using Patient Reported Outcomes: Initiating Exercise Is Associated with Better Outcomes Than No Exercise. Isabel Castrejón[1], Selda Celik[2], Theodore Pincus[1] and Yusuf Yazici[3]. [1]Rush University Medical Center, Chicago, IL, [2]NYU School of Medicine, New York, NY, [3]New York University School of Medicine, New York, NY.

Background/Purpose: Extensive evidence indicates major benefits of exercise in rheumatoid arthritis[1] and many other rheumatic diseases,[2] not only for cardiovascular and general fitness, but also for better rheumatologic clinical status. Most reported exercise data are derived from structured research studies rather than from usual care. A multidimensional health assessment questionnaire (MDHAQ) designed for usual care includes a query concerning exercise status for the rheumatologist to analyze possible associations with clinical outcomes. The objective of this study was to compare baseline demographic and clinical data and changes in status over 1 year, in patients classified into 4 categories according to the level of exercise.

Methods: Each patient seen at an academic rheumatology setting completes an MDHAQ at each visit while waiting to see the rheumatologist. The MDHAQ includes scores for physical function, pain, patient global estimate (PATGL), and RAPID3 (Routine Assessment of Patient Index Data), an index of these 3 measures, each scored 0–10; total=0–30. Patients were classified into 4 groups according to exercise 3 times a week at baseline and 1 year: EX at baseline & 1 year later, no EX at baseline but EX 1 yr later, EX at baseline but no 1 yr later and no EX at baseline or 1yr later. Mean baseline data and percentage change from baseline to 1 year were analyzed and compared by analysis of variance (ANOVA), with multivariate adjustment

for age, disease duration, education, sex and baseline physical function (MANOVA).

Results: 795 patients, including 221 with RA, were classified into 4 exercise groups: EX at baseline & 1 year later, no EX at baseline but EX 1 yr later, EX at baseline but no 1 yr later and no EX at baseline or 1yr later. Patients doing exercise at baseline were younger with a higher level of education than the NO exercise group (data not shown). Patients reporting no exercise at baseline and exercise 1 year later had greater improvement in scores than those in all other groups. Patients reporting exercise at baseline but not 1 yr later were the only group with poorer status. A potential limitation for our study is that it was unknown if change in exercise status preceded or resulted from change in clinical status.

	EX at baseline & 1 year later N=268 (33.7%)		No EX at baseline but EX at 1 year N=126 (15.8%)		EX at baseline No EX at 1 year N=77 (9.7%)		No EX at baseline or 1 year later N=324 (40.7%)	
	Baseline Mean (SD)	Mean change (%)	Baseline Mean (SD)	Mean change (%)	Baseline Mean (SD)	Mean change (%)	Baseline Mean (SD)	Mean change (%)
MDHAQ-FN (0–10)	1.5 (1.8)	−0.2 (−13.3)	2.3 (2.1)	−0.8 (−34.7)	2.0 (1.9)	0.3 (15.0)	2.7 (2.1)	−0.01 (−0.4)
MDHAQ-PN (0–10)	3.9 (2.9)	−0.5 (−12.8)	5.0 (3.1)	−1.7 (−34.0)	4.4 (2.9)	−0.2 (−4.5)	5.6 (3.0)	−0.8 (−14.3)
PATGL (0–10)	3.6 (2.7)	−0.4 (−11.1)	4.5 (2.8)	−1.8 (−40.0)	4.2 (2.8)	0.2 (4.8)	5.4 (2.7)	−0.8 (−14.8)
RAPID3 (0–30)	9.0 (6.5)	−1.2 (−13.3)	11.8 (7.3)	−4.4 (−37.3)	10.5 (6.3)	0.3 (2.8)	13.7 (6.9)	−1.7 (−12.4)
RADAI (0–48)	7 (9)	−2.1 (−28.0)	10 (10)	−3.9 (−37.9)	10 (8)	0.1 (1.2)	12 (11)	−0.3 (−2.4)

P<0.0001 for all comparisons. *Negative change indicates improvement & positive change worsening*

Conclusion: Exercise 3 times a week is associated with better clinical status. The best status was seen for patients who report no EX at baseline but performing EX 1yr later while poorest status was seen in patients reporting exercise at baseline but no 1 yr later. Regular exercise may be of therapeutic relevance in the management of rheumatic diseases by reducing pain and improving physical function. This clinically relevant information concerning exercise is available on MDHAQ for routine care settings.

The Odds of Work Disability, Unemployment and Depending on Living Allowances Are More Influenced By the Number of Morbidities Than By the Presence of a Musculoskeletal Disease. Antje van der Zee-Neuen[1], Polina Putrik[2], Sofia Ramiro[3], Andras Keszei[4], Rob de Bie[1], Astrid M. Chorus[5] and Annelies Boonen[2]. [1]Maastricht University, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [4]RWTH Aachen University, Aachen, Germany, [5]Netherlands Organization for Applied Scientific Research, Leiden, Netherlands.

Background/Purpose: The prevalence of multimorbidity (≥ 2 chronic morbidities in 1 person), is increasingly common also in patients at working age. Musculoskeletal diseases (MSKD) are among the most frequently occurring chronic diseases and comorbidities. However, little is known about the association of multimorbidity with official work disability and even less about its association with economic unemployment or dependence on living allowances (LA). Also, the additional influence of MSKD as comorbidity is unclear. We aimed to explore 1) whether an increasing number of morbidities is associated with increased odds to be work disabled (WD), unemployed or depending on LA & 2) whether presence of MSKD is associated with these outcomes or has an important additional contribution when combined with other morbidities.

Methods: In a Dutch epidemiological study, 8904 subjects (≥18 years old) completed a questionnaire on socio-demographic and lifestyle factors, self-reported physician-diagnosed diseases & work status. Persons at working age (18–65 years) who were either employed, formally WD, economically unemployed or receiving LA were included in the analyses (n=5396). Two multinomial regression models were computed with work status (i.e. employed, WD, unemployed or LA) as outcome and adjusted for age, gender, education, body mass index and smoking status. In model 1 the number of morbidities was the independent variable of interest and in model 2 either the single diseases (distinguishing MSKD from all other single diseases) or combinations of 2 or ≥3 diseases, including and excluding MSKD. Paid employment was used as reference outcome and estimates were compared to the healthy.

Results: MSKD occurred in 925 cases (17%) of the sample. Multimorbidity was present in 755 cases (14%). Of all cases with 2 morbidities 265/490 (54%) reported a MSKD. In cases with ≥3 morbidities 198/265 (75%) reported a MSKD.The odds to be WD increased steeply with every additional morbidity and the same trend but less pronounced was seen for unemployment and dependence on a LA (Table 1). Small (but no significant) increments were seen when exploring the role of MSKD in multimorbidity (e.g. the odds to be WD were 9.2 times higher than to be employed for persons suffering from 2 morbidities including MSKD and these odds were somewhat lower (8.8) when none of the 2 morbidities was MSKD). The odds to be unemployed or to receive a LA were slightly (but not significantly) higher for persons suffering from 2 co-occurring morbidities when 1 of these was a MSKD compared to 2 co-occurring morbidities without MSKD. (Table 1)

Conclusion: An increasing number of morbidities is associated with increased odds of WD, and to a lesser extent also with unemployment and dependence on a LA. There is a small additional adverse influence of the co-occurrence of MSKD in those suffering from 2 morbidities on all work outcomes. Multimorbidity requires more attention in considering patients' work outcome.

Table 1 Association of multimorbidity and combinations with and without MSKD with employment status

Prevalence of Pain Reporting in Different Ethnic Groups in the UK: Results from a Large Biobank. Marcus Beasley, Gareth T. Jones, Tatiana Macfarlane and Gary J. Macfarlane. University of Aberdeen, Aberdeen, United Kingdom.

Background/Purpose: Very large epidemiological studies designed to investigate genetic and environmental influences on disease, known as 'biobanks' can be used to look at associations between rare exposures and health for which smaller studies may lack power. The purpose of this study was to look at the association between ethnicity and pain in the UK Biobank.

Methods: UK Biobank recruited ½ million people across Great Britain. Participants attended assessment centers and answered questions on health and lifestyle by touch-screen questionnaire. They were asked "In the last month have you experienced any of the following that interfered with your usual activities?", and could indicate: headache, face pain, neck/shoulder pain, back pain, abdominal pain, hip pain, knee pain, or pain all over. For each positive answer, participants were asked if the pain had lasted at least three months, which was defined as chronic. Questions were also asked on gender, age, ethnicity, income, employment status, adverse life events and mental health. Self-reported ethnicity was classed as white, mixed, south Asian,

black, Asian (Chinese), or other. Life events recorded were: serious illness, injury, or death to a partner or close relative, marital separation, and financial difficulties. Mental health included mood swings, feelings of guilt and loneliness, and being tense. Prevalence of any pain, chronic pain, and regional pains was calculated for each ethnic group, standardised to age/gender structure in the UK 2011 Census. Risk ratios adjusted for age and sex with 99% confidence intervals were calculated using white as the referent group. Risk ratios for any pain and chronic pain were adjusted for income, employment status, life events, and mental health.

Results: Pain questions were answered by 498,071 participants between the ages of 40 and 69. Compared to the white group (prevalence 60.3%), persons identified as mixed (66.3%), south Asian (71.8%), black (70.2%), or other (71.5%) were more likely to report pain (see table). Relationships were similar for chronic pain, although less strong. Asian (Chinese) were no more likely to report pain (61.0%) and less likely to report chronic pain. After adjustment for potential confounders differences between groups remained but were smaller. Excess prevalence of regional pains was observed for all groups compared to whites apart from Asian (Chinese), who were more likely than whites to report neck or shoulder pain, and less likely to report hip pain and facial pain.

Conclusion: This study has shown differences in pain reporting according to self-reported ethnicity. These are partly explained by socio-economic and psychosocial factors, and adverse life events. The large numbers of centers in this study means the results are more generalizable compared to those from single center studies. Difference in pain prevalence between groups has implications for allocation of healthcare resources where populations differ.

		Ethnic group specific prevalence (%)					
		White	Mixed	South Asian	Black	Asian (Chinese)	Any other

The Association Between Doctor-Diagnosed Arthritis and Falls and Fall Injuries Among Middle-Aged and Older Adults. Kamil E. Barbour[1], Louise Murphy[2], Kristina A. Theis[3], Charles G. Helmick[2], Jennifer Hootman[2] and Judy A. Stevens[2]. [1]CDC, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Centers for Disease Control and Prevention, Atlanta, Georgia.

Background/Purpose: Falls are the leading cause of injury-related morbidity and mortality among older adults (age ≥65 years), with more than one in three falling each year, resulting in direct medical costs of nearly $30 billion. Arthritis can lead to poor neuromuscular function (i.e., gait speed and balance), a major risk factor for falling. Although the association between arthritis and increased falls risk among older adults is well documented, little is known about arthritis and falls among middle-aged adults (45–64 years).

Methods: We analyzed data from the 2012 Behavioral Risk Factor Surveillance System (BRFSS), an annual, random-digit–dialed landline and cellphone survey representative of the noninstitutionalized adult population aged ≥18 years from the 50 states, DC, Puerto Rico, and Guam (n=338,734 respondents age ≥45 years). Respondents were considered to have arthritis if they answered "yes" to, "Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" They were considered to have fallen if they answered one or more to, "In the past 12 months, how many times have you fallen?" Those reporting one or more falls were also asked, "How many of these falls caused an injury? By an injury, we mean the fall caused you to limit your regular activities for at least a day or to go see a doctor?" We analyzed number of falls as a categorical (zero, one, or two or more) and binary variable (no falls, or one or more falls). Fall injury was categorized as a binary variable (yes or no). Prevalence ratios (PRs) and 95% confidence intervals (CIs) were estimated in log binomial and multinomial regression models which adjusted for age, sex, race, education, body mass index (BMI), self-rated health status, physical activity, heart disease, and stroke.

Results: Among middle-aged adults, the prevalence of arthritis, falls, and fall injuries was 33.8%, 25.6%, and 9.7%, respectively, whereas the prevalence among older adults was 53.4%, 27.1%, and 9.6%, respectively. Among middle-aged adults with arthritis, the prevalence of one or more falls, two or more falls, and fall injuries was 1.58 (95% CI: 1.53, 1.63), 1.92 (95% CI: 1.82, 2.02), and 2.10 (95% CI: 1.97, 2.23) times higher compared with middle-aged adults without arthritis. Among older adults with arthritis, the prevalence one or more falls, two or more falls, and fall injuries was 1.38 (95% CI: 1.34, 1.45), 1.69 (95% CI: 1.59, 1.80), and 1.63 (95% CI: 1.52, 1.75) times higher compared with older adults with arthritis.

Conclusion: These findings establish the significant relationship between arthritis and falls and fall injuries among middle-aged adults and demonstrate that these associations are similar in magnitude to those already recognized among older adults. Raising awareness of falls and fall injuries among middle aged adults is an important first step in mitigating negative fall consequences in this population. The high burden of falls and fall injuries among middle-aged and older adults with arthritis can be addressed through greater dissemination of arthritis management and fall prevention programs in clinical and community practice.

Frequency and Risk Factors for Recurrent Falls in Community-Dwelling Elderly: A Population-Based Prospective Cohort Study in Brazil. the São Paulo Ageing & Health (SPAH) Study. Ketty LLL Machado[1], Diogo S. Domiciano[1], Luana G. Machado[2], Camille P. Figueiredo[2], Jaqueline B. Lopes[2], Valéria Caparbo[2], Liliam Takayama[2], Ricardo M. Oliveira[3] and Rosa Maria Pereira[2]. [1]Faculdade de Medicina, University of São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]RDO Diagnosticos Medicos, São Paulo, Brazil.

Background/Purpose: Falls are among the leading external causes of mortality in the elderly. This issue acquires substantial importance in low-income countries where the population's aging has been faster. Several clinical factors (including age, drugs and previous fracture) have been associated with increased fall risk. However, few studies performed a concomitant evaluation of clinical data, laboratory bone exams and bone mineral density (BMD) to determine more accurately the contribution of each of these variables to fall risk in community-dwelling elderly. Our aim was to investigate the association between bone parameters and falls in a population-based prospective cohort of community-dwelling older adults.

Methods: Risk factors for recurrent falls were determined in 705 community-dwelling individuals (448 women and 257 men) aged ≥ 65 years. Specific questionnaire (clinical data), BMD and laboratory tests -including 25-hydroxyvitamin D (25OHD), intact PTH (iPTH) and serum cross-linked C-telopeptide (CTX) were performed at baseline and after a mean follow-up of 4.3±0.8 years. Individuals with recurrent falls (2 or more falls in the last year from the date of the second evaluation) were considered chronic fallers. Potential risk factors for recurrent falls were compared between fallers and non-fallers. Logistic regression models were used to used to identify independent predictors of recurrent falls.

Results: The frequency of chronic fallers was 16.5% (95% CI: 13.8–19.2). In multivariate analysis, independent risk factors for recurrent falls were visual impairment (OR = 2.49, 95% CI 1.30–4.74, p = 0.006), chronic use of psychotropic drugs (OR = 2.47, 95% CI 1.37–4.49, p = 0.003), previous fracture (OR = 2.78, 95% CI 1.48–5.20, p = 0.001), persistently low serum 25OHD (<20ng/mL) (OR = 1.71, 95% CI 1.10–2.64, p = 0.020)

and loss of total hip BMD between the two assessments (OR = 1.21, 95% CI 1.17–1.25, p = 0.03 for each 5%-decrease).

Conclusion: In addition to traditional clinical risk factors for falls, significant loss of total hip BMD and persistently hypovitaminosis D were associated with recurrent falls in Brazilian community-dwelling elderly. In this way, recognizing these factors is essential to recommend preventive actions to reduce recurrence of falls and might improve the health outcomes in this population.

Influence of the Polymorphism IL1β (−511 A/C) and IL6 (- 174 G/C) on the Activity, Radiographic Damage and Clinical Forms of Patients with Psoriatic Arthritis (PSA). Tatiana Carranco[1], Noelia Cubino[1], Clara Cieza-Borrela[1], Ismael Calero[1], Maria Dolores Sanchez[1], C. Hidalgo-Calleja[2], Alba Quesada[1], Andres Plata[1], Agustin Diaz Alvarez[1], Ricardo Usategui[3], Rogelio Gonzalez[3], C.a. Montilla-Morales[2] and J. Del Pino-Montes[2]. [1]HOSPITAL CLINICO UNIVERSITARIO DE SALAMANCA, SALAMANCA, Spain, [2]University of Salamanca Hospital, Salamanca, Spain, [3]IBSAL, SALAMANCA, Spain.

Background/Purpose: PSA is a chronic inflammatory disease associated to psoriasis which affects the joints, vertebrae and enthesis. Interleukin-1 is an inflammatory cytokine. A higher expression of IL-1 has been observed in the synovial fluid of patients with PSA. Interleukin-6 promotes synovitis and enhances bone resorption. No studies have analyzed the relation between PSA patients with polymorphisms of IL-1β (−511 A/C) and IL-6 (−174 G/C) and the activity, the presence of erosions or the clinical form of presentation. We relate the polymorphisms of IL-1β (−511 G/A) and IL-6 (−174 G/C) with inflammatory activity, radiographic damage and clinical forms in a group of PSA patients.

Methods: We studied 125 patients diagnosed with PSA according to the CASPAR criteria. The patients were classified depending on whether they presented peripheral, axial or mixed. The activity in the peripheral or mixed forms was measured according to the number of swollen, painful joints, visual analogue scale, ESR and CRP. The DAS 28 index was calculated. For the axial and mixed forms, the BASDAI index, the visual analogue scale, ESR and CRP were used. In the assessment of radiographic damage we used the SvH and mSASSS. All patients underwent an analysis of the polymorphism in the promoter region of IL-1β (−511 G/A) and IL-6 (−174 G/C).

Results: 59.2% of the patients were men. 13 patients showed axial involvement (10.4%), 38 a mixed involvement (30.4%), and 74 a peripheral involvement (59.2%). The distribution and genotype of the polymorphism of IL-1β (−511 G/A), with regard to the number of swollen joints and DAS >3.2 are included in Table 1. In the logistic regression model: DAS >3.2 (p=0.018; OR: 3.46). In the allele analysis, 30.92% of the carriers of the G allele showed DAS over 3.2, compared with 12.5% of the patients with the A allele (OR: 3.13); p<0.0004; 95% CI: 1.43–6.82; adjusted p<0.008). No differences were found regarding the distribution of the polymorphism in the different clinical forms of the disease or the radiographic damage. With regard to the polymorphism of IL-6 (−174 G/C) in the group of G/G homozygous patients, compared with the combined group of G/A and A/A patients, we found differences in the clinical forms of PSA and in the frequency of appearance of HLA-B27 antigen (Table 1). In the logistic regression analysis: types of disease (p=0.007; OR=2.741) and HLA-B27 (p=0.001; OR=0.103). The G allele was not more frequently found in peripheral forms (70.86%) than in mixed forms (57.42%) (OR=1.89; p<0.03; 95% CI: 1.06–3.39; adjusted p<0.05). We did find a lower association of the G allele with HLA-B27 (15.78%) compared with the C allele (28.57%) (OR= 0.469; p=0.02; 95% CI: 0.238–0.923; adjusted p<0.03).

Conclusion: The G allele of polymorphism IL-1β (−511 A/C) was associated with the presence of more inflammatory activity. We found a trend in patients who carried the G allele of the polymorphism IL-6 (−174 G/C) to present with a peripheral form of the disease.

Table 1.

	IL1β (−511 A/C)	Mean (SD)	p
NSJ	G/G	2.09 (1.99)	0.03

Robust Identification of Anti-TNF Non-Responders in RA from Blood. Ty Thomson, Reynald Lescarbeau, David Drubin, David Fryburg, David de Graaf, Renée Deehan, Daphna Laifenfeld and Aaron Van Hooser. Selventa, Cambridge, MA.

Background/Purpose: The number of biologic therapies approved for use in treating rheumatoid arthritis (RA) has grown steadily over the past 15 years. While many patients are treated with anti-TNF therapies, 30–40% of these patients fail to respond adequately as their disease progressively worsens. Tools to guide disease management and identify a priori which patients are likely to be non-responsive to anti-TNF therapies would allow these patients to seek alternative therapies to achieve faster relief from symptoms, avoid unnecessary treatment side effects, and avoid further disease progression.

Methods: Four published gene expression data sets containing a total of 91 patients were used to train a classifier to identify anti-TNF non-responders. Gene expression measurements, collected prior to patient treatment with the anti-TNF infliximab, were grouped into disease-relevant biological signaling mechanisms to provide a stable, quantitative representation of biological state. Regularized logistic regression was used to train a classifier to identify non-responders, and a classifier score threshold was selected to optimize for detection of non-responders with high specificity.

Results: Repeated 10-fold cross-validation resulted in highly-specific prediction of non-response (specificity = 92%; likelihood ratio = 5.53; area under the receiver operator characteristic curve (AUROC) = 78%, p-value<0.00001; Figure 1), while still correctly identifying a significant fraction of non-responders (sensitivity = 45%). Prediction of non-response on independent infliximab treated cohorts, consisting of an independent 27 patient cohort as well as each of the four training when left out in turn from training, resulted in AUROCs between 63% and 80% and associated p-values between 0.029 and 0.15. Specificity of the classifier for infliximab and its therapeutic target TNF was supported by a lack of association with responses in small rituximab (anti-CD20) and tocilizumab (anti-IL6R) treated cohorts.

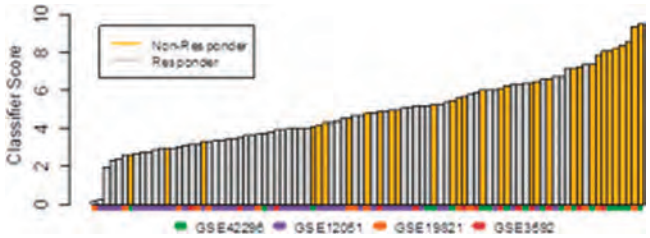

Figure 1. A representative patient stratification from 10-fold cross validation, matching the mean AUROC of 78% across all cross validation repeats, shows the classifier score for each patient. Patients were sorted by classifier score and colored by their clinical response calls.

Conclusion: The classifier developed in this study identifies RA patients who are unlikely to respond to infliximab, and thus are good candidates for

alternative biologic therapies. The test robustly predicts non-response across multiple patient cohorts. Future iterations of the test could include additional training cohorts and expansion to include complementary prediction of response to other RA therapies.

Identification of Synovial Genes and Pathways Associated with Disease Progression in a Cohort of Early Symptomatic Osteoarthritis Using a Transcriptomic Approach. Arjen B. Blom[1], Peter L. van Lent[1], Martijn H. van den Bosch[1], Hans Cats[2], Frank H.J. van den Hoogen[3], Floris P.J.G. Lafeber[4], Wim B. van den Berg[1] and Peter M. van der Kraan[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Ubbergen, Netherlands, [3]Rheumatology Centre Sint Maartenskliniek and Radboud university medical center, Ubbergen (Nijmegen), Netherlands, [4]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: If and how the synovial activation that is observed in over 50% of osteoarthritis (OA) patients contributes to irreversible joint pathology, is not known. The purpose of this study was to identify pathways that may determine progression of cartilage damage in this disease.

Methods: From 25 patients with knee OA that entered the CHECK Cohort study (Cohort Hip and Cohort Knee) and 6 controls, synovial biopsies were collected at baseline. CHECK is a prospective 10-year follow-up study on participants with early osteoarthritis-related complaints initiated by the Dutch Arthritis Association. Progression was determined based on change of joint space width (JSW) and osteophyte formation in radiographs, as analyzed using the KIDA (Knee Image Digital Analysis) system. Synovial samples from baseline were studied using histology and affymetrix U133-plus-2.0 chips, which were analyzed using Partek Genomics Suite software and DAVID.

Results: Histologically, lining thickness and synovitis were enhanced in the CHECK biopsies compared to control synovia. Next we compared synovial tissue of CHECK-patients with radiological damage with CHECK-patients without joint damage at baseline. Among the genes that were strongest associated with cartilage damage were *MMP1* (18-fold), *MMP3* (10-fold), and *S100A8* (6-fold). Immunohistochemical staining revealed that expression of MMP-1 and MMP-3 was highest in the synovial lining layer. Enrichment analysis showed that chemotaxis, innate immune response and MMPs were significantly associated with joint damage at baseline. To determine whether any of the regulated genes and pathways were predictive for progression of joint damage between baseline and t=5 yrs, we identified 13 patients that were marked progressors and 8 non-progressors, based on JSW and osteophyte size. At baseline, neither minimum JSW nor osteophyte size differed between the groups. Approximately 200 genes were expressed more than 2-fold higher in synovium of progressors, versus non-progressors. Among these genes were genes from the wnt-signaling pathway: *WISP1*, *FZD1*, *FZD8* and *FZD10*, whereas *FRZB* was downregulated. In addition, pro-inflammatory factors like *IL1*, *IL6*, *S100A9* and *MMP1* were increased. Macrophage markers like *CD14*, MHC class II genes, scavenger receptor A3 and *CXCR2*were positively associated with progression. This indicates that expression of these factors may predict, or even be involved in, progression of joint damage in OA patients. Using DAVID we identified inflammatory response, macrophage differentiation, blood vessel formation, ossification and cell migration to be enriched in patients that show progression of damage 5 yrs later. Histologically, the progressors showed a higher thickness of the lining layer at baseline compared to non-progressors, 2.0 vs 1.2 respectively on an arbitrary scale from 0–3.

Conclusion: These data suggest an active role for the synovium in OA pathology, and identify pathways that may be involved. From histology and the expression data, it appears that presence of macrophages is associated with progression of joint damage in OA. In addition, synovial expression of wnt-signaling genes seems important in progression of damage.

Epigenome Profiling Reveals Robust Hypomethylation of Interferon Signature Genes in Lupus Neutrophils. Patrick Coit[1], Sri Yalavarthi[1], Wenpu Zhao[2], Mariana J. Kaplan[2] and Amr H. Sawalha[1]. [1]University of Michigan, Ann Arbor, MI, [2]National Institutes of Health, Bethesda, MD.

Background/Purpose: Lupus neutrophils play an important role in tissue damage (including glomerulonephritis and lupus skin involvement), as well as endothelial damage in lupus patients. Several studies have suggested altered functional capacity of lupus neutrophils compared to healthy controls, and the expansion of a neutrophil subset with a lower density (low density granulocytes or LDGs) in lupus. We characterized the DNA methylome of normal-density neutrophils and LDGs from lupus patients, and age-, sex-, and ethnicity-matched healthy controls to gain insight into chromatin architectural differences and how these differences might alter neutrophil function and induce pathogenicity in lupus.

Methods: We included 8 lupus patients and 8 healthy age-, sex-, and ethnicity-matched controls for these studies. Low density granulocytes (LDGs) and normal-density neutrophils were isolated from each lupus patient, and normal-density neutrophils were isolated from healthy controls. Neutrophils and LDGs were extracted using density gradient centrifugation and magnetic bead separation with over 95% purity in every sample. DNA was extracted and bisulfite conversion performed. A genome-wide DNA methylation study was performed using the Illumina HumanMethylation 450 BeadChip array, which includes over 485,000 methylation sites across the entire genome. The array covers 99% of RefSeq genes, including promoter regions, 5'-UTR, first exon, gene body, and 3'-UTR. 96% of all CpG islands are also covered. Statistical and bioinformatics analysis was performed to identify differentially methylated loci, gene ontologies, and pathways.

Results: We identified 619 differentially methylated CpG sites in normal-density neutrophils between lupus patients and healthy matched controls. Very interestingly, we find a robust and consistent demethylation of interferon signature genes in both normal-density neutrophils and LDGs in lupus patients. The top 30 hypomethylated CpG sites in lupus neutrophils are presented in **Table 1**. These data suggest that the chromatin structure in lupus granulocytes supports the expression of higher levels of type-1 interferon regulated genes, and that neutrophils directly contribute to the interferon signature in lupus. Curiously, however, our data so far suggest that LDGs and normal-density neutrophils from lupus patients are virtually identical in their chromatic architecture with no methylation differences across the genome between these two distinct granulocyte subsets.

Table 1: Top 30 hypomethylated CpG sites in lupus normal-density neutrophils compared to age-, sex-, and ethnicity-matched healthy control neutrophils. Significant and consistent hypomethylation in interferon signature genes is noted

CpG ID	Chr	Position (Hg19)	Gene(s)	Methylation Patients	Methylation Controls	Fold Change (patients/controls)	*P* value

a HPLC-SRM-MS Based Method for the Detection and Quantification of Methotrexate Used at Doses in Clinical Practice for Patients with Rheumatological Disease in Urine. James Bluett[1], Isabel Riba-Garcia[2], Richard Unwin[2], Suzanne Verstappen[3] and Anne Barton[4]. [1]Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester, United Kingdom, [2]Centre for Advanced Discovery and Experimental Therapeutics (CADET), Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [3]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom, [4]Arthritis Research UK Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Methotrexate (MTX) is a recommended first-line therapy in 2013 EULAR guidelines for active rheumatoid arthritis (RA). Despite this, up to 54% do not adequately respond to MTX. Non-adherence rates vary depending on the method used to measure adherence. Currently there is no gold standard for measurement of MTX adherence. Whilst an ELISA method exists to detect MTX levels at the doses used for chemotherapy regimes, this is not sensitive enough for the low dose MTX used to treat patients with rheumatological conditions. Detection of MTX and its major metabolite 7-OH-MTX in urine may be an improved method to detect adherence in routine practice, when used in the lower dose range (7.5 – 30 mg/wk). The aim, therefore, was to develop a liquid chromatography-selected reaction monitoring mass spectrometry (HPLC-SRM-MS) method to determine the presence of low concentrations of MTX and 7-OH-MTX in urine.

Methods: Donated drug-free samples from RA patients were frozen at −80°C after collection. Samples were thawed at room temperature and then prepared by spiking purchased MTX, 7-OH-MTX and the internal standard MTX-d_3. Samples were diluted and protein removed by precipitation. Supernatent was subsequently analysed using HPLC with a reversed-phase column on line to a triple quadrupole mass spectrometer operated in positive mode. Analytes were measured in selected reaction monitoring mode for the following mass transitions: 455.1 >308.1 *m/z* for MTX 471.1 >324.1 *m/z* for 7-OH-MTX and 458.1 >311.1 *m/z* for MTX-d_3. Method validation consisted of accuracy, lower limit of quantification, recovery, linearity, precision and stability at room temperature and -80°C. All samples were measured in triplicate.

Results: For MTX and 7-OH-MTX respectively, average recovery of analyte following sample preparations was 118%±8.9% and 86%±18.6%. The lower limit of quantitation (LLOQ) was 2.5 and 5nM. The coefficient of variance for intraday run was 3.0% and 2.5% respectively. The method was linear from the LLOQ up to 1000nM (r^2=0.99, 1.00 respectively). Stability testing revealed no loss at 7 days when samples were stored at -80°C, although storage at room temperature produced an average loss of 27%±6% and 10%±39% respectively within 24 hours.

Conclusion: We have developed a rapid, simple and cost effective HPLC-SRM-MS method to measure MTX and 7-OH-MTX concentrations in urine, which is sensitive to the low doses used to treat RA and other musculoskeletal diseases. The method requires limited sample preparation and may be a novel biochemical assay for measurement of adherence to MTX therapy.

PECAM-1 GENE Polymorphisms and Soluble PECAM-1 LEVEL in Rheumatoid Arthritis and Systemic LUPUS Erythematosus Patients Is There a Link with Clinical Atherosclerotic Events? Omer Nuri Pamuk[1], Hilmi Tozkir[2], Mehmet Sevki Uyanik[1], Hakan Gurkan[2], Julide Duymaz[2], Salim Donmez[3], Metin Yazar[2] and Gulsum Pamuk[1]. [1]Trakya University Medical Faculty, Edirne, Turkey, [2]Trakya University Medical Faculty, EDIRNE, Turkey, [3]Trakya University School of Medicine, Edirne, Turkey.

Background/Purpose: Platelet-endothelial cell adhesion molecule-1 (PECAM-1/CD31) which plays a role in the transmigration of leucocytes into tissues is a member of the immunoglobulin (Ig) superfamily. It was reported that the expression of PECAM-1 on synovial tissue in inflammatory arthritis is enhanced. The genetic polymorphisms of PECAM-1 were found to play roles in atherosclerotic events. We determined PECAM-1 polymorphisms, soluble PECAM-1 and CD40L levels in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE); and evaluated their associations with clinical atherosclerotic complications.

Methods: We included 100 RA and 81 SLE patients and 94 healthy controls into the study. The clinical features about patients were obtained from medical records. Past cardiovascular complications were recorded. The most frequent gene polymorphisms of PECAM-1 were studied in our genetics laboratory. Soluble PECAM-1 and CD40L levels in serum were determined with ELISA.

Results: The frequencies of 373C (rs668) and 1688A (rs12953) alleles were higher in RA patients when compared to controls (p values, 0.03 and 0.023). RA and SLE patients had significantly higher allele frequencies for 2008A (rs1131012) when compared to controls (p values, 0.021 and 0.001). SLE patients had significantly more frequent AA genotype for rs1131012 polymorphism than RA patients and controls (p values, 0.007 and <0.001). Soluble PECAM-1 level was significantly higher in RA patients than in SLE patients and healthy controls (p values <0.001). The sCD40L level was also significantly higher in RA group than in SLE and control groups (p values, 0.006 and 0.047). The levels of sPECAM-1 and sCD40L were significantly higher in RA patients with AA genotype (rs1131012) than in patients with AG genotype (p values, 0.046 and 0.008). Atherosclerotic complications were more frequent in SLE patients with AG genotype (rs12953) than those with AA genotype (p=0.021). SLE patients with CC genotype (rs668) had a significantly lower frequency of atherosclerotic complications than those with CG genotype (p=0.045).

Conclusion: We found associations between various PECAM-1 polymorphisms and RA, SLE; PECAM-1 and sCD40L levels were significantly higher in RA patients than in SLE and control groups. Soluble PECAM-1 level in RA was found to be linked to a certain genotype; PECAM-1 polymorphisms in SLE were protective against atherosclerotic complications.

Cellular Responses of IL6 Inhibition (Tocilizumab) in Rheumatoid Arthritis Using High-Accuracy Tandem Mass Spectrometry. Michael Kruse Meyer[1], Marlene Andersen[2], Grethe N. Andersen[1] and Allan Stensballe[3]. [1]Hospital of Vendsyssel/Aalborg University, Hjørring, Denmark, [2]Aalborg University, Hjørring, Denmark, [3]Aalborg University, Aalborg, Denmark.

Background/Purpose: In this study we are analyzing leukocyte subtype responses from patients with rheumatoid arthritis (RA) to IL6 inhibition. A large contribution to RA immunopathogenesis is caused by the pleiotropic effects of interleukin 6 (IL6), which we are investigating directly on the biological active constituents of the cell, i.e. the proteins, using *state-of-the-art*mass spectrometry. This has enabled us to quantify changes in protein expression of thousands of proteins as a result of biologic treatment, and mapping of post-translational modifications such as citrullination, and phosphorylation.

Methods: 10 ACA positive RA patients fulfilling the ACR criteria are being enrolled prior to monotherapy IL6 inhibition and 4 months after compared to 10 healthy controls. PBMC were isolated and subdivided into $CD14^+$, $CD4^+$, $CD8^+$, $C19^+$, and $CD56^+$cells using immunoaffinity Dynabeads. Each cell type was prepared for mass spectrometry analysis (Thermo Q Exactive Plus), by a filter-aided sample preparation (FASP) method. MS data was searched against a human isoform database derived from UNIPROT using the Matrixscience MASCOT, and MaxQuant search engines. Differentially expressed proteins were filtered by requiring 2 peptides pr. protein, ANOVA (P-value) cutoff 0.05, q-value (false discovery adjusted p-value using multiple hypothesis testing) cutoff 0.05, and a power of at least 80%. The method was validated using known expression responses to IL6 inhibition. While responses have been shown via array and RT-qPCR, we obtained a broader quantitative differential protein expression profile.

Results: The initial results provided the identification of 4258 different proteins obtained by combining 3 technical replicates of the

5 cell types. In brief, several pro-inflammatory proteins were down regulated, while anti-inflammatory proteins were up regulated. For example in $CD14^+$cells, interferon-induced guanylate-binding protein 1 (belonging to the TRIFF pathway), and CXCL2 (also known as macrophage inflammatory protein 2-α) were relatively down regulated by 8.04 fold and 1.14*10$\hat{4}$ fold, respectively while TGFβ was up regulated by 16.8 fold. Myeloid differentiation primary response protein (MyD88) was relatively down regulated by 2.3 fold, which could be explained by IL6 inhibition. The down regulation of both the TRIFF pathway, and MyD88 indicates a down regulation of CD14 (monocyte differentiation antigen) dependent signaling, and hence a reduction in the NFκB signaling and TNFα production. Of note, we found that STAT6 was relatively down regulated by 4.7 fold, which has recently been suggested to correlate with decreased CD14 signaling in CD14−/− mice.

Conclusion: Our proteomics driven strategy enable detection and mapping of valuable information of pro-, and anti-inflammatory responses to IL6 inhibition treatment on the protein level. This detailed insight into in vivo individual cell responses in patients will improve diagnostic and treatment optimization and drive personalized medicine. Our method may reveal hidden mechanisms in treatment success or failure.

Elevated Peripheral Blood Leukocyte Inflammatory Gene Expression in Radiographic Progressors with Symptomatic Knee Osteoarthritis: NYU and OAI Cohorts. Mukundan Attur[1], Alexander Statnikov[1], Svetlana Krasnokutsky Samuels[1], Virginia B. Kraus[2], Joanne Jordan[3], Braxton D. Mitchell[4], Michelle Yau[5], Jyoti Patel[1], Constantin F. Aliferis[1], Marc C. Hochberg[4], Jonathan Samuels[1] and Steven B. Abramson[1]. [1]NYU Langone Medical Center, New York, NY, [2]Duke University Medical Center, Durham, NC, [3]The University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of Maryland School of Medicine, Baltimore, MD, [5]University of Maryland, Baltimore, MD.

Background/Purpose: We and others have demonstrated low grade inflammation exists in OA joint tissues, where it may contribute to disease pathogenesis. In the current studies we assessed whether inflammatory events occurring within joint tissues were reported in the peripheral blood leukocytes (PBLs) of patients with symptomatic knee OA (SKOA).

Methods: PBL inflammatory gene expression (IL-1, TNFα, COX-2) was assessed in two independent cohorts of patients with SKOA, and a cohort of healthy control subjects: 1) 111 patients with tibiofemoral medial OA and 21 healthy volunteers from the NYUHJD Cohort, and 2) 200 patients from the OAI progression cohort who had "high quality radiographs", at both baseline and 24 months, and had KL2 or 3 in the signal knee at baseline. Radiographic progression was defined as narrowing of medial joint space width (JSW) in the signal knee between baseline and 24-months in each cohort. Fast progressors were defined as subjects who had JSN >0.5mm over 24 months. For measuring predictive performance, we used the area under the curve (AUC) of a receiver operating characteristics (ROC). OAI SKOA subjects were dichotomized as radiographic non-progressors (JSN <0.0 mm) and progressors (JSN >0.0mm) for association studies.

Results: Elevated PBL expression of IL-1, TNFα or COX-2 at baseline identified SKOA patients who were "fast progressors" (mean JSN 0= 0.71, 0.75 and 0.71 mm / 24 months, respectively) compared to patients with levels below the median (Table 1). In a multivariable model, anthropometric traits alone (BMI, gender, age) did not predict progression, whereas addition of PBL gene expressions improved prediction of fast progressors (JSN >0.5mm). We next examined inflammatory gene expression in PBLs of radiographic progressors in the OAI cohort. Similar to the NYUHJD cohort, elevated expression of IL-1β, TNFα and COX-2 mRNA at baseline distinguished radiographic progressors from non-progressors (Table 2).

Conclusion: We identified, and confirmed in two cohorts, increased inflammatory gene expression (IL-1, TNFα or COX-2) by PBLs that predict radiographic progression in patients with SKOA. The data indicate that inflammatory events within joint tissues of patients with SKOA are reported in the peripheral blood. These PBL transcriptome signals of local joint inflammation merit further study as potential biomarkers for OA disease progression.

Table 1 Association of PBL transcriptome IL-1β, TNFα and COX-2 (relative gene expression levels were dichotomized by median), with joint space narrowing (JSN) at 24 months in NYUHJD cohort.

	IL-1β (PBL mRNA)			TNFα (PBL mRNA)			COX-2 (PBL mRNA)		
	OA^{IL-1} (n = 54)	OA^{n} (n = 55)	*p value*	$OA^{TNF\alpha}$ (n = 54)	OAnl (n = 55)	*p value*	OA^{COX-2} (n = 54)	OA^{nl} (n = 55)	*p* value
Baseline									
Medial knee JSW (mm)	3.85 (1.39)	3.46 (1.29)	0.13	3.60 (1.28)	3.70 (1.45)	0.71	3.76 (1.43)	3.55 (1.27)	0.42
24 month									
Medial knee JSW (mm)	3.14 (1.58)	3.12 (1.49)	0.93	2.85 (1.58)	3.41 (1.43)	0.06	3.05 (1.57)	3.21 (1.49)	0.57
JSN (mm)	0.71 (0.93)	0.34 (0.82)	0.032*	0.75 (1.03)	0.30 (0.67)	0.007*	0.71 (0.90)	0.34 (0.86)	0.027*

Table Area under the curve (AUC) of a receiver operating characteristics (ROC) of PBL inflammatory gene expression for distinguishing radiographic progressors from non-progressors in the OAI cohort. For multivariable models, we used 10-fold stratified cross-validation repeated with 100 different splits of data into 10-folds.

Progressors (JSN>0.0mm) vs. non-progressors (JSN<0.0mm)	AUC	CI	p value
IL-1β	0.781	0.71–0.85	<0.0001
TNFα	0.692	0.61–0.77	<0.0001
COX-2	0.664	0.58–0.75	<0.0001
IL-1β + TNFα + COX-2	0.813		<0.0001

***HLA-DPB1*04:01* Confers Risk for PR3-ANCA Positive ANCA-Associated Vasculitis (AAV), but Protects Against MPO-ANCA Positive AAV, in a Japanese Population.** Aya Kawasaki[1], Misaki Hidaka[1], Narumi Hasebe[1], Ken-ei Sada[2], Shigeto Kobayashi[3], Hidehiro Yamada[4], Hiroshi Furukawa[5], Kunihiro Yamagata[1], Takayuki Sumida[1], Nobuyuki Miyasaka[6], Shigeto Tohma[5], Shoichi Ozaki[4], Seiichi Matsuo[7], Hiroshi Hashimoto[8], Hirofumi Makino[2], Masayoshi Harigai[6] and Naoyuki Tsuchiya[1]. [1]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [3]Juntendo University Koshigaya Hospital, Tokyo, Japan, [4]St. Marianna University School of Medicine, Kawasaki, Japan, [5]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [6]Tokyo Medical and Dental University, Tokyo, Japan, [7]Nagoya University Graduate School of Medicine, Nagoya, Japan, [8]Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Epidemiologic difference between European and Asian populations is observed in antineutrophil cytoplasmic antibody (ANCA) – associated vasculitis (AAV). Granulomatosis with polyangiitis (GPA) is prevalent in European populations, while microscopic polyangiitis (MPA) is common in Japanese. Genetic factors appear to contribute to the difference in epidemiology, which was supported by a recent genome-wide association study (GWAS) (Lyons et al., 2012). The GWAS indicated that GPA / proteinase 3 (PR3)-ANCA was associated with *HLA-DP* region, whereas MPA / myeloperoxidase (MPO) – ANCA was associated with *HLA-DQ* region. These results were consistent with the previous studies showing the association of GPA with *HLA-DPB1*04:01* in European populations, as well as our study that reported *HLA-DRB1*09:01-DQB1*03:03* haplotype was associated with MPA in Japanese (Tsuchiya et al., 2006). However, due to the rarity of AAV, contribution of *HLA-DPB1* to either MPA or GPA has not been reported in a Japanese population.

In this study, by means of multicenter collaborative study in Japan, we investigated whether *HLA-DPB1* is associated with susceptibility to AAV in Japanese, and whether the differences in *HLA-DPB1* allele frequency can in part account for the population difference in AAV subsets.

Methods: Association of *HLA-DPB1* was examined in 356 Japanese patients with AAV and 580 healthy controls. According to the European Medicines Agency algorithm, 220 patients were classified as MPA, 69 as GPA and 35 as eosinophilic granulomatosis with polyangiitis (EGPA). Among the patients, 300 were positive for MPO-ANCA and 41 were positive for PR3-ANCA. *HLA-DPB1* typing was performed by the PCR-SSOP (Sequence Specific Oligonucleotide probes) method.

Results: *HLA-DPB1*04:01*, which was reported to be a risk allele to GPA in European populations, is decreased in MPA (dominant model,

P=0.031, odds ratio [OR] 0.53), and more strikingly in MPO-ANCA positive AAV (P=0.0026, OR 0.44). *DPB1*05:01* was also decreased in MPA (allele model, P=0.0063, OR 0.72). On the other hand, *DPB1*04:01* was increased in PR3-ANCA positive AAV (allele model, P=0.010, OR 2.38). Interestingly, although significant association was not detected in GPA as a whole, *DPB1*04:01* was significantly increased when only PR3-ANCA positive GPA was examined (P=5.7E-4, OR 3.18), but not in MPO-ANCA positive GPA.

Conclusion: This study demonstrated that *DPB1*04:01* is a risk allele to PR3-ANCA positive AAV also in the Japanese population. In contrast. *DPB1*04:01* was protective against MPO-ANCA positive AAV. In view of the population difference in the *DPB1*04:01* allele frequency in the Japanese (6.1%) and in the European populations (42.5% in USA, The Allele Frequency Net Database), *DPB1*04:01* may in part account for the epidemiological difference in the prevalence of MPO-ANCA and PR3-ANCA positive AAV, in addition to the *DRB1*09:01-DQB1*03:03* haplotype.

Table 1 Association of *DPB1*04:01* with AAV in a Japanese population

	n	Allele frequency	P	OR (95%CI)	Carrier frequency	P	OR (95%CI)
MPA	220	16 (0.036)	0.050	0.58 (0.33–1.00)	15 (0.068)	0.031	0.53 (0.30–0.95)
GPA	69	12 (0.087)	0.24	1.46 (0.77–2.76)	10 (0.145)	0.56	1.23 (0.60–2.52)
MPO+ GPA	39	2 (0.026)	0.32	0.40 (0.10–1.68)	2 (0.051)	0.30	0.39 (0.09–1.67)
PR3+ GPA	32	11 (0.172)	5.7×10^{-4}	3.18 (1.65–6.15)	9 (0.281)	0.0084	2.85 (1.31–6.21)
MPO+ AAV	300	18 (0.030)	0.0046	0.47 (0.28–0.79)	17 (0.057)	0.0026	0.44 (0.26–0.75)
PR3+ AAV	41	11 (0.134)	0.010	2.38 (1.23–4.60)	9 (0.220)	0.066	2.05 (0.95–4.41)
Healthy control	580	71 (0.061)		70 (0.121)

Whole Exome Sequencing Analysis Performed on a Patient with Fibroblastic Rheumatism. Michal Feldon MD[1], Keith A. Sikora[1], John B. Harley[2], Jennifer L. Huggins[1], Hermine I. Brunner[3] and Kenneth M. Kaufman[4]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH, [3]PRCSG, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center and the University of Cincinnati, Cincinnati, OH.

Background/Purpose: Fibroblastic Rheumatism is a rare disease, first described in 1980 with almost 30 cases reported thus far. One-third of the patients are children. The disease is characterized by sudden and rapidly progressive symmetric arthritis in large and small joints with cutaneous nodules over hands and para-articular sites. Sclerodactyly with thickened palmar fascia and Raynaud's phenomenon can also be seen. Laboratory tests are usually normal and the diagnosis is based on the histology of the nodules. The etiology of the disease is unknown and no genetic testing has been published on patients with fibroblastic rheumatism to date.

The objective of this study was to identify possible causative candidate genes for this disease using whole exome sequencing.

Methods: We performed exome sequencing analysis on the DNA of a 14 year old patient with biopsy-proven fibroblastic rheumatism and her unaffected brother. It was performed at Perkin Elmer DNA Sequencing and Analysis Branford, CT. Target enrichment was performed using Illumina TruSeq Exome capture. Sequencing was performed on an Illumina HiSeq 2000. Alignment and variant calls were made using the Broad Institute's Genome Analysis Toolkit (GATK). Variant calls were analyzed using Golden Helix SNP and Variation Suite ver 7.7.5.

We focused on candidate variations that altered the amino-acid sequence of a protein and followed either a recessive homozygous, compound heterozygous or dominant model. Genotypes common with the unaffected sibling were removed as candidates.

Results: After quality control filtering and requiring a minor allele frequency of ≤1% in the general population, we identified 191 different candidate variations. Of those, 156 mutations fit a dominant model in which the patient was heterozygous for the polymorphism; 6 were recessive homozygous and 29 were compound heterozygous variants in 14 genes.

Several interesting candidate genes causing variants in the dominant model were identified (Table).

Conclusion: Although we did not identify one strong candidate gene, these results will form a basis for comparison to variants identified in other patients. If this is, indeed, a disorder with genetic etiology, we believe the identification of one responsible gene can assist in future genetic research of other arthritic syndromes.Table

Mutation	Gene name	Amino acid	Protein function	Related to disease
1:151804213 Stopgain	RORC [RAR related orphan receptor C]	Arg10	DNA-binding transcription factor and member of the NR1 subfamily of nuclear hormone receptors. In mice this gene inhibits the expression of FAS ligand and IL2	Dermatitis; one suspect gene for Systemic lupus Erythematosus (SLE).
4:99027142 Stopgain	C4orf37/STPG2 [Sperm-Tail PG-Rich Repeat-Containing 2]	Arg192	No known function	Rheumatoid arthritis and response to anti TNF alpha medication
1:201182308 Stopgain	IGFN1 [immunoglobulin-like and fibronectin type III domain containing 1]	Gln2763	protein-coding gene	Muscular dystrophy; bone repair.
5:70860710 Stoploss	BDP1/PTPN18 [Protein Tyrosine Phosphatase, Non-Receptor Type 18]	Glu12	The protein encoded by this gene is a member of the protein tyrosine phosphatase (PTP) family. The encoded protein localizes to aggregates in the nucleus, and is required for transcription from all three types of polymerase III promoters	Rheumatoid arthritis and response to anti TNF alpha medication; Pyoderma gangrenosum

Amerindian Ancestry Influences Polyautoimmunity. Nicolás Molano-González, John Castiblanco, Ruben-Dario Mantilla, Adriana Rojas-Villarraga and Juan-Manuel Anaya. Center for Autoimmune Diseases Research (CREA), Universidad del Rosario., Bogota, Colombia.

Background/Purpose: Polyautoimmunity [i.e., the presence of two or more autoimmune diseases (ADs) in a single patient] is a frequent phenomenon in autoimmunity, ranging from 10% to 40%. Since polyautoimmunity is most frequently observed in Latin Americans than in Europeans and the diverse population of Latin America and the Caribbean is a powerful resource for elucidating the genetic basis of complex traits due to its high admixture, we aimed to study the effect of ancestry on polyautoimmunity in a Latin American population.

Methods: A total of 508 subjects were examined [240 cases with a single AD, 87 with polyautoimmunity, of whom 36 presented with multiple autoimmune syndromes (MAS, i.e., 3 or more ADs), and 181 matched-controls with no AD]. Genotyping of 32 ancestry informative markers was performed. The individual admixture profile was built in STRUCTURE 2.3.4 by using data of people from known ethnic groups: African (n=148), European (n=160) and Native American (n=278). Different models were calculated varying the number of ancestral populations. The estimated logarithm P(X⎮ and the mean value of the log-likelihood were used to choose the most parsimonious model. Ancestry differences between cases (AD, polyautoimmunity and MAS) and controls were assessed by a MANOVA model on ARL transformed ancestral profiles, and fitted in R software 3.0.2.

Results: A high European profile (50%) followed by a similar contribution of the remaining ancestral populations (African 26%, Amerindian 24%) was observed in the studied population. Significant differences of ancestry profiles among the four groups analyzed were detected (Pillai test, p-value: 0.001). The MAS group carried a higher Amerindian composition than the other three groups (p-value: 0.01) along with a lesser European ancestry (p-value: 0.003).

Conclusion: The Amerindian ancestry component affect the development of polyautoimmunity. These results increase the understanding of genetics of autoimmunity and may contribute to design strategies to characterize patients at risk of polyautoimmunity.

Protective Association of *HLA-DRB1*13:02* Against MPO-ANCA Positive ANCA-Associated Vasculitis in a Japanese Population. Naoyuki Tsuchiya[1], Narumi Hasebe[1], Ken-ei Sada[2], Shigeto Kobayashi[3], Hidehiro Yamada[4], Hiroshi Furukawa[5], Kunihiro Yamagata[1], Takayuki Sumida[1], Nobuyuki Miyasaka[6], Seiichi Matsuo[7], Shigeto Tohma[5], Shoichi Ozaki[4], Hiroshi Hashimoto[8], Hirofumi Makino[2], Masayoshi Harigai[6] and Aya Kawasaki[1]. [1]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [3]Juntendo University Koshigaya Hospital, Tokyo, Japan, [4]St. Marianna University School of Medicine, Kawasaki, Japan, [5]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [6]Tokyo Medical and Dental University, Tokyo, Japan, [7]Nagoya University Graduate School of Medicine, Nagoya, Japan, [8]Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Epidemiology of antineutrophil cytoplasmic antibody (ANCA) – associated vasculitis (AAV) is substantially different between European and Asian populations. In the Japanese population, the majority of AAV patients are positive for myeloperoxidase (MPO) – ANCA. In studies with a small sample size, we previously reported significant association of *HLA-DRB1*09:01-DQB1*03:03*, a haplotype common in Asians but rare in other populations, with MPO-ANCA positive AAV (Tsuchiya et al., 2003; Tsuchiya et al., 2006). In the present study, we substantially increased the sample size, and compared *HLA-DRB1* associations among AAV subgroups, and also made an attempt to detect other *DRB1*alleles associated with risk or protection.

Methods: *HLA-DRB1*genotypes were determined by using WAK Flow HLA-typing kit (Wakunaga, Hiroshima, Japan) in 356 Japanese AAV and 596 healthy controls. Among the patients, 220 were classified as microscopic polyangiitis (MPA), 69 as granulomatosis with polyangiitis (GPA), 35 as eosinophilic granulomatosis with polyangiitis (EGPA), and 32 were unclassifiable, according to the European Medicines Agency algorithm. Among all patients, 300 were positive for myeloperoxidase (MPO)-ANCA and 41 for proteinase 3 (PR3)-ANCA. The second risk allele and protective allele were examined by relative predispositional effects (RPE) method. Bonferroni correction was employed to correct for the number of compared alleles.

Results: Positive association of *DRB1*09:01* carrier frequency was confirmed in MPA (P=0.0036, Pc=0.0076, odds ratio [OR] 1.81). In addition, significant negative association with *DRB1*13:02* was detected in MPA (P=0.001, Pc=0.0244, OR 0.43). In GPA, tendency toward positive association was detected in *DRB1*08:02* (P=0.031, Pc=0.65, OR 2.56) and negative association in *DRB1*13:02* (P=0.037, Pc=0.77, OR 0.38). The associations were more striking when the patients were classified according to the specificity of ANCA. In MPO-ANCA positive patients, *DRB1*09:01* was increased ($P=2.3x10^{-5}$, $Pc=4.8x10^{-4}$, OR 1.89), while *DRB1*13:02* was decreased ($P=3.7x10^{-5}$, $Pc=7.8x10^{-4}$, OR 0.38). RPE method confirmed negative association of *DRB1*13:02* ($P_{RPE}=7.3x10^{-4}$, OR_{RPE} 0.47), and also suggested *DRB1*08:02* as the second risk allele ($P_{RPE}=0.025$, OR_{RPE} 1.82). In PR3-ANCA positive patients, suggestive association was observed for *DRB1*11:01* (P=0.021, Pc=0.65, OR 3.80), but not for *DRB1*09:01* (P=0.86, OR 1.02). Genotype comparison suggested that carriage of *DRB1*13:02* cancels the risk of *DRB1*09:01* to MPO-ANCA positive AAV in **09:01/*13:02* heterozygotes.

Conclusion: *DRB1*09:01* is associated with MPO-ANCA positive, but not with PR3-ANCA positive, AAV. Because *DRB1*09:01* is a very common *HLA-DRB1* allele in East Asian bur rare in European populations, such a difference in the genetic background may be associated with the difference in the prevalence of MPO-positive and PR3-positive AAV in both populations. In addition, *DRB1*13:02* was identified as a protective allele against MPO-ANCA positive AAV.

Association of Leukocyte Immunoglobulin-like Receptor A3 (*LILRA3*) with Systemic Sclerosis. Yuki Hachiya[1], Aya Kawasaki[1], Takashi Matsushita[2], Hiroshi Furukawa[3], Shouhei Nagaoka[4], Kota Shimada[5], Shoji Sugii[5], Takayuki Sumida[1], Shigeto Tohma[3], Minoru Hasegawa[6], Manabu Fujimoto[1], Shinichi Sato[7], Kazuhiko Takehara[2] and Naoyuki Tsuchiya[1]. [1]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Kanazawa University, Kanazawa, Japan, [3]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [4]Yokohama Minami Kyousai Hospital, Yokohama, Japan, [5]Tokyo Metropolitan Tama Medical Center, Tokyo, Japan, [6]University of Fukui, Yoshida-gun, Fukui, Japan, [7]The University of Tokyo, Tokyo, Japan.

Background/Purpose: The leukocyte immunoglobulin-like receptors (*LILRs*) are a gene family located in leukocyte receptor complex at 19q13.4. LILRs are expressed mainly in immune cells as transmembrane receptors, and some of LILRs have been shown to regulate immune cell activation. LILRA3 is the only secreted protein among LILRs, but its function remains unclear. Furthermore, *LILRA3* has a 6.7-kb deletion polymorphism which lacks most of the coding region, and its frequency is especially high in the East Asian populations (71.0% in the Japanese, 18.5% in the German)(Hirayasu et al., 2006, Koch et al., 2005). Previous studies in European populations reported association of the deletion allele with multiple sclerosis (MS) (Koch et al., 2005) and Sjögren's syndrome (SS) (Kabalak et al., 2009), while recent studies from China reported association of homozygous non-deletion genotype with rheumatoid arthritis (Du et al., 2014a), systemic lupus erythematosus (SLE) and SS (Du et al., 2014b). In this study, we examined whether *LILRA3* deletion polymorphism is associated with systemic sclerosis (SSc) in a Japanese population.

Methods: 373 Japanese patients with SSc and 867 healthy Japanese controls were examined. All patients fulfilled the American College of Rheumatology criteria. 124 were classified as having diffuse cutaneous (dc) SSc, while 201 as limited cutaneous (lc) SSc from available clinical data, according to the classification by LeRoy et al. 82 were positive for anti-topoisomerase 1 antibody (ATA+) and 158 for anti-centromere antibody (ACA+). Six patients were positive for both ATA and ACA. 140 patients were classified as having interstitial lung disease (ILD) based on high resolution CT. The *LILRA3* deletion was genotyped by PCR-sequence specific primers. This study was reviewed and approved by the ethics committees of each participating institute. Informed consent was provided by all subjects.

Results: We observed higher frequency of *LILRA3* deletion in ATA+ SSc patients compared with healthy controls (P=0.015, OR= 1.68 under the allele model, P=0.014, OR=1.83 under the recessive model) (Table1). This association was not observed in ACA+ SSc. In the case-only analysis, the deletion allele frequency of ATA+ACA- SSc was significantly increased when compared with ATA-ACA+ SSc (P=0.0094, OR=1.93).

Conclusion: Our study demonstrated the first evidence for the association between the *LILRA3* deletion and ATA+ SSc. The risk allele was in agreement with that of MS and SS in the German population, but was the opposite to that of RA and SLE in the Chinese population. This study supported the association of *LILRA3* with genetic susceptibility to multiple autoimmune diseases, and its role requires further study.

Table 1. Association between *LILRA3* deletion polymorphism and SSc

	n	Genotype frequency			del allele frequency	Allele model		Recessive model		Dominant model

Background/Purpose: TRIM21, also referred to as Ro52 or SS-A1, belongs to the tripartite motif-containing (TRIM) family. TRIM21 is not only important as an autoantigen, but also as a component of the signaling pathway relevant to the disease processes of autoimmune rheumatic diseases. TRIM21 is induced by type I interferon, ubiquitylates proteins of the interferon-regulatory factor (IRF) family, and regulates type I interferon and proinflammatory cytokines. Furthermore, TRIM21 has also been reported to function as an intracellular Fc receptor. To date, it is not clear how these different aspects of TRIM21 are functionally related. Until now, several very small scale studies suggested the association of some SNPs in *TRIM21* with susceptibility to systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS). However, to our knowledge, systematic association study covering all the tagSNPs has not been reported. In this study, we conducted a systematic association study between SLE and*TRIM21*in a Japanese case-control set with more than 1,000 individuals.

Methods: Nine tagSNPs in *TRIM21* region were selected based on JPT HapMap data with the criteria of minor allele frequency > 0.05 and r^2 threshold of 0.80. 530 Japanese SLE and 518 healthy Japanese controls were genotyped for the tagSNPs using TaqMan allele discrimination assay, and case-control association study was performed. Prediction of functional relevance of the SNPs was done by using SNP Function Prediction (FuncPred) website (http://snpinfo.niehs.nih.gov/snpinfo/snpfunc.htm). This study was reviewed and approved by the ethics committees of each participating institute. Informed consent was provided by all subjects.

Results: Among the 9 tagSNPs, association was detected in 3 SNPs. At rs7947461 in intron 1, the frequency of T allele (P=0.04, odds ratio [OR] 0.76, 95% confidence interval [CI] 0.58–0.98) and that of the T/T genotype (P=0.04, OR 0.72, 95% CI 0.53–0.99) were decreased. At rs9261010 in exon 2 coding for a synonymous substitution, T allele frequency (P=0.04, OR 0.81, 95%CI 0.67–0.99) and T/T genotype frequency (P=0.05, OR 0.62, 95% CI 0.39–1.00) were decreased. Furthermore, at rs4144331 in the 3' untranslated region (UTR), decrease in T allele frequency (P=0.04, OR 0.76, 95%CI 0.58–0.98) and in T/T genotype frequency (P=0.04, OR 0.75, 95% CI 0.56–0.99) were observed. A bioinformatic analysis predicted that rs4144331 may affect binding of miRNA hsa-miR-1300.

Conclusion: These results suggested that of *TRIM21* polymorphisms may be associated with susceptibility to SLE. Further replication studies as well as functional studies are required.

Microbiomes of Inflammatory and Non-Inflammatory Thoracic Aortic Aneurysms. Pauline Funchain*[1], Gary S. Hoffman*[2], Lars Svensson[3], Eric Roselli[3], Gosta Pettersson[3], Douglas Johnston[3], Edward Soltesz[3], Ritu Chakravarti[4], Alison Clifford[3] and Charis Eng[5]. [1]Genomic Medicine Institute, Lerner Research Institute, Cleveland, OH, [2]Center for Vasculitis Care and Research, Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic, Cleveland, OH, [5]Case Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH.

Background/Purpose: Aortitis may occur in the context of multifocal large and medium-sized vessel diseases such as giant cell arteritis (GCA) or Takayasu arteritis (TAK) and as an isolated focal finding (focal idiopathic aortitis, FIA). In each setting, the aortic root and arch are the most common locations for aortic injury that is presumed to be autoimmune. It is not clear whether the propensity to affect the proximal aorta in these diseases suggests common pathways in pathogenesis that could include infection, abnormalities in immune tolerance or response, presence of neo-antigens, or alterations in substrate microbiome. A better understanding of disease pathogenesis may lead to new therapies and improved outcomes. Thus, we sought to describe the microbiome of inflammatory and non-inflammatory thoracic aortic aneurysms (TAA).

Methods: Patients with TAA who underwent surgical reconstruction were prospectively enrolled over a period of 3 years. TAA specimens were sterilely collected and snap frozen. Clinicopathologic data were gathered on all patients. Patients who had histologic evidence of inflamed aortas and diagnoses of GCA, TAK or who were found at surgery to have FIA were matched by age, gender and race to patients with non-inflammatory lesions including bicuspid aortic valves, chronic hypertension, Marfan syndrome and other causes of cystic medial degeneration. Total DNA, including human and bacterial, was isolated from TAA. V1–4 regions of the gene encoding bacteria-specific 16S rRNA were amplified and Sanger sequenced. Principal-coordinate analysis (PCoA) plots were created based on de novo operational taxonomic unit classification via the MacQIIME 1.7 toolkit. Hierarchical taxonomic composition of sequences was performed using a custom pipeline and visualized with Krona.

Results: Twenty-seven TAA were analyzed: 7 GCA, 5 FIA, 2 TAK, and 13 non-inflammatory. Hypertension and hyperlipidemia were the most common comorbidities, and were not significantly different between inflammatory and non-inflammatory groups. All TAA hosted bacterial communities of varying abundance. Autoimmune-associated TAA microbiomes cluster on PCoA plots according to type of aortitis, with the clearest separation seen between FIA and TAK samples. GCA and non-inflammatory TAA microbiomes overlap on PCoA plots, but are separate from FIA and TAK. Both GCA and non-inflammatory TAA microbiomes appear to contain sub-group clusters. Gross visualization of taxonomic composition using Krona plots shows differences between GCA specimens compared to non-inflammatory samples at the phyla level, with a tendency toward increased Proteobacteria, decreased Actinobacteria, and minimal Bacteroidetes in GCA. Overall, TAA microbiomes did not show clustering by age, sex, or prednisone use. Some clustering was seen with tobacco use.

Conclusion: TAA are not sterile. Specimens from patients with different disease associations host distinct microbial communities. Further analysis is needed to assess whether differences in microbial communities play etiologic roles or are secondary results of different types of aortic injury.

Global miRNA Expression Profiling in Peripheral Blood and Synovial Fluid Mononuclear Cells of Patients with Enthesitis Related Arthritis. Sushma Singh, Ramnath Misra and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Enthesitis related arthritis (ERA) is the most common category of JIA in India. MicroRNA dysregulation has been associated with arthritis and autoimmune diseases. In rheumatoid arthritis (RA) over-expression of miR-146a, miR-155 miR-132 and miR-16 has been found in PBMC. Data on miRNA profiling in serum of patients with systemic lupus erythematosus (SLE) shows over-expression of miR-142-3p and miR-181a whereas miR-106a, miR-17, miR-20a, miR-203, and miR-92a were found to be down-regulated. No such data is available in case of ERA. Thus we studied global miRNA expression profile of ERA patients using peripheral blood mononuclear cells and synovial fluid mononuclear cells (PBMCs and SFMCs). PBMCs from healthy subjects were used as controls.

Methods: Total RNA was isolated from PBMCs and SFMCs of ERA patients (n= 8 each) and PBMCs of healthy controls (n= 8). miRNA profiling was done using Agilent Human miRNA Microarray G4470A chips. Log_2-transformed expression values of miRNAs were analysed using RMA algorithms. Differential expression analyses were done using Empirical Bayes moderated t statistics. Highly dysregulated miRNAs were validated by quantitative RT-PCR by comparing fold change (in relation to Let-7a as internal control) in 13 PBMCs with 11 SFMCs from ERA patients. Targets of

dysregulated miRNAs were predicted by computational analysis using databases like DIANA LAB, miR Base, Target Scan, etc.

Results: The miRNAs profiling of ERA PBMCs were not significantly different from healthy controls. While comparing ERA SFMCs 38 miRNAs were down-regulated and 52 were up-regulated at cut offs of 0.05 as compared to ERA PBMCs. Among them miR-34a, miR-210, miR-29b, miR-155, miR-21, miR-27a, miR-132, miR-140-5p, miR-15a, and miR-660 were upregulated and miR-146a, miR-126, miR-130a, miR-150, miR-26a, miR-23b, miR-199a, miR-451, miR-151 and miR-221 were down-regulated in SFMCs. Among these 5 down-regulated and 5 up-regulated miRNAs were validated by RT-PCR using 11 ERA SFMCs and 13 ERA PBMCs.The comparison of fold change between ERA SFMCs and ERA PBMCs (p value) of dysregulated miRNAs showed: miR-34a ($p=$**0.035**), miR-210 ($p=0.424$), miR-29b ($p=0.865$), miR-155 ($p=0.072$), miR-21 ($p=$**0.047**), miR-146a ($p=$**0.006**), miR-126 ($p<$**0.001**), miR-130a ($p<$**0.001**), miR-150 ($p=0.150$) and miR-26a ($p=$**0.011**). The targets of dysregulated miRNAs formed a part of multiple immune pathways like MAPK signaling pathways, TLR signaling pathways, T cell receptor signaling pathways, mTOR signaling pathways, Wnt signaling pathways, etc.

Conclusion: ERA SFMC has a distinct miRNA gene expression profile compared to ERA PBMCs. miR-34a and miR-21 are significantly up-regulated whereas miR-146a, miR-126, miR-130a and miR-26a are significantly down-regulated in ERA SFMCs and all these dysregulated miRNAs are involved in multiple immune pathways. This difference in SFMC may be related to difference in composition of cells, cytokine mileu that modulates miRNA expression as well as differential expression of miRNAs as they have feedback regulatory function.

Genetic Variants in *IL-6, IL-10, C5-TRAF1* and *FCRL3* and Progression of Joint Damage in Rheumatoid Arthritis; A Study on Six Cohorts. H.W. van Steenbergen[1], L. Rodriguez-Rodriguez[2], E. Berglin[3], A. Zhernakova[4], R. Knevel[1], J. Ivorra-Cortes[5], T.W.J. Huizinga[1], B. Fernández-Gutiérrez[6], P.K. Gregersen[7], S. Rantapää-Dahlqvist[8] and A.H.M. van der Helm-van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department of Rheumatology, Hospital Clínico San Carlos, Madrid, Spain, [3]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umeå, Sweden, [4]University Medical Center Groningen, Groningen, Netherlands, [5]University Hospital la Fe, Valencia, Spain, [6]Hospital Clínico San Carlos, Madrid, Spain, [7]The Feinstein Institute for Medical Research, Manhasset, NY, [8]Umeå University Hospital, Umeå, Sweden.

Background/Purpose: Understanding the mechanisms underlying the inter-individual differences in radiographic progression is relevant and heritability studies have shown that genetic factors explain part of these inter-individual differences. Indeed, some genetic variants have been identified and replicated in independent studies or found significant in meta-analyses. The literature on genetic variants and joint destruction in RA was systematically reviewed recently; for genetic variants in *IL-6*, *IL-10*, *C5-TRAF1*, and *FCRL3* the existing literature was indefinite on whether these variants are associated with joint destruction. We aimed to clarify associations of genetic variants in *IL-6*, *IL-10*, *C5-TRAF1* and *FCRL3* with radiographic progression by evaluating six independent cohorts.

Methods: In total 5,895 sets of radiographs of 2,493 RA patients included in the Leiden EAC, Umeå, HCSC-RAC, Wichita, NDB and NARAC cohorts were studied in relation to rs1800795 (*IL-6)*, rs1800896 (*IL-10)*, rs2900180 (*C5-TRAF1)* and rs7528684 (*FCLR3)*. Associations with radiographic progression rates were tested per cohort using an additive model, adjusting for age, gender and treatment when appropriate. The results on yearly radiographic progression rates were combined in inverse variance weighted meta-analyses. Analyses were done on the total RA population and after stratification for anti-citrullinated peptide antibodies (ACPA). Furthermore, the associated region *C5-TRAF1* was fine-mapped.

Results: No associations were found for rs1800795 (*IL-6)*, rs1800896 (*IL-10)* and rs7528684 (*FCLR3)* in the total RA population and after stratification for ACPA. Also the directionality of the effects was diverse. Although for rs2900180 in *C5-TRAF1* no significance was obtained in the total population or in ACPA-positive RA, an association was observed in ACPA-negative RA (p value meta-analysis $5.85\text{x}10^{-7}$). In all data sets with ACPA-negative RA, the minor allele was associated with more radiographic progression. Fine-mapping revealed a region of 66 Kb that was associated with radiographic progression; the lowest p-value was for rs7021880 in *TRAF1*. The p-value for rs7021880 in meta-analysis was $6.35\text{x}10^{-8}$. Previous studies indicate that the region of rs7021880 was associated with RNA expression of *TRAF1* in monocytes after lipopolysaccharide stimulation.

Conclusion: In contrast to initial reports, variants in *IL-6*, *IL-10* and *FCLR3* were not associated with radiographic progression in the present large meta-analyses. Although an association between rs2900180 in *C5-TRAF1* and joint destruction was initially identified in the total RA population, we here replicated an association of rs2900180 in *C5-TRAF1* and linked variants in a 66 Kb region with radiographic progression in ACPA-negative RA.

Quantitative Proteomics Using Dimethyl Isotope Labeling for Comparison of Fresh Frozen Versus Formalin-Fixed, Paraffin-Embedded Tissue for Lupus Nephritis. Abhimanyu Amarnani, Joseph Capri, Puneet Souda, David Elashoff, Ivan Lopez, Julian Whitelegge and Ram Singh. University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: Lupus nephritis (LN) progresses from mild focal inflammation, to diffuse proliferative nephritis, to fibrosis and end-stage renal disease. Though the understanding of LN has progressed, there is a need to use global, data-driven research methodologies to elucidate its molecular pathogenesis. As a foundation for this goal, we aimed to develop a quantitative proteomics workflow that can directly study formalin-fixed, paraffin-embedded (FFPE) archived clinical tissues. This applicable workflow could therefore provide a powerful tool to study the progression of LN, albeit if we can trust that data obtained are without substantial sample processing bias.

Methods: To obviate the need for large pieces of human LN tissue, we used kidney tissues from lupus-susceptible NZM.2328 mice that develop glomerulonephritis that mimics LN in humans. Identical transverse kidney tissue cuts from 10-month-old female NZM-2328 mice with high-grade proteinuria were processed as FFPE and fresh frozen tissue (FFT). FFPE and FFT sections were digested with trypsin and stable isotope labeled for protein identification and quantification. Our workflow includes a combination of methodologies including filter aided sample preparation (FASP), in-solution dimethyl isotope labeling, strong cation exchange StageTip fractionation, along with nano-LC MS/MS through an Orbitrap XL mass spectrometer. Two separate experiments were run where three conditions were studied in each: two exact technical replicate FFT conditions and one FFPE condition. Within our workflow, combining FASP and in-solution dimethyl isotope labeling, relative quantitative values were obtained via direct comparison of each pair of conditions within each experiment.

Results: We developed and validated a workflow that allows for a direct comparison of FFPE tissue to FFT. Through our workflow validation experiments, we observed an almost 100% protein identification overlap between FFPE and FFT from a LN kidney. A consistent identification of over 1400 proteins in both FFPE and FFT indicate no selection bias with tissue processing. Although, quantification differences did exist when comparing FFPE-to-FFT, the quantitative changes (quantification ratios) of proteins in FFPE tissues were consistent across replicate experiments. This reliability is seen with global hierarchical clustering as well as with specific protein categories such as TGFβ signaling, the KEGG SLE annotated pathway, the GSEA annotated lupus CD4 T cell vs. myeloid function upregulation, and B cell function related proteins, which have been implicated in LN pathogenesis.

Conclusion: Our methodology is the first to directly compare FFT and FFPE tissue in a manner that can be readily applied to archived clinical samples. Our results demonstrate the utility of this workflow by its ability to equally identify proteins between FFPE and FFT, minimizing sample processing bias, and by providing consistent protein quantification values of FFPE tissue between technical replicates and across separate experiments. We conclude that this clinically oriented proteomics workflow, when applied to archived, FFPE tissue can be reliably utilized to study LN pathogenesis.

Long Noncoding RNA Nron Regulates the Activity of NFAT5 through Ubiquitin-Independent Proteasome Pathway in Rheumatoid Arthritis. Kunihiko Umekita[1], Michelle Trenkmann[1], Christoph Kolling[2], Akihiko Okayama[3], Renate Gay[1], Steffen Gay[1] and Mojca Frank Bertoncelj[4]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland, [3]University of Miyazaki, Miyazaki, Japan, [4]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Long noncoding RNAs (lncRNAs) are increasingly recognized as master regulators of gene expression. The lncRNA NRON, noncoding repressor of nuclear factor of activated T cells (NFAT) can repress the cytoplasmic-nuclear translocation and function of NFAT1–4 transcriptional factors. Recently, we have reported that NRON regulates also the activity of NFAT5, affecting thereby the function of rheumatoid arthritis synovial fibroblasts (RASF). In addition, the ubiquitin-independent proteasome system has been shown to play an important role in regulating the cellular levels of NFAT5. Our objective was to investigate the regulation of NRON levels in RASF and to explore the role of NRON in protein turnover of NFAT5.

Methods: The levels and subcellular localization of NFAT5 protein in RASF were analyzed by Western blotting using α-tubulin for normalization. RASF were transfected with siRNA targeting NRON or scrambled siRNA using Lipofectamine 2000. RASF were treated with TNFα (10ng/ml), p38MAPK inhibitor (p38i, 10uM) SB202190, and/or proteasome inhibitor MG132 (1.0uM). Gene expression was measured by quantitative real-time PCR with normalization to GAPDH or β2-microglobulin. ELISA was used to measure IL-6 secretion from RASF.

Results: The levels of NRON were significantly decreased and the levels of NFAT5 protein were increased in RASF after 2hr of TNFα stimulation, while the levels of NFAT5 mRNA were not changed. Down regulation of NRON after silencing or TNFα stimulation was accompanied by the translocation of NFAT5 from the cytoplasm to the nucleus of RASF, increasing the transcription of known NFAT5 target genes, such as IL-6 (x-fold$\pm$SD: 3.0$\pm$2.2, p=0.03, n=4;) and MMP13 (x-fold$\pm$SD: 4.7$\pm$2.0, p=0.03, n=4). The secretion of IL-6 in the culture medium of RASF was also significantly increased (mean$\pm$S.D: 1676$\pm$479 vs 2433$\pm$504 pg/mL, p=0.007, n=5). The treatment of RASF with p38i significantly repressed not only the TNFα-induced up regulation of IL-6 but also the TNFα-induced down regulation of NRON (p= 0.001 and p= 0.04, n=5, respectively). Additionally, the proteasome-dependent degradation of NFAT5 was significantly enhanced by p38i (p= 0.01, n=5). Blocking the proteasome activity by MG132 inhibited the p38-induced degradation of NFAT5. Furthermore, the p38i-induced degradation of NFAT5 was inhibited also after silencing of NRON in RASF.

Conclusion: Our data show that TNFα down regulates the expression of lncRNA NRON in RASF by enhancing the activity of p38MAPK. Down regulation of NRON not only enhances the nuclear translocation and transcriptional activity of NFAT5 but also increases the total amount of NFAT5 in RASF by influencing the turnover of NFAT5 via ubiquitin-independent proteasome system. This novel data show the complex and multilevel capacities of the lncRNA NRON in regulating the function of NFAT5, thereby promoting proinflammatory and matrix-destructive responses of RASF.

Protein Profiling of Secretome Human Cartilage to Identify Potential EARLY Specific Biomarkers in Osteoarthritis. Lucia Lourido, Valentina Calamia, Patricia Fernandez-Puente, Jesus Mateos, Francisco J. Blanco Garcia, Beatriz Rocha, Carolina Fernández-Costa, Carlos Fernandez-Lopez, Natividad Oreiro and Cristina Ruiz-Romero. Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatologia. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). As Xubias, 15006., A Coruña, Spain.

Background/Purpose: Osteoarthritis (OA) is characterized by the progressive loss of cartilage structural extracellular matrix (ECM) components. The release of these proteins from the tissue can vary according to the stage of the disease and the specific joint affected. The aim of this study was to perform a quantitative proteomics approach to identify and quantify those proteins released from normal (N) and OA human articular cartilages capable of predicting the early stage of hip and knee OA.

Methods: Tissue explants were obtained from the dissection of 4 N and 4 OA cartilages, both from 2 femoral heads and 2 tibial condyles. Among the OA samples, we differentiated the wounded zones (WZOA) from those corresponding to the area adjacent to the lesion, or unwounded zones (UWOA). Cartilage shavings from each donor were cut into 6 mm discs and three discs/donor were placed into 96-well plates and cultured during 6 days. The conditioned media from each condition (N, WZOA and UWOA) were collected and their proteins were digested with trypsin. The resulting peptides were labelled with different isobaric tags using the iTRAQ reagents (ABSciex). Then, labelled peptides from the different conditions were mixed, desalted and separated by liquid chromatography (LC). The resulting fractions were grouped and resolved by reversed-phase nano-LC coupled to mass spectrometry (MS). The identification and relative quantification of the proteins was carried out with Protein Pilot 3.0 software.

Results: Globally we were able to identify 186 proteins released from the cartilage explants. After statistical analysis we found secreted proteins showing differences in abundance ($0.7 \leq$ ratio ≥ 1.3, $p \leq 0.05$) between the different OA zones (WZOA and UWOA) and N samples from the different joints. We classified them into 3 sets of proteins: a first group of proteins modulated specifically in UWOA sample (early OA biomarkers); a second group of proteins altered only in WZOA samples (late OA biomarkers), and finally a third group modified in both OA zones (progression biomarkers). Some of these modulated proteins are common early and progression biomarkers for both hip and knee OA (Table1). Furthermore, we also identified that the release of cartilage intermediate layer protein 1 (CILP1), a protein involved in cartilage scaffolding, is increased in UWOA from hip OA cartilage but not in UWOA from knee OA, being a possible early specific biomarker for hip OA. This specific modulation was confirmed by Real-time PCR and western blot in other human cartilage samples (n=3).

Conclusion: We describe a novel panel of cartilage-secreted proteins with potential biomarker value. Interestingly, we have identified a specific protein, which specifically indicates hip OA onset. This protein is now being explored in biological fluids (synovial fluid and serum) for the development of early diagnosis and/or anti-OA therapy monitoring strategies.

Table 1: A panel of different types of potential protein biomarkers of hip (H) OA and knee (K) OA is listed in the table. Proteins showing a gradual increase among OA samples (UWOA and WZOA) compared to normal cartilage (N) are indicated as early and progression biomarkers. CILP1 specifically indicates hip OA onset.

Possible Effects of Medicare-Only Insurance Coverage on the Use of Biologics in Patients with RA. Marcia Genta. Dallas Arthritis Center, Dallas, TX.

Background/Purpose: Biologics, a relatively new widely used class of medication that can substantially improve the course of RA, are expensive and their use is not reimbursed by all insurances. The aim of this study was to determine whether there was a difference in the usage of biologics between RA patients with only Medicare or Medicare-replacement and those who had other insurance coverage.

Methods: Demographic and clinical information.medication history, and insurance data were extracted from the electronic records of all patients with a diagnosis of RA managed at the Dallas Arthritis Center (DAC) for at least 3 months in 2013. Patients were then stratified into the following categories, based on their type of insurance coverage: *1) Medicare only*: Medicare coverage with no supplemental insurance of any kind, and no medication-specific financial support from charitable organizations; *2) Medicare-Medicaid:* both Medicare and Medicaid coverage; *3) Medicare integrated:* supplemental insurance in addition to Medicare (private or public insurances or Medicare part D); and *4) Private only:* private insurance only. Unadjusted odds ratio were used to determine the likelihood of patients with different types of insurance coverage as compared to patients covered exclusively by Medicare. This latter group was arbitrarily assigned an Odds Ratio of 1.

Results: Our search yielded 529 unique patients (median age 62 years, range 19 to 91; 79% female) with a confirmed diagnosis of RA; 13 patients who received financial support from private foundations to purchase the needed medications were excluded from the analysis. The remaining 516 patients represent our study group. Table 1 depicts the distribution of the insurance coverage amongst the study patients:

Insurance	Total patients	Median age	Female (%)
Medicare only	118	70 (41–88)	91 (77.1)
Medicare-Medicaid	67	66 (28–91)	56 (83.6)
Medicare Integrated	52	68 (36–87)	40 (76.9)
Private only	279	56 (19–91)	231 (82.8)

Table 2 shows the relative usage of biologics amongst the different groups

Insurance	Total RA patients	RA patients on any biologic	% RA patients on any biologic	OR (95% CI)	*p*
Medicare only	118	22	20%	1	
Medicare-Medicaid	67	25	37%	2.44 (1.23–4.81)	$p<.05$
Medicare-Integrated	52	20	38%	2.56 (1.24–5.29)	$p<.05$
Private only	279	102	37%	2.36 (1.39–3.99)	$p<.001$

Conclusion: Patients with Medicare only coverage who received no assistance from private foundations were significantly less likely to be treated with biologics than patients with any other type of coverage. In this study, we did not evaluate each patient's disease activity. Therefore, the possibility that fewer Medicare-only patients needed biologics than patients with other types of coverage must be considered. A study designed to include disease activity as a variable is currently under way. If confirmed, these results suggest that efforts are needed to increase Medicare patients' access to medications that can significantly improve the course of their disease and quality of life.

Disclosure: M. Genta, None.

Comparison of Patient Characteristics, Healthcare Costs, and Biologic Persistence Between Patients with Rheumatoid Arthritis Initiating First- or Second-Line Subcutaneous Abatacept, Adalimumab, or Etanercept. S Johnston[1], F Lobo[2], D McMorrow[1], R Fowler[1], D Smith[1] and A Nadkarni[2]. [1]Truven Health Analytics, Bethesda, MD, [2]Bristol-Myers Squibb, Plainsboro, NJ.

Background/Purpose: There are currently very limited comparative published data on the characteristics, healthcare costs, and biologic persistence among patients with RA who have been treated with SC abatacept in a real-world care setting. This study compared patient characteristics, healthcare costs, and biologic persistence among patients with RA initiating SC abatacept or one of the two most commonly used SC anti-TNF-α agents, adalimumab and etanercept.

Methods: This was a retrospective, observational cohort study using a large US administrative claims database. Patients included in the study had initiated SC abatacept, adalimumab, or etanercept between 1/1/2009 and 10/1/2012 (index), were continuously enrolled for 12 months before (baseline) and ≥3 months after index, were aged ≥18 years at index, and had ≥1 baseline medical claim with an International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) diagnosis code for RA (714.0x). First-line initiators used no biologic pre-index; second-line initiators used only one biologic pre-index. Patient characteristics were measured at baseline. Biologic persistence (follow-up) was defined as the period extending from index until the first occurrence of switch to another biologic, censoring at disenrollment from health insurance, or 12/31/2012. Total healthcare costs (medical and pharmacy) were measured during baseline and follow-up on a per-patient-per-month basis. Changes in healthcare costs from baseline to end of available follow-up were compared using multivariable regression (difference-in-difference method). Biologic persistence was compared using multivariable survival analyses.

Results: The study results are shown in the Table. Patients treated with SC abatacept had baseline characteristics indicative of the poorest health status (e.g., higher baseline number of unique diagnoses and baseline costs). In all analyses, SC abatacept had the numerically lowest increase from baseline in healthcare costs and hazards of non-persistence, with differences often being statistically significant.

Table

		First-line			Second-line	
	SC abatacept (n=163)	Adalimumab (n=7098)	Etanercept (n=8776)	SC abatacept (n=256)	Adalimumab (n=2055)	Etanercept (n=1303)
Baseline number of unique diagnoses, mean (SD)	17.1 (12.8)	14.0 (8.7) p<0.001	14.3 (8.9) p<0.001	15.9 (10.4)	14.2 (8.9) p<=0.006	14.3 (8.5) p<=0.011
Baseline number of unique medications, mean (SD)	18.0 (10.4)	15.3 (9.3) p<0.001	15.4 (9.5) p<0.001	18.7 (9.9)	17.5 (9.7) p<=0.082	18.1 (10.1) p<=0.44
Baseline healthcare costs, mean (SD)	$2025 ($2843)	$1153 ($1725) p<0.001	$1199 ($1944) p<0.001	$2663 ($2462)	$2162 ($1779) p<0.001	$2231 ($1941) p<0.001
Adjusted healthcare cost difference*	ref.	$640 p<=0.0012	$657 p<=0.0010	ref.	$120 p<=0.0425	$94 p<=0.1304
Adjusted hazard ratio of non-persistence*	ref.	1.504 p<=0.1241	1.691 p<=0.0466	ref.	1.982 p<=0.0003	1.737 p<=0.0057

*As calculated using difference-in-difference; positive $ value indicates lower increase from baseline in healthcare costs for SC abatacept; hazard ratio >1 indicates lower hazards of non-persistence (longer durations of persistence) for SC abatacept.

Conclusion: In this study of patients with RA initiating first- or second-line biologics, SC abatacept was initiated in patients with poorest health status and therefore higher baseline healthcare costs compared with adalimumab or etanercept. Despite this, SC abatacept often had the lowest increase from baseline in healthcare costs and longest duration of biologic persistence.

96

Comparison of Cardiovascular Risk Factor Management in Patients with RA and Matched Non-RA Patients. H Cawston[1], E Alemao[2], F Bourhis[1], T Le[3], M Al[4], M Rutten-van Molken[4], KP Liao[5] and DH Solomon[5]. [1]OptumInsight, Nanterre, France, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Hopewell, NJ, [4]Erasmus University, Rotterdam, Netherlands, [5]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: The relative risk of acute myocardial infarction in RA patients (pts) has been shown to range from 1.5 to 2.0, with a 1.4–2.7-fold higher risk of stroke. This study aimed to compare management of traditional cardiovascular (CV) risk factors such as lipids and blood pressure in pts with and without RA.

Methods: A retrospective cohort study was conducted from 1987 to 2010, using the GOLD database from the Clinical Practice Research Datalink. Pts presenting with ≥1 RA read diagnosis code after January 1 1988 (index code), with no RA or juvenile RA codes before the RA index code with ≥12 months of data reported before the first RA code, and without any psoriatic arthritis-related codes over the entire period were included. Pts with RA were matched 1:4 to non-RA pts, based on their year of entry in the database, CV risk category (National Cholesterol Education Program classification), CV treatment status and a risk score measuring the probability of having RA. The index code of non-RA pts was defined as the closest health encounter to the index code of their match. Prescriptions for antidyslipidemic, hypertensive and diabetic treatments were evaluated for up to 5 years post index code. The percentage of pts attaining UK CV targets was also evaluated.

Results: Between 1987 and 2010, 24,859 RA pts were identified and matched to 87,304 non-RA pts. RA pts were followed for an average (SD) of

5.8 (4.4) years, were 60.0 (15.1) years old; 69% were female, 39% were hypertensive and 27% dyslipidemic at index date, based on diagnoses, prescriptions and tests. Similarly, non-RA pts were followed for an average of 5.7 (4.4) years, were 60.2 (15.9) years old; 66% were females, 38% hypertensive and 28% dyslipidemic. The percentage of RA pts prescribed antihypertensives increased from 38.2% at diagnosis to 45.7% at 5 years, from 14.0% to 20.6% for antidyslipidemics, and from 5.1% to 6.4% for antidiabetics (Table). Index rates and changes over time were similar in non-RA pts, although slightly lower for antihypertensives. There was no difference between RA and non-RA pts reaching hypertension targets at 1 year (25.8% vs 26.9%, $p=0.50$) although there was for dyslipidemia and diabetes (16.4% vs 18.5%, $p<0.01$; and 48.7% vs 44.3%, $p<0.01$, respectively). Blood pressure, lipids and diabetes-related testing were similar in both groups over time since diagnosis, although CRP and ESR were higher in RA pts at diagnosis (24.6 mg/L and 31.9 mm/hr, respectively), decreasing over time. These values were lower and did not vary over time in non-RA pts.

Conclusion: There were no differences between RA and non-RA patients in the frequency of prescriptions and testing, although there was a modest 2% lower achievement in lipid targets. Based on this analysis, it seems the higher CV risk in RA patients is unlikely to be driven by differences in traditional CV risk factor management alone.

Table Summary of treatment received, by time since index

	Time point	RA patients (N=24,859)	Non-RA patients (N=87,304)
Antihypertensive treatment	At index date	38.2%	37.4%
	At 5 years	45.7%	43.0%
	Absolute increase (95%CI)	+7.5% (6.5%; 8.6%)	+5.6% (5.1%; 6.2%)
Lipid-lowering treatment	At index date	14.0%	14.8%
	At 5 years	20.6%	21.4%
	Absolute increase (95%CI)	+6.7% (5.8%; 7.5%)	+6.6% (6.1%; 7.0%)
Antidiabetic treatment	At index date	5.1%	5.8%
	At 5 years	6.4%	6.7%
	Absolute increase (95%CI)	+1.3% (0.8%; 1.8%)	+1.0% (0.7%; 1.2%)

Identification of Tuberculosis in Rheumatoid Arthritis Patients Initiating Therapy with Biologic or Non-Biologic Disease-Modifying Anti-Rheumatic Drugs Using Health Insurance Claims Data. T Simon[1], N Liu[2], N Baker[3], N Lin[2] and V Hoffman[4]. [1]Bristol-Myers Squibb, Hopewell, NJ, [2]Optum Epidemiology, Waltham, MA, [3]Bristol-Myers Squibb, Hopewell, MA, [4]Optum Epidemiology, Ann Arbor, MI.

Background/Purpose: Biologic DMARDs used for the treatment of RA may increase the risk of tuberculosis (TB). [1] Large healthcare claims databases are useful in assessing rare events such as TB, but confirmation of these events can be challenging. As part of an ongoing post-marketing safety evaluation, we sought to characterize potential TB cases in claims data among RA patients initiating biologic and non-biologic DMARDs.

Methods: A prospective cohort study of adults who initiated biologic or non-biologic DMARDs and who had at least 6 months' prior continuous health plan enrollment (baseline) and a baseline claim for RA (International Classification of Diseases, 9th Revision [ICD-9] 714.xx) between December 1, 2005 and March 31, 2013 was conducted using administrative data from a large United States healthcare insurer. Potential TB events following drug initiation were identified with diagnosis codes associated with healthcare claims (ICD-9 010.xx- 018.xx) and characterized using criteria from a published validation algorithm for TB detection by Calderwood et al. (2010)[2], including the presence of claims suggestive of at least two TB treatments (e.g., pyrazinamide, rifampin, isoniazid, ethambutol) within 60 days, prescription for pyrazinamide, and acid-fast bacilli (AFB) testing in the preceding 60 days or subsequent 14 days. Potential TB events were also characterized by the presence of chest x-ray claims within 60 days.

Results: We identified 15,183 biologic DMARD initiators and 50,492 non-biologic DMARD initiators contributing 32,230 and 100,580 person-years of follow-up, respectively. Biologic DMARD initiators were more likely than non-biologic DMARD initiators to have previously used another biologic during the baseline period (20% vs 9%) and more likely to have a baseline claim for a TB skin test (26% vs 4%). A total of 251 potential TB events were identified during follow-up, 59 among biologic DMARD initiators and 192 among non-biologic DMARD initiators. Among the potential cases, 2 (3%) biologic DMARD initiators and 2 (1%) non-biologic DMARD initiators had claims for pyrazinamide, and 4 (7%) biologic DMARD initiators and 4 (2%) non-biologic DMARD initiators had claims for at least 2 different anti-TB medications. A total of 5 (8%) potential cases among biologic DMARD initiators and 6 (3%) potential cases among non-biologic DMARD initiators had an AFB test claim. A total of 28 (47%) potential cases among biologic DMARD initiators and 103 (54%) potential cases among non-biologic DMARD initiators had a claim for chest x-ray.

Conclusion: Few potential TB events identified on the basis of diagnosis codes had additional supporting claims. Claims-based algorithms based on diagnosis codes alone are likely insufficient for accurate identification of TB cases in administrative data. Consideration of claims indicative of TB treatment or diagnostic work-up in combination with diagnosis codes may improve identification of TB events in safety surveillance.

Costs of Musculoskeletal Diseases in the United States, 1996–2011: Population Growth, Population Aging, Health Care Utilization, or Prices? Edward H. Yelin[1], Miriam G. Cisternas[2], Laura Trupin[1] and Stuart Gansky[1]. [1]University of California, San Francisco, San Francisco, CA, [2]MGC Data Services, Carlsbad, CA.

Background/Purpose: Medical care costs have been a major concern for public policy for a generation. Concern about costs of musculoskeletal conditions (MUSC) has been fueled by the aging of the population which puts a growing fraction of the population at risk for these conditions. We document the growth in medical care costs of MUSC from 1996–2011 and analyze the role that aging of the population, age-specific prevalence of the conditions, increased medical care utilization, and increased prices for services play in this growth.

Methods: We analyzed the 1996–1998 and 2009–2011 Medical Expenditure Panel Survey (MEPS).Using three-year periods provides more stable estimates of long-term trends. In MEPS, persons self-report conditions causing utilization, disability, or symptoms. Responses are coded to ICD-9-CM 3-digit codes; musculoskeletal codes included arthritis and joint pain, spine conditions, osteoporosis, musculoskeletal injuries, and other musculoskeletal conditions. We calculated per person and aggregate costs in constant 2011 dollars, by type (ambulatory, hospital, prescription medications, and "other" which includes devices, ED visits, personal assistance, and other services).

Results: Between 1996–1998 and 2009–2011 prevalence of musculoskeletal conditions rose by 35%, from 76.0 to 102.5 million while costs rose 117%, from $367.2 to $796.2 billion (Table 1). The increased costs resulted from larger populations aged 45–64 and ≥ 65, increased prevalence of MUSC in these age groups, higher unit prices for ambulatory care, hospital admissions, and prescriptions as well as increased numbers of prescriptions used (Table 2). Hospital admissions and ambulatory care utilization did not increase appreciably during this time.

Conclusion: The aging of the baby boom generation will lead to short term increases in the population at greatest risk for MUSC. Reducing costs of these conditions will require public health approaches to reduce the prevalence of MUSC through such mechanisms as weight control and exercise programs as well as change in the organization of health care to attenuate the increases in the unit prices of services, especially of prescription medications.

Table 1 Number and Percent of US Population with Musculoskeletal Conditions and Mean and Aggregate Health Care Costs in 1996–1998 and 2009–2011

			Health Care Costs (in 2011 dollars) for Musculoskeletal Conditions

Impact of Comorbidities on Health Resource Utilization in Patients with Spa. Mariano Andrés[1], Francisca Sivera[2], Sabina Pérez-Vicente[3], Loreto Carmona[4] and Paloma Vela[1]. [1]Hospital General Universitario de Alicante, Alicante, Spain, [2]Hospital General Universitario de Elda, Alicante, Spain, [3]Unidad de Investigación de la Sociedad Española de Reumatología, Madrid, Spain, [4]Instituto de Salud Musculoesquelética, Madrid, Spain.

Background/Purpose: Similar to other rheumatic disorders, patients with spondyloarthritis (SpA) show an increased prevalence of comorbidities compared to the general population [1]. Comorbidities influence management, prognosis and quality of life of SpA patients [2], but their impact on the utilization of health resources has been scantly explored so far.

Methods: The emAR II was a descriptive, multi-center, cross-sectional study, performed in Spain between 2009 and 2010. The records of patients with a SpA diagnosis plus at least a visit to the Rheumatology department within the previous two years were selected using an equiprobabilistic method. Health care utilization was collected during the previous 2-year period as: a) hospital admissions; b) visits to the rheumatology clinics; c) referrals to other medical specialists by the rheumatologist; and d) diagnostic procedures ordered due to SpA. The following comorbidities were registered: hypertension, diabetes, coronary heart disease, chronic heart failure, stroke, neoplasm, infections, peptic ulcer disease, chronic kidney disease, liver disease, and anticoagulation therapy. Additional descriptive and confounding variables were collected. Association between use of resources and comorbidities was assessed by lineal regression for continuous variables and logistic regression for binary variables, accounting for Poisson distribution.

Results: 1,168 patients' records from 45 centres were reviewed in detail (recruitment rate: 73%), mean (±SD) age 50.1 (±13.8) years. 68% males. Main SpA forms were ankylosing spondylitis and psoriatic arthritis. The use of resources was as follows: 248 admissions in 196 patients (19.2%, rate 12.1 per 100 patient-years), 5908 visits to rheumatology clinics (median (IQR) 4 visits per patient (3–6), rate 254 per 100 patient-years), 844 referrals to other specialists (rate 200 per 100 patient-years), and 85560 diagnostic procedures (rate 1753 per 100 patient-years). Analysis results are shown in Table 1. Hypertension, diabetes, coronary heart disease, chronic heart failure, infections, neoplasms, chronic kidney disease, and anticoagulation showed a positive, significant association with hospital admissions. The occurrence of infections was the only comorbidity significantly associated to visits, while no comorbidity showed a significant association to referrals. Infections and neoplasms were significantly associated to the diagnostic procedures.

Conclusion: Comorbidities in SpA influence health resources utilization, except for referrals to other specialties. This finding, added to the known impact in other areas of the disease, makes the identification of comorbidities advisable.

Evaluation of Real World Experience with Non-Biologic DMARD in the Treatment of RA: Data from an Electronic Health Record Database. D. Wiederkehr[1], J. Harnett[1], R. Gerber[2], D. Gruben[2], E.Y. Mahgoub[3], G. Wallenstein[1] and A. Koenig[3]. [1]Pfizer Inc, New York, NY, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Non-biologic (NB) disease-modifying antirheumatic drugs (DMARD) such as methotrexate (MTX) are commonly used to treat rheumatoid arthritis (RA). However, NB-DMARD can have adverse events or inadequate response that lead to premature discontinuation. Up to 50% of patients initiating MTX may discontinue at 2 years. [1–3] The objective of this exploratory analysis was to evaluate real world treatment patterns and impact on healthcare resource use (HCRU) among patients whose first DMARD regimen was select NB-DMARD as monotherapy or in combination with other NB-DMARD.

Methods: This retrospective cohort study evaluated patients aged ≥18 years at index with ≥3 physician visits ≥30 days apart for RA (ICD-9 code: 714.xx) who were newly prescribed/administered a select NB-DMARD (MTX, leflunomide, sulfasalazine, hydroxychloroquine) from 2007–2011 in a de-identified electronic health record (EHR) database (Humedica). The index date was the date of the first select NB-DMARD prescription/administration in the EHR (ie, no DMARD in ≥6 months pre-index), and patients were followed for ≥1 year. Patients were categorized by initial treatment with NB-DMARD monotherapy (NBmono) or ≥2 select NB-DMARD at index (NBcombo). Patient baseline characteristics, 1-year post-index treatment patterns and HCRU were evaluated in EHR. RA-related costs were evaluated for a subset of patients with clinical information linked to healthcare claims (Optum) of commercial and Medicare Advantage health plans.

Results: Of 10,338 RA patients receiving any DMARD therapy, 73% received NBmono and 6% NBcombo; patient characteristics are presented in the Table. NBcombo patients tended to have a lower DCCI score, fewer were treated by a rheumatologist, and tended to have more NSAIDS/steroids/opioids at index; <1% of patients had other NB-DMARDs within 30 days of index. During the 1-year follow-up, NBcombo patients were less likely than NBmono patients to continue their index NB-DMARD treatment regimen; treatment patterns are presented in the Table. NBcombo patients had fewer RA-related emergency room (mean difference -0.01) and office (−0.46) visits but more prescriptions (1.1), other outpatient visits (0.04), and inpatient admissions (0.01) in the post-index period. In 204 NB-DMARD patients with claims data, the mean monthly cost was $267 (49% attributed to prescriptions, 42% to office/outpatient visits); costs for NBcombo were 6% higher vs NBmono.

Conclusion: Among RA patients treated with DMARDs, 79% received NB-DMARD (92% initiated as monotherapy). Approximately one third of NB-DMARD pts did not continue with any DMARD therapy in the 1-year follow up. NBcombo pts were less likely to continue their index treatment regimen, and only 14% initiated a biologic DMARD.

Country of Residence and Its Wealth Determine Disease Activity Levels in RA: Results from Multi-National Study Across 17 Countries (COMORA). Polina Putrik[1], Sofia Ramiro[2], Andras Keszei[3], Ihsane Hmamouchi[4], Maxime Dougados[5], Till Uhlig[6], Tore K. Kvien[6] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [3]Uniklinik RWTH Aachen University, Aachen, Germany, [4]Mohamed V Souissi University, Rabat, Morocco, [5]Paris Descartes University, Paris, France, [6]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Socio-economic (SE) inequalities in health persist both between and within countries and even increased in the recent years. Therefore, it is important to explore whether country level factors may contribute to health inequities in patients with RA. The objectives of this study was to (1) investigate whether country level factors contribute to explain Disease Activity Score (DAS28) (2) explore whether uptake of biologic disease modifying anti-rheumatic drugs (bDMARDs) mediates the relationship between country welfare and DAS28.

Methods: Data from a cross-sectional multinational (17 countries) study (COMORA) was used. The outcome was DAS28. Contribution of country to DAS28 was explored in multivariable linear regression models, adjusting for potential confounders, using forward selection and accounting for multiple testing. The country with lowest DAS28 (Netherlands (NL)) was used as reference. Next, the country of residence was replaced by GDP (dichotomized in low and high GDP), to investigate the contribution of socio-economic welfare. Improvement in R^2(model fit) of the two models that included either country or GPD was compared. Finally, the mediating role of uptake of bDMARDs in the relationship between GDP and DAS28 was explored by testing indirect effects.

Results: A total of 3920 RA patients from 17 countries (range 30–411) were included in COMORA dataset. Mean age was 56 y.o. (SD13), 82% females. Mean DAS28 was 3.7 (range 2.6 (NL) – 5.2 (Morocco)), and 32% of patients were currently treated with bDMARDs (range 3%(Uruguay) – 74% (UK)). Country differences in DAS28 varied from 0.2 (France) to 2.3 (Morocco) compared to NL, after adjustment for individual factors (Figure 1A). In societies with low GDP disease activity was on average 0.98 units higher, compared to high GDP countries (Figure 1B). Additional contribution of country to $R^2$was 0.15 and of GDP 0.08. Seven percent of the differences in DAS28 between low and high GDP countries were mediated by (lower) uptake of bDMARDs (Figure 2).

Conclusion: Substantial differences in DAS28 between countries were observed after adjusting for individual factors. In countries with low GDP disease activity was higher than in countries with high GDP. Lower uptake of biologics mediated part of the relationship between (low) GDP and (high) disease activity. Inequities across countries should come at focus of international societies of rheumatology and policy-makers.

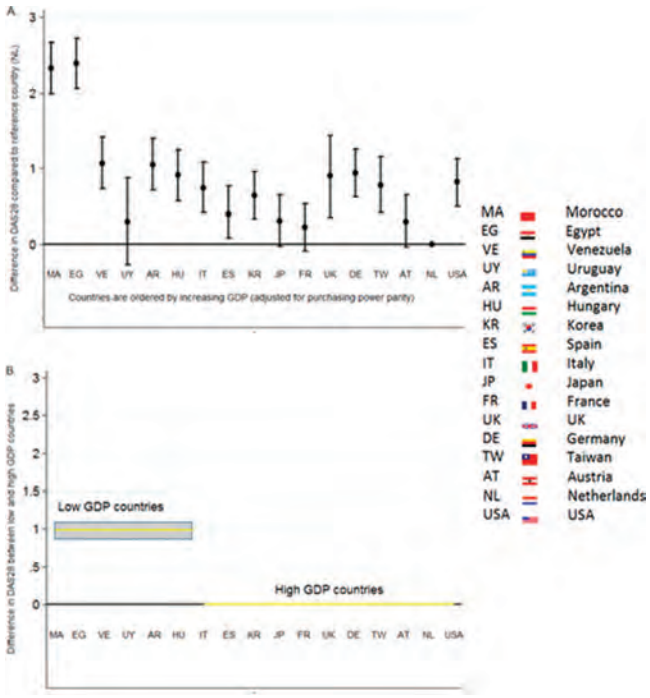

Figure 1. Differences in average DAS28 between individual countries (Figure 1A) and countries grouped by GDP (Figure 1B). Estimates are derived from models adjusted for age, gender, education, high rheumatoid factor or anti-citrullinated protein antibody, and comorbidities.

Real-World Utilization, Patient Characteristics and Persistency of Certolizumab Pegol Vs Other Anti-TNFs for the Treatment of Rheumatoid Arthritis in the United Kingdom. Frances Humby[1], Stephen Kelly[1], Angela V. Bedenbaugh[2], Nawab Qizilbash[3], Jochen Dunkel[4], Belén San-Jose[5], Ignacio Mendez[5], Jennifer Timoshanko[6] and Jeyanesh Tambiah[2]. [1]William Harvey Research Institute, Queen Mary University of London, London, United Kingdom, [2]UCB Pharma, Smyrna, GA, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]UCB Pharma, Monheim, Germany, [5]OXON Epidemiology, London, United Kingdom, [6]UCB Pharma, Slough, United Kingdom.

Background/Purpose: Several anti-TNFs are currently approved in Europe for RA treatment including certolizumab pegol (CZP), adalimumab (ADA), etanercept (ETN), golimumab and infliximab. UK NICE guidance recommends CZP as a first-line biologic therapy for patients (pts) with RA, in conjunction with a Pt Access Scheme that provides CZP free of charge for the first 12 weeks (wks). The objective was to assess real-world CZP, and other subcutaneous anti-TNFs (ADA or ETN), RA pt characteristics and treatment utilization in the UK.

Methods: A descriptive, retrospective, observational chart analysis was conducted in 4 UK rheumatology clinics. Medical data were collected over 52(−6/+9) wks for biologic-naïve pts initiating an anti-TNF (N=187); visit schedule was not prescribed therefore exact visit timing varied across pts. Data are reported for CZP pts and those receiving Other Anti-TNFs. Treatment persistency was assessed up to Wk52 using Kaplan-Meier estimates with pts censored at treatment discontinuation (ie. stop first anti-TNF treatment and switch to another/stop anti-TNFs) and excluding reinitiators (ie. pts with a gap in therapy returning to treatment within follow-up period).

Results: Baseline (BL) data were available for 110 CZP pts and 77 pts receiving Other Anti-TNFs (Figure 1A). At initiation, 14.5% (16/110) and 20.8% (16/77) pts received CZP and Other Anti-TNF monotherapy, respectively. Of those receiving combination therapy, 79.8% (75/94) CZP and 78.7% (48/61) Other Anti-TNF pts received concomitant MTX.

Due to the retrospective nature of data collection, not every pt had all data available; data were collected for 110, 108, 82 CZP pts and 77, 74, 50 Other Anti-TNF pts over 12, 24, 52 wks, respectively. Treatment persistency was 95.5%, 82.6%, 71.8% for CZP and 90.9%, 73.5%, and 65.0% for Other Anti-TNF pts at 12, 24, 52 wks, respectively (all lower bounds above 60% for corresponding CIs) (Figure 1B). Mean treatment persistency was 46.3 (95% CI: 43.2–49.4) and 43.1 (95% CI: 38.5–47.7) wks for CZP and Other Anti-TNF pts, respectively. Of pts initiating CZP, 2.7% switched therapy to another anti-TNF at any time during follow-up (n=3; 1 pt each 0–11, 12–24, 25–52 wks). Similarly, 6.5% of Other Anti-TNF pts switched to another anti-TNF (n=5; 4 pts before Wk12, 1 pt 12–24 wks). Compared to CZP pts, the risk of discontinuation in the Other Anti-TNF group was 37.4% greater (Hazard Ratio=1.374; 0.820–2.302). The majority of discontinuations occurred within the first 24 wks for both groups.

Conclusion: In this descriptive study, BL demographics/disease activity for pts treated with anti-TNFs in the UK were broadly similar between groups. Treatment persistency in this real-world observational study was also similar between CZP and Other Anti-TNFs in anti-TNF naïve pts. Interpretation of data is limited due to general caveats inherent to retrospective analyses.

Figure 1: Baseline patient demographics/disease characteristics (A) and persistency on treatment up to 52 weeks (B) for patients receiving CZP (n=110) and Other Anti-TNFs (n=77)

Rheumatology e-Consult Services: a Rheumatology Workforce Management Model. Thomas Schmidt[1], Charles Lappan[2] and Daniel Battafarano[3]. [1]SAUSHEC/ Brooke Army Medical Center, San Antonio, TX, [2]United States Army, San Antonio, TX, [3]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX.

Background/Purpose: The regional distribution of adult rheumatologist in the United States (U.S.) was recently analyzed by the American College of Rheumatology (ACR)[1]. Regional workforce shortages were recognized with suggested options to address this concern. Electronic digital consultation (e-Consult) is one proposed solution. An e-Consult service was implemented by the U.S. Army to assist providers in remote global areas.

Methods: A retrospective analysis of rheumatology e-Consults from May of 2006 to May of 2014 was performed. Military providers from all services submitted consultation requests via a secure email site with digital file attachments. Patient identifiable information was excluded. A total of 24 rheumatology staff and fellows provided e-Consult services, and a program manager monitored and aggregated data for rheumatology. Collaboration with other e-Consult services was available and facilitated through the program manager.

Results: A total of 193 rheumatology e-Consults were processed. The average response time was 5.3 hours with 98% answered within 24 hours. There were 122 requests (63%) from Iraq and Afghanistan. Diagnoses included: inflammatory arthritis (65; 22 polyarticular, 18 RA, 14 gout, 8 infectious, 3 monoarticular), seronegative spondyloarthropathy (27; 9 psoriatic arthritis, 6 reactive, 6 undifferentiated, 1 inflammatory bowel disease), arthralgias/myalgias (24), elevated CPK (8), lupus (7; 4 SLE, 2 discoid, 1 pernio), Raynaud's phenomenon (7), mechanical pain (7), positive ANA (6), sicca syndrome (4), DM (1) and 37 other. e-Consult collaboration was common and primarily with dermatology (29) and infectious disease (13).

Conclusion: Over an 8-year period an Army rheumatology e-consult service successfully assisted remote providers with diagnosis and management of rheumatic diseases. This global, collaborative model provided timely subspecialty care and input to providers that did not have immediate access to a rheumatologist. A similar digital and collaborative management model may facilitate rheumatology support for non-rheumatologists in underserved or remote areas.

Reasons for Leaving an Academic Career in Research Among Rheumatologists in the United States. Alexis Ogdie[1], Ami Shah[2], Una Makris[3], Alfred Kim[4], Sheila Angeles-Han[5], Amit Golding[6], J. Michelle Kahlenberg[7], Eyal Muscal[8], Flavia V. Castelino[9] and Amanda Nelson[10]. [1]University of Pennsylvania, Philadelphia, PA, [2]John Hopkins University, Baltimore, MD, [3]Dallas VA Medical Ctr, Dallas, TX, [4]Washington Univ School of Med, Saint Louis, MO, [5]Emory University School of Medicine, Atlanta, GA, [6]Baltimore VA and University of Maryland School of Medicine, Baltimore, MD, [7]University of Michigan, Ann Arbor, MI, [8]Texas Children's Hospital, Houston, TX, [9]Massachusetts General Hospital, Boston, MA, [10]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Reasons for leaving an academic career in research among rheumatologists

Background/Purpose: Retention of academic rheumatologists in research careers is increasingly challenging in the current funding environment. However, beyond funding, reasons for leaving a career in research remain unknown. The objective of this study was to examine factors for leaving a career in research among rheumatologists.

Methods: A web-based survey was conducted among the domestic ACR membership from Jan-Mar 2014. Inclusion criteria were current or previous fellowship in rheumatology, ACR membership, and an available email address. Non-rheumatologist members were excluded. The survey assessed demographics, research participation, barriers/facilitators to a career in research, and free text response for reasons for leaving a career in research. After excluding incomplete surveys and duplicates, demographics were summarized. Content analysis was used to extract relevant themes from free text comments.

Results: Ninety-seven respondents (among 430 complete responses) indicated that they had previously pursued a career in research but decided to switch career paths. This career change occurred a median of 10 years ago (interquartile range [IQR] 3–20) and a median of 7 years after completing fellowship (IQR 2–14). Previous research types and current positions are presented in the **Table**. Approximately half of respondents were female. The most commonly cited reasons for leaving a research career were difficulty obtaining funding and lack of department or division support (**Table**). Among 27 free text comments, respondents noted additional reasons for leaving research including new opportunities in administration, teaching and clinical care, great clinical burden and insufficient protected time to be successful in research endeavors, increasing age, difficulty financially supporting a family, difficulty covering loans with low salary, need for increased job security, lack

of mentorship, unsupportive environment or institution, need to move to a new geographic area without opportunities for research, and fear of having to move if not successful in obtaining funding or achieving tenure. When asked what would have kept these investigators in research, the most common responses included increased protected time and availability of internal grant funding mechanisms.

Conclusion: This is the largest known study examining reasons for leaving a career in academic research. While financial reasons were the most commonly cited reason for leaving a career in research, division support and protected time were similarly important. These results suggest that enhancing institutional support of academic research in rheumatology should be an important emphasis in order to support and sustain research careers.

Table: Participants who decided to leave a research career (N=97)

Female (N(%))		45 (46%)
Year of fellowship completion (median and IQR)		1993 (1983–2005)
Years Since Transition (median and IQR)		10 (3–20)
Years after fellowship when transition occurred (median and IQR)		7 (2–14)
Current Position	Adult Rheumatologist	78 (80%)
	Pediatric Rheumatologist	14 (14%)
	Adult Fellow	5 (5%)
	Pediatric Fellow	0 (0%)
Current Place of Employment	Academic Medical Center	52 (54%)
	Clinical Practice	24 (25%)
	Industry	17 (18%)
	Government	2 (2%)
	Retired	2 (2%)
Academic Appointment	Instructor or other Junior Faculty	6 (6%)
	Assistant Professor	14 (14%)
	Associate Professor	21 (22%)
	Professor	22 (23%)
	Other (or no academic appointment)	34 (35%)
Previous Type of Research	Clinical	47 (48%)
	Epidemiology/Health Services	8 (8%)
	Translational	36 (37%)
	Basic Science	49 (51%)
Factors Contributing to Decision to Leave	Difficulty obtaining grant funding	55 (57%)
	Lack of division/department support	51 (53%)
	Better compensation	38 (39%)
	Lack of mentorship	38 (39%)
	Tired of writing grants	33 (34%)
	Personal reasons*	26 (27%)
	Desire to spend more time in clinical care	20 (21%)
	Exciting opportunities in industry	10 (10%)
	Did not enjoy research work	6 (6%)
What would have retained you in a research career?	Provide internal grant funding mechanisms	54 (56%)
	Increase protected time	50 (52%)
	Increase income	31 (32%)
	Increase work flexibility	25 (26%)
	Provide greater leadership opportunities	25 (26%)
	Nothing would have incentivized me to stay in academics	9 (9%)

*Personal reasons included desire to move geographically (N=16) or desire to spend more time with family (N=15).

Resource Use and Health Related Quality of Life Burden of Gout Exacerbated By Common Comorbidities: Results from the 2012–2013 National Health and Wellness Survey. Robert Morlock[1], Natalia M. Flores[2], Kathy Annunziata[3], J. Chapnick[4] and Sulabha Ramachandran[5]. [1]Ardea Biosciences, San Diego, CA, [2]Kantar Health, Foster City, CA, [3]Kantar Health, Princeton, NJ, [4]Kantar Health, Horsham, PA, [5]AstraZeneca, Wilmington, DE.

Background/Purpose: Gout is caused by chronic high serum uric acid (SUA) levels (i.e., hyperuricemia), which leads to the deposition of monosodium urate crystals in musculoskeletal structures (e.g., joints), kidneys, and other connective tissues and urate crystal deposition disease, which can result in chronic inflammation leading to acute gout flares and tophi. Hyperuricemia is a metabolic disorder caused mainly by inefficient renal excretion of uric acid. Because SUA levels are often not at target, it is important to examine how this may relate to resource use and health utility. Additionally, this study examines other factors such as comorbidities and how they may exacerbate the relationship between high SUA levels, resource use, and health utility.

Methods: The data are from the combined 2012 and 2013 U.S. National Health and Wellness Survey (NHWS), a representative, cross-sectional general health survey (2012 NHWS: $N = 71{,}157$; 2013 NHWS: $N = 75{,}000$) of which 3,729 self-reported being diagnosed with gout. Those diagnosed were categorized into uncontrolled ($N = 2{,}215$) and controlled ($N = 344$) gout ("controlled gout" defined as: SUA ≤6 mg/dL and no flares in past year), omitting those whose control status was unknown ($N = 1{,}170$). Weights were calculated to be representative of the U.S. adult population and analyses were based on the weighted data. Resource use in the past six months, health related quality of life (SF-36v2: mental and physical component summary (MCS, PCS) and SF-6D (health utility), and work productivity loss (WPAI) were assessed across the two groups. Comorbidities (e.g., diabetes, hypertension) and their relationship to resource use and health utility were also examined.

Results: Those with uncontrolled gout reported being hospitalized (13.8% vs. 8.1%) and visiting the ER (22.3% vs. 11.7%) more than those with controlled gout. Additionally, those with uncontrolled gout reported lower MCS (Mean = 47.22 vs. Mean = 51.96), PCS (Mean = 41.95 vs. Mean = 46.32), and health utility (Mean = 0.66 vs. Mean = 0.73) scores than those with controlled gout. Furthermore, those with uncontrolled gout reported higher work productivity loss (24.5% vs 16.2%) and activity impairment (40.2% vs. 28.2%) than those with controlled gout. Having a common comorbidity with uncontrolled gout increased resource usage compared with either 1) those uncontrolled without the comorbidity or 2) with controlled gout, as was shown with diabetes (ER visits: 27.2% vs. 13.7% and 22.6%, respectively).

Conclusion: These findings support that uncontrolled gout results in greater hospitalization and twice as many ER visits than controlled gout. This, combined with lower health utility than controlled gout, suggests a significant humanistic and economic impact. These impacts may be further compounded when comorbidities are present.

Patient Reported Outcomes Following Upper Extremity Arthroplasties in RA -a Report from the Swedish National Register of Rheuma Surgery (RAKIR). Ann Bremander[1], Sofia Forsberg[2], Emelie Gull[2] and Anna Nilsdotter[2]. [1]Spenshult Research and Development Center, Halmstad, Sweden, [2]Halmstad Central Hospital, Halmstad, Sweden.

Background/Purpose: RAKIR, the Swedish National Register of Rheuma Surgery was created to follow joint surgery in patients with RA (rheumatoid arthritis). The aim of this study was to analyze PROMs (patient reported outcome measures) from RAKIR concerning HRQoL (health related quality of life), pain and function in RA patients admitted for arthroplasty in the upper extremity. A secondary aim was to study expectations and satisfaction related with these procedures.

Methods: 106 (87 women, age mean 63, SD 13 years) patients with RA admitted for arthroplasty in the upper extremity, followed in RAKIR, were included (2007–2011). All patients answered the questionnaires SF-36, HAQ and QDASH preoperatively, 6 months postoperatively and at a 2–6 year follow-up (2013). Questions concerning expectations and satisfaction were asked at the same time.

Results: RA patients operated on with arthroplasty in the upper extremity (shoulder n=36, elbow n=20, wrist n=21 and MCP n=29) showed a significant improvement in HRQoL, pain and function 6 months after surgery ($p \leq 0.05$, n=61). The improvement remained 2–6 years later (n=50). The patients' expectations concerning pain relief was fulfilled, the expectations concerning improvement in ADL and function was surprisingly low but in an even greater extent fulfilled.

Conclusion: Long term follow-up with PROMs showed that patients with RA, in need of arthroplasty in the upper extremity, are satisfied, experience pain relief as well as improved function and HRQoL as long as 2–6 years after surgery. However, the response rate in a register is dependent on the patients' benignity and may influence the results.

Use of Internet in Adolescents and Young Adults with JIA. Philomine A. van Pelt[1], Constance H.C. Drossaert[2], Radboud JEM Dolhain[3], A.a. Kruize[4], Jaap Huisman[5] and Nico Wulffraat[4]. [1]Erasmus MC, Rotterdam, Netherlands, [2]University of Twente, Enschede, Netherlands, [3]Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands, [4]University Medical Center Utrecht, Utrecht, Netherlands, [5]Wilhelmina's Children Hospital UMC Utrecht, Utrecht, Netherlands.

Background/Purpose: Internet-use is increasing since it is an efficient way to find information. Information obtained via Health Related Internet (HRI) sites, or online peer support groups might increase knowledge and self-management in adolescents and young adults with Juvenile Idiopathic Arthritis (JIA). This study evaluates the frequency of use and perceived relevance of HRI use and its association with demographic, disease-related and psycho-social variables.

Methods: In a cross-sectional study, all consecutive JIA patients from the outpatient clinic (age 10 – 27 years) who gave informed consent were asked to complete a self-reported questionnaire. Frequency of using HRI-sites (regarding information about JIA, medication-use and aspects of JIA related to social life) as well as having online contact with fellow patients were evaluated. Perceived relevance of HRI use and contact with fellow patients were also investigated. Demographic variables, disease activity, medication and emotional behavior and coping were assessed as possible predictors.

Results: 142 patients were included and 98% had access to internet. 71% had used internet to search general information on JIA, but specific topics such as medication, were less searched for (6–35%). Most favorite sites to look for information were www.reumafonds.nl (Dutch Arthritis Foundation; 20%); www.google.com (16%); www.jong-en-reuma.nl (UMCU hospital site for rheumatic diseases; 14%) and www.printo.it (Pediatric Rheumatology European Society information site; 3%). One in four adolescents had ever visited a forum or had online contact with peers. Most favorite discussion fora were www.reumaforum.nl (peer support for general rheumatic diseases; 14%); www.jeugdreuma.com (parents of children support forum; 5%) and www.Youth-R-Well.com (peer support information and forum for 16–30 year old patients; 5%). Whereas most had used the internet to find information about JIA, the perceived relevance of HRI-sites and of opportunities for online peer contact was rated low (medians respectively 2,0 and 1,0 on a scale 0–10).

Female gender was positively associated with HRI use ($P<0.01$), other demographic and disease related factors were not associated with HRI use. Coping styles "confrontation" and "reassuring thoughts" were associated with increased HRI use, but only in males. Internalizing and externalizing problem behavior were not significantly associated.

Conclusion: Frequency of Health Related Internet use in young people with JIA was less than expected and considered of low relevance. Besides female gender no demographic and disease related factors were associated. HRI in present form cannot replace regular information as an additional source to increase knowledge.

Patient Reported Outcomes Following Total Knee Arthroplasty in Rheumatoid Arthritis and Osteoarthritis. Anand Dusad[1], Sofia Pedro[2], Kevin Garvin[1], Curtis Hartman[1], James O'Dell[1], Ted R. Mikuls[1] and Kaleb Michaud[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center and National Data Bank, Omaha, NE.

Background/Purpose: Due to the progressive and debilitating nature of knee arthritis, total knee arthroplasty (TKA) is the ultimate outcome. TKA is an effective surgical intervention for relieving pain and restoring function in patients with end-stage knee arthritis. Even though the beneficial impact of TKA is well documented, its effect on patient reported indices of pain and health related quality of life (HRQoL), especially in the RA population, are scarce. We examined the effects of TKA on pain and HRQoL in RA and OA patients.

Methods: Rheumatologist-diagnosed RA (n=834) and OA (n=315) patients undergoing primary TKA during 1999–2012 were identified. Measures of pain, function and HRQoL were obtained in three consecutive 6-month intervals: pre-operative (baseline), peri-operative and post-operative (recovery). Descriptive statistics and one-way ANOVA were used to compare TKA outcomes by diagnosis. Effect sizes were calculated between baseline and recovery period for each measure and graphs were plotted to follow these over time (±3 years of TKA), for both RA and OA patients.

Results: Patients with RA and OA were similar in age (65 vs. 68 years, respectively) and elapsed time [baseline sampling to TKA and TKA to recovery] (4.4 vs. 4.5 and 10.4 vs. 10.3 months). Post TKA, significant improvements were observed for most domains of pain, function and HRQoL indices within both disease groups ($p<0.001$). The beneficial effects of TKA were more profound in OA patients, as compared to RA, for all measures of pain and HRQoL indices except for RADAI/total joint count [RA (−0.42) vs. OA (−0.30)] and EQ-5D [RA (0.07) vs. OA (0.06)]. By effect size, maximum significant ($p<0.001$) improvement was shown in index knee pain (RA -1.69 vs. OA -1.85). Beyond pain outcomes, EQ-5D and SF-36 PCS were the most responsive HRQoL measures in detecting post-TKA improvement in RA and OA ($p<0.001$ in both groups), respectively (Table 1). For all outcomes examined, improvements were greatest in the first post-operative year, showing gradual declines thereafter.

Conclusion: TKA is highly effective in reducing clinically relevant index knee pain to a greater extent than other subjective HRQoL indices in patients with RA, although this improvement is less marked than that observed in OA patients. Gains observed in pain, function, and HRQoL are most striking in the first 12 months following TKA, paralleling levels reported often years prior to joint replacement. From our results, TKA acts as a "time machine" by which a patient returns to a reduced pain and less disabled lifestyle, before the arthritic process catches up, which is strikingly faster in RA.

Table 1. Mean change (SD) and effect size between baseline and recovery period

	RA	Effect size	OA	Effect size
Index knee pain (0–3)#	**−1.47 (0.88)**	−1.69	**−1.47 (0.79)**	−1.85
VAS Pain (0–10)#	**−1.12 (2.67)**	−0.42	**−1.74 (2.60)**	−0.67
RADAI-Total joint count (0–16)@	**−0.40 (4.92)**	0.08	−0.31 (4.61)	−0.07
RADAI-Total joint score (0–48)@	**−1.41 (10.07)**	−0.14	**−1.88 (8.47)**	−0.22
HAQ@	**−0.09 (0.66)**	−0.14	**−0.15 (0.59)**	−0.25
HAQ II	**−0.18 (0.64)**	−0.29	**−0.19 (0.58)**	−0.32
SF-36 PCS (0–100)	**3.59 (9.80)**	0.37	**4.57 (9.89)**	0.46
EQ-5D (US) (0–1)	**0.07 (0.20)**	0.40	**0.06 (0.20)**	0.32

and @ represent indices with significantly ($p<0.05$) less and more severe scores, respectively, in RA (vs. OA) patients undergoing TKA at baseline. Bold numbers represent significant ($p<0.05$) values between baseline and recovery within the respective groups

Knee Arthroscopy in an International Training Centre: An Audit of Safety and Impact on Work Days. Carl Orr[1], Paul MacMullan[1], Phil Gallagher[2], Mairead Murray[1], Madeline O'Neill[1] and Douglas J. Veale[3]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: The utility of synovial biopsy has been confirmed as an important research tool in increasing our understanding of the pathogenesis of RA, evaluating new treatments and identifying potential therapeutic targets (1, 2). More rheumatology units are introducing arthroscopy as part of their research programs,(3). In 2004, we published data showing that complication rates are very low (4), however it is critically important to continue to monitor safety and audit our outcomes.

All procedures are performed under local anaesthesia in a state of the art, built-for-purpose facility.

We collected and analysed the experience reported by patients following arthroscopy in our unit, examining parameters such as overall tolerability, pain, time out of work post-arthroscopy and complications.

Methods: Consecutive patients returning to the arthroscopy programme since July 2013 completed a questionnaire including 16 questions, three visual analogue scales (VAS 0mm-100mm), as well as binary questions.

Results: 136 (47 male) respondents are included, age 20–82 years (mean 53.76, SD 13.86).

91.2% (124/136) of patients felt they had received adequate information before the procedure. 84.6% (115/136) reported that the procedure matched

their expectations. The main concern before the arthroscopy was potential pain during the procedure cited by 78.7% (107/136).

The mean VAS for pain during the procedure was 50mm (SD 34.6); in the first 48 hours after the procedure 31mm (SD 28.2); and 15mm (SD 24.1) in the month following the procedure. There was no correlation between diagnosis, age or sex to VAS.

64.0% (73/114) were out of work for less than 2 days, 29.8% (34/114), and 6.1% (7/114). The remainder of patients left this field blank. No significant complications were reported. 66.9% (91/136) felt improvement in their knee symptoms following arthroscopy.

Conclusion: Knee arthroscopy remains a safe and well tolerated research procedure. The procedure is well tolerated under local anaesthesia, and many patients experience an improvement in their knee symptoms. Patients are out of work for very short periods following arthroscopy and no significant complications were reported.

Use of Smartphones in Collecting Patient Reported Outcomes: Can Passively-Collected Behavior Determine Rheumatic Disease Activity? Early Results from a Nation-Wide Pilot Study. Kaleb Michaud[1], Sofia Pedro[1], Rebecca Schumacher[1], Karim Wahba[2] and Sai Moturu[2]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]ginger.io, San Francisco, CA.

Background/Purpose: Rheumatoid arthritis (RA) and other rheumatic diseases (RD) are associated with depression, fatigue, and disturbed sleep, symptoms that often impact behavior. Many smartphone apps allow patients with RDs to regularly report their disease activity for better self-management and clinical followup. Recent advances in reality mining technology combined with the growing use of smartphones have shown measurable changes in phone behavior due to health issues like depression, stress, and influenza. We sought to learn if there are associations of phone behavior with RD patient reported outcomes.

Methods: We invited 700 patients in the National Data Bank for Rheumatic Diseases to participate by installing a custom app on their smartphone and answering questions regularly: a daily pain VAS for 60 days and a weekly Patient Activity Scale-II (PAS-II) for 6 months. Passive data collected included mobility distance, number of unique calls and text messages, call durations, call counts, and number of missed calls. A principal component analysis (PCA) based on the correlation data was performed on the passive data. The scree plot and the Kaiser criterion were used to select the number of components. A hierarchical cluster analysis was also performed using Euclidean dissimilarity metric and the average linkage criterion, with Calinski/Haralasz rule for the optimal choice of number of clusters. In addition, GEE models examined the association of passive data with weekly PAS-II components. Possible confounders included age, sex, disease, education, income, employment, smoking, and marital status in addition to variables such as season, holiday weekend, and time of day. QIC criterion was used to select the best models.

Results: While 150 patients participated, we limited our analysis to the 55 with Android phones due to more extensive passive data. Three components were extracted, explaining a total variation of 81%. The first was an overall measure of the use of the phone (50% explained variance); the second was a contrast between the use of text messages vs. calls (20%); and a third was a function of mobility and radius. The cluster analysis found 2 groups with a larger cluster (N=42) mostly of RA patients, with a lower overall use of the phone, lower time on the phone, and lower radius, and a second cluster having a greater overall use of the phone, higher radius, and having mostly OA and Fibromyalgia. The use of texting compared to calls was always preferred in both groups. Multivariable models suggested that patients with worse disease activity tended to answer less calls and talk for less time, but compensated with more text messages. They also tended to have greater mobility but less overall travel radius. Holidays and the summer were comparatively better for their diseases. Worse-off patients also left the study sooner.

Conclusion: With our exploratory analysis, we were able to characterize phone behavior in 3 components and 2 profiles that well-distinguished RD diagnosis. Our longitudinal models showed significant association of phone behavior with pain and PAS-II scores over time. This pilot study holds promise for passive behavior to be used in patient self-management and clinical followup.

Low Rates of Bone Mineral Density Testing in Medicare Beneficiaries with Breast Cancer Starting Aromatase Inhibitor Therapy. Mamatha Siricilla, Ruili Luo, Linda Elting and Maria E. Suarez-Almazor. The University of Texas, MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Aromatase inhibitors (AI) are increasingly used as adjuvant hormonal therapy in postmenopausal women with estrogen receptor-positive breast cancer. It is well recognized that therapy with AI increases the risk of bone loss and fractures. Therefore, it has been recommended that women who are beginning AI therapy undergo bone mineral density (BMD) measurement at baseline and periodic intervals. The objective of our study was to determine the rates and predictors of dual-energy x-ray absorptiometry (DXA) scan use in breast cancer patients started on AI in the state of Texas who were Medicare beneficiaries.

Methods: In a retrospective cohort study, we identified all Medicare female beneficiaries diagnosed with breast cancer in the period 2005–2010 from the Texas Cancer Registry/Medicare claims-linked database available through the Comparative Effectiveness Research on Cancer in Texas (CERCIT) consortium. Claims for DXA were obtained from Medicare part B for a period from one year before to 6 months after AI initiation. We also evaluated the use of bone-conserving agents (BCA). We collected data for prescription drugs from Medicare part D claims. We used multivariate logistic regression models to determine the association of sociodemographic variables with DXA use after controlling for disease stage and type of AI.

Results: Our breast cancer study cohort included 3587 women. Of these, 1999 (55.7%) underwent DXA between 1 year before and 6 months after AI initiation. Women aged 75 and above were less likely to receive DXA (odds ratio [OR], 0.80 (0.70–0.91) and less likely to receive either DXA or BCA (OR, 0.80; 95% CI, 0.70–0.92) than were women aged 66–74 years. African American women were less likely to receive DXA (OR, 0.70; 95% CI, 0.53–0.92) and less likely to receive either DXA or BCA than were non-Hispanic white women (OR, 0.68; 95% CI, 0.52–0.90).

Women living in urban areas were less likely to undergo DXA than women living in big metropolitan areas (OR, 0.71; 95% CI, 0.53–0.97). Women with state buy-in enrollment plans were less likely to receive DXA (OR, 0.61; 95% CI, 0.51–0.73) and less likely to receive either DXA or BCA (OR, 0.62; 95% CI, 0.51–0.74) than were women with no such enrollment.Of 3587 patients, 681 (18.98%= 19%) received BCA and 2162 (60.3%) either received either BCA or DXA when starting AI.

Conclusion: Slightly more than 50% of Texas Medicare female beneficiaries with breast cancer beginning AI treatment received DXA. Rates of DXA varied with the patient's age, size of area of residence, and socioeconomic status. Differences between ethnic groups in the use of DXA/BCA were noted, with fewer African American women compared to white women receiving DXA or BCA.

Relationship Between Rheumatology Physician Supply and Travel Distances to Rheumatologists for Medicare Beneficiaries in the United States. Gabriela Schmajuk[1], Chris Tonner[2] and Jinoos Yazdany[2]. [1]UCSF / San Francisco VA, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Workforce shortages in rheumatology have been reported in the face of an aging population and increased number of people gaining insurance under the Affordable Care Act. Population-wide studies of rheumatology supply and the distances that patients travel to see a rheumatologist have not been performed. We used national Medicare data to examine the actual distances patients travel for rheumatology care and hypothesized that patients travelling farthest would reside in low-supply areas.

Methods: Data derive from nationwide Medicare fee-for-service medical claims for 2009 for a 5% random sample of beneficiaries. All patients ≥ age 18 with 12 months of continuous enrollment in Medicare Parts A and B who had at least 1 visit to a rheumatologist were included. We calculated distance between the center of the patient's 5-digit ZIP code and the center of the rheumatologist's office 5-digit ZIP code for the first rheumatologist seen during the calendar year. We averaged distances according to health referral regions (HRRs), regional health care markets for tertiary medical care, and compared average distance with the supply of rheumatologists per HRR (publically available data through the Dartmouth Atlas). Individuals from HRRs with fewer than 40 eligible beneficiaries were censored from this analysis to increase the precision of our estimates.

Results: We studied 44,043 Medicare patients who had at least one visit to a rheumatologist during 2009, representing 245 HRRs. Median distance traveled was 9.3 miles (IQR 4–22). 10% of patients travelled ≥50 miles to see a rheumatologist. Of those traveling long distances, 22% resided in an HRR with the lowest supply of rheumatologists (<0.85 per 100,000 residents) but over 25% resided in an HRR in the 2 highest quintiles of supply (> 1.30 per 100,000 residents). When distances were averaged according to HRR, 13 (4%) of HRRs had an average travel distance of ≥50 miles; only 4 of these HRRs had a supply of rheumatologists in the lowest quintile (Figure).

Conclusion: A substantial proportion of patients in the United States travel significant distances to visit a rheumatologist, although a minority of these patients resides in areas with the lowest supply of rheumatologists. These findings are contrary to our original hypothesis that rheumatologist supply is the main reason for long travel distances. Whether factors such as physician participation in health plans, tertiary care referral patterns, and patient preferences affect travel distance will require additional study.

Dermatologic Rheumatism: Our Experience with a Multidisciplinary Dermatology/Rheumatology Clinic. Archana Sharma[1], Lin A. Brown[2], Dorothea Barton[3] and John Mecchella[4]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [3]Dartmouth Hitchcock Medical Center, Lebanon, NH, [4]Giesel school of medicine and Dartmouth Hitchcock Medical Center, Lebanon, NH.

Background/Purpose: Multidisciplinary clinics are becoming increasingly common as a way to bring together multiple specialists to care for patients with complex diseases. While multidisciplinary clinics commonly involve pulmonologist and cardiologist for patients with pulmonary hypertension, rheumatology and dermatology combined clinic are thought to be less common. Managing skin lesions in patients with known or possible autoimmune diseases can be a diagnostic and therapeutic challenge which often requires the combined expertise of dermatology and rheumatology. Previous studies have shown the benefit of managing patients with psoriasis and psoriatic arthritis in a combined dermatology and rheumatology clinic but to our knowledge there have not been any studies reporting the experience of a general dermatology/rheumatology clinic. We feel that our multidisciplinary clinic adds significant value to complex patients and this study sought to evaluate the clinical experience of a dermatology/rheumatology clinic.

Methods: We performed a retrospective chart review of all patients presenting to our dermatology / rheumatology combined clinic between July 2008 to April 2014 at Dartmouth-Hitchcock Medical Center. A total of 126 patients were seen over 158 visits. We reviewed demographic data, initial diagnosis, treatment modalities including procedures like skin biopsy, change in initial diagnosis and treatment.

Results: Of the 126 patients evaluated, 73% were referred by rheumatology and 27% by dermatology. The majority of participants were females (75%) and the mean age of the patients was 52 years. The average wait period to be seen in the clinic after the referral was made was 3.8 weeks. A skin biopsy was done in 24% patients during the visit and 19% had a skin biopsy reviewed at the visit. The most common initial diagnosis were connective tissue disease related rash (9.5%), SLE (9%) and vasculitis (9%). This was followed by drug rash, psoriasis and psoriatic arthritis. Seventy-seven patients (61%) had a change in diagnosis and treatment as a result of this combination clinic visit. Of the 77 patients who had a treatment change, 18% received DMARD therapy and 8% received biologics. On follow-up, 28.5% patients had significant or complete improvement, 43.5% patients had partial improvement, 12% reported no improvement at all and 16% were lost to follow up.

Conclusion: This study shows that the majority of patients seen in our multidisciplinary clinic had a change in the diagnosis and/or treatment. We believe that this clinic brings value to patients by simplifying the care of these complex patients by having multiple specialists in the same room with the patients. This integrated care approach improves the quality of care for our patients with skin and musculoskeletal diseases. Moreover this combined clinic increases access for these patients and as patients may receive appropriate treatment sooner, it may reduce the overall health care costs for these patients.

Treat-to-Target (T2T) and Measuring Outcomes in RA Care: a 2014 Longitudinal Survey of US Rheumatologists. John J. Cush[1] and Jeffrey R. Curtis[2]. [1]Baylor Research Institute and Baylor University Medical Center, Dallas, TX, [2]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background/Purpose: Changes in US rheumatologic practice for rheumatoid arthritis (RA) patients in the past decade have been influenced by novel therapies, increasing disease metric use and practice economics. This survey of US rheumatologists (Rheums) examined how commonly disease activity measures are used in clinical practice and if they inform decision-making or alter clinical practices over time.

Methods: In 2014, 2027 US Rheums were invited (via 2 emails) to an online survey that included 26 questions on demographics, practice characteristics, RA care practices, DMARDs/biologic use and the use of disease activity metrics. This 2014 cross-sectional survey of Rheums was compared with 2005 and 2008 responses (Table) to assess changes over time. Rheums doing metrics (Metric Rheums) were compared to those who do not (Non-Metric Rheums) with regard to their treatments and practices.

Results: Recruitment for this survey is ongoing. Thus far there are 317 respondents (18% response), with responders being mostly male (71%) with a mean age of 52.8 yrs. 40% of Rheums were in practice >25 yrs; up from 18.2% in 2005. Respondents were largely from private practice (67%) or academics (24%). Compared to 2005, US Rheums do fewer annual x-rays (16 vs 48%), MRI (1.7 vs 8%), or ultrasound (3.9 vs 1.9%). Rheums reported they achieve high rates of ACR 20-like responses (72.6%) and remission (39%) in their patients. Disease activity measures increased since 2005, with the HAQ or its variants being most measured at each visit, followed by the RAPID3 and the CDAI (Table). Metrics were done by 45% of Rheums - owing to improved care (76%), decision making (67%) and ease of use (50%). More than half (55%) did not collect formal measures largely because of the time required (63%), not on their EMR (32%) or just not needed (32%). Metric and non-Metric Rheums were equally committed to research, joint exams and lab testing. Metric and non-Metric Rheums did not differ in the number of patients on TNF inhibitors (47.1 vs 47.4%), or in the management of 3 clinical vignettes differing only in the amount of metric data provided. All rheums were more likely to inject joints when less data was provided and more likely to change or add biologics when more metrics were available. For those failing their first TNFi, 66.7% would choose another TNFi (down from

74.5%), while with others switched to abatacept (19%), tocilizumab (7%), rituximab (2%) or tofacitinib (1%). While a minority (20%) of Rheums don't believe in the T2T "hype", 43% assert they have always practiced in a T2T manner and 37% have adopted a T2T strategy for RA care.

Conclusion: Routine use of RA disease activity measures has become a practice standard in less than half of US rheumatologists. Despite their collection, there is little evidence that metrics are changing how patients are managed.

Changes over time in practice, TNFi and clinical metric use*

	2005	2008	2014

Biologic Dmards Modify the Association Between Patient Expectations and Outcomes of Total Knee Replacement in Rheumatoid Arthritis Patients. Hassan Ghomrawi[1], Lisa Mandl[2], Mark P. Figgie[2], Michael Alexiades[2] and Susan M. Goodman[2]. [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: Unmet patient expectations of total knee replacement (TKR) correlate with postsurgical dissatisfaction, and are linked to outcomes. Patients with rheumatoid arthritis (RA), may have lower expectations than patients with osteoarthritis (OA), due to the systemic nature of the disease and its other manifestations such as fatigue. Biologic DMARDs enhance RA patient quality of life. The effect of pre-operative use of these medications on patient expectations and outcomes of TKR is not known. The purpose of this study was to assess the correlation of preoperative expectations with TKR outcomes in RA patients on biologics and those not on biologics, compared to matched OA patients undergoing TKR.

Methods: Validated RA patients were identified from an institutional TKR registry and their use of biologics was recorded from chart review. RA patients were matched to OA patients on age, sex, prior TKR, and preoperative activity level using the Lower Extremity Activity Scale (0–18, 18 highest level of activity). Preoperative patients completed the validated Hospital for Special Surgery (HSS) Knee Expectations Survey (19 items, score range 0–100, 100 is highest expectation). At 2 years, patients completed the WOMAC pain and function. Preoperatively, expectation scores between RA patients on biologic DMARDS, conventional therapy and matched OA patients were compared. We used regression to determine the association between expectation scores and 2-year WOMAC pain and function subscale scores, adjusted for baseline score.

Results: One hundred fourteen RA cases, 46.5% on biologics, were matched to 228 OA cases. The RA cases were 11.8% male and the average age was 62.6 +/−12.2 years. The average pre-operative LEAS score was 8.3 +/−2.9, which corresponds to being able to walk around the house and walk for several blocks at a time without any assistance. 16.7% of the patients had a prior contralateral TKA. The mean duration of RA was 19.7 +/− 13.4 years. RA patients on biologics had expectations similar to matched OA patients (total expectation score 76.3 ± 8.1 vs. 77.4 ± 17.4, p = 0.71), while RA patients not on biologics had expectations that were clinically and statistically significantly lower (69.9 ± 22.4 vs. 77.1 ± 19.0, p-value = 0.03). Higher expectations scores were associated with better 2-year WOMAC function and pain scores (2-year WOMAC pain coefficient=0.393, p-value<0.001, 2-year WOMAC function coefficient=0.441, p-value<0.001) in RA patients not on biologics therapy but not in RA patients on biologic DMARDS (2-year WOMAC pain coefficient=−0.126, p-value=0.426, 2-year WOMAC function coefficient=0.005, p-value=0.977) nor matched OA patients (2-year WOMAC pain coefficient=−0.037, p-value=0.614, 2-year WOMAC function coefficient=0.060, p-value=0.460).

Conclusion: Expectations of post-operative outcomes are only significantly related to post-operative pain and function in RA patients not on biologic DMARDS; there is no relation in RA patients on biologics or in OA patients. The reasons for this are unclear, and whether this is due to unrealistic expectations in OA and RA patients on DMARDS or that biologics reduces the need to manage expectations needs to be explored.

Is Socioeconomic Status at Diagnosis Associated with Long-Term Direct Medical Costs in Systemic Sclerosis? a General Population-Based Cohort Study. Natalie McCormick[1], Mohsen Sadatsafavi[2], Wenjia Chen[2], Carlo A. Marra[3] and J. Antonio Avina-Zubieta[4]. [1]University of British Columbia/Arthritis Research Centre of Canada, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Univ of British Columbia, Vancouver, BC, [4]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Low socioeconomic status (SES) is associated with negative health outcomes and higher healthcare costs in general populations, but the impact of SES on costs in systemic sclerosis (SSc) is unknown. To address this knowledge gap, we examined the relationship between SES at diagnosis, and direct medical costs for 5 years after diagnosis, in a general population-based context. We hypothesized that baseline SES would be associated with higher costs.

Methods: Data Source: Our administrative data captured *all* provincially funded outpatient encounters and hospitalizations (1990–2010), and *all* dispensed medications (1996–2010) regardless of funding source, in the province of British Columbia.

Sample: We assembled a general population-based cohort of all incident cases of SSc who received care from 1996–2010, based on the following validated algorithm: a) two ICD-9-CM codes for SSc at least 2 months apart but within a 2 year period by a non-rheumatologist physician; or b) one ICD code by a rheumatologist or hospitalization. Statistics Canada neighborhood income quintile data for the year of SSc diagnosis was used to define SES.

Cost Calculation: Costs for outpatient services and prescriptions were summed directly from billing data. Case-mix methodology was used for hospitalizations.

Statistical Analysis: Early mortality is common in SSc and likely associated with high costs before death, but failure to account for this censoring will underestimate the long-term costs of SSc. To address this, follow-up was divided into 90-day periods with costs per-period weighted by the person-specific inverse probability of being alive in each period. A generalized linear model was used to

1) Evaluate the relationship between SES and direct medical costs, after adjusting for sex, age and baseline Charlson's comorbidity index; and

2) Predict the cumulative 5-year costs (adjusted for censoring) for cases in each SES group.

Parametric bootstrapping was used to obtain 95% confidence intervals (CI). Costs are reported in 2010 Canadian dollars.

Results: We identified 1,116 incident SSc cases (83% female, mean age 56.2 years) contributing 3,392 person-years. 5-year costs totaled $36,559,914 with 24% from outpatient, 48% from hospital and 28% from medications.

Age (p=0.0278), Charlson's co-morbidity score (p < 0.0001) and being in the lowest (p=0.0364) or middle (p=0.0015) SES quintile (vs. the highest) were significantly associated with costs. Predicted cumulative 5-year costs for the lowest-SES cases were 42% greater than the highest-SES ($55,035 vs. $38,664). Highest-SES cases had the lowest medication costs (**see Table**). Cases in the middle SES quintile at diagnosis had the highest outpatient, hospital and overall costs.

Conclusion: The long-term healthcare costs of SSc cases are substantial (averaging $51,643 per-person over 5 years), and associated with SES, being 42% greater, on-average, for the lowest-SES than the highest.

Socioeconomic Quintile at Diagnosis	N Cases	N Female (%)	Mean Age at Diagnosis (SD)	Median Baseline Charlson Comorbidity Score (IQR)	N Months of Follow-Up	N 90-Day Costing Periods	N Ever-Hospitalized (%)	Unadjusted Overall Costs	Covariate-Adjusted Mean Per-Person Predicted Costs (95% CI) Outpatient	Hospital	Medication	Overall

Predictors of Gout Flares in a US Managed Care Setting. Robert Jackson[1], Aki Shiozawa[1], Erin Buysman[2], Aylin Altan[2], Stephanie Korrer[2] and Hyon K Choi[3]. [1]Takeda Pharmaceuticals International, Inc, Deerfield, IL, [2]Optum, Eden Prairie, MN, [3]Boston University School of Medicine, Boston, MA.

Background/Purpose: Gout is the most common inflammatory arthritis in the US, and acute gout flares are among the most painful events experienced by humans. The goal of this study was to assess gout flares in a managed care setting to better understand the patient characteristics that are associated with frequent flares.

Methods: This was a retrospective cohort study using administrative claims data from a large US health plan of commercially insured and Medicare Advantage enrollees. Patients had evidence of gout based on medical and pharmacy claims indicating gout between January 1, 2009 and April 30, 2012. The 12 months prior to the index gout claim was used to assess baseline confounders including demographics, comorbid conditions, baseline health care resource utilization, and baseline serum uric acid (sUA) levels. Gout flares were assessed in the 12 months following the index gout claim based on diagnoses for gout or joint pain followed within 7 days by claims for NSAIDs, colchicine, corticosteroids, or joint aspiration/drainage. A negative binomial model was used to assess the relationship between patient characteristics and the count of gout flares in the 12-month follow-up period.

Results: Our study included 102,703 patients with gout; 56,611 patients (55%) had evidence of at least one gout flare in 12 months of follow-up, and 13,502 (13%) had multiple flares. Patients had on average 0.73 flares per year, and the average time between flares in patients with multiple flares was 115 days. Characteristics associated with a higher count of flares included Black race, lower net worth, residing in the South census region, high levels of baseline ambulatory utilization, new initiation of urate lowering drugs (ULT) during follow-up, and higher baseline sUA (Table). Cardio-metabolic-renal comorbidities appeared to be associated with fewer flares; however, this may be due to our definition of flares in the claims based on medication use (e.g., NSAIDs) that is often contraindicated with these conditions. Age and gender were not significantly associated with flare frequency after controlling for other confounders.

Conclusion: This large contemporary study of gout patients in a managed care setting indicates over half of patients experiencing at least one flare in a 12-month period, and nearly a quarter of those patients experiencing multiple flares. Black race, lower economic status, Southern region of residence, initiation of urate lowering therapy, and higher baseline sUA were associated with a higher risk for flares. These data may help identify patients at high risk for flares who could be targeted with a gout management plan aimed at preventing flares.

Table. Adjusted Incidence Rate Ratios for Gout Flares According to Patient Characteristics

Difficult to Treat Gouty Arthritis Associated with Poor Health Related Quality of Life and High Resource Utilization: Post- Hoc Analysis. Louis Bessette[1], Frédéric Lioté[2], Carmen Moragues[3], Rüdiger Moericke[4], Zhang Zhiyi[5], Alberto Ferreira[6], Pascal Lecomte[6], Sophia Kessabi[6], Haijun Tian[7] and Jasvinder Singh[8]. [1]CHUL, Quebec, QC, [2]Hôpital Lariboisière & University Paris Diderot, Paris, France, [3]Hospital Platón, Barcelona, Italy, [4]Institut für Präventive Medizin & Klinische Forschung GbR, Magdeburg, Germany, [5]The First Affiliated Hospital of Haerbin Medical University, Haerbin, China, [6]Novartis Pharma AG, Basel, Switzerland, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [8]Mayo Clinic, Rochester, MN.

Background/Purpose: Difficult-to-treat (DTT) group in the MOTION study included symptomatic refractory gouty arthritis (RGA) patients with ≥3 flares, refractory to NSAIDs/colchicine/steroids or to uric acid lowering therapy (ULT) due to contraindication, intolerance, or lack of efficacy. There is lack of evidence on burden of illness in DTT patients. The study assessed burden of illness in DTT patients over 1 year.

Methods: A post hoc descriptive comparison was done between DTT vs the other refractory gout (ORG) patients using data from the MOTION (1 year, multinational, non-interventional, prospective, observational) study. Among DTT patients, outcomes for patients with tophi at baseline and patients who discontinued ULT prior to study entry were also summarized. The study outcomes (evaluated at baseline, by time point and pooled yearly) included health status using EuroQol Group 5-Dimension (EQ-5D) questionnaire, the Gouty arthritis Assessment Questionnaire–Gouty arthritis Impact Scale (GAQ-GIS), pain assessment, healthcare utilization over 1 year and lost work productivity. Patient and physician satisfaction with treatment were measured by the Patient Global Assessment of Response to Treatment and Investigator Global Assessment of Response to Treatment. Continuous and categorical variables were reported as (mean ± SD) and as proportions, respectively, for the DTT and ORG patient groups.

Results: Among 454 patients enrolled in the MOTION study, 64 DTT patients (tophaceous group=29, discontinued ULT=35) were included in the analysis (mean age 55.2, males 85.9%). DTT patients had lower mean EQ-5D utility score and EQ-5D VAS score compared to ORG group, with worse scores in the tophaceous group (Table 1). Tophaceous group patients experienced greater difficulty on all EQ-5D dimensions and pain/discomfort was the most affected dimension in all groups. DTT patients expressed greater overall gouty arthritis concern compared to ORG patients (76.5 vs 72.4%), with highest score in the tophaceous group (85.5%) for pooled data. Tophaceous group reported a higher score on all five dimensions of GAQ GIS. About 45.3% of DTT patients reported severe pain during last flare vs 37.2% ORG patients. Healthcare utilization was greater among DTT than ORG patients (35.9 vs 21.1%). A higher proportion in the tophaceous group visited emergency unit (55.2%), hospital (41.4%) and doctors (89.7%) over one year. Physicians and patients in DTT group were more likely to report poor response to treatment compared to ORG group. DTT group missed 23.4% of their working days compared to 15.6% in ORG patients at baseline, the highest being the tophaceous group (31%).

Conclusion: DTT patients had worse health status and reported higher resource utilization with significantly poorer outcomes reported in tophaceous gout patients, suggesting a high unmet medical need in such patients.

Table-1: Mean EQ-5D utility score and EQ-5D VAS pooled for all visits

	EQ-5D utility score (Mean ± SD)	ED-5D VAS (Mean ± SD)
DTT patients (N = 64)	0.78±0.23	73.37±20.40
DTT with tophi at baseline (N = 29)	0.65±0.24*	66.32±18.09*
DTT with discontinued ULT (N = 35)	0.78±0.24	74.02±18.38
Other refractory gout (ORG) (N = 390)	0.81±0.21	75.12±20.96

* $p<0.05$ *vs.* other refractory gout patients

Sonographic Evaluation of the Fifth Metatarsophalangeal Joint Erosion in Rheumatoid Arthritis. Nevsun Inanc[1], Gulsen Ozen[1], Sibel Z. Aydin[2], Esen Kasapoglu Gunal[3] and Haner Direskeneli[1]. [1]Marmara University School of Medicine, Istanbul, Turkey, [2]Koc University Faculty of Medicine, Istanbul, Turkey, [3]Goztepe Medeniyet University Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Joint erosions in RA correlate with structural damage progression and functional capacity. Therefore, detection and the follow-up of erosions are of paramount importance for RA diagnosis, monitoring and prognostication. The 5th MTP is usually the first and most commonly destructed joint in RA. Ultrasound (US) is a useful and as good tool as MRI to detect 5th MTP erosions especially in early RA patients. Although a few MRI studies revelaed that most of the MTP erosions were located at the plantar aspect of the joint, it is unknown whether plantar or dorsal or lateral plane US better detects 5th MTP erosions. In this study we aimed to determine the best ultrasonographic plane for detection of 5th MTP joint erosion in RA patients and to assess clinical characteristics of patients with 5thMTP erosions.

Methods: The 5thMTP of 92 feet of 48 RA patients were evaluated by B-mode and power- Doppler US for signs of erosion. US images were obtained from 3 different aspects, the dorsal, lateral and the plantar surface of the foot, in longitudinal and tranverse scans. The presence of erosion was determined according to OMERACT definition. Patients were also assessed clinically (tender/swollen joint count, DAS28, HAQ scores) along with disease characteristics. Each erosion in each aspect were recorded seperately.

Results: The study cohort consisted of 48 RA patients (F/M=35/13, mean age 50.7±12.3 years, mean DAS28 score 4.04±1.47, HAQ score 0.94±0.88) with mean disease duration of 8.2±7.3 years. RF and anti- CCP positivity were 66.7% and 60.4% respectively. The 5th MTP erosions were detected in 35 of 48 patients (72.9%) and 62 of 92 feet (67.4%). Of the erosions 15 (16.3%) were observed at dorsal plane whereas plantar and lateral planes revelaed majority of the erosions, 53 (57.6%) and 52 (56.5%), respectively. In 26 feet (28.3%), erosions were observed on both plantar and lateral planes, in 15 feet (16.3%) erosions were observed in all three planes. None of the patients had erosion just in dorsal plane examination of the 5th MTP. The presence of 5th MTP erosion in plantar aspect of foot was significantly higher than both lateral and dorsal aspect ($P<0.0001$, $P=0.002$, respectively). Patients with dorsal erosion had significantly higher disease duration (13.8 years vs 6.5 years, $P=0.005$). Patients with erosions in any aspects have similar disease characteristics including RF, anti-CCP positivity, disease duration, HAQ scores and current biologic requirement, when compared to patients without erosions.

Conclusion: The 5th MTP erosions in RA patients can be better detected with plantar plane US than dorsal and lateral aspect evaluations. These data also indicate that dorsal aspect US of foot may miss erosions in early disease and insufficient when performed solely.

Can We Use Ultrasound to Identify Rheumatoid Arthritis Patients in Remission Who Cannot Taper Their Medication? Myrthe van der Ven[1], T. Martijn Kuijper[1], A. H. Gerards[2], Ilja Tchetverikov[3], A.E.a.M. Weel[1], D. van Zeben[4], J.M.W. Hazes[1] and J.J. Luime[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Vlietland Hospital, Schiedam, Netherlands, [3]Albert Schweitzer Ziekenhuis, Dordrecht, Netherlands, [4]Sint Franciscus Gasthuis, Rotterdam, Netherlands.

Background/Purpose: Tapering medication in rheumatoid arthritis (RA) patients is becoming increasingly important due to the effectiveness of both biological therapy and tight-controlled treatment. Patients are able to reach the state of remission in which they may be able to taper their medication. Whom to taper and when to taper (amount of time in remission) is unclear. Ultrasound (US) data from cross-sectional studies suggest that the presence of subclinical synovitis might increase the risk of disease flare preventing patients to be tapered. Our objective was to detect subclinical synovitis by US and to relate this to the occurrence of flare in RA patients that continue synthetic and biological DMARDs for 3 months while being in remission.

Methods: Patients who are participating in the TARA (TApering strategies in Rheumatoid Arthritis) study and were examined by US were selected for this analysis. TARA is a single-blinded randomized controlled trial that includes RA patients (aged >17 years) who are treated with the combination of a synthetic DMARD and adalimumab or etanercept and are in remission (DAS44<2.4 & SJC ≤1). In the first 3 months of this study patients continue their medication and if they maintain their disease state, are randomized to (i) tapering the synthetic DMARD or (ii) tapering their TNF blocker. US examination included 26 joints (MCP2–5, PIP2–5, wrists, MTP2–5) graded on greyscale (GS; 0–3) and power Doppler (PD; 0–3). A joint with subclinical synovitis was defined as GS >1 and/or PD >0, while flare was captured by DAS44≥2.4 or SJC >1.

Results: For this analysis we included 67 patients. In total 39 patients (58%) had subclinical synovitis. Three patients (8%) with subclinical synovitis experienced a flare while continuing their combination of synthetic and biological treatment. Patients without subclinical synovitis did not differ from patients with subclinical synovitis if we compared clinical features such as tender joints, serology or acute phase reactants. ACPA was slightly higher in the patients without subclinical synovitis but did not reach statistical significance.

Conclusion: In 58% of the patients we detected subclinical synovitis. However, after three months a low flare rate (4%) was observed among patients in remission continuing their combination therapy of synthetic and biological DMARDs. Although the patients who flared had subclinical synovitis, using GS >1 and/or PD >0 in at least one joint might not be sufficient to discriminate who will clinically flare.

Table 1: Baseline characteristics of patients without and with subclinical synovitis (n=67)

	No subclinical synovitis (n=28)	Subclinical synovitis (n=39)
Women (%)	66	69
Age, years (mean, SD)	52 (12)	58 (12)
PD (%)	*NA*	73
Sum score GS>1 and/ or PD>0 (median, IQR)	*NA*	4 (2–8)
SJC (median, IQR)	0 (0–0)	0 (0–0)
TJC (median, IQR)	0 (0–1)	0 (0–1)
RF positive (%)	56	56
ACCP positive (%)	74	60
ESR (median, IQR)	7 (4–15)	9 (5–16)
DAS score (mean, SD)	1.0 (0.6)	1.2 (0.6)
Disease flare after 3 months (%)	0	8

SD = standard deviation; IQR = interquartile range; NA = not applicable.

121

Predictors of Persistence of Power Doppler Ultrasound Synovitis in Rheumatoid Arthritis Patients in Clinical Remission. Nathalie Filippi[1], Cédric Lukas[1], Jacques Morel[2], Bernard Combe[2] and Gael Mouterde[1]. [1]Hopital Lapeyronie, Montpellier, France, [2]Hôpital Lapeyronie, Montpellier, France.

Background/Purpose: Ultrasound (US) is a sensitive tool for the evaluation of joint inflammation in patients with RA, and can detect synovitis even when clinical remission is present [1]. Predictors of persistence of such subclinical power Doppler ultrasound (PDUS) synovitis, like potentially severity of the disease, concomitant treatments, or duration of the remission, remain undetermined. The aims of this study were: (1) to assess the proportion of patients with persistent PDUS synovitis in a cohort of patients with RA in clinical remission (DAS28-ESR<2.6 and without clinically active synovitis); (2) to determine predictors of persistence of PDUS synovitis in these patients.

Methods: RA patients fulfilling 2010 *ACR-EULAR* classification criteria, treated with DMARDS or biologic and in clinical remission (DAS28-ESR<2.6 and without clinically active synovitis, i.e. no joint showing both pain and swelling), were included in this transversal study. Following data were collected: clinical and biological characteristics of arthritis, socio economic factors, and radiographs of hands, wrist and feet. A standard US examination on 40 joints for the presence of synovial hypertrophy and power Doppler signal was performed by an independent investigator blinded to clinical data. A subclinical US synovitis was defined by the presence of a power Doppler signal≥2 in at least one joint. Logistic regression was performed to evaluate the association between subclinical US synovitis and baseline variables at the patient level. The reliability was evaluated with intraclass correlation coefficients (ICCs) based on independent assessments of 30 patients by two investigators.

Results: The 94 patients included had a mean (standard deviation) age of 61.2 years (11.2), mean disease duration of 9.6 years (8.1), a mean duration of remission of 11.9 months (15.4). 60% and 68% of the patients were rheumatoid factor and anti-CCP antibody positive respectively. The mean DAS28-C reactive protein was 1.71 (0.47), median 1.67, and 57.4% of the patients had erosive disease. 61.7% received methotrexate, 57.4% biologic treatment and 11.7% corticosteroids. Inter-observer reliability of assessment of synovial hypertrophy and PD signal were very good (ICC=0.954 and 0.985 respectively). Baseline clinical characteristics and US findings were similar whatever the duration of remission (<6 months, n=47 and ≥6 months, n=47). In multivariate analysis, presence of antiCCP (OR=3.68 [95% CI 1.21–11.1], p=0.021), DAS28-CRP >1.67 (OR=2.97 [95% CI 1.12–7.87], p=0.028) were predictors of persistence of PDUS synovitis, whereas current smoking was negatively associated (OR=0.07 [95% CI 0.01–0.59], p=0.015). The duration of the remission was not associated with PDUS synovitis after adjustment in this cohort.

Conclusion: Our results suggest that RA patients in clinical remission are more likely to have persistence of PDUS synovitis if they have anti-CCP antibodies and higher DAS28-CRP value. Current smoking appears to be a protective factor in this cohort, which might potentially be due to vasoconstriction induced by tobacco.

The Use of Ultrasound to Detect Residual Joint Inflammation in Patients with Rheumatoid Arthritis in Clinical Disease Remission.

Gurjit S. Kaeley[1], Midori Jane Nishio[2], Janak Goyal[3], Daryl MacCarter[4], Alvin Wells[5], Anabela Cardoso[6], Shufang Liu[7], Jasmina Kalabic[8] and Hartmut Kupper[8]. [1]University of Florida, Jacksonville, FL, [2]Diablo Clinical Research, Walnut Creek, CA, [3]Raritan Bay Medical Center, Perth Amboy, NJ, [4]Coeur d'Alene Arthritis Clinic, Coeur d'Alene, ID, [5]Rheumatology & Immunotherapy Center, Franklin, WI, [6]AbbVie, Amadora, Portugal, [7]AbbVie Inc., North Chicago, IL, [8]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

Background/Purpose: Patients (pts) with rheumatoid arthritis (RA), who achieve clinical disease remission by treatment with disease- modifying agents may have residual joint inflammation and vascularization, which can be detected by Power Doppler (PD) ultrasonography. The aim of this analysis was to evaluate the proportion of RA pts with PD activity, 24 weeks (wks) after the addition of adalimumab (ADA) to methotrexate (MTX).

Methods: MUSICA (NCT01185288), a 24 wk double-blind, randomized, controlled trial evaluated the efficacy of 2 different dosages of MTX (7.5 or 20 mg/wk) plus ADA (40 mg every other wk) in RA pts with inadequate response to MTX. For this analysis, the MTX dosage groups were combined. Synovial vascularization was assessed by PD US at 10 joints (bilateral dorsal and volar views of metacarpophalangeal joints 2, 3, 5; dorsal images alone of metatarsophalangeal joint 5 and wrists), at baseline (BL), wks 4, 8, 12, 16, 20 and 24. Images were scored by ultrasound-experienced rheumatologists using a semi-quantitative 4-grade scale.Joint swelling was assessed for the same 10 joints (SJC10). Disease activity was assessed by 28-joint count disease activity score using C-reactive protein (DAS28[CRP]) (remission < 2.6, LDA < 3.2, MDA 3.2- < 5.1, HDA ≥ 5.1), and simplified disease activity index (SDAI) (remission ≤3.3, LDA ≤11, MDA 11-≤26, HDA >26). Pearson's coefficient (ρ) was used to assess correlation between continuous variables.

Results: After 24 weeks of treatment with ADA +MTX, 44/309 pts (14%) were in DAS28 (CRP) remission (mean PD score, 3.3); 18/309 (5.8%) pts were in SDAI remission (mean PD score, 2.7). 23/44 pts (52%) in DAS28 remission, and 9/18 (50%) in SDAI remission had a PD score ≥ 2, indicating inflammatory activity. At wk 24, for the 10 joints selected, 30/44 (68%) pts in DAS28(CRP) remission had positive PD scores, while only 15 pts (34%) had ≥ 1 swollen joint, and only 5 pts (13.6%) had ≥ 1 tender joint. Ten out of 18 (55%) pts in SDAI remission had a positive PD score, while none had swollen/tender joints. A poor correlation (ρ<0.2) was observed between PD scores and clinical disease scores such as DAS28, SJC66, SJC28, TJC68, TJC28, CDAI, SDAI, PhGA, PGA-pain and disease duration. There was poor correlation (ρ=0.184) between the change from BL to wk 24 in PD scores, and the change from BL to wk 24 in DAS28(CRP) or SDAI. The corresponding shifts in disease activity, mean PD score and SJC10 scores are presented (Table).

Table 1. Mean changes in PD score, DAS28(CRP) score and SJC10 from BL to wk 24

DAS disease state shift (BL→wk 24)	N	Mean change in PD score	Mean change in DAS28(CRP) score	Mean change in SJC10
MDA→MDA	24	−0.5	−0.6	−1.1
MDA→LDA	29	−0.8	−2.2	−2.4
HDA→HDA	41	−1.0	−0.6	−1.3
HDA→MDA	94	−1.8	−2.0	−2.7
HDA→LDA	57	−2.3	−3.6	−4.3

Mean changes in PD score, SDAI score and SJC10 from BL to wk 24

SDAI Disease state shift (BL→wk 24)	N	Mean change in PD score	Mean change in SDAI score	Mean change in SJC10
MDA→MDA	9	−0.7	−7.1	0.2
MDA→LDA	15	−0.4	−15.0	−1.9
HDA→HDA	55	−1.1	−12.6	−1.1
HDA→MDA	85	−1.9	−26.4	−2.7
HDA→LDA	81	−1.9	−35.9	−4.1

PD, power Doppler; DAS28(CRP), disease activity state 28 using c-reactive protein; SJC10, swollen joint count (10 joints); SDAI, simplified disease activity index; LDA, low disease activity; MDA, moderate disease activity; HDA, high disease activity.

Conclusion: In agreement with other studies, residual joint inflammation was detected by PD US in pts in clinical remission; therefore ultrasound can offer additional information to that obtained from clinical disease measures.

Combination with Joint Power Doppler Signals with Anti-Citrullinated Peptide Antibody Predicts Joint Destruction in Rheumatoid Arthritis.

Yohei Kirino[1], Maasa Hama[1], Kaoru Minegishi-Takase[1], Yosuke Kunishita[1], Daiga Kishimoto[1], Ryusuke Yoshimi[1], Yukiko Asami[1], Atsushi Ihata[2], Shigeru Ohno[3], Atsuhisa Ueda[1], Mitsuhiro Takeno[4] and Ishigatsubo Yoshiaki[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama Minami Kyosai Hospital, Yokohama, Japan, [3]Yokohama City University Medical Center, Yokohama, Japan, [4]Yokohama City University Hospital, Yokohama, Japan.

Background/Purpose: Categorizing RA patients who require intensive treatments is highly warranted to optimize the therapy and to avoid overtreatments. We here evaluated the use of predicting joint destruction with joint power Doppler (PD) signal in musculoskeletal ultrasonography (MSUS).

Methods: We performed a retrospective study of 331 RA patients (female n = 280 and male n = 51, mean age 57.9 ± 13.2 y.o) who underwent MSUS from 2002 to 2012. Correlations of progression of joint destructions in 1,308

2nd and 3rd MCP joints with analysis of PD signals of the same joints, clinical findings, age, and disease duration at the study entry, gender, observation period, ACPA, and RF were analyzed in patient- and joint-based fashions, using univariate and multivariate logistic regression analyses and generalized linear mixed model.

Results: Patients' characteristics were as follows: mean disease duration 5.7 ± 7.5 years, observation period 4.6 ± 2.6 years, RF positivity 79.9%, ACPA positivity 76.4%. PD positive 2nd and 3rd joints showed higher rate of joint destruction, especially in ACPA positive patients. Moreover, PD positive joints in ACPA positive patients showed joint destruction even in joints without swelling. Multivariate analysis determined PD, SJ, observation period, and ACPA as independent risks for joint destruction.

Conclusion: PD, SJ, and ACPA are independent predictors for the joint destruction of 2nd and 3rd MCPs in RA. Progression of joint destruction was maximal in PD positive joints in ACPA positive patients, raising the possibility that RA patients are categorized by MSUS findings.

Ultrasound Power Doppler Findings in the Wrists and Hands Joints of Anti-CCP Antibody Positive Individuals with Non-Specific Musculoskeletal Symptoms and the Development of Inflammatory Arthritis. Jackie L. Nam, Laura Hunt, Elizabeth M.A. Hensor, Philip G. Conaghan, Richard J. Wakefield and Paul Emery. NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom.

Background/Purpose: The use of musculoskeletal ultrasound is increasing in rheumatology practice. Recently we have shown that use of power Doppler signal (PD) on ultrasound in the wrists and hands in patients who present with non-specific musculoskeletal symptoms and are anti-CCP antibody positive can aid the identification of those who will develop an inflammatory arthritis (IA). [1]The aim of this study was to investigate the ultrasound findings at a joint-level in these patients and the use of PD in identifying patients who progressed to inflammatory arthritis (IA).

Methods: In a prospective observational cohort study, patients with new non-specific MSK symptoms and positive anti-CCP underwent imaging with ultrasound at baseline and were followed up for the development of IA. Patients attended for regular follow-up assessments and if necessary were seen earlier if joint symptoms changed. PD findings of the wrists, MCPs and PIPs were scored using a semi-quantitative method from 0 to3 PD using a standard method. Using multilevel binary logistic regression we modelled the association between presence of PD score >0 at baseline and presence of IA in that joint at follow-up; joints (level 1) were nested within patients (level 2).

Results: Our first 100 consecutive patients (73 females, mean age 51 years) were followed up for median 19.8 months (range 0.1–69.0); 50 developed IA after a median 7.9 months (range 0.1–52.4), 34 within 12 months. The majority who progressed to IA in at least 1 joint (43/50) fulfilled the 2010 ACR/EULAR criteria for rheumatoid arthritis. A total of 2200 joints were scanned. The majority of patients (67%) did not have any PD signal present; maximum score in any joint was 1 in 17% and 2 in 16%. None had a joint scoring 3. Progression to clinical synovitis was rare in joints scoring 0 (5% progressed) compared to joints scoring 1 (16%) or 2 (59%). The presence of positive PD signal (any score >0) in a joint at baseline was associated with a 10-fold increase in odds of the joint developing clinical swelling [OR=10.6 (5.3, 21.1), p<0.001].

Conclusion: Our findings suggest that in patients presenting with non-specific MSK symptoms and are anti-CCP antibody positive, ultrasound features of inflammation at a patient- and at a joint-level can aid the identification of patients at risk of developing IA. Results of our larger cohort will be presented.

125

PD Signal Detected By Ultrasonography Relates to Joint Destruction in Rheumatoid Arthritis Under Biologics Therapy in Real World. Maasa Hama[1], Yumiko Sugiyama[1], Naomi Tsuchida[1], Yosuke Kunishita[1], Daiga Kishimoto[1], Reikou Kamiyama[1], Kaoru Minegishi-Takase[1], Ryusuke Yoshimi[1], Yohei Kirino[1], Mitsuhiro Takeno[2], Atsuhisa Ueda[1] and Yoshiaki Ishigatsubo[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama City University Hospital, Yokohama, Japan.

Background/Purpose: Biologic DMARD (biologics) therapy for rheumatoid arthritis (RA) strongly suppresses joint destruction regardless of its efficacy for disease activity. On the contrary power Doppler (PD) signal detected by ultrasonography (US) is said to be the most potent predictive factor for subsequent radiologic progression. This study aimed to clarify whether PD signal predicts joint destruction of RA patients under biologics therapy in daily practice.

Methods: RA patients who began and continued to receive biologics for more than six months were included. Clinical, laboratory, and US examinations were conducted sequentially from baseline (1st) to the last observation (last). Bilateral wrists and all of the MCP and PIP joints were examined by PDUS and the PD signals were graded from 0 to 3 in each joint. The total PD score was defined as the sum of scores of individual joint, and mean score of several assessments during observational period was also calculated. Structural damage of hands at baseline and at the last was measured by using modified Sharp scoring method for hand X-ray (TSS). Patients having the change in TSS (delta TSS) exceeded 0.5 U per year were defined as showing radiologic progression.

Results: Objectives were 100 RA patients (female 85%, age 59.1±13.4 y.o., disease duration 8.0±8.2 years, 1st DAS28 4.84±1.43). Sixty-three patients continued the same drug (anti-TNF 31, tocilizumab 26, abatacept 6) whereas 37 patients switched biologics. During continuing biologics therapy for 25.3±16.8 months, structural damage progressed in 51% of the patients, who were classified into progressive group, including 18 patients with achieving clinical remission. The progressive group contained more patients who switched agents, and showed higher 1st DAS28 and higher last DAS28 as well as higher last total PD score, compared to the other group. Furthermore, yearly radiologic progression (delta TSS) weakly related to 1st, last, and mean total PD score in addition to 1st DAS28, 1st CRP, and 1st and last MMP-3. Multiple regression analysis using stepwise method revealed that both 1st CRP and mean total PD score were independently associated with joint destruction. For joint-based analysis of total 2200 joints, radiologic progression were seen in 155 joints (7.0%), of which wrists were mainly affected joints, and the existence of PD signal in a joint at any time during observational period was the potent risk for subsequent destruction of the joint (Table).

Conclusion: To practice 'Treat to Target' for achieving radiologic remission in real world, monitoring individual joint by PDUS will be helpful in carrying out optimal intervention even under biologics treatment.

n=2200	Progression	Non-progression	OR (95% CI)	P value
1st PD (+) joint, n (%)	74 (48.1%)	223 (10.9%)	7.81 (5.52, 11.1)	<0.0001
last PD (+) joint, n (%)	36 (24.8%)	83 (4.5%)	6.97 (4.51, 10.8)	<0.0001
mean PD (+) joint, n (%)	91 (59.1%)	282 (13.8%)	9.04 (6.40, 12.8)	<0.0001

126

Asymptomatic Versus Symptomatic Ankle Joints in Rheumatoid Arthritis: A High Resolution B-Mode and Power Doppler Ultrasound Study. Mohammed Alsuwaidi[1], Boris P. Ehrenstein[1], Wolfgang Hartung[1] and Martin Fleck[2]. [1]Asklepios Clinic Bad Abbach, Bad Abbach, Germany, [2]University Medical Center of Regensburg, Regensburg, Germany.

Background/Purpose: Despite a crucial role for RA patients' mobility, the ankle joints are frequently clinically neglected, and omitted in activity scoring systems including DAS 28. In addition, only few studies have assessed pathologies detected by ultrasonography of the ankle in symptomatic RA patients (1). Therefore, the type and degree of involvement of the ankle joints were evaluated in established RA patients regardless of symptomatology utilizing standardized high resolution musculoskeletal ultrasound (MSUS) including power Doppler ultrasonography (PDUS).

Methods: A total number of 160 ankle joints of 80 consecutive RA patients fulfilling the ACR/EULAR classification criteria 2010 were examined using MSUS (*Logic E9, GE Healthcare, Buckinghamshire, GB with a ML6–15 linear probe with 6– 15 MHz*) and PDUS according to the EULAR MSUS guidelines (2). In addition, the talonavicular joint, and the flexor and extensor tendons were investigated. Furthermore, ankle pain (VAS score 0–10) was recorded for each patient on joint level. Only VAS = 0 was determined as asymptomatic.

Results: 80 RA patients (52 female, 28 male) with a median age of 60 years (range 28 –81) and a disease duration of 5 years (range 0 – 44) were enrolled in our study. The median DAS28 was 5,0 (range 0,8 -7,8). 97 ankles were painfull (VAS 1–10), whereas 63 ankles were asymptomatic (VAS = 0). Overall, the predominant pathology was arthritis of the tibiotalar and/or talonavicular joint in 124 ankles (77%), followed by tenosynovitis of the flexor tendons in 44 ankles (28%). In symptomatic ankles 59% showed arthritis of the tibiotalar joint (TTJ) and 35% synovitis in the talonavicular joint (TNJ). In 35% of the asymptomatic ankles TTJ synovitis could be detected and 18% TNJ arthritis. PDUS activity was higher in the subgroup of symptomatic ankles (10% of symptomatic ankles (10/97) compared to 2% of asymptomatic patients (3/63). For detailed information see table 1.

Conclusion: Most frequent pathologies detected by MSUS were arthritis of the tibiotalar and talonavicular joint, followed by tenosynovitis of the flexor tendons. Pathologic findings are significantly more frequent in symptomatic ankles but also common in completely asymptomatic ankles of RA patients, whereas overall PDUS activity is low and if present predominately observed in symptomatic patients.

Table 1:

Pathologies	Arthritis tibiotalar (%)	Arthritis talonavicular	Tenosynovitis (M. tibialis posterior +/or M. flexor digitorum)	PDUS positive Arthritis
All ankles (n = 160)	79 (66%)	45 (28%)	44 (27%)	12 (7,5%)
Symptomatic ankles (n=97)	57 (59%)	34 (35%)	32 (33%)	10 (10%)
Asymptomatic ankles (n=63)	22 (35%)	11 (18%)	12 (19%)	2 (3%)
Chi^2	p = 0.003	p = 0.016	n.s.	n.s.

Metacarpophalangeal Cartilage Loss in Rheumatoid Arthritis. a Simple and Fast Ultrasonographic Assessment Comparing Patients and Healthy Controls. Tomas Cazenave[1], Christian A. Waimann[1], Marwin Gutierrez[2], Emilio Filippucci[3], Gustavo Citera[1] and Marcos G. Rosemffet[1]. [1]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Università Politecnica delle Marche, Jesi, Italy, [3]University of Ancona, Jesi, Italy.

Background/Purpose: There is evidence supporting the use of ultrasonography (US) as a valid and reliable imaging tool to evaluate cartilage in patients with arthritis. The aims of our study were to measure cartilage thickness in rheumatoid arthritis (RA) patients compared with Healthy Subjects (HS) and evaluate the relationship between US findings and clinical variables.

Methods: We designed a cross-sectional study including patients with diagnosis of RA (ACR/EULAR 2010) and HS. Data collected included clinical and demographic characteristics, Body Mass Index (BMI), 28-joint disease activity score (DAS28) and labor characteristics. US evaluation was performed by two rheumatologist with experience on US who were blind to clinical data. The hyaline cartilage of the metacarpal heads for fingers 2–5 was bilaterally scanned from the dorsal aspect with metacarpophalangeal joints in a full flexed position. Two perpendicular measurements at the central cartilage area (transverse and longitudinal views) were obtained and average cartilage thickness recorded. The association between RA characteristics and cartilage thickness was assessed using univariate and multivariate models, adjusted for sex, age, BMI and labor characteristics. Differences between HS and RA patients were compared using t-test. A two-sided P value of 0.05 was considered statistically significant.

Results: We included 98 subjects: RA=45 and HS=53. Mean age was 49 ± 13 years, mean BMI was 25± 4 and 70% were female. Patients with RA were significantly older and had lower BMI than HS. Patients with RA had a mean disease duration of 8 ± 7 years, 60% had erosive disease and mean DAS28 of 4.8 ± 1.4. A total of 784 joints were evaluated (RA=360 and HS=424). Time to perform US examination was 6 minutes per patient. Correlation between transverse and longitudinal view was 0.97 ($p<0.01$). Interobserver correlation was very good (ICC >0,92). Patients with RA had significantly lower cartilage thickness than HS (mean: 0.43 mm versus 0.58 mm, $p<0.01$). After adjusting for sex, age, BMI and type of job, RA was independently associated with cartilage thinning (β -0.51, $p<0.01$).

In patients with RA, those who were older, had longer disease duration, women and erosive disease, had significantly lower values of cartilage thickness. On multivariate regression analysis, only longer disease duration remained significantly associated with lower values of cartilage thickness.

Conclusion: Patients with RA showed significantly lower values of cartilage thickness as compared to healthy controls, having disease duration the highest impact on this fact. The impact of cartilage thinning on pain and functional capacity deserves further investigation.

A Rapid 4- Joint Ultrasonographic Score to Daily Monitoring Disease Activity in Patients with Rheumatoid Arthritis: Validity and Sensitivity to Change. Tomas Cazenave[1], Christian A. Waimann[2], Gustavo Citera[3] and Marcos G. Rosemffet[3]. [1]IREP, Buenos Aires, Argentina, [2]Hospital Olavarria, Olavarria, Argentina, [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: Ultrasound has demonstrated to be a sensitivity and specific tool to assess patients with Rheumatoid Arthritis (RA). However, the feasibility of this technology in daily clinical practice is still under debate. The purpose of our study was to evaluate the validity and sensitivity to change of a rapid 4-joint ultrasonographic score that could be applied to daily monitoring disease activity in patients with RA.

Methods: We included patients with RA (ACR/EULAR 2010). Data was collected at baseline, 3 and 12 months. Each patient underwent clinical (DAS28) and ultrasonographic (US) evaluation of 28-joints. Power Doppler (PD) and gray scale (GS) were graded from 0 to 3, according to OMERACT standards. Three ultrasonographic scores were calculated: 4-joints (bilateral radio and intracarpal joint and second metacarpophalangeal), 6-joints (4-joints plus bilateral fifth metatarsophalangeal), and 28- joints. US scores come as the result of the addition of PD and GS score, with a total score ranged from 0 – 36, 0 – 48, 0 – 174, respectively. We evaluated psychometric properties of

4-joints score in comparison with others US scores, including criterion, construct validity and internal consistency (Cronbach's α coefficients). Sensitivity to change was measured at 12 months using standardized response mean (SRM) and classified according Cohen's effect size. The minimal important change (MIC) was defined as a change of 1.96 times the standard error of measurement.

Results: 49 patients were included. All patients completed annual visits. Mean age was 53 ± 10 years, 85% were female, and disease duration was 8 ± 5 years. Baseline DAS28 score was 4.8 ± 1.5. Mean 4-joints ultrasonographic score was 12 ± 6 (Doppler subscale 5 ± 3; Synovitis subscale 6 ± 3). The score showed an acceptable confiability and a moderate to good correlation with DAS28, 6 and 28 joints US scores (Table 1). The 4-joint US examination was able to measures change in clinical status (SRM=0.98, large effect size). A change in score ≥5 was defined as a minimal important change. The ultrasonographic evaluation of 4-joint US score was fast, taking 5 minutes per patient, in comparison with 8 and 35 minutes for 6 and 28 joints scores, respectively.

Table 1.

							Correlation matrix (r)		
US score	Baseline mean±SD	Floor effect	Celling effect	Cronbach's α coefficients	MIC	SRM	US 6-joints score	US 28-joints score	DAS28
4-joints	12 ± 6	0%	0%	0.84	4.9	0.98	0.96*	0.80*	0.60*
6-joints	14 ± 7	0%	0%	0.84	5.5	0.94	—	0.83*	0.65*
28-joints	34 ± 20	0%	0%	0.94	5.0	0.72	—	—	0.77*

* P-value <0.05

Conclusion: A reduced US score of 4 joints showed to be a valid tool to detect and monitor disease activity in patients with RA. The quickness and high ability to detect clinical changes make this score a feasible and useful tool in daily rheumatology practice.

Disclosure: T. Cazenave, None; **C. A. Waimann**, None; **G. Citera**, None; **M. G. Rosemffet**, None.

Seven Joints Ultrasound Scoring System May be Useful and Effective in Assessing Disease Activity in Patients with Rheumatoid Arthritis in the State of Remission in Daily Clinical Practice. Petra Hanova[1], Jakub Zavada[1], Jana Hurnakova[1], Martin Klein[1], Olga Sleglova[1], Marta Olejarova[1], Martin Komarc[2], Ladislav ŠEnolt[1] and Karel Pavelka[3]. [1]Institute of Rheumatology, Charles University, 1st Medical Faculty, Prague, Czech Republic, [2]Institute of Biophysics and Informatics, Prague, Czech Republic, [3]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Background/Purpose: To evaluate if the 7-joint ultrasound scoring system (US7) is able to find synovitis in patients in remission of RA.

Methods: Patients with rheumatoid arthritis (RA) in the state of remission according to DAS 28 < 2,6 criteria with duration at least 3 months were identified. HAQ, SJC, TJC were evaluated for 1 year in 3 months interval. The US7 was assessed by every visit. US7 scoring system was well described and uses semiquantitative assessment of grey scale (GS) and power-doppler (PD) synovitis and incorporates erosion count together with evaluation of soft tissue parts (tenosynovitis) on the dominant hand and foot. Participating sonographers were blinded to clinical assesments and used the same US machine with not changed settings during the study follow up and reached reasonable interobserver and intraobserver reliability in using US7 scoring system. Spearmann coefficient was used to calculate statistical correlations.

Results: 73 patients were registered, 212 patient visits were made and 1484 joints were investigated. 13 patients (17,3%) in clinical remission according to DAS28<2,6 had no synovitis in US7 (GS0, PD0), only tenosynovitis was present in 3 patients (4,1%). 62 patients (82,7%) had subclinical synovitis in US7 at the baseline (GS/PD >0). In 34 patients (46%) PD ≥2 was found. Relapse rate during one-year observation (DAS28 >2,6) was 17% both in 3rd and 6th months, 9% in 9th month and 18% in 12thmonth. Total score of GS and PD synovitis on US7 significantly correlated with DAS28 and SDAI in months 3,6 and 12 (all p<0,01). This statistical significance was not reached at baseline and in month 9 with relapse rates of 0 and 9% respectively, thus only subclinical synovitis was more frequently seen while DAS28<2,6. There was observed a strong correlation between presence of synovitis and tenosynovitis (TS) on US7 (p<0,01) but no correlation of TS itself and other disease activity was found (DAS28, SDAI, HAQ, CRP). Number of erosions increased during one-year observation.

Conclusion: It was possible to find a high percentage of subclinical synovitis in patients in remission of RA according to previous studies published using other scoring systems. PD signals were in majority of investigations absent or very low (0 or 1), what is in good correlation with data published. There was no statistical difference in disease activity found in US7 score between patients with DMARDs and biological therapy in our sample. US7 may be a simple and effective tool to evaluate the disease activity of RA not only in active disease but also in the state of remission in daily clinical practice. Other studies are needed to confirm these findings with US7.

Supported by the project (Ministry of Health, Czech Republic) for conceptual development of research organization 023728 (Institute of Rheumatology) and by project No. NT12437.

Inter-Rater Reliability of the US-7 Score in a Population of Volunteers: Is a Post-Hoc Analysis of Still Images Comparable to the Dynamic Analysis? Results from the German "Rheuma-Truck" Cohort. Dr. Philipp Sewerin[1], Dr. Stefan Vordenbäumen[1], Sarah Ohrndorf[2], Marina Backhaus[2], Dr. Oliver Sander[1], Prof. Dr. Matthias Schneider[3], Prof. Dr. Benedikt Ostendorf[1] and Aiko Liedmann[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Charite University Hospital, Berlin, Germany, [3]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: To investigate the value of a follow-up analysis of ultrasonographic still images versus dynamic investigation using the US-7 ultrasound score.

Methods: "Rheuma-Truck" was a mobile rheumatology office located in different city center of North Rhine Westphalia, Germany offering a screening for rheumatic diseases including Rheuma-Check questionnaire, lab-tests (MCV capillary test), imaging (US, capillaroscopy), and if positive a consultation with a rheumatologist to everybody free of charge. Ultrasound (MyLab 25 Gold, Esaote linear scanner, 15, Typ LA435) of the dominant hand of 605 volunteers was performed. Moreover in 236 of these volunteers the foot was obtained by ultrasound. Thus a total of 3497 joints were examined by ultrasound. Live images were analyzed according to the US-7 scoring system dynamically on site by a trained rater. Still images were stored in a standardized manner in section planes according to US7. These images were assessed by 3 additional experts blinded to the dynamic scoring. The agreement upon all four raters is assessed in two measures a(0) and a(1). These are the percentages of study subjects who are rated equally (a(0)) or equally up to +/− 1 score point (a(1)) by all four raters.

Results: The mean age of the investigated cohort was 52.72 years (min. 10, max. 89 years). Sex distribution shows 72.2% females and 27.8% males. 181 (29.9%) volunteers displayed any inflammatory sign according to US-7 scoring. Using a(0) (all raters rated all subject equal) dorsal wrist showed an accordance between all 4 raters of 62%, the palmar wrist of 98%, the ulnar wrist of 87%, MCP-2 of 77%, MCP-3 85%, PIP-2 70%, PIP-3 81%, MTP -2 72% and MTP-5 96%. Using a(1) (up to +/−1) we obtained accordance's of the dorsal wrist of 87%, palmar wrist 100%, ulnar wrist 94%, MCP-2 94%, MCP-3 94%, PIP-2 91%, PIP-3 91%, MTP-2 89% and MTP-5 98%.

The accordance between still images and dynamic assessment according to a(1) was 100% for the palmar wrist, 100% for the ulnar wrist, 100% for MCP-2, 100% for MCP-3, 97% for PIP-2, 100% for PIP-3, 100% for MTP -2, and 100% for MTP-5 using the US-7 scoring system.

Conclusion: Inter-rater reliability (between all 4 raters) was good with an average of 93.1%. The accordance between still images and dynamic interpretation by using the US-7 scoring system was excellent with 99.6% consensus. Post-hoc evaluation of still images is a valid and reliable tool for the evaluation and interpretation of the US-7 scoring system as shown here in a population of volunteers.

Detection of Synovitis and Erosions with an Automated Ultrasound System: Data from a Prospective Cohort with Early and Established RA.
Matthias Witt[1], Janette Frielinghausen[2], Jan Leipe[2], Hendrik Schulze-Koops[2], Ruediger Mueller[3] and Mathias Grunke[2]. [1]University of Munich, Munich, Germany, [2]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany, [3]Kantonspital St. Gallen, St. Gallen, Switzerland.

Background/Purpose: Arthrosonography has proven to be a sensitive and reliable, but time-consuming method for the evaluation of arthritis in small joints of patients with RA (1, 2). The automated breast volume scanner (ABVS) was developed to acquire series of consecutive B-mode pictures of the female breast. In a pilot study, we have recently described the possible application of this system to finger joints of RA patients (3). This study was performed to confirm the value of ABVS in detecting swelling and erosions of the finger, wrist and foot joints in patients with RA in comparison to conventional manual ultrasound (mUS).

Methods: Patients with RA were assessed by clinical and sonographic examination of the MCP, PIP, wrist and MTP joints. In addition, data for DAS-28, SDAI, CDAI and HAQ was gathered. ABVS was conducted using the ACUSON S2000 (Siemens, Germany), mUS was performed on MyLab 70 (Esaote, Italy). The ABVS transducer was equipped with a linear array of 11 MHz and each automatic sweep of the scanner generated 15.4 × 16.8 cm × 2.5 cm volume data sets. The system was set to perform an automatic scanning time of 65 seconds per scan with a slice thickness of 0.5 mm. mUS was performed with a 8–18 MHz linear transducer.

Results: We included 44 patients with established (n=30) and early (n=14) RA with a mean DAS28 of 4.4 ± 1.8 and a mean swollen joint count of 8 ± 6.3. In total, 1548 small joints were assessed. ABVS revealed synovitis in 20,7 % of the examined joints, compared to 18.4 % with mUS. Erosions were seen in 196 joints with ABVS and in 168 joints with mUS. Correlation of US findings with clinical activity parameters were weak for both methods except for the swollen joint count with 0.41 for ABVS and 0.73 for mUS and physicians' global assessment with 0.43 and 0.57 for ABVS and mUS, respectively. Defining mUS as gold standard, the sensitivity of ABVS for the detection of joint swelling was 0.64 with a specificity of 0.88. Concerning erosions, sensitivity and specificity were 0.64 and 0.88. The negative predictive value was 0.91 for joint swelling and 0.92 for erosions. The interrater and intrarater agreements were 0.83 and 0.85 for ABVS and 0.84 and 0.88 for mUS, respectively.

Conclusion: ABVS is a simple and time-sparing method for the detection of joint swelling and erosions. Compared to manual ultrasound as gold standard, ABVS has an acceptable sensitivity and a very good negative predictive value which makes it a promising screening method for small joint synovitis in RA.

Do Ultrasound (PDUS) and DAS28 Measure Different Aspects of Disease Activity? Analyses from the First Prospective International Phase IIIb Study of PDUS Response in Abatacept-Treated Patients with Rheumatoid Arthritis (RA).
Maria-Antonietta d'Agostino[1], M Boers[2], R Wakefield[3], H Berner Hammer[4], O Vittecoq[5], M Galeazzi[6], P Balint[7], I Möller[8], A Iagnocco[9], E Naredo[10], M Ostergaard[11], C Gaillez[12], E Barre[13], M Le Bars[14] and On behalf of the OMERACT-EULAR-Ultrasound Task Force. [1]AP-HP Ambroise Paré Hospital, Boulogne-Billancourt, France, [2]VU University Medical Center, Amsterdam, Netherlands, [3]University of Leeds, Leeds, United Kingdom, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]University Hospital, Rouen, France, [6]University of Siena, Siena, Italy, [7]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [8]Instituto Poal, Barcelona, Spain, [9]Sapienza Università di Roma, Roma, Italy, [10]Hospital Universitario Severo Ochoa, Madrid, Spain, [11]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [12]Formerly of Bristol-Myers Squibb, Rueil-Malmaison, France, [13]Bristol-Myers Squibb, Braine-L'Alleud, Belgium, [14]Bristol-Myers Squibb, Rueil-Malmaison, France.

Background/Purpose: A composite (power Doppler/grayscale ultrasound [PDUS]) synovitis score, developed by the OMERACT-EULAR-Ultrasound Task Force, was shown to be responsive in RA patients with inadequate response to MTX who were treated with abatacept (ABA); a rapid parallel change in PDUS and DAS28 was demonstrated. [1] Data from clinical studies that have utilized PDUS indicate that it could be useful in monitoring RA treatment effects;[2] however, discordant correlations have been found between ultrasound scores and clinical outcomes measured at the same time point. [3–7] In this secondary analysis of the APPRAISE study, we explored correlations between changes in PDUS and clinical scores.

Methods: Individual joint PDUS scores were combined in the Global OMERACT-EULAR Synovitis Score (GLOESS) of metacarpophalangeal joints 2–5 (primary objective), reduced joint set (9 paired) and all examined joints (22 paired). Correlation between changes in GLOESS and clinical scores were assessed through: effect size, expressed as standardized response means of GLOESS and mean changes in DAS28 from baseline to Weeks 1, 12 and 24; Pearson's correlation coefficient, for assessing correlation between early and late changes in DAS28, and early and late changes in all GLOESS scores; and Spearman's correlation coefficient, for assessing correlation between early changes in GLOESS and lower levels of synovitis at Week 24. Furthermore, the relationship between GLOESS and clinical response was explored by analyzing the correlation between changes from baseline in the number of tender and swollen joints and matched joint GLOESS.

Results: No significant correlations were found between: changes from baseline in DAS28 and GLOESS, or component scores (synovial hypertrophy, PD, joint effusion) at any time point; or between early (baseline to Weeks 1, 2 or 4) changes in GLOESS, or components, and changes in the sum of swollen joints from baseline to Weeks 12 or 24. Within the assessment method, i.e. between clinical scores, or between GLOESS at different time points, moderate-to-high correlations were found between early (to Week 12) and late (Week 24) improvements in DAS28, and similarly between changes in GLOESS (any joint set): Pearson's coefficient range 0.37–0.71. Only changes in GLOESS at Week 12 were able to differentiate between early versus late clinical responders: Pearson's coefficient (95% CI): 22 joint: 0.71 (0.57, 0.80); 9 joint: 0.62 (0.46, 0.74).

Conclusion: PDUS is a responsive measure of joint activity in patients starting abatacept, but the extent of PDUS response does not correlate with extent of clinical response. Early PDUS changes could differentiate early versus late clinical responders, suggesting that PDUS adds independent information on response to treatment which needs to be explored further.

On-Demand Ultrasonography Assessment in the Most Affected Joint Is Efficient for Management of RA Patients in Daily Practice.
Ryusuke Yoshimi[1], Takeno Mitsuhiro[2], Yukihiro Toyota[1], Naomi Tsuchida[1], Yumiko Sugiyama[1], Yosuke Kunishita[1], Daiga Kishimoto[1], Reikou Kamiyama[1], Kaoru Minegishi-Takase[1], Maasa Hama[1], Yohei Kirino[1], Atsuhisa Ueda[1] and Yoshiaki Ishigatsubo[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama City University Hospital, Yokohama, Japan.

Background/Purpose: Musculoskeletal ultrasonography (US) is recognized as a useful tool for the diagnosis and monitoring of rheumatoid arthritis (RA). Although several sets of power Doppler (PD) US assessment procedures in arbitrary combinations of selected joints have been proposed, they do not always cover all of the affected joints. Here we investigated whether US

assessment in a selected joint on demand from patients is useful for monitoring RA in daily practice.

Methods: PDUS was performed in 8 joints, including bilateral MCP 2, MCP 3, wrist and knee joints, as a routine examination in a cumulative total of 207 patients with RA. At the examination, patients declared the most symptomatically affected joint. In patients who had the most affected joint except the routine 8 joints, the joint was additionally scanned. PD signals were scored semiquantitatively from 0 to 3 in each joint, and total PD score-8 was calculated by summing up PD scores of the routine 8 joints. Patients with positive PD signals in any joints were regarded as having active synovitis. The sensitivity and specificity of assessment in the most affected joint for detection of active synovitis in any of the routine 8 joints were evaluated.

Results: The patients were divided into three groups based on the most affected joints. Group A consisted of 110 patients having the most affected joint among the routine 8 joints, whereas 69 patients having the most affected joint other than the routine 8 joints were included in Group B. The remaining 28 patients were asymptomatic and categorized into Group C. Total PD score-8 was significantly higher in the symptomatic groups (Group A and B) than the asymptomatic group (Group C) (3.41 ± 3.19 vs 1.25 ± 1.80, $P = 5.9 \times 10^{-4}$). In the symptomatic groups, PD scores of the most affected joints showed high correlation with total PD score-8 (Figure 1; $r = 0.52$, $P = 5.8 \times 10^{-14}$). For detection of active synovitis of any of the routine 8 joints, the sensitivity and specificity of assessment in the most affected joint were 66.2% and 94.6%, respectively, in the symptomatic groups (Group A and B), 82.6% and 100%, respectively, in Group A, and 36.0% and 89.5%, respectively, in Group B. In two patients (2.9%) who were classified into Group B, PD signals were detected in the most affected joints (left ankle and right elbow), despite the negative results in the routine 8 joint assessments. These data suggested that US finding in the most affected joint represents those of routine 8 joint examination in Group A, whereas it gives supplemental information to the routine 8 joint examination in Group B.

Conclusion: This study suggests that on-demand US assessment in the most affected joint is efficient for management of RA patients in daily practice.

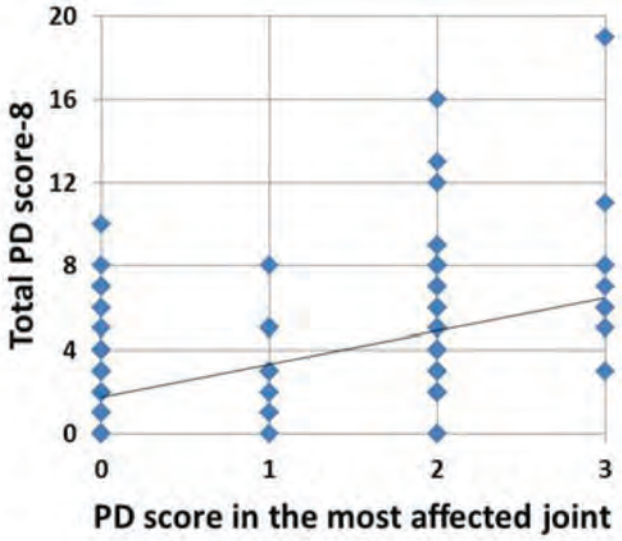

Figure 1 The PD score in the most affected joint correlates well with Total PD score-8.

Histopathological Correlation of Ultrasound-Defined Active Synovitis in Patients with Rheumatoid Arthritis in Clinical Remission. Preliminary Results.

Julio Ramirez[1], Virginia Ruiz-Esquide[1], Raquel Celis[2], Alicia Usategui[3], Regina Faré[4], Andrea Cuervo[1], Sonia Cabrera-Villalba[5], Maria Victoria Hernández[6], Jose Inciarte-Mundo[1], Jose L. Pablos[4], Raimon Sanmarti[7] and Juan D. Cañete[5]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Arthritis Unit, Rheumatology Dpt, Hospital Clinic of Barcelona and IDIBAPS, Barcelona, Spain, [3]Instituto de Investigación Hospital 12 de Octubre (i+12), Madrid, Spain, [4]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [5]Hospital Clinic, Barcelona, Spain, [6]Hospital Clínic of Barcelona. IDIBAPS. University of Barcelona, Barcelona, Spain, [7]Clinic Hospital, Barcelona, Spain.

Background/Purpose: We recently demonstrated that 45.4% of patients with RA in clinical remission have ultrasound (US)-defined active synovitis (synovial hypertrophy (HS) grade 2 or higher and Power Doppler [PD] signal) (Ramírez J et al, arthritis Research and Therapy 2014). Here we analysed the histological correlate of US-defined active synovitis in a subset of patients in whom synovial biopsy was performed.

Methods: By protocol, we obtained at baseline 6–8 ultrasound-guided synovial biopsies of all patients with (PD) signal who had signed the informed consent. Immunohistochemical staining was performed by the the peroxidase technique for the following antibodies: CD3 (T lymphocytes), CD20 (B lymphocytes), CD31 (vessels), CD68 (macrophages), CD117 (mast cells), Hsp47 (Fibroblast-like synoviocytes)(Izquierdo E et al, Arthritis Rheum 2011) and basic FGF. Quantifications were perfomed by Digital Image Analysis (Olympus). Serum bFGF was analyzed by Quantibody® Human Array (RayBiotech). US scans of both knees and hands (wrists, metacarpophalangeal [MCP], proximal interphalangeal [PIP]) were performed by an experienced rheumatologist using a high sensitivity equipment (Acuson Antares®, Siemens AG, Erlangen, Germany) with a 8–12 MHz linear probe. We quantified the presence of synovial hypertrophy (grades 0–3) and (PD) signal (grades 0–3) in all patients.

Results: We have included 24 patients with synovial biopsy. Regarding US assessment, 100% of patients had PD signal (by protocol), 79.2 % had Synovial HS grade 2 or higher, while 70.8% met criteria for US-defined active synovitis (HS > 2 + [PD] signal) at least in one joint.

The number of B cells (CD20+)/mm2 (p=0.017) and immunostained fractional area of Hsp47+ fibroblasts (p=0.035) in synovial tissue were significantly higher in patients with *US-defined active synovitis*. Furthermore, these patients had a non-significant greater number of CD31+ vessels per area (p=0.061).

The expression of bFGF in the synovial tissue showed a strong trend to correlation with its concentration in serum (p = 0.064). We also analyzed the expression of bFGF in synovial tissue in two control populations (19 patients with active RA and 8 healthy controls). bFGF expression was higher in patients with active rheumatoid arthritis (DAS28 >3.2) than in patients in remission. Furthermore, bFGF expression was lower in healthy controls than in patients in remission. Thereby, these preliminary results point to bFGF expression is parallel to disease activity.

Moreover, a significant correlation of *global US score* of each patient with the number of T cells (CD3+)/mm^2 (p=0.010) and B cells (CD20+)/mm2 (p=0.001), and a strong trend to significance in mast cells CD117+ (p=0.064) were found.

Conclusion: These preliminary results support that US-defined active synovitis has a histopathological substrate which is associated with fibroblasts and B cells. Also, the grade of infiltration of the synovium by T and B lymphocytes is associated with the US global score of the patient. Finally, correlation between synovial tissue expression and serum levels of bFGF, a mainly fibroblast-derived factor, point.

Comparison of the Ultrasonography Images and Synovial Pathology of the Joints in Patients with Rheumatoid Arthritis Treated with Biological Agents.

Asami Abe, Hajime Ishikawa and Akira Murasawa. Niigata Rheumatic Center, Shibata, Japan.

Background/Purpose: An early diagnosis and tight disease control have increased in importance in the era of biological therapy for rheumatoid arthritis (RA). Ultrasonography (US) of the various joints permits an evaluation of synovitis and bone erosion in real time. It has proven to be useful to detect synovitis in the early stage of the disease.The objectives of this study were to investigate whether the ultrasonography (US) images of a surgically-treated joint reflect synovial pathology or clinical indicators, and to compare the results in patients using non-biological agents (NB) and biological agents (Bio) for disease control.

Methods: Rheumatoid arthritis (RA)-related orthopedic surgery was performed in 301 joints, including five shoulders, 43 knees, 36 elbows, 90 wrists, 75 fingers, nine ankles and 43 toes between January 2011 and September 2013. US was performed preoperatively, and the grade of the Power Doppler (PD) signal was weighted. The Rooney score of the synovial pathology, the DAS28-ESR (4), and the MMP-3 and CRP levels were investigated. The Bio treatments were IFX in 13, ETN in 22, TCZ in 18, ADA in seven, ABT in one, GLM in four and CZP in three.

Results: The PDS, DAS28, MMP-3 and Rooney score in the patients using Bio were significantly lower than those in the patients using NB. The MMP-3 values for the patients using ETN were higher than those for the patients using IFX, and the DAS28 was higher for patients using ETN than for patients using TCZ. The DAS28 and fibrosis (as a Rooney score item) in the patients using TCZ were significantly lower than those in patients using TNF-α inhibitors. The PDS, CRP, MMP-3 and Rooney score in the patients using IFX were significantly lower than those in the patients using NB. The PDS, DAS28 and Rooney score in the patients using TCZ were significantly lower than those in the patients using NB. However, there were no significant differences in any items between patients using NB and patients using ETN or ADA.

Conclusion: The activity of RA synovitis at the surgically-treated site was suppressed in patients using Bio. There were some differences in the clinical data, pathological scores, PDS and DAS28 among the patients receiving different types of Bio.

Serum Calprotectin (S100A8/9) Is an Independent Predictor of Ultrasound Synovitis in Patients with Rheumatoid Arthritis. Jana Hurnakova[1], Jakub Zavada[1], Petra Hanova[2], Hana Hulejova[1], Martin Klein[1], Herman F. Mann[1], Olga Sleglova[1], Martina Olejarova[1], Sarka Forejtova[3], Olga Ruzickova[1], Martin Komarc[4], Karel Pavelka[1] and Ladislav Senolt[3]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic, [2]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic, [3]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [4]Institute of biophysics and informatics, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic.

Background/Purpose: Serological biomarkers specifically reflecting pathological processes may have added value in assessing joint inflammation in rheumatoid arthritis (RA). Calprotectin (S100A8/9 protein) has been demonstrated as an important marker of clinical and laboratory disease activity and structural joint damage in RA[1]. Matrix metalloproteinase-3 (MMP-3) is directly involved in progressive joint damage; however, its role as a marker of disease activity in RA remains unclear[2]. Musculoskeletal ultrasound has superior sensitivity over clinical examination in evaluating synovial inflammation in RA. The aim of this study was to evaluate the associations between serum calprotectin, MMP-3, clinical and ultrasound parameters of RA disease activity in a cross-sectional study.

Methods: A total of 37 patients with RA (24 females, median disease duration 18 months), underwent clinical examination (DAS28) and 7-joint ultrasound score (US-7) of clinically dominant wrist, second and third metacarpophalangeal and proximal interphalangeal, and second and fifth metatarsophalangeal joints to assess synovitis and tenosynovitis by gray-scale (GS) and power Doppler (PD) ultrasound using semiquantitative grading (0–3). Blood samples were taken at the same day as ultrasound examination was performed and levels of serum calprotectin, MMP-3 and C-reactive protein (CRP) were subsequently measured. Clinical and laboratory measures were correlated with ultrasound findings using Spearman's correlation coefficient. A multiple regression analysis adjusted for age and sex was used to determine the predictive value of calprotectin, MMP-3 and CRP for PD synovitis.

Results: Calprotectin significantly correlated with DAS28 ($r=0.385$, $p<0.05$) and in particular with CRP levels ($r=0.629$, $p<0.001$) and swollen joint count ($r=0.465$, $p<0.005$). In addition, calprotectin was significantly associated with GS ($r=0.359$, $p<0.05$) and PD synovitis ($r=0.497$, $p<0.005$). On the other side, no such association was found for MMP-3. Using adjusted multiple regression analysis, calprotectin was the only independent predictor of active PD synovitis ($p<0.05$).

Conclusion: This study show a significant association between calprotectin and clinical, laboratory as well as ultrasound assessment of RA disease activity. Circulating calprotectin, but not MMP-3, may represent an important biomarker for monitoring synovial inflammation in RA.

Evaluation of Metalloproteinase-3 As a Soluble Biomarker of Synovitis Using Weighted Joint Counts Assessed Clinically and on Ultrasound Imaging. Agata Burska[1], Elizabeth Hensor[2], Jackie L. Nam[2], Lukasz Kozera[3], Richard J. Wakefield[2], Paul Emery[2] and Ann W Morgan[4]. [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]Faculty of Pharmacy and Laboratory Diagnostics, Wroclaw Medical University, Wroclaw, Poland, Wroclaw, Poland, [4]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Synovial inflammation is known to play a central role in articular cartilage degradation in rheumatoid arthritis (RA); it could be a passive marker of disease, or the driving force in the onset of early joint damage. In this study we aimed to determine if circulating metalloproteinase-3 (MMP-3) and hyaluronic acid (HA) would outperform CRP as surrogate biomarkers for synovitis detection.

Methods: Patients fulfilled 1987 ACR RA classification criteria, had 3–12mth symptom duration, active disease (DAS44 >2.4) and were DMARD naïve. In a subset, grey scale (GS) and power Doppler (PD) ultrasound (US) semi-quantitative scores (0–3) were assigned to wrists, MCPs & PIPs 2&3 and MTPs 1–5 bilaterally at baseline[1]. For this analysis both counts (joints scoring GS >1, PD >0, simultaneously GS >1 & PD >0) and score totals were created. To reflect burden of synovitis, clinical and US counts and totals were weighted by first multiplying each joint's score by a weight, determined by its relative area[2], before summating. Samples were tested for MMP-3 and HA using a novel research use only multiplex platform IMPACT(Immunological Multi-Parameter Chip Technology)(Roche Professional Diagnostics, Germany)[3]. We calculated bootstrapped confidence intervals(CI) for the differences in the strength of Kendall's tau-a associations between markers and joint assessments in Stata 13.1.

Results: Data were available for 59 patients: mean age 52.7 (range 19–78); 71% female; 64% RF +ve; median disease duration 1mth. Median (IQR) values for markers were CRP 27mg/L (10, 100); MMP-3 59ng/mL (42, 119); HAμg/mL 37 (20, 70).

None of the associations were particularly strong (Table 1); the strongest were between the weighted clinical joint counts and MMP3 and CRP. Most of the associations with MMP3 were numerically stronger than with CRP, but the differences were neither substantive nor statistically significant.

In patients with normal CRP (<10 mg/L) there appeared to be substantive associations between total GS and MMP-3 (tau-a=0.34) and between total PD and HA (tau-a=0.35); however, sample size was small (n=14).

Table1: Associations between markers of inflammation and clinical and ultrasound measures of synovitis, weighted for joint area (n=59).

	Kendall's Tau-a			Differences between tau-a values (95% CI)		
Weighted joint assessment	MMP-3	HA	CRP	MMP-3 minus HA	CRP minus MMP-3	CRP minus HA
GS total	0.30	0.26	0.24	0.03 (−0.15, 0.21)	−0.06 (−0.25, 0.13)	−0.03 (−0.27, 0.22)
GS count (score>1)	0.23	0.20	0.21	0.04 (−0.16, 0.23)	−0.03 (−0.22, 0.17)	0.01 (−0.23, 0.25)

PD total	0.32	0.30	0.28	0.02 (−0.17, 0.22)	−0.04 (−0.21, 0.13)	−0.02 (−0.25, 0.22)
PD count (score>0)	0.31	0.26	0.28	0.05 (−0.13, 0.24)	−0.03 (−0.20, 0.15)	0.02 (−0.20, 0.25)
'Active' count (GS>1&PD>0)	0.34	0.26	0.26	0.09 (−0.11, 0.28)	−0.08 (−0.25, 0.09)	0.01 (−0.21, 0.23)
SJC28	0.39	0.22	0.42	0.17 (0.00, 0.34)	0.02 (−0.17, 0.22)	0.19 (−0.01, 0.40)
SJC44	0.39	0.21	0.37	0.18 (−0.01, 0.36)	−0.02 (−0.22, 0.18)	0.16 (−0.07, 0.38)

Conclusion: This is the first time that weighted joint counts, which account for joint surface area, have been used in the assessment of soluble synovial biomarkers in RA. Neither MMP3 nor HA performed better as surrogate biomarkers of synovitis than CRP when elevated. Further studies are underway to evaluate the clinical utility of MMP3 as a soluble biomarker of subclinical synovitis at CRP levels<10mg/L.

Can Ultrasonography of Peripheral Entheses Play a Role in the Diagnosis and Understanding of Diffuse Idiopathic Skeletal Hyperostosis (DISH)? Reuven Mader[1], Irina Novofastovski[2], Salvatore Iervolino[3], Alex Pavlov[4], Leonid Chervinsky[5], Naama Schwartz[5] and Nicola Pappone[3]. [1]Technion Institute of Technology, Haifa, Israel, [2]Ha Emek Medical Ctr, Afula, Israel, [3]"Salvatore Maugeri" Foundation, IRCCS Scientific Institute, Telese Terme, Italy, [4]Bnai Zion Medical Center, Haifa, Israel, [5]Ha'Emek Medical Center, Afula, Israel.

Background/Purpose: to investigate musculoskeletal ultrasound (MSUS) as a diagnostic modality in DISH and to explore if it might help in elucidating its pathogenesis and events that precede the calcification/ossification process.

Methods: Fifty patients with DISH and 34 patients with osteoarthritis of the lower limbs without DISH were investigated. Data regarding demographics and traditional cardiovascular risk factors was collected from all patients. An ultrasonography was performed according to the Glasgow Ultrasound Enthesitis Scoring System (GUESS) by observers who were blinded to the diagnosis or the clinical findings in the patients.

Results: The total mean GUESS score for patients with DISH was 14.12 ±5.2 and for patients without DISH 5.32 ±4.99 ($p<0.0001$). Univariate logistic regression analysis found a strong association between the GUESS and the probability of having DISH ($p<0.0001$). The area under the ROC curve (AUC) revealed that the GUESS accuracy in diagnosing DISH was 88.53% with sensitivity and specificity of 92% and 70.6% respectively, at a cutoff value of 6.36. A stepwise logistic regression analysis of the statistically significant items in the GUESS, isolated 4 items, the presence of either all of them or, the first 3 items yielded the likelihood of having DISH to be 98.8%, and 90.6% respectively.

Conclusion: The GUESS and the stepwise logistic regression analysis demonstrated a high likelihood of having DISH. MSUS might shed light on the early entheseal changes in DISH, and the temporal relationship between the spinal and peripheral involvement in this condition. Further studies are needed to confirm these results.

Ultrasound Enthesitis in Primary Care Psoriasis Patients with Musculoskeletal Complaints. M. van der Ven[1], M.C. Karreman[1], A.E.a.M. Weel[1], I. Tchetverikov[2], M. Vis[1], T.E.C. Nijsten[1], J.M.W. Hazes[1] and J.J. Luime[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Albert Schweitzer Hospital, Dordrecht, Netherlands.

Background/Purpose: Psoriasis patients with enthesitis can classify as psoriatic arthritis since the introduction of the CASPAR classification criteria in 2006. However, the presence of a tender enthesis is not necessarily indicative for underlying inflammatory disease as it could be related to overuse, metabolic disease or ageing. Therefore, we need a better way to identify the inflammatory component of entheseal involvement in psoriasis. To detect these inflammatory components and structural changes in the entheses, ultrasonographic examination can be applied to identify inflammatory disease of the entheses. Our objective was to determine the prevalence of ultrasound abnormalities among psoriasis patients in primary care.

Methods: Adult patients with psoriasis (ICPC S91) were identified from 97 general practitioners in the Rotterdam area. These patients were invited to participate in the SENSOR study. Patients who reported pain in joints, entheses or the lower back were eligible and invited for clinical evaluation. If physical examination indicated a painful enthesis on the LEI/MASES or arthritis, ultrasonographic examination of the entheses was performed. The six entheses of the Madrid Sonographic Enthesis Index (MASEI) and the lateral epicondyle tendon insertion (elbow) were evaluated according to the MASEI scoring system. Positive inflammatory components on ultrasound included the presence of power Doppler signal (<2mm of the bony cortex) and increased thickness of the enthesis of the plantar fascia (>4.4mm).

Results: In total, 527 patients with psoriasis who reported musculoskeletal symptoms were clinically evaluated. 83 patients (47 female, mean age: 54 years) had at least one tender enthesis on the LEI/MASES and were evaluated by ultrasound. Another 23 patients (9 female, mean age: 54 years) suspected for presence of arthritis were evaluated by ultrasound as well. In 98 (92%) patients we detected ultrasound abnormalities [Table 1]. In 47 (44%) patients we found abnormalities indicating inflammatory disease at the enthesis. 28 (26%) patients were power Doppler positive on ultrasound, 4 (4%) patients had a thickened plantar fascia and in 15 (14%) patients both inflammatory components were present. In 51 (48%) patients we found structural changes without indication for inflammatory disease. There was no difference in ultrasound findings between patients suspected for enthesitis and patients suspected for arthritis.

Conclusion: In 44% of primary care psoriasis patients (n=106) we observed ultrasound abnormalities (presence of power Doppler and/or thickened plantar fascia) indicating inflammatory disease. Additionally, one or more structural ultrasound changes in the enthesis were observed in the majority of the patients. Whether this also indicates inflammatory disease requires further exploration.

Table 1 Ultrasound abnormalities in the entheses using the MASEI score (n=106)

Insertion	PD signal	Structure	Thickness	Bursitis	Erosion	Calcification
Lateral epicondyle tendon (elbow)*	**20 (19)**	*17 (16)*	47 (44)		*34 (32)*	44 (42)
Triceps tendon*	**0**	*25 (24)*	18 (17)		*9 (8)*	25 (24)
Quadriceps tendon*	**12 (11)**	*12 (11)*	50 (47)		*3 (3)*	62 (58)
Proximal patella tendon*	**2 (2)**	*3 (3)*	28 (26)		*2 (2)*	14 (13)

Are Entheses Ultrasound Findings Similar in Axial Spa Patients and in Athletes? Marie-Alix Lanfranchi[1], Olivier Leluc[2], Alice Tavano[1], Vincent Pradel[1], Sophie Morange[1], Christophe Chagnaud[1], Pierre Lafforgue[1] and Thao Pham[1]. [1]APHM, Aix Marseille University, Marseille, France, [2]APHM, Marseille, France.

Background/Purpose: Spondyloarthritis (SpA) are characterized by inflammatory and structural changes in the entheses (enthesitis). However, enthesitis is not only observed in SpA and can also be seen after a hypersollicitation of the enthese as during intensive sport.

The purpose of the study was to compare ultrasound (US) findings of entheses between 3 groups: axial SpA patients, athletes and healthy controls.

Methods: We conducted a prospective cross-sectional study of 30 axial SpA (2009ASAS criteria), 30 athletes and 30 controls. Athlete subjects practiced a sport resulting in a strain on lower limbs, such as running or soccer, at least 6 hours per week. Controls practiced less than an hour per

week. Clinical evaluation and US were performed at the same day. Physicians performing clinical and US examination were blinded to each other. The US was performed at by two radiologists, using both grey scale (GS) and power Doppler (PD) for calculation of the MASEI index (Madrid Sonographic Enthesis Index) and the analysis of its subitems (bursistis, calcification, erosion, power doppler, thicknening of tendon, structural change) (Toshiba Aplio 500, linear transducer, frequency of 6–18 MHz). *Analysis*: To compare groups we used chi-square and one-way analysis of variance (ANOVA) with Bonferroni correction for post-hoc tests (depending on categorical/continuous variables), and Mann Whitney test for correlation (SPSS 17.0 version).

Results: Patients and controls demographic and clinical characteristics are shown in table 1. In SpA patients mean (SD) BASDAI and ASDAS were 3,14 (1,9) and 1,78 (1,01), respectively. Mean MASEI and each sub-item scores were significantly different between SpA patients and both healthy control groups. There was no difference between athlete and non-athlete groups. No correlation between heel pain and MASEI score or PD of the calcaneal enthese was found. The inter-reader correlation for MASEI scoring was 0.68 (Cohen's kappa coefficient).

Conclusion: The MASEI score was significantly higher in patients with SpA compared to healthy control, athletes and non-athletes. Even if the MASEI score was somewhat higher in the athlete group than in the non-athlete control group, the difference was not significant. The 17-cutoff seems relevant to distinguish SpA from control, whatever their physical activity.

	SpA (n = 30)	Athletes (n = 30)	Non-athlete controls (n = 29)	p
Age, years (mean, SD)	36 (7)	29 (9)	30 (8)	
Gender, male (%)	70.0	70.0	41.4	
Heel pain, ever (%)	55.2	20.7	0	
CRP (mg/l) (mean, SD)	4 (11)	2 (7)	2 (3)	
HLA B27 + (%)	51.1	3.4	3.4	
X-rays sacroiliitis ≥3 (%)	86.7	3.6	10.3	
ASAS criteria + (%)	100	0	0	
MASEI score (mean, SD)	26.3 (13)	12.2 (7)	10.4 (6)	<0.0001
MASEI > 17 (%)	70.0	16.7	14.3	<0.0001

141

Prevalence of Subclinical Enthesopathy in Asymptomatic First Degree Relatives of Patients with Spondyloarthritis. Tomas Cazenave[1], Natalia Zamora[2], Marcelo Audisio[3], Ana M. Bertoli[4], Guillermo Py[3], Walter Spindler[5], Javier Rosa[6], David A. Navarta[7], Teresita de Alvarellos[8], Luciana Mas[9], Gustavo Citera[10] and Marcos G. Rosemffet[10]. [1]IREP, Buenos Aires, Argentina, [2]Echeverría 955, Buenos Aires, Argentina, [3]Servicio de Reumatología del Hospital Nacional de Clínicas, Córdoba., Cordoba, Argentina, [4]Instituto Reumatológico Strusberg, Cordoba, Cordoba, Argentina, [5]Centro Médico Privado de Reumatología, Tucumán, Argentina, [6]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [7]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [8]Hospital Privado de Córdoba, Córdoba, Argentina, [9]Hospital Privado Centro Medico De Córdoba, Cordoba, Argentina, [10]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: There are no studies evaluating enthesis involvement detected by US in relatives of spondyloarthritis (SpA) patients. **Objectives:** 1) To evaluate and compare the prevalence of subclinical enthesopathy detected by US in first degree relatives of patients with spondyloarthritis and healthy controls (HC), 2) To evaluate associations between US findings, clinical variables and presence of HLA-B27.

Methods: We designed a multicenter cross-sectional study including asymptomatic first-degree relatives of patients with Ankylosing Spondyitis (RAS) or Psoriatic Arthritis (RPsA), and a group of sex-age matched healthy controls (HC). Each subject underwent clinical and ultrasonographic evaluation. All RAS subjects were tested for the presence of HLA-B27. Demographic and clinical data were recorded including presence of comorbidities, physical activity and body-mass index. Two rheumatologists who were blinded to clinical examination performed the ultrasound evaluation. Ten enthesal sites were evaluated: bilateral quadriceps tendon, proximal and distal patellar ligament, Achilles tendon and plantar aponeurosis. Ultrasonographic enthesopathy (UE) was defined as the presence of at least one of the following characteristics: thickening, erosion, enthesophytes and/or bursitis. The Glasgow Ultrasound Enthesitis Scoring System (GUESS) was calculated, which range from 0 to 36, being 36 the highest involvement. An alternative model was tested, evaluating the addition of Power Doppler (PD) assessment to the GUESS. Differences among groups were compared using chi-squared test and ANOVA with post-hoc analysis (Games Howell) Interobserver agreement between both ultrasonographers was estimated by the intraclass correlation coefficient (ICC).

Results: We included 101 subjects from 5 rheumatology centers (RAS=44, RPsA= 13, HC=44). Clinical and demographic findings were comparable among groups. Fifty-two perecent were men with a median age of 32 years (IQR: 24.5–41.5). Eighteen RAS subjects (40.9%) were HLA-B27 positive. A total of 1010 enthesal sites were evaluated. Eighty-nine out of 101 subjects (88.1%) showed at least one UE, being enthesophyte at the Achilles tendon, thickening at the proximal and distal insertions of the patellar tendon (51%, 46% and 40%, respectively) the most frequent findings. US evaluation demonstrated a higher frequency of enthesal involvement in Spondyloarthritis relatives (RAS and RPsA) when compared to HC at the following sites: Left sub-quadricipital bursa (15.8% vs 2.3% p=0.04), thickening at the proximal insertion of the left patellar tendon (12.3% vs 0% p=0.018) and thickening of the left Achilles tendon (15.8% vs 0% p=0.005). The mean GUESS score in the three groups were: RAS: 5.16 ±3.22, RPsA: 4.15 ± 5.33 and HC: 3.52 ±2.69. The mean GUESS score was significantly higher in RAS group as compared to HC (p=0.031). Mean GUESS was higher in HLA-B27 subjects as compared with those negatives (5.50 ±3.34 vs 4.92 ±3.18, p value =0.56).

Conclusion: First degree relatives of patients with SpA had a higher frequency of enthesopathy and a higher GUESS score than healthy controls.

Prevalence of Subclinical Entheseal Involvement in Patients with Paediatric Inflammatory Bowel Disease: An Ultrasonographic Study. Alberto Batticciotto[1], Dario Dilillo[2], Marco Antivalle[3], Martina Nugnes[2], Valentina Varisco[1], Matteo Ferrari[2], F. Atzeni[3], Gian Vincenzo Zuccotti[2] and P. Sarzi-Puttini[3]. [1]L. Sacco University Hospital, Milano, Italy, [2]Pediatric Department, L. Sacco University Hospital of Milan, Milan, Italy, [3]Rheumatology Unit, L. Sacco University Hospital of Milan, Milan, Italy.

Background/Purpose: Joint involvement is the most frequent extra-intestinal manifestation of paediatric inflammatory bowel disease (IBD). Various recent studies focused on the clinical prevalence of enthesitis in children and adults with IBD[1], and others have demonstrated the ability of ultrasound (US) to visualise the acute and chronic signs of entheseal inflammation with greater sensitivity than a clinical examination, although there is a lack of consensus concerning the US definition of entheseal abnormalities and their prognostic value especially in the paediatric field[2]. The aim of this study was to evaluate the prevalence of subclinical entheseal involvement in patients with pediatric IBD using a high frequency ultrasound probe.

Methods: Twenty-seven pediatric IBD patients (13 with Crohn's disease [CD] and 14 with ulcerative colitis [UC]; 15 females and 12 males; mean age 13.7 years, range 7–21 years) without any clinical signs or symptoms of musculo-skeletal involvement and 24 healthy age- and gender-matched controls (14 females and 13 males; mean age 14.2 years, range 8–20 years) underwent an US examination (ESAOTE MyLAB 70 6–18 MHz linear array transducer). Brachial triceps, femoral quadriceps, Achilles, plantar fascia, and proximal and distal patellar entheses were all scored using the 0–136 Madrid Sonographic Enthesis Index (MASEI). Clinical and clinimetrical variables were assessed in both groups (MASES, BASDAI, BASFI, cHAQ, PCAI/PCDAI).

Results: None of the patients had a MASEI score suggesting early spondyloarthritis involvement but their average score was significantly higher than controls (3.15±2.84 *vs* 0.96±1.12, p=0.0006). There was also a significantly higher percentage of patients with at least one enthesis with power Doppler (PD) score ≥2 (37% *vs* 16%; p= 0.037) and at least one enthesis with dishomogeneous echostructure (59% *vs* 0%; p= 0.000). There were no between-group differences in terms of erosions (0% *vs* 0%), calcifications (7.4% *vs* 12.5%; p=0.656) or structural thickness (37% *vs*33.3%; p=0.507). In paediatric IBD group we cannot find correlation

between the total MASEI score and gender (p=0.12), age (p=0.20), disease duration (p=0.18) or IBD activity (p=0.83).

Conclusion: US detectable enthesopathy is frequent in paediatric IBD patients without any clinical signs or symptoms of musculo-skeletal involvement. Further studies involving a larger number of patients are needed to confirm these preliminary data.

Detailed Anatomical Distribution of Synovial Inflammation Revealed By Ultrasound in Patients with Blau Syndrome. Kei Ikeda[1], Naotomo Kambe[2], Syuji Takei[3], Taiji Nakano[2], Yuzaburo Inoue[2], Minako Tomiita[4], Natsuko Oyake[5], Takashi Satoh[2], Tsuyoshi Yamatou[3], Tomohiro Kubota[3], Ikuo Okafuji[6], Nobuo Kanazawa[7], Ryuta Nishikomori[8], Naoki Shimojo[2], Hiroyuki Matsue[2] and Hiroshi Nakajima[1]. [1]Chiba University Hospital, Chiba, Japan, [2]Chiba University Graduate School of Medicine, Chiba, Japan, [3]Kagoshima University Hospital, Kagoshima, Japan, [4]Chiba Children's Hospital, Chiba, Japan, [5]Hitachinaka General Hospital, Hitachinaka, Japan, [6]Kobe City Medical Center General Hospital, Kobe, Japan, [7]Wakayama Medical University, Wakayama, Japan, [8]Kyoto University Graduate School of Medicine, Kyoto, Japan.

Background/Purpose: Arthritis is the most frequent manifestation of Blau syndrome, an autoinflammatory disorder caused by the genetic mutation of *NOD2*. However, the detailed information on arthritis in Blau syndrome which the therapeutic strategy should be based on was lacking. This multi-center study aimed to accurately characterize the articular manifestation of Blau syndrome and also to demonstrate the utility of musculoskeletal ultrasound in Blau syndrome.

Methods: Patients who had been diagnosed with Blau syndrome by genetic analysis of *NOD2* were recruited. A total of 102 synovial sites in 40 joints were assessed semiquantitatively by ultrasound for gray-scale synovitis and synovial power Doppler (PD) signal.

Results: Ten patients whose age ranged from 10 months to 37 years enrolled in this study. Although only four joints (0.8 %) were tender on physical examination, 81 joints (16.9 %) were clinically swollen. Moreover, 240 (50.0 %), and 124 (25.8 %) joints showed GS synovitis and synovial PD signal on ultrasound, respectively. Importantly, GS synovitis was present in 168 out of 399 non-swollen joints, in which 61 also exhibited synovial PD signal. Among 40 joint regions, the ankle, the wrist, and the proximal interphalangeal joints were the most frequently and severely affected joints (Figure). Comparisons between different synovial tissues demonstrated a significantly higher proportion of the joints with tenosynovitis as compared with that with intra-articular synovitis (41.5 % vs. 27.9 %, $P < 0.0001$). In respect of age and treatment, synovial PD signals were minimal in the youngest patient and in the oldest two patients, and were relatively mild in patients receiving treatment with methotrexate plus TNF antagonists. In two patients who underwent the 2nd ultrasound examination, total PD scores markedly decreased after initiating the treatment with a TNF antagonist.

Conclusion: The detailed information on synovial inflammation obtained by ultrasound confirms the dissociation between pain and inflammation and the frequently involved joint regions and synovial tissue in the arthritis of Blau syndrome. Our data also demonstrate that ultrasonography can be a potent tool in monitoring the activity of synovial inflammation and in investigating the pathophysiology of arthritis in this rare but archetypical autoinflammatory condition.

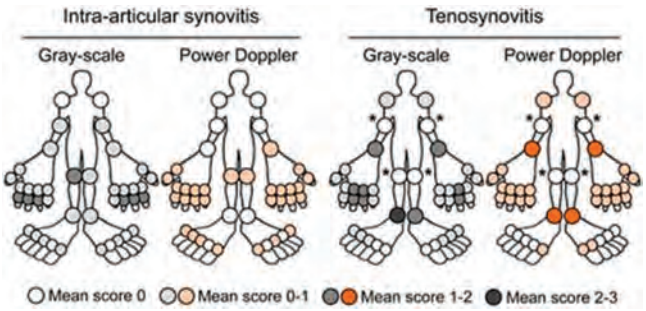

Figure. Mean gray-scale and power Doppler scores for intra-articular- and teno-synovitis in each joint

Mean ultrasound scores for each joint in 10 patients are shown in color grades. Only 1st ultrasound examinations in Patient 5 and 6 are included.

* Ultrasound scores for tenosynovitis are not applicable in elbows and knees where typical tenosynovium does not exist.

Sonographic Differentiation of Heel Pain: Focal Degenerative Versus Systemic Inflammatory Enthesitis. Patrick Hook[1], Diana Vradii[2], Maureen Dubreuil[3], Hau Pham[3] and Eugene Y. Kissin[1]. [1]Boston University School of Medicine, Boston, MA, [2]Mid Coast Hospital Medical Center, Brunswick, ME, [3]Boston University Medical Center, Boston, MA.

Background/Purpose: Plantar fasciitis and Achilles tendonitis are commonly encountered in a rheumatologic practice due to either degenerative (DG) or systemic inflammatory conditions (SYS). While sonographic findings in both DG and SYS have been described in numerous studies, no study has systematically compared these two causes of heel pain. The aim of our study is to determine whether sonographic findings in the Achilles tendon and plantar fascia can be used to differentiate DG from SYS states.

Methods: Patients over the age of 18 with pain at the Achilles tendon or plantar fascia presenting to the Podiatry, Dermatology or Rheumatology clinics were enrolled. Exclusion criteria: previous heel trauma, surgery or recent corticosteroid heel injections. Medical chart review, a focused history, and a comprehensive musculoskeletal physical examination determined patient categorization as DG, SYS, or undetermined cause of heel pain. Patients' Achilles tendons and plantar fascia were imaged with a GE Logiq e ultrasound and 12MHz linear array transducer. Doppler settings: PRF 0.8, low wall filter and Doppler gain set to maximize signal with minimal artifact. We evaluated tendon thickness, retro-calcaneal bursal size, cortical erosions, and Doppler signal at the enthesis and at the cortical margin. Continuous variable were compared between the degenerative and inflammatory groups using t tests, and proportions were compared using Chi squared or Fischer's exact tests.

Results: Interim analysis of the first 46 patients recruited includes 20 in the SYS group and 22 in the DG group (4 undetermined). SYS group consists of 15 patients with psoriatic arthritis, 4 with non-psoriatic spondyloarthritis, and 1 with rheumatoid arthritis. Male:female ratio was 15:5 in the SYS group, and 6:16 in the DG group. While there were no significant differences in tendon thickness between the groups (Table), both the presence of erosions (SYS 70% vs. DG 23%, p=0.002), and the presence of Doppler at the enthesis (SYS 55%, vs. DG23%, p=0.03) were significantly more common in the SYS group (Table). Surprisingly, erosion size and degree of Doppler signal did not help distinguish the groups (Table). Doppler signal at the cortical margin was not more specific to the inflammatory group than enthesis Doppler overall (Table).

Conclusion: While there were no significant differences in tendon thickness, degenerative causes of heel enthesitis were less likely to show Doppler signal and erosive changes than systemic inflammatory enthesitis. However, erosions were seen in some heel enthesitis not associated with systemic inflammatory disease.

Table. Clinical characteristics and sonographic findings for subjects included in the study

	Inflammatory (N = 20)	Degenerative (N = 22)	P value
Male, % (N)	75.0% (15)	27.2% (6)	
Body Mass Index (kg/m^2)	32.3 +/− 5.9	33.9 +/− 8.5	
Age (range)	46 (20–69)	47 (25–77)	
Plantar fascia pain, % (N)	65.0% (13)	77.3% (17)	
Achilles pain, % (N)	90.0% (18)	59.1% (13)	
Achilles Proximal Thickness (cm)	0.55 +/− 0.16	0.45 +/− 0.11	0.09
Presence of Erosions	70.0% (14)	22.7% (5)	0.0021
Presence of Erosions > 2 mm	35.0% (7)	18.2% (4)	0.30

Presence of Doppler at Enthesis	55.0% (11)	22.7% (5)	0.03
Presence of Doppler > 1 at Enthesis	25.0% (5)	13.6% (3)	0.45
Presence of Doppler at Cortical Margin	40.0% (8)	13.6% (3)	0.052

A Cut-Off Value Analysis By Ultrasound for the Diagnosis of Giant Cell Arteritis (GCA). Hisayo Horiuchi, Kenta Misaki, Rintaro Saito, Yuri Nakamura, Yoshie Gon, Takumi Nagamoto, Hirotaka Yamada and Toshihiko Yokota. Kurashiki Central Hospital, Kurashiki, Japan.

Background/Purpose: Ultrasonography (US) of the superficial temporal arteries was introduced in the 1990s. The diagnostic value of US of the superficial temporal artery wall in giant cell arteritis (GCA) has been extensively reported. In order to clarify the effectiveness of US preceding pathological diagnosis, we examined cut-off values of ultrasonography-derived halo signs (intima-media thickness, IMT).

Methods: Twenty-eight patients with suspected GCA were examined by US before biopsy from October 2010 to June 2014, inclusive. US was performed unilaterally or bilaterally by two ultrasonographers and the greatest analyzed. Superficial temporal artery biopsy was used as the reference standard. The Cohen's Kappa test for Inter-Observer variation was 0.703 (95%CI: 0.390 to 1.015).

Results: Unilateral halo sign had a sensitivity of 83.3 % and specificity of 40.0 %. In ROC analysis, a cut-off of greatest dimension of halo > 0.51 mm was the most accurate for prediction with a sensitivity of 66.7 % and specificity of 80.0 %. The diagnostic odds ratio was 8.0 (95% CI, 1.28 – 50.04).

Conclusion: This is the first report that examined the cut-off values of IMT in diagnosing GCA. The measurement of the greatest dimension of the ultrasonography-derived halo sign (IMT) increased the diagnostic yield for pathological diagnosis.

Ultrasonographic Evaluation of Joint and Tendon Involvement in Patients with Early Systemic Lupus Erythematosus (SLE) in Comparison with Early Rheumatoid Arthritis (RA). Takehisa Ogura, Ayako Hirata, Norihide Hayashi, Rie Kujime, Hideki Ito, Sayaka Takenaka, Sumie Nakahashi, Kennosuke Mizushina, Naoko Yamashita, Yuki Fujisawa and Hideto Kameda. Toho Univ, Tokyo, Japan.

Background/Purpose: Although both systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) may lead to the joint deformity, different characteristics such as the absence or the presence of bone destruction have been recognized as well: lupus arthritis is typically non-erosive and often accompanied by Jaccoud's deformity. Therefore, we examined characteristics of joint and tendon lesions in SLE patients as compared with RA patients by using ultrasonography.

Methods: Thirteen SLE and 32 RA patients were selected from the treatment-naïve patients with joint symptoms, visiting Toho University Ohashi Medical Center between January 2011 and March 2014. Enrolled patients had at least one swollen or tender joint. The wrist, metacarpophalangeal and proximal interphalangeal joints and related extensor/flexor tendons were ultrasonographically examined from both palmar and dorsal sides. Their joints and tendons including tendon sheaths were evaluated using a gray-scale (GS) for synovial thickening and synovial fluid retention, and power Doppler (PD) for blood flow according to a semiquantitative method based on a scale of grades 0 to 3, and patients graded with GS ≥ 2 or PD ≥ 1 were judged as having joint synovitis and or tendinitis/tenosynovitis.

Results: Joint synovitis and tendinitis/tenosynovitis were observed in 11 (79%) and 12 (86%) of 13 SLE patients, respectively, and in 31 (91%) and 18 (53%) of 32 RA patients, respectively. Thus, SLE patients had tendinitis/tenosynovitis more frequently ($p=0.034$) as compared with RA, and particularly in the wrist joints ($p=0.008$, Table 1). Moreover, the concordance of joint synovitis and tendinitis/tenosynovitis in the same region was less in SLE patients ($\kappa=0.18$) as compared with RA ($\kappa=0.44$).

Conclusion: Joint synovitis was similarly observed ultrasonographically in both SLE and RA patients, while tendinitis/tenosynovitis was more frequently observed in SLE patients than in RA patients. In addition, tenosynovitis in SLE patients may develop rather independently from synovitis.

	SLE number	n=13 (%)	RA number	n=32 (%)	p
Joint synovitis	11	(78.6)	31.0	(91.2)	0.196
Wrist	10	(71.4)	27.0	(79.4)	0.672
MCP	9	(64.3)	25.0	(73.5)	0.704
PIP	3	(21.4)	18.0	(52.9)	0.056
Tenosynovitis	12	(85.7)	18.0	(52.9)	0.034
Wrist	10	(71.4)	10.0	(29.4)	0.008
Finger extensor tendons	6	(42.9)	9.0	(26.5)	0.305
Finger flexor tendons	8	(57.1)	14.0	(41.2)	0.337

US Lung Examination in SSc Patients: A Comparison of Two Different Scoring Systems. Andrea Delle Sedie[1], Cristina Lodato[1], Elisa Cioffi[1], Linda Carli[2], Stefano Bombardieri[1] and Lucrezia Riente[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]GenOMeC PhD, University of Siena, Siena, Italy.

Background/Purpose: Systemic sclerosis (SSc) is a disease characterized by a progressive fibrosis of the skin and internal organs, which can lead to death. Lung involvement includes a wide range of disorders and interstitial lung disease (ILD) is the most common manifestation, being clinically significant in about 40% of patients. Recently, the role of US in the assessment of ILD (counting the B-lines, generated by the reflection of the US beam from thickened sub-pleural interlobar septa) has been confirmed after comparison with high-resolution computed tomography (HRCT) and a few scoring systems proposed. The comprehensive examination of lung intercostal spaces (LIS) is time consuming (54 LIS in each patient) (1) and a previous attempt to give a simplified US B-line scoring system has been made in patients with connective tissue diseases (2), an evaluation on 8 different thoracic areas is also performed (3–4).

Aim of the study was to compare the comprehensive examination and the 8-area scoring system and define which could be more effective in clinical practice.

Methods: 79 SSc patients were enrolled independently of the presence of any dispnoea. Each patient underwent a lung US with comprehensive US B-line assessments by an experienced rheumatologist. A cut-off of >12 B-lines was decided based on the correlation between US and HRCT in 76 patients, then US was performed alone in the rest of the SSc patients. The presence/absence of B-lines was registered in each LIS. The second scoring system was positive when ≥3 B-lines were present in a single LIS in ≥1 area.

Results: 46 patients were positive for ILD (ILD+) and 33 negative when using the comprehensive examination; the 8-area scanning protocol showed 44 ILD+ and 35 negative. Using the two different scoring systems ILD+ and ILD- patients were the same in 67 cases. Seven of the remaining patients were ILD+ only using the comprehensive scan (in 4 of them the total B-lines score was <16, so really close to the cut-off) and 5 only using the 8-area scan. The time needed for the comprehensive assessment was longer than the one for the 8-area scanning protocol (the latter does not assess posterior thorax and, if a LIS is positive, there is no need to scan the other LIS in the same area).

Conclusion: The results provided by the two scoring systems are largely overlapping in the identification of ILD+ patients. Considering the shorter time needed for the assessment, the 8-area scanning protocol could be more useful for screening.

Value of Ultrasonography Parotid Glands in Patients with Suspected Primary Sjögren's Syndrome. Marina Oliver[1], Lida Santiago[2], Paula Gonzalez[1], Diego Vila[1], Sebastian fernandez Nacul[1], Santiago Scarafia[3], Marta Mamani[4] and Anastasia Secco[3]. [1]Rivadavia Hospital, Buenos Aires, Argentina, [2]hospital rivadavia, CABA, Argentina, [3]Hospital Bernardino Rivadavia, Buenos Aires, Argentina, [4]Hospital Rivadavia, Capital Federal, Argentina.

Background/Purpose: Primary Sjogren's syndrome (pSS) is an autoimmune disorder characterised by chronic lymphocytic infiltration of exocrine tissues. Currently new non-invasive techniques are being continuously introduced as a diagnosis tool. Ultrasonography (US) of salivary glands in these patients merits special interest as a rapid, inexpensive, non-radiating and widely accessible modality.

Methods: The aim of the study is to assess the diagnostic value of ultrasonography (US) in those patients underwent minor salivary gland biopsy (MSGB) by suspected Primary Sjögren Syndrome (pSS).

All patients underwent bilateral parotid glands US and MSGB. The same expert blinded examiner performed the US. All patients were scanned using an MyLab 25 US scanner (Esaote Italy) with a 10–18 MHz linear-array transducer. The following parameters were assessed: homogeneity, hypoechoic areas, hyperechoic foci, Power Doppler (PD) and margins graded from 0 to 2 (0: well-defined, 1: ill-defined, 2: blurred) and gland size was measured. The gold standard was the MSGB. According to the quantity and type of US variables, we determined the following cut-off values (at least unilateral parotid finding) A: presence or absence of heterogeneity on unilateral or bilateral parotid glands B: presence or absence of any variable (not more than one and excluding heterogeneity) on unilateral or bilateral parotid glands. C: presence or absence of three or more variables (any variable) on unilateral or bilateral parotid glands.

Results: We included a total of forty-five biopsies (32 negative and 13 positive). 95.56% were female, the median symptoms length was 2 years (IQR 1–7), no differences were observed between both groups. According to A cut-off values had 30. 77 % sensitivity (S) (CI 17.28– 44.25), 78.13% specificity (Sp) (CI 66.05–90.20), 36.36 % positive predictive value (PPV) (22.31–50.42), 73.53% Negative Predictive Value(NPV) (CI 60.64–86.42), likelihood ratio (LR) + 1.41 (CI 0.49–4.0), and the area under the curve (AUC) 0.54 (CI 0.40–0.69). B findings showed 46.15% S (CI 41.59– 60.72), 68.75% Sp (CI 55.21–82.29), 37.50% PPV (CI 23.36–51.64), 75.86% NPV (CI 63.86–88.36%), LR + 1.48 (CI 0.68–3.22), AUC 0.57 (CI 0.41–0.74). We observed C findings with a 30.77% of Sensitivity (CI 17.28–44.25), 90.63% Specificity (CI 82.11–99.14), 57.14% PPV (CI 42.78– 71.60), 31% NVP (CI 63.89–88.74), LR + 3.28 (CI 0.85–12.67), AUC 0.61(CI 0.47–0.77).Bilateral parotid US showed an AUC similar to B findings.

Conclusion: We considered that C findings are the best cut-off values because it demonstrated greater specificity and slightly better AUC. Nevertheless, in our study the US of parotid gland not prove to be an appropriate diagnostic tool to replace the MSGB.

Automated Digital Analysis of Major Salivary Gland Ultrasound Images. Daniel S. Hammenfors[1], Preben G. Nes[2], Johan G. Brun[1], Roland Jonsson[1] and Malin V. Jonsson[3]. [1]Haukeland University Hospital, Bergen, Norway, [2]Sogn and Fjordane University College, Førde, Norway, [3]University of Bergen, Bergen, Norway.

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune chronic inflammatory disease mainly affecting the salivary and lacrimal glands, with symptoms such as dryness of the mouth and eyes as well as fatigue. The diagnosis is based on the objective findings of reduced secretion of saliva- and/or tears, the detection of auto-antibodies against Ro/SSA and/or La/SSB in serum, and the observation of focal mononuclear cell infiltration in minor labial salivary gland biopsies. In the recent years, interest in major salivary gland ultrasonography as a diagnostic tool for pSS has increased. Several scoring systems evaluating glandular homogeneity and echogenicity have been suggested, presenting a challenge for both researchers and clinicians. The aim of this study was to develop a reliable automated digital evaluation of ultrasound images as a useful tool for the clinician and as an objective method for the researcher.

Methods: The parotid glands of patients (n=26) fulfilling the AECG criteria (Vitali et al 2002) had previously been examined using a GE LogiqE9 with a linear high-frequency transducer (6–15MHz) and the images evaluated using a simplified grading system (0–3) (Hocevar et al, 2005). The stored images were analysed digitally with a pilot version of the software developed for this study. Briefly, the software analyses local variability in grayscale values. The algorithm used for the digital analysis was developed using MATLAB (MathWorks, Natick, Massachusetts).

The patients were randomly selected from a previously characterized cohort (n=97) where the ultrasound findings correlated with objective findings such as reduced saliva secretion, minor salivary gland inflammation and elevated autoantibody titers, as well as sicca symptoms of the mouth (manuscript found acceptable for publication in *Clinical and Experimental Rheumatology* 2014).

Results: Preliminary findings show an excellent correlation between the scores obtained with the simplified grading system (0–3) and the automated digital evaluation ($p > 0.05$, $r = 0.816$, $n = 26$). Mean digital score for images graded 0–3 were -9.833 (grade 0), -6.018 (grade 1), 2.752 (grade 2) and 6.850 (grade 3), respectively.

Conclusion: The preliminary results of ultrasound image analysis show an excellent correlation between the automated digital analysis and the evaluation by a trained clinician. In future studies, automated analysis will enable an objective and reproducible analytic method for the researcher as well as provide a useful diagnostic and possibly prognostic tool for the clinician.

Ultrasonographic Evaluation of Major Salivary Glands in Primary Sjogren's Syndrome: Comparison of Two Scoring Systems and Diagnostic Value of Sonoelastography. Xia Zhang, Jing He and Zhanguo Li. Peking University People's Hospital, Beijing, China.

Background/Purpose: Primary Sjogren's syndrome (pSS) is a chronic systemic autoimmune disease characterized by clinically xerophthalmia and xerostomia. Those standard tests of salivary glands involvement has some deficiency. To date, a precise and feasible evaluation method for primary Sjogren's syndrome (pSS) remains to be established. Ultrasonography (US) is a promising technique, as it is convenient, economic, and non-invasive. A consensus has not been reached regarding the evaluation of typical SGUS changes for pSS, and at present, two main scoring systems exist (range 0–16, 0–48, respectively). To date, it's unknown which one is more practical and useful. On the other hand, sonoelastography (SE) is a rapidly developping technique by which the tissue elasticity can be measured. SE has been investigated in the differential diagnosis of focal nodule of breast, thyroid, prostate and salivary gland and liver fibrosis, as an accurate and reproducible method. However, the application of sonoelastography to salivary diffuse pathologic lesions never reported. We aimed to assess and compare the usefulness of two existing SGUS scoring systems for primary pSS and explore the performance of SE in the diagnosis of pSS.

Methods: US and SE examination of major salivary glands was conducted for 105 pSS patients and 41 non-SS patients with 10 Sicca syndrome, 5 hypothyroidism, 19 rheumatoid arthritis, 7 systemic lupus erythematosus and 16 healthy subjects. The ultrasonographic features were graded using two different scoring systems (0–16, 0–48, respectively) obtained from the grades of bilateral parotid and submandibular glands. On the other hand, elastographic images was determined with a qualitative 4-point scoring method (range 0–16).Receiver operating characteristic (ROC) curves were used to describe and compare the diagnostic accuracy of the two US echostructure scoring systems for pSS, simutaneously, to evaluate the performance of qulalitative elasticity scoring by sonoelastography.

Results: 1) SGUS scores for the pSS group were significantly higher than those for the non-pSS group ($P < 0.001$). The maximal combination of sensitivity and speciality was 80% and 93% at an optimal US cut-off value of 7 in the 0–16 system, and was 88.6% and 84.2% at a best cut-off of 15 in the 0–48 system. For the 0–48 system, the sum of the scores of all four glands provided the best diagnostic accuracy. 2) Scores of elasticity for pSS group were significantly higher than those for non-pSS group by different calculated qulalitative methods ($p < 0.001$). Referring to the ROC curves, the sum of the scores of all four glands provided the largest AUC-ROC (0.916, 95% CI 0.87 – 0.962). The maximal sensitivity and specificity were 81% and 87% at an optimal cut-off value of 9 for the sum of the scores of all four glands.

Conclusion: SGUS showed good sensitivity and specificity for noninvasive assessment of salivary glands for pSS diagnosis. Moreover, compared to the 0–16 system, the 0–48 system had a slightly higher sensitivity. The qualitative assessment of salivary elasticity with SE was of diagnostic value to pSS.

Sonographic Measurements Can be Misleading for Diagnosing Carpal Tunel Syndrome in Patients with Rheumatoid Arthritis. Ilker Yagci[1], Merve Akdeniz Leblebicier[2], Basak Mansiz Kaplan[2], Demet Ozturk Gokbakan[2] and Gulseren Akyuz[1]. [1]Marmara University School of Medicine, Istanbul, Turkey, [2]Marmara School of Medicine, Istanbul, Turkey.

Background/Purpose: To compare the nerve cross sectional areas (CSA) in patients with RA without any sign of peripheral neuropathy to healthy controls.

Methods: The study group was generated from referrals to Rheumatic Diseases Outpatient Clinics. Clinical, electrophysiological and sonographic assessments were done by three blinded resarchers. Clinical assessment included Tinnel's sign, Phalen test, tenar atrophy and Flick sign, KATZ hand diagram and Boston Questionnaire. Median, ulnar and tibial motor, median, ulnar and sural sensory nerve conduction studies (NCS) were performed. The patients who had an electrodiagnostic or clinical peripheral neuropathy were excluded from the study. Nerve CSA's were measured in various levels; hamatum hook, psiform bone, radio-ulnar joint, distal 1/3 of forearm, and elbow levels for median nerve; radio-ulnar joint, psiform bone, distal 1/3 of forearm, and medial epicondyle for ulnar nerve. Three different measurements were obtained and the average measure was used for the each level.

Results: The study was completed with 30 women with RA and 30 healthy women. There were no statistical significance according to age, and body mass index. Despite both of the groups had no clinical and electrophysiological neuropathy, the sonographic measurements showed that median nerve CSA's at radioulnar joint, psiform and hamatum levels of patients with RA were larger than healthy controls. Ulnar nerve CSA's of all levels statistically increased in patients with RA ($p<0.05$). If the psiform level median nerve CSA >10 mm2 was used as sonographic carpal tunnel syndrome (CTS) criterion, 23/60 hands of 30 patients with RA and 5/60 hands of 30 healthy controls could be misdiagnosed as CTS.

Conclusion: Median and ulnar nerve CSA's were larger than healthy control in patients with rheumatoid arthritis without clinical and electrophysiological peripheral neuropathy. The rheumatologists should be careful to diagnose CTS in patients with RA with using US.

Subclinical Synovial Inflammation in Gout. Priya Chowalloor[1], Patrick Cheah[2] and Helen I. Keen[1]. [1]The University of Western Australia, Crawley, Australia, [2]Sir Charles Gairdner Hospital, Nedlands, Australia.

Background/Purpose: Gout is poorly managed in the community. Long standing poorly controlled gout can lead into progressive destructive arthropathy, decreased quality of life and increased mortality. Aims of this study is to assess the burden of subclinical synovitis in gout both in acute and intercritical phases. Subclinical synovitis may have implications for the long term outcome of patients with gout.

Methods: This pilot study included 30 participants with gout according to either ACR or EULAR criteria. Subjects with any other inflammatory joint disorders were excluded. Subjects were examined twice. One visit was during the period of acute gout and second was during the intercritical phase. The intercritical phase visit was done at least four weeks after the resolution of symptoms of acute gout. Examinations performed during each visit include tender and swollen joint count, musculoskeletal ultrasound (US) of 52 peripheral joints for gray scale synovitis and power Doppler (PD). Blood was collected for ESR, high sensitivity CRP (hs CRP) and uric acid.

Results: Median age of the subjects was 69 (IQR 52.5–74) and BMI was 26.40(IQR 23.12–29.40). Females were 7.4%. Median disease duration was 3 years (IQR 11-2). The mean interval between visits was 3.6 months (SD 2.4).

	Flare visit	Intercritical visit	P value
Number of subjects seen	27	27	
Hs CRP	8.19 (3.57–37.45)*	5.15 (1.39–8.46)*	0.054
ESR	28 (14.5–44.75)*	13.5 (5.75–33)*	0.031
Serum uric acid	0.44 (0.36–0.5)*	0.38 (0.2975–0.485)*	0.405
Number of joints clinically involved	1 (1–2)*	0 (0–0)*	0.007
Number of joints involved on US (defined as a PD score of >/= 2)	5 (3–11)*	4 (3–7)*	0.139
Number of joints involved only by US and not clinically	4 (2–9)*	4.5 (3–7.25)*	0.901
Most commonly involved joints by US	1st MTP (n = 30), knee (n = 17), wrist (n = 17) and 2nd MCP (n = 16)	1st MTP (n = 21), wrist (n = 17), 2nd MCP (n = 17) and knee (n = 14)	

*Median (IQR)

Conclusion: Ultrasound demonstrates subclinical synovitis during acute and intercritical periods. Interestingly, whilst there were significantly less clinically active joints during the intercritical period ($p=0.007$) there was not less joints involved by US ($p=0.139$). Ultrasound may be important in the monitoring of inflammation in the management of gout.

Musculoskeletal Ultrasound of Finger and Foot Joints in a Population of Volunteers: Is Osteoarthritis an Underestimated Problem? Results from the German "Rheuma-Truck" Cohort. Dr. Philipp Sewerin[1], Dr. Stefan Vordenbäumen[1], Aiko Liedmann[1], Sarah Ohrndorf[2], Marina Backhaus[2], Dr. Oliver Sander[1], Prof. Dr. Matthias Schneider[3] and Prof. Dr. Benedikt Ostendorf[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Charite University Hospital, Berlin, Germany, [3]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: To investigate the frequency of osteoarthritis (OA) in musculoskeletal ultrasound of the MCP, MTP and PIP joints in a volunteer population using the US-7 score.

Methods: "Rheuma-Truck" was a mobile rheumatology office located in different city center of North Rhine Westphalia, Germany offering a screening for rheumatic diseases including Rheuma-Check questionnaire, lab-tests (MCV capillary test) and imaging (US, capillaroscopy). Musculoskeletal ultrasound (MyLab 25 Gold, Esaote linear scanner, 15, Typ LA435) of the dominant hand of 605 volunteers (Rheuma-Truck-Cohort) was performed, using US-7 score for the detection of inflammatory joint alteration. Additionally, the foot joints were investigated according to US-7 criteria in 236 volunteers. Osteoarthritis in US was defined as the presence of osteophyte formations (discrete, moderate or severe). Due to the US-7 scoring system DIP joints were not assessed. Descriptive statistics for the patients were obtained and are reported as means $\pm$ standard deviation, ranges, frequencies or proportions as appropriate. Correlation coefficients are Pearson-correlations.

Results: 605 volunteers of the "Rheuma-Truck" Cohort were screened by musculoskeletal ultrasound according to the US-7 scoring system. The mean age of the investigated population was 52.72 years (min. 10 years; max. 89 years). Sex distribution shows 72.2% females and 27.8% males. 181 volunteers were displayed arthritis by ultrasound. Moreover 337 (55.7%) probands showed sonographically detectable sings for osteoarthritis in the investigated joints. The mean age of the OA-positive probands was 57.78 years (min. 12, max. 89 years). The sex distribution reflected that of the entire cohort (72.4% f; 27.6% males). 73.1% of the sonographically positive OA volunteers were older than 50 years, 13% between 40–50 years, 5.2% between 30–40 years and 8.7% under 30 years. MCP-2 was the most frequently involved joint, wherein 36.6% of the sonographically positive OA volunteers showed osteophytes. The MCP-3 was sonographyically positive in 15.4% followed by the wrist (10.4%), PIP-2 (9.3%), PIP-3 (7.6%), MTP-2 and 5 (each 7.2%). Of all volunteers enrolled, 16.8% (102 of 605) were diagnosed with both, OA an RA. Of all patients diagnosed with RA, 56.4% (102 of 181) also showed sonographically detectable OA-sings.

Conclusion: In the "Rheuma-Truck" Cohort, nearly 3 of 4 volunteers over 50 y of age exhibited sonographic findings compatible with osteoarthritis. Also nearly 14% of newly diagnosed OA according to ultrasonographic findings were below the age of 40. Strikingly, MCP joints were the most frequently involved joints within the US-7 scoring, which however ignores the DIP-joints. Thus, this study highlights a previously unrecognized high burden of hand OA.

Cimt in Individuals with Rheumatoid Arthritis Compared to Individuals with Type2 Diabetes. Helen Pahau Sr. [1], Leanne Short[2], Brian Haluskas[3], Vibeke Videm[4] and Ranjeny Thomas[5]. [1]The University of Queensland, Woolloongabba, Australia, [2]University of Queensland, Woolloongabba, Australia, [3]the University of Queensland, Woolloongabba, Australia, [4]Department of Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology, and Department of Immunology and Transfusion Medicine, Trondheim University Hospital,, Trondheim, Norway, [5]University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: It is well known that patients with RA or Type 2 diabetes (T2DM) have increased risk of atherosclerosis and CVD. Carotid ultrasound measurement of the intima media thickness is the most commonly used method to validate progression of atherosclerosis. We aim to investigate the characteristics of cardiovascular risk and progression of carotid intima media thickness in individuals with Rheumatoid Arthritis compared to individuals with type2 diabetes.

Methods: Participants with T2DM were recruited from hospital clinics and the community in the same geographic area as RA participants. The participants with T2DM participated in a randomised trial of exercise intervention for 4 weeks and patients with previous CV events were excluded in that study. All participants were subjected to B-Mode ultrasonography of the common carotid artery to measure Carotid intima media thickness, and to undertake a physical assessment, routine laboratory investigations and history of CV risk profile. Average CIMT were measured on individuals with RA and individuals with Type2 diabetes at two time points, separated by a mean of 4.8 and 2.4 years respectively, using carotid duplex scanning and automated software.

Results: The study comprised 290 individuals: 78 with RA and 212 with T2DM. The RA patients were significantly older and had a higher proportion of smokers and previous CV events. The T2DM had higher BMI, diastolic blood pressure (BP) and triglycerides, lower HDL cholesterol and higher statin use.

At baseline, CIMT measurements were similar in the RA and T2DM cohorts at baseline (0.88mm (0.19) vs. 0.86 (0.21) $p=0.80$). Despite a shorter follow-up, 91 % of the T2DM cohort had CIMT at follow-up compared to 54 % of the RA cohort ($p<0.0005$). In a regression model for yearly rate of CIMT change, the only significant variables were diabetes ($p<0.0005$) and ever use of statins ($p=0.01$). Baseline CIMT was not significantly associated with the yearly rate of CIMT change. In a supplementary adjusted logistic regression analysis where the outcome was CIMT progression compared to unchanged or reduced CIMT, the OR for progression in T2DM compared to RA was 11.4 (5.2–25.0). In the RA cohort, DMARD use at baseline was associated with significantly lower CIMT values at follow-up ($p=0.04$).

Conclusion: Diabetes patients have a much higher risk of CIMT progression than RA patients when adjusting for relevant risk factors and baseline CIMT.

Cost-Effectiveness Analysis of HLA-B5801 Genotyping in the Treatment of Gout Patients with Chronic Renal Insufficiency in Korea. Dong-Jin Park[1], Kyung-Eun Lee[1], Sung-Hwan Park[2] and Shin-Seok Lee[1]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: Allopurinol-induced severe cutaneous adverse reactions (SCARs) are relatively rare, but cause high rates of morbidity and mortality. Studies have shown that the HLA-B5801 allele and renal impairment are strongly associated with SCARs. Recent American College of Rheumatology guideline recommends that, prior to treatment with allopurinol, the HLA–B5801 genotype of gout patients at high risk for SCARs, including Korean patients with chronic renal insufficiency, should be determined. However, whether such genotyping is cost-effective is unknown. This study evaluated the cost-effectiveness of HLA-B5801 genotyping for treatment of gout in patients with chronic renal insufficiency in Korea.

Methods: A decision analytic model over a time period of 12 months was employed to compare the cost and outcomes of treatment informed by HLA-B5801 genotyping with that of a conventional treatment strategy using a hypothetical cohort of gout patients with chronic renal insufficiency. Direct medical costs were obtained from real SCAR patients from two tertiary hospitals. Outcomes were measured as a total expected cost and an incremental cost-effectiveness ratio.

Results: In the base model, the total expected cost and probability of continuation of gout treatment without SCARs with the conventional and HLA-B5801 screening strategies were US $1,193 and US $1,055, and 97.8% and 100%, respectively. The result was robust according to sensitivity analyses.

Conclusion: Our model suggests that gout treatment informed by HLA-B5801 genotyping is less costly and more effective than treatment without genotyping, and HLA-B5801 genotyping could considerably reduce the occurrence of allopurinol-induced SCARs and related deaths.

Colchicine and the Risk of Acute Cardiovascular (CV) Events Among Gout Patients: The New York Department of Veterans Affairs Retrospective Cohort Study. Daria B. Crittenden[1], Jessica N. Kimmel[1], Virginia C. Pike[1], Rebecca Boas[1], Daniel Diaz[1], Cilian J. White[1], Michael DeBerardine[2], Grace Kim[1], Pajazit Morina[1], Avni Shah[1], Binita Shah[2], Steven P. Sedlis[3], Jeffrey D. Greenberg[4], Craig T. Tenner[2], Christopher J. Swearingen[5], Svetlana Krasnokutsky Samuels[2], Bruce N. Cronstein[1] and Michael H. Pillinger[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]VA New York Harbor Health Care System, New York, NY, [3]NYU School of Medicine, Division of Cardiology, New York, NY, [4]NYU School of Medicine, New York, NY, [5]University of Arkansas for Medical Sciences, Little Rock, AR.

Background/Purpose: Gout patients are at increased risk for CV disease, possibly owing to chronic inflammation. Colchicine is commonly used in gout, and inhibits inflammatory cell types that are also implicated in atherosclerosis. In a cross-sectional study, we observed an association between colchicine use and decreased myocardial infarction (MI) among gout patients (Crittenden et al, J Rheum 2012). To further assess colchicine's possible effect on CV risk in this population, we performed a retrospective cohort study of gout patients taking or not taking colchicine at the VA NY Harbor Health Care System.

Methods: We identified all active patients with ICD-9 codes for gout or hyperuricemia from 2000-09. Charts were manually screened to confirm gout (based on ACR criteria) and pharmacy records used to identify subjects taking daily colchicine for >30 continuous days (colchicine group). Gout patients who never received colchicine formed the control group. Among the colchicine group, we defined colchicine lapse as any period of colchicine non-use ≥ 2 weeks after medication cessation (to account for drug elimination time). Outcomes included a composite incidence rate of MI+stroke+transient ischemic attack (TIA); individual components of the composite outcome; and C-reactive protein level (CRP; lowest level attained during the period observed).

Results: Of 7,819 potential subjects, 1638 patients met gout criteria. 381 were excluded for <30 days colchicine use, leaving 1257 to be analyzed. 804 colchicine users had 3,630 years of follow-up (2270 years of active use and 1360 years of lapse). 453 patients never used colchicine, with 2,087 years of follow-up. Colchicine users had significantly more hyperlipidemia (60 vs 49%, $p=0.003$), and history of MI (14 vs 9 %, $p=0.01$) and percutaneous intervention (10 vs 6%, $p=0.006$) than controls, as well as higher urate levels (8.5 vs 8.0 mg/dL, $p=0.05$) and allopurinol use rates (23 vs 18%, $p=0.03$). We observed no significant difference between colchicine users and non-users for the composite outcome (control, 0.011 events/subject-year; colchicine, 0.016 events/subject-year, $p=0.23$) or individual component outcomes (adjusted for allopurinol use), but due to a low event rate we were not able to adjust fully for patient risk factors. However, within the colchicine group we observed a significant, 57% reduction in the composite outcome event rate during times of active colchicine use vs lapse (0.012 vs 0.021 events/subject-year, $p=0.04$). When colchicine users were divided into consistent (medication possession ratio ≥ 0.9) vs inconsistent (MPR <0.9) users, consistent

colchicine users had lower CRP levels (0.7 mg/dL) than either never users (2.7 mg/dL) or inconsistent users (1.9 mg/dL) (never vs consistent $p<0.001$, inconsistent vs consistent $p<0.001$), despite higher background CV risk.

Conclusion: Among gout patients prescribed colchicine on an ongoing basis, composite CV event rates were significantly lower during colchicine use vs colchicine lapse, and consistent colchicine use was associated with lower CRP concentrations. Additional studies are underway to clarify the possible benefit of colchicine in reducing acute CV events among gout patients.

Can We Diagnose Acute Gout without Joint Aspiration? Results of a Prospective Study of 112 Patients Presenting with Acute Arthritis.

Pascal Zufferey, Roxana Valcov, Isabelle Fabreguet, Alexandre Dumusc and Alexander So. RHU/CHUV, Lausanne, Switzerland.

Background/Purpose: The gold standard for the diagnosis of acute MSU induced arthritis is crystal identification by microscopy after joint aspiration. Alternative diagnostic tools that have been proposed include joint ultrasonography (US) and a clinical score for gout (Nijmegen Score – NS) that has been validated in a primary care setting. Most US studies have been performed in patients with known gouty arthritis. The primary objective was to compare the performance of US as diagnostic tool with the NS in the diagnosis of suspected acute gouty arthritis, using synovial fluid analysis as a gold standard. The secondary objective was to evaluate whether the performance of NS could be enhanced by combining with US data.

Methods: All consecutive patients who presented with acute arthritis suspected to be of microcrystalline origin between October 2012 and May 2014 were prospectively included. The duration of arthritis symptoms was <10 days. All patients underwent a clinical and an US evaluation of the symptomatic joint as well as of the knees, the ankles and the first MTP joints (multiple joints). Joint aspiration of the symptomatic joint was performed within 24 hours.. US was performed by2 rheumatologists skilled in US who were blinded to the clinical data. The NS was calculated "a posteriori" by a clinician not implicated in the primary evaluation of patients. We applied a cut-off value of > 8 as proposed by the authors of the NS for the diagnosis of gout (1). US diagnosis of gout was evaluated firstly on typical US signs ("Double contour" and or tophi) in the symptomatic joint and secondly on signs of gout in all the other joints.

Results: 117 patients were included. Joint fluid was obtained in 112 patients. MSU crystals were detected in 61 patients (54%), CCP crystals were found in 29 (26%) and no crystals were found in 22 (20%). The mean ($\pm$ SD) NS scores differed significantly between gout 8.8 ($\pm$2.4) and non-gout groups 4.6 ($\pm$2.8) ($p < 0.05$). In CPP patients, the mean NS score was 4.3($\pm$2.3). US signs of gout were found in symptomatic joints of 40 patients, and by multiple joints US, signs of gout were found in 68 patients.

The table describes the sensitivity, the specificity, and the positive predictive value (PPV)of the NS, US and the combination of both US and NS in the diagnosis of gouty arthritis. NS score alone or US of the affected joint alone had moderate sensitivity but reasonable specificity for diagnosis of gout in our cohort. The best diagnostic performance was obtained with either US in multiple joints or the NS + US in the symptomatic joints.

	Clinical score (>8)	USSymptomatic joint	US Multiple joints	Clinical score +US symptomatic joint	Clinical score+US multiple joints
Sensitivity: %	62	60	84	80	90
Specificity %	86	92	78	82	74
PPV%	84	90	84	84	81

Conclusion: The NS score alone or US alone of the affected joints were moderately sensitive in the diagnosis of acute gout, but had good specificity. Combining the NS score with US evaluation of the symptomatic joint enhanced the diagnostic performance but does not replace the need for crystal-identification by microscopy in the diagnosis of acute gouty arthritis.

Performance of Joint Ultrasonography in the Diagnosis of Suspected Acute Crystal Arthritis: Results of a Prospective Study of 112 Patients.

Pascal Zufferey[1], Isabelle Fabreguet[1], Roxana Valcov[1], Alexandre Dumusc[1] and Alexander K. So Sr.[2]. [1]RHU/CHUV, Lausanne, Switzerland, [2]CHUV, Lausanne, Switzerland.

Background/Purpose: The gold standard for diagnosing gout and CCP arthritis is the identification of monosodium urate (MSU) crystals in joint fluid. Ultrasound (US) features of gouty and CPP arthritis have been described (1,2), and the technique has been proposed as a diagnostic tool in acute arthritis. There have been limited studies on the performance of this technique as a diagnostic tool when applied to the setting of acute arthritis.

The primary objective was to determine the performance of ultrasound as a diagnostic tool for CCPD and urate acute crystal arthritis, using crystal identification by microscopy as a gold standard.

Methods: 117 consecutive patients who presented an acute arthritis of <10 days duration of suspected microcrystalline origin between October 2012 and January 2014 were prospectively included in the study. Aspiration of the symptomatic joint was performed and crystals identified by polarizing light microscopy. All patients underwent an US of the symptomatic joint as well as both knees, ankles and 1stMTP joints that was performed by a rheumatologist who was "blinded" to the clinical history within 24 hours of joint aspiration. An "US diagnosis" was made based of the findings in the symptomatic joint as well as the other joints examined by US.

Results: In 112 patients joint fluid was obtained. 53 had MSU, 27 CCPD and 9 had both crystals. No crystals were detected in 23. US signs of gout, CCP or mixed crystal deposition were found in symptomatic joints of 40/38/7 patients respectively, and by multiple joints US, in 68/59/16 patients.

Table 1 describes the sensitivity, the specificity, and the positive predictive value (PPV) and negative predictive values (NPV)

	Gout US Symptomatic joint	Gout US Multiple joints	CCP US symptomatic joint	CCP US multiple joints
Sensitivity : %	60	84	60	81
Specificity %	92	76	80	62
PPV%	92	82	60	52
NPV%	62	77	80	87

The sensitivity of US signs in the symptomatic joint for both gout and CCP is poor. US is more specific for the diagnosis of gout that CCP arthritis (PPV >90% against 60%).

By US of multiple joints, the sensitivity of US for both diagnoses rose significantly but the specificity and the PPV decreased, especially for CCP (PPV52%). In absence of US signs in all the joints, CCP arthritis is highly unlikely (NPV 87%).

Conclusion: In patients with a clinical suspicion of acute microcrystalline arthritis, US examination may be of assistance in the diagnosis if joint aspiration is not feasible. The examination of multiple joints is required to obtain the best clinical utility.

Canakinumab in Frequently Flaring Gouty Arthritis Patients, Contraindicated, Intolerant or Unresponsive to non-Steriodal Anti-Inflammatory drugs and/or Colchicine: Safety and Efficacy Results from Long Term Follow-up.

Naomi Schlesinger[1], Rieke Alten[2], Thomas Bardin[3], H. Ralph Schumacher Jr. [4], Mark Bloch[5], Karine Lheritier[6], Dominik Richard[6], Andrea Stancati[6] and Alexander So[7]. [1]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Charité University Medicine, Berlin, Germany, [3]Hôpital Lariboisière, Paris, France, [4]University of Pennsylvania VA Medical Center, Philadelphia, PA, [5]Holdsworth House Medical Practice, Sydney, Australia, [6]Novartis Pharma AG, Basel, Switzerland, [7]Centre Hospitalier Universitaire Vaudois, University of Lausanne, Lausanne, Switzerland.

Background/Purpose: Frequently flaring acute gouty arthritis (GA) patients (pts), in whom NSAIDs and/or colchicine are contraindicated, not tolerated or ineffective, need effective alternative treatments.[1] Canakinumab

(CAN) is a selective, human anti-interleukin-1β antibody, the only biologic approved (in the European Union) for the treatment of difficult-to-treat GA pts. Here, we present the cumulative results from a single long-term extension of two phase III studies. The primary objective is to evaluate the long-term safety of CAN (s.c.) in GA pts with frequent flares. Frequency of new flares, mean number of doses/pt, pts' assessments of gouty pain intensity and pts' global assessment (PGA) of response (both on Likert scale) were measured as secondary objectives. The effectiveness of CAN enabling successful urate lowering therapy (ULT) was explored by assessing serum uric acid (SUA) level in pts' initiating or modifying their ULT while exposed to CAN.

Methods: GA pts, who completed two multicenter randomized (CAN and triamcinolone acetate [TA]) phase III core and respective randomized extensions (E1) of the same design, rolled over into respective open-label extensions, E2, followed by a single extension phase, E3. In E2 and E3, all pts were treated with CAN 150 mg on demand upon new flare. These treatment groups were analyzed as 'CAN Group' [CG] and 'TA Group' [TG], i.e. all patients who were initially randomized to receive CAN or TA, respectively, and received at least one dose of study drug. Safety was assessed in terms of exposure-adjusted incidence of adverse events (AEs) per 100 patient-years (pyr). Maximum total cumulative duration of the study was 3 years.

Results: Of the 456 pts randomized in core studies, 335 entered the E1s. After E1 completion, 272 pts entered E2s. Following E2 completion, 136 pts entered and 122 completed E3. In CG, the mean number of doses/pt was 2.68 over 3 years. Overall, the exposure adjusted incidence of AEs in CG was lower (264.6/100 pyr) than in TG (308.8/100 pyr). Re-treatment with CAN did not result in any increased incidence of AEs. Overall, the incidence of exposure adjusted SAEs in CG and TG was 17.3 and 17.7 per100 pyr, respectively. The overall incidence of SAEs did not change in pts re-treated with CAN in CG (15.2 vs 15.1 per 100 pyr). Overall 4 deaths (2 in CG, 2 in TG) were reported: 1 intracranial hemorrhage [pt not re-treated with CAN]; 1 pneumonia [pt re-treated with CAN], 1 sudden cardiovascular death and 1 pneumococcal sepsis [TG pt who never received CAN]). None of these deaths were suspected to be study drug related. Thirty percent (n=12) of the pts initiating or modifying ULT during the E3 (n=40) reached target SUA levels (<6mg/mL). Mean flare rate per year was lower in CG compared with TG (1.109 vs 2.459). All CAN-treated pts' maintained pain intensity and PGA response scores upon 'on demand' retreatment over 3 years.

Conclusion: These results support the long-term safety of CAN treatment in pts' with frequent GA flares. AEs in CG were lower than in TG. The safety profile was consistent with that observed in the previous studies. Over the cumulative duration of 3 years, efficacy of CAN was maintained.

All Men with Gout Should be Screened for Erectile Dysfunction. Naomi Schlesinger[1], Diane C. Radvanski[2] and John Kostis[3]. [1]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ.

Background/Purpose: Erectile dysfunction (ED) is common in the general population. The likelihood of ED increases progressively with age; however, it is not an inevitable consequence of aging. The importance of cardiovascular disease (CVD), as an underlying cause of ED is well established. Patients who present with ED have an increased rate of CVD and silent coronary artery disease (CAD). ED and gout share common risk factors such as age, metabolic syndrome, hyperuricemia and inflammation.

Our aim was to determine whether men with gout may have an increased prevalence of ED as compared to men without gout.

Methods: In this cross sectional study, men aged 18–89 presenting to the Rheumatology clinic between 8/26/10 and 5/13/2013, were asked to participate. The presence of ED was determined by filling out a Sexual Health Inventory in Men (SHIM). SHIM scores correlate with ED severity: 22–25 Normal erectile function (no ED); SHIM score $\leq$ 21 ED and a score of $\leq$ 10 denotes severe ED. The patient's history, physical examination and recent laboratory studies were reviewed as well.

Descriptive statistics and subgroup analyses were used to summarize the data. We used chi-square tests for independence to compare categorical variables.

Results: 201 men completed the SHIM questionnaires; 83 had gout. A significantly greater proportion of gout patients had ED (n=63; 76%) compared with patients without gout (n=61; 52 %) (p= 0.0007). A significantly greater proportion of gout patients (43%) had severe ED compared with patients without gout (30%) (p=0.007). The mean SHIM score of all patients was 16.88 (SD$\pm-$0.83). Gout patients had an average SHIM score of 14.38 (SD$\pm$1.01) versus 18.53 (SD$\pm$ 0.964) in patients without gout ($p < 0.0001$). In a multivariate analysis the association between gout and ED remained statistically significant even after adjusting for age (p=0.0009), hypertension, LDL, GFR, obesity, depression (p=0.0154) and diabetes (p=0.0085).

Conclusion: ED is present in most men with gout and is frequently severe. Increasing awareness of the presence of ED in gout patients should in turn lead to earlier medical attention and treatment for this distressing condition as well as evaluation of possible silent CAD. We propose that all men with gout be routinely screened for ED.

Ultrasonographic Measurement of Renal and Carotid Artery Resistive Indices and Diastolic Function of the Heart in Gout Patients. Rada Gancheva[1], Atanas Kundurdjiev[2], Mariana Ivanova[1], Todor Kundurzhiev[3], Rasho Rashkov[1] and Zlatimir Kolarov[1]. [1]University Hospital "St. Iv. Rilski", Clinic of Rheumatology, Sofia, Bulgaria, [2]University Hospital "Alexandrovska", Clinic of Nephrology, Sofia, Bulgaria, [3]Medical University, Faculty of Public Health, Sofia, Bulgaria.

Background/Purpose: Our aim was to assess the impact of gout on kidneys, diastolic function of the heart and carotid arteries. We examined ultrasonographic parameters that reflect resistance and compliance of the vessels and diastolic function of the left ventricle. Renal resistive index (RRI) and common carotid artery resistive index (CCARI) were measured. Diastolic function of the heart was assessed by parameters of the transmitral blood flow: E/A ratio and deceleration time (DT) which depend on preload and may give false negative results (pseudonormalization of mitral blood flow). That is why with the use of tissue doppler Em was determined which does not depend on preload and helps to differentiate normal from pseudonormal mitral blood flow as it decreases progressively with the worsening of diastolic dysfunction.

Methods: A total of 117 patients (pts) were included in the study: Healthy controls without conventional CV risk factors – 37 pts, 18 males and 19 females in a mean age 47.4$\pm$13.8 years, asymptomatic hyperuricemia pts – 24 pts, 13 males and 11 females in a mean age 55.8$\pm$13.5 years and gout pts – 56 pts, 50 males and 6 females in a mean age 57$\pm$11.6 years, 36 of the pts with gout were without tophi and 20 were gouty tophi pts. All pts included in the study underwent a complex multimodal ultrasonography: 1. RRI was measured in both kidneys at the level of interlobar arteries with 3.5MHz transducer working with pulse repetition frequency (PRF) of 2.5MHz. 2. Echocardiography was performed with 2.5MHz transducer Phased Array working with Pulsed doppler frequency of 2.5MHz. 3. Carotid arteries were examined with 10MHz linear transducer working with PRF of 5MHz. Ultrasonographic examinations were performed once by one researcher who was unaware with the protocol of the study. Statistical analyses were done by ANOVA, Post-Hoc Tukey, Kruskal-Wallis and Mann-Whitney tests.

Results: There was no significant difference in serum uric acid levels between asymptomatic hyperuricemia and gout pts (p=0.865). In all examined ultrasonographic parameters there was statistically significant difference between healthy controls and the other groups of pts with $p<0.001$. Comparing parameters between asymptomatic hyperuricemia and gout pts we estimated no significant difference in RRI (p=0.692), E/A (p=0.195), DT (p=0.611), but we observed a tendency of lower Em (mean$\pm$SD, 0.13$\pm$0.17 vs 0.09$\pm$0.03, p=0.084) and higher CCARI (mean$\pm$SD, 0.69$\pm$0.05 vs 0.71$\pm$0.05, p=0.057) in gout pts. Comparing gouty tophi pts to gout pts without tophi we observed that tophi pts had significantly higher RRI (mean$\pm$SD, 0.69$\pm$0.06 vs 0.65$\pm$0.05, p=0.013) and significantly higher CCARI (mean$\pm$SD, 0.74$\pm$0.05 vs 0.70$\pm$0.05, p=0.027). Tophi pts also had significantly lower Em compared to gout pts without tophi (mean$\pm$SD, 0.07$\pm$0.02 vs 0.09$\pm$0.03, p=0.014). We did not estimate a significant

difference in E/A ratio (p=0.233) and DT (p=0.419) between these two groups.

Conclusion: We suggest that with the progression of the disease arteriosclerotic type vessel changes progress and diastolic function of the heart worsens.

Development of Preliminary Remission Criteria for Gout Using Delphi and 1000Minds Consensus Exercises. Hugh de Lautour[1], Nicola Dalbeth[2] and William Taylor[3]. [1]Auckland District Health Broad, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago, Wellington, New Zealand.

Background/Purpose: There are currently no agreed remission criteria for gout. The aim of this study was to establish consensus for elements of potential remission criteria for use in clinical trials of gout.

Methods: Experts in gout from multiple countries (n=88) were invited by email to participate in this web-based questionnaire study to identify remission criteria as an outcome measure for gout clinical trials. For the purposes of this project, remission was defined as the absence of symptoms and signs attributable to gout, when these symptoms or signs can or are expected to return in the future (for example, if the patient stopped treatment). Three rounds of a Delphi consensus exercise were conducted by online survey. Questions focused on domains for inclusion in remission criteria, based on the OMERACT core domains for chronic gout studies. Respondents were then asked to choose which option would indicate remission for each domain. Consensus in the Delphi exercise was defined as >80% agreement in responses. The Delphi exercise was followed by a discrete choice experiment using 1000Minds to further explore the extent of variation in relative weighting for components of remission (particularly the time over which no flares should be observed).

Results: There were 49 respondents (56% response rate). There was consensus about which domains should be included in remission criteria from the Delphi exercise; 98% agreement for serum urate, 96% for flares, 92% tophi, 83% pain due to gout and 93% patient global assessment of gout disease activity (PGA). Consensus was reached that serum urate measurements should be measured at least twice over a set timeframe and that all measurements should be <6mg/dL (94% agreement). There also was consensus that, for both pain and PGA measurements, the results of two separate measurements over a set timeframe would be averaged. There was agreement that timeframes of three months or less were not suitable for measurement of remission. However, consensus was not achieved in the Delphi exercise about the timeframe for remission with equal responses for six months (51%) and one year (49%). In the discrete choice experiment, the range of opinions remained widely distributed, indicating an ongoing lack of consensus between the 6 and 12 month timeframe. The difference in relative weighting accorded to 'no flares observed over 12 months' compared to 'no flares observed over 6 months' ranged from 0.04 to 0.26 (out of a total weighting available of 1.0), with the middle 80% of respondents ranging from 0.04 to 0.24.

Conclusion: These consensus exercises have identified domains for remission criteria for gout, and methods for reporting these domains. Additional analysis is required to determine the relative advantages of a 6 or 12 month timeframe, particularly for the observation of no flare.

Disclosure: H. de Lautour, None; **N. Dalbeth**, None; **W. Taylor**, None.

Is the Rate of Skin Reactions to Febuxostat Increased in Patients with a History of Skin Intolerance to Allopurinol? a Retrospective, Hospital-Based Study Involving 101 Patients Consecutively Treated with Allopurinol and Febuxostat. Thomas Bardin[1], Gérard Chales[2], Tristan Pascart[3], René-Marc Flipo[4], Jean-Claude Roujeau[5], Aurélie Delayen[6] and Pierre Clerson[7]. [1]Hôpital Lariboisière, Paris, France, [2]CHR - Hopital Sud, Rennes, France, [3]Saint-Philibert Hospital, LOMME, France, [4]Rene Salengro hospital, Lille, France, [5]University Paris Est, Créteil, France, [6]Orgamétrie biostatistiques, Roubaix, France, [7]Orgametrie, Roubaix, France.

Background/Purpose: Allopurinol can lead to skin toxicity. Minor skin reactions are reported in 2–4% of patients and life threatening severe cutaneous reactions (SCARs) in 0.1–0.4%. SCARs are more frequent in patients with a history of minor reaction to allopurinol, precluding re-challenge with the drug. Febuxostat is structurally distinct from allopurinol and could be an interesting option in patients who developed skin reaction to allopurinol. However, the frequency of skin reactions to febuxostat has been suggested to be increased in patients with skin intolerance to allopurinol, therefore challenging the value of this option. The aim of our study was to investigate the cutaneous tolerance of febuxostat in gouty patients who had experienced skin intolerance to allopurinol as compared to those who had not.

Methods: We exhaustively identified gouty patients who had sequentially received allopurinol and febuxostat in the Rheumatology departments of 4 French university hospitals and collected data from hospital files using a predefined protocol. Patients who had not visited the prescribing physician at least two months after the initiation of febuxostat were excluded. The odds ratio (OR) for skin reaction to febuxostat in patients who had a cutaneous reaction to allopurinol as compared to those who had not, was calculated. For estimating the 95% confidence interval (CI) we used two methods: Miettinen's method and a bootstrap method. For bootstrapping, 5000 random subsamples having the same size than the study population were drawn with replacement. An OR was calculated for each replicate. The limits of the 95% CI correspond to the antilog of the 2.5^{th} and 97.5^{th} of log(OR) considered as a randomly distributed variable.

Results: The hospital files of 554 gouty patients were examined. 113 had sequentially been treated with allopurinol and febuxostat. Among them 12 did not visit the prescribing physician after the initiation of febuxostat and were excluded from analysis. The analyzed population therefore included 101 patients (86 males, mean age 61±14 years). 22 patients had a history of cutaneous adverse event to allopurinol (16 minor reactions and 6 severe reactions including 2 systemic epidermal necrosis, 1 DRESS, 2 severe drug-induced skin rash and 1 angioedema). 2 (9.1%) of these 22 patients experienced skin reactions to febuxostat (one diffuse rash in a patient with a history of systemic epidermal necrosis and one localised pruritus in a patient who had the same reaction with allopurinol). Among the 79 patients without history of skin reaction to allopurinol, 2 (2.5%) had a minor skin reaction to febuxostat (one localized vesicular eruption and one pruritus). OR was statistically not significant: 3.85 [0.51–29.04] with the Miettinen's method and 3.86 [0.80–18.74] with the bootstrap method. In addition, renal failure did not modify the risk of skin reaction to febuxostat (P=0.97 in univariate analysis and 0.98 in a multivariate model combining renal failure and intolerance to allopurinol).

Conclusion: These results suggest that the risk of skin reaction to febuxostat is moderate and not significantly increased by a history of cutaneous adverse event to allopurinol nor by renal failure.

164

Gouty Patients with History of Adverse Reaction to Allopurinol Are Not at Higher Risk of Reaction to Febuxostat. Thomas Bardin[1], René-Marc Flipo[2], Pascal Richette[3] and Pierre Clerson[4]. [1]Hôpital Lariboisière, Paris, France, [2]Rene Salengro hospital, Lille, France, [3]INSERM 1132, Université Paris-Diderot, Hôpital Lariboisière, Paris, France, [4]Orgametrie, Roubaix, France.

Background/Purpose: Allopurinol is the standard drug for urate-lowering management of gout. Allopurinol is safe in most patients. The most frequent side effects are minor cutaneous reactions, which occur in approximately 2–4 % of patients. Severe, life-threatening cutaneous adverse reactions are observed in 0.1%-0.4% of patients. They include toxic epidermal necrolysis, Steven Johnson syndrome and drug rash with eosinophilia and systemic symptoms (DRESS). They are more frequent in patients with a history of minor reaction to allopurinol, precluding re-challenge with the drug. Febuxostat is a non-purine xanthine oxidase inhibitor which is structurally distinct from allopurinol. Febuxostat is an interesting alternative to allopurinol, especially in patients who do not reach the serum urate target, because of renal impairment or intolerance to allopurinol. The potential for cross reactivity between febuxostat and allopurinol is of obvious clinical importance when assessing treatment alternatives to allopurinol. Skin reactions have been reported in 0.5% to 1.6% of patients treated by febuxostat (Ernst 2009) and have been suspected to be more frequent in patients with previous cutaneous intolerance to allopurinol.

Methods: CACTUS was a non-interventional cross-sectional multicentre study conducted in France by GP from November 2010 to May 2011, with the aim to describe characteristics of gouty patients according to the achieved

urate-level. The study involved 2762 adult gouty patients. Among them 1513 had a history of consecutive treatments with allopurinol and febuxostat and were involved in a post-hoc analysis aiming at answering two questions: 1) Was the risk of adverse reaction to febuxostat increased in patients with prior adverse reactions to allopurinol? 2) If yes what was the magnitude of the risk? History of reaction with allopurinol was cross-tabulated with history of reaction with febuxosat, allowing calculation of the odds ratio as a measure of risk. This post-hoc analysis was initially aimed at assessing skin reaction rates. Details on adverse events were not collected. Assuming that any discontinuation of either allopurinol or febuxostat for adverse event was related to a skin reaction obviously led to overestimate the rate of skin reactions with both treatments, but still gave some insight into the existence of drug cross-reactivity.

Results: Among 92 patients who had a history of adverse event to allopurinol, only one (1.1%) experienced a reaction with febuxostat. Among 1421 patients who had no history of allopurinol adverse event, two (0.1%) experienced a reaction with febuxostat resulting in a non-significant odds ratio of 7.8 [0.7–86.8].

Conclusion: In a post-hoc analysis of the CACTUS study, patients with a history of adverse reaction to allopurinol did not carry significantly higher risk of adverse reaction to febuxostat. Most patients intolerant to allopurinol tolerated febuxostat. Absence of cross-reactivity between allopurinol and febuxostat need to be confirmed by other studies.

Disclosure: T. Bardin, AstraZeneca, Ipsen, Menarini, Novartis, Sobi, 8; **R. M. Flipo**, Ipsen, Menarini, 5; **P. Richette**, None; **P. Clerson**, Ipsen, Menarini, 5.

165

Prevalence of Gout in the Adult Population of France in 2013. Thomas Bardin[1], Pierre Clerson[2], Stéphane Bouée[3], Gerard H. Chales[4], Michael Doherty[5], René-Marc Flipo[6], Charles Lambert[7], Frédéric Lioté[8], Thierry Poireaud[9], Thierry Schaeverbeke[10] and Pascal Richette[11]. [1]Hôpital Lariboisière, Paris, France, [2]Orgametrie, Roubaix, France, [3]Cemka, Bourg la Reine, France, [4]CHR - Hopital Sud, Rennes, France, [5]University of Nottingham, Nottingham, United Kingdom, [6]Rene Salengro hospital, Lille, France, [7]Ipsen, Boulogne Billancourt, France, [8]Hôpital Lariboisière & University Paris Diderot, Paris, France, [9]Menarini, Rungis, France, [10]Bordeaux University Hospital, Bordeaux, France, [11]INSERM 1132, Université Paris-Diderot, Hôpital Lariboisière, Paris, France.

Background/Purpose: The prevalence of gout has been studied in several Western countries by various methods to approach gout diagnosis, and has been estimated to vary from 0.9 to 3.9 %. The prevalence of gout remained unknown in France. The aims of our study was to design a tool that would allow a confident diagnosis of gout in an epidemiological setting and to assess the current prevalence of gout in France.

Methods: This was a two phase study. In phase one, we designed a questionnaire to detect gout that would be suitable for telephone interviews by non-physicians. A 62-item questionnaire covering clinical features, co-morbidities and treatment of gout was administered by phone, by non physicians unaware of the patient diagnoses in a case control study. 102 people with crystal-proven gout and 142 controls who had other types of arthritis with no urate crystal in their synovial fluid were included. Logistic regression analysis and classification and regression trees (CARTs) were used to select items discriminating cases from controls. In phase two, a random sample of adults resident in metropolitan France (including Corsica) was derived from the national telephone (fixed and mobile) directory, using the next birthday method in cases of multiple users. The telephone questionnaire was administered by non-physicians to subjects who acknowledged present or past non traumatic acute pain in a peripheral joint. The target size for the interview survey was 10,000 participants. Statistical analysis took into account several factors (area, size of the urban centre, sex, age, occupation, known distribution of fixed or mobile users).

Results: In phase one, two logistic regression models (sensitivity 88.0% and 87.5%; specificity 93.0% and 89.8%, respectively) and one CART model (sensitivity 81.4%; specificity 93.7%) revealed 11 informative items that allowed correct classification of 90.0%, 88.8% and 88.5% of patients respectively. In the second phase the response rate varied between 34 % (fixed phone sample) and 38 % (mobile sample). 10,026 participants were interviewed between March and June 2013. 373 declared having suffered from acute, non traumatic joint pain, of whom a diagnosis of gout was made in 84 to 102 subjects, according to the algorithm used. This led to an estimated prevalence of gout of 0.9% (95% CI: 0.8, 1.1) in the general population, with no significant geographic variation. Prevalence was greater in men and increased with age. Interestingly prevalence estimate on self declaration only gave a much higher prevalence estimate (3.7%).

Conclusion: Gout prevalence in the adult population of metropolitan France in 2013 was estimated to be 0.9%. Studies using self declaration might grossly overestimate the prevalence of gout.

Risk Factors for Gout Attack Recurrence during Urate-Lowering Allopurinol Treatment. Myeong Jae Yoon[1], Ji Ae Yang[2], Sang Hyun Joo[1], Sang Jin Lee[1], Jin Young Moon[1], Hyun Mi Kwon[1], Dong Jin Ko[1], Yeong Wook Song[1] and Eun Bong Lee[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea.

Background/Purpose: Gout is a recurrent inflammatory arthritis caused by crystal deposition of monosodium urate, which can be prevented urate-lowering agents such as allopurinol. However, gout attack can still recur during urate-lowering therapy. In this study we investigated the risk factors associated with recurrence of gout attacks during allopurinol treatment.

Methods: A total of 527 gout patients were enrolled, who took allopurinol at least for 6 months at Rheumatology Clinic of Seoul National University Hospital between March 2001 and March 2013. The patients were divided into those who have ever experienced recurrence of gout attack (recurrence group) and those who haven't (non-recurrence group) during allopurinol treatment. To reveal the risk factors for gout recurrence, we compared baseline deomographic characteristics, concomitant diseases, uric acid level, creatinine level, presence of tophi, type of prophylactic treatment (non-steroidal anti-inflammatory drugs, colchcine, glucocorticoids) and concomitant treatment. Multiple logistic regression analysis was applied to find the best model to explain the recurrence.

Results: The mean (SD) age of the enrolled patients was 58.7 (14.9) years and 96.2% were male. The patients were followed-up for mean (SD) duration of 3.17 (2.64) years. During urate-lowering therapy, 323 patients (61.3%) experienced recurrence of gout attack. In recurrence group, baseline uric acid level was significantly higher than non-recurrence group (8.6 $\pm$ 2.0 vs 8.1 $\pm$ 1.9 mg/dL, p=0.0043 by Student t-test). The presence of tophi was more commonly observed in recurrence group (29.4% vs 18.6%, p=0.006 by chisquare test). The other variables showed no difference between recurrence and non-recurrence groups, which include age, sex, concomitant diseases, the presence of urinary stone, the type of prophylaxis treatment and initial creatinine level. In multivariate logistic regression analysis, high uric acid level (Uric acid $>$ 8.5 mg/dl) and the presence of tophi were found to be risk factors for gout attack during allopurinol treatment (Table 1).

Conclusion: Our study revealed that patients who show uric acid level $>$ 8.5 mg/dL and/or tophi at baseline have higher risk for recurrence of gout attack during allopurinol treatment. Adequate education and closer follow-up will be required for those risky patients when allopurinol is started.

Table 1. Risk factors for recurrence of gout attack during allopurinol treatment, multivariate logistic regression analysis

Clinical variables	Odds ratio	95% confidence interval	P-value
Tophi	1.78	1.16–2.74	0.009
Serum uric acid ^{3}8.5 mg/dL	1.54	1.07–2.21	0.019
Prophylaxis			
NSAID	0.72	0.36–1.44	0.3555
Colchicine	1.03	0.648–1.628	0.911
NSAID+colchicine	2.57	0.897–7.381	0.079
Glucocorticoid	0.82	0.45–1.50	0.522

Target Serum Urate: Do Patients Know Their Goal? Brian W. Coburn[1], Kayli A. Bendlin[2], Harlan Sayles[1], Kathryn S. Hentzen[2], Michaela M. Hrdy[2] and Ted R. Mikuls[1]. [1]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center, Omaha, NE.

Background/Purpose: Treat-to-target approaches are used to achieve therapeutic goals in conditions such as diabetes and rheumatoid arthritis. This strategy has also been widely endorsed in gout using urate lowering therapy (ULT). However, suboptimal rates of serum urate (sUA) goal achievement and ULT dose titration in clinical data indicate that providers are not routinely adopting treat-to-target strategies in gout. According to the Chronic Care Model a viable strategy for improving outcomes may be to directly engage gout patients in their care, an approach that requires patient knowledge of sUA goals. The objective of this study was to examine knowledge of sUA goals among gout patients treated with ULT and to identify factors associated with this knowledge.

Methods: Questionnaires were mailed to 1437 gout patients receiving an allopurinol prescription between August 1, 2011 and July 31, 2012. Of these, 886 (62%) surveys were returned. Patients were asked in a multiple choice format "What is the ideal blood uric acid level to aim for when treating gout?" In addition to sociodemographic, health, and gout-related factors, analysis included Patient Activation Measure (PAM™) scores which quantifies an individual's self-perceived combination of skills, knowledge and confidence necessary to become engaged in their own care (range 0 to 100). A continuous measure, PAM™ scores are categorized into 4 levels from low activation (1) to high activation (4). Associations of factors with knowledge were examined using multivariable logistic regression.

Results: Only 13% of patients correctly identified a sUA goal for ULT (< 6.0 mg/dl); 78% reported that they "didn't know" and 9% chose an incorrect answer (Table 1). This was despite a generally high level of knowledge about gout including its cause (87% correct), cause of acute flares (69%), classic symptoms (93%), use of allopurinol as ULT (83%) and indefinite duration of ULT (69%). Older age and PAM™ score were independently associated with knowing the target sUA. An increase of 15 points was associated with a 32% increase in the odds of knowing goal sUA.

Table 1 Association of Patient Characteristics with Knowledge of Target Serum Urate Among Gout Patients Receiving Urate Lowering Therapy

	Bivariate			Multivariable	
	Knew	Did not know	P	Odds Ratio (95% CI)	P
N = 886	109 (13%)	755 (87%)			
Age, mean (SD)	69.6 (10.3)	72.8 (10.2)	<0.01	0.974 (0.954–0.994)	0.011
Male	108 (99%)	744 (99%)	0.54		
Non-Hispanic Caucasian *	95 (89%)	677 (91%)	0.54		
Married *	63 (59%)	425 (57%)	0.64		
High school graduate *	99 (93%)	661 (88%)	0.12		
Body mass index	32.7 (5.1)	32.2 (6.3)	0.31		
Age at first gout attack	47.4 (15.8)	50.3 (15.4)	0.07		
Serum urate at diagnosis	7.3 (2.0)	7.0 (2.1)	0.16		
Patient activation score (0–100 scale)	62.6 (11.5)	59.4 (11.6)	0.01	1.019 (1.001–1.037)	0.044
Confidence (0–10 scale)†, median (SD)	8.8 (2.0)	8.8 (2.4)	0.32		

Values in bivariate analysis are frequency (%) or mean (±SD) except where noted. * The following variables were dichotomized for analysis: non-Hispanic Caucasian vs. other, currently married vs. not married and high school graduate vs. less than high school graduate. † Composite average confidence in 4 aspects of the treatment plan: discussion of medication, discussion of lifestyle and diet, able to summarize the plan and able to do all the tasks in the plan.

Conclusion: In this population, we observed a lack of knowledge among ULT-treated gout patients about target sUA levels. Younger patients and those demonstrating lower activation were more likely to be deficient in knowledge of their sUA goal. Interventions to improve outcomes among gout patients may benefit from improving activation.

Positive Association Between Tomato Consumption and Serum Urate: Investigating an Anecdotal Trigger of Gout Flares. Tony R. Merriman[1], Nicola Dalbeth[2], Peter B. B. Jones[3], Lisa K. Stamp[4], Murray Cadzow[1], Ruth Topless[1] and Tanya Flynn[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [4]University of Otago, Christchurch, Christchurch, New Zealand.

Background/Purpose: Gout is characterised by intermittent flares of inflammation in response to monosodium urate crystals in the joints. Gout flares can be triggered by dietary factors that raise serum urate. Tomato consumption is an anecdotal trigger of gout flares. This study aimed to measure the frequency of tomato consumption as a self-reported trigger of gout flares in a New Zealand gout sample set, and to use publically available data to test the hypothesis that tomato consumption is associated with levels of serum urate.

Methods: 1324 New Zealand people (of Māori, Pacific Island, European or other ancestry) with clinically ascertained gout were asked about dietary triggers of gout. European individuals from the Atherosclerosis Risk In Communities (ARIC, n=7517), Cardiovascular Health Study (CHS, n=2151) and Framingham Heart Study (FHS, n=3052) were used to test for association between serum urate and self-reported tomato intake using two models. Model 1 was adjusted for age, BMI, average calorie intake (kcal/day), principal components analysis vectors 1 and 2 from genome-wide genotype data and model 2 additionally adjusted for meat, seafood/fish, sugar sweetened soft drinks/juices, dairy products, coffee, vitamin C and alcohol consumption.

Results: At least one dietary trigger was reported by 970/1324 (73.3%) of the New Zealand participants with gout. Tomatoes as a dietary trigger was mentioned by 178/970 (18%) participants, making this the 4th most commonly reported dietary trigger in New Zealand men and women. Seafood or fish (634/970; 65%), alcohol (501/970; 52%) and red meat (374/970; 39%) were more frequently reported than tomatoes. In the analysis of the ARIC, CHS and FHS datasets, there was association between tomato intake and serum urate levels (β=0.66 μmolL^{-1} per weekly serving; P=0.006), which was evident in both men and women (Table; Model 1). This association was also maintained after adjustment for consumption of all other urate associated dietary exposures (all: β=0.66 μmolL^{-1}, P=0.008) (Table; Model 2).

Conclusion: Tomatoes are a common self-reported trigger of gout flares. Whilst our descriptive and observational data are unable to support the claim that tomato consumption is a trigger of gout attacks, the positive association between tomato consumption and serum urate levels suggests that the self-reporting of tomatoes as a dietary trigger by people with gout has a biological basis.

Is Gout a Coronary Heart Disease Risk Equivalent, Similar to Diabetes? Jasvinder A. Singh[1], Rekha Ramachandaran[2], Jie Zhang[3], Fenglong Xie[2], Shuo Yang[2], Huifeng Yun[4] and Jeffrey R. Curtis[2]. [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Univ. of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background/Purpose: Diabetes is a well-recognized risk factor for heart disease, increasing the risk of heart disease by 2–3 fold in many studies. Recent ACC/AHA lipid guidelines have a different pathway for diabetes

patients. Gout has been shown to be a risk factor for myocardial infarction and stroke in some cohort studies. It is not known whether gout is as strong a risk factor for acute myocardial infarction as diabetes, a question we attempted to answer with the current study. We compared the incidence of hospitalized acute myocardial infarction (MI) between patients with DM and or RA.

Methods: We used claims data from 2006 to 2010 that included a mix of private and public health plans with medical and pharmacy coverage. Four mutually exclusive cohorts were identified: 1) Gout and DM; 2) Gout only; 3) DM only; and 4) neither gout nor diabetes. Patients with prior CHD during a baseline period of ≥ 1 year were excluded using relevant diagnosis codes. Outcomes were defined as at least one overnight stay, unless the patient died, plus the presence of ≥ 1 inpatient hospital claim with a discharge ICD-9 code 410.x1 in any position for Acute MI or presence of ICD-9 code for stroke (430.XX, 431.xx, 433.x1(433.01, 433.11, 433.21, 433.31, 433.81, 433.91), 434 (434.01, 434.11, 434.91,excluding 434.x0), 436.XX) in any position. We compared the age- and gender-specific incidence of acute MI and stroke rates across the four cohorts. We assessed univariate and multivariable-adjusted hazard rates of acute MI and stroke.

Results: A total of 298,929 patients had diabetes, 91999 had gout, 37573 had both and 1,099,373 had neither. Compared to patients with neither, those with gout or DM or both were older. Incidence of acute MI was lowest in patients with neither, followed by patients with gout, diabetes and both –e.g. in men, respective rates/1000 person-years were 0.0138, 0.0271, 0.0291 and 0.0475. Similar trend were noted for stroke. In unadjusted analyses, both gout and DM increased the risk of acute MI and stroke by a similar magnitude (**Table 1**). In multivariable-adjusted analyses, gout was associated with significantly lower risk of acute MI than diabetes, but no significant differences were noted between gout and DM for the risk of stroke (**Table 1**). Patients with both gout and DM had 1.26 and 1.29-times higher hazard of acute MI and stroke, compared to patients with diabetes only (**Table 1**).

Conclusion: Gout increases the risk of incident MI significantly but does not appear to be a CHD risk equivalent comparable to DM for incident MI. Gout is a CHD risk equivalent comparable to DM for stroke. Having both gout and DM confers incremental risk compared to DM alone for both MI and stroke.

Table 1. Unadjusted and multivariable-adjusted hazards of MI and stroke with gout and diabetes

Increased Risk of Skin Reactions with Gout Medications: An Analysis of VA Databases. Jasvinder A Singh[1], Shuo Yang[2] and Jeff Foster[3]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Dermatologic side effects to use of gout treatments are concerning to patients. The goal of the study was to assess the risk of occurrence of Drug Rash with Eosinophilia and Systemic Symptoms (**DRESS**) with gout medications.

Methods: This retrospective study utilized the Veterans Affairs (VA) administrative and clinical databases from fiscal year 2001 to 2012. Patients with considered to have prevalent gout based on the presence of >=1 International classification of diseases, ninth revision (ICD-9) codes for gout during an inpatient visit or during [3]2 codes during outpatient visits. We defined exposure to allopurinol, febuxostat, colchicine as at least 30-day filled prescription; since pegloticase is given as a set of infusions, exposure was defined 1 or more infusion. Control population included patients not exposed to any of the four medications, i.e., Urate-lowering therapies (ULT) including Xanthine oxidase inhibitors (allopurinol, febuxostat) and pegloticase or anti-inflammatory medication, colchicine. DRESS was defined as the 1st presence of a code 995.27 in either inpatient or outpatient encounter, that occurred on or after filling the index prescription. Each patient contributed to exposed and non-exposed periods. Switching from one ULT to another led to censoring the patient from contributing to that medication and beginning to contribute the person-time to the current/new ULT. ULT and colchicine did not censor each other, since both can be used together. We used Cox proportional hazards models that assessed hazards of DRESS adjusted for the following factors: Model 1: drug exposure, age, gender, body mass index, race, marital status, region; Model 2: variables in model 1, plus baseline Charlson comorbidities.

Results: There was 198839/220184.7 patients/PYs exposed to allopurinol, 3116/2093.7 patients/PYs to febuxostat; 30/10.2 patients/PYs to pegloticase and 150623/144225.4 patients/PYs to colchicine.

In the multivariable-adjusted Cox proportional hazards model that adjusted for demographics (Model 1), compared to controls allopurinol, febuxostat, colchicine and pegloticase were each associated with statistically significantly higher risk of DRESS (**Table 1**). Results were similar when models were additionally adjusted for comorbidity (Model 2).

Conclusion: Allopurinol and colchicine were associated with a 2-fold increase in hazards of DRESS. With much smaller numbers, pegloticase was associated with dramatic increase in the risk. Febuxostat did not reach statistical significance for increased risk of DRESS in full model, although the odds were similar to allopurinol and it was significantly associated with the risk of DRESS in smaller model. More research is needed to define the risk factors for these reactions with gout medications to allow a more judicious and safer use in high-risk populations.

Table 1. Risk of DRESS with gout medications

	Model 1 (demographics) Hazard ratio (95% CI)	p-value	Model 2 (demographics + comorbidity) Hazard ratio (95% CI)	p-value
Allopurinol	1.97 (1.65, 2.36)	<0.0001	1.86 (1.55, 2.24)	<0.0001
Febuxostat	2.54 (1.04, 6.16)	0.04	2.17 (0.90, 5.26)	0.086
Pegloticase	141 (32, 613)	<0.0001	105 (23.2, 474)	<0.0001
Colchicine	2.08 (1.69, 2.55)	<0.0001	1.89 (1.53, 2.33)	<0.0001

High-Protein Diet (Atkins Diet) and Uric Acid Response. Na Lu[1], Iris Shai[2], Yuqing Zhang[1], Gary Curhan[3] and Hyon Choi[3]. [1]Boston University School of Medicine, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Harvard Medical School, Boston, MA.

Background/Purpose: The conventional low-purine dietary approach to gout offers limited efficacy, palatability, and sustainability, and promotes increased consumption of refined carbohydrates and saturated fat that can actually worsen gout's cardiovascular (CV)-metabolic comorbidities. In contrast, effective dietary approaches to reduce CV-metabolic conditions (including obesity) could also lower serum uric acid (SUA) levels by lowering adiposity and insulin resistance. Similarly, high-protein, low-carbohydrate diets such as the Atkins diet may lower SUA despite substantial purine loading and ketogenesis. Indeed, a small study (n=13) that employed a high-protein diet with reduced calories found that mean SUA levels decreased from 9.6 to 7.9 mg/dL, with reduced gout attacks over 16 weeks (Ann Rheum Dis 2000). Additional benefits included an improved lipid profile. We investigated the SUA response to the Atkins diet among overweight or obese individuals over a 6 month period.

Methods: Our study population was derived from the Dietary Intervention Randomized Controlled Trial (DIRECT) of overweight or obese participants (BMI ≥ 27). The Atkins diet (i.e., high protein, low-carbohydrate, no calorie restriction) was one of DIRECT's intervention groups and was a focus of the current analysis. We used serum samples at -80°C to compare SUA levels at baseline and 6 months among 74 participants with complete datasets and analyzed the SUA level response as well as lipid profile, weight change, fasting insulin levels, and glucose levels.

Results: The mean age was 51 years and the mean BMI was 31. Most participants (91%) were men. The overall rate of adherence to the diets in DIRECT was > 95% during our 6-month study period. Baseline SUA level was 6.0 mg/dL and the overall SUA change at 6 months was -0.8 mg/dL. This change varied substantially according to baseline characteristics (**Table**), particularly baseline SUA levels. Individuals (N=18) with SUA levels > 7mg/dL (above the saturation point) showed a decrease in mean SUA levels from 7.9 to 5.5 mg/dL (p <.0001). Of the 18, 11 (61%) reached SUA < 6mg/dL (the usual anti-gout SUA therapeutic target) and 6 (33%) reached SUA level < 5mg/dL (the SUA therapeutic target for advanced gout) (**Figure**). Those with obesity and younger individuals (<50 years) tended to have a larger SUA decline. Additional benefits included significant improvements in HDL-cholesterol, total cholesterol/HDL-C ratio, triglyceride levels, and fasting insulin levels (p <.0001).

Conclusion: Our findings suggest that the Atkins diet (i.e., a high protein diet without calorie restriction) can reduce SUA levels despite substantial purine loading. This effect may be more pronounced and clinically meaningful among those with hyperuricemia or obesity. Comparative effectiveness research with other proven CV-metabolic diets would help determine the optimal dietary approach to lower SUA levels.

Overall Analysis	N	Baseline (Mean ± SD)	6-Month Change, Mean (95% CI)	p-value

Sleep Apnea and Risk of Incident Gout: A Population-Based Body-Mass Index Matched Cohort Study. Yuqing Zhang[1], Christine Peloquin[1], Maureen Dubreuil[2], Edward Roddy[3], Na Lu[1], Tuhina Neogi[1] and Hyon Choi[4]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University Medical Center, Boston, MA, [3]Keele University, Keele, United Kingdom, [4]Harvard Medical School, Boston, MA.

Background/Purpose: Sleep apnea is common among obese individuals with comorbidities (up to ~30%), a typical profile of gout patients. Since hypoxia associated with sleep apnea can enhance nucleotide turnover (thereby generating purines, which are metabolized to uric acid), sleep apnea could predispose individuals to gout. Furthermore, previous studies have reported that patients with sleep apnea have a higher prevalence of hyperuricemia. All of these findings suggest that patients with sleep apnea may experience an increased risk of incident gout. We evaluated the risk of developing gout in individuals with incident sleep apnea in a general population context.

Methods: We conducted a matched cohort study in a UK general practice database (The Health Improvement Network, THIN) to test proposed hypothesis. We identified individuals aged 20–89 years with the first diagnosis of sleep apnea from Year 2000 to 2013. For each sleep apnea patient, up to four comparators were selected and matched on sex, age, year of birth, body mass index (BMI) (± 0.5kg/m^2), and year of index date (i.e., year of sleep apnea diagnosis). We excluded subjects with sleep apnea or gout prior to study entry as well as subjects without at least one GP visit within the two years prior to study entry. We identified all cases of incident gout based on diagnosis Read code. We estimated the incidence rates of gout and used a Cox-proportional hazard model to assess the association of sleep apnea and the risk of incident gout, after further adjusting for the number of physician visits, alcohol use, BMI, age, use of aspirin, diuretics and losartan, and chronic renal disease, diabetes, hypertension and ischemic heart disease.

Results: Included in this analysis were 9865 newly diagnosed sleep apnea patients (women: 28%, mean age: 53 years, mean BMI: 33.4 kg/m^2) and 43,598 comparators (women: 28%, mean age: 54 years, mean BMI: 32.2 kg/m^2). Over the follow-up period, 1353 incident gout patients were diagnosed. The incidence rate of gout was higher in sleep apnea patients (7.9/1000 person-years) than in the comparators (6.1/1000 person-years) (Figure). After adjusting for all potential confounders, patients with sleep apnea had a 20% higher risk of developing gout than the comparators (hazard ratio =1.2, 95% CI: 1.0–1.4). The corresponding hazard ratios over 6-months, 1-year, and 2-years were 1.7 (95% CI: 1.1–2.8), 1.6 (95% CI: 1.2–2.1), and 1.4 (95% CI: 1.1–1.7), respectively.

Conclusion: This large general population-based study indicates that sleep apnea is associated with a high risk of incident gout. As sleep apnea is common in patients with a typical profile of gout patients and its associated hypoxia is treatable (e.g., with non-invasive ventilation Continuous Positive Airways Pressure), further clarification of the role of sleep apnea on gout attacks among gout patients could add considerably to effective management of gout.

173

Self-Management Education for Patients with Gout: A Review of Existing Resources. Megan Johnston[1], Gareth Treharne[2], Peter T. Chapman[3] and Lisa K. Stamp[1]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]Christchurch Hospital, Christchurch, New Zealand.

Background/Purpose: Inadequate patient self-management education resources may contribute to poor management and outcomes for gout. Patient education resources need to be easy to read and should provide clear and consistent messages regarding lifestyle, diet, and treatment recommendations for gout patients to implement. The aim of this project was to review existing educational resources for gout patients in order to identify strengths and weaknesses and to compare resources cross-nationally.

Methods: Twenty-four patient education resources for gout were identified: 12 print items and 12 websites. The print items are those given to patients by health professionals in New Zealand or are provided by relevant health

organizations in New Zealand, Australia, the United States, Canada, and the United Kingdom. The top ten websites based on a Google search using the keyword "gout" were included, as well as two interactive websites aimed at gout patient self-management. Resources were assessed for coverage of essential information, ease of reading, and dietary recommendations.

Results: All identified resources provided some information about the nature of gout (e.g. caused by too much uric acid in the body) and lifestyle issues (e.g. body weight, nutrition). However, inconsistent messages were given regarding the relative influence of diet on gout, with some resources suggesting little impact of diet and others implicating diet as a major factor in gout management. There was also discordance in certain dietary recommendations, particularly regarding non-meat proteins such as legumes. 50.0% of the resources identified a target serum urate level but only 29.1% recommended checking serum urate levels. Co-morbidities associated with gout not universally discussed included: kidney problems (87.5%), heart disease (58.3%), and diabetes (41.7%). Resources were largely consistent cross-nationally although some differences were found (see Table 1). New Zealand resources were more likely to mention target serum urate levels and to advise patients to continue taking urate-lowering therapies during acute attacks than American or British resources. Certain dietary recommendations also differed within resources from different countries. 50.0% of the resources were written at a highly complex reading level.

Conclusion: A considerable amount of room for improvement exists in current self-management educational resources for gout patients. Inconsistent messages, lack of information on key topics, and inaccessible writing styles were the primary issues identified. Examining resources developed internationally may provide additional information useful for developing educational resources for gout patients. Further research with gout patients is required to determine the resources that patients perceive as most informative and actionable.

Table 1. Content of Gout Patient Education Resources by Country

Content Category	New Zealand (n = 10)	United States (n = 7)	United Kingdom (n= 4)
	Mean Scores		
Readability†	62.6	65.7	61.4
Reading grade level‡	8.4	8.29	9.0
	Percent of Resources Covering Each Category		
Uric acid	100%	100%	100%
Crystal formation	90%	100%	100%
Long term treatment	100%	86%	50%
Acute treatment	100%	100%	50%

Long Term Safety and Efficacy of Canakinumab Liquid Formulation in Acute Gouty Arthritis Patients: Results from a 36 Week Extension Study. P Sunkureddi[1], E Tóth[2], J. P Brown[3], R Moericke[4], D. Richard[5], K Lheritier[5], A Stancati[5] and A Kivitz[6]. [1]Clear Lake Rheumatology, Nassau Bay, TX, [2]Flór Francis Hospital Rheumatology Department, Kistarcsa, Hungary, [3]CHU de Québec Research Centre and Laval University, Québec, QC, [4]Institut für Präventive Medizin & Klinische Forschung GbR, Magdeburg, Germany, [5]Novartis Pharma AG, Basel, Switzerland, [6]Altoona Center for Clinical Research, Duncansville, PA.

Background/Purpose: Gouty arthritis (GA) patients who experience frequent flares and have comorbidities have limited treatment options. Canakinumab (CAN), a selective, human, anti-interleukin1β monoclonal antibody, has been approved in the European Union for the treatment of difficult-to-treat GA patients. A liquid formulation, presented as pre-filled syringe (CAN-PFS) has been developed to improve upon the lyophilized form (CAN-LYO) that requires reconstitution. Cumulative safety and efficacy results covering a total of 48 weeks are presented.

Methods: GA patients completing the 12 week core study[1] were enrolled in a 36 week open label extension (E1) study. All patients entering E1 received CAN-PFS 150 mg sc on demand upon new GA flare irrespective of assigned treatment during randomization [CAN-PFS, CAN-LYO or triamcinolone acetonide 40 mg (TA)]. The primary objective was to confirm long term safety of CAN-PFS vs TA. Secondary objectives included evaluation of CAN-PFS vs TA and CAN-LYO vs PFS for the time to first new flare over 48 weeks. Long-term safety outcomes and safety upon re-treatment were assessed as exposure-adjusted incidence rate of adverse events (AEs) and serious AEs (SAEs).

Results: Of 397 patients randomized in the core study, 232 (58.4%) entered E1, of which 198 (50%) completed E1. Baseline characteristics were comparable between the treatment groups. The exposure-adjusted incidence of AEs was lower for both CAN-PFS (254.9/100 pyr) and CAN-LYO (224.8/100 pyr) groups when compared with TA (362.7/100 pyr) over the 48 weeks. The exposure-adjusted incidence of AEs in patients randomized to TA was lower after switching to CAN-PFS compared with the incidence prior to switching treatment (218.9/100 vs 319.7/100 pyr, respectively). In patients randomized to TA, the exposure-adjusted incidence rates of infections were similar before and after switching from TA to CAN-PFS (36.5/100 vs 37.2/100 pyr, respectively). The exposure-adjusted incidence of SAEs was 14.7/100, 16.1/100, 15.5/100 pyr in patients randomized to CAN-PFS, CAN-LYO and TA groups, respectively. SAEs increased from 0/100 pyr to 4.1/100 pyr in patients who switched from TA to CAN-PFS. Infections and infestations were the most frequently reported SAE in the CAN-PFS (3.4/100 pyr), CAN-LYO (3.2/100 pyr), TA (0/100 pyr) groups. Over the cumulative duration of 48 weeks, one death (cardiac failure), not suspected to be related to study drug, was reported in a patient randomized to CAN-PFS who was not re-treated over 48 weeks. CAN-PFS treatment significantly delayed time to first new flare vs TA patients with a relative risk reduction of 55% (HR, 0.45; 95% CI, 0.32 to 0.64; $p<0.0001$) over 48 weeks.

Conclusion: These results support the long term safety and efficacy of canakinumab liquid formulation in patients with frequent GA flares compared with a potent long acting corticosteroid, TA. The safety profile of on-demand retreatment was consistent with the one observed in the core study and no new safety signals were observed. Canakinumab significantly reduced the risk of new flares compared to TA.

Efficacy and Safety of Canakinumab in Acute Gouty Arthritis Patients with Chronic Kidney Disease Stage Greater Than or Equal to 3: A Post-Hoc Analysis of 12-Week Data. P Sunkureddi[1], E Tóth[2], J. P Brown[3], A Kivitz[4], A Stancati[5], D. Richard[5], K. Lheritier[5] and R Moericke[6]. [1]Clear Lake Rheumatology, Nassau Bay, TX, [2]Flór Francis Hospital Rheumatology Department, Kistarcsa, Hungary, [3]CHU de Québec Research Centre and Laval University, Québec, QC, [4]Altoona Center for Clinical Research, Duncansville, PA, [5]Novartis Pharma AG, Basel, Switzerland, [6]Institut für Präventive Medizin & Klinische Forschung GbR, Magdeburg, Germany.

Background/Purpose: Chronic kidney disease (CKD) limits the treatment options in acute gouty arthritis (GA) patients due to intolerance and contraindications to available therapies. Efficacy and safety of canakinumab (CAN), a selective, human, anti-IL-1β monoclonal antibody, formulated as a

lyophilized (LYO) powder requiring reconstitution with water vs triamcinolone acetonide (TA) in patients with acute GA was demonstrated in previous phase III trials. Here, we report the efficacy and safety of CAN liquid formulation (CAN-PFS) vs TA in a subgroup of patients with CKD stage ≥3.

Methods: This was a 12-week, multicenter, double-blind, active controlled study. Pts (≥18-≤85 yrs) meeting the ACR 1977 preliminary criteria for acute GA and contraindicated, intolerant or refractory to NSAIDs and/or colchicine, with ≥3 flares in the previous year, were randomized 1:1:1 to receive a single dose of CAN- PFS 150 mg sc or CAN- LYO 150 mg sc or TA 40 mg im and re-dosed "on demand" upon each new flare. Here, we report results from a *post-hoc* analysis of the 12-week data for GA patients with CKD stage ≥3 (estimated Glomerular Filtration Rate (eGFR) <60ml/min). The primary endpoint was pain intensity in the target joint, measured on 0–100 mm VAS scale at 72 h. Secondary endpoints included time to first new flare, and safety over 12 weeks.

Results: Of 388 patients, 76 had CKD stage ≥3 at baseline (CAN-PFS, n=24; CAN-LYO, n=28; TA, n=24). CAN-PFS provided a statistically significant reduction in pain intensity in the target joint vs TA from 72h post dose (estimated difference, -14.6mm; 95% CI:−29.0,-0.1, p≤0.05) until 7 days post dose (−16.1mm; 95% CI: -28.4, -3.7, p=0.0115). The two CAN treatment arms were comparable. Over 12 weeks, a single dose of CAN-PFS showed a significant relative risk reduction of 90% for time to first new gout flare vs TA [HR 0.10, 95% CI (0.01, 0.78); p≤0.05]. Adverse events (AEs) were reported in 12 (50%), 11 (39.3%) and 10 (41.7%) patients in CAN-PFS, CAN-LYO and TA groups, respectively. The most frequent AEs were infections (CAN-PFS, n=3 (12.5%); CAN-LYO, n=6 (21.4%); TA, n=2 (8.3%). Serious AEs were reported in a total of 7 patients (CAN-PFS, n=2 (8.3%); CAN-LYO, n=4 (14.3%); TA, n=1 (4.2%), with infections (CAN-PFS, n=1 (4.2%); CAN-LYO, n=2 (7.1%); TA, n=0), being the most common SAEs. No deaths were reported during the study.

Conclusion: This post-hoc analysis provides evidence for the efficacy of CAN-PFS compared with a potent long-acting corticosteroid in providing significant pain relief and reducing incidence of new flares in gouty arthritis patients with CKD stage ≥3 with limited treatment options. The safety profile in this sub-population was consistent with that of the overall study population and with that known from previous studies.

Comparative Cardiovascular (CV) Risk and Outcomes Among Patients with Gout, Osteoarthritis (OA), or Both. Svetlana Krasnokutsky[1], Robert T. Keenan[2], Laura Schneck[1], Craig Tenner[3], Helene Strauss[3], Daria Crittenden[4], Aaron Lehmann[1] and Michael H. Pillinger[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]Duke University, Durham, NC, [3]NYU School of Medicine, New York, NY, [4]Amgen, Thousand Oaks, CA.

Background/Purpose: Gout is associated with increased CV risk, both dependent on, and independent of traditional CV risk factors. Recent studies suggest that OA, traditionally considered non-inflammatory, may also carry increased CV risk. To date, few studies have directly compared the relative CV risk of individual rheumatologic diseases. We used the VA NY Harbor Health Care System electronic medical record to compare the rates of CV risk factors and prevalence of CV outcomes among patients with gout versus OA, the two most common forms of arthritis in the US. We also determined CV outcome prevalence in patients with both gout and OA concurrently.

Methods: We identified male patients with an active medical record between January 2007 and June 2008 and an ICD-9 code for gout. We further separated the cohort into gout patients who did (gout+OA), or did not (gout-only) have a concurrent ICD-9 code for OA. Additionally, we identified patients with diagnostic codes for OA but no gout (OA-only). For each group we collected demographics, diagnoses of CV risk factors, and diagnoses of CV events. The primary outcome was a composite index (CV4) consisting of any diagnosis of MI, angina, CABG surgery, and/or CAD. Secondary outcomes included the individual diagnoses within the CV4, as well as CHF and death (all causes). One-way ANOVA with Tukey post-hoc comparisons were used to test for differences between groups.

Results: 1280 subjects had an ICD-9 diagnosis of gout. Of these, 297 had gout+OA, and 983 had gout-only. We further identified 1231 OA-only subjects. Gout+OA, gout-only, and OA-only subjects were similar in age and ethnicity. Gout subjects, with or without OA, had higher baseline rates of CV risk factors including HTN, HLD, and chronic kidney disease (p<0.0001 for each comparison) than OA-only subjects. Gout-only subjects had higher rates of DM vs OA-only subjects (p=0.011). Gout subjects, with or without OA, had higher prevalence rates of CV4 events versus OA-only subjects; individual component outcomes were also more prevalent among the gout subjects with or without OA (Table 1). Gout subjects, with or without OA, had higher rates of CHF and death compared with OA-only patients. Gout+OA subjects demonstrated non-significant trends towards increased CV4, CAD, CHF and death vs. gout-only subjects. Patients with gout+OA, but not gout-only, had increased rates of death compared to OA alone.

Conclusion: Adverse CV outcomes occur more commonly among gout patients compared with patients with OA only, at least partly due to greater prevalence of traditional risk factors. We also observed non-significant trends towards increased risk of some CV outcomes (CV4, CAD, CHF, death) in patients with both gout+OA compared to patients with gout-only, and only gout+OA patients had increased mortality compared to OA alone. Larger sample sizes may clarify whether there is an additive effect of gout and OA on CV outcomes.

Table 1 1" endpoint: composite of CV outcomes (CV4)
2" endpoints: CABG, MI, Angina, CAD CHF, Death

	Group 1 OA-only (n = 1231)	Group 2 Gout-only (n = 983)	Group 3 Gout + OA (n = 297)	Significance, ANOVA
Composite Endpoint	23.7	28.2	30.3	p = 0.047 for groups 1 vs 2; p = 0.054 for groups 1 vs 3
CABG, %	1.6	4.3	3.0	p<0.0001 for groups 1 vs 2
MI, %	1.9	2.2	2.0	NS
Angina, %	0.6	3.5	3.0	p<0.0001 for groups 1 vs 2; p = 0.024 for 1 vs 3
CAD, %	22.7	25.0	29.6	p = 0.003 for groups 1 vs 2; p = 0.041 for 1 vs 3
CHF, %	4.6	10.8	12.1	p<0.0001 for groups 1 vs 2 and 1 vs 3
Death, %	2.4	4.0	6.4	NS for groups 1 vs 2; p = 0.003 for 1 vs 3

Increase in Thyroid Stimulating Hormone (TSH) Levels in Patients with Gout Treated with Inhibitors of Xanthine-Oxido-Reductase. Fernando Perez-Ruiz[1], Ana M. Herrero-Beites[1], M. Angeles Aniel-Quiroga[2] and Sandra P Chinchilla[2]. [1]BioCruces Health Research Institute, Baracaldo, Spain, [2]Hospital Universitario Cruces, Baracaldo, Spain.

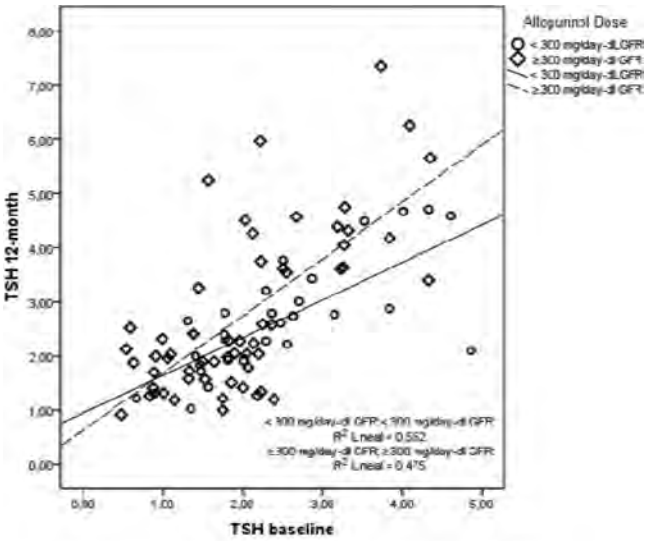
Background/Purpose: Increase in thyroid stimulating hormone (TSH) levels over upper normal limit has been reported in a small percentage of patients treated with febuxostat, but a mechanistic explanation is not yet available.

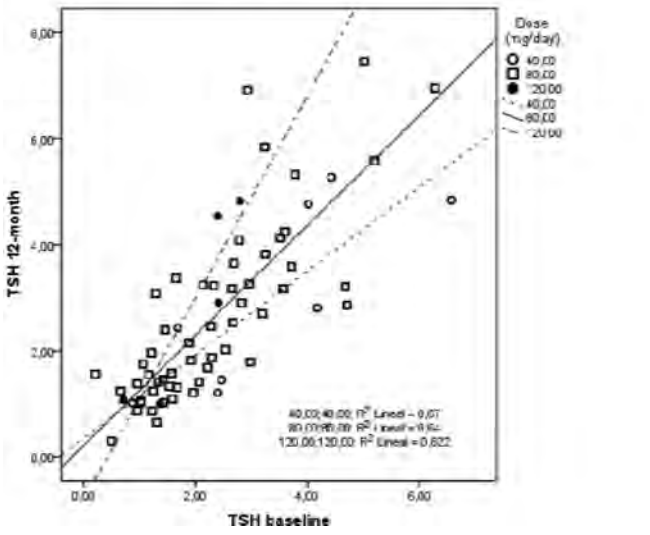
Methods: In a case-control design study, we tested TSH levels in patients with gout at baseline with that every 6-month during follow-up during treatment with febuxostat. Patients to be started allopurinol and an available measurement of TSH 6 months prior to baseline evaluation were used as controls, a follow-up TSH level being measured at 12-month follow-up. Patients with abnormal TSH levels or previous thyroid disease were not included.

Results: Eighty-eight patients treated with febuxostat and 87 with allopurinol were available for comparison. Patients with febuxostat had more severe hyperuricemia and gout, renal impairment, and previous treatment, but were similar in other characteristics. A similar increase in TSH levels was observed in both groups (0.4 and 0.5 μUI/mL for febuxostat and allopurinol, respectively). At 12-mo, 7/88 (7.9%) of patients on febuxostat and 4/87 (3.4%) of patients on allopurinol showed TSH levels over 5.5 μUI/mL, but the upper quartiles for baseline TSH distribution were higher in patients on febuxostat (Table). Doses prescribed (corrected for estimated glomerular filtration rate in patients on allopurinol) and baseline TSH levels were determinants of TSH levels at 12-month follow-up (Figures). No impact on clinical status or free T4 levels was observed in patients with TSH levels over the normal limit.

Table. TSH levels at baseline evaluation and 12-month follow-up. Doses for allopurinol are shown as prescribed and corrected per dL of estimated glomerular filtration rate

Allopurinol Dose	Baseline TSH (μUI/ml)	12-mo TSH (μUI/ml)	p
≤ 300 mg/d (N=81)	2.1±1.0	2.7±1.3	0.000
>300 mg/d (N=6)	2.3±1.3	2.4±1.7	0.760
≤ 300 mg/d-dL EGFR (N=29)	2.5±1.0	2.8±1.0	0.079
> 300 mg/d-dL EGFR (N=58)	2.0±0.9	2.7±1.5	0.000
Febuxostat Dose			
40 mg/d (N= 10)	3.3±1.8	3.0±1.7	0.381
80 mg/d (N= 73)	2.3±1.3	2.6±1.7	0.033
120 mg/d (N=5)	2.0±0.9	2.9±1.8	0.032





Conclusion: both allopurinol and febuxostat increase TSH levels in a dose-dependent, with no apparent impact on free T4 levels, suggesting a class (xanthine-oxidase inhibition) effect with no apparent impact on free T4 levels.

The Effect of Initiating Pharmacologic Insulin on Serum Uric Acid Levels in Patients with Diabetes. Lindsey MacFarlane[1], Chih-Chin Liu[2] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA.

Background/Purpose: Substantial evidence links gout and hyperuricemia to diabetes. Previous studies report an association between increasing uric acid (UA) levels, insulin resistance, and type 2 diabetes (T2DM). Elevation in serum insulin is purported to increased serum UA levels through increased renal urate absorption. This study sought to evaluate the effect of initiating insulin for T2DM on serum UA levels.

Methods: We conducted a retrospective analysis on patients with both T2DM and gout. Patients were selected from a linked dataset from an electronic medical record (EMR) and Medicare claims data. This data set includes patients at one academic medical center with diagnoses of gout and hyperuricemia as confirmed in the EMR who also had T2DM (defined as hemoglobin A1c (HbA1c) > 6.5%, ICD-9-CM code 250.x or use of diabetic medications). An insulin-initiating cohort and a non insulin-initiating cohort were compared for changes in UA. Cohorts were matched on sex, age at first UA measurement, and length of time between UA measurements. The first UA measurement occurred before insulin initiation and the second at least 3 months later; matched time points were used in the non-initiators.

Potential cofounders including HbA1c, creatinine, body mass index, length of time between UA measurements and medications (allopurinol, hydrochlorothiazide, losartan, tacrolimus, cyclosporine) were adjusted for in a series of linear regression models.

Results: 23 patients met criteria for insulin initiation and 23 were matched non-insulin initiators. Mean age was 59 and 57 years for the insulin and non-insulin cohorts, respectively, both cohorts were 52% female. Patients initiating insulin had a larger increase in mean UA levels, 6.41mg/dl to 7.66mg/dl (mean change 1.25 mg/dl, interquartile range, IQR: -0.7,2.3) compared to non-insulin initiators, mean increase from 6.17mg/dl to 6.23mg/dl (mean change 0.06 mg/dl, IQR: -1.1,0.9 p = 0.06). Of the covariates, only length of time between UA measurements had an unadjusted p-value < 0.05 and was advanced to the final adjusted model. The final linear regression showed that insulin use was associated with a 1.25mg/dl greater increase in UA levels when compared to non-insulin initiators (p value = 0.02). Adjusting for allopurinol did not attenuate results. (Table)

Conclusion: Insulin initiation in patients with T2DM was associated with a statistically significant increase in serum UA levels. This may have clinical implications, including risk of gout flares. Gout attack prophylaxis might be useful in the setting of insulin initiation among patients with gout. A prospectively designed study would help overcome potential limitations of our retrospective design.

Table 1 Regression analysis of covariate effects on change in uric acid in insulin initiators

	Model	β	95% CI	P
A	Crude Model: Insulin + UA1	1.29	0.15, 2.44	**0.03**

Effect of Allopurinol on All-Cause Mortality in Adults with Incident Gout: Propensity Score Matched Landmark Analysis. Chang-Fu Kuo[1], Matthew J. Grainge[2], Christian Mallen[3], Weiya Zhang[2] and Michael Doherty[2]. [1]Chang Gung Memorial Hospital, Taipei, Taiwan, [2]University of Nottingham, Nottingham, United Kingdom, [3]Keele University, Keele, United Kingdom.

Background/Purpose: Although current guidelines recommend allopurinol as a first-line urate-lowering treatment for gout patients, whether the balance of potential benefits and risks can translate to any influence on survival in gout patients remains unclear. The objective of this study was to examine the association between allopurinol use and all-cause mortality for patients with incident gout.

Methods: This study was conducted using the UK Clinical Practice Research Data-link. Patients were included if they were aged 20 years or older, were given first ever gout diagnosis between 1995 and 1999, and had no evidence of gout or prescription for ULT prior to the time of diagnosis. We used propensity score matched landmark analysis to compared incident gout patients who received allopurinol for at least 6 months within exposure window and those did not for all-cause mortality.

Results: Of 23,332 incident gout patient identified, the propensity-matched cohorts contained 1,016 patients exposed to allopurinol on the date one year from diagnosis (landmark date) and 1,016 allopurinol non-users. They were significantly older and had more comorbidity and multiple medications than the overall incident gout patients. Over a median follow-up period of 10 years after the landmark date, there were 437 allopurinol users and 443 allopurinol non-users who died during follow-up. Allopurinol users and non-users had similar risk for all-cause mortality (hazard ratios 0.99; 95% confidence interval. 0.87–1.12). In the three-year landmark analysis, 3,519 allopurinol users (1,280 died) were compared with 3,519 non-users (1,265 died). The hazard ratio for all-cause mortality was 1.01 (95% confidence interval 0.92–1.09).

Conclusion: This propensity score matched landmark analysis in a population of incident gout patients in the UK primary care setting found a neutral effect on the risk of all-cause mortality. Our study provides reassurance for prescription of allopurinol in gout patients early in their disease course to prevent untoward consequences of chronic uncontrolled hyperuricaemia.

180

Analytical Comparison Between Point of Care Uric Acid Testing Meters. Jonathan Paraskos[1], Zsofia Berke[2], Jason Cook[1], Jeffrey N. Miner[3], Martin Braddock[1], Adam Platt[1] and Glen Hughes[1]. [1]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [2]AstraZeneca, Mölndal, Sweden, [3]Ardea Biosciences, Inc., San Diego, CA.

Background/Purpose: Gout is a chronic, painful, debilitating form of arthritis resulting from elevated levels of serum uric acid (SUA), termed hyperuricemia. Hyperuricemia is caused by either overproduction or, more commonly, inadequate excretion of uric acid. Resultant monosodium urate crystal deposition in joints/soft tissue can cause attacks of severe pain, swelling, and inflammation (i.e., flares), as well as the development of tophi. A key goal in gout treatment is achievement of sustained lowering of SUA. A point-of-care (POC) test meter that gives accurate and reliable SUA measurements may have the ability to improve patient care through more frequent testing and improving individualized gout management. Such a device can provide a convenient and rapid measure of a patient's SUA levels to monitor and immediately adjust therapy to achieve SUA targets recommended in international guidelines. In addition, a device for home use could enhance patient disease understanding and may promote treatment compliance.

Methods: Five commercially available uric acid meters were acquired (UASure, Benecheck-Plus, Kernel MultiCheck, EasyTouch-GU, and HumaSens-Plus). All devices were CE marked and approved for European market use only. Analytical performance in all experiments was determined using a single batch of manufacturer test strips. Precision characteristics of each meter were identified by using each device to measure the same finger prick blood samples using 6 replicates taken from 3 healthy volunteers repeated over 3 consecutive days. Meters identified with a precision coefficient of variation (CV) <17% then had accuracy determined by comparing SUA measurements with a laboratory uricase reference method, as well as the linearity of measurement determined by blood spiking with known UA concentrations. Ease of use observations were also made on each instrument.

Results: Performance of the UASure device was found to be suboptimal from precision and ease-of-use perspectives, due to difficulty experienced in obtaining SUA readings. Ease of operation of a POC meter is essential to ensure successful adoption by patients, and so, this meter was not evaluated further. The Kernel and EasyTouch meters, which in appearance seem to be similar devices, demonstrated CVs of 25.9 and 27.2%, respectively. Due to the high CVs, these 2 meters were discontinued from further evaluation. Both BeneCheck and HumanSens had acceptable precision values across the 54 samples measured (CVs: 9.5 and 11.5%, respectively). In 3 healthy volunteers, the BeneCheck and HumanSens meters gave SUA values that were concordant with the uricase test (mean accuracy of 103% and 107%, respectively) and had averaged spiked blood recoveries across 4 sUA concentrations of 114% and 129%, respectively.

Conclusion: The HumaSens and BeneCheck meters were easy to use and have appropriate analytical characteristics to allow reliable SUA monitoring. These POC uric acid testing meters may help with detection of hyperuricemia, thereby assisting in the assessment of urate lowering therapy effectiveness, achievement of target SUA levels, and potentially preventing complications of hyperuricemia and gout.

181

Adherence to Treatment Recommendations of Gout: A Patient Survey in China. Feng Sheng, Xuejun Zeng and Weigang Fang. Peking Union Medical College Hospital, Beijing, China.

Background/Purpose: The prevalence of gout appeared to be increasing in China as its economy developed rapidly in the past three decades. Though efficacious and affordable treatment of gout was widely available, the disease was not well controlled in many countries of the world including China. Poor adherence to treatment recommendations was one major reason leading to unsatisfactory management. Patients' adherence to medical treatment of gout was reported to be 17–44% in developed countries, but the data were unknown in China.

Methods: A structured survey was carried out by telephone interview in 349 patients recruited from Gout Clinic at Peking Union Medical College Hospital in 2014. They all satisfied the ACR classification criteria for gout, 1977, and had dietary education when their diagnosis was made or confirmed in our clinic as baseline. 271 patients with urate lowering therapy (ULT) indications were also provided with medication recommendations and/or prescriptions according to the ACR and EULAR guidelines. Demographic data and clinical characteristics were collected at baseline. Patients' adherence to dietary and medication recommendations was measured by food frequency questionnaire and proportion of accumulative days of ULT medication consumption, respectively in the survey. Consumption of alcohol (beer, wine, spirit and yellow rice wine), seafood and internal organs less than once a month and limited intake of red meat was defined as dietary adherence, and ULT ≥80% of time since baseline was defined as medication adherence. Multivariable logistic regression models were used to estimate the independent association between patient characteristics and adherence. Patients' explanations for medication non-adherence were also asked.

Results: The dietary and medication adherence were 44.2% and 21.9%, respectively. Older patients (age ≥60), high serum urate levels (>642umol/L) and tophi at baseline were associated with dietary adherence independently. Tophi and chronic kidney disease at baseline were associated with medication adherence independently, but the longer the time between baseline and the survey was, the less proportion of patients were adherent to ULT medication (Table 1). The main reasons patients reported leading to their medication non-adherence included remission after treatment (35.1%), concern of side effects (22.7%), insufficient patient education (9.5%) and adverse events (8.1%).

Conclusion: Patients' adherence to treatment recommendations of gout was poor in China.Older age, high serum urate levels and comorbidity (tophi and chronic kidney disease) at baseline were associated with treatment adherence. As time elapsed, less patients were adherent to ULT medications.

Table 1. Characteristics associated with treatment adherence of gout

Characteristics	Adjusted OR(95%CI)	p
Dietary adherence		
Age		
<30	1 (Ref.)	
30–39	0.44 (0.12–1.57)	0.20

Effect of Urate-Lowering Therapy on Radiographic Changes in Gout Patients. Seulkee Lee, Inyoung Kim, Hyemin Jeong, Jiwon Hwang, Hyungjin Kim, Jaejoon Lee, Hoon-Suk Cha and Eun-mi Koh. Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Background/Purpose: The aim of this study was to investigate the radiographic changes in patients with gout in association with the control of serum uric acid level.

Methods: A retrospective observational study in a single tertiary medical center was performed. Sixty one patients who had at least one erosive change on baseline radiography or tophus on physical examination were included. Follow up radiography was taken at least 5 years apart from baseline radiograph. The primary endpoint was the changes in the radiographic damage scores based on modified Sharp/van der Heijde (mSvH) score in association with the control of serum uric acid level during the study period. Patients were divided by three groups which consist of improved, no change, aggravated patients for subgroup analysis. The changes in the size of soft tissue density in radiograph were also measured.

Results: The mean age was 55±13 years and 60 (98%) patients were male. Disease duration was 11±7 years and mean serum uric acid level was 8.8±1.9 mg/dL at baseline. Follow up duration between two radiographies was 10.8±3.6 years. All patients were receiving urate-lowering therapy. The change in the mean mSvH score between baseline and follow visit was not statistically significant (6.77 vs. 6.69, respectively). The patient number of improved, no change, aggravated groups was 22, 14, and 25 and the baseline plain radiographic damage score was 12.1, 4.85, and 3.7 respectively. As expected, the change in damage scores was positively correlated to AUC of uric acid level ($r = 0.32$, $p=0.01$). The patients with longer disease duration at baseline were more likely to have improvement in the follow up radiograph. ($r = 0.46$, $p=0.004$). In subgroup analysis, only the baseline radiographic damage score was significantly different from each other. In improved group, the change of damage scores was negatively associated with disease duration at baseline ($r = 0.48$, $p = 0.024$).

Conclusion: Our study demonstrated that radiographic damage in gout may be reversible to some extent and that the magnitude of improvement depends on the degree of serum uric acid control.

Musculoskeletal Ultrasound Reveals Calcific Deposition Arthropathy in Seronegative Inflammatory Arthritis Patients. Sheila L. Arvikar[1], Janice Lin[2] and Minna J. Kohler[3]. [1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Massachusetts General Hospital / Harvard Medical School, Boston, MA.

Background/Purpose: Rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) have vastly improved the diagnosis of rheumatoid arthritis (RA), but the diagnosis and management of seronegative RA patients remains a challenge. Musculoskeletal ultrasound (US) can improve the diagnosis of synovitis, and also reveal crystalline deposition potentially contributing to arthritis in a subset of patients.

Methods: We retrospectively reviewed clinical and US characteristics of 26 consecutive seronegative RA patients found to have crystalline deposits by US performed by 1 US-trained rheumatologist over 1 year. Images from 7 age-matched disease controls (4 osteoarthritis (OA), 2 seropositive RA, and 1 seronegative RA) were also reviewed. All images were reviewed by a 2nd rheumatologist.

Results: Typical of RA cohorts, the 26 patients were predominantly female (62%), with a median age of 57. RF and ACPA were by definition negative. Median levels of inflammatory markers were in normal ranges. 62% of the patients met 2010 ACR/EULAR classification criteria for RA. Median symptom duration was 1.4 years, and only 5 patients were receiving disease-modifying antirheumatic drugs (DMARDs) at the time of US. Metacarpophalangeal (MCP) joints were most commonly symptomatic (65%). By X-ray, only 2 patients had chondrocalcinosis, and 1 had erosion.

There was 100% inter-reader agreement of the US images, encompassing 7 anatomic sites (shoulder, elbow, wrist, hand, knee, ankle, and foot). Images in all 26 patients revealed multiple hyperechoic densities consistent with the US appearance of calcium pyrophosphate dihydrate (CPPD) vs. calcium hydroxyapatite crystals, and were not typical of gout. Calcific deposits, in all cases associated with synovitis, were identified in joints, tendons, and/or tendon sheaths. By comparison, control imaging demonstrated few scattered calcifications without synovitis in only 1 OA patient.

Nearly all 26 patients (90%) had calcifications in both joints and tendons. Calcification pattern in joints was most commonly round (79%), followed by punctate (45%), whereas calcification pattern in tendons was more frequently punctate (79%) followed by linear (42%). Over half (58%) of patients had all 3 patterns. Nine (35%) patients had US evidence of bony erosions. There were no effusions amenable to aspiration. Subsequent testing of 10 patients revealed elevated parathyroid hormone levels in 4 patients, a risk factor for CPPD.

Conclusion: Our findings of hyperechoic deposits associated with synovitis on US suggests that crystalline disease, such as CPPD arthropathy, may be an explanation for arthritis in a subset of seronegative RA patients. Although microscopic analysis is the gold standard in diagnosis of crystalline arthropathy, US may be valuable, particularly when X-rays are unrevealing and effusions amenable to aspiration are lacking. Detection of crystals may reveal abnormalities such as hyperparathyroidism, and may affect treatment strategies. Studies with synovial tissue or fluid crystal analysis prospectively evaluating the prevalence of crystal deposition are needed to evaluate the role for US in the screening of seronegative RA patients.

184

Ultrasound Versus X-Rays Versus Synovial Fluid Analysis for the Diagnosis of Calcium Pyrophosphate Dihydrate Deposition Disease: Is It CPPD? Georgios Filippou[1], Antonella Adinolfi[1], Sauro Lorenzini[2], Ilaria Bertoldi[1], Valentina Di Sabatino[1], Valentina Picerno[1], Luca Sconfienza[3], Mauro Galeazzi[1] and Bruno Frediani[1]. [1]University of Siena, Siena, Italy, [2]Rheumatology Unit, Azienda Ospedaliera Universitaria Senese, Siena, Italy, [3]University of Milan, Milan, Italy.

Background/Purpose: The diagnosis of calcium pyrophosphate crystal (CPP) deposition disease (CPPD) is mainly based on the synovial fluid analysis and Xrays. US has demonstrated high sensitivity and specificity values for diagnosing CPPD compared to synovial fluid analysis as the gold standard, but less is known about sensitivity and specificity of synovial fluid analysis itself. Aim of the study is to compare ultrasonography, synovial fluid analysis and X-rays performances in the diagnosis of CPPD using a real gold standard.

Methods: We enrolled in our study all patients waiting to undergo knee replacement surgery due to severe osteoarthritis. Each patient underwent US examination of the knee, focusing on the menisci and the hyaline cartilage, the day prior to surgery, scoring each site according to the presence/absence of CPP as defined previously. The day of the surgery, synovial fluid of the knee (if present) was aspirated by the surgeon. After surgery, the menisci, condyles and the synovial fluid were retrieved and examined microscopically. Synovial fluid analysis was performed on wet preparations. For the meniscus and cartilage microscopic analysis, six samples were collected, either from the surface and from the internal of the structure trying to cover a large part of it. All slides were observed under transmitted light microscopy and by compensated polarised microscopy. A dichotomous score was given for the presence/absence of CPP. US and microscopic analysis were performed by different operators, blind to each other's findings. X-rays of the knees were collected and assessed for the presence of CPPD by a Radiologist expert in musculoskeletal imaging, blind to other findings. Sensitivity and specificity of US, synovial fluid and X-Rays were calculated using microscopic findings of the menisci and cartilage as the gold standard.

Results: We enrolled in the study 42 patients (14 males), mean age of 74 years old (±8.4). All patients underwent US of the knee, synovial fluid was present in 32 patients and X-rays have been collected form 34 patients. 2x2

contingency tables and diagnostic accuracy values for each exam are summarized in table 1.

Count

		Reference Standard positive	Reference Standard negative	Total
US	positive	24	2	26
	negative	1	14	15
Total		25	16	41

Count

		Reference Standard positive	Reference Standard negative	Total
X-Rays	positive	15	1	16
	negative	5	13	18
Total		20	14	34

Count

		Reference Standard positive	Reference Standard negative	Total
Synovial Fluid	positive	14	0	14
	negative	4	14	18
Total		18	14	32

	Sensitivity (CI 95%)	Specificity (CI 95%)	PPV	NPV	Accuracy
US	96% (±0.07)	87% (±0.16)	92%	93%	93%
Xrays	75% (±0.18)	93% (±0.13)	94%	72%	82%
Synovial fluid analysis	77% (±0.19)	100% (0)	100%	78%	88%

Conclusion: US demonstrated higher sensitivity values for identifying CPP deposits in the knee joint than synovial fluid analysis. Specificity values on the other hand were higher for the microscopic analysis as expected. Globally we believe that for its intrinsic characteristics, the non invasive nature, for the high values of both specificity and specificity, and last but not least, for the capability to address differential diagnosis US should be the first exam to be performed when CPPD disease is suspected. As this study demonstrates, the presence of CPP crystals in the synovial fluid, definitely confirms the diagnosis but a negative microscopic exam does not exclude it.

Distribution of Haemochromatosis Arthropathy. High Ankle and Mid Foot Prevalence; A Diagnostic Clue? Patrick Kiely[1] and Alex Richardson[2]. [1]St. Georges Healthcare NHS Trust, London, United Kingdom, [2]St George's Healthcare NHS Trust, London, United Kingdom.

Background/Purpose: Long delays in diagnosis of haemochromatosis are frequent and lead to an adverse affect on hepatic and cardiac outcome. Arthropathy is a highly prevalent and early feature, which could act as a trigger for diagnosis if sufficiently distinctive. We conducted a survey of patients with haemochromatosis to assess the prevalence and distribution of joint symptoms and their relation to the diagnosis.

Methods: A questionnaire was sent to members of the UK Haemochromatosis Society (~1500) in December 2013. Questions assessed how the diagnosis of haemochromatosis was made; symptoms, duration, the prevalence and distribution of affected joints, and the role of a rheumatologist.

Results. Questionnaires were returned by 470 people with haemochromatosis, 97% white, 53% male. The genotype was C282Y homozygous 52%, C282Y/H63D heterozygous 7%, C282Y/wild type heterozygous 5%, unknown 33%. The diagnosis was made at a mean age of 56 years, following family member screening in 20%, well man/woman screening in 23% and as result of symptoms in 57%. At diagnosis the most frequent symptoms attributed to haemochromatosis were fatigue 65% and joint pain 60% (Fig 1), with a mean duration of 8 years (0–65) and mean Ferritin 1752 mg/L. The diagnosis was most frequently made by a GP 38%, Haematologist 24%, Gastroenterologist 21.5% and Rheumatologist 7%.

88% of respondents reported joint pain, stiffness or swelling. Joint symptoms preceded the diagnosis of haemochromatosis by more than 5 years in 47%, by more than 1 year in 78.5% and post dated the diagnosis in 14.5%. The most prevalent areas affected were hand or wrist 66%, ankle or mid foot 49%, and knee 44% (Fig 2). In the hands the prevalence of symptoms was 1st CMC 60%, wrist 52%, MCP 47%, PIP 48%, and DIP joints 41%. No formal arthritic diagnosis was given to 45%, OA 29%, haemochromatosis arthropathy 11.5%. Dupuytrens disease was reported by 13% of men and 8% of women. Venesection was reported to have helped joint symptoms in 5%, made no impact in 20% and in 51% new joints had become affected following de ironing. A negative impact on employment from arthropathy was reported by 21%, with 9% losing their job.

Conclusion: In haemochromatosis, joint symptoms are highly prevalent at diagnosis, with the ankle and mid foot involved in 49%. In addition to MCP joint disease, an osteoarthritis-like presentation at a relatively young age in the hind or mid foot might be a distinguishing feature to prompt investigations leading to an earlier diagnosis.

ACR Poster Session A
Orthopedics, Low Back Pain and Rehabilitation
Sunday, November 16, 2014, 8:30 AM–4:00 PM

186

The Association Between Low Back Pain and Radiographic Features: A Systematic Review with Meta-Analysis. Joachim Raastad[1], Michael Reiman[2], Remy Coeytaux[2], Leila Ledbetter[3] and Adam P. Goode[2]. [1]Bergen University College, Bergen, Norway, [2]Duke University, Durham, NC, [3]Duke University, Durahm, NC.

Background/Purpose: Low back pain (LBP) is a prevalent condition. Plain film radiography is a commonly used imaging technique for this condition. Radiographic features (RF) such as disc space narrowing (DSN), osteophytes, spondylosis, endplate sclerosis, spondylolisthesis and facet joint osteoarthritis have all been debated as potential pain generators in the lumbar spine. The aim of this study is to: 1) determine the association between LBP and lumbar spine RF in both community and occupation-based groups; and 2) to determine if there are differences in these associations between these two groups.

Methods: A systematic electronic search of PubMed, EMBASE, CINAHL and Cochrane was conducted with keywords related to LBP and lumbar spine RFs. The search was restricted from inception of each respective

database to April 2014. Inclusion criteria consisted of observational studies of adults (≥18 years) with and without non-specific LBP. Studies were excluded if they investigated LBP related to infection, malignancy or rheumatologic nature or were conducted in cadavers. Quality assessment was conducted with the Item Bank for Assessment of Risk of Bias and Precision for Observational Studies of Interventions or Exposures. Random effect models were used for all pooled analyses with associations represented by odds ratios (OR) and 95% confidence intervals (95% CI). Statistical heterogeneity was indicated with an I^2 value >50%.

Results: Twenty-eight (22 community-based and 6 occupation-based) studies met the eligibility criteria consisting of 26,107 subjects. A significant, positive association was found between DSN and LBP that did not differ (p=0.22) between community (OR=1.47 ((95% CI 1.36–1.58)) and occupation-based studies (OR=1.76 ((95% CI 1.34 –2.33)). No significant statistical heterogeneity was present in either estimate (I^2=0.0%). A significant association was found between spondylolisthesis and LBP in occupation-based studies (OR=2.21 ((95% CI 1.44 – 3.39)) that differed significantly (p<0.01) from community based studies (OR=1.12 ((95% CI 1.03 – 1.23)). These individual estimates were also homogeneous (I^2<1.0%). The association between other radiographic features was modest (i.e., spondylosis and osteophytes) or non-significant (i.e., endplate sclerosis and facet joint osteoarthritis). Quality of included studies varied with the majority of studies demonstrating good quality.

Conclusion: A significant positive association was found with DSN and LBP that did not differ between community and occupational-based studies. The fact that no differences exist between these two groups may be related to the influence that genetic factors have on disc degeneration. A significant strong association was found between spondylolisthesis and LBP among the occupational group but was weakly associated in the community-based group, supporting spondylolisthesis as a potential unique pain generator in the lumbar spine.

Revision Arthroplasty in Rheumatoid and Osteoarthritis: Does Methotrexate Decrease Radiographic Lucency in RA Patients? Mike Wei[1], Douglas N. Mintz[2], Lisa A. Mandl[2], Arielle Fein[2], Jayme C. Burket[2], Yuo-Yu Lee[2], Wei-Ti Huang[2], Vivian P. Bykerk[2], Mark P. Figgie[2], Edward F. DiCarlo[2], Bruce N. Cronstein[3] and Susan M. Goodman[2]. [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Rheumatoid arthritis (RA) patients have excellent total hip arthroplasty (THA) survival, and methotrexate (MTX), an anti-inflammatory disease modifying drug which may affect bone reabsorption, may play a role. The purpose of this study is to determine the diagnosis leading to revision THA (rTHA) in RA patients and to assess the association of radiographic lucency with MTX use.

Methods: All patients with validated diagnosis of RA in the institution's THA registry undergoing rTHA from May 2007 - February 2011 were eligible. Diagnosis leading to rTHA and medication use was determined by chart review. Osteolysis was evaluated on available radiographs by measuring maximum lucency in each Gruen zone. Differences within RA patients with/without MTX in osteolysis, demographics, and medications were assessed with chi-squared, Fisher's exact tests or Mann-Whitney U tests as appropriate. The error rate for multiple comparisons of lucency in the different Gruen zones was corrected via false discovery rate methods. A secondary analysis was performed to determine differences in diagnoses leading to revision between RA and matched OA controls (2:1 match by sex age +/− 5 years). OA exclusion criteria included presence of rheumatic diseases, use of MTX, and lack of records.

Results: 51 RA rTHA were identified and compared with 103 OA **(Table 1).** Mean age for RA was 57.7 v 59.4 years for OA (p = 0.240). 82.4% RA were female v 83.5% OA (p = 0.859). RA had lower BMI than OA (25.5 v 28.2; p = 0.166). There was no difference in diagnosis leading to rTHA, including infection (RA 3.9 v OA 6.8%; p = 0.719) or dislocation (RA 23.5 v OA 23.3%; p = 0.975). There was no significant difference in the length of time the implant was in before revision: RA 11.0 v OA 8.8 years (p = 0.060). Among RA with/without MTX, **(Table 2)** there was no difference in use of biologics (30.0 v 43.3%, p = 0.283), steroids (47.6 v 50.0%, p = 0.867) or bisphosphonates (23.8 v 33.3%, p = 0.543). There was no difference in rTHA diagnosis with/without MTX, including loosening (52.4 v 56.7%, p = 0.762). There was no significant difference in lucencies with MTX use in any Gruen zone. Patients with MTX had femoral stem subsidence of 3.7mm v no subsidence without MTX (p = 0.006).

Conclusion: There was no difference in the diagnosis leading to rTHR in RA and OA, although RA trended longer prior to rTHA. In this small retrospective study, there were no significant differences associated with MTX exposure or radiographic lucency among RA patients. The significance of subsidence is not clear. Further study of arthroplasty survival in RA patients is warranted.

Time Trends in Total Ankle Arthroplasty in the U.S.: A Study of the Nationwide Inpatient Sample. Jasvinder Singh and Rekha Ramachandaran. University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To assess the time-trends in utilization, clinical characteristics and outcomes of patients undergoing total ankle arthroplasty (TAA) in the U.S.

Methods: We used the Nationwide Inpatient Sample (NIS) data from 1998 to 2010 to examine time-trends in the utilization rates of TAA. We used the Cochran Armitage test for trend to assess time-trends across the years and the analysis of variance (ANOVA), Wilcoxon test or chi-squared test (as appropriate) to compare the first (1998–2000) and the last time periods (2009-10).

Results: TAA utilization rate increased significant from 1998 to 2010: 0.13 to 0.84 per 100,000 overall, 0.14 to 0.88 per 100,000 in females and from 0.11 to 0.81 per 100,000 in males ($p<0.0001$ for each comparison for time-trends). Compared to the 1998–2000, those undergoing TAA in 2009-10: were older (41% fewer patients <50 years, $p<0.0001$); less likely to have RA as the underlying diagnosis (55% fewer patients, $p=0.0001$); more likely to have Deyo-Charlson index of two or more (197% more, $p=0.0010$); and had a shorter length of stay at 2.5 days (17% reduction, $p<0.0001$). Mortality was rare, ranging 0 to 0.6% and discharge to inpatient facility ranged 12.6–14.1%; we noted no significant time-trends in either ($p>0.05$).

Conclusion: The utilization rate of TAA increased rapidly in the U.S. from 1998 to 2010, but post-arthroplasty mortality rate was stable. Underlying diagnosis and medical comorbidity changed over time and both can impact outcomes after TAA. Further studies should examine how the outcomes and complications of TAA have evolved over time.

Sex Differences in Characteristics, Utilization and Outcomes of Patient Undergoing Total Elbow Arthroplasty: A Study of the U.S. Nationwide Inpatient Sample. Jasvinder A Singh[1] and Rekha Ramachandaran[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To compare patient characteristics, utilization rates and outcomes after total elbow arthroplasty (TEA) by sex.

Methods: We used the nationwide Inpatient Sample from 1998–2011 to study sex-related time-trends in patient characteristics, comorbidity and outcomes after TEA. We used chi-square test, analysis of variance and the Cohran-Armitage test to assess differences in utilization rates and characteristics over time by sex and logistic regression to compare mortality, discharge disposition and the length of hospital stay.

Results: Overall TEA utilization increased significantly from 0.45 in 1998 to 0.96 per 100,000 in 2011 ($p<0.0001$). The utilization rates were significantly higher in females compared to males throughout the study period: 0.62 vs. 0.29 in 1998 ($p<0.0001$) and 1.31 vs. 0.70 in 2011 ($p<0.0001$). Compared to males, females undergoing TEA were more likely to be White (79.7% vs. 71.4%; $p<0.0001$), have rheumatoid arthritis (16.7% vs. 8.1%; $p<0.0001$) and have Deyo-Charlson index of 2 or more (11.3% vs. 5.9%; $p<0.0001$) and were older (63.5 vs. 51.4 years; $p<0.0001$). Compared to males undergoing TEA, females had significantly lower mortality, 0.1% vs. 0.4% ($p=0.03$); lower proportion were discharged to home, 81.9% vs. 89.6% ($p<0.0001$) and fewer has index hospital stay above the median, 30.0% vs. 33.0% ($p=0.01$); most differences were significant after multivariable adjustment.

Conclusion: TEA utilization in the U.S. more than doubled in the last 14 years, with rates higher in females than males. Females had better outcomes after TEA than men. Preoperative risk communication should be sex-specific based on these data.

Hospital Volume Predicts Outcomes and Complications after Total Shoulder Arthroplasty. Jasvinder A Singh[1] and Rekha Ramachandaran[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To assess the association of hospital procedure volume for total shoulder arthroplasty (TSA) with patient outcomes and complications.

Methods: We used the Nationwide Inpatient Sample (NIS) from 1998–2011 to study the association of hospital annual TSA procedure volume with patient characteristics and TSA outcomes, including discharge disposition (home vs. inpatient facility), length of index hospitalization, post-arthroplasty periprosthetic fracture and revision. Annual hospital TSA volume was categorized as <5, 5–9, 10–14, 15–24 and ≥25 TSA procedures annually.

Results: Patients receiving TSA at higher volume hospitals were more likely to be female ($p<0.0001$), of White race ($p<0.0001$). Compared to low volume hospitals (<5, 5–9, 10–14 procedures annually), patients receiving TSA at higher volume hospitals (15–24, ≥25) had significantly lower likelihood of: (1) being discharged to an inpatient medical facility, 16.5%, 13.4%, 13.0%, 12.7% and 11.5% ($p<0.0001$); (2) hospital stay >median, 46.6%, 40.4%, 36.6%, 34.4% and 29.2% ($p<0.0001$); (3) post-arthroplasty fracture, 1.2%, 0.8%, 0.9%, 0.6% and 0.8% ($p=0.0004$); (4) transfusion, 8%, 7.1%, 6.7%, 7.1% and 5.5% ($p=0.006$); and (5) TSA revision, 0.5%, 0.3%, 0.2%, 0.3%, 0.3% ($p=0.045$), respectively.

Conclusion: In this study, we found that higher annual hospital TSA volume was associated with better TSA outcomes. These findings document the impact of annual hospital TSA volume on TSA outcomes. Patients, surgeons and policy-makes should be aware of these findings and take them into account in decision-making, policy decisions and resource allocation.

Utilization and Outcomes Following Total Shoulder Arthroplasty in Elderly and Non-Elderly Patients. Jasvinder A Singh[1] and Rekha Ramachandaran[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To assess the age-related differences in total shoulder arthroplasty (TSA) outcomes and utilization and associated time-trends.

Methods: Nationwide Inpatient Sample (NIS) from 1998–2010 was used to study the time-trends in TSA utilization and outcomes, overall and by age. Age was categorized as <50, 50– 64, 65–79 and ≥80. Time trends in TSA utilization were compared using logistic regression or the Cochran Armitage test.

Results: The overall TSA utilization increased from 2.96 in 1998 to 12.68/100,000 in 2010. Compared to 1998–2000, significantly lower rates were noted in 2009-10 for: mortality, 0.2% vs. 0.1% ($p=0.0041$); discharge to an inpatient facility, 14.5% vs. 13.3% ($p=0.039$); and hospital stay >median, 51.2% vs. 29.4% ($p<0.0001$). TSA utilization rates/100,000 by age groups, <50, 50–64, 65–79 and ≥80 years were: 0.32, 4.62, 17.82 and 12.56 in 1998 ($p<0.0001$); and 0.65, 17.49, 75.27 and 49.05 in 2010 ($p<0.0001$) with increasing age-related difference over time ($p<0.0001$). Across the age categories, there were significant differences in the proportion: discharged to inpatient facility, 3.2% vs. 4.2% vs. 14.7% vs. 36.5% in 1998 ($p<0.0001$) and 1.8% vs. 4.3% vs. 12.5% vs. 35.5% in 2010 ($p<0.0001$) and the proportion with hospital stay >median, 39.7% vs. 40.2% vs. 53% vs. 69% in 2008 ($p<0.0001$) and 17.2% vs. 20.6% vs. 28.7% vs. 50.7% in 2010 ($p<0.0001$).

Conclusion: In a nationally representative sample, we noted increasing age-related differences indicate a changing epidemiology of TSA. Age-related differences in outcomes can guide us to focus on those with worst outcomes.

Title: Use of Non-Traditional Modalities for Pain Management after Knee or Hip Joint Replacement. Jasvinder Singh[1], Celeste Lemay[2], Jeroan Allison[3] and Patricia D. Franklin[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Massachusetts Medical School, Worchester, MA, [3]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Pain management is a major focus of the post-arthroplasty rehabilitation. A variety of pain treatments are used, including narcotics and non-narcotic analgesics. To our knowledge, there are limited or

no data regarding the use of non-pharmacologic treatment modalities in post-total joint replacement (TJR) period.

Methods: A subset of patients from a national joint registry undergoing primary TJR (total knee or hip replacement, TKR/THR) between 5/2013 and 6/2014 were queried at 2- and 8-weeks regarding pain severity and use of non-pharmacologic modalities. Frequency distributions were used to describe the cohort. We used bivariate statistical tests to compare groups including the chi-square, Fisher's exact, t tests and Wilcoxon-Mann-Whitney test.

Results: There were 969 primary TKR and 584 primary THR respondents at 2-weeks and 1,022 primary TKR and 563 primary THR respondents at 8-weeks. The use of non-medication modalities was common in primary TKR patients at 2-weeks: cold packs (86%), meditation (6%), deep breathing (20%), heat (15%), relaxation (20%), walking (33%), distraction (51%), prayer (32%), massage (28%), listening to music (11%) and imagery (2%); numbers were similar and slightly lower for the 8-week follow-up. Use of most non-medication modalities was significantly lower in primary THR patients.

Compared to non-users, users of non-medication pain management strategies at 2-weeks were significantly: younger (65.6 vs. 68.8 years), more likely to be female (61% vs. 51%), White (93% vs. 89%), have college education or higher (70% vs. 62%) and had household income of $45K or higher (55% vs. 48%). There were no significant differences in race distribution or mean body mass index (30.6 vs. 30.0).

Compared to non-users, patients who reported using non-medication pain management strategies at 2-weeks and 8-weeks had significantly higher mean pain levels (3.0 vs. 2.0 on 0–10 scale; $p<0.0001$) and pain interference with activities of daily living (p-values <0.02) and physical therapy ($p=0.007$).

Conclusion: Use of non-medication pain management strategies was common 2- and 8-weeks after primary TKR and THR. Certain patient groups used these modalities more than others. Use of these strategies was associated with more pain and pain interference, which might indicate that patients with higher pain severity and impact were more likely to use these strategies. This hypothesis needs to be tested with examination of longitudinal data.

193

Pre-Operative Pain and Function: Profiles of Patients Selected for Total Knee Replacement Among Surgeons in the United States. Uyen Sa D.T. Nguyen, David C. Ayers, Wenjun Li, Leslie Harrold and Patricia D. Franklin. University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: When knee pain is severe and frequent, or mobility and daily activities become difficult, a total knee replacement (TKR) remains the most effective treatment to relief pain and to improve function. In the US, the annual rate of TKRs in people 65 years or older increased almost 9-fold between 1979 and 2006. The latest US hospital-discharge data indicated a significant increase in use among the younger patients (< 65 years of age). Among the 719,000 TKRs performed in 2010, about 50% were in people < 65. It remains unclear the reasons for such increased TKR use. We examined profiles of patients selected for TKR in a recently established US national registry of total joint replacements (TJR).

Methods: We used data from the Function and Outcomes Research for Comparative Effectiveness in TJR (FORCE-TJR), a national cohort of TJR patients operated by more than 130 surgeons in 22 sites nationwide. The current study included participants with primary and unilateral TKRs that were not indicated by rheumatoid arthritis. Participants were enrolled between April 2011 and Feb 2014, and had completed a pre-operative Knee Injury and Osteoarthritis Outcome Score (KOOS) and Short-Form 36-item (SF-36) functional health survey. Data were also collected on patient demographics, body mass index, general health and comorbid conditions. We classified patients as having high or low pain (KOOS Pain<70 vs. ≥70), and low or high physical function (SF-36 PCS <40 vs. ≥40). We then classified patients into four groups: 1) low pain-high function, 2) high pain-high function, 3) low pain-low function, and 4) high pain-low function. Descriptive statistics including patient demographic and clinical characteristics of the four groups were compared.

Results: The majority (95%) of patients had high pain and/or low physical function. A small percentage of people (5%), however, had low pain and high function. Many in this latter group reported pain fairly daily (49%) or were aware of their knee problem daily or constantly (85%) despite a very small percentage having experienced severe or extreme pain on stairs (4%) or pain in bed (1%). Moreover, over half had a lot of limitations or difficulties in vigorous activities such as running. Compared with the group with high pain and low function, the group with low pain and high function on average were older, less obese, more highly educated, more likely men, and were generally healthier. Differences for all characteristics by groups were statistically significant at $P<0.05$, except for race.

Conclusion: The overwhelming majority of TKRs were performed to relieve pain and/or restore physical function. However, a small percent of TKR utilization was in patients with low pre-operative pain and high function, probably for quality of life issues. Further investigation is needed to determine the reasons for TKR use among these patients as this may have an important policy implication.

Characteristics*	Group 1 Low Pain High Function (n=288)	Group 2 High Pain High Function (n=931)	Group 3 Low Pain Low Function (n=228)	Group 4 High Pain Low Function (n=4,582)
Demographics				
Age (Years, Mean (SD))	69.8 (7.4)	66.6 (8.6)	70.1 (8.9)	66.2 (9.3)

Differences in Total Knee Replacement Outcomes Based on Age. Leslie Harrold[1], David Ayers[1], Wenjun Li[1], Vincent Pellegrini[2], John Grady-Benson[3], Jeroan Allison[1] and Patricia D. Franklin[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Medical University of South Carolina, Charleston, SC, [3]Connecticut Joint Replacement Institute, Hartford, CT.

Background/Purpose: The fastest growing segment of the population undergoing total knee replacements (TKR) are patients younger than <65 years, yet little is known regarding their outcomes as compared to older patients. We examined, from a national sample of TKR patients, differences in clinical outcomes of pain and function following surgery based on age.

Methods: Patients undergoing primary TKR from 7/1/11 through 8/30/13 for osteoarthritis were identified from a national research consortium which enrolls patients from >130 surgeons across 22 states in the US. The registry gathers data from patients, surgeons and hospitals on patient demographics, underlying type of arthritis, body mass index, non-arthritis comorbid conditions, arthritis in non-operative hip and knee joints, back pain, global function based on the Short Form 36 Physical Component Score (PCS), and mental health using the SF-36 Mental Component Score (MCS). We evaluated both change in operative joint pain and function as well as the 6-month post-operative pain and function score based on the estimated Western Ontario and McMaster Universities Arthritis Index (WOMAC) using the Knee Injury and Osteoarthritis Outcome Score (KOOS; range of 0–100 with higher being better). Descriptive statistics were performed as well as linear and mixed model multivariable regressions examining differences based on age.

Results: There were 1164 patients <65 years and 2012 patients ≥ 65 years who underwent primary TKR. Younger patients were more likely to be nonwhite (8.7% vs. 5.0%, $p<0.001$), heavier (body mass index 33 vs. 30,

p<0.001), with worse emotional health (51.5 vs. 53.9, p<0.001), fewer comorbid conditions (p <0.001), and greater number of non-operative painful hip and knee joints (p<0.03). At the time of surgery, younger patients had greater pain (50.5 vs. 55.7, p<0.001) and functional impairment (53.2 vs. 54.9). Overall both younger and older patients had substantial pain relief and functional gain, improvement of 30.4 – 32.6 and 28.7 – 29.4 respectively based on the KOOS. In adjusted analyses, at 6-months post-operatively younger patients had slightly greater pain (−2.5, p <0.002) and less improvement in function (−2.2, p<0.016).

Conclusion: Both younger and older TKR patients had substantial pain and disability at the time of TKR and achieved substantial pain relief and functional gain following surgery. However, younger patients had statistically significant less improvement in pain and function, although the clinical significance of this difference is unknown.

Dependence on Walking Aids and Patient-Reported Outcomes after Total Knee Arthroplasty. Jasvinder A Singh[1] and David Lewallen[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: To examine whether function and pain outcomes of patients undergoing primary total knee arthroplasty (TKA) are changing over time.

Methods: The Mayo Clinic Total Joint Registry provided data for time-trends in preoperative and 2-year post-operative activity limitation and pain in primary TKA patients from 1993–2005. We used chi-square test and analysis for variance, as appropriate. Multivariable-adjusted analyses were done using logistic regression.

Results: In a cohort of 7,229 patients who underwent primary TKA during 1993–2005, mean age was 68.4 years (standard deviation (SD), 9.8), mean BMI was 31.1 (SD, 6.0) and 55% were women. Crude estimates showed that preoperative moderate-severe overall limitation were seen in 7.3% fewer patients and preoperative moderate-severe pain in 2.7% more patients in 2002-05, compared to 1992-95 (p<0.001 for both). At 2-years, crude estimates indicated that compared to 1992-95, moderate-severe post-TKA overall limitation was seen in 4.7% more patients and moderate-severe post-TKA pain in 3.6% more patients in 2002-05, both statistically significant (p^{2}0.018) and clinically meaningful. In multivariable-adjusted analyses that adjusted for age, sex, anxiety, depression, Deyo-Charlson index, body mass index and preoperative pain/limitation, patients had worse outcomes 2-year post-TKA in 2002–2005 compared to 1993-95 with an odds ratio (95% confidence interval (CI); p-value) of 1.34 (95% CI: 1.02, 1.76, p=0.037) for moderate-severe activity limitation and 1.79 (95% CI: 1.17, 2.75, p=0.007) for moderate-severe pain.

Conclusion: Patient-reported function and pain outcomes after primary TKA have worsened over the study period 1993-95 to 2002-05. This time-trend is independent of changes in preoperative pain/limitation and patient characteristics.

Dependence on Walking Aids Is Associated with Pain and Mobility Limitation after Total Hip Arthroplasty. Jasvinder A Singh[1] and David Lewallen[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: To assess the association of dependence on walking aids with pain and function outcomes after total hip arthroplasty (THA).

Methods: We used the Mayo Clinic Total Joint Registry to study patients who underwent primary or revision THA between 1993–2005 and completed a 2-year or 5-year pain and function outcomes survey. Multivariable-adjusted logistic regression assessed the associations, adjusting for clinical/demographic variables and preoperative pain and function.

Results: Primary THA cohort had 5,707 patients at 2-year and 3,289 at 5-years; revision THA included 2,667 patients at 2-year and 1,627 patients at 5-years. Compared to patients with no dependence on walking aids, patients with some or complete dependence on walking aids had significantly higher odds (95% confidence interval) of: (1) moderate-severe pain post-primary THA at 2-years: 3.40 (2.06, 5.62) and 4.79 (2.88, 7.97); (2) moderate-severe pain post-primary THA at 5-years: 3.92 (2.21, 6.95) and 3.47 (1.97, 6.11); (3) moderate-severe pain post-revision THA at 2-years, 4.67 (2.76, 7.91) and 2.95 (1.65, 5.27); (4) moderate-severe pain post-revision THA at 5-years: 3.95 (1.86, 8.38) and 5.16 (2.59, 10.3); (5) moderate-severe mobility limitation post-primary THA at 2-years: 10.7 (6.78, 17.0) and 14.2 (8.32, 24.3); (6) moderate-severe mobility limitation post-primary THA at 5-years: 13.2 (7.34, 23.7) and 21.4 (10.6, 43.2); (7) moderate-severe mobility limitation post-revision THA at 2-years: 4.90 (2.87, 8.37) and 8.26 (4.12, 16.6); (8) moderate-severe mobility limitation post-revision THA at 5-years: 5.12 (2.32, 11.3) and 10.1 (4.53, 22.7), respectively.

Conclusion: Post-THA dependence on walking aids is associated with worse pain and function outcomes post-THA.

197

Differences in Total Hip Replacement Outcomes Based on Age. Leslie Harrold[1], David Ayers[1], Wenjun Li[1], Courtland Lewis[2], Philip Noble[3], Regis O'Keefe[4], Jeroan Allison[1] and Patricia D. Franklin[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Hartford Hospital, Hartford, CT, [3]Baylor College of Medicine, Houston, TX, [4]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: The fastest growing segment of patients who undergo total hip replacement (THR) are younger than <65 years, yet little is known regarding their outcomes as compared to older patients. We examined, from a national sample of THR patients, differences in clinical outcomes of pain and function following surgery.

Methods: Patients undergoing primary THR from 7/1/11 through 12/30/13 for osteoarthritis were identified from a national research consortium which enrolls patients from >130 surgeons across 22 states in the US. The registry gathers data from patients, surgeons and hospitals on patient demographics, underlying type of arthritis, body mass index, non-arthritis comorbid conditions, arthritis in non-operative hip and knee joints, back pain, global function based on the Short Form 36 Physical Component Score (PCS), and mental health using the SF-36 Mental Component Score (MCS). We evaluated both change in operative joint pain and function as well as the 6-month post-operative pain and function based on the estimated Western Ontario and McMaster Universities Arthritis Index (WOMAC) using the Hip Disability and Osteoarthritis Outcome Score (HOOS; range 0–100 with higher being better). Descriptive statistics were performed as well as linear and mixed model multivariable regression models examining differences based on age.

Results: There were 1030 patients <65 years and 1242 patients ≥ 65 years who underwent primary THR. Younger patients were more likely to be nonwhite (6.7% vs. 4.1%, p<0.01), heavier (body mass index 29.3 vs. 28.2, p<0.001), with worse emotional health (50.1 vs. 53.1, p<0.001), and fewer comorbid conditions (p <0.001). At the time of surgery, younger patients had greater pain (47.2 vs. 51.7, p<0.001) and functional impairment (45.2 vs. 47.0, p=0.02). Overall both younger and older patients had substantial pain relief and functional gain, mean improvement of 40.1 – 43.2 and 39.1 – 42.2 respectively based on the HOOS. In adjusted analyses, both younger and older patients had similar levels of improvement in pain and function as well as similar mean post-operative 6-month pain (90.4 vs. 91.9, p=0.15) and function scores (86.2 vs. 87.4, p=0.42).

Conclusion: Both younger and older THR patients had substantial pain and disability at time of THR, and achieved significant pain relief and functional gain at 6 months following surgery. In this national sample of THR patients, both younger and older patients had good clinical outcomes following surgery with respect to pain relief and functional gain.

Implant Survival and Patient-Reported Outcomes after Total Hip Arthroplasty in Young Patients with JIA. Ishaan Swarup, Ella Christoph, Lisa A. Mandl, Susan M. Goodman and Mark P. Figgie. Hospital for Special Surgery, New York, NY.

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a common rheumatologic disease in children that often persists into adulthood. The hip joint is commonly involved, and total hip arthroplasty (THA) is the standard treatment for patients who fail non-operative management. This study evaluates implant survival in JIA patients who underwent a primary THA at our institution before the age of 35. It also describes patient-reported outcomes for JIA patients after THA.

Methods: Patient characteristics and implant data were collected by a retrospective chart review. Follow-up surveys were used to determine implant survival and patient-reported outcomes. Kaplan-Meier survival analysis was performed to evaluate implant survival, and the hip disability and osteoarthritis outcome score (HOOS) was used to describe patient-reported outcomes.

Results: Patient data was reviewed for 91 JIA patients under the age of 35 that underwent a primary THA at our institution between 1982 and 2011. Follow-up data was available for 56 patients. A preliminary analysis of 35 patients (60 primary THAs) revealed a mean time to follow-up of 12 years (Range: 2–23 years). The 10-year and 20-year implant survival was 80% (95% CI: 66%-89%) and 64% (95% CI: 46%-77%), respectively. Primary THA with standard implants had a longer survival compared to custom implants (p-value=0.02) with no other significant differences in implant survival stratified by patient age and sex, implant bearing surface, and use of cement for implant fixation. The mean HOOS scores were 89 (95% CI: 84–94) for pain, 87 (95% CI: 83–91) for symptoms, 86 (95% CI: 79–93) for ADLs, and 76 (95% CI: 69–83) for sports. Male patients reported better HOOS-Symptom scores compared to female patients (96 vs. 85, p-value=0.026), and patients with standard implants reported better HOOS-Pain (95 vs. 73, p-value <0.001) and HOOS-Symptom (91 vs. 78, p-value=0.016) scores compared to patients with custom implants.

Conclusion: THA is an excellent treatment option for JIA patients under the age of 35 with very good long-term implant survival and favorable patient-reported outcomes after surgery.

Disclosure: I. Swarup, None; **E. Christoph**, None; **L. A. Mandl**, None; **S. M. Goodman**, None; **M. P. Figgie**, None.

Increasing Complexity of Patients Undergoing Primary Total Hip Arthroplasty in the U.S. Jasvinder A Singh[1] and David Lewallen[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: To examine the time-trends in key demographic and clinical characteristics of patients undergoing primary total hip arthroplasty (THA).

Methods: We used the data from the Mayo Clinic Total Joint Registry from 1993–2005 to examine the time-trends in demographics (age, body mass index (BMI)), medical (Deyo-Charlson index) and psychological comorbidity (anxiety, depression) and underlying diagnosis of patients undergoing primary THA. Chi-square test and analysis for variance were used. Multivariable-adjusted logistic regression (age, sex, comorbidity-adjusted) compared 1993-95 to other study periods. Odds ratio (OR) and 95% confidence interval (CI) are presented.

Results: The primary THA cohort consisted of 6,168 patients with 52% women. Compared to 1993-95, significantly more patients (by >2-times for most) in 2002-05 had: BMI≥40, 2.3% vs. 6.3%; depression, 4.1% vs. 9.8%; and anxiety, 3.4% vs. 5.7%; and significantly fewer had an underlying diagnosis of rheumatoid/inflammatory arthritis, 4.2% vs. 1.5% ($p^2$0.01 for all). In multivariable-adjusted models, compared to 1993-95, significantly more patients in 2003-05 had (all p-values^{2}0.01): BMI≥40, OR, 2.79 (95% CI: 1.85, 4.22); Deyo-Charlson Index≥3, 1.32 (1.07, 1.63); depression, 2.25 (1.66, 3.05); and anxiety, 1.71 (1.19, 2.15). Respectively, fewer patients had a diagnosis of RA/inflammatory arthritis: 0.28 (0.17, 0.46; p<0.01). Over the 13-year study period, Deyo-Charlson index increased by 22% (0.9 to 1.1) and the mean age decreased by 0.7 years (65.0 to 64.3) (p<0.01 for both).

Conclusion: Obesity, medical/psychological comorbidity and underlying diagnosis changed rapidly in primary THA patients over 13-years. Studies of THA outcomes and utilization should take these rapidly changing patient characteristics into account.

Leg Length Inequality and Hip Osteoarthritis. Chan Kim[1], Jingbo Niu[1], Mary Clancy[2], Ali Guermazi[3], Michael C. Nevitt[4], Neil A. Segal[5], William F. Harvey[6], Cora E Lewis[7] and David T. Felson[8]. [1]Boston University, Boston, MA, [2]Boston University Sch Med, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]UCSF (University of California, San Francisco), San Francisco, CA, [5]University of Iowa, Iowa City, IA, [6]Tufts Medical Center, Boston, MA, [7]University of Alabama Birmingham School of Medicine, Birmingham, AL, [8]University of Manchester, Manchester, United Kingdom.

Background/Purpose: Leg length inequality (LLI), a side-to-side difference in lower limb lengths, is common. In the Multicenter Osteoarthritis Study (MOST), in persons with LLI, the shorter limb was found to have an increased incidence, prevalence and progression of knee osteoarthritis (OA) compared to the longer limb. The shorter leg is likely to sustain increased impact force of the foot during gait thus transmitting a greater impulse up the ipsilateral leg. LLI is easily treatable and therefore could be a potentially modifiable risk factor for disease. However, the association of LLI and hip OA has not been prospectively studied. Therefore, we examined the association of LLI with hip OA in the MOST cohort.

Methods: The MOST cohort is a multicenter, longitudinal community based study of 3026 recruited for studying knee OA. Long limb films were obtained at baseline and 60 months, which were used to assess LLI and radiographic hip OA. Radiographic measurement of LLI is the gold standard measure. We defined LLI ≥ 1 cm based on previous literature, but we also assessed LLI ≥ 2 cm.

Radiographic hip OA was defined using UCSF criteria. Hips with prevalent JSN were defined as hips with any JSN at either superolateral or superomedial joint space at baseline. Hips with progressive JSN were defined as any with worsening JSN at 60 month follow-up. Associations between LLI and radiographic hip OA were assessed using logistic regression models with generalized estimating equations.

First, we examined cross-sectional baseline data. Because LLI may be generated by the existence of unilateral hip OA (which may slightly shorten the limb), we examined the longitudinal relationship of baseline LLI with incident hip OA and progressive JSN.

Results: Of the 3026 subjects, 125 subjects with either knee or hip replacements at baseline were excluded. Then, 55 subjects with missing LLI measurements were excluded (mostly due to poor quality films). We used radiographic OA data on both hips for all subjects, but for 17 subjects who had missing OA status for one hip, the contralateral hip was used in analyses. At baseline, neither LLI ≥ 1 cm nor 2 cm were associated with prevalent radiographic hip OA. In the longitudinal analyses, LLI ≥ 1 cm was not associated with incident radiographic hip OA. However, LLI ≥ 2 cm was associated with increased risk of incident radiographic hip OA (adjusted OR 7.13 [CI 95% 1.74,29.18]) for the shorter leg, but this was based on a small number in the group with LLI ≥ 2 cm (13 hips). LLI ≥ 2 cm increased risk for prevalent ipsilateral JSN (adjusted OR 5.49 [CI 95% 1.94,15.52]), LLI did not increase risk for progressive JSN (not shown).

Conclusion: LLI ≥ 1 cm was not associated with prevalent or incident radiographic hip OA or prevalent or progressive JSN. Although the sample size was small, LLI ≥ 2 cm was associated with increased risk for incident radiographic hip OA in the shorter leg and prevalent JSN in the shorter leg.

Measures of Hip Morphology Are Related to Development of Incident Radiographic Hip Osteoarthritis over 6 to 13 Year Follow-up: The Johnston County Osteoarthritis Project. Amanda E. Nelson[1], Jamie L. Stiller[1], Xiaoyan A. Shi[2], Kirsten M. Leyland[3], Jordan B. Renner[4], Todd A. Schwartz[5], Nigel K. Arden[3] and Joanne M. Jordan[6]. [1]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [2]SAS Institute, Inc, Cary, NC, [3]NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom, [4]University of North Carolina Department of Radiology, Chapel Hill, NC, [5]University of North Carolina Gillings School of Global Public Health, Dept of Biostatistics, Chapel Hill, NC, [6]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Alterations in hip morphology, such as femoroacetabular impingement, have been associated with incident hip OA and total hip replacement (THR), but have rarely been assessed in community-based samples and have never been assessed in African Americans (AA).

Methods: This case-control study was nested within a large community-based cohort. Case hips had Kellgren Lawrence grade (KLG)<3 on baseline supine pelvis radiographs and KLG≥3 (mild/moderate hip OA, or THR for OA) at the 1st or 2nd follow-up (mean 6 and 12.7 years, respectively) visit. Control hips had KLG<3 at both baseline and follow-up, with a gender/race distribution similar to cases. Validated software (Oxmorf) was used to assess 27 aspects of hip morphology. Unadjusted analyses comparing cases and controls included chi-squared and t-tests, as appropriate. Generalized estimating equations regression models, adjusted for age, race, BMI, and side were employed, accounting for within-person correlation.

Results: A total of 263 hips, 76 case and 187 control, were included from 136 individuals (25% male, 29% AA, mean age 62 ± 9 years and BMI 30 ± 6 kg/m^2). Case hips were more often right hips (67%, p<0.001), with no differences by age or BMI. Reliability for all measures was acceptable (intra-[ICC 0.7–1.00] and inter-reader ICC 0.5–1.00). Nearly all measures were significantly different by sex (p<0.03 in t-tests) so further analyses were sex-stratified; no interactions were seen for age, race, BMI, or baseline KLG.

For analyses by case/control status, we focused on 7 continuous and 3 categorical hip morphology measures (Table). Among men, higher baseline AP alpha angle, extrusion index, acetabular index, and modified triangular index height were associated with case status at follow-up, while greater baseline minimum joint space width (mJSW) and coxa profunda had a protective effect. Among women, higher AP alpha angle, lower mJSW, presence of protrusio acetabuli and the triangular index sign were significantly associated with case vs. control status. Strength of some associations varied by side (data not shown). With all measures simultaneously included in the model, the associations between AP alpha angle and mJSW remained significant for both men and women, as did the triangular index sign among men only.

Conclusion: Cam-type morphology (higher AP alpha angle and triangular index) and smaller mJSW were associated with incident radiographic hip OA in both men and women, with no differences by race. Newly identified variations in these associations by side are of interest and will be the subject of future work.

Table. Associations between measures of hip morphology and case/control status for men (left) and women (right)

Is Schuss View Alone Enough for the Diagnosis of Femorotibial Osteoarthritis ? the Khoala Cohort Study. Christian Roux[1], Bernard Mazieres[2], Evelyne Verrouil[2], Anne-Christine Rat,[3], Patrice Fardellone[4], Bruno Fautrel[5], Jacques Pouchot[6], Alain Saraux[7], Francis Guillemin[8], Liana Euller Ziegler[9] and Joel Coste[10]. [1]Hopital Archet 1 - Université Nice Sophia Antipolis, Nice, France, [2]CHU Toulouse, Toulouse, France, [3]Université de Lorraine, Université Paris Descartes, Apemac, EA 4360, Nancy, France, [4]Hôpital Nord, C.H.U. d'Amiens, Amiens, France, [5]CHU - Hôpital Pitié-Salpêtrière, Paris, France, [6]Hopital Louis Mourier, Colombes, FRANCE, France, [7]CHU de la Cavale Blanche and Université Bretagne occidentale, Brest Cedex, France, [8]INSERM, Centre d'Investigation Clinique - Epidémiologie Clinique (CIC-EC) CIE6, Nancy, France, [9]CHU de Nice -Université Nice Sophia Antipolis, Nice, France, [10]CHU Hotel Dieu, Paris, France.

Background/Purpose: Associating an anteroposterior (AP) extended-knee X-ray with a semiflexed AP or posteroanterior (PA) view is considered the gold standard for radiologically diagnosing tibiofemoral osteoarthritis (OA), but limited data only support the diagnostic value of this approach. Our objective is to compare the contribution of these different views to diagnosis.

Methods: From 2007 to 2009, a population-based two-phase prevalence study was conducted to create the KHOALA cohort (Knee and Hip OA long-term assessment) (1). It was conducted in 6 French centers (Amiens, Brest, Nancy, Toulouse, Nice, and Paris). For the current work, we included the first 350 participants aged 40 to 75 years old regardless of their Kellgren Laurence (KL) stage.

A first reading of Schuss + standard AP views was carried out by an expert rheumatologist (BM). A second reading of Schuss X rays only was carried out remotely, (blinded to the results of the first lecture), by the same examiner. Analysis focused on the comparison of KL stage of each knee, as well as on osteophytes detection and localization: Medial Condyle (MC), Lateral (LC), Medial Tibial Plateau (MTP) or Lateral (LTP) (all ranked from 0 to 3), Joint space narrowing (JSN) (ranked from 0 to 4) and bone sclerosis (MC, LC, MTP, LTP).

Results: 350 subjects were included. Mean age was 58 years (8.6), Body Mass Index (BMI) was 29.8 (5.4). Time between the two readings was 2 years.

	Standard AP + Schuss		Schuss		Standing AP view	
KL stage	Right Knee n (%)	Left Knee n (%)	Right Knee n (%)	Left Knee n (%)	Right knee n (%)	Left knee n (%)
KL≥ 2	**110 (31)**	**87 (25)**	**83 (24)**	**64 (18)**	**95 (27)**	**72 (21)**
Osteophytes						
MC	**31 (9)**	**30 (9)**	**32 (9)**	**32 (9)**	**29 (8)**	**28 (8)**
LC	**10 (3)**	**12 (3)**	**20(6)**	**17 (5)**	**17 (5)**	**10 (3)**
MTP	**39 (11)**	**35 (10)**	**38 (11)**	**28 (8)**	**22 (9)**	**32 (9)**
LTP	**25 (7)**	**23 (6)**	**21 (6)**	**16 (5)**	**21 (6)**	**18 (5)**
JSN	**71 (20)**	**60 (17)**	**60 (17)**	**52 (15)**	**42 (12)**	**37 (11)**

Comparing two readings showed a significantly higher proportion of KL ≥ 2 patients when the two X-ray views were combined (right knee: p < 0.0001; left knee: p < 0.001). In contrast, a more in-depth analysis taking into account JSN, osteophytes, and bone condensation did not confirm this difference. A comparison of Schuss versus AP alone demonstrated the superiority of the Schuss view in evaluating JSN (p=0.0001 and p=0.0001) with no difference in osteophyte detection. A lower rate of JSN detection with Schuss view X-ray alone in high-BMI patients is suggested.

Conclusion: In our study, Schuss is superior to AP view to detect knee OA. Adding an AP view to the Schuss view leads to higher number of grades 1(not confirmed osteophytes). The marked differences in KL are probably due to KL scale limitations. No differences appear in JSN and osteophyte detection, the main features of OA. Due to the higher cost and radiation exposure involved in associating views, the Schuss view alone tends to be used for OA diagnosis in the general population.

Predictors of Radiographic Progression of Interphalangeal Finger Joints in Erosive Osteoarthritis: A Prospective Study. Paulien Meersseman, Celine Van De Vyver, Gust Verbruggen, Dirk Elewaut and Ruth Wittoek. Department of Rheumatology Ghent University Hospital, Ghent, Belgium.

Background/Purpose: Predictors of radiographic progression in erosive osteoarthritis (OA) are important in identifying patients with high risk of disease activity and consequently functional loss. Disease duration, number of tender joints and number of joints with palpable effusion at baseline are already identified as clinical predictors of radiographic progression. The aim of this study is to confirm the existing predictors in a prospective cohort. Additionally, potentially other clinical and radiographic predictors will be identified.

Methods: One hundred and twelve patients with erosive OA were selected from an already existing cohort that was recruited from April 2007 through January 2010 at the Ghent University Hospital. X-rays, clinical and demographic data of the 1st assessment were present. All patients were reassessed between January 2014 and March 2014. All interphalangeal finger joints on both radiographs were scored according to the Verbruggen and Veys method. Radiographic progression was defined as a joint progressing from at least one anatomical phase, excluding the progression from a 'N' phase to a 'S' phase. A generalized estimating equation (GEE) model with a binary logistic function was used to explore the following potential clinical and radiographic predictors on joint level: disease duration (≤5 years, >5 years), presence of erosive joints in the dominant hand, presence of painful joints, tender joints, or joints with palpable effusion, the presence of a joint in 'J' phase and in 'E' phase. All variables were dichotomous (present or absent).

Results: Three clinical and two radiographic predictors were retained: a painful joint, a tender joint, a joint with palpable effusion, a joint in 'J' phase and a joint in 'E' phase. A joint with palpable effusion was the strongest clinical predictor (odds ratio (OR): 2.474) (table 1). A joint in 'E' phase was the strongest radiographic predictor (OR: 90.628) (table 2).

Table SEQ Table * ARABIC 1: Clinical predictors for radiographic progression by GEE modeling

Variables	GEE-OR (95% CI)	P-value
Disease duration (≤5 years, >5 years)	1.028 (0.711–1.487)	0.882
Erosive joint in dominant hand	0.879 (0.671–1.151)	0.348
Painful joint	1.529 (1.013–2.310)	0.043
Tender joint	1.973 (1.344–2.897)	0.001
Joint with palpable effusion	2.474 (1.419–4.314)	0.001

CI: confidence interval.

Table SEQ Table * ARABIC 2: Radiographic predictors for radiographic progression by GEE modeling

Variables	GEE-OR (95% CI)	P-value
Presence of 'J' phase	17.418 (8.785–34.538)	<0.001
Presence of 'E' phase	90.628 (40.109–204.781)	<0.001

Conclusion: A painful joint, a tender joint, a joint with palpable effusion, 'J' phase and 'E' phase were identified as predictors of radiographic progression in erosive OA. The strongest clinical and radiographic predictor was a joint with palpable effusion and the presence of an 'E' phase respectively. These predictors should be considered when selecting patients for therapeutic trials with potential disease-modifying osteoarthritic drugs.

204

Ultrasonographic Predictors for Clinical and Radiological Progression in Knee Osteoarthritis after 2 Years Follow up. Karen Bevers[1], Johanna E. Vriezekolk[2], J.W.J. Bijlsma[3], Els van den Ende[2] and Alfons A. den Broeder[2]. [1]St Maartenskliniek, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Pathophysiology of osteoarthritis (OA) is not completely understood. Identifying patients with progression might help to direct future research on therapeutic interventions. As OA is known to affect the entire joint including soft tissue structures, structural changes in these tissues, visualised by ultrasound (US), might predict progression. The aim of this study was to investigate the association between a set of US features and radiographic and clinical progression of knee OA after two years of follow up.

Methods: A total of 125 patients fulfilling American College of Rheumatology clinical criteria for knee OA[1] underwent US examination of the most symptomatic knee. The US protocol included assessment of synovial hypertrophy, joint effusion, infrapatellar bursitis, Baker's cyst, medial meniscus protrusion and cartilage thickness. Clinical progression was defined using the inverse OARSI responder criteria [2]or progression to total knee replacement. A 2-point or more increase in Altman score or progression to total knee replacement was considered radiologic progression. Regression analyses were performed with US features as independent variables and progression (two separate models for clinical progression and radiographic progression) as dependent variable.

Results: A total of 31 (25%) patients fulfilled the criteria of clinical progression and 60 (48%) patients fulfilled the criteria of radiologic progression. Presence of Baker's cyst showed a statistically significant association with clinical (OR: 3.07; 95% CI: 1.21 – 7.78) as well as radiological (OR: 2.84; 95% CI: 1.17 – 6.90) progression. Synovial hypertrophy showed a weaker but consistent association with clinical- as well as radiologic progression (OR: 2.11; 95% CI: 0.80 – 5.57)

Conclusion: We demonstrated a longitudinal association between Baker's cyst (and to a lesser extent synovial hypertrophy) at baseline and radiological and clinical progression after two years. When confirmed, these inflammatory variables might be candidate features to help define knee OA patients with worse prognosis.

Natural History and Clinical Significance of Meniscal Tears over 8 Years in a Largely Non-Osteoarthritic Cohort. Hussain Ijaz Khan[1], Dawn Aitken[1], Changhai Ding[2], Leigh Blizzard[3], Jean-Pierre Pelletier[4], Johanne Martel-Pelletier[4], Flavia Cicutinni[5] and Graeme Jones[2]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart,7000, Australia, [3]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Tasmania, Australia, [4]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [5]Monash University, Melbourne, Australia, Melbourne, Australia.

Background/Purpose: Meniscal tears are a key player in knee osteoarthritis (OA) and family history of the disease has been shown to play an important role. However, there is limited longitudinal data on the natural history of meniscal tears. The aim of this study was to track natural history of meniscal tears over 8 years, describe the association with change in pain and describe structural and non-structural predictors of change in meniscal tears.

Methods: 220 participants [mean age 47 (28–63); 57% female] were studied at baseline and 8 years. Approximately half were the adult offspring of subjects who had a knee replacement performed for knee OA and the remaining half were randomly selected controls without a family history of OA. Meniscal tears were evaluated, using T-1 weighted fat saturated MRI, on a 0–2 (0=absence; 1=simple; 2=complex tear) scale within 6 defined regions: anterior horn, body, and posterior horn at both medial and lateral menisci. Cartilage volume/defects, bone marrow lesions (BMLs), meniscal extrusion and effusion were assessed on MRI and joint space narrowing (JSN) and osteophytes on radiographs using standard protocols. Pain was assessed using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

Results: Using updated methodology, 22% of the participants had a meniscal tear at any site at baseline, without a significant difference between the two groups at any site. 16% of the participants had any increase in meniscal score (incident tears + increase from baseline score) over 8 years. Offspring had a significantly higher change in mean meniscal score compared to controls over 8 years **(total knee score: offspring= 0.493, controls= 0.164, p=0.034)**. Change in meniscal tears was independently associated with worsening pain over 8 years (Table 1). There was also a significant offspring-control interaction **(all p<0.05)** at all sites, with offspring having a significantly higher increase in pain on WOMAC scale per unit change in tears compared to controls (Table 1). Higher BMI at baseline was independently associated with a greater risk of increase in mean meniscal score **(total**

knee: RR= 1.10 (1.04, 1.16)). Change in total medial tears was associated with cartilage loss over 8 years in the medial (tibial + femoral) compartment **(β= -176 (−302, -49))** only. Change in tears at all sites was associated with change in compartment specific and total knee BMLs **(total knee: β=+0.39 (+0.26, +0.53))**. Furthermore, change in tears showed the strongest independent correlation with change in both JSN **(ρ=+0.37, p= <0.01)** and osteophytes **(ρ=+0.31, p= <0.01)** in the medial compartment.

Conclusion: In this midlife cohort, meniscal tears are common. Change in tears is independently associated with change in pain, BMLs, cartilage volume and radiographic OA. In turn, change in tears is influenced by family history of OA and BMI but not history of knee injury.

Table 1: Association between change in meniscal tears and change in pain over 8 years

	Change in pain over 8 years	
Change in tears (site)	**Unadjusted β (95%CI)**	**Adjusted[a] β (95%CI)**
Total medial meniscus	**+3.81 (+2.45, +5.20)**	**+2.84 (+1.1, +4.57)**
Offspring	**+4.93 (+3.41, +6.46)**	**+3.72 (+1.64, +5.79)**
Controls	−0.87 (−3.91, +2.17)	−1.19 (−4.35, +1.96)

Risk Factors for Increased Extrusion of the Meniscus Body in Subjects Free of Radiographic Knee Osteoarthritis: 6-Year MRI Data from the Osteoarthritis Initiative. Fan Zhang[1], Jaanika Kumm[2], Fredrik Svensson[1], Aleksandra Turkiewicz[1], Richard Frobell[1] and Martin Englund[1]. [1]Lund University, Lund, Sweden, [2]Tartu University, Tartu, Estonia.

Background/Purpose: Meniscal body extrusion on knee MRI is strongly associated with the development and progression of knee osteoarthritis (OA). However, there is very limited evidence of risk factors for the development of meniscal extrusion.

Thus, our objective was to determine risk factors associated with increased meniscal body extrusion using quantitative measurements from knee MRIs in subjects free of radiographic OA at baseline. We hypothesized that body mass index (BMI), sex, age, and incident ipsilateral meniscal tear are possible risk factors.

Methods: Data for these analyses are from the OAI public use data. A cohort of 340 subjects with age between 45 and 55 (mean age 50 years, 51% women, mean BMI 26.7) with bilateral knee MRIs available at the baseline, 24 months, 48 months, and 72 month exam and no radiological signs of knee OA (both knees' KL grade = 0 at baseline) were selected. We assessed mid-coronal IW 3-Tesla MR images from baseline and the 72 month follow-up visit. One observer measured widths of the tibia plateau and meniscal body extrusion to the closest 0.1 mm using Sante DICOM Editor (64-bit) software (intraobserver ICC ranging from 0.75 to 0.99). One reader assessed meniscal integrity (presence of tear) at all four time points. To take into account knee size, we calculated an extrusion index as ([meniscal body extrusion]/[tibia width]*100). We evaluated risk factors for increased meniscal body extrusion index from baseline to the 72-month exam by a multivariable linear regression mixed model for medial and lateral compartment, respectively, adjusting for the fact that the same person contributed with two knees and with the covariates: clinical site, age, sex, baseline BMI, baseline extrusion index, and incident meniscal tear.

Results: Mean (SD) medial extrusion index in the right knee at baseline and 72-month follow-up was 3.43 (1.23) and 3.32 (1.30), respectively (similar values in the left knee). The corresponding values for lateral compartment were 1.54 (1.31) and 1.13 (1.52). In the medial compartment we found that female sex (0.35; 95% confidence interval [CI] 0.16–0.53), incident meniscal tear (0.29; 95% CI 0.22–0.55), and the baseline value of the extrusion index (0.63; 95% CI 0.56–0.70) were associated with increased extrusion index by the 72 month follow-up. Results were similar for the lateral compartment (data not shown).

Conclusion: We found female sex, incident meniscal tear, and higher baseline value of extrusion to be risk factors for increased meniscal body extrusion in middle-aged subjects free of radiographic OA. Findings provide new evidence of the causal chain of events in the "meniscal pathway" to knee OA.

Changes in Knee Compartment Distriubtion of Cartilage Loss and Bone Marrow Lesions over 7 Years: The MOST Study. Joshua Stefanik[1], Ali Guermazi[2], Jingbo Niu[1], Frank Roemer[3], C.E. Lewis[4], Neil A. Segal[5], Michael Nevitt[6] and David T. Felson[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Klinikum Augsburg, Augsburg, Germany, [4]University of Alabama at Birmingham, Birmingham City, AL, [5]University of Iowa, Iowa City, IA, [6]UCSF, San Francisco, CA.

Background/Purpose: Knee osteoarthritis (OA) occurs in both the patellofemoral joint (PFJ) and tibiofemoral joint (TFJ). Little is known about the natural history of OA and it has been hypothesized, based on findings from radiographic studies, that OA occurs first in the PFJ and subsequently progresses to involve the TFJ. This has not been evaluated using MRI, which is more sensitive than radiographs to identify structural damage, particularly in the PFJ. The purpose of this study was to describe patterns of change in cartilage loss and bone marrow lesions (BMLs) among knee joint compartments over 7 years. Specifically, we describe whether disease remains isolated to one compartment or develops in the other, and which compartment tended to be initially involved.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort study of 3,026 individuals with or at risk for knee OA. Participants had MRI of their knee at baseline and 84-month of follow up. Two musculoskeletal radiologists used the Whole Organ Magnetic Resonance Score (WORMS) to assess cartilage morphology and BMLs in the PFJ and TFJ at baseline and 7 years. At baseline and 84-months, knees were categorized as having full-thickness cartilage loss (any region within a compartment with WORMS 2.5, 5 or 6) isolated to the PFJ, isolated to the TFJ, mixed (both PFJ and TFJ) or no full-thickness loss in either compartment. In sensitivity analyses any cartilage loss (WORMS ≥2) and any BML (WORMS ≥1) were used to categorize disease in knee compartments.

Results: 994 knees had complete MRI readings at baseline and 84-months. The mean age and BMI at baseline were 61.7 (±7.5) years and 29.7 (± 4.7) kg/m^2, respectively, and 61% were female. Among 570 knees without full-thickness cartilage loss at baseline, the incidence of isolated PFJ, isolated TFJ and mixed full-thickness cartilage loss was 12, 13 and 5%, respectively. The remaining 70% did not develop full-thickness cartilage loss at follow up. Among 334 knees that had full-thickness cartilage loss isolated to the PFJ or TFJ at baseline, only 62 (19%) developed full-thickness cartilage loss in the other compartment while 272 (81%) continued to only have the initial compartment affected with full-thickness cartilage loss. Among 62 knees that started with isolated full-thickness loss in the PFJ or TFJ and developed full-thickness cartilage loss in the other compartment, it more often progressed from the PFJ 44 (71%) than from the TFJ 18 (29%). Similar patterns were seen in sensitivity analyses when disease was defined using any cartilage loss and any BML.

Conclusion: Over 7 years of follow-up it is uncommon for cartilage loss and BMLs to "spread" to the other compartment in the knee. Furthermore, of knees that develop cartilage loss and BMLs in the other compartment, most knees start with damage isolated to the PFJ, suggesting that mixed disease may start in the PFJ.

Correlates of Knee Bone Marrow Lesions in Younger Adults. Benny Samuel Eathakkattu Antony[1], Graeme Jones[2], Alison Venn[3], Lyn March[4], Flavia Cicutinni[5], Andrew Halliday[6], Leigh Blizzard[3], Marita Cross[7], Terry Dwyer[8] and Changhai Ding[2]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart,7000, Australia, [3]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Tasmania, Australia, [4]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia,

[5]Monash University, Melbourne, Australia, Melbourne, Australia, [6]Royal Hobart Hospital, Australia, Hobart, Australia, [7]University of Sydney Institute of Bone and Joint Research, Royal North Shore Hospital, Sydney, Australia, [8]Murdoch Children's Research Institute, Melbourne, Australia.

Background/Purpose: Bone marrow lesions (BMLs) of the knee joint are a key player in osteoarthritis of the knee. However, little is known of their determinants, especially in young adults. The aim of this study was to examine the structural and functional correlates of BMLs in younger adults including physical activity and to determine whether bone mass, cholesterol and hormones measured 5 years prior are associated with current BMLs.

Methods: Subjects broadly representative of the Australian population (n=330, aged 31–41 years, female 48.7%) were selected from the Childhood Determinants of Adult Health study. They underwent T1 and T2-weighted fat- suppressed magnetic resonance imaging in their knee. BMLs, cartilage defects, meniscal tears and cartilage volume were measured. Knee pain was assessed by self-administered Western Ontario and McMasters osteoarthritis index (WOMAC) questionnaire. Physical activity was measured by IPAQ questionnaires at the time of MRI. Heel bone mass, cholesterol and hormone levels (in females) were assessed 5 years prior.

Results: The prevalence of any BMLs in the knee joint was 17%. Cross-sectionally, any BML in the knee was associated with age (PR: 1.09, 95% CI: 1.00, 1.19), previous knee injury (medial tibiofemoral BMLs PR: 2.20, 95% CI: 1.03, 4.71) and total WOMAC knee pain (PR: 1.05, 95% CI: 1.02, 1.09). BMLs were associated with other structural abnormalities such as total knee cartilage defects (PR: 2.65, 95% CI: 1.47, 4.80) and total meniscal tears (PR: 1.70, 95% CI: 0.99, 2.94).

High Density Lipoprotein (HDL) cholesterol measured 5 years prior was negatively associated with any BML (PR: 0.36, 95% CI: 0.15, 0.87). Testosterone measured 5 years prior in females (PR: 0.99, 95% CI: 0.99, 1.00) and speed of sound in both sexes (bone mass, PR: 0.98, 95% CI: 0.97, 0.99) were negatively associated with femoral BMLs. Moderate physical activity was protective (PR: 0.93, 95% CI: 0.87, 0.99) while vigorous activity showed a deleterious trend (PR: 1.01, 95% CI: 1.00, 1.02) with BMLs as we reported in older and middle aged adults. All these models were adjusted for age, gender, BMI, duration of follow-up and injury.

Conclusion: BMLs in young adults are associated with increased knee symptoms, a history of injury and other knee structural lesions. Moderate physical activity (not vigorous) may be protective with BML. A higher bone mass and HDL cholesterol in both sexes and testosterone in women may be protective with the development of BMLs in young adults.

Physical Performance and Obesity Measures Are Associated with Tibial Cartilage Volume and Explains the Sex Difference in Cartilage Volume.

Benny Samuel Eathakkattu Antony[1], Alison Venn[2], Flavia Cicutinni[3], Lyn March[4], Leigh Blizzard[2], Terry Dwyer[5], Marita Cross[6], Graeme Jones[7] and Changhai Ding[7]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Tasmania, Australia, [3]Monash University, Melbourne, Australia, Melbourne, Australia, [4]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, [5]Murdoch Children's Research Institute, Melbourne, Australia, [6]University of Sydney Institute of Bone and Joint Research, Royal North Shore Hospital, Sydney, Australia, [7]Menzies Research Institute Tasmania, University of Tasmania, Hobart,7000, Australia.

Background/Purpose: The factors associated with knee cartilage volume in younger population are insufficiently explored. The aims of this study were to describe the associations between physical activity, physical performance, body composition, inflammatory and hormonal factors and tibial cartilage volume and to explore if these factors explained the sex difference in tibial cartilage volume observed in young adults.

Methods: Subjects broadly representative of the Australian population (n=328, aged 31–41 years, female 48.7%) were selected from the Childhood Determinants of Adult Health study. They underwent T1 and T2 weighted fat-suppressed magnetic resonance imaging (MRI) scans of their knees. Tibial bone area and cartilage volume were measured from MRI. Physical activity (long version of IPAQ questionnaires) and physical performance measures such as long jump, leg muscle strength, and physical work capacity at 170 heartbeats per minute (PWC_{170}) were measured. Sex hormone binding globulin (SHGB, females only), testosterone (females only), C-reactive protein and fibrinogen were measured 5 years prior. Fat mass and lean mass were calculated from skinfold.

Results: After adjustment for age, sex, BMI, injury, tibial bone area and duration of follow-up, physical performance measures including PWC_{170} (β: 3.4 mm^3, 95% CI: 1.1, 5.8) and long jump (β: 4.3 mm^3, 95% CI: 0.5, 8.0) measured 5 years prior were positively associated with tibial cartilage volume. Physical activity measures (hr/week) including total physical activity (β: 18.0 cm^3, 95% CI: 7.9, 28.2), vigorous (β: 32.1 mm^3, 95% CI: 7.9, 56.4), moderate (β: 20.6 mm^3, 95% CI: 0.8, 40.3) and walking (β: 23.7 mm^3, 95% CI: 4.4, 43.1) measured 5 years prior were positively associated with tibial cartilage volume. The associations of physical activity were independent of fitness levels and current physical activity level.

Lean body mass (β: 26.4 mm^3, 95% CI: 13.6, 39.1) was positively and fat mass (β: -11.8 mm^3, 95% CI: -22.2, -1.4) was negatively associated with cartilage volume. Fibrinogen was negatively associated with the cartilage volume (β: -0.15 mm^3, 95% CI: -0.28, -0.018). SHBG in females was positively (β: 0.67 mm^3, 95% CI: 0.14, 1.2) and free androgen index in females was negatively associated with tibial cartilage volume.

Males had greater tibial cartilage volume than females in adjusted analysis. The magnitude of this association (β of adjusted analysis) decreased by 54%, 47%, 42%, 37%, and 24% after further adjustment for lean body mass, leg strength, fat mass, $PWC_{170}$and fibrinogen, respectively, but remained largely unchanged after adjustment for other factors.

Conclusion: Lean mass, physical activity and physical performance measures are beneficially, while obesity measures and fibrinogen are negatively associated with tibial cartilage volume in young adulthood. The sex difference in tibial cartilage volume is largely explained by variations in body composition and physical performance measures. Physical activity measured 5 years prior was independent of the fitness and current physical activity levels, suggesting cartilage development in younger life can be modified by environmental intervention.

Preliminary Assessment of Predictive Validity of Cartilage Thickness MRI Biomarkers in Knee OA - the Fnih OA Biomarkers Consortium.

David J. Hunter[1], Jamie E. Collins[2], Michael C. Nevitt[3], John A. Lynch[4], Virginia B. Kraus[5], Jeffrey N. Katz[2], Elena Losina[2], Frank Roemer[6], Ali Guermazi[7], Wolfgang Wirth[8] and Felix Eckstein[8]. [1]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, [2]Brigham and Women's Hospital, Boston, MA, [3]UCSF (University of California, San Francisco), San Francisco, CA, [4]University of California at San Francisco, San Francisco, CA, [5]Duke University Medical Center, Durham, NC, [6]Klinikum Augsburg, Augsburg, Germany, [7]Boston University School of Medicine, Boston, MA, [8]Paracelsus Medical University, Salzburg, Austria.

Background/Purpose: We sought to investigate if cartilage thickness change over 24 months predicts clinically relevant progression (radiographic and/or symptomatic) in knee OA over a 48 month period.

Methods: The OA Biomarkers Consortium undertook a nested case-control study of progressive knee OA within the Osteoarthritis Initiative (OAI). Main inclusion criteria were KLG 1, 2 or 3 at baseline and availability of knee radiograph and magnetic resonance imaging (MRI) at baseline and 24 months. The primary case group (n=194) was defined by the combination of knee radiographic progression (medial tibiofemoral joint space loss (mTF JSL) >= 0.7mm) **AND** pain progression (persistent worsening in WOMAC pain score, reaching a MCID threshold of 9 points on a 0–100 scale), each achieved for the first time at the 24, 36 or 48 month follow-up compared to baseline; referred to as "JSL and pain progressor". We defined two additional case subsets in order to distinguish structural from pain progression: 103 subjects with JSL but no pain increase comprised "JSL only progressors": and 103 with a persistent increase in pain but no JSL comprised "Pain only progressors". "Nonprogressors" (n=200) were participants with a knee eligible for the study that did not meet either progression definition (pain or mTF JSL). Manual segmentation of the femorotibial cartilages was performed by trained readers to generate cartilage thickness. The measures used in this analysis were (i) change in cMFTC (central medial femorotibial compartment), and (ii) change in ccMF (central medial femur) and cMT (central medial tibia). Association between cartilage thickness measures and progressors vs nonprogressors was assessed using a logistic regression model

adjusting for baseline age, sex, BMI, KLG and baseline pain level. Additional analyses were conducted to detect marginal effects of cartilage thickness on changes in pain and mTF JSL.

Results: Participants had mean age of 61.5 years, 59% female and the majority were obese. Changes in cartilage thickness from BL to 24 months in the cMFTC, ccMF and cMT were greater for all three progressor groups combined compared to nonprogressors and significantly associated with increased odds of being a progressor (Table). The ORs for cartilage thickness changes ranged from 1.6 to 2.8, with the largest ORs associated with cartilage thickness changes in the ccMF OR 2.8 (95%CI 2.1 to 3.7). Further analysis suggested that these associations were with structural progression and not pain progression.

Table. Change in cartilage thickness at 24 months and prediction of case control status *OR (95% CI) p value*. ORs represent the change in odds of being a progressor per 1SD increase of normalized changes in cartilage thickness.

Region	All progressors (n=400) vs. nonprogressors (n=200)	Nonprogressors (n=200)	Pain only progressor (n=103)	JSL only progressor (n=103)	JSL and pain progressor (n=194)
Change in cMFTC	**2.5 (1.9, 3.3)**	ref	0.9 (0.6, 1.3)	**3.8 (2.7, 5.4)**	**3.8 (2.7, 5.3)**
Change in ccMF	**2.8 (2.1, 3.7)**	ref	1.0 (0.6, 1.5)	**4.0 (2.8, 5.7)**	**3.8 (2.7, 5.4)**
Change in cMT	**1.6 (1.3, 1.9)**	ref	0.8 (0.6, 1.2)	**1.8 (1.4, 2.4)**	**1.9 (1.5, 2.5)**

Conclusion: Changes in cartilage thickness markers over 24 months clearly differentiate progressors from nonprogressors. These associations are largely attributable to mTF JSL and not to pain increases.

211

Association Between Baseline External Knee Adduction and Flexion Moments during Gait and Medial Tibiofemoral Cartilage Thickness Loss over Two Years in Persons with Knee Osteoarthritis (OA).

Alison H. Chang[1], Kirsten C. Moisio[1], Felix Eckstein[2], Joan S. Chmiel[1], Orit Almagor[1], Pottumarthi Prasad[3], Karen W. Hayes[1], Laura Belisle[1], Yunhui Zhang[1], Jamie Rayahin[4] and Leena Sharma[1]. [1]Northwestern University, Chicago, IL, [2]Paracelsus Medical University, Salzburg, Austria, [3]NorthShore University HealthSystem, Evanston, IL, [4]University of Illinois at Chicago, Chicago, IL.

Background/Purpose: The external knee adduction moment (KAM) during gait has been characterized as a surrogate for dynamic medial knee load and is believed to be a risk factor for medial knee OA disease progression. By incorporating both load magnitude and duration, KAM impulse may provide a cumulative measure of KAM sustained during each step of walking. A reduction in KAM may be accompanied by a deleterious increase in the external knee flexion moment (KFM). Few longitudinal studies have evaluated the association between KAM impulse and peak KFM and subsequent medial OA disease progression. We hypothesized that in persons with knee OA, greater baseline peak KAM, KAM impulse, and peak KFM during gait are each associated with baseline-to-2-year worsening of medial cartilage thickness loss.

Methods: Participants had knee OA (K/L grade equal or greater than 2 in at least 1 knee). Baseline knee kinematics and kinetics during gait were recorded using an 8-camera Digital Real-Time Eagle motion analysis system, and 6 AMTI force plates; inverse dynamics used to compute peak KAM, KAM impulse, and peak KFM. MRI scans of both knees were done at baseline and 2-year visits. Regions of interest (ROI) were the entire medial tibial and weightbearing femoral surfaces; tibial external, central, and posterior subregions and femoral external and central subregions. Disease progression in each ROI was analyzed as: 1) baseline-to-2-year cartilage thickness loss equal or greater than 5%, and 2) % cartilage loss from baseline to 2 years later. We used logistic and continuous outcome regression models with GEE, adjusting for gait speed, age, and gender, then further adjusting for radiographic disease severity.

Results: The study sample included 385 knees (203 persons): mean age 64.2 years (SD 9.9); BMI 28.4 kg/m^2 (5.7); 156 (76.8%) women. In Table 1, peak KAM and KFM were not associated with cartilage thickness loss at least 5% in the fully adjusted models. In contrast, KAM impulse was associated with thickness loss at both medial surfaces and in all but the tibial posterior subregions. For the continuous outcomes, greater peak KAM and KAM impulse were each associated with greater mean 2-year % thickness loss at the medial tibial surface, particularly the external and central subregions, and at the weightbearing femoral surface, particularly the central subregion (Table 2).

Conclusion: Higher baseline KAM impulse was associated with 2-year medial tibiofemoral cartilage thickness loss using both definitions of progression. Peak KFM was not associated with cartilage loss. These findings support targeting KAM parameters, particularly KAM impulse, in an effort to delay disease progression.

Table 1 Adjusted odds ratios (95% CI) for medial tibiofemoral cartilage thickness loss outcomes (n = 385 knees; 203 persons)

		Cartilage thickness loss (defined as ≥ 5%) at 2-year follow-up (n=385 knees)

Relation of Shoe Stability to Risk of Knee Cartilage Damage: The Multicenter Osteoarthritis Study.

K. Douglas Gross[1], Howard J. Hillstrom[2], Jingbo Niu[3], Michael C. Nevitt[4], James C. Torner[5], Cora E. Lewis[6] and David T. Felson[1]. [1]Boston University School of Medicine, Boston, MA, [2]Hospital Special Surgery (HSS), New York, NY, [3]Boston University, Boston, MA, [4]UCSF (University of California, San Francisco), San Francisco, CA, [5]University of Iowa, Iowa City, Iowa City, IA, [6]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Clinical guidelines recommend that "every patient with knee osteoarthritis should receive advice concerning appropriate footwear", yet the recommended content of this advice is not specified. Some studies suggest that highly flexible shoes can protect the tibiofemoral (TF) joints against excessive load during gait, while other studies underscore the importance of stable or supportive shoes as a means of protecting the patellofemoral (PF) joint against maltracking brought about by foot pronation. The purpose of this observational study was to determine the relationship between the stability characteristics of a person's usual walking shoe and the 2-year risk of worsening cartilage damage in the medial TF, lateral TF, and PF knee compartments.

Methods: The Multicenter Osteoarthritis Study (MOST) includes middle aged and older adults that have or are at risk of knee OA. Subjects were asked to bring their usual walking shoes and, adapting the methods of Barton et al.,

examiners at the 60-month visit scored the sagittal, torsional, and heel counter stability of each subject's shoe as 0= flexible or 1= stable / supportive (kappa ≥ 0.69). A Summative Shoe Stability Score (0–3) was calculated as the sum of the three component test scores. 1.0T MRIs were obtained at the 60 and 84-month exams, and one knee per subject was scored using Whole Organ MRI Scores (WORMS) to indicate the extent of cartilage damage (0–6) in each of 5 sub-regions of the medial and lateral TF compartments, and each of 4 sub-regions of the PF compartment (kappa ≥ 0.63). Using separate logistic regression models for each compartment, we estimated the relative odds of worsening knee cartilage damage in categories of increasing shoe stability, while adjusting for covariates. Generalized estimating equations accounted for non-independence between sub-regions of a compartment.

Results: 1126 subjects (mean +/− sd age 66.8 +/− 7.5 yrs, BMI 29.6 +/− 4.8 kg/m^2; 61.7% female, 89.8% white) contributed 1124, 1123, and 1116 knees to the analysis of cartilage damage in the medial TF, lateral TF, and PF compartments, respectively. A majority of shoes (64.3%, 68.3%, and 55.0%, respectively) were scored as stable / supportive during sagittal, torsional, and heel counter stability tests, with 47.8% of shoes obtaining the maximum Summative Shoe Stability Score of 3 and only 25.5% obtaining the minimum score of 0. Relative odds of worsening cartilage damage in the medial TF, lateral TF, and PF knee compartments did not change across categories of increasing shoe stability ($p > 0.05$ for all comparisons).

Conclusion: These observational findings do not confirm an association between usual walking shoe stability and 2-year risk of worsening cartilage damage in medial TF, lateral TF, or PF knee compartments. Future studies are needed to clarify the shoe characteristics that are most relevant for persons with knee OA.

Table. Relative odds of worsening knee cartilage damage in categories of increasing shoe stability

	Medial TF Cartilage Damage		Lateral TF Cartilage Damage		PF Cartilage Damage

Foot Center of Pressure in Knee Osteoarthritis (OA) and Its Association with Knee Load Reduction with Barefoot Walking. Christopher Ferrigno, Roy H. Lidtke, Markus Wimmer, Anjali Nair, Laura E. Thorp, Louis F. Fogg, Joel A. Block and Najia Shakoor. Rush University Medical Center, Chicago, IL.

Background/Purpose: Biomechanical factors including excessive knee loading have been shown to be important in the pathophysiology, severity and progression of knee osteoarthritis (OA). Several biomechanical interventions reduce knee loads by altering foot mechanics, and there is a great deal of interest in better understanding mechanical relationships between the foot and knee. We have previously shown that barefoot walking in OA is associated with a significant reduction in knee loading compared to conventional footwear. Here we evaluate the role of foot center of pressure (COP) in predicting the unloading response of the knee when walking barefoot.

Methods: Participants with radiographic (KL grades ≥ 2) and symptomatic (at least 30mm pain of 100mm scale while walking) medial compartment knee OA underwent gait analyses with their own shoes and while walking barefoot. For simultaneous COP and 3-D ground reaction force acquisition, a pressure platform (Emed, Novel, Munich, Germany) was mounted onto a force plate (Bertec, Columbus, OH) and the stacked assembly was leveled with the walkway. All capture systems were run at 100 Hz to allow for accurate syncing of stance phase, knee moments, and plantar pressures. Foot COP was quantified by determining a custom Medial to Lateral Pressure Index (MLPI) while barefoot. The peak knee adduction moment (KAM) was evaluated as a surrogate of medial knee loading. Linear regression was used to evaluate the relationship between foot COP and percent reductions in the KAM with walking barefoot compared to own shoes. The relationships between foot COP and other gait parameters and OA severity were also evaluated.

Results: 22 participants (15 women, mean age (SD) of 62±11) were evaluated. 10 had a KL grade of 2 and 12 had a KL grade of 3 at the affected knee. Barefoot walking was associated with a 15% reduction in the KAM compared to walking with participants own shoes (2.55±1.00 vs 2.17±1.01%BW*ht, $p<0.001$); notably, the magnitude of reduction of the KAM with barefoot walking was associated with a more medial foot COP after adjusting for speed and stride length (adjusted $r^2=0.509$, $p=0.049$). A medialized foot COP was associated with worse KL grade, slower walking speed and shorter strides during gait ($r^2=0.564$, $p=0.002$). Radiographic severity explained 9 to 26% of the variance in the foot COP while speed and stride length explained 17 to 47%.

Conclusion: Foot mechanics are important contributors to knee loading in OA. There is controversy in the literature regarding the foot COP and how it may relate to various foot-targeted interventions in OA. This study suggests that a more medial foot COP is associated with greater reductions in the KAM during barefoot walking. Thus, foot COP may help predict knee loading responses to walking barefoot or an intervention that simulates barefoot walking.

Knee Instability and Advanced Function Decline in Persons with Knee Osteoarthritis. Leena Sharma, Joan S. Chmiel, Orit Almagor, Kirsten Moisio, Alison H. Chang, Yunhui Zhang, Laura Belisle and Karen W. Hayes. Northwestern University, Chicago, IL.

Background/Purpose: Knee instability in the setting of osteoarthritis (OA) encompasses a spectrum of symptoms and phenomena, including a feeling of low overall confidence in the knees, low confidence that the knees will not buckle or give way (buckling confidence), actual episodes of buckling, and excessive frontal plane motion. Current treatment for knee OA does little to address instability. Given the central role of the knee in weightbearing activity, confidence and buckling in particular may influence nature and intensity of activity, and could be important proximal factors in a chain of events leading to function decline and disability. It is unclear whether these factors are more important to outcome than instability objectively measured during gait. We hypothesized that overall confidence, buckling confidence, buckling, and excessive frontal plane motion during gait are each associated with poor 2-year function outcome.

Methods: Persons with OA in at least one knee were queried at baseline about overall knee confidence using the KOOS question (how troubled are you by the lack of confidence in your knees, higher worse), buckling confidence (i.e., confidence that knees will not buckle or give way, higher better), and any knee buckling in the past 3 months, and underwent quantitative gait analysis (3-dimensional knee kinematics and kinetics during ambulation recorded using an 8-camera Digital Real-Time Eagle motion analysis system, and 6 AMTI force plates). Physical function was assessed using the Late-Life Function Instrument – Advanced Lower Extremity Domain scaled score; quintiles were used to categorize these scores into groups. Poor outcome was defined as moving into a worse function group or remaining in the 2 worst function groups between baseline and 2 years. Logistic regression was used to evaluate the relationship between baseline instability measures, knee confidence and poor baseline-to-2-year function outcome, adjusting for potential confounders.

Results: 212 persons [163 (77%) women, mean age 65 (10, SD), BMI 28.5 (5.7)] comprised the sample.

98 (46%) had a poor outcome. As shown in the Table, buckling in the past 3 months, buckling confidence, and overall knee confidence, but neither varus-valgus excursion nor maximal varus-valgus angular velocity during gait were associated with the outcome in univariate analyses. In fully-adjusted models, these findings persisted (except for buckling confidence which

approached significance). Age and self-efficacy were also consistently associated with the outcome.

Conclusion: Worse baseline overall knee confidence and recent buckling, but neither varus-valgus excursion nor angular velocity using quantitative gait analysis were associated with greater risk of poor 2-year function outcome. Interventions to address confidence and buckling may improve outcome in knee OA.

TABLE. Results from logistic regression models to evaluate associations of each instability variable with odds of a poor function outcome; unadjusted and adjusted odds ratios (OR) and associated 95% confidence interval (CI). 95% CIs that exclude 1 are statistically significant

Instability variable (baseline)	Unadjusted OR (95% CI)	Fully adjusted* OR (95% CI)
Varus-valgus excursion during gait	0.95 (0.85, 1.06)	1.01 (0.89, 1.15)
Maximum varus-valgus angular velocity during gait	0.99 (0.98, 1.01)	0.99 (0.97, 1.01)
Buckling, past 3 months (yes/no)	***2.27 (1.28, 4.03)***	***2.05 (1.01, 4.16)***
Confidence knees will not buckle (higher better, continuous)	***0.63 (0.47, 0.85)***	0.68 (0.46, 1.01)
Overall knee confidence (higher worse, continuous)	***1.80 (1.27, 2.56)***	***1.66 (1.02, 2.70)***

*adjusted for age, gender, BMI, pain (ICOAP), function self-efficacy, depressive symptoms, disease severity (K/L, worse of 2 knees), knee extensor strength (better of 2 knees)

External Hip Adduction Moment and Progression of Medial Tibiofemoral Cartilage Damage and Bone Marrow Lesions in Persons with Knee Osteoarthritis. Kirsten Moisio[1], Alison H. Chang[1], Ali Guermazi[2], Joan S. Chmiel[1], Orit Almagor[1], Pottumarthi Prasad[1], Yunhui Zhang[1], Karen W. Hayes[1], Laura Belisle[1], Jamie Rayahin[3] and Leena Sharma[1]. [1]Northwestern University, Chicago, IL, [2]Boston University School of Medicine, Boston, MA, [3]University of Illinois at Chicago, Chicago, IL.

Background/Purpose: Gait mechanics at the hip may affect medial joint loading at the knee in persons with knee OA. Greater external hip adduction moment (reflecting torque generation by hip abductor muscles) during gait may limit excessive hip drop or trunk lean. This, in turn, may prevent excessive medial knee joint loading and eventual progression of knee OA. Little is known about the relationship between hip adduction moment and progression of medial tibiofemoral OA by MRI. We hypothesized that greater baseline external hip adduction moment is associated with reduced risk of baseline-to-2-year progression of medial tibiofemoral cartilage damage and bone marrow lesions in persons with knee OA.

Methods: Participants with knee OA, defined by osteophyte presence in at least one knee, underwent quantitative gait analysis at baseline. Both knees underwent 3.0T MRI at baseline and two year follow-up using double oblique coronal and axial FLASHwe, coronal T1weighted spinecho, and sagittal, axial and coronal fat suppressed turbo spin echo sequences. Cartilage damage and bone marrow lesions assessed using WORMS, blinding readers to hypotheses and all other data. Logistic regression with GEE used to account for correlation between limbs, assess the association between baseline hip adduction moment and baseline-to-2-year cartilage damage progression and bone marrow lesion progression, defined as any worsening of score in medial compartment or joint surface. Analyses adjusted for gait speed, age, gender, and disease severity (K/L grade). Results reported as ORs and 95% CIs.

Results: 204 persons [64.2 years (±9.9), BMI 28.5 kg/m^2 (±5.7), 76.5% women] contributing 391 knees comprised the study sample. Mean hip adduction moment was 4.43 (±0.9) %BW*HT. Table 1 shows a greater hip adduction moment was significantly associated with reduced likelihood of cartilage damage progression in the medial tibiofemoral compartment and medial femoral surface. After adjustment for covariables, these associations were no longer significant. Table 2 shows means (SD) of the hip adduction moment at baseline for knees with/without cartilage damage and bone marrow lesion progression in specific subregions.

Conclusion: In persons with knee OA, greater hip adduction moment was associated with reduced likelihood of 2-year medial tibiofemoral cartilage damage progression and bone marrow lesion progression, but findings were no longer significant in adjusted analyses. The consistently protective direction of findings at compartment, joint surface, and subregional levels warrants further evaluation at longer follow-up.

Table 1 Unadjusted and adjusted ORs (95% CIs) for medial tibiofemoral OA progression at 2 years

Hip Adiposity, Not Local Knee Adiposity, Is Associated with Knee Pain Independent of Radiographic Osteoarthritis Severity. Grace H. Lo[1], Ajay Balasubramanyam[2], Jeffrey B. Driban[3], Lori Lyn Price[3], Charles B. Eaton[4] and Timothy E. McAlindon[3]. [1]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Tufts Medical Center, Boston, MA, [4]Memorial Hospital of Rhode Island, Pawtucket, RI.

Background/Purpose: Elevated body mass index (BMI) is associated with pain in knee OA. However, it is unclear if adiposity closer in proximity to the knee might have a greater influence on pain in that joint. To address this question, we assessed whether fat measured around the knee or around the hip was associated with prevalent knee pain.

Methods: We performed a cross-sectional study of a subgroup of the incidence subcohort of the Osteoarthritis Initiative (OAI) who had DXA scans from the 72-month visit analyzed for knee and hip adiposity. Participants from 2 clinical sites were included. DXA scans of the right knee and one hip (usually the right) were acquired on identical GE Lunar Prodigy scanners, generating knee fat and hip fat percentages. Knee pain was assessed using the question from the 72-month visit, "In the past 12 months, have you had pain, aching or stiffness in or around your knee on most days for at least one month?" Posterior-anterior semiflexed knee radiographs were read for Kellgren-Lawrence (KL) grade (0–4) from the 48-month visit. We performed logistic regression with knee fat percent quartiles as the predictors and frequent knee pain as the outcome. Adjusted results included KL grade as a covariate. We repeated these analyses evaluating hip fat percent quartiles as the predictor.

Results: 359 participants, 51% female, were included with a mean age of 64.8 (8.0) years and BMI of 28.1 (4.9) kg/m^2. The frequency of KL grades 0 – 4 included were 44%, 19%, 21%, 13%, and 3% respectively. Table 1 illustrates that increasing knee fat percent quartiles were minimally associated with knee pain though both unadjusted and adjusted odds ratios were not statistically significant. In contrast, hip fat percent quartiles were associated with knee pain with the p for trend for both unadjusted and adjusted odds ratios being statistically significant.

Table 1 Fat percentiles of the knee and hip as predictors for frequent knee pain.

Knee Fat Percent Quartiles	Prevalence of Knee Pain	Unadjusted OR	Adjusted OR (for KL Grade)
Quartile 1 (6–25%)	12/88 (14%)	Referent	Referent
Quartile 2 (25–34%)	21/90 (23%)	1.4 (0.7–2.8)	1.2 (0.6–2.7)
Quartile 3 (35–44%)	18/90 (20%)	1.3 (0.5–2.4)	1.0 (0.5–2.3)
Quartile 4 (44–64%)	22/90 (24%)	1.4 (0.7–3.0)	1.3 (0.6–2.9)
		p for trend = 0.13	p for trend = 0.40
Hip Fat Percent Quartiles	**Prevalence of Knee Pain**	**Unadjusted OR**	**Adjusted OR (for KL Grade)**
Quartile 1 (10–21%)	10/86 (12%)	Referent	Referent
Quartile 2 (22–26%)	20/88 (23%)	2.1 (1.0–4.7)	1.8 (0.8–4.2)
Quartile 3 (26–32%)	19/88 (22%)	2.0 (0.9–4.4)	1.8 (0.8–4.2)
Quartile 4 (32–44%)	27/88 (31%)	3.2 (1.5–6.9)	2.4 (1.1–5.6)
		p for trend = 0.005	p for trend = 0.05

Conclusion: Hip adiposity, not local knee adiposity, was associated with knee pain independent of radiographic OA severity. These findings suggest that local adiposity may not have a clinically relevant influence on knee pain. Instead adiposity of the hip, one adjacent joint away, has a greater influence on knee pain. Understanding whether the mechanism of this relationship is biomechanically driven or driven by adipokines will be instructive in better understanding the causes of knee pain and identifying new targets of therapy.

The Relationship of Quadriceps and Hamstrings Intramuscular Fat and Lean Muscle with Power in Women with Knee Osteoarthritis. Michael J. Davison[1], Monica R. Maly[1], Karen A. Beattie[1], Peter J. Keir[1] and Jonathan D. Adachi[2]. [1]McMaster University, Hamilton, ON, [2]Division of Rheumatology, McMaster University, Hamilton, ON.

Background/Purpose: Reduced quadriceps and hamstrings strength is a risk factor for knee osteoarthritis (OA). This strength loss is partly due to the loss of lean muscle mass, increased pain and neuromuscular inhibition. Intramuscular fat, or fat within a muscle belly, is related to poor physical performance and radiographic disease progression in OA. We investigated the relationship between intramuscular fat fraction and lean muscle volume of the quadriceps and hamstrings with isotonic knee extensor and flexor power in women with knee OA.

Methods: Women (n=20) with radiographic and symptomatic knee OA had the thigh of their most symptomatic knee imaged using 3.0T magnetic resonance imaging (MRI). The iterative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) sequence obtained 60 fat-separated images (3 mm slice thickness). Images were analyzed using SliceOmatic® software with a region-growing algorithm to quantify intramuscular fat and lean muscle tissue volumes (cm^3) separately for the quadriceps and hamstrings (Figure 1). Intramuscular fat was represented as a fraction (%) of total muscle volume. Using a dynamometer, participants completed ten isotonic knee extensions and flexions, with resistance at 20% of maximum voluntary isometric contraction. Mean peak power (W or N×m/s) was calculated using the five highest contractions. Electromyography (EMG) measured the activation of the vastus lateralis and biceps femoris during contractions. Mean peak EMG amplitude was calculated from the five highest activations.

Results: Mean sample characteristics (±SD): age 65±5 yrs; Body Mass Index (BMI) 30±5 kg/m^2. There was a positive relationship between quadriceps lean muscle volume and knee extensor power (B=0.634; p=0.004), controlling for vastus lateralis activation. Also, there was a positive relationship between hamstrings lean muscle volume and knee flexor power (B=1.173; p=0.010), controlling for biceps femoris activation. No relationships were found between quadriceps or hamstrings intramuscular fat fractions and isotonic knee extensor (B=4.351; p=0.764) or knee flexor (B=−4.793; p=0.645) power, respectively.

Conclusion: Lean muscle volume of the quadriceps and hamstrings, but not intramuscular fat fraction, were significant factors in the knee extensor and flexor powers of women with knee OA. Our findings suggest that the volume of thigh lean muscle is of primary importance in the physical performance of women with knee OA, independent of neuromuscular activation. Although intramuscular fat has been implicated in radiographic disease progression, its role in thigh strength and power is uncertain. Further investigation is needed of intramuscular fat and its relationship to other factors of physical performance, such as neuromuscular activation.

Surface Area and Fatty Infiltration of Vastus Medialis Measured By Magnetic Resonance Imaging Are Risk Factors for the Progression of Knee Osteoarthritis and Discriminate Two Osteoarthritis Phenotypes. Johanne Martel-Pelletier[1], Jean-Pierre Raynauld[1], François Abram[2], Marc Dorais[3], Yuanyuan Wang[4], Jessica Fairley[4], Flavia Cicuttini[4] and Jean-Pierre Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Medical Imaging Research & Development, ArthroLab Inc., Montreal, QC, [3]StatSciences Inc., Notre-Dame de l'Île Perrot, QC, [4]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia.

Background/Purpose: Osteoarthritis (OA) is the most common arthritic condition but its treatment still remains symptomatic. Understanding factors affecting the progression of this disease may enable the development of disease-modifying therapies. Vastus medialis (VM) muscle surface has been proposed in recent OA studies to be associated with cartilage volume loss over time. However, the VM may include a significant proportion of fatty infiltration, which could also influence knee metabolism and mechanics. These two parameters can be visualized and quantified by MRI. Using data from a recent randomized clinical trial in knee OA[1], this study contrasted the VM surface area and fatty infiltration (% Fat) with cartilage volume loss and changes in bone marrow lesions as assessed by MRI.

Methods: OA patients, diagnosed according to American College of Rheumatology clinical and radiological criteria, were from the according-to-protocol population (n=143) of a 2-year randomized clinical trial, and had MRI acquisitions at baseline and 2 years. MR images of the VM (mm^2) were assessed semi-automatically and VM % Fat by a fully automated software. Univariate and multivariate analyses were performed to assess the relationship between VM area and its % Fat, cartilage volume loss, and bone marrow lesion changes over 2 years.

Results: The median baseline of the VM area and % Fat were chosen to stratify patients. Female ($p \leq 0.001$), higher BMI ($p \leq 0.008$), and disability ($p \leq 0.040$) were associated with both a higher baseline VM surface area and % Fat. Higher baseline VM area was associated with greater cartilage volume loss in the medial compartment, medial femur, and lower cartilage volume loss in the lateral plateau (all $p \leq 0.048$). Change in % Fat, but not in surface area, was associated with an increase in the bone marrow lesion score in the global knee and cartilage volume loss in the global knee, lateral compartment, lateral femur, and medial plateau (all $p \leq 0.035$). Multivariate analyses revealed correlations between % Fat, but not surface area, and cartilage volume loss in the global knee (p=0.011) and most subregions studied. Importantly, % Fat change was independently associated with bone marrow lesion change at 2 years (p=0.001). All of the above changes were found irrespective of the treatment the patients had during the clinical trial.

Conclusion: This study is the first to demonstrate that the % Fat in the VM is strongly associated with cartilage volume loss and the presence and progression of bone marrow lesions. Importantly, two different OA phenotypes were evidenced: i) low VM area phenotype comprising female patients with lower BMI, being more symptomatic at baseline, having more cartilage volume damage at baseline, and at 2 years less cartilage volume loss in the medial femur and more cartilage volume loss in the lateral plateau; ii) higher VM % Fat phenotype comprises female patients with higher BMI, having more disability at baseline, more cartilage volume damage at baseline, and at 2 years more cartilage volume loss in the medial plateau and lateral femur.

DXA Body Composition, Sarcopenia and Knee and Hip Osteoarthritis: Results from the Khoala Cohort. Clémence Jeanmaire[1], Isabelle Chary-Valkenaere[1], Damien Loeuille[2], Lorraine Bernard[3] and Anne-Christine Rat,[4]. [1]CHU Nancy, Vandoeuvre Les Nancy, France, [2]CHU Brabois, Vandoeuvre les Nancy, France, [3]INSERM, CIC-EC, CIE6, Vandoeuvre Les Nancy, France, [4]Université de Lorraine, Nancy, F-54000, France; Inserm,, CIC-EC, CIC 1433, Nancy, F-54000, France; CHU de Nancy, Clinical Epidemiology and Evaluation Department, Nancy, F-54000, France; CHU de Nancy, Rheumatology department, Nancy, France.

Background/Purpose: Obesity is a well known risk factor for the development and progression of knee osteoarthritis (OA), and to a lesser extent of hip OA. However, types of obesity and body composition abnormalities could have different impact on OA severity. Body composition has rarely been studied in hip OA and has never been compared to knee OA.

The purpose of this study was to analyze the associations between body composition and sarcopenia and OA location and severity (clinical and structural), in patients with symptomatic hip and/or knee OA.

Methods: Skeletal muscle and fat mass were measured using dual X-ray absorptiometry (DXA) in a subset of patients of the Knee and Hip OsteoArthritis Long term assessment (KHOALA) cohort[1].

Skeletal muscle mass index (SMI) was defined as appendicular skeletal muscle mass (ASM) / body weight. The SMI cutoff values used for sarcopenia were 26.8% for men and 21.0% for Women [2].

Pain and function were measured by WOMAC index and quality of life (QoL) by SF36. Structural severity was graded on X-Ray according to Kellgren and Lawrence's classification.

Percentages of patients in each group of body composition defined by presence or absence of obesity (BMI ^{3} 30 kg/m^2)) and/or sarcopenia were compared in knee and/or hip OA.

We also compared severity of OA (Xrays grade, pain, function and quality of life) in each group of body composition.

Results: *A DXA was performed in 381 patients among the* 878 patients included in the cohort*: women 254 (66.7%), mean (STD) age 63.6 (8.4), Hip OA 91 (23.9%), knee OA 267 (70.1), obesity 146 (38.8%), sarcopenia 105 (27.6%).*

Associations between joint and OA severity according to body composition *group are presented in table.*

	Normal body composition N=205 N (%)	Non obese patients with sarcopenia N=25 N (%)	Obese patients without sarcopenia N=65 N (%)	Obese patients with sarcopenia N=80 N (%)	p

WOMAC Function (mean (std))	24.1 (17.3)	36.2 (24.3)	34.7 (21.5)	35.9 (20.5)	<0.001
WOMAC Pain (mean (std))	27.0 (18.5)	36.8 (25.7)	38.7 (20.8)	39.6 (22.1)	<0.001

WOMAC [0,100], 0=best, 100=worse), SF36 PCS: Physical component summary, MCS: Mental component summary, 0=worse, 100=best

Normal body composition was significantly more frequent in patients with hip than knee OA, but frequency of patients with sarcopenia was not different in hip or knee OA.

Normal body composition seemed to decrease in more severe Kellgren stages but the associations did not reach statistical significance.

Physical component summary score was higher and pain score lower in patients with normal body composition than in patients with obesity. In patients with normal BMI, scores did not differ with or without sarcopenia.

Function score was lower in patients with normal body composition than in other patients. No difference was found between obese patients with or without sarcopenia. No difference was found between patients with sarcopenia and normal BMI and obese patients.

Conclusion: Impact of OA on pain, function and QoL was not different between obese patients and patients with sarcopenia and normal BMI. Impact of OA was worse in obese patients with or without sarcopenia than in patients with normal body composition.

Lower Extremity Presarcopenia Is Associated with the Severity of Knee Pain. Yun-Hong Cheon[1], Wan-Hee Yoo[2], Young Sun Suh[3], Hyun-Ok Kim[3], Ki-Soo Park[3], Sang-Il Lee[3] and Hye-Ji Jeon[3]. [1]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Chonbuk National University School of Medicine, Jeonju, South Korea, [3]Gyeongsang National University School of Medicine, Jinju, South Korea.

Background/Purpose: Presarcopenia, which is defined as skeletal muscle mass loss, and knee pain have been gained attention with ageing. Little is known about the association of lower extremity presarcopenia (LEPS) and severity of knee pain. Thus, this study was conducted to the relationship between severity of self-reported knee pain and LEPS.

Methods: From the 5th Korean National Health and Nutrition Examination Survey (KNHNES V1–2, n=17,476), the data of 721 participants, who underwent dual x-ray absorptiometry (DXA) and bilateral knee plain radiographs, and complained knee pain were analyzed. LEPS was defined as a lower extremity skeletal muscle mass index below -2SD of the value in sex-matched young reference groups. Participant were categorized into 4 groups; normal, LEPS, non-LEPS with obesity (NLEPSO), LEPS with obesity (LEPSO).

Results: LEPS and LEPSO are significantly associated with the severity of knee pain (LEPS 6.9±0.4, LEPSO 7.2±0.5, $P<0.05$). These results did not change after adjusting for various confounding factors. In participants with non-radiographic knee OA (n=268), the severity of knee pain was related with LEPS (7.2±0.6, $P<0.05$). In radiographic knee OA participants (n=452), LEPSO was related with severity of knee pain (7.3±0.5, $P<0.05$). Sex, smoking status, osteoporosis, and vitamin D levels were not related with the severity of self-reported knee pain.

Conclusion: LEPS is directly associated with severity of knee pain. This attribution supports increasing muscle mass is very important to reduce knee pain. Thus, early detection of LEPS may help physicians to detect pain-sensitive LEPS patients who can benefit from early intervention such as exercise.

An Analysis of Age-Related Loss of Skeletal Muscle Mass and Its Significance on Osteoarthritis in a Korean Population. Hyunje Kim, Minjung Kim, Choong Ki Lee and Young Hoon Hong. Yeungnam University, Daegu, South Korea.

Background/Purpose: This study was conducted in order to analyze the effects of sarcopenia and sarcopenic obesity on age-related OA of the knee in a Korean population.

Methods: All the subjects who visited Yeungnam University Hospital Health Promotion Center between 2008 and 2012 in order to undergo a routine medical examination, including BIA, were enrolled. BMR was calculated using the Cunningham equation, BMI as weight/height^2 (kg/m^2), SMI as ASM/body mass●100 (%), and PBF as FM/body mass●100 (%). The body components were evaluated by BIA using InBody 720 (Biospace, Seoul, Korea). A total of 522 knees with antero-posterior X-rays from 381 subjects in the population were enrolled in this study. The presence and severity of

bony changes for OA were measured and graded twice according to the Kellgren-Lawrence (K/L) grade.

Results: The mean and SD of SMI, BMI and PBF in healthy subjects aged 18 to 39 (total of 5,723 subjects; 2,959 males, 2,764 females) are shown at Table 1-1. Table 1–2 revealed characteristics and BIA parameters of this study population. Negative correlation was observed between SMI and age ($r=-0.157$, $p<0.01$), which was more prominent in females ($r=-0.313$, $p<0.01$) than in males ($r=-0.164$, $p<0.001$) (Table 2). Members of the population aged over 50 showed a significant decrease of SMI ($r=-0.166$, $\beta=-0.112$, $p<0.01$). The population over 50 years of age showed a significant increase of PBF as compared with that of the population under 50 ($r=0.117$, $\beta=0.125$, $p<0.01$).

A cross-tab analysis was done according to sarcopenia classification and body composition by PBF in the aspect of K/L grades (Table 3-1). Knees with sarcopenia class I and class II, and obesity showed a trend toward the higher K/L grade in the higher sarcopenia class and sarcopenic obesity ($p<0.01$). Results of logistic regression analysis between SMI and K/L grade showed a significantly high incidence of a higher K/L grade in subjects with a lower SMI, and significantly high incidence of a lower K/L grade was observed in those with a higher SMI ($p<0.01$) (Table 3-2).

Conclusion: This study provides evidence that sarcopenia and sarcopenic obesity are correlated with development of and progression to severe OA. Thus, the results of this study may indicate interactive correlation of SMI and PBF as age-related alteration of body composition with age related OA.

Table 1-1. Reference values for the classification of sarcopenia from a sex-matched, healthy Korean population aged between 18 and 39 years

		BIA

OA Phenotypes Rather Than Disease Stage Drive Structural Progression – Identification of Structural Progressors from 2 Phase III Randomized Clinical studies with Symptomatic Knee OA. Morten Asser Karsdal[1], Anne C. Bay-Jensen[2], Asger Bihlet[3], Peter Alexandersen[4], Inger Byrjalsen[3], Bente J. Riis[3] and Claus Christiansen[3]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Cartilage Biomarkers and Research, Nordic Bioscience, Herlev, Denmark, [3]Nordic Bioscience, Herlev, Denmark, [4]Center for Clinical and Basic Research, Vejle, Denmark.

Background/Purpose: Osteoarthritis (OA) is a heterogeneous disorder, with several possible drivers of disease progression. Up to 50% of OA patients do not structurally progress, emphasizing the importance for identification of fast progressors, and the phenotypes associated with that. There is therefore a medical need for in-depth, post-hoc analysis of clinical studies in OA. The aim of the analysis was to investigate the associations between JSW, KL-score, pain and JSN (joint space narrowing), as well as BMI, by combining data from two phase III studies (N=2,206) to identify key characteristics for disease progression.

Methods: This is a post-hoc analysis of two randomized, double-blind, multi-center, placebo-controlled trials NCT00486434 and NCT00704847 evaluating the efficacy and safety of 2-years treatment with oral salmon calcitonin in subjects with painful knee OA, enrolling 1,176 and 1,030 subjects. The analysis includes baseline data on KL-score, JSW, pain and function scores from the WOMAC questionnaire, as well as demographics.

Results: *Diagnostic measures;* At baseline, combined analysis of signal and non-signal knees, the mean JSW was comparable in knees of KL-0 and -1 and significantly decreased with increasing KL-2, -3 and -4 ($p<0.01$). JSW (KL2/3) was significantly lower in the non-target knees as compared to the target knees (3.32 ± 0.03mm vs. 3.42 ± 0.02mm, $p<0.0001$, mean±SEM). There was a clear positive and significant correlation between KL-score and WOMAC pain and total WOMAC, albeit the variance in pain measures was from min-to-max for all KL categories, emphasizing the heterogeneity of this patient population and pain perception. Prognostic measures; 32% of target knees did not progress, and only 51% had changes over minimum significant change (MSC). Only minor differences were observed between target and non-target and KL-2 versus KL-3. The mean JSN at 2-years for the non-target knee was 0.25 ± 0.02mm and 0.32 ± 0.02 for the target knee ($p<0.01$). Patients were stratified in quartiles for WOMAC pain and BMI, as well as WOMAC pain and KL-scores, and investigated for JSN. Q3 WOMAC pain progressed more than Q2 and Q4 in both scenarios.

Conclusion: These data from the largest clinical trial dataset in OA to date clearly describe significant associations between KL-score, JSW, pain and BMI in patients with symptomatic knee OA. 50% of patients did not progress

more than MSC, highlighting the importance for identification of structural progressors and the phenotypes associated with these. Patients with symptomatic OA at baseline progressed significantly faster than patients with asymptomatic disease, however with important variations that need accounting for when designing clinical trials, such as relations to pain, BMI and JSN. Different levels of progression were observed in relation to KL score and pain, in which the third WOMAC pain quartile (Q3), but not the fourth quartile (Q4), progressed significantly faster than the first and second pain quartiles. These results suggest that disease phenotypes rather than disease status are responsible for disease progression. Consequently, this dataset is ideally suited for identification of different phenotypes of OA, and biomarkers associated with those.

Risk Factors for Clinical Vertebral Fractures in Japanese Men and Women with Rheumatoid Arthritis: Results from a Large Prospective Observational Cohort Study.

Osamu Ishida[1], Takefumi Furuya[1], Eisuke Inoue[2], Kensuke Ochi[1], Katsunori Ikari[1], Atsuo Taniguchi[2], Hisashi Yamanaka[1] and Shigeki Momohara[2]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at high risk of developing vertebral fractures. Previously, utilizing data from our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort study, we reported clinical risk factors for clinicalvertebral fractures in Japanese patients with RA. However, in our previous studies, which analyzed data from 2000 to 2005, the number of patients with verified clinical vertebral fractures was only 40. The aim of this study was to re-evaluate the associations between potential risk factors and the occurrence of clinical vertebral fractures in a larger number of Japanese patients with RA.

Methods: IORRA is a prospective observational cohort study of Japanese patients with RA established in 2000 at the Institute of Rheumatology, Tokyo Women's Medical University. A total of 10,240 Japanese patients with RA (82% female; mean age, 56 years) were enrolled in IORRA cohort study from 2000 to 2011. Self-reported vertebral fractures were verified with patient medical records and radiographs. Independent contributions of various risk factors to clinical vertebral fracture occurrence were analyzed with Cox proportional hazards models.

Results: During a mean follow-up of 4.9 years, 399 patients reported 638 clinical vertebral fractures. Among these patients, 187 clinical vertebral fractures in 187 patients (18 men, 169 women) were verified with medical records (n = 95) and radiographs (n =92). The vertebral fractures were mainly caused by spontaneous events (65%) and falls (25%). Vertebral fractures occurred at lumbar (36%), thoracic (37%), and both (27%) levels of the spine. In men with RA, multivariate Cox regression analyses estimated that the risk of sustaining a clinical vertebral fracture increased by 2.51 for every 10 years of increased age, 2.96 for Japanese version of Health Assessment Questionnaire-Disability Index (J-HAQ-DI), and 1.17 for daily prednisolone dose (Table 1). In women with RA, multivariate Cox regression analyses estimated that the risk of sustaining a clinical vertebral fracture increased by 1.30 for Disease Activity Score 28 (DAS28), 2.35 for history of any previous fractures, 1.67 for every 10 years of increased age, 1.39 for J-HAQ-DI, and 1.08 for daily prednisolone dose (Table 1). Among the eight domains of the J-HAQ-DI, J-HAQ-DI (arising) was significantly associated with the clinical vertebral fractures in Japanese patients with RA (hazard ratio 1.26, 95% confidence interval [CI] 1.02–1.54).

Conclusion: We confirmed the associations between clinical vertebral fractures and advanced age, J-HAQ-DI, and high daily prednisolone dose in a larger number of patients and found significant correlations between clinical vertebral fractures and DAS28, history of any previous fractures, and J-HAQ-DI (arising) in Japanese patients with RA. These clinical risk factors appear to be different between men and women in Japanese RA patients.

Table 1 Hazard ratios (95% confidence interval) for the occurrence of clinical vertebral fractures in Japanese men and women with RA: Multivariate analyses.

Risk factors	Men	Women
DAS28	0.73 (0.36–2.48)	1.30 (1.05–1.63)
History of any prior fracture	1.32 (0.45–3.81)	2.35 (1.69–3.27)
Age, per 10 years	2.51 (1.34–4.73)	1.67 (1.42–1.97)
Japanese HAQ-DI	2.96 (1.02–3.60)	1.39 (1.08–1.79)
Daily prednisolone dose, mg/day	1.17 (1.06–1.29)	1.08 (1.05–1.12)

Is the Protective Effect of Obesity Against Hip Fracture Due to Changes of Proximal Femur Shape?

Alexander Oldroyd and Marwan Bukhari. Lancaster University, Lancaster, United Kingdom.

Background/Purpose: The association between increasing body mass index (BMI), increasing bone mineral density (BMD) and lower hip fracture risk has been demonstrated by previous research. Studies have implicated variations of proximal femur shape in hip fracture risk. Research has indicated that BMI affects hip fracture risk by its associations with both BMD and proximal femur shape.

This study aims to investigate if variations of proximal femur shape associated with BMI are associated with hip fracture risk, independent of BMD, in a large population of women aged over 50 years.

Methods: Data of women aged over 50 years that attended for a DXA scan at a UK hospital were collated. The following Hip Structural Analysis (HSA) measurements were used to characterise the shape of the proximal femur: distance from centre of femoral head to centre of femoral neck (d1), distance from centre of femoral head to inter-trochanteric line (d2), mean femoral neck diameter (d3), distance from centre of mass of femoral neck to superior neck margin (y), hip axis length (HAL), cross-sectional moment of inertia (CSMI) and the neck/shaft angle. Multiple regression analysis was used to investigate for associations between BMI and each HSA measurement, adjusted for age, femoral neck BMD and significant osteoporosis risk factors. Logistic regression analysis modelling was used to investigate for associations between previous contralateral hip fracture and each HSA measurement, adjusted for age, BMI, femoral neck BMD and significant osteoporosis risk factors.

Results: Data of 8,788 women was analysed. Analysis revealed that a wider (d3, y) and shorter (d1) femoral neck with increased cortical thickness (CSA, CSMI) were associated with a clear significant relationship with increasing BMI (tables 1 and 2). Further analysis revealed that proximal femur shape was not significantly associated with previous contralateral hip fracture (table 2).

Conclusion: This study of a large population of older women identified that a wider and shorter femoral neck with increased cortical thickness was associated with increasing BMI; however, variations of proximal femur shape associated with BMI were not associated with previous hip fracture status.

Association Between Lean Mass and Hip Bone Mineral Density. Charlotte Beaudart, Jean-Yves Reginster, Justine Slomian, Fanny Buckinx and Olivier Bruyere. University of Liège, Liège, Belgium.

Background/Purpose: Fat mass and lean mass (LM) represent 95% of body weight. However, the role of each component on bone mineral density (BMD) is not clear. In this study, we aimed to investigate the correlation between LM mass and hip BMD.

Methods: Voluntary subjects aged 65 years or older were recruited in an outpatient clinic in Liège, Belgium. Hip BMD as well as LM were measured by dual X-ray absorptiometry.

Results: 123 subjects were recruited for this study (88.5% of women, mean age 74.6 ± 6.4 years). LM was positively correlated with hip BMB (r=0.40; p<0.001). In a multiple regression analysis adjusted for sex, age, body mass index (BMI), physical activity, alcohol and tobacco consumption and presence of prior fracture, this relationship was still significant (b=0.35; p=0.02). In line with this result, we found a higher correlation between LM and hip BMD in men than in women (r=0.60 versus r=0.32 respectively), but also in subjects presenting a BMI higher than 25 kg/m^2 compared to the others (r=0.51 versus r=0.09), in subjects aged between 65 years and 80 years compared to older (r=0.38 versus r=0.29) and in subjects spending at least 1000 kcal/week for their leisure time activity (i.e. Minnesota test) compared to the others (r=0.44 versus r=0.28).

Conclusion: A positive association was found between LM and hip BMD. Strategies aiming to increase lean body mass in subjects aged 65 years or older could be of great public health interest in the field of bone health.

Improved Prediction of Hip Fracture Using the Health Assessment Questionnaire-Disability Index and FRAX® in Japanese Patients with Rheumatoid Arthritis: A Prospective Observational Study. Takefumi Furuya[1], Eisuke Inoue[2], Kensuke Ochi[1], Osamu Ishida[1], Atsuo Taniguchi[2], Shigeki Momohara[2] and Hisashi Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: The World Health Organization Fracture Risk Assessment Tool (FRAX®) algorithm can be used to estimate 10-year probabilities of hip and major osteoporotic fractures. Previously, we and others have reported a significant association between the Health Assessment Questionnaire-Disability Index (HAQ-DI) and clinical fracture risk in patients with rheumatoid arthritis (RA). This has generated interest in the possible role the HAQ-DI could play in improving fracture risk assessment for Japanese patients with RA. The aim of this study was to evaluate the prognostic accuracy of the Japanese version of FRAX® to predict the 10-year probability of hip and major osteoporotic fractures in Japanese patients with RA, and investigate whether the HAQ-DI can further improve the prediction of hip and major osteoporotic fractures.

Methods: We analyzed the database of the Institute of Rheumatology Rheumatoid Arthritis (IORRA) study, our large prospective observational cohort study in Japanese patients with RA. IORRA study subjects included 3,095 women and 703 men with RA ranging in age from 40 to 90 years. The mean (± standard deviation) age was 60.6 ± 9.6 years. Self-reported major osteoporotic fractures of the hip, vertebrae, humerus, and wrist were verified using patient medical records. The association of FRAX® with fractures was evaluated by the Cox model, and C-statistics were used in the risk prediction model to account for censored *survival*data. The Japanese version of HAQ-DI (J-HAQ-DI) was used in the assessment in conjunction with FRAX®, without considering bone mineral density (BMD) values, and C-statistics were used for the 10-year risk calculated by the Cox model.

Results: A total of 3,789 Japanese patients with RA were followed for an average of 5.8 years. Using FRAX® without BMD, the mean 10-year predicted fracture probability for hip and major osteoporotic fractures was 5.3% and 14.5%, respectively. Among the patients, 52 (1.4%) and 216 (5.7%) presented with hip and major osteoporotic fractures (including n=52 hip, n=85 vertebral, n=41 humeral, and n=38 distal radial fractures), respectively. For hip fractures, the C-statistic was 0.735 (95% CI: 0.665, 0.804) for the statistical model prediction based on both J-HAQ-DI and FRAX®, and it was 0.688 (95% CI: 0.613, 0.762) for FRAX® alone. For major osteoporotic fractures, the C-statistic was 0.678 (95% CI: 0.636, 0.719) for both J-HAQ-DI and FRAX®, and 0.664 (95% CI: 0.624, 0.704) for FRAX®alone.

Conclusion: We evaluated the performance of FRAX® in Japanese patients with RA using our longitudinal study data. Our results were similar to those in other previously reported FRAX® studies. However, the J-HAQ-DI improved hip fracture risk assessment when used in conjunction with this conventional risk assessment tool in Japanese patients with RA.

Increasing Fat-Mass May Reverse Bone Loss As Detected By DXA Scan. William Hedges[1] and Marwan Bukhari[2]. [1]Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom.

Background/Purpose: Low body mass index (BMI) is a known risk factor for loss of bone mineral density (BMD). It is a part of the FRAX ™ 10-year fracture risk stratification tool developed by the World Health Organisation. It is also known that weight loss through dieting decreases BMD, whilst weight loss through exercise preserves it. The effects of fat-mass and change in fat-mass have not been examined extensively. This could have implications for health advice given to those at significant risk of fragility fractures. This study aimed to identify factors influencing change in bone density related to fat-mass and any confounders.

Methods: Data were analysed from patients having dual-energy X-ray absorptiometry (DXA) assessment between 2007 and 2010. Patients were included if they had multiple scans which included measurements of lean mass and fat mass. Our scanners limited these to scans of the AP spine. Linear regression was performed to determine the relationship between changes in fat mass and BMD. A backwards stepwise linear regression model was fitted with inclusion of confounders including: sex, risk factors, previous fractures, baseline BMI and age at menopause.

Results: 23,239 patients were included in the study, of which 702 met our inclusion criteria. This included 93 males (13%) and 609 females (87%). Mean age at first scan in the whole cohort was 64.5 years (SD11.2). The mean interval between scans was 3.0 years (SD 0.89). Step-wise linear regression identified a positive correlation between increasing fat-mass and t-score per unit time between scans (coefficient 28.4, p<0.01 95%CI 26.6–30.1). Controlling for the above factors didn't alter the results. We identified previous pelvic and femur fractures (p<0.05) and history of inflammatory diseases (p<0.05) as independent risk factors influencing bone density related to fat mass. This relationship was true for patients that were underweight (BMI <18.5), normal weight (BMI 18.5–25), and overweight patients (BMI >25).

Conclusion: Increasing fat mass between DEXA scans is associated with an increase in t-scores. Other factors associated with increasing fat-mass include previous pelvic and femur fractures, as well as history of inflamma-

tory disease. However, excessive fat-mass is associated with increased cardiovascular (CVD) and metabolic disease states. Increasing fat-mass is therefore not viable for all patients. Those at particular risk of fragility fractures and not CVD, e.g. BMI<18.5, may be able to improve their long-term risk by gaining weight.

Is Adult Hypophosphatasia a Cardiovascular Risk Factor? Leyre Riancho-Zarrabeitia[1], Maria T. García-Unzueta[1], Alfonso Corrales[1], Juan Gómez-Gerique[1] and José A. Riancho[2]. [1]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla. IDIVAL. University of Cantabria, Santander, Spain.

Background/Purpose: Mild forms of adult hypophosphatasia may have subtle manifestations, and may go unrecognized. The aim of this study was to get a better knowledge of its clinical spectrum.

Methods: We performed a computerized search of low total alkaline phosphatase among laboratory records. The diagnosis of hypophosphatasia was confirmed by measuring serum pyridoxal phosphate (PLP) and bone alkaline phosphatase. Carotid ultrasonography was performed in patients and controls with a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer.

Results: Over a 31 month period, we identified 130 individuals with at least one determination of serum alkaline phosphatase less than 26 u/l. After reviewing the clinical records, unexplained persistently low levels were found in 42 individuals who accepted to participate in the study (10 men, 32 women). Age range was 20–77 yr (mean 51). Total alkaline phosphatase levels were positively correlated with bone alkaline phosphatase ($r=0.52$, $p<0.001$). Serum PLP was inversely correlated with bone alkaline phosphatase. Ten individuals (24%) had PLP levels above the reference range of 175 nmol/l, consistent with hypophosphatasia. In comparison with those with normal PLP levels, these individuals had higher frequency of hypertension (50 vs 12%, $p=0.02$). Likewise, individuals with hypophosphatasia showed a trend to have early atherosclerotic disease. Carotid ultrasound showed bilateral plaques in 4 out of 9 patients (44%), and only in 26% of the age and sex-matched controls. The intima-media thickness also tended to be increased in the patients (670 ± 70 vs. 648 ± 110 microns; $p=0.18$).

Conclusion: These preliminary data suggest that individuals with adult hypophosphatasia may be at increased cardiovascular risk. The results should be confirmed in larger studies.

Disclosure: L. Riancho-Zarrabeitia, None; **M. T. García-Unzueta**, None; **A. Corrales**, None; **J. Gómez-Gerique**, None; **J. A. Riancho**, None.

Correlates of Heel Bone Mass in Young Adults: The Role of Cholesterol over 20 Years from Childhood to Early Adulthood. Benny Samuel Eathakkattu Antony[1], Changhai Ding[2], Alison Venn[3], Terry Dwyer[4] and Graeme Jones[2]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart,7000, Australia, [3]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Tasmania, Australia, [4]Murdoch Children's Research Institute, Melbourne, Australia.

Background/Purpose: The association between lipids and bone mass in adult life is controversial and there is limited evidence in childhood. The aim of this study was to describe the association between cholesterol measured in childhood and young adult life and bone mineral density (BMD) in younger adults.

Methods: Subjects broadly representative of the Australian population ($n=1431$, female=52%, age=26–36) were selected from the Australian Schools Health and Fitness Survey of 1985. They underwent various measurements including leg strength, standing long jump, and physical work capacity at 170 heart beats per minute (PWC_{170}). Physical activity, smoking and alcohol history were recorded using questionnaires. Fasting lipid profiles were assessed in childhood and 20 years later in adulthood. A single Sahara bone ultrasound densitometer was used to determine heel bone mass in adulthood.

Results: In multivariable analysis, childhood High Density Lipoprotein (HDL) was positively (β: 0.056 g/cm^2, 95% CI: 0.005, 0.108) and total cholesterol (TCH, normal Vs high β: -0.042 g/cm^2, 95% CI: -0.081, -0.003) and Low Density Lipoprotein (LDL, normal Vs high β: -0.019 g/cm^2, 95% CI: -0.039, 0.000) were negatively associated with BMD in adulthood. Similarly, adulthood TCH (β: -0.007 g/cm^2, 95% CI: -0.015, -0.001) and LDL (β: -0.011 g/cm^2, 95% CI: -0.019, -0.003) were negatively associated with adult life BMD. The association between childhood HDL and adulthood BMD remained significant after further adjustment for adulthood HDL levels. Subjects who remained in the abnormal category of TCH from childhood to adulthood (high-high) had the least bone mass compared to other category changes of TCH from childhood to adulthood.

These results were independent of gender, alcohol consumption and duration of follow-up from childhood to adulthood. The other confounders included in this analysis were independently associated with BMD, such as age (negatively associated with BMD, β: -3.58 mg/cm^2 per year, 95% CI: -6.14, -1.01), physical activity (vigorous activity, β: 0.04 mg/cm^2 per min/week, 95% CI: 0.01, 0.08), BMI in childhood and adulthood (both positively associated with BMD) and smoking (β: -18.34 mg/cm^2, 95% CI: -27.35, -9.34). Duration and pack year of smoking were independently and negatively associated with BMD while performance measures including PWC_{170} (β: 0.33 mg/cm^2 per Watts, 95% CI: 0.15, 0.51), leg muscle strength (β: 0.24 mg/cm^2 per Kg, 95% CI: 0.02, 0.45) and long jump (β: 0.71 mg/cm^2 per cm, 95% CI: 0.40, 1.02) were positively associated with BMD.

Conclusion: HDL in childhood was beneficially and high TCH was detrimentally associated with adulthood BMD. LDL and TCH in adulthood were detrimentally associated with BMD. The effect of childhood HDL was independent of the adulthood HDL levels. These results indicate that cholesterol may have long-term effects on bone mass from childhood to early adulthood.

Risk Factors That Predict Poor Bone Health in Those Aged over 75 Years - a Cross Sectional Study. James Fowler[1], Christopher Varley[2], Alexander Oldroyd[2] and Marwan Bukhari[2]. [1]University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom.

Background/Purpose: .No studies have been conducted into the over 75 population specifically to assess the risk factors that predict BMD loss. The Framingham Osteoporosis Study (age range 69–90) found that gender, weight loss, alcohol use and smoking were the only risk factors that predicted significant increase in the loss of BMD(1). However that study did not analyse

other risk factors such as glucocorticoid use, previous fragility fracture, family history of osteoporosis and rheumatoid arthritis. Furthermore we have shown that bone loss in the lumbar spine and the femoral neck could differ and this was not examined in the elderly.

The aim of this study was to establish which risk factors would predict BMD loss in the over 75 year old population in the lumbar spine and the femoral neck.

Methods: A cohort of patients referred between 2004 and 2011 to a DEXA scanner in the North West of England who over the age of 75 were identified. The sites of bone that were scanned for BMD loss were the L1-L4 vertebrae and the non dominant femoral neck. The risk factors collated included age, gender, BMI, current smoking, family history of osteoporosis, rheumatoid arthritis, current corticosteroid use, history of fragility fracture and current alcohol excess. A regression model was then fitted to determine predictors of BMD loss in those aged over 75. This was done at both the femoral neck and the lumbar spine adjusting for age and gender.

Results: 4,655 patients over the age of 75 were identified; the mean age of the cohort was 79.2 (SD 3.9), with 3732 (80%) females The following risk factors were found to be significantly associated with increased BMD loss in the hip when adjusted: height with a beta coefficient of 0.004 (95% CI 0.003, 0.004), weight 0.005 (95% CI 0.004, 0.006), BMI 0.012 (95% CI 0.011, 0.013) and history of fragility fracture -0.034 (95% CI -0.045, -0.023). The following risk factors were found to be significantly associated with increased bone loss in the lumbar spine after adjusting: height with a beta coefficient of 0.006 (CI 95% 0.004, 0.007), weight 0.007 (95% CI 0.006, 0.0074), BMI 0.014 (CI 95% 0.0135, 0.016), rheumatoid arthritis 0.036 (95% 0.007,0.06) and history of fragility fracture -0.05 (−0.066, -0.04). Glucocorticoid use, tobacco use, alcohol use and family history of osteoporosis were not found to be associated.

Conclusion: Risk factors for increased BMD loss in patients over 75 years old were height, weight, BMI and history of fragility fracture in both the hip and the lumbar spine with rheumatoid arthritis being a risk factor for only the lumbar spine. The results from this study suggest that assessing bone health in the elderly is complex and assuming that risk factors do not change with age is not the case.

Factors Predicting Fracture in the over-75s: An Observational Case-Control Study. Christopher Varley[1], James Fowler[2], Alexander Oldroyd[1] and Marwan Bukhari[3]. [1]Lancaster University, Lancaster, United Kingdom, [2]Lancaster Univeristy, Lancaster, United Kingdom, [3]Royal Lancaster Infirmary, Lancaster, United Kingdom.

Background/Purpose: In the over 75s the diagnosis of osteoporosis may be assumed following a fracture, making the need for a dual energy absorptiometry scan (DEXA) optional [1]. In those presenting without fracture, it has been suggested that referral for a DEXA scan in the over 75s should require the presence of 2 risk factors for osteoporotic fracture[2]. However, the strength of these risk factors for predicting fractures in this specific age range has not been properly assessed. This study aims to assess the sensitivity of the risk factors in predicting fractures in patients aged 75 and over.

Methods: Using a nested case-control approach, a cohort of patients aged over 75 and referred between 2004 and 2011 to a DEXA scanner were indentified. The patients were divided into two cohorts depending on their fracture history. The risk factors assessed were hip and spine BMD, family history of fragility fracture, smoking, alcohol excess, steroid use, body mass index (BMI) and rheumatoid arthritis. Logistic models were fitted predicting fractures in the group, adjusting for age and gender.

Results: 4,663 patients over the age of 75 were identified; the median age of the cohort was 79.2 years (SD 3.1 years), with 3732 (80%) females. Fracture was the presenting feature in 1830 (39.25%) of the subjects. The only risk factors which were significantly increased in the fracture group, when adjusted for age and gender, were reduced BMD in the hip (OR: 1.65, CI: 1.21 – 2.42), reduced BMD in the spine (OR: 3.81, CI: 2.81 – 5.16) and rheumatoid arthritis (OR: 6.42 CI: 3.56 – 11.58). The other risk factors of smoking, alcohol excess, family history, steroids and BMI were not significantly associated with fractures when adjusted for age and gender with steroids showing an apparent protective effect (OR 0.74 95%CI 062, 0.87).

Conclusion: Most of the traditional risk factors which predict bone mineral density loss and fracture, such as smoking, alcohol, low BMI and steroid use do not predict fragility fracture in the over 75s, with a curious beneficial effect of steroids. This study has found that the factors which most predict fracture in the elderly are a low BMD in both the hip and spine, and rheumatoid arthritis. This shows that the current clinical advice to not routinely DEXA scan the over 75 year old patients is potentially incorrect; in this age group a patient's hip and spine BMD can provide useful information for judging fracture risk. Limitations of this study include it's observational design, but this association should be studied further.

Significance of Serum Srankl and Osteoprotegerin Concentration in Patients with Rheumatoid Arthritis. Kotaro Shikano, Kaichi Kaneko, Mai Kawazoe, Shotaro Masuoka, Hiroshi Sato, Emiko Shindo, Natsuki Fujio, Makoto Kaburaki, Sei Muraoka, Nahoko Tanaka, Tatsuhiro Yamamoto, Kenji Takagi, Natsuko Kusunoki, Tomoko Hasunuma and Shinichi Kawai. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is known as a cause of secondary osteoporosis. The previous studies reported that receptor activator for nuclear factor κB ligand (RANKL) and osteoprotegerin (OPG) were involved in patients with osteoporosis of various causes. Serum soluble RANKL (sRANKL) is a molecule that may possibly be related to RANKL expression in osteoblasts. The purpose of this study is to investigate serum levels of sRANKL, OPG and several bone metabolism markers in patients with RA.

Methods: RA patients and healthy controls were recruited at Toho University Omori Hospital and the Research Center for Clinical Pharmacology of Kitasato University, respectively. 360 patients with RA [mean age 61.5±13.4 (SD) years, male 66 and female 294 (menopause 229), mean disease duration 119±6.0 (SD) months] were included. We measured serum levels of sRANKL and OPG in RA patients and healthy controls. Serum levels of bone formation markers [intact aminoterminal propeptide of type I procollagen (P1NP) and bone specific alkaline phosphatase (BAP)], and bone resorption markers [type I collagen cross-linked N- telopeptide (NTX) and tartrate-resistant acid phosphatase form 5b (TRACP-5b)] were measured in the same subjects. In addition to these, we observed the background of the RA patients, such as age, sex, disease duration, stage classification, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Disease Activity Score (DAS) 28-ESR, Health Assessment Questionnaire (HAQ), Sharp score, and bone mineral density (BMD).

Results: The serum level of sRANKL [median (25th to 75th percentile range)] in patients with RA [0.09 (0.01–0.21) pmol/L] was significantly increased compared to that of healthy controls [0.03(0–0.19) pmol/L]. As well, the serum level of OPG of RA [5.24 (4.04–5.67) pmol/L] was significantly increased in comparison to healthy subjects [3.61(3.04–4.13) pmol/L]. The serum sRANKL level was negatively correlated with age, CRP and ESR by univariate analysis. In multivariate analysis, sRANKL was negatively correlated with age and disease duration, whereas, it was positively correlated with HAQ. The serum level of OPG was positively correlated with CRP, DAS28-ESR and MMP-3 as well as age by univariate analysis. In multivariate analysis, OPG was positively correlated with age and MMP-3. Both of serum sRANKL and OPG did not correlate with Sharp score and BMD in RA patients. There was no statistical correlation between the serum levels of sRANKL and OPG in RA patients and healthy controls.

Conclusion: In this study, we showed that both of the serum levels of sRANKL and OPG were significantly higher than those in healthy controls. Since sRANKL was correlated with disability index of HAQ, it is suggested that we should pay attention to deterioration of osteoporosis especially in the RA patients with severely impaired activities of daily living. On the other hand, OPG was correlated with disease activity of RA, suggesting that further attention to osteoporosis will be necessary even for the RA patients with the lower disease activities or remission.

Significance of Serum Marker Levels of Wnt/β-Catenin Signaling Pathway in Patients with Systemic Autoimmune Diseases Under Glucocorticoid Therapy; A Prospective Study. Mai Kawazoe, Kotaro Shikano, Kaichi Kaneko, Shotaro Masuoka, Hiroshi Sato, Emiko Shindo, Natsuki Fujio, Sei Muraoka, Makoto Kaburaki, Nahoko Tanaka, Tatsuhiro Yamamoto, Kenji Takagi, Natsuko Kusunoki, Tomoko Hasunuma and Shinichi Kawai. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Glucocorticoids are widely used to treat a variety of diseases, including systemic autoimmune diseases. Although glucocorticoids improve the outcome for patients with these diseases, various side effects of long-term treatment, such as osteoporosis, have become an important problem. Glucocorticoids decrease bone density through multiple mechanisms by inhibition of bone formation and by enhancement of bone resorption. Recently, the identification of the Wnt/β-catenin signaling pathway has led to considerable interest as one of the mechanism of osteoporosis in postmenopausal women. Wnt/β-catenin signaling pathway is mediated by Wnt3a and plays an important role in bone formation. Sclerostin and Dickkopf1 (Dkk-1) have been identified as antagonists of Wnt signaling. Therefore the purpose of this study is to clarify the clinical significance of the Wnt signaling pathway by measuring the serum levels of sclerostin, Dkk-1, Wnt3a and bone turnover markers in patients with recent onset of glucocorticoid therapy.

Methods: Patients were recruited at Toho University Omori Medical Center. This study was approved by the Ethics Committee of the Medical Center. Forty patients (25 females [14 postmenopausal], 55.2 ± 2.9 yr [mean ± SD]) with systemic autoimmune diseases (vasculitis syndrome 16, systemic lupus erythematosus 12, polymyositis / dermatomyositis 9, and adult-onset Still's disease 3) who received initial glucocorticoid therapy with prednisolone daily (30–60 mg) were prospectively enrolled in this study. Their mean bone mineral density at starting of prednisolone therapy was 0.944 g/cm2. Mean C -reactive protein was 4.08 ± 0.51 (S.D.) mg/dl. Regular doses of bisphosphonates (alendronate or risedronate) were co-administered in all patients. We measured serum sclerostin, Dkk-1, Wnt3a and bone turnover markers at 0, 1, 2, 3 and 4 weeks after start of glucocorticoid therapy.

Results: Serum sclerostin level was significantly ($p<0.05$) increased from 1st to 2nd weeks after starting of glucocorticoid therapy in comparison to previous value. Serum Dkk-1 level had a tendency to decrease, but there was no significant difference. Serum Wnt3a level had a trend to decrease after glucocorticoid therapy. Serum bone formation markers, osteocalcin and procollagen type I N-terminal peptide, decreased from 1st to 4th weeks, whereas bone alkaline phosphatase did not change. Serum bone resorption markers, tartrate-resistant acid phosphatase isoform 5b and N-telopeptide crosslinked of type I collagen did not change.

Conclusion: We found that glucocorticoid therapy caused increased level of serum sclerostin and a trend of decreased Wnt3a level. It is suggested that suppression of Wnt/β-catenin signaling pathway might, at least in part, be a cause of severe osteoporosis in patients with systemic autoimmune diseases under glucocorticoid therapy.

The Decrease in Prescription of Anti-Osteoporotic Drugs Has No Impact on Hip Fracture Incidence. Karine Briot[1], Milka Maravic[2] and Christian Roux[3]. [1]Paris Descartes University, Paris, France, [2]Hopital Leopold Bellan, Paris, France, [3]Paris Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: Controversies exist about the change in hip fracture incidence among countries. In France, we previously showed that the incidence of hip fractures decreased in both genders, especially in the elderly from 2002 to 2008 in parallel with availability of bone densitometry and effective antiosteoporotic treatments. However these prescriptions are decreasing, since 2009 (1), and recent studies show declining of osteoporosis management after fragility fractures. The aim of this study was to assess the incidence of hip fractures in men and women aged 60 years and over, from 2008 to 2013 in France.

Methods: Data were drawn from the French Hospital National Database which includes all hospitalizations. Hospital data for hip fractures between 2002 and 2013 were numbered and the incidence rates per 1,000,000 adjusted on age (60–74; 74–84, and ≥ 85 years), and gender was calculated using the data of the French population.

Results: The number of hip fractures increased in women (+5%; from 49,287 in 2002 to 50,215 in 2013) and in men (+22%, from 12,716 to 15,482 in 2013). Between 2002 and 2013, the French population increased by 21 and 29% in women and in men. Incidence of hip fractures over 60 years decreased by -14% in women (6,929 and 5,987 per million in 2002 and 2013, respectively) and a slight decrease of -1%was observed in men (2,344 and 2,316 per million in 2002 and 2013, respectively). An age-specific incidence decrease was also confirmed, in particular, in the elderly in both genders (≥ 85 years) with a decrease of -29% in women and -24% in men ($p<0.00001$).

Conclusion: Over the last 12 years, the incidence of hip fractures decreased in France in women and men aged over 60 years. This decrease is particularly important in the elderly in both genders. This is observed in parallel with the decrease in prescription of antiosteoporotic treatments. Further studies are needed to assess potential changes in hip fractures risk factors during the last decade.

Lower P1NP Serum Levels: a Predictive Marker of Bone Loss after One-Year Follow-up in premenopausal SLE Patients. Luciana Seguro[1], Caio B. Casella[1], Valéria Caparbo[1], Ricardo M. Oliveira[2], Alessandra C Bonfa[1], Eloisa Bonfa[1] and Rosa M R Pereira[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]RDO Diagnosticos Medicos, São Paulo, Brazil.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with high risk of low bone mass/fractures but this risk is still controversial in premenopausal women. Our aim was to determine the one-year incidence of bone mineral density (BMD) loss in premenopausal SLE women and the value of bone turnover markers as predictors of this complication.

Methods: This study enrolled a convenience sample of 63 premenopausal SLE patients. BMD was evaluated by dual X-ray absorptiometry at lumbar spine and hip at baseline and after 12 months. BMD changes above the least significant change were considered significant. Serum levels of P1NP and CTX (electrochemiluminescence), OPG and RANKL (ELISA) were determined at baseline.

Results: Mean age was 31.1±6.8years, disease duration was 5.25±3.8years. 36.5% of patients presented BMD loss and 17.5% BMD gain at lumbar spine and/or hip. Patients were divided in three groups: BMD loss (BL), no BMD change (NC) and BMD gain (BG). Patients with BL and NC received similar cumulative/mean/maximum glucocorticoid doses during the study, but patients with BG received lower doses ($p<0.05$). Baseline P1NP levels were different in the groups (BL:36.95±23.37 vs. NC:54.63±30.82 vs. BG:84.09±43.85 ng/ml; $p=0.031$ BL vs. NC, $p<0.001$ BL vs. BG and $p=0.039$ NC vs. BG). There was no difference in CTX, OPG or RANKL levels. After multivariate analysis P1NP remained as an independent risk factor for BMD loss ($p<0.03$).

Conclusion: This study provides original evidence that lower levels of P1NP, the most specific bone formation marker, are predictive of BMD loss over 12 months in premenopausal SLE patients.

Risk Factors for Prevalent and Progressive Bone Deficits Among Adult Men and Women with Cystic Fibrosis. Joshua Baker[1], Putman Melissa[2], Karen Herlyn[3], Angela S. Pizzo[4], Allen Lapey[5], Joel Finklestein[2] and Peter A. Merkel[6]. [1]Philadelphia VA Medical Center, Philadelphia, PA, [2]Harvard University, Boston, MA, [3]University Hospital Schleswig-Holstein, Lübeck, Germany, [4]Mercy Hospital, Portland, ME, [5]Massachusetts General Hospital, Boston, MA, [6]Vasculitis Center, University of Pennsylvania, Philadelphia, PA.

Risk Factors for Prevalent and Progressive Bone Deficits Among Adult Men and Women with Cystic Fibrosis

Background/Purpose: Cystic Fibrosis (CF) is associated with an increased risk of osteoporosis and incident fracture. Factors associated with prevalent and

progressive bone deficits in adults with CF have not been comprehensively studied. This study assessed the independent predictors of baseline bone mineral density (BMD) and 2-year changes BMD in adults with CF.

Methods: Sixty-four adult patients with CF, ages 18–57, were recruited from the Massachusetts General Hospital Cystic Fibrosis Care Center. Dual energy absorptometry (DXA) was performed at the spine and radius at baseline and 2-years. Estimates of fat-free mass index (FFMI) and fat mass index (FMI) were determined using height, weight, and tetrapolar bioelectric impedance analysis. All subjects underwent lung spirometry within 1 month of the study visit to measure forced vital capacity (FVC) and forced expiratory volume (FEV1). Linear regression models evaluated predictors of baseline BMD Z-scores and change in anterior-posterior (AP) spine BMD Z-score over the 2-year follow-up. Osteopenia was defined as a BMD Z-score of $^{2}-1.0$.

Results: Osteopenia was present in 52% of subjects. Compared to patients without osteopenia, subjects with osteopenia were more likely to be male (67% v. 32%, $p=0.009$), more likely to be current users of glucocorticoids (21% v. 0%, $p<0.001$), had lower percent body fat (19% v. 23%, $p=0.04$), and were more likely to have had a previous fracture (60% v. 46%, $p=0.007$). In multivariable models, greater estimated FFMI and greater height, but not greater FMI, were associated with greater BMD after adjusting for sex (Table 1). Low FVC and greater adiposity were associated with greater loss of BMD at the A/P spine over two years ($p<0.05$) (Table 2).

Conclusion: Male sex, short stature, and low lean mass at baseline are associated with low BMD among adults with CF. Greater adiposity and lower lung function in women are predictors of negative change in BMD Z-score at the A/P spine at 2-years of follow-up.

Table 1: Multivariable associations between baseline body composition factors and baseline bone density Z-score at different measurement locations.

Analysis of Vitamin D Receptor Gene Polymorphisms and Bone Mineral Density in a Population of Women with Rheumatoid Arthritis in Use of Steroid. Juliana Lucena[1], Fernanda G. G Chaer[2], Rogerio Castro Reis[3] and Branca Souza[1]. [1]Santa Casa Sao Paulo, sao paulo, Brazil, [2]Santa Casa de Sao Paulo, São Paulo, Brazil, [3]Santa Casa de Sao Paulo, São Paulo, Brazil.

Background/Purpose: To determinate the association between vitamin D receptor (VDR) gene alleles and bone mineral density (BMD), comparing a group of healthy pre-menopausal white women to a group of pre-menopausal white women with rheumatoid arthritis (RA), treated with corticosteroid (CE). In the RA group, analysis of the correlation between BMD and VDR genotypes, RA activity, severity, and duration of CE treatment was also performed.

Methods: forty healthy volunteers and 50 patients with RA were recruited. The VDR genotypes were assessed by PCR amplification followed by Bsml digestion on DNA isolated from blood leukocytes.

Results: There was no association between the genotypes of VDR and BMD in both groups, nor any association of genotype BB with subgroups of RA and osteopenia in femoral neck or lumbar spine. The RA group had an average BMD lower than the control group ($p=0.004$ in L2-L4 and $p=0.007$ in femoral neck). The patients with RA and femoral neck osteopenia had a higher rate of joint destruction ($p=0.03$). The correlation analysis confirmed the influence of the joint destruction rate in BMD of femoral neck and showed a negative correlation between duration of CE treatment and BMD in L2-L4 ($p=0.003$).

Conclusion: results indicate that in this populations of RA women, VDR gene polymorphism should not predict the BMD. This study on RA suggests that the severity of joint destruction is associated with lower femoral neck BMD, and that the duration of CE treatment is correlated with lumbar spine BMD.

RANKL and OPG Gene Polymorphisms: Association with Vertebral Fractures and Bone Mineral Density in Premenopausal Systemic Lupus Erythematosus. Alessandra C. Bonfa, Luciana P.C. Seguro, Valéria Caparbo, Eloisa Bonfa and Rosa M R Pereira. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: To evaluate single nucleotide polymorphisms (SNPs) of the receptor activator of NF-κB ligand (RANKL), RANK and osteoprotegerin (OPG) genes in premenopausal systemic lupus erythematosus (SLE) patients and their association with sRANKL and OPG serum levels, vertebral fractures and bone mineral density(BMD).

Methods: 211 premenopausal SLE patients (ACR criteria) and 154 healthy controls were enrolled. SNPs of RANKL 290A >G (rs2277438), OPG 1181G >C (rs2073618), 245T >G (rs3134069), 163 A >G (rs3102735) and RANK A >G (rs3018362) were obtained by real-time PCR. sRANKL/OPG serum levels were determined by ELISA. BMD and vertebral fractures were evaluated by dual energy X-ray absorptiometry.

Results: SLE patients and controls had similar frequencies of the RANKL 290 G allele ($p=0.91$), OPG 1181 C allele ($p=0.83$), OPG 245 G allele ($p=0.80$), OPG 163 G allele ($p=1.00$) and RANK G allele ($p=0.75$). Further analysis of SLE patients revealed that the frequency of the RANKL 290 G allele was lower in patients with fractures than in patients without fractures (28.1 vs. 46.9%, $p=0.01$). In addition, the frequency of the OPG 245 G allele was higher in patients with low BMD than in patients with normal BMD (31.4 vs. 18.1%, $p=0.04$). No association of OPG 1181 G >C, OPG 163 A >G and RANK A >G SNPs with BMD/fractures was found. Additionally, no association was observed between RANKL/OPG/RANK SNPs and sRANKL/OPG serum levels.

Conclusion: Our study provides novel data demonstrating that RANKL/OPG genetic variations play a role in bone remodeling and, particularly, in its major complication, fracture, in premenopausal patients with SLE.

Does Adjusting BMI for Lean Mass Deficits Affect Calculated Fracture Risk Using FRAX in Rheumatoid Arthritis? Brittany Adler[1] and Joshua F. Baker[2]. [1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Osteoporotic fractures are a cause of morbidity in rheumatoid arthritis (RA) and low body mass index (BMI) is a risk factor for osteoporotic fractures in RA. Emerging evidence suggests that low lean mass is responsible for bone structural deficits among those with low BMI. Therefore we hypothesized that adjusting BMI for lean mass deficits commonly seen in RA would alter prediction of risk using the FRAX tool. We studied the effect of utilizing a lean mass-adjusted BMI as an independent variable in the FRAX tool in the determination of fracture risk.

Methods: Whole-body dual energy absorptiometry (DXA) was previously performed in 40 RA subjects and 500 controls. We have previously identified independent associations between the total fat mass index (FMI)

and appendicular lean mass index (ALMI) among 500 healthy control subjects. Based on our published model, we determined the expected ALMI for RA subjects based on their age, sex, race, and FMI. We then multiplied the actual BMI by the ratio of the actual to expected ALMI to determine a lean mass-adjusted BMI. We calculated fracture risk among RA subjects using the FRAX calculator, and evaluated the differences in fracture risk prediction using the lean mass-adjusted BMI compared to the standard BMI both with and without using bone density results from DXA.

Results: Using the lean mass-adjusted BMI in place of standard BMI, the calculated risk of a major osteoporotic fracture increased in 21 (52.5%), decreased in 8 (20%), and was unchanged in 11 (27.5%) subjects. The mean absolute change in calculated 10-year major osteoporotic fracture risk using lean mass-adjusted BMI was 0.28% ± 0.70 (p=0.02). Similarly, the calculated risk of hip fracture using lean mass-adjusted BMI was increased in 23 (57.5%), decreased in 6 (15%), and unchanged in 11 (27.5%) subjects. The mean absolute change in calculated 10-year hip fracture risk was 0.25% ± 0.60 (p=0.01). The calculated risk of hip fracture using lean mass-adjusted BMI was most increased among subjects with a BMI <25 kg/m^2. For subjects with a BMI<25 (n=11) the estimated fracture risk was significantly increased by 0.67% ± 0.87 (p=0.03), as compared to -0.09% ±0.37 (p=0.2) for subjects with a BMI >25 (n=29) (p for comparison=0.005). When bone density at the hip was included into the FRAX calculation, the differences in calculated fracture risk using the lean mass-adjusted BMI and standard BMI were completely attenuated (Figure 1).

Conclusion: Using lean mass-adjusted BMI in place of standard BMI in the FRAX equation results in an increase in calculated fracture risk for most patients with RA, particularly among those with a normal BMI (BMI<25). Incorporation of bone density measures significantly reduced these differences in risk prediction, which suggests that use of a lean mass-adjusted BMI would not affect risk prediction when bone density is available.

An Observational Study on the Influence of Glucocorticoid Exposure on Bone. Joseph Heath[1], Alexander Oldroyd[1], Maarten Boers[2] and Marwan Bukhari[1]. [1]Lancaster University, Lancaster, United Kingdom, [2]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: It is well known that glucocorticoids are detrimental to bone health and has been postulated that their influence is more than their effect on reduction of bone mineral density (BMD). This has not been localised to type of bone involved as trabecular bone and cortical bone differ. The FRAX ™ tool uses the hip BMD as a predictor of future fracture risk, which is a measure of cortical rather than trabecular bone. Recently, we have shown that hip structure analysis (HSA) is also e predictor of fracture. We aimed to study in an observational manner the effect of corticosteroid (CS) use on the bone in the lumbar spine (trabecular bone) and the hip (cortical bone), in addition to any differences in HSA.

Methods: Patients who are identified from a cohort recruited from the North West of England referred for a bone densitometry (DEXA) scan and receiving CS. Patients were divided into those that had sustained a fragility fracture (cases) and compared to those who had not (controls). Analysis was carried out using the student t-test for continuous variables and the Chi^2 test for categorical variables. Logistic regression analysis was carried out to investigate any significant association between BMD and bone fracture in patients receiving CS. HSA variables were also included in the model.

Results: There were 3,360 patients (73.46% female) identified as receiving CS, of which 779 (23.18%) had suffered from a facture. Mean age of patients who suffered a fracture was significantly higher than those who did not; 62.33 (SD=13.09) vs 67.39 (SD=11.75) respectivly (p value = <0.001). Females were significantly more likely to suffer a fracture compare to males; 33.86% vs 20.00% respectively (p.value=<0.001). After adjusting for age and sex, the mean difference in BMD between patients on steroids who suffered a facture compared to those who did not suffer a fracture at the femoral neck was 0.06 g/cm2 (95%CI=0.05–0.08) and at the lumbar spine was 0.09 g/cm2 (95%CI=0.07–0.10). Logistic regression analysis after adjustment showed that patients who were on steroids were likely to have a lower BMD at the femoral neck (OR=0.13, 95%CI=0.06–0.34) and the lumbar spine (OR=0.13, 95%CI=0.08–0.21). Modelling HSA showed that after adjustment, Cross sectional moment of inertia and not hip axis length was different between the cohorts (OR 0.95 95%CI 0.95,0.98 vs OR 0.99 95%CI 0.98,1.01 respectively).

Conclusion: In this cohort of patients fractures in those taking steroids are associated with increasing age, female sex, and lower BMD. Patients who are taking CS and suffer from a fracture are significantly more likely to have a lower BMD. Differences in Hip structure are also seen. This study does not support the theory that CS are an independent variable in fracture risk in patients. Further prospective studies are needed.

Reduced Estimated Glomerular Filtration Rate Was Improved after Cessation of NSAID and Switching to Tramadol Hydrochloride/Acetaminophen Tablets (Ultracet™) in Patients with Chronic Musculoskeletal Pain. Kenji Miki[1], Hiroshi Kajiyama[2], Kenrin Shi[3], Shigeshi Mori[1], Masao Yukioka[4] and Masao Akagi[1]. [1]Faculty of Medicine, Kindai University, Osaka-Sayama, Japan, [2]Saitama Medical University, Saitama, Japan, [3]Osaka University Hospital, Suita, Japan, [4]Yukioka Hospital, Osaka, Japan.

Background/Purpose: NSAID is widely used in patients with chronic musculoskeletal pain, but often deteriorates renal function with acute decline of estimated glomerular filtration rate (eGFR). However, there is little evidence on the long-term effect of chronic NSAID use, whether the eGFR decline is irreversible or not.

Methods: We studied 100 patients with chronic musculoskeletal pain (age 66.8 ± 18.4 years; 29 men, 71 women; 46 patients with lumbago, 28 with osteoarthritis, 26 with other complaints) over a followup period of 2 years. The baseline eGFR of the 100 patients was 85.13±25.63 mL/min/1.73m^2. We compared eGFR change during the first year with daily NSAID administration and that during the following year with daily administration of tramadol hydrochloride/acetaminophen tablets, in the same patient. eGFR was calculated as follows; male,194*Scr O-1.094*age O-0.287; female: eGFR (male)*0.739. As for the NSAID during the first year, meloxicam was administered in 33 patients, loxoprofen in 29, diclofenac in 19, and celecoxib in 11.

Results: eGFR change was -0.973 mL/min/1.73m^2 during the first year with NSAID administration, whereas it was +0.047 mL/min/1.73m^2 during the following year with tramadol hydrochloride/acetaminophen tablets administration. The difference of eGFR change between the two medications was statistically significant (paired t test, p=0.002; Figure), suggesting the cessation of NSAID and switching to tramadol hydrochloride/acetaminophen tablets can improve the renal function deteriorated by NSAID. As for the specific NSAIDs during the first year, cessation of diclofenac and meloxicam followed by switching to tramadol hydrochloride/acetaminophen tablets resulted in a significant improvement in eGFR (paired t test, p=0.0008 and p<0.0001, respectively; Figure), whereas switching from loxoprofen just showed a tendency of improvement (paired t test, p=0.0604; Figure). On the other hand, cessation of celecoxib and switching to tramadol hydrochloride/acetaminophen tablets did not show significant improvement in eGFR (paired t test, p=0.9389; Figure). Improvement of eGFR after switching to tramadol hydrochloride/acetaminophen tablets was also recognized in 4 patients with diabetes and 12 patients with intake of angiotensin receptor blockers, but did

not reach statistical significance. There was no correlation between age and eGFR change over the one year either with NSAID or with tramadol hydrochloride/acetaminophen tablets.

Conclusion: Our findings suggest that reduced eGFR due to one year administration of NSAID could be reversible to a certain degree by cessation of NSAID and switching to tramadol hydrochloride/acetaminophen tablets. The degree of eGFR improvement was different depending on the types of NSAID.

WOMAC Pain Score Reflects Preceding Daily Pain Ratings in Knee Osteoarthritis Interventional Randomized Clinical Trials. Michael H. V. Nguyen[1], Renita Evonne Yeasted[2] and Thomas J. Schnitzer[2]. [1]University of Washington School of Medicine, Seattle, WA, [2]Northwestern University, Chicago, IL.

Background/Purpose: The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) is a validated and widely used instrument for assessing osteoarthritis (OA) knee and hip pain, stiffness and physical function. The recall period for specific outcome measures is 48 hours. This study aimed to examine the correlation between WOMAC pain score and reported actual pain levels one, two and 5 days prior to completing the WOMAC instrument.

Methods: Data were obtained from three OA studies: an observational study (OBS) convenience sampling of OA and the placebo arm of two interventional randomized control trials (IRCTs). All participants were ≥ 40 years of age, met the ACR definition for OA, and self-reported a minimum pain intensity of ≥ 4 on Numeric Rating Scale (NRS) for pain (0 – no pain; 10 – worst pain possible). Participants were asked to report pain twice daily (IRCTs, electronic tablet) or three times daily (OBS, smartphone) over a 12–16 week period, and WOMAC was completed at regular clinic visits. For each participant, mean pain ratings were calculated for the day of clinical exam, as well as 1 day, 2 days, and 5 days prior and compared to the WOMAC pain score for question 1. Pearson's correlation was computed to assess the relationship between WOMAC pain score and self-reported pain using Stata 13.

Results: In total, data were collected from 162 participants (123 studied in clinical trials and 39 studied in the observational study). The demographics for all three groups were similar and typical of adults with OA. Among clinical trial participants, there was a strong, positive correlation between WOMAC and self-reported pain for all time points [r=0.8505, n=392 (exam day); r=0.8482, n=474 (1 day prior); r=0.8575, n=415 (2 day prior); r=0.8173, n=267 (5 day prior); all values $p < 0.05$] (Figure 1). Among observation study participants, there was a moderate, positive correlation between WOMAC and self-reported pain significant only at 1 day prior to exam [r=0.3741, n=56] (Figure 2).

Conclusion: The findings of this study demonstrate a high correlation within individuals between WOMAC pain scores and self-reported daily preceding pain intensity in ICRT. This correlation was independent of the look-back period (one, two or five days). Less strong correlations were observed in OBS study settings. These findings are consistent with lower daily pain variability in interventional trials than in the observational setting and have implications on assessing and managing pain in non-IRCT settings.

Safety of Solumatrix Diclofenac in Adults with Osteoarthritis: Results of a 12-Month, Phase 3 Study. Roy Altman[1], Allan Gibofsky[2], Marc C. Hochberg[3], Byron Cryer[4], Alan J. Kivitz[5], Vibeke Strand[6], Olaolu Imasogie[7] and Clarence Young[8]. [1]University of California–Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [2]Hospital for Special Surgery, New York, NY, [3]University of Maryland School of Medicine, Baltimore, MD, [4]University of Texas Southwestern Medical Center, Dallas, TX, [5]Altoona Center for Clinical Research, Duncansville, PA, [6]Stanford University, Palo Alto, CA, [7]Iroko Pharmaceuticals LLC, Philadelphia, PA, [8]Iroko Pharmaceuticals, LLC, Phila, PA.

Background/Purpose: Osteoarthritis (OA) is a frequent cause of disability in adults. NSAIDs such as diclofenac are often prescribed to treat OA pain. However, NSAIDs are associated with serious dose-related gastrointestinal (GI) and cardiovascular adverse effects, leading the FDA to recommend NSAID use at the lowest dose for the shortest duration necessary to achieve treatment goals. SoluMatrix® diclofenac has been developed using SoluMatrix Fine Particle Technology™ to provide efficacy at low doses and is approved for treatment of mild to moderate acute pain in adults. We report results from a 12-month, open-label phase 3 study investigating SoluMatrix diclofenac in patients with OA.

Methods: This multicenter study treated 601 chronic NSAID/acetaminophen users, aged ≥40 years with knee and/or hip OA. Patients initially received SoluMatrix diclofenac 35-mg capsules BID; the dosing regimen could be increased to TID if necessary and subsequently reduced as needed. Safety analyses included incidence of adverse events (AEs), serious AEs (SAEs), AEs leading to discontinuation, and clinical laboratory test results.

Results: Most patients were women (372/601, 61.9%) with a mean (± SD) age of 59.7 ± 8.9 years. Mean (± SD) trial drug administration duration

was 274.9 ± 125.7 days. AEs were reported by 451/601 (75.0%) patients (**Table**). The most frequently reported events included: upper respiratory tract infection (47/601, 7.8%), headache (46/601, 7.7%) and urinary tract infection (44/601, 7.3%). GI ulcer was reported in 1 patient (0.2%), considered related to study medication. Hypertension was reported in 17/601 (2.8%) patients, and serum creatinine increased in 7/601 (1.2%). SAEs were reported in 42/601 (7.0%) patients. Two patients (2/601, 0.3%) experienced myocardial infarction; both considered unrelated to study drug (**Table**). AEs led to discontinuation in 99/601 (16.1%) patients. Alanine aminotransferase or aspartate aminotransferase ≥3× the upper limit of normal was noted in 20 patients (3.3%), which was associated with elevated bilirubin in one patient and improved following treatment discontinuation.

Conclusion: SoluMatrix diclofenac was generally well tolerated. These data extend the SoluMatrix diclofenac experience to include patients requiring extended treatment for OA pain.

Table.

Adverse Event	SoluMatrix Diclofenac 35 mg TID (n =302)[a]	SoluMatrix Diclofenac 35 mg BID (n =601)[a,b]	Combined SoluMatrix Diclofenac (n =601)[a,c]
Most Frequent (>5% in Any Treatment Group) Adverse Events			
Any AE	186 (61.6)	340 (56.6)	451 (75.0)
URI	21 (7.0)	27 (4.5)	47 (7.8)

Onset, Magnitude, and Durability of Pain Relief in Patients with Knee OA Receiving a Fixed-Dose Combination Tablet of Enteric-Coated (EC) Naproxen Plus Immediate-Release (IR) Esomeprazole Magnesium Versus Celecoxib and Placebo: Pooled Results from Two Randomized Controlled Trials. John Fort[1], Robert Holt[2], Amy Y. Grahn[3], Jana Steinmetz[4], Ying Zhang[1] and Jeffery Kent[5]. [1]Pozen, Inc, Chapel Hill, NC, [2]University of Illinois-Chicago, Vernon Hill, IL, [3]Horizon Pharma, Inc., Deerfield, IL, [4]Premier Research, Naperville, IL, [5]Horizon Pharma, Inc, Deerfield, IL.

Background/Purpose: Over 40% of patients with OA report having significant knee pain every day. (1) Previously published data have demonstrated the overall comparable efficacy of EC naproxen/IR esomeprozole to celecoxib and superiority to placebo in the management of knee OA. (2) EC naproxen/IR esomeprazole also significantly reduced the incidence of endoscopic ulcers and improved UGI tolerability compared with EC naproxen alone in previous trials and maintained GI protective effect with low-dose aspirin (3). This new analysis characterizes time-to-first pain relief, effect size, and sustainability of naproxen/IR esomeprazole and celecoxib with placebo.

Methods: Two double-blind, double-dummy, placebo-controlled trials in patients aged ≥50 years with knee OA randomized to either EC naproxen 500mg/IR esomeprazole 20mg BID (n=487) or celecoxib 200mg/day (n=486) or placebo (n=246). Acute response endpoints assessed: 1) Time to first significant response during days 1–7 as measured by Patient Global Assessment Likert scale, 2) Western Ontario and McMaster Osteoarthritis Index (WOMAC) pain subscale using a visual analog scale (VAS) during days 1–7, and 3) American Pain Society Patient Outcome Questionnaire (APS-POQ) scores over the first 7 days. Endpoints to assess sustainability of naproxen/esomeprazole included: 1) Routine Assessment of Patient Data (RAPID)-3 and 2) WOMAC Stiffness, Total and Pain VAS at 6/12 weeks. Time to first significant response was analyzed using the log-rank test and estimated using the Kaplan-Meier analysis method. Other endpoints were analyzed using ANCOVA models with baseline values as covariates. Least square means, confidence intervals, and p-values were generated on change from baseline differences compared to placebo. Effect sizes (Cohen's D) and correlation coefficients (Spearman, Pearson) were estimated descriptively.

Results: EC Naproxen/IR esomeprazole produced statistically significant decreases in WOMAC Pain on Days 2–7 (Figure) and at Weeks 6 and 12; APS-POQ pain assessments were significantly improved on Days 2–7. RAPID and WOMAC Total/Pain/Stiffness scores decreased significantly at Weeks 6 and 12. Responses were comparable to celecoxib. Pain relief effect sizes were moderate and median days to good-excellent response was 6 days. Total RAPID-3 to WOMAC and WOMAC to RAPID Pain were highly correlated with each other (correlation > 0.80) at 6 and 12 weeks.

Conclusion: EC naproxen/IR esomeprazole produces a moderate-large early pain response which is maintained for 12 weeks. RAPID-3 was found to be highly correlated with the typical OA measure (WOMAC) and might be a useful clinical tool for measuring NSAID response.

Neuropathic PAIN in Patients with Ankylosing Spondylitis. Pinar Borman[1], Ferda Kaygisiz[2], Aysegul Yaman[1] and Aynur Karagoz[2]. [1]University of Hacettepe Faculty of Medicine, Ankara, Turkey, [2]Ankara Training and Research Hospital, Ankara, Turkey.

Background/Purpose: There is only one study in the literature indicating that neuropathic pain occurs in ankylosing spondylitis (AS) (1).

Methods: The aim of this cross sectional study was to evaluate frequency of neuropathic pain in AS patients and to determine the relation with disease variables and occurrence of neuropathic pain. Fifty-eight AS patients who were not having any comorbid disease and/or using drugs that would cause neuropathy, were recruited to the study. Demographic properties (age, sex,

disease duration) and clinical characteristics (functional status and disease activity assessed by BASFI and BASDAI respectively, ESR, CRP and quality of life determined by ASQoL questionnaire) were recorded. The neuropathic property of back pain was assessed by both LANSS and DN4 scales. Descriptive statistics was used for clinical variables and frequency of neuropathic pain. The difference of clinical variables between patients with and without neuropathic pain, were examined using t tests and chi square tests. Spearman test was used for correlation analyses. The significance threshold was set as $p < 0.05$.

Results: Fifty-eight AS patients (17 female, 41 male) with a mean age of 45±18 years were included to the study. 33 patients (56.9%) and 31 patients (53.4%) were defined as having neuropathic pain depending on the LANSS (scores >12) and DN4 (scores >4) questionnaire scores respectively. The mean score of LANSS scale was correlated with ASQoL, BASFI, BASDAI, and DN4; and the mean score of DN4 scale was correlated with ASQoL, BASFI, LANSS and BMI. The mean levels of BASFI and ASQoL were significantly higher in patients having neuropathic pain than in patients not having ($p<0.05$) (Table 1). The percentage of patients with neuropathic pain was higher in female than in male patients (58.8% vs 51.2% by DN4, 64.7% vs 53.6% by LANSS).

Conclusion: Neuropathic pain is determined in more than half of the patients with AS and related with functional status and quality of life. In conclusion neuropathic pain is common in AS patients. Diagnosis and treatment of neuropathic pain are warranted in order to increase functional ability and quality of life in patients suffering from AS.

Cognitive Task Related Hypoperfusion of Frontal Gyrus in Patients with Chronic Fatigue. Jason Craggs[1], Song Lai[1], Ricky Madhavan[1], Donald Price[1], Michael Robinson[1] and Roland Staud[2]. [1]University of Florida, Gainesville, FL, [2]Univ of Florida Med Ctr/JHMHC, Gainesville, FL.

Background/Purpose: Patient with Chronic Fatigue Syndrome (CFS) frequently report cognitive complaints, including lack of concentration and forgetfulness. Previous neuropsychological studies reported attentional and memory dysfunction in CFS patients. We wanted to determine the association between mental fatigue and brain activity as measured by arterial spin labeling (ASL). The perception of mental fatigue was induced with the Paced Auditory Serial Attention test (PASAT) that involves attention, working memory and executive function. We measured cerebral blood flow (CBF) changes in CFS patients and compared them to healthy controls (HC).

Methods: CFS was determined using the CDC Criteria. 15 CFS patients (age = 50.5±13.0)) and 12 HC (age = 49.2±12.2) underwent a 3 Tesla Achieva MRI during rest using a pseudo-continuous arterial spin labeling (pCASL) sequence. pCASL can quantify CBF without using exogenous contrast agents by magnetically labeling inflowing blood. Individual scans were corrected for motion and spatially smoothed, then label and control pairs were subtracted to create a perfusion image. The perfusion image was used to calculate a quantified CBF map, which was then normalized to standardized space. After practice trials, participants were placed in the MRI scanner where they viewed a computer screen and listened to PASAT stimuli. Subjects continuously rated their level of exhaustion on a VAS. Groups were compared using voxel-wise independent samples t-tests. Statistical parametric maps were thresholded using a cluster forming t-statistic greater than 4.0 ($p < 0.00025$) and a spatial extent of 20 contiguous voxels (160 mm^3) to control for multiple comparisons.

Results: Fatigue ratings were 0.4 (0.6) and 3.9 (2.1) for HC and CFS patients, respectively ($p < 0.01$). Overall cerebral blood flow was similar between groups ($p > .05$). CFS patients showed reduced blood flow in the right hemisphere superior frontal gyrus. In the significant cluster, HC participants had a mean (SD) CBF of 66.12 (7.89) compared to 63.24 (6.22) (ml/100g/min) in CFS patients ($t(25) = 4.73$, $p = 0.007$, Cohen's $d = 1.80$).

Conclusion: More reduced cerebral perfusion was observed in the right superior frontal gyrus of CFS patients compared to HC during PASAT. The superior frontal gyrus plays a major role in the Attention Network. Reduced blood flow of this area may be a cause or consequence of chronic fatigue as well as impaired attention and cognition often observed in CFS.

Is the Basdai Score Driven By Pain in Ankylosing Spondylitis Patients Treated with Anti-TNF? Proton Rahman[1], Algis Jovaisas[2], William Bensen[3], Wojciech Olszynski[4], Anna Jaroszynska[5], Philip Baer[6], Maqbool Sheriff[7], Dalton Sholter[8], Eliofotisti Psaradellis[9], John S. Sampalis[9], Francois Nantel[10], Allen J Lehman[10], Susan Otawa[10] and May Shawi[10]. [1]Memorial University of Newfoundland, St. John's, NF, [2]University of Ottawa, Ottawa, ON, [3]Division of Rheumatology, McMaster University, Hamilton, ON, [4]University of Saskatchewan, Saskatoon, SK, [5]Private Practice, Burlington, ON, [6]Private Practice, Scarborough, ON, [7]Nanaimo Regional General Hospital, Nanaimo, BC, [8]University of Alberta, Edmonton, AB, [9]JSS Medical Research, Montreal, QC, [10]Janssen Inc., Toronto, ON.

Background/Purpose: The present standard for measuring disease activity in AS is the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) which focuses on five major symptoms including fatigue, axial pain, peripheral pain, enthesitis and morning stiffness (severity and duration). Given that the BASDAI instrument contains two pain questions, the objective was to assess whether pain symptoms are the main drivers of BASDAI scores among AS patients treated with anti-TNFs in routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab (IFX) or golimumab (GLM) as first biologics or after having been treated with a biologic for <6 months. Patients with AS treated with IFX or GLM and enrolled between 2005 and 2014 were included in this analysis. A modified weighted BASDAI score (m-BASDAI) was calculated excluding the axial (Q2) and peripheral (Q3) pain questions of the BASDAI. The correlation of BASDAI, each of its components, and the modified BASDAI (m-BASDAI) was assessed with the Pearson correlation coefficient. BASDAI low disease activity (LDA) and m-BASDAI LDA were defined as a score ≤3. The association between the number of administered analgesics (0, 1, >1) and BASDAI/m-BASDAI was assessed with one-way ANOVA.

Results: A total of 413 AS patients with 1,709 assessments were included in this analysis. Correlation analysis showed a strong correlation between the full BASDAI and m-BASDAI scores ($r=0.98$, $P<0.001$). With respect to the individual BASDAI questions, a strong positive linear correlation was observed between all questions and the BASDAI score as well as the m-BASDAI score (Table 1). As expected, a lower correlation was observed between Q2 and Q3 with the m-BASDAI relative to BASDAI. Axial pain was most strongly correlated with the severity of morning stiffness, whereas the highest correlation of peripheral pain was observed with localized tenderness. The cross-tabulation of BASDAI LDA and m-BASDAI LDA showed a strong measure of agreement (kappa=0.871, $P<0.001$). Omission of the pain questions from BASDAI resulted in a comparable proportion of LDA cases (41.7% vs. 40.9%) when using the same LDA definition.

Increased use of analgesics (0 vs. 1 vs. >1) over 2 years of follow-up was associated with significantly ($P<0.05$) higher mean scores in BASDAI, m-BASDAI, and each of the BASDAI components. No significant association was observed between increased use of analgesics and treatment retention.

Table 1: Correlation between individual BASDAI Questions and BASDAI Outcomes

BASDAI Question	BASDAI*	m-BASDAI*	Q2:Spinal Pain*	Q3: Joint Pain/Swelling*
Q1: Fatigue	0.85	0.88	0.76	0.61
Q2: Spinal pain	0.92	0.87	–	0.68
Q3: Joint pain/Swelling	0.84	0.75	0.68	–
Q4: Areas of localized tenderness	0.89	0.89	0.76	**0.73**
Q5: Morning stiffness severity	0.89	0.90	**0.82**	0.67
Q6: Morning stiffness duration	0.75	0.78	0.64	0.55

$P<0.001$ for all correlations

Conclusion: Higher levels of AS pain are significantly associated with a higher BASDAI score and increased use of analgesic medications among patients treated with anti-TNFs. In addition to pain, fatigue, tenderness, and morning stiffness are likewise important contributing components in the BASDAI score and the disease burden of AS.

A Phase 3 Open-Label Trial of Low-Dose Solumatrix Diclofenac in Patients with Osteoarthritis Pain: Impact of Long-Term Administration on Patient-Reported Outcomes. Vibeke Strand[1], Allan Gibofsky[2], Marc Hochberg[3], Roy Altman[4], Byron Cryer[5], Alan Kivitz[6], Olaolu Imasogie[7] and Clarence Young[8]. [1]Stanford University, Palo Alto, CA, [2]Hospital for Special Surgery, New York, NY, [3]University of Maryland School of Medicine, College Park, MD, [4]University of California–Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]Altoona Center for Clinical Research, Duncansville, PA, [7]Iroko Pharmaceuticals LLC, Philadelphia, PA, [8]Iroko Pharmaceuticals, LLC, Phila, PA.

Background/Purpose: Diclofenac is used for the treatment of osteoarthritis (OA), but, like other NSAIDs, it is associated with serious dose-related adverse events. The FDA has encouraged providers to prescribe NSAIDs at the lowest effective dose. SoluMatrix® diclofenac was developed to provide efficacy at low doses and is approved for treatment of mild to moderate acute pain in adults. A 1-year, open-label, multicenter, phase 3 study in patients with OA evaluated the safety and patient–reported outcome measures associated with SoluMatrix diclofenac.

Methods: The study treated 601 patients age≥40, with knee and/or hip OA, who were chronic NSAID/acetaminophen users. Patients initially received SoluMatrix diclofenac 35-mg capsules BID. The dose could be increased to TID, and subsequently reduced back to BID as needed. Health-related quality of life (HRQOL) was evaluated by the Short Form-36™ version 2 (SF-36v2), which was completed at baseline and at weeks 12, 24, 32, 40, 48; and 52/early termination visit (ET).

Results: During the study, 299/601 (49.8%) patients remained on the SoluMatrix diclofenac 35-mg BID and 302/601 (50.2%) patients increased their SoluMatrix diclofenac dosage to 35-mg TID at least once (316 events), mostly due to the need for more analgesia (214/316, 67.7% events). In total, 20.6% (65/316) of the dosing increases from BID to TID were reduced back to BID, mainly due to satisfactory analgesia (21/65, 32.3%). Patients receiving SoluMatrix diclofenac treatments reported clinically meaningful improvement (≥2.5) in SF-36v2 Physical Component Score from baseline at 12 throughout 52 weeks dosing period (**Table**). Based on values that exceed normative scores at baseline, SF-36v2 Mental Component Scores were not expected to improve (**Table**). Clinically meaningful improvements from baseline to week 52/ET (≥5) were reported for the SF-36v2 Bodily Pain domain scores (+5.5). Improvements in Physical Functioning (+4.3) and Role Physical (+3.6) were also observed (**Table**). Only 12 patients (2%) withdrew from the study due to lack of efficacy.

Conclusion: Low-dose SoluMatrix diclofenac capsules 35-mg BID or TID were associated with improved HRQOL in patients with OA pain and represent a potentially promising treatment option for these patients.

Table.

SoluMatrix Diclofenac 35 mg BID and TID Combined

	Baseline	Week 52/ ET	Change From Baseline to Week 52/ ET
Number of Patients	601	555	–
SF-36v2 Physical Component Score Mean (SD)	39.5 (7.72)	44.2 (8.29)	4.5 (6.89)[a]
SF-36v2 Mental Component Score Mean (SD)	52.0 (9.60)	52.3 (9.44)	0.1 (8.41)
SF-36v2 Domain Scores Mean (SD)	**Baseline**	**Week 52/ ET**	**Change From Baseline to Week 52/ ET**
Physical Functioning	37.8 (8.64)	42.2 (9.48)	4.3 (8.14)
Role Physical	41.3 (8.64)	45.1 (8.79)	3.6 (7.99)
Bodily Pain	40.1 (6.72)	45.8 (8.27)	5.5 (8.55)[b]
General Health	51.2 (8.87)	51.5 (8.97)	0.1 (6.04)
Vitality	48.1 (8.89)	50.4 (9.25)	2.3 (8.00)
Social Functioning	46.5 (9.43)	48.9 (9.12)	2.1 (8.97)
Role Emotional	45.2 (10.57)	47.1 (10.22)	1.5 (10.04)
Mental Health	51.2 (8.71)	51.9 (9.19)	0.5 (8.06)

BID= twice daily; ET = early termination; TID= three times daily
[a]Change from baseline in scores ≥ minimally clinically important difference (MCID) ≥2.5 for physical component score.
[b]Change from baseline in scores ≥ minimally clinically important difference (MCID) ≥5.0 for SF-36v2 domain scores.

Early Gout Pain Response at 28 Hours Predicts Response at 5 Days on Both Patient Pain and Physician Global Assessment. Paul M. Peloso[1], Ted R. Mikuls[2], Brian W. Coburn[3], H. Ralph Schumacher Jr. [4], Davis F. Gates[1], Zoran Popmihajlov[1], Walter L. Straus[1] and R. Andrew Moore[5]. [1]Merck & Co., Inc., Whitehouse Station, NJ, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, USA, Omaha, NE, [4]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [5]University of Oxford, Nuffield Division of Anaesthetics, Oxford, England.

Background/Purpose: This *post-hoc* analysis from a randomized trial[1] in acute gout asked whether early pain responses predict subsequent pain and investigator global responses.

Methods: Patient assessment of pain captured at 28 hours (the first measurement after 24 hours of dosing) was considered as the "early onset" timepoint and was compared to the patient's subsequent pain and investigators global assessment of response to therapy (IGART) at Day 5. Pain was assessed on a Likert scale (none = 0, mild = 1, moderate = 2, severe = 3, extreme = 4) and IGART was assessed on a 0–4 point scale (excellent to none). All patients had moderate or greater pain at entry. Early onset of pain relief was defined as "No worse than mild pain" when patients reported pain as "None = 0 or Mild Pain = 1". Of the 150 gout patients, all of whom met the 1977 ACR criteria, randomization assigned patients to either etoricoxib 120 mg daily or indomethacin 150 mg daily in a 1:1 ratio. As the analgesic response was similar for etoricoxib and indomethacin in the primary trial, these arms were pooled for this analysis. The 141 patients with complete follow up data were included. Analyses were conducted in SAS® v.9.3.

Results: Ninety percent (90.1%) of patients with mild or no pain at 28 hours continued with mild or no pain at Day 5, vs. 66.7% of those not reaching mild or no pain at 28 hours. More patients with monoarticular than polyarticular gout reached mild or no pain at 28 hours (Breslow-Day, $p=0.008$). Monoarticular gout patients with mild or no pain at 28 hours (98.3%) continued to have mild or no pain at Day 5 vs. 70.6% who did not reach mild or no pain at 28 hours ($p<0.001$). Patients with polyarticular gout reporting mild or no pain at 28 hours continued with mild or no pain at Day

5 (66.7%), vs. 61.5% who attained mild or no pain at 5 Days without reporting mild or no pain at 28 hours (p=NS). Polyarticular gout responded less well early and late vs. monoarticular gout (Table 1‘). Mild or no pain at 28 hours correlated with IGART scores of “very good or excellent” at Day 5. Mild or no pain patients at 28 hours had very good or excellent IGART scores at Day 5 (92.6%) vs. 71.7% without mild or no pain at 28 hours (p<0.001). The trend of early pain response with very good/excellent IGART was consistent for monoarticular and polyarticular gout (Breslow-Day p=0.869). Supportive correlations (Pearson’s) for pain and IGART were r=0.498 at 28 hours and r=0.651 at Day 5 (both p <0.0001).

Table 1. 28-Hour Pain Onset vs Subsequent Pain Response at Day 5

28-Hour Pain Response	Moderate or Greater Pain at Day 5	Mild or No Pain at Day 5	Percent Responder	Patient Population
NO (Mod. or > pain)	20	40	66.7%	All Patients With Gout
YES (Mild or no pain)	8	73	90.1%	
		CMH Test[a]	0.003	
		Breslow-Day Test	0.008	
NO	10	24	70.6%	Monoarticular Gout
YES	1	59	98.3%	
		Chi-Squared Test	<0.001	
		Fisher’s Exact Test	<0.001	
NO	10	16	61.5%	Polyarticular Gout
YES	7	14	66.7%	
		Chi-Squared Test	0.716	
		Fisher’s Exact Test	0.768	

[a]CMH test controls for monoarticular/polyarticular gout comparison.

Conclusion: Early patient pain response of mild or no pain appeared to predict subsequent pain and investigator responses at 5 Days in monoarticular gout. Early response among polyarticular gout patients did not predict subsequent pain response indicating a potentially less stable pain response. This analysis suggests early re-evaluation after 24 hours and modification of gout treatment would benefit patients

Chronic Fatigue Is Associated with Hypoperfusion of Parahippocampal Gyrus. Andrew O’Shea[1], Jason Craggs[1], Ricky Madhavan[1], Donald Price[1], Song Lai[1], Michael Robinson[1] and Roland Staud[2]. [1]University of Florida, Gainesville, FL, [2]Univ of Florida Med Ctr/JHMHC, Gainesville, FL.

Background/Purpose: Cerebral hypoperfusion of the whole brain has previously been reported in chronic fatigue syndrome (CFS) patients. However, discrepancies exist in the literature in regards to the spatial extent of such abnormal brain perfusion, as well as the effect sizes of these abnormalities as previously used methods did not allow precise localization of such perfusion abnormalities. We measured global and local resting state cerebral blood flow (CBF) in CFS patients and compared them to healthy controls (HC).

Methods: CFS was determined using the CDC Criteria. 15 CFS patients (age = 50.5±13.0)) and 12 HC (age = 49.2±12.2) were MRI scanned with a 3 Tesla Achieva during rest using a pseudo-continuous arterial spin labeling (pCASL) sequence. pCASL can quantify CBF without using exogenous contrast agents by magnetically labeling inflowing blood. Individual scans were corrected for motion and spatially smoothed, then label and control pairs were subtracted to create a perfusion image. The perfusion image was used to calculate a quantified CBF map, which was then normalized to standardized space. Groups were compared using voxel-wise independent samples t-tests. Statistical parametric maps were thresholded using a cluster forming t-statistic greater than 4.0 ($p < 0.00025$) and a spatial extent of 20 contiguous voxels (160 mm^3) to control for multiple comparisons.

Results: Overall cerebral blood flow was similar between groups (p >.05). CFS patients showed reduced blood flow in the right hemisphere parahippocampal gyrus. In the significant cluster, HC participants had a mean (SD) CBF of 40.51 (7.89) compared to 27.69 (6.22) (ml/100g/min) in CFS patients ($t(25) = 4.73$, $p = 0.00008$, Cohen’s $d = 1.80$).

Conclusion: Reduced cerebral perfusion was observed in the right parahippocampal gyrus of CFS patients. The parahippocampal gyrus plays a major role in the processing of memory and cognition. Reduced blood flow of this area may be a cause or consequence of chronic fatigue as well as impaired memory and cognition often observed in CFS.

Preliminary Validation of the Michigan Body Map. Chad M. Brummett[1], Jenna Goesling[2], Rishi Bakshi[1], Jennifer Wolfe[2], Stephanie Moser[1], David A. Williams[3] and Afton L. Hassett[4]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Health System, Ann Arbor, MI, [3]Univ of MI Hlth System-Lobby M, Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI.

Background/Purpose: One of the hallmark features of fibromyalgia and other centralized pain states is widespread body pain. We developed the Michigan Body Map (MBM) to assess widespread body pain in clinical care and in epidemiological studies. The MBM is a one-sided body image with check boxes for 35 body areas and a box for “No Pain.” The aim of the present study was to assess patients’ understanding of and accuracy when completing the MBM, as well as to assess preference when compared to the 2011 Survey Criteria for Fibromyalgia widespread pain index (WPI) and the body map from the Brief Pain Inventory (BPI).

Methods: 85 patients from the University of Michigan’s Physical Medicine and Rehabilitation Spine Center were included in this study. Written informed consent was obtained. The first phase (n=25) assessed how well participants understood the questionnaire and concurrent validity when compared to a standardized verbal assessment. In the second phase, the MBM’s reliability was assessed using a test-retest assessment 1–2 weeks after the first assessment (n=20). In the third phase, participants were randomized to complete the MBM and either the WPI (n = 20) or BPI (n = 20) to assess construct validity and were also asked preference questions about the body maps.

Results: In the first phase, participants completed the MBM quickly (76.8+/− 64.5 sec). The majority of participants correctly noted right and left, marked only areas of chronic pain (3 months or more), and felt that the measure allowed them to note all of their areas of pain (Table 1). Of the 875 potential check boxes (25 patients × 35 body areas), 63 (7.2%) were incorrectly endorsed as either missed or reversed right/left. In the second phase, the majority of participants had slight discrepancies in the test-retest (ICC =.60, median 1.5 body areas different); however, these differences did not lead to significant changes in the calculated widespread pain score. In the third phase, the MBM was preferred when compared to the 2011 Survey Criteria for Fibromyalgia WPI (Table 2). There were no differences in participant preferences between the MBM and BPI (Table 2).

Conclusion: Overall, participants demonstrated good understanding of the MBM and preferred it to the WPI from the Fibromyalgia Survey Criteria. When compared to the BPI body map, the MBM offers advantages in quantifying, as there is no ambiguity as to the area that was checked. Some participants confused right and left in the MBM and body areas tended to be underreported when compared to verbally assessing each of the 35 possible body areas individually.

Table 1. First phase: Assessment of understanding

	N (%)
Identified right/left correctly	
Yes	16 (64%)
No	5 (20%)
Missing	4 (16%)
Pain present for 3 months or more	
Yes	19 (76%)
No	1 (4%)
Missing	5 (20%)
Able to indicate all areas of pain	
Yes	21 (84%)
No	4 (16%)

Table 2. Third phase: Questionnaire preference

	MBM vs. BPI		MBM vs. WPI	
	MBM	BPI	MBM	WPI
Preference	45%	45%	70%	15%
Best depicts areas of pain	30%	55%	70%	5%
Easier to complete	20%	40%	50%	30%
Best distinguishes left from right	20%	40%	45%	25%

Evaluating Neuropathic Complaints By DN4 and Lanss Scales after Local Corticosteroid Therapy in Carpal Tunnel Syndrome. Taner Dandinoglu[1], Murat Karadeniz[2], Volkan Yılmaz[3], Levent Tekin[4] and Ümit Dinçer[4]. [1]Bursa Military Hospital, Bursa, Turkey, [2]Çorlu Military Hospital, Tekirdağ, Turkey, [3]Mevki Military Hospital, Ankara, Turkey, [4]Gülhane Military Medical Academy, Haydarpaşa Training Hospital, İstanbul, Turkey.

Background/Purpose: The purpose of this study was to evaluate the neuropathic symptoms after local steroid injection in CTS. Since 2001, neuropathic pain scales have been used in the assessment and follow-up of neuropathic pain. DN4 and LANSS pain questionnaires have been applied to groups, mostly consisted of radiculopathy and polyneuropathy cases, before and after various treatments and the results have been compared with the electrophysiologic findings. However to our knowledge there is yet no such study focusing on neuropathic complaints and the relationship between neuropathic pain and electrophysiological findings before and after local corticosteroid injection.

Methods: Forty-one patients aged 22–65 years and diagnosed with carpal tunnel syndrome by nerve conduction studies who were also found to have a neuropathic symptoms were included in the study. All patients received local steroid injection into the carpal tunnel while the questionnaires and nerve conduction studies were performed before and 2 months after the injection.

Results: Local steroid injection was found effective on clinical and electrophysiologic parameters as well as on DN4 and LANSS scores in CTS patients ($p<0.05$) (Table 1). Electrophysiologic severity exhibited no statistically significant relationship with DN4 and LANSS scores, before and after treatment ($p>0.05$).

Conclusion: These findings suggests that the treatment of neuropathic complaints should be planned independently from the electrophysiologic findings and minimally invasive local steroid injection appears to be effective with regard to clinical and electrophysiologic aspects in CTS patients with neuropathic complaints.

Table 1. DN4 and LANSS Scores Before and After the Treatment

	Pre-Treatment Mean±SD	Post-Treatment Mean±SD	Difference Mean±SD	P
DN4	6.12±1.50 (6.00)	1.46±1.96 (1.00)	**−4.65±1.51**	**0.001****
LANSS	15.85±2.71 (16.00)	3.22±5.16 (0.00)	**−12.63±4.83**	**0.001****

*Wilcoxon Signed Ranks Test **p<0.01*

The Effect of Milnacipran on Pain in Rheumatoid Arthritis Patients with Widespread Pain: a Randomized Blinded Crossover Trial. Yvonne C. Lee[1], Elena Massarotti[2], Robert R. Edwards[3], Bing Lu[1], Chih-Chin Liu[4], Yuanyu Lo[1], Alyssa Wohlfahrt[1], Nancy Kim[5], Daniel J. Clauw[6] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham & Women's Hosp, Boston, MA, [3]Brigham & Womens Hospital, Chestnut Hill, MA, [4]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [5]Massachusetts General Hospital, Charlestown, MA, [6]University of Michigan, Ann Arbor, MI.

Background/Purpose: Clinical trials have shown that serotonin norepinephrine reuptake inhibitors, such as milnacipran, decrease pain in chronic non-inflammatory pain conditions like fibromyalgia and osteoarthritis. We examined the effect of milnacipran on self-reported pain intensity and experimental pain sensitivity among rheumatoid arthritis (RA) patients with widespread pain on a stable treatment regimen.

Methods: Thirty-two subjects with RA completed a double-blind, crossover study. Subjects were randomized to receive milnacipran 50 mg twice daily or placebo for 6 weeks, followed by a 3-week washout and crossed over to the other arm for the remaining 6 weeks. Subjects completed the Brief Pain Inventory – short form (BPI-sf) to assess self-reported pain intensity and the Symptom Intensity Scale (SIS) to assess symptoms of fibromyalgia. Subjects also underwent quantitative assessments of pressure pain thresholds at joint and non-joint sites, using a Wagner FPK 20 algometer. Pain thresholds at the trapezius were measured before and after a noxious conditioning stimulus to assess conditioned pain modulation, a measure of the descending analgesic pain pathways. The primary outcome was change in self-reported pain, measured by the BPI-sf average pain intensity. Secondary outcomes included changes in the SIS score, pain thresholds and conditioned pain modulation. Changes in pain measures were compared between milnacipran and placebo using Wilcoxon signed rank tests and linear mixed models.

Results: After 6 weeks of milnacipran, BPI-sf average pain intensity decreased 0.7 (SD 1.7) points on a 0–10 scale, compared to a decrease of 0.3 (SD 2.0) after 6 weeks of placebo ($P = 0.37$) (Table). Thumbnail pressure pain threshold increased by 0.7 (SD 1.4) during milnacipran treatment compared to -0.02 (SD 1.4) during placebo ($P = 0.04$). None of the other secondary outcome measures differed significantly between treatment periods. In the subgroup of subjects with swollen joint count less than or equal to 1, BPI-sf average pain intensity decreased 1.0 (SD 1.6) points, compared to an increase of 0.1 (SD 1.9) during placebo ($P = 0.04$). In this subgroup, the increase in thumbnail pressure pain threshold was also significantly higher during milnacipran treatment compared to placebo ($P = 0.003$).

Conclusion: This randomized, blinded cross-over trial of milnacipran vs. placebo revealed no overall differences in improvements in pain intensity, fibromyalgia symptoms and experimentally assessed pain measures. Subgroup analyses among patients with 0–1 swollen joints suggested that milnacipran may have a role in diminishing overall pain among RA patients who have minimal evidence of inflammatory disease activity. This finding needs to be replicated in a larger study, designed specifically to examine the effects of milnacipran among RA patients in remission or with low disease activity.

Table: Means (standard deviations) for measures of pain

	Placebo			Milnacipran			*P*-values	
	Baseline	6-weeks	Change	Baseline	6-weeks	Change	Unadjusted[b]	Adjusted[c]
BPI-sf Average Pain Intensity[a]	5.2 (2.1)	4.9 (2.1)	−0.3 (2.0)	5.6 (2.0)	4.8 (2.2)	−0.7 (1.7)	0.42	0.37
Symptom Intensity Scale	5.1 (2.1)	4.3 (2.4)	−0.8 (1.9)	5.2 (2.0)	4.5 (8.3)	−0.7 (1.6)	0.89	0.83
Thumbnail Pain Threshold	5.8 (3.0)	5.8 (2.8)	−0.02 (1.4)	5.3 (2.7)	6.0 (2.8)	0.7 (1.4)	**0.04**	0.04
Trapezius Pain Threshold	4.9 (2.8)	5.5 (3.1)	0.6 (1.5)	5.1 (3.1)	5.5 (3.1)	0.4 (1.3)	0.89	0.44
Wrist Pain Threshold	5.3 (2.7)	5.9 (3.0)	0.6 (1.6)	5.0 (2.4)	5.9 (2.9)	0.9 (1.5)	0.35	0.34
Knee Pain Threshold	7.0 (3.1)	7.3 (3.1)	0.3 (1.8)	6.9 (3.2)	7.3 (3.2)	0.3 (1.4)	0.72	0.82
Conditioned Pain Modulation	0.8 (1.0)	0.9 (1.3)	0.1 (1.2)	0.8 (1.1)	0.9 (1.1)	0.1 (1.5)	0.39	0.96

Pain As Predictor of Organ Involvement in Fabry Disease. Pierre Kaminsky[1], Frederic Barbey[2], Roland Jaussaud[3], Francis Gaches[4], Vanessa Leguy-Seguin[5], Eric Hachulla[6], Thierry Zenone[7], Christian Lavigne[8], Claire Douillard[9], Isabelle Marie[10], Boris Bienvenu[11], Bertrand Dussol[12] and Olivier Lidove[13]. [1]CHU Nancy, Vandoeuvre, France, [2]CHU Vaudois, Lausanne, Switzerland, [3]CHU de Reims, Reims, France, [4]Hôpital Ducuing, Toulouse, France, [5]CHU Dijon, Dijon, France, [6]Lille University, Lille, France, [7]CH de Valence, Valence, France, [8]CHU d'Angers, Angers, France, [9]CHU Lille, Lille, France, [10]CHU de Rouen, Rouen, France, [11]CHU Côte de Nacre, CAEN, France, [12]AP Marseille, Marseille, France, [13]Hôpital Croix-Saint-Simon, PARIS, France.

Background/Purpose: Fabry disease (FD) in a X-linked hereditary lysosomal disorder due to alphagalactosidase A deficiency, leading to the accumulation of its substrate (globotriaosylceramide) in vessels, neurons, and heart. Pains are the most clinical dishabiliting symptom in children and young adults, characterized by chronic or acute burning sensation in the extremities. These acroparesthesias are often misdiagnosed as rheumatological disorders. Angiokeratomas, hypohidrosis and cornea verticillata are other common early clinical symptoms while hearing loss, hypertrophic cardiomyopathy, renal involvement and cerebrovascular disorders are the main complications, occurring after the second decade. Early diagnosis is crucial since the sooner enzyme replacement therapy (ERT) is prescribed in FD patients, the more efficient it is. The goal of this study was to determine the clinical

pertinence of acroparesthesia to predict organ involvement in Fabry patients.

Methods: Two hundred Fabry patients were systematically investigated for clinical symptoms i.e. acroparesthesia (ACR), angiokeratoma (AGK), hypohidrosis (HHD), and cornea verticillata (CV) and for organ complications i.e. hypoacousia (HAC), cerebrovascular (CER), renal (KDN) and heart (HEA) complications. Statistical analysis included Fischer'exact test and multiple stepwise logistic regression, a p-value lower than 0.01 being considered a significant.

Results: Patients were 78 males, aged 37.7 ± 14.3 years and 122 females, aged 42.2 ± 16.4 years. Male patients were more symptomatic than women for pain (70.5% vs 50.0%; p=0.004) but also for other clinical symptoms: AGK (64.% vs 27.9%; p<0.0001), HHD (66.7% vs 18.0%, p<0.0001), CV (62.8% vs 45.9%, p= 0.02). They were also more severely affected: HAC (40.0% vs 20.8%, p= 0.004)), HEA (53.8% vs 31.1%, p= 0.001), KDN (39.7 vs 16.3%; p<0.001), but not for CER. Compared with others, patients who presented pains had a rik of HAC 3.03 higher (1%CI: 1.41 – 6.50), of KDN 2.12 higher (1%CI 1.02 – 4.38), of HEA 1.80 higher (1%CI 1.08 – 3.00) than others. Presence of HHD, AGK and CV also correlated with organ complications. In multivariate analysis, after adjustement for age and gender, the absence of pain was an independent predictor for the absence of HAC (p< 0.0001), of HEA (p< 0.001), and of KDN (p= 0.008). The same results were obtained after inclusion of AGK, HHD and CV in multivariate analysis.

Conclusion: Fabry patients who exhibited chronic or acute acroparesthesia are at higher risk of organ involvement. Pains appear the best clinical predictor for Fabry complications. This early clinical symptom should be recognized by clinicians in order to start ERT as soon as possible.

Characteristics of Pain in Fabry Disease. Olivier Lidove[1], Esther Noel[2], Eric Hachulla[3], Francis Gaches[4], Claire Douillard[5], Bernadette Darne[6], Kim Heang Ly[7], Christian Lavigne[8], Agathe Masseau[9], Laurent Aaron[10], Boris Bienvenu[11], Thierry Zenone[12], Philippe Vitielli[6], Vanessa Leguy-Seguin[13] and Jean Marc Ziza[14]. [1]Hôpital Croix-Saint-Simon, PARIS, France, [2]CHU de Strasbourg - Hopital Civil, Strasbourg, France, [3]Université Lille Nord de France, Faculté de Médecine Henri Warembourg, Lille, Lille, France, [4]Hopital Joseph Ducuing, Toulouse, France, [5]CHU Lille, Lille, France, [6]Monitoring Force, Maisons-Laffitte, France, [7]CHU Dupuytren, Limoges, Limoges, France, [8]CHU d'Angers, Angers, France, [9]Nantes University Hospital, Nantes, France, [10]Hôpital Jacques Coeur, Bourges, Bourges, France, [11]CHU Côte de Nacre, CAEN, France, [12]CH de Valence, Valence, France, [13]CHU Dijon, Dijon, France, [14]Hopital Croix-Saint-Simon, Paris Cedex 20, France.

Background/Purpose: Fabry disease (FD) is an X-linked disorder caused by a deficiency of lysosomal alpha-galactosidase A resulting in accumulation of glycosphingolipids. Clinical manifestations include a small-fiber neuropathy associated with debilitating pain. Because enzyme therapy (ERT) is available, early diagnosis in FD is crucial. The objective of this study is to characterize the pain in male (M) and female (F) FD patients.

Methods: An observational, non-interventional, retrospective, multicentre, national study was performed in France between January 2013 and April 2014. This study was approved by the ethics committee (CNIL approval: 1588616). All FD patients were eligible. FD was confirmed in all cases by enzyme alpha-galactosidase A activity and/or gene mutation analysis. Characteristics of pain were reported by the patient and by a referent physician in each case. The Neuropathic Pain Symptom Inventory (NPSI) was assessed at time of evaluation and at the moment in life when "pain was at its worst".

Results: A total of 79 patients were analyzed, median age 43 + 14 yrs.

Table 1: Summary of results

	Males	Females	p value
N (%)	33 (42)	46 (58)	
Index case	21	7	
Age at pain onset	10.9 + 8.3	19.3 + 15.4	
Maximal intensity	Median 7 (quartiles 5,9)	Median 6 (quartiles 5,8)	NS
Frequency of crisis > 10/year	54.5%	34.8%	NS
Associated symptoms: (joint pain, fever, abdominal pain)	18, 16, 9	21, 15, 9	
Aggravating factors (temperature change/humidity, effort/ sport, infectious episodes)	22, 19, 20	33, 25, 20	
Persistent burning pain	18	15	
Pain at its worst	8.2 + 2.2	7.4 + 2.5	NS
Persistent burning pain	Median 3 (quartiles 0,5)	Median 5 (quartiles 2,6)	0.04
Persistent pain in adulthood	22	34	NS
Previous or current ERT	91%	50%	<0.0001
Age at first infusion	31 + 11.1	42.1 + 15	<0.01
Efficacy of carbamazepine (pain crisis)	21	10	
Efficacy of physiotherapy (pain)	6	7	
Depression	11	18	
School attendance	66.7%	82.6%	<0.01
Part-time work	3%	23.9%	<0.01
Handicap expertise	51.5%	21.7%	<0.01

Before diagnosis of FD, other causes of pain were considered (M: n=15; F: n=8): anxiety (n=25), growing pain (n=17), rheumatic fever (n=7), rheumatoid arthritis (n=1), Still disease (n=1). Raynaud's phenomenon was present in 25 patients (30%). Only 18% of M and 15% of F had no pain according to the physician. The association of crisis and persistent pain was the most frequent phenotype (M: 51%, F: 43%). Pain crisis corresponded to burning sensation (M=F), tingling (M=F), electric discharge (M only). Pain crisis duration ranged from few minutes (one third) to few days (M: 18.2%, F: 11%). Other symptoms were more frequent in M than in F: sweating disorders (p=0.02), lymphedema (p=0.02), high creatinine level (p=0.04). Intra-familial other cases of pain in extremities were found with differences between genders: father's pain only in F (p=0.002), children's and cousin's pain more frequently found in F (p=0.003 and p=0.002, respectively). NPSI questionnaire was performed in 75 cases. Agreement between patient and physician was good (kappa 0.73, CI95% 0.57–0.90). Patients with pain were treated with ERT in 69.4% of cases whereas patients without pain were treated with ERT in 61.5%. ERT was the most effective therapy on pain in only two males.

Conclusion: Diagnosis and treatment of neuropathic pain are important in FD. Burning pain in the extremities, and frequent pain in relatives may be a tool for an early diagnosis. The higher frequency of chronic pain in females may imply clinical, psychological, and social components of pain. Treatment of pain in FD patients should not be limited to pharmacological therapies, but include personal and family management, to address psychosocial functioning.

Quality of Life Assessment of Adults Patients with X-Linked Hypophosphoremia. Karine Briot[1], Hélène Ché[1], Adrien Etcheto[1], Anya Rothenbuhler[2], Peter Kamenicky,[2], Agnès Linglart[2] and Christian Roux[3]. [1]Paris Descartes University, Paris, France, [2]Hôpital Bicêtre, Kremlin Bicêtre, France, [3]Paris Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: X-Linked Hypophosphatemia (XLH) is the most common form of heritable rickets. Although disease severity is variable, adults with XLH may suffer from skeletal symptoms leading to function disability. There are no data on the consequences of these symptoms on quality of life (QoL) of adults with XLH. The objective was to evaluate the QoL and the variables associated with low QoL in adult patients with XLH.

Methods: We conducted a cross sectional study in adult patients with XLH, who consulted in rheumatology, for skeletal symptoms, between 2013 and 2014. We assessed the intensity of pain (VAS Visual Analogic Scale) and QoL using 3 Patient Reported Outcomes: HAQ (Health Assessment Questionnaire, high if >0.5), RAPID3 (Routine Assessment of Patient Index Data 3, high if >6) and 36-item short-form health (SF36) survey. We also collected demographic and disease characteristics, radiographic features and data on treatments of XLH. We described the QoL of XLH patients and analysed the variables associated with low QoL.

Results: Thirty two patients with XLH (27 women; mean age of 42.8 yrs) with PHEX mutations were included. 15 (48.4%), 16 (51.6%), 12 (40%) received respectively phosphate supplements, vitamin D analogues, and 25 OH-vitamin D supplements, at the time of assessment. X-rays showed osteoarthritis (knee, hip or spine) (n=27, 90%), enthesopathies (n=19, 61.3%) and sequelae of insufficiency fractures (n=4, 14.8%). Skeletal pain

was reported by 64.3% of patients with a mean VAS of 4.6 (+/−2.6). Age is significantly associated with low QoL ($p \leq 0.05$), indicated by high scores of HAQ (mean value 0.71±0.6, HAQ >0.5 in n=19), RAPID3 (mean value 11.32 ± 6.4, RAPID3 >6 in n=23), and physical domains of SF36 (physical functioning (mean value 58.4± 23.6) and physical role (mean value 37.5± 39.1)). Osteoarthritis was associated with low QoL indicated by high HAQ ($p \leq 0.05$). Radiographic enthesopathies were significantly higher in patients with high RAPID3 and low bodily pain scale of SF36 (mean value 55± 24) ($p \leq 0.05$). Phosphate supplements, vitamin D analogues and physiotherapy treatments were associated with high general health (mean value 40.23±17.1) and social functioning (mean value 70.31±21.7) scales of SF36 ($p \leq 0.05$).

Conclusion: This study showed that QoL of adults with XLH is altered; age and radiographical involvement (osteoarthritis and enthesopathies) are significantly associated with low QoL; adults treated for XLH reported better general health and social functioning scores.

Pain Characteristics Among Patients with Rheumatoid Arthritis in the Context of Patient-Physician Discordance in Disease Activity Assessments. John M. Davis III, Cynthia S. Crowson, Tim Bongartz, Clement J. Michet, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN.

Background/Purpose: Healthcare must be patient-centered to achieve optimal outcomes and quality of life. From this perspective, it is significant that patients with rheumatoid arthritis (RA) sometimes rate their disease activity as much higher than their rheumatologists. This 'discordance' is mediated in part by patient-reported pain. In this study, our objective was to characterize the qualities of pain reported by patients in the context of patient-physician discordance.

Methods: We conducted an observational study of consecutive patients with RA recruited between July 2008 and December 2010. A physician joint assessor, who was independent from treatment decision-making, performed a standardized clinical evaluation. Positive discordance was defined as the patient global assessment being ≥25-mm higher than the physician global assessment of disease activity. Patients completed the pain visual analog scale (VAS; range: 0 – 100 mm) and the Short Form McGill Pain Questionnaire (SF-MPQ), including the sensory (range: 0 – 33) and affective (range: 0 – 12) scales. Examples of sensory characteristics are "sharp, aching or throbbing," and examples of affective characteristics are "sickening, fear-causing, or punishing-cruel." We abstracted electronic medical records to collect demographics, laboratory data, smoking status, and body mass index (kg/m^2). Correlations between explanatory variables and the presence of positive discordance were determined using Spearman methods, adjusting for RA characteristics.

Results: A total of 127 patients with RA were recruited (mean age 55.6 years; mean disease duration 6.8 months; 63% female). The mean (SD) pain VAS was 47 (26) mm. The median (range) scores for the SF-MPQ sensory and affective scales were 10 (0 to 29) and 2 (0 to 9). Positive discordance (i.e., patient high) was associated with higher pain ($r = 0.37$, $p = <0.001$) and fatigue ($r = 0.32$, $p<0.001$). The SF-MPQ data showed that positive discordance was more strongly associated with affective characteristics of pain ($r = 0.30$, $p <0.001$) than sensory characteristics of pain ($r = 0.23$, $p = 0.013$). The association of positive discordance with SF-MPQ affective pain was independent of age, sex, rheumatoid factor, anti-CCP antibodies, body mass index, smoking status, and use of prednisone or disease-modifying drugs.

Conclusion: The significance of this study is that in the context of positive discordance, patients are more likely to describe their pain using words that have affective or emotional connotations. This finding could reflect activation of pain, mood, and fear networks in the brain. Future research should evaluate the connectivity between these brain networks in the setting of patient-physician discordance and determine their relationship to subclinical immune/inflammatory status. The positive impact could be the development of new approaches that better alleviate pain and improve quality of life in our patients.

Development of Pediatric Item Banks to Measure Pain Behavior in the Patient Reported Outcomes Measurement Information System. Esi Morgan DeWitt[1], Kimberly Barnett[1], Wen-Hung Chen[2], Jennifer Farrell[1], Dennis Revicki[2], Adam Carle[1], Karon Cook[3], Kenneth Goldschneider[1], Carlton Dampier[4], David D. Sherry[5] and Susmita Kashikar-Zuck[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Evidera, Bethesda, MD, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Emory University School of Medicine, Atlanta, GA, [5]Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: The NIH Patient Reported Outcomes Measurement Information System (PROMIS) has created publicly available patient reported outcomes measures in several domains of physical, social and emotional health. Measurement of pediatric pain in PROMIS is currently limited to pain interference. Pain behaviors are observable actions or reactions that communicate pain including verbal, non-verbal and pain reducing behaviors. Numerous validated parent/provider-rating scales of pain behavior in children exist but there are currently no validated self-report measures of pain behavior in school-age children and adolescents. Such measures could be useful in establishing targets for treatment and assessing outcomes. The aim of this study is to enhance PROMIS pediatric pain assessment by developing and testing pediatric pain behavior item banks for self- and proxy-report.

Methods: Candidate items were developed through a qualitative item review process, and were in the format, "In the past 7 days, when I was in pain. . ." Patients ages 8 to 17 years, or parents/guardians of children, with a chronic painful condition (fibromyalgia, juvenile idiopathic arthritis, sickle cell disease) were recruited through outpatient clinics at 3 centers. Child participants completed approximately 100 PROMIS items concerning their pain (including 47 candidate pain behavior items), physical function, fatigue, and psychosocial well-being. Proxies responded to socio-demographic and health history items and 51 new candidate proxy-report pain behavior items were collected. A confirmatory factor analysis (CFA) was performed on the child and guardian pain behavior data, with model fit assessed by the comparative fit index (CFI) and root mean square error of approximation (RMSEA). Item response theory (IRT) analysis was performed on the pain behavior items based on the graded response model. Differential item functioning (DIF) was assessed by age group and disease group.

Results: 450 children (71% female, M_{age} 13.54), and 232 proxies participated. CFA indicated unidimensionality in the child (CFI=0.962; RMSEA=0.079) and proxy pain behavior responses (CFI=0.970; RMSEA=0.080). The responses for the child and proxy data had good IRT model fit and were free of local dependence. Slopes for the pediatric responses ranged from 1.81 ("rubbed body where hurt") to 4.40 ("moved slower"), and thresholds ranged from -2.00 to 4.95. For the proxy data, slopes ranged from 1.51 ("think of something fun") to 3.48 ("tried not to move"), and thresholds ranged from -3.02 to 2.43. Items performed well across disease groups and age. There was little DIF either by age group (8–12, 13–18) or by sample (child vs. proxy). Child and proxy scores were correlated at 0.70. Correlations between pain behavior and pain intensity were 0.60 in children and 0.65 in proxy sample.

Conclusion: The PROMIS pediatric pain behavior item-banks for self and proxy report are suitable for use in non-adaptive format as short forms or in dynamic format as computerized adaptive tests in clinical research with the potential for adoption into clinical care.

Validation of the Dutch-Flemish Promis Physical Functioning Item Bank in Patients with Chronic Pain. Martine Crins[1], Caroline Terwee[2], Niels Smits[3], Anton de Vries[3], Henrica de Vet[2], Joost Dekker[2], Rene Westhovens[4], David Cella[5], Karon Cook[5], Dennis Revicki[6], Jaap van Leeuwen[7], Maarten Boers[2] and Leo D. Roorda[8]. [1]Amsterdam Rehabilitation Research Center | Reade, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]VU University Medical Center EMGO Institute for Health and Care Research, Department of Epidemiology and Biostatistics,

Amsterdam, Netherlands, [4]University of Leuven, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration; Rheumatology, University Hospital Leuven, Leuven, Belgium, [5]Northwestern University Feinberg School of Medicine, Chicago, IL, [6]Outcomes Research, United BioSource Corporation, Bethesda, MD, [7]CEO Leones Group BV, Amsterdam, Netherlands, [8]Amsterdam Rehabilitation Research Center | Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands.

Background/Purpose: In the assessment of chronic pain patients it is important to measure physical functioning. The National Institutes of Health's Patient-Reported Outcomes Measurement Information System (PROMIS) initiative developed an item bank for measuring physical functioning. This PROMIS physical functioning item bank was translated into Dutch-Flemish language according to the FACIT methodology. The aim of current study was to validate the Dutch-Flemish translation of the PROMIS physical functioning item bank (DF-PROMIS-PF) in patients with chronic pain.

Methods: A paper-and-pencil or web-based survey including the full DF-PROMIS-PF (121 items), was completed by 857 chronic pain patients (77% female, mean age 49y) satisfying the ACR classification criteria of chronic pain and referred to an outpatient secondary care center for rheumatology and rehabilitation in the Netherlands. One-dimensionality was evaluated by one-factor confirmatory factor analysis. With the future strategy to develop computer adaptive tests (CAT), item response theory (IRT) models were used to evaluate the item characteristics of the two item banks. A graded item response model (GRM) was fitted and Differential Item Functioning (DIF) was evaluated for e.g. language (Dutch vs. English), by ordinal regression models. Furthermore, construct validity was studied.

Results: Through computer technical limitation, the item bank was separated during statistical analysis into DF-PROMIS-PF_A (50 PFA-items) and DF-PROMIS-PF_{BC} (45 PF_B- and 26 PF_C-items). These interim analysis showed that the DF-PROMIS-PF_A and DF-PROMIS-PF_{BC} demonstrated good fit to a one-dimensional model (both CFI=0.976 and TLI=0.975). The first factor accounted for 57% of the questionnaire variance. The results showed acceptable test information (SE<0.3) for theta between -2.3 and 3.8 for DF-PROMIS-PF_A and between -1.6 and 4 for DF-PROMIS-PF_{BC}. The items demonstrated no DIF with respect to survey version. DIF was present with respect to gender (2 items), age (4 items) and language (11 items). However, the impact of DIF on the total item scores was minimal. The analyses of the full DF-PROMIS-PF are in progress and will be presented at the ACR conference.

Conclusion: The first results indicate that the DF-PROMIS-PF fits a GRM and demonstrates good coverage across the range of the physical functioning domain. Nearly all Dutch item parameters match the American item parameters and likely Dutch-specific item calibrations are not needed. The DF-PROMIS-PF can be used to develop a CAT.

Validation of the Dutch-Flemish Promis Pain Behavior and Pain Interference Item Banks in Patients with Chronic Pain. Martine Crins[1], Leo D. Roorda[2], Niels Smits[3], Henrica de Vet[4], Rene Westhovens[5], David Cella[6], Karon Cook[6], Dennis Revicki[7], Jaap van Leeuwen[8], Maarten Boers[4], Joost Dekker[4] and Caroline Terwee[4]. [1]Amsterdam Rehabilitation Research Center | Reade, Amsterdam, Netherlands, [2]Amsterdam Rehabilitation Research Center | Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [3]VU University Medical Center EMGO Institute for Health and Care Research, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands, [4]VU University Medical Center, Amsterdam, Netherlands, [5]University of Leuven, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration; Rheumatology, University Hospital Leuven, Leuven, Belgium, [6]Northwestern University Feinberg School of Medicine, Chicago, IL, [7]Outcomes Research, United BioSource Corporation, Bethesda, MD, [8]CEO Leones Group BV, Amsterdam, Netherlands.

Background/Purpose: In the assessment of chronic pain patients it is important to measure pain behavior and pain interference. The National Institutes of Health's Patient-Reported Outcomes Measurement Information System (PROMIS) initiative developed item banks for measuring pain behavior and pain interference. These PROMIS item banks were translated into Dutch-Flemish language according to the FACIT methodology. The aim of current study was to validate the Dutch-Flemish translation of the PROMIS pain behavior item bank (DF-PROMIS-PB) and the Dutch-Flemish PROMIS pain interference item bank (DF-PROMIS-PI) in patients with chronic pain.

Methods: A paper-and-pencil or web-based survey, including the full DF-PROMIS-PB (39 items, 6-point Likert scale) and DF-PROMIS-PI (41 items, 5-point Likert scale), was completed by 1042 chronic pain patients satisfying the ACR classification criteria of chronic pain and referred to an outpatient secondary care center for rheumatology and rehabilitation in the Netherlands. One-dimensionality was evaluated by one-factor confirmatory factor analysis. With the future strategy to develop computer adaptive tests (CAT), item response theory (IRT) models were used to evaluate the item characteristics of the two item banks. A graded item response model (GRM) was fitted and Differential Item Functioning (DIF) was evaluated for e.g. language (Dutch vs. English), by ordinal regression models. Furthermore, construct validity was studied.

Results: DF-PROMIS-PB and DF-PROMIS-PI demonstrated good fit to a one-dimensional model (CFI=0.960; 0.988 resp. and TLI=0.958; 0.987 resp). The first factor accounted for 42% (DF-PROMIS-PB) and 66% (DF-PROMIS-PI) of the questionnaire variance. The results showed acceptable testinformation (SE<0.3) for theta between -1.9 and 3.6 for DF-PROMIS-PB and between -3.3 and 2.8 for DF-PROMIS-PI. 14 out of 741 (1.9%) DF-PROMIS-PB item pairs and 62 out of 820 (7.6%) DF-PROMIS-PI item pairs were marked as possibly locally dependent. The items demonstrated no DIF with respect to age, gender, and survey version. DIF with respect to language was present for 6 DF-PROMIS-PB items and 2 DF-PROMIS-PI items. However, the impact of DIF on the total item scores was minimal.

Conclusion: The DF-PROMIS-PB and the DF-PROMIS-PI fit a GRM and demonstrate good coverage across the range of the pain behavior and pain interference domain. Nearly all Dutch item parameters match the American item parameters and likely Dutch-specific item calibrations are not needed. The DF-PROMIS-PB and DF-PROMIS-PI can be used to develop a CAT.

Longitudinal Assessment of Promis Pediatric Item Banks in Children with Chronic Musculoskeletal Pain. Esi Morgan DeWitt[1], Adam Carle[1], Kimberly Barnett[1], Jennifer Farrell[1], Kenneth Goldschneider[1], Carlton Dampier[2], David D. Sherry[3] and Susmita Kashikar-Zuck[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Emory University School of Medicine, Atlanta, GA, [3]Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Assessing clinical status in musculoskeletal pain syndromes requires self-report of pain and function. Yet, the field suffers from a lack of psychometrically sound, consistently applied measurement tools, limiting clinical practice and research. In this study, we used longitudinal data to evaluate the validity and responsiveness of the Patient Reported Outcomes Measurement Information System (PROMIS) pediatric item banks (physical function (PF), pain impact, fatigue, emotional distress, social role) among children receiving treatment for chronic musculoskeletal pain at two clinics. We expected each domain to improve across time, but we expected domains most closely aligned with treatment (i.e., pain and fatigue) to improve more and domains more distally related (i.e., peer relationships) to improve less. Additionally, we expected scores to improve more quickly among children receiving intensive, inpatient treatment vs. those receiving treatment at an outpatient clinic.

Methods: Across 2 multi-disciplinary pediatric pain clinics, we collected data from patients receiving treatment for a chronic painful condition (n= 145: aged 8–18 years). Across 3 visits, patients completed PROMIS self-report short form measures (~7 items each) that assessed: pain impact, PF-upper extremity, PF-mobility, fatigue, anger, anxiety, depressive symptoms, and peer relationships. PROMIS measures are normed in the general population and have a mean of 0 and standard deviation (SD) of 1. For each measure, higher values reflect more of the measured domain (e.g., higher pain impact scores reflect more pain impact, higher PF-mobility scores reflect better mobility). We used longitudinal growth models (LGM) to examine change across time.

Results: At study's start, mean domain levels ranged from -1.26 SDs below the general population (mobility) to 0.97 SDs above (pain), indicating more pain and poorer function. LGM revealed that each domain demonstrated statistically significant improvement across time. The average monthly change ranged from 0.014 (peer relationships) to -0.074 (pain). Fatigue, PF-mobility and showed changed at rates similar pain impact's. PF-upper extremity's, anxiety's, and depression's changed at rates similar to peer relationships'. In all models, rates of change showed statistically significantly differences across site in the expected directions.

Conclusion: We tested responsiveness to change of PROMIS pediatric domains in youth with chronic musculoskeletal pain. Consistent with expectations, 1) children in the pain clinics reported poorer quality than general population; 2) domains most closely related to treatment (pain impact, fatigue, and mobility) demonstrated the most change, 3) domains more distally related to treatment (e.g., peer relationships) showed the least improvement, and 4) across domains, the measures indicated intensive, inpatient treatment resulted in more rapid improvement than outpatient treatment. Results support the construct validity and responsiveness of PROMIS instruments. Future clinical research in pediatric pain should consider utilizing the PROMIS pediatric items banks.

Nutraceutical Products and Pain or Non-Pain Medications Use in Patients with Knee Osteoarthritis. Mei Chung[1], John B. Wong[2], Shaoyu Chang[2] and Chenchen Wang[2]. [1]Tufts University School of Medicine, Boston, MA, [2]Tufts Medical Center, Boston, MA.

Background/Purpose: Knee osteoarthritis (OA) causes substantial health burden and economic costs including medications and neutraceuticals for pain. The aim of this analysis was to describe contemporary use of medications and nutraceutical products in patients with knee OA.

Methods: Knee OA patients meeting ACR criteria for enrollment into a randomized clinical trial reported their use of prescription and over-the-counter medications and nutraceutical products during the prior 6 months using the HAQ health utilization form. We analyzed the number of pain medications, non-pain medications, and nutraceutical products taken by each patient and WOMAC questionnaire measures of pain and physical function. The T-test, Fisher's exact test and multivariable ordered logistic regression were used to assess statistical differences between groups and associations. All p-values were two tailed, and results were reported as mean±standard deviation.

Results: In 204 knee OA patients (mean age 60.2 years, 70% female, mean WOMAC pain 254±95 and WOMAC function 899±352), 157 (77%), 166 (81%), 150 (74%) reported taking at least one pain, non-pain medication, or nutraceutical (7% glucosamine), respectively (**Table 1**). On average, each patient used 1.2±0.9 pain medications, 2.8±2.5 non-pain medication, and 2.4±2.3 nutraceutical products. Nutraceutical product use was higher in Whites (3.0±2.4) than in Blacks (1.8±2.0) or Asians (1.7±2.0). Patients using nutraceuticals were significantly older (+3.9, P=0.02) than those who did not without any significant differences by gender. Similarly patients who using non-pain medications were older than those who did not (+3.7 years, P=0.05. In contrast, pain medication users were significantly younger (−4.4 years, P=0.01) than those did not, and more women used pain medications than men (81% vs. 67%, P=0.05). WOMAC pain and function scores were significantly lower in nutraceutical users than in non-users (pain: 241±97 vs. 291±96, P=0.001; function: 859±357 vs. 1011±316, P=0.006). After controlling for age and sex, a higher number of nutraceuticals was associated with an improved WOMAC pain (P=0.05) and function (P=0.03) scores, but the number of pain and non-pain medications were not significantly associated WOMAC pain or function.

Conclusion: Nutraceutical and pain-medication use in OA patients is quite common and much higher in our patient population than in the Osteoarthritis Initiative (*Arthritis Research & Therapy 2013, 15:R106*). Concomitant and frequent uses of NSAIDs pain medications, nutraceutical products, and other medications for comorbidities in older knee OA patients is an area of concern, given the increased potential for side effects and drug-drug or drug-nutrient interactions.

Disclosure: Supported by R01 AT005521 from the National Center for Complementary and Alternative Medicine.

Table 1 Self-reported uses of non-pain and pain medications, and nutriceutical products in knee OA patients

Nutriceutical products (patient n = 150)	Freq	Percent	Non-pain medication classes (patient n = 166)	Freq	Percent
Vitamin D and/or Calcium	201	41.4%	Hypertension	138	24.2%

Efficacy and Safety of Cannabinoid Treatments in the Rheumatic Diseases: A Systematic Review of Randomized Controlled Trials. Tara Landry[1], Mary-Ann Fitzcharles[2], Peter A. Ste-Marie[2] and Yoram Shir[2]. [1]Mcgill University Health Centre, Montreal, QC, [2]McGill University Health Centre, Montreal, QC.

Background/Purpose: The endocannabinoid system functions to maintain homeostasis in the human body and thereby has effects on modulation of pain and inflammation. Cannabinoid preparations are available as synthetic or plant derived products and may be effective for the management of pain associated with musculoskeletal conditions. We have conducted a systematic review to examine the evidence on the efficacy and side effects of cannabinoids (phyto- and syntheto-) in the management of rheumatic pain.

Methods: A comprehensive literature search of the following databases was conducted in September 2013: MEDLINE; Embase Classic + Embase; BIOSIS Previews; Scopus; CENTRAL; DARE; CINAHL; PsycINFO; AMED. Additional searches for ongoing clinical trials were also run in ClinicalTrials.gov, International Clinical Trials Registry Platform, Current Controlled Trials, Natural Standard, as well as various Drug and Device Regulatory Approval Sites. Further studies were identified in Web of Science and Scopus (March 2014) by citations searches for studies citing included studies, as well as by examining their reference lists. Randomized controlled trials (RCT's) with outcomes investigating pain and sleep disturbance in rheumatic conditions, with comparison of an active therapy with placebo were included. Study quality was assessed using the JADAD scale (out of 5). In view of a paucity of studies, heterogeneous populations, and different products, only a systematic review is reported.

Results: Of the 1407 articles screened, 12 underwent full text examination. Excluded were survey reports, observational studies, case series, case reports and commentaries, with 7 remaining articles. Of these 3 were excluded: two included patients with non-rheumatic diseases, 1 was an open-label study of effect of THC on experimentally induced pain. The remaining 4 studies comprised 201 patients (58 RA, 72 FM, and 74 OA). One study examined the effect of nabiximols in RA, two studies examined nabilone in FM (one a non-inferiority study with amitriptyline as comparator), and one examined effect of a fatty acid amide hydrolase-1 (FAAH1) inhibitor in OA. The quality of the trials was good, with a mean 3.75

JADAD score. The study of FAAH1 inhibitor was stopped at interim analysis for futility. For the remaining 3 trials, duration was from 5–8 weeks, with significant analgesic effect in two, significant sleep effect in two, and one in FM reporting improved quality of life. No serious adverse events were reported, with dizziness and drowsiness the most common adverse effects for about a quarter of patients. There were no studies of inhaled herbal cannabis identified.

Conclusion: Small sample sizes, heterogeneity of rheumatic conditions and products, only a single comparative trial and absence of any study of herbal cannabis allow for only limited conclusions. The results suggest that pain relief and positive effect on sleep may have some potential for therapeutic benefit for rheumatic patients, but in view of this small body of current evidence cannabinoid treatments cannot be recommended for management of rheumatic complaints.

Prevalence of Medicinal Marijuana Use Among 1000 Rheumatology Patients Attending a Community-Based Rheumatology Clinic: A Prospective Cross-Sectional Study. Peter A. Ste-Marie[1], Yoram Shir[1], Emmanouil Rampakakis[2], John S. Sampalis[2], Martin Cohen[3], Michael Starr[1], Mark A Ware[1] and Mary-Ann Fitzcharles[1]. [1]McGill University Health Centre, Montreal, QC, [2]JSS Medical Research, Montreal, QC, [3]Mcgill University Health Centre, Montreal, QC.

Background/Purpose: With a worldwide groundswell of interest in cannabinoids as a possible treatment option for persons with rheumatic diseases, and with few pharmacologic cannabinoid options available, patients may be using marijuana mostly to self-medicate. “Severe arthritis” was cited as the diagnosis for 65% of persons legally authorized to possess medicinal marijuana in Canada in 2014. With knowledge that most medicinal marijuana is obtained illegally, and by extrapolating from Canadian census data of 2011, conservative estimates are that 4% of persons with rheumatic complaints may be using cannabis, with an even higher rate expected for those in rheumatology care. As there is currently no knowledge of the prevalence of use of marijuana in a defined rheumatology population, we have prospectively examined the use of herbal cannabis for 1000 rheumatology attenders.

Methods: The study was approved by the Institutional Ethical Review board and informed consent was obtained from every participant. During a two month period (April-May 2014), consecutive patients attending an academic, community based rheumatology clinic staffed by 3 rheumatologists were invited to participate. Patients were either newly referred or attending for a follow up visit. The study comprised 2 questionnaires completed at the time of the visit: 1) demographic and disease related information completed by the rheumatologist, 2) patient anonymous report of current health status, pain severity and past or current marijuana use for either recreational or medicinal purposes, or both.

Results: Of the 1067 patients attending, 1000 (96%; 74% females; mean age 63 ± 15 yrs) agreed to participate. Thirty seven patients refused to participate and 30 were not eligible. Disease categories were as follows: inflammatory arthritis 516 (52%), osteoarthritis or back pain, 489(49%) soft tissue rheumatism or fibromyalgia, 218 (22%), and other condition, 99(10%) with some overlap of diagnoses. Medicinal marijuana was reportedly used by 28 patients (2.8%; 95% CI: 1.9–4.2). Users vs. non users were more likely to be younger, 53.vs.63 yrs ($p=0.0003$), unemployed or disabled 46% vs. 8% ($p<0.0001$), and with a trend to be male. Diagnoses did not differ between the users and nonusers, but users reported poorer global well-being 5.5 vs. 3.9 ($p=0.0029$), more pain 6.3 vs 4.8 ($p= 0.0088$), and previous recreational cannabis use 82% vs 19% ($p< 0.0001$). The Physician global assessment of health status did not differ significantly between the groups 3.2 vs 2.8 ($p=0.2991$).

Conclusion: Contrary to the expected rate, only 2.8% of patients, receiving rheumatology care for multiple rheumatic disease categories, reported current use of medicinal marijuana. With use observed across all disease categories, familiarity with marijuana as a recreational product may explain use for some. Perceived health status was poorer for users, with almost half not working.

An Examination of the Interaction of Opioid Use, Pain, and Depression. Jenna Goesling[1], Matthew Henry[1], Stephanie Moser[2], Paul Hilliard[2], Afton L. Hassett[1] and Chad Brummett[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI.

Background/Purpose: In the past two decades there has been an increase in the use of opioids to treat chronic pain. Despite this trend, there is little empirical evidence to support the use of long-term opioid therapy in clinical practice. Chronic pain and psychiatric disorders are highly comorbid, yet patients with psychiatric diagnoses are typically excluded from opioid efficacy trials. Clinically, patients with depression and anxiety are more likely to receive opioid therapy. We hypothesized that patients taking opioids would present with a worse clinical phenotype (i.e., more pain, less functioning, and more symptoms of depression and anxiety). We also hypothesized that the relationship between opioid use and pain severity and pain interference would be moderated by depression.

Methods: A total of 2,104 new patients seeking treatment for chronic pain at the University of Michigan’s Back & Pain Center were included. Pain severity and pain interference were measured with the Brief Pain Inventory (BPI), symptoms of depression and anxiety were assessed with the Hospital Anxiety and Depression Scale (HADS), catastrophizing was assessed using the related subscale from the Coping Strategies Questionnaire (CSQ), and physical functioning was assessed using PROMIS SF1. Chi-square, t-tests, and analysis of covariance tests were conducted.

Results: Opioid use was associated with a worse clinical phenotype (Table 1). Depression moderated the relationship between opioid use and pain interference (Figure 1) and pain severity (Figure 2). There was no difference in pain interference by opioid group for depressed patients, but non-depressed opioid users reported more pain interference than non-depressed non-opioid users ($p<.001$) (Figure 1). The same moderated effect was found for pain severity ($p<.001$) (Figure 2).

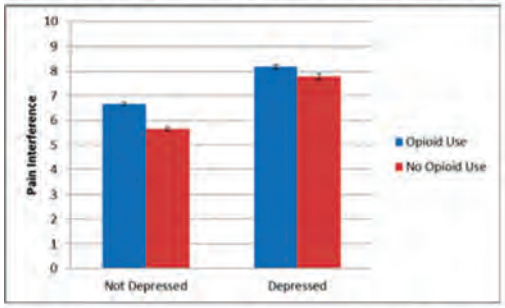
Conclusion: The relationship between opioid use, pain, and depression is complex. Understanding the interaction at a biopsychosocial level is important in order to inform clinical practice. Although causal conclusions cannot be made, this study found patients using opioids present with a worse clinical phenotype. Future longitudinal studies are needed to assess directionality of the relationship and determine whether opioids are the best course of treatment for depressed patients.

Table 1 Phenotypic profiles of opiold and non-opiold users.

	Opiold use		
	Yes N = 1,176	No N = 928	p^a
Male	484 (41.2%)	378 (40.7%)	.844
Caucasian	1,073 (91.2%)	817 (88.0%)	.016
Age	49.03 (14.2)[b]	48.9 (15.3)	.806
HADS Depression	9.70 (4.3)	7.77 (4.6)	<.001
HADS Anxiety	9.06 (4.4)	7.99 (4.3)	<.001
CSQ	17.6 (9.4)	14.5 (9.5)	<.001
PROMIS	29.9 (7.7)	33.9 (8.5)	<.001
BPI Pain Interference	7.33 (1.8)	6.20 (2.3)	<.001
BPI Pain Severity	6.58 (1.6)	5.97 (1.9)	<.001

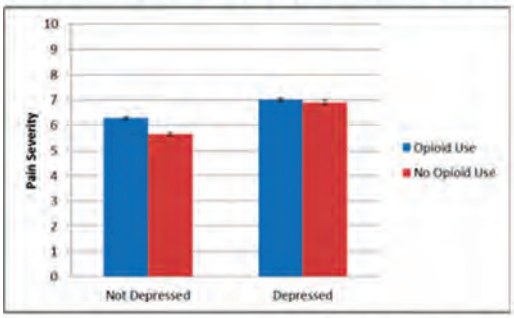
a. Chi-square tests were conducted for categorical variables and independent samples t-tests were conducted for continuous variables.
b. Mean and standard deviation reported for continuous variables.

Figure 1. Relationship between opioid use and pain interference moderated by depression.



Note: A 2*2 analysis of covariance model was conducted and found that the relationship between opioid use and pain interference was moderated by depression ($F(1,2103) = 12.88$, $p < .001$). Gender, race, age, and HADS Anxiety scores were included as covariates. Participants with a score of 11 or higher on the HADS Depression subscale were considered depressed.

Figure 2. Relationship between opioid use and pain severity moderated by depression.



Note: A 2*2 analysis of covariance model was conducted and found that the relationship between opioid use and pain severity was moderated by depression ($F(1,2103) = 11.95$, $p = .001$). Gender, race, age, and HADS Anxiety scores were included as covariates. Participants with a score of 11 or higher on the HADS Depression subscale were considered depressed.

Selective and Peripheral-Specific Trk Inhibitor Shows Potent Analgesic Effect Comparable to Morphine in Rat Osteoarthritis Model without CNS Toxicity. Takeshi Nagaura, Tetsuya Yasuhiro, Keisuke Oda, Yuya Ezaki, Takashi Koyanagi, Satoshi Itadani, Hiroyuki Nitta, Hiroshi Wakazono, Seishi Katsumata and Yasushi Hirota. Ono Pharmaceutical Co., Ltd., Osaka, Japan.

Background/Purpose: Tropomyosin receptor kinase (Trk) receptors are a family of three closely related receptor tyrosine kinases; TrkA, TrkB and TrkC. Especially, the peripheral TrkA in sensory neuron is a promising target for musculoskeletal pain such as osteoarthritis (OA) since the activation of TrkA receptor by nerve growth factor (NGF) induces hyperalgesia and anti-NGF antibodies show potent analgesic effects in moderate to severe OA patients. However, sustained inhibition of TrkA in brain raises concerns about deteriorating cognitive impairment such as Alzheimer's disease, because NGF/TrkA signal is important to maintain the function of cholinergic neuron. We discovered a highly selective and orally available Trk inhibitor which shows potent *in vivo* TrkA inhibitory activities at low plasma concentrations with a low brain penetration. In this study, we evaluated the analgesic effects of peripheral-specific Trk inhibitor on monosodium iodoacetate (MIA)-induced OA pain in rats.

Methods: Male SD rats (215~265 g) were briefly anaesthetized with isoflurane, and 3 mg MIA solution or saline was intra-articularly injected into right knee. The peripheral-specific Trk inhibitor or vehicle (distilled water containing 20% Wellsolve) was orally administrated twice a day for 8 days from 14 day after MIA injection. Morphine was subcutaneously administrated 1 hour before evaluation of pain-related behavior. Pain-related behavior was evaluated by the percent weight borne on right leg.

Results: The peripheral-specific Trk inhibitor does-dependently inhibited the pain-related behavior of MIA-treated rats in which acetaminophen and nonsteroidal anti-inflammatory drugs did not show analgesic effects. The analgesic effect of it at 1 mg/kg b.i.d. or more was comparable to that of morphine at 3 mg/kg which significantly impaired motor coordination in rats. Although repeated administration of high doses of peripheral-specific Trk inhibitor for 14 days increased food consumption and weight gain in normal rats, there was at least 36-fold margin calculated by area under the concentration-time curve between effective dose in MIA model and no affecting dose to them.

Conclusion: The selective and peripheral-specific Trk inhibitor will be a potent and safer medication for OA pain.

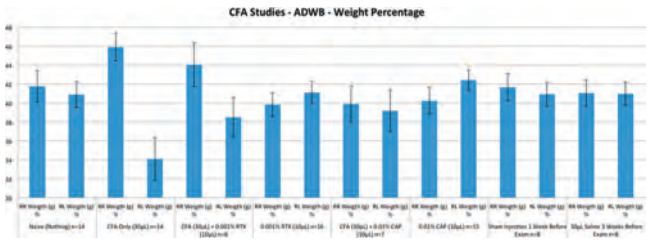
The Effect of Treatment with Resiniferatoxin and Capsaicin on Dynamic Weight Bearing Measures and Evoked Pain Responses in a Chronic Inflammatory Arthritis Murine Model. Joseph Bert[1], Christopher W. Dorman[2], Sandra Frizelle[2], Sonia C. Funkenbusch[2], Hollis E. Krug[3] and Maren L. Mahowald[4]. [1]University of Minnesota Internal Medicine Residency, Minneapolis, MN, [2]Minneapolis VA Health Care System, Minneapolis, MN, [3]VA Health Care System, Minneapolis, MN, [4]University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, MN.

Background/Purpose: Capsaicin (CAP) and Resiniferatoxin (RTX) are vanilloid receptor agonists that when given by intra-articular injections, can normalize Evoked Pain Scores (EPS) and Automated Dynamic Weight Bearing (ADWB) measures in carrageenan-induced acute inflammatory arthritis. To determine whether these vanilloid receptor agonists might have benefit in chronic inflammatory arthritis pain, we measured changes in ADWB and EPS due to joint pain in mice with Complete Freund's Adjuvant (CFA) induced chronic inflammatory arthritis with and without treatment with intra-articular (IA) injections of CAP and RTX.

Methods: Chronic Inflammatory arthritis was produced by intra-articular injection of 30 μl of Complete Freund's Adjuvant (CFA) into the left knee of C57BL6 male mice 3 weeks prior to pain behavior testing. One group of mice was injected with IA RTX (10μl of 0.001%) 7 days prior to measurement of EPS and ADWB. Similarly, another group of mice were injected with 10μl of 0.01% IA CAP 7 days before pain behavior testing. Evoked pain behavior was measured by tallying fights and vocalizations per one minute with repeated palpation of the knee at 15.6 psi. ADWB (weight on each limb and time on each limb) was measured using an Automated Dynamic Weight Bearing apparatus (Bioseb, Vitrolles, France).

Results: Chronic Inflammatory arthritis pain is demonstrated by increased EPS and reduced ADWB measures in the affected limb of arthritic mice. Na●ve mice have low EPS (0.5) and equal left to right DWB ratios for weight (1.01) and time (1.006). Chronic inflammatory arthritis induced by IA CFA resulted in a significantly increased EPS (3.5) and a decrease in left to right ADWB ratios for weight (0.76) and time (0.93) when compared with controls. Treatment with IA CAP 7 days prior to pain behavior testing resulted in improvement in EPS (1.38) and near normalization of left to right ADWB ratios for weight (0.99) and time (1.01) when compared to the chronic inflammatory arthritis model. Treatment with IA RTX 7 days prior to the exam led to improved EPS (1.67) and improved left to right ADWB ratios for weight (0.90) and time (0.98) when compared to the chronic inflammatory arthritis model. IA CAP alone and IA RTX alone did not have an impact on EPS or ADWB ratios when given 7 days prior to pain behavioral testing.



Conclusion: Using ADWB and EPS, we were able to quantitate pain in a murine chronic arthritis model. Intra-articular CFA administration resulted in a significant increase in EPS and decreased ADWB measures in the affected limb. Treatment with CAP and RTX in these mice improved pain measures as assessed by EPS and ADWB measures. These results are comparable to those previously reported when mice were pretreated in an acute inflammatory arthritis model. The optimal dose of RTX and CAP for therapeutic benefit and duration of response has yet to be determined.

Discontinuation of Concomitant Medication for Enthesitis-Related Arthritis during 52 Weeks of Treatment with Adalimumab. Shirley ML Tse[1], Rubén Burgos-Vargas[2], Gerd Horneff[3], Aileen L. Pangan[4], Jasmina Kalabic[5], Kristina Unnebrink[5] and Jaclyn K. Anderson[4]. [1]The Hospital for Sick Children, University of Toronto, Toronto, ON, [2]Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico, [3]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

Background/Purpose: Children with enthesitis-related arthritis (ERA) require medical therapy to control inflammation and restore normal function; however, the use of multiple medications and for longer periods than needed is of special concern in the pediatric population. The objective of this analysis is to evaluate the proportion of patients (pts) who discontinued one or more concomitant medications for pediatric ERA during the first 52 weeks (wk) of adalimumab (ADA) treatment.

Methods: This is a phase 3, multicenter, randomized, double-blind study in pts aged ≥6 to <18 years (yr) with active ERA not responsive to ≥1 NSAID and ≥1 DMARD. Pts were randomized 2:1 to receive blinded ADA (24 mg/m^2 BSA up to 40 mg every other wk) or placebo (PBO) for 12 wks followed by open-label (OL) ADA up to 144 wks. Active disease was defined as: ≥3 active joints (AJC; swelling not due to deformity or joints with loss of motion plus pain and/or tenderness) and evidence of enthesitis in ≥1 location (documented in the past or present at baseline [BL]). Pts could enter the study on stable doses of concomitant NSAIDs, DMARDs (methotrexate [MTX] or sulfasalazine [SSZ]), and corticosteroids (CSs); doses remained stable during the first 12 wks except as medically required due to adverse event (AE). Dose adjustment or treatment induction with these agents was permitted after wk 12. Discontinuation of concomitant ERA medications was not required in the protocol and was at the discretion of the treating physician. Concomitant use was defined as use of the drug at any time during the study through wk 52.

Results: 46 pts were randomized (PBO 15, ADA 31). At BL, mean duration of ERA symptoms was 2.6 yrs; mean AJC was 7.8, and mean enthesitis count was 8.1. Mean % change from BL to wk 12 in AJC (primary endpoint) was greater in the ADA group vs. PBO (−63% vs -12%, $P=0.039$), with 89% overall reduction in AJC from BL through wk 52. Prior use of NSAIDs, DMARDs, and CSs was reported in 100%, 91%, and 57% of pts, respectively. Concomitant use of ERA drugs at BL is shown in the table. 16 pts (35%) stopped NSAIDs, 5 pts (11%) stopped DMARDS (2 SSZ, 3 MTX), and 7 pts (15%) stopped CSs without restarting prior to wk 52; NSAIDs were stopped in 3 pts due to AEs. 3 pts discontinued the study due to AE (2) or inefficacy (1) during OL period. Of those remaining in the study at wk 52, 8/43 (19%) were completely off concomitant ERA drugs. At wk 52 mean % change from BL in AJC was -81.8% in pts who stopped NSAIDs, -72.4% in pts who stopped DMARDs, -97.1% in pts who stopped CSs, and -82.9% in pts who stopped all NSAIDs and DMARDs.

Table Concomitant Medications for Enthesitis-Related Arthritis

	Placebo/ Adalimumab N = 15 n (%)	Adalimumab/ Adalimumab N = 31 n (%)	Total N = 46 n (%)
NSAIDs			
At baseline	13 (87)	24 (77)	37 (80)
At week 52[a]	8 (57)	14 (48)	22 (51)
DMARDs			
At baseline	11 (73)	21 (68)	32 (70)
At week 52[a]	9 (64)	18 (62)	27 (63)
Corticosteroids			
At baseline	4 (27)	8 (26)	12 (26)
At week 52[a]	3 (21)	4 (14)	7 (16)
NSAID +DMARD			
At baseline	10 (67)	15 (48)	25 (54)
At week 52[a]	5 (36)	7 (24)	12 (28)
ADA Monotherapy[b]			
At baseline	0	1 (3)	1 (2)
At week 52[a]	3 (21)	5 (17)	8 (19)

[a]Observed data; includes pts who started ERA concomitant medication after the double-blind period; includes 3 pts who discontinued the study after week 12 and prior to week 52; N=14/29/43, PBO/ADA/total.
[b]ADA monotherapy = no concomitant NSAID, DMARD, or corticosteroid.
ADA, adalimumab; DMARD, disease-modifying antirheumatic drug; NSAID, nonsteroidal anti-inflammatory drug.

Conclusion: Clinical improvement with ADA through 52 wks allowed some pts to discontinue concomitant NSAIDs, DMARDs, or CSs for ERA at the investigator's discretion. Clinical response was generally maintained in pts who stopped 1 or more concomitant medications. Standardized discontinuation of concomitant ERA medications in ADA responders may have resulted in a higher number of pts able to discontinue concomitant ERA therapies.

Disease Burden Is Comparable in Children with Enthesitis-Related Arthritis and Polyarticular Juvenile Idiopathic Arthritis. Pierre Quartier[1], Jasmina Kalabic[2], Zbigniew Zuber[3], Kirsten Minden[4] and Jaclyn K. Anderson[5]. [1]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [2]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [3]St. Louis Children's Hospital, Krakow, Poland, [4]Charité Universitätsmedizin Berlin, Berlin, Germany, [5]AbbVie Inc., North Chicago, IL.

Background/Purpose: To compare baseline disease characteristics of pediatric patients (pts) with enthesitis-related arthritis (ERA) and polyarticular juvenile idiopathic arthritis (pJIA) from clinical trials with adalimumab (ADA).

Methods: Baseline (BL) data were derived from 1 study in ERA (M11–328) and 2 studies in pJIA (M10–444, DE038). M11–328 was a Phase 3, double-blind (DB), placebo-controlled, multicenter study in pediatric pts aged 6–17 years (yrs) at BL with ERA as defined by International League of Associations for Rheumatology (ILAR). Disease activity was defined by 1) ≥3 active joints (swelling not due to deformity or joints with limitation of motion (LOM) plus pain and/or tenderness) AND evidence of enthesitis in ≥1 location (either past or present at BL). Pts were inadequate responders or intolerant to ≥1 nonsteroidal anti-inflammatory drug (NSAID) and ≥1 disease-modifying antirheumatic drug (DMARD). M10–444 was a Phase 3b open-label multicenter study in pts aged 2 to <4 yrs and age ≥4 yrs weighing <15 kg with moderately to severely active pJIA (ILAR categories: polyarticular rheumatoid factor (RF) positive, polyarticular RF negative, extended oligoarthritis, undifferentiated, and systemic arthritis). Active disease was defined as arthritis affecting ≥5 joints at BL. EU pts must have previously failed, had insufficient response to, or intolerance to ≥1 DMARD. Study DE038 was a multicenter, Phase 3, randomized, DB study in pts aged 4–17 yrs with pJIA by American College of Rheumatology (ACR) criteria (onset may have been systemic, polyarticular, or oligoarticular/pauciarticular). Active disease was defined as ≥5 swollen joints (SJC) and ≥3 joints with LOM at screening. A trial of NSAIDs was required, and pts were stratified according to methotrexate use.

Results: 203 pJIA pts (M10–444, n=32, DE038, n=171) and 46 ERA pts were evaluated. Polyarticular JIA pts were predominantly female compared to ERA pts (pJIA, 79–88% vs ERA, 33%). (Table) C-reactive protein (CRP) was elevated at BL in 66% of pts in DE038 compared to about 39% of the 2–4 year-old pJIA pts and ERA pts. Mean active joint count (AJC) at BL was greater in pJIA pts than in ERA pts (10 and 17.2 vs 7.8 joints). Mean BL tender joint count (TJC) was similar in pJIA study DE038 and M11–328 compared to a lower TJC in the younger age group enrolled in M10–444. Mean physician's global assessment of disease activity, parent's global assessment (PaGA) of pt's overall well-being, PaGA of pt's pain, and childhood health assessment questionnaire scores were similar across JIA subtypes.

Table Baseline Demographics and Disease Characteristics

	Polyarticular JIA		ERA
	M10–444 N = 32	DE038 N = 171	M11–328 N = 46
Demographics			
Age, years	3.0 (0.7)	11.3 (3.5)	12.9 (2.9)
Female, n (%)	28 (87.5)	135 (78.9)	15 (32.6)
White, n (%)	25 (78.1)	157 (91.8)	35 (76.1)
Body mass index, kg/m^2	15.5 (1.3)	19.4 (5.1)	19.7 (4.4)
HLA-B27 positive, n (%)	1 (3.1)	37 (22.0)[a]	29 (67.4)[b]
RF positive, n (%)	1 (3.1)	37 (22.0)	0
Prior JIA medications, n (%)	31 (96.9)	−*	46 (100)
Prior NSAIDs, n (%)	20 (62.5)	−*	46 (100)
Prior DMARDs, n (%)	25 (78.1)	110 (64,3)	42 (91.3)
Methotrexate, n (%)	25 (78.1)	103 (60.2)	29 (63.0)
Prior corticosteroids, n (%)	22 (68.8)	−*	21 (45.7)
Disease duration, years	1.0 (0.8)	3.8 (3.9)[c]	1.9 (2.1)
Disease Characteristics			
AJC (0–73)	10.0 (7.5)	17.2 (10.4)	7.8 (6.6)[d]
TJC (0–75)	3.8 (5.0)	11.4 (12.4)	12.9 (10.1)[d]
SJC (0–66)	8.9 (7.4)	14.8 (9.4)	6.2 (6.4)[d]
LOM (0–69)	8.6 (7.7)	13.5 (9.2)	4.9 (3.5)[d]
PGA of disease activity (0–10 cm VAS)	5.5 (2.0)	5.9 (1.8)	5.3 (2.2)
PaGA of pt's overall well-being (0–10 cm VAS)	4.8 (2.6)	4.8 (2.3)	5.1 (2.4)
PaGA of pt's pain (0–10 cm VAS)	4.6 (2.6)	5.0 (2.5)[c]	5.6 (2.3)
CHAQ (0–3)	1.2 (0.7)	1.1 (0.7)	0.8 (0.6)
Elevated CRP, n (%)	12 (38.7)[e]	112 (65.9)[c]	18 (39.1)
CRP (mg/dL)	1.6 (2.4)[e]	2.6 (4.1)[c]	9.0 (16.0)[f]

Values are the mean (standard deviation) unless otherwise stated. *Data not available. [a]N=168. [b]N=43. [c]N=170. [d]AJC 0–68, TJC 0–72, SJC 0–68, LOM 0–66. [e]N=31. [f]high-sensitivity CRP, mg/L. AJC, active joint count; CHAQ, childhood health assessment questionnaire; CRP, C-reactive protein; DMARD, disease-modifying antirheumatic drug; ERA, enthesitis-related arthritis; JIA, juvenile idiopathic arthritis; LOM, limitation of motion; PaGA, parent's global assessment; PGA, physician's global assessment; SJC, swollen joint count; TJC, tender joint count; VAS, visual analog scale.

Conclusion: In this comparison of JIA pts enrolled in ERA and pJIA studies, at baseline the burden of inflammatory disease as measured by AJC and SJC was slightly higher in pJIA as compared to ERA. However, AJC and SJC do not encompass all aspects of disease in JIA and overall, physicians and parents assessed disease burden similarly with similar impairment in physical function observed in children with ERA and pJIA.

Predicting Treatment Response to Etanercept in Juvenile Idiopathic Arthritis: Results from the British Society for Paediatric and Adolescent Rheumatology Etanercept Cohort Study (BSPAR-ETN). Lianne Kearsley-Fleet[1], Rebecca Davies[1], Mark Lunt[1], Taunton R. Southwood[2], Kimme L. Hyrich[3] and on Behalf Of The BSPAR Etanercept Cohort Study[1]. [1]University of Manchester, Manchester, United Kingdom, [2]Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom, [3]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Etanercept (ETN) is licensed in Europe for use in children with Juvenile Idiopathic Arthritis (JIA) and is routinely prescribed after failure of other DMARDs. Previous findings regarding response to treatment for JIA suggest that patients with less severe disease at start of treatment are those patients who are more likely to respond to treatment. The objectives of this study were to (1) investigate the influence of ETN on disease activity in patients with severe JIA over the initial first year of treatment and (2) explore factors associated with treatment response over this same period.

Methods: This analysis used patients in the British Society for Paediatric and Adolescent Rheumatology ETN Cohort study (BSPAR-ETN) with JIA starting ETN therapy who had follow up records at baseline and 1 year. Only patients with ILAR criteria of systemic arthritis, oligoarticular arthritis, polyarticular arthritis, and psoriatic arthritis were included. Univariable and multivariable backward stepwise logistic regression was performed to identify factors associated with (1) a good treatment response (ACR Pedi 50) and (2) achieving minimal disease activity (MDA) at 1 year. Patients who stopped ETN therapy within the 1st year for an adverse event or unknown reason were excluded from the model as initial treatment response on therapy was not captured. Patients who stopped for inefficacy were classified as non-responders. Imputation was used to account for missing baseline and 1 year disease activity measures.

Results: A total of 422 patients were included in this analysis; 73% female, median age at start of ETN therapy 11.0 years (interquartile range (IQR) 7.3, 13.3), disease duration at start of ETN 4 years (IQR 2, 7); 14 stopped ETN due to inefficacy, 8 due to adverse events and 7 for other reasons. No child stopped for remission within the 1st year. Median baseline JADAS-71 was 17 (IQR 12, 26). At 1 year this decreased to 3 (IQR 1, 10; $p<0.001$). Of the 407 patients included in the model, at 1 year, 75%, 70%, 59%, and 41% had reached ACR Pedi 30, 50, 70 and 90 respectively, and 49% had achieved MDA. Independent predictors of achieving MDA at 1 year included a history of uveitis (Odds Ratio (OR) 2.60 [95% CI 1.06, 6.37]), younger age (OR age ≥ 9 years old compared to <9 years 0.57 [95% CI 0.35, 0.92]) and lower disability (OR 0.59 per unit CHAQ increase [95% CI 0.40, 0.87]). In addition, as age increased, patients had reduced odds of achieving ACR Pedi 50 at 1 year (OR 0.93 per unit increase [95% CI 0.88, 0.99]).

Conclusion: Among this "real-world" cohort of children with severe JIA, a significant proportion of children achieve MDA and good ACR Pedi response scores within 1 year of starting ETN although few clinical factors could predict this outcome. The finding of a lesser response in older children warrants further investigation and may relate to differences in disease phenotype, drug pharmacokinetics or adherence.

Factors Associated with Choice of First Biologic Among Children with Juvenile Idiopathic Arthritis: A Combined Analysis from 2 UK Paediatric Biologic Registers. Rebecca Davies[1], Lianne Kearsley-Fleet[1], Eileen Baildam[2], Michael W. Beresford[3], Helen E. Foster[4], Taunton R. Southwood[5], Wendy Thomson[6], Kimme L. Hyrich[7], on Behalf Of The BSPAR Etanercept Cohort Study[1] and The Biologics for Children with Rheumatic Diseases (BCRD) study[1]. [1]University of Manchester, Manchester, United Kingdom, [2]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [3]Institute of Translational Medicine (Child Health), University of Liverpool, Liverpool, United Kingdom, [4]Newcastle University, Newcastle upon Tyne, United Kingdom, [5]Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom, [6]Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [7]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom.

Background/Purpose: The management of juvenile idiopathic arthritis (JIA) has been revolutionised by the introduction of biologics such as etanercept (ETN), approved in the UK in 2002. Since that time, the use of biologics in children and young people (CYP) has expanded, including the use of those licensed for JIA (adalimumab (ADA), tocilizumab (TCZ),

abatacept) as well as those licensed for rheumatoid arthritis (rituximab, infliximab (IFX) and anakinra (ANA)). ETN is most often the first choice biologic in the treatment of JIA; however there may be occasions where ETN is not the preferred choice, for reasons of either efficacy or safety. Understanding how biologics are being selected will help inform future practice and research. Therefore, the aim of this analysis was to describe the choice of first-line biologics in UK CYP with JIA and explore possible reasons behind this choice.

Methods: Both the British Society for Paediatric and Adolescent Rheumatology Etanercept Cohort Study (BSPAR-ETN), established 2004, and the Biologics for Children with Rheumatic Diseases (BCRD) study, established 2010, are ongoing prospective observational cohorts, collecting detailed information on CYP starting either ETN (BSPAR-ETN) or any other biologic (BCRD) for JIA. At start of therapy, demographic and disease information is collected. Biologic-naive patients registered on or after 01/01/2010 starting their first biologic were identified and baseline disease characteristics compared between therapies, using descriptive statistics. An additional cohort of children starting ETN <2010 were also included to analyse changes in ETN prescribing since initial approval.

Results: To 07/04/2014, 870 patients were recruited starting a first-line biologic (123 BCRD; 747 BSPAR-ETN (582<2010, 165≥2010) (Table). From 2010, children with systemic JIA (sJIA) were almost exclusively prescribed ANA or TCZ. Choice between anti-TNF therapies was largely driven by prevalence of uveitis (5% ETN versus 70% ADA and 72% INF). Children starting ETN were also more likely to have a polyarticular subtype. Only half of the patients starting ETN received concomitant methotrexate compared to the other biologics (69–90%). Compared to ETN patients pre-2010, CYP starting ETN from 2010 had shorter disease duration and were less likely to be receiving corticosteroids, have lesser prevalence of sJIA and lower rates of uveitis.

Conclusion: Although ETN remains the most common biologic prescribed for JIA, there has been a clear shift towards the use of alternative biologics, including unlicensed biologics, in certain patient situations, largely driven by disease subtype and the presence of uveitis. This channelling of certain children towards specific therapies will need to be considered both in terms of future comparative effectiveness studies and also as a guide to ongoing research priorities within rheumatology.

KG, Ludwigshafen, Germany, [18]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Department of Pediatrics, University of Cincinnati, Cincinnati, OH, [19]PRINTO-IRCCS, Genova, Italy.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is one of the most common rheumatic diseases of childhood. Adalimumab (ADA) is approved for moderate to severe polyarticular JIA (pJIA) in patients (pts) ≥4 years (yrs) in the US**,** Australia, and Japan and in the EU for pts ≥2 yrs. The study objective was to evaluate long-term safety and effectiveness of ADA in pts with moderately to severely active pJIA who are prescribed and treated with ADA in routine clinical practice. 5 yr interim data will be presented.

Methods: This is an ongoing, multicenter, non-interventional, observational registry of pts with moderately to severely active pJIA who are treated with either ADA±methotrexate (MTX) or MTX alone as part of their routine clinical care. 800 pts (500 in ADA arm/300 in MTX arm) were to be enrolled in the US, EU, and Australia. The follow-up observational period is 10 yrs from enrollment into one of the treatment arms. Observational adverse events (AEs) were recorded from the first day in the registry through last contact, irrespective of the duration of registry treatment. Clinical outcomes were assessed by 27-joint juvenile arthritis disease activity score (JADAS27), based on C-reactive protein (CRP).

Results: As of January 2014, enrollment is complete. 842 pts (540 in ADA arm/302 in MTX arm) were treated in the registry as of the March 28, 2014 cutoff date. The mean pJIA disease duration at registry enrollment was 1.3 and 3.7 yrs and the mean duration days of study exposure was 643 and 653 for MTX and ADA arms, respectively. At baseline, mean AJC73 was 5.8 and 5.4 for MTX and ADA, respectively, and childhood health assessment questionnaire disability index (CHAQ-DI) was 0.6 for both groups. Overall, 153 pts (50.7%) in the MTX arm and 132 pts (24.4%) in the ADA arm discontinued registry drug. Of those, 22 (7.3%) and 23 (4.3%) pts in the MTX and ADA arm, respectively, discontinued due to an AE, and 39 of the 153 pts in the MTX arm discontinued as they switched to the ADA arm of the registry. The observational AEs are summarized in the Table. No deaths, malignancies, or opportunistic infections were reported. In the ADA arm, there were 13 (2.4%) pts with serious infectious AEs (including abdominal abscess, acute tonsillitis, appendicitis, cellulitis, gastroenteritis, mononucleosis, viral meningitis, pneumonia, pyelonephritis, scarlet fever, subcutaneous abscess, tonsillitis, urinary tract infection, and varicella). Frequencies and rates of treatment-emergent AEs were similar to those reported for observational AEs. Mean JADAS27 improved from 12.1 at baseline to 9.4, 6.1, 5.1, 4.4 at months 1, 3, 6, and 12 for pts in the MTX arm and from 12.1 at baseline to 7.4, 5.5, 4.4, 4.5 in the ADA arm, respectively (observed data).

Table Overview of Observational Adverse Events (AEs)

	MTX		ADA ± MTX	
	N=302 n (%)	PYs=863.9 E (E/100 PYs)	N=540 n (%)	PYs=1226.8 E (E/100 PYs)
Any AE	135 (44.7)	351 (40.6)	169 (31.3)	447 (36.4)
At least "possibly drug related" per the investigator	68 (22.5)	121 (14.0)	80 (14.8)	147 (12.0)

Severe AE	11 (3.6)	15 (1.7)	19 (3.5)	31 (2.5)
Serious AE	17 (5.6)	26 (3.0)	35 (6.5)	56 (4.6)
AE leading to discontinuation of study drug	20 (6.6)	26 (3.0)	27 (5.0)	39 (3.2)
Infectious AE	75 (24.8)	133 (15.4)	93 (17.2)	149 (12.1)
Serious infectious AE	8 (2.6)	11 (1.3)	13 (2.4)	15 (1.2)
Injection site-related AE	6 (2.0)*	8 (0.9)	24 (4.4)	29 (2.4)

E, events; PYs, patient years.

*3 patients experienced injection site-related AEs with etanercept injections.

Conclusion: Overall, ADA is well-tolerated in these pts with active pJIA. No new safety signals were observed, and based on this interim analysis, the known safety profile of ADA remains unchanged.

Treatment Prescribing Patterns in a Cohort of Patients with Juvenile Idiopathic Arthritis (JIA). Data from the Childhood Arthritis Prospective Study. Rebecca Davies[1], Roberto Carrasco[2], Helen Foster[3], Eileen Baildam[4], Alice Chieng[5], Joyce Davidson[6], Yiannis Ioannou[7], Lucy R. Wedderburn[8], Wendy Thomson[9], Kimme L. Hyrich[10] and on Behalf Of Childhood Arthritis Prospective Study (CAPS)[11]. [1]University of Manchester, Manchester, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]Newcastle University, Newcastle, United Kingdom, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]Manchester Children's Hospital, Manchester, United Kingdom, [6]Royal Hospital for Sick Children, Glasgow, United Kingdom, [7]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom, [8]Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom, [9]Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [10]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [11]university of Manchester, Manchester, United Kingdom.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a heterogenous disease, classified according to the International League of Associations for Rheumatology (ILAR). Initial treatment is based largely on disease severity; intra-articular injections for oligoarthritis, methotrexate (MTX) for polyarthritis and systemic presentations. The recent licensing of biologic therapies for use in JIA has revolutionised treatment. It is not known what proportion of children who present with polyarthritis will require biologic therapy. Although not studied formally, it is recognised a proportion of children with oligoarthritis, may also require systemic therapy to control symptoms. Therefore, the aim of this study was to describe prescribing patterns within new onset JIA patients over the first 3 years following presentation to rheumatology.

Methods: Children with at least 3 years of follow-up within the Childhood Arthritis Prospective Study (CAPS), a prospective observational inception study of inflammatory arthritis, were included.

For analysis, children were grouped into a disease pattern according to the physician-assigned ILAR category and number of active joints at first presentation (baseline): oligoarticular, polyarticular, systemic (sJIA) and enthesitis-related arthritis (ERA). Treatment exposures over the 3 year period were determined and categorised into NSAID, intra-articular steroids, disease modifying anti-rheumatic drug (DMARD) including MTX and biologics including etanercept (ETN) and infliximab (INF).

Results: 790 children had 3 years of follow-up. Of these, 78 had missing ILAR subtype data and were excluded, leaving 712 in total (406 oligoarticular, 221 polyarticular, 42 sJIA and 43 ERA). Over a 3 year period, almost 100% of children with polyarticular and 50% with oligoarticular presentation received a DMARD. 46% with polyarticular and 17% with oligoarticular presentation also received a biologic (Figure 1). The most recent ILAR category among children with oligoarticular onset who received a biologic included 39% extended oligoarthritis, 19% polyarthritis, 4% ERA, 11% other; 27% had persistent oligoarthritis. All sJIA patients were treated with DMARDs with 36% having biologics, primarily ETN and INF. 63% of ERA patients received a DMARD, with 26% later receiving a biologic.

Conclusion: Over a three year period almost all patients with a polyarticular presentation received treatment with MTX and almost 50% also received a biologic therapy. A high proportion of children with an oligoarticular presentation also went on to receive DMARDs and biologics, with many children receiving this treatment for persistent oligoarthritis. This is despite the lack of clinical trial evidence for effectiveness in this subtype. Further studies on the efficacy/effectiveness in this subtype should be undertaken to ensure appropriate use of advanced therapies in this population.

Arthritis pattern at presentation	N	Ever had a DMARD, n(%)	Ever had a biologic, n(%)
Oligoarthritis	406	204 (50)	70 (17)
Polyarthritis	221	217 (98)	98 (44)
Systemic arthritis	42	42 (100)	15 (36)
Enthesitis-related arthritis	43	27 (63)	11 (26)

Environmental Risk Factors and Development of Juvenile Idiopathic Arthritis. Susan Shenoi[1], Kathryn B Whitlock[2] and Carol A Wallace[3]. [1]Seattle Childrens Hospital, seattle, WA, [2]Seattle Children's Hosptial, Seattle, WA, [3]Seattle Children's Hospital/Univ of Washington, Seattle, WA.

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of disorders that is characterized by chronic arthritis in children without known etiology. Environmental factors that act as triggers in a genetically susceptible host are one of the current postulated etiologies of JIA. Although research that focusses on environmental risk factors in JIA is scant, to date there has been some data to suggest a role of infections, exposure to smoking and lack of breastfeeding. This case control study examines the association of selected environmental risk factors in children with JIA.

Methods: JIA cases were identified at outpatient rheumatology clinic visits over 18 months (2012 to 2013) at a major Children's facility. Enrolled JIA cases were asked to identify three control playmates of similar age and gender without JIA. Both cases and controls completed a one time questionnaire on environmental risk factors in reference to critical time period (at JIA case symptom onset). Controls who responded were frequency-matched to cases by age and gender. Logistic regression adjusted for age and gender was used to determine associations with JIA, and odds ratios are reported with 95% confidence intervals.

Results: 223 JIA cases and 86 controls submitted data that was analyzed. Baseline demographic characteristics were similar between cases and controls. Approximately 5% of mothers smoked during pregnancy among cases and controls with OR 0.8 (95% CI: 0.3 –2.4; p value 0.7). Maternal smoking at JIA onset had OR 1 (95% CI: 0.5 –2.3). The odds of JIA for other selected environmental risk factors were as follows: breastfeeding in first year of life: 1.1 (95% CI: 0.6 –2.1), hospitalization with infection in first year of life: 1.7 (95% CI: 0.5 – 5), daycare attendance <6 years of age 1.3 (95% CI: 0.8 – 2.1), household pets 1.2 (95% CI: 0.7 – 2), urban residence 0.7 (95% CI: 0.4 –1.1), stressors in family (death, divorce, move, new school, unemployment) 1 (95% CI: 0.6 –1.7). Limitations of the study include selection bias as cases were identified though outpatient rheumatology visits and overmatching that was accounted for in the analysis.

Conclusion: There was no association between maternal smoking during pregnancy or subsequent maternal smoking at JIA symptom onset, infections

in first year of life, daycare attendance, household pets, urban residence or family stressors and development of JIA in this case control study.

Growth during Tocilizumab Therapy for Polyarticular-Course Juvenile Idiopathic Arthritis: 2-Year Data from a Phase 3 Clinical Trial. Kamal N. Bharucha[1], Hermine I. Brunner[2], Nicola Ruperto[3], David A. Cabral[2], Abraham Gedalia[2], Valeria Gerloni[3], Christian Jorgensen[3], Athimalaipet Ramanan[3], Daniel Lovell[2], Alberto Martini[4], James Frane[5], Chris Wells[6] and Fabrizio De Benedetti Sr. [7]. [1]Genentech, South San Francisco, CA, [2]PRCSG, Cincinnati, OH, [3]PRINTO, Genoa, Italy, [4]Istituto Giannina Gaslini, Genova, Italy, [5]Consultant, Santa Monica, CA, [6]Roche Products Ltd., Welwyn Garden City, United Kingdom, [7]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy.

Background/Purpose: Elevated interleukin-6 (IL-6) levels have been associated with low growth velocity in patients with juvenile idiopathic arthritis (JIA). [1] The efficacy of tocilizumab (TCZ), an IL-6 receptor inhibitor, in patients with polyarticular-course JIA (pcJIA) was demonstrated up to 104 weeks in the phase 3 CHERISH trial. [2] Growth was evaluated in patients with pcJIA treated with TCZ for up to 104 weeks in CHERISH.

Methods: Patients with active pcJIA for ≥6 months and inadequate responses to methotrexate received open-label (OL) TCZ intravenously every 4 weeks (randomly assigned 1:1 to receive 8 or 10 mg/kg for body weight [BW] <30 kg or 8 mg/kg for BW ≥30 kg) for 16 weeks. At week 16, patients with ≥JIA ACR30 response were randomly assigned 1:1 to receive placebo or to continue TCZ double-blind for 24 weeks. At week 40, all patients entered an OL extension and received TCZ according to BW through week 104. Height velocity and height standard deviation scores (SDS) were measured in patients with Tanner stage <4 (the subset of study patients with the highest growth potential) provided they did not receive the growth hormone somatotropin during the study.

Results: Of 188 patients who received ≥1 dose of TCZ, 123 patients with Tanner stage <4 were included in the growth population (1 patient received somatotropin and was excluded from the growth population). At baseline, the growth population had a mean World Health Organization (WHO) height SDS ± SD of –0.5 ± 1.2. The baseline height SDS was not related to age or disease duration (Spearman's rank correlations $r = 0.08$ and $r = –0.12$, respectively). For patients with Tanner stage <4 at baseline and height data at year 2 of the study (n = 103), baseline mean height SDS increased significantly (by 0.40) from baseline to year 2 of treatment ($p < 0.0001$ vs baseline). At year 2, 71.8% (74/103) of these patients had an increased height SDS compared with their baseline height SDS, with a mean height velocity of 6.7 ± 2.0 cm/year (n = 103). For patients with available data at year 2 (n = 103), the mean daily oral corticosteroid doses (± SD) at baseline and year 2 of treatment were 0.05 mg/kg (± 0.08) and 0.02 mg/kg (± 0.05), respectively.

Conclusion: Mean height SDS of patients with pcJIA was below normal at baseline. The majority of patients who were Tanner stage <4 at baseline (71.8%) had an increased height SDS at year 2 (end of study).

Nearly 20% of Children ARE NOT Correctly Classified According to Current ILAR Classification in a Printo Dataset of More THAN 12,000 Juvenile Idiopathic Arthritis Patients. Alessandro Consolaro[1], Francesca Bovis[2], Ekaterina Alekseeva[3], Violeta Vladislava Panaviene[3], Jordi Anton[3], Susan Nielsen[3], Gordana Susic[3], Maria Trachana[4], Troels Herlin[5], Nico Wulffraat[3], Pavla Dolezalova[3], Yosef Uziel[6], Nahid Shafaie[3], Ingrida Rumba-Rozenfelde[3], Valda Stanevicha[3], Nicolino Ruperto[3], Daniel Lovell[7], Angelo Ravelli[8] and Alberto Martini[1]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]PRINTO - Istituto Giannina Gaslini, Genoa, Italy, [3]Istituto Giannina Gaslini, Genoa, Italy, [4]Aristotle University, Thessaloniki, Greece, [5]Aarhus, Genoa, Italy, [6]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel, [7]PRCSG, Cincinnati, OH, [8]Istituto Gaslini-PRINTO, Genova, Italy.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is an exclusion diagnosis that encompasses all forms of arthritis that begin before the age of 16 years, persist for more than 6 weeks, and are of unknown origin. In the ILAR classification, this heterogeneous group of chronic arthritides has been categorized on clinical and laboratory grounds to try to identify homogeneous, mutually exclusive categories suitable for etiopathogenic studies. However, the ILAR classification is complex and includes several inclusion and exclusion criteria. As a result, the correct placement of a patient in a specific category is not simple.

Methods: Patients enrolled in the multinational study of the EPidemiology, treatment and Outcome of Childhood Arthritis (EPOCA study) and in the Pharmacovigilance in patients treated with biologics± methotrexate study (Pharmachild) were merged in a single database, after exclusion of overlapping patients. The reasons that led to a "provisional" ILAR classification (i.e. lack of fitting into an ILAR category despite ILAR category attribution by the attending physician) in the two datasets and the queries regarding classification raised to the investigators by the PRINTO staff were analyzed and grouped into major categories according to the inclusion or exclusion criterion involved.

Results: A total of 12,141 patients were included in the study. The Table shows, for each JIA subtype, the most frequent drawbacks leading to a provisional classification. Most problems were related to the lack of 2 determinations of rheumatoid factor (RF) at least 3 months apart, the missing data in the indication of the presence or absence of psoriasis in the patient or in the presence or absence of a history of psoriasis in a first degree relative, the lack of assessment of HLA-B27 antigen, or the discrepancies in data results in the indication of a family history of spondyloarthropathies.

	N	Provisional diagnosis N (%)	Reasons for provisional diagnosis N (%)			
			Rheumatoid factor	Psoriasis	Spondylitis features	HLA-B27
Systemic arthritis	1365	295 (21.6)	219 (74.2)	83 (28.1)	67 (22.7)	34 (11.5)
Oligoarthritis	4887	1127 (23.1)	837 (74.3)	353 (31.3)	314 (27.9)	144 (12.8)
Polyarthritis RF-negative	2991	379 (12.7)	273 (72)	183 (48.3)	157 (41.4)	69 (18.2)
Polyarthritis RF-positive	492	277 (56.3)	266 (96)	33 (11.9)	28 (10.1)	10 (3.6)
Psoriatic arthritis	433	101 (23.3)	63 (62.4)	22 (21.8)	23 (22.8)	7 (6.9)
Enthesitis related arthritis	1323	217 (16.4)	118 (54.4)	90 (41.5)	–	–
Total	12141	2396 (19.7)	1776 (74.1)	764 (31.9)	589 (24.6)	264 (11)

Conclusion: In current clinical practice nearly 20% of JIA patient were categorized according to physician diagnosis attribution despite the lack of fulfillment of the ILAR exclusion criteria. Most frequently, this was related to the lack of assessment of RF or the inconsistency in indication of the presence of psoriasis in a first-degree relative.

Is It Worth Allowing the Presence of Morning Stiffness in the Definition of Inactive Disease in Juvenile Idiopathic Arthritis? Alessandro Consolaro[1], Maddalena Allegra[1], Maria C. Gallo[1], Benedetta Schiappapietra[1], Serena Calandra[1], Cristina Robbiano[1], Federica Mongelli[2], Cecilia Bava[2], Alberto Martini[1] and Angelo Ravelli[3]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Istituto Giannina Gaslini and University of Genova, Genova, Italy.

Background/Purpose: Morning stiffness is a major symptom of juvenile idiopathic arthritis (JIA) and it is usually associated with active disease. However, it is common view that children with disease quiescence may have some degrees of residual morning stiffness. The 2004 preliminary criteria for inactive disease (ID) in JIA did not include the assessment of morning stiffness, whereas the 2011 revision of the criteria has allowed the presence of morning stiffness lasting ≤ 15 minutes. However, it is still uncertain whether the disease status of children with ID who have or do not have morning stiffness is comparable. Aim of the study was to compare the disease status of children with JIA who meet the 2011 revised criteria for ID and have or do not have a minutes morning stiffness lasting ≤ 15.

Methods: A database at the study center including 785 patients who had undergone a total of 2957 visits, which included a parent report of the presence and duration of morning stiffness, was analyzed to identify all visits in which patients met the criteria for ID. In each visit, the duration of morning stiffness was categorized as follows: ≤15 min, 15–30 min, 30–60 min, 1–2 hr, > 2 hr. Clinical assessments included demographic features, and parent-reported outcomes. In case a patient met the ID criteria in more than 1 visit, only the first visit was retained.

	Patients meeting 2004 ID criteria Patients meeting 2011 ID criteria			
	No MS N = 390	MS ≤ 15 min N = 41	MS > 15 min N = 29	p-value
Median (IQR) disease duration	3.8 (1.8; 7.3)	2.8 (1.4; 6)	5.7 (2.6; 7.9)	0.30
Functional ability (JAFS score) ≥1, N (%)	64 (16.4)	18 (43.9)	23 (79.3)	<0.001
Physical health (PRQL PhS) ≥1, N (%)	173 (44.4)	32 (78)	28 (96.6)	<0.001
Psychosocial health (PRQL PhS) ≥1, N (%)	188 (48.2)	29 (70.7)	24 (82.8)	<0.001
VAS well-being ≥1, N (%)	155 (40.4)	32 (82.1)	28 (100)	<0.001
VAS pain ≥1, N (%)	102 (26.8)	28 (68.3)	21 (87.5)	<0.001
Acceptable symptom state, N (%)	366 (95.6)	33 (80.5)	16 (57.1)	<0.001

MS: morning stiffness; IQR: interquartile range

Results: A total of 460 visits in which the patient met the criteria for ID were evaluated. Absence of morning stiffness was reported in 390 (84.8%) visits, whereas in 70 visits (15.2%) there was morning stiffness. Among the visits with morning stiffness, in 41 (8.9%) duration was ≤15 min, and in 29 (6.3%) duration was >15 min. Table shows the comparison of disease duration and parent-reported outcomes between patients with absence or presence of morning stiffness.

Conclusion: Among patients who met the 2011 criteria for ID, those with morning stiffness ≤15 min had worse parent-reported outcomes than those without morning stiffness. This finding suggests that parents may not perceive their child's disease state as true remission when lower degrees of morning stiffness are present. Notably, a sizeable proportion (6.3%) of children meeting the 2004 ID criteria had morning stiffness lasting > 15 min. The change of the criterion "Duration of morning stiffness of ≤ 15 minutes" to "Absence of morning stiffness" in the definition for ID should be considered.

Focus on Patient Reported Outcomes in Juvenile Idiopathic Arthritis: There Is Room to Improve Care. Alysha Taxter[1], Keshia Maughn[1], Edward M. Behrens[2] and Pamela F. Weiss[3]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: National registry cross-sectional data show significant differences in patient-reported outcomes (PROs) across juvenile idiopathic arthritis (JIA) subtypes. This study aimed to assess predictors of PROs in JIA in a tertiary care clinic setting.

Methods: This is a retrospective study of children meeting ILAR JIA criteria evaluated in a tertiary pediatric rheumatology clinic between 2010–2012. Pain over the past week was assessed with a visual analogue scale (VAS; 0,10). Function was estimated with the childhood health assessment questionnaire (CHAQ; 0, 3). Physician global disease activity was measured using a VAS (0,10). We tested the association of clinical characteristics with pain and function using multivariable linear and ordinal logistic regression, accounting for clustering by subject. Pair-wise correlation was used to compare the association of physician disease assessment and each PRO.

Results: During the study period there were 542 subjects evaluated at 2,689 visits. The distribution of JIA categories was oligoarticular (37%), polyarticular RF+ (3%), polyarticular RF- (19%), systemic (8%), psoriatic (9%), enthesitis-related arthritis (ERA) (18%), undifferentiated (6%). Patients with ERA and undifferentiated reported higher pain intensity ($p<0.01$), higher pain prevalence ($p<0.01$), and poorer function ($p<0.01$) than other JIA categories. In multivariable analyses, older age, female sex, higher active joint count, NSAID use, DMARD use, and the ERA and undifferentiated categories were associated with higher pain scores (Table). Higher active joint count, NSAID use, glucocorticoid use, and ERA were associated with worse function. In patients with ERA, higher tender enthesitis count and female sex were significantly associated with higher pain intensity and poorer function. In patients with undifferentiated arthritis, higher active joint count and glucocorticoid use were associated with worse function. Correlation between the physician assessment of disease activity and patient-reported pain intensity and function were low (r=0.5, 0.4, respectively).

Conclusion: At our tertiary care center children with ERA and undifferentiated JIA had higher pain intensity and more frequent pain than other JIA categories. These results suggest that current treatment regimens may not be equally effective across JIA categories or as efficacious for particular disease attributes that are more common in the ERA and undifferentiated categories.

Table Association of clinical characteristics with pain and function

	Pain B-Coefficient (95% CI)	Function B-Coefficient (95% CI)
JIA category	Reference	Reference
Oligoarticular	0.45 (−0.10, 0.99)	0.08 (−0.07, 0.23)

Biologic Treatment of Adult Patients with Juvenile Idiopathic Arthritis Followed in the National Registry. Katerina Jarosova[1], Karel Hejduk[2], Michal Uher[2] and Jiri Vencovsky, MD, DSc[3]. [1]Institution of Rheumatology, Prague, Czech Republic, [2]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic, [3]Charles University Institute of Rheumatology, Prague, Czech Republic.

Background/Purpose: To analyze the efficacy and safety of biologic agents in adult patients with juvenile idiopathic arthritis (JIA).

Methods: ATTRA is the Czech national registry of patients with different forms of chronic arthritis who are treated with biologic drugs. Using this registry, we have analyzed adult JIA patients, who switched their treatment between biologic agents. Patients were treated in recommended doses for RA and the first drug was infliximab (44.3%), etanercept (36.7%), adalimumab (18.1%), or golimumab (0.9%). Those patients, who failed to improve in DAS28 by at least 1.2 after 3 months at 2 consecutive visits, who lost the response during the treatment, or who had to be discontinued due to adverse event, were switched to an alternative TNF inhibitor (TNFi) or to rituximab, abatacept or tocilizumab. Survival on therapy after 1st and 2nd biologic agents was calculated. Clinical efficacy was assessed with DAS28. Safety assessments were done for all patients during the whole follow-up period. No guidelines have been issued for the preference between the 1st or 2nd drug type and this was left solely to treating physician decision and was based on the assessment of overall clinical situation.

Results: Two hundred and ten adult JIA patients were treated with anti-TNF agents in the 1st instance. Mean age of patients was 22.4 years, duration of disease was 12.7 years and 62% were women. Ninety (42.9%) patients received more than one biologic agent. DAS28 showed excellent and persistent improvement for those patients who remained on the first drug. The treatment responses to a second biologic agent were also significant, although with smaller differences to baseline DAS28 values. DAS28 at the initiation of the first TNFi was 6.01±1.28 and decreased significantly to 2.69±1.47 after 12 months and to 2.21±1.46 after 24 months; DAS28 at initiation of the

second TNFi or other biologic agent was 5.59±1.53 and decreased to 2.77±1.39 and 2.74±1.00 after 12 and 24 months, respectively. Survival on the treatment was shorter in patients who switched the biologic agent in comparison with the first users (p = 0.017). The survival on the drug in first users and in switched patients was as follows: 0.93 (95% CI: 0.90–0.97) and 0.89 (95% CI: 0.82–0.95) in the first year; 0.87 (95% CI: 0.83–0.92) and 0.77 (95% CI: 0.68–0.86) in the second year. Adverse events that lead to treatment discontinuation were seen in 4% and 6% after one year and in 6% and 10% after 2 years therapy in the first and subsequent biologic agents groups, respectively. Treatment discontinuation due to inefficacy was observed in 1% and 6 %, and in 5% and 12% with the 1st and 2ndline treatment in years 1 and 2.

Conclusion: biologic treatment in adult patients with juvenile idiopathic is effective and safe. Similarly to patients with RA, it is possible to regain efficacy after switching to second biologic drug in a majority of patients, although with somewhat lower difference between the entry and 2 years DAS28 evaluations. Good adherence to therapy was observed for both first and second biologic agents.

Supported by the project (Ministry of Health, Czech Republic) for conceptual development of research organization 00023728 (Institute of Rheumatology).

Retrospective Review of Immobilization Vs. Immediate Resumption of Activity in Patients with Oligoarticular Juvenile Idiopathic Arthritis and Corticosteroid Knee Injections. Elaine Ramsay[1], Heather Benham[2], Jenna Tress[3], Janille Diaz[4] and David D. Sherry[3]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Texas Scottish Rite Hospital for Children, Dallas, TX, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]The Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Intraarticular corticosteroid injection (IACI) is one of the most common treatment modalities in oligoarticular Juvenile Idiopathic Arthritis (JIA). There is widespread use of IACI in the treatment of arthritis, but recommendations following the procedure vary, as there are no published studies on splinting patients post-IACI. Post-injection, Texas Scottish Rite Hospital for Children (TSRHC) splints patients for 24 hours while The Children's Hospital of Philadelphia (CHOP) does not. The aim of this study was to compare the number of cases of recurrent arthritis and re-injection following IACI.

Methods: Data (see Table) were retrospectively collected at CHOP and TSRHC. All patients diagnosed with oligoarticular JIA according to ILAR criteria (2nd revision, 2001) between 2008–2010 were included. Chi square and T test were utilized for preliminary analysis.

Results: 131 patients at CHOP and 70 patients at TSRHC received a knee IACI. The average age was 9.1 (CHOP) v. 6.7 (TSRHC) (p=0.0002). There were more Hispanics at TSRHC (6 v. 10, p=0.055), and a higher number of ANA positive patients (54 v. 74, p=0.003). Overall mean joint disease severity scores (sum of range of motion restriction, joint swelling and tenderness) at CHOP were higher (3.4 v. 2.3, p <0.001). Mean dose of triamcinolone hexacetonide was higher at CHOP (1.4 mg/kg v 0.8 mg/kg, p<0.001). Arthritis reoccurred in 37 (28%) at CHOP v. 30 (43%) at TSRHC (p=0.041). 37 patients at CHOP received re-injection of the same knee v. 5 at TSRHC (p <0.001).

Conclusion: TSRHC patients were younger and more frequently ANA positive and Hispanic. Joint disease severity scores were higher at CHOP, and patients received a higher mean dose of triamcinolone hexacetonide IACI. The number of recurrent arthritis cases was similar between institutions and there was a trend toward more recurrent arthritis at TSRHC, but CHOP completed a larger amount of repeat injections. This may indicate that TSRHC begins systemic immunosuppression if IACI fails to clinically remit the knee. Future plans include comparison of time to recurrent arthritis to see if splinting extends remission. If it does, the practice of splinting knees following IACI may be beneficial in children with oligoarticular JIA. Examining co-variables such as age, ethnicity, ANA status, disease activity, steroid type and dose, and concomitant medications are planned. Limitations of this study include: 1) possibility that some subjects with oligoarticular JIA were missed; 2) some subjects were lost to follow-up; 3) variation in recording and practice styles. Also, the study only examined knee IACIs, splinting duration was less than reported in adults, and adherence was not monitored.

Table

		CHOP n=131 (%)Not splinted post injection	TSRHC n=70 (%) Splinted post injection	P

Background/Purpose: The availability of methotrexate (MTX) and biological agents has provided a major change in the treatment of children with juvenile idiopathic arthritis (JIA). However, limited information exists on the safety of the current available treatements. An international registry named Pharmachild (European Union grant 260353) has been set up by the Pediatric Rheumatology International Trials Organisation (PRINTO)/ Paediatric Rheumatology European Society (PRES). In parallel several national registries with the same purpose have been set up in different European Countries for the follow-up of these patients.

Methods: We merged into a unified database the baseline demographic data of JIA patients treated with MTX or biologicals coming from the Pharmachild registry and from the national registries of Germany, United Kindgom, Sweden and Portugal. Events of special interest (ESI) and moderate/severe/serious adverse events (AE) related to the drugs were

collected. Data are presented as frequencies (%) or medians with 1st and 3rd quartiles.

Results: About 61% of the patients have been treated with biologicals alone or in combination with MTX, and 29% only with MTX. The events of special interest ranged from 0.1 to 15.0% and the other adverse events from 4.8% to 69.9%.

Agreement Between Enthesitis Evaluation By Manual Palpation and Dolorimetry in Juvenile Spondyloarthritis. Lauren Minor[1], Keith Sikora[2], April D. Brundidge[3], Robert A. Colbert[4] and Hemalatha Srinivasalu[5]. [1]NIAMS, NIH, Bethesda, MD, [2]NIAMS, NIH, Bethesda, DC, [3]NIAMS NIH, Bethesda, MD, [4]NIAMS/NIH, Bethesda, MD, [5]Children's National Medical Center, Washington, DC.

Background/Purpose: Enthesitis is a characteristic feature of spondyloarthritis (SpA). Clinical evaluation of enthesitis by palpation is subject to differences in pressure used at different sites or by different examiners over time. Use of a dolorimeter allows calibration of the exact pressure used in assessment of tenderness. The purpose of this study was to assess agreement between manual and dolorimetric testing of entheseal points in juvenile SpA (JSpA).

Methods: Patients less than 18 years of age and diagnosed with JSpA based on ILAR criteria for ERA (over 75%), and Psoriatic arthritis and ESSG criteria for undifferentiated arthritis were included in the study. Forty JSpA patient encounters (age range 7–18 y) and 10 healthy controls (range 10–25 y) were included in the study. Thirty-three entheseal sites were assessed by manual palpation followed by dolorimetry by the same examiner. Three different examiners participated in the study. Tenderness elicited at less than 4 kg pressure using a 20 lb dolorimeter was considered positive by dolorimetry; tenderness with thumb pressure with blanching of the examiner's nail bed was considered positive by manual palpation. Kappa statistics were performed by SPSS to assess agreement between manual and dolorimetric testing. Kappa value (k) > 0.6 indicates substantial agreement; $0.41 < k < 0.6$ is considered moderate, and $0.21 < k < 0.4$ shows fair agreement.

Results: The table displays kappa values for all 33 entheseal sites indicating the degree of agreement, for all 40 JSpA encounters. Substantial agreement between manual and dolorimetric assessment was noted in 42% of sites (14/33); moderate agreement was seen in 39% of sites (13/33) and fair agreement in 12% (4/33). Kappa values of corresponding right and left entheseal sites showed no statistical difference (paired t-test = 0.6). Of a total of 10 positive entheseal sites by manual palpation and 5 sites by dolorimetry in the 10 healthy controls, only one entheseal site showed agreement by both methods. Similar analysis on 30 adult SpA patients yielded 57% sites with substantial and 15% with moderate agreement.

Conclusion: There was substantial to moderate agreement between clinical enthesitis evaluation by manual and dolorimetric methods in 81% of sites, with fair agreement in another 12% in JSpA. Since a single exam was performed at each visit, inter-rater reliability was not assessed. Although manual testing standardized for nail blanching and dolorimetry exhibited considerable agreement, use of dolorimetry may enhance objectivity for enthesitis evaluation among JSpA patients in clinical trials. Future studies are needed to address inter-rater reliability between the two methods and to correlate with ultrasound and/or MRI.

Single Hub and Access Point for Paediatric Rheumatology in Europe (SHARE)– Evidence Based Recommendations for Diagnosis and Treatment of Juvenile Idiopathic Arthritis. S.J. Vastert[1], Victor Boom[1], Jordi Anton[2], Tamás Constantin[3], Pavla Dolezalova[4], Gerd Horneff[5], Pekka Lahdenne[6], Bo Magnusson[7], Kirsten Minden[8], K. Nistala[9], Pierre Quartier[10], Ingrida Rumba-Rozenfelde[11], Nicolino Ruperto[12], Vanessa Remy Piccolo[13], Ricardo A. G. Russo[14], Yosef Uziel[15], Carine Wouters[16], Alberto Martini[17], Angelo Ravelli[18], Helen Foster[19] and Nico Wulffraat[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Pediatric Rheumatology Unit. Hospital Sant Joan de Déu. Universitat de Barcelona, Barcelona, Spain, [3]University Childrens Hospital, Budapest, Hungary, [4]General University Hospital, Prague, Czech Republic, [5]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [6]Helsinki University Central Hospital, Helsinki, Finland, [7]Astrid Lindgren Children's Hospital, Stockholm, Sweden, [8]German Rheumatism Research Center, Berlin, Germany, [9]University College London, London, United Kingdom, [10]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [11]University of Latvia, Riga, Latvia, [12]Istituto Giannina Gaslini, Genoa, Italy, [13]Hopital Necker Enfants Malades, Paris, France, [14]Hospital de Pediatria Garrahan, Buenos Aires, Argentina, [15]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel, [16]University of Leuven, Laboratory of Pediatric Immunology, University Hospital Leuven, Leuven, Belgium, [17]Istituto Giannina Gaslini, Genova, Italy, [18]University of Genova, Genova, Italy, [19]Newcastle University, Newcastle, United Kingdom.

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is one of the most common chronic pediatric rheumatic diseases (PRD). As is the case for most PRD's, evidence-based guidelines are sparse and management is based to great extent on physician's experience. Moreover, there are differences between nations regarding availability and financing of biological therapies. In 2012, a European initiative called SHARE (Single Hub and Access point for pediatric Rheumatology in Europe) was launched to optimize and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. One of the aims of SHARE was to provide evidence based recommendations for diagnosis and treatment of JIA.

Methods: Evidence based recommendations were developed using the European League Against Rheumatism (EULAR) standard operating procedure[1]. An expert committee was instituted, consisting of pediatric rheumatologists from across Europe with expertise in JIA. The expert committee defined search terms for the systematic literature review. Two independent experts scored articles for validity and level of evidence. Recommendations

derived from the literature were evaluated by an online survey. Those with less than 80% agreement during the online survey were reformulated. Subsequently, all recommendations were discussed by the experts at a consensus meeting using the nominal group technique[2]. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 4723 articles, of which 174 were considered relevant. The included articles were scored for validity and level of evidence. Recommendations were formulated based on the valid papers and were discussed and adjusted where needed during the consensus meeting. In total, 10 recommendations for diagnosis and 31 for treatment were accepted with more than 80% agreement. Topics covered for diagnosis and for treatment are shown in *Table 1*.

Table 1 Juvenile Idiopathic Arthritis

Diagnosis	Treatment
The value of MRI in the diagnosis arthritis	Steroids (locally and systemically administered)
The value of ultrasound in the diagnosis of arthritis	DMARDS
Biomarkers for diagnosis of JIA	Biologicals
Diagnosis of complications	Treatment of complications

Conclusion: The SHARE initiative provides recommendations for diagnosis and treatment of JIA and thereby facilitates improvement and uniformity of care throughout Europe. In the subsequent phase of the project, best practices identified from literature will be completed with the 'experts opinion' in order to formulate diagnostic and management guidelines as best practices for care of JIA patients throughout Europe.

Drug Safety in Treatment of Juvenile Idiopathic Arthritis (JIA): Biologic Therapy Compared with MTX. Gerd Horneff[1], Hans Huppertz[2], Gerd Ganser[3], Johannes Peter Haas[4], Ivan Foeldvari[5] and Kirsten Minden[6]. [1]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [2]Prof Hess Children's Hospital, Bremen, Germany, [3]Sankt Josef Stift, Sendenhorst, Germany, [4]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [5]Department of Pediatric Rheumatology, Hamburger Zentrum für Kinder und Jugendrheumatologie, Hamburg, Germany, [6]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: Drug surveillance of biologics in juvenile patients using registries is of immense importance as patient numbers and duration in clinical trials are limited. There is a special interest in allergic, autoimmune, hematologic, infectious, thrombotic, vascular and malignant disorders.

Methods: Patients with JIA were prospectively observed in the German JIA biologic registry BiKer. Predefined adverse events of special interest (AESI) were recorded by physicians. Total Rate per exposure year (EY) and risk ratio (RR) were calculated with 95 % confidence intervals. Differences were analyzed using the Wald test. Biologics naïve patients were recruited from JIA patients receiving methotrexate (controls). In all three biologics cohorts, methotrexate as well as other DMARDS were allowed to be given concomitantly.

Results: Methotrexate (without a biologic agent) was applied to a total of 1517 patients, Etanercept (ETA) to 1925, Adalimumab (ADA) to 498 and Tocilizumab (TOC) to 104 patients for a total exposure time or 3019; 3958; 561 and 103 years, respectively. A total of 1227 adverse events (AE) were reported In the control group (406/1000 PY[389–424]) with 44 classified as serious (15/1000PY[11–20]). In the ETA cohort there were 1131 AE (286/1000PY [272–300]) and 149 SAE (38/1000PY[32–44]), in the ADA cohort 373 AE (665/1000 PY [625–703]) and 28 SAE (50/1000 PY [35–71] and in the TOC cohort there were 97 AE (941/1000 PY [878–973]) with 10 SAE (97/1000 PY [54–170]. In the control cohort, a total of 252 AE qualified as ESI, upon ETA 234, upon ADA 60 and upon TOC 13 (table).

Thus, compared to the control group the incidence of severe infections is significantly higher upon ETA and ADA, that of autoimmunity and uveitis are significantly higher upon ADA, and MAS is significantly more frequent upon TOC, while the incidence of hepatic events is lower in all the biologics cohorts than with MTX alone. A higher RR failing to reach level of significance was found for chronic inflammatory bowel disease with ETA, and anaphylaxis with TOC. Further ESI including malignancies revealed no differences.

Conclusion: This progress report from the ongoing BiKeR-registry showed a higher incidence for several adverse events of interest including severe infections, autoimmunity, uveitis, anaphylaxis and MAS while the total rate is surprisingly low. In general, JIA patients tolerated biologic treatment very well. Differences between the cohorts are at least in part biased by differences in JIA category distribution and preexisting uveitis risk.

Using the 2011 ACR Recommendations for the Treatment of Juvenile Idiopathic Arthritis (JIA) to Evaluate a Single Centre Treatment Pathway: A Feasibility Study. Katherine Green[1], Marinka Twilt[2] and Taunton R. Southwood[3]. [1]Birmingham Children's Hospital, Birmingham, United Kingdom, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom.

Background/Purpose: The 2011 ACR recommendations for the treatment of Juvenile Idiopathic Arthritis (ACR-JIA) are evidence-based, consensus-approved therapeutic pathways for the safe and effective treatment of JIA. Our aim was to determine the feasibility of applying ACR-JIA to evaluate the treatment pathway in a single centre JIA polyarthritis cohort.

Methods: We conducted a retrospective analysis of a single-centre paediatric JIA cohort by reviewing case notes, investigations and treatment databases of all newly diagnosed JIA polyarthritis patients in the 2 years after ACR-JIA publication. 35 patients with multiple joint arthritis fulfilled ILAR criteria for the diagnosis of JIA: systemic arthritis (n=5, analysed separately), polyarthritis (n=25) and Extended Oligoarthritis (n=5, analysed together with polyarthritis (total n=30) as these groups are managed similarly in the ACR Recommendations). Using the Recommendations, disease severity and poor prognostic features were used to categorize the patients and critical therapeutic time points (disease duration of 8–12 weeks from diagnosis to starting methotrexate, and if methotrexate was ineffective, 14–28 weeks from starting methotrexate to starting etanercept) were calculated. Drug monitoring frequency was also determined.

Results: 25 females and 10 males (median age at onset 13, range 1.5–15 years) were included in the evaluation. Median age at disease onset for

poly/extended oligoarthritis was 10 years (1.5–16), with a median of 12 joints (12–38) active at presentation, and for the systemic group median age at onset was 6 years (2–7), with a median number of 6 active joints (2–10). 3 polyarthritis patients were rheumatoid factor positive. In the polyarthritis/extended oligoarthritis group, 2 patients with polyarthritis had poor prognostic features, 23 had moderate and 6 had high disease severity. None of the systemic patients had poor prognostic factors, 2 had moderate and 2 had high disease severity.

22/30 patients with polyarthritis/extended oligoarthritis followed the ACR recommendations for treatment according to their disease severity, commencing methotrexate therapy within a median of 6 weeks (3–32 weeks) of diagnosis. Etanercept was commenced in a total of 9 patients (30%) within a median of 6 months (1.5–24 weeks) subsequent to commencing methotrexate. This was due to intolerance in 5 patients (56%), inefficiency in 2 cases (22%) and both intolerance and inefficiency in 2 cases (22%). A total of 7 patients did not follow ACR-JIA guidelines due to excessive length of time between diagnosis and commencing methotrexate or etanercept treatment, most commonly due to delays in funding approval or insufficient regular drug monitoring tests. All patients with systemic arthritis followed the ACR-JIA recommendations.

Conclusion: Overall, 28/35 patients followed ACR-JIA. This study demonstrates the feasibility of using the ACR-JIA recommendations to evaluate a clinical pathway. It also highlights the potential influence of the local health economy in achieving rapid commencement of new JIA therapies and the challenges of ensuring regular drug monitoring in all patients.

287

Role of Joint Status in Decreased Accelerometer-Assessed Daily Physical Activity in Juvenile Idiopathic Arthritis. Mette Noergaard, Marinka Twilt and Troels Herlin. Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is often associated with decreased physical activity (PA). Although improved disease control has opened up the possibilities for JIA-children to participate in dynamic sport activities, various limitations secondary to the disease seem to restrict an adequate integration in sport activities. Accurate, objective measurements of PA and identification of specific factors limiting PA in JIA-children are therefore needed.

This study aimed to: 1. Compare accelerometer-assessed PA in JIA-children with normative data of age- and gender-matched healthy controls. 2. Relate accelerometer-assessed PA to joint status in the lower extremities (LE) in JIA-children regarding active arthritis as well as persistent LOM (contractures) and exceeded range of motion (ROM) (hypermobility).

Methods: In 61 patients with JIA PA was assessed using the hip-worn GT1M Actigraph accelerometer during wakening hours for one week, providing at least 3 separate days each of 8 hours of valid recording accelerometer using 10 second intervals of recording (epochs).

Joint status was valuated using a joint activity count of 71 joints. Also, LE-joints (hips, knees, ankles, toes) were examined for persistent LOM and exceeded ROM (Beighton score-items including alternative items to cover all LE-joints). Demographic, disease- and pain-related parameters were also obtained.

Results: For each age-group between 10–16 years accelerometer data of the 61 JIA patients were compared with 239±93 normative controls. Values of mean counts per minute (c/min), recorded minutes with moderate and high PA (>1000 c/min) and high PA (>2500 c/min) were significantly lower in patients than in normative controls ($p \leq 0.004$), with the more severe JIA-subcategories having the lowest values.

PA of JIA-children was significantly correlated to joint swelling ($p=0.004$) and LOM of the hips and the ankles, but not the knees; no matter if due to active arthritis or contractures. No significant correlations were found between PA of JIA-children and reported pain ($p=0.59$) and hypermobility ($p=0.58$).

Conclusion: Accelerometer-assessed PA-levels of JIA-children were significantly lower than those of normative controls. LOM of hips and ankles, but surprisingly not the knees, were significantly associated with impaired PA. This emphasizes the importance of obtaining full ROM specifically in hips and ankles of JIA-children for the purpose of adequately participating in sport activities.

Establishing Clinical Meaning and Defining Important Differences in Patient Reported Outcome Measures of Physical Function, Fatigue and Pain Interference in Juvenile Idiopathic Arthritis. Esi Morgan DeWitt[1], Bin Huang[2], Kimberly Barnett[1], Adam Carle[1], Constance Mara[1] and Karon Cook[3]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center/University of Cincinnati School of Medicine, Cincinnati, OH, [3]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Patient reported outcome measures (PROs) are used increasingly in clinical care. A framework to interpret scores according to degree of clinical severity would enhance their practical use. Furthermore, use of PROs in evaluation of treatment effectiveness over time requires establishment of minimal important differences (MID) in change scores.

Methods: We identified clinical severity thresholds and MID for measures of mobility, upper extremity function, fatigue, and pain interference working with patients with juvenile idiopathic arthritis (JIA) and parents of JIA patients using standard setting methodology modified from educational testing. Data from Patient-Reported Outcomes Measurement Information System (PROMIS) item bank longitudinal validation collected on 121 JIA patients was used to develop clinical vignettes across a range of symptom severity. Vignettes were created based on most likely item responses at different levels on the T score metric [mean = 50; SD = 10]. Vignettes were anchored at 5-point intervals (0.5 SDs). Parents and patients participated in separate one-day meetings. Vignettes were ordered and placed on cards. Panelists identified adjacent vignettes considered to represent upper and lower boundaries separating category cut points (i.e., none /mild problems, mild/moderate, moderate/severe). Cut scores were defined as mean score for boundary vignettes. To define MIDs panelists responded to items to represent "just enough improvement to make a difference". Average change scores served as estimates of MID.

Results: For pain interference, mobility, and upper extremity function patients set higher cut points for severity than parents, typically by 0.5 SD. Parents tended to set higher MID scores than JIA patients. Size of MID varied according to severity classification of the symptom. MIDs estimated by the panelists were typically larger than the MIDs determined using statistical methods.

Conclusion: We used a modified educational standard setting method to estimate clinically relevant cut points to classify severity for PROMIS measures of mobility, upper extremity, fatigue and pain interference. Parallel exercises identified these cut points from the perspectives of patients with JIA and parents of a child with JIA. We explored a novel means of determining MID from the patient/parent perspective. This allows for meaningful interpretation of PROMIS measures in a clinical setting. In summer 2014, the method will be repeated with clinicians serving as panelists. Results will be compared across panel groups. MIDs generated by the 3 panelist groups and those generated statistically from the longitudinal study sample will be compared.

Patient-Reported Outcomes in Children with Moderately to Severely Active Polyarticular or Polyarticular-Course Juvenile Idiopathic Arthritis Who Are Prescribed and Treated with Adalimumab. Gerd Horneff[1], Carol A. Wallace[2], Pierre Quartier[3], Daniel J. Kingsbury[4], Kirsten Minden[5], Mareike Bereswill[6], Vishvas Garg[7], Hartmut Kupper[6] and Jasmina Kalabic[6]. [1]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [2]University of Washington School of Medicine and Seattle Children's Hospital, Seattle, WA, [3]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [4]Randall Children's Hospital at Legacy Emanuel, Portland, OR, [5]Kinderklinik der Charite, Otto-Heubner Centrum, Berlin, Germany, [6]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [7]AbbVie Inc., North Chicago, IL.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is one of the most common rheumatic diseases of childhood and adolescents, and improvement in health-related quality of life and functional disability is an important therapeutic goal in the treatment of patients (pts) with JIA. The objective was to evaluate pt-reported outcomes (PROs) in pts with moderately to severely active polyarticular or polyarticular-course JIA (pJIA) who are prescribed and treated with adalimumab (ADA) ± methotrexate (MTX) in routine clinical practice.

Methods: This is an ongoing, multicenter, non-interventional, observational registry of pts diagnosed with moderately to severely active pJIA that are prescribed and treated in a routine clinical setting with either ADA±MTX or MTX alone. Pts with resistant disease, that had received prior MTX treatment, were prescribed and treated with ADA as second line therapy. A cohort of pts with prescribed MTX, naïve to biologics, served as controls. Physical function was measured by the Disability Index of Childhood Health Assessment Questionnaire (DICHAQ), which ranges from 0 (no disability) to 3 (worst disability), and the minimal clinically important difference for improvement is -0.188. Quality of life was assessed by the Child Health Questionnaire-Parent Form (CHQ-PF50), with a scale of 0 (worst possible health state) to 100 (best possible health state). The currently study is limited using data up to 12 months, and all data are as observed.

Results: 842 pts (540 in ADA arm/302 in MTX arm) were enrolled and treated in the registry. The majority of the pts were female (76% and 69% for MTX and ADA, respectively). The mean age at baseline was 9.6 and 12.2 yrs and the mean pJIA disease duration at baseline was 1.3 and 3.7 yrs for MTX and ADA arms, respectively. At baseline mean DICHAQ was 0.62 for both MTX and ADA treatment arms. For those pts with data at both baseline and 12 months, the mean change in DICHAQ was -0.24 and -0.22 for the MTX and ADA arms, respectively, indicating a clinically meaningful difference. From baseline to 12 months, the scores of the individual health concepts in the CHQ-PF50 increased for both the MTX and ADA treatment arms, with the exception of Family Cohesion, as the scores had little change over time (Table). Parental emotional impact had a substantial increase as mean scores changed from 57.8 to 73.0 and 57.0 to 68.8 in the MTX and ADA treatment arms from baseline to 12 months, respectively.

Table Summary of Child Health Questionnaire Parent Form (CHQ-PF50)

	Baseline		Month 12	
	MTX	ADA ± MTX	MTX	ADA ± MTX
Global Health				
Mean (SD)	73.1 (22.7)	63.1 (25.6)	80.8 (17.6)	73.5 (21.4)
n	287	466	158	282
Physical Functioning				
Mean (SD)	73.1 (27.5)	71.8 (28.2)	86.1 (21.1)	81.8 (25.9)
n	295	473	171	297
Role/Social Limitations – Emotional/ Behavioral				
Mean (SD)	84.7 (26.1)	79.9 (27.9)	92.3 (17.7)	89.8 (20.1)
n	293	472	170	296
Role/Social Limitations – Physical				
Mean (SD)	78.9 (29.7)	75.0 (30.3)	90.7 (20.6)	86.9 (25.9)
n	292	472	170	295
Bodily Pain/Discomfort				
Mean (SD)	54.8 (26.4)	53.3 (28.3)	75.1 (24.2)	70.2 (27.0)
n	295	473	171	296
Behavior				
Mean (SD)	75.3 (17.2)	77.2 (16.3)	80.5 (14.7)	80.4 (17.2)
n	293	472	170	296
Global Behavior				
Mean (SD)	80.3 (19.6)	79.6 (19.8)	81.9 (18.8)	80.9 (19.7)
n	276	441	140	263
Mental Health				
Mean (SD)	74.8 (16.3)	74.7 (17.6)	79.6 (15.1)	78.8 (16.6)
n	293	470	171	295
Self Esteem				
Mean (SD)	78.6 (19.9)	75.5 (20.9)	84.7 (17.2)	9.5 (20.8)
n	290	470	169	294
General Health Perceptions				
Mean (SD)	60.0 (18.1)	53.0 (17.4)	61.2 (17.7)	55.5 (18.1)
n	295	471	171	294
Change in Health				
Mean (SD)	2.8 (1.3)	3.3 (1.4)	4.3 (0.9)	4.2 (1.0)
n	291	463	166	280
Parental Impact – Emotional				
Mean (SD)	57.8 (26.3)	57.0 (26.9)	73.0 (21.5)	68.8 (25.6)
n	294	472	169	295
Parental Impact – Time				
Mean (SD)	77.5 (25.6)	76.6 (27.2)	87.1 (19.9)	83.7 (22.1)
n	294	472	169	293
Family Activities				
Mean (SD)	77.6 (22.0)	78.6 (21.7)	86.8 (16.4)	85.0 (18.9)
n	294	472	169	295
Family Cohesion				
Mean (SD)	80.7 (19.4)	76.8 (20.9)	79.5 (21.3)	77.4 (22.1)
n	293	469	169	291

Conclusion: Over the course of 12 months of treatment, pts with pJIA in the ADA treatment arm demonstrated clinically meaningful improvements in functional disability as well as an increase in the scores of the individual health concepts, indicating an improvement in health-related quality of life. The extent of improvement was comparable to that in the MTX treatment arm.

Patterns of Active Joint Involvement in JIA. Simon W.M. Eng[1], Mira Van Veenendaal[2], Alan M. Rosenberg[3], Kiem Oen[4], Quaid Morris[1] and Rae S.M. Yeung[2]. [1]University of Toronto, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]University of Saskatchewan, Saskatoon, SK, [4]University of Manitoba, Winnipeg, MB.

Background/Purpose: JIA encompasses a set of heterogeneous diseases with chronic joint inflammation. Although the ILAR criteria consider joint counts, they do not reflect specific joint involvement patterns. We sought to study these patterns, through unsupervised pattern recognition techniques, to better characterize homogeneous subpopulations of children with JIA.

Methods: Principal component analysis was conducted on baseline joint involvement data from 807 treatment-naive patients satisfying the ILAR criteria to identify composite variables, or principal components (PCs), that distinguish patients from each other. Cluster analysis was conducted on patient PC scores to identify signatures of joint involvement.

Results: 4 PCs were identified that explained 46% of variance among patients. The PCs summarized (1) overall joint count, (2) finger vs. toe involvement, (3) large vs. small joint involvement, and (4) SI joint involvement. On these PCs, 12 distinct signatures were identified whose "fingerprints" or defining characteristics are depicted in Figure 1. These signatures described joint involvements based on clinically meaningful combinations of characteristics given by the PCs. The signatures were clearly able to distinguish homogeneous patient subpopulations both within and between ILAR subtypes based on joint involvement (Figure 2).

Conclusion: Our analysis recovered distinct patterns of joint involvement in an assumption-free manner that will be useful in defining homogeneous patient subpopulations within and across the ILAR subtypes in JIA.

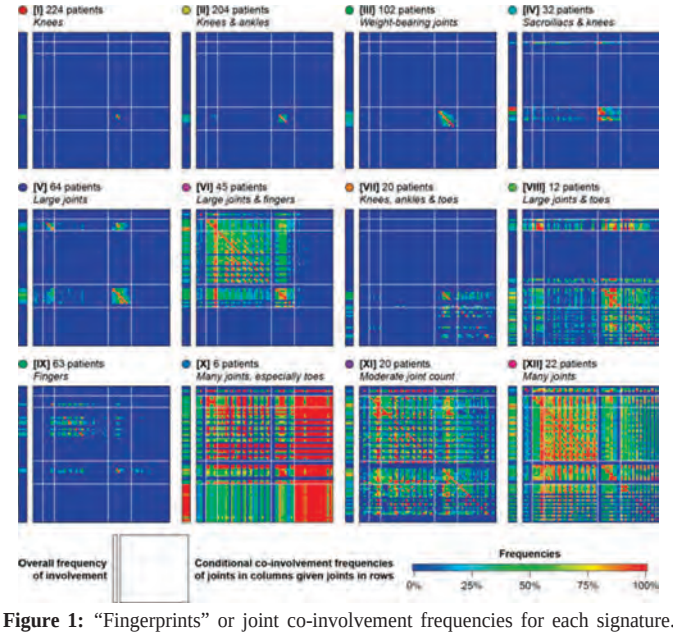

Figure 1: "Fingerprints" or joint co-involvement frequencies for each signature. Vertical heat maps represent overall frequencies of joint involvement among patients in each signature. Square matrices represent frequencies of involvement of joints in columns given the involvement of joints in rows.

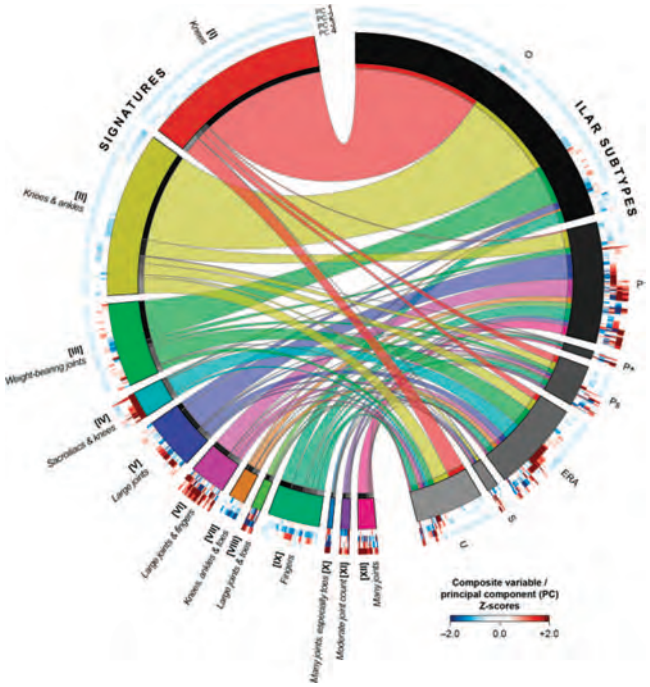

Figure 2: Relationships between the signatures and ILAR subtypes. Heat maps (outermost rings) depict PC scores for each patient. The innermost ring depicts the ILAR subtype composition of each signature and signature composition of each ILAR subtype. Ribbons link patients between signatures (left) and ILAR subtypes (right).

Development of a Serious Game Designed for Children with Juvenile Idiopathic Arthritis. Jean-David Cohen[1], Damien Bentayou[2], Marcantoine Bernard-Brunel[2] and Sonia Tropé[3]. [1]CHU LAPEYRONIE, MONTPELLIER, France, [2]CG Artist, PESSAC, France, [3]ANDAR, Paris, France.

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most common chronic paediatric rheumatic disease and cause of physical and psychological disability, with family and school consequences.

If the advances in therapeutics as biologicals have revolutionized the outcome of children with JIA, it is necessary to develop educational materials to increase their independence and improve their quality of life.

Information about the disease and treatments, the ability to cope with difficult situations, having good reflexes concerning biotherapies are all skills needed to live well the disease every day.

Democratization of computers and smart phones has led us to develop a serious game for children as an educational learning instrument.

Methods: The game was developed according to the steps of Assessment, Design, Development, Implementation, and Evaluation (ADDIE model).

A steering committee was formed with a pediatric rheumatologist, a patient organization and an agency of video game developers including an art director, a lead programmer and a graphist.

Decisions were strained by a limited budget support.

The National Association against Rheumatoid Arthritis initiated the project and provides funding, manages logistics and monitoring.

The pediatric rheumatologist initially established a series of themes to be developed in accordance with the association and transmitted scientific data to developers.

The developers have proposed animations and graphics, game plays.

The committee has defined the specifications at different points during physical meetings and conference calls:

- Format
- Themes and key messages
- Graphics (places, people)

Results:

The committee has decided to create an adventure game with differents interactives activities.

The following directions have been validated:

- Development of a serious game powered by Unity¨ for computers, smartphones and tablets to allow use in all places (waiting rooms), designed to run on the IOS (apple) and Android operating systems.
- Definition of key messages and themes: family, school, sport, hospital, rehabilitation, treatment, further investigations.
- Graphic choices:

á Hospital (single place with the greatest number of possible themes)

á Two avatars (one boy, one girl) to facilitate the identification of players.

Conclusion: To our knowledge, this is the first application dedicated to JIA.

To ensure the appropriateness of its speech, its ergonomics and ease of use, the global level of satisfaction, a neuropsychiatrist and the KOURIR organization (parents of children with JIA), will evaluate the beta version.

Adaptations would be made prior to the release of the game. Eventually, other game trays could complement this version in the future (adding school and home).

Flares in Children with JIA: Results from the Reacch-out Cohort. Lori B. Tucker[1], Jaime Guzman[1], Kiem Oen[2] and ReACCh Out Investigators[3]. [1]BC Children's Hospital and University of British Columbia, Vancouver, BC, [2]Children's Hospital of Winnipeg and University of Manitoba, Winnipeg, MB, [3]BC Children's Hospital, Vancouver, BC.

Background/Purpose: Disease flares are a concern to patients with JIA, their parents, and caregivers alike; but little is known of disease manifestations during a flare in children who have achieved inactive disease (ID) or whether flares differ among subtypes. The aim of this study is to describe flares in children with JIA and determine differences in flare characteristics among JIA subtypes.

Methods: We studied children diagnosed with JIA between 2005 and 2010 who had at least one visit with ID (no active joints, no extra-articular manifestation, and a physician global assessment $<$ 10mm) while being prospectively followed in the Research in Arthritis in Canadian Children

emphasizing Outcomes (ReACCh-Out) cohort. They received usual pediatric rheumatology care at 16 Canadian centres. Flare was defined as loss of any criteria for ID. In addition a flare was imputed on the basis of an intra-articular injection alone in absence of other documentation of disease activity. Treatment of flares were recorded if there was a change, addition, or restart of anti-rheumatic or anti-uveitis treatment.

Results: Of 1492 children recruited in ReACCh-Out, 1146 had at least one visit with ID, with median follow-up of 24 mo (IQR 12,39) following first record of ID. A total of 1,191 flares were observed in 531 children (46.3%) after their first ID episode: 31% with systemic JIA and 44–50% with other subtypes. Arthritis was a feature of the majority of flares but there were significant differences in frequencies across subtypes ($p=0.001$). Frequencies of nonarticular flares also differed among subtypes ($p<0.001$) and were most common in children with systemic, enthesitis related arthritis and undifferentiated subtypes. Flares due to uveitis were seen in patients with oligoarticular, rheumatoid factor negative, and undifferentiated subtype most commonly. The majority of flares occurred while patients were still on treatment for their JIA and overall 45% were not associated with treatment changes (Table).

Table: Characteristics of disease flare across JIA subtypes

Feature	All	Systemic	Oligo	RF neg	RF pos	Psoriatic	ERA	Undiff
# subjects	1146	68	488	212	35	75	155	113
# subjects with flare	531	21	232	106	17	36	69	50
# flares	1191	82	483	233	56	70	133	134
Flare signs (% of flares):								
Arthritis flares	79	58.5	83	85	93	86	63	72
Non-articular flares	18	41.5	13	12	7	14	35	22
PGA $\geq$ 1 without other signs	10	29	8	7	7	9	13.5	7.5
Treatment at time of flare (% of flares):								
Flare on treatment	70	91.5	56.5	83	86	60	78	71
Flare off treatment	27	7	39	15.5	14	40	19.5	25
No change in treatment following flare	45	66	40	48	50	46	48	37

Conclusion: Flare characteristics in JIA differ among disease subtypes. An increase in PGA alone accounts for flare some patients, suggesting that PGA includes consideration of disease manifestations not included in our flare definition. Our results suggest that while disease flares occur in approximately half of children with JIA managed with usual care, many are mild and require no treatment change.

Long Term Functional Outcome and Quality of Life of Patients with Refractory Juvenile Idiopathic Arthritis Treated with Etanercept: Results of the Dutch Arthritis and Biologicals in Children Register. Janneke Anink[1], Femke Prince[1], Maryanne Dijkstra[1], Marieke H. Otten[1], Marinka Twilt[2], Rebecca ten Cate[3], Simone Gorter[4], Yvonne Koopman-Keemink[5], Marion A.J. Van Rossum[6], Esther P.A. Hoppenreijs[7] and Lisette W.A. van Suijlekom-Smit[1]. [1]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Maastricht University Medical Center, Maastricht, Netherlands, [5]Hagaziekenhuis Juliana Children's Hospital, The Hague, Netherlands, [6]Reade, location Jan van Breemen, Amsterdam, Netherlands, [7]Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: Juvenile idiopathic arthritis patients refractory to methotrexate are eligible for treatment with biologic agents. A longitudinal sub-analysis (n=53) of the Dutch Arthritis and Biologicals in Children register previously showed that disability and health related quality of life (HRQoL) improved shortly after treatment with etanercept. Our aim was to investigate long term functional outcome, HRQoL and treatment changes in the same patients, who started etanercept >5 years ago.

Methods: Patients were traced and questioned on education and employment. Data on recent disease status, comorbidities and structural damage were retrieved. Disability was assessed by (Child) Health Assessment Questionnaire ((C)HAQ), HRQoL was measured by Child Health Questionnaire, Short Form 36 and Health Utilities Index Mark 3. Linear mixed models were used to analyze changes over time.

Results: 43 patients (81% response) started etanercept median 8.5 years (IQR: 7.7–10.3) ago. Median age was 22 years (IQR: 18–24). 42% had a (C)HAQ of 0.00. HRQoL was similar to HRQoL shortly after start of etanercept, except for the domains bodily pain and general health perception, which deteriorated to levels comparable to those at start of etanercept. VAS pain also worsened (median 12 (IQR:2–43)), but not to the extent as the bodily pain domain on the SF-36.The unemployment rate (12%) was comparable to the general population; educational level was higher (77% of patients >17 years had achieved at least upper secondary education). 40% of patients switched to other biologic agents, 40% were still using etanercept and 20% were off anti-rheumatic treatment. 14% had had joint surgery. There were no reports of malignancies.

Conclusion: The improvement in HRQoL after start of etanercept was sustained after 8.5 years. Disability was low. On many aspects of daily life, patients functioned comparably to or better than the general population. The need for surgery for 14% of patients stresses the importance of early treatment of JIA. Chronic pain - even when the disease is inactive - remains an important issue that should not be overlooked.

Long-Term Pharmacokinetics of Body Surface Area-Adjusted Doses of Golimumab Following Repeated Subcutaneous Administrations in Pediatric Patients with Polyarticular Juvenile Idiopathic Arthritis. Jocelyn H. Leu, Alan M. Mendelsohn, Joyce Ford, Hugh M. Davis, Honghui Zhou and Zhenhua Xu. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: To assess the pharmacokinetics (PK) and PK-efficacy correlations of body surface area (BSA)-adjusted dosing of 30 mg/m^2 golimumab administered subcutaneously (SC) every 4 weeks (q4w) + methotrexate (MTX) through Week 48 in pediatric patients (ages 2 to <18 years) with juvenile idiopathic arthritis (JIA).

Methods: GO-KIDS is a randomized-withdrawal, double-blind, placebo-controlled, parallel-group, multicenter Phase 3 trial of SC golimumab 30 mg/m^2 (maximum 50 mg) q4w + MTX (10–30 mg/m^2/week) in pediatric patients with active JIA despite current MTX therapy (median 15 mg/week). PK, safety, and efficacy evaluations were performed q4w through week 16. At Week 16, patients who were ACR JIA 30 responders were randomized (1:1) to 30 mg/m^2 golimumab or placebo q4wks through Week 48 with GLM reinstituted upon flare (defined as per JIA ACR flare criteria) or initiation of new DMARDS, biologics, systemic immunosuppressives. Serum trough concentrations were also obtained at Weeks 12, 16, 24 and 48. Serum golimumab trough concentrations for 154 patients were determined via a validated immunoassay. The relationships of ACR pediatric 30 response and disease flare status with steady-state trough levels at Week 48 were assessed.

Results: Trough serum golimumab concentrations in patients receiving SC 30 mg/m^2 golimumab q4w through Week 48 were maintained over time. Steady-state trough golimumab levels were similar across different age groups, and were also similar to those seen in adult RA patients who received 50 mg SC q4w in Phase III clinical trials. There were no apparent differences in pediatric ACR JIA 30 response rates and disease flare rates among the 4 groups of JIA patients categorized by the 4 quartiles of steady-state trough golimumab levels at Week 48. In addition, there were no apparent PK differences between patients who did and did not experience disease flares in the randomized golimumab group. Mean (SD) and median trough serum golimumab concentrations (mg/mL) by age groups and body weight quartiles are presented in the table.

Conclusion: Treatment with 30 mg/m^2 SC golimumab q4w + MTX resulted in sustained steady-state trough serum golimumab concentrations over time. The PK/efficacy correlation analyses demonstrated that the BSA-adjusted dosing regimen of 30 mg/m^2 SC golimumab q4w provided adequate drug exposure for the desired efficacy.

	Age Groups (Years)

Intra-Articular Corticosteroid Injections in Juvenile Idiopathic Arthritis: Results from a UK Prospective Collaborative Study. Eileen Baildam[1], Roberto Carrasco[2], Susannah Holt[3], Helen Foster[4], Lucy R. Wedderburn[5], Alice Chieng[6], Joyce Davidson[7], Yiannis Ioannou[8], Kimme L. Hyrich[9] and Wendy Thomson[10]. [1]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [4]Professor of Paediatric Rheumatology, Newcastle Upon Tyne, United Kingdom, [5]UCL, UCLH, GOSH NHS Trust, London, United Kingdom, [6]Royal Manchester Children's Hospital, Manchester, United Kingdom, [7]Royal Hospital for Sick Children, Glasgow, United Kingdom, [8]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom, [9]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [10]Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Intra-articular corticosteroid injections (IACI) are a standard treatment in juvenile idiopathic arthritis (JIA). This study assessed response to IACI in a large prospective cohort of children and young people (CYP) recruited at initiation of treatment.

Methods: Participants were in the Childhood Arthritis Prospective Study (CAPS), an on-going prospective inception cohort study in 7 UK paediatric rheumatology centres, recruiting CYP <16 years with new inflammatory arthritis persisting for ≥ 2 weeks. Demographics, disease features, joint count, treatment details, Childhood Health Assessment Questionnaire (CHAQ), physician's global assessment (PGA), parent's general evaluation of well-being (PGE), ESR are collected at first presentation, 6 months, then yearly.

Results: Of 1477 CYP recruited to CAPS 759 completed 3 years follow-up and 603 (79.5%) were treated with IACIs. 185 (24.4%) required IACI alone (with a single episode of injection as the only treatment in 100, (13 % of the total cohort) usually the knee in 80 %. Most injected patients required additional treatments, 393 (69.3%) commenced a DMARD or biologic agent. Of these, 93 patients received both DMARD/ biologic and IACI at the same time.

Of the 185 patients treated only with IACI, 85 had more than one episode of injections. For this group the median time to first injection was 14 days (IQR 6.36) and time from first to second injection was 318 days (IQR 162–525) illustrating a prolonged effect from the first injection.

390 of the 759 patients completing 3 years of follow-up had oligoarticular JIA of whom 332 (85%) received steroid injections, 163 (42%) treated exclusively with IACI 85 (25%) receiving only one episode of injection.

Baseline predictors of the need for DMARD in addition to IACI were a higher total active and limited joint counts, ESR, physician's global and the CHAQ score ($p<0.0001$), and pain scores ($p<0.003$).

Conclusion: Approximately one quarter of patients required monotherapy with IACI alone. Only 13% of all patients and 25% of oligo-articular course patients were managed with a single injection. Higher measures of disease activity were significantly associated with the need for DMARD therapy in addition to IACI.

Baseline Characteristics	Only IACI, only 1 episode (N=100)	Had IACI plus DMARD (N=393)	P value
Age (Median, IQR)	6.75 (3.82, 11.2)	7.05 (3.3, 10.9)	0.9
Female (n, %)	57 (57)	276 (70.4)	0.01
Ethnicity (White, n, %)	96 (96)	364 (92.8)	0.09
Disease duration (Median, IQR), months	5.5 (3.07, 10.4)	5.4 (2.9, 10.6)	0.99
Active joint counts (Median, IQR)	1 (1, 2)	4 (1, 8)	<0.0001
Limited joint counts (Median, IQR)	1 (0.5, 1)	2 (1, 5)	<0.0001

Countermeasures Against Methotrexate Intolerance in Juvenile Idiopathic Arthritis Instituted By Parents Show No Effect. Andrea Scheuern, Nadine Fischer, Johannes-Peter Haas and Boris Hugle. German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany.

Background/Purpose: Methotrexate (MTX) is the mainstay treatment in the therapy of children with juvenile idiopathic arthritis (JIA) and can lead to prolonged remission and improved quality of life. However, JIA patients frequently develop intolerance to MTX, with anticipatory and associative gastrointestinal adverse effects before drug intake arising as a conditioned response. Parents frequently try to alleviate these symptoms with a variety of countermeasures reported to help against nausea.

The objective of this study was to investigate the course of MTX intolerance in pediatric patients over a period of 6 months, as well as the effect of countermeasures by parents on the severity of MTX intolerance.

Methods: Consecutive patients admitted to the German Center for Pediatric and Adolescent Rheumatology from October 2012 until April 2014 were included in this study. MTX intolerance was measured using the validated Methotrexate Intolerance Severity Score (MISS) questionnaire. Inclusion criteria were 1) diagnosis of JIA, 2) treatment with MTX for at least 3 months prior to inclusion, and 3) confirmation of MTX intolerance by a MISS value of ≥ 6. Exclusion criteria were other diseases leading to nausea and/or abdominal complaints, and concomitant medications possibly inducing nausea (excepting biologics and non-steroidal anti-inflammatory drugs).

Methotrexate dose, MISS and countermeasures instituted by the parents were determined at 4 time points (at inclusion, at 6 weeks, 3 months and 6 months). Countermeasures were classified into 4 criteria: antiemetic drugs, covert dosing, taste masking and complementary medicine. **Results** were analyzed using descriptive statistics and non-parametric testing (Wilcoxon signed rank test).

Results: 38 patients were included (63% female, median age at inclusion 11.7 years, median disease duration 7.1 years). Average MISS at inclusion was 10.8 ± 4.1, and after 6 months 12.2 ± 7.2 (p = 0.316). In 6/38 patients (16%), MTX was reduced or discontinued during the study. In 89 time intervals between study visits, 40 countermeasures were introduced by the parents.

Countermeasure	n	MISS before introduction	MISS after introduction	p
Antiemetic drugs	9	10.56	13.78	.080
Covert dosing	11	12.64	12.64	.766
Taste masking	9	11.67	13.22	.120
Complementary medicine	11	12.73	14.18	.089

Conclusion: If MTX intolerance is present, symptoms will not decrease over the course of 6 months. Various modalities used by the parents as countermeasures against nausea show no discernible effect.

S100 Proteins in Oligoarticular Juvenile Idiopathic Arthritis. Alexandra R Aminoff[1], Carol A Wallace[1], Sarah Ringold[1], Anne Stevens[2] and Jessica M Foster[3]. [1]Seattle Children's Hospital/Univ of Washington, Seattle, WA, [2]Seattle Children's Hospital, Seattle, WA, [3]Seattle Children's Research Institute, Seattle, WA.

Background/Purpose: There is a lack of reliable biomarkers that correlate with active juvenile idiopathic arthritis (JIA). The S100A8/A9 heterodimer (calprotectin) and S100A12 are proinflammatory molecules that have been shown to correlate with risk of relapse in JIA. Our objectives were to compare calprotectin and S100A12 levels in children with newly diagnosed oligoarticular JIA to those of healthy controls and to determine whether baseline levels of these proteins in oligoarticular JIA are associated with disease course.

Methods: This was a prospective, observational cohort study of newly diagnosed oligoarticular JIA patients at Seattle Children's Hospital. Plasma calprotectin and S100A12 levels were measured using commercially-available enzyme-linked immunosorbent assay (ELISA) kits and compared to healthy pediatric controls using the Wilcoxon rank sum test.

Results: The oligoarticular JIA cohort (n=25) was 68% female, with a mean age of 5.6 years (range 2.1–14.4 years) and the historic pediatric control group (n=30) was 67% female, with a mean age of 9.1 years (range 1.3–13.4 years). The oligoarticular JIA cohort had significantly elevated calprotectin levels (median 1246 ng/ul, range 202–5694) compared to controls (median 730 ng/ul, range 124–1668), p value 0.005. For S100A12, the oligoarticular JIA cohort again had significantly elevated levels (median 48,800 pg/ml, range 0–350,400) compared to controls (median 13,400 pg/ml, range 0–178,700), p value=0.002.

Conclusion: Patients with oligoarticular JIA have significantly higher calprotectin and S100A12 levels at the time of diagnosis compared to healthy controls. A longitudinal analysis is underway to determine if these baseline S100 protein levels correlate with subsequent disease course. A reliable biomarker to aid in the prediction of disease course at diagnosis would potentially allow providers to identify children who would benefit from earlier aggressive therapy.

Long-Term Impact of Juvenile Idiopathic Arthritis in the Greek adults' Psychosocial Life. Despoina Dimopoulou[1], Maria Trachana[2], Polyxeni Pratsidou-Gertsi[3], George Garyfallos[4], Prodromos Sidiropoulos[5], Athina Theodoridou[1] and Alexandros Garyfallos[1]. [1]4th Department of Internal Medicine, Aristotle University, Hippocratio Hospital, Thessaloniki, Greece, [2]Aristotle University, Thessaloniki, Greece, [3]1st Department of Pediatrics, Aristotle University, Thessaloniki, Greece, [4]2nd Department of Psychiatry Aristotle University, Thessaloniki, Greece, [5]University of Crete, Heraklion, Greece.

Background/Purpose: Juvenile idiopathic arthritis (JIA) seems to have a negative impact on patients' life style mostly due to the disease chronicity. No relevant data have been published for Greek young adults so far. /To capture the impact of disease burden in the psychosocial profile of adults with JIA, 17.2 years after disease onset.

Methods: A total of 96 (66 females) patients were enrolled. Psychosocial distress was assessed by the Greek version of the self-completed paper-based General Health Questionnaire (GHQ-28). A second questionnaire regarding marital status, education level and employment status was completed by all patients. Disease activity status at the last follow-up visit was assessed according to the Wallace's criteria while the level of disease activity by the Disease Activity Score-28 (DAS-28). The patient's assessment of global disease activity was measured on a Visual Analogue Scale (VAS) 0 to 10. Structural damage was scored by the the Juvenile Arthritis Damage Index-Articular (JADI-A) and by the Total modified Sharp/van der Heijde Score (TmSvdHS). Physical ability was assessed by the Health Assessment Questionnaire-Disability Index (HAQ-DI).

Results: The GHQ-28 case score depicted impaired psychosocial status in 18 patients (18.7%). The level of psychosocial distress was significantly correlated with DAS28 at the last follow up visit ($r=0.446$, $p<0.001$). The presence of disease activity was correlated with higher degree of depression ($p=0.032$) and social dysfunction ($p=0.008$). Interestingly, patients without or with mild physical disability (HAQ-DI=0–0.49) differed from those with moderate-to-severe disability (HAQ-DI=0.5–3) in the fields of somatization ($p=0.004$) and social dysfunction ($p<0.001$), but not of depression. Higher degree of depression was recorded in the unemployed patients ($p=0.018$) and in those with mandatory education ($p=0.018$). In contrast, structural damage (JADI-A, TmSvdHS), marital status and current use or duration of corticosteroid treatment didn't find to influence patients' psychosocial profile. Global disease activity rated by the patient was found to be the only significant predictor of psychosocial distress in the multivariate analysis [B=0.057 95%CI (0.017, 0.097), P=0.005].

Conclusion: Psychosocial distress is evident in a considerable proportion of the patients (~19%), indicating a constant impact of the disease on every-day life. The tight control of disease activity is therefore crucial in order to prevent symptoms of depression in these JIA adults.

A Controlled Trial of Intra-Articular Corticosteroids with or without Methotrexate in Oligoarticular Juvenile Idiopathic Arthritis. Angelo Ravelli[1], Giulia Bracciolini[2], Sergio Davì[2], Angela Pistorio[2], Alessandro Consolaro[2], Sara Verazza[2], Bianca Lattanzi[2], Giovanni Filocamo[2], Sara Dalprà[2], Maurizio Gattinara[3], Valeria Gerloni[3], Antonella Insalaco[4], Fabrizio De Benedetti[5], Adele Civino[6], Luciana Breda[7], Loredana Lepore[8], Maria Cristina Maggio[9], Franco Garofalo[10], Silvia Magni-Manzoni[5], Donato Rigante[11], Antonella Buoncompagni[2], Marco Gattorno[2], Clara Malattia[1], Stefania Viola[2], Paolo Picco[2], Nicolino Ruperto[12] and Alberto Martini[1]. [1]Istituto Giannina Gaslini and University of Genova, Genova, Italy, [2]Istituto Giannina Gaslini, Genova, Italy, [3]Istituto Ortopedico Gaetano Pini, Milano, Italy, [4]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [5]Ospedale Pediatrico Bambino Gesù, Roma, Italy, [6]Ospedale Cardinale G. Panico, Tricase, Italy, [7]Ospedale Policlinico, Chieti, Italy, [8]Istituto Burlo Garofolo, Trieste, Italy, [9]University of Palermo, Palermo, Italy, [10]Ospedale degli Infermi, Biella, Italy, [11]Università Cattolica Sacro Cuore, Rome, Italy, [12]Istituto Giannina Gaslini, Genoa, Italy.

Background/Purpose: In contrast with the numerous randomized controlled trials conducted in polyarticular or systemic juvenile idiopathic arthritis (JIA), little evidence-based information is available for oligoarticular JIA. As a result, the management of children with this subtype, which is the most prevalent in Western countries, is largely empiric. Intra-articular corticosteroid (IAC) injection is the therapy of first choice for oligoarthritis in many pediatric rheumatology centers. However, although IAC injections are usually highly efficacious, relapses of synovitis are common and sometimes occur only a few months after the procedure. It is still unclear whether concomitant administration of methotrexate (MTX) may increase and prolong the effectiveness of IAC injections. The aim of the study was to compare the efficacy of IAC injection administered as monotherapy or in association with MTX in children with oligoarticular JIA in a phase II, randomized, actively controlled, multicenter trial.

Methods: Inclusion criteria were oligoarticular JIA by ILAR criteria, age < 18 years, and parent informed consent. Patients who were previously treated with synthetic or biologic DMARDs, had undergone an IAC injection < 3 months, were newly injected only in 1 knee, or had active uveitis were excluded. Patients enrolled were randomized 1:1 to receive either IAC therapy alone (Arm 1) or IAC therapy plus MTX (Arm 2). MTX was given orally at 15 mg/m2/week (maximum 20 mg/week). All patients were followed for 12 months and were assessed at 3, 6 and 12 months. The primary outcome was synovitis flare, defined as recurrence, persistence or new onset of synovitis in 1 or more injected or uninjected (i.e. previously unaffected) joints. Flare rate/probability was compared by chi-square and Kaplan-Meier methods.

Results: A total of 207 patients (50 boys and 157 girls) were enrolled, 102 in Arm 1 and 105 in Arm 2. Fifteen patients lost to follow-up <6 months were included only in the intention-to-treat (ITT) cohort. Patients in arms 1 and 2 were comparable for demographic features and median number of injected joints (2 vs. 2). In the ITT cohort (n=207) flare of synovitis occurred in 133 patients (64.2%), 69 (67.6%) in Arm 1 and 64 (60.9%) in Arm 2 (p=0.31), whereas in the as-observed (AO) cohort (n=192) flare of synovitis occurred in 118 patients (61.4%), 64 (66%) in Arm 1 and 54 (56.8%) in Arm 2 (p=0.19). By Kaplan-Meier analysis, the probability of synovitis flare in the 2 treatment arms was comparable in both ITT and AO cohorts (log-Rank test: p=0.18 and 0.07, respectively). However, among the 118 patients who flared in the AO cohort, flare in injected joints occurred more frequently in Arm 1 than in Arm 2 (46/64, 71.9% vs. 29/54, 53.7%; p=0.04).

Conclusion: Flare of synovitis in injected joints occurred less frequently in patients who received concomitant MTX. However, the association of oral MTX did not increase the overall effectiveness of IAC therapy, owing to the high frequency of new onset of synovitis in uninjected joints. Trial registration identifying number: FARM7Y279L, AIFA, Italy.

Patient-Reported Joint Count in Juvenile Idiopathic Arthritis: The Reliability of a Mannequin Format. Maryanne Dijkstra[1], Janneke Anink[1], Philomine A. van Pelt[2], Johanna M.W. Hazes[2] and Lisette W.A. van Suijlekom-Smit[1]. [1]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a common chronic disease, requiring regular monitoring. Patient-reported outcomes can assist monitoring, may promote patient self-management and can be useful in epidemiological surveys. Our objective was to evaluate reliability of a mannequin-format patient-reported joint-count in JIA, and to detect changes in agreement at a follow-up visit.

Methods: JIA patients aged 12–21 marked joints with active arthritis on a mannequin (see Figure 1) before their regular clinic visit. The physician performed a joint-count without having seen the patient's assessment. For two subsequent clinic visits, agreement between the physician and patient-reported joint-counts was assessed using Intraclass Correlation Coefficient (ICC) and kappa statistics. The ability of the patient-reported joint-count to discriminate between active and inactive disease was evaluated using positive and negative predictive values. Sensitivity to change was estimated using Pearsons's rho and standardized response mean (SRM).

Results: 75 JIA patients were included. In general, patients had a low number of active joints (median 1 joint, indicated by the physician). ICC was moderate (0.61) and kappas ranged from 0.3–0.7. At the follow-up (n= 53), kappas were similar; the ICC was 0.19. When a patient scored 0 joints, the physician confirmed this in 93–100%. When the patient marked ≥ 1 joints, the physician confirmed arthritis in 59–76%. Sensitivity to change was moderate (Pearson's rho: 0.44, p=0.001, SRM in worsening patients: 0.67).

Conclusion: Agreement between physician and patient on joint-counts was reasonable. Untrained patients tended to overestimate presence of arthritis when they marked active joints on a mannequin-format joint-count. When the patient indicated absence of arthritis, the physician usually confirmed this. The sensitivity to change was moderate for patients who worsened over time.The agreement did not improve at follow-up; future research should focus on the possibility of achieving this through training. For now, the patient-reported joint-count cannot fully replace the physicians' joint-count in clinical practice; it may be used in epidemiological studies with caution.

Pregnancies in Females with Juvenile Idiopathic Arthritis (JIA) Who Were Exposed to Biologics and/or Methotrexate – Results from a Biologic Register. Katrin Stüdemann[1], Martina Niewerth[1], Jens Klotsche[1], Angela Zink[2], Gerd Horneff[3] and Kirsten Minden[4]. [1]German Rheumatism Research Center, Berlin, Germany, [2]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [3]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [4]Charité University Medicine, Berlin, Germany.

Background/Purpose: JIA often continues into adult life and affects about 1 in 1,000 people of childbearing age. Little is known about the impact of JIA and its treatment with non-biologic (nb) and biologic (b) disease modifying antirheumatic drugs on pregnancy and its outcome. We therefore investigated pregnancy outcomes in females with JIA exposed to DMARDs.

Methods: Patients with a pregnancy history, who were enrolled in the JIA biologic registers BiKeR and JuMBO, were interviewed regarding pregnancy complications and outcomes. Prospectively collected patient-reported data on disease activity and functional status, and physician-reported data on treatment and pregnancy-related adverse events were also considered in the analyses.

Results: Out of 875 JIA patients followed into adulthood, 91 pregnancies were reported in 70 patients (58 females patients, 12 partners of male patients). Until June 2014, reports on pregnancies were evaluable for 50 females with 60 pregnancies. The majority had polyarticular JIA (72%), another 16% enthesitis-related arthritis. The median age at conception was 20.9 years (ys, range 13.8–29.0), the median disease duration 11.6 ys (range 3.3–26.1).

All patients were ever treated with bDMARDs (94%) and/or nbDMARDs (100%), 48% were exposed at conception (10 to

bDMARDs only, 10 to b and nbDMARDs, 4 to nbDMARDs only). In the group of DMARD exposed (n=25 pregnancies) and unexposed patients (n=35 pregnancies), pregnancy outcomes were as follows: 13 (52%) and 26 (74%) live births, 0 and 1 stillbirth, 1 and 0 extrauterine gravidity, 3 and 3 spontaneous abortions, 8 and 5 elective pregnancy terminations, respectively. DMARDs were discontinued in the exposed patients 4.9 weeks (median, range 2.7–22.3) after conception.

Of 39 pregnancies with live births, complications were reported in two-thirds of the cases, with similar frequency in exposed and unexposed patients. Most frequently reported complications were hyperemesis gravidarum, pregnancy diabetes, urinary obstruction, preterm contractions and hemorrhages (n=5 each). Almost half of the patients (48%) were delivered by Cesarean section. There were 3 pre-term deliveries and 3 small for gestational age neonates. The median birth weight was 3,110 grams (range: 1,080-4,150) after a median gestational age of 39.0 weeks (range: 30–42). No birth defects were reported. Two neonates required intensive neonatal care.

During pregnancy, disease activity of JIA remained stable or even improved in two-thirds of patients. Within the first 6 months after delivery, about half of women experienced a disease flare. Patients on DMARDs within the 3 months before conception had more often a disease flare than those not being exposed.

Conclusion: Exposure to DMARDs did not seem to increase the risk of adverse pregnancy outcomes, however, that needs to be confirmed in larger patient cohorts. Data suggest that severely affected JIA patients are at risk of pregnancy morbidity and instrumental delivery.

Qualitative Assessment of Important Long-Term Outcomes in Juvenile Idiopathic Arthritis. Melissa L. Mannion[1], Michelle Williams[1], Gerald McGwin Jr. [1], Kenneth G. Saag[2] and Timothy Beukelman[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: JIA is not a childhood disease, but a chronic disease that begins in childhood. Long term outcomes that physicians and patients care most about may not be reflected by short term surrogate outcomes. The aim of this study was to identify and characterize the factors that pediatric rheumatologists use to define a successful disease outcome for JIA patients in young adulthood, with the ultimate goal of creating an outcome assessment tool to provide a gold standard for comparing different treatment approaches for JIA.

Methods: In depth interviews were conducted with pediatric rheumatologists to generate themes regarding successful treatment, acceptable disease states, and optimal disease management outcomes for young adults with JIA. Interviews were recorded and transcribed then coded via *in vivo* coding based on grounded theory resulting in mutually exclusive categories. Initial coding was for outcome themes and recoding for outcome descriptions to maintain the depth and meaning of the qualitative data.

Results: 13 pediatric rheumatologists from the US were interviewed; 8 were female, there was representation of all census regions and 54% had been practicing for more than 10 years. Coding for outcome theme identified 507 descriptive codes in 65 categories. These codes were regrouped into 14 outcome topics and quantized; chronic arthritis/joint damage, physical/functional, medication, pain/fatigue, expectations, vocation/profession, social/participation, daily life/activities of daily living, health, vision, family, independence, appearance, and mental health. The themes with the most codes were chronic arthritis/joint damage, physical/functional, and medication. The median number of outcome theme codes per physician was 28 with a range of 14 to 55. The outcome theme categories were quantized based on the number of participants who mentioned the category; the categories mentioned by all 13 practitioners were chronic arthritis/joint damage, physical/functional, and expectations followed by medication and pain/fatigue mentioned by 12 practitioners. Recoding for outcome description resulted in 157 codes in 9 mutually exclusive description categories; ability, active disease/remission, feel normal, everything that they want to do, understanding, satisfaction, indistinguishable from peers, and acceptance. The description categories with the most codes were ability and burden/interference. The median number of outcome description codes per physician was 12 with a range of 7 to 18. Ability and burden/interference were mentioned by all 13 physicians.

Conclusion: This study begins to characterize the factors that pediatric rheumatologists use to define a successful disease outcome for JIA in young adulthood. Physicians prioritized physical outcomes, function and medication adverse effects in the definition of successful JIA management. Further studies are needed to characterize the factors that the patients prioritize. With additional studies, the definition of a gold standard based on physician and patient input will enable patients to be better informed about their treatment options and expected future outcomes.

303

Predicting Chronic Pain in Children with Juvenile Idiopathic Arthritis: Results from the Childhood Arthritis Prospective Study. Amir Rashid[1], Kate Holliday[1], Lis Cordingley[2], Roberto Carrasco[1], Bo Fu[1], Helen E. Foster[3], Eileen Baildam[4], Alice Chieng[5], Joyce Davidson[6], Lucy Wedderburn[7], Kimme Hyrich[8] and Wendy Thomson[9]. [1]The University of Manchester, Manchester, United Kingdom, [2]Centre for Musculoskeletal Research, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]Newcastle University, Newcastle upon Tyne, United Kingdom, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]Royal Manchester Children's Hospital, Manchester, United Kingdom, [6]Royal Hospital for Sick Children, Glasgow, United Kingdom, [7]University College London (UCL), London, United Kingdom, [8]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [9]Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom.

· **Background/Purpose:** Pain is the most common symptom of JIA and has been associated with disease activity. However, disease activity has only accounted for a small amount of the variance in pain. This suggests predictors beyond clinical factors may be important in determining pain. The objectives of this study were to predict, at first presentation, children who are likely to have poor pain outcomes and how these children differ from those that improve.

· **Methods:** Participants were children with new inflammatory arthritis who were recruited into the CAPS cohort and followed systematically with baseline data for the 100mm visual analogue scale (VAS) for pain available. A two-stage approach was used for the analysis. Firstly, pain trajectories were modelled in children with pain VAS at presentation and at one or more follow-up visits (up to five years post baseline) using a discrete mixture-model. Secondly, multinomial logistic regression was used to determine the association between baseline variables and trajectory groups (95%CI). These variables included the core outcome variables (active and limited joint counts, physician's global assessment (PGA), parent/patient general evaluation (PGE), childhood HAQ (CHAQ) score), gender, age at onset and disease duration.

· **Results:** 957 children were included. A three group trajectory model of pain was selected as the most clinically relevant model (Figure) and included a Low-Low pain group (trajectory 1), a High-Low pain group (trajectory 2) and a High-High pain group (trajectory 3). Children in the High-Low group and High-High group had significantly older age at onset, longer disease durations, more involved joints, higher PGE, PGA, pain and CHAQ scores at presentation, compared to children in the Low-Low group. Higher pain at baseline predicted membership of the High-High group (RRR 1.1 (95% CI 1.05, 1.1) and High-Low Pain (RRR 1.1 (95% CI 1.1, 1.1) compared to Low-Low group; and predicted membership in the High-Low group compared to the High-High group (RRR 0.98 (95% CI 0.97, 0.99). Both Higher CHAQ scores and older age at onset predicted membership in the High-High group compared to both the Low-Low group and the High-Low group. Longer disease duration at presentation predicted membership in the High-High group (RRR 1.03 (95% CI 1.01, 1.04) and the High-Low group (RRR 1.02 (95% CI 1.001, 1.03) compared to Low-Low group.

· **Conclusion:** Even when adjusting for core outcome variables at presentation, participants who present earlier in their disease, are younger at disease onset and report less pain and functional problems upon presentation are less likely to report pain over time. Age at onset, functional problems and pain at presentation differentiated between high levels of pain which improved or persisted over time.

Juvenile Rheumatoid Arthritis and Future Risk for Cardiovascular Disease; A Multicenter Population-Based Study. Jason Anderson[1], Katelyn Anderson[1], Hanne Aulie[2], Cynthia S. Crowson[1], Thomas Mason II[1], Stacy P. Ardoin[3], Ann M. Reed[1] and Berit Flato[2]. [1]Mayo Clinic, Rochester, MN, [2]Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [3]Ohio State University College of Medicine, Columbus, OH.

Background/Purpose: Several studies suggest an increased frequency of cardiovascular disease (CVD) in patients with rheumatoid arthritis, but little is known about CVD risk in patients with juvenile rheumatoid arthritis (JRA). The objective of this study was to evaluate the frequency of CVD and CVD risk factors in adults with a prior diagnosis of JRA compared to controls.

Methods: A retrospective, partly population-based cohort study was independently conducted utilizing patients at two major academic institutions (Cohorts 1 and 2). Each institution employed a unique methodology to evaluate for the common endpoint of clinical CVD outcomes and risk factor development with comparison to control groups of similar age and sex. Cohort 1 was an inception cohort of residents of a geographically defined area who were diagnosed with JRA in 1960–1993. CVD and CVD risk factors were ascertained via medical record review and telephone survey for the subset of patients currently aged ≥30 years. Cohort 2 included patients diagnosed with JRA in 1980–1985 who participated in a clinical exam or completed a survey in 2011–2012 (i.e. 29 year follow-up).

Results: Among 41 patients with JRA and 28 controls in cohort 1, 3 patients (7%) had CVD, compared to 0 controls ($p = 0.43$). Of these, 1 patient had CVD prior to age 30 with ages at time of CVD diagnosis ranging from 21–39 years. Types of CVD included 1 patient with venous and arterial thrombosis, 1 patient with coronary artery disease and myocardial infarction, and 1 patient with angina pectoris. Analysis for the presence of CVD risk factors in Cohort 1 demonstrated 15 patients (56%) with hyperlipidemia, compared to 0 controls ($p = 0.019$). Twenty patients (49%) were ever smokers, compared to 10 controls (36%) ($p = 0.004$). Other risk factors including hypertension, diabetes mellitus, and family history of CVD were elevated in the JRA cohort but did not obtain statistical significance. Among 170 JRA patients with 29 year follow-up and 91 controls in Cohort 2, 2 patients (2%) had CVD, compared to 0 controls ($p = 0.29$). Types of CVD included 1 patient with myocardial infarction and 1 patient with angina pectoris and myocardial infarction. Analysis for the presence of CVD risk factors in Cohort 2 demonstrated 14 patients (8%) with hypertension, compared to 2 controls (2%) ($p = 0.049$). Ninety patients (54%) were ever smokers, compared to 36 controls (40%) ($p = 0.028$). Other CVD risk factors measured and elevated in the JRA cohort included use of antilipemic medication, use of antihypertensive medication, and CVD in first degree relative, but statistical significance was not obtained. The presence of diabetes mellitus was equal in the JRA cohort and control group for Cohort 2.

Conclusion: Certain CVD risk factors including hyperlipidemia, hypertension, and smoking appear to be more common among patients with JRA than in age-matched controls. There may be a trend toward increased numbers of CVD events, and occurrence of CVD at younger ages in patients with JRA, although statistical significance was not demonstrated in this study. Continued longitudinal follow-up of these cohorts and larger population-based studies are needed to establish a definitive relationship between JRA and CVD.

Understanding the Molecular Pathogenesis of and Response to Canakinumab Treatment in TNF Receptor-Associated Periodic Syndrome By Gene Expression Profiling of Whole Blood from Patients. R. Torene[1], M. Gattorno[2], H. Lachmann[3], L. Obici[4], A. Meini[5], V. Tormey[6], R. Caorsi[2], L. Baeriswyl[7], U. Affentranger[7], S. Starck-Schwertz[7], M. Letzkus[7], N. Hartmann[7], K. Abrams[8] and N. Nirmala[1]. [1]Novartis Institutes for BioMedical Research, Cambridge, MA, [2]G. Gaslini Institute, Genova, Italy, [3]Royal Free Hospital, London, United Kingdom, [4]IRCCS Policlinico San Matteo, Pavia, Italy, [5]Spedali Civili, Brescia, Italy, [6]Galway University Hospitals, Galway, Ireland, [7]Novartis Institutes for BioMedical Research, Basel, Switzerland, [8]Novartis Pharmaceutical Corporation, East Hanover, NJ.

Background/Purpose: TNF receptor-associated periodic syndrome (TRAPS) is an autoinflammatory disease causing unprovoked fevers, myalgia, abdominal pain, rash, headaches, and, in severe cases, AA amyloidosis. It is an autosomal dominant condition resulting from variants in the TNF super family receptor 1A (*TNFRSF1A*) gene. [1] A hallmark of TRAPS is a huge activation of the inflammatory response in the absence of autoantibodies or antigen-specific T-cells. [1] Canakinumab is a high-affinity, human, selective, anti-IL-1β monoclonal antibody, developed for the treatment of autoinflammatory diseases. [2] The objective of this analysis is to determine whether gene expression in whole blood can support a molecular mechanism for the activity of canakinumab in TRAPS patients.

Methods: Twenty patients with active TRAPS received open-label canakinumab 150mg sc/month for 4 months in an efficacy and safety study. These patients were assessed at Day 15 for response by physician global assessment (PGA) disease activity scale. Whole blood was collected at baseline, Day 15 and Day 113 from 19 of these patients and 1 sample each from 19 untreated age-matched healthy volunteers for analysis of gene expression levels by microarrays.

Results: All 20 patients showed improvements in PGA score (Figure 1-left). Gene expression profiles of these patients were altered by treatment with canakinumab. Forty-six differentially expressed genes showed a >2-fold change after treatment with expression levels that shifted towards that of healthy volunteers. The disease-causing gene (*TNFRSF1A*, Figure 1-right), drug target gene (*IL-1β*), and other inflammation related genes (e.g., *MAPK14*) were downregulated after treatment and several inflammation related pathways were evident among the differentially expressed genes. Many of the high confidence differentially expressed genes had expression levels that correlated with neutrophil count, however, neutrophil count alone could not account for the expression differences observed.

Conclusion: Altogether, the gene expression data support a model in which canakinumab increases neutrophil apoptosis and reduces pro-inflammatory signals through its inhibition of IL-1β. Canakinumab is able to reverse the overexpression of several genes associated with inflammatory response, including IL-1β. Interestingly, IL-1β blockade normalized the overexpression of the disease-causing gene, *TNFRSF1A*, at the RNA level, suggesting a direct impact on the main pathogenic mechanism of TRAPS.

Association of Kawasaki Disease with Tropospheric Winds in Central Chile: Is Wind-Borne Desert Dust a Risk Factor?. Arturo Borzutzky[1], Alvaro García[2], Rodrigo Hoyos-Bachiloglu[1] and Hector Jorquera[3]. [1]Millennium Institute on Immunology and Immunotherapy, Pontificia Universidad Católica de Chile, Santiago, Chile, [2]Pontificia Universidad Católica de Chile School of Medicine, Santiago, Chile, [3]Centro de Desarrollo Urbano Sustentable (CEDEUS), Santiago, Chile.

Background/Purpose: Kawasaki disease (KD) has been reported to have seasonal variations in many different countries, as well as geographical and temporal clustering. It has been found that KD cases diagnosed in Japan, Hawaii and San Diego, USA increase when tropospheric wind patterns arrive from central Asia, suggesting a common, wind-borne causal agent.

Methods: We analyzed KD cases hospitalized in Santiago, Chile to look for associations with local, regional and large scale meteorological variables. We compiled monthly data of KD incidence rates, local meteorological variables, regional winds and several El Niño Southern Oscillation (ENSO) indices for 2001–2010; we considered standardized anomalies in all analyses. We used dynamic linear regression models to account for data autocorrelation.

Results: Zonal (U) winds at 1000 and 925 mb above Santiago show a strong correlation with KD data on univariate linear regression ($P<0.001$), but no significant association was observed for other unlagged meteorological variables. We then fitted multivariate dynamical regressions using time series ARX models; model selection was carried out by minimizing Akaike's Information Criterion (AIC) and several model structures — using different lags in meteorological variables — were explored. This multivariate dynamic regression showed that meteorological variables explain 38% of variance in KD rates. A unit increase in northerly wind at 3 lagged months, temperature at 1 and 3 lagged months and monthly change of ENSO 4 index are associated with changes in KD rates of 0.203 (95% CI 0.049 – 0.358), 0.181 (95% CI 0.014 – 0.347], 0.192 (95%CI 0.030 – 0.353) and -0.307 (95% CI -0.458 -0.156), respectively.

Conclusion: We found a statistical association of KD at Santiago, Chile with tropospheric, northerly wind patterns suggesting dust transported from the Atacama Desert could include a causative agent. A novel result is that ENSO dynamics also explain part of KD variability with a decrease in KD when La Niña is dissipating or El Niño is on the rise; hence climate scale dynamics might be taken into account in future studies worldwide — at least as a potential explanatory variable that may confound KD seasonality on a global scale.

307

Sibling Exposure and Risk of Juvenile Idiopathic Arthritis. Jessica Miller[1], Anne-Louise Ponsonby[2], Angela Pezic[1], Jonathan Akikusa[3], Roger Allen[4], Jane Munro[4] and Justine Ellis[1]. [1]Murdoch Childrens Research Institute, Parkville, Australia, [2]The University of Melbourne, Parkville, Australia, [3]Royal Childrens Hospital, Parkville, Australia, [4]Royal Children's Hospital, Melbourne, Australia.

Background/Purpose: Susceptibility to juvenile idiopathic arthritis (JIA) is presumed to be determined by the interplay of genes and environment. Our understanding of the genetic basis of JIA risk has increased markedly over the last few years, but the environmental factors remain largely unknown. The hygiene hypothesis suggests that exposure to microbes in early life may protect against the development of immune disorders. Measures of early life hygiene have been associated with asthma, allergy, multiple sclerosis (MS) and type 1 diabetes. Exposure to siblings may be a marker of exposure to childhood infection, and we have previously shown that higher infant sibling exposure prior to school age is associated with a decreased risk of MS. We therefore hypothesised that sibling exposure may also be associated with JIA.

Methods: Participants were drawn from the CLARITY JIA biobank in Victoria, Australia. Cases (n = 302; mean age 8.5y ± 4.7 SD; 67% female) were children born in Victoria who were diagnosed with JIA by a paediatric rheumatologist at the Royal Children's Hospital (RCH), Melbourne. Systemic JIA cases were excluded. Controls (n = 676; mean age 7.1y ± 4.1 SD; 41% female) were healthy children born in Victoria and visiting the RCH day surgery unit for a minor surgical procedure. At recruitment, families completed a questionnaire that collected birthdates of the index child and siblings, along with data on other potential confounders including index child age and sex, maternal age at birth, gestational age at birth, child sleeping arrangements and socio-economic status. We compared birth order, only-child status, total number of siblings, and cumulative years of sibling exposure by age six, between cases and controls using logistic regression.

Results: We found that, compared to being an only child, having any siblings conferred a protective effect on JIA risk (adjusted OR = 0.46, 95% CI 0.28 – 0.74, p = 0.001). The protective effect appeared to increase with increasing number of siblings (Table 1).

Table 1: Total number of siblings born within 18 years of the index child

	JIA Cases No. (%)	Controls No. (%)	Adjusted OR (95% CI)	P
0	47 (16.5)	79 (12.0)	1.00	
1	123 (43.3)	327 (49.8)	0.46 (0.28, 0.76)	0.002
2	86 (30.3)	165 (25.1)	0.50 (0.29, 0.87)	0.014
≥ 3	28 (9.9)	86 (13.1)	0.25 (0.13, 0.48)	< 0.001

A protective effect of siblings was also observed when we considered cumulative sibling years by age 6 (e.g. ≥ 3y exposure vs no exposure, adjusted OR = 0.49, 95% CI 0.30 – 0.79, p = 0.003). There was no association between birth order and JIA risk. We also compared cases to a second control sample (n = 341, mean age 8.1 years ± 3.6 SD; 45% female) collected from the community and weighted to represent the Victorian child population. JIA odds ratios were found to be similar by this approach, although confidence intervals were wider, reflecting the smaller size of the community control sample.

Conclusion: In the CLARITY JIA case-control sample, increased exposure to siblings is associated with a reduced risk of disease. This suggests that increased microbial exposure in childhood may confer protection against the development of JIA.

Tenascin-C, a TLR4 Ligand Levels in Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis: Cross-Sectional and Longitudinal Study. Anuj Shukla, Priyanka Gaur and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Tenascin-C (TNC) is an extracellular matrix glycoprotein, which binds to TLR4 and leads to its activation. Monocytes of children with Enthesitis related arthritis (ERA) show TLR4 overexpression. TNC may serve as an endogenous stimulator of TLR4 in ERA. Thus we

studied the serum and synovial fluid levels of TNC in children with ERA and its association with disease activity.

Methods: TNC levels were measured in serum of 80 children with ERA satisfying ILAR criteria. 15 children were followed-up while on regular NSAID treatment and levels were reassessed at 3 months. 17 paired serum-synovial fluid samples and 25 healthy control serum samples were also analyzed. Disease activity was assessed by physician global assessment; tender, swollen and damaged joint counts; enthesitis score, ESR and CRP.

Results: Patients were mainly boys (9:1) with average age at disease onset of 11.2 years and duration of disease of 4.4 years. 80% had peripheral arthritis, 63% active enthesitis, 43% clinical sacroilitis, 39% inflammatory back-pain, and 8% had a history of acute anterior uveitis. Most of the children were HLA-B27 positive (90%, n=72) and 29% had positive history of JIA-ERA or spondyloarthritis in the family.

The average physician global assessment (0–10) was 4.5±2.2. Average early morning stiffness was 50±57 minutes with 4±4-tender and 3±3-swollen joints. Average ESR and CRP were 72±37 mm at 1 hour and 6.9±5.6 mg/dl. 25% children had at least one damaged joint with an average count of 2±2. 16 children out of 80 had no tender and swollen joints and were classified as inactive disease.

The mean serum TNC level in children with active disease was 67.1±44.9 ng/ml and was significantly higher than the inactive 40.6±36.7 ng/ml ($p=0.01$) and healthy control 21±15.2 ng/ml ($p<0.001$). Median levels were higher in HLA-B27 positive 70.1 ng/ml vs. negative disease 22.8 ng/ml ($p=0.003$).

Serum levels correlated positively with disease activity parameters like physician global assessment (r=0.4, 95%CI=0.15 to 0.58, p=0.001), early morning stiffness (r=0.34, 95% CI = 0.1 to 0.55, p=0.005), tender joint count (r=0.4, 95%CI=0.2 to 0.6, p=0.0003), swollen joint count (r=0.46, 95%CI=0.27 to 0.6, $p<0.0001$), ESR (r=0.42, 95%CI=0.21 to 0.6, p=0.0002) and CRP (r=0.32, 95%CI=0.1 to 0.5, p=0.007) and negatively with duration of disease (r=−0.33, 95%CI=−0.5 to -0.17, p=0.003). TNC levels did not correlate with enthesitis scores and damaged joint counts. In ROC analysis for active vs. inactive disease, TNC (AUC=0.754) was equivalent to ESR (AUC=0.787) and CRP (AUC=0.789).

Treatment with regular and adequate dose of NSAIDs lead to a significant fall in the serum levels at 3 months of follow-up (p=0.0003). The median synovial fluid TNC level in JIA-ERA was 17.39 ng/ml. Synovial fluid levels were significantly lower than the paired serum values (p=0.01).

Conclusion: Circulating TNC levels are significantly raised and correlate with various clinical and laboratory parameters of disease activity in children with ERA. It is equivalent to ESR and CRP as a measure of disease activity. Regular NSAID treatment results in significant fall in the levels at 3 months probably related to control of disease activity.

Clinical Significance of Cytokine Profile with Interleukin-18 and -6 in Systemic Juvenile Idiopathic Arthritis. Masaki Shimizu, Natsumi Inoue, Yuko Tasaki, Sayaka Ishikawa, Kazuyuki Ueno and Akihiro Yachie. School of Medicine, Institute of Medical, Pharmaceutical, and Health Sciences, Kanazawa University, Kanazawa, Japan.

Background/Purpose: Innate proinflammatory cytokines interleukin (IL)-6 and IL-18 are critical for perpetuating the inflammatory processes in systemic juvenile idiopathic arthritis (s-JIA) and macrophage activation syndrome (MAS). To assess the role of IL-6 and IL-18 in the pathogenesis of s-JIA and MAS, and to investigate the clinical significance of serum cytokine profile with IL-6 and IL-18 in s-JIA and MAS, we analyzed the serum IL-6 and IL-18 in patients with s-JIA and compared them with the clinical features of s-JIA.

Methods: 71 patients with s-JIA including 23 patients with MAS were analyzed. Levels of IL-6 and IL-18 were quantified in serum by enzyme-linked immunosorbent assay. **Results** were compared with clinical features of s-JIA.

Results: Two distinct s-JIA patient subsets based on their serum IL-6 and IL-18 levels were identified: an IL-18 dominant (IL-18/IL-6 >1000) and an IL-6 dominant (IL-18/IL-6<1000). The IL-6 dominant subset had a significantly greater number of joints with active disease and higher serum levels of matrix metalloproteinase-3, whereas the IL-18-dominant subset was more likely to develop MAS. The cut off value of serum IL-18 to predict the development of MAS was 52500pg/ml with 91.3% of sensitivity and 81.3% of specificity. The patients with IL-18 dominant pattern were likely to have monophasic or polycyclic disease course, whereas the patients with IL-6 dominant pattern were likely to have persistent disease course. Serum IL-18 levels in patients achieved remission decreased to the levels <1,000 pg/mL in inactive phase and normalized in remission phase. In contrast, serum IL-18 levels in patients experienced relapse during withdrawal of steroid within 12 months after disease onset demonstrated a sustained elevation of serum IL-18 levels (>1,000 pg/mL) during the inactive phase.

Conclusion: Two subsets of patients with s-JIA, one which is prone for arthritis and another with prone for MAS, can be identified on the basis of their serum IL-6 and IL-18 levels. These two subsets appear to be characterized by certain distinct clinical features. Monitoring the cytokine profile with IL-18 and IL-6 might be useful to predict disease course. Furthermore, serum IL-18 levels reflect the biological activities of the immune system in s-JIA and may predict the development of MAS and the prognosis of s-JIA.

Differential Expression of microRNA in Monocytes from Children with Systemic Juvenile Idiopathic Arthritis: Implications for Polarized Phenotype. Grant Schulert[1], Ndate Fall[1], Nan Shen[2] and Alexei Grom[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Shanghai Institutes for Biological Sciences Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China.

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is an autoinflammatory disease of childhood, and the predominant effector cells are mononuclear phagocytes rather than lymphocytes as in autoimmune diseases such as rheumatoid arthritis (RA). Previous gene expression data has shown that monocytes in SJIA have a novel phenotype with clear proinflammatory activation as well as features of alternative activation. This aberrant phenotype may contribute to the potential of these children to develop macrophage activation syndrome (MAS). What controls monocyte/macrophage differentiation in SJIA is unknown. MicroRNA are small, non-coding RNA that serve as transcriptional negative regulators to fine-tune gene expression programs involved in cell differentiation, metabolism and immunity. There is growing evidence that miRNA contribute to the pathogenesis of human disease, including RA. These regulators have also been implicated in controlling differentiation of monocytes and macrophages. However, miRNA expression in SJIA has not been examined. Here, we examine miRNA expression profiles in peripheral blood monocytes from children with SJIA.

Methods: We enrolled children with active SJIA, defined as presence of active arthritis or systemic features, as well as those with new-onset disease or clinically inactive disease (CID). Freshly isolated CD14+ monocytes were isolated by magnetic beads separation, and used to generate RNA which in turn was used to quantitate the expression of 384 miRNA and controls on the TaqMan ™ MicroRNA Array A.

Results: We found that monocyte expression of mir-125a-5p was significantly elevated in children with active SJIA compared to those with CID (relative expression 16.8 vs. 3.0, $p<0.05$). In addition, expression of mir-125a-5p was significantly correlated with markers of disease activity including ferritin ($R=0.73$, $p<0.001$) as well as presence of systemic features such as hepatosplenomegaly. Recently miR-125a-5p has been suggested to play an essential role in monocyte polarization. We also found several specific miRNA with differential expression in monocytes from children with new-onset disease compared to those with active established disease. One of these, miR-187, has been implicated in negative regulation of inflammatory cytokines including IL-6. We find that miR-187 expression strongly correlates with markers of disease activity including C-reactive protein ($R=0.813$, $p<0.05$), ferritin ($R=0.644$, $p<0.05$) and soluble IL-2 receptor ($R=0.779$, $p<0.05$) as well as presence of systemic features. Interestingly, while monocyte expression of miR-146a has been correlated with disease activity in RA, we found no difference in expression between monocytes from patients with active SJIA and those with CID.

Conclusion: These results provide the first report of miRNA expression profiles in children with SJIA. Taken together, these data suggest that differential miRNA expression contributes to the phenotype of monocyte/macrophages in SJIA, and may have implications for disease pathogenesis and development of MAS. Further work will examine impact of miRNA expression on monocyte function and differentiation.

Inhibition of Natural Killer (NK) Cell Cytotoxicity By Interleukin-6 (IL-6): Implications for the Pathogenesis of Macrophage Activation Syndrome. Loredana Cifaldi[1], Giusi Prencipe[2], Ivan Caiello[2], Claudia Bracaglia[2], Raffaele Strippoli[3] and Fabrizio De Benedetti Sr. [2]. [1]Paediatric Haematology/Oncology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [3]Cellular Biotechnologies and Haematology, Sapienza Rome University, Rome, Italy.

Background/Purpose: MAS occurs frequently in patients with active systemic juvenile idiopathic arthritis(s-JIA) and because of the similarities with Haemophagocytic Lymphohistiocytosis (HLH) is classified among secondary HLH. s-JIA is characterized by high levels of Interleukin-6 (IL-6). Impairment of natural killer (NK) cell function and decrease perforin expression have also been reported in sJIA. Aim of this study was to evaluate the effect of IL-6 on NK cell cytotoxic function.

Methods: Following in vivo treatment with poly(I:C), splenic NK cell cytotoxic activity from wild-type (WT) or IL-6 transgenic (IL-6TG) mice was evaluated using the chromium51 release assay. NK cell number, perforin, granzymeB, CD69 and CD107a expression were evaluated by flow cytometric analysis. Human polyclonal NK cells were expanded from peripheral blood mononuclear cells (PBMCs) in co-cultures with the feeder cell line RPMI8866 in the presence of tocilizumab, an IL-6 receptor blocker, or isotype control. IL-6 production in the supernatants of human polyclonal NK cells was measured by ELISA. PBMCs from healthy donors were treated with IL-6. NK cell cytotoxic activity, perforin and CD107a expression were evaluated as above.

Results: Following poly(I:C) administration, in vivo generation of splenic NK cell cytotoxicity was markedly reduced in IL6TG mice compared to WT mice. In IL6TG mice number of NK cells, number of CD69+ NK cells and degranulation were comparable to WT mice. Defective expression of both perforin and granzymeB were found in NK cells from IL6TG mice. High levels of IL-6 were found in the supernatants of human polyclonal NK cells. Neutralization of IL-6 effects with tocilizumab in co-cultures of human PBMCs increased human NK cell cytotoxicity and perforin expression. Addition of IL-6 to human PBMCs decreased perforin expression in NK cells.

Conclusion: Both in vivo in mice and in vitro in humans, IL-6 inhibits NK cytotoxicity down-regulating perforin expression. In patients with prominent inflammatory response, such as that present in s-JIA, high levels of IL-6 may contribute to the induction of MAS also by inhibiting cytotoxicity inducing a defect similar to that of primary HLH.

Mutations in the MTHFR Gene Are Not Associated with Methotrexate Intolerance in Patients with Juvenile Idiopathic Arthritis. Andrea Scheuern, Nadine Fischer, Johannes-Peter Haas and Boris Hugle. German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany.

Background/Purpose: Methotrexate (MTX) is the drug used most frequently in the therapy of juvenile idiopathic arthritis (JIA). However, long-term treatment in children frequently leads to intolerance, with marked revulsion and refusal of treatment. Mutations in the gene for methylenetetrahydrofolate reductase (MTHFR) can lead to increased toxicity of MTX and could possibly represent an initial stimulus for this conditioned response.

The objective of this study was to investigate the relation of common mutations in the MTHFR gene and occurrence of MTX intolerance in pediatric patients with juvenile idiopathic arthritis treated with MTX.

Methods: Consecutive patients admitted to the German Center for Pediatric and Adolescent Rheumatology from October 2012 until April 2014 were included in this study. Inclusion criteria were 1) diagnosis of JIA and 2) treatment with MTX for at least 3 months prior to inclusion. Exclusion criteria were other diseases leading to nausea and/or abdominal complaints, and concomitant medications possibly inducing nausea (excepting biologics and non-steroidal anti-inflammatory drugs). Intolerance to MTX was determined using the validated Methotrexate Intolerance Severity Score (MISS) questionnaire; presence of MTX intolerance was assumed for MISS values of $\geq$ 6. Presence of the two most common mutations in the MTHFR gene (C677T and A1298C) was tested using a polymerase chain reaction assay, as described previously. **Results** were analyzed using descriptive statistics and univariate analysis.

Results: 114 patients were included (71% female, median age at inclusion median 12.6 years, median disease duration 4.1 years). Of those, 49 (43%) showed MTX intolerance. 42% of patients were heterozygous, and 7% homozygous for the C677T mutation of the MTHFR gene, 45% of patients were heterozygous, and 12% homozygous for the A1298C mutation; frequencies of both mutations are comparable to published data. Compared to the homozygous wild type, MTX intolerance was not found significantly more frequent in patients with hetero- and homozygous ($p = 1.000$) or homozygous ($p = 0.125$) C677T mutations, nor in patients with hetero- and homozygous ($p = 0.775$) or homozygous ($p = 0.444$) A1298C mutations. Compound heterozygous mutations for C677T and A1298C were also not found significantly more frequently in patients with MTX intolerance ($p = 0.809$).

Conclusion: Mutations in the MTHFR gene are not found significantly more frequently in JIA patients with intolerance to MTX. Development of MTX intolerance appears not to be causally related to toxicity associated with the MTHFR gene.

Elevated Cardiovascular Disease Burden and Inflammatory Biomarker Levels in Adults with Juvenile Idiopathic Arthritis. Siobhan Crittenden[1], Elizabeth Coulson[1], Vijay Kunadian[2], Wan-Fai Ng[2] and H. E. Foster[3]. [1]Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom, [2]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [3]Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom.

Background/Purpose: Rheumatoid Arthritis (RA) is associated with a 50 % greater cardiovascular mortality rate than the general population, attributable to the increased prevalence of traditional risk factors and inflammatory molecules involved in coronary atherosclerosis. Many young people with Juvenile Idiopathic Arthritis (JIA) have their disease persisting into adulthood. Since persistent systemic inflammation is known to accelerate the atherosclerotic process, individuals with JIA and especially those with persistent inflammation may have a greater cardiovascular risk. This study was to assess the prevalence of traditional cardiovascular risk factors and carotid artery Intima-Media Thickness (cIMT) as a surrogate cardiovascular outcome. Additionally, potential biomarkers for predicting and monitoring of cardiovascular risks will be sought.

Methods: 51 adults with JIA (median age: 34.0 years, range: 18 – 63 years) were recruited from an adult continuity clinic along with 27 age- and gender- matched controls (median age 35.5 years, range: 18 – 62 years). JIA subtypes were defined by ILAR classification. After informed consent, cIMT was examined using B-mode ultrasound by one observer (EJC), and clinical data and blood samples were collected. cIMT images were analysed using the M'ath software package (Intelligence in Medical Technologies). Serum levels of potential cardiovascular risk biomarkers previously indentified in other adult inflammatory arthritides, such as systemic inflammatory and adhesion molecules, were quantified using ELISA kits (R&D Systems) or Cytometric Bead Arrays (BD Biosciences). Data were analysed using FCAP Array software.

Results: A significantly higher proportion of adults with JIA compared to controls had a pre-existing diagnosis of hypertension (12 % vs. 1 %, $p = 0.029$). Mean CRP and cIMT were significantly greater in patients than in controls (9.0 mg/ml vs. 5.6 mg/l, $p=0.006$, and 0.540 mm vs. 0.492 mm, $p=0.039$ respectively), especially among those with systemic JIA and RF+ polyarticular JIA. cIMT correlates with age (Pearson's coefficient 0.67, $p < 0.001$). Serum levels of MPO, IL-12p70, IL-12/23p40, IL-4, IL-8, TNFα and IL-21 were significantly different between the adult JIA and control group. Among the JIA subgroups, the polyarticular JIA group has the highest level of LTA, while the oligoarticular JIA group has the highest level of CD40L. Extended oligoarticular JIA has higher levels of IP10 and IL-8. After correcting for age, hypertension and smoking, IL-12/23p40 ($p < 0.01$) and IL-12p70 ($p = 0.035$) remain independent predictors for the differences in cIMT between patients and controls.

Conclusion: Adults with JIA have increased cIMT, as well as serum levels of CRP and several pro-inflammatory cytokines compared to healthy controls. Furthermore, IL-12p70 and IL-12/23p40 could potentially be used as biomarkers for cardiovascular risk. IL-12 plays an important role in JIA pathogenesis, promoting Th1 response and inflammatory cytokines such as TNFα. It is noteworthy that MPO, which is linked with plaque development, thrombus formation and is a predictor of CVD in healthy individuals, is upregulated in adults with JIA.

Next Generation Sequencing Reveals Restriction of the Treg Cell Repertoire and an Abundance of Shared Synovial Treg Clonotypes in JIA. Lauren A. Henderson[1], Stefano Volpi[1], Francesco Frugoni[1], Susan Kim[1], Robert P. Sundel[1], Fatma Dedeoglu[1], Mindy S. Lo[1], Erin Janssen[1], Melissa M. Hazen[1], Mary Beth Son[1], Ronald Mathieu[1], David Zurakowski[2], Robert C. Fuhlbrigge[1], Jolan E. Walter[3], Yu Nee Lee[1], Peter A. Nigrovic[1] and Luigi D Notarangelo[1]. [1]Boston Children's Hospital, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]Massachusetts General Hospital for Children, Bpstpm, MA.

Background/Purpose: Regulatory T cell (Treg) dysfunction has been documented in juvenile idiopathic arthritis (JIA), but the basis for this lapse in suppressive capacity is incompletely understood. Animal models of autoimmunity demonstrate that a diverse and polyclonal Treg repertoire is essential for immune system homeostasis and Treg cell function. We therefore employed next generation sequencing (NGS) to analyze the repertoires of synovial fluid (SF) and peripheral blood (PB) Treg and effector T cells (Teff) in JIA.

Methods: Paired SF and PB samples were obtained from patients with JIA. Control samples included PB from age-matched, healthy children and SF from patients with Lyme arthritis. Treg ($CD4^+CD25^+CD127^{lo}$) and Teff ($CD4^+CD25^-$) cells were isolated from SF and PB mononuclear cells by fluorescence-activated cell sorting. The T cell receptor (TCR) β chain was amplified by multiplex PCR with genomic DNA serving as the template (ImmunoSEQ™). The PCR products were sequenced using the Illumina HiSeq platform. Subsequently, the data was analyzed using the ImmunoSEQ™ set of online tools, the International ImMunoGeneTics system (IMGT) HighV-QUEST platform, and the Immunoglobulin Analysis Tool (IgAT). The pre-specified primary aim was to evaluate the clonality of SF and PB Treg and Teff populations in JIA patients. Based on data evaluating the Treg repertoire and autoimmunity in animal models, we calculated that a sample size of 5 JIA patients would provide sufficient power for this study.

Results: 5 patients with JIA, 3 healthy controls, and 2 patients with Lyme arthritis were studied. In the PB of controls, the Treg and Teff repertoires were equally polyclonal. In contrast, JIA PB Treg cells were more clonal than control PB Treg, control PB Teff, and JIA PB Teff cells (ANOVA $p<0.0001$ with Bonferroni correction). JIA disease severity, as measured by the active joint count, correlated with the PB Treg clonality ($\rho=0.95$, $p=0.005$). Clonal abnormalities were not observed in the JIA PB Teff repertoire. In SF, JIA Treg cells were significantly more clonal than JIA PB Treg and Teff cells, JIA SF Teff cells, and control PB Treg and Teff cells (ANOVA $p<0.0001$with Bonferroni correction). JIA patients shared a substantial portion of SF Treg clonotypes, significantly more than SF Teff cells (Wilcoxon $p=0.0002$). In some JIA patient pairs, up to 19% of SF Treg clonotypes were shared. Further, these shared SF Treg clonotypes were private to JIA patients and were not identified in Lyme arthritis. In further support of disease specific TCRs in JIA SF, convergent recombination was seen preferentially in the SF Treg compared to the PB Treg compartment (Wilcoxon $p=0.002$). Skewed TCRβ variable family and joining gene usage, including overuse of gene segments that have been associated with other autoimmune conditions, was observed in JIA Treg and Teff cells.

Conclusion: Our data identified an unexpected restriction of the SF and PB Treg repertoires in JIA with sharing of SF Treg clonotypes across arthritis patients. These findings suggest that inadequacy in the Treg repertoire may contribute to Treg cell dysfunction and the perpetuation of inflammation in JIA, possibly in response to shared antigenic triggers.

NLRC4-Related Macrophage Activation Syndrome (NLRC4-MAS): A Novel Primary Autoinflammatory Syndrome Caused By Activating Mutations in NLRC4. Scott Canna[1], Adriana Almeida de Jesus[2], Sushanth Gouni[1], Stephen Brooks[1], Kristien J. Zaal[1], Bernadette Marrero[1], Yin Liu[2], Michael Dimattia[1], Gina A. Montealegre Sanchez[2], Hanna Kim[2], Dawn C. Chapelle[2], Nicole Plass[2], Yan Huang[2], Angelique Biancotto[3], J. Alex Duncan[4], Susanne Benseler[5], John J. O'Shea[1], Alexei A. Grom[6], Zuoming Deng[2], Ronald M. Laxer[7] and Raphaela Goldbach-Mansky[2]. [1]NIAMS/NIH, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [3]NHLBI/NIH, Bethesda, MD, [4]University of North Carolina School of Medicine, Chapel Hill, NC, [5]Alberta Children's Hospital Research Institute/University of Calgary, Calgary, AB, [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [7]The Hospital for Sick Children, University of Toronto, Toronto, ON.

Background/Purpose: Macrophage Activation Syndrome (MAS) is a life-threatening systemic inflammatory complication of many rheumatic diseases and its causes are unknown. While genetic defects causing impaired cytotoxicity result in a similar entity called primary Hemophagocytic Lymphohistiocytosis (HLH), MAS has no known primary genetic cause.

Methods: We performed detailed clinical, genetic, and immunologic evaluation of a patient with early onset, recurrent MAS-like disease including whole exome sequencing, serum cytokine analysis, and whole blood transcriptional profiling. We also tested monocyte and macrophage inflammasome activation, cytokine production, and cell death. We also evaluated the inflammatory effects of this mutation in a transduced monocytic cell line.

Results: We identified a 7 year-old female with recurrent MAS-like episodes, including pancytopenia and hyperferritinemia, since 2 months of age. Genetic testing identified a *de novo* threonine to serine conversion in *NLRC4*, a cytosolic danger sensor, Nod-like Receptor (NLR), and component of the NLRC4 inflammasome. The patient's serum and transcriptional profiles were distinct from NOMID and similar to MAS-prone diseases, with high, constitutive IL-18 elevation. Patient monocytes and monocyte-derived macrophages showed over-production of IL-1β and IL-18, enhanced cell death, and spontaneous ASC aggregate formation. These findings were reproduced in THP1 monocytes constitutively expressing mutant NLRC4. The patient has weaned from steroids and colchicine and has been flare-free after six months of IL-1 receptor antagonist (anakinra) therapy.

Conclusion: Like mutations in NOD2 causing Blau Syndrome and in NLRP3 causing the cryopyrinopathies, activating mutations in the nucleotide-binding region of NLRC4 cause a novel "inflammasomopathy". However, *NLRC4* mutations uniquely manifest as recurrent MAS. Strengthening the NLRC4-MAS association, our findings have been independently corroborated in an unrelated kindred[1]. Ongoing investigation of NLRC4-MAS to determine its unique inflammatory characteristics will shed light on the pathogenesis of MAS and related systemic inflammatory disorders.

Cytokines in Systemic Juvenile Idiopathic Arthritis and Macrophage Activation Syndrome: Tipping the Balance Between Interleukin-18 and Interferon-Gamma. Karen Put[1], Anneleen Avau[1], Ellen Brisse[1], Tania Mitera[1], Stéphanie Put[1], Paul Proost[2], Brigitte Bader-Meunier[3], Rene Westhovens[4], Benoît Van den Eynde[5], Ciriana Orabona[6], Francesca Fallarino[6], Lien De Somer[7], Thomas Tousseyn[8], Pierre Quartier[3], Carine Wouters[7] and Patrick Matthys[1]. [1]University of Leuven, Laboratory of Immunobiology, Rega Institute, Leuven, Belgium, [2]University of Leuven, Laboratory of Molecular Immunology, Rega Institute, Leuven, Belgium, [3]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [4]University of Leuven, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration; Rheumatology, University Hospital Leuven, Leuven, Belgium, [5]Institut de Duve, Université catholique de Louvain, Brussels, Belgium, [6]Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy, [7]University of Leuven, Laboratory of Pediatric Immunology, University Hospital Leuven, Leuven, Belgium, [8]University of Leuven, Department of Imaging and Pathology, Leuven, Belgium.

Background/Purpose: To study the role of interferon-gamma (IFN-γ) in the pathogenesis of systemic juvenile idiopathic arthritis (sJIA) and macrophage activation syndrome (MAS) by searching for an IFN-γ profile and assess its relation with other cytokines.

Methods: Patients with inactive (n=10) and active sJIA (n=10), MAS (n=5) and healthy controls (n=16) were enrolled in the study. Cytokines and IFN-γ-induced proteins were determined in plasma by ELISA and HPLC-MS, in patient peripheral blood mononuclear cells (PBMCs) (qPCR, flow cytometry, western blot and ELISA) and in lymph node biopsies of one patient during both sJIA and MAS episodes (immunohistochemistry). IFN-γ responses were investigated in healthy donor PBMCs, primary fibroblasts and endothelial cells.

Results: Plasma IFN-γ, IL-6 and IL-18 were elevated in active sJIA and MAS. Levels of IFN-γ and IFN-γ-induced proteins (IP-10/CXCL-10, IL-18BP and IDO) in MAS were highly surpassing levels in active sJIA. Free IL-18 and ratios of IL-18/IFN-γ were higher in active sJIA versus MAS. MAS PBMCs showed a hyporesponsiveness to IFN-γ *in vitro*. Endothelial cells and fibroblasts expressed IFN-γ-induced proteins *in situ* in lymph node stainings of a MAS patient and *in vitro* upon stimulation with IFN-γ.

Conclusion: Patients with active sJIA and MAS show distinct cytokine profiles with highly elevated plasma levels of IFN-γ and induced proteins typically found in MAS. In addition to PBMCs, histiocytes, endothelial cells and fibroblasts may contribute to an IFN-γ profile in plasma. Increasing levels of IFN-γ compared to IL-18 may raise suspicion for development of MAS in sJIA.

Myeloid Related Proteins 8 and 14 (MRP 8/14) - Potential Biomarkers of Disease Activity of Arthritis in Children with Trisomy 21. Charlene Foley, Orla Killeen and Emma Jane MacDermott. The National Centre for Paediatric Rheumatology, Dublin, Ireland.

Background/Purpose: JIA is an umbrella term used to describe a heterogeneous group of diseases.To date no specific markers exist in clinical practice to predict disease activity & outcome. MRP8/14 are calcium-binding proteins secreted by infiltrating phagocytes in synovial inflammation.Studies have shown that their serum concentrations correlate sensitively & specifically with synovial inflammation in JIA. It is believed that they are predictive biomarkers that can indicate subclinical disease activity & identify patients at risk of relapse during times of clinically inactive disease.They have also been shown to identify patients more likely to respond to treatment with Methotrexate.To date there have been no studies looking specifically at their use in Down's Arthropathy (DA).

Objectives: To evaluate the use of standard (ESR&CRP) & novel (MRP8/14) inflammatory markers as biomarkers of disease activity in DA & JIA.

Methods: Between May 2013-May 2014 new cases of JIA & DA attending the NCPR had blood drawn to measure their CRP, ESR & MRP 8/14 levels at diagnosis.Corresponding Active Joint Count (AJC) was documented. Paired synovial fluid (SF) samples were taken for analysis from children requiring steroid joint injections as treatment for their arthritis. Serum (Se) & SF concentrations of MRP 8/14 were determined by sandwich ELISA.The reader of laboratory assays was blinded for diagnosis & inflammatory activity.CRP & ESR were measured as part of routine clinical assessment.

Results: 32 children (20 JIA,12 DA) had serum samples taken for CRP, ESR & MRP8/14 levels at diagnosis. 14 of these children had paired synovial fluid samples taken.The average AJC was 4 (range 1–11).Table1 highlights accuracy of each measurement as a marker of disease activity.In DA, a significant correlation was detected between AJC & both ESR and MRP 8/14 (SF).Combining results for the DA & JIA cohort, a significant positive correlation was noted between paired samples of MRP8/14 in Se & SF.

Table 1 *(n=32 Serum, n=14 Synovial Fluid)*

Dx	StatisticalTest	Variable1	Variable2	Correlation	p value
DA	Correlation	Active Joint Count	ESR	Positive	p<0.05
			MRP 8/14 SF	Positive	p<0.05
			CRP	No Correlation	ns
		MRP 8/14 SF	ESR	Positive	p<0.01
JIA & DA	Correlation	MRP 8/14 synovial fluid	MRP 8/14 serum	Positive	p<0.05

Dx	Statistical Test	Variable 1	Variable 2	Outcome	p value
JIA & DA	Paired t test	MRP 8/14 SF	MRP 8/14 Se	SF MRP8/14 signif.higher than matched SeMRP8/14	p<0.01

Conclusion: MRI with contrast remains the gold standard for diagnosis of synovitis.In reality, clinical assessment is the major diagnostic tool.DA is a more challenging condition than JIA, in light of confounding illness & the often-associated non-verbal state.In DA a simple biomarker of disease would be invaluable. We have shown that CRP is a poor marker of disease activity in JIA & DA so the need for a more specific biomarker is evident.Our preliminary results suggest that children with DA have elevated SF levels of MRP 8/14 that correlate to disease activity.SF concentrations of MRP 8/14 are significantly higher than their paired Se samples, however our results show significant positive correlation between the two.This suggests that Se MRP 8/14 levels are potential accurate markers of SF levels.MRP 8/14 may be a useful biomarker of disease activity in DA, aiding timely diagnosis & instigation of appropriate treatment, in turn, helping to improve clinical outcomes for this patient group.

HLA-B27 Subtypes in Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis. Rajni Srivastava, Shikha Agnihotry, Rakesh Aggarwal and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: HLA-B27 has a high degree of genetic polymorphism, with more than 105 known subtypes. Enthesitis Related Arthritis (ERA) is most common form of Juvenile Idiopathic Arthritis (JIA) in Asian and Indian population. It has strong association with HLA B27 similar to the adult ankylosing spondylitis (AS). Since the disease occurs in children and different HLA B27 subtypes confer different susceptibility to AS we studied the HLA-B27 subtypes associated with ERA and AS to see if there is any difference.

Methods: Samples were collected from 135 patients with ERA and 121 patients with AS. Genomic DNA was isolated from whole blood using salting out technique and HLA B27 typing was done using ARMS-PCR. Primers for intronic region of HLA-DR were used as internal control. HLA-B27 subtyping was done by sequencing using a group-specific amplification of the second and third exon region of HLA B27 gene.

Results: Hundred and seven out of 135 patients with ERA (79%) and 102/121 (84%) of AS patients were HLA B27 positive. HLA B*2705 and 04 were the most common subtypes. HLA B2*27:02, 07 and 018 were seen rarely. The frequency of HLAB*27:05 was 70% in ERA as compared to 56.8% in AS (p=0.032) whereas HLAB*27:04 was 21.4% in ERA and 36.2% in AS (p=0.013). No correlation was seen between B*27 subtypes (B*2704 and B*2705) and clinical features of JIA-ERA.

Conclusion: HLAB*27 subtype frequencies are different in ERA and AS. It is possible that the presence of ancestral subtype HLA B*27:05 leads to early onset of disease.

Systemic Juvenile Idiopathic Arthritis and Exposure to Fine Particulate Air Pollution. Andrew Zeft[1], Sampath Prahalad[2], Rayfel Schneider[3], Alexei Grom[4], Fatma Dedeoglu[5], Pamela F. Weiss[6], Carter Mix[7] and C. Arden Pope[7]. [1]The Cleveland Clinic, Cleveland, OH, [2]Emory University, Atlanta, GA, [3]The Hospital for Sick Children, Toronto, ON, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]on behalf of CARRAnet Investigators, Palo Alto, CA, [6]The Children's Hospital of Philadelphia, Philadelphia, PA, [7]Brigham Young University, Provo, UT.

Background/Purpose: Environmental factors are understood to play a pathogenic role in the etiology of Systemic Onset Juvenile Idiopathic Arthritis (SJIA). Fine particulate matter (aerodynamic diameter £2.5-mm cut point, $PM_{2.5}$) is a measurable component of ambient urban pollution, and positive associations of short-term $PM_{2.5}$ exposure with the reported clinical presentation of SJIA in young children have been described in a regional cohort. Our objective was to further establish associations between short-term ambient pollution exposures and the reported clinical event dates of SJIA onset in cases residing from multiple metropolitan regions.

Methods: A case-crossover study design was used to analyze associations of short-term $PM_{2.5}$ exposures with the event date of SJIA symptom onset from cases residing in the metropolitan regions of Boston, Philadelphia, Atlanta, Cincinnati, and Toronto. Time trends, seasonality, month, and weekday were controlled for by matching. Selected exposure windows (up to 14 days) of $PM_{2.5}$ were examined.

Results: Positive, statistically significant associations between $PM_{2.5}$ concentrations and elevated risk of SJIA onset were not observed. The most positive associations of short-term $PM_{2.5}$ exposure with the reported clinical onset of SJIA were in children <5.5 years of age (RR 1.75, 95% CI 0.85–3.62). An ad hoc extended pooled analysis including previously reported cases residing from Utah's metro areas identified an increased risk of SJIA for children <5.5 years of age (RR = 1.76, 95% CI 1.07–2.89 per 10 $\mu g/m^3$ increase in 3-day lagged moving average of $PM_{2.5}$).

Conclusion: Even in this multi-city, multi-period study only small, statistically insignificant $PM_{2.5}$-SJIA associations are observed. However, similar to previously observed results, the $PM_{2.5}$-SJIA association is most suggestive in preschool aged children. More subjects with spatial and temporal specificity may be required by the analysis to demonstrate effects, and further research may be useful in larger numbers of SJIA cases and in geographic areas which experience a greater ambient particulate burden.

Autoantibodies in Juvenile Systemic Sclerosis. Katharine Moore[1], J. Lee Nelson[1], Marvin J. Fritzler[2], Marisa S. Klein-Gitelman[3], Ann M. Reed[4], Tzielan C. Lee[5] and Anne M. Stevens[6]. [1]University of Washington, Seattle, WA, [2]Mitogen Advanced Diagnostics Laboratory, Faculty of Medicine, University of Calgary, Calgary, AB, [3]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [4]Mayo Clinic, Rochester, MN, [5]Stanford University School of Medicine, Stanford, CA, [6]Seattle Children's Research Institute, Seattle, WA.

Background/Purpose: There are no known biomarkers for organ involvement, response to therapy, or prognosis in juvenile systemic sclerosis (jSSc). In adults with systemic sclerosis, a number of serum autoantibodies have been described, many of which have been associated with clinical phenotypes. Knowing the pattern of organ involvement associated with a particular autoantibody can be of benefit, with implications for both treatment and screening. The objective of this study was to determine the frequency and clinical significance of an extended panel of both scleroderma-specific and scleroderma-associated autoantibodies in patients with jSSc.

Methods: Stored plasma samples from 28 pediatric patients with systemic sclerosis, 26 with localized scleroderma and 35 age-matched healthy controls were tested for antinuclear antibodies (ANA) as well as antibodies against Ro52, platelet-derived growth factor receptor, Ku, PMScl-75, PMScl-100, Th/To, hUF/NOR-90, fibrillarin, RP155, RP11, centromere proteins A/B (CENP-A, CENP-B), and topoisomerase I/Scl-70 RNA. The majority of the stored samples were obtained after the initiation of treatment. Line immunoassay was used, with the exception of Th/To, which were assessed for by chemiluminescence.

Results: Of the 28 patients with jSSc, the most common antibodies detected were anti-PMScl-100 (17.9%), anti-Scl-70 (14.3%), anti-CENPB (10.7%) and anti-CENPA (7.1%). Anti-PMScl-75 and anti-RP155 were found in one patient each. By comparison, no autoantibodies were detected in the plasma from either healthy pediatric controls or juvenile localized scleroderma patients, except for ANA in five (17.9%) of the localized scleroderma samples and one control. Of the patients with jSSc, 15 (53.6%) were ANA positive but negative for both anti-Centromere (CENP-A /B) and Ant-Scl70. Of these, three carried antibodies to PMScl-100. There were no significant differences in antibody profile between limited and diffuse systemic disease, or with specific clinical disease manifestations.

Conclusion: In this cohort, the presence of autoantibodies targeting PMscl-100, Scl-70, and CENPA/B were highly specific for systemic sclerosis compared to localized scleroderma or controls. Testing for PMscl-100 helped capture additional patients who were ANA positive but anti-Centromere/anti-Scl70 negative, but there remained jSSc patients with ANA of unknown antigen specificity. Furthermore, the association of autoantibodies with systemic but not with localized scleroderma reinforces the concept of two distinct disease processes.

Mutations of Familial Hemophagocytic Lymphohistiocytosis (FHL) Related Genes and Abnormalities of Cytotoxicity function tests in Patients with Macrophage Activation Syndrome (MAS) Occurring in Systemic Juvenile Idiopathic Arthritis (sJIA). Claudia Bracaglia[1], Elena Sieni[2], Martina Da Ros[2], Carmela De Fusco[3], Concetta Micalizzi[4], Valentina Cetica[2], Benedetta Ciambotti[2], Maria Luisa Coniglio[2], Antonella Insalaco[1], Fabrizio De Benedetti Sr. [1] and Maurizio Arico' Sr. [5]. [1]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Department of Pediatric Hematology-Oncology, Meyer Children's Hospital, Florence, Italy, [3]Department of Pediatric Hematology-Oncology, Pausillipon Children's Hospital, Naple, Italy, [4]Department of Pediatric Hematology-Oncology, G. Gaslini Children' s Hospital, Genoa, Italy, [5]Istituto Toscano Tumori (I.T.T.), Florence, Italy.

Background/Purpose: MAS is a severe complication of rheumatic diseases, mostly sJIA. Clinical and laboratory features are similar to those of FHL resulting from mutations in selected genes involved in the cytotoxicity pathway. We investigated the presence of mutations of FHL-related genes and of abnormalities in degranulation and perforin expression, in patients with MAS occurring in the context of sJIA.

Methods: From the HLH Italian National Registry, we selected patients with MAS defined according to the HLH 2004 criteria and with confirmed diagnosis of sJIA based on ILAR criteria. Mutation analysis was performed by Sanger sequencing of FHL-related genes. Perforin expression and degranulation were analyzed using flow-cytometry.

Results: We identified 31patients (17 females; 25 Southern European, 6 Indian) with MAS and sJIA. Eleven patients (35.5%) had 14 monoallelic mutations in *PRF1* (n=7), *UNC13D* (n=1), *STX11* (n=1), *STXBP2* (n=4), and *Rab27a* (n=1). Three patients had mutations in 2 genes. Both degranulation and perforin expression were evaluated in 18 patients. At least one test was defective in 11 patients (61%). The clinical and laboratory features of patients with monoallelic mutation and/or with abnormalities in at least one functional test, were not different from those of the remaining patients. However, re-occurrence of MAS tended to be more frequent in patients carrying mutations (mutated 27% versus non-mutated 10%) and in patients showing abnormalities in at least 1 functional test (abnormal 18% versus 0%). One patient died of MAS: she carried the N252S *PRF1* variant and showed reduced perforin expression.

Conclusion: Monoallelic mutations in FHL-related genes and partial defect in either perforin expression or degranulation capacity are frequently observed in patients with sJIA who develop MAS. Additional genetic studies are warranted to identify additional genes potentially linked to MAS development.

Superior Therapeutic Efficacy of a Novel Oral Small Molecule Retinoic Acid Receptor-Related Orphan Receptor Gamma T [Rorgt] Inverse Agonist Inv-17: A Promising Safe & Efficacious Treatment for Rheumatoid Arthritis. Anderson Gaweco[1], Samantha Palmer[1], Rambon Shamilov[1], Caroline Stremnitzer[1], Katie Matthews[1], Michael Fisher[1], William Windsor[1], James Blinn[1], Ellen M. Ginzler[2] and Jefferson Tilley[1]. [1]Innovimmune Biotherapeutics, Brooklyn, NY, [2]SUNY-Downstate Medical Center, Brooklyn, NY.

Background/Purpose: T helper 17 [T_H17] cells and its production of T_H17 cytokines IL-17A and IL-17F play a critical role in the pathogenesis of RA and collagen-induced arthritis [CIA]. Retinoic acid receptor-related orphan receptor gamma t [RORgT] is a nuclear hormone receptor that specifically regulates T_H17 cells by acting as a control switch for T_H17 differentiation, function and cytokine production. Lead development efforts of several proprietary novel chemical scaffolds of the INV-17 portfolio of small molecule RORgT inverse agonists led to the identification of an INV-17 clinical compound candidate demonstrating potent *in vitro* pharmacological effects against T_H17 cells and cytokines coupled with optimal druggable properties. To establish the preclinical Proof of Concept in RA prior to advancing to IND-enabling development, the *in vivo*treatment efficacy of INV-17 was assessed in the mouse CIA model.

Methods: Disease was induced in DBA1 mice according to a standard protocol. Prior mouse *in vivo*pharmacokinetic [PK] studies determined the optimal oral bioavailability and drug exposure of INV-17 enabling p.o. dosing in this study. To assess the preclinical efficacy in a mouse CIA model, INV-17 was administered orally for 28 days as a therapeutic treatment regimen following chicken collagen CII/CFA disease induction on day 0 and CII/IFA booster immunization on day 15 in DBA1 mice. Upon disease-onset, mice with a clinical arthritis score > 1 (Scale: 0–16) were randomized to receive 28-day dosing with INV-17 at 30 mg/kg (n=10) or comparator controls: Vehicle (n=11) or Dexamethasone [Dex] (n=9).

Results: Successful disease amelioration following INV-17 and Dex treatments was observed with statistically significant reduction of cumulative arthritis score of 6.02 +/− 0.26 [mean +/− SEM] ($p<0.001$) and 0.42 +/− 0.2 ($p<0.001$), respectively, in contrast to the vehicle group of 8.81 +/− 0.43. Significant improvement in clinical disease scores in INV-17 treated mice was evident starting on arthritis day 13 ($p=0.04$) with maximal therapeutic effects observed on arthritis day 16 ($p=0.0007$) through day 26 ($p=0.0003$) until end of study ($p=0.01$). INV-17 drug levels were assessed in peripheral blood and hind joints confirming optimal INV-17 pharmacokinetic exposures and oral bioavailability. INV-17 was well tolerated and INV-17-treated mice were unremarkable with optimal body conditions.

Conclusion: The superior safety and therapeutic efficacy data following 28-day treatment of an orally bioavailable small molecule INV-17 clinical candidate compound provide the first report establishing the preclinical POC in RA with pharmacological intervention of RORgT inverse agonism. This compelling evidence supports advancing INV-17 into IND-enabling development stage and highlights the potential promise of INV-17 as a safe & efficacious novel RA DMARD treatment.

Anti-Inflammatory Marine Compound, Lyy-B2, Ameliorates Rheumatoid Arthritis through Inhibition of Osteoclast Differentiation. Yen-You Lin[1], Hsin-Pai Lee[1], Shi-Ying Huang[1], Han-Chun Hung[1], Chien-Wei Feng[1], Chun-Hong Chen[1], Jui-Hsin Su[2], Ping-Jyun Sung[3], Jyh-Horng Sheu[1], Yen-Hsuan Jean[4] and Zhi-Hong Wen[1]. [1]National Sun Yat-Sen University, Kaohsiung, Taiwan, [2]National Dong Hwa University, Pingtung, Taiwan, [3]National Museum of Marine Biology & Aquarium, Pingtung, Taiwan, [4]Pingtung Christian Hospital, Pingtung, Taiwan.

Background/Purpose: Osteoclasts are multinucleated giant cells of macrophage/monocyte lineage, and are believed to play major roles in joint destruction caused by rheumatoid arthritis (RA). Nuclear factor of activated T cells, cytoplasmic 1 (NFATc1) is a key transcription factor which up regulates the osteoclastic-related protein expression of cathepsin K, matrix metalloproteinase-2 (MMP-2), matrix metalloproteinase-9 (MMP-9), and tartrate-resistant acid phosphatase (TRAP), and promotes osteoclast differentiation resulting in bone resorption. In recent years, a significant number of natural products with anti-inflammatory activity have been discovered from marine organisms, and several of these compounds are now under clinical trials. In the present study, we evaluated a culture of LYY-B2, a soft coral-derived compound with anti-inflammatory and anti-arthritic properties.

Methods: We used lipopolysaccharide (LPS)-stimulated murine macrophages to evaluate the anti-inflammation and anti-osteoclast formation properties of LYY-B2, *in vitro*. Lewis rats (180–220g) were used to evaluate the possible effects of LYY-B2, *in vivo*, on adjuvant-induced arthritis (AIA) and collagen-induced arthritis (CIA) animal models. We also examine the joint features of LYY-B2 attenuation of RA by histology and immunohistochemistry.

Results: LYY-B2 significantly inhibited pro-inflammatory induced nitric oxide synthase protein expression in LPS-stimulated macrophages. Moreover, it also attenuated multinucleated cell formation, osteoclast-related gene expression (MMP9 and cathepsin K) and expression of osteoclast-related proteins (TRAP and actin ring). Our animal experiments revealed that LYY-B2 (5mg/kg) significantly inhibited AIA and CIA joint characteristics in rats. Moreover, using histological analysis, we have found that LYY-B2 also improved the histopathologic features of RA. Immunohistochemical results show that LYY-B2 inhibited expression of osteoclast-related proteins cathepsin K, MMP 2, MMP 9, CD11b, and NFATc1 in ankle tissues of AIA- and CIA-rats.

Conclusion: The present findings indicated that LYY-B2 could be of potential use as a therapeutic agent to treat rheumatoid arthritis through inhibition of osteoclast differentiation.

Regulation of TNF-α-Mediated Activation of Rheumatoid Synovial Fibroblasts By Transcription Factor Snail. Chrong-Reen Wang, Shih-Yao Chen, Ai-Li Shiau, I-Ming Jou, Ming-Fei Liu and Chao-Liang Wu. National Cheng Kung University Medical College, Tainan, Taiwan.

Background/Purpose: Transcription factor Snail plays active roles in various biological functions and is involved in many disease states. We hypothesized that this molecule regulates TNF-α-mediated activation of rheumatoid synovial fibroblasts (SF), and examined its roles in expression of Cadherin-11 (Cad-11) and α-smooth muscle actin (α-SMA, a myofibroblast marker), invasive ability and IL-6 production.

Methods: Synovial tissues were obtained from patients with rheumatoid arthritis (RA), a diagnosis according to 2010 RA classification criteria, and an experimental arthritis model of collagen-induced arthritis (CIA) in rats. SF were treated with TNF-α or a Wnt signaling inducer, and CIA joints were injected with a TNF-α antagonist. The expression of Snail in SF and joints was modulated by lentiviral vector-mediated transfer of cDNA or short hairpin RNA.

Results: There were higher expression levels of Snail and Cad-11 with a positive correlation in synovial tissues from RA patients and CIA rats. Stimulation with TNF-α or activation of Wnt signaling up-regulated the expression levels of Snail, Cad-11 and α-SMA in SF, and TNF-α antagonist therapy down-regulated their expression levels in CIA joints. While Snail-overexpressed SF transfectants had increased expression levels of Cad-11 and α-SMA and enhanced TNF-α-mediated invasive capacity and IL-6 production, Snail-knockdowned CIASF transfectants had decreased expression levels and the opposite effect on these functions. In addition, Snail-overexpressed normal rat joints had hyperplastic synovium with increased expression levels of Cad-11 and α-SMA. In CIA joints, silencing the expression of Snail ameliorated arthritis with reduced Cad-11 expression and extracellular matrix (ECM) deposition, whereas overexpressing Snail exacerbated arthritis with increased Cad-11 expression and ECM deposition.

Conclusion: This study demonstrates for the first time that transcription factor Snail regulates TNF-α-mediated activation of rheumatoid SF, and these findings might contribute to the pharmacological development of therapeutics targeting SF in RA patients.

Tadalafil Decreases Joint Inflammation in TNF-Tg Mice By Restoring Passive Lymphatic Transport. Echoe M. Bouta[1], Igor Kuzin[2], Ronald Wood[3], Christopher T. Ritchlin[3], Andrea Bottaro[2] and Edward M. Schwarz[1]. [1]University of Rochester, Rochester, NY, [2]Cooper Medical School, Camden, NJ, [3]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease with enigmatic episodic flares. Using longitudinal imaging, we recently demonstrated that arthritic knee flare in tumor necrosis factor transgenic (TNF-Tg) mice is associated with the loss of the lymphatic pulse and B-cell clogging of the lymphatic sinuses in the adjacent popliteal lymph node (PLN), which is ameliorated by B-cell depletion therapy that restores passive lymphatic flow from inflamed joints. To test the hypothesis that similar efficacy can be obtained via vasodilatory therapy that opens lymphatic vessels parallel to the clogged PLN, we evaluated the effects of tadalafil, a FDA-approved PDE5 inhibitor, on lymphatic transport, synovitis and bone erosion in TNF-Tg mice experiencing knee flare.

Methods: TNF-Tg mice with collapsed PLN underwent contrast enhancement MRI (CE-MRI), power Doppler (PD) ultrasound, near infrared indocyanine green (NIR-ICG) imaging prior to and after treatment via gavage every other day with tadalafil or placebo for six weeks.

Results: Fold change in ICG clearance from the footpad, a marker of lymphatic transport, was found to be higher in tadalafil treated animals compared to placebo (15.62$\pm$23.25 vs. 2.77$\pm$1.17) (Figure 1A and B). As expected, lymphatic contraction frequency decreased over time in the placebo and tadalafil treatment groups, consistent with progression of the disease and lymphatic dilation respectively. Lymph node contrast enhancement (LNCE), an alternative biomarker of lymphatic transport to the PLN that is measured via CE-MRI, decreased slightly (0.87$\pm$0.10 fold change) in the placebo group, indicating further PLN collapse. In contrast, tadalafil induced a slight increase (1.05$\pm$0.12 fold change) in LNCE, indicating a halt in PLN collapse. Additionally, mice treated with tadalafil showed a greater PLN volume compared to placebo (15.56$\pm$10.15 mm^3 vs. 9.97$\pm$6.09 mm^3), indicative of increased transport to the PLN. PD within the joint, a measure of inflammation, was found to be significantly lower after tadalafil treatment compared to placebo (0.011$\pm$0.01 mm^3 vs. 0.08$\pm$0.02 mm^3) (Figure 1C). Placebo treated animals were shown to have a 1.36$\pm$0.23 fold change in knee synovial volume, while tadalafil treatment showed a lower fold change, 0.95$\pm$0.28 (Figure 1D).

Conclusion: Tadalafil treatment increases passive lymphatic transport, as evidenced by increased ICG clearance, PLN volume and LNCE; in conjunction with decreased lymphatic contraction. In addition, this increase in lymphatic transport results in decreased PD volume within the joint, indicative of decreased joint inflammation. These results in addition to flow cytometry and histology of joints and PLNs will be presented.

IL-1 Receptor Antagonis (IL-1Ra)-Fc Ameliorate Autoimmune Arthritis By Regulation of the Th17 Cells/Treg Balance and Arthrogenic Cytokine Activation. Hong Ki Min[1], Sung Hwan Park[2], Mi-La Cho[3], Ji Hyeon Ju[1], Seung-Ki Kwok[1], Seon-Yeong Lee[3], Seung Min Jung[1], Kyung-Su Park[4] and Jennifer Lee[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [3]Catholic University of Korea, Seoul, South Korea, [4]St. Vincent Hospital, SuWon Gyeonggi-do, South Korea.

Background/Purpose: IL-1β signalling has critical role on pathogenesis of various inflammatory arthritis including rheumatoid arthritis (RA). We aimed to investigate the therapeutic effects of human IL-1 receptor antagonist with Fc fragment (hIL-1Ra-Fc) on autoimmune arthritis and find out the possible mechanisms by which hIL-1RA-Fc has anti-arthritic effects in a murine model of RA and arthritis patient.

Methods: Collagen-induced arthritis (CIA) murine model was induced in DBA/1J mice. The levels of various cytokines were determined by using enzyme-linked immunosorbent assay. The joints of mouse were assessed for clinical arthritis score and histologic features. Th17 cells and Treg cells were stained by using antibodies specific for CD4, IL-17, CD25, and FoxP3. Osteoclastogenesis was determined by TRAP stain and real-time PCR.

Results: hIL-1RA-Fc reduced the clinical arthritis, histological inflammation and cartilage score in CIA model. The expression of proinflammatory cytokines, VEGF, and RANK were reduced in affected joint of hIL-1Ra-Fc treated mice. hIL-1Ra-Fc treated mice showed decreased number of Th17 cells with increased Treg cells in spleens. hIL-1Ra-Fc reduced Th17 cell differentiation by inactivation of STAT-3 signalling, reciprocally induced Treg cell differentiation through STAT-5 signalling. In addition, Suppression of gene expression of IL-17, TNF-α, RANKL and VEGF were decreased, while increased Foxp3 gene expression in PBMC of RA patients after administration of hIL-1Ra-Fc.

Conclusion: The anti-arthritis effects of hIL-1RA-Fc are associated with regulating balance between Th17 cells and Treg cells and with suppressing osteoclastogenesis and angiogenesis in affected joints.

AMPK Activation in Inflammatory Arthritis. Monica Guma[1], Yun Wang[2] and Ru Liu-Bryan[2]. [1]University of California, San Diego, La Jolla, CA, [2]UCSD/VAMC, La Jolla, CA.

Background/Purpose: AMP-activated protein kinase (AMPK) is a serine/threonine protein kinase involved in the regulation of cellular energy homeostasis. It is a central regulator of both lipid and glucose metabolism. Many studies have suggested that AMPK activation can also exert significant anti-inflammatory and immunosuppressive effects. We evaluated whether modulating this pathway altered pathogenic mechanisms in inflammatory arthritis.

Methods: The AMPK agonist A-769662 (60mg/kg/bid) was tested in two arthritis models: In antigen induced arthritis (AIA), mice were primed with mBSA in complete Freund's adjuvant and then given an intraarticular challenge with mBSA in the knee on day 21. In passive serum arthritis, K/BxN serum was injected on day 0. Joints were harvested and prepared for histological assessment. IL-6 expression in joints and sera was measured by ELISA. Human fibroblast-like synoviocyte (FLS) and bone marrow derived macrophage (BMDM) function was tested using A-769662 (250uM) as follows: 1) phosphorylation of p65 NF-kappaB by Western Blot, 2) IL-6 secretion by ELISA, 3) NO secretion by Griess method, 4) cell survival in H_2O_2 treated cells by phase contrast light microscopy.

Results: AMPK pathway activation by A-769662 reduced inflammatory infiltration and joint damage in both animal models. In passive K/BxN model, day 8 scores were 8.2 ± 3 and 2.4 ± 3 ($P<0.05$) for vehicle and A-769662-treated mice, respectively. In AIA model joint histology scores for vehicle and A-769662-treated mice for synovial hypertrophy were 2.9 ± 0.9 and 1.6 ± 1.1 ($p=0.01$), bone erosion scores were 2.2 ± 1 and 1.5 ± 1.1 ($p<0.05$), and cartilage damage scores were 2 ± 0.6 and 1.2 ± 0.6 ($p<0.05$), respectively. IL-6 expression in serum and arthritic joints was significantly decreased in A-769662 treated mice. The mechanism of AMPK action was evaluated in FLS and BMDM. AMPK activation with A-762664 reduced IL-6 and NO secretion by $52\pm5.6\%$ and 76 ± 7.5 %respectively ($p<0.05$), and p65 NF-kappaB phosphorylation after TLR stimulation in BMDM. Additionally, AMPK activation also significantly increased H_2O_2-induced apoptosis in FLS.

Conclusion: Activating AMPK pathway suppressed inflammatory arthritis in mice as well as IL-6 expression in serum, arthritic joints and cultured BMDM. These data suggest that AMPK signaling activation could be an effective therapeutic strategy for IL-6 dependent inflammatory arthritis.

Etanercept, Abatacept and Anakinra Treatment Ameliorates Inflammation and Pain in a Novel Mono-Arthritic Multi-Flare Model of Streptococcal Cell Wall Induced Arthritis: Further Characterization in a Rodent Model of Collagen Induced Arthritis. Kalyan Chakravarthy, Robert Faltus, Anwar Murtaza and Milenko Cicmil. Merck Research Laboratories, Boston, MA.

Background/Purpose: We developed a novel mono-arthritic multi-flare Rat Streptococcal Cell Wall (SCW) model which captures certain aspects of disease with flares and remission of inflammation similar to Rheumatoid Arthritis (RA). To delineate the role of TNF, T cells, and IL-1 in pathogenesis of SCW-induced arthritis, we investigated the activity of clinical agents, Etanercept, Abatacept and Anakinra. Comparative evaluation of these targeted therapies was also performed in the rat Collagen Induced Arthritis (CIA) model.

Methods: SCW arthritis was induced in female Lewis rats with an intra-articular injection in the hind ankle joint on day 1 (flare 1) followed by two intravenous challenges on days 21 (flare 2) and 42 (flare 3) of SCW extract PG-PS 100p. CIA was induced using methods previously described in literature. Inflammation and pain were monitored by measuring paw swelling (mechanical calipers) and withdrawal threshold (von-Frey assay) respectively. Additional biomarkers assessed by cytokine profiling, cell phenotyping, bioluminescence/μCT imaging and histopathology were also performed in the local joint.

Results: In the SCW model late prophylactic administration of Etanercept, Abatacept and Anakinra significantly inhibited paw swelling by $\geq60\%$ ($p<0.001$), $\geq60\%$ ($p<0.001$), 88% ($p<0.001$) and pain by 37% ($p<0.05$), $\geq28\%$ ($p<0.05$) and 64% respectively in flare 2. Etanercept in flare 3 inhibited paw swelling by 60% ($p<0.001$) and partially inhibited pain by 27%. Interestingly, prior treatment with Etanercept in flare 2 followed by a wash out period of 14 days and re-administration in flare 3 led to a loss in efficacy, potentially due to immunogenicity. Abatacept administration in flare 3 had no effect on either paw swelling or pain in rats that were treated in flare 3 alone or in rats that were treated previously in flare 2. In the CIA model, both late prophylactic and therapeutic treatment with Etanercept inhibited paw swelling by 50% ($p<0.001$). A loss of efficacy with Etanercept was also observed in the CIA model when administered prophylactically possibly due to immunogenicity. Prophylactic, late prophylactic and therapeutic administration of Abatacept in the CIA model significantly inhibited paw swelling by 100% ($p<0.001$), 42% ($p<0.001$) and 34% ($p<0.001$) respectively. The additional biomarkers corroborated with efficacy in both models.

Conclusion: We developed a novel multi-flare SCW model that can be used to evaluate clinically relevant parameters of inflammation and pain simultaneously. Using clinical agents Etanercept, Abatacept and Anakinra targeting TNF, T cells and IL-1 respectively we have delineated distinct pathogenic mechanisms of inflammation and pain at different stages of disease in the SCW model. We also show similar profiles of efficacy in late prophylactic and therapeutic regimens in the CIA model. The flaring mechanism in the SCW model allows for drug washout periods in between compound administration. This might provide useful pre-clinical insights on potential immunogenicity mechanisms that may be relevant in a clinical setting. Our novel model can facilitate innovative assessment of anti-rheumatic agents in multiple flares and offers a powerful tool for drug discovery.

A Novel, Small Molecule Cyclin-Dependent Kinase 4/6 Inhibitor As the New Option for Treatment of Rheumatoid Arthritis. Hiroshi Takahashi[1], Tsuyoshi Mizuno[1], Toshimichi Nakamura[1], Yuri Sakai[1], Yumiko Muroga[1], Kyohei Horie[1], Naoki Hase[1], Hitoshi Kohsaka[2] and Tsuyoshi Kimura[1]. [1]Teijin Pharma Limited, Hino, Tokyo, Japan, [2]Tokyo Medical and Dental University (TMDU), Tokyo, Japan.

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is characterized by infiltration of immune cells to the synovial tissues and their hyperplasia. Therapeutic strategies to inhibit proin-

flammatory cytokines or immune cells with biological agents and methotrexate are the mainstay in the current treatment of RA. However, they cannot induce complete remission in all of the patients. Combination therapy of two biologics such as etanercept and abatacept failed to show the synergistic effects. Cyclin-dependent kinases (CDK) are key regulators of the cell cycle progression, and several CDK inhibitors have been developed for treatment of cancer. Recently, it was reported that cell cycle inhibition of synovial fibroblasts with a small molecule CDK4/6 inhibitor ameliorated progression of arthritis without attenuating acquired immune responses in an animal model of RA. Although CDK4/6 is thus an attractive target for treatment of RA, its inhibitors have not yet been developed for clinical use in RA treatment. In this study, we show that we have developed a novel and potent CDK4/6 inhibitor, Compound T and its derivatives for RA treatment. We examined Compound T for its anti-arthritic effects in monotherapy and in combination therapy with TNF blockade in animal models of RA.

Methods: Novel synthetic compounds were evaluated in kinase assays to determine in vitro CDK4/6 inhibitory activity and selectivity for CDKs and other kinases. The effects of these compounds on cell cycle were tested by the SubG1 method. Pharmacokinetic (PK) studies and hERG channel binding assay were performed to determine PK and safety profiles of the test compounds. In vivo efficacy of Compound T was tested in collagen induced arthritis (CIA) as well as anti-collagen antibody induced arthritis (CAIA) of mice. Compound T was orally administered to both models to see the effects on the arthritis score. The effect of combination treatment of Compound T with etanercept was tested in the CAIA model.

Results: Compound T inhibited CDK4 and 6 potently (IC50 is about 1 nM) and selectively to other kinases in the cell free assay. Compound T inhibited cell cycle at the G0/G1 phase without inducing cell death in the cell based assay. Oral administration of Compound T alone suppressed the arthritis score, compared to vehicle treatment, in the CAIA and CIA models. In the CAIA model, combination of oral Compound T with intraperitoneal etanercept synergistically suppressed the progression of arthritis compared to monotheray with Compound T or with etanercept at maximum effective dose. In hERG binding assay, Compound T had binding activity at the high concentration range, but several compounds among its derivatives showed low binding affinity against hERG.

Conclusion: Compound T we synthesized is a potent inhibitor of CDK4/6 and selective to other kinases. Oral treatment with Compound T suppressed the arthritis score in both CAIA and CIA models of mice. CDK4/6 inhibitors should offer a new option for better treatment of RA.

Prolactin Reduces Bone Erosion in Adjuvant-Induced Arthritis. Maria G. Ledesma-Colunga, Norma Adan, Ana L. Reyes-Lopez, Fernando Lopez-Barrera, Gonzalo Martinez de la Escalera and Carmen Clapp. Institute of Neurobiology, National University of Mexico (UNAM), Queretaro, Mexico.

Background/Purpose: Bone erosion is an important feature of rheumatoid arthritis (RA) that frequently results in lifelong crippling. The receptor activator of NFkB ligand (RANKL)/osteoprotegerin (OPG)/RANK receptor (RANK) system triggers bone loss in arthritis and is activated by proinflammatory cytokines such as TNFa. Prolactin (PRL), the hormone essential for lactation, may protect against bone loss in RA. PRL stimulates bone formation and frequently increases in the circulation of patients with RA. Moreover, hyperprolactinemia reduces chondrocyte apoptosis, proinflammatory cytokine expression, pannus formation, joint swelling, and pain in adjuvant-induced arthritic (AIA) rats (Adan et al., J Clin Invest 123:3902, 2013). Here, we investigate whether eliciting hyperprolactinemia before or after inducing AIA reduces the systemic levels of TNFa and inhibits the expression of the RANKL/OPG/RANK system and bone erosion in arthritic ankle joints.

Methods: Progression of inflammation (joint swelling) was analyzed in rats implanted or not with osmotic minipumps delivering PRL beginning 3 days before of 15 days after the injection of Complete Freunds' adjuvant (CFA). At maximal inflammation (21 days post CFA), bone erosion was evaluated histochemically, RANKL/OPG/RANK, TNFa, and PRL receptor (PRLR) mRNA levels in arthritic joints were quantified by qRT-PCR; and systemic TNFa protein levels were determined by ELISA.

Results: Expression of the PRLR was significantly elevated in the joints of AIA rats. Treatment with PRL before or after inducing AIA reduced local (hind paw) expression and serum levels of TNFa. Moreover, PRL reduced the AIA-induced increase of RANKL and RANK expression in joints, but did not modify that of the RANKL inhibitor OPG. Consistent with these findings, treatment with PRL before inflammation onset significantly reduced the AIA-induced loss of cortical and trabecular bone.

Conclusion: PRL-induced down-regulation of TNFa/RANKL/RANK expression may protect against bone destruction in arthritis, supporting the therapeutic potential of hyperprolactinemia in RA. Funded by UNAM grant IN200312.

Improvement of the Stability of RNA Aptamers Against Interleukin-17A. Natsuki Otaki[1], Asako Sasaki[1], Shinsuke Hiramoto[1], Masakazu Nagamine[1], Shigeyuki Mori[1], Tomoyoshi Kayo[1], Kuniyoshi Hota[1], Masayuki Takahashi[1], Kazuhiko Haruta[1] and Yoshikazu Nakamura[2]. [1]Zenyaku Kogyo Co., Ltd., Tokyo, Japan, [2]RIBOMIC Inc., Tokyo, Japan.

Background/Purpose: Aptamers are RNA or DNA oligonucleotides selected for their capacity to specifically bind and inhibit the function of a target protein. The effect is similar to neutralizing antibodies that defend the body against pathogenic antigens. These potentially therapeutic oligonucleotides often have short half-lives, however, because they are rapidly degraded by nucleases in peripheral blood and excreted by the kidneys. Here we describe an RNA aptamer against IL-17A that resists degradation in serum and decreases the severity of collagen-induced arthritis in DBA/1 mice.

Methods: *In vitro assay of serum stability*. After substituting a methoxy group for the 2′ hydroxyl group of ribose, we incubated the RNA aptamers in mouse serum for 0.5 to 72 hours at 37°C. Controls were incubated in phosphate buffered saline. Next, samples were added to quenching buffer (8 M urea, 10 mM EDTA, 0.05% bromophenol blue). Then, the RNA fragments were electrophoresed in 20% polyacrylamide gels that contained 8 M urea in TBE buffer. Bands were visualized by staining the gel with SYBR Green II. Each fraction of intact aptamer was normalized to its corresponding control. *Pharmacokinetic studies in mice.* Aptamers were PEGylated with 40-kDa polyethylene glycol and conjugated with 3′-inverted deoxythymidine. Then, these aptamers were infused as a single bolus into the tail vein of a C57BL/6J *mouse* at 1 mg/kg. Aptamer concentrations in plasma were measured by enzyme-linked oligosorbent assay. *Collagen-induced arthritis in mice.* Mice were immunized with bovine type II collagen in Freund's complete adjuvant on day 1. On day 22, they were boosted with bovine type II collagen in Freund's incomplete adjuvant. PEGylated aptamers were injected intraperitoneally at 5 mg/kg once a day from day 22 to day 37. Objective signs of arthritis for each paw were scored using a scale of 0 to 4.

Results: *In vitro* assay of aptamer 17M-340 for serum stability showed very little degradation after 72 hours incubation. By contrast, prototype aptamer Apt21-2 or 17M-4 were rapidly degraded within 24 hours. *In vivo*, the plasma half-life of 17M-340 was 9.3 hours, more than ten-fold that of 17M-4. Finally, intraperitoneal injection of 17M-340 but not 17M-4 reduced the objective score of collagen-induced arthritis significantly ($p \leq 0.05$).

Conclusion: The anti-IL-17A aptamer is 31-base oligoribonucleotide that forms a stem-loop structure. Substitution of a methoxy group for the 2' hydroxyl group of ribose at three positions in the stem and one position in the loop markedly increased stability of the aptamer *in vivo*. Our findings raise the

possibility that RNA aptamers such as 17M-340 may be effective treatments for patients with chronic inflammatory diseases.

Deletion of the Prolactin Receptor Aggravates the Course of Antigen-Induced Arthritis. Norma Adan, Maria G. Ledesma-Colunga, Ana L. Reyes-Lopez, Fernando Lopez-Barrera, Gonzalo Martinez de la Escalera and Carmen Clapp. Institute of Neurobiology, National University of Mexico (UNAM), Queretaro, Mexico.

Background/Purpose: Prolactin (PRL), the hormone essential for lactation, may protect against joint damage in rheumatoid arthritis. PRL frequently increases in the circulation of patients with rheumatoid arthritis, and eliciting hyperprolactinemia in rats before or after inducing the adjuvant model of inflammatory arthritis reduced chondrocyte apoptosis, proinflammatory cytokine expression, pannus formation, joint swelling, and pain (Adan et al., J Clin Invest 123:3902, 2013).

Methods: To better understand the role of PRL in inflammatory arthritides, antigen-induced arthritis (AIA) was induced in PRL receptor-deficient ($Prlr^{-/-}$) mice from two susceptible genetic backgrounds (C57BL/6 and 129Svj). On day 0, preimmunized or control animals were injected into the knee joint with methylated-BSA antigen (mBSA) or vehicle, respectively, and parameters of inflammation were evaluated at days -1, +1, +3, and +5 post-mBSA.

Results: In the 129Svj strain, $Prlr^{-/-}$ mice showed an earlier onset of AIA but similar clinical severity (joint swelling and pain) compared to wild type mice. However, PRLR-deficient mice had a two-fold increase in synovial hyperplasia and higher levels of circulating IL-6. In the C57BL/6 strain, $Prlr^{-/-}$ mice displayed similar joint swelling but increased mechanical allodynia compared to $Prlr^{-+/+}$ mice. Consistent with augmented pain, a two-fold enhanced synovial hyperplasia occurred in the absence of the PRLR, although circulating levels of IL-6 were similar between $Prlr^{-/-}$ and $Prlr^{-+/+}$ mice.

Conclusion: Loss of the PRLR correlates with an aggravated AIA phenotype with different symptoms depending on the genetic background. These findings support the protective role of the PRL system in inflammatory arthritis. Work supported by UNAM-Grant IN200312.

Inflammatory Arthritis in K/BxN Mice Is Associated with Abnormal HDL Function. C. Charles-Schoeman, Ani Shahbazian, Yuen Yin Lee and Srinivasa T. Reddy. UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: Patients with rheumatoid arthritis (RA) have significantly increased cardiovascular (CV) morbidity and mortality. Abnormal function of high density lipoprotein (HDL) has been implicated as a mechanism for this increased CV risk. The current work investigated HDL function in the K/BxN mouse model of RA.

Methods: Male KRN mice were crossed with NOD female mice expressing the MHC class II molecule A^{g7} to generate K/BxN mice. 29 mice were assessed for arthritis activity using caliper measurements of hindlimbs and clinical scores 3 times weekly until sacrifice/serum collection at 21 weeks. HDL function was assessed by a previously published cell free assay (*A&R* 2009; 60: 2870) and paraoxonase 1 (PON1) activity was assessed using both paraoxon and dihydrocumarin as substrates (*A&R*2013; 65: 2765). Total and HDL cholesterol (HDL-C) were assessed by standard assays.

Results: Greater arthritis activity measured by higher hind limb scores in K/BxN mice was significantly associated with decreased ability of HDL to inhibit LDL oxidation (higher HDL inflammatory index (HII)); $r = 0.5$, $p=0.01$ for correlation of hind limb scores with HII at 21 weeks), and decreased PON1 activity measured using both paraoxon and dihydrocumarin as substrates ($r = -0.6$, $p=0.0001$ and $r = -0.7$, $p<0.0001$ respectively). Higher arthritis activity in K/BxN mice (hind limb scores) was also associated with greater suppression of total cholesterol (TC) and HDL-C, (r values $= -0.6$, p values $=0.001$). A marked correlation was observed between the suppression of HDL-C levels and impairment in HDL function ($r = -0.8$ for correlation of HDL-C with HII, $p<0.0001$).

Conclusion: Inflammatory arthritis in K/BxN mice is associated with suppression of HDL- C levels and the generation of more pro-inflammatory, dysfunctional HDL particles. These results are consistent with our prior work showing an association of higher disease activity in RA patients with worse HDL function. This model will be used for further evaluation of mechanisms linking abnormal HDL function to CV risk in RA.

Interleukin-33 Suppresses Experimental Arthritis through Promoting $Foxp3^+$ Regulatory T-Cells and Type-2 Immune Responses in Mice. Jerome Biton[1], Allan Thiolat[1], Sara khaleghparast Athari[1], Delphine Lemeiter[2], Roxanne Herve[1], Patrice Decker[1], Jean-Philippe Girard[3], Stephane Roga[3], André Herbelin[4], Anais Levascot[4], Marie-Christophe Boissier[2] and Natacha Bessis[1]. [1]INSERM UMR 1125, Li2P, University Paris 13, Sorbonne Paris Cité and Rheumatology Department, Avicenne Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), Bobigny, France, [2]INSERM UMR 1125, Li2P, University Paris 13, Sorbonne Paris Cité, Bobigny, France, [3]Centre National de la Recherche Scientifique, Institut de Pharmacologie, dUniversité de Toulouse, Université Paul Sabatier, Institut de Pharmacologie et de Biologie Structurale et de Biologie Structurale, toulouse, France, [4]INSERM U1082, Pôle Biologie Santé,, poitiers, France.

Background/Purpose: Interleukin (IL)-33 is a new member of the IL-1 family that exerts pleiotropic activities in innate and adaptive immunity. With its receptor ST2, they have newly emerged as key molecules strongly involved in several inflammatory and autoimmune disorders. Recent evidence suggests that the IL-33/ST2 axis is strongly involved in the pathophysiology of rheumatoid arthritis (RA). However in RA models, the role of IL-33 and its receptor is still controversial. We aimed at deciphering IL-33 mode of action after administration in an experimental model of RA, namely collagen-induced arthritis (CIA).

Methods: CIA was induced by immunization of C57Bl/6 mice with type 2 collagen. IL-33 was ip administrated in CIA mice and cells were analyzed by flow cytometry on day 28 after CIA induction.

Results and Conclusion We show a previously unshown dramatic inhibition of mouse collagen-induced arthritis (CIA) development after repeated administration of IL-33. This therapeutic effect was related to an enhanced type-2 immune response, including the expansion of eosinophils, Th2 cells, innate type 2 lymphoid cells (ILC2, defined as $CD25^+$ c-Kit^+ Lin^- Sca-1^+ $ST2L^+$) and an increase in Th2 cytokines levels in the serum of treated mice. Moreover, our work brings out the interplay between Treg and IL-33. Since IL-33 acts directly on Treg via ST2L, we showed that IL-33 treatment of CIA majors Treg frequency and increases the suppressive capacities of those cells. IL-33 also induces the emergence of a $CD39^{+/high}$ Treg population in a ST2L dependant manner In the light of our present study, IL-33 can exert powerful anti-inflammatory properties in CIA, integrating the establishment of a type-2 immune response, the expansion and the activation of Treg. Our study reveals an undescribed mechanism by which IL-33 inhibits arthritis development, thus updating and strengthening the crucial role of IL-33 in RA.

The Additive Inflammatory *in Vivo* and *in Vitro* Effects of Thymic Stromal Lymphopoietin (TSLP) and IL-7 in Arthritis Underscore the Therapeutic Rationale for blockade of Their Common Receptor Subunit. M.R. Hillen[1], S.A.Y. Hartgring[1], T.R.D.J. Radstake[2], C.E. Hack[1], F.P.J.G. Lafeber[1] and J.a.G. van Roon[1]. [1]UMC Utrecht, Utrecht, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Interleukin (IL)-7 and thymic stromal lymphopoietin (TSLP) are cytokines that signal through the IL-7Ra subunit and play proinflammatory roles in experimental arthritis and rheumatoid arthritis (RA). IL-7R blockade can potentially block signalling of both cytokines. In this study the potential of IL-7R and TSLPR signalling inhibition as well as simultaneous inhibition was investigated in murine experimental arthritis. In

addition, the additive effects of IL-7 and TSLP in human RA *in vitro* dendritic cell (DC)/T-cell co-cultures were studied.

Methods: Proteoglycan-induced arthritis was induced in wildtype mice (WT) and mice deficient for the TSLP receptor subunit (TSLPR) and mice of both genotypes were treated with anti-IL-7R or PBS. Arthritis severity was assessed and paw lysate and serum were collected for cytokine analyses. CD1c DCs and CD4 T-cells were isolated from blood of RA patients and were co-cultured in presence of IL-7, TSLP or the combination of both cytokines and proliferation and cytokine production were assessed.

Results: Arthritis severity and synovitis were significantly decreased in TSLPR−/− mice treated with anti-IL-7R compared to control mice (Arthritis severity; mean area under the curve ± SEM: 25 ± 5.9 vs. 50.7 ± 6.9; $p<0.01$). This was associated with strongly reduced radiographic joint damage and osteoclast activity, which were significantly lower in TSLPR−/− mice treated with anti-IL-7R compared to WT mice treated with anti-IL-7R, PBS treated TSLPR−/− mice or PBS treated WT mice (Radiographic joint damage: Mean score ± SEM: 0.1 ± 0.1, 0.6 ± 0.1, 0.3 ± 0.1, 1.4 ± 0.2 respectively; all $p<0.001$). This was associated with decreased levels of IL-17, IL-6, IL-1β and CD40L, which were all robustly downregulated by combined blockade of IL-7 and TSLP signalling (all $p<0.05$). In DC/CD4 T-cell co-cultures from RA patients, TSLP and IL-7 additively increased T-cell proliferation ($p<0.01$) and production of Th17-associated cytokines (IL-17, IL-22, IL-6; all $p<0.05$) and T-cell attracting chemokines (all $p<0.05$).

Conclusion: TSLP and IL-7 additively promote production of Th17-specific and Th17-associated cytokines, linked with enhanced inflammation and immunopathology. As both cytokines signal via the IL-7Ra, these data emphasize the need for drugs that target this subunit to abrogate activity of both ligands and prevent immunopathology in RA.

Effect of Etanercept on Endothelial Dysfunction in Rat Adjuvant-Induced Arthritis. Perle Totoson[1], Katy Maguin-Gaté[1], Daniel Wendling[2] and Céline Demougeot[1]. [1]EA 4267 « Fonctions et Dysfonctions Epithéliales », Faculté de Médecine-Pharmacie, Besançon, France, [2]CHU J Minjoz, Besancon, France.

Background/Purpose: Growing evidence indicate that Rheumatoid Arthritis (RA)-associated increase in cardiovascular risk is secondary to the presence of endothelial dysfunction (ED). Although Tumor Necrosis Factor inhibitors are unanimously approved for the treatment of RA, their effect on ED is still controversial. The present study aimed to determine the impact of etanercept on ED as well as the mechanisms involved in the model of adjuvant-induced arthritis (AIA) rats.

Methods: AIA was induced by an intradermal injection of *Mycobacterium butyricum* in the tail of male Lewis rats. At the first signs of arthritis, AIA rats received etanercept (10 mg/kg/ 3 days, s.c) or saline (controls AIA) for 21 days. Arthritis score was daily evaluated. At the end of experiment, preconstricted isolated aortic rings were relaxed with acetylcholine (Ach, $10^{-11}-10^{-4}$moles/liter) in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), cyclooxygenase-2 (NS398), arginase (nor-NOHA), endothelium-derived hyperpolarizing factor (EDHF) (apamin/charybdotoxin) and superoxide anions production (Tempol). Blood pressure was measured by invasive method.

Results: Compared to controls AIA, etanercept significantly reduced arthritis score (−34%, $p<0.001$). This was associated with an improvement of Ach-induced relaxation ($p<0.05$). These beneficial effects of etanercept on ED were mediated by a decrease in cyclooxygenase-2 and arginase activity, a decrease in superoxide anions production and an increase in NO synthase activity. EDHF production was unaffected by the treatment. Surprisingly, no correlation was found between the arthritis score and Ach-induced relaxation (Emax) ($r=-0.195$; $p=0.246$). Last, etanercept significantly increased systolic blood pressure (125.2 ± 5.7 vs 107.1 ± 5.5 controls AIA, $p<0.05$), but not diastolic blood pressure.

Conclusion: Our study demonstrated that etanercept decreases endothelial dysfunction in conduit arteries despite increasing blood pressure. The beneficial effects involved the modulation of vascular NO synthase, cyclooxygenase-2, arginase and superoxide anions production pathways. Our data suggested that these effects are, at least in part, independent on arthritis severity reduction.

Bombina Variegate peptide8/Prokineticin 2: A Novel Arthritis-Inducible Chemokine. Haruyasu Ito, Ken Yoshida, Kentaro Noda and Daitaro Kurosaka. Jikei University School of Medicine, Tokyo, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disorder characterized by the joint destruction. Chemokines play important roles as monocyte and neutrophil recruiters in RA. *Bombina variegate* peptide 8 (Bv8), one of such chemokines is highly expressed in various tissues including the brain, testis, and bone marrow. Bv8 has a diversity of functions, being involved in angiogenesis, neurogenesis, circadian rhythm, and pain threshold. We have previously reported that Bv8 expression level was elevated in the synovial tissue of collagen induced arthritis (CIA) mice. However, it is still unknown whether Bv8 can induce arthritis. Therefore, in this study, we investigated the expressions of Bv8 and its receptors (PKR1, PKR2) in CIA mice. And, we also examined whether Bv8 recruits polymorphonuclear neutrophils (PMNs) and monocytes *in vitro* and induces inflammatory arthritis *in vivo*.

Methods: CIA was induced in 6-week-old DBA/1j male mice. PKR1 and PKR2 mRNA expression levels of joints in CIA mice were measured by real-time PCR on days 28 and 35 and compared to those in normal mice. Immunohistochemical (IHC) staining was performed to semi-quantitate PKR1 or PKR2 expression on day 28 in the synovial tissue. We performed monocyte and neutrophil chemotaxis assays in response to recombinant Bv8 (rBv8) using Boyden chambers. Resuls were expressed as the fold increase of the number of migrated cells compared to PBS. To test Bv8 for inflammatory activity *in vivo*, we injected PBS or rBv8 (10^{-10}M, 20μl) into knee joints. The knee circumference measurements were taken in a blinded manner before and 24 hours after the intraarticular injection for all mice. IHC stainings for PMNs (Gr-1/Ly6G) and monocytes (F4/80) were performed on paraffin sections from mouse knee joints to quantify Gr-1/Ly6G and F4/80 positive cells in the Bv8 group compared to the PBS group, respectively.

Results: In the CIA group, PKR1 mRNA expression level was significantly higher on days 35 than the control group ($p<0.05$), and PKR2 mRNA expression level was significantly higher on days 28 and 35 than the control group ($p<0.05$). IHC stainings for PKR1 and PKR2 both showed significantly higher expressions of receptors in synovial tissue in the CIA group compared to the control group. PMN chemotaxis assays showed that rBv8 had significantly increased PMN chemotactic activity at 10^{-12} M compared to PBS ($p<0.05$). Joints injected with rBv8 had significantly increased knee circumference than those injected with PBS ($p<0.05$). The number of Gr-1/Ly6G positive cells was significantly higher in mouse knee joints injected with rBv8 compared to PBS ($p<0.05$). There was no significant difference in the number of F4/80 positive cells in both groups.

Conclusion: As well as Bv8, PKR1 and PKR2 expression levels were elevated in the synovial tissue of the CIA group. Bv8 recruited PMNs *in vitro* and induced neutrophil-driven inflammatory arthritis. These results indicate that Bv8 may have a previously unrecognized pathogenesis in RA by recruiting neutrophils. Targeting Bv8 may provide a new therapeutic strategy to treat inflammatory arthritis.

Toll-like Receptor Dependent Autoantigens and Vesicles from P.Gingivalis in Animal Models of RA to Modulate Collagen and Collagen Antibody Induced Arthritis. Christina Grimm, Bianka Marklein, Gerd Burmester and Karl Skriner. Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: A variety of animal models suggest that TLR signaling is important in the pathogenesis of RA and the generation of specific autoantibodies. This study was conducted with sera from patients with rheumatoid arthritis, as well as with arthritis animal models to identify identical autoantigens dependent on TLR 7 and 9 in human and animal models for disease modifying use. Moreover TLR2 and TLR 4 modulating bacterial vesicles from P gingivalis containing PAD (Peptidyl-Arginine Deiminase) which is involved in citrullination was used to study the TLR2/4 in arthritis.

Methods: Using protein filter technology (28000 human protein filter) the autoantigen profile of RA patients, mouse collagen and zymosan induced

arthritis, as well as collagen and pristan induced arthritis in rats and TLR7, TLR9 deficient double-deficient and MyoD88 and Tir8 deficient mice of the MRL-lpr/lpr background were obtained. Cationic liposomes transferring siRNAs, bacterial vesicles, lipomannan and LPS were used for the validation of their potential as therapeutic target in collagen or collagen antibody induced arthritis (CAIA).

Results: We found 18 identical proteins targeted in human and animal situations of arthritis. These data identify mRNA binding hnRNPs proteins which are part of P bodies, stress granules and components of messenger RNA stability complex as well as CRP binding proteins as target molecules in mice, rats and humans with RA. Moreover, we found MyoD88 independent autoantigens which are not expressed in the thymus or proteins such as high mobility group box proteins 1 and 2 which are MyoD88 independent sensors of nucleic-acid-mediated innate immune responses. Systemic administration of siRNAs with cationic liposomes inhibiting expression of Toll dependent autoantigens overexpressed and targeted by autoantibodies in the human and mouse synovial tissue were used for the validation of their potential to inhibit collagen induced arthritis in C57BL/6J mice. Moreover P.gingivalis vesicles containing the the PAD induce a mild inflammatory response in the CAIA model of arthritis. P.gingivalis LPS and lipomannan treated animals show a 80% reduction of athrithis score compared to E. coli LPS in a C57BL/6J CAIA model.

Conclusion: Systemic blocking of common RNA or DNA binding proteins overexpressed in synovial target tissue appears to modify arthritis. *P. gingivalis* vesicles evolved the ability to intercept and undermine a subset of TLR2/4 signalling events for corrupting innate immunity and modulate RA.

Role of Beta-Catenin Signaling to Control Dendritic Cell Function in Collagen-Induced Arthritis. Celso Henrique Alves[1], Julia L. Ober-Blöbaum[2], Inge Brouwers-Haspels[1], Patrick S. Asmawidjaja[1], Anne-Marie Mus[1], Björn E. Clausen[2] and Erik Lubberts[3]. [1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [3]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation and synovial infiltration of immune cells. T-cell priming by activated dendritic cells (DCs) contributes to the pathogenesis of RA. DCs are professional antigen presenting cells that have the dual ability to stimulate immunity and maintain tolerance. Microbial and pro-inflammatory stimuli trigger their maturation into immunostimulatory DCs that express high levels of MHC/peptide complexes, costimulatory molecules and pro-inflammatory cytokines to induce an adaptive immune response. DCs are also important to establish self-tolerance either via the generation of regulatory T cells (Tregs) or via the induction of apoptosis or anergy of auto-reactive effector cells. However, the signaling pathways mediating the tolerogenic DC function *in vivo* remain largely unknown. Recently, the b-catenin pathway has been suggested to promote a regulatory DC phenotype *in vitro*. While activation of β-catenin causes the phenotypic maturation of bone marrow-derived DCs, these cells fail to produce immunogenic cytokines and instead drive Treg differentiation *in vitro*and protection from autoimmune disease in mice.

The aim of this study was to unravel the *in vivo*role of β-catenin signaling to control DC function in collagen-induced arthritis (CIA).

Methods: C57BL/6 mice with a conditional deletion or activation of the β-catenin gene specifically in DCs were generated by crossing CD11c-Cre transgenic mice to *β-catenin*$^{FL/FL}$ and *β-catenin*$^{FL(EX3)/FL(EX3)}$animals, respectively. CIA was induced in the mutant mice and littermate controls by intra-dermal immunization with 100 μg chicken type II collagen in complete Freund's adjuvant on days 0 and 21. CIA incidence and severity was monitored macroscopically using a clinical score. On day 35, the animals were sacrificed, and spleen, draining lymph nodes, serum, ankles and knees were collected. The profiles of different T-cell and DC populations as well as their cytokine production were analyzed by flow cytometry.

Results: Deletion or overexpression of *β-catenin* in CD11c$^+$cells did not affect the onset, progression and severity of CIA.

CD11c-specific deletion of *β-catenin* resulted in an increased frequency of splenic CCR6$^-$CXCR3$^+$CD4$^+$ T cells and in an increase of naturally occurring Tregs (FoxP3$^+$CD25$^-$CD4$^+$) as well as of adaptive Tregs (FoxP3$^+$CD25$^+$CD4$^+$).

Overexpression of *β-catenin* in DCs caused an increase of splenic CCR6$^+$CXCR3$^-$CD4$^+$ (Th17) and CCR6$^-$CXCR3$^+$CD4$^+$ (Th1) T-cells. The latter produced elevated levels of the Th1 cytokine IFNγ and of the immunosuppressive cytokine IL-10. We also observed an increased frequency of naturally occurring FoxP3$^+$CD25$^-$CD4$^+$ and of adaptive FoxP3$^+$CD25$^+$CD4$^+$Tregs.

Conclusion: Our preliminary data indicate that changes in the levels of β-catenin expression in DCs did not alter the course and severity of CIA. However, the increase in IL-10 and in the Treg frequency during arthritis suggests that activation of β-catenin signaling may enhance the regulatory function of DCs.

Death Receptor 3 Causes Vascular Dysfunction in a Murine Model of Rheumatoid Arthritis. Jessica O Williams[1], Eddie C.Y. Wang[2], Derek Lang[1] and Anwen S. Williams[2]. [1]Institute of Molecular and Experimental Medicine, Cardiff University School of Medicine, Cardiff, United Kingdom, [2]Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom.

Background/Purpose: Increased cardiovascular (CV) risk is prevalent in several forms of inflammatory arthritides. The mechanisms that regulate CV disease during early inflammatory arthritis are ill-defined. Studies in humans and animal models identify matrix metalloproteinase 9 (MMP-9) as a potential regulator of CV pathology. Macrophages are early sentinels of both joint inflammation and vascular dysfunction. They are considered a major source of MMP-9 and can be induced *in vitro* to produce this metalloproteinase in response to Death Receptor 3 (DR3) signalling. Ablation of DR3 expression reduces MMP-9 levels in arthritic joint tissues during experimental arthritis. Here, for the first time, we measure DR3-dependent vascular dysfunction, associated macrophage infiltration and MMP-9 expression in vascular and perivascular adipose tissues (PVAT) with a view to understanding DR3's role in initiating early CV damage during inflammatory arthritis.

Methods: Murine collagen-induced arthritis (mCIA) was induced in DBA/1 mice (WT). Constriction responses to serotonin (5HT) were used to assess vascular function in isolated sections of thoracic aorta (±PVAT) in non-mCIA and mCIA mice with mild disease. DR3-dependent changes in vascular function were analysed using age-matched DBA/1 DR3 deficient mice (DR3$^{-/-}$). Region specific (thoracic aorta and PVAT) leukocyte infiltration was determined using haematoxylin and eosin staining, whilst localisation of F4/80$^+$ macrophages were visualised and MMP-9 expression quantified after immunohistochemical staining.

Results: The onset of mild arthritis was associated with inflammatory changes in the aortic vessel wall, characterised by increased macrophage infiltration ($p<0.05$) and DR3 expression ($p<0.001$). Total MMP-9 expression was unaltered (non-mCIA vs. mCIA mice). Macrophages (F4/80+), DR3 and total MMP-9 expression were all significantly elevated in PVAT ($p<0.05$ for all). The mCIA vascular tissues (±PVAT) exhibited significant contractile dysfunction compared to non-mCIA controls ($p<0.001$). The presence of PVAT was associated with a significant ($p<0.001$) dextral shift in constriction response curves but had no effect on maximal constriction. In DR3$^{-/-}$ non-mCIA mice, leukocyte infiltration ($p<0.05$) and total MMP-9 ($p<0.01$) levels were increased in PVAT but not in the aortic vessel wall. Vascular function was unaltered (WT versus DR3$^{-/-}$) and PVAT retained its ability to shift the constriction response curve to the right ($p<0.001$) in both genotypes. mCIA had no impact on the leukocyte ingress or MMP-9 production in the aortic vessel wall or PVAT (WT versus DR3$^{-/-}$). However, loss of DR3 further impaired vascular function (±PVAT) in comparison to WT ($p>0.001$).

Conclusion: The onset of mCIA drives an inflammatory response in the PVAT; associated with macrophage infiltration, increased expression of DR3 and MMP-9, and is detrimental to vascular function. Loss of DR3 perpetuates vascular dysfunction independently of leukocyte ingress and MMP-9 production. Further studies are justified to deduce the impact of DR3 on vascular function, in particular, the potential link with cardiovascular co-morbidities allied to arthritis.

Vascular Permeability As an Imaging Biomarker for Chronic Inflammatory Arthritis: A Dynamic Contrast Enhanced Magnetic Resonance Imaging Study. Eon Jeong Nam[1], Yongmin Chang[1], Jang-Woo Park[1], Shijin Sung[1], Jungwan Hong[1], Md. Hasan Al Faruque[1], Jongmin Lee[1] and Young Mo Kang[2]. [1]Kyungpook National University School of Medicine, Daegu, South Korea, [2]Kyungpook National Univ Hosp, Daegu, South Korea.

Vascular permeability as an imaging biomarker for chronic inflammatory arthritis: A dynamic contrast enhanced magnetic resonance imaging study.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease in which adequate diagnosis of disease activity is particularly important for optimizing treatment outcomes. Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) is used to detect inflammatory changes in synovial joints, and to discriminate active and inactive stages of disease. However, DCE-MRI has not been previously used to evaluate quantitative kinetic parameters, such as vascular permeability. The aim of this study was to investigate the quantitative changes in vascular permeability associated with chronic inflammatory arthritis.

Methods: Arthritis was induced in DBA/1J mice by immunization with bovine type-II collagen emulsified in complete and incomplete Freund's adjuvants. The severity of arthritis was monitored using the clinical arthritis index (CAI). R images of mice were obtained at different stages of arthritis progression, and 3 weeks after methotrexate (MTX) treatment. Immunohistochemical staining with an anti-CD31 antibody was used to assess vessel density.

Results: Permeability maps on the knee joint revealed less heterogeneity during the active stage, compared to early and late stages of arthritis. Vascular permeability increased progressively until the active stage of arthritis was reached, and thereafter declined gradually. The pattern of permeability changes quantified using DCE-MRI was consistent with the vascular densities and disease activity. Furthermore, vascular permeability and densities decreased significantly in a dose-dependent manner after treatment with MTX.

Conclusion: Vascular permeability assessed by DCE-MRI can be used as an imaging biomarker for tracking disease progression, and for monitoring therapeutic efficacy in inflammatory arthritis.

The Caspase 8/RIPK3 Signaling Axis Has Opposing Roles in Myeloid and Dendritic Cells during Progression of a Murine Model of Acute Inflammatory Arthritis. Carla M. Cuda[1], Alexander Misharin[2], George Kenneth Haines III[3] and Harris R. Perlman[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]The Mount Sinai Hospital, New York, NY.

Background/Purpose: Rheumatoid arthritis (RA) manifests in persistent synovial inflammation, cellular infiltration and pro-inflammatory cytokine production, and results in progressive joint destruction. Both myeloid cells and dendritic cells (DCs) have been implicated in RA progression and persistence: DCs through either antigen presentation to autoreactive T cells or differentiation into synoviocytes and myeloid cells (including macrophages and neutrophils) through the production of degradative enzymes, cytokines, and chemokines. However, the mechanisms underlying these activities are not fully elucidated. We recently identified that caspase 8, an enzyme that initiates apoptosis and suppresses necroptosis by inhibition of RIPK1/3 signaling in a multitude of cells, is a novel DC and myeloid cell-specific inhibitor of inflammatory processes independent of its known role in cell survival. Recently, a genome-wide association study identified an RA risk single nucleotide polymorphism within the locus that contains the gene that encodes for caspase 8. However, the impact of DC and myeloid cell-specific loss of caspase 8 on arthritis progression has yet to be examined.

Methods: Mice with caspase 8 flanked by *loxP* sites ($Casp8^{fl/fl}$, WT) were bred to mice expressing Cre under control of the lysozyme M gene promoter (Cre^{LysM}) expressed by myeloid cells or the CD11c gene promoter (Cre^{CD11c}) expressed by dendritic cells. $Cre^{LysM}Casp8^{fl/fl}$ and $Cre^{CD11c}Casp8^{fl/fl}$ mice were crossed with RIPK3$^{-/-}$ mice to determine the involvement of this signaling partner. The K/BxN serum-transfer model of arthritis was utilized and clinical severity was assessed. Ankle sections were stained with H&E and scored by a pathologist blinded to the study to assess pathology. Flow cytometric analysis was used to characterize naïve joints.

Results: The expression of CD206 (mannose receptor, involved in phagocytosis) was decreased on macrophages of naïve $Cre^{LysM}Casp8^{fl/fl}$ joints, and CD86 was elevated on CD11b^{+} DCs from naïve $Cre^{CD11c}Casp8^{fl/fl}$ joints. $Cre^{LysM}Casp8^{fl/fl}$ presented with accelerated resolution of arthritis, as assessed by reduced changes in ankle width on day 4, 7, 9 and 11 and clinical scores on day 7 and 9, as well as reduced pathology compared to WT. In stark contrast, $Cre^{CD11c}Casp8^{fl/fl}$ mice showed accelerated initiation of arthritis, as evidenced by increased changes in ankle width and clinical scores on day 2 and 4, as well as increased joint damage compared to WT. However, the in both cases, knockout of RIPK3 in $Cre^{LysM}Casp8^{fl/fl}$ and $Cre^{CD11c}Casp8^{fl/fl}$mice was sufficient to reverse the effect of caspase 8 deletion alone on arthritis initiation and resolution.

Conclusion: While deletion of caspase 8 specifically in myeloid cells promotes the acceleration of arthritis resolution, DC-specific caspase 8-deletion exacerbates arthritis initiation. In both situations, blockade of RIPK3 reverses the effect of caspase 8 deletion, indicating that the caspase 8/RIPK3 signaling axis plays an important cell-specific role in disease pathogenesis. These data have implications for RA by elucidating previously unknown cell-specific functions of a potentially useful target for therapy.

Reduced Macrophages in the Synovium Contribute to the Effective Treatment of Spontaneous Arthritis Observeded in Human TNF-Transgenic Mice. Robert Birkett, Qi Quan Huang, Bo Shi and Richard Pope. Northwestern University Feinberg school of Medicine, Chicago, IL.

Background/Purpose: Macrophages in rheumatoid arthritis (RA) synovial tissue (ST) produce high levels of inflammatory cytokines/chemokines and exhibit enhanced differentiation into osteoclasts in the pannus, playing the pivotal role in promoting inflammation and joint destruction. Recent observations demonstrate that effective therapy employing a TNF inhibitor results in a selective reduction of sublining RA ST macrophages within 24 hours. However, neither ingress of monocytes into the tissue nor apoptosis of macrophages in the RA tissue accounted for the reduction of macrophages. Therefore, employing a murine model, studies were performed to define the role of CCR7 expression to promote macrophage egress from inflamed joints as a potential mechanism for therapeutic response.

Methods: CCR7 expression in RA synoival macrophages was determined by two color immunohistochemistry employing anti-CCR7 and anti-CD68, RT-PCR and immunoblotting. A human TNF transgenic (hTNF-tg) mouse line which spontaneously develops arthritis was employed, and treated with infliximab, administered intraperitoneally (10mg/kg, 1–3 doses). The clinical severity of the arthritis was defined as the sum score of joint swelling, inflammation, deformity and grip strength. Ankle histology was performed. The immune cell phenotypes and apoptosis were determined by flow cytometry. Ankle cell migration was tracked by PKH26 intra-articular injection and cell identification by flow cytometry.

Results: CCR7 was increased in macrophages in RA ST and synovial fluid. CCR7 expression on normal human macrophages was significantly increased at the mRNA and protein levels following incubation with TNFa, Pam3 or LPS. As expected the hTNF-tg mice developed arthritis beginning at week 4, progressing through week 12. The hTNF-tg mice treated with infliximab for 72 or 168 hours demonstrated significant clinical improvement. Histologic analysis identified significant reduction of inflammation, bone erosion and pannus formation after 168 hours of therapy. Flow cytometric analysis demonstrated that ST macrophages were significantly reduced at 24 hours, prior to clinical improvement, and 72 and 168 hours following the initiation of therapy. In contrast, other cell types including granulocytes, B or T lymphocytes and dendritic cells were not consistently or not significantly reduced. No increase of macrophage apoptotosis or necrosis in ankle ST was

observed following treatment. Futher, although there was a reduction of PKH26 labeled macrophages in the ankles following therapy, there was also a reduction of macrophages in the popliteal lymph nodes and no increase in the percentage of PKH26 labeled macrophages was detected.

Conclusion: These observations demonstrate increased CCR7 on macrophages in the RA joint and that CCR7 on macrophages was increased by inflammation. Macrophages, but not other cell types, in the inflamed synovium of hTNF-Tg mice were reduced early prior to clinical or histologic improvement, but we have yet to document egress as the mechanism. The role of CCR7 in the therapeutic reduction of macrophages is being pursued by crossing hTNF-Tg mice with those deficient in CCR7−/−.

A Low Salt Diet Ameliorates Clinical Manifestations in Collagen-Induced Arthritis. Bettina Sehnert[1], Sandy Pohle[2], Agnes Schröder[2], Jens Titze[3] and Reinhard E. Voll[1]. [1]University Hospital Freiburg, Freiburg, Germany, [2]University of Erlangen-Nürnberg, Erlangen, Germany, [3]Vanderbilt University School of Medicine, Nashville, TN.

Background/Purpose: A genetic predisposition, but also environmental factors including infections and smoking modulate manifestation and severity of inflammatory autoimmune disease like rheumatoid arthritis (RA). Recently, the induction of pathogenic Th17 cells as a consequence of increased salt intake was demonstrated in an animal model of multiple sclerosis. The impact of dietary factors such as low salt consumption on the inflammatory status in arthritis has not yet fully characterized. The aim of the study was to investigate the association between salt intake and clinical manifestations in a mouse model of arthritis.

Methods: DBA/1 mice were immunized with *bovine* type II *collagen* (CII) in complete Freund's adjuvant (CFA). Two weeks before immunization experimental diet was started and the mice were divided in two groups. The LS (low-salt) group (n=9) received a diet containing a sodium content <0.03% and tap water. The HS (high-salt) group (n=10) were fed with a diet containing 4 % NaCl in combination with 0.9% NaCl supplemented tap water. The feeding lasted 62 days. Arthritis severity was assessed by clinical scoring to a graded scale (0–4). At the end of the experiment hind paws were removed for histological analysis. The stained sections (hematoxylin/eosin, toluidine blue and tartrate-resistant acid phosphatase) were graded on a scale from 0–3. Levels of *IgG1 and IgG2a* antibodies against bovine collagen type were measured by ELISA.

Results: Administration of a low salt diet resulted in a decreased arthritis severity compared to the HS-group. Further, the incidence of arthritis was significantly lower in the LS group. The histopathological analysis revealed reduced infiltrations with inflammatory cells in the group fed with the low salt diet. Also the destruction of cartilage and bone was less pronounced in the LS compared to the HS group. ELISA experiments showed that the level of pathogenic IgG2a antibodies against CII was markedly increased in HS-mice, whereas low salt consumption reduced anti-CII IgG2a levels significantly. The titers of CII-specific IgG1 were similar in both groups. This resulted in decreased IgG2a:IgG1 ratio in the LS group and indicates a shift toward a more Th2-dominated immune response.

Conclusion: Low salt diet ameliorates clinical and histological signs in murine collagen-induced arthritis. The low salt consumption inhibits the humoral IgG2a response against CII and protects against antibody-mediated joint destruction. We conclude that a low salt diet might ameliorate RA and support treatment of immune-mediated arthritides.

Treatment of Collagen Induced Artritis with Human Embrionic Stem Cell-Derived Multipotent Mesenchymal Stromal Cells (hESC-MSC). Gabriel Criado[1], María J. Pérez-Lorenzo[1], María Galindo[1], Jose L. Pablos[1], Pablo Menéndez[2] and Elena Gonzalo-Gil[3]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Josep Carreras Leukemia Research Insitute, Barcelona, Spain, [3]Instituto de Investigación Hospital 12 de Octubre (i+12), Madrid, Spain.

Background/Purpose: Inhibition of TGFβ signaling in human Embryonic Stem Cells (hESC) generates mesenchymal stromal cells (hESC-MSC) with osteogenic, adipogenic and chondrogenic potential. These cells have immunosuppressive and anti-inflammatory properties in vitro and have shown a protective effect in experimental models of acute inflammation. The aim of the present study was to test their therapeutic potential in an experimental setting of chronic inflammation, the collagen-induced arthritis model (CIA).

Methods: Arthritis was induced in 8–10 weeks old male DBA/1 mice by intradermal immunization with 200 mcg of chicken type II collagen (CII) in Complete Freund's Adjuvant (CFA). Mice were treated starting on the day of arthritis onset with three doses of 10^6 cells / mouse hESC-MSC every other day and arthritis severity was evaluated daily during ten days. Effect of in vivo treatment was assessed by flow cytometry to detect Treg ($FoxP3^+$), Th1 ($IFNg^+$) and Th17 ($IL17^+$) CD4 T cells in lymph nodes. To analyze T cell responses in vitro, lymph node cells were stimulated with CII, proliferation was measured by incorporation of the colorimetric reagent WST-1 and IFNg and IL17 levels were quantified by ELISA. Serum levels of anti-CII antibodies were determined by ELISA. Detection of ehESC-MSC in mouse tissues was performed by quantitative PCR (qPCR) of HLA-C and quantification of murine and human indoleamine 2,3 dioxygenase (IDO) was performed by quantitative PCR. Statistical differences were analyzed by ANOVA and Mann-Whitney U-test using GraphPad Prism software. P values < 0.05 were considered significant.

Results: Treatment of CIA mice with hESC-MSC reduced diseased severity compared to control-treated mice. Differences appeared the first day after treatment and were significant and sustained in the group receiving 3 doses. Therefore, administration of 3 doses was the schedule used for subsequent experiments. Anti-CII antibodies levels were not affected by treatment. Analysis of CD4 T cell populations in treated mice showed an enrichment in $FoxP3^+$ Treg cells (8.56 ± 0.89 % vs 5.89 ± 0.81% in control mice, *P= 0.026) in inguinal lymph nodes. IFNg producing cells were also increased (0.88 ± 0.09 % vs 0.54 ± 0.02 %, **P= 0.008) but not IL17 producing cells (0.93 ± 0.09 % vs 0.84 ± 0.05 %, P= 0.54). In vitro stimulation with CII caused higher production of IFNg and IL17 in lymph node cultures from hESC-MSC treated mice although not statistically significant (IFNg: 539.0 ± 219.3 pg/ml vs 147.8 ± 93.55 pg/ml, P= 0.09, IL17: 238.3 ± 134.1 pg/ml vs 72.39 ± 72.39 pg/ml, P= 0.24) and proliferation was not affected. hESC-MSC treated mice that showed MSC colonization in lymph nodes, as detected by HLA- expression, had significantly higher expression of murine indoleamine 2,3 dioxygenase than their treated non-colonized and not treated counterparts ($6.88 \pm 0{,}94$ Units vs $1.049 \pm 0{,}36$ in non-colonized and $1.82 \pm 0{,}24$ in non-treated mices, **P= 0.009 and * *P= 0.004, respectively).

Conclusion: Treatment with hESC-MSC ameliorates CIA by inducing IFNg and indoleamine 2,3 dioxygenase.

Salt Aggravates Arthritis By Th17 Polarization. Seung Min Jung[1], Hong Ki Min[1], Jung Hee Koh[1], Jin Young Kang[1], Jennifer Lee[1], Seung-Ki Kwok[1], Kyung-Su Park[2], Hyeok-Jae Ko[3], Wan-Uk Kim[4], Ho-Youn Kim[1], Sung-Hwan Park[1] and Ji Hyeon Ju[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]St. Vincent Hospital, SuWon Gyeonggi-do, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Daejeon, South Korea, [4]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: Sodium chloride (NaCl) recently has been shown to drive autoimmune diseases through the induction of pathogenic interleukin 17-producing T helper (Th17) cells. This study investigated the effect of NaCl on Th17 cell differentiation in human and murine arthritis.

Methods: To evaluateth *in vivo* arthritogenic effect of NaCl, collagen-induced arthritis (CIA) mice were fed a normal or high-salt diet *ad libitum*, and paw swelling was scored visually. Splenocytes were analysed by flow cytometry for RORgt expression, and splenic $CD4^+$ T cells were differentiated into Th17 cells. Peripheral blood mononuclear cells obtained from patients with rheumatoid arthritis (RA) and osteoarthritis (OA) were cultured under Th17 cell-differentiating conditions in a high-salt environment and were analysed by flow cytometry to quantify the Th17 cell population.

Results: NaCl increased murine and human Th17 cell differentiation in a dose-dependent manner and aggravated arthritis in CIA mice. Joint inflammation was more severe in the high-salt-fed CIA mice. T cells from high-salt-fed CIA mice expressed a higher level of RORgt and were more

likely to differentiate into Th17 cells. Th17 cells were located primarily in arthritic joints, and also observed the intestinal tract of high-salt-fed CIA mice. Na^+ and IL-17 concentrations were higher in synovial fluid from RA patients than in fluid from OA patients. There was a tendency towards increased RORgt expression after NaCl treatment in arthritic patients.

Conclusion: This study suggests that NaCl can aggravate arthritis by affecting Th17 differentiation. Limiting salt intake might be helpful in the management of arthritis.

Smoking Status Is Associated with Inflammatory Cytokine Profile and Disease Activity: Decreased Inflammation and Disease Improvement with Smoking Cessation? Jeremy Sokolove[1], Harlan Sayles[2], Catriona Wagner[3], Lauren J. Lahey[1], Geoffrey M. Thiele[2], William H. Robinson[1], Andreas Reimold[4], Gail S. Kerr[5], Grant W. Cannon[6] and Ted R. Mikuls[2]. [1]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [4]Dallas VA and Univ of TX Southwestern Med Ct, Dallas, TX, [5]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [6]Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: Cigarette smoking is a risk factor for RA and has been associated with increased disease severity and lower rates of disease remission. We examined whether smoking cessation might be associated with reduced disease activity and investigated the association of autoantibody levels with smoking status.

Methods: RA patients from the Veterans Affairs RA (VARA) registry were studied (n = 1468, 76.9% anti-CCP2+, 90.7% male, median age 63 [IQR 57–72], median disease duration 8.45 years [IQR 2.8–18]). Baseline serum samples were evaluated for levels of 19 distinct ACPA and 17 cytokines using the BioPlex platform. Baseline smoking status was recorded as current, former, or never. Cross-sectional associations of baseline smoking status with disease activity (DAS28) and its constituents as well as baseline levels of ACPA, and baseline levels of cytokines were assessed.

Results: Multiple measures of RA disease activity including DAS28 were significantly higher among current smokers compared with either former or never smokers ($P<0.01$), an effect limited to the seropositive (anti-CCP2 positive) population (Table 1). The number of inflammatory cytokines found in high concentration was significantly higher among current smokers compared with both former and non-smokers (FDR q-value <0.1%). Levels of both anti-CCP2 as well as ACPA subtypes were lower in never smokers but similar between current and former smokers while levels of RF were highest in current smokers, and lower in both former smokers and lowest in never smokers (Table 2).

Conclusion: Current smoking is strongly associated with increased RA disease activity as well as elevation in pro-inflammatory serum cytokines compared to both former and never smokers. Our findings suggest that continued tobacco exposure promotes greater RA disease activity, particularly in ACPA positive patients though independent of titer or specificity. The observation of reduced disease activity among former smokers, approaching that of never smokers, suggests that the effects of smoking may be reversed by smoking cessation. Whether RF may be a mediator of this effect remains to be clarified.

Table 1: Measures of disease activity, ACPA, and cytokine expression among anti-CCP2 positive RA patients; *p-values among smoking groups generated using Scheffe's method for multiple comparisons

Lindegaard[1], Merete Lund Hetland[3], Kim Hoerslev-Petersen[4], Kirsten Junker[5], Kristian Stengaard-Pedersen[6], Tine Lottenburger[2], Torkell Ellingsen[1], Ib Hansen[6], Jens Kristian Pedersen[1], Ulrik B. Lauridsen[7], Anders Svendsen[8], Ulrik Tarp[6], Jan Pødenphant[9], Mikkel Østergaard[10] and Peter Junker[1]. [1]Department of Rheumatology, Odense University Hospital, Odense, Denmark, [2]Department of Rheumatology, Vejle Hospital, Vejle, Denmark, [3]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark, [4]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark, [5]Institute of Molecular Medicine, Cardiovascular & Renal Research, University of Southern Denmark, Odense, Denmark, [6]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [7]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup Hospital, Glostrup, Denmark, [8]The Danish Twin Registry, Epidemiology, Institute of Public Health, Odense, Denmark, [9]Department of Rheumatology, Copenhagen University Hospital at Gentofte, Gentofte, Denmark, [10]Copenhagen Center for Arthritis Research, Copenhagen University Hospital at Glostrup, Glostrup, Denmark.

Background/Purpose: Galectin-3 (Gal-3), a 26kD beta-galactoside binding protein, has been implicated as a pro-inflammatory mediator in animal arthritis and rheumatoid arthritis (RA) in humans. Thus, Gal-3 is overexpressed by fibroblast-like synoviocytes in the rheumatoid synovium, particularly upon adhesion to cartilage components. Moreover, Gal-3 is increased in serum in animal arthritis and in serum and synovial fluid in patients with long-standing RA as compared with osteoarthritis and healthy individuals.

The aims of this investigation were to quantify the serum level of Gal-3 in a large cohort of patients with newly diagnosed RA before treatment, and to study possible associations with clinical, serological and imaging findings.

Methods: One hundred and sixty DMARD naïve patients with RA of recent onset were included (the CIMESTRA cohort)(1). One hundred and nineteen volunteer blood donors served as healthy controls. Variables included demographics, clinical disease measures (Disease Activity Score in 28 joints-DAS28, Health Assessment Questionnaire-HAQ, Visual Analog Scales– patients global assessment, pain and physicians assessment), autoantibody status and MRI of the non-dominant wrist. Gal-3 was measured by ELISA (R&D).

Results: Gal-3 was significantly increased in RA patients, 4.49 ug/L (*95% CI 4.17;4.81*) compared with healthy controls, 3.96 ug/L (*3.70;4.22*; p = 0.02).

Gal-3 correlated positively with Capsular Reactive Protein (CRP), Erythrocyte Sedimentation Rate(ESR), and HAQ, but not with joint counts, DAS28 or rheumatoid nodules (table 1.a). Stratification according to autoantibody seropositivity and smoking showed that Gal-3 was significantly higher in seropositive than in seronegative RA, particularly in smokers (table 1.b). A similar pattern was observed in IgM-RF only and IgM-RF+anti-CCP positive subsets (p = 0.01 and p = 0.03). There was no association between Gal-3 and anti-ccp titer. By contrast, Gal-3 was positively correlated with bone marrow edema in patients (p = 0.03).

Gal-3 mean (ug/L)	4.73*#	4.00*	5.01#	4.05	4.17	3.96
(*95 CI*)	(4.32; 5.13)	(3.49; 4.51)	(4.52; 5.51)	(3.20; 4.91)	(3.48; 4.87)	(3.28; 4.63)

*: Significant differences between smoking subgroups #: Significant differences between RA subgroups and healthy controls

Conclusion: In this study we show that Gal-3 is increased in DMARD naïve patients with RA of recent onset. The associations with autoantibody seropositivity and bone marrow edema provide additional evidence for a role of Gal-3 in the RA disease pathway and hence that Gal-3 has potential as a seromarker for synovial pathology in RA.

Rho-Associated Protein Kinase (ROCK) Activity Is Elevated in Rheumatoid Arthritis (RA) Patients and May be Responsive to RA Therapies. Reena Khianey, Cristina Rozo, Sanjay Gupta, Vivian P. Bykerk, Susan M. Goodman and Alessandra B. Pernis. Hospital for Special Surgery, New York, NY.

Background/Purpose: Rho-associated protein kinases (ROCKs) regulate cytoskeletal reorganization and gene expression through protein phosphorylation, and are implicated in the pathogenesis of a wide range of disorders including SLE. ROCK activation is associated with TH17 differentiation and production of interleukin 17 (IL17) and IL21, two cytokines associated with SLE and RA. We aimed to 1) evaluate ROCK activity and cytokine profile in RA patients, and 2) correlate ROCK activity with use of disease modifying anti-rheumatic drugs (DMARDs), smoking status, erosions, disease duration, and disease activity.

Methods: We performed a cross-sectional analysis of 26 RA patients meeting 2010 ACR/EULAR criteria compared to 18 age±5 years, gender, and race/ethnicity matched healthy controls. ROCK activity in peripheral blood mononuclear cells (PBMC) lysates was determined by an ELISA. Plasma samples were analyzed by specific ELISAs for IL-17 and IL21. Statistical analyses were performed using GraphPad Prism 6.0 using appropriate non-parametric tests.

Results: Clinical characteristics of RA patients are noted in Table 1. RA PBMCs expressed significantly higher levels of ROCK activity than did healthy control PBMCs (0.4085 vs. 0.3303; $P = 0.0023$). DMARD untreated RA patients had a trend towards higher ROCK activity compared to DMARD treated RA patients, (0.6935 vs. 0.3925; $P = 0.0867$), (Figure 1). Spearman's correlation revealed no association of ROCK activity levels with disease duration (r= 0.277, $P = 0.171$) or disease activity as measured by Clinical Disease Activity Index (CDAI) (r=0.162, $P = 0.429$). There was no significant difference in ROCK levels based on erosions ($P = 0.440$) or smoking status ($P = 0.651$). Patients with moderate or high disease activity (CDAI ≥10.1) had increased ROCK levels (OR=1.96, 95% CI 0.3866–9.938), but this was not statistically significant. No statistically significant differences in IL17 and IL21 levels between RA patients and healthy controls were detected.

Conclusion: ROCK levels were higher in RA patients compared to healthy controls suggesting ROCK deregulation in RA pathogenesis. There was a trend towards higher ROCK activity in DMARD untreated RA patients suggesting that ROCK activity is sensitive to RA therapies. Further studies are needed to understand the role of ROCK activity in RA.

Table 1: Clinical Characteristics of RA Patients, n=26

Mean Age, ±SD, range	**57.5±13.8 (23–79)**
Female, n, (%)	23 (88.5)
Race, n, (%)	
White	15 (57.7)
Black	3 (11.5)
Mixed	4 (15.4)
Asian	4 (15.3)
Mean Disease Duration in months, ±SD, range	56.0±55 (3–240)
Erosive Disease, n, (%) [imaging available on 15 patients]	4/15 (26.7)
Autoantibody Status	
IgM RF or ACPA positive, n, (%)	3 (11.5)
IgM RF and ACPA negative, n, (%)	3 (11.5)
IgM-RF and ACPA positive, n, (%)	20 (76.9)
Mean ACPA titer (U),* ± SD, range	195.1±67.9 (60–250)
Mean IgM-RF titer (IU/mL)* ± SD, range	143.8±166.8, (21.1–587)
*[titers available on 20 patients]	
Disease Activity Parameters	
Mean ESR (mm/hr) ± SD, range	22.5 ± 14.5 (5–44)
Mean CRP (mg/dL) ±SD, range	1.2 ± 0.5 (1 – 3.2)
CDAI,Mean ± SD, Range	13.0 ± 7.3, (6–30)
Current smokers, n, (%)	4 (15.4)
Current Medications, n, (%)	
NSAIDs alone	8 (30.8)
Hydroxychloroquine alone	1 (3.8)
Conventional DMARDs (Methotrexate ± Leflunomide)	8 (30.8)
Anti TNF agents (Etanercept, Adalimumab)	8 (30.8)
Prednisone	1 (3.8)

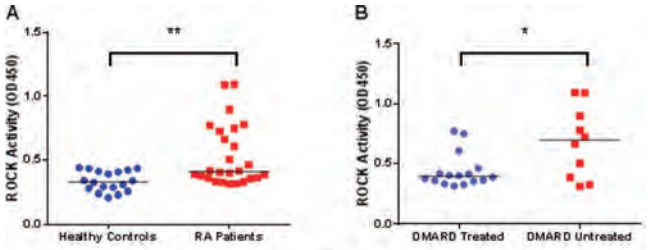

Figure 1 – Rho associated protein kinase (ROCK) activity in rheumatoid arthritis (RA) patients as compared with healthy control subjects. A. Peripheral blood mononuclear cells (PBMCs) were derived from heparinized blood samples obtained from 26 RA patients and compared to 18 matched healthy control subjects. ** = $P = 0.0023$ by Mann Whitney U test. B. ROCK activity in PBMCs from RA patients treated with DMARDs and RA patients untreated. * $P = 0.0867$ by Mann Whitney U test. Each data point in A and B represent a single subject; horizontal lines show the median.

Doctor, Will My Fatigue be Better If I'm in Remission? an Exploratory Analysis of 1284 Rheumatoid Arthritis (RA) Patients Indicates Fatigue Is the Only Aspect of Patient-Perceived Impact to Remain Significant in ACR/EULAR Boolean Remission. Laure Gossec[1], Bruno Fautrel[1], John Kirwan[2], Andra Balanescu[2], Maarten de Wit[3], Ben A.C. Dijkmans[2], Matthias Englbrecht[2], Philippe Gaudin[4], Feride Gogus[2], Turid Heiberg[3], Tore Kristian Kvien[2], Emilio Martín-Mola[5], Marco Matucci-Cerinic[2], Kati Otsa[3], Adeline Ruyssen-Witrand[4], Tuulikki Sokka-Isler[2], Martin Soubrier[4] and Maxime Dougados[2]. [1]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital,

Paris, France, [2]RAID working group for EULAR, Zurich, Switzerland, [3]PsAID taskforce, EULAR, Zurich, Switzerland, [4]COMEDRA trial group, Paris, France, [5]Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: Fatigue is an important issue for patients with rheumatoid arthritis (RA). The ACR/EULAR Boolean definition of remission comprises values <=1/10 for joint counts, CRP and patient global assessment; fatigue is not specifically assessed. Near-remission (defined as remission for joint counts and CRP but with patient global assessment > 1/10) is a status which may, or may not, be an acceptable objective for patients. Fatigue levels in this status are unknown.

Objectives: To assess fatigue levels and other aspects of impact, in patients in ACR/EULAR remission, compared to patients in near-remission and not in remission.

Methods: Ancillary analysis of the RAID database, based on an international multicenter cross-sectional study of consecutive RA patients from 12 European countries, and the baseline data in COMEDRA, a French national study in stable RA patients (refs 1, 2). Remission, near-remission and non-remission were assessed cross-sectionally and patient-reported impact of RA including fatigue was assessed using the RA Impact of Disease (RAID) score (ref 1). The RAID assesses pain, function, fatigue, sleep, coping and well-being; each component of the RAID score ranges from 0 (no impact) to 10 (high impact). Patients in remission were compared to those in near-remission and not in remission for mean levels and the proportion of patients with a score <=1/10, in each of the RAID components. The discriminant capacity of fatigue and of the other RAID components for the status of remission was assessed by Cohen's effect size.

Results: In total, 1284 patients had complete data for this analysis: mean (±standard deviation) age 57±11 yrs, disease duration 13±10 yrs, 78% women. Mean RAID score was 3.3±2.2. Mean fatigue in this population was 4.1±2.7. With the ACR/EULAR Boolean definition, only 87 (6.8%) were in remission and 84 (6.5%) were in near-remission. In remission patients, all the components of the RAID were very low (mean value below 1), except fatigue (mean value of 1.2±1.8; i.e., fatigue was above 1/10 in 25% of the patients in remission, versus 9–21% for the other aspects of RA impact. Near-remission was characterised by more impact of RA for all components of the RAID but particularly fatigue (mean fatigue 4.0±2.3, similar to patients not in remission: 4.3±2.7). Fatigue levels, psychological well-being and sleep had the lowest discriminant capacity to distinguish patients in remission versus not.

Conclusion: The ACR/EULAR definition of remission is extremely stringent and rarely attained for patients with long-standing RA. Fatigue was the only aspect of the impact of RA to remain at significant levels for many patients in Boolean remission, and was much higher in patients in near-remission. More work is needed to understand the link between fatigue and disease activity.

Remaining Pain in Spite of Suppressed Inflammation in Early Rheumatoid Arthritis – Long-Term Strongly Increased Risk for Widespread Pain and Fatigue. Maria E.C. Sandberg[1], Saedis Saevarsdottir[2], Reem Altawil[3], Lars Klareskog[4], Lars Alfredsson[1] and Jon Lampa[3]. [1]The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Pain is common in rheumatoid arthritis (RA), even after adequate inflammatory disease control. Important long-term health effects of RA are fatigue, sleeping disturbances and a significant portion of patients also develop generalized pain, often leading to decreased quality of life. The aim of the present study was to investigate the distribution of remaining pain dimension in RA, which patients that may be at increased risk, and whether it is a risk factor for long-term generalized (widespread) pain and fatigue.

Methods: We used the cases (incident RA patients aged 18–70 recruited 1996–2009) from the Swedish population-based case-control study; EIRA, linked to the Swedish Rheumatology Quality Register (N=1633). Three years after diagnosis an additional questionnaire was sent out, assessing fatigue, pain outside joints and sleeping problems (N=186). Remaining pain was defined as pain on visual-analog scale (VAS) ≥20 mm and CRP <10 g/L at the 12 month follow-up visit. Logistic regression was used both to calculate the odds ratio (OR) of baseline clinical parameters as possible predictors of remaining pain, adjusted for sex, age and period and also OR of widespread pain (WSP; pain outside joints in all four quadrants)/any pain outside joints/sleeping problems/fatigue, as an effect of remaining pain.

Results: 35% of the patients had remaining pain at 12 months after diagnosis. Several factors at diagnosis significantly and independently increased the risk for remaining pain at 12 months: higher HAQ (ORs per additional unit; OR=1.28 [95%CI: 1.02 – 1.60]), tender joint count (OR=1.04 [95%CI: 1.02 – 1.06]) and patient global assessment (OR=1.25 [95%CI: 1.12 – 1.38] per 20 units). A higher CRP, ESR and swollen joint count all significantly and independently decreased the risk for remaining pain. (OR=0.84 [95%CI: 0.76 – 0.92] per 10 units), (OR=0.89 [95%CI: 0.80 – 0.99] per 10 units), (OR=0.97 [95%CI: 0.94 – 1.00] per joint); respectively. After 3 years; 7% had WSP, 36% had any pain outside joints, 17% had sleeping problems (defined as quite big/very big problem by the patient) and 26% had significant fatigue (VAS ≥40). Regarding the effect of remaining pain at 12 months on WSP/any pain outside joints/sleeping problems/fatigue we, despite our somewhat few observations, found strongly increased risk for these conditions after 3 years in those with remaining pain after 12 months: OR: WSP=3.48 [95%CI: 1.24–9.73], any pain outside joints= 2.67 [95%CI:1.44–4.94], sleeping problems=3.82 [95%CI:1.61–9.06], fatigue=2.43 [95%CI:1.25–4.72]. All these ORs remained after adjustment for very high baseline pain levels (VAS > 70), indicating that presence of WSP/fibromyalgia at diagnosis had no major impact on the results.

Conclusion: More than a third of all RA-patients have remaining pain despite satisfactory inflammation control 12 months after diagnosis. This condition is a very strong predictor for development of widespread pain 3 years after diagnosis. Moreover, we found strong associations with long-term non-joint-related pain, sleeping problems and fatigue. These observations stress the importance to acknowledge and optimize pain treatment also in patients with adequate inflammation control early in RA.

Sensitivity of Unique Multidimensional Health Assessment Questionnaire Items Compared to Items on Both the HAQ and MDHAQ in Patients with RA and SLE. Narender Annapureddy[1], David Giangreco[1], Isabel Castrejón[1], Nisha Shetty[2], Theodore Pincus[1], Joel Block[1] and Meenakshi Jolly[1]. [1]Rush University Medical Center, Chicago, IL, [2]St. Anthony's Hospital, St. Louis, MO.

Background/Purpose: Patients with rheumatic diseases have significantly better clinical status in recent years than in previous decades, including rheumatoid arthritis (RA)[1] and systemic lupus erythematosus (SLE). [2] Therefore, many items in the health assessment questionnaire (HAQ) which were almost always elevated in 1980 when the HAQ[3] was reported may be normal at this time. In 1999, 16% of patients were reported to have HAQ scores of zero, suggesting "no difficulty" in function, but most nonetheless reported problems with function as well as psychosocial issues reflecting "floor effects." Therefore, a multidimensional HAQ (MDHAQ) was developed to include 13 queries in the user-friendly HAQ format, 8 simple activities of daily living (ADL) from (and identical to) the HAQ, and 5 not on the HAQ: 2 complex activities – "walk 2 miles or 3 kilometers" and "participate in recreation and sports as you would like", and 3 "psychological" queries – sleep quality, anxiety and depression. We analyzed mean scores for each of the 13 MDHAQ items in patients with RA and SLE in routine care in an academic rheumatology setting.

Methods: An MDHAQ is completed in an academic rheumatology setting by each patient at each visit. The MDHAQ queries 13 items (Table) in the patient-friendly HAQ format, all scored 0–3, with 4 response options: without any difficulty=0, with some difficulty=1, with much difficulty=2 and unable to do=3. Mean scores were analyzed in 140 female patients, 70 who met criteria for RA and 70 for SLE. Mean scores for each item was computed and compared using a t-test with a p-value of ≤ 0.05 considered significant on 2-tailed tests. Exploratory factor analysis (Principal Component analysis with varimax rotation) on the 13 items was performed.

Results: Mean scores for the 8 items a-h found on the HAQ were <0.70 in patients with RA and <0.50 in patients with SLE (Table), but scores were

>0.70 in patients with RA and >0.50 in patients with SLE for all 5 items i-m found only on the MDHAQ. Scores of 0 (floor effects) were seen in >49% of RA and >63% of SLE patients for the HAQ and MDHAQ items vs <47% for RA and <54% of SLE patients for the unique MDHAQ items. Most items loaded into 3 Components: A: activities of simple living (a-h in SLE and items a-c, e-g in RA), B: complex activities (i and j) and C: psychological (k-m). Differences between RA and SLE patients were significant only for items a, b and j.

MDHAQ Item	RA patients			SLE patients		
* = Found on HAQ and MDHAQ # = Found only on MDHAQ	Mean (SD)	% 0 (Floor effect)	Factor loading	Mean (SD)	% 0 (Floor effect)	Factor loading
a. Dress yourself, including tying shoelaces and doing buttons?*	0.67 (0.63)	50	A	0.43 (0.79)	64	A
b. Get in and out of bed?*	0.70 (0.79)	49	A	0.37 (0.57)	67	A
c. Lift a full cup or glass to your mouth?*	0.39 (0.66)	70	A	0.27 (0.56)	77	A
d. Walk outdoors on flat ground?*	0.66 (0.76)	50	B	0.42 (0.69)	70	A
e. Wash and dry your entire body?*	0.50 (0.70)	60	A	0.36 (0.64)	72	A
f. Bend down to pick up clothing from the floor?*	0.69 (0.77)	49	A	0.46 (0.65)	63	A
g. Turn regular faucets on and off?*	0.46 (0.69)	66	A	0.28 (0.45)	72	A
h. Get in and out of a car, bus, train, or airplane?*	0.64 (0.70)	49	A/B	0.49 (0.70)	63	A
i. Walk 2 miles, if you wish? #	1.26 (1.06)	29	B	1.03 (1.03)	39	B
j. Participate in recreational activities and sports as you would like, if you wish? #	1.59 (1.13)	23	B	1.13 (1.14)	41	B
k. Get a good night's sleep? #	1.28 (0.97)	23	C	1.13 (0.99)	31	C
l. Deal with feelings of anxiety or being nervous? #	0.79 (0.91)	47	C	0.54 (0.65)	54	C
m. Deal with feelings of depression or feeling blue? #	0.76 (0.85)	46	C	0.56 (0.67)	54	C

Conclusion: Scores of 0 are seen on considerably more HAQ items than MDHAQ items. The MDHAQ identifies patient problems, which are not captured by the HAQ, similar in RA and SLE. Documentation of improvement is not possible when baseline scores are zero. The MDHAQ might be considered for usual clinical care as well as in clinical trials.

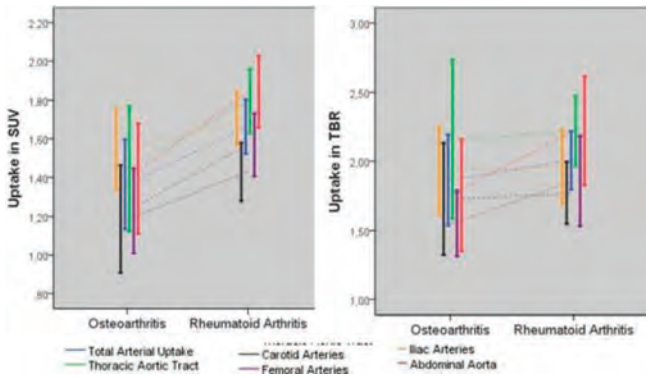
Increased Vascular Wall Inflammation in Patients with Active Rheumatoid Arthritis As Measured By an 18F-FDG-PET/CT Scan. Rabia Agca[1], Alper M. van Sijl[1], Yvo M. Smulders[1], Alexandre E. Voskuyl[1], Connie J. van der Laken[1], Ronald Boellaard[1], Karel-Jan D.F. Lensen[1] and Michael T. Nurmohamed[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands.

Background/Purpose: Patients with rheumatoid arthritis (RA) have an elevated risk of developing cardiovascular disease (CVD). Like active RA, atherosclerosis is an inflammatory process. There are indications that aortic inflammation in atherosclerosis can be detected on an ^{18}F-Fluorodeoxyglucose-positron emission tomography/computed tomography scan (^{18}F-FDG-PET/CT).

Objective: To quantify ^{18}F-FDG uptake in large arteries of RA patients using PET/CT, as potential reflection of vascular wall inflammation in areas of atherosclerosis, and its association with disease activity in patients with RA as compared to controls.

Methods: ^{18}F-FDG-PET/CT scan was performed in patients with active RA (DAS28 > 4.0; n=29) and in controls with osteoarthritis (n=11). Semi-quantitative FDG-uptake was determined by calculation of the mean standardized uptake value (SUV) and tissue-to-background ratio (TBR) using ^{18}F-FDG activity in the vena cava as background. One volume of interest (VOI) of an arterial segments with maximum ^{18}F-FDG uptake was used for SUV calculation (focal arterial uptake). Total arterial uptake was estimated by using the mean of all focal arterial uptakes in all arteries.

Results: Focal as well as total arterial uptake of ^{18}F-FDG was the highest in patients with RA. SUV was significantly higher in RA for the thoracic aortic tract, the abdominal aorta and the femoral arteries as compared to OA controls. C-reactive protein was associated with an increased total arterial uptake as well as an increased focal arterial uptake in the thoracic aortic tract, the abdominal aorta, the iliac arteries and the femoral arteries. DAS28 >2,6 was also correlated to total arterial uptake and uptake in the thoracic aortic tract, the abdominal aorta and the iliac arteries. There were no significant differences in TBR between RA and OA.



Conclusion: Increased focal vascular wall uptake of ^{18}F-FDG as sign of vascular inflammation was found in several arterial segments of RA patients. C-reactive protein and clinical RA activity were correlated with ^{18}F-FDG uptake in most of these arteries. Overall, total arterial uptake was higher in RA patients and it was correlated with C-reactive protein and disease activity. The lack of differences in TBR measurements requires further study.

355

Increased Left Ventricular Mass Index and Decreased Ejection Fraction Are Associated with Disease Activity in Rheumatoid Arthritis Patients without Cardiac Symptoms; Comparison Between Non-Biologic and Biologic Dmards Treatment Groups, Using a Cardiac Magnetic Resonance Imaging. Hitomi Kobayashi[1], Yasuyuki Kobayashi[2], Atsuma Nishiwaki[1], Hirotake Inomata[1], Noboru Kitamura[1], Hidetake Shiraiwa[1], Takamasa Nozaki[1], Natsumi Ikumi[1] and Masami Takei[3]. [1]Nihon University School of Medicine, Tokyo, Japan, [2]St.Marianna University School of Medicine, Kawasaki, Japan, [3]Nihon University School of Medicine, Itabashi Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) experience an excess risk of congestive heart failure (CHF), but effects of disease-modifying anti-rheumatic drugs (DMARDs) on cardiac structure and function are uncertain. Cardiac magnetic resonance imaging (CMR) has been used to identify early functional and structural changes in the left ventricle (LV) before development of clinically overt CHF. We evaluated LV function and structure using a CMR in RA patients (pts) without cardiac symptoms, and determined the impact of non-biologic and biologic DMARDs (bDMARDs).

Methods: Consecutive RA pts and healthy control without a history or clinical findings of hypertension, cardiovascular disease, diabetes, or dyslipidemia were enrolled. RA pts received biologic or non-biologic DMARDs (nbDMARDs). All subjects underwent evaluation of LV function and structure using non-contrast CMR. LV function was based on LV ejection fraction (EF), end-systolic volume (ESV), end-diastolic volume (EDV), stroke volume (SV), and cardiac output (CO). LV hypertrophy was measured by absolute LV mass (LVM) and LV mass index (LVMI) determined by LVM/body surface area. Subjects were classified into four categories based on LVMI and LVM/EDV of control subjects, with the mean + 2 SD of each measure defined as elevated LVMI and LVM/EDV.

Results: We compared 90 female RA pts (mean age, 55.9±7.1 years) with a matched 20-patient control group (mean age, 52.7±4.6 years). 46 RA pts received nbDMARDs [43, methotrexate (MTX) (8.1±2.1mg); 3, other drugs)] and 44 RA pts received bDMARDs [(18, infliximab (3 mg/kg); 26, tocilizumab (8 mg/kg) plus MTX (8.0±1.4 mg)]. Among the RA groups, there were no significant differences in characteristics such as age, cardiovascular risk factors, RA duration, MTX dose, and proportion of corticosteroid users. The Simplified Disease Activity Index (SDAI) was significantly

higher in the nbDMARDs group than in the bDMARDs group (22.3±1.5, 5.6±1.9. $p=0.002$). Compared to the control group, the nbDMARDs group showed significantly higher LVMI and lower EF ($p<0.001$, $p=0.003$, respectively). There were no significant differences in LVMI and EF between the control and the bDMARDs groups. LV structure was classified as (1) concentric remodeling (LVMI<66.9 and LVM/EDV >1.02); (2) concentric hypertrophy (LVMI >66.9 and LVM/EDV >1.02); (3) eccentric hypertrophy (LVMI >66.9 and LVM/EDV <1.02); and (4) normal geometry (LVMI<66.9 and LVM/EDV<1.02). Among those with abnormal LV geometry, 32% of RA patients in the nbDMARDs group showed eccentric hypertrophy. 98% of RA patients in the bDMARDs group showed normal geometry. LVMI and EF were significantly associated with SDAI (r=0.567, $p<0.001$; r=−0.312, $p=0.003$, respectively). Mass/EDV tended to be associated with SDAI ($p=0.07$). Adjustment for ESR did not modify the association of SDAI with EF and LVMI ($p=0.017$, $p=0.005$, respectively).

Conclusion: Our results showed that increased LV mass Index and decreased EF were associated with SDAI. Biologics treatment may reduce progression of subclinical LV abnormalities in association with the reduction in disease activity. It can be presumed that disease activity may be an important contributor to the development of LV abnormalities in RA.

The Rheumatoid Arthritis Impact of Disease Score Is Associated with Disease Activity By Clinical, Laboratory and Ultrasonographic Measures: Validation in an inception Cohort of DMARD naïve Patients with Rheumatoid Arthritis. Lena Bugge Nordberg, Elisabeth Lie, Anna-Birgitte Aga, Marthe Thoresen Maehlen, Inge Olsen C, Till Uhlig, Tore K. Kvien, Espen A. Haavardsholm and the Arctic study Group. Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: The Rheumatoid arthritis impact of disease (RAID) score is a relatively new patient-derived composite score assessing the seven most important domains of the impact of rheumatoid arthritis (RA). It is unknown how the RAID score correlates with other disease measures in patients with early RA. We aimed to examine associations between the RAID score and different clinical, laboratory and ultrasonographic disease measures as well as other patient reported outcome measures (PROMs) in an inception cohort of DMARD naïve patients with early RA.

Methods: Consecutive patients from 11 rheumatology centers in Norway who fulfilled the 2010 ACR/EULAR classification criteria for RA were included from October 2010 to April 2013. All patients had symptom duration (from first swollen joint) <2 years and were DMARD naïve with indication for DMARD treatment. Patients were stratified according to level of RAID score at baseline, and a RAID score of ≤3 was considered low, >3–6 moderate and >6 high. Disease measures were compared across RAID levels using either Kruskal-Wallis or ANOVA, and we assessed the correlation between the RAID score and other measures using Pearson or Spearman correlation coefficients, as appropriate.

Results: A total of 229 patients were included, 61.1% female, 81.2% ACPA-positive and with mean (SD) age 51.0 (13.6) years. At baseline, mean (SD) RAID score was 4.5 (0.7), and 28.4%/47.6%/24.0% of the patients had low/moderate/high RAID score according to the above specified cut-offs. Differences in disease measures were all statistically significant across the low, moderate and high RAID groups, with the exception of the power Doppler ultrasonography score (table). Correlation analysis revealed statistically significant correlations between RAID score and all other measures, again with the exception of the power Doppler ultrasonography score. Correlations between RAID and Patient global, EQ-5D and Pain (VAS), respectively, were strong (r≥0.70), and the correlations between RAID and Ritchie, DAS44, Physician global, fatigue and SF-36 Physical and Mental Components Summary measures were moderate (r ≥0.4–0.7). The remaining correlations were weak (r<0.4).

	Low RAID≤3, n=65	Moderate RAID>3-6, n=109	High RAID>6, n=55	P

Development and Validation of a Diagnostic Bead-Based Multiplex Autoantibody Assay:Screening for Autoantibodies to Detect "Seronegative" Rheumatoid Arthritis. Stefan Vordenbäumen[1], Angelika Lueking[2], Carmen Theek[2], Ralph Brinks[1], Rebecca Fischer-Betz[1], Jutta Richter[1], Ellen Bleck[1], Jacqueline Detert[3], Gerd Burmester[4], Peter Schulz-Knappe[2] and Matthias Schneider[1]. [1]Heinrich-Heine-University, Düsseldorf, Germany, [2]Protagen AG, Dortmund, Germany, [3]Charité - University Medicine Berlin, Berlin, Germany, [4]University Medicine, Berlin, Germany.

Background/Purpose: Autoantibodies (auto-Ab) against citrullinated peptides (ACPA) and rheumatoid factor (RF) are important biomarkers in the diagnostic process of rheumatoid arthritis (RA). However, RF or ACPA are undetectable in up to 30% of RA patients who can be referred to as „seronegative". In these cases, the diagnosis is often challenging. Early diagnosis in turn is important for improved outcome. In search for an optimized serologic diagnostic strategy, a comprehensive auto-Ab screening was performed in RA patients.

Methods: 5,892 recombinant human antigens were covalently coupled to fluorescent beads, incubated with patients' sera and detected by a secondary, fluorescent antibody using Luminex xMAP technology. In an explorative phase, auto-Ab profiles were compared between 72 established RA patients according to ACR/EULAR criteria, 71 matched healthy controls, and 129 systemic lupus erythematosus (SLE) patients in an age- and gender-adjusted manner. Predefined multi- and univariate analyses were employed to generate a diagnostic panel of auto-Ab for further testing. In a validation phase, the diagnostic potential of this panel was assessed in 116 RA patients from a randomized controlled trial (HIT-HARD) against 116 matched healthy controls employing logistic regression modelling.

Results: A panel of 11 auto-Ab (including ACPA) showed the best diagnostic properties and was further assessed. In the explorative phase sensitivity/specificity/area under the curve (AUC) were 0.9/0.9/0.97 for RA patients against healthy controls and 0.79/0.92/0.93 against SLE. Omitting ACPA resulted in slightly weaker test performance with sensitivity/specificity/AUC of 0.9/0.86/0.95. When only seronegative (ACPA and RF negative) patients were considered, sensitivity/specificity/AUC was 1.0/1.0/1.0 against healthy controls. In the validation phase on early RA patients from the HIT-HARD study, the panel showed sensitivity/specificity/AUC of 0.71/0.53/0.68 with ACPA and only slightly weaker performance at 0.71/0.52/0.67 without ACPA. Seronegative patients were detected with sensitivity/specificity/AUC of 0.09/0.96/0.78.

Conclusion: The multiplex bead-based approach showed promising results concerning the identification of potential diagnostic markers for seronegative RA. The need for rigorous validation of such explorative approaches to control for over-fitting is clearly demonstrated. Future improvements of the technology such as citrullination of recombinant antigens may further enhance detectability of "seronegative" patients.

Parity and Severity of ACPA-Positive/Negative Rheumatoid Arthritis. Results from the Swedish EIRA Study. Mitra Pikwer[1], Cecilia Orellana[2], Henrik Källberg[2], Andreas Pikwer[3], Carl Turesson[4], Lars Klareskog[5], Lars Alfredsson[6], Saedis Saevarsdottir[7] and Camilla Bengtsson[8]. [1]Institute of Environmental Medicine, Eskilstuna, Sweden, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Centre of Clinical Research Sörmland, Eskilstuna, Sweden, [4]Rheumatology, Department of Clinical Sciences, Malmö, Sweden, [5]Rheumatology Unit, Karolinska University Hospital, Karolinska institutet, Stockholm, Sweden, [6]Centre of Occupational and Environmental Medicine, Stockholm, Sweden, [7]Institute of Environmental Medicine, Karolinska Institutet,, Stockholm, Sweden, [8]The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Female sex and older age are known risk factors for rheumatoid arthritis (RA). The disease is however heterogeneous, and a common division occurs between the presence/absence of autoantibodies to citrullinated peptide antigens (ACPA) where ACPA-positive disease generally has a worse outcome. In a recent study we reported that parous women of reproductive age (18 to 44 years at diagnosis) had an increased risk of ACPA-negative, but not of ACPA-positive RA, and that this association was stronger closer to partum[1]. There are diverging results regarding the effect of parity on the severity of RA.

Our purpose was to explore if parity has impact on disease severity of RA, stratified into different phenotypes.

Methods: We studied female RA cases aged 18–70, who participated in the Epidemiological Investigation of Rheumatoid arthritis, EIRA, a population-based case-control study from the middle and southern parts of Sweden. All patients included fulfilled the American Collage of Rheumatology (ACR) 1987 criteria for RA and were diagnosed by a rheumatologist, and included within 1 year of diagnosis. Information on disease severity (Health Assessment Questionnaire, HAQ and disease activity score 28, DAS28) was gathered from the Swedish Rheumatology Register, SRQ at inclusion, 3, 6, 12 and 24 months after diagnosis. Mixed models for repeated measurements over time were used to take account of the variation at different time point at individual level and to compare mean DAS28 and HAQ-scores over time. ANCOVA analysis was used to compare mean differences of clinical outcome measures at all time points.

Results: A total of 1237 female cases, with complete information, were included in the study with a mean age of 51 at inclusion. In all, 82% had ever given birth to a child before diagnosis and 65 % were ACPA-positive. Mixed models analysis showed associations between parity and ACPA negative but not ACPA positive disease. Parous women, aged 18–44, who would develop ACPA negative disease, had on average 1.17 higher DAS 28 ($p < 0.001$) and 0.43 higher HAQ ($p < 0.001$) compared to nulliparous women during the follow up time, adjusted for age. These findings remained after individually adjustment for smoking, living area and level of education. There was an opposite trend among parous ACPA negative women (aged 45 to 70), were parous women had 0.26 lower DAS 28 ($p=0.14$) and 0.06 lower HAQ ($p=0.46$). ANCOVA analysis for different time points noted an association between higher DAS 28 and HAQ levels and parity in the ACPA negative reproductive age group at all time points, except at baseline. In ACPA negative older age group we observed a milder disease in parous women, although only significant at baseline.

Conclusion: Parity influenced ACPA negative disease, where parous women who developed RA during their fertile years had on average higher DAS 28 and HAQ compared to nulliparous women. Parity was not a predictor of severity in ACPA positive disease.

14-3-3η Cit:Arg Antibody Ratios: Are We Overlooking the Prognostic Utility of Citrullinated Antibodies By Only Looking at Titers? Anthony Marotta[1], Samina Turk[2], Mairead Murphy[1], WP Maksymowych[3] and Dirkjan van Schaardenburg[2]. [1]Augurex Life Sciences Corp., North Vancouver, BC, [2]Reade, Amsterdam, Netherlands, [3]University of Alberta, Edmonton, AB.

Background/Purpose: Citrullination is a post-translational modification whereby arginine (Arg) is deiminated by PAD enzymes to form citrulline (Cit). In RA, there are auto-antibodies (AAb) to Cit and native proteins[1, 2]. With other types of PTM, such as phosphorylation, modifications are assessed as a degree of change in reactivity from the native state to inform biochemically relevant and potentially deleterious events. Current ACPA assays are designed to measure reactivity to the Cit form of a peptide without accounting for the relative change in Cit:Arg reactivity. This may overlook important information related to citrullination and its relationship with clinical outcomes. 14-3-3η is a ubiquitous intracellular protein whose extracellular expression in RA leads to its citrullination and the development of specific cit-reactive AAb. In this study we investigated whether anti-cit 14-3-3η AAbs inform joint damage prognosis in early RA.

Methods: Anti-cit 14-3-3η levels were measured in 139 DMARD-naïve early RA patients from the READE cohort using the MSD ECL platform, 4 highly reactive 14-3-3η cit/arg peptides formed the basis of the assay. For each of the 4 sites, citrullination reactivity was defined as a 50% increase in Cit:Arg read units. Overall anti-cit-14-3-3η positivity was defined as reactivity to at least one of the four sites. Contingency analysis was used to assess the association between ACPA and 14-3-3η anti-cit:arg ratio positivity. Univariate and stepwise multivariate analyses were performed to identify predictors of radiographic damage progression (DSHS year 3 $\geq$ 3.0).

Results: Of 139 patients, 71% were ACPA positive and 51% were 14-3-3η anti-cit:arg ratio positive. A univariate analysis evaluating the association of anti-cit-14-3-3η titres and cit:arg ratios with radiographic progression revealed that the ratios were significantly associated ($p<0.01$) while titres were not. Contingency analysis revealed a strong association between APCA and 14-3-3η anti-cit:arg ratios, LR=19.1 $p<0.0001$. By Fisher Exact test, ACPA and 14-3-3η anti-cit:arg ratios were associated with radiographic progression at yr 3; LR=5.3 $p=0.02$ and 6.4 $p=0.01$, respectively. In a model incorporating ACPA and 14-3-3η anti-cit:arg ratio controlling for baseline total sharp score, the ratios independently predicted radiographic progression Chi-Sq=6.4 $p=0.01$, while ACPA did not. In a multivariate model including baseline TSS, disease duration, age, ESR, gender together with RF, 14-3-3η and 14-3-3η anti-cit:arg ratio positivity, the only independent predictors of radiographic damage progression were 14-3-3η protein and the cit:arg ratios; Chi-Sq=5.2 ($p=0.02$) and 4.0 ($p=0.05$), respectively.

Conclusion: Both the 14-3-3η protein and 14-3-3η anti-cit:arg ratios are independent predictors of radiographic progression. The ratios (but not anti-cit-14-3-3η titres) are a stronger predictor than ACPA. These data underscore 1) the potential benefit of accounting for cit:arg ratios rather than only cit titres in cit assays and 2) that the prognostic utility of 14-3-3η anti-cit:arg ratios should be further investigated.

88% of Recent Onset Polyarthritis Patients Are Positive for 14-3-3η Markers and 14-3-3η Auto-Antibodies Inform a Favourable Prognosis. Gilles Boire[1], Nathalie Carrier[2], Artur Jose de Brum-Fernandes[2], Patrick Liang[3], Ariel Masetto[4], Yuan Gui[5], Mairead Murphy[5], WP Maksymowych[6] and Anthony Marotta[5]. [1]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [2]Universite de Sherbrooke, Sherbrooke, QC, [3]CHUS, Sherbrooke, QC, [4]CHUS, Fleurimont, QC, [5]Augurex Life Sciences Corp., North Vancouver, BC, [6]University of Alberta, Edmonton, AB.

Background/Purpose: The 14-3-3η protein has been described as a mechanistic marker that is detectable in serum during the very early stages of RA development. A specific anti-14-3-3η autoantibody response is present in RA serum and is postulated to be protective when it effectively clears systemic 14-3-3η. This study examined the baseline expression of 14-3-3η

markers (protein and pan-autoantibodies) in a recent onset polyarthritis cohort and their association with the progression of joint damage.

Methods: 335 subjects were evaluated; 40 DMARD-naïve patients from the Sherbrooke EUPA cohort and 295 controls. Median age was 50 yrs, 2 months median disease duration, 75% were female and 60% were positive for RF and 55% for ACPA. Controls included 106 healthy and 189 disease controls consisting of connective tissue disease, OA, AS or autoimmune disorders. 14-3-3η protein levels were previously tested in this cohort using the Augurex 14-3-3η ELISA (cut-off $\geq$0.19 ng/ml) and 50% of the recent onset polyarthritis patients were positive. 14-3-3η AAb levels were measured on the MSD ECL platform using an established positive cut-off $\geq$380 U/ml. The group that was 14-3-3η AAb-only positive, in whom the 14-3-3η protein would have been cleared, was compared to the remainder of the cohort in terms of differences in radiographic progression over 30 months using the Mann-Whitney U-test. The Fisher Exact test was used to determine the association between marker positivity and radiographic progression (SHS$\geq$3 at 30 months).

Results: Median (IQR) 14-3-3η AAb values were significantly higher in early RA 617 U/ml (473–742) vs all controls 264 U/ml (200–348), $p<0.0001$ delivering a ROC AUC of 0.89 (95%CI:0.85–0.94). When compared to healthy subjects, the ROC AUC was 0.95 (95%CI:0.92–0.99), $p<0.0001$ delivering 93% specificity and 85% sensitivity with a likelihood ratio (LR) of 11.3. Thirty-four patients (85%) were 14-3-3η AAb positive, 88% were positive for either of the 14-3-3η markers and a Pearson correlation between the two 14-3-3η markers of $r < 0.01$ highlighted their complementary nature. Of the 40 patients, 15 (38%) were only positive for the 14-3-3η AAbs and had significantly less joint damage progression at 30 months, median (IQR) ΔSHS 0 (0–3.5) vs the rest of the cohort, 5 (−0.3–11.5), $p<0.03$. The Fisher exact test revealed that 14-3-3η AAb positivity (in the absence of the 14-3-3η protein) is associated with less radiographic progression at 30 months yielding an Odds Ratio of 5.3 (95%CI 1.2–23.9). $p=0.03$.

Conclusion: 14-3-3η and anti-14-3-3η biomarkers identify 88% of recent onset polyarthritis patients and those who are only positive for 14-3-3η AAbs have a more favorable radiographic prognosis. This is potentially due to the more effective clearance of deleterious 14-3-3η protein by anti-14-3-3η antibodies in these patients.

Citrullinated 14-3-3η Antibodies Are Specific for Early and Established RA and Are Complementary to ACPA. Anthony Marotta[1], Dirkjan van Schaardenburg[2], Gilles Boire[3], Désirée van der Heijde[4], Robert Landewé[5], Maarten Boers[6], C.F. Allaart[4], Mairead Murphy[1], Samina Turk[2], Vivian P. Bykerk[7], Edward Keystone[8], Katherine A. Siminovitch[8] and WP Maksymowych[9]. [1]Augurex Life Sciences Corp., North Vancouver, BC, [2]Reade, Amsterdam, Netherlands, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [6]Jan van Breemen Research Institute/Reade, Amsterdam, Netherlands, [7]Divison of Rheumatology, Hospital for Special Surgery, New York, NY, [8]Mount Sinai Hospital, Toronto, ON, [9]University of Alberta, Edmonton, AB.

Background/Purpose: Citrullination is a post-translational modification whereby arginine (Arg) is deiminated by PAD enzymes to form citrulline (Cit). In RA, current ACPA assays measure the ACPA titer without determining whether the observed reactivity is specific for the citrullinated or arginilated form of the peptide. Brink showed that autoantibodies (AAb) directed to uncitrullinated peptides may occur prior to the development of cit specific antibodies. Consequently, important information related to citrullination and its relationship to clinical outcomes might be overlooked. 14-3-3η is normally an intracellular protein whose extracellular expression in RA leads to the development of specific pan-reactive AAb to the native protein that inform joint damage prognosis, and also cit-14-3-3η-reactive AAbs. In this study we examined 14-3-3η cit:arg reactivity and its complementarity to ACPA in diagnosing RA.

Methods: A total of 623 subjects were evaluated; 190 DMARD-naïve early RA patients (READE n=139, Sherbrooke n=40, iCOBRA n=11), 115 with classified established RA (n=65 from the RAPPORT cohort; 50 from the year 3 time point of the BeSt study). 318 controls constituted 106 healthy and 212 disease controls with connective tissue disease, OA, AS and autoimmune conditions. AAb levels were measured using the MSD ECL platform. Seven (7) cit/arg sites on 14-3-3η were examined for differential AAb reactivity between RA and controls using the Kruskal-Wallis test and ROC curve analysis. The paired t-test was used to determine differences in cit:arg reactivity. Anti-cit-14-3-3η positivity at an individual cit site was defined by a 50% increase in reactivity to the cit site over the corresponding arg site, with overall anti-cit positivity defined as positive at a least one cit site.

Results: The significantly higher reactivity of anti-cit 14-3-3η in RA versus controls, based on ROC analysis and assessment of cit:arg fold reactivity, resulted in the prioritization of 4 cit sites (1, 2, 4, 7) which reside on the protein surface. Reactivity was not confined to the cit form of the peptide since significantly higher reactivity to the arg peptide was also apparent in RA versus controls. Importantly, 50% of early and 54% of established RA patients were anti-cit-14-3-3η positive. While the Fisher Exact test revealed a significant association between anti-cit-14-3-3η and ACPA positivity (LR = 19.1 $p<0.0001$), in ACPA negatives, 25% of early and 41% of established RA patients were positive for anti-cit-14-3-3η. Combining ACPA and anti-cit-14-3-3η reactivity improved the early RA capture rate (table).

	Early RA (n=190)		Established RA (n=115)	
Based on ACPA	**ACPA -ve (n=60)**	**ACPA +ve (n=130)**	**ACPA -ve (n=27)**	**ACPA +ve (n=88)**
Cit-14-3-3η eta Ab, % (n)	25% (15)	62% (80)	41% (11)	58% (51)
Combination of Markers				
ACPA	68% (130)		77% (88)	
Cit-14-3-3η	50% (95)		54% (62)	
Either Marker	76% (145)		86% (99)	

Conclusion: In RA, AAbs exist against 14-3-3η native and citrullinated protein. Anti cit-14-3-3η AAbs are expressed in early and established RA and complement ACPA as a diagnostic aid. Relative cit:arg AAb reactivity should be accounted for in citrullination assays to properly assess the burden of citrullination in RA.

14-3-3η Early RA Biomarkers: Does Seronegative RA Exist? Dirkjan van Schaardenburg[1], WP Maksymowych[2], Maarten Boers[3], Samina Turk[1], Mairead Murphy[4] and Anthony Marotta[4]. [1]Reade, Amsterdam, Netherlands, [2]University of Alberta, Edmonton, AB, [3]Jan van Breemen Research Institute/Reade, Amsterdam, Netherlands, [4]Augurex Life Sciences Corp., North Vancouver, BC.

Background/Purpose: RF and ACPA are used for early diagnosis and in prediction models for the risk of RA development in arthralgia patients. There remains a high unmet need for biomarkers in the earliest stages of RA to assist with detection and prognosis to enable therapy initiation within the first 6–12 weeks of symptom onset. The 14-3-3η serum protein and its corresponding anti-14-3-3η auto-antibodies are early complementary markers to RF/ACPA. This study describes their expression and diagnostic utility as well as their complementarity to RF/ACPA in early RA.

Methods: 14-3-3η plasma protein levels were measured on the Augurex ELISA and 14-3-3η auto-antibody levels on the Meso-Scale-Discovery electro-chemiluminescent platform in 409 consecutive early RA patients (Reade cohort) according to the 2010 ACR/EULAR RA classification criteria. Patients were DMARD-naïve, had a rheumatologist-confirmed diagnosis, median symptom duration was 4 months, mean age was 54 years and 73% were female. For 14-3-3η auto-antibody level determination, a composite score of six (6) peptides was generated. Peptides were selected based on their individual highest sensitivity for 100% specificity and their complementarity to maximize patient capture. An auto-antibody score of $\geq$380 U/ml was determined to be the best positive cut-off. Serum 14-3-3η protein levels were previously determined in these subjects with a positive diagnostic cut-off of $>$ 0.19 ng/ml. Positive baseline status for each of the 14-3-3η markers and RF and ACPA were compared to examine the extent of early RA patient capture rate versus RF/ACPA.

Results: In the 409 patients, 67% (n=275) were positive for the 14-3-3η protein with median (IQR) titres of 0.63 (0.10–5.13) ng/ml

and 77% (n=313) were positive for 14-3-3η auto-antibodies with median (IQR) values of 527 (387–753) U/ml. RF and ACPA positive rates in this cohort were 63% (n=259) and 69% (n=282), respectively. 76% (n=310) of patients were positive for one or both of RF and ACPA, 93% (n=394) were positive for either of the 14-3-3η markers and 96% for any one of the four markers. This represents 23% more patients identified by 14-3-3η markers alone compared to RF/ACPA, and 27% more when the four markers are used together.

Conclusion: 14-3-3η markers identify 93% of early RA patients compared to RF/ACPA alone at 76%. The combination of all four markers captures 96% of early RA patients which creates the opportunity to treat more patients within the therapeutic window and improve clinical outcomes.

Increased Prevalence of Plasma Anti-Nuclear, Anti-SSA, and Connective Tissue Disease Associated Antibodies in African American Patients with Rheumatoid Arthritis. Rayford R. June[1], Douglas P. Landsittel[2], Bruce Rabin[3], S. Louis Bridges Jr. [4], CLEAR Investigators[4], TEAR Investigators[4], Thomas A. Medsger Jr. [1] and Larry W. Moreland[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Center for Health Care Research Data Center, Pittsburgh, PA, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: African American (AA) patients with rheumatoid arthritis (RA) have been shown to have worse disability scores, increased disease activity scores, and reduced use of disease modifying anti-rheumatic drugs. The frequency of antinuclear antibodies (ANA) in Caucasian (CAU) RA has been reported, but ANA occurrence in AA RA patients is unknown. ANA positive CAU RA patients have an increased autoimmune genetic risk score and this phenotype is associated with coexistent Sjögren syndrome (SS). There is a high frequency of anti-SSA antibodies in SS. We hypothesized that AA RA patients have an increased frequency (compared to CAU RA patients) of ANA, anti-SSA, and other connective tissue disease (CTD) associated autoantibodies.

Methods: We assayed plasma samples from two published RA cohorts: (1) AA patients in the Consortium for the Longitudinal Evaluation of African-Americans with Early Rheumatoid Arthritis (CLEAR II) and (2) CAU patients from the Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) Trial. All patients met the revised 1987 American College of Rheumatology classification criteria for RA. A total of 587 CLEAR and 390 TEAR samples were tested for ANA by indirect immunofluorescence (IIF) and the multiplex bead array (MBA) Bioplex 2200 ANA Screen. Differences in prevalence between AA and CAU RA patients was assessed using tests of proportions with chi-square and Fisher's exact tests. Multivariable logistic regression was used to adjust results for age, sex, body mass index (BMI), modified HAQ, RF and anti-CCP positivity.

Results: ANA by IIF was positive (≥ 1:80) significantly more frequently in AA RA patients (187/587 or 32%) compared with CAU RA patients (65/390 or 17%, p<0.001). The pattern of nuclear staining among patients with a positive ANA significantly differed by racial/ethnic group (p<0.001), with AA RA patients having higher frequencies of speckled staining (64% vs. 46%; p=0.01) where as CAU RA patients had higher frequencies of nucleolar staining (10% vs. 3%; p=0.03). Anti-SSA was detected in twice as many AA RA patients (80/587 or 14% vs. 22/390 or 6%, p<0.001). Systemic lupus associated antibodies (anti-Sm, anti-RNP, anti-Sm/RNP, and anti--chromatin) were also higher in this population (see Table 1). Higher prevalence of ANA and anti-SSA remained significant (p<0.001) after adjustment. In the AA RA patients, logistic regression showed only RF was associated with ANA and anti-SSA without previous TNF use or disease duration significant.

Conclusion: We found that the prevalence of ANA, anti-SSA, and other CTD associated autoantibodies is higher in AA RA patients than in a CAU RA cohort. The increase in ANA prevalence is greater than the published difference in ANA by race (15% vs. 3%) and suggests the existence of a meaningful serological subset of AA RA patients beyond the currently recognized serologic subsets identified by RF and anti-CCP antibodies.

Table 1 ANA and Multiplex Bead Array Prevalence in AA and CAU RA Patients

	AA % Positive	CAU % Positive	P-Value
ANA IIF ('1:80)	31.9	16.7	p<0.001
SSA	13.6	5.6	p<0.001
SSB	2.7	1.3	p=0.123
SSA AND/OR SSB	14.1	5.9	p<0.001
DS DNA	3.7	2.7	p=0.237
Sm	1.5	0	p=0.014
Sm/RNP	4.8	0.3	p<0.001
RNP	5.3	2.6	p=0.038
Chromatin	3.1	0.8	p=0.015
Ribosomal P	0.2	0	p>0.99
Centromere B	2.9	0.8	p=0.021

In Early Rheumatoid Arthritis, the Multi-Biomarker Disease Activity Score at Different Time-Points Is Predictive of Subsequent Radiographic Progression. Karen Hambardzumyan[1], R.J. Bolce[2], Saedis Saevarsdottir*[3], Kristina Forslind[4], Ingemar F. Petersson[5], Pierre Geborek[6], Eric H. Sasso[2], David Chernoff[2], Scott Cruickshank[7] and Ronald F. van Vollenhoven[8]. [1]the Karolinska Institute, Stockholm, Sweden, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institute, Stockholm, Sweden, [5]Lund University, Lund, Sweden, [6]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden, [7]Scott Cruickshank and Associates, Inc., Santa Barbara, CA, [8]Unit for clinical therapy research (ClinTrid), Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The prediction of radiographic progression in early rheumatoid arthritis (eRA) patients is important for optimal treatment. We previously demonstrated that a multi-biomarker disease activity (MBDA) score (Vectra DA®) at baseline (BL) was predictive for radiographic progression over the first year of treatment of eRA patients from the Swedish Farmacotherapy (SWEFOT) trial. The objective of this study was to evaluate the MBDA score, at different time-points and its change during treatment, as a predictor of radiographic progression over the first two years of treatment in eRA patients.

Methods: The analyses were performed on radiographic progression of patients from the SWEFOT trial, assessed by van der Heijde modified Sharp scores (SHS) from BL to years 1 and 2 (n=220) and from Year 1 to Year 2 (n=133); and on the MBDA and disease activity scores (DAS28) and C-reactive protein (CRP) at BL (n=220), Month 3 (n=220) and Year 1 (n=133). Radiographic progression was defined as ΔSHS >5. Mann-Whitney U and Chi-square tests were used for comparisons of disease activity measures between progressors and non-progressors, and for determining significance of proportion of radiographic progressors.

Results: The median values for year 1-progressors (n=41) and non-progressors (n=179) were MBDA score, 70 and 58 (p=0.001); CRP (mg/L) 28 and 18 (p=0.049); and DAS28, 6.1 and 5.7 (p=0.136), respectively. After 3 months of MTX therapy the corresponding values were 48 and 40 (p=0.001), 9 and 9 (p=0.213), and 4.8 and 4.0 (p=0.009), respectively. At BL, 3 months and 1 year, patients with low MBDA score had a lower mean ΔSHS and a smaller proportion of subsequent radiographic progressors than those with low CRP or low DAS28 (table).

The highest risk for progression from BL to year 1 or 2 (25% and 41%, respectively), or from year 1 to year 2 (32%), was observed among patients with high MBDA score at BL which remained high at 3 or 12 months. In contrast, much lower risk of radiographic progression from BL to year 1 and 2 was detected among those patients whose BL high MBDA score dropped to low by month 3 (6% and 18% respectively) and very low risk of radiographic progression from Year 1 to Year 2 was among those patients who achieved low MBDA score by month 12 (4%). All patients with persistent low MBDA score throughout 1 year did not progress radiographically over 2 years. Those who had a moderate MBDA score at BL and achieved low MBDA at months 3 or 12 did not progress either.

Disease activity time-point	Time-period for radiographic progression	Proportion of Radiographic progressors (DSHS>5) MBDA score Low (<30)	Moderate (>29–44)	High (>44)	CRP (mg/L) Low (≤10)	Moderate (>10–30)	High (>30)	DAS28 Low (≤3.2)	Moderate (>3.2–5.1)	High (>5.1)
BL	*From BL to year 2 (n=220)*	0/5 0.0%	5/28 17.9%	60/187 32.1%	13/66 19.7%*	18/72 25.0%*	34/82 41.5%*	NA	18/64 28.1%	47/156 30.1%
Month 3	*From BL to year 1 (n=220)*	1/33 3.0%*	14/91 15.4%*	24/96 25.0%*	23/157 14.6%	5/39 12.8%*	11/24 45.8%	10/78 12.8%	14/87 16.1%	15/55 27.3%
	From BL to year 2 (n=205)	3/33 9.1%*	21/82 25.6%*	37/90 41.1%*	34/147 23.1%*	16/38 42.1%*	11/20 55.0%*	17/72 23.6%	26/82 31.7%	18/51 35.3%
Year 1	*From year 1 to year 2 (n=133)*	2/60 3.3%*	3/36 8.3%*	12/37 32.4%*	10/112 8.9%*	4/14 28.6%*	3/7 42.9%*	4/66 6.1%*	8/54 14.8%*	5/13 38.5%*
		ΔSHS Mean (median)								
BL	*ΔSHS from BL to year 1*	0.8 (0)	1.1 (0)	3.4 (1)	2.1 (0)	2.1 (0)	4.7 (2)	NA	2.4 (1)	3.3 (1)
Month 3	*ΔSHS from BL to year 1*	0.5 (0)	2.3 (1)	4.7 (3)	2.1 (0)	3.9 (3)	7.6 (4.5)	2.1 (0)	2.7 (1)	5.0 (1)
	ΔSHS from BL to year 2	1.5 (0)	3.6 (2)	7.2 (4.5)	3.5 (1)	6.1 (4.5)	12.3 (6)	3.7 (1)	3.9 (2)	8.0 (3)
Year 1	*ΔSHS from year 1 to year 2*	0.6 (0)	1.0 (0)	4.8 (2.5)	1.3 (0)	4.5 (2.5)	8.4 (4)	1.2 (0)	2.3 (0)	6.1 (3)

*Significantly different proportions of progressors (defined by Chi-square test).
NA – not applicable.

Conclusion: MBDA scores at BL and at 3 and 12 months of treatment, as well as change in MBDA category were predictive of subsequent radiographic progression during up to 2 years. At all measured time points, having a low MBDA score was associated with low risk for subsequent radiographic progression.

Differential Relative Contribution of Individual Components on DAS28 over Time: An Analysis from the Prospective, Observational, Biological Treatment Registry Across Canada. Denis Choquette[1], Dalton Sholter[2], Isabelle Fortin[3], Michael Starr[4], Carter Thorne[5], Milton Baker[6], Regan Arendse[7], Philip Baer[8], Michel Zummer[9], Jude Rodrigues[10], Maqbool Sheriff[11], Emmanouil Rampakakis[12], John S. Sampalis[12], Francois Nantel[13], Allen J Lehman[13], Susan Otawa[13] and May Shawi[13]. [1]Notre Dame Hospital, Montreal, QC, [2]University of Alberta, Edmonton, AB, [3]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [4]Montreal General Hospital, Montreal, QC, [5]Southlake Regional Health Centre, Newmarket, ON, [6]University of Victoria, Victoria, BC, [7]University of Saskatchewan, Saskatoon, SK, [8]Private Practice, Scarborough, ON, [9]Université de Montréal, Montreal, QC, [10]Clinical Research and Arthritis Centre, Windsor, ON, [11]Nanaimo Regional General Hospital, Nanaimo, BC, [12]JSS Medical Research, Montreal, QC, [13]Janssen Inc., Toronto, ON.

Background/Purpose: DAS28 is an important outcome for clinical research and practice assisting with therapeutic decisions. The main contributors to DAS28 are joint tenderness and acute-phase reactants. A simulation analysis showed that, due to its logarithmic transformation in the DAS28 formula, the ESR contribution is greater in the lower than in the higher DAS28 range. This analysis assessed the relative contribution of individual DAS28 components and examined its clinimetric properties in rheumatoid arthritis (RA) patients treated with infliximab in a Canadian real-world setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after treatment with a biologic for <6 months (M). RA patients treated with infliximab between 2002–2012 and with ≤60M of follow-up were included. The association between treatment duration and parameter improvement was assessed using linear regression. Slope correlation was assessed with the Pearson's correlation coefficient.

Results: 832 patients evaluated over 4,002 visits were included. Longer treatment duration was associated with significant (P<0.001) improvements in DAS28, TJC28, SJC28, PtGA, ESR, and CRP. Correlation analysis of the rate of change over time showed a high correlation (0.7–0.9) of DAS28 with TJC28, SJC28, and PtGA but low correlation with ESR (r=0.418) and CRP (r=0.411).

Overall, the relative contribution of TJC28, SJC28, PtGA, and ESR in DAS28-ESR was 22%, 9%, 12%, and 57%, respectively. For DAS28-CRP, the relative TJC28, SJC28, PtGA, and CRP contributions were 25%, 10%, 12%, and 20%. Over 60M of treatment, the mean relative contribution of TJC28 (M0:31%, M60:17%), SJC28 (M0:15%, M60:5%), and PtGA (M0:15%, M60:9%) significantly (P<0.001) decreased whereas the weight of ESR contribution increased (M0:39%, M60:69%). Similar results were obtained with DAS28-CRP although the CRP contribution was lower compared to ESR.

Increased DAS28-ESR was associated with higher relative contributions (per unit of DAS28-ESR increase) of TJC28 [parameter estimate (B) = 5.3], SJC28 (B=2.1), and PtGA (B=0.7) but lower ESR contribution (B=−8.1). Similarly, increased DAS28-CRP was associated with lower relative CRP contribution (B=−2.0).

Conclusion: This analysis shows that TJC28 and acute-phase reactants have a greater weight than SJC28 and PtGA within DAS28. Furthermore, the relative contribution of acute-phase reactants is greater with lower DAS28, due to their logarithmic nature. These findings suggest that biologic variability and variability in laboratory techniques may have significant impact on classifying remission or DAS28 changes among patients with low DAS28 and on therapeutic plan changes.

Soluble 4-1BB Is a Marker of Joint Involvement and Disease Activity in Rheumatoid Arthritis. Morten Aagaard Nielsen[1], Thomas Andersen[1], Kristian Stengaard-Pedersen[2], Kim Hoerslev-Petersen[3], Merete Lund Hetland[4], Peter Junker[5], Mikkel Ostergaard[6], Malene Hvid[1] and Bent Deleuran[2]. [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark, [4]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup University Hospital, Glostrup, Denmark, Glostrup, Denmark, [5]University of Southern Denmark, Odense, Denmark, [6]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark.

Background/Purpose: 4-1BB is induced on T cells after antigen encounter and promotes clonal expansion and accumulation of high numbers of antigen-specific effector-type T cells primarily in the joint. This leads to survival of CD4 T cells and CD8 T cells and enhance TCR-dependent activities such as cytokine production. 4-1BB has previously been linked to rheumatoid arthritis (RA). We examined the role of 4-1BB in early treatment naïve RA (eRA, the OPERA cohort) and chronic RA (cRA).

Methods: Soluble 4-1BB was measured by ELISA in plasma from 77 treatment naïve eRA patients (disease < 3 month), at baseline, after 3 months, and after 12 months of treatment in addition to age and gender matched healthy volunteers (HV) (n=54). Treatment was methotrexate + placebo (MTX) (n=41) or MTX + Adalimumab (ADA) (n=36). Clinical disease was assessed by: DAS28, CRP, number of swollen (SJ40) and tender joints (TJ40), IgM-RF and ACPA. In addition s4-1BB was also measured by ELISA in both plasma and synovial fluid (SF) from 8 cRA patients (disease duration > 6 years (24 (7–48) years) with active disease.

Membrane bound 4-1BB was measured on peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) by flow cytometry in cRA, and in PBMC from HV (n=9). Paired samples were compared by Wilcoxon signed rank test, non-paired samples by Mann-Whitney rank sum test. Correlations were tested using Spearman's rho (ρ). Data are expressed as median (IQR).

Results: In eRA plasma levels of s4-1BB were significantly elevated at baseline (9.8 (4.0–23.0) pg/ml) compared with HV (4.0 (4.0–4.9) pg/ml) (P < 0.01). After 12 months treatment 4-1BB levels were similar to levels in HV. No differences were seen in the s4-1BB plasma levels over time between the ADA and MTX group. We observed correlation with baseline s4-1BB with SJ40 (ρ =0.3) and DAS28 at 24 month (ρ =0.3) (both p<0.05)). A significant association with the presence of IgM-RF was observed.

In cRA patients significantly elevated levels were measured in the SF ((102 (44.9 –134.4) pg/ml) compared with plasma ((5.24 (3.91–40.3) pg/ml) (P < 0.01). Further, plasma s4-1BB showed a strong correlation with the corresponding levels in the synovial fluid. (ρ=0.7, p< 0.01).

In cRA the expression of 4-1BB on the total number of T cells was significantly higher in SFMCs (4.12% (2.24–12.52) %) compared with PBMCs (1.55% (0.93–3.57) %) and PBMCs from HV (0.91 (0.53–2.35) %)

(both $p < 0.01$). Further 4-1BB was primarily expressed by CD45RO+ T-cells.

Conclusion: 4-1BB plasma levels were significantly elevated in treatment naïve eRA patients and decreased to levels comparable with HV within 12 months of successful treatment.

The discovery that s4-1BB is association with number of swollen joints and DAS28 as far as 2 years post treatment initiation, and since the s4-1BB in plasma reflects the levels seen in the SF in active cRA, all points to 4-1BB being a potential marker of disease activity. 4-1BB expression is mainly present on activated T cells in the joint of patients with active cRA. This confirms that 4-1BB is present in the inflamed joint in cRA.

Taken together this supports a central role of 4-1BB in the T cell activity in the inflamed joint; the centre of disease development in eRA.

In Early Rheumatoid Arthritis Patients with Non-Response to Methotrexate Monotherapy the Change in Multi-Biomarker Disease Activity Score Is Differentially Associated with Subsequent Response to Non-Biological Versus Biological Therapy. Karen Hambardzumyan[1], R.J. Bolce[2], Saedis Saevarsdottir[3], Kristina Forslind[4], Ingemar F. Petersson[5], Pierre Geborek[6], Eric H. Sasso[2], David Chernoff[2], Scott Cruickshank[7] and Ronald F. van Vollenhoven[8]. [1]the Karolinska Institute, Stockholm, Sweden, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institute, Stockholm, Sweden, [5]Lund University, Lund, Sweden, [6]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden, [7]Scott Cruickshank and Associates, Inc., Santa Barbara, CA, [8]Unit for clinical therapy research (ClinTrid), Karolinska Institute, Stockholm, Sweden.

Background/Purpose: For patients with early RA (eRA), methotrexate (MTX) is recommended as first-line treatment and in non-responders both the addition of conventional non-biological disease modifying anti-rheumatic drug therapy (triple DMARD therapy) and of biological (anti-TNF) therapy are supported by data. Identification of patients with a higher likelihood of responding to one or the other of these options would lead to more personalized medicine and an increased effectiveness of therapy. The objective of this study was to evaluate the change in the multi-biomarker disease activity (MBDA) score (Vectra DA®) during MTX therapy as a predictor of response to subsequent non-biological triple versus biological therapy.

Methods: Patients with eRA and DAS28 >3.2 entered the Swedish Farmacotherapy (SWEFOT) clinical trial and received MTX monotherapy for 3 months, at which time clinical non-responders (DAS28 >3.2) were randomized to receive non-biological triple DMARD therapy (arm A) or anti-TNF (infliximab) therapy with MTX (arm B). For this study, 129 non-responders at month 3 (n=62 from arm A and n=67 from arm B) were analyzed by MBDA score at baseline (BL) and month 3. The assessment of changes in the MBDA score (ΔMBDA) from BL to month 3 as a predictor for response (according to DAS28 and EULAR response criteria) to triple or anti-TNF therapy at year 1 was done by defining small (≤6), moderate (7–20) and large (>20) decreases by tertiles. Small and moderate decreases were combined together (small/moderate) and compared versus large decreases for arms A and B. The proportion of patients in arm A versus arm B with response at year 1 was evaluated by the odds ratio (OR) for patients with small/moderate versus large decreases. Homogeneity of the odds ratios between the two cohorts was assessed by Breslow-Day test.

Results: The mean (median) decreases in MBDA score from BL to month 3 for year 1 responders (n=66) and non-responders (n=63) were 12.9 (10) and 10.8 (9), respectively (p=0.431), and Month 3 mean (median) MBDA scores were 47.1 (45) and 50.3 (47), respectively (p=0.336). Of patients who had small/moderate decreases in MBDA score during MTX monotherapy, 43% responded to subsequent triple therapy and 57% responded to anti-TNF (OR=0.577). In contrast, among patients with a large decreases in MBDA score from BL to month 3, 67% responded to subsequent triple therapy and 37% to anti-TNF treatment (OR=3.33). Thus the relative treatment effect of arm A versus arm B differed according to the degree of change in the MBDA score from BL to 3 months (p=0.032). Similarly, good EULAR response was achieved by the majority (67%) of patients from arm A, who had large decrease in MBDA score and also the majority (57%) of patients from arm B, who had small/moderate decrease of the MBDA score.

Conclusion: Among patients with early RA who did not achieve low disease activity on MTX monotherapy, those patients with the greatest decrease in MDBA score were more likely to respond to triple therapy whereas patients with lesser decrease of the MBDA score were more likely to respond to anti-TNF therapy. These findings suggest that in MTX non-responders, the changes in MBDA score may help guide subsequent therapy.

Serum C1M Level Predicts Disease Progression and Early Treatment Efficacy in Rheumatoid Arthritis. Anne C. Bay-jensen[1], Anne Sofie Siebuhr[1], Inger Byrjalsen[2], Claus Christiansen[2] and Morten Asser Karsdal[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark.

Background/Purpose: Rheumatoid arthritis (RA) is partly characterized by joint destruction. Personalized health care is needed in RA to enable i) prediction of those patients that will progress most rapidly and in most need of aggressive intervention, and ii) prediction of those that will respond to a given treatment and those that will not, and thereby limiting the cases of serious side effects. Serum C1M is specific measure of connective tissue degradation, which originates from the down-stream signaling pathways of inflammatory cytokines IL-6, IL-1 and TNFα. The aims of the study were to investigate: i) whether levels of C1M could predict who would structurally progress over 1-year, ii) to which level C1M was suppressed by tocilizumab (TCZ), and iii) whether baseline levels or early changes of C1M could predict responders to TCZ either on disease activity or structural protection.

Methods: The LITHE Biomarker study (NCT00106535) was a 1-year phase III, double-blind, placebo-controlled, parallel group study of TCZ 4mg/kg+MTX (n=200), 8mg/kg+MTX (n=186) or PBO+MTX (n=199) in patients with moderate-severe active RA, but MTX-IR. All patients had radiographically confirmed joint erosion at baseline. Fasting serum was collected at baseline and week 4, 16, 24 and 52 weeks. Patients who failed to respond to treatment (≤ 20% improvement in both swollen and tender joint counts) at week 16 were designated early non-responders. Radiographs (total Genant-modified Sharp scoring system (mTSS) and joint space narrowing (JSN)) and DAS28 were obtained at baseline, week 24 and 52. The study was approved by ethical committees at each participating institution. All patients provided written informed consent. C1M was measured in samples taken at baseline and week 4. Spearman's ranked correlation was done on baseline level and 4-week change of C1M, age, body mass index (BMI), disease duration, DAS28, JSN and mTSS weeks 24 and 52. Multiple regression analysis was performed on log-transformed data for delta structural progression (JSN and mTSS) and C1M, adjusted for age, BMI, disease duration, baseline CRP and radiography.

Results: At baseline, C1M was significantly correlated to DAS28 (ρ=0.25, P<0.0001), mTSS (ρ=0.14, P=0.0006), and JSN (ρ=0.12, P=0.0056). C1M was at correlated to change in JSN and mTSS (p<0.0001). The level of C1M was at the level of the placebo group when treated with 4mg/kg TCZ, whereas the 8mg/kg TCZ suppressed the level by 49.2% lower than at baseline, p<0.0001). The level of C1M remained at a significantly lower level in the 8 mg/kg TCZ + MTX than in PBO group throughout the study (p<0.0001). The difference in C1M between early responders and non-responders when treated with 8 mg/kg were significant (AUC 0.71, p=0.0010). C1M was not correlated to age, BMI or disease duration.

Conclusion: Baseline C1M levels correlated to worsening joint structure over one year, demonstrating this as the first structural progression marker for RA. Early changes in C1M were associated with structural efficacy. These data in combination with other technologies may be a part of the identification of those RA patients that are in most need of aggressive treatment, and the monitoring of these patients.

Validation of Snapshot, a Rheumatoid Arthritis Assessment Tool, Against CDAI, DAS28 (ESR), and DAS28 (CRP) in Canadian Patients with Rheumatoid Arthritis. William G Bensen[1], Wynn Bensen[2], Melissa Deamude[2], Cynthia Mech[2], Robert Bensen[2], Arthur N. Lau[3] and Alpesh Shah[4]. [1]St Josephs Hospital and McMaster University, Hamilton, ON, [2]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [3]Division of Rheumatology, McMaster University, Hamilton, ON, [4]MSc in Clinical Epidemiology, University of Western Ontario, London, ON.

Background/Purpose: Measuring disease activity in Rheumatoid Arthritis (RA) remains an elusive goal. Both DAS and CDAI have an inherent weakness because similar numbers can result from dissimilar clinical situations. Snapshot, a hands on immediate clinical tool, shows where a patient stands with SJC, TJC, MD and Patient Global, and visualizes the discrepancies between MD and patient assessments. We have validated Snapshot Traditional (SS-T) (SJC-PtGlobal), Snapshot MD (SS-M) (SJC-MD global) and Snapshot Patient (SS-P) (TJC-Pt. global) to DAS28 (ESR), DAS28 (CRP) and CDAI. in 96 Canadian RA patients, at onset, and disease control.

Methods: We validated Snapshot (SS-T, SS-M and SS-P) in data from 96 patients of active RA using SAS version 9.3. The Snapshot scores were validated against DAS28 (ESR), DAS28 (CRP) and CDAI scores. We used Pearson correlation coefficients to assess the correlation (r) and ordinary linear regression analysis to estimate regression coefficients (β) between Snapshot and other measures (DAS28 and CDAI). We also assessed the extent of agreement between Snapshot and other measures DAS28 using Bland-Altman plots.

Results: The results revealed direct significant linear correlation of Snapshot with DAS28 and CDAI (r=0.83 with DAS28 (ESR), 0.92 with DAS28 (CRP), 0.94 with CDAI for SS-T, r=0.82 with DAS28 (ESR), 0.91 with DAS28 (CRP), 0.91 with CDAI for SS-P and r=0.70 with DAS28 (ESR), 0.79 with DAS28 (CRP), 0.89 with CDAI for SS-M). In a linear regression model with DAS28 (ESR) as a predictor, regression coefficients (β) were 1.33 (p<0.001), 0.98 (p<0.001) and 1.27 (p<0.001) for SS-T, SS-M and SS-P respectively with good model fit. Bland-Altman plots showed high degree of agreement between Snapshot and DAS28 (ESR) with 96.7% (SS-T), 96% (SS-M) and 95.6% (SS-P) of the observations of the difference between Snapshot and DAS28 lying between mean±2SD. Similar results were observed for change score data (for disease control).

	SS change score (Pt. Global and SJC)		SS change score (MD Global and SJC)		SS change score (Pt. Global and TJC)	
	Pearson's correlation (P-value)	Regression coefficient (95% confidence interval)	Pearson's correlation (P-value)	Regression coefficient (95% confidence interval)	Pearson's correlation (P-value)	Regression coefficient (95% confidence interval)
DAS28 (ESR) change score	0.839 (<0.0001)	1.47 (1.26, 1.68)	0.751 (<0.0001)	1.15 (0.93, 1.37)	0.824 (<0.0001)	1.32 (1.12, 1.52)
DAS28 (CRP) change score	0.896 (<0.0001)	1.68 (1.49, 1.86)	0.813 (<0.0001)	1.33 (1.12, 1.53)	0.885 (<0.0001)	1.51 (1.34, 1.69)
CDAI change score	0.915 (<0.0001)	0.16 (0.14, 0.17)	0.921 (<0.0001)	0.14 (0.13, 0.15)	0.911 (<0.0001)	0.15 (0.13, 0.16)

Conclusion: All Snapshots (SS-T, SS-M, SS-P) validated well with DAS28 and CDAI in measuring RA disease activity with the benefit of one second visual recognition for patient and MD at the clinical visit and without calculation. The discrepancy between MD and patient values is obvious and prompts an alternative therapeutic decision. Some patients understate their disease as compared to their SJC and need more RA therapy, while others overstate because of soft tissue pain, or depression. We prefer Snapshot Traditional. Snapshot offers an immediate and validated clinical tool for doctors and patients allowing better understanding of disease activity and need for therapeutic intervention.

Double Positivity of RA Serologies More Prevalent But Associated with Clinical Response in a Diverse Ethnic Cohort with Rheumatoid Arthritis

Background/Purpose: The presence of both the anti-citrullinated peptide antibody (ACPA) and a rheumatoid factor (RF) are associated with RA disease severity and portend a poor prognosis. Whether ethnic minorities differ in the prevalence of RA-related serologies from Caucasian RA counterparts is unknown, as is their role as determinants of a clinical response in this patient subset.

Methods: Ethnic Minority RA Consortium (EMRAC) patients with at least one follow up visit were evaluated. Comparisons of demographic (age, gender, race, education, smoking), RA disease status (RF, ACPA, nodules/erosions), RA treatment (prednisone, DMARD, biologics) variables amongst ethnic subsets were made as well as frequencies of clinical response (D MDHAQ – 0.3 and D RAPID3 –3.6) from baseline. Baseline differences between ethnic subsets were compared using Chi-square for categorical and Kruskal-Wallis for continuous variables. Logistic regression associating outcome at follow up and between ethnic subsets were estimated, adjusting for age, smoking, race, education, baseline RAPID3, and double positivity of RA-related serologies.

Results: Follow up visits in 671 EMRAC patients provided data for analyses (Table). African American patients were older (p=0.02), and had longer follow up compared to either Caucasians or Hispanics (p< 0.001). Either a positive ACPA (60%, 46.3% vs 14.3%, respectively, p<0.001) or RF (79.6%, 71.7%, respectively vs 42.1%, p<0.001) were more frequent in AA and Hispanics versus Caucasian patients. In patients who were double positive, the odds ratio for a clinical response was 2.7 (95% CI 1.37, 5.35) for MDHAQ and 3 fold (95% CI 1.37, 6.76) for RAPID3. There was a greater frequency of both ACPA+/RF+ in ethnic subsets who had a clinical response in both MDHAQ (AA 57.9%, Hispanics 46.9% vs Caucasian 16.7%) and RAPID3 (AA 64.9%, Hispanic 55% vs Caucasian 17.9%). Hispanic patients with RF+/CCP+ had a 67% increased odds of a RAPID response compared to Caucasians and 8% to AA, while AA had a 55% increase in odds for clinical response compared to Caucasians – but none achieving statistical significance.

Conclusion: In a diverse cohort, double positivity of RA-related serologies while more prevalent, are associated with increased odds of a clinical response regardless of ethnicity.

RAPID3 Outcomes by Race and Double Positive RA Serology Status

	Caucasian	African-American	Hispanic
		HAQ Response	
RF-ACPA-	40 (66.7%)	15 (15.8%)	11 (34.4%)
RF+ACPA-	10 (16.7%)	20 (21.1%)	5 (15.6%)
RF-ACPA+	0 (0%)	5 (5.3%)	1 (3.1%)
RF+ACPA+	10 (16.7%)	55 (57.9%)	15 (46.9%)
		RAPID Response	
RF-ACPA-	27 (69.2%)	11 (19.3%)	6 (30%)
RF+ACPA-	4 (10.3%)	6 (10.5%)	3 (15%)
RF-ACPA+	1 (2.6%)	3 (5.3%)	0 (0%)
RF+ACPA+	7 (17.9%)	37 (64.9%)	11 (55%)

The Impact of Missing Anti-Citrullinated Protein Antibody (ACPA) on Outcomes in Early Rheumatoid Arthritis: From the Canadian Early Arthritis Cohort. Jenny Shu[1], Vivian P. Bykerk[2], Gilles Boire[3], Carol A. Hitchon[4], J. Carter Thorne[5], Diane Tin[5], Edward C. Keystone[6], Boulos Haraoui[7] and Janet E. Pope[8]. [1]University of Western Ontario, London, ON, [2]Hospital for Special Surgery, New York, NY, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]University of Manitoba, Winnipeg, MB, [5]Southlake Regional Health Centre, Newmarket, ON, [6]University of Toronto, Toronto, ON, [7]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [8]St Joseph Health Care, London, ON.

Background/Purpose: The impact of missing ACPA in early inflammatory arthritis patients was studied to determine if failure to perform ACPA testing could cause a care gap.

Methods: 2191 patients recruited to CATCH were allocated to 3 groups: 1. seropositive (rheumatoid factor positive (RF+) and/or ACPA+), 2. seronegative (RF- /ACPA-) and 3. missing ACPA (RF negative [RF-]). Analyses were adjusted for age, sex, symptom duration, and smoking status if $p<0.1$. Data were also imputed to determine effect on results. One-third of ACPA were missing as this test is not reimbursed in all jurisdictions.

Results: More seropositive patients fulfilled 2010 ACR/EULAR RA criteria. Group 3 was slightly older, less: % female, symptom duration, and smoking. At 3 months, group 3 was treated with less DMARDs and methotrexate ($P<0.00002$), but there were no significant differences in DAS28, HAQ-DI, proportion receiving corticosteroids, or physician/patient global assessments. See table for full results.

Conclusion: Patients with missing ACPAs were less likely to fulfill RA criteria and were treated differently with fewer medications but had similar outcomes at three months. Cost-effectiveness of ensuring ACPA testing availability in suspected RA is unknown. Imputed data did not alter results. There could be a care gap in the unknown ACPA group who were RF negative, but there were no significant differences in DAS28, 3 month change in DAS28, or HAQ-DI despite less treatment. We cannot determine whether performing ACPA in RF positive suspected ERA adds value as we combined the seropositive group into any seropositive result. The cost effectiveness of performing ACPA in RF negative patients could be debated if early RA is already suspected.

Diagnostic Accuracy and Associated Costs of Rheumatoid Factor Testing in Primary Care: A Population-Based Cohort Study in Spain. Raashid Luqmani[1], Klara Morsley[2], Anne Miller[3], Christopher J. Edwards[4], M. Kassim Javaid[5], Daniel Prieto-Alhambra[6], Rafael Pinedo-Villanueva[7], Manuel Medina Peralta[8], Sebastian Calero Munoz[8], Nigel Arden[9], Francesc Fina-Aviles[8] and Cyrus Cooper[10]. [1]Oxford NIHR Musculoskeletal Biomedical Research Unit, Oxford, United Kingdom, [2]Nuffield Orthopaedic Centre, Oxford, United Kingdom, [3]Nuffield Orthopaedic Centre, Oxford University Hospitals NHS Trust, Oxford, United Kingdom, [4]University Hospital Southampton, Southampton, United Kingdom, [5]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, UK, Oxford, United Kingdom, [6]NIHR Musculoskeletal Biomedical Research Unit, Oxford, United Kingdom, [7]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom, [8]Institut Català de la Salut, Barcelona, Spain, [9]NIHR Musculoskeletal Biomedical Research Unit University of Oxford, Oxford, United Kingdom, [10]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom.

Background/Purpose: To assess the sensitivity, specificity, and predictive values of rheumatoid factor (RF) as a test for rheumatoid arthritis (RA) in primary care, and to estimate the costs associated with the use of RF in primary care settings.

Methods: Design: a retrospective cohort study using electronic data from the Information System for the Development of Research in Primary Care (SIDIAP database), which contains the complete primary care records and laboratory results of more than 5 million people (over 80% of the population) in Catalonia, Spain.

Setting: primary care.

Participants: patients aged 18 or above registered in the SIDIAP database with at least one RF test performed between 01/01/2006 and 31/12/2011, excluding those who had a diagnosis of RA at the start of the study period.

Outcome measures: RA diagnosis (as coded in medical records) within the first year after RF testing, and cost of RF testing per case of RA.

Results: 495,434 patients out of an eligible 4,796,498 (10.3%) people were tested for RF at least once during the study period. 107,362 (21.7%) were sero-positive of which 2,768 (2.6%) of these were diagnosed with RA in the following year. Similarly, 1,141/388,072 (0.3%) sero-negative participants were subsequently diagnosed with RA. RF testing had a sensitivity of 70.8% (95% CI 69.4 to 72.2), specificity 78.7% (78.6 to 78.8), and positive and negative predictive values of 2.6% (2.5 to 2.7) and 99.7% (99.6 to 99.7) respectively. An estimated €3,963,472 was spent on RF testing in the duration of the study, with a cost of €1,432 per true positive case.

Conclusion: The low prevalence of RA in this primary care population resulted in a very high cost of testing for every case of RA diagnosed. Limiting RF testing to patients with a higher pre-test probability would significantly reduce the overall cost of testing.

Biomarkers of Cardiac Dysfunction and Inflammation in Plasma Predict Occult Coronary Plaque Burden and Composition in Rheumatoid Arthritis. George A. Karpouzas[1], Joel Estis[2], John Todd[2] and Matthew Budoff[1]. [1]Harbor-UCLA Medical Center, Torrance, CA, [2]Singulex, Alameda, California, Alameda, CA.

Background/Purpose: Rheumatoid arthritis (RA) is associated with accelerated coronary atherogenesis, myocardial infarction, and mortality. We previously reported a higher prevalence, severity, and different composition of occult coronary plaque in patients with RA compared to age and gender matched non-rheumatic disease controls (NRD). We now explore whether various plasma inflammatory biomarkers, or their combinations, predict occult coronary plaque presence, various burden outcomes, and composition in the same cohort of patients with RA.

Methods: One hundred and fifty RA subjects without symptoms or prior diagnosis of cardiovascular disease underwent 64-slice computed tomography angiography (CTA). Coronary artery calcium score (CAC), segment involvement score (SIS- n of segments with plaque), stenosis severity score (sum of individual segmental stenosis- SSS) and plaque burden score (sum of segmental plaque burden- PBS) were computed. Plaques were further characterized as non-calcified (NCP), mixed (MP), or calcified (CP). High-sensitivity cardiac Troponin-I (cTnI), tumor necrosis factor-alpha (TNFα), vascular endothelial growth factor (VEGF), interleukin-6 (IL-6), interleukin-17A and F (IL-17A, IL-17F), were quantified at the time of CTA, using Erenna immunoassay (Singulex, Alameda, CA). Associations of individual biomarkers with all plaque outcomes were evaluated with linear regression models. Ability of individual or combinations of binarized biomarkers to predict plaque outcomes was explored in logistic regression models adjusted for age and gender (model 1), or additional cardiac risk factors (CRFs, model 2).

Results: Higher tertiles of cTnI correlated with plaque prevalence, as well as increasing CAC, SIS, SSS, and PBS (p-values 0.006, 0.005, 0.01, and 0.009 respectively- not shown). IL-6 and cTnI individually and independently predicted various plaque parameters after age and gender adjustments (model 1, table 1). The combination of high cTnI with high IL-6 predicted plaque burden after adjustments both for age and gender, as well as additional CRFs (model 2- table 1). Very high-risk plaque outcomes for future cardiac events (CAC >100, SIS >5, SSS >5, obstructive plaque, or composite outcome) were best predicted by cTnI alone. Similarly, cTnI was the only biomarker predicting presence of higher-risk NCP or MP [OR (95% CI) of 2.37 (1.13–4.94)], however, significance was lost after age and gender adjustments [1.97 (0.92–4.24)].

Conclusion: In patients with RA, biomarkers of cardiac dysfunction (cTnI) and inflammation (IL-6) may predict the presence, various burden outcome severity, and composition of occult coronary plaque as evaluated by CTA. Their associations and prognostic implications for atherosclerosis deserve further evaluation.

Table 1

	outcome	Unadjusted OR (95% CI)	Model 1[1] OR (95% CI)	Model 2[2] OR (95% CI)
c-TnI	CAC (>0 vs. 0)	*2.5 (1.2–5.2)*	1.8 (0.8–4.0)	1.7 (0.8–4)
	CAC>100 vs.≤100	*7.1 (2.5–20.7)*	*6 (1.9–19)*	*10.4 (2.4–45.5)*

IL-33 and Soluble ST2 Levels As Novel Predictors for Remission and Progression of Carotid Plaque in Early Rheumatoid Arthritis: A Prospective Study. Jiayun Shen[1], Qing Shang[1], Ying Ying Leung[2], Shui Lian Yu[1], Chun-Kwok Wong[3], Edmund Li[1], Tracy Y. Zhu[1] and Lai-Shan Tam[1]. [1]Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, [3]Department of Chemical Pathology, The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Clinical remission is achievable for patients with early rheumatoid arthritis (ERA). Identification of predictors for response of treatment may provide risk estimation and help for the development of personalized medicine. On the other hand, patients with ERA die prematurely primarily because of cardiovascular disease. The aim of this study is to study the association between the baseline IL-33 and soluble ST2 (sST2) levels with disease remission and progression of carotid atherosclerosis in ERA patients.

Methods: Ninety-eight ERA patients were enrolled. Disease activity and the presence of carotid plaque were evaluated at baseline and 12 months later. Plasma IL-33 and sST2 levels were determined using enzyme-linked immunosorbent assay kits.

Results: Baseline IL-33 and sST2 levels were associated with inflammatory markers and cardiovascular (CV) risk factors. 44(45%), 18(18%) and 21(21%) patients achieved remission based on 28-joint disease activity score (DAS28), Boolean and simplified disease activity score (SDAI) criteria at 12 months. Patients with detectable IL-33 at baseline were less likely to achieve DAS28 (P=0.010) and SDAI remission (P=0.021), while a lower baseline sST2 level was able to predict DAS28, Boolean and SDAI remission (P=0.005, 0.001 and <0.001, respectively). By multivariate analysis, a lower baseline sST2 level independently predict Boolean (OR: 0.789, P=0.005) and SDAI remission (0.812, P=0.008). Regarding carotid atherosclerosis, 9/98(9.2%) patients with plaque progression were observed. Baseline IL-33 was detectable in 8/9(89%) and 42/83(51%) of patients with and without plaque progression (P=0.029). Baseline detectable IL-33 was an independent predictor for plaque progression after adjusting for traditional CV risk factors (27.523, P=0.017).

Conclusion: Lower baseline sST2 levels independently predict disease remission and baseline detectable IL-33 independently predicts carotid plaque progression in ERA patients. This study suggests that inflammation induced by the IL-33/ST2 axis may play a significant role in the development of cardiovascular disease in RA.

Table 1. Multivariable analysis for remission of disease and progression of carotid plaques

Events at month 12	Factors*	OR	95% CI	*P* value
DAS28 remission	Disease duration	2.371	1.050−5.353	0.038
(Event**: n=42, 47%)	ESR	0.970	0.953−0.988	0.001

Evaluation of RAPID3 with Minimal Joint Count and ACR/EULAR Provisional Remission Definitions As Predictors of Future Good Radiographic + Functional Outcome in a Double-Blind, Phase 3, Randomized Controlled Trial of Tocilizumab. Martin J. Bergman[1], Jeffrey Yourish[2], Jinglan Pei[2], Jenny Devenport[2], William Reiss[2] and Edward Keystone[3]. [1]Taylor Hospital, Ridley Park, PA, [2]Genentech, South San Francisco, CA, [3]University of Toronto and Mount Sinai Hospital, Toronto, ON.

Background/Purpose: Based on treat-to-target guidelines, the goal of treatment should be remission. Definitions for remission recommended by the ACR/EULAR task force include joint counts and a laboratory test and were selected to predict later good radiographic and functional outcomes. [1] Despite these guidelines, rheumatologists still do not regularly measure disease activity. RAPID3, developed as a tool for monitoring disease activity, is advantageous because it requires only patient input. This analysis evaluated the performance of RAPID3 with minimal joint count (for physician input), compared with ACR/EULAR proposed remission definitions, to predict future good radiographic + functional outcome.

Methods: LITHE was a 5-year, double-blind, phase 3 study of tocilizumab (TCZ) in patients with moderate to severe RA who had inadequate responses to MTX therapy. [2] Patients were randomly assigned 1:1:1 to receive placebo + MTX, TCZ 4 mg/kg + MTX, or TCZ 8 mg/kg + MTX for 24 weeks, with an option to escape starting at week 16. Associations between various year 1 measures were evaluated against rates of good radiographic + functional outcome at year 2, specifically no worsening of Genant-Sharp Score (GSS) and HAQ-DI, and HAQ-DI $\leq$0.5. [1] Logistic regression was used to estimate odds ratio (OR), positive predictive value (PPV), negative predictive value (NPV), and sensitivity/specificity of the measures.

Results: In total, 690 patients had sufficient 2-year data to evaluate year 2 outcome: 73% of patients had no worsening of GSS score, 58% had no worsening of HAQ-DI, 22% had HAQ-DI $\leq$0.5, and 15% met all 3 criteria. ORs with 95% confidence intervals (CIs) for all year 1 measures were >1, indicating that all were statistically significantly associated with year 2 outcome, though no one measure had superior association ($p < 0.05$ for all; overlapping 95% CIs for OR). NPV and specificity were high (>80%), but PPV and sensitivity for all measures were low (range, 28–49% and 16–39%, respectively), which meant the measures could successfully identify patients who did not achieve the year 2 outcome but were not very good at identifying patients who achieved the outcome (Table).

Conclusion: Consistent with publications on other therapies/populations,[3–5] these results suggest the RAPID3 plus $\leq$1 joint count performed similarly to more complex measures. However, given that no single measure had especially high PPV or sensitivity, it is important that the patient be fully evaluated to understand what individual factors might contribute to his or her long-term prognosis.

Table. Performance of Year 1 Measures for Predicting Year 2 Outcome of Good Radiographic + Functional Outcome[a]

Year 1 Measure	Odds Ratio	95% CI	n[b]	PPV, %	NPV, %	Sensitivity, %	Specificity, %
RAPID3 $\leq$6 with SJC66 $\leq$1	3.461	2.098, 5.692	683	28.8	87.5	34.0	84.6
RAPID3 $\leq$3 with SJC66 $\leq$1	3.973	2.182, 7.148	683	35.3	86.7	22.6	92.4
RAPID3 $\leq$6 with SJC28 $\leq$1	3.149	1.951; 5.068	681	28.5	87.9	38.7	82.1
RAPID3 $\leq$3 with SJC28 $\leq$1	4.257	2.403; 7.486	681	36.8	87.1	26.4	91.7
SDAI $\leq$3.3 only	3.956	2.230; 6.969	623	37.3	86.0	26.7	90.9
ACR/EULAR Boolean criteria only	5.246	2.539; 10.792	687	47.4	86.4	17.0	96.6
SDAI $\leq$3.3 or Boolean criteria	3.932	2.240; 6.861	624	37.2	86.1	27.6	90.6
SDAI $\leq$3.3 and Boolean criteria	5.422	2.555; 11.473	686	48.6	86.3	16.0	96.9

CI, confidence interval; NPV, negative predictive value; PPV, positive predictive value; SDAI, Simplified Disease Activity Index; SJC, swollen joint count; TJC, tender joint count; VAS, Visual Analogue Scale.
Boolean criteria are SJC $\leq$1, TJC $\leq$1, CRP $\leq$1 mg/dL, and patient global assessment (0–10 VAS scale) $\leq$1.
Each odds ratio is estimated from a separate logistic regression for predicting year 2 outcome, all with these covariates: age, treatment at baseline, and region.
Sensitivity and specificity are based on basic 2 $\times$ 2 tables of measure vs outcome.
[a]Year 2 outcome (good radiographic + functional outcome): no worsening of Genant-Sharp Score and HAQ-DI at year 2 vs year 1, and HAQ-DI $\leq$0.5 during year 2.
[b]Patients who had sufficient data to evaluate the year 2 outcome (n = 690) plus each year 1 measure are shown; patients failing 1 of the criteria were included even if other criteria were missing, whereas patients achieving each measure/outcome had all criteria observed.

Using the Multi-Biomarker Disease Activity Score As a Complementary Inclusion Criterion for Clinical Trials in Rheumatoid Arthritis May Enhance Recruitment. Ronald F. van Vollenhoven[1], Rebecca J. Bolce[2], Karen Hambardzumyan[3], Saedis Saevarsdottir[4], Kristina Forslind[4], Ingemar Petersson[5], Eric H. Sasso[2], CC Hwang[2], Oscar Segurado[2] and Pierre Geborek[6]. [1]Unit for clinical therapy research (ClinTrid), Karolinska Institute, Stockholm, Sweden, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]the Karolinska Institute, Stockholm, Sweden, [4]Karolinska Institute, Stockholm, Sweden, [5]Lund University, Department of Orthopedics, Clinical Sciences Lund, Lund, Sweden, [6]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden.

Background/Purpose: Clinical trials in rheumatoid arthritis (RA) often require elevated C-reactive protein (CRP) as an inclusion criterion, which may limit recruitment by excluding some patients with active disease. The multi-biomarker disease activity (MBDA) score (Vectra® DA) quantifies disease activity with a score of 1 to 100 and can be high (>44) when CRP is low, e.g., $\leq$1 mg/dL. This study explored the hypothesis that, by using MBDA score >44 as a clinical trial inclusion criterion complementary to CRP >1 mg/dL, the number of eligible patients can be increased while maintaining ability to detect treatment responses and radiographic progression.

Methods: The Swedish Farmacotherapy (SWEFOT) trial, disease modifying anti-rheumatic drugs (DMARD)-naïve patients with early RA were enrolled without a CRP requirement, and received methotrexate (MTX) monotherapy from baseline (BL); at 3 months, non-responders to MTX (NR, DAS28 >3.2) received treatment intensification with triple therapy or MTX plus infliximab. For the present study, we analyzed two populations from SWEFOT: 1) DMARD-naïve patients, based on enrollment at BL, and 2) MTX non-responders, based on the Month 3 assessment. In both analyses, patients were grouped according to CRP ($\leq$1 vs. >1 mg/dL) and MBDA score ($\leq$44 vs. >44) at the defining time point, and clinical outcomes were assessed from BL to 3 months for DMARD-naïve patients treated with MTX; and from 3 to 12 months for MTX NRs receiving triple therapy or anti-TNF. Radiographic progression was assessed by change (Δ) in Sharp van der Heijde score (SHS) from BL to 1 year for both analyses.

Results: In the DMARD-naïve population (N=220), BL values, changes in clinical disease activity from BL to Month 3, and ΔSHS from BL to year 1 were similar for patients with MBDA score >44 and CRP $\leq$1 mg/dL (n=37) vs. patients with CRP >1 mg/dL (n=154). If the two groups are combined, the resulting group (n=191) has 24% more patients and similar clinical and radiographic outcomes, compared with the CRP >1 mg/dL group. For the MTX NRs (N=127), values at Month 3 and their changes to Month 12 were also similar for patients with MBDA score >44 and CRP $\leq$1mg/dL (n=23) vs. those with CRP >1 mg/dL (n=49). Combining these two groups results in a group with 47% more patients (n=72) and similar outcomes, compared with the CRP >1 mg/dL group. (See table) In comparison, for patients with MBDA score $\leq$44 and CRP $\leq$1 mg/dL, there is less change in clinical disease activity at Month 12 for the MTX NRs, and less

radiographic progression at Month 12 for the DMARD-naïve and MTX NR groups.

Table: Mean changes in disease activity measures from BL to 3 months for DMARD-naïve patients and from Month 3 to 12 months for MTX non-responders

	DMARD-Naïve Patients			
			Conventional approach	New approach
Response Measurement	CRP ≤1 mg/dL and MBDA ≤ 44	CRP ≤1 mg/dL and MBDA >44	CRP >1 mg/dL	CRP >1 mg/dL or MBDA >44
N	29	37	154	191
MBDA	−5.5	−11.9	−16.4	−15.6
DAS28	−1.5	−1.6	−1.8	−1.8
TJC	−5.2	−5.0	−4.6	−4.6
SJC	−5.0	−5.9	−5.8	−5.8
CDAI	−12.2	−12.9	−13.2	−13.2
ΔSHS >3 at Year 1 (%)	10%	35%	33%	34%

	MTX Non-responders			
			Conventional approach	New approach
Response Measurement	CRP ≤1 mg/dL and MBDA ≤44	CRP ≤1 mg/dL and MBDA >44	CRP >1 mg/dL	CRP >1 mg/dL or MBDA >44
N	55	23	49	72
MBDA	−4.2	−15.4	−23.2	−20.7
DAS28	−1.1	−1.4	−2.0	−1.8
TJC	−3.0	−4.3	−4.0	−4.1
SJC	−3.3	−4.2	−6.7	−5.9
CDAI	−8.0	−10.5	−13.6	−12.6
ΔSHS >3 at Year 1 (%)	24%	39%	53%	49%

Conclusion: These analyses suggest that if a clinical trial of DMARD-naïve or MTX-NR patients with RA were to include patients with MBDA score >44 even though CRP was ≤1mg/dL, the number of eligible patients would be increased by 24% and 47%, respectively, compared with the conventional approach to enrollment based on CRP >1 mg/dL alone, while maintaining clinical and radiographic outcomes.

Fatigue Fluctuates Substantially over Time in Rheumatoid Arthritis Patients Despite Stable Disease Activity during Treatment with Biological Agents. Emilie Lund Egsmose, René Cordtz and Ole Rintek Madsen. Copenhagen University Hospital Gentofte, Hellerup, Denmark.

Background/Purpose: Fatigue (FTG) is a symptom commonly reported by patients with rheumatoid arthritis (RA). Little is known about its nature and etiology. The number of studies including FTG as an outcome measure has increased rapidly during recent years and FTG is considered a potential marker of RA disease activity in the clinic (1). In order to judge whether a given change in any disease marker in the individual patient is due to "measurement error" or to real change it is essential to know how large the natural variation of the disease marker is when the disease activity is constant.

The purpose of the present study was to examine intra-individual FTG fluctuations in patients with stable RA during treatment with a biological agent.

Methods: 233 RA patients treated with a biological agent and with stable disease activity were identified in the Danish registry for biological treatment in rheumatology (DANBIO). Stable disease activity was defined as a change in DAS28-CRP ≤ 0.6 between two consecutive visits with complete clinical data sets available including FTG. Paired data from a single set of such two consecutive visits were extracted for each patient. Data comprised DAS28-CRP and its individual components, HAQ and global assessment of the patient (PaGl) and the physician (PhGl) as well as patient reported FTG scored on 0–100 visual analogue scales (VAS). Bland-Altman analyses were used to assess the lower and upper 95 % limits of agreement between the two consecutive FTG assessments and the corresponding bias (the mean of individual differences). Associations between intra-individual inter-visit differences (Δ) in FTG and in other measures of disease activity were evaluated using Pearson's linear correlation analyses and by stepwise multiple regression with ΔFTG as the dependent variable. A p-value ≤ 0.05 was considered statistically significant.

Results: Mean age was 60±15 years, female/male ratio 3.2, mean time from treatment start to the first visit 136.1±117.8 (range 0–485) weeks, mean inter-visit duration time 22.3 ± 20.7 weeks, mean DAS28 3.1±1.2 and mean FTG 43.3±27.6. Mean ΔDAS28-CRP was 0.0±0.3 (range −0.6 to 0.6) (NS). The bias for FTG was 0.9 ±18.8 (NS) and the lower and upper limits of agreement −35.9 and 37.7, respectively. No significant correlation was found between the absolute value of ΔFTG and the inter-visit duration time ($r = 0.043$, NS). ΔFTG was weakly correlated with ΔPain ($r = 0.33$, $p < 0.01$) and ΔPaGl ($r = 0.39$, $p < 0.001$) and were not significantly correlated with change in any other single measure of disease activity or ΔDAS28-CRP. In a multiple regression analysis including Δ of all disease activity measures including DAS28-CRP as independent variables, ΔFTG was significantly predicted by only ΔPaGl (beta = 0.26, $p < 0.001$) and ΔPain (beta = 0.15, $p < 0.05$). No statistically significant difference in FTG or ΔFTG was found between males and females.

Conclusion: In individual RA patients, large fluctuations in FTG were observed over time although the disease activity was stable. If FTG is considered to reflect disease activity, changes in FTG less than approximately 35 on a VAS-scale may be interpreted as natural variation or pure measurement error.

The Use of Week 12 CDAI, RAPID3 and DAS28(CRP) Responses to Predict Optimal Response to Methotrexate. Gerd Burmester[1], Gurjit S. Kaeley[2], Jeffrey R. Curtis[3], Yusuf Yazici[4], Benoit Guerette[5], Xin Wang[5], Alan Friedman[5] and Vibeke Strand[6]. [1]Charité University Medicine, Berlin, Germany, [2]University of Florida, Jacksonville, FL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]New York University School of Medicine, New York, NY, [5]AbbVie, Inc., North Chicago, IL, [6]Stanford University, Palo Alto, CA.

Background/Purpose: The prediction of treatment outcomes based on early response could guide treatment decisions in patients (pts) with rheumatoid arthritis (RA). The objective was to determine if disease state at wk 12 in pts treated with a lower dose of methotrexate (MTX) + adalimumab (ADA), assessed by CDAI, DAS28(CRP) and RAPID3, was predictive of an SDAI response at a later time point, comparable to that achieved by pts receiving a high dose of MTX+ADA.

Methods: Data for this post hoc analysis originated from 2 randomized controlled trials. In CONCERTO, pts with early RA received ADA + 2.5, 5, 10 or 20 mg/wk MTX. In MUSICA, pts with moderate to severe RA and an inadequate response to MTX, received ADA + 7.5 or 20 mg/wk MTX. "Achievers" were defined as pts achieving optimal SDAI responses comparable to those in the top 40thpercentile (pct) receiving 20 mg/wk MTX + ADA. For CONCERTO, achievers had SDAI scores at wk 16 ≤6.8, wk 20 ≤5.0 and wk 26 ≤4.2; for MUSICA, achievers had SDAIs at wk 16 ≤15.4, wk 20 ≤11.8 and wk 24 ≤11. The following outcomes at wk 12 were compared in achievers vs non-achievers: CDAI, DAS28(CRP) and RAPID3. The likelihood of predicting optimal SDAI responses was assessed by ROC analysis using logistic regression with wk 12 CDAI, DAS28(CRP) and RAPID3 as predictors. Optimal ROC thresholds based on sensitivity and specificity, as well as those with satisfactory negative and positive predictive values (N/PPV), were calculated.

Results: In CONCERTO, 11/98 (11.2%), 10/100 (10%), 21/99 (21.2%) and 21/98 (21.4%) of pts receiving 2.5, 5, 10 and 20mg/wk MTX, respectively, were achievers; In MUSICA, 29/154 (18.8%) and 28/155 (18.1%) in 7.5 and 20 mg /wk MTX groups, respectively, were achievers. ROC-AUC, PPV and NPV indicated that wk 12 CDAI, DAS28(CRP), and RAPID3 were good predictors of optimal SDAI responses (table). Across selected thresholds, all three criteria provided good NPV for all MTX groups. In CONCERTO, non-achievers in CDAI remission/LDA at wk 12 achieved SDAI remission (≤3.3) or LDA (≤11) at wk 26; most pts in CDAI MDA or HDA at wk 12 did not. In MUSICA, in the 7.5 mg MTX treatment group, non-achievers in CDAI remission/LDA at wk 12 reached SDAI LDA (≤11) or MDA (11–26) at wk 24; 72.5% of pts in wk 12 CDAI MDA did not achieve optimal SDAI responses.

Table: AUC, PPV and NPV of wk 12 CDAI, RAPID3 and DAS28 (CRP) for prediction of optimal SDAI response

MTX dose (mg/wk)	Wk 12 criterion	Area under curve (95%CI)	ROC thres-hold	Sensitivity	1-specificity	PPV	NPV

For CONCERTO, optimal SDAI response was SDAI at wk 16 '6.8, wk 20 ≤5.0 and wk 26 ≤4.2; for MUSICA, optimal SDAI response was SDAI at wk16 ≤15.4, wk20 ≤11.8 and wk 24 ≤11.
ROC thresholds with NPV≥0.8 and PPV≥0.6 are presented, except for the groups indicated by the asterisk, where the optimal ROC cut-off is presented.

Conclusion: CDAI and RAPID3 are quick, convenient tools to assess treatment response, and correlated well with DAS28(CRP) as predictors of later outcome in the CONCERTO and MUSICA trials. In pts with early RA receiving lower doses of MTX, the achievement of remission or LDA targets at wk 12 was predictive of a subsequent optimal SDAI treatment response comparable to pts receiving higher MTX doses. Based on these data, pts in MDA/HDA at wk 12 might benefit from an adjustment of therapy.

What Level of Disease Activity at 6 Months Predicts Achieving or Sustaining Remission at 12 Months? Edward Keystone[1], Philip Baer[2], Boulos Haraoui[3], J Antonio Avina-Zubieta[4], Andrew Chow[5], Dalton Sholter[6], Denis Choquette[7], Emmanouil Rampakakis[8], John S. Sampalis[8], Francois Nantel[9], Allen J Lehman[9], May Shawi[9] and Susan Otawa[9]. [1]Mount Sinai Hospital, University of Toronto, Toronto, ON, [2]Private Practice, Scarborough, ON, [3]University of Montreal Hospital Centre, Montreal, QC, [4]University of British Columbia, Department of Experimental Medicine, Vancouver, BC, [5]McMaster University, Hamilton and Credit Valley Hospital, Mississauga, ON, [6]University of Alberta, Edmonton, AB, [7]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [8]JSS Medical Research, Montreal, QC, [9]Janssen Inc., Toronto, ON.

Background/Purpose: Achievement of clinical remission in rheumatoid arthritis (RA) is a process that may take several months. Identification of clinical signs predicting future remission may assist physicians in clinical decision making. The aim of this analysis was to describe the association between DAS28-ESR scores at 6 months and remission at 12 months in RA patients treated with infliximab (IFX) in a real-world, clinical practice setting.

Methods: BioTRAC is an ongoing, prospective Canadian registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with IFX or golimumab as first biologics or after having been treated with a biologic for <6 months. Eligible patients for this analysis included RA patients treated with IFX who were enrolled between 2002 and 2012 and had available DAS28 data at 6 and 12 months of follow-up. The association between DAS28-ESR score at 6 months and remission achievement at 12 months was assessed with logistic regression. Receiver operator curve (ROC) analysis was used to determine the optimal cut-off points for achieving and maintaining remission.

Results: A total of 293 patients were included with a mean (SD) age of 56 (13.5) years and disease duration of 10.0 (9.7) years. Mean (SD) DAS28 was 3.8 (1.5) and 3.5 (1.5) at 6 and 12 months, respectively, and the percent with DAS28-ESR remission was 24.6% and 27.0%. Of the patients in remission at 6 months, 65.3% sustained the remission at 12 months, while of those not in remission at 6 months, 14.5% achieved remission at 12 months ($P<0.001$). Logistic regression analysis showed a significant inverse association between DAS28-ESR score at 6 months and the likelihood of achieving remission at 12 months [for each increase in DAS28-ESR score by one unit there was a 64.6% lower probability of achieving remission; $P<0.001$]. ROC curve analysis identified a DAS28 score at 6 months ≤ 3.54 as most accurately predicting remission at 12 months with a sensitivity of 82% and a specificity of 70% (Figure 1A). Stratified analysis showed that, among patients in remission at 6 months, a DAS28 score of ≤2.13 was the optimal cut-off for predicting sustained remission at 12 months (68% sensitivity, 64% specificity) (Figure 1B).

Conclusion: The results of this analysis demonstrate that a DAS28-ESR target of ≤3.54 at 6 months maximizes the likelihood of remission at 12 months while a value of ≤2.13 should be targeted for optimal sustainment of remission.

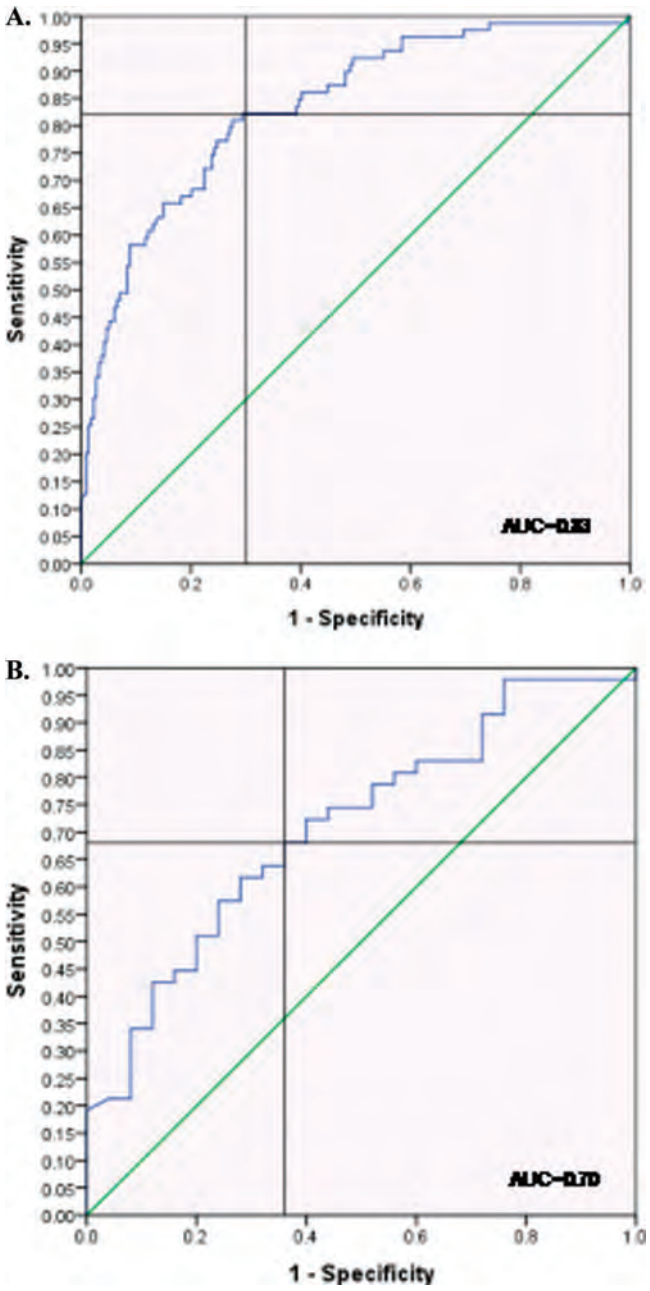

Figure 1. ROC curves showing the optimal DAS28-ESR cut-offs at 6 months for achieving (A) or sustaining (B) remission at 12 months

In Palindromic Rheumatism, Older Age, Shorter Interval Between Attacks and Positive Anti-CCP Antibodies May Predict Progression to RA. Masatoshi Hayashi[1], Jackie L. Nam[2], Laura Hunt[2], Elizabeth Hensor[2], Toshihisa Kanamono[1], Toshihisa Kojima[3], Naoki Ishiguro[3] and Paul Emery[4]. [1]Nagano Red Cross Hospital, Nagano, Japan, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]Nagoya University Graduate School of Medicine, Nagoya, Japan, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., United Kingdom, Leeds, United Kingdom.

Background/Purpose: Palindromic rheumatism (PR) is a clinical syndrome characterised by episodes of joint swelling that settle spontaneously. A proportion of patients with PR progress and develop rheumatoid arthritis (RA). Understanding the factors associated with progression would have value for management and understanding pathogenesis. We therefore identified potential factors associated with the development of RA in these patients.

Methods: A retrospective analysis was done on 55 patients with PR followed up in our rheumatology early arthritis clinics. For inclusion, patients had either a history or physical examination findings consistent with synovial swelling that returned to normal between episodes in the absence of an alternative diagnosis. Medical history, clinical examination and laboratory findings were compared between the group that progressed to ACR/EULAR 2010 RA (progression) and the group that did not (non-progression). Comparisons between groups were made with Mann-Whitney U tests or Pearson's chi-square tests, according to data type.

Results: Of the 55 patients, 28 (51%) developed RA and 27 (49%) did not over a mean (SD) period of 28.3 (40.0) and 17.2 (19.0) months of follow-up. Factors that differed between the groups were: age at PR onset (non-progression vs. progression median 39 vs. 48 years; table), duration of interval between attacks (30 vs. 45 days), anti-cyclic citrullinated peptide (anti-CCP) positivity (96% vs. 73%), and anti-CCP titre (164 vs. 57 U/ml).

Conclusion: In our cohort of patients with PR, a relatively high proportion progressed to RA. Features on history and anti-CCP anti-body positivity, particularly high antibody titres, were found to be associated with evolution to RA. These data should be of value in managing therapy and follow-up of PR patients.

Table Characteristics of patients with palindromic rheumatism who progressed to RA in comparison with those without progression to RA at the first visit.

Distribution and Clinical Significance of Anti-Heterogenic Nuclear Ribonucleoprotein A2 Antibody in Connective Tissue Diseases. Wang Yong Sr., Mu Fangxiang, Wu Hong and Fang Yongfei. Southwest Hospital, Third Military Medical University, Chongqing, China.

Distribution and clinical significance of anti-heterogeneous nuclear ribonucleoprotein A2 antibody in connective tissue diseases

Background/Purpose: The heterogeneous nuclear ribonucleoprotein A2 (hnRNP-A2) has been described as an important autoantigen in rheumatoid arthritis (RA) since it is targeted by autoantibodies. To explore clinical significance of anti-heterogeneous nuclear ribonucleoprotein A2 (hnRNP-A2) antibody, we dectect the distribution of anti-hnRNP-A2 antibody in 1888 patients with connective tissue diseases.

Methods: Serum anti-hnRNP A2 antibody level was measured by solid-phase enzyme linked immunosorbent assay (ELISA) in 1464 patients with RA, 209 patients with systemic lupus erythematosus (SLE), 63 patients with mixed connective tissue disease (MCTD), 60 patients with Sjogren syndrome (SS), 47 patients with polymyositis/dermatomyositis (PM/DM), and 45 patients with systemic sclerosis (SSc). The positivity rate of anti-hnRNP-A2 antibody was compared among various patient groups, and its correlation to clinical and laboratory parameters and its diagnostic significance were analyzed.

Results: The positivity rate of anti-hnRNP-A2 antibody was 38.0%(556/1464), 36.8%(77/209), 52.4%(33/63), 5.0%(3/60), 4.3%(2/47), and 8.9%(4/45) in RA, SLE, MCTD, SS, PM/DM and SSc, respectively. The rate differed insignificantly between the RA, SLE and MCTD groups ($P > 0.05$), but was significantly higher than in other disease groups ($P < 0.01$). The titers of anti-hnRNP-A2 antibody were significantly higher in the RA, SLE, MCTD groups than in other disease groups ($P < 0.01$), but differed insignificantly between the RA, SLE, MCTD groups ($P > 0.05$). In RA patients, anti-hnRNP-A2 antibody weakly correlated negatively to anti-Cyclic citrullinated peptide (CCP) antibody ($r = -0.135$, $P < 0.01$), but correlated insignificantly to age, course of disease, time of morning stiffness, erythrocyte sedimentation rate, C reactive protein, rheumatoid factor (RF), anti-keratin antibody (AKA) and glucose phosphate isomerase (GPI) ($P > 0.05$).

Conclusion: Anti-hnRNP-A2 antibody can be found in various connective tissue diseases, and its positivity rate is relatively high in RA, SLE and MCTD. It is not a RA-specific antibody. In RA, anti-hnRNP-A2 antibody does not coincide with other RA-related serological indicators; hence, it may serve as an adjunctive indicator for RA diagnosis.

Key Words: heterogeneous nuclear ribonucleoprotein A2 (hnRNP-A2); Rheumatoid Arthritis (RA); Connective Tissue Diseases.

What Is More Predictive of Achieving Remission at 12 Months: The Percentage of Baseline Improvement or the Actual Disease State Achieved at 6 Months? Edward C. Keystone[1], Carter Thorne[2], Michael Starr[3], Jude Rodrigues[4], Philip Baer[5], Regan Arendse[6], J. Antonio Avina-Zubieta[7], Denis Choquette[8], Emmanouil Rampakakis[9], John S. Sampalis[9], May Shawi[10], Francois Nantel[10], Allen J Lehman[10] and Susan Otawa[10]. [1]University of Toronto, Toronto, ON, [2]Southlake Regional Health Centre, Newmarket, ON, [3]McGill University Health Centre, Montreal, QC, [4]Clinical Research and Arthritis Centre, Windsor, ON, [5]Private Practice, Scarborough, ON, [6]University of Saskatchewan, Saskatoon, SK, [7]Arthritis Research Centre of Canada, Richmond, BC, [8]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [9]JSS Medical Research, Montreal, QC, [10]Janssen Inc., Toronto, ON.

Background/Purpose: The aim of rheumatoid arthritis (RA) treatment is to optimize symptom control and, when possible, achieve sustained remission. Therefore, identification of clinical signs predicting future remission is valuable to clinical decision making. One question faced by clinicians is whether the achievement of a lower disease activity value or a higher rate of change of disease activity is indicative of better future disease outcomes. The purpose of this analysis was to determine whether change in disease activity measures or the actual values achieved at 6 months were more predictive of remission at 12 months in RA patients treated with infliximab (IFX) in a real-world, clinical practice setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA with IFX or golimumab as first biologics or after

having been treated with a biologic for <6 months. Eligible people for this study included RA patients treated with IFX enrolled between 2002–2012 with available 12-month information on remission. Multivariate logistic regression models with the parametric Wald statistic and the log-likelihood ratio were used to assess the independent contribution of the actual value and the change at 6 months in predicting 12-month remission as defined by DAS28 (<2.6), SDAI (≤3.3) and CDAI (≤2.8) criteria. These two statistics assess the extent of contribution of an individual predictor to an outcome of interest - higher values signify greater contribution - and can be used to compare the contribution of different predictors in a standardized fashion.

Results: 436 patients were included with mean age of 56.1 yrs and disease duration of 10.4 yrs. With respect to 12-month DAS28 remission, a stronger association was observed with the actual DAS28 score compared to the percent improvement in DAS28 at 6 months. The Wald statistic for the percent change and actual value of DAS28 at 6 months was 5.38 and 46.88, respectively, while the change in log-likelihood was 4.98 (P=0.026) and 61.64 (P<0.001), respectively, indicating that the actual DAS value achieved is significantly more predictive of remission when compared to percent change in DAS from baseline.

For SDAI remission at 12 months, the respective Wald values for percent change and actual value at 6 months were 0.075 and 18.28 and log-likelihood changes were 0.07 (P=0.788) and 24.08 (P<0.001). For CDAI remission at 12 months, the Wald statistic was 0.01 and 34.42 for 6 month percent change and actual value, respectively, and change in log-likelihood was 0.01 (P=0.934) and 34.23 (P<0.001). Similar results were obtained when predicting low disease activity at 12 months.

Conclusion: These results demonstrate that the actual disease outcome value achieved at 6 months is a stronger predictor of remission at 12 months than the percent change in disease activity. These findings suggest that the treatment target in a real-world setting should be set as specific endpoints and not as change over time.

How Low Is Low Disease Activity? an Analysis from a Prospective, Observational Registry. Edward C. Keystone[1], Boulos Haraoui[2], John Kelsall[3], Carter Thorne[4], Philip Baer[5], William Bensen[6], Denis Choquette[7], Regan Arendse[8], Dalton Sholter[9], Niall Jones[9], Algis Jovaisas[10], Emmanouil Rampakakis[11], John S. Sampalis[11], Francois Nantel[12], May Shawi[12], Allen J Lehman[12] and Susan Otawa[12]. [1]University of Toronto, Toronto, ON, [2]University of Montreal Hospital Centre, Montreal, QC, [3]The Mary Pack Arthritis Centre, Vancouver, BC, [4]Southlake Regional Health Centre, Newmarket, ON, [5]Private Practice, Scarborough, ON, [6]St Josephs Hospital and McMaster University, Hamilton, ON, [7]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [8]University of Saskatchewan, Saskatoon, SK, [9]University of Alberta, Edmonton, AB, [10]University of Ottawa, Ottawa, ON, [11]JSS Medical Research, Montreal, QC, [12]Janssen Inc., Toronto, ON.

Background/Purpose: Composite measures of disease activity can facilitate clinical decision-making to achieve treatment goals, and treating-to-target has been shown to improve outcomes. Both CRA and ACR/EULAR recommend that treatment target should be remission or, when not possible, low disease activity (LDA). Low levels of acute phase reactants, patient-reported disease activity (PtGA), or tender joints included in such measures may result in meeting LDA criteria while having significant residual disease activity. This analysis examined the levels of individual components of composite measures in RA patients with LDA.

Methods: BioTRAC is an ongoing, prospective registry of RA, AS, or PsA patients initiating treatment with infliximab or golimumab as first biologics or after having been treated with a biologic for <6 months. In this analysis, data from RA patients treated with infliximab for 6–18 months who were enrolled between 2002–2012 were used. LDA was defined using the DAS28-ESR (2.6–3.2), CDAI (2.8–10.0), and SDAI (3.3–11.0) criteria.

Results: 321 RA patients with mean age of 57.1 years and mean duration since diagnosis of 10.5 years were included, providing information from 488 instances of LDA. Among patients with DAS28 LDA, mean (min, max) TJC28 was 1.3 (0,9), SJC28 was 1.2 (0,7), PtGA was 2.1 (0.0,10.0), and ESR was 21.0 (1.0,75.0). Similarly, disease parameters in patients with CDAI and SDAI LDA were, respectively: TJC28 [1.4 (0,6); 1.5 (0,8)], SJC28 [1.1 (0,7); 1.0 (0,6)], PtGA [2.3 (0.0,8.5); 2.3 (0.0,9.6)], MDGA [1.7 (0.0,9.0); 1.6 (0.0,9.0)], and CRP [6.7 (0.0, 68.0)]. More than two swollen joints were present in 18.2%/14.1%/14.5% of DAS28 / CDAI / SDAI instances, respectively, and MDGA was >2 in 24.0%% / 18.6% / 18.2% of instances. With respect to HAQ-DI, patients with DAS28, CDAI and SDAI LDA had a mean (min, max) score of 0.96 (0.00,2.88), 1.00 (0.00,2.88), and 0.96 (0.00,2.88), respectively; with 8.5%, 11.3%, and 9.8% of cases having HAQ-DI≥2.0 indicating severe to very severe disability.

Conclusion: Despite meeting the LDA criteria, significant residual disease may exist as indicated by the number of swollen joints and MDGA. Furthermore, a significant proportion of patients in LDA may have severe to very severe disability, although this may be due to long disease duration and irreversible damage. Altogether, although targeting LDA results in improved outcomes, it may not be an appropriate target for a significant portion of patients. Furthermore, treatment decisions should not be based solely on composite measures, but also take into consideration the global patient picture.

Using Patient Reported Outcome Measures to Classify Disease Activity States in Rheumatoid Arthritis: A Comparison of Patient Activity Score (PAS) and Routine Assessment of Patient Index Data (RAPID). Erin Carruthers[1], Noura AL Osaimi[2], Charles H Goldsmith[3], Paul Adam[4] and Diane Lacaille[5]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]University of Ottawa, Ottawa, ON, [3]Simon Fraser University, Burnaby, BC, [4]Mary Pack Arthritis Centre, Vancouver, BC, [5]Arthritis Research Centre of Canada, Vancouver, BC.

Background/Purpose: In RA the target for treatment is clinical remission or minimal disease activity. Patient involvement in monitoring their disease activity could enhance treatment by providing early warning when targets are not met, indicating the need to re-evaluate treatment. Several patient reported outcome measures of disease activity have been developed and validated. The objective of this study is to compare the agreement between patient and rheumatologist (MD) derived disease activity states using these measures.

Methods: Consecutive RA patients seen by 7 rheumatologists were invited to participate. Patients completed a questionnaire before their visit. MD joint count and lab values were obtained from charts. We evaluated 4 patient reported disease activity measures: i) PASII; ii) RAPID with 3 measures (RAPID3); iii) RAPID with 4 measures (RAPID4); iv) modified-RAPID4 (m-RAPID4) using HAQII instead of MDHAQ. The following MD derived measures served as gold standards: i) Clinical Disease Activity Index (CDAI); ii) Simplified Disease Activity Index (SDAI); iii) Disease Activity Score 28 (DAS28). Disease states were categorized into remission, low, moderate or high, according to published cut points. Because change in treatment is recommended with moderate or high disease activity, we also compared two categories: remission or low vs. moderate or high. Agreement between patient and MD derived disease states was evaluated using *Agreement Coefficient 1 (AC1)* for two category comparisons and *Agreement Coefficient 2 (AC2)*, weighted with quadratic weights, for four category

comparisons. AC values > 0.62 were considered good agreement. Z tests were used to evaluate the significance of the difference between pairs of ACs.

Results: We recruited 150 RA patients [mean (SD) RA duration: 11.9 (11.3) y; age: 57.8 (16.3) y; 81% female]. See **Table 1** for agreement between patient and MD derived disease activity states. Overall, PASII showed the best agreement with MD measures. When comparing ACs for four category disease activity states, all pairwise comparisons were significantly different (all but one $p < 0.001$), except when comparing agreement between RAPID4 and m-RAPID4 with CDAI ($p = 0.054$), and between RAPID3 and RAPID4 with SDAI ($p = 0.075$). When comparing ACs for two categories, significant differences were detected in the agreement between PASII and RAPID3 with CDAI, RAPID3 and 4 with CDAI, PASII and RAPID3 with DAS28, PASII and RAPID5 with DAS28, RAPID3 and 4 with DAS28, and RAPID4 and m-RAPID4 with DAS28) (all $p < 0.05$).

Table 1. Agreement between patient and MD derived indices measured across four and two disease activity categories.

A	Comparison across four categories (remission vs. low vs. moderate vs. high)		
PATIENT MEASURES	**RHEUMATOLOGIST MEASURES**		
	CDAI-MD	**SDAI-MD**	**DAS28-MD**
	AC2 [95% CI]	**AC2 [95% CI]**	**AC2 [95% CI]**
PASII	**0.67 [0.55, 0.79]**	**0.67 [0.54, 0.79]**	0.47 [0.33, 0.62]
RAPID3	0.54 [0.40, 0.68]	0.60 [0.46, 0.73]	0.29 [0.14, 0.45]
RAPID4	0.60 [0.47. 0.73]	**0.65 [0.52, 0.78]**	0.39 [0.24, 0.54]
m-RAPID4	0.58 [0.45, 0.91]	**0.64 [0.51, 0.77]**	0.33 [0.18, 0.49]
B	**Comparison across two categories (remission or low vs. moderate or high)**		
PATIENT MEASURES	**RHEUMATOLOGIST MEASURES**		
	CDAI-MD	**SDAI-MD**	**DAS28-MD**
	AC1 [95% CI]	**AC1 [95% CI]**	**AC1 [95% CI]**
PASII	**0.86 [0.83, 0.90]**	**0.86 [0.82, 0.90]**	**0.67 [0.59, 0.75]**
RAPID3	**0.70 [0.63, 0.76]**	**0.73 [0.67, 0.79]**	0.29 [0.13, 0.44]
RAPID4	**0.77 [0.71, 0.83]**	**0.78 [0.72, 0.84]**	0.43 [0.29, 0.56]
m-RAPID4	**0.73 [0.66, 0.79]**	**0.75 [0.68, 0.81]**	0.35 [0.20, 0.49]

AC1 = agreement coefficient 1; AC2 = quadratic weighted agreement coefficient 2
All p-values 2 tailed, $p < 0.001$
Bolded values (AC > 0.62) are considered good agreement

Conclusion: Our results suggest that patients can self-monitor disease activity. PASII shows the best agreement with all MD measures. Given the similarities in the components of the measures compared, this difference may be due to cut points used to categorize disease states.

Validation of a Prognostic Model to Predict Structural Damage Assessed By X-Ray in Patients with RA Using MRI Data from a Clinical Trial. EA Alemao[1], S Joo[2], S Banerjee[1], P Allison[3], P Emery[4], M Weinblatt[5] and KP Liao[5]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Hopewell, NJ, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Leeds, Leeds, United Kingdom, [5]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: We developed and validated a prognostic model for rapid radiographic progression (RRP) using X-ray data to identify RA patients (pts) at risk of structural joint damage. The objective of this study was to determine the RRP model performance using MRI as the outcome for structural joint damage.

Methods: We analyzed data from a Phase IIB clinical study with the anti-IL-6 monoclonal antibody clazakizumab. This was a randomized, comparator-controlled, double-blind study of moderate-to-severe RA pts with inadequate response to MTX. Outcome data were available for MRI scans of the hands (12 wks) as well as disease activity and functional status (12 and 24 wks). MRI outcomes of synovitis, erosions and bone edema were evaluated using the RA-MRI scoring system (RAMRIS). We applied our prognostic model for RRP to pts in this study. The model includes seropositivity status, body weight, disease duration, DAS28 (CRP) and Total Sharp Score to determine the probability of RRP for each pt. The external validity of the model was evaluated for discrimination (receiver operating characteristic [ROC]) and calibration (Hosmer–Lemeshow goodness-of-fit chi-square). Based on the calculated probability of RRP, pts were categorized by probability into low (0–0.25), moderate (>0.25–0.75) and high (>0.75) risk of RRP. Analysis of variance was used to study the association between predicted probability of RRP at baseline to MRI outcome at 12 wks. Additionally, we examined the association between RRP prediction and disease activity [SDAI, DAS28 (CRP)] and functional status (HAQ) at 12 and 24 wks.

Results: There were 418 pts in the clazakizumab Phase IIB study; average age was 50.4 yrs (SD 12.3); 82.1% were female. The RRP model when applied to clazakizumab Phase IIB had an overall ROC of 0.73 (95% CI 0.62, 0.83) and Hosmer–Lemeshow chi-square of 13.5 (df=8; p=0.1). Baseline probability of RRP was evaluated in 387 (92.6%) pts with available data. Of these, the majority (96.1%) were in the moderate- and high-risk (48.1% each) RRP groups. Pts in the moderate-risk group, when compared with those in the high-risk group, tended to be younger (mean age [SD] 48.3 [12.9] vs 52.2 [11.0] yrs). Compared with the moderate-risk RRP group, pts at high risk of RRP had significantly higher MRI measures of erosion, synovitis and joint space narrowing. In addition, pts at baseline in the high–risk group compared with the moderate-risk group had significantly higher disease activity scores and higher physical activity scores as measured by HAQ at 12 and 24 wks (Table).

Table Differences between MRI, disease activity, and functional outcomes in pts at high risk versus moderate risk of RRP

	12 weeks		24 weeks	
Outcomes	**Δ (high versus moderate) risk of RRP**	**95% CI**	**Δ (high versus moderate) risk of RRP**	**95% CI**
MRI scores				
Erosion (MRI)	**10.84**	7.03, 14.66	–	–
Synovitis (MRI)	**2.63**	1.54, 3.71	–	–
Edema (MRI)	1.06	–0.90, 3.02	–	–
Joint space narrowing (MRI)	**6.54**	3.59, 9.50	–	–
Disease activity and functional outcomes				
DAS28 (CRP) C	**0.72**	0.36, 1.09	**0.78**	0.42, 1.14
SDAI	**8.22**	4.38, 12.05	**8.11**	4.63, 11.58
HAQ	**0.43**	0.25, 0.60	**0.47**	0.29, 0.65

Each line represents a mutivariable linear regression model of outcomes

Conclusion: The RRP model based on X-ray progression had good validity in predicting structural joint damage measured by MRI. In line with clinical thinking, we observed that patients at high baseline risk of RRP compared with those with moderate risk tended to have higher disease activity and worse functional status in the longer term.

Association of Pharmacogenetic Markers with Treatment Response in Patients with Rheumatoid Arthritis. Ute I. Schwarz[1], Janet E. Pope[1], Edward Keystone[2], Boulos Haraoui[3], Carter Thorne[4], Yun-Hee Choi[1], Melanie Poulin-Costello[5], Nabil Bayan[5] and Richard B. Kim[1]. [1]Western University, London, ON, [2]Mount Sinai Hospital, University of Toronto, Toronto, ON, [3]University of Montreal Hospital Centre, Montreal, QC, [4]Southlake Regional Health Centre, Newmarket, ON, [5]Amgen Canada Inc., Mississauga, ON.

Background/Purpose: In the **CA**nadian **M**ethotrexate and **E**tanercept **O**utcome Study (CAMEO) continued therapy with etanercept (ETN) and methotrexate (MTX) led to better outcomes at month 24 than the withdrawal of MTX in MTX inadequate responders (MTX-IR) with active rheumatoid arthritis (RA). Patients had to tolerate MTX at a dose of ≥ 15 mg/wk or 10 mg/wk if intolerant. Similar disease activity was observed in both treatment arms at 12 months in the subgroup of patients who achieved low disease activity (disease activity score [DAS28] < 3.2) at 6 months of combination therapy, whereas if not in low DAS28 combination therapy was more effective. Recent evidence suggests that polymorphisms in genes related to metabolism and cellular transport pathways of MTX and to the biological targets of ETN may help predict clinical response in RA. This pre-defined CAMEO sub-study explored pharmacogenetic markers as novel predictors of treatment outcome in patients failing MTX prior to starting ETN.

Methods: All patients were treated with ETN+MTX for 6 months, followed by randomization to either ETN+MTX or ETN alone for an

additional 18 months. After consent, DNA extraction and genotyping was performed using TaqMan Genotyping Assays. Fifteen genetic variants in 12 genes related to MTX and 4 variants in 3 genes related to TNF were analyzed. The contribution of genetic variants to therapeutic response (improvement in DAS28 [ΔDAS28] from baseline to months 6, 12, 18 and 24; total Sharp score [TSS] at 12 and 24 months) was assessed using mixed models with adjustments for age and sex.

Results: Assessments were performed in 111 patients (mean age 55.2 years, 73% female, 98% Caucasians). Univariate analyses did not suggest an association of genetic variants related to response to ETN ($p > 0.25$). Patients receiving ETN+MTX after randomization (N=64) were included for multivariate analyses at 12, 18 and 24 months. Patients expressing the *ATIC* 347GG, *GGH* 452CC, *MTHFD1* 1958A, *ABCB1* 3435C, or *SLCO1B1* 521C alleles were more likely to have an improvement with combined therapy as reflected by a significantly higher ΔDAS28 from baseline to follow-up (Table 1). At 12 and 24 months, patients having the *ATIC* 347GG and *ABCB1* 3435CC alleles showed moderately higher TSS (Table 2). Radiographic assessments also indicated that *ABCC2* 1249A carriers appear to be less responsive compared with GG carriers.

Conclusion: Genetic polymorphisms in drug transporters and metabolic enzymes related to MTX pathways were associated with clinical response after combined treatment in MTX-IR patients. No association between response to ETN and TNF gene variants was observed.

Levels of IgG Autoantibodies to Oxidation-Associated MDA Neo-Determinants Are a Biomarker for Systemic Inflammation and Disease Activity in SLE and RA. Caroline Grönwall, Lelise Getu, Jeffrey D. Greenberg, Robert M. Clancy and Gregg J. Silverman. New York University School of Medicine, New York, NY.

Background/Purpose: Monitoring disease activity in patients with autoimmune rheumatic disease is an essential part of clinical care. Highly reactive malondialdehyde (MDA) arise from reactive oxygen species and lipid peroxidation and can covalently modify proteins and increased levels of MDA may be associated with the inherent autoimmune pathogenic process. We therefore hypothesized that levels of IgG-autoantibodies to MDA-modified proteins may reflect core disease activity.

Methods: In the current study, serum IgG anti-MDA levels were compared in 71 healthy controls, 30 OA, and 15 PsA, 283 SLE and 162 RA patients identified by ACR criteria. IgG anti-MDA was measured by sandwich ELISA using MDA-modified BSA. Statistical differences were assessed by Mann-Whitney test and Spearman analysis.

Results: Compared to controls (5±3 RU/ml), IgG anti-MDA was significantly increased in patients with PsA (7.4±4 RU/ml, p=0.01), SLE (17±21 RU/ml, p<0.0001) and RA (13±11 RU/ml, p<0.0001). In SLE patients, IgG anti-MDA significantly correlated with the disease activity assessed by SELENA-SLEDAI (p<0.0001, R=0.34, n=219) and levels were higher in SLE patients with active disease (SLEDAI≥6, 18.9±17.3 RU/ml, p=0.001) than with low disease activity (SLEDAI >6, 11.5±16.6). In RA, IgG anti-MDA was significantly higher in new onset RA (<6 mo, 21±13 RU/ml, p<0.0001) than in chronic RA (>2 yr, 10±8 RU/ml). Notably, new onset RA patients had more active disease by DAS28 (5.7±1.2, p=0.01) than chronic RA patients generally on therapy (4.8±1.5). Importantly, IgG anti-MDA significantly correlated with DAS28-ESR (p<0.0001, R=0.35, n=157; with 16 seroneg), and compared to RA patients with more controlled disease (DAS28<3.2, 6±3) the levels were higher in moderate disease (DAS28 3.2–5.1, 12±11 RU/ml, p=0.005) and further elevated in active disease (DAS28 >5.1, 15±12 RU/ml, p=0.001). IgG anti-MDA also correlated with TNFα (p=0.002, R=0.39), IL-6 (p=0.03, R=0.27), and CRP levels (p=0.003, R=0.37) in DMARD naïve RA patients (n=62).

Conclusion: IgG autoantibodies to MDA-modified determinants may provide a biomarker for disease activity in rheumatic autoimmune diseases. These autoantibodies could therefore provide a valuable early objective metric for diagnosis and for assessing disease activity. The potential mechanisms responsible for induction of IgG anti-MDA autoantibodies during the pathogenesis of systemic inflammation merits further study.

Soluble TREM-1 Is a Biomarker of Anti-CCP-Positive, DMARD-Naive Early Rheumatoid Arthritis. Shachaf Ofer-Shiber[1], Elisheva Pokroy-Shapira[1], Yair Molad[2], Shirly Oren[1], Hagit Shay-Aharoni[1] and Ilan Babai[3]. [1]Rabin Medical Center, Beilinson Hospital and Sackler Faculty of Medicine, Tel Aviv University, Petach Tikva, Israel, [2]Rabin Medical Center, Beilinson Hospital and Sackler Faculty of Medicine, Tel Aviv University, Petah Teqva, Israel, [3]Rabin Medical Center, Beilinson Hospital, Petach Tikva, Israel.

Background/Purpose: Triggering receptor expressed on myeloid cells-1 (TREM-1) is a cell-surface receptor, expressed mainly on monocytes and neutrophils and involved in amplification of the inflammatory response. Previous studies have shown an upregulation of TREM-1 in synovium of patients with rheumatoid arthritis (RA) as

well as increased levels of soluble TREM-1 (sTREM-1) in synovial fluid and blood of patients and animal model of RA. We sought to determine the serum sTREM-1 levels in disease-modifying anti-rheumatic drug (DMARD)–naïve early rheumatoid arthritis (ERA), to investigate the association of sTREM-1 levels with Disease Activity Score in 28 joints (DAS28) and seropositivity for anti- cyclic citrullinated peptide *(*CCP) antibody, and to determine the predictive value of sTREM-1with respect to clinical response to DMARD therapy.

Methods: Twenty-two consecutive patients with DMARD-naïve ERA were prospectively evaluated for serum sTREM-1 by means of ELISA at diagnosis and at the following clinic visit after low dose prednisone and/or DMARD have been administered, and related to DAS28 and serum level of anti-CCP Ab'. We compared the sTREM-1 level to that of 31 patients with established RA as well as to 24 controls.

Results: Serum sTREM-1 level was significantly higher in the DMARD-naïve ERA group (2,122.9±388.9 ρg/ml) compared to established RA group (1,478.0±280.0 ρg/ml, $p = 0.001$) and normal control (34.4±7.4 ρg/ml, $p < 0.001$). In the ERA group, elevated basal sTREM-1 level was significantly associated with DAS28-CRP ($p = 0.001$, HR3.23, 95% CI 1.4 – 8.12), DAS28-ESR ($p = 0.04$, HR 2.34 95%CI 0.1–8.12), as well as predicted higher DAS28 at the following encounter after DMARD treatment was administered ($p = 0.001$, HR 3.2 95% CI 1.1–7.2), as well as in patients with established RA. Higher serum sTREM-1levels were significantly associated with higher titers of anti-CCP antibody ($p < 0.001$).

Conclusion: Our results suggest that serum sTREM-1 may provide a novel biomarker of DMARD-naïve ERA as well as of disease activity and seropositivity for anti-CCP antibody in RA.

High 11B-HSD1 Activity Is Associated with Progression to Rheumatoid Arthritis in Patients with a New Onset of Inflammatory Arthritis. Dominika Nanus[1], Andrew Filer[2], Lorraine Yeo[1], Dagmar Scheel-Toellner[3], Rowan Hardy[1], Gareth Lavery[1], Paul Stewart[4], Christopher Buckley[1], Mark Cooper[5] and Karim Raza[1]. [1]University of Birmingham, Birmingham, United Kingdom, [2]Rheumatology Research Group, MRC Centre for Immune Regulation, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom, [3]Rheumatology Research Group, Centre for Translational Inflammation Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham B15 2TT, UK, Birmingham, United Kingdom, [4]University of Leeds, Leeds, United Kingdom, [5]ANZAC Research Institute, Sydney, Australia.

Background/Purpose: Inadequate endogenous glucocorticoid (GC) synthesis during inflammation has been proposed as an aetiological factor in the development of rheumatoid arthritis (RA). It has been shown that inflamed synovial tissue from patients with RA can generate active GCs through the expression of the 11β-hydroxysteroid dehydrogenase type 1 enzyme (11β-HSD1), which converts cortisone to cortisol. We examined whether the total body activity of 11β-HSD1 was associated with the risk of developing persistent arthritis in patients first presenting with joint inflammation.

Methods: Blood and urine, were obtained from 76 patients with early arthritis (symptoms ≤ 12 weeks duration). The final diagnostic outcome was determined after 18 months clinical follow up when patients were assigned to one of the following three outcome groups. (1) Persistent inflammatory arthritis that did not fulfil 1987 ACR classification criteria for RA, n=13. (2) Persistent RA, according to 1987 ACR classification criteria, n=18. (3) Resolving inflammatory arthritis, n=24. Patients were classified as having a resolving inflammatory arthritis if they had no clinically apparent joint swelling at final follow-up, were not receiving disease modifying drugs or steroids and had not received such drugs in the previous 3 months. In addition, patients who fulfilled 1987 ACR classification criteria for RA and had a symptom duration of more than 12 weeks at initial assessment were recruited as patients with 'established RA', n=20. Total body 11β-HSD1 activity was determined by urinary gas chromatography/mass spectrometry and calculated as the tetrahydrocortisol+allotetrahydrocortisol/tetrahydrocortisone ((THF+alloTHF)/THE) and the cortols/cortolones ratios. Urinary 11β-HSD2 activity was measured as the UFF/UFE ratio. Arthritis severity was assessed by ESR, CRP and DAS28.

Results: Systemic measures of 11β-HSD1 activity were significantly higher in patients with early arthritis whose disease went on to persist, and also in the subgroup of patients with persistent disease who developed RA, when compared with patients whose synovitis resolved over time (persistent RA, 1.34 (0.013) and resolving inflammatory arthritis, 0.96 (0.07), P=0.012), mean (SEM). Levels of ESR at baseline were not significantly different between the different outcome groups. However the levels of CRP in patients with early synovitis that persisted were higher than that in patients whose synovitis resolved. We observed a significant positive correlation between systemic 11β-HSD1 activity and both ESR and CRP in patients with established RA but not in any of the early arthritis patients group.

Conclusion: The present study demonstrates that patients with a new onset of synovitis whose disease subsequently resolved had significantly lower levels of systemic 11β-HSD1 activity when compared with patients whose synovitis developed into RA or other form of persistent arthritis. This observation is contrary to that predicted on the basis of previous work and raises the possibility that a high total body 11β-HSD1 activity during early arthritis may reduce the probability of disease resolution.

Prevalence and Correlates of Patient-Physician Discordance in Early Rheumatoid Arthritis. John M. Davis III, Cynthia S. Crowson, Tim Bongartz, Clement J. Michet, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN.

Background/Purpose: Patients with rheumatoid arthritis (RA) sometimes rate their global disease activity differently than their rheumatologists. Previous studies describing this 'discordance' have primarily included patients with established disease (i.e., mean disease duration >10 years). The objective of this study was to evaluate the prevalence and correlates of patient-physician discordance in patients with early disease (i.e., duration <3 years).

Methods: We conducted an observational study of consecutive patients with RA recruited between July 2008 and December 2010. RA was defined by the Leiden early RA prediction rule or the 1987 ACR criteria. A physician joint assessor, who was independent from treatment decision-making, performed a standardized clinical evaluation. Discordance was defined by a ≥25-mm difference between the patient and physician global assessments of disease activity. A higher patient-than-physician global assessment defined positive discordance, and a higher physician-than-patient global assessment defined negative discordance. Patients completed visual analog scales for pain and fatigue, the Health Assessment Questionnaire (HAQ), and the Medical Outcomes Study Short Form 36 (SF-36). We abstracted the electronic medical records to collect demographics, laboratory data, smoking status, and body mass index (kg/m^2). Correlations between explanatory variables and the presence of positive or negative discordance were determined using Spearman methods.

Results: A total of 127 patients with RA were recruited. The mean age was 55.6 years, mean disease duration was 6.8 months, and 63% of patients were female. The prevalence of positive (i.e., patient high) and negative (i.e., physician high) discordance was 10.2% and 16.5%, respectively. Positive discordance was associated with higher pain ($r = 0.37$, $p = <0.001$), fatigue ($r = 0.32$, <0.001) and HAQ disability ($r = 0.31$, $p<0.001$). Poor health-related quality of life on the SF-36 physical component scale ($r = -0.29$, $p = 0.001$) and mental component scale ($r = -0.20$, $p = 0.02$) also correlated with positive discordance. Notably absent were associations of discordance with age, sex, radiographic damage, body mass index, smoking, anti-CCP antibodies, or use of prednisone or disease-modifying medications. In contrast, negative discordance (i.e., physician high) was associated with higher numbers of swollen joints ($r = 0.19$, $p = 0.03$), positive rheumatoid factor ($r = 0.18$, $p = 0.046$), and with lower pain and better overall physical and mental health on the part of the patient.

Conclusion: The contribution of this study is that prevalence and correlates of patient-physician discordance are similar in early and established RA. Patients with early RA take into account their pain, fatigue and adverse quality of life when making their global disease assessments whereas physicians emphasize objective inflammation and laboratory markers. As 'treat-to-target' algorithms increasingly focus on quantitative targets, these data behoove clinicians to fully consider the disease experience to provide optimal patient care.

Self-Assessment Tool of Rheumatoid Arthritis Disease Activity: Handgrip Strength Measured By a Smartphone Connected to a Dynamometer. Francisco Espinoza Sr. [1], Yves-marie Pers Sr. [2], Pierre LeBlay Sr. [2] and Christian Jorgensen[2]. [1]Rheumatology Department, Division of Internal Medicine, School of Medicine, University of Los Andes, Santiago, Chile, [2]Clinical Immunology and Osteoarticular Diseases Therapeutic Unit, CHU Lapeyronie., Montpellier, France.

Background/Purpose: Patient self-management should become a key component of rheumatology care. Development of modalities using personal technologies resources represents an attractive way to assess periodic disease's activity. We previously developed a Smartphone application and a software to measure the dominant handgrip strength in rheumatoid arthritis (RA) patients. This pilot-study was performed in healthy and RA volunteers for testing and calibrating the system with a classical dynamometer. Then using this novel handheld device, we conducted an exploratory study to correlate RA disease activity with handgrip strength. Here we present our preliminary results.

Methods: We included 50 patients with RA. All patients fulfilled the 2010 ACR/EULAR criteria for RA. We excluded patients with health issues that could affect the test (hand or wrist surgery, myopathy, carpal tunnel syndrome, etc). Patients received visual and audio instructions from the Smartphone application and one-trained operator was present. The 28-joint disease activity score (DAS28) and modified Health Assessment Questionnaire (mHAQ) were measured for all participants. Linear regression and Two-Way ANOVA test were performed. The results were adjusted by age and sex.

Results: 96% of patients were females. Mean age was 62,59 + 12,9. Mean DAS28 was 3,41 ± 1,38 and 38% of patients were in remission (DAS28<2,6). 22% were treated with Methotrexate or Leflunomide and 76% were treated with a bDMARD in association or not with a sDMARD. No patients reported difficulties or pain performing the test. Mean duration of the test was 3.5 minutes ± 0.22 and handgrip strength level was 9,63 ± 5,49 Kg. A significantly negative correlation between the index of handgrip strength test and DAS28 was identified ($r=-0.79, -0.85$ to -0.34, $p<0,01$). We observed a significant correlation with the mHAQ ($r=0.85$, 0,67 to 0,96, $p<0,01$). In a subgroup of 15 patients we evaluated the handgrip strength after treatment modifications or disease flare-up exacerbations and we founded a significantly correlation with DAS28 changes ($r=-0.93$, -0.76 to -0.54, $p<0.001$). Ultimately we observed a tendency to correlate index of handgrip strength, adjusted by age and sex, and the presence of ultrasonography synovitis in a subgroup of 10 patients ($p=0.076$).

Conclusion: Our preliminary data showed that Smartphone self-evaluation of handgrip strength is a feasible way to assess RA disease activity. Moreover, we will continue to follow longitudinally our RA patients in order to determinate if this test could be used to detect flare-up or response to treatment. Then, we will validate this simple tool of self-assessment RA activity in a larger outpatients cohort.

Neuroendocrine Hormone and Metabolic Peptide Levels in the Earliest Phases of Rheumatoid Arthritis – Do Free Fatty Acids Play a Role? Man Wai Tang[1], Frieda A. Koopman[2], Jan P.M. Visscher[2], Marjolein J.H. de Hair[2], Danielle M. Gerlag[2] and Paul P. Tak[2]. [1]Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease associated with several neuroendocrine hormones and metabolic peptides. The crosstalk between the hormones and the immune system is important for homeostasis during inflammation. Therefore, we hypothesize that disturbances in hormones may gradually result in an inflammatory disease and hormones may be even disturbed years before onset of arthritis. The aim of this study is to determine the hormone levels in RA patients and individuals at risk for developing RA and compare those with the levels in healthy controls.

Methods: In total 18 neuroendocrine hormones and metabolic peptides (triglycerides (TG), free fatty acids (FFAs)) and pancreatic polypeptide (PP) were measured in fasting serum samples from 22 RA patients, 45 individuals at risk for developing RA by the presence of RA-specific autoantibodies and 16 healthy controls.

Results: The median (IQR) PP level was significantly higher in RA patients (34 (23–58) pmol/L) and individuals at risk (31 (24–45) pmol/L) compared to healthy controls (10 (6–27) pmol/L), respectively $P=0.004$ and $P=0.002$. The TG level was significantly higher in RA patients (1.03 (0.75–1.29) mmol/L) and a trend towards elevated TGs in individuals at risk (0.94 (0.72–1.15) mmol/L) compared to healthy controls (0.70 (0.59–1.02) mmol/L), respectively $P=0.036$ and $P=0.09$. The FFA level was significantly higher in RA patients (0.59 (0.47–0.65) mmol/L) compared to healthy controls (0.40 (0.35–0.50 mmol/L; $P=0.011$) and a trend towards elevated FFAs in individuals at risk (0.53 (0.40–0.59) mmol/L; $P=0.06$)compared to healthy controls. In RA patients, the FFA level was positively correlated with disease activity parameters, but not confounded by body mass index or other variables. All other hormones and peptides were comparable between the three study groups.

Conclusion: FFA, TG and PP levels were higher in RA patients than in healthy controls. PP levels were higher in at risk individuals than in healthy controls and FFA and TG levels showed a similar trend. Moreover, the FFA level was positively correlated with disease activity parameters. This may support a role for FFAs, TGs and PPs in the pathogenesis of RA and these peptides may contribute, even in the at risk phase of RA, to the increased risk of cardiovascular diseases. Furthermore, PPs and FFAs can be potential biomarkers to identify individuals in the at risk phase of RA, who may develop RA later on.

Influence of Body Mass Index on Disease Activity and Radiographic Joint Damage in Rheumatoid Arthritis: A Systematic Review and Meta-Analysis. Celine Vidal[1], Thomas Barnetche[2], Jacques Morel[3], Bernard Combe[3] and Claire Daien[1]. [1]Hopital Lapeyronie, Montpellier, France, [2]Rheumatology department, Bordeaux University Hospital, bordeaux, France, [3]Hôpital Lapeyronie, Montpellier, France.

Background/Purpose: Overweight and obesity in patients with rheumatoid arthritis (RA) are rising conditions. Adipose tissue has pro inflammatory properties by producing adipokines which could play a role in RA activity. The prognosis of overweight and obese patients with RA is not well established.

Methods: We conducted a systematic review and meta-analysis to assess the influence of body mass index on disease activity (DAS 28) and radiographic joint damage (RJD) in patients with RA. We searched MEDLINE and The Cochrane Database publications up to April 2014 with MeSH terms ("body mass index" OR "obese") AND "rheumatoid arthritis". Studies reporting DAS 28 and/or its components, Health Assesment Questionnaire (HAQ) and RJD according to body mass index (BMI)groups were included. Two investigators abstracted data and rated study quality and applicability. Statistical analysis used weighted mean differences with a fixed or random effects model, except for radiographic analysis in which standardized means were used as different radiographic scores were assessed in studies.

Results: Among the 579 citations retrieved with MeSH terms, 52 articles suited inclusion criteria and 7 of them were included in meta-analysis. Activity was assessed in 4 studies, involving 1402 patients, and revealed an association between obesity in RA and higher DAS 28 (+ 0.14, $p=0.04$, $I^2=0\%$).Health Assessment Questionnaire (HAQ) was evaluated in 2 studies, involving 1264 patients, and also revealed a positive association with obesity (+ 0.1, $p=0.03$, $I^2=0\%$). RJD was reported in 4 studies, involving 1465 patients, revealing a negative association with obesity ($p=0.03$, $I^2=38\%$). According to the systematic review, the increase of DAS 28 could be explained by an increase of tender joint counts and global health assessment.

Conclusion: Obesity in RA is associated with higher DAS 28 and HAQ. However, obese patients with RA have lower RJD. This increase of DAS28 in obese patients could be explained by pro inflammatory fat cytokines or the general tendency of higher pain levels due to comorbidities resulting from obesity. Conversely, the increase of adiponectine observed in obese patients

may play a protective role on joint damage. Altogether, this work highlights the importance of obesity on RA prognosis and supports the need of future studies to better understand the mechanisms behind.

Very Low or High Body Mass Index Negatively Affects patients' Ability to Achieve Sustained Remission in Early RA in a Multicenter Canadian Cohort. Susan M. Goodman[1], Yan Ma[1], Wei Zhang[1], Elizabeth Schulman[2], Janet E. Pope[3], Carol Hitchon[4], Susan J. Bartlett[5], Boulos Haraoui[6], Daming Lin[7], Gilles Boire[8], Diane Tin[9], J. Carter Thorne[10], Shahin Jamal[11], Edward C. Keystone[12] and Vivian P. Bykerk[1]. [1]Hospital for Special Surgery, New York, NY, [2]New York Presbyterian - Cornell Campus - HSS, New York, NY, [3]St Joseph Health Care, London, ON, [4]University of Manitoba, Winnipeg, MB, [5]Johns Hopkins University, Baltimore, MD, [6]University of Montreal Hospital Centre, Montreal, QC, [7]Mount Sinai Hospital, University of Toronto, Toronto, ON, [8]CHUS - Sherbrooke University, Sherbrooke, QC, [9]Southlake Regional Health Centre, Newmarket, ON, [10]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [11]Vancouver General Hospital, Vancouver, BC, [12]University of Toronto, Toronto, ON.

Background/Purpose: To determine if patients with a very low body mass index (BMI) (<18.5) or high BMI (≥ 25) are able to achieve sustained remission (susREM) in an early RA (ERA) cohort.

Methods: Initial BMI and disease activity (DAS28) were prospectively measured over 3 years in patients from CATCH (Canadian Early Arthritis Cohort). Patients were categorized into 6 groups based on World Health Organization BMI classifications (class 1–6) Differences between BMI groups in patients' demographics and clinical outcomes were assessed using Chi-square/Fisher's exact tests or Kruskal-Wallis tests. Multivariate regression based on generalized estimating equations (GEE) methods was used to compare the likelihood of achieving susREM between groups, where susREM was defined as DAS28<2.6 × 2 at consecutive visits 3–12 months apart.

Results: 944/2524 eligible patients with a measured BMI and ≥ 2 consecutively measured DAS28 scores over 3 years formed the study cohort. Only 15 (2%) patients were underweight (category (Cat) 1). Overall 65% were either overweight (34% in Cat 3) or obese (31% in Cat 4–6), representing a rate higher than the WHO reported 47% national average. Patient characteristics in the 6 BMI categories were studied (**Table 1**). Univariate analysis, presented for BMI strata show patients with higher BMI were older (p<0.0001), more often female (p<.001) with worse function at baseline by HAQ-DI (p<001). Those with very low or high BMI had a higher CRP (p=0.0004) and ESR (p<0.001), and those with low or normal BMI were more often smokers (p<0.0001). Patients in the highest BMI strata had higher Patient Global Assessments of disease (PtGA) (p=0.03) and pain (p=0.04). Variables that did not differ among groups included Physician's Global assessments (MDGA)(p=0.9), ACPA and RF positivity [(p=0.16)],(p=0.26)], symptom duration (p=0.66), DAS28 (p=0.06) at study entry, or steroid (p=0.3) or methotrexate (MTX) use (p=0.9) over the first 3 months. In the multivariate analysis patients in all BMI categories except for class 4 (p value=0.678 were significantly less likely to achieve susREM compared to normal BMI. Early MTX use, not smoking, being Caucasian and achieving a low disease activity state (LDAS) by 6 months increased the odds of achieving susREM (**Table 2**).

Conclusion: The chance of achieving sustained remission is decreased in underweight, and overweight / obese ERA patients, more so in the morbidly obese (class 5–6). Early use of MTX, an early response to treatment, and non-smoking status improve the odds of sustained remission independent of BMI. BMI should be considered among the modifiable risk factors for poor RA outcomes.

Could Osteoprotegerin and TNF-Related Apoptosis-Inducing Ligand Assessments Help Us to Manage Early Rheumatoid Arthritis? Results from the Espoir Cohort. Rachel Audo[1], Claire I. Daien[2], Laura Papon[1], Cédric Lukas[3], O Vittecoq[4], B Combe[5] and Jacques Morel[5]. [1]IGMM, CNRS UMR5535, Montpellier, Montpellier, France, [2]Lapeyronie Hospital, Montpellier, France, [3]Hopital Lapeyronie, Montpellier, France, [4]Rouen University Hospital & Inserm U905, Rouen, France, [5]Hôpital Lapeyronie, Montpellier, France.

Background/Purpose: TNF-Related Apoptosis Inducing Ligand (TRAIL) is a member of the TNF familly. Its soluble receptor Osteoprotegerin (OPG) also inhibits Receptor activator of nuclear factor kappa-B ligand (RANKL). We previously reported that, in a cohort of early arthritis (< 2 years), a high OPG/TRAIL ratio at baseline was associated with remission (DAS28<2.6) at 6 months, suggesting that OPG and TRAIL could be used to predict outcomes in early arthritis.

Methods: The aim of this study was to confirm these results in the larger French cohort ESPOIR. To be included, patients should have an early arthritis (< 6 months). We studied patients clinical status at 12 months (M12) and radiographic progression (Sharp's score) at 24 months (M24). TRAIL and OPG concentrations in serum were measured at baseline (M0). Values of TRAIL and OPG were log transformed to be normalized. We first compared TRAIL and OPG between patients with arthritis responding to ACR/EULAR

2010 criteria (RA) and undifferentiated arthritis (UA). We then compared logOPG, logTRAIL and logOPG/logTRAIL using general linear model adjusted for DAS28, rheumatoid factor and anti-citrullinated protein antibodies positivity, and total Sharp score at M0. Logistic regression was used to determine predictive value for remission (DAS28 ≤2.6) and radiographic progression (DSharp score >0).

Results: TRAIL, OPG and TRAIL/OPG at M0 were not different between RA (n = 641) and UA patients (n = 53). Among RA patients, patients in remission at M12 had a significantly lower concentration of M0 logOPG than those with DAS28 >2.6 (2.93±0.18 (n=204) vs 2.98±0.16 pg/ml (n=341), respectively, p=0.002 and p=0.026 after adjustment). M0 TRAIL and M0 OPG/TRAIL were not significantly different between patients in remission at M12 and others. Logistic regression adjusted for DAS28, rheumatoid factor and anti-citrullinated protein antibodies positivity, and total Sharp score at M0 showed that logOPG≥3.1 (=1259 pg/ml) was predictive of absence of M12 remission (B=0.55, CI: 0.33–0.90, p=0.018), with a sensibility of 21%, a specificity of 87%, a positive predictive value of 75% and a negative predictive value of 38%.

Patients with progression of Sharp score erosion at M24 had significant lower M0 logTRAIL (2.96±0.22 vs 3.00±0.19, p=0.009 and p=0.002 after adjustment). M0 OPG and M0 OPG/TRAIL were not significantly different between patients with or without radiographic progression at M24. Logistic regression adjusted for DAS28, rheumatoid factor and anti-citrullinated protein antibodies positivity, and total Sharp score at M0 showed that logTRAIL≤2.95 (891 pg/ml) was predictive of erosion progression (B=0.47, CI: 0.30–0.72, p=0.001) with a sensibility of 52%, a specificity of 63%, a VPP of 39% and a VPN of 74%.

Conclusion: Concentrations of TRAIL and OPG could not help in distinguish UA and RA. Low M0 OPG is associated with remission at M12 and low TRAIL is associated with erosion progression at M24 after multiple adjustments for usual prognosis factors. This suggests a promoting effect of OPG on disease activity and a protective role of TRAIL on bone erosion. However, no relevant threshold could be determined to use OPG and TRAIL in daily practice to identify early RA patients at risk of poor outcomes.

Disease Activity Scoring: Comparing Patient and Physician Global Assessment of Disease Activity in Rheumatoid Arthritis. Boulos Haraoui[1], Denis Choquette[1], Jean-Pierre Raynauld[1], Jean Pierre Pelletier[1], Louis Bessette[2], Edith Villeneuve[1], Marie-Anaïs Rémillard[1], Isabelle Fortin[3], Diane Sauvageau[1] and Louis Coupal[1]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, QC, [3]Centre de rhumatologie de l'est du Québec (CREQ), Rimouski, QC.

Background/Purpose: Visual analogue scales (VAS) are routinely used in daily clinical practice and are part of the different composite outcome measures. Studies often report weak to moderate positive correlations between physician and patient assessment of disease activity. It is thought that they are driven by different considerations such as pain, fatigue and mental status for patients and objective measures such as joint counts and CRP/ESR for physicians. While absolute values of patient and physician global disease activity do not always correlate, changes may offer a better correlation. We evaluated those changes in RA patients initiating a first anti-TNF.

Methods: We extracted from the RHUMADATA® clinical database and registry patient and physician global assessments of disease activity of RA patients treated for at least 6 months with a first anti-TNF agent (adalimumab, etanercept or infliximab). Pearson correlations coefficients between pre, post and pre-post changes in patient and physician assessments were computed (SAS v 9.13) and compared. We used t-tests to verify if pre-post differences in global assessments were related to disease duration (less or equal to two years vs greater than two years), age (less or equal to 50 years vs greater than 50 years), gender and DAS 28 (less or equal to 3.2 vs greater than 3.2). A general linear model (GLM) was used to further assess if disease duration, age, gender and DAS score explained the discrepancies in physician and patients pre-post global assessments differences.

Results: The global disease activity scores from 83 patient-physician pairs were available for this analysis. Pre-treatment assessments were made within 0 and 176 days (mean 33 days) of biologic initiation while post treatment assessments occurred between 182 and 799 days (mean 268 days). Patient and physician pre, post, and pre-minus-post global assessment means and standard deviations are presented. The pre and post and change treatment Pearson correlations coefficients between patient and physician assessments are respectively r2=0.34 (p=0.001), r2=0.19 (p=0.08) and 0.15 (p=0.19).

Physician and patient global disease activity assessment

	Physician		Patient		Difference (patient-physician)	
	Mean	StdDev	Mean	StdDev	Mean	StdDev
Pre-treatment	5.27	1.98	5.58	2.96	0.31	2.94
Post-treatment	1.42	1.79	3.79	2.81	2.37	3.02
Difference (post-pre)	−3.85	2.31	−1.79	2.95	–	

Physician pre-post differences in global assessment were not significantly different across disease duration, gender, age and DAS scores. Similar results were observed in the patient assessments except for disease duration. Smaller differences were observed in subjects having a disease duration of two years or less. The GLM revealed that no factors other than rater (physician or patient) explained the observed differences.

Conclusion: While the pretreatment initiation global disease activity assessments showed moderate correlation, the change in these assessments exhibited a weak relationship. Both physicians and patients agree on disease activity improvement although their magnitudes differ. Of the factors explored, only rater (physician or patient) seem to explain these differences.

Th9 Lymphocytes in Rheumatoid Arthritis. Rossella Talotta[1], Angela Berzi[2], Fabiola Atzeni[1], Donata Dell'Acqua[1], Piercarlo Sarzi-Puttini[1] and Daria Trabattoni[2]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]Chair of Immunology, Department of Biomedical and Clinical Sciences "L. Sacco, Milan, Italy.

Background/Purpose: Th9 cells are IL-9-secreting Th lymphocytes that are involved in the immunological responses underlying parasitic infections and allergic diseases. In the case of autoimmune diseases, Th9 cells seem to be involved in the pathogenesis of experimental autoimmune encephalomyelitis. No study has yet evaluated the effects of Th9 responses in rheumatic diseases such as rheumatoid arthritis (RA). The aim of this study was determine the prevalence of Th9 lymphocytes in RA patients and identify their possible association with the discontinuation of biological treatment with infliximab (IFX).

Methods: We enrolled 55 consecutive RA outpatients: 15 not receiving any immunosuppressive drug; 20 responders to IFX treatment; and 20 who had discontinued IFX because of adverse events or inefficacy and were being treated with other biological agents (ABA, TCZ, ETN or CTZ) and traditional immunosuppressive drugs. The matched control group consisted of 10 healthy subjects. After giving their informed consent, the subjects underwent blood sampling for the isolation of peripheral blood mononuclear cells (PBMCs). The PBMCs were cultured with/without IFX 50 ƒÝg/L for 18 hours, and the percentage of Th9 cells was assessed by means of flow cytometry. Th9 lymphocytes were identified as IFNγ-, IL4-, IL17-, IL9-secreting CD4+ T cells.

Results: Cytometric analysis revealed no significant decrease in the percentage of Th9 cells after IFX exposure in any of the groups, but there were significantly fewer cells in the healthy controls than the RA patients both before and after the IFX stimulation assay (Fig.1). The higher frequency of Th9 cells in the patients was not associated with higher levels of anti-nucleus autoantibodies or other auto-antibody subsets, or with a higher likelihood of experiencing an adverse event or lack of efficacy on IFX treatment.

Conclusion: IL-9 levels are increased in RA patients, in whom it plays a crucial role. Th9 cells are the major producers of IL-9, and their prevalence is higher in RA patients than in healthy subjects, although they do not seem to affect the outcome of biological therapies.

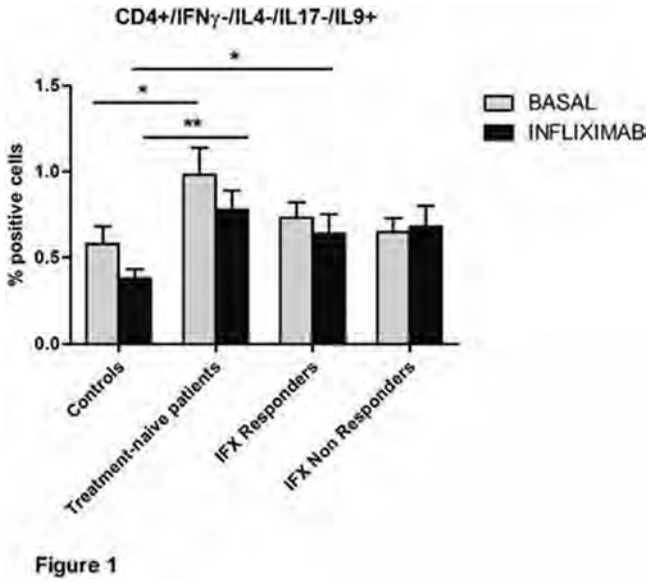

Figure 1

Anti-Rheumatic Therapy Decreases Syndecan-1 Shedding in Rheumatoid Arthritis (RA). Ivana Hollan[1], Gunnbjørg Hjeltnes[2], Torstein Lyberg[3], Stefan Agewall[3], Allan Wiik[4], Knut Mikkelsen[1], Øystein T. Førre[5], Tram T. Vuong[3] and Svein O. Kolset[3]. [1]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [2]Innlandet Hospital Trust, Lillehammer, Norway, [3]University of Oslo, Oslo, Norway, [4]Statens Serum Institute, Copenhagen S, Denmark, [5]Oslo University Hospital, Oslo, Norway.

Background/Purpose: Intact glycocalyx is of importance for healthy endothelial function. Changes in the endothelial glycocalyx, characterized by increased levels of circulating syndecan-1, might be related to accelerated atherosclerosis in RA. The aim of this study was to examine the level of serum (s-) syndecan-1 in patients with RA, and the effect of anti-rheumatic treatment on the s-syndecan-1 levels.

Methods: We selected 32 patients with active RA from the Norwegian observational PSARA study. Due to clinical decision, the patients should start either with methotrexate or methotrexate (MTX) and anti-tumor necrosis factor (TNF) regimen. The patients were examined before the treatment initiation (visit 1) and after 6 weeks (visit 2) of the treatment. S-syndecan-1 was measured by ELISA.

Results: The mean age of the patients was 59±8 years, and 27% were men. 12 patients recieved MTX and 20 recieved MTX and anti-TNF treatment. S-syndecan-1 levels significantly decreased from visit 1 (49 ± 52 ng/ml) to visit 2 (45±50 ng/ml), p=0.047. The difference was independent of age, sex and difference in DAS28. The s-syndecan-1 reduction was greater in the MTX than MTX and anti-TNF group (10 ± 13 vs. 1 ± 1 ng/ml), p=0.048.

Conclusion: Anti-rheumatic treatment reduces s-syndecan-1 in RA. Thus, a glycocalyx ameliorating effect may contribute to the reduction of cardiovascular morbidity and mortality due to anti-rheumatic treatment. In theory, the greater reduction of s-syndecan-1 in the MTX than in the combined group might be due to differences in patient population, as patients starting with MTX are likely to have a less severe RA, with a shorter disease duration, than those starting with anti-TNF. Interestingly, although MTX is considered as a less potent anti-rheumatic drug than anti-TNF, it may have a protective effect on glycocalyx, which may explain its cardioprotective effect observed in previous studies. This effect might be at least partially independent of its anti-inflammatory properties.

Lipid Concentrations and Particle Sizes in Drug Naive Patients with Rheumatoid Arthritis. Aulikki Kononoff[1], Hannu Kautiainen[2], Pasi Soininen[3], Antti Kangas[4], Leena Laasonen[5], Leena Arstila[1], Pia Elfving[1], Elina Savolainen[6], Helena Niinisalo[7], Mika Ala-Korpela[4] and Oili Kaipiainen-Seppanen[1]. [1]Department of Medicine, Kuopio University Hospital, Kuopio, Finland, [2]Unit of Primary Health Care, Kuopio University Hospital, Kuopio, Finland, [3]Computational Medicine, Institute of Health Sciences, University of Oulu, Oulu, Finland, [4]NMR Metabolomics Laboratory, School of Pharmacy, University of Eastern Finland, Kuopio, Finland, [5]Helsinki Medical Imaging Center, Helsinki University Hospital, Helsinki, Finland, [6]Kuopio Municipal Hospital, Kuopio, Finland, [7]Suonenjoki Health Center, Suonenjoki, Finland.

Background/Purpose: Excess mortality attributed to cardiovascular causes has been described among patients with rheumatoid arthritis (RA). Atherosclerotic lipid profile has been reported in patients with drug naïve RA without comorbidities. In a European study on inflammatory and atherogenic lipoprotein markers, patients with RA had significantly higher levels of small, dense LDL and lower levels of large, light LDL than controls. The size of LDL particles was smaller in RA patients compared to controls. We have investigated lipid concentrations and particle sizes among patients with newly diagnosed RA in a population based cohort.

Methods: Concentrations and sizes of lipoprotein subclass particles were analyzed by proton nuclear magnetic resonance spectroscopy of native serum samples from patients with RA participating in Northern Savo 2010 Study.

Results: Sixty-three patients, 34 female and 29 male patients with RA satisfying the ACR/Eular 2010 classification criteria were divided into tertiles according to the disease activity measured by DAS28 (<3.9, 3.9–4.7, >4.7). Small LDL concentrations were lowest in the tertile with the highest disease activity, p= 0.031, and the particle size in LDL also increased with increasing disease activity, p<0.001. In HDL, the total, medium and small particle concentrations showed a linear decrease along with the disease activity, p=0.0012, 0.0079 and <0.001, respectively.

Conclusion: Marked changes in lipid concentrations and particle sizes occurred in drug naïve patients with RA and they were associated with disease activity.

Clinical Utility of 14-3-3η in the Evaluation of Inflammatory Arthritis. Lance Feller[1], Paul Tuttle IV[2] and Terry L. Moore[2]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis University, Saint Louis, MO.

Background/Purpose: 14-3-3 proteins are chaperonins found in all eukaryotic cells. There are multiple isoforms which are thought to be involved in intracellular signaling and transcription regulation. Among their targets are phosphatases, kinases and transmembrane receptors. There are seven known isoforms in mammals. Recent work has implicated the η (Eta) isoform as having diagnostic potential in inflammatory arthritis. In this study we investigated the utility of measuring 14-3-3η when evaluating of inflammatory arthritis.

Methods: Measurements of 14-3-3η were obtained during evaluation of joint pain in patients presenting between July 2013 and May of 2014. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP Ab) were measured. Joint imaging was evaluated for erosive changes. A chart review was later conducted to evaluate the utility of standard measures versus 14-3-3η.

Results: 120 patients were evaluated. 21 had RA, 8 had juvenile idiopathic arthritis (JIA), and 6 had psoriatic arthritis (PsA). 30 patients had connective tissue disease (CTD). 10 had fibromyalgia (FMS), 3 had mono-

clonal gammopathies, 1 had enteropathic arthritis, and 1 had erosive osteoarthritis (OA). 8 had only OA, 2 had benign hypermobility syndrome, 1 had amyopathic dermatomyositis, 2 had celiac disease, and 2 had crystal induced arthropathies. 7 were antinuclear antibody (ANA) positive without synovitis or CTD. 3 patients had granulomatosis with polyangiitis, 2 had suspected PsA, 2 had chronic urticaria, and 11 had no associated condition.

Of the 21 RA patients, 18 were RF positive, 16 were anti-CCP Ab positive, and 16 were 14-3-3η positive. All 16 14-3-3η positive patients with RA were RF positive. 9 had joint erosions, of which 8 were RF, anti-CCP Ab and 14-3-3η positive. 14-3-3η was 76.2% sensitive for RA, and 89% specific. Its positive predictive value (PPV) was 61.5%, and negative predictive value (NPV) was 94.2%. 4 of the 8 JIA patients were 14.3.3η and RF positive. 4 were also anti-CCP Ab positive, of which 2 had measurable 14-3-3η. 3 JIA patients had joint erosions. When JIA and RA were considered together, the sensitivity and specificity of 14-3-3η was 68.9 and 89% respectively, while PPV and NPV were 66.7 and 90%. The correlation of 14-3-3η and RF titers in RA was 0.63 ($p<0.01$) and 0.65 ($p<0.001$) in the combined RA/JIA cohort.

All 6 patients with PsA were seronegative. 2 had joint erosions.

30 patients had CTD; 6 were RF positive, 2 were anti-CCP Ab positive, and 5 were 14-3-3η positive. 3 of the five 14-3-3η positive patients also produced RF, while 1 had anti-CCP Ab.

All FMS patients were seronegative. Of the 8 patients with purely OA, 1 had 14-3-3η. 1 patient with celiac disease had 14-3-3η. 1 patient with a positive ANA and joint pain had 14-3-3η. 1 patient with joint pain and no evidence of synovitis produced 14-3-3η.

Of the 17 patients with RF without RA, 10 were positive for 14-3-3η, while 6 produced anti-CCP Ab.

Conclusion: 14-3-3η protein titers are associated with RA. Their general trend follows RF. Based upon the results from our study, 14-3-3η is both sensitive and specific for RA, with value in evaluating JIA as well. A larger sample size is necessary to evaluate utility with JIA.

Association of Anti-Thyroid Autoantibodies with Fibromyalgia in Rheumatoid Arthritis. Jowairiyya Ahmad[1], Helena Blumen[2], Claudene George[3], Asha Shrestha[1] and Clement Tagoe[4]. [1]Albert Einstein College of Medicine/Montefiore Medical Centre, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine/Montefiore Medical centre, Bronx, NY, [4]Albert Einsetin College of Medicine/Montefiore Medical Centre, Bronx, NY.

Background/Purpose: Autoimmune thyroiditis has been linked independently with fibromyalgia and chronic widespread pain. We studied how the presence of autoimmune thyroiditis affects the clinical presentation of rheumatoid arthritis with particular reference to chronic pain syndromes.

Methods: We studied a cohort of 203 patients with a diagnosis of rheumatoid arthritis for whom the presence or absence of autoimmune thyroid antibodies was documented. The relationships between thyroid autoantibodies and the presence fibromyalgia and chronic widespread pain were examined. Logistic regression analyses were performed to determine the statistical significance of these associations.

Results: In our sample of 203 patients, we identified 34% of patients who tested positive for anti-thyroid peroxidase antibodies (anti-TPO). Thirty five percent of patients tested positive for anti-thyroglobulin antibodies (anti-TG). Among the thyroid autoantibody-positive patients, 37 % had a diagnosis of fibromyalgia or chronic widespread pain. Additional patient variables considered included age, sex, body mass index (BMI) and the presence of comorbidities, including type II diabetes.

Logistic regression analyses (adjusted by age, sex, diabetes and BMI) indicated that anti-TPO positive patients were more likely to be diagnosed with fibromyalgia and report the presence of chronic widespread pain, with an odds ratio of 3.42, 95% *CI* (1.665–7.017), $p < .001$. The odds ratio between anti-TG and fibromyalgia was not significant, $p > .05$. Patients who were either anti-TPO or anti-TG positive were more likely to be diagnosed with fibromyalgia with an odds ratio of 2.70, *CI* (1.193–6.082), $p < .05$.

When adjusted for degenerative disc disease, patients who were either anti-TPO or anti-TG positive were more likely to be diagnosed with fibromyalgia with an odds ratio of 2.508, CI (1.094–5.749), $p < .05$. Similarly patients with anti-TPO were more likely to have fibromyalgia with an adjusted OR of 3.356, CI (1.608–7.003), $p < .05$.

Conclusion: There is a strong positive association between the presence of anti-thyroid autoantibodies and hence autoimmune thyroiditis, with fibromyalgia syndrome and chronic widespread pain in patients with established rheumatoid arthritis.

Can GP88 (Progranulin) be Used As a Biomarker for the Diagnosis and Therapy Evaluation of Rheumatoid Arthritis? Masao Sato[1], Masao Takemura[1], Kuniaki Saito[2] and Yasuko Yamamoto[2]. [1]Matsunami Reserch Park, Gifu, Japan, [2]Kyoto University, Kyoto, Japan.

Background/Purpose: GP88 (progranulin; PGRN), a glycoprotein with a molecular weight of approximately 88000, is suggested to play an important role in the immune response and growth of tumors. Recently, its high affinity for the tumor necrosis factor receptor has been reported and there have been studies on its anti-inflammatory effects in autoimmune diseases. The objectives of the present study were to measure serum PGRN levels in rheumatoid arthritis (RA) patients, to analyze the changes of PGRN levels in RA patients treated with biological products, and to analyze whether PGRN is useful as a biomarker for the diagnosis and therapy evaluation of RA.

Methods: Serum PGRN levels were measured using ELISA in 149 healthy subjects (78 men and 71 women) who underwent health checkups (controls) and in 68 RA patients and 24 knee osteoarthritis (OA) patients before the start of treatment, who met the 2010 ACR/EULAR classification criteria and visited the arthritis outpatient clinic. Among RA patients who were non-responsive to methotrexate (MTX), the cryopreserved serum samples of 11 patients who were administered infliximab (IFX) were analyzed to determine the PGRN levels during the course of treatment (at baseline, week 6, week 14, week 22, and week 48).

Results: PGRN levels in the controls were 40.5 $\pm$ 14.3 ng/mL in men (mean age, 54.2 years; range, 25–68) and 41.0 $\pm$ 10.9 ng/mL in women (mean age, 51.0 years; range, 28–69), and there were no sex and age differences. PGRN levels were significantly higher in RA patients (51.2 $\pm$ 12.5 ng/mL) than in OA patients (43.9 $\pm$ 5.8 ng/mL) ($p<0.01$) and controls ($p<0.001$). Among the RA patients, 10 women and 1 man (mean age, 62.0 years; range, 27.0–78.0) received IFX treatment. MTX was administered orally at 6–8 mg/week, and IFX was administered at 3 mg/kg. Mean PGRN levels at the different time points were as follows: baseline, 45.0 ng/mL; week 6, 46.4 ng/mL; week 14, 50.8 ng/mL; week 22, 48.9 ng/mL; and week 48, 50.4 ng/mL, and there were no significant changes. Because disease activity was high at week 48 and IFX was considered ineffective, 2 cases received a different biological product. Mean PGRN levels in these 2 cases were as follows: baseline, 60.1 ng/mL; week 6, 61.3 ng/mL; week 14, 68.3 ng/mL; week 22, 74.9 ng/mL; and week 48, 79.5 ng/mL, showing an increasing tendency with the treatment course.

Conclusion: Serum PGRN levels were found to be significantly higher in RA patients than in OA patients and controls. Further, no changes in the PGRN levels were found in the group that showed a good response to IFX treatment. However, in cases resistant to IFX, PGRN levels were high when IFX was introduced, followed by an increasing tendency with the treatment course. Owing to the small number of cases in the present study, it is difficult to obtain a clear result. However, the findings showed the possibility of using PGRN levels for the differential diagnosis of RA patients and the therapy evaluation of IFX.

Metaflammation, PEDF and Chemerin: Potential Systemic Factors Which Link Obesity to Response to Therapy in Early Rheumatoid Arthritis. Elisa Gremese, Barbara Tolusso, Anna Laura Fedele, Maria Rita Gigante, Silvia Canestri, Clara Di Mario, Angela Carbonella and Gianfranco Ferraccioli. Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy.

Background/Purpose. Obesity per se is a systemic, low-grade inflammatory state and the adipose tissue is an endocrine organ that releases bioactive substances, including pro-inflammatory cytokines, like TNFα and IL6 and specific adipokines. There are only few data about early RA (ERA), suggesting that obesity associates with disease outcomes. In this work we aimed to evaluate whether the body weight, and fat metabolic (PEDF-Pigment Epithelium-Derived Factor) and

meta-inflammatory parameters (Chemerin), could be associated with the outcomes in terms of disease remission and treatment in ERA patients (symptoms duration <12 months).

Methods. 164 ERA patients, treated according to a treat-to-target strategy, were enrolled. At each visit the ACR/EULAR core data set was registered. Baseline BMI was collected and baseline interleukin-6, PEDF and Chemerin plasma levels were evaluated by ELISA's methods.

Results. Of the 164 ERA patients (75.9% female, age 55.4±14.6 years, 34.3% very ERA, 66.9% seropositive, baseline DAS 3.4±1.0), 75 (45.7%) were normal weight, 66 (40.2%) overweight and 23 (14.0%) obese. Overweight and obese patients showed a higher disease activity at baseline compared to normal-weight patients (DAS: 3.6±1.0 vs 3.3±0.9, p=0.02). At baseline, BMI values correlated with baseline PEDF (r=0.33, p<0.001) and chemerin (r=0.31, p<0.001) plasma levels. Moreover, chemerin plasma levels correlated with age (r=0.31, p<0.001), baseline inflammatory markers (IL-6: r=0.28, p<0.001; ESR: r=0.39, p<0.001, CRP: r=0.35, p<0.001), swollen joint count (r=0.26, p<0.001), tender joint count (r=0.23, p<0.001), HAQ (r=0.24, p=0.002), DAS (r=0.34, p<0.001), CDAI (r=0.28, p<0.001) and SDAI (r=0.32, p<0.001). On the other hand, PEDF plasma levels correlated only with age (r=0.35, p<0.001) and baseline inflammatory markers (ESR: r=0.17, p=0.03, CRP: r=0.22, p=0.01). At 6 and 12 months none of the patients had a significant reduction of body-weight. A significant reduction of the disease activity at 6 and 12 months follow-up was observed in the three subgroup of ERA patients (normal-weight, overweight and obese patients). In the same manner, circulating chemerin levels significantly decreased over time; conversely, the circulating levels of PEDF remained unchanged. These findings were observed both in patients reaching and not reaching remission at 12 months of follow up.

Fourteen obese RA patients (BMI 35.3±3.2) with an active disease (DAS 3.5±0.7) underwent a dietary regimen for weight loss for six months, with no change in RA treatment. At the sixth month, the mean reduction in percentage of BMI was 8.9±5.3% and the average percentage of DAS reduction was 46.8±20.2% (DAS T6: 1.8±0.6, p=0.01 with respect to DAS T0).

Conclusion. In ERA patients, PEDF and chemerin seem to be biomarkers of obesity and metaflammation, respectively. Chemerin seems to be linked to RA disease activity and to treatment response, irrespective of body weight category, supporting its dual role in inflammation and metabolism and providing a link between chronic inflammation and obesity.

The Relationship Between Disease Activity and Levels of HMGB1 in Patients with Rheumatoid Arthritis. David S. Pisetsky[1], Diane Spencer[2], Stephen R. Wisniewski[3], Jason Lyons[3], Melissa Saul[4], Mandy J. McGeachy[5], Yong Gil Hwang[6], Heather Eng[3] and Larry W. Moreland[6]. [1]Durham VAMC, Durham, NC, [2]Duke University Medical Center, Durham, NC, [3]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [4]University of Pittsburgh, School of Medicine, Pittsburgh, PA, [5]Univeristy of Pittsburgh, Pittsburgh, PA, [6]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: HMGB1 (High Mobility Group Box 1), a non-histone nuclear protein, is a prototypic alarmin that displays immunological activity following release during cell death or immune cell activation. As shown in studies of patients with rheumatoid arthritis (RA) and animal models, HMGB1 plays a key role in pathogenesis; HMGB1 has increased expression in synovial tissue and blockade of HMGB1 can attenuate disease in animal models. While the role of HMGB1 in mediating disease has been well studied, its role as a biomarker has received less attention. The present study therefore explored the expression of HMGB1 in the blood of RA patients, investigating correlations with various clinical features.

Methods: This study utilized samples from the RACER (Rheumatoid Arthritis Comparative Effectiveness Research) cohort. Patients varied in disease duration and received therapy determined by clinical response. Disease activity was assessed by DAS 28 scores using C-reactive protein as the acute phase reactant. The samples, selected to provide a range of disease activity, were divided into 4 groups: remission; low activity; moderate activity; and high activity. Levels of HMGB1 were determined by ELISA using the Shino-test kit. The concentrations of HMGB1 in the plasma from 10, non-RA control subjects were also measured.

Results: Among 100 patients with RA, HMGB1 levels varied from 1.1 to 19.3 ng/ml (median value = 5.73 ng/ml) which was significantly higher than those of the control population (range = 0.72–3.28; median value = 1.93 ng/ml). Despite the increase in HMGB1 levels in the RA population, the median values of the 4 disease activity groups were similar (remission, 5.98; low 5.09; moderate 5.64; high, 6.02). These differences did not reach statistical significance by a non-parametric ANOVA. In contrast, CRP levels showed a statistically significant association with disease activity by a non-parametric ANOVA (<0.0001). As a previous study suggested a relationship with disease duration, the results were analyzed in terms of duration less than 5 years, 5–10 years, 15–20 years and greater than 20 years. This analysis failed to reveal a relationship with disease duration. Values of males and females were also similar.

Conclusion: These studies demonstrate that levels of HMGB1 are elevated in the blood of patients with RA and show a relationship to disease activity distinct from that of CRP. As HMGB1 levels were increased in patients either in remission or with low disease activity, these findings suggest ongoing inflammation that may not be apparent with either the DAS 28 or CRP. Furthermore, since HMGB1 can also arise from cell death, the elevation of HMGB1 levels, even with remission or low disease activity, may reflect tissue destruction that persists even with inflammation restrained.

14-3-3η: A Mechanistic Biomarker That Supports the Concept of "Uncoupling" of Inflammation and Joint Damage. Dirkjan van Schaardenburg[1], Mairead Murphy[2], Yuan Gui[2], Samina Turk[1], WP Maksymowych[3], Kelly Young[4] and Anthony Marotta[2]. [1]Reade, Amsterdam, Netherlands, [2]Augurex Life Sciences Corp., North Vancouver, BC, [3]University of Alberta, Edmonton, AB, [4]Rheumatoid Patient Foundation, Cocoa, FL.

Background/Purpose: In RA, irreversible joint damage often begins within the first year of symptom onset. A compelling and growing body of data describing the "uncoupling" of inflammation and joint destruction indicates that radiographic monitoring is important in all RA patients, regardless of clinical response. C-reactive protein (CRP) is an acute phase reactant that is routinely used alongside clinical assessment to evaluate response to treatment in RA although ~30–40% of patients have normal levels. 14-3-3η is a modifiable serum/plasma mechanistic biomarker that is a potent regulator of MMP expression and its positive status in early RA predicts radiographic progression. This study examines 14-3-3η's relationship with CRP in an early RA cohort and whether its baseline expression in CRP-normal patients relates to radiographic outcome at year 1.

Methods: Baseline serum 14-3-3η protein titres were measured in a cohort of 409 early RA patients from the Reade Institute; all patients were treatment naive at baseline. Median patient age was 56 years and 73% were female. Patient plasma was tested on the 14-3-3η ELISA (cut-off ≥0.19 ng/ml) and differences in joint damage progression over three years along 14-3-3η positive/negative status groups was evaluated within the whole cohort and between CRP-normal (≤10 mg/L) and elevated groups. Statistical analyses were performed (GraphPad Prism 5.0) using Spearman correlations to compare relationships between variables and the Mann-Whitney u-test to assess median differences between groups.

Results: 67% of patients were positive for the 14-3-3η protein and 60% of patients had elevated CRP (> 10mg/L). The Spearman correlation of baseline CRP and 14-3-3η titres showed no relationship between the two variables (r= 0.06). Baseline CRP titres correlated with TSS at year 1 (r=0.17, p=0.0007) as well as the change in TSS from baseline to year 1 (r=0.17, p=0.0005) but not with baseline TSS. Patients who were 14-3-3η protein positive had more radiographic progression than 14-3-3η negative patients over years 1, 2 and 3; p-values = 0.006, 0.008 and 0.009, respectively (Table). In patients with normal CRP (≤10 mg/L), 14-3-3η positive patients (n=105) had a higher mean (SD) radiographic progression at year 1 of 1.4 (3.4) versus the 14-3-3η negative group (n=55), 0.7 (2.3), p<0.05.

Median (min-max)	14-3-3η Negative[n]	14-3-3η Positive[n]	p-value
SHS Y1	0(0–3)[131]	1(0–5)[273]	0.02
SHS Y2	1(0–5)[133]	2(0–8)[271]	0.02
SHS Y3	1.5(0–6)[128]	3(0–10)[264]	0.01
Δ SHS Y1	0(0–1)[131]	0(0–2)[274]	0.006
Δ SHS Y2	0(0–2.5)[133]	1(0–6)[271]	0.008
Δ SHS Y3	0(0–4)[127]	2(0–7)[264]	0.009

Conclusion: 14-3-3η is a mechanistic joint damage marker that does not correlate with the acute phase reactant CRP in early RA. These two markers provide unique information to assist in the clinical management of RA patients informing the uncoupling of inflammation and joint damage.

The Utility of HLA-DR Genotypification As a Complementary Tool to Discriminate Undifferentiated and Rheumatoid Arthritis Patients in Early Arthritis. Fernando Dal Pra[1], Gustavo Citera[2], Margarita Landi[3], Christian A. Waimann[4], Luis Alejandro Cayetti[2], Sergio Paira[5], Federico Ceccatto[6], Teresita Alvarellos[7], Luciana Mas[7], Josefina Marcos[8], Mercedes García[8], A Salas[8], Alejandro Martinez[9], Rafael Chaparro[10], Oscar Luis Rillo[9], Edson Veloso[11], Ricardo V. Juárez[12], Maria Elena Crespo[13], Antonio Catalán Pellet[14], Anastasia Secco[14], Lucila Marino[14] and V Martire[14]. [1]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]Instituto Rehabilitacion Psicofisica, Buenos Aires, Argentina, [4]Hospital Olavarria, Olavarria, Argentina, [5]Hospital Jose Maria Cullen, Santa Fe, Argentina, [6]Hospital Jose María Cullen, Santa Fé, Argentina, [7]Hospital Privado Centro Medico De Córdoba, Cordoba, Argentina, [8]HIGA San Martín, La Plata, Argentina, [9]Hospital General de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [10]Hospital Gral. de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [11]Sanatorio y Universidad Adventista Del Plata, Entre Rios, Argentina, [12]Hospital Señor del Milagro, Salta, Argentina, [13]Hospital Señor Del Milagro, Salta, Argentina, [14]Hospital Bernardino Rivadavia, Buenos Aires, Argentina.

Background/Purpose: Only half of patients with undifferentiated arthritis (UA) will progress to rheumatoid arthritis (RA) after two years of follow-up. Particular human leukocyte antigens class II-DR (HLA-DR) alleles have been associated with a higher risk to develop RA, however these alleles may vary among ethnic groups. The aim of our study was to investigate the frequency of HLA-DR alleles and evaluate the association with the development of rheumatoid arthritis in an early arthritis cohort in Latin America.

Methods: We designed a case-control study. Cases were defined as patients with diagnosis of RA from an early arthritis cohort (<2 years of disease duration). Two control groups were selected. First group was obtained from the mentioned cohort and included patients with UA. The second control group was obtained from the national register of cadaveric organ donors (Healthy Subjects, HS). HLA-DR genotypes frequencies were estimated for each group. We calculated the odds ratio (OR) to develop RA in general population and undifferentiated arthritis. Statistical analysis was performed with two-tailed Pearson's chi-squared test with Bonferroni adjustment (p-value after Bonferrroni adjustment, Pc). A stepwise logistic regression model using RA vs UA diagnosis as dependent variable was performed to identify the association of HLA-DR alleles and RA development in patients with UA, adjusted by smoking, gender and presence of rheumatoid factor (variable significance entry criteria $P < 0.15$). A p-value less than 0.05 was considered statistically significant.

Results: We included a total of 1859 subjects: AR=347; UA=52; Cs=1460. When comparing with HS, RA patients had an increased frequency of DR4 [RA=50% vs HS=31%, OR 2.3 (1.7 – 2.8), Pc<0.0001], DR9 [RA=12% vs HS=7%, OR 1.9 (1.3 – 2.8), Pc=0.02], and lower frequency of DR7 [RA=13% vs 21%, OR 0.6 (0.4 – 0.8), Pc=0.02], DR11 [RA=10% vs 21%, OR 0.4 (0.3 – 0.6), Pc<0.0001], DR15 [RA=9% vs 15%, OR 0.5 (0.4 – 0.8), Pc=0.04]. Among patients with early arthritis, being heterozygote or homozygote for DR-4 allele could not differentiate between patients with RA and UA. On the other hand, patients with UA showed higher frequency of DR7, DR11 and DR15 than RA (23%, 21%, 17% vs 13%, 11% 9%, respectively), but did not reach statistical significance after adjustment for multiple comparisons. Stepwise regression indicated that the presence of DR15 was significantly associated with lower risk of RA [OR=0.35 (0.12–0.97, p=0.04].

Conclusion: In our cohort of patients with early arthritis, the genotypification of HLA-DR alleles was not useful to discriminate between RA and UA. Only the presence of DR15 allele was associated with a lower probability of RA, however the poor precision of the estimates makes it difficult to address the utility of this determination in daily clinical practice.

Serum 14-3-3η Protein Supplements Traditional Rheumatoid Arthritis Biomarkers. Olga Zhukov[1], Jonnielyn Rivera[1], Charles M. Rowland[2], Joanna M. Popov[1] and Stanley J. Naides[3]. [1]Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, [2]Celera, Alameda, CA, [3]Quest Diagnostics Nichols Institute, San Juan Capistrano, Albania.

Background/Purpose: The 14-3-3 family of chaperonin proteins consists of 7 isomers. The tissue distribution of the 14-3-3η (eta) isoform is limited to synovial tissue and brain. 14-3-3η is released from synovial tissue into the synovial fluid and serum in patients with rheumatoid arthritis (RA) and, to a lesser extent, erosive psoriatic arthritis (ePsA). Extracellular 14-3-3η induces signaling pathways that lead to production of proinflammatory mediators including metal η loproteinases, RANKL, IL1, TNFα, and additional 14-3-3η, thereby exacerbating disease. Serum 14-3-3η measurement has been shown to aid diagnosis and prognosis of rheumatoid arthritis, and may have utility in assessing disease activity. The purpose of this study was to investigate the potential value of adding 14-3-3η to traditional biomarkers of rheumatoid factor (RF) and citrullinated cyclic peptide antibody (CCP).

Methods: Consecutive serum samples (n=1944) referred to an esoteric diagnostic laboratory for a "Rheumatoid Arthritis Diagnostic Panel" were tested for RF by nephelometry, CCP by immunoassay (INOVA QUANTA Lite™ CCP3.0 IgG ELISA), and 14-3-3η by a proprietary laboratory-developed test (ELISA).

Results: Of 1944 sera tested, 248 (12.8%; 95% CI 11.3%–14.3%,) were positive for 14-3-3η. 1483 of the 1944 samples (76.3%; 95% CI 74.3%–78.1%) were negative for both RF and CCP. Of these seronegative samples, 91 (6.1%; 95% CI 5.0%–7.5%) were positive for 14-3-3η. 14-3-3η was also in positive in 46 of 245 RF+/CCP- samples (18.8%; 95% CI 14.4%–24.1%); 107 of 161 RF+/CCP+ samples (66.5%, 95% CI 58.9%–73.3%); and only 4 of 55 RF-/CCP+ samples (7.3%, 95% CI 2.9%–17.3%).

Conclusion: Serum 14-3-3η was positive in 12.8% of individuals tested for RA biomarkers. The population likely includes individuals without RA, with seropositivity for RF and/or CCP but no joint disease, or with other rheumatic diseases; these factors may account for the lower rate of 14-3-3η positivity relative to that reported in clinically defined early RA. Further, 14-3-3η was positive in 18.8% of RF+/CCP- samples, suggesting that this marker may be useful in further demonstrating joint specificity of an isolated positive RF result. Adding 14-3-3η testing to RF and CCP increases detection of individuals warranting further evaluation for RA and possibly ePsA, and may assist primary care physicians in triaging referrals to rheumatologists. Subsequent studies with detailed clinical correlation are warranted.

14-3-3η Auto-Antibody Positivity Informs Better Clinical Outcomes in RA. D. van Schaardenburg[1], Mairead Murphy[2], Samina Turk[3], Walter P Maksymowych[4] and Anthony Marotta[2]. [1]Jan van Breemen Research Institute, Amsterdam, Netherlands, [2]Augurex Life Sciences Corp., North Vancouver, BC, [3]Reade, Amsterdam, Netherlands, [4]University of Alberta, Edmonton, AB.

Background/Purpose: We have previously reported pilot data that patients who are only positive for 14-3-3η auto-antibodies (AAb) and negative for the 14-3-3η protein have a lower radiographic trajectory over 3 years. 14-3-3η AAbs have been described as "protective" based on their currently understood mechanism of clearing "harmful" extracellular 14-3-3η protein. In this study, we investigated how 14-3-3η AAb plasma expression informs clinical variables at baseline and over 3 years in a substantial cohort of patients with early RA.

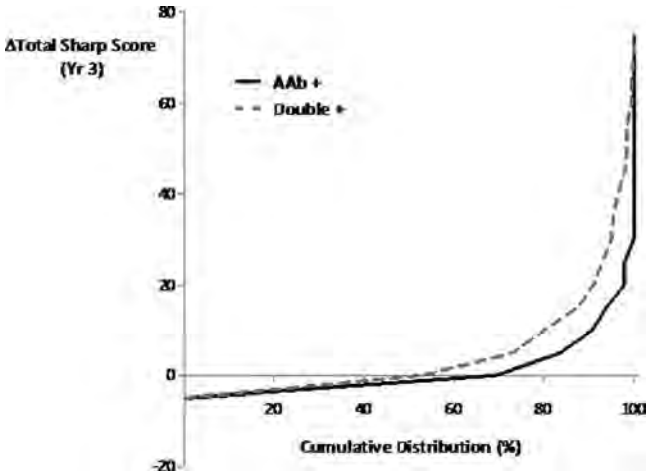
Methods: Baseline serum 14-3-3η protein and AAb levels were measured in a cohort of 409 early RA patients; all patients were treatment naive

at baseline. Median patient age was 56 years and 73% were female. 14-3-3η protein levels were tested using the Augurex 14-3-3η ELISA (cut-off ≥0.19 ng/ml) and 67% of patients were positive. 14-3-3η AAb levels were measured on the MSD ECL platform and using a diagnostic cut-off of 380 U/ml, 77% of patients were +ve. Patients were grouped into 4 groups: 1) Negative for both markers, 2) Positive for the 14-3-3η protein only, 3) Positive for the 14-3-3η AAb only and 4) Positive for both markers. Assessment of differences across these 4 groups was performed using Kruskal-Wallis Analysis of Variance (ANOVA) with Dunn's post-hoc testing to identify differences between individual groups.

Results: Across the four 14-3-3η biomarker expression groups (table), ANOVA revealed significant differences in RF and CCP positive rates and titers ($p<0.0001$), baseline TSS, SJC28 and ESR (≤0.01). Patients who were only 14-3-3η auto-antibody positive had significantly lower positivity rates and titers of RF and CCP ($p<0.0001$).

	ANOVA (4 groups)	Double −	Protein +	AAb +	Double +	P-value
Baseline						
RF +	< 0.0001	14%	81%	34%	79%	< 0.0001
CCP +	< 0.0001	41%	79%	35%	87%	< 0.0001
SJC28	0.0007	7	7	9	7	0.0002
ESR	0.02	18	27	31	32	NS

Over the 3 years, 14-3-3η auto-antibody +ve patients had significantly lower radiographic progression compared to patients who were double positive ($p=0.004$). 14-3-3η auto-antibody +ve patients also had significantly greater changes in response to treatment in SJC28 ($p=0.0004$) and DAS28 (0.006) compared to the double positive patient group.



Conclusion: At baseline, the combination of a positive 14-3-3η auto-antibody test and a negative 14-3-3η protein test is significantly associated with a less severe RA disease profile and a better prognosis in regards to radiographic progression, SJC and DAS outcomes at 3 years. This data supports a protective role for 14-3-3η auto-antibodies.

Soluble CD163 Is a Marker of Disease Activity in Early Rheumatoid Arthritis and Reflects TNFα Levels. Stinne Greisen[1], Holger Jon Møller[2], Kristian Steengaard-Petersen[2], Merete Lund Hetland[3], Kim Hoerslev-Petersen[4], Peter Junker[5], Mikkel Ostergaard[6], Malene Hvid[7] and Bent Deleuran[7]. [1]Aarhus University, Aarhus C, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark, [3]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup University Hospital, Glostrup, Denmark, Glostrup, Denmark, [4]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark, [5]Odense University Hospital, Odense, Denmark, [6]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [7]Aarhus University, Aarhus, Denmark.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by joint inflammation and eventually destruction, where TNFa is a central mediator of both processes. Soluble CD163 is a plasma marker of macrophage activation. CD163 is a scavenger receptor specifically expressed by macrophages and responsible for binding hemoglobin-haptoglobin complexes. The soluble form is cleaved from the cell surface by TACE/ADAM17, the metalloproteinase also responsible for the cleavage of TNFa, suggesting a close association between sCD163 and TNFa. In RA, sCD163 has been suggested as a marker of disease activity and progression [1]. We aimed to investigate plasma sCD163 in very early RA (eRA) patients.

Methods: Soluble CD163 was measured by ELISA in plasma samples from 154 eRA patients belonging to the OPERA cohort[2]. Age 53.5 years (51–56), 70% females, average disease duration: 3 months. Patients were randomized to conventional methotrexate and placebo (MTX+PLA) or MTX and adalimummab (MTX+ADA) treatment. Clinical disease was assessed by: Disease activity index (DAS28), health assessment questionnaire (HAQ), CRP, swollen joints (SJC40), tender joints (TJC40), simple disease activity index (SDAI), clinical disease activity index (CDAI), visual analogue scale (VAS) for pain, total sharp score (TSS), IgM-RF and ACPA. Statistical analysis was performed by student's t-test, Spearman's Rank correlation and linear regression.

Results: Plasma concentration of sCD163 at baseline was 2.40 mg/l (CI: 2.21 mg/l-2.56 mg/l)) corresponding to the upper part of the HV reference interval (0.69mg/l - 3.86mg/l). After three months of treatment sCD163 had decreased significantly in both treatment groups (to 1.81 mg/l (1.68mg/l – 1.95 mg/l), $p<0.001$). Though the decrease in the MTX+ADA group was more prominent than in the MTX+PLA group. Withdrawal of ADA after 12 months of treatment was followed by incremental sCD163 levels during the subsequent 12 months (1.73mg/l (1.55mg/l -1.94mg/l to 2.07mg/l (1.88mg/l – 2.28mg/l ($p<0.001$)). At baseline sCD163 correlated with CRP and all investigated markers of disease activity (ρ = 0.16–0.28, $p<0.05$). We observed no correlation with TSS, IgM-RF and ACPA. The correlation between sCD163 and CRP at baseline could be fitted to a linear regression model ($\beta=8.28$, $p<0.001$). In the MTX+PLA group, this linear regression was also observed after 6 months and 1 year of treatment ($\beta=7.5$ and 9.9, respectively, both $p<0.001$). In the MTX+ADA group the close association was only observed after 3 months of treatment ($\beta=10.9$, $p<0.007$).

Conclusion: Soluble CD163 correlated with markers of disease activity in eRA. The correlation with CRP was very close and followed a linear regression model. Our results also indicate that sCD163 is associated with TNFa, as withdrawal of anti-TNF treatment was clearly reflected in increased sCD163 levels and correlation with CRP is diminished in the MTX+ADA treatment group. Plasma sCD163 thus reflects anti-TNF treatment and is a potential new disease activity marker in eRA.

Vascular Endothelial Function Changes during Treatment in Patients with Rheumatoid Arthritis. Johana Zacariaz[1], Eliana Lancioni[1], Tomas Cazenave[2], Florencia Marengo[2], Emilce Edith Schneeberger[2], Lucas Aparicio[3], Margarita Morales[3], Jorge Norscini[4], Gabriel Waisman[3], Javier Rosa[5], Gustavo Citera[2] and Enrique R. Soriano[6]. [1]Rheumatology Unit, Internal Medicine Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]Hypertension Section, Internal Medicine Department, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Neurology Department, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [5]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [6]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Rheumatoid Artrhitis (RA) patients have an increased risk for accelerated atherosclerosis. Endothelial dysfunction and arterial stiffness, assessed by measurement of carotid-femoral pulse wave velocity (PWV) and common carotid artery intima-medial thickness (CCA-IMT), respectively, are proven surrogate markers of premature and potentially reversible atherosclerosis. Disease modifying anti-rheumatic drugs (DMARDs), and particularly biologic treatments, because of their higher capacity for controlling inflammation, might improve these surrogate markers of atherosclerosis. To assess the short-term effect (1 year) of treatment with conventional synthetic DMARDs, TNF-inhibitors, or Abatacept, on endothelial function and arterial stiffness in RA patients.

Methods: Consecutive patients meeting 1987 ACR classification criteria for RA in whom their treating Rheumatologist prescribed a new DMARD or a change in DMARD (including biologics), were included. Patients with history of cardiovascular disease were excluded from the study. Common carotid artery (CCA) intima-medial thickness (IMT) and carotid plaques (CP) were measured in the right common carotid artery using high-resolution B mode ultrasound with a 10 MHz linear transducer. Carotid-femoral pulse wave velocity (PWV) was measured using a hand-held tonometry probe. Clinical evaluation included assessment of disease activity using the Disease Activity Score including 28 joint count (DAS28), the Argentinean validated HAQ-DI, blood pressure measurement, and 10-year risk for coronary events using the Framingham 2010 risk equation. All measurements were performed at baseline, and after one year of treatment. In patients switching or stopping treatment, measurements were completed within one month of treatment stop/change.

Results: Thirty-four patients were included. Baseline characteristics and follow up outcomes, according to treatment at the initiation of the study are shown in the table. After a mean follow up of 12.1 (SD: 2,2) months there was a significant reduction in DAS28 in all three treatment groups, [mean 4.7 (SD:1.3) vs 4 (SD: 1.2); p=0.0425], while there was no difference in HAQ [1.2 (SD:0.8) vs 1.1 (SD:0.7); p=0.3244], in any of them. All patients had normal baseline PWV, and there were no significant changes after one year in any of the treatment groups. In a similar way, there were no differences between baseline and follow up mean CCA-IMT. No patient developed new carotid plaques.

Conclusion: After one year of treatment, there were no significant changes in surrogate markers of atherosclerosis in long standing RA patients, with low basal cardiovascular risk. Parameters of endothelial dysfunction and arterial stiffness remained within normal values after one year of follow up.

ABCB1 and ABCG2 Drug-Efflux Transporters Function and Its Association with Disease Activity in a Cohort of Patients with Rheumatoid Arthritis. Yemil Atisha-Fregoso[1], Hilda Fragoso-Loyo[2], Juan Jakez-Ocampo[3], Guadualupe Lima[4], Miguel Baños[2], Virginia Pascual-Ramos[1], Irazu Contreras-Yañez[2] and Luis Llorente[5]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México, Mexico, [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico, [5]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico.

Background/Purpose: ABCB1 (P-gp) and ABCG2 (BCRP) are part of the adenine triphosphate (ATP)-binding cassette (ABC) transporter proteins. These proteins mediate efflux of drugs from inside the cells and can confer a multidrug resistance phenotype. Since among its substrates are included drugs that are part of the treatment in Rheumatoid Arthritis (RA) such as prednisone and chloroquine (for ABCB1) and methotrexate and sulfasalazine (for ABCG2), these transporters might contribute to the resistance to treatment observed in some patients.

The objective of this study was to determine the activity of these transporters in patients with active and inactive rheumatoid arthritis.

Methods: We included patients with Rheumatoid Arthritis (2010 ACR/EULAR criteria) from the early rheumatoid arthritis cohort of our Institute. ABCB1 (P-gp) and ABCG2 (BCRP) functional activity was measured in peripheral mononuclear cells by flow cytometry. The percentage of cells able to extrude substrates for ABCB1 (daunorubicin) and ABCG2 (mitoxantrone) were recorded. The specificity of the assay was confirmed with specific inhibitors (verapamil for ABCB1 and KO143 for ABCG2). Thirty healthy controls were also evaluated to established normal values. The study was approved by our local ethics committee. For the statistical analysis continuous variables were compared with Student t or Mann-Whitney U tests and categorical variables with chi square or Fisher exact test as appropriate.

Results: Thirty seven patients (all women) had been included. The mean age was 38.3 ± 12.3 years and a disease duration of 5 ± 3.3 years. Twenty patients had inactive and 17 active disease according to DAS28 (1.2 ± 1.5 vs 4.1 ± 1; p<0.001). There were no differences in age, disease duration or use of prednisone (76.5 vs 80%), methotrexate (94.1 vs 95%), antimalarials (41.2 vs 40%) or sulfasalazine (35.3 vs 25%) among active and inactive patients (respectively, all with p >0.05).

The median percentage value of cells able to extrude daunorubicin in active patients was 4.4% (IQR 0.7–19.7%) vs 0.9 (IQR 0.5–3.4) in inactive patients, while the median percentage of cells that extruded mitoxantrone in active patients was 1.7% (IQR 0.4–11.4%) vs 0.7% (IQR 0.4–1.8) in the inactive patients. These differences were no statistically significant.

Only 2 of 20 (10%) inactive patients were positive for ABCG2 and 8 of 17 (47%) active patients were positive (p=0.023) while for ABCB1 9/17 (53%) of active patients were positive and 6/20 (30%) of inactive patients were positive (p=0.157).

Conclusion: Patients with active RA have a higher percentage of positivity for the ABCG2 transporter compared with those in remission independently of treatment and disease duration. Follow up of these patients is currently ongoing to determine if the functional activity of these efflux pumps entails a higher risk of persistent activity or risk of RA reactivation.

Determinants of Radiological Progression in Rheumatoid Arthritis: Relationship with Serum Levels of OPG, RANKL and DKK-1. Carmen Gómez-Vaquero[1], Irene Martín-Esteve[1], Jose Ivorra[2], Jose Antonio Narvaez[1], Javier Hernandez Gañan[1], Pedro Alia[1] and Javier Narváez[3]. [1]Hospital Universitari de Bellvitge - IDIBELL, Barcelona, Spain, [2]Department of Rheumatology, Hospital Universitario y Politécnico La Fe., Valencia, Spain, [3]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Osteoprotegerin (OPG), RANKL, and DKK-1 act as regulators of bone resorption and formation. The uncoupling of bone remodelling that occurs in rheumatoid arthritis (RA) originates generalized bone loss and joint erosions.

Our aims are: 1) In patients with RA, to determine the serum levels of OPG, RANKL and DKK-1 and its relationship with radiological progression in hands. 2) To assess their relations with the activity and disability parameters of RA.

Methods: From a previous study in which we had radiographs of hands and frozen sera from all patients (T0), we selected the ones controlled since the diagnosis of the disease in an Early Arthritis Clinic of a university hospital through a strategy of tight control. They came back to make radiographs of hands and collection of sera (T1). Study variables were: 1) Demographics: age, sex, body mass index (BMI); 2) RA history: duration, RF, anti-CCP antibodies; 3) Disease activity: mean DAS28 and CRP between T0 and T1; 4) Disability: mean HAQ; 5) RA treatment; 6) Serum levels of OPG, RANKL and DKK-1; and 7) Sharp-van der Heijde Index (SHI) of hands, analyzing together and separately erosions (SHI-Ero) and joint space (SHI-Spa).

Results: Ninety-seven patients (60 women) were included with a mean age of 53 ± 14 years and a mean BMI of 25.9 ± 4.9 kg/m2. At T0, mean RA duration was 1.6 ± 1.5 years. Sixty-one percent of the patients had RF + and 62%, anti-CCP antibodies +. Mean DAS28 was 2.61 ± 0.96; CRP, 5.9 ± 7.1 mg/L; and HAQ, 0.330 ± 0.331. Seventy-six percent of the patients had low activity (DAS28 < 3.2) and 23%, moderate activity (DAS28 ≥ 3.2 and <

5.1); only one patient presented high activity (DAS28: 5.21). Mean time between T0 and T1 was 3.3 ± 1.5 years.

	SHI	SHI-Ero	SHI-Spa	OPG pmol/L	RANKL* pmol/L	OPG/RANKL*	DKK-1 pmol/L
T0	5.2 ± 7.1	0.8 ± 2.3	4.5 ± 5.9	3.9 ± 1.8	0.3 ± 0.3	53.5 ± 55.1	29.9 ± 11.0
T1	7.8 ± 10.9	1.4 ± 3.7	6.3 ± 8.1	4.1 ± 2.2	0.4 ± 0.4	29.7 ± 39.4	26.4 ± 18.9

* RANKL levels were below the limit of detection in 82 (T0) and 72 (T1) patients.

Mean annual progression of SHI was 0.9 ± 2.2; SHI-Ero, 0.2 ± 0.6, and SHI-Spa, 0.7 ± 1.7. The annual progression of SHI, SHI-Ero and SHI-Spa correlated with CRP levels ($p < 0.01$) and with the titer of anti-CCP antibodies; SHI-Spa progression correlated also with age ($p < 0.05$). We found no relation between SHI and OPG, RANKL or DKK-1.

Patients whose ISH worsened (48%) were older and had higher BMI and RA activity than patients in which ISH didn't worsen (52%).

Conclusion: The progression of radiological damage in a series of RA patients controlled in an Early Arthritis Clinic is dependent on the activity of the disease and the titer of anti-CCP antibodies. Serum levels of OPG, RANKL and DKK-1 do not seem useful to predict progression of radiographic damage.

Association of Antinuclear Antibodies with Lung Disease, Malignancy and Joint Replacement in Rheumatoid Arthritis. Reshmi Raveendran[1], Bobby Kwanghoon Han[2], Quan-Zhen Li[3] and Nancy J. Olsen[1]. [1]Penn State MS Hershey Medical Center, Hershey, PA, [2]Cooper Medical School of Rowan University, Camden, NJ, [3]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: Antinuclear antibodies (ANAs) are present in a significant proportion of patients with rheumatoid arthritis (RA). Positivity for ANA in RA has been associated with use of TNF inhibitor therapies and with the presence of overlapping disorders such as Sjogren's syndrome. We hypothesized that ANA positivity might be associated with other clinical or immunologic manifestations of RA.

Methods: Peripheral blood samples were obtained from CCP-positive RA patients (N=50) and 8 patients with systemic lupus erythematosus (SLE) who were seen in outpatient clinics. Clinical and laboratory features of disease were determined by chart review. Serum was used for measurement of ANA by ELISA and for detection of IgG and IgM autoantibodies on an 84-component protein array. Whole blood samples were used for quantitation of expression levels of 3 genes in the Type I interferon signature (MX1, OAS1, IFI27) using real-time PCR. Groups were compared for significant differences using 2-tailed t and Fisher's exact tests. Continuous variables were analyzed for correlations with Pearson's test.

Results: ANA positivity was present in 23/50 (46%) of the RA patients and this group tended to be older (60 vs 52 years; P=0.02), have longer mean disease duration (10 vs 7 years; P = 0.09), a lower prevalence of smoking (30% vs 63%; P=0.027), and somewhat higher prevalence of TNF inhibitor therapies (48% vs 26%; p=0.14) than the ANA negative group. Gender distributions were similar. The erythrocyte sedimentation rate was modestly correlated with ANA level (R=0.3; P=0.038). Malignancies were exclusively seen in the ANA+ group (8 cancers in 6 patients; P=0.008 vs ANA-). Only 2 of these were after starting TNF inhibitor therapy. 9 patients had lung disease, including interstitial fibrosis and bronchiectasis, and 6 of these were in the ANA+ group (NS), but lung disease in nonsmokers was only observed in ANA+ patients (P=0.038). Two of the 27 ANA-negative patients had had a single joint replacement each, compared to 6/23 ANA-positive patients, 4 of whom had more than one replaced joint (P=0.027). Other connective tissue diagnoses including Sjogren's Syndrome and thyroid conditions were not different in the two groups. On the autoantigen array, ANA + and – subgroups of RA did not show any significant differences for IgM autoantibodies while 12 IgG autoantibodies were higher in the ANA+ group (P £ 0.04). Compared to SLE, the ANA+ RA group had significant elevation of 13 IgM autoantibodies, but did not show any elevated IgGs. ANA positivity in the RA patients was not associated with elevation of the Type I IFN genes.

Conclusion: ANA positivity in patients with CCP+ RA may define a clinical subset that has a greater risk of lung disease, malignancy and joint replacement surgery. The presence of ANA was associated with elevation of the Type I IFN signature. The paradoxical observation that smoking was less prevalent in the ANA+ group that had higher malignancy rates is not explained. If ANA expression in RA is not associated with the Type I IFN signature as in SLE, then other pathogenetic pathways may be involved, possibly including those involved in immune surveillance.

Relationship Between Range of Motion of Joints in Upper Limbs and Physical Function in Patients with Long-Standing Rheumatoid Arthritis: Multicenter Prospective Cohort Study for Evaluation of Joint Surgery on Physical Function. Toshihisa Kojima[1], Hajime Ishikawa[2], Keiichiro Nishida[3], Jun Hashimoto[4], Hisaaki Miyahara[5], Sakae Tanaka[6], Nobuhiko Haga[6], Yasuo Niki[7], Masayo Kojima[8] and Naoki Ishiguro[1]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Niigata Rheumatic Center, Niigata, Japan, [3]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama city, Japan, [4]National Hospital Organization, Osaka Minami Medical Center, Kawachinagano, Japan, [5]National Hospital Organization Kyushu Medical Centre, Fukuoka, Japan, [6]The University of Tokyo Hospital, Tokyo, Japan, [7]Keio University School of Medicine, Tokyo, Japan, [8]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.

Background/Purpose: Even now, in clinical practice, most of RA patients have long-standing disease and structural damage in their joints. Reconstructive joint surgery should be needed for further improvements of physical function for long-standing RA patients. It is very important to understand how much range of motion (ROM) should be needed to gain better physical function in each case.

The purpose of this study is to explore the characteristics of functional impairment and relationship ROM of joints and physical function in RA patients who were needed joint surgery using multicenter prospective cohort.

Methods: We started the prospective study in September, 2012 (Study registration: UMIN000012649). We collected data on age, sex, disease duration, drug therapies, and disease activity. Functional evaluations were made using the HAQ-DI, DASH (Disability of Arm, Shoulder and Hand; upper limb function), and JSSF-RA (foot and ankle function), and patient subjective evaluations using the EQ-5D (QOL) and BDI-II (depression). Joint range of motion was also measured as part of this evaluation. This study is supported by grant from the Japanese Ministry of Health, Labour and Welfare.

Results: 347 surgical patients were registered. Mean values for age, disease duration, and sex were 65.2 years, 18 years, and 88% female, respectively. Actually, even long-standing RA patients who were needed joint surgery had remission or low disease activity in this baseline data (median values for DAS28 (3.0) and CRP (0.33 mg/dl). 23.8% of the patients were treated with biologics. We confirmed the significant correlation between HAQ-DI and EQ-5D, BDI-II; DASH and BDI-II ($P<0.05$). Assistive use of upper limb was required for arising, climbing stairs, standing up from the sofa, and walking outside by 52%, 51%, 44%, and 29% of patients, respectively.

We found significant relationship between ROM of joints in upper limb (shoulder, elbow and wrist) and the level of disability in HAQ-DI: Question 2 (shampoo hair), Q4 (arising), Q11 (tub bathing), and Q16 (opening and closing a wide mouth jar).

ROMs of the joints [age-adjusted mean values (95% CI)] which represented nearly non-existent levels of disability in each questioner of HAQ-DI, are as follows; wrist; flexion-extension 69.9 (61.4–78.5)°, pronation and supination 151.0 (145.4–158.6)°, elbow; flexion 135.3 (131.9–138.7)°, and shoulder; flexion 129.6 (122.2–137.0)°. (Fig. A and B).

Conclusion: ROMs of the joints in upper limbs were significantly associated with many kinds of daily activity including arising and bathing. The information should be important for assessment of disability in patients with long-standing RA. The ROM as shown in this study could be target of surgical procedure. It will be validated by further analysis of longitudinal data of this study.

a Dual-Center, Double Blind Randomized Study for a New Scientific Approach in Assessment of Tender Joints in Inflammatory Arthritis Using the Smart Joint Assessor Glove Device (Smart JAG Device). Mohammad Khan[1], Larry Willis[2], Swapan Nath[3], Cheryl Guest[2], Lindsey Gillispie[4] and Mary Jane Rorick[4]. [1]Arthritis & Rheumatology Center of Oklahoma, Oklahoma City, OK, [2]Arthritis & Rheumatology Center of Oklahoma, PLLC, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]McBride Orthopedic Hospital, Oklahoma City, OK.

Background/Purpose: Tender Joint Count (TJC) is a vital quality measure to assess the progression of Inflammatory Arthritis both from a therapeutic and a diagnostic standpoint. To date no scientific instruments are available to validate and standardize a Joint Count and these assessments remain largely subjective to the Joint Assessor. Physician variability, depending upon the technique and the force used in Tender joint count assessments, can significantly impact the Disease Activity Scores. Both inter and intra-observer variability bias in assessing Tender Joint Count can be pivotal in impacting the outcome of a trial.

Objectives: Primary Objective Tender Joint Count Assessments are significantly accurate using the Smart JAG Device than with conventional Joint Assessments.

Secondary Objective Establishing a high degree of consistency over time to monitor therapeutic response and improved joint function.

Methods: We present a smart hand held glove device for Tender Joint Count Assessment. The first of its kind that allows standardizing a joint exam based on scientific rationale.

We examined 100 patients (2800 joints) with moderate to severe inflammatory arthritis as defined by ACR criteria for their respective disease states maintained on DMARD therapy. A standardized 28 Joint Count was performed on all subjects. Each subject underwent a Tender Joint Exam by a total of 4 different assessors that were blindly randomized to the device. Two Joint Assessors performed the joint count using the device and two performed without the device. All joint assessors were blinded. Each joint count was performed after approximately 30 minute intervals. All assessors were blindly randomized to the device. The device was programmed at 4kg pressure to beep as a signal so that the same amount of pressure was applied consistently throughout on all the joints measured. The device beeped every time on reaching the desired pressure. This smart device has the capability of connecting via wireless connection to computer software with a built-in voice recognition system. Tender Joints are captured based on voice recognition of the Assessor in real time. The software has LED mode feature for the hearing impaired. At the conclusion of the Joint Assessment, this software is able to give a total Tender Joint Count with memory capability that can be retrieved. It can also calculate a CDAI and DAS-28 if needed.

Results: There was striking difference in consistencies between the 2 groups. We found only 4.5% discrepancy within the device users as compared to 15% in non-device users. We performed a "paired t-test" between the discrepancy measures from the 2 groups. We found strong statistical significance between the 2 groups. ($p<9.8 \times 10\text{-}8$).There were no significant differences in the overall mean tender joints in either group.

Conclusion: The device measures tender joints with high accuracy and has less discrepancy between different users. Can be used by other health care personnel as joint assessors and has a high yield to assess therapeutic efficacy over time. It is also much less time consuming and standardizes tender joint exams by keeping the pressure as constant with less inter and intra observer variability.

416

Using Patient Reported Outcome Measures to Classify Disease Activity States in Rheumatoid Arthritis: A Comparison of Patient-Derived Versions of Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI) and Disease Activity Score 28 (DAS28). Erin Carruthers[1], Noura AL Osaimi[2], Charles H Goldsmith[3], Paul Adam[4] and Diane Lacaille[5]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]University of Ottawa, Ottawa, ON, [3]Simon Fraser University, Burnaby, BC, [4]Mary Pack Arthritis Centre, Vancouver, BC, [5]University of British Columbia, Vancouver, BC.

Background/Purpose: In RA the target for treatment is clinical remission or minimal disease activity. Patient self- monitoring of disease activity may enhance treatment by providing early warnings when targets are not met, indicating the need to re-evaluate treatment. The objective of this study is to compare agreement between patient and rheumatologist (MD) derived disease activity states using Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI) and Disease Activity Score 28 (DAS28).

Methods: Consecutive RA patients presenting for follow-up to seven rheumatologists were invited to participate. Consenting patients completed a questionnaire and performed a self-report joint count before their visit. MD joint count and lab values were obtained from charts. Disease activity was evaluated using patient and MD versions of CDAI, SDAI and DAS28. In patient versions, patient joint counts were used and MD global assessments were replaced with patient global assessments (for CDAI and SDAI). Disease states were categorized into remission, low, moderate or high, according to published cut points. Because change in treatment is recommended with moderate or high disease activity, we also compared instruments using two categories: remission or low vs. moderate or high. Agreement between patient and MD derived disease states were evaluated using Agreement Coefficient 1 (AC1) for two category comparisons and Agreement Coefficient 2 (AC2), weighted with quadratic weights, for four category comparisons. AC values > 0.62 were considered good agreement. Z tests were used to evaluate the statistical significance of the difference between pairs of ACs. All p values were 2 tailed.

Results: We recruited 150 RA patients [mean (SD) RA duration: 11.9 (11.3) y; age: 57.8 (16.3) y; 81% female]. **Table 1** shows agreement between patient and MD derived disease activity measures (all p values < 0.001). There was good agreement between patient and MD derived disease activity states from the same measure, except when comparing patient and MD DAS28 across four categories, which had slightly lower agreement. There was no significant difference in the agreement between the patient and MD versions of the three measures when using four categories [CDAI vs. SDAI AC2: $p = 0.480$; CDAI vs. DAS28 AC2: $p = 0.633$; SDAI vs. DAS28 AC2: $p = 0.915$] or two categories [CDAI vs. SDAI AC1: $p = 0.580$; CDAI vs. DAS28 AC1: $p = 0.052$; SDAI vs. DAS28 AC1: $p = 0.062$].

Conclusion: Our results suggest that patients can self-monitor disease activity using patient derived CDAI, SDAI or DAS28 measures. Good agreement was found between the disease activity states derived from patient data and MD data from the corresponding measure, except for DAS28 when using four categories. There was no statistically significant difference in the agreement across measures.

Table 1. Agreement between patient and MD derived indices measured across four and two disease activity categories.

A	Comparison across four categories (remission vs. low vs. moderate vs. high)		
PATIENT MEASURES	RHEUMATOLOGIST MEASURES		
	CDAI-MD AC2 [95% CI]	SDAI-MD AC2 [95% CI]	DAS28-MD AC2 [95% CI]
CDAI-Pt	**0.67 [0.55, 0.79]**	**0.67 [0.54, 0.79]**	0.43 [0.29, 0.58]
SDAI-Pt	**0.62 [0.49, 0.75]**	**0.68 [0.56, 0.81]**	0.39 [0.24, 0.55]

DAS28-Pt	0.55 [0.42, 0.69]	0.50 [0.35, 0.64]	0.58 [0.45, 0.71]

B — **Comparison across two categories (remission or low vs. moderate or high)**

Normal Scores of "0" (floor effects) Are Seen in 33–83% of Patients with Rheumatoid Arthritis (RA) on 8 HAQ Activities Which Also Are Found on the MDHAQ, but in Fewer Than 32% of Patients on 2 Unique MDHAQ Complex Activities "Walk 2 Miles or 3 Kilometers," and "Participate in Recreation and Sports." Isabel Castrejón[1], Martin J. Bergman[2], Kathryn A. Gibson[3], John Meyerhoff[4] and Theodore Pincus[1]. [1]Rush University Medical Center, Chicago, IL, [2]Taylor Hospital, Ridley Park, PA, [3]Liverpool Hospital, Liverpool, Australia, [4]Sinai Hospital, Baltimore, MD.

Background/Purpose: Patients with rheumatoid arthritis (RA) have significantly better clinical status in recent years compared with previous decades. [1] Health assessment questionnaire (HAQ) scores were almost always elevated in 1980 when the HAQ was reported. [2] In a 1999 report, 16% of patients had HAQ scores of zero, suggesting "no difficulty" in function, but most nonetheless reported problems with function as well as psychosocial issues, reflecting "floor effects". [3] Therefore, a multidimensional HAQ (MDHAQ) was developed to include 13 queries in the user-friendly HAQ format, 8 simple activities of daily living (ADL) from the HAQ, and 2 unique complex activities: "walk 2 miles or 3 kilometers" and "participate in recreation and sports as you would like," and 2 psychological items. We analyzed mean scores and percent of patients with scores of "0", suggesting normal function, for each of the 10 MDHAQ activities in patients with RA in 3 rheumatology settings, 2 in the USA and one in Australia.

Methods: All patients at 3 settings in Ridley Park, PA, USA, Baltimore, MD, USA, and Liverpool, NSW, Australia, complete an MDHAQ at each visit in the reception area before seeing the physician. The MDHAQ queries 10 activities, 8 simple activities on the HAQ and 2 unique complex activities only on the MDHAQ (Table), all scored 0–3, with 4 response options: without any difficulty=0, with some difficulty=1, with much difficulty=2 and unable to do=3. Mean scores were analyzed in RA patients. Statistical significance was evaluated using Wilcoxon signed rank tests.

Results: A total of 314 patients were analyzed. A similar pattern was observed at each of the three sites. Mean scores were less than 0.92 (0–3 scale) for all 8 HAQ items in all patient groups; 33%-83% scored "0" on these items. Mean scores were greater than 1.27 on the 2 complex activities, "walk 2 miles/3 kilometers" and "participate in recreation/sports as you would like." Fewer than 32% of patients scored "0" on these items.

	Questionnaire items	USA, PA: RA (n=224 pts) Mean (% 0)	USA, MD: RA (n=27 pts) Mean (% 0)	Australia: RA (n=63 pts) Mean (% 0)
Traditional HAQ items	a. Dress yourself	0.49 64%	0.65 46%	0.62 55%
	b. Get in and out of bed	0.43 64%	0.52 54%	0.53 67%
	c. Lift a cup to your mouth	0.18 83%	0.27 71%	0.33 75%
	d. Walk outdoors on flat ground	0.58 58%	0.81 37%	0.39 67%
	e. Wash/dry one's body	0.39 70%	0.73 42%	0.52 64%
	f. Bend down to pick up clothing	0.57 57%	0.61 46%	0.60 54%
	g. Turn on taps/faucets	0.29 77%	0.50 54%	0.64 54%
	h. Get in and out of car/bus	0.57 55%	0.92 33%	0.54 59%
Unique MDHAQ items	i. Walk 2 miles/3 kilometers	1.48 30%	1.85 8%	1.27 32%
	j. Participate in recreation/sports	1.48 24%	1.77 4%	1.64 20%

Conclusion: The 2 unique MDHAQ complex activities identify patient problems which are not captured by the 8 items from the HAQ, similarly in USA and Australia. This information may be valuable in clinical management and documentation of improvement over time, which is not possible when baseline scores are zero. The MDHAQ might be considered for usual clinical care as well as in clinical trials.

Prevalence of Morning Stiffness in a US Registry Population of Rheumatoid Arthritis Patients. Vibeke Strand[1], Robert J. Holt[2], Katherine C. Saunders[3], Jeffery D. Kent[4], Ping Xu[5], Amy Y. Grahn[4], Marc Mason[3] and Carol J. Etzel[3]. [1]Stanford University, Palo Alto, CA, [2]University of Illinois - Chicago, Chicago, IL, [3]Corrona, LLC., Southborough, MA, [4]Horizon Pharma, Inc., Deerfield, IL, [5]Axio Research LLC, Seattle, WA.

Background/Purpose: Morning stiffness is a symptom of rheumatoid arthritis (RA) that is frequently reported and thought to reflect disease activity, but its etiology is poorly understood.

Methods: Using the Corrona RA registry, data from RA patients enrolled from October 2001–February 2014 were evaluated cross sectionally at: enrollment and last visit between January 2013 and February 2014 for those with at least one visit during that interval. Longitudinal data from 2003 to 2014 were summarized to estimate changes in prevalence of morning stiffness over time reported by all Corrona RA patients.

Results: Prevalence of morning stiffness at enrollment was 74.1% and at last visit was 69.9%; mean (SD) duration 1.7 hours (± 3.1) and 1.5 hours (± 3.0), respectively. Approximately 50% of patients reporting morning stiffness with a duration ≥ 1 hour at last visit. Patients with morning stiffness were significantly less likely to be working 39.2% vs 47.3% and were more likely to have a BMI ≥ 30 (42.2% vs 29.9%) at last visit. Similar rates of treatment with biologic DMARDs as mono therapy or in combination with non-biologic DMARDs were observed in patients with and without morning stiffness. Among patients with no reported morning stiffness at time of enrollment, time in months to first visit with reported morning stiffness was not significantly different between patients with or without prior biologic DMARD experience(Figure 1).

Conclusion: Morning stiffness continues to be reported by a high proportion of US patients despite treatment with non-biologic and biologic DMARDs and the overall prevalence has remained relatively stable over the past 10 years. Patients reporting this symptom were also more likely to be not working. More research is needed to better understand how to manage morning stiffness in clinical practice.

Comparative Dynamics of Rheumatoid Arthritis Disease Activity and Disease Severity Measures Using Rarbis, Ciras and DAS28 in a Population Based Cohort of Patients with RA. Arun K. Chandran[1], Cynthia S. Crowson[1], Birkan İlhan[2], C. John Michet[1], Eric L. Matteson[1] and Elena Myasoedova[1]. [1]Mayo Clinic, Rochester, MN, [2]Marmara University School of Medicine, Istanbul, Turkey.

Background/Purpose: There is an extensive list of composite scores of rheumatoid arthritis (RA) activity status for the use in clinical practice including Disease Activity Score (DAS) and DAS-28. Much less common are validated definitions and scores of RA activity and severity for use in healthcare databases. The Record based Index of Severity (RARBIS) and the Claims-based Index for RA Severity (CIRAS) are methods used for this purpose. Our objective was to assess the dynamics of the CIRAS and RARBIS as measures of RA disease severity over time and to assess their correlation with DAS28.

Methods: A population-based inception cohort of 525 patients with incident RA (as per the 1987 ACR Criteria) in 1988–2007 was retrospectively identified and followed until 7-1-2012. The available data to calculate the RARBIS (joint surgeries, erosions, extra-articular manifestations, arthritis flares, morning stiffness, rheumatoid factor [RF] positivity, acute phase reactants and antirheumatic medications) were collected at every visit via medical record review. Claims data were used to calculate the CIRAS at every visit using 1 year prior data on number of inflammatory marker tests, platelet counts, chemistry panels, rheumatology visits, rehabilitation visits, assessment of RF, and Felty's syndrome. DAS28 was also collected, when available. RA flare was defined based on OMERACT 9 definition. Scores were compared using Spearman's correlation.

Results: The 525 patients (mean age 55; 71% female) in our cohort had 15,649 visits (mean 30 visits per patient) with an average of 10.3 years follow-up. The mean RARBIS with medication at RA incidence was 3.3 (SD 1.4) and the CIRAS was 4.5 (SD 1.9). There was an increase in both, CIRAS and RARBIS scores during the first year of disease (Figure). Thereafter, the CIRAS scores tended to decrease, but the RARBIS values showed little change over the disease course. The flare rate decreased significantly during the follow-up by 0.3 per 100 person-years per year ($p<0.001$). There was a statistically significant correlation between RARBIS and CIRAS scores ($r=0.19$, $p<0.001$). DAS28 was available in only 278 visits. There was a moderate correlation between DAS28 and RARBIS ($r=0.40$; $p<0.001$) and a weaker correlation between CIRAS and DAS28 ($r=0.16$; $p=0.008$).

Conclusion: The uniform increase in CIRAS and RARBIS values during the first year after index date may reflect initial spike of RA activity and initial extensive work up of RA disease. Subsequent decline in CIRAS scores is concordant with decreasing flare rates, and could be due to the gradual decrease in the need for comprehensive laboratory workup and decreased frequency of rheumatology visits in patients with established disease. CIRAS and RARBIS scores were found to be significantly correlated with DAS28 suggesting that these indices may be helpful measures of RA activity/ severity in healthcare database research.

Figure 1. Trends in CIRAS (solid line) RARBIS with medications (dashed line) and RARBIS without medications (dotted line) [upper panel] and flare rate [lower panel].

Less Is More: The Shorter Physical Function Measure Promis-PF10a Outperforms HAQ in an Ethnically Diverse, Urban Rheumatoid Arthritis Clinic Population. Elizabeth R. Wahl, Andrew J. Gross, R Krishna Chaganti, Lianne S. Gensler, Vladimir Chernitskiy, Laura Trupin, Patricia P. Katz and Jinoos Yazdany. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Patient-reported outcome measures are important tools that assess the impact of disease on patients' lives; in RA, patient-reported physical function is especially relevant. In contrast to legacy measures such as the Health Assessment Questionnaire (HAQ) or Short Form 36 Health Survey (SF-36), the Patient-Reported Outcome Measurement Information System (PROMIS) scales are brief and intended to address psychometric flaws in earlier measures such as ceiling effects. However, use of PROMIS in clinical practice has been limited. The current study evaluates the ceiling and floor effects of the PROMIS Physical Function short form 10a (PROMIS-PF10a) relative to the HAQ, and compares the construct validity of these measures to a commonly used measure of disease activity (Clinical Disease Activity Index, CDAI), among patients with RA in an ethnically diverse urban clinic.

Methods: We abstracted demographic and clinical data from the electronic health record (EHR) of patients from a university-based rheumatology clinic. Eligible patients had 2 ICD-9 codes for RA between February 2013 and March 2014, had completed PROMIS-PF10a and HAQ, and had CDAI scores recorded by a clinician. We characterized score distributions for PROMIS T-scores and HAQ, including percent of patients with minimum and maximum possible scores. Construct validity was evaluated by examining the matrix of correlation coefficients (Pearson's r) among PROMIS-PF10a, HAQ and CDAI.

Results: Analyses included 78 patients. 78% were female, mean age was 57.0± 14.4 years, 59% were Caucasian, 15% Hispanic/Latino, and 10% Asian. 82% were RF or CCP positive, 51% had erosive disease and mean disease duration was 12± 11 years. The mean PROMIS-PF10a score was 44.3; the mean HAQ score was 0.82. The distribution of PROMIS-PF10a scores more closely approximated a normal distribution (Figure), and had a lower proportion of scores at the ceiling (Table). There was a statistically significant correlation between PROMIS-PF10a and HAQ scores of $r = -0.61$, and a modest significant correlation between PROMIS-PF10a and CDAI scores of $r = -0.48$. The relationship between HAQ and CDAI was not statistically significant ($r = 0.19$).

Conclusion: In this ethnically diverse RA clinic population, the shorter PROMIS-PF10a had a distribution closer to normal with less ceiling effect, which enables better discrimination at higher levels of functioning. PROMIS-PF10a also had a higher correlation with CDAI scores than HAQ. Further studies are needed to understand the relative responsiveness of changes in PROMIS physical function scores compared to legacy measures.

Table. Score Characteristics and Floor/Ceiling Effects for PROMIS-PF10a and HAQ.

		Scores			Floor (poorest function)	Ceiling (best function)
MEASURE	Mean ± SD	Median	Min	Max	N (%)	N (%)
PROMIS-PF10a	44.3 ± 9.3	41.4	27.1	61.7	0	10 (12.8%)
HAQ	0.82 ± 0.66	0.88	0	2.25	0	15 (19.2%)

Higher PROMIS-PF10a scores reflect better function while higher HAQ reflects poorer function. Normalized PROMIS-PF10a scores can range from 14.1–61.7. A score of 50 represents average function in a healthy individual; each 10-point decrement represents one standard deviation from this norm. HAQ scores range from 0–3. A score of 0 represents no limitation in functioning.

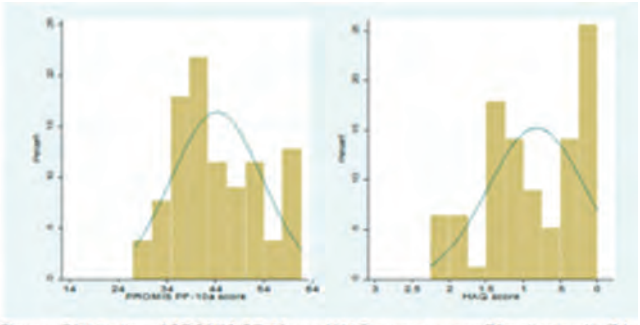

Figure. Distribution of PROMIS PF-10a and HAQ scores among 78 patients with RA.

Prediction of Remission By Patients and Physicians: Does the Doctor Know Best? WG Bensen[1], Boulos Haraoui[2], Carter Thorne[3], Edward Keystone[4], Michel Zummer[5], Isabelle Fortin[6], Rafat Faraawi[7], Andrew Chow[8], Milton Baker[9], Niall Jones[10], Emmanouil Rampakakis[11], John S. Sampalis[11], May Shawi[12], Francois Nantel[12], Allen J Lehman[12] and Susan Otawa[12]. [1]St Josephs Hospital and McMaster University, Hamilton, ON, [2]University of Montreal Hospital Centre, Montreal, QC, [3]Southlake Regional Health Centre, Newmarket, ON, [4]Mount Sinai Hospital, University of Toronto, Toronto, ON, [5]Université de Montréal, Montreal, QC, [6]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [7]McMaster University, Hamilton, ON, [8]McMaster University, Hamilton and Credit Valley Hospital, Mississauga, ON, [9]University of Victoria, Victoria, BC, [10]University of Alberta, Edmonton, AB, [11]JSS Medical Research, Montreal, QC, [12]Janssen Inc., Toronto, ON.

Background/Purpose: Patient (PtGA) and physician (MDGA) assessment of global disease activity have been used as outcome measures individually or as part of composite scores in the measurement of rheumatoid arthritis (RA) disease severity and the evaluation of treatment effectiveness. However, discordance between the two is common[1]. The question arising is which global measure is a more valid predictor of disease remission.

The aim of the analysis was to compare PtGA and MDGA with respect to their association with remission based on DAS-28, SDAI and CDAI, using a sequential cross-sectional analysis.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab as first biologics or after having been treated with a biologic for <6 months. Eligible patients for this study included RA patients treated with IFX who were enrolled between 2002 and 2012 with available information on 6-, 12-, or 18-month remission. Logistic regression analysis with the parametric Wald statistic was used to compare the independent association of MDGA and PtGA with remission at 6, 12 and 18 months. The WALD statistic assesses the extent of contribution of an individual predictor to an outcome of interest and can be used to compare the contribution of different predictors.

Results: A total of 657 patients were included with mean (SD) age of 56.2 (13.5) years and disease duration of 10.1 (10.0) years. Significant ($P<0.001$) associations were observed between both PtGA and MDGA and achievement of remission at the corresponding assessments regardless of remission type. For DAS28 remission, the Wald statistic at 6, 12 and 18 months for MDGA vs. PtGA was 26.9 vs. 39.2, 12.7 vs. 35.9, and 19.8 vs. 22.5, respectively. For SDAI remission the MDGA and PtGA Wald statistics were 27.7 vs. 24.5, 27.8 vs. 28.5, and 32.4 vs. 23.4, respectively, at 6, 12 and 18 months. For CDAI remission, the Wald statistic for MDGA vs. PtGA at these time points was 34.8 vs. 26.9, 38.1 vs. 37.2, and 39.5 vs. 27.1. Similar results were obtained for predicting low disease activity.

Conclusion: The results of this analysis show that PtGA is a better predictor of DAS28 disease remission compared to MDGA. This could be explained by the fact that DAS28 includes PtGA and not MDGA. However, for CDAI and SDAI, physicians were better in predicting remission although the superiority of the MDGA was not consistent over time.

Correlation of RAPID3, DAS28 and CDAI in Disease Activity and Effects of Education Level and Co-Morbid Diseases on This Assesment in RA. Kubilay Sahin[1], Yasar Karaaslan[2], Zeynep Ozbalkan[1], Ahmet Omma[1] and Nesibe Yesil[1]. [1]Ankara Numune Education and Research Hospital, Ankara, Turkey, [2]Hitit University, Corum, Turkey.

Background/Purpose: RAPID3 is an activity index based on only the patient's report in RA. It doesn't require joint counts and it isn't time consuming. Therefore this situation makes the index very attractive for physicians. It has been shown in clinical studies that RAPID3 gives corralated information with DAS28 and CDAI.

In this study, we aimed to determine the correlation of RAPID3, DAS28 and CDAI in the assesment of disease activity and effects of education level and co-morbid diseases on this assesment in RA patients who were followed in a tertiary rheumatology clinic of Turkey.

Methods: 246 RA patients (80.1% female, mean age: 53.2±12.1 years) followed up for at least 3 months between January-June 2013 were included to the study. All patients were asked to fill out RAPID3 questionnaires. Uneducated patients completed the survey with the help of medical secretary. RAPID3, DAS28 and CDAI was calculated in all patients. Patients were subdivided according to disease severity as group A (remission-minimal disease activity) and group B (medium-severe disease activity) for all scoring systems. All data were analyzed using statistical software; SPSS (Statistical Package For Social Sciences) for Windows 20 (SPSS Inc, Chicago, IL). One way Annova, Kruskal Wallis analysis, kappa analysis and Spearman correlation were used for statistics. A level of $p < 0.05$ was considered significant.

Results: 27.2% of the patients were uneducated, the rest were educated graduating from 50.8% primary school, 16.6% secondary/high school and 5.3% university. Mean training period of the patients was 4.9 years. 47.6% of the patients had at least one comorbid disease (i.e. hypertension, diabetes, hypo/hyperthyroidism, coronary artery disease, lung disease or obesity). Correlation of RAPID3 with the DAS28 and CDAI score was statistically significant ($p<0.001$). Similarly, educational status and the presence of comorbid disease didn't effect this correlation ($p<0.001$). Kappa analysis showing compliance of RAPID3 with DAS28 and CDAI scores was also significant ($p<0.001$).

100% of the patients with severe disease activity according to DAS28 also had moderate/severe disease activity according to the RAPID3. 77% of patients who were in remission according to DAS28 have near remission–minimal disease activity according to RAPID3. Patients with high disease activity according to the CDAI also had severe disease activity (100%) according to RAPID3, while 97% of patients who were in remission according to the CDAI have near remission-minimal disease activity according to RAPID3.

Conclusion: Similar to previous studies, RAPID3 was significantly correlated with DAS28 and CDAI score. Even though RAPID3 could be effected by patients educational status, when we compared the patients as educated/uneducated, there was no significancy. At the same time, presence of co-morbid diseases didn't effect the correlation of RAPID3 with DAS28 and CDAI. RAPID3 can provide quantitative information in uneducated patients and with presence of comorbid diseases just like DAS28 and CDAI.

Circulating Anti-Citrullinated Peptide Antibodies and Cytokines As Biomarkers of Response to Disease-Modifying Antirheumatic Drugs Therapy in Early Rheumatoid Arthritis. Mahmood MTM Ally[1], Pieter Meyer[2], Bridget Hodkinson[3], Eustasius Musenge[4], Gregory Tintinger[2], Mohammed Tikly[5] and Ronald Anderson[1]. [1]University of Pretoria, Pretoria, South Africa, [2]university of pretoria, pretoria, South Africa, [3]University of the Witwatersrand, Johannesburg, South Africa, [4]University of Witwatersrand, Johannesburg, South Africa, [5]C H Baragwanath Hospital, Johannesburg, South Africa.

Background/Purpose: Serial measurement of circulating anti-citrullinated peptide antibodies (ACPA) and cytokines is of potential importance in the management of patients with rheumatoid arthritis (RA). However, the utility of this strategy in monitoring responses to traditional disease-modifying antirheumatic drugs (DMARDs) in early RA is largely untested.

Methods: A cohort of 140 predominantly (88.5%) black female South African patients with early RA median (IQR) symptom duration 9.7 (11.4)

months was treated with synthetic DMARDs, mostly methotrexate (MTX), either as monotherapy or combination DMARD therapy, mostly combined with low-dose oral corticosteroids (CS). The simple disease activity index (SDAI) was used to evaluate clinical response, while circulating ACPA and a panel of circulating cytokines/chemokines/growth factors were measured using immunofluorimetric and multiplex suspension bead array procedures respectively at baseline and after 6 months of therapy. Shared epitope genomic analysis was done using PCR typing of the HLA-DRB1 allele.

Results: Following 6 months of therapy, the median SDAI declined from a baseline of 41.39 to 16 ($p=0.0001$) for the entire cohort. This decline in disease activity was paralleled by significant falls in median serum ACPA levels (516.6 vs. 255.65 units, $p=<0.0001$) and several of the circulating cytokines (IL-4, IL-6, IL-7, IL-8, G-CSF, VEGF, CCL4; $p<0.023$ – $p<0.0001$) which were most evident in the subgroup of patients treated with a combination of MTX and CS. No significant correlations between these biomarkers and disease activity were observed. Baseline ACPA levels, but not SDAI or cytokines, were significantly higher in the subgroup of risk allele-positive patients (594.1 vs. 255.7 units, $p<0.05$), while no associations with ACPA and a smoking history were evident.

Conclusion: The use of synthetic DMARDs in early RA is associated with significant decreases in SDAI, paralleled by a decrease in ACPA and predominantly pro-inflammatory cytokines. However, the lack of correlation of ACPA and the other biomarkers with therapy-associated alterations in disease activity in the short term appears to preclude the utility of serial measurement of these biomarkers to monitor early responses to therapy, while the long-term, prognostic potential remains to be established.

The Comparison Between Physical and Ultrasound Joint Examination for the Hand Joints in Patients with Rheumatoid Arthritis. Norihide Hayashi, Takehisa Ogura, Ayako Hirata, Rie Kujime, Munetsugu Imamura, Sayaka Takenaka, Kennosuke Mizushina, Sumie Nakahashi, Hideki Ito, Naoko Yamashita and Hideto Kameda. Toho Univ, Tokyo, Japan.

Background/Purpose: To establish the importance of joint examination by ultrasound (US) in daily clinical practice of patients with rheumatoid arthritis (RA), we compared the US findings with the joint examination findings sorted by the presence of tenderness and/or swelling in the hand (proximal) interphalangeal (IP/PIP), metacarpophalangeal (MCP) and wrist joints.

Methods: A total of 208 RA patients (158 female, the mean age of 66 years) completed clinical, laboratory and US assessments between October 2011 and December 2013. Clinical joint assessments determined the presence of tenderness alone (T) or swelling alone (S), both (TS) or none (N) of them. US synovitis was defined as gray-scale (GS) imaging score ≥ 1 (graded 0–3) or a synovial power Doppler (PD) signal score ≥ 2 (graded 0–3).

Results: Among total joints assessed, US synovitis was observed in 146 of 178 TS joints (82%), 50 of 128 T joints (28%), 130 of 201 S joints, and 309 of 3710 N joints. Therefore, joint swelling is more closely associated with US synovitis than joint tenderness. Next, even among TS joints, US synovitis was observed only in 50% (23/46) of IP/PIP joints, which was significantly less than 95% (55/58) and 92% (68/74) for the wrist and MCP joints, respectively ($p<0.01$). Among N joints, conversely, US synovitis was observed in 32% (92/286) of the wrist joints, which was greater than 9%(56/624) for the MCP joints and 9% (52/1898) of IP/PIP joints ($p<0.0001$).

	TS	T	S	None
Wrist (n = 416)				
US+	55	13	37	92
US-	3	7	15	194
MCP (n = 2080)				
US+	68	25	73	165
US-	6	40	33	1670
IP/PIP (n = 2080)				
US+	23	12	20	52
US-	23	81	23	1846
Total (n = 4576)				
US+	146	50	130	309
US-	32	128	71	3710

Conclusion: Based on the US findings, physical joint examination of the IP/PIP and the wrist joints tends to overestimate and underestimate synovitis, respectively. Thus, clinical importance of US examination in daily clinical practice may differ among joint sites, probably due to the structural complexity in the wrists and the co-existing osteoarthritis in IP/PIP joints.

Beyond Disease Activity: Patient Global Scores Also Reflect Treatment Expectations and Emotional Reactions to Living with Rheumatoid Arthritis. Susan J. Bartlett[1], Maria Celia Bazan Bardales[2] and Ines Colmegna[3]. [1]Johns Hopkins University, Baltimore, MD, [2]McGill University, Montreal, QC, [3]McGill University - Royal Victoria Hospital, Montreal, QC.

Background/Purpose: Illness perceptions (IP) are the beliefs and expectations that an individual has about medical conditions. IP have been found to cluster around five coherent themes (identity; cause; time-line; consequences; and cure/control). Positive IPs have been associated with higher adherence, better disease outcomes and wellbeing in several chronic diseases. Relatively less is known about how illness perceptions impact patient perceptions of wellbeing and other disease outcomes in rheumatoid arthritis (RA).

Methods: Consecutive English speaking RA patients seen at an academic center between 2013– 2014 were asked to complete the Illness Perception Questionnaire – Revised (IPQ-R). Clinical RA indicators were obtained at each visit. Spearman correlations were calculated between IPQ-R scales and CDAI. Adjusted regression models evaluated the effect of IPQ-R on patient global scores.

Results: 50 RA patients completing the survey were mostly female (n=38;76%) with a mean (SD) education of 15 (4) yrs, and median (IQR) HAQ score of.25 (1.0). Eight (16%) had an RA duration $\leq$ 1 year and 20 (40%) of 1–5 years. Most were seropositive for RF (61%) and anti-CCP (66%); 15 (30%) were on biologics. CDAI scores classified 13 (26%) in remission and 18 (36%), 13 (26%) and 6 (12%) with low, moderate and high disease activity levels, respectively.

Timeline-Cyclic (rho =.32) and Personal Control (rho =.28) were significantly (p's <.05) and directly associated with CDAI; Treatment Control (rho = -.40) was inversely related to CDAI in a dose response manner (mean difference 2.3 and 3.8 between remission, low, and mod-high levels). After controlling for disease activity, Treatment Control and Emotional Representations were independent additional predictors (p's <.05) explaining 62% of the variance in patient global scores. Genetic risk factors (39%), altered immunity (26%) and psychological factors (24%) were viewed as the primary reason or an important contributing factor for developing RA. Patients who attributed their RA to psychological factors had significantly higher mean Cyclical Timeline scores (14.8 vs. 12.1; p=.004) reflecting attitudes of greater unpredictability and uncertainty around their disease.

Conclusion: Understanding patients' beliefs about the cause of their RA, as well as expectations about controllability, may offer insight into patient behaviors (e.g., adherence to treatment) that impact long-term outcomes. Beliefs about causes of RA may also affect expectations of whether and how the disease can be controlled. Clinicians may find useful to directly explore patients' expectancies around treatment, and to provide hope, encouragement and ongoing support when expectations are low.

Exploring the DAS: What Is the Level of Agreement in the Classification of Remission and Low Disease Activity (LDA) Among the Various Versions of the Disease Activity Score (DAS) and Their Correlation? an Analysis from a Prospective, Observational Registry. WG Bensen[1], Edward Keystone[2], Philip Baer[3], Jude Rodrigues[4], J. Antonio Avina-Zubieta[5], Wojciech Olszynski[6], Denis Choquette[7], Suneil Kapur[8], Manisha Mulgund[9], John S. Sampalis[10], Emmanouil Rampakakis[10], Francois Nantel[11], Allen J Lehman[11], May Shawi[11] and Susan Otawa[11]. [1]St Josephs Hospital and McMaster University, Hamilton, ON, [2]Mount Sinai Hospital, University of Toronto, Toronto, ON, [3]Private Practice, Scarborough, ON, [4]Clinical Research and Arthritis Centre, Windsor, ON, [5]Arthritis Research Centre of Canada, Richmond, BC, [6]University of Saskatchewan, Saskatoon, SK, [7]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [8]University of Ottawa, Ottawa, ON, [9]Private Practice, Hamilton, ON, [10]JSS Medical Research, Montreal, QC, [11]Janssen Inc., Toronto, ON.

Background/Purpose: Two versions of DAS28 are available, DAS28-4 comprising 4 variables [tender and swollen joint counts, acute phase reactant (APR), and patient global assessment] and DAS28-3 where patient global has been omitted. Despite the difference between DAS28-4 and DAS28-3 thresholds for remission and low disease activity (LDA) are the same. Additionally, the APR used to calculate the DAS may be either ESR or CRP. The aim of this analysis is to describe the agreement between these four possible indices, DAS28-4 ESR, DAS28-4 CRP, DAS28-3 ESR and DAS28-3 CRP and to compare them in terms of classifying remission and LDA in a real-world, routine clinical care setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab. In this analysis, data from RA patients who were treated with infliximab between 2002–2014 or with golimumab between 2010–2014 and had available information in all indices were used. The definitions for remission were as follows: DAS28-3/4 <2.6; LDA was defined as: DAS28-3/4 <3.2. Correlation between the different indices was assessed with the Pearson's correlation coefficient (r) and classification agreement was assessed with Cronbach's alpha (CA) and the kappa statistic.

Results: Eight hundred sixty nine RA patients who had 3,517 complete assessments were included in the analysis. Non-remission was classified by all indices in 61.4% of cases, while remission was achieved in one (5.9%), two (10.3%), three (5.3%), or all four (17.2%) indices. Similarly, non-LDA was classified by all indices in 46.1% of cases, while LDA was achieved in one (6.2%), two (10.9%), three (5.4%), or all four (31.3%) indices.

Overall, a strong linear positive correlation ($r > 0.8$) was observed between all indices. When looking at the internal consistency in terms of classifying disease state, the CA was 0.905 for remission and 0.923 for LDA suggesting an overall high internal consistency. However, when looking at the individual inter-item correlations (Table 1), the agreement between indices was variable with DAS28-3 CRP and DAS28-4 CRP showing the highest correlation and DAS28-3 ESR and DAS28-4 CRP showing the lowest correlation. When comparing DAS28-4 ESR with DAS28-3 ESR, the latter categorized 16.5% of DAS28-4 ESR remission cases as non-remission and 3.0% of DAS28-4 ESR non-remission cases as remission. With respect to LDA, DAS28-3 ESR categorized 9.1% of DAS28-4 ESR LDA cases as non-LDA and 4.7% of DAS28-4 ESR non-LDA cases as LDA. Similar results were observed with DAS28 CRP.

Conclusion: The results of this analysis show that, despite being highly correlated, variability exists in the classification of remission and LDA by the various DAS indices. These results suggest that decision making based on disease state achieved may vary significantly based on the type of APR used in the DAS index.

Table 1 Inter-Item Correlation Matrix of DAS Remission / LDA Types

Remission	*DAS28-4 ESR*	*DAS28-4 CRP*	*DAS28-3 ESR*	*DAS28-3 CRP*
DAS28-4 ESR	–	0.678	0.824	0.670
DAS28-4 CRP	0.678	–	0.589	0.846
DAS28-3 ESR	0.824	0.589	–	0.631
DAS28-3 CRP	0.670	0.846	0.631	–
LDA				
DAS28-4 ESR	–	0.728	0.864	0.702
DAS28-4 CRP	0.728	–	0.670	0.846
DAS28-3 ESR	0.864	0.670	–	0.696
DAS28-3 CRP	0.702	0.846	0.696	–

Multimedia Patient Education Tool for Patients with Rheumatoid Arthritis. Maria A. Lopez-Olivo[1], Aparna Ingleshwar[1], Robert Volk[1], Andrea Barbo[1], Maria Jibaja-Weiss[2], Heather Lin[1] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: Effective patient education provides individuals with essential information about their disease and treatment alternatives, and aids informed decision-making. The purpose of our study was to test the efficacy of a multimedia patient education tool (MM-PtET) including storylines and testimonials for patients with rheumatoid arthritis (RA).

Methods: Patients were recruited from 5 centers and through advertisement. Inclusion criteria were: (i) age $\geq$18 years (ii) diagnosis of RA by a rheumatologist (iii) disease duration $\leq$10 years (iii) adequate cognitive status and, (iv) ability to communicate in English or Spanish language. After completion of a baseline questionnaire, participants reviewed materials of the group to which they Patients were randomized to receive a MM-PtET or a written booklet, both with the same written information. They completed self-report questionnaires before and after viewing the assigned materials. Primary outcome measures included: a) Disease knowledge, and b) Decisional conflict. Secondary outcomes included: a) Acceptability, and b) Educational tool evaluation. We compared differences between and within groups for outcomes of interest. Linear regression was performed to assess the influence of the intervention and patient characteristics on the knowledge score.

Results: 221 participants were randomized (111=MM-PtET, 110=written booklet). Mean age was 51 ± 13 years, mean disease duration was 5 ± 3 years, 85%were female 24% had inadequate health literacy levels and 41(%) were Spanish speaking. Post randomization, both, intervention and control groups, showed significantly higher knowledge scores (Intervention: 5.5 ± 2.1 vs 7.6 ± 1.5 and, Control: 5.5 ± 2.1 vs 7.1 ± 2.0; $p<0.05$ for both groups) and, significantly lower "Informed" and "Values clarity" scores ($p<0.05$ for both scales). No statistically significant differences was observed between the two groups for knowledge improvement and decisional conflict scales ($p > 0.10$ for both measures). The majority of the participants in both groups gave a favorable response to all evaluation questions, with no significant differences in response options observed between the two groups ($p > 0.05$). Regarding acceptability, MM-PtET group participants were more likely to rate the presentation as "Excellent" for the following items: impact of RA, medication options, evidence about medications, benefits of medication, and self-care options ($p<0.05$ for all). Also, compared to the control group, more participants in the MM-PtET group found the length of the material presented as "just right" (Intervention vs Control: 92% vs 80%, $p=0.03$). Regression analysis indicated that, being in MM-PtET group, shorter disease duration and being Hispanic compared to White, was predictive of greater knowledge improvement ($p<0.05$, Adjusted $R^2=0.08$).

Conclusion: Viewing of the MM-PtET was as effective and more acceptable than reading written materials in RA patients. Hispanics and patients with shorter disease duration may achieve the greatest benefit from multimedia tools incorporating narratives and stories.

Patient-Physician Discordance of Disease Activity Assessments Predicts Inadequate Treatment Response in Early Rheumatoid Arthritis. John M. Davis III, Cynthia S. Crowson, Tim Bongartz, Clement J. Michet, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN.

Background/Purpose: Discordance between patients' and physicians' global assessments of disease activity occurs in up to a third of clinical evaluations for rheumatoid arthritis (RA). In this study, we sought to determine the association between the presence of patient-physician discordance at baseline and clinical disease activity after the 24 weeks of disease-modifying therapy.

Methods: We conducted an observational study of consecutive patients with newly diagnosed RA recruited between July 2008 and December 2010. RA was defined by the Leiden early RA prediction rule. The primary rheumatologist prescribed disease-modifying therapy, which did not follow any study protocol. Standard disease activity assessments were performed by a single joint assessor, who was independent of treatment decision-making, at baseline and at 24 weeks of follow-up, including tender and swollen joint counts, patient and physician global assessments of disease activity (0 – 100 mm visual analog scales), and the C-reactive protein. Discordance was defined by $\geq$25-mm difference between the patient and physician global assessments. A higher patient-than-physician global assessment defined positive discordance, and a higher physician-than-patient global assessment defined negative discordance. The outcome variable of interest for this analysis was the Disease Activity Score in 28 joints, 3-variable version (which excludes the patient global assessment), using the C-reactive protein

(DAS28-CRP). The association between discordance and DAS28-CRP at 24 weeks was determined using linear regression models, adjusting for multiple study covariates.

Results: A total of 66 patients were included in this study. The mean age was 56.4 years, and 66% was female. As initial treatment, 51% of patients received methotrexate, 25% hydroxychloroquine, and 58% prednisone. Patient-physician discordance was present at 27% of the baseline visits, 10% with positive discordance (i.e., patient high) and 17% with negative discordance (i.e., physician high). The presence of positive discordance was predictive of higher DAS28-CRP after 24 weeks of disease-modifying therapy (β coefficient = 1.58; p = 0.017) whereas negative discordance was not predictive (β coefficient = 0.65; p = 0.091), after adjusting for age, sex, disease duration, rheumatoid factor, anti-CCP antibodies, baseline tender joint count, baseline swollen joint count, baseline CRP, initial DMARD, prednisone use, and smoking status.

Conclusion: In conclusion, discordance in which patient's assessment of disease activity is higher than the physician's assessment is predictive of significantly higher DAS28-CRP after 24-weeks of disease-modifying therapy. Further research is necessary to explicate factors underlying patient-physician discordance and to develop strategies for managing these factors. This work is anticipated to improve treatment outcomes for patients with RA.

Investigation of MRI Bone Changes in Early-Stage RA Patients Achieved in Sustained Clinical Good Response: Sub-Analysis from Nagasaki University Early Arthritis Cohort. Mami Tamai[1], Kazuhiko Arima[2], Yoshikazu Nakashima[1], Masataka Umeda[1], Shoichi Fukui[1], Ayako Nishino[1], Takahisa Suzuki[1], Yoshiro Horai[1], Akitomo Okada[3], Tomohiro Koga[1], Shin-ya Kawashiri[2], Naoki Iwamoto[1], Kunihiro Ichinose[1], Hideki Nakamura[1], Tomoki Origuchi[4], Masataka Uetani[5], Kiyoshi Aoyagi[2] and Atsushi Kawakami[1]. [1]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan, [4]Department of Health Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [5]Department of Radiological Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background/Purpose: Given the improved detection of joint injury by MRI than by clinical examination, EULAR recommendations for the use of imaging of the joints in the clinical management of RA states that MRI may be useful in monitoring disease activity. However, few data have been established that specifically address how MRI should be applied to consider the outcome of RA. We have tried to examine whether MRI is useful to predict the development of radiographic progression in patients with early-stage RA from Nagasaki University Early Arthritis Cohort.

Methods: This is a sub-analysis from the 1-year observational study from seventy-six early-stage RA patients recruited consecutively from Nagasaki University Early Arthritis Cohort in which the subjects received Gd-enhanced MRI of both wrists and finger joints. All of the patients had been received DMARDs during 1 year after entry and we have selected 36 patients in which the favorable clinical response was obtained by DMARDs. The favorable clinical response was defined by decrement of DAS28 $\geqq$ 1.2 at 3 months as well as achievement of DAS28 low disease activity or remission at 6 months. Synovitis, osteitis and bone erosion determined by Gd-enhanced MRI were scored by Rheumatoid Arthritis Magnetic Resonance Imaging score (RAMRIS). Plain radiographic progression was studied by Genant-modified Sharp score. The association of MRI findings with plain radiographic progression at 1 year was investigated.

Results: Median age, disease duration and Genant-modified Sharp score at entry from 36 patients were 55 y.o., 2.4 months and 0, respectively. Although all of the 36 patients showed the favorable clinical response, radiographic progression was found in 7 patients at 1 year. Although there were no significant differences between the patients with radiographic progression (N = 7) and those without radiographic progression (N = 29) in age, gender, disease duration, RF, ACPA, CRP, matrix metalloproteinase-3 and DAS28 at entry, the significant differences were found in the rate (100% vs 51.7%, p < 0.05) and RAMRIS score of osteitis (median score 5 vs 1, p = 0.0012) at baseline, the rate (100% vs 31.0%, p = 0.001) and RAMRIS score of bone erosion (median score 3 vs 0, p = 0.004) at baseline. In addition, initial therapy with MTX was significantly less in the patients with radiographic progression as compared those without radiographic progression (14.3% vs 69.0%, p = 0.013). Multivariate logistic regression analyses, the most appropriate model is selected on the basis of Akaike's information criteria in the SAS system®, version 9.2, have shown that MRI osteitis at entry, MRI bone erosion at entry and initial MTX therapy tended to associate with plain radiographic progression.

Conclusion: MRI bone changes appear to predict poor radiographic outcome in patients with early-stage RA despite the favorable clinical response is achieved. Our present data indicate again the importance of MTX as initial DMARDs in early RA patients.

Minimally Important Difference in the European Quality of Life-Five Dimensions in Patients with Rheumatoid Arthritis. Daisuke Hoshi, Eiichi Tanaka, Eisuke Inoue, Kumi Shidara, Yoko Shimizu, Akiko Kobayashi, Naoki Sugimoto, Eri Sato, Yohei Seto, Ayako Nakajima, Shigeki Momohara, Atsuo Taniguchi and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Patient-reported outcomes (PROs) have been recognized as important in evaluating disease status of rheumatoid arthritis (RA). The minimally important difference (MID) in PROs has been studied in RA for physical function, however, the MID for quality of life assessed by European Quality of Life-Five Dimensions (EQ-5D) has not yet been analyzed. Thus, we conducted this study to elucidate MID for EQ-5D.

Methods: Participants were patients with RA who enrolled in the IORRA study conducted in October 2011 and April 2012. The IORRA study was established as a large observational cohort of RA patients.in October 2000 and the data collection was conducted biannually. The database includes the EQ-5D, the disease activity score in 28 joints (DAS28), and the Japanese version of the Health Assessment Questionnaire (J-HAQ) for physical disability. Patients self-rated their change in overall status in April 2012 as much better, somewhat better, the same, somewhat worse, or much worse compared to that in October 2011 using a 5-point Likert scale. In this study, the MID for EQ-5D in patients who rated themselves as somewhat better were analyzed. The MID is the means of each patient's change in the EQ-5D, and the responsiveness to change was evaluated using effect size (ES) which of 0.2 to 0.5 is usually considered as relevant value for the MID.

Results: A total of 4,847 patients in this study had a mean (standard deviation [SD]) age of 60.4 (13.4) years, disease duration of 14.2 (10.0) years, DAS28 score of 2.9 (1.1), J-HAQ score of 0.64 (0.73), and EQ-5D of 0.800 (0.18), and 85.0% were women. Among them, 745 patients self-rated themselves somewhat better. The mean (SD) change in EQ-5D was 0.018 (0.17) with ES of 0.11 for patients who self-rated themselves somewhat better. When patients rated themselves somewhat better were stratified by baseline DAS28 into groups of remission, low, moderate and high disease activity, the mean (SD) changes in EQ-5D were −0.0002 (0.15), 0.017 (0.15), 0.032 (0.13) and 0.58 (0.12) with ES of 0.001, 0.11, 0.23 and 0.49, respectively. When stratified by baseline J-HAQ into groups of low (J-HAQ<0.5), moderate (0.5≤J-HAQ<1.5) and high (J-HAQ≥1.5) physical disability, the mean (SD) changes in EQ-5D were 0.004 (0.13), 0.027 (0.12) and 0.032 (0.13) with ES of 0.03, 0.21 and 0.24, respectively. When stratified by baseline disease duration into groups of < 2 years, 2–5 years, 5–10 years and ≥10 years, the mean changes (SD) in EQ-5D were 0.043 (0.12), 0.021 (0.16), 0.015 (0.16) and 0.014 (0.16) with ES of 0.33, 0.16, 0.09 and 0.08, respectively. Finally, the MID in EQ-5D in patients with baseline DAS28 >3.2, baseline J-HAQ >0.5 and disease duration <5 years was demonstrated as 0.036 with ES of 0.39.

Conclusion: This study demonstrated the MID in EQ-5D in RA patients from the IORRA cohort. The MID in EQ-5D varies in concordance with disease activity, physical disability and disease duration.

Joint Dermal Temperature Specifically Identifies the Individual RA Patient Most Likely to Develop Radiographic Change on Sharp Score; An Exam in Less Than a Minute Can Predict Who Specifically Needs Biologic Therapy. Maria Greenwald[1], Joann Ball[2] and Harold Paulus[3]. [1]Desert Medical Advances, PALM DESERT, CA, [2]Desert Medical Advaces, Palm Desert, CA, [3]UCLA, Los Angeles, CA.

Background/Purpose: Joint dermal temperature (temp) measured in less than a minute can identify specifically the individual RA patient most likely to develop radiographic change on Sharp Score in the next year. There is great debate regarding which patients should be treated with expensive therapies for rheumatoid arthritis (RA). Certain subsets of RA patients are more likely to cripple, such as sero-positive disease, those earlier in disease onset, and earlier age at onset, and higher inflammatory non-specific markers (like amyloid, fibrinogen). However, can we identify a specific patient at most risk for radiographic changes. We evaluated the power of touch to determine disease. It has long been noted in the literature that skin over a gout joint is "hot", which we define as a temp equal to or above central temp. Elevated skin temps occur also over septic joints and RA. The hot joint will identify which individual is destined for new xray erosions.

Methods: A digital clinic dermal thermometer was used to record vital signs, both at skin on the forehead and over any painful joint, most often the wrist. The dermal temp can be measured accurately and in less than a minute (accuracy ±0.1 F). Sequentially 208 sero-positive RA patients on MTX (15–25 mg/week) and with baseline plus one year follow up hand/feet xrays were enrolled. No biologic therapy was permitted. Xrays were scored by a single reader (MG) with a modified van der Heijde total Sharp score (mTSS) without sequence order or identifiers. Medical history, WESR, CRP, baseline medications and xray were performed at screening. A small group of subjects without RA (n=25) were used as controls to evaluate the usual range of joint temp.

Results: The dermal temp at a wrist of normal persons without RA is −12.0±4.6 F. The "hot" joint RA group had a joint temp in excess of central temp +1.06±0.69 (CI 0.23) and neared a 4-fold higher individual risk of new erosions compared to those RA "cool" joints. Results were highly significant, $p<0.001$. Sensitivity for joint temp predicting erosions is 91.7% and specificity for joint temp predicting erosions 78%. Newer onset of RA, younger age, and WESR were mildly significant ($P<0.05$) but had poor specificity and sensitivity.

Conclusion: A simple dermal temperature taken with a standard digital thermometer can quickly and accurately identify RA patients who are at high risk for further destructive change on MTX alone. This can be submitted to insurers, national health registries, and provides objective data to what we have known for centuries, that the human hand can detect active disease.

Rheumatoid Arthritis-Associated Interstitial Lung Disease: Risk Factors for Disease Progression. Yashaar Chaichian, Imre Noth, Mary Strek, Tammy O. Utset and Rekha Vij. University of Chicago Medical Center, Chicago, IL.

Background/Purpose: Rheumatoid arthritis (RA) is the most common systemic connective tissue disease in the U.S. Interstitial lung disease (ILD) is a frequent extra-articular manifestation of RA that contributes significantly to morbidity and mortality. While risk factors for developing ILD have been identified, less is known about factors that predict prognosis. The objectives of this study were to identify factors associated with RA-ILD progression and determine how often RA-ILD pulmonary activity parallels joint disease activity.

Methods: We performed a retrospective analysis of adult patients with RA-ILD at the University of Chicago Medical Center. Demographic and clinical information were extracted from medical records. All patients met ACR 1987 classification criteria for RA. ILD diagnosis required interstitial abnormalities on high-resolution chest CT plus confirmation by a pulmonologist, with or without restrictive pattern on pulmonary function tests (PFTs) or compatible lung biopsy. Progressive RA-ILD was defined as decrease in forced vital capacity of ≥10% or diffusing capacity for carbon monoxide of ≥15% on serial PFTs ≥8 weeks apart. Progressive joint disease was defined as evidence of new erosion or persistent flare by rheumatologist on successive visits ≥8 weeks apart. Patients with parallel ILD and joint activity had worsening in PFTs and joint disease activity within 3 month overlapping period. Subgroups of patients were compared using Fisher's exact tests for categorical variables and ANOVA for continuous variables.

Results: We identified 47 RA-ILD patients. Thirty six (77%) had progressive RA-ILD and 11 (23%) had stable RA-ILD. High-titer rheumatoid factor (RF), >3 times upper limit of normal, was associated with progressive RA-ILD ($p=0.0394$) while high-titer cyclic citrullinated peptide (CCP) antibody ($p=0.0973$) and smoking history ($p=0.0933$) trended towards association. Twenty eight patients had serial rheumatology assessments coinciding with PFTs: 9 (32%) had parallel ILD and joint disease activity, and 19 (68%) had non-parallel disease activity. Usual interstitial pneumonia (UIP) was the most common radiographic pattern in patients with progressive and stable RA-ILD. There was a slight predominance of UIP as the radiographic pattern in patients with non-parallel ILD and joint disease activity. Radiographic patterns other than pure UIP were slightly more frequent in patients with parallel ILD and joint disease activity.

Conclusion: High-titer RF was associated with RA-ILD progression in this cohort. High-titer CCP antibody and smoking history trended towards

association with progressive RA-ILD. Thus, we propose that RA-ILD patients with these risk factors merit closer monitoring for disease progression. For the majority of our RA-ILD cohort, ILD and joint disease activity did not parallel one another. This finding highlights the importance of monitoring joint and lung disease separately, as different factors may contribute to articular and pulmonary disease flares in RA-ILD patients. Furthermore, these results suggest that articular and pulmonary disease activity should be considered separately for therapeutic decision-making.

Bronchiectasis: A Model for Chronic Bacterial Infection Inducing Autoimmunity in Rheumatoid Arthritis. Anne-Marie Quirke[1], Elizabeth Perry[2], Alison Cartwright[1], Clive Kelly[3], Anthony De Sozya[4], Paul Eggleton[5], David Hutchinson[2] and Patrick Venables[1]. [1]University of Oxford, Oxford, United Kingdom, [2]Royal Cornwall Hospital, Truro, United Kingdom, [3]Queen Elizabeth Hospital, Gateshead, United Kingdom, [4]The Freeman Hospital, Newcastle, United Kingdom, [5]University of Exeter, Exeter, United Kingdom.

Background/Purpose: Anti-citrullinated peptide antibodies (ACPA) are associated with smoking in patients with rheumatoid arthritis (RA). Bronchiectasis (BR), which tends to occur in non-smokers, has been recognised as an uncommon, but potent risk factor for RA for 50 years. Here we examine the potential of BR in generating ACPA in patients with BR alone and in patients with BR and RA (BRRA).

Methods: The multi-centre study included 122 patients with BR alone, 50 BRRA, 50 RA without lung disease, compared with 87 asthma and 79 healthy subjects as controls. All RA patients met the 2010 ACR criteria for RA. ACPA were measured using CCP2 and fine specificities to citrullinated α-enolase (CEP-1: ^{4}KIHA-cit-EIFDS-cit-GNPTVE^{21}), citrullinated vimentin (cVim: ^{59}VYAT-cit-SSAV-cit-L-cit-SSVP^{74}) and citrullinated fibrinogen, β chain (cFib: ^{36}NEEGFFSA-cit-GHRPLDKK^{52}), with their arginine control peptides (REP-1, Vim, and Fib) by ELISA. The cut-off for positivity for CCP2 was 5 U/ml as per manufacturers instructions and for the remaining peptides was calculated using the 95th percentile of the healthy controls. The Mann-Whitney U test was used to calculate p-values for differences between the results for each assay and Spearman non-parametric correlations between datasets were calculated.

Results: In the BR patients without RA, there was an increased antibody reponse to the uncitrullinated variants of the antigens tested in this study. Anti-CCP2 antibodies were positive in 5% of patients, significantly increased above the healthy ($p< 0.001$) and asthma ($p<0.01$) controls. The anti-CCP2 arginine control test (anti-CPArg) was also significantly increased in 19%. Similarly, antibodies to the arginine control peptides from the specific citrullinated antigens were also increased: REP-1 19% ($p <0.01$), Vim 16% ($p<0.01$) and Fib 9% (p ns), compared to both healthy and asthma controls. There was a corresponding increase in antibodies to the citrullinated peptides which in each case strongly correlated with their uncitrullinated variants (Spearman ρ values $=0.512– 0.798$), further supporting the findings of a citrulline-independent autoantibody response in BR.

In contrast to the BR patients, the BRRA patients had a highly citrulline specific ACPA response and the rate of seropositivity in BRRA vs RA was significantly increased for each ACPA tested: anti-CCP, 88% vs 48%; anti-CEP-1, 60% vs 24%; anti-cVim, 56% vs 20% and anti-cFib 74% vs 40% (each $p<0.001$) despite a lower frequency of smoking (42% vs 58%; $p=0.06$). The citrulline specificity of the RA ACPA response was confirmed by the lack of correlation with response to the arginine-containing peptides (Spearman ρ values < 0.298). Collectively, these data show that the citrulline specificity of ACPA in BRRA is increased compared to BR alone and its magnitude is increased compared to RA without any lung disease.

Conclusion: These findings provide further evidence linking BR to RA by indicating that BR may generate ACPA in two stages: firstly a citrulline independent B-cell response to host or bacterial antigens in the lungs with a subsequent evolution of citrulline specificity in the cases where BR evolves into BRRA.

Characterization of Lung Inflammation in the Lungs of Early Rheumatoid Arthritis. Gudrun Reynisdottir[1], Vijay Joshua[2], Aase Haj Hensvold[2], Lars Klareskog[3] and Anca I Catrina[2]. [1]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet,, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Karolinska institutet, Stockholm, Sweden.

Background/Purpose: We have previously demonstrated that lung abnormalities are present already at disease onset in ACPA positive RA patients. We aimed to further investigate lung changes in patients with rheumatoid arthritis (RA) in dynamic in a follow-up clinical study.

Methods: 105 RA patients (with patient-reported symptom duration less than 1 year and naive to DMARD treatment) were investigated by lung HRCT and functional pulmonary testing at disease onset and 6 months after. All patients were started on methotrexate. A smaller subgroup of these patients (n=24) were subjected to bronchoscopy and mucosal large bronchial biopsies and bronchoalveolar lavage (BAL) samples were retrieved at disease onset (n=24) and after 6 months (n=21). Additional 16 large bronchial biopsies and 79 BAL samples from healthy volunteers were available. Histological analysis for identification of inducible bronchia associated lymphoid tissues (iBALT) and lymphocyte infiltration were performed. Further immunohistochemical analysis was performed in RA biopsies to detect PAD enzymes, CD3, HLA-DQ and HLA-DR and to identify citrullinated targets.

Results: Both parenchymal and airway HRCT abnormalities were more frequent among RA patients than controls (54% as compared to 30%, OR 2.7, $p<0.05$ for parenchymal changes and 66% as compared 42%, OR 2.7, $p<0.05$ for airway changes). Fibrosis (12/105, 11%) was solely detected in RA patients. At follow up 4 out of these 12 patients show some progress signs while the remaining 8 were stable.

Bronchial lymphocyte infiltration and iBALT formation was observed at baseline in half of the ACPA+ RA patients but only 1 out of 6 ACPA- patients (17%) and 1 out of 9 healthy volunteers (10%). Signs of such infiltration were still present at 6 months. Higher expression of HLA-DR, HLA-DQ and citrullinated targets was observed in bronchial biopsies of ACPA+ as compare to ACPA- RA ($p<0.05$). CD3 expression also showed a tendency to higher expression in the ACPA+ as compared to ACPA- RA patients. HLA-DR expression showed a tendency to decrease at 6 months but no significant changes were observed.

ACPA+ RA patients had significantly higher proportions of BAL lymphocytes and neutrophils as compared to healthy controls ($p<0.05$). The increased relative numbers of BAL lymohcoytes at disease onset was found reduced after 6 months of treatment ($p<0.05$). Markers of T cell activation (CD69 and CD103) were expressed by significantly more CD4+ BAL T cells in ACPA+ RA patients as compared to healthy controls, but no significant changes were observed at follow-up.

Conclusion: HRCT changes, signs of inflammation and accumulation of highly activated and differentiated BAL CD4+ T cells are present early in the lungs of ACPA+ RA patients and show relatively minimal changes during 6 months follow-up.

Smoking Functions As a Negative Regulator of IGF-1 Levels and Adipokine Network in Patients with Rheumatoid Arthritis. Maria Bokarewa[1], Malin Erlandsson[2], Sofia Töyrä Silfverswärd[3], Andreea Ioan-Fascinay[4] and Roberto Doria Medina[3]. [1]University of Goteborg, Goteborg, Sweden, [2]University of Gothenburg, Gothenburg, Sweden, [3]University of Göteborg, Göteborg, Sweden, [4]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Smoking is an important player in the pathogenesis of rheumatoid arthritis (RA) being tightly connected to the genetic (carriage of HLA-DRB1 shared epitope) and serological (production of autoantibodies) risk factors for the development of RA. The molecular events connecting cigarette smoking to severe joint inflammation and low efficacy of

anti-rheumatic drugs, are poorly understood. Adipokines is a family of signalling molecules originating from adipose tissue and regulating carbohydrate metabolism and soft tissue regeneration. In RA, adipokines are connected to the disease activity and progressive radiological joint damage. Numerous effects of adipokines are mediated through insulin receptor/insulin-like growth factor-1 receptor (IGF-1R) complex.

Here we address a potential connections between cigarette smoking and changes in IGF-1 signalling and adipokine network function in patients with RA.

Methods: 543 patients from 2 independent RA cohorts (Göteborg, n=350 and Leiden, n=193) were included in this observational study. Patients were divided by their smoking habits defined as present smokers (n=126), ex smokers (n=177) and never smokers (n=240). Serum levels of total IGF-1 and adipokines (adiponectin, leptin, resistin and visfatin) were measured with sandwich ELISAs. The patient groups were compared by quantitative statistics and the association between smoking and serum parameters were evaluated by bivariate and multivariate correlation analysis.

Results: The two studied cohorts differed in disease duration, where the Leiden cohort consisted of early RA patients (DD md 0.4 years), higher disease activity (DAS28 md 5.1) and higher VAS-pain (md 46mm), while the Göteborg cohort consisted of patients with established RA (DD md 7.5 years), low DAS28 (md 3.0) and VAS-pain (md 27mm). In both cohorts the smokers were more often men ($P<0.001$).

Serum levels of IGF-1 were significantly lower in the present smokers followed by ex smokers. RA patients who never smoked had significantly higher serum levels of IGF-1 ($P<0.001$). Levels of adiponectin were also higher in never smokers ($P=0.002$). The correlation between leptin and resistin observed in the whole material was significantly weaker in the present smokers (rho=0.357) compared to the never smokers (rho=0.520). The present smokers had stronger correlations between IGF-1 and leptin (rho=0.233, $P=0.009$), resistin (rho=0.210, $P=0.018$). These correlations were not observed in the never smokers or the ex smokers.

The logistic regression analysis showed that low levels of IGF-1 were associated with low levels of leptin and visfatin and with current smoking. Neither age, gender, DAS28 nor BMI was contributing significantly in the regression model. Clinical impact of low leptin levels evaluated in a different logistic regression model showed an association with high DAS28, male gender and high BMI.

Conclusion: Smoking is associated with lower serum levels of IGF-1 in RA patients. The link between IGF-1 and the adipokines network is dependent on the smoking habit of the patient, and potentially supporting sustained disease activity and reducing regeneration processes in the damaged arthritic joints in RA patients.

Increasing Cartilage Turnover in Smokers Developing Rheumatoid Arthritis Is Associated with High Disease Activity in Early Disease. Carl Turesson[1], Christina Book[2], Ulf Bergström[2], Lennart Jacobsson[2] and Tore Saxne[3]. [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Lund University, Malmö, Sweden, [3]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden.

Background/Purpose: Autoantibodies and other biomarkers of rheumatoid arthritis (RA) that may be detected years before disease onset in a subset of investigated individuals could be affected by exposures such as smoking. Changes in biomarker levels from the pre-clinical phase to early RA may reflect mechanisms that determine the disease phenotype. Cartilage oligomeric matrix protein (COMP) is a marker of cartilage turnover that has been shown to predict progression of joint damage in RA. Our purpose was to investigate the relation between COMP and smoking, as well as changes in COMP from the pre-clinical phase to early RA, and how these relate to early disease activity.

Methods: Between 1991 and 1996, 30 447 subjects from a defined catchment area were included in a health survey. From this population, individuals who developed RA after inclusion were identified by linking the health survey database to a community based RA register and local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 ACR criteria for RA. One control for each validated case, matched for sex, year of birth and year of screening, who was alive and free of RA when the index person was diagnosed with RA, was selected from the health survey database. Furthermore, the identified sample of incident cases of RA was linked to an inception cohort of early RA patients (symptom duration <12 months) from the same area. Serum COMP in pre-RA cases and controls, as well as in patients with early RA, was measured with a sandwich ELISA (AnaMar).

Results: Serum was available from 167 individuals (131 women, mean age at screening 63 years) who were diagnosed with RA after inclusion in the health survey (a median of 5 years later (range 1–13)). COMP levels were significantly lower among current smokers compared to non-smokers in pre-RA cases (mean 10.1 vs. 11.5 U/L; $p=0.009$) as well as in controls (mean 10.7 vs 11.9 U/L; $p=0.046$). Fifty-seven cases (44 women) were also included in the early RA cohort after a median of 4.9 years (interquartile range 3.6–6.7). At inclusion, their mean age was 65 years, 56 % were anti-CCP positive and the mean DAS28 was 4.6 (SD 1.1). COMP levels increased significantly from the pre-RA sample to inclusion in the early RA cohort (mean change 1.6 U/L (SD 4.2); $p=0.006$). An increase in COMP tended to be associated with higher DAS28 at inclusion in the early RA cohort (β 0.09; 95 % confidence interval (CI) −0.01 to 0.18; adjusted for age, sex and baseline COMP). This association was observed in particular among smokers at baseline (n=22) (adjusted β 0.22; 95 % CI 0.04 to 0.39) and to a lesser extent in non-smokers (n=35) (adjusted β 0.06; 95 % CI −0.07 to 0.19).

Conclusion: COMP levels were lower in smokers among pre-RA cases as well as in controls who did not develop RA. Increasing COMP in the pre-clinical phase of RA appeared to be associated with a severe RA phenotype, in particular among smokers. The relation between early changes in cartilage turnover and long term outcomes in RA should be further studied.

Anti-Citrullinated Heat Shock Protein 90 Antibodies Identified in Bronchoalveolar Lavage Fluid Are a Marker of Lung-Specific Immune Responses. Lisa Harlow[1], Bernadette Gochuico[2], Ivan Rosas[3], Tracy Doyle[3], Juan Osorio[3], Timothy Travers[4], Carlos Camacho[4], Chester V. Oddis[4] and Dana P. Ascherman[1]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]National Institutes of Health, Bethesda, MD, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Previous work has demonstrated an association between serum anti-citrullinated HSP90 antibodies and rheumatoid arthritis-associated interstitial lung disease (RA-ILD). To further investigate this potential pathogenic relationship, we assessed anti-citrullinated HSP90 antibody profiles in bronchoalveolar lavage fluid (BALF) isolated from RA patients with and without ILD.

Methods: BALF and corresponding serum samples were collected from a well-defined cohort of RA patients with various stages of ILD. Specimens obtained from these subjects were then subjected to enzyme-linked immunosorbent assays (ELISAs) using recombinant HSP90 isoforms and derivative peptides as substrate antigens. While comparison of resulting BALF-associated antibody profiles to those identified in healthy controls and patients with idiopathic pulmonary fibrosis (IPF) permitted assessment of disease specificity, evaluation of matching serum specimens provided insight regarding relative antibody production in lung and extra-pulmonary tissue compartments.

Results: 9/21 RA-derived BALF specimens demonstrated either IgG or IgA antibodies targeting citrullinated HSP90 proteins/peptides, highlighting disease specific immune responses (with a predilection for RA-ILD) that did not occur in IPF patients (0/5) or healthy control subjects (0/5). Discordance between these antibody responses and BALF anti-CCP2 reactivity (IgG, IgA) provided clear evidence of antigen specificity (as only 3/21 BALF samples possessed antibodies recognizing both CCP2 and citrullinated HSP90 derivatives). Furthermore, comparison of antibody profiles between BALF and matching serum specimens revealed several different recognition patterns favoring predominant production of anti-citrullinated HSP90 antibodies within the lung microenvironment.

Conclusion: IgG and IgA anti-citrullinated HSP90 antibodies occur preferentially in BALF derived from patients with RA-ILD, supporting the connection between this antibody specificity and parenchymal lung disease. Moreover, qualitative as well as quantitative differences in anti-citrullinated HSP90 profiles between BALF and serum indicate that the lung plays a direct role in shaping the immune repertoire of RA/RA-ILD.

Distinct Profiles of Proinflammatory Macrophages in Rheumatoid Arthritis and Coronary Artery Disease. Tsuyoshi Shirai[1], Eric L. Matteson[2], David G. Harrison[3], Barbara B. Wallis[4], Themistocles L. Assimes[1], Jorg J. Goronzy[1] and Cornelia M. Weyand[1]. [1]Stanford University School of Medicine, Stanford, CA, [2]Mayo Clinic, Rochester, MN, [3]Vanderbilt University School of Medicine, Nashville, TN, [4]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.

Background/Purpose: Patients with RA have an increased risk of developing coronary artery disease (CAD) compared to the general population. The underlying pathological process of CAD is atherosclerosis, which is a chronic inflammatory disease caused by maladaptive inflammatory responses. Macrophages are key players in the progression of atherosclerosis, contributing through proinflammatory effector functions, such as cytokine production. It is currently unknown whether accelerated CAD in RA results from similar or distinct pathomechanisms that underlie non-RA CAD. This study was designed to define and compare proinflammatory macrophages in patients with CAD and RA to clarify their potential contribution to the process of atherosclerosis.

Methods: Healthy controls, patients with RA who satisfied the ACR classification criteria, and patients with CAD who had a history of at least one myocardial infarction in the absence of co-existent autoimmune disease, were enrolled into this study. Monocytes isolated from peripheral blood mononuclear cells were differentiated into macrophages with M-CSF for 5 days. Macrophages were further differentiated into M1 or M2 with IFN-γ and lipopolysaccharide or IL-4 and IL-13, respectively, for 2 days. RNA was purified from macrophages, and the expressions of 55 genes were measured using quantitative PCR. Cytokine production was quantified by multi-parametric flow cytometry.

Results: The gene expression signatures of macrophages derived from healthy controls, RA and CAD were significantly different ($p<0.01$). CAD macrophages were characterized by high production of IL-6 and IL-1β (7.8 and 6.4-fold upregulation compared to controls, $p=0.04$ and $p=0.03$, respectively), a phenotype that RA macrophages did not share. CAD macrophages expressed high levels of chemokine receptors including CCR2, CCR5, and CCR7, while RA macrophages expressed similar levels of chemotactic receptors as healthy macrophages. The expression of the transcription factors Kruppel-like factor (KLF)-2 and KLF-4 also distinguished CAD and RA macrophages. KLF-2 and KLF-4 were distinctly low in CAD macrophages ($p=0.04$ and $p= 0.02$, respectively), but well maintained in RA macrophages. A characteristic feature of RA macrophages was the high expression of CCL18, a CC chemokine attracting predominantly T lymphocytes. The signature of RA macrophages included the suppression of activation-induced IFN-β, indicating a down-regulation of type 1 IFN-dependent immunity.

Conclusion: CAD macrophages have a signature of super-inflammatory effector cells, characterized by the loss of negative regulators of inflammation (KLF-2; KLF-4) and the gain of cytokine production capability, releasing high amounts of IL-6 and IL-1β. Because of high expression of chemotactic receptors, they can efficiently navigate through the atherosclerotic plaque to enhance inflammation. In contrast, RA macrophages appear less mobile and are able to amplify inflammation through the CCL18-dependent recruitment of T cells. The data suggest that macrophage-dependent immune responses are fundamentally different in RA and CAD.

The Anti-IL-6 Antibody Sirukumab Inhibits Vascular Inflammation in a Human Surrogate Model of Atherosclerosis. Ryan Feaver[1], Sol Collado[2], Stephen Hoang[2], Erica Berzin[2], Allison Armstrong[3], Debbie Gardner[4], Paul Fisher[5], Hao Liu[6], Aaron Mackey[2], David Manka[2], Brian Wamhoff[2], David Shealy[4] and Brett Blackman[2]. [1]HemoShear, LLC, Charlottesville, VA, [2]HemoShear, LLC., Charlottesville, VA, [3]HemoShear, LLC., Virginia, VA, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Janssen Research & Development, LLC., Spring House, PA, [6]Immunology Research, Janssen Research and Development, LLC., Spring House, PA.

Background/Purpose: Rheumatoid arthritis (RA) and atherosclerosis are chronic inflammatory diseases that share many biological features. Prevalence of atherosclerosis is increased by approximately 2-fold in RA, with at least 2 prominent molecular links between the two diseases: IL6 and TNFα signaling. Elevated circulating IL6 is an independent risk factor for cardiovascular disease and correlates with RA disease progression in patients. To test the hypothesis that compounds used for the treatment of RA decrease vascular inflammation under atherogenic conditions.

Methods: To elucidate the impact of RA treatments on vessel wall health, a novel *in vitro* human surrogate system that co-cultures human endothelial (EC) and smooth muscle cells (SMC) was used. Atheroprone flow conditions were applied, based upon human hemodynamic blood flow from the carotid bifurcation, a site prone to developing atherosclerosis. Atherogenic risk factors were added to the culture medium, including *in vivo* circulating concentrations of oxidized LDL (oxLDL) and TNFα. In addition, soluble IL-6 receptor (sIL6R) was added at a concentration typically seen in patient sera. RNA sequencing and multiplex protein assays were used to perform transcriptomic and bioanalytical pathway analyses of the response of the human surrogate system. We compared treatments that target pathogenic RA pathways including anti-IL6 and anti-IL6 receptor antibody (sirukumab or tocilizumab, respectively), anti-TNFα antibody (adalimumab) and a small molecule inhibitor of JAK (tofacitinib) at C_{min} doses.

Results: Using this model, the combination of sIL6R, TNFα and oxLDL induced a robust transcriptional response of inflammatory genes under atheroprone hemodynamics compared to control conditions without sIL6R or TNFα and with non-oxidized LDL. The anti-IL6/IL6R treatments (sirukumab, tocilizumab) significantly improved the vascular health phenotype relative to control IgG treatment. Both sirukumab and tocilizumab dramatically decreased adhesion molecule gene expression and NFkB-dependent genes while simultaneously increasing vasculoprotective responses such as eNOS and KLF2 expression, and promoting a contractile SMC phenotype. Adalimumab showed a weaker but similar trend compared to IL6 inhibition, while tofacitinib was not effective in suppressing inflammation or promoting vascular health. Sirukumab and tocilizumab were more effective in suppressing TNFα signaling than adalimumab. Although broadly comparable, sirukumab was more potent than tocilizumab in suppressing inflammation and promoting vascular health.

Conclusion: These data suggest that the IL6 pathway inhibitors (sirukumab and tocilizumab) potently suppress inflammation and promote vascular health in an *in vitro* model of RA-associated cardiovascular disease. In contrast the TNFa inhibitor, adalimumab, and JAK inhibitor, tofacitinib, were less effective in alleviating the disease phenotype. Collectively, the data suggest that IL6 inhibition may provide vascular protection in patients with RA.

440

Comparison of C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR) with Estimated Glomerular Filtration Rate (eGFR) in Patients with Rheumatoid Arthritis (RA). Ilias Oikonomopoulos[1] and John D. Carter[2]. [1]University of South Florida Morsani College of Medicine, Tampa, FL, [2]University of South Florida, Tampa, FL.

Background/Purpose: It has previously been demonstrated that the ESR and CRP correlate in patients with RA but with a high degree of variability. Reasons for this variability are not completely understood, but anemia, adiposity, and age can play a role. It has previously been suggested that ESR and CRP are inversely related to renal function in a non-RA population; it is felt that underlying inflammation is the explanation for the negative correlation with the CRP, specifically. The aim of this study is to see if the CRP and/or ESR inversely correlate with renal function in patients with RA.

Methods: This is a retrospective chart review of RA patients followed at USF Health. Subjects were identified by ICD-9 code (714.0) and they had to have a CRP, ESR, hemoglobin (Hgb) and eGFR performed on the same day. The most recent labs were utilized and no patient was included twice. Patients were excluded if they were <18 years of age or had a history of blood cancers known to affect inflammatory markers. The co-primary endpoints were the correlation between CRP and eGFR as well as ESR and eGFR. Secondary endpoints included correlation between CRP and ESR as well as both inflammatory markers with Hgb and the patients' age. Spearman correlation coefficients (rho) were utilized to determine significance.

Results: 158 patients met the inclusion criteria; 136 (86%) were females with a mean age of 58.82 years (+/− 11.44 SD; range 26–84 years). 93/130 (71.5%) of these subjects were seropositive; status was unknown on 28

patients. The mean CRP and ESR in these subjects was 0.89mg/dL (+/− 1.37mg/dL SD) and 16.07mmHg (+/− 16.61mmHg SD), respectively; the mean eGFR and Hgb was 82.76 mL/min/1.73m^2 (+/− 20.92 mL/min/1.73m^2 SD) and 12.77g/dL (+/− 1.31g/dL SD), respectively. There was no correlation between the CRP and the eGFR (rho = 0.041; p = 0.60) [Fig 1]; there was also no correlation between the ESR and the eGFR (rho = −0.037; p = 0.64) [Fig 1]. There was a correlation between the CRP and ESR but with a high degree of variability (rho = 0.596; p < 0.0001) [Fig 1]. The ESR correlated weakly with Hgb and it did so in an inverse fashion (rho = −0.348; p<0.0001); the CRP did not appear to correlate with the Hgb (rho = −0.115; p = 0.15). There was no correlation with either CRP or ESR and age (rho = −0.075 and 0.006 respectively).

Conclusion: This retrospective chart review of 158 patients with RA suggests there is no correlation between CRP and/or ESR with renal function. Renal function does not appear to be an explanation for some of the variability that is documented between CRP and ESR in patients with RA.

Arthritis Associated Autoantibodies in Non-Rheumatoid Arthritis Patients with Mucosal Inflammation. Koen M. J. Janssen[1], Menke J. de Smit[1], Elisabeth Brouwer[1], Berber Doornbos-van der Meer[1], Arie Jan van Winkelhoff[1], Arjan Vissink[2], Josje Altenburg[3], Nivine Levarht[4], Marije K. Verheul[4], Leendert A. Trouw[4] and Johanna Westra[1]. [1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [3]Medical Center Alkmaar, Alkmaar, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) associated autoantibodies, such as anti-citrullinated protein antibodies (ACPA), rheumatoid factor (RF) and anti-carbamylated protein antibodies (anti-CarP), can be present in serum years before clinical manifestation of RA. High ACPA-levels have been associated with a negative disease outcome. Recently, initiation of ACPA-response has been hypothesized to occur at inflamed mucosal surfaces, e.g., in the oral cavity. Therefore, it is of particular interest to investigate the IgA ACPA response and other IgA autoantibodies. The aim was to assess ACPA and anti-CarP autoantibodies levels (IgG and IgA) in serum of patients with mucosal inflammation at different sites, namely in periodontitis, cystic fibrosis and bronchiectasis patients, all without a diagnosis of RA.

Methods: Autoantibody levels were assessed in periodontitis, cystic fibrosis and bronchiectasis patients. As controls, healthy subjects without periodontitis (HC) and a cohort of established RA-patients were added (Table 1). IgG anti-CCP2 levels were measured by ELISA (EuroDiagnostica, cut-off mean +2SD of HC). IgA anti-CCP2 levels were measured by a modified anti-CCP2 ELISA. Citrulline specificity of the anti-CCP2 response was assessed by measuring antibody levels against the arginine control peptide CAP (EuroDiagnostica). Serum IgM and IgA RF levels (cut-off >15, >25 IU/ml, respectively) and IgG antibodies against carbamylated FCS (cut-off mean +2SD of a distinct healthy control cohort) were measured by an in-house ELISA. IgG and IgA antibody levels against four citrullinated peptides (fibrinogen-1, 2, α-enolase and vimentin) were measured by ELISA in which the reactivity was corrected for the native peptides and positivity was defined as mean + 2SD of HC.

Results: Although RA autoantibody levels in periodontitis, cystic fibrosis and bronchiectasis patients were overall low, IgG seropositivity for anti-CAP (9.6%, 9.8% and 13.8%, respectively), anti-CCP2 (13.2%, 24.4% and 21.3%, respectively), and anti-CarP (3.5%, 7.3% and 3.8%, respectively) tended to be more prevalent in these groups compared to HC (5.6%, 5.6% and 0%, respectively). Comparable results were observed for IgA seropositivity. No increased seropositivity was observed for antibodies against the four citrullinated peptides. In bronchiectasis patients, seropositivity for IgM and IgA RF was significantly increased (18.8%, 23.8%) compared to HC (0%, 2.8%).

Table 1: Characteristics of patients and healthy controls assessed for presence of autoantibodies.

	Healthy controls	Periodontitis patients	Cystic fibrosis patients	Bronchiectasis patients	Rheumatoid arthritis patients
No. of subjects	36	114	41	80	88
Age, mean ± SD	34 ± 15	51 ± 9**	29 ± 8*	63 ± 11**	60 ± 11**
Female, sex (%)	56	59	49	63	69

Group characteristics were compared to healthy controls using Mann Whitney test. *p< 0.05, **p< 0.0001

Conclusion: Presence of anti-CCP2 and anti-CarP is slightly more prevalent in serum of non-RA patients with mucosal inflammation. The increased levels of anti-CAP indicate that at least part of the increased anti-CCP2 reactivity might not be citrulline specific. In conclusion, our observations might be clinically relevant as we presume that once ACPAs are initiated they can mature in individuals that are genetically pre-disposed for RA.

Anti-Carbamylated Protein Antibody Levels Are Elevated in Seropositive Rheumatoid Arthritis and Correlate with Anti-Sa/Citrullinated Vimentin Antibody Levels. Gregory J. Challener[1], Jonathan D. Jones[1], B. JoNell Hamilton[1], Gilles Boire[2], Artur José de Brum-Fernandes[2], Pierre Cossette[2], Patrick Liang[2], Ariel Masetto[2], Nathalie Carrier[2], Henri A. Ménard[3] and William F.C. Rigby[1]. [1]Geisel School of Medicine at Dartmouth College, Lebanon, NH, [2]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [3]Research Institute of the McGill University Health Center, Montreal, QC.

Background/Purpose: Recent studies indicate that the breach of immune tolerance that occurs in rheumatoid arthritis (RA) extends beyond the citrullination of arginines (as recognized by anti-citrullinated protein antibodies; ACPA) to homocitrullination of lysines. Since 2011, humoral responses to homocitrullinated proteins (subsequently referred to as anti-carbamylated protein antibodies; ACarP Ab) have been reported in both early and established seropositive RA. We analyzed the relationship of serum/plasma levels of ACarP Ab to several clinical and serologic parameters, using both established and early RA cohorts.

Methods: Carbamylation of fetal calf sera was performed as previously described [1]. Patients with established RA (n=212) were recruited at Dartmouth-Hitchcock Medical Center (Lebanon, NH, USA). Serum and/or plasma ACarP Ab, anti-Sa Ab, CXCL13, rheumatoid factor (RF), ACPA (specifically, anti-CCP2 Ab) and total IgG were measured by ELISA. Seropositivity (positive for RF, anti-CCP or both) and C-Reactive Protein

level were determined by the clinical lab. A confirmatory analysis was performed using samples from early RA patients included in the Sherbrooke, QC (Canada) cohort. T-test, ANOVA and correlation analysis were utilized to evaluate relationships between variables. 63 healthy controls were also evaluated for levels of ACarP Ab.

Results: Among seropositive patients in the Dartmouth cohort (n=164), 46.6% exhibited elevated levels of ACarP Ab. ACarP Ab titers correlated with levels of ACPA (p=0.004) and IgM-RF (p=0.04). Seropositive patients in the early RA Sherbrooke cohort (n=173) displayed similar trends; 38.2% had elevated ACarP Ab levels, and ACarP Ab titer was highly associated with levels of ACPA (p=0.005) and weakly associated with IgM-RF (p=0.06). The relationship of ACarP Ab levels with baseline clinical parameters (age, DAS28-CRP, erosions, etc.) was either weak or absent in both cohorts. Intriguingly, we observed a highly significant correlation between anti-Sa status and ACarP Ab titer among seropositive patients in the Sherbrooke cohort ($p<0.0002$), with 47.9% of anti-Sa-positive patients harboring elevated levels of ACarP Ab versus 25.4% of anti-Sa-negative patients. This observation led us to test seropositive RA samples in the Dartmouth cohort for anti-Sa status; once again, a highly significant relationship was observed ($p<0.000001$); 62.6% of anti-Sa-positive patients showed elevated ACarP Ab levels versus 26.9% of anti-Sa-negative patients.

Conclusion: This is the first investigation of ACarP Ab levels in a population of established RA patients in the US, comparing it with an early RA Canadian cohort. A large proportion of each seropositive RA cohort exhibited elevated levels of ACarP Ab (38.2–46.6%). Most compellingly, we identified a strong relationship between levels of ACarP Ab and anti-Sa reactivity that raises the mechanistic question of how antibody responses to carbamylated proteins and citrullinated vimentin (Sa) are linked *in vivo*.

Sputum Anti-Citrullinated Protein Antibodies in Patients with Long Standing Rheumatoid Arthritis. Ari Polachek[1], Wilma Vree Egberts[2], Elizabeth Fireman[3], Daphna Paran[3], Ido Drokman[4], Ilana Kaufman[4], Irena Wigler[5], Dan Caspi[6], David Levartovsky[7], Ger JM Pruijn[8] and Ori Elkayam[9]. [1]Tel Aviv Medical Center, Tel Aviv, Israel, [2]Radboud University Medical Centre, Nijmegen, Israel, [3]Tel-Aviv Medical Center, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [4]Sourasky Medical Center, Tel-Aviv, Israel, [5]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [6]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [7]Tel Aviv Medical Ctr, Tel Aviv, Israel, [8]Department of Biomolecular Chemistry, Radboud University, Nijmegen, Netherlands, [9]Tel-Aviv Medical Center, Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel.

Background/Purpose: The lung has been implicated in the pathogenesis of rheumatoid arthritis (RA). The aim of this study was to evaluate the presence of autoantibodies to citrullinated (Cit) and non-citrullinated (Arg) forms of 2 cyclic synthetic peptides (ACPA) in the sputum of patients with long standing rheumatoid arthritis.

Methods: Twenty RA patients (80% female, mean age 62 years) and 15 age/gender matched healthy controls (81% female, mean age 58 years) participated in this study. Demographic and epidemiological data, including age, gender, disease duration and smoking habits, were collected. All the subjects underwent complete lung function tests, and provided induced sputum. The severity of the disease was evaluated in the RA patients by means of DAS score, and hand and feet X rays. Antibodies to Cit and Arg peptides in the sputum of the RA patients and healthy controls, as well as in the serum of the RA patients, were determined by ELISA.

Results: The RA patients suffered from long standing disease (mean disease duration of 12 years), displayed moderate disease activity (mean DAS 3.44), and showed a mean Sharp van der Heijde score of 57.5. Seventy % of the patients were on DMARDs and 65% on biologics, mainly TNF alpha blockers. Sixty % and 68 % of the RA and healthy controls, respectively, were defined as "ever smoker". Eleven of the 20 RA patients showed in most cases high titers of ACPA in their sera. Six of the seropositive (55%) and none of the seronegative RA patients and none of the healthy controls showed detectable levels of ACPA in their sputum. The ratio between the reactivity with Cit and Arg peptides in the sputum was significantly higher in RA sputum than in control sputum (1.33 +/− 1.2 vs. 0.64 +/− 0.14, p=0.02). A positive correlation was found between sputum ACPA and age and serum ACPA in RA patients, as well as between sputum anti-Cit/Arg reactivity ratio and the proportion of neutrophils and lymphocytes in the sputum. No significant correlation was found between sputum ACPA and disease severity, smoking or lung function tests.

Conclusion: ACPA can be detected in the sputum of RA patients and are correlated with the presence in the serum. These findings further strengthen the hypothesized role of the lungs in RA pathogenesis.

Evidence for Citrullination of the Nuclear Transciption Factor Inhibitor of DNA Binding 1 (Id1) in Rheumatoid Arthritis. Ray A. Ohara[1], Gautam Edhayan[1], Christine M. Ha[1], M. Asif Amin[1], Ali S. Arbab[2], Phillip L. Campbell[1], David A. Fox[1] and Jeffrey H. Ruth[1]. [1]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [2]Georgia Regents University, Augusta, GA.

Background/Purpose: Citrullination is a post-translational modification mediated by peptidyl arginine deiminase (PAD) enzyme in which arginine is converted to citrulline. Inhibitor of DNA binding 1 (Id1) is known to be actively transcribed in endothelial progenitor cells (EPCs) and cells that exhibit hyperproliferative responses. Previously, we showed that Id1 is expressed in rheumatoid arthritis synovial tissues (RA STs) and upregulated in RA synovial fluids (SFs), suggesting that Id1 may be post-translationally modified in RA. A more detailed analysis of the structure of Id1 reveals a relatively small protein of approximately 16kDa, but containing 10 modifiable arginines. We show that Id1 can be citrullinated, and that RA STs and SFs contain citrullinated Id1 (cit-Id1), suggesting that cit-Id1 may be pathogenic in the course of RA. We also show that by immunodepletion of Id1, we can reduce the angiogenic potency and overall amount of citrullinated protein in RA SF.

Methods: Id1 concentrations in RA SFs were measured by enzyme-linked immunosorbent assay (ELISA). To further explore the role of Id1 in RA SF, we immunodepleted Id1 with a neutralizing antibody or non-specific IgG ("sham depleted"), and used this in the severe combined immunodeficient (SCID) mouse chimera. Mice grafted with human RA ST were injected i.v. with fluorescently dye-tagged EPCs while receiving simultaneous intragraft injections with the treated SFs. To examine Id1 citrullination, we modified recombinant human (rhu) Id1 by incubation with rabbit PAD enzyme. Cit-Id1 was measured for deimination by a cit-ELISA using an anti-modified citrulline antibody. Citrullinated bovine serum album (BSA) was used as a relative standard. RA SFs imunodepleted with either Id1 or sham depleted were also measured by cit-ELISA to determine the total amount of citrullinated protein contained in RA SFs before and after Id1 depletion. Finally, we homogenized RA ST and performed immunoprecipitation (IP) of Id1 to determine the presence of Id1 and cit-Id1 by Western blotting using anti-human Id1 and anti-modified citrulline antibodies.

Results: We found a 50% reduction in EPC recruitment to intragraft injections of RA SF immunodepleted of Id1 compared to sham depleted RA SF (*$p<0.05$). We measured the amounts of total citrullinated protein in RA SF, and found that by removal of Id1, we could significantly reduce the total amount of citrullinated protein in RA SF (*$p<0.05$). Western blot analysis of Id1 and cit-Id1 confirmed that we could discriminate cit-Id1 from non-cit-Id1, and that we could successfully modify Id1 in vitro. Similarly, Id1 isolated by IP from RA ST homogenates showed that we could detect both Id1 and cit-Id1 in RA ST homogenates, and that a significant portion of the total Id1 in RA ST was in modified form.

Conclusion: We identify Id1 as an angiogenic factor, capable of recruiting EPCs to RA ST. We also show for the first time that Id1 can be modified using rabbit PAD enzyme. The significant shift downward in total citrullination in RA SFs depleted of Id1 indicates that cit-Id1 is present and elevated in the RA SF. We also show that Id1 in the RA ST is also citrullinated. Taken together, we show that Id1 functions as an angiogenic mediator and is robustly deiminated in RA tissues.

Differing Specificities of Anticitrullinated Peptide/Protein Antibodies in Palindromic Rheumatism and Rheumatoid Arthritis: A Case-Control Study. Sonia Cabrera-Villalba[1], María José Gomara[2], Julio Ramirez[1], Georgina Salvador[3], Virginia Ruiz-Esquide[1], M. Victoria Hernández[1], José Inciarte-Mundo[1], Andrea Cuervo[1], Celia Saura[1], Juan D. Cañete[1], Isabel Haro[2] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]IQAC-CSIC, Barcelona, Spain, [3]Hospital Universitario Mutua Terrassa, Barcelona, Spain.

Background/Purpose: Palindromic rheumatism (PR) may evolve to rheumatoid arthritis (RA), particularly in patients with citrullinated peptide/protein antibodies (ACPA), although a significant number of patients do not progress to RA in the long term. Differences in ACPA specificities have been shown between patients with established and preclinical RA. It is unclear whether ACPA specificities differ between patients with longstanding PR and RA. To determine whether there are differences in the recognition of epitopes between patients with longstanding PR and established RA by analysis of different ACPA specificities.

Methods: Case-control study. Cases: patients with pure PR, with no evolution to RA or other rheumatic disease at study entry. Controls: patients with established RA (ACR-87) matched by sex, disease duration and ACPA positivity (commercial CCP2 test [Eurodiagnostica]; NV<50U). ACPA specificity in sera was determined by ELISA test using a synthetic citrullinated peptide of *fibrin* as antigen: [Cit^{630}] α-Fibrin (617–631)(p18), two peptides of *vimentin* ([Cit^{71}] Vim (47–72)(p48), [$Cit^{64,69,71}$] Vim (47–72)(p55)) and one peptide of *α-enolase*: [$Cys^{4,22}$, $Cit^{9,15}$] Enolase (5–21)(CEP-1). The cut off for each ELISA test was established by ROC curves, with a specificity of 98% compared to a healthy population (blood donors, n=64). The presence and number of different ACPA specificities in the two groups was analyzed.

Results: We included 108 patients: 54 PR and 54 RA. 62.9% were female and 66.7% in both groups were CCP2 positive. No significant differences between groups in mean age (51.2±11.3 y vs 54.7±11.8 years) and disease duration (11.6±10.7 y vs. 8.3±6.1 years) were found. PR patients had a lower frequency of some ACPA specificities than RA, which was significant in the case of p 48 vimentin (1.9% RP vs. 14.8% AR, p: 0.015) and, especially, p 55 vimentin (PR 24.1% vs. 59.3% RA, p: <0.001). The mean number of ACPA specificities was lower in PR than in RA patients (0.9±0.9 PR vs. 1.4±1.03 AR, p=0.008). The percentage of sera with no ACPA specificity was greater in PR than in RA patients (42.6% vs 22.2% p= 0.02) (see Table). No differences between groups in the levels of different ACPA specificities were observed.

Conclusion: Patients with PR had a lower frequency of some antigenic specificities of ACPA in comparison with RA patients, especially in the case of citrullinated vimentin**.** PR patients also had a lower total number of specificities than RA patients. PR patients with fewer ACPA specificities and no recognition of citrullinated vimentin may have a better prognosis, without progression to RA.

Table: ACPA specificities in patients with PR and RA

	PR n = 54	RA n = 54	p
CCP2, n,%	36 (66.7)	36 (66.7)	1
CCP2, levels	392.6 ± 527.6	487.4 ± 584.4	0.37

Immunoglobulin a Antibodies to Cyclic Citrullinated Protein Predominate in Individuals at-Risk for Future Rheumatoid Arthritis. Gregory M. Ingolia[1], M. Kristen Demoruelle[1], Mark C. Parish[1], Ryan W. Gan[2], Jason R. Kolfenbach[1], Michael H. Weisman[3], Jane H. Buckner[4], Peter K. Gregersen[5], Ted R. Mikuls[6], James R. O'Dell[7], Richard M. Keating[8], Alvin Yee[9], Michael Mahler[9], Jill M. Norris[2], Kevin D. Deane[1] and V. Michael Holers[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Colorado School of Public Health, Aurora, CO, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Benaroya Research Institute at Virginia Mason, Seattle, WA, [5]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [6]University of Nebraska Medical Center, Omaha, NE, [7]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, [8]Scripps Clinic, La Jolla, CA, [9]INOVA Diagnostics, San Diego, CA.

Background/Purpose: Immunoglobulin A (IgA) autoantibodies (Abs) to citrullinated proteins (ACPAs) are present in the preclinical period of RA development, a finding that suggests a mucosal site of Ab generation (Kokkonen 2011). IgA ACPAs have also been found in subjects at-risk for future RA based on a family history of disease (Arlestig 2012; Barra 2013). In addition, we have identified apparent local lung mucosal generation of IgA RA-related Abs in at-risk subjects (Willis, Demoruelle 2013). Additional findings that serum IgA ACPA predominates during the early natural history of RA would further support initial mucosal generation of RA-related autoimmunity.

Methods: Three groups from the Studies of the Etiology of RA (SERA) project were evaluated: 77 AtRisk subjects who were first-degree relatives of patients with RA or subjects identified through health fair screening and all were serum positive for ≥1 Ab including CCP2 (IgG, Axis-Shield), CCP3.1 (IgG/IgA, INOVA) and rheumatoid factor IgA/M/G (INOVA) without inflammatory arthritis, 53 subjects with seropositive RA (1987 criteria), and 71 blood donor controls. Each subject was tested for ACPA IgA/M/G using CCP3 antigen ELISAs (research use only; donated by INOVA), and by a technician blinded to group status. Positivity for CCP isotypes was mean levels +2 standard deviations in a separate set of 70 random blood donors. Shared epitope (SE) status was determined in AtRisk and RA subjects using published methods (Kolfenbach 2009).

Results: When comparing isotype proportions, IgA-CCP was positive in a higher number of AtRisk subjects than IgM (46.8% vs. 27.3%, p=0.03) (Table), and the prevalence was higher than IgG, although this was not statistically significant (46.8% vs. 39.0%; p=0.33). In contrast, in RA IgG-CCP was more common than IgA and IgM (86.8% vs. 69.8% and 47.2%, respectively; p's^{2}0.03). In Controls, IgA-CCP was also positive in a higher number of subjects than IgM or G (12.7% vs. 2.8% and 1.4%, respectively; p's^{2}0.03). In AtRisk, smoking was associated with positivity for ≥1 CCP isotype; this was not seen in RA, however, RA subjects were more likely to be current smokers than AtRisk. In AtRisk and RA there was no association between CCP isotypes the SE.

Conclusion: The high IgA ACPA positivity in AtRisk and high IgG APCA in RA suggest that mucosal processes may be an early feature of RA-related autoimmunity that later transition to an IgG-dominant process. IgA ACPA positivity in controls also suggests that IgA-CCP is present in wider populations and perhaps related to non-disease-specific immune responses. These findings as well as the association of smoking with ACPA isotypes in AtRisk subjects and current smoking with RA status need exploration in larger studies that examine the genetic, environmental and mucosal factors that may be involved in the evolution of ACPA isotypes in transition from preclinical to clinically apparent RA.

	Controls	AtRisk	RA
N	71	77	53
Age* (mean, SD)	54.9 (12.5)	50.3 (14.5)	58.5 (14.1)
%Female*	79%	71%	83%
%Non-Hispanic White*		71%	85%
Ever smoker*		36%	45%
Current smoker*		8%	45%
≥1 allele with the shared epitope (SE)*		56%	76%
Proportions of CCP positive subjects using commercial assays			
CCP2 (Axis-Shield)**	0.0%	18.2%	83.0%
CCP3.1 (INOVA)**	0.0%	51.9%	84.9%
Proportions of CCP isotype positive subjects			
IgA ACPA**	12.7%	46.8%	69.8%
IgM ACPA **	2.8%	27.3%	47.2%
IgG ACPA **	1.4%	39.0%	86.8%
≥1 ACPA isotype	16.9%	75.3%	88.7%

Comparisons of proportions of CCP isotype positivity within groups

IgA ACPA vs. IgM	**12.7% vs. 2.8%; p = 0.03**	**46.8% vs. 27.3%; p = 0.01**	**69.8% vs. 47.2%; p = 0.02**
IgA ACPA vs. IgG	**12.7 vs. 1.4%; p = 0.01**	46.8% vs. 39.0%; p = 0.33	–
IgG ACPA vs. IgA	–	–	**86.8% vs. 69.8%; p = 0.03**
IgG ACPA vs. IgM	1.45 vs. 2.8%; p = 0.56	39.0% vs. 27.3%; p = 0.12	**86.8% vs. 47.2%; p<0.01**

*Race, smoking and SE status were unavailable for blood donor controls; none of the AtRisk or RA subjects were related. The mean age of AtRisk subjects was less than than RA ($p<0.01$) although there were no significant differences in groups in sex or race. RA subjects were more likely to be current smokers and have ≥1 allele with the SE when compared to AtRisk ($p<0.05$).
**Positivity for all autoantibodies was significantly higher in RA than other groups, and higher in AtRisk when compared to controls. Within the AtRisk subjects, smoking was associated with positivity for ≥1 ACPA isotype (odds ratio 2.4; 95% CI 1.2–33.3; $p<0.01$); in RA, there was no significant association between smoking and any specific ACPA isotype. In AtRisk and RA, there was no association between any ACPA isotype and the presence of ≥1 SE allele.

Rheumatoid Factor Isotypes in Relation to Antibodies Against Citrullinated Peptides in Individuals before Onset of Rheumatoid Arthritis. Mikael Brink[1], Monika Hansson[2], Linda Mathsson-Alm[3], Johan Rönnelid[3], Lars Klareskog[2] and Solbritt Rantapää-Dahlqvist[4]. [1]Umeå University, Umeå, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Uppsala University, Uppsala, Sweden, [4]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Rheumatology, Sweden, Umeå, Sweden.

Background/Purpose: The presence of rheumatoid factor (RF) and antibodies against citrullinated peptides (ACPA) has been shown to precede the development of rheumatoid arthritis (RA) by several years. The relationships between the separate antibody development of RF and ACPAs are unclear.

Methods: Three isotypes (IgA, IgG and IgM) of RF has been analyzed in samples from 333 pre-symptomatic individuals (contributing with 596 samples), who subsequently developed RA and 495 population controls, all donors to the Biobank of Northern Sweden. The pre-symptomatic samples were collected in median 6.1 (IQR 7.1) years before symptom onset. Cut-offs for RF isotypes were set at 95% specificity using ROC-curves. Data from the RF-isotypes were compared against ten ACPA specificities previously analyzed on a microarray based on the ImmunoCAP ISAC system (Phadia). RF isotypes were analyzed using the EliA on the ImmunoCAP 2500-system (Phadia).

Results: The frequency of RF isotypes in pre-symptomatic individuals were 25.7% for IgA, 17.6% for IgG and 26.7% for IgM, significantly more prevalent compared with controls ($p<0.0001$). The concentrations for each isotype increased gradually the closer to onset of symptoms the sample was collected.

All three isotypes were associated with smoking (Odds ratio (OR) IgA= 2.5 (95%CI 1.8–3.6), IgG 2.1 (1.4–3.2) and IgM 2.4 (1.7–3.4), respectively) but not with HLA-SE or PTPN22 T-variant. The combinations of each of the RF isotypes with ACPA specificities (a-Enolase (CEP-1/Eno5–21), fibrinogen (Fib)β36–52, Fibα591, filaggrin (CCP-1/Fil307–324), vimentin ((Vim) 60–75 or Vim2–17) were associated with significantly shorter time to onset of symptoms ($p<0.001$–0.05). The OR (95%CI) for disease development in IgA, IgG and IgM positive individuals were in combination with Fib36–52, CEP-1 or Fil307–324 further increased from 7.1 (4.5–11.2), 4.5 (2.8–7.3) and 7.4 (4.7–11.7), respectively to OR= 12.5–19.6 for IgA, 7.5–16.2 for IgG and 17.4–20.7 for IgM.

Conclusion: RF isotypes predicted development of RA and in particular using combinations of both ACPAs and RF isotypes the association with disease development was high and the predating time shorter.

Citrulline-Specific Autoimmunity Resides in Quiescent Circulating Memory B Cells in Rheumatoid Arthritis. Adam Pelzek, Caroline Grönwall, Jeffrey D. Greenberg and Gregg J. Silverman. New York University School of Medicine, New York, NY.

Background/Purpose: The detection of anti-citrullinated protein antibodies (ACPA) aids RA diagnosis, while B cell depletion by anti-CD20 can provide clinical benefits. We therefore undertook investigations of the phenotypic and functional properties of citrulline (Cit)-specific B cells in the bloodstream of RA patients.

Methods: RA met 2010 ACR/EULAR criteria. PBMC were cultured +/− CpG2006/IL-21/sCD40L, and ELISpots performed. CD19+ B cell subsets were FACS sorted and cultured with CD40L-cell line/CpG2006/IL-21. Sera and supernatants were evaluated for total IgG, and for IgG1 and IgG4 subclasses by bead-based multiplex analysis, against 8 sets of paired Cit/native cyclic self-peptides, plus CCP3, CQP3 (Cit to Q), Cit/native fibrinogen (Fib), tetanus toxoid (TT) and control ligands. We also surveyed 87 CCP3-seropositive and 50 seronegative RA serum samples, plus panels of disease specific control samples (SS, OA, PsA, SLE).

Results: ELISpots documented the presence of circulating anti-Cit B cells, as seropositive RA had 41.3+/−0.5 CCP3+ IgG (mean +/−SE) but only 1.9+/−0.6 CQP+ spots/$10^{(6)}$ PBMC, while these were undetectable in seronegative RA and healthy adults. Anti-TT ISC were detected at 71.1+/−2.6 and 65.4+/−1.2 spots/$10^{(6)}$PBMC in seropositive RA and controls, respectively. By multiplex assay, ACPA fine specificity reactivities in sera were compared with supernatant antibodies from stimulated PBMC. In 36 PBMC from seropositive RA, highly significant correlations by ACPA fine specificity were found in comparisons with sera ACPA by Spearman correlations. From sorted B cells, we found ACPA-secreting B cells were enriched among CD19+IgD-CD27+ switched-memory (0.019 – 0.059% of CD19+CD27+IgD-), and included highly CCP3-reactive IgG. Yet, only rare weakly CCP3-reactive naïve B cells (IgD+CD27-) were detected, and none amongst pre-switched memory (IgD+CD27+). From subclass-specific sera multiplex assays, amongst IgG1 ACPA-expressing seropositive RA, about half showed anti-CCP3 IgG1 only, while the remainder had both anti-CCP3 IgG1 and IgG4. Whereas reactivity levels were generally greater for IgG1 than IgG4, IgG1 responses usually displayed great Cit than native antigen-specific responses, while the IgG4 displayed greater reactivity with the native (non-Cit) form in 5/9 antigen sets.

Conclusion: In seropositive RA PBMC, IgG ACPA in vitro secretion was detected across all treatment groups tested (MTX, MTX+TNFi, MTX+abatacept), suggesting these cells persist despite therapeutic intervention. DAS28 score correlated with neither the level nor specificity of supernatant or sera ACPA. Pilot studies also suggest ACPA-secreting B cells predominantly reside within peripheral switched memory. Our data therefore suggest that seropositive RA patients have recirculating but quiescent memory B cells with repertoires akin to serum ACPA patterns. Furthermore, while IgG1 autoantibodies in RA are predominantly Cit-specific, with subclass switch to IgG4 there may be epitope spreading with progression to include recognition of determinants on the native forms of the self-antigens. Our studies highlight defects in B cell tolerance in RA that may help guide development of better therapy.

Citrullinated-Vimentin-Specific Regulatory T-Cell Responses Associate with ACPA Positive Individuals with Non-Specific Musculoskeletal Symptoms. Aamir Aslam[1], Jackie L. Nam[1], Laura Hunt[1], Chadi Rakieh[1], Ann W. Morgan[2] and Paul Emery[1]. [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom.

Background/Purpose: The pathogenesis of RA can be conceptualised by sequential phases that precede the development of synovitis. Autoimmune antibody responses, including ACPA, can precede clinical synovitis. Our demonstrating a role for T-regs in ACPA-positive individuals without synovitis, may focus the development of treatments that can strengthen T-reg function.

Methods: 21 ACPA+ individuals with arthralgia but without clinically detectable inflammatory arthritis, 20 individuals with ACPA+ early RA (<12months after starting DMARD) and 20 healthy volunteers were recruited from clinical studies. Peripheral blood mononuclear cells were incubated with peptide pools covering the entire sequence of citrullinated vimentin (CitVim); in some incubations, anti-IL-10 neutralising antibody was added. After 72 hours, IL-10 and IFN-g T-cell responses were enumerated by ELISpot. A positive response was defined by a stimulation index (ratio of spots with peptide to spots with negative control) >3.

Results: CitVim-reactive T-cells were readily detected in healthy volunteers, ACPA+ arthralgia and RA and there was a significant difference in the quality of this response between these groups: there was a sequential reduction in the percentage of individuals who had IL-10 CitVim-specific T-cell responses and an increase in IFN-g responses as we move from health to ACPA+ arthralgia to RA (Fig. 1). In order to determine whether IL-10 from CitVim specific T-cells had a regulatory role, we blocked IL-10 function

with a neutralising antibody and found an increase in the magnitude of the IFN-g CitVim responses in the ACPA+ arthralgia, whereas in health there were no IFN-g responses (Fig. 2).

Conclusion: We demonstrate a sequential change from a regulatory (IL-10-predominant) to an inflammatory (IFN-g) CitVim-specific T-cell response as we move from health to ACPA+ arthralgia to RA. We have also shown that autoreactive IL-10 T-reg responses are actively inhibiting IFN-g responses in ACPA+ arthralgia individuals. It is plausible that such regulatory T-cell responses prevent progression to disease in health and in pre-clinical RA.

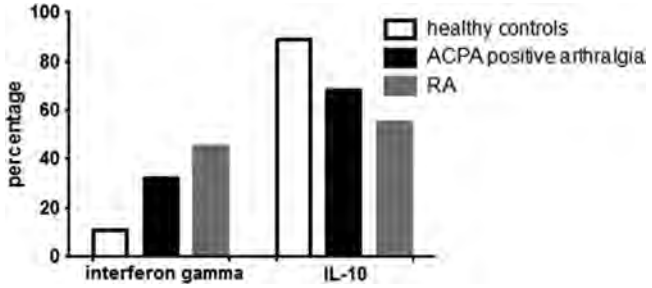

Fig. 1. IL-10 and IFN-g responses to CitVim peptide pools can be detected by ELISpot. The percentage of individual with IL-10 and IFN-gamma cit-vim specific T-cell responses differed between RA, ACPA+ arthralgia and healthy volunteers (c^2=28.4, p<0.0001).

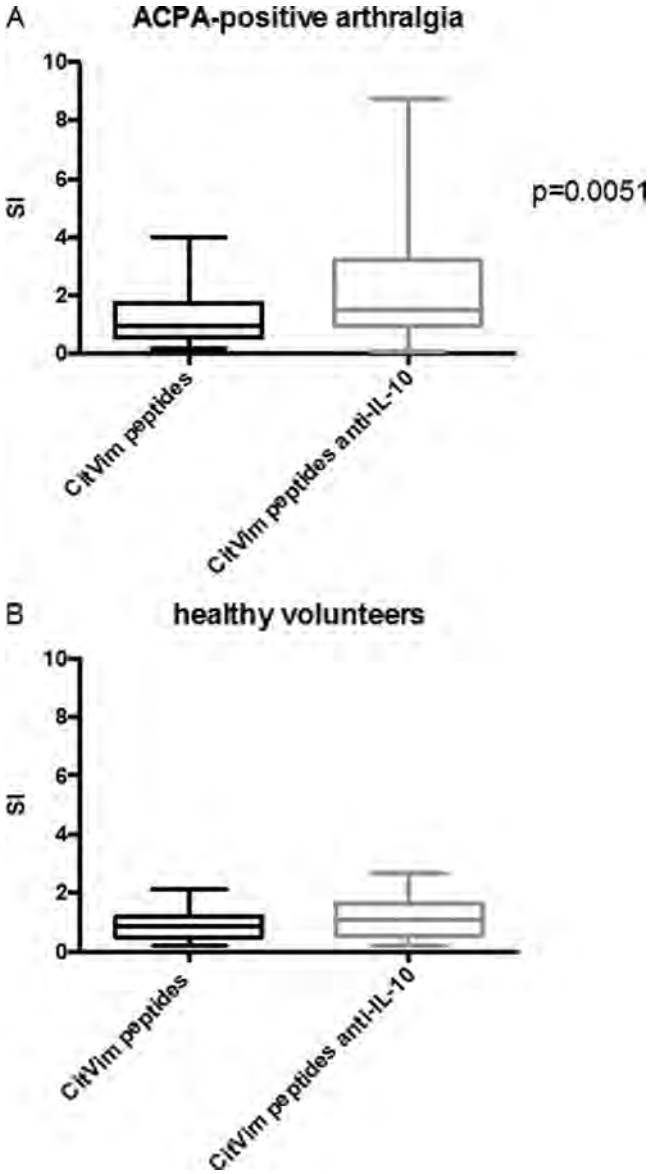

Fig. 2. IL-10 mediated suppression of CitVim IFN-g T-cell responses. **A.** There was an increase in CitVim IFN-g T-cell responses after IL-10 blockade in ACPA+ arthralgia (N=5, p=0.0051). **B.** In healthy volunteers there was no increase (N=5).

The Mucosal Anti-Citrullinated Protein Antibody Response in Pre-Clinical Rheumatoid Arthritis. Anneke van der Horst[1], Ivy Y.K. Choi[2], Dirkjan van Schaardenburg[3], D.M Gerlag[2], Paul Tak[2], Dörte Hamann[1] and Rogier M. Thurlings[2]. [1]Sanquin Diagnostic Services, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Reade, Amsterdam, Netherlands.

Background/Purpose: Recent data suggest rheumatoid arthritis (RA) may originate from an autoimmune response in inflamed mucosa. RA is associated with gingival and airway inflammation and alterations in the microbiomal composition in the gut. Furthermore, anti-citrullinated (cit) protein antibodies (ACPA) of the IgA class, the main secreted mucosal antibody, precede arthritis by years in a proportion of RA patients. When aiming to prevent arthritis it is critical to understand the source and regulation of autoantibody production in preclinical RA.

Objective to determine whether ACPA are produced at mucosal sites in ACPA positive individuals at risk for RA and to compare the ACPA isotype and fine specificity in mucosal fluids to peripheral blood.

Methods: Saliva, sputum, faeces and peripheral blood were collected from 15 individuals with anti-cyclic cit protein (anti-CCP2) antibody positive arthralgia who are part of a cohort that is being prospectively followed for the possible development of arthritis. Saliva and sputum were collected during an early morning visit. Sputum was induced by inhalation of sodium chloride aerosols 4.5%. Mucus plugs were selected from sputum for extraction of supernatants. Faeces was collected at the same visit using stool collection kits and extracted using 6% BSA phosphate buffered saline. ACPA of IgA and IgG class were measured in mucosal fluids and blood using two cit fibrinogen peptides, one enolase peptide and one vimentin peptide and their respective arginine peptides as control.

Results: Thirteen of 15 individuals tested positive for the anti-CCP2 test and ACPA in their blood at the day of mucosal fluid collection. Two patients tested positive for anti-CCP2 but negative for ACPA. Two other patients had high reactivity against both cit peptides and arginin controls and were also considered ACPA negative. Anti-cit fibrinogen, enolase and vimentin antibodies were detected in respectively 11, 4 and 3 individuals. The saliva of 4 patients contained IgA ACPA with positive tests for anti-cit enolase and anti-cit fibrinogen. The saliva of another patient tested positive for IgG anti-cit enolase and anti-cit fibrinogen. Other saliva, sputum and faeces samples tested negative for ACPA. All 5 patients with ACPA in saliva tested positive for the same antibodies in blood. In addition, in 3 of 5 patients ACPA were detected in blood that were not detected in saliva, including anti-cit fibrinogen, anti-cit vimentin and anti-cit enolase antibodies.

Conclusion: Collection of saliva allows for the detection of ACPA in the saliva of a proportion of anti-CCP positive individuals at risk for RA. In these patients, IgG ACPA in blood are directed against more peptides compared to IgA ACPA in saliva. Future analyses should focus on further defining the precise source and regulation of mucosal ACPA compared to systemic ACPA.

The Association of Fine Specificities of Anti-Citrullinated Protein Antibodies (ACPA) with disease Severity in African-Americans with RA. Maria I. Danila[1], Richard Reynolds[1], Gordon Wu[1], Hemant Tiwari[1], William H. Robinson[2], Jeremy Sokolove[3], CLEAR Investigators[1] and S. Louis Bridges Jr. [11]University of Alabama at Birmingham, Birmingham, AL, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA.

Background/Purpose: RA is characterized by the presence of autoantibodies to citrullinated proteins (ACPA) and joint damage. The role of fine specificities of ACPA in radiographic severity has not been defined. The purpose of the current study was to evaluate whether fine specificities of ACPA are associated with radiographic severity of RA in African Americans.

Methods: Using a custom Bio-Plex™ bead-based autoantibody assay platform, we measured anti-CCP antibody and 19 autoantibodies targeting citrullinated proteins and peptides (vimentin, fibrinogen, histone 2A, histone 2B, and apolipoprotein E, clusterin, biglycan, enolase, fillagrin). We analyzed sera from 692 African-American patients with RA. A total antibody score was defined for each patient as the standardized sum of the log transformed autoantibodies. The total antibody score was used as predictor variable for radiographic severity. Radiographic severity defined as total Sharp/van der Heijde scores of hands/feet was the dependent variable. Zero-inflated negative binomial regression models were used to test the association of the autoantibody score with radiographic severity defined as total Sharp/van der Heijde scores of hands/feet given the covariates gender, BMI, smoking status and disease duration.

Results: High correlation coefficients among the autoantibodies were observed. Using zero-inflated negative binomial regression, the total sum of standardized antibodies had a statistical significant (p-value =0.002) effect among patients with a total RA radiographic severity (total score >0). For each unit increase in the total sum of standardized autoantibodies, the total radiographic score increases by 0.3 units. In addition, disease duration was found to be statistically significant (p-value <0.0001).

Conclusion: Autoantibodies against citrullinated autoantigens are associated with joint damage in this cross sectional study of African Americans with RA. Future work will focus on longitudinal aspects of antibodies to specific peptides/proteins and their role in progression of radiographic damage.

The Use of Multiplex Bead Array to Follow the Effect of Rituximab on IgG and IgA Serum Autoantibody Responses to Citrullinated Epitopes in Patients with Rheumatoid Arthritis. Geraldine Cambridge[1], Lauren J. Lahey[2], Maria J. Leandro[1], William H. Robinson[2] and Jeremy Sokolove[2]. [1]Centre for Rheumatology, Department of Medicine, University College London, London, United Kingdom, [2]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA.

Background/Purpose: The majority of patients with established Rheumatoid arthritis (RA) have autoantibodies against the Fc of IgG (Rheumatoid factors-RhF) and to citrullinated protein antigens (ACPAs). As ACPAs recognize epitopes on many different proteins, the full complement of reactivity is unknown so they are usually detected using cyclic citrullinated peptides (CCP). Seropositivity for RhF and/or ACPA is a strong predictor of a positive clinical response to rituximab (RTX) therapy. Although playing an important pro-inflammatory role in RA, ACPA, measured using CCP as substrate, are less dynamic than RhF in relation to RTX treatment. Using an antigen array comprising citrullinated antigens identified as present in RA synovia we have explored changes in fine specificity and levels of IgG- and IgA-ACPAs following RTX.

Methods: 17 patients with active RA (DAS28 ≥ 5.1) fulfilling ACR criteria were included. All had undergone one cycle of RTX (2 weekly infusions of 1g), showed adequate depletion in the peripheral blood (<5 CD19+ cells/μl) at 1–3 months, and had clinically responded (ΔDAS28≥1.2) at 3 months. Follow-up was from 4–13 months up to re-treatment or relapse. A custom, bead-based, antigen array comprising 30 putative RA-associated citrullinated, and 20 corresponding native antigens was used for measurement of ACPA (assessed using mean fluorescence intensity-MFI). To compensate for number of binding sites per antigen, MFI were Z-normalised. Positive results were regarded as those with SD >1 above population mean.

Results: Before RTX, IgG- and IgA-ACPA often shared specificities to a variable number of citrullinated and native antigens. Post-RTX, the overall median % decrease in MFI for ACPA from baseline to when B-cells were depleted, was modest for IgG-CCP (7.3%) and more pronounced for IgA-CCP (20.0%). At relapse, median % decrease in MFI for IgG-CCP was 3.3% but IgA-CCP remained high at 20.5%. The patterns of antibody binding to individual peptide or protein epitopes were considerably more dynamic than those to CCP. In general, the same citrullinated epitopes were recognized by both IgA- and IgG-ACPA in each sample but additional specificities could be present in either autoantibody class. IgG- and IgA-ACPA also tended to respond in parallel to RTX treatment. Prior to relapse, steep rises in IgG- or IgA-ACPA recognizing individual, or several, epitope specificities were observed, particularly when relapse occurred several months after B cell return (9/17 patients). Rises usually occurred in ACPA specificities present before RTX but new epitope specificities could emerge.

Conclusion: The use of multiplex antigen arrays for analysis of the ACPA response in RA patients after RTX has revealed that populations of ACPA-producing cells behave differently in response to B cell depletion therapy. Recognition of particular epitopes was highly variable and dynamic, suggesting some derivation from short-lived parent plasmablasts, which were not reflected in the relatively static, 'global' IgG-CCP measurements. IgA-ACPA responses to RTX therapy were also varied and did not necessarily recognize the same epitopes although patterns of response were similar to those of IgG-ACPA.

In a Periodontal Disease Cohort without RA, Indeterminate or Low-Positive Anti-CCP-2 Antibodies Are Associated with Multiple Distinct ACPA. Jerry A. Molitor[1], Bryan S. Michalowicz[2], Ryan T. Demmer[3], Jane H. Buckner[4], Mark H. Wener[5] and William H. Robinson[6]. [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota School of Dentistry, Minneapolis, MN, [3]Columbia Univ. Mailman School of Public Health, New York, NY, [4]Benaroya Research Institute at Virginia Mason, Seattle, WA, [5]University of Washington, Seattle, WA, [6]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Periodontal disease (PD) and RA share the risk factors HLA DR B1 shared epitope (SE) and tobacco exposure (TE). PD may represent a risk factor for subsequent RA. Individuals with multiple ACPA have increased risk of subsequent RA. We developed a prospective cohort with moderate to severe PD but no clinical features of RA, determining: i) the prevalence of HLA-DRB1 alleles; ii) seropositivity to CCP-2 antibodies (CCP-2) and ACPA; iii) whether HLA-DRB1 alleles were associated with CCP-2 or ACPA; and iv)if HLA-DRB1 alleles modified the association between CCP-2 and ACPA.

Methods: CCP-2 and IgM RF were performed by CLIA–certified assays. CCP-2 or RF+ individuals were offered clinical assessment to ensure they were free of RA by 2010 ACR/EULAR criteria. Sera were analyzed by multiplex assay for distinct ACPA. Positive cutoffs for ACPA were established by ROC analysis of prior studies. HLA DRB1 SE alleles were assayed by PCR. Proportions and 95% confidence intervals (CI) were estimated using Fisher's Exact Test. Mantel-Haenszel odds ratios (OR) were computed as appropriate. Interaction was assessed via the Breslow-Day test.

Results: Median age was 60 years. Key findings;

Characteristic	# (181 total)	Percentage
Male	120	66.3
Ever used tobacco	131	72.3
Detectable CCP-2 (> 0.5 u)	30	16.6
CCP-2 indeterminate or greater (> 1.5 u)	11	6.1
RF positive (> 10)	10	5.5
≥1 ACPA	62	34.3
≥3 ACPA	12	6.6
HLADRB1*0401	33	18.2
HLADRB1*0101	34	18.8

The most common ACPA was anti-citrullinated histone 2A; n=44(24%), all other ACPA occurred in < 7% of participants. There was a significant relationship between the presence of an indeterminate or low positive CCP-2 and the presence of ≥ 3 distinct ACPA (OR [95%CI] = 23.4[5.5, 100.1], p=0.0001). The presence of DRB1*0401 was marginally associated with an indeterminate or low positive CCP-2 (OR= 3.2[0.8, 12.3], p=0.09), and with the presence of ≥ 3 ACPA (OR= 5. 3[1.6, 17.5, p=0.01). RF was not associated with any specific ACPA, nor was it associated with indeterminate or low positive CCP-2. No relationships between tobacco exposure and any specific ACPA or RF were seen. Among DRB1*0401 negative individuals, prevalence estimates of ≥ 3 ACPA among those with an indeterminate or low positive CCP-2 vs. negative CCP-2 were 17% vs. 4%.This relationship was markedly stronger among DRB1*0401 positive individuals; prevalence estimates of ≥ 3 ACPA among those with an indeterminate or low positive CCP-2 vs. negative CCP-2 were 100% vs. 7% (p for interaction=0.06).

Conclusion: In this PD cohort, indeterminate or low positive CCP-2 is associated with the presence of ≥ 3 distinct ACPA. HLA DRB1*0401 alleles

were associated with an increased risk of ≥ 3 ACPA, and with the presence of an indeterminate or higher CCP-2. These results have implications for the follow-up of individuals with RA risk factors and indeterminate or low positive CCP-2 findings, and for the design of RA prevention trials.

The Specificity of Anti-Carbamylated Protein Antibodies for Rheumatoid Arthritis in a Setting of Early Arthritis. Jing Shi, H.W. van Steenbergen, J. a. B. van Nies, E.W.Nivine Levarht, Annette H. M. van der Helm- van Mil, Tom W. J. Huizinga, René E.M. Toes and Leendert A. Trouw. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Anti-carbamylated protein (anti-CarP) antibodies have been described in rheumatoid arthritis (RA) and arthralgia patients [1;2] and occur in subsets of the anti-CCP2 positive and negative patients [1;3]. In anti-CCP2 negative RA patients the presence of anti-CarP was associated with more severe joint destruction [1]. Here we investigated the sensitivity and specificity of anti-CarP antibodies for RA in a setting of early arthritis.

Methods: Anti-carbamylated fetal calf serum (anti-Ca-FCS), anti-CCP2 antibodies and rheumatoid factor (RF) IgM were measured by ELISA using serum samples available from a large inception cohort; the Leiden Early Arthritis Clinic cohort (EAC). For the anti-CarP antibodies we used as a cut-off for positivity the mean + 2 times the standard deviation of the healthy controls [1].

Results: In total 2086 sera of Leiden EAC patients suffering from early arthritis were analyzed for the presence of anti-Ca-FCS antibodies. Anti-CarP antibodies were present in 26% of the patients and in 2% of the controls. We observed that the sensitivity and specificity of anti-Ca-FCS in the EAC cohort for RA are 44% and 89%. As a reference the sensitivity and specificity of anti-CCP2 antibodies are 54% and 95% and for RF IgM are 59% and 90%. Analyzing the early arthritis patients that did not fulfil the EULAR/ACR 2010 criteria for RA that were anti-CarP positive (n=127) revealed that these patients were mainly diagnosed as undifferentiated arthritis (45%), reactive arthritis (9%), psoriatic arthritis (9%) or peripheral spondyloarthritis (8%).

Conclusion: Anti-CarP antibodies, as determined by the reactivity to carbamylated FCS, are predominantly present in RA but can also be detected in other forms of arthritis. The prognostic relevance of anti-CarP antibodies in these latter patients will have to be determined.

Clinical and Tissue Specificity of Antibodies Against Carbamylated Proteins in Patients with Rheumatoid Arthritis. Antonio Gonzalez[1], Ariana Montes[1], Eva Perez-Pampin[1], Maria Dolores Boveda[2] and Juan J. Gomez-Reino[3]. [1]Instituto Investigacion Sanitaria- Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [2]Insitituto Investigacion Sanitaria- Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [3]University of Santiago de Compostela, Santiago de Compostela, Spain.

Background/Purpose: Antibodies against carbamylated proteins (CarP) are a new type of autoantibodies specific of patients with rheumatoid arthritis (RA) relative to healthy controls, but their specificity in relation with other rheumatic diseases has not been established. In addition, they have been analysed with CarP from Fetal Calf Serum (FCS) raising doubts about their protein specificity.

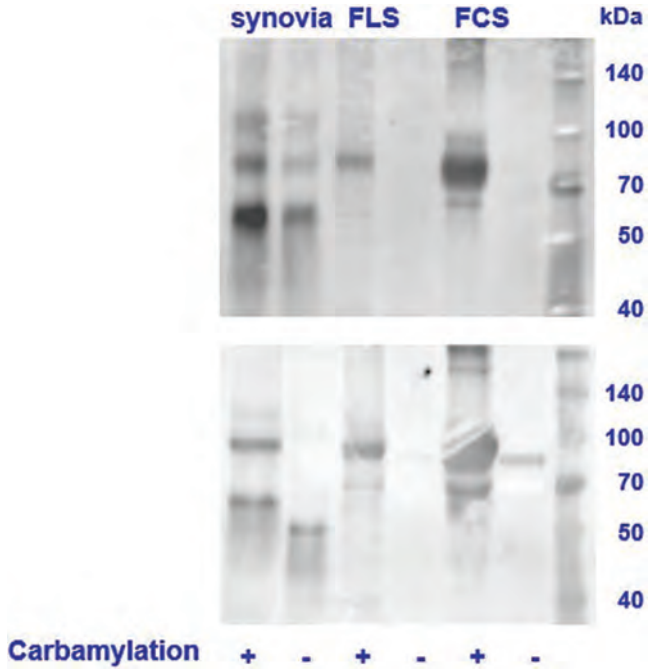
Methods: Anti-CarP FCS from 520 patients with RA was compared with reactivity in 208 healthy donors and 90 patients with each of the following diseases: osteoarthritis (OA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). In addition, anti-CarP-FCS from 97 patients with RA was correlated with reactivity against CarP from seven human tissues.

Results: Anti-CarP-FCS antibodies were found in 35.9 % of the patients with RA. These antibodies were also observed in 4.8 % of the healthy controls, 4 % of the OA patients, 6 % of the PsA patients and 24.4 % of the AS patients. Therefore, their specificity was high in relation with healthy controls and in relation with OA and PsA patients, but not in relation with patients with AS. These results reinforce the nature of anti-CarP as an independent autoantibody system that will be worth to study in AS patients.

Protein extracts from FCS and the 7 analysed tissues were carbamylated with similar efficiency allowing for meaningful comparisons of the serum reactivities against them. There were at least some sera showing reactivity against each of the tissues analysed, but the frequencies and titers showed clear differences in function of the tissue used as source of CarP (Table 1).

			Titer correlation		Concordance	
Tissue	**Positive, %**	**% of the FCS+**	**ρ Spearman**	***P-value***	***Gamma***	***P-value***
FCS	57.7	–	Ref.	Ref.	Ref.	Ref.
FLS	49.5	91.7	0.76	$<10^{-15}$	0.94	$<10^{-15}$
synovia	40.2	89.7	0.48	$<10^{-7}$	0.88	$<10^{-14}$
Liver	52.6	70.6	0.64	$<10^{-10}$	0.72	$<10^{-7}$
Tyroid	29.9	82.8	0.31	$<10^{-3}$	0.69	$<10^{-4}$
Kidney	45.4	77.3	0.46	$<10^{-4}$	0.65	$<10^{-5}$
Spleen	16.5	68.8	0.19	n.s	0.38	n.s
Lung	26.8	61.5	–0.08	n.s	0.09	n.s

In addition, the reactivities that best correlated with anti-CarP-FCS were against CarP from FLS and synovia. However, Western blot analysis showed a different pattern of binding of RA patient sera when the CarP were from synovia or from FCS in Western blots (Figure 1).



These results indicate the protein specificity of the anti-CarP antibodies present in RA sera.

Conclusion: The anti-CarP-FCS antibodies are moderately prevalent in patients with RA and highly specific of them in comparison with healthy controls, or patients with OA or PsA, but not with AS. Furthermore, analysis of reactivity against CarP from different tissues shows that the anti-CarP reactivity is dependent of specific CarP, which are different depending on the tissue. Fortunately, results with FCS, which has been used as source of CarP for testing RA sera, strongly correlate with synovia. This correlation contributes to confidence in the previously reported clinical and genetic associations of this new type of autoantibodies.

AAA-Atpase p97 Regulates Autophagy-Associated Cell Death in Arthritis. Masaru Kato[1], Kerstin Klein[2], Caroline Ospelt[3], Christoph Kolling[4], Michihito Kono[1], Shinsuke Yasuda[1], Renate E. Gay[5], Steffen Gay[3] and Tatsuya Atsumi[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]University Hospital Zurich, Zurich, Switzerland, [3]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [4]Schulthess Clinic, Zurich, Switzerland, [5]Zurich University Hospital, Zurich, Switzerland.

Background/Purpose: Recently we described a hypersensitivity of rheumatoid arthritis synovial fibroblasts (RASF) compared to osteoarthritis synovial fibroblasts to autophagy under conditions of severe endoplasmic reticulum (ER) stress, leading to a massive cytoplasmic vacuolization, the formation of poly-ubiquitinated protein aggeregates and non-apoptotic cell death. Valosin containing protein (p97/VCP) is an ATPase implicated in the degradation of ubiquitin-labelled proteins through the proteasome. We hypothesized that the inhibition of p97 further sensitizes RASF to autophagy-associated cell death due to impaired proteasomal degradation and subsequent overloaded autophagy.

Methods: RASF were transfected with siRNA targeting p97 or treated with the selective p97 inhibitor DBeQ (5 μM). To induce ER stress, RASF were treated with thapsigargin (TG, 5 nM-5 μM). 3-methyladenine (5 mM) was used as an autophagy inhibitor. The distribution of poly-ubiquitinated proteins was evaluated by immunofluorescence microscopy. Cell death was evaluated by flow cytometry using annexin V/propidium iodide staining. Collagen-induced arthritis (CIA) was induced in Lewis rats. Scrambled or p97 siRNA-atelocollagen complexes were injected into ankle joints of rats. Three, seven and eleven days after the injection, CIA was scored from 0 to 4 according to paw thickness and ankle diameter.

Results: Both siRNA-mediated knockdown and inhibition of p97 in RASF boosted a cytoplasmic vacuolization, the formation of poly-ubiquitinated protein aggeregates and cell death under 5 μM TG treatment, and this cell death was inhibited by 3-methyladenine. Smaller amounts of TG (50 or 500 nM) induced a cytoplasmic vacuolization and the formation of poly-ubiquitinated protein aggeregates in p97-inhibited RASF but not in control RASF. Intra-articular injection of p97 siRNA significantly suppressed CIA (Day 3, $p = 0.002$; Day 7, $p = 0.002$; Day 11, $p = 0.04$; $n = 6$) in rats.

Conclusion: Our data indicate that the inhibition of p97 promotes autophagy-associated cell death in RASF and suppresses CIA in vivo. p97 may be a new potential target in the treatment of arthritis.

ACR Poster Session A

Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy: Safety of Biologics and Small Molecules in Rheumatoid Arthritis

Sunday, November 16, 2014, 8:30 AM–4:00 PM

457

First Confirmation Data of Long Term Safety for Tocilizumab in Real-World Setting; 3 Year Follow-up Postmarketing Surveillance of 5573 Patients with Rheumatoid Arthritis in Japan. Kazuhiko Yamamoto[1], Hajime Goto[2], Kenzo Hirao[3], Atsuo Nakajima[4], Hideki Origasa[5], Nobuhiro Takagi[6], Minako Tomobe[6] and Kyoichi Totsuka[7]. [1]Univ Tokyo Gr School of Med, Tokyo, Japan, [2]Fukujuji Hospital, Tokyo, Japan, [3]Heart Rhythm Center, Tokyo Medical and Dental University, Tokyo, Japan, [4]Tokyo Metropolitan Police Hospital, Tokyo, Japan, [5]University of Toyama School of Medicine, Toyama, Toyama, Japan, [6]Chugai Pharmaceutical, Tokyo, Japan, [7]Kitatama Hospital, Tokyo, Japan.

Background/Purpose: To evaluate the long-term safety of tocilizumab (TCZ) for the treatment of rheumatoid arthritis (RA) in a real-world clinical setting in Japan.

Methods: In this long-term extension of the single-arm, observational postmarketing surveillance study of TCZ, patients who received at least 1 dose of intravenous TCZ (8 mg/kg) between April 2008 and August 2010 were observed for 3 years. Patient characteristics and the incidences of mortality, serious infection, malignancy, GI perforation and serious cardiac dysfunction were evaluated during observation period. The analyses included the adverse events (AEs) after discontinuation of TCZ. Data were summarized as the proportion (95% CI) of patients experiencing each event or as incidence rates presented as the number of patients per 100 patient-years (PY).

Results: In total, 5573 patients were enrolled, with a total observation of 15,106 PY. Excluding patients who died, transferred hospitals, or were lost to follow-up, a total of 5327 patients (95.59%) completed 1 year, 4850 (87.03%) completed 2 years, and 4527 (81.23%) completed 3 years of observation. The mean and median treatment duration was 2.1and 2.9 years, respectively. The overall mortality rate during the observation period was 2.58% (144/5573 patients). The most common cause of death was infection (28.47%), followed by respiratory disease (15.97%), malignancy (14.58%), and cardiac dysfunction (9.03%). The standardized mortality ratio (SMR) in comparison with the general Japanese population was 1.27 (95% CI, 1.08–1.50), which is comparable to the SMR reported in a large observational cohort of Japanese patients with RA (all-patient mortality between 1.46 [95% CI, 1.32–1.60] and 1.90 [95% CI, 1.75–2.07]).[1] The incidence rate of malignancy during the observation period was 2.24% (0.83/100 PY), and the standardized incidence ratio (SIR) was 0.79 (95% CI, 0.66–0.95), which was stable over time. Only malignant lymphoma had a significantly higher incidence compared to the general Japanese population, with a SIR of 3.13 (95% CI, 1.82–5.39) which is comparable to that of all RA patients compared with the general population (SIR, 6.07; 95% CI, 3.71–9.37).[2] There was no increase in rate of any AEs with prolonged observation, while incidence of fatal events, serious infection, GI perforation and serious cardiac dysfunction decreased over time. (Table).

Conclusion: The safety profile of TCZ was consistent over time with respect to mortality, serious infections, malignancy, gastrointestinal perforation, and serious cardiac dysfunction. These data confirm the long-term safety of TCZ use in patients with RA in a real-world clinical setting in Japan.

Meta-Analysis of Serious Infections with Tofacitinib and Biological Treatment in Rheumatoid Arthritis Clinical Trials. V. Strand[1], S. Ahadieh[2], J. French[3], J. Geier[4], S. Krishnaswami[5], S. Menon[5], T. Checchio[2], R. Riese[6] and J. Gomez-Reino[7]. [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]Pharmacometrics, Pfizer Inc, Groton, CT, [3]Metrum Research Group, Tariffville, CT, [4]Pfizer Inc, New York, NY, [5]Clinical Pharmacology, Pfizer Inc, Groton, CT, [6]Pfizer Inc, Groton, CT, [7]Hospital Clinico, Universitario de Santiago, Santiago, Spain.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Serious infection events (SIEs) have been reported in the tofacitinib RA trials. Limited head-to-head comparator data are available within the tofacitinib RA development program to directly compare rates of events relative to approved biologic therapies. Here we present a meta-analysis of published randomized controlled trials (RCTs) and corresponding long-term extension (LTE) studies to contextualize the risk of SIEs for tofacitinib relative to biologics approved for treatment of moderate to severe RA.

Methods: A systematic literature search (Medline, Embase, PubMed, and regulatory submission documents for approved therapies) was conducted through October 2013. A total of 66 RCTs and 22 LTE trials met the inclusion criteria for the meta-analysis. Incidence rates (per 100 patient-years) of SIEs for each therapy across trials were estimated based on RCT and LTE data using a random effects model. Relative and absolute risk comparisons to placebo were made using RCT data only, based on Mantel-Haenszel methods. Placebo-controlled data ranging between 3–12 months for biologics and 3 months for tofacitinib were assessed. Statistical heterogeneity was assessed using I^2 statistic.

Results: Incidence rate (per 100 patient-years [95% CI]) estimates from the meta-analysis were 3.04 (2.49, 3.72) for abatacept, 3.72 (2.99, 4.62) for rituximab, 5.45 (4.26, 6.96) for tocilizumab, and 4.90 (4.41, 5.44) across TNF inhibitor (TNFi) therapies. The tofacitinib incidence rates from the five Phase (P) 3 trials only were 3.02 (2.25, 4.05) and 3.00 (2.24, 4.02) for 5 mg twice daily (BID) and 10 mg BID, respectively. The incidence rates in the ongoing LTE studies (as of August 2013) were 2.50 (2.05, 3.04) for 5 mg BID and 3.19 (2.74, 3.72) for 10 mg BID. The risk ratio (RR; [95% CI]) for TNFi relative to placebo in methotrexate inadequate responder (MTX-IR) trials (n=24) was 1.50 (1.00, 2.25). The tofacitinib RRs, relative to placebo, in P3 were 2.21 (0.60, 8.14) for 5 mg BID and 2.02 (0.56, 7.28) for 10 mg BID. Risk differences (expressed as difference in incidence percent; RD; [95% CI]) relative to placebo were 0.94% (0.25%, 1.63%) for TNFi therapies, 0.38% (−0.24%, 0.99%) for tofacitinib 5 mg BID, and 0.40% (−0.22%, 1.02%) for tofacitinib 10 mg BID. Separate analyses of MTX-naïve studies (n=10) showed a RR of 1.24 (0.87, 1.77) for TNFi relative to MTX. RRs from the tofacitinib ORAL Start (A3921069) study vs. MTX were similar to the TNFi estimates for both tofacitinib doses (i.e. 1.10 [0.39, 3.11] for 5 mg BID and 0.75 [0.25, 2.26] for 10 mg BID).

Conclusion: This meta-analysis provided an indirect quantitative assessment of the SIEs for biological therapies to contextualize data from the tofacitinib RA clinical development program. Comparisons of incidence rates, RRs and RDs suggest that risk of SIEs with tofacitinib is comparable to published rates for biologic therapies in the treatment of moderate to severe RA.

Evaluation of the Effect of Tofacitinib on Measured Glomerular Filtration Rate in Patients with Active Rheumatoid Arthritis. J. Kremer[1], A.J. Kivitz[2], J.a. Simon Campos[3], E.L. Nasonov[4], H. Tony[5], B. Vlahos[6], C. Hammond[6], J. Bukowski[6], H. Li[6], S. Schulman[6], S. Raber[7], A. Zuckerman[8] and J. Isaacs[9]. [1]Albany Medical College and The Center for Rheumatology, Albany, NY, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Hospital CEM/BIOCEM, Merida, Mexico, [4]Nasonova State Institute of Rheumatology, Moscow, Russia, [5]University Hospital Würzburg, Würzburg, Germany, [6]Pfizer Inc, Collegeville, PA, [7]Pfizer Inc, San Diego, CA, [8]Pfizer Inc, Groton, CT, [9]National Institute for Health Research Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle, United Kingdom.

Background/Purpose: In the clinical development program of the oral Janus kinase inhibitor tofacitinib for the treatment of rheumatoid arthritis (RA), small mean increases in serum creatinine (SCr) (<4 μmol/L least mean squares difference from placebo [PBO] for tofacitinib 5 and 10 mg twice daily [BID] at Month 3) were observed and plateaued early. Further analyses using pooled data from five Phase 3 and two long-term extension (LTE) studies suggested that tofacitinib had a small and reversible effect on mean SCr in patients (pts) with RA; the mean SCr changes plateaued, remained within normal limits and did not appear to be associated with acute renal failure or progressive worsening of renal function in the LTE studies. This study aimed to assess changes in measured glomerular filtration rate (mGFR) with tofacitinib relative to PBO in pts with active RA.

Methods: In this double-blind, PBO-controlled, Phase 1 study (NCT01484561) RA pts were randomized 2:1 to oral tofacitinib 10 mg BID in Period 1 (P1) then PBO BID in Period 2 (P2) (tofacitinib→PBO); or oral PBO BID in both P1 and P2 (PBO→PBO). P1 and P2 were 6–7 and 4–5 weeks in duration, respectively. Each pt underwent mGFR evaluations by iohexol serum clearance at 4 time points (run-in, pre-dose 1 in P1, end of P1, and end of P2); estimated GFR (eGFR) was calculated using the Cockcroft-Gault equation. The primary endpoint was the geometric mean change in mGFR from baseline to end of P1. Secondary endpoints included the geometric mean change in mGFR from baseline to end of P2 and from end of P1 to end of P2, change in eGFR and SCr, RA clinical efficacy and safety.

Results: 148 pts were randomized to tofacitinib→PBO (N=97) and PBO→PBO (N=51). Baseline characteristics were similar between groups. In tofacitinib→PBO, tofacitinib treatment in P1 was associated with a reduction of 8% (90% confidence interval [CI]: 2%, 14%) from baseline in geometric mean mGFR vs PBO→PBO. The reduction in geometric mean mGFR associated with tofacitinib in P1 reversed on PBO in P2, and there was no difference vs PBO→PBO in the adjusted geometric mean fold change of mGFR at the end of the study (tofacitinib→PBO: PBO→PBO: 1.04; 90% CI: 0.97, 1.11). Similar results were observed for eGFR and SCr (Table). Of note, during P2 there was a 5% reduction (90% CI: 1%, 10%) in mGFR (but not eGFR) in PBO→PBO. Clinical efficacy and safety were consistent with prior studies.

Conclusion: This study suggests that small mean increases in SCr and mean decreases in eGFR in pts with RA treated with tofacitinib may occur in parallel with small mean decreases in mGFR, and that changes in these parameters with short-term tofacitinib treatment appear reversible after discontinuation. Safety monitoring will continue in ongoing and future clinical trials and routine pharmacovigilance.

ANCOVA, analysis of covariance; CI, confidence interval; eGFR, estimated glomerular filtration rate; FAS, full analysis set; mGFR, measured glomerular filtration rate; OC, observed case.
FAS (OC) include available data from all randomized patients who took at least one dose of study medication (tofacitinib→PBO or PBO→PBO). Data collected after patients (one in Period 1 and two in Period 2, all in to facitinib→PBO) took a wrong treatment bottle were excluded. Missing data were not imputed.
ANCOVA model included treatment and baseline of the endpoint as a covariate. The analysis was performed on the log-transformed scale and then exponentially back-transformed to derive the geometric mean fold change and 90% confidence intervals on the original scale.

Analysis of Non-Melanoma Skin Cancer Across the Tofacitinib Rheumatoid Arthritis Clinical Program. J.R. Curtis[1], E.B. Lee[2], G. Martin[3], X. Mariette[4], K.K. Terry[5], Y. Chen[6], J. Geier[7], J. Andrews[5], M. Kaur[6], K. Kwok[7] and C. Nduaka[5]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Seoul National University College of Medicine, Seoul, South Korea, [3]Dermatology and Laser Center of Maui, Kihei, HI, [4]Paris-Sud University, Paris, France, [5]Pfizer Inc, Groton, CT, [6]Pfizer Inc, Collegeville, PA, [7]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). The incidence of non-melanoma skin cancer (NMSC) in the tofacitinib RA program was evaluated using data from randomized Phase (P) 1, 2, 3, and open-label long-term extension (LTE) studies (P1P2P3LTE studies).

Methods: NMSC data (cut-off date: August 30, 2013) were pooled from two P1, eight P2, six P3, and two LTE studies; LTE data collection and analyses are ongoing; study databases have not yet been locked. Patients in P1, P3 and LTE studies were treated with tofacitinib 5 mg or 10 mg twice daily (BID) either as monotherapy or with background disease-modifying antirheumatic drugs (DMARDs). LTE patients rolled over from qualifying P1, P2, and P3 studies; patients from P2 studies were treated with tofacitinib 1 to 30 mg BID or 20 mg once daily. Incidence rates per 100 patient-years (py) of exposure (IRs) for first new NMSC were calculated for combined doses (all doses) of tofacitinib in the P1P2P3LTE patient population. The overall NMSC IR was analyzed as well as IRs for subgroup analyses according to the following conditions: dose of tofacitinib (5 mg vs 10 mg); tofacitinib monotherapy vs tofacitinib + background DMARDs; previous treatment with tumor necrosis factor inhibitors (TNFi); age of patients (≥65 vs <65); ethnic background; and time period.

Results: A total of 6,092 tofacitinib-treated patients (representing 15,103 py of exposure) received tofacitinib (all doses) in the P1P2P3LTE studies. One or more events of NMSC occurred in 83 patients receiving tofacitinib (all doses). Of these 83, squamous cell carcinomas (SCC) occurred in 39 patients, and basal cell carcinomas (BCC) occurred in 52 patients. A total of five patients had a history of NMSC prior to tofacitinib exposure compared with 78 patients who did not. In the whole P1P2P3LTE population, the IR for NMSC overall was 0.55 (95% confidence interval [CI] 0.45, 0.69); the IRs for SCC and BCC were 0.26 (0.19, 0.35) and 0.35 (0.26, 0.45), respectively. The IRs for patients from the P1/2/3 and LTE cohorts receiving tofacitinib 5 mg BID were 0.61 (0.34, 1.10) and 0.41 (0.26, 0.66), respectively; for patients receiving tofacitinib 10 mg BID, the IRs were 0.47 (0.24, 0.90) and 0.79 (0.60, 1.05), respectively. Patients on background DMARDs had a numerically higher IR (IR 0.64, 95% CI 0.49, 0.84) than patients on tofacitinib monotherapy (IR 0.43, 95% CI 0.30, 0.64). There was a higher rate of NMSC in patients previously treated with TNFi (IR 1.01, 95% CI 0.67, 1.51) vs TNFi-naïve patients (IR 0.47, 95% CI 0.37, 0.61). Patients ≥65 years old had a higher rate of NMSC (IR 1.67, 95% CI 1.19, 2.35) vs patients <65 years old (IR 0.38, 95% CI 0.29, 0.51). Patients of White ethnicity had the highest IR of NMSC vs patients of Asian, Black, or Other ethnicity (0.86 vs 0.03, 0.00, or 0.14). The IRs for NMSC, analyzed in 6-month intervals (through >42 months), were stable over time.

Conclusion: The overall IR for NMSC in the tofacitinib clinical development program remained stable over time. The NMSC IRs appear to be consistent with published estimates in patients with RA treated with TNFi (IR 0.22–0.66).[1]

Comprehensive Summary of the Efficacy and Safety of Tofacitinib 5mg Twice Daily in Patients with Rheumatoid Arthritis and an Inadequate Response to Disease-Modifying Antirheumatic Drugs.

P. Bird[1], W. Bensen[2], B. El-Zorkany[3], J. Kaine[4], B.H. Manapat-Reyes[5], V. Pascual-Ramos[6], D. Witcombe[7], A. Anisfeld[8], K. Soma[9], R. Zhang[9] and K. Thirunavukkarasu[7]. [1]Combined Rheumatology Practice, Sydney, Australia, [2]St. Joseph's Healthcare, McMaster University, Hamilton, ON, [3]Department of Rheumatology, Cairo University, Cairo, Egypt, [4]Sarasota Arthritis Research Center, Sarasota, FL, [5]Section of Rheumatology, Department of Medicine, University of the Philippines - Philippine General Hospital, Manila, Philippines, [6]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [7]Pfizer Australia, Sydney, Australia, [8]Pfizer Inc, New York, NY, [9]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib has been approved in the US and other countries at the recommended dose 5 mg BID in patients (pts) with rheumatoid arthritis (RA) and an inadequate response (IR) to prior DMARDs. Several Phase 3 studies have been conducted as part of the tofacitinib clinical development program. Here we provide a comprehensive summary of efficacy and safety outcomes with the 5 mg BID dose from five DMARD-IR Phase 3 studies.

Methods: Week 12 efficacy and safety data for tofacitinib 5 mg BID and placebo (PBO) were compiled from five Phase 3 studies (NCT00814307, ORAL Solo; NCT00856544, ORAL Sync; NCT00853385, ORAL Standard; NCT00847613, ORAL Scan; and NCT00960440, ORAL Step). Pts with RA received tofacitinib as monotherapy (ORAL Solo) or with background DMARDs (ORAL Sync, ORAL Standard, ORAL Scan, ORAL Step). All pts in ORAL Standard and ORAL Scan had an IR to MTX, those in ORAL Step had an IR to TNFi, those in ORAL Solo were biologic or nonbiologic DMARD-IR, and those in ORAL Sync were nonbiologic DMARD-IR. Endpoints evaluated included ACR20, ACR50, ACR70 response rates, DAS remission (DAS28-4[ESR]<2.6), change in Health Assessment Questionnaire-Disability Index (HAQ-DI), adverse events (AEs), discontinuations due to AEs, serious adverse events (SAEs), and serious infection events (SIEs). For binary variables, such as ACR20/50/70 and DAS28-4(ESR)<2.6, non-responder imputation (NRI) was used.

Results: Baseline demographics and disease characteristics were generally similar within and between studies, except TNFi-IR pts having a longer history of RA than DMARD-IR. ACR20 rates were significantly improved with tofacitinib vs PBO either as monotherapy or with background DMARDs; ACR50 and ACR70 rates demonstrated similar patterns (Table 1). After only 12 weeks of treatment, significantly more pts receiving tofacitinib 5 mg BID than PBO achieved DAS28-4(ESR)<2.6, apart from those in ORAL Solo (Table 1). Significant changes from baseline in HAQ-DI were also observed with tofacitinib vs PBO, both as a monotherapy or with background DMARDs (Table 1).

Frequencies of AEs and SAEs were similar between tofacitinib and PBO across all studies (Table 1). Discontinuations due to AEs, by pts receiving tofacitinib, were ≤7% in all groups. Pooled and long-term analyses of Phase 3 and long-term extension studies have further described the AE profile associated with tofacitinib therapy.[1]

Conclusion: This comprehensive summary demonstrates that, regardless of prior therapy, short-term treatment with tofacitinib 5 mg BID significantly reduced signs and symptoms of RA, as measured by ACR20/50/70, DAS28-4(ESR)<2.6, and HAQ-DI. There were no unexpected safety findings at the US-recommended dose.

Infections and Gastrointestinal Side Effects in a Comparison of Rheumatoid Arthritis Therapies. Bei-Hung Chang[1], Lien Quach[1], Mary Brophy[2], Keri Hannagan[2], Edward C. Keystone[3], Ted R. Mikuls[4] and James R. O'Dell[5]. [1]VA Boston Healthcare System, Boston, MA, [2]VA Boston Heathcare System, Boston, MA, [3]University of Toronto, Toronto, ON, [4]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [5]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: TNF inhibitors and combinations of conventional disease-modifying antirheumatic drugs are commonly added to treat methotrexate non-responsive rheumatoid arthritis patients. In the 48-week double blind, RACAT trial (NEJM 2013;369:307–18), 353 methotrexate suboptimal-responders were randomized to two treatment strategies, either first adding sulfasalazine and hydroxychloroquine, triple therapy (T, N=178), or etanercept (E, N=175) to methotrexate. Participants without significant improvement in DAS28 at 24 weeks switched treatment while maintaining the blind. We examined differences between T and E in the most common adverse events reported in the trial, gastrointestinal (GI) toxicity and infections, taking into account possible confounding factors.

Methods: All adverse events during the trial were recorded and coded by blinded reviewers. Serious (SAE) or non-serious (NAE) infectious and GI events reported during the intervention period and for 4 weeks after completing the intervention were included in the analysis. The trial design posed challenges for analysis for 13 switcher patients who had infection (N=8) or GI (N=5) events occur both before and after switching treatment (either T to E or E to T). For these switchers we included in the analysis only the infections that occurred when patients were currently on T and GI events that occurred when patients were currently on E. This is a conservative approach because infections were the most common side effect for E and GI events were for T. We calculated the rate of event, total number of events, and the mean duration in the treatment when events occurred. Logistic and linear regression models were used for treatment comparison with and without controlling for participant characteristics (age, sex, race, BMI, smoking) and comorbidities.

Results: Participants who were on E were more likely to have infection NAEs (OR= 1.68, p=0.02) and had a higher total number of events (mean of 0.7 vs. 0.4, p=0.004) than participants who were on T. Participants who were on T had a higher number of GI NAEs than those on E (mean 0.55 vs. 0.34, p=0.02). Furthermore, the amount of time on the treatment when the GI events occurred was shorter for T than E (mean duration 10.0 vs. 17.7 weeks, p=0.001). The same conclusions remain after using regression models to control for patient characteristics and comorbidities. Serious infections and GI events were rare for both treatments. However, there were a greater number of SAE infections that occurred when receiving E than T (12 vs. 4). Pneumonia was the most common SAE infection for both treatments (6 E and 2 T).

Conclusion: In RACAT, infectious NAEs were significantly increased in participants receiving E compared with T even after controlling for participant demographics and comorbidities. GI NAEs were significantly more frequent in T and occurred earlier in the course of therapy. Though numbers of SAE were small, there was a trend toward greater number of infectious SAEs when receiving E, which were predominately pneumonias. Our study findings might help clinicians when prescribing medications by considering patients' tolerance of each treatment's more common adverse events.

Golimumab 5-Year Safety: an Analysis of Pooled Data from the Long Term Extensions of Randomized, Double-Blind, Placebo-Controlled Studies in Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis. Jonathan Kay[1], Roy Fleischmann[2], Edward C. Keystone[3], Elizabeth C. Hsia[4], Neil Goldstein[4], Benjamin Hsu[4], Yiying Zhou[4], Jürgen Braun[5] and Arthur Kavanaugh[6]. [1]UMass Memorial Medical Center, Worcester, MA, [2]Metroplex Clinical Research Center, University of Texas, Dallas, TX, [3]Mount Sinai Hospital, Toronto, ON, [4]Janssen Research & Development, LLC., Spring House, PA, [5]Rheumazentrum Ruhrgebiet, Herne, Germany, [6]University of California San Diego, La Jolla, CA.

Background/Purpose: To present an analysis of pooled data through approx 5yrs of follow-up from 5 completed golimumab(GLM) Ph3 SC trials across rheumatological indications.

Methods: SC placebo (PBO) or GLM (50mg or100mg) was administered q4wks in Ph3 trials. After wk24/52, pts in the Ph3 studies entered LTE and received GLM50mg or 100mg q4wks in an unblinded fashion. Dose adjustment from 50mg to 100mg and 100mg to 50mg was allowed once. Concomitant meds included DMARDs (mostly MTX). AEs were analyzed based on treatment received by a pt during the course of the study; PBO, 50mg only, 100mg only, or 50mg and 100mg. Because pts could cross-over from PBO to GLM, a pt may appear in both PBO and GLM columns. Due to the short duration of the PBO-controlled portion, comparisons between GLM and PBO grps are limited.

Results: In Ph3 trials, 639pts received PBO, 671 GLM50mg, 765 GLM50mg and GLM100mg, and 792 GLM100mg through 5yrs. In Ph3, 5.2%, 15.4%, 9.5% and 19.9% of PBO, GLM50 only, GLM50 and GLM100mg, and GLM100mg only pts, respectively, discontinued due to AE through 5yrs. The incidences per 100PY of deaths, serious infections (including TB, opportunistic infections [OI]), demyelination, and malignancies are presented. Injection site reactions were low; most were mild, and 2 cases led to discontinuation. No GLM SC-treated pt developed anaphylaxis/serum sickness-like reaction. Malignancies occurring during the 5 Ph3 trials included skin cancers, solid tumors, and lymphoma. In comparison to SEER, overall incidence of malignancies in GLM-and PBO-treated pts was similar to that expected in the general US population. Incidence of lymphomas per 100 pt-years of follow-up was greater in the GLM100mg dose grp through 5yrs and higher than that expected in the general US population.

Conclusion: The safety of continued SC GLM exposure demonstrates that GLM was generally well-tolerated with overall low rates of discontinuation due to AEs. Safety profiles were generally similar between GLM dose with exception of higher rates of serious infections, including TB and opportunistic infections, and lymphoma in the GLM100mg grp. Results are confounded by LTE design in which pts could receive GLM100mg after being exposed to GLM50mg with higher GLM dose used for pts with more refractory disease and by limited exposure to PBO making the comparisons between PBO and treatment grps of less value.

Analysis of Pooled Data from Two Randomized Controlled Trials and Their Open-Label Extensions: Long-Term Safety in Rheumatoid Arthritis before and after Certolizumab Pegol Dose Increase/Decrease. Boulos Haraoui[1], Vivian P. Bykerk[2], Ronald van Vollenhoven[3], Marc de Longueville[4], Kristel Luijtens[4], Pauline Ralston[5] and Arthur Kavanaugh[6]. [1]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [2]Hospital for Special Surgery, New York, NY, [3]The Karolinska Institute, Stockholm, Sweden, [4]UCB Pharma, Brussels, Belgium, [5]Giant Professional Ltd, London, United Kingdom, [6]University of California San Diego, La Jolla, CA.

Background/Purpose: Certolizumab pegol (CZP) is approved for adult patients (pts) with rheumatic diseases (RA, PsA and AS) at a maintenance dose of 200mg every 2 wks (Q2W) or 400mg every 4 wks (Q4W). In RAPID1[1] (52 wks) and RAPID2[2] (24 wks) randomized clinical trials (RCTs; NCT00152386 and NCT00160602), CZP was administered at a loading dose of 400mg at Wks 0, 2, and 4, followed by CZP 200mg Q2W, or at CZP 400mg Q2W in pts with active RA. All pts entering open-label extensions (OLEs; NCT00175877 and NCT00160641) received CZP 400mg Q2W for ≥6 months. The dose was subsequently reduced to CZP 200mg Q2W for all pts[3,4] as feeder studies revealed that the null hypothesis of no difference between doses could generally not be rejected. We present safety data evaluating the potential effect of CZP dose change over 12 wks prior to and post dose-escalation or dose-reduction, in line with treat-to-target.

Methods: Post-hoc analysis was performed on pooled RAPID1 and RAPID2 CZP data: 1) dose-escalation from CZP 200mg Q2W to CZP 400mg Q2W, 2) dose-reduction from CZP 400mg Q2W to CZP 200mg Q2W (Figure).

Results: 557 pts randomized to CZP 200mg Q2W in the RCTs entered the OLEs, with dose-escalation to 400mg Q2W. Of these, 210 pts (37.7%) experienced an adverse event (AE) in the 12 wks prior to dose-escalation versus 203 pts (36.4%) in the 12 wks post dose-escalation (Table). 94.4% of AEs were mild-moderate: 65 and 71 pts, respectively, experienced AEs considered to be drug-related. Serious AEs are reported in the table. The incidence of infections increased post dose-escalation. Malignancies were reported in 3 pts during 12 wks prior to (1 testis, 2 basal cell carcinoma [BCC]) and post (testis, lung, and peritoneal) dose-escalation. During OLEs, 1110 pts received CZP 400mg Q2W for ≥6 months before dose-reduction. Of these, 365 pts (32.9%) experienced an AE in the 12 wks prior to dose-reduction versus 342 pts (30.8%) in the 12 wks post dose-reduction; 94.1% of AEs were mild-moderate: 102 and 91 pts, respectively, experienced AEs considered drug-related. Incidence of SAEs and infections was similar prior to and post dose-reduction. 2 pts reported malignancies in the 12 wks post dose-reduction (1 gastric, 1 BCC). 2 cases of opportunistic infection (including tuberculosis) were reported in the 12 wks post dose-reduction. Overall, the number of AEs leading to withdrawals was low and no deaths were reported during the dose-escalation and dose-reduction study periods evaluated.

Conclusion: Overall, despite a modest infection rate increase after dose-escalation, no new safety concerns emerged during dose-escalation or dose-reduction, and AE rates were generally similar between periods. However, the natural trend of a decreasing rate of AEs was observed over time, as is usual in RA clinical trials.

18-Month Worldwide Post-Marketing Surveillance Experience of Tofacitinib. S. Cohen[1], J.R. Curtis[2], Roy Fleischmann[1] and Y. Chen[3]. [1]Metroplex Clinical Research Center, Dallas, TX, [2]University of Alabama, Birmingham, AL, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: Post-marketing surveillance is an important part of monitoring adverse events (AEs) following the approval of new drugs. Tofacitinib is an oral Janus kinase inhibitor approved in the United States in November 2012 for the treatment of rheumatoid arthritis (RA). An analysis of the post-marketing spontaneous (PMS) reports, covering a period of 18 months, was conducted to evaluate the safety of tofacitinib in the post-marketing setting.

Methods: Tofacitinib worldwide PMS reports received in the Pfizer safety database from 6 November 2012 to 5 May 2014 were analyzed. The type and estimated reporting rate of serious AEs of interest, including infections, neoplasm events, gastrointestinal (GI), and hepatobiliary disorders, by 6-month interval were reviewed. The reporting rate of SAEs was calculated by dividing the number of SAEs by the estimated patient-years of exposure (PYs). The PYs were estimated based on estimated worldwide sales and an estimated daily regimen of 5 mg twice daily.

Results: A total of 2,496 case reports with 6,295 AEs were received. The majority of reported AEs were non-serious (83.4%). Of the 1,043 SAEs, 21.8% of the events were related to infections, 8.7% were GI disorders, 3.55% were neoplasm events, and 0.6% were hepatobiliary disorders. The reporting rate of serious infections (SIs) was 5.1, 6.2, and 2.48 per 100 PYs for the

first/second/third 6-month interval, respectively. The most commonly reported SI events (n ≥ 10) include pneumonia (33), urinary tract infection (26), sepsis (15), diverticulitis (11), and herpes zoster (HZ) infections (10). A small number of opportunistic infections (OI) were reported including reactivation of tuberculosis (2), disseminated HZ (1), histoplasmosis (1), Cytomegalovirus gastritis/ oesophagitis (1), and unspecified OI (1). The reporting rate of serious neoplasm events across the first/second/third intervals was 0.14, 1.02, and 0.54 per 100 PYs, respectively. The commonly-reported serious neoplasm events (n ≥2) include lymphoma (6), bladder cancer (3), brain neoplasm (3), lung neoplasm malignant (2), basal cell carcinoma (2), and unspecified neoplasm malignant (2). Most of the case reports did not have sufficient information for a causality assessment. In the reports where time to onset was provided, eight events were diagnosed before or within 2 months of the initiation of tofacitinib. Across the reporting period, no significant change in reporting rate was noted for GI and hepatobiliary disorders. Of the 91 reported serious GI events, the most commonly reported events (n ≥ 5) including diarrhea (11), nausea (6), vomiting (6), GI hemorrhage (5), and hematochezia (5).

Conclusion: Review of AEs from PMS reports did not reveal any new safety signal compared with the safety profile identified from tofacitinib RA clinical studies during its development program. SAEs including SIs and malignancy have been reported in the post-marketing setting and the safety profile of tofacitinib will continuously be monitored via pharmacovigilance. Limitations of PMS reports (such as under-reporting and reporting bias) and estimated reporting rate due to lack of denominators should be considered when interpreting these results.

Should Anti-Tnfa treatment of RA be Stopped before Orthopedic Surgery? Charlotte Mabille[1], Adeline Ruyssen Witrand[2], Thomas Barnetche[3], Arnaud Constantin[2] and Alain G. Cantagrel[2]. [1]hopital Purpan, Toulouse, France, [2]CHU Purpan - Hôpital Pierre-Paul Riquet, Toulouse, France, [3]Rheumatology department, Bordeaux University Hospital, bordeaux, France.

Background/Purpose: Anti-TNFs have greatly contributed to improve RA prognosis. Hence, the needs for orthopedic surgery have considerably decreased in the past years. However, surgery, whether programmed or not, whether orthopedic or not, is sometimes necessary in patients treated with TNF inhibitors. Current recommendations are to discontinue biologic DMARDs to reduce the risk of surgical site infection. The guidelines for periopetrative cessation periods of biologic DMARDs differ among countries but generally a stop of the biotherapy 2 to 6 weeks before programmed surgery is recommended. Anti-TNF can be resumed after wound healing.

The purpose of this current study was to ask:

1. Whether patients treated with anti-TNF are really at risk for infection upon surgery.

2. Whether stopping anti-TNF treatment increases the risk of infection upon surgery.

Methods: We have conducted a systematic review of the literature indexed in Pubmed, Embase, and Cochrane using the following keywords: "Rheumatoid arthritis AND surgery AND infection AND (adalimumab OR certolizumab OR etanercept OR golimumab OR infliximab)". This search was conducted up to February 2014 and was limited to papers in English and French languages. Reviews and case reports were excluded.

We selected studies reporting numbers of infections observed post-surgery by

i) comparing patients using anti-TNF with patients using DMARDS without biologicals and

ii) comparing patients keeping up with anti-TNF with patients who interrupted anti-TNF before surgery.

Results: Fourteen studies reported the frequency of post-surgery infections of RA patients undergoing orthopedic surgery, most often joint replacement.

Eleven studies were pooled in order to evaluate the infection risk in patients treated with anti-TNF compared with patients treated with DMARD without biologics. There were 4,925 surgeries and 121 infections in patients using anti-TNF and 60,678 surgeries and 711 infections in patients with DMARD alone. Thus, patients treated with anti-TNF are at higher risk of post-surgery infection (OR = 1.95 [1.34–2.85]). Some joints such as foot, ankle and elbow seem to be at higher risk.

Six studies were pooled for meta-analysis evaluating the benefits of stopping anti-TNF as post-infection risk is concerned. Two studies were not informative, as no infection was reported in any of them. Stopping the anti-TNF treatment did not modify the infection risk: OR = 0.70 [0.39–1.25].

Conclusion: This meta-analysis shows that patients treated with anti-TNF are more exposed to risks of infection after orthopedic surgery. The increased rate of infection in those patients was not ameliorated by stopping anti-TNF before surgery. This could lead clinicians, at least in surgeries with lower risks of infection, to reconsider stopping anti-TNF before surgery since this may expose patients to a flare-up.

Evaluation of the Rabbit Risk Score for Serious Infections in a UK Anti-TNF Treatment Cohort. Lucia Silva-Fernandez[1], Mark Lunt[1], Kath D. Watson[1], BSRBR Control Centre Consortium[1], Deborah P. Symmons[1], Kimme Hyrich[1] and On behalf of the BSRBR[2]. [1]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom, [2]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: Serious infections (SI) are a major concern in patients treated with tumour necrosis factor inhibitors (TNFi). The RABBIT Risk Score (RRS) (1) allows a calculation of the expected number of SI over a one year period of TNFi treatment according to patient characteristics. This score was developed in a cohort of German patients with rheumatoid arthritis (RA) enrolled in the RABBIT biologics register and then validated in a second cohort from the same register. The aim of the present study is to assess the reliability of the RRS in two cohorts of patients with RA treated with TNFi from the British Society for Rheumatology Biologics Register (BSRBR)-RA.

Methods: The BSRBR-RA is an ongoing national prospective cohort study of subjects with RA starting biologic therapy. Patients were recruited to a first TNFi cohort (old) between 2001 and 2008 and to a second TNFi cohort (new) from 2010 to date. Risk factors included in the RRS include age. Health Assessment Questionnaire (HAQ) score, chronic lung disease, chronic renal disease, previous serious infection, number of treatment failures, mean daily glucocorticoid dose and treatment with TNFi. As the BSRBR-RA does not capture the dose of oral steroids or intramuscular injections (common in the UK), we applied a modified version of the score to both cohorts assuming that all patients receiving steroids would take between 7.5–14 mg of prednisolone per day. We calculated the expected number of patients with at least one SI in the first year of therapy and compared to the observed numbers in each cohort. To evaluate the predictive performance of the RRS we calculated the area under the curve (AUC).

Results: 13,121 patients were recruited to the old cohort and 1,475 patients were recruited to the new cohort. There were significant differences between cohorts (Table). Patients from the old cohort had a longer disease duration, higher DAS28 and HAQ score, and more likely to be receiving steroids compared to newer patients. The crude incidence rate of SI was lower in the new cohort (29.3 new vs 62.3 old/1000 patient-years) as was the expected and observed number of patients with ≥1 SI during the first year of therapy. The predictive performance of the RRS was better for the new cohort (AUC=0.82) than for the old cohort (AUC=0.62).

	Old cohort (n=13,121)	New cohort (n=1,475)	p
Age (years), mean (SD)	56.1 (12.3)	56.5 (12.6)	0.128
Gender: n (%) female	10,010 (76.3)	1,116 (75.7)	0.591
RA disease duration (years), Median (IQR)	11 (6 – 19)	6 (2 – 14)	0.0001
DAS28, mean (SD)	6.5 (1.0)	5.9 (1.0)	0.0001
HAQ score, mean (SD)	2.0 (0.6)	1.6 (0.7)	0.0001
RF +, n (%)	8,493 (64.8)	821 (55.6)	<0.0001
Steroid use (%)	5,867 (44.7)	358 (24.3)	<0.0001
Smoking			0.065
Current, n (%)	2,861 (22.0)	279 (20.2)	
Ex-smoker, n (%)	4,922 (37.8)	505 (36.5)	
Never smoked, n (%)	5,238 (40.2)	600 (43.4)	
More than 5 previous DMARDs, n (%)	325 (2.5)	4 (0.3)	<0.0001
Diabetes, n (%)	750 (5.8)	115 (7.9)	0.001

Chronic lung disease, n (%)	2,060 (15.9)	252 (18.5)	0.012
Chronic renal disease, n (%)	330 (2.5)	28 (1.9)	0.149
Crude incidence rate of serious infections in the first year per 1,000 patient-years (95% Confidece Interval)	63.3 (59.0 – 67.9)	29.3 (20.8 – 41.3)	
Number of observed first serious infections in the first year	771	33	
Number of expected first serious infections in the first year	496	27	
Area under the curve (95% Confidence Interval)	0.62 (0.60 – 0.64)	0.82 (0.73 – 0.91)	

Conclusion: TNFi are being used earlier in RA patients with lesser disease activity, steroid use and disability. These patients are also experiencing lower SI rates. Among these cohorts of UK patients, the RRS underestimated the total number of SI, although some misclassification of steroid dose and differential access to TNFi resulting in other unmeasured patient differences may have contributed. The predictive power improved in a more recent cohort which strengthens the utility of this score in current routine clinical practice.

Identification of Baseline Risk Factors for Adverse Events in Certolizumab Pegol Treated Rheumatoid Arthritis Patients. Boulos Haraoui[1], John Wade[2], Marc de Longueville[3], Pauline Ralston[4] and Jeffrey R. Curtis[5]. [1]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [2]University of British Columbia, and Vancouver General Hospital, Vancouver, BC, [3]UCB Pharma, Brussels, Belgium, [4]Giant Professional Ltd, London, United Kingdom, [5]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Despite efficacy of anti-tumor necrosis factors (anti-TNFs) in treating chronic immune conditions, some patients (pts) report serious adverse events (SAEs) highlighting a need to identify at risk pts before starting treatment.[1,2] We examine safety data for rheumatoid arthritis (RA) pts treated with the anti-TNF, certolizumab pegol (CZP), in the RAPID1 and RAPID2 randomized clinical trials (RCTs; NCT00152386/NCT00160602) and their open-label extensions (OLEs) to identify baseline (BL) risk factors for specific SAEs, with the goal of risk stratifying pts for adverse outcomes to provide more personalized estimates of expected risks and benefits of therapy.

Methods: Post-hoc analysis was performed on CZP safety data pooled across RCTs (RCT CZP data) and RCT+OLE periods (All CZP data). Pts with prior anti-TNF/biologicals use (4.1%) were excluded from analyses due to limited pt numbers in this group. 3 non-sequential stepwise multivariate Cox proportional hazards models were used to estimate relative risk (Hazard Ratio [HR]; entry $p \leq 0.2$, stay $p \leq 0.25$) of BL covariates to the first serious infectious event (SIE), major cardiovascular event (MACE), or all-cause death. Any event between first CZP dose and 84 days after the last study dose or pt withdrawal was included. BL covariates included age ($<$ or $\geq$65 years), presence of comorbidity (any treated cardiac disorder, diabetes or COPD), systemic steroid use (0, $>$0–5, $>$5 mg/day), methotrexate dose ($\leq$ or $>$15 mg/week), RA disease duration ($<$ or $\geq$2 years), and a range of BL disease activity measures.

Results: A total of 311 placebo (PBO) pts (130.5 pt-years [PY]) and 1224 CZP pts (798.5 PY) were included in the RCT analyses, with 3 and 50 pts, respectively, reporting $\geq$1 SAE of interest. 1 and 2 PBO pts experienced $\geq$1 SIE or MACE, respectively, and 1 died while 40 and 8 CZP pts experienced $\geq$1 SIE or MACE, respectively, and 7 died. BL predictors of SIEs for the RCT data were treated comorbidities and systemic steroid use (Figure A). For All CZP data, 246/1506 RA pts (5778.6 PY) reported SIE/MACE/death: 201 and 32 pts reported $\geq$1 SIE or MACE, respectively, with 38 deaths. Time to first SIE was associated with several covariates screened as potential risk factors. BL treated comorbidity had marked associations with time to first SIE (Figure B). No other covariates examined were considered relevant to the outcome. Age was a predictor of MACE and death but the low number of events limits interpretation of this finding.

Conclusion: CZP-treated pts with certain comorbidities were twice as likely to experience SIEs and the risk remained elevated when data were pooled across RCT +OLEs. Knowledge of BL characteristics related to an increased risk of SAE of interest should help clinicians to better identify those pts and help manage some of the risks related to anti-TNFs.

Safety of Rituximab in Patients with Chronic Inflammatory Arthritis. Seven-Year Follow-up Observational Study. Andrea Cuervo[1], M. Victoria Hernández[1], Sonia Cabrera[1], Jose Inciarte-Mundo[1], Julio Ramirez[1], Virginia Ruiz-Esquide[1], Juan D. Cañete[2] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clinic, Barcelona, Spain.

Background/Purpose: Rituximab (RTX) is a biologic therapy approved for the treatment of active rheumatoid arthritis (RA) refractory to tumour necrosis factor antagonists. It causes B cell depletion, with a progressive reduction of the levels of immunoglobulin (Ig) that may be associated with an increased risk of infection. Our objective was to analyse the long-term safety of treatment with RTX in patients with RA and other inflammatory arthritis, and especially the risk of severe infections.

Methods: We made a retrospective descriptive study including patients treated by the Rheumatology Department of a tertiary hospital from June 2006 to December 2013 who had received at least one cycle of treatment with RTX. We analysed: demographic data (age, sex), diagnosis and disease duration, positive rheumatoid factor (RF) or anti-cyclic citrullinated peptide antibodies (anti-CCP); previous biologic treatment; concomitant treatment: disease-modifying antirheumatic drugs (DMARD) and/or concomitant glucocorticoids (GC); number of cycles received; levels of immunoglobulin (Ig) and adverse effects, especially severe infections.

Results: 53 patients were included (85 % female, mean age 58.9 $\pm$ 12.9) until December 2013, who received a total of 169 cycles of RTX (mean: 3.3 $\pm$ 2.2 cycles/patient) during 7 years. Diagnoses were: RA (75.5 %), overlap syndrome (11.3 %), systemic lupus erythematosus (5.7 %), psoriatic arthritis (3.7 %), seronegative oligoarthritis (1.9 %) and juvenile idiopathic arthritis (1.9 %). Mean disease duration was 15.1 $\pm$ 8.4 years, 79.2 % were RF/anti-CCP positive, 67.9 % had received prior biological treatment, 37.7 % had received $\geq$ 2 or more biologic drugs, 77.3% received concomitant DMARDs (47.2% methotrexate, 30.2 % leflunomide, 11.3% hydroxychloroquine and 3.8 % mycophenolate mofetil) and 79.2% received GC. A progressive, significant decrease in IgG levels ($p = 0.018$), IgM ($p = 0.018$) and IgA (0.05), already evident after the first RTX cycle, was observed, although only 13.2% of patients had Ig levels below the normal range. Twenty-five adverse events were reported, of which 19 were considered drug-related: 2 infusion reactions, 2 cases of leukopenia and 15 infections (7 respiratory tract, 5 urinary tract, 1 soft tissue infection, 1 case of bacteremia and 1 septic shock), and 4 of which were considered serious according to medical criteria, although no patient discontinued RTX for those reasons. No opportunistic infection or malignancy was reported. Patients with low Ig levels did not have a greater number of infections than those with normal Ig levels.

Conclusion: After prolonged exposure to RTX, serious adverse events, including infections, were stable over time and multiple treatment courses, and showed a good safety profile, even in patients with reduced Ig levels.

Safety Profile of Biologic Agents for Rheumatoid Arhtisitis Treatment after the Complication with Methotrexate-Related Lymphoproliferative Disorder.

Shuntaro Saito[1], Yuko Kaneko[1], Katsuya Suzuki[1], Michihide Tokuhira[2] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical Center, Saitama Medical University., Saitama, Japan.

Background/Purpose: Lymphoproliferative disorder (LPD) is a rare complication in patients with rheumatoid arthritis(RA) treated with methotrexate(MTX). Although not a few patients experience exacerbation of RA disease activity after withdrawal of MTX, there have been very few reports referring how to treat RA with MTX-LPD. This study is to investigate the safety profile of biologic agents as a RA treatment after the diagnosis of MTX-LPD.

Methods: We retrospectively studied all 32 RA patients regarded as being complicated with MTX-LPD from 2007 to 2013 in our institution. The patients were classified into 2 groups: patients treated with biologic agents after MTX withdrawal (Biologics group) and patients treated with conventional synthetic disease modifying anti-rheumatic drugs (csDMARD) other than MTX or prednisolone (PSL) (non-biologics group). The rates of LPD recurrence after these RA treatments were compared. The recurrence rates were analyzed by Kaplan-Meier curves and compared by log-rank test.

Results: Four patients were excluded because three died before the restart of RA treatment and one needed no treatment, so twenty eight patients were analyzed in this study. Baseline characteristics of 28 patients were following: age,65; Female, 89%; duration of MTX administration, 7.5 years; RA disease duration,14.1years; disease activity score (DAS) 28, 2.95. Of 28 patients, 22 patients were pathologically diagnosed as LPD, and 10 were highly suspected of LPD with imaging tests. Seven patients were treated of LPD with chemotherapy prior to restart of RA therapy. 17 Patients were treated with biologic agents and the drugs used were following; tocilizumab (TCZ) in 9 patients, tumor necrosis factor inhibitors (TNFi) in 6, abatacept in 1, rituximab in 1. Eleven patients were treated with PSL and/or csDMARDs; PSL alone in 5, salazosulfapyridin (SASP) in 3, bucillamin in 2, tacrolimus (Tac) in 1 patient. LPD relapsed in 2 patients in biologics group, and in 1 in non-biologics group. No significant difference in recurrence rates between the two groups analyzed by Kaplan-Meier curves and Log-rank test (Figure, p=0.84).

Among 7 patients who had been treated with chemotherapy before the RA disease activity exacerbation, 3 were treated with biologics and 4 with non-biologic; PSL alone in 2, SASP in 1, Tac in 1. No LPD recurrence was observed in these 7 patients in follow up duration (mean 33 months).

Additional analysis with 22 patients that were pathologically diagnosed of LPD showed similar results.

Conclusion: Biologics agents did not increase LPD recurrence compared to csDMARD, and could be the choice of RA treatment in post-MTX-LPD.

<Figure> Recurrence free RA treatment period [months]

Improving of Safety in Treatment with Biologics during First Seven-Years Experiences; Long-Term Results from Observational Cohort Study of Clinical Practice Using Multicenter Registry in Japan.

Toshihisa Kojima[1], Nobunori Takahashi[1], Koji Funahashi[2], Shuji Asai[2], Yutaka Yoshioka[2], Kenya Terabe[2], Nobuyuki Asai[2], Toki Takemoto[2], Naoki Ishiguro[1], Atsushi Kaneko[3], Yuji Hirano[4], Yuichiro Yabe[5] and Yasuhide Kanayama[6]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Nagoya University Hospital, Nagoya, Japan, [3]Nagoya Medical Center, Nagoya, Japan, [4]Toyohashi Municipal Hospital, Toyohashi, Japan, [5]JCHO Tokyo Shinjuku Medical Center, Tokyo, Japan, [6]Toyota Kosei Hospital, Toyota, Japan.

Background/Purpose: Many evidences including clinical trials of biologics lead us earlier and more aggressive treatment strategy for patients with rheumatoid arthritis (RA). It is stated as "treat-to-target", that is remission. It is critical issue in clinical practice how to evaluate risks and to balance between safety and efficacy of treatment, which could be related to experience.

The aims of this study are to explore the learning curve of treatment with biologics during the first 7 years in Japan (2003–2010) based on safety results associated with the changes in baseline characteristics according to treat-to-target strategy in RA patients treated with biologics using multicenter registry; Tsumumai Biologics Communication Registry (TBCR).

Methods: We analyzed changes in baseline characteristics by initiation year of 1st biologics and the incidence rate of adverse event (AE) caused discontinuation of 1st biologics in patients who were registered in TBCR from 2003 to 2008 and followed up to 2010. Predictive factors at baseline for incidence of adverse event were determined using multivariable Cox's proportional-Hazards regression model.

Results: A total of 874 cases (2052 person-years) were observed. Patients with younger age (≤53 ys) had significantly shorter disease duration (<2 years), less dysfunction, joint damage, and disease activity (DAS28-CRP) at 2008, compared to 2003–2005 while patients with older age (>64 ys) had no significant changes. During total observation, 122 AEs (6.0 events/100 person-years) were occurred. The incidence rate of AEs were significantly higher in older age group than in younger age group (p<0.001, log-rank test). Kaplan-Meier curves showed that the incidence rate of AEs was significantly decreased with year of initiation, especially in older age group and that the differences was remarkable up to 6 months. Actually, multivaliable analysis showed that, during 2 years observation, older age [OR 1.8, 95%CI (1.1–3.0)], worse physical function [OR 2.1, 95%CI (1.4–3.1)], MTX use [OR 0.4, 95%CI (0.3–0.7)], and etanercept use (vs infliximab use) [OR 0.4, 95%CI (0.3–0.7)] had significant impacts on incidence of the AEs. Interestingly, initiation year had significant impacts on incidence of AEs up to 6 months [initiation at 2008: OR 0.3, 95%CI (0.1–0.7), compared to initiation 2003–2005] and while the impact disappeared up to 2 years observation. The impact of MTX use and etanercept use was not detected up to 6 months observation. Incident rate of the AEs in pateints with older age who were initiated biologics at 2008 was comparable to patients with younger age. These results suggested that, during first 3 years (2003–2005), we could not evaluate risk factors properly, especially in respiratory system, with inadequate experience.

Conclusion: We clearly demonstrated improving of safety of 1st biologics with first 7-years experiences in real clinical practice using multicenter registry of biologics in Japan.

Abatacept Can be Used Safely for RA Patients with Interstitial Lung Disease. Shinji Motojima[1], Tamao Nakashita[2], Akira Jibatake[3] and Katsutoshi Ando[4]. [1]Kameda Medical Center, Kamogawa City, Japan, [2]Kameda Medical Center, Kamogawa-city, Japan, [3]Kameda Medical Center, Kamogawa city, Japan, [4]Juntendo university, tokyo, Japan.

Background/Purpose: Interstitial lung disease (ILD) associated with RA is a big concern particularly in Japanese patients evidenced by the reports that the cause of death in approximately 10 % of patients with RA is ILD compared with only few percent in western countries. We have reported that ILD exacerbated in 24 % (14/58) of RA patients associated with ILD when TNF-inhibitors were administrated and 2 of 14 died of ILD, although the degree of exacerbation was minimal in half of the patients (ACR 2012). Here we retrospectively analyzed the effects of abatacept (ABT), a CTLA4-Ig fusion protein, on RA associated with ILD.

Methods: Subjects were 16 patients with RA (male/female = 6/10, mean age 71 years-old) associated with ILD who were administrated with ABT for longer than 52 weeks and analysis was done for the changes between 0 to 52 weeks, because the exacerbation of ILD developed between 4 to 52 weeks of administration of TNF-inhibitors with the mean of 24 weeks in our previous study. Chest CT scan was done before and 52 weeks after administration of ABT. Chest X-ray film (CXR) was taken at least every 3 months. When newly developed shadows were found on CXR or when patients complained of respiratory symptoms for more than 2 weeks, chest CT scan was done. The severity of ILD was graded into 4, grades 0 to grade 3, according to the extent of ILD on chest CT by the method of Gochuico et al. (Arch Intern Med 2008). Chest CT images were graded by 2 independent respirologists.

Results: All the patients completed 52 weeks administration and no-one abandoned ABT due to the exacerbation of ILD. The grades of ILD (grade 0/1/2/3) before and at 52 weeks were 0/9/4/3 and 2/7/4/3, respectively. In 2 patients with grade 1, the grade decreased to 0, suggesting the improvement of ILD. We further attempted to analyze more in detail the CT images according to the method by Kondoh et al. (Respirology 2013), and obtained what % of lung fields have findings of ILD. All the abnormalities suggestive of ILD before and at 52 weeks were 12.9 +/− 12.7 (mean +/− SD) and 12.2 +/− 13.9, respectively, and no significant differences were found. Mean DAS28-ESR and SDAI decreased from 4.47 +/− 1.44 to 2.84 +/− 0.85, and from 16.9 +/− 11.7 to 8.1 +/− 4.2, respectively, and the differences were statistically significant. The mean dose of PSL decreased from 6.6 mg/day to 5.6 mg/day significantly (n = 15). KL-6, a biomarker of ILD, did not change significantly.

Conclusion: ABT can be used safely for RA patients with ILD. ABT even may improve ILD and is an appropriate treatment option for such patients.

Authors do not have any COI.

Complications of Varicella Zona Virus Infections Are More Frequent in Patients Treated with Biologic Drugs When Combined with Steroids. Jacques Morel[1], Florence Tubach[2], Yannick Allanore[3], Daniel Wendling[4], Celine Cozic[5], Emmanuelle Dernis Labous[6], Eric Legangneux[7], Thao Pham[8], Sophie Odoit[9], Isabelle Roitg[10], Isabelle Koné-Paut[11], Pierre Quartier[12], Jean Sibilia[13] and Severine Guillaume Czitrom[14]. [1]Hopital Lapeyronie, Montpellier, France, [2]Universite Paris Diderot, Paris, France, [3]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France, [4]CHU J Minjoz, Besancon, France, [5]CHD la Roche sur Yon, La Roche Sur Yon, France, [6]Ch Du Mans, Le Mans, France, [7]Centre Hospitalier Public du Cotentin, 50100, France, [8]Sainte Marguerite Hospital, Marseille, France, [9]CHU de la Réunion, Saint Denis, France, [10]Hopital De Perpignan, Perpignan, France, [11]CHU Bicêtre, Le Kremlin Bicêtre, France, [12]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [13]University Hospital of Strasbourg, Strasbourg, France, [14]Ch De Bicetre, Le Kremlin Bicetre Cedex, France.

Background/Purpose: To assess varicella zona virus (VZV) infection features under biological drugs.

Methods: A call for observations was sent from april 2013 to april 2014 by email through the Club Rheumatism et Inflammation website to collect varicella zona virus (VZV) infections in adults and children under biologic DMARDs (bDMARDs). Cases collected between february 1st 2004 and january 31th 2007, by the french observational study RATIO were added. Khi-two or Fisher tests were used for qualitative variables when appropriate.

Results: 103 VZV infections were collected in 76 adults and 27 children receiving anti-TNF (71), anti-IL-1 (10), rituximab (10), tocilizumab (8) and abatacept (4) for rheumatoid arthritis (46), spondyloarthritis (15), juvenile induced idiopathic arthritis excluding Still's diseases (11), Still's disease (11), Crohn's disease (8), psoriasis or psoriatic arthritic (3), connectivite connective tissue disease (2) and other chronic inflammatory diseases (6). Adult patients were mainly women (72.4%), 56% aged 19–60 years old and the others were over 60. At the time of infection, associated to bDMARDs were NSAIDs in 5 patients were on NSAID, steroids in 43 on steroids, conventional synthetic (cs) DMARDs in 54 on conventional synthetic (cs) DMARDs and 9 immunosuppressive drugs in 9. VZV infections occurred late after drug onset (> 6 months for 97.2% of patients with steroids, 70.2% for bDMARDs and after 3 years for cs DMARDs for 70.4%. 27 children aged less than 18, mainly girls (74.1%) were treated with methotrexate (15) or immunesuppressive drugs (2) combined with NSAIDs for 10 patients in addition to bDMARDs. Most children were on steroids (11), or bDMARDs (16) for at least 6 months when VZV infection occurred. None of the patients had been vaccinated against VZV. Zoster was more frequently observed in adults (68/76 adults), whereas varicella was most often reported in children (18/27). For varicella, 4 complications were reported in adults (2 skin and 2 disseminated) and 2 in children (1 ophthalmic and 1 disseminated). Complications were more frequent for zoster: 40 in adults (28 skin, 6 neurological, 6 ophthalmic) and 2 in children (1 neurological and 1 ophthalmic). Complications were significantly higher in patients on steroids (p=0.02 vs non steroid group) and tend to be more elevated in anti-TNF group (p=0.055 vs non TNF inhibitor bDMARDs). None received IV immunoglobulin. 90 patients (71 adults and 19 children) were treated with an anti-herpes virus (HSV) drug usually prescribed oral for 1 to 2 weeks and intravenously in 28 patients. NSAIDs were pursued in 11% of the children and 83% of the adults. bDMARDs were at least transiently interrupted in 63 patients (62%) and csDMARDs were stopped for 17 patients. Outcome was favourable for 98 patients with no death.

Conclusion: In this retrospective study, VZV infections were mainly varicella in children and zoster in adults. Outcome was favourable in most cases even when bDMARDs or NSAIDs were pursued and remarkably, even when no specific treatment of VZV infection was applied. Under bDMARDS, complications of VZV infections occurred more frequently in patients treated with steroids.

Assessment of 12-Month Efficacy and Safety of 168 Certolizumab-pegol Rheumatoid Arthritis Treated Patients from a Multicenter Retrospective National Study in Spain. Vicente Torrente-Segarra[1], Ana Urruticoechea[2], Héctor Corominas[1], Amalia Sánchez[3], Juan

Víctor Tovar[4], Alejandro Muñoz[5], Anna Martínez[6], José Antonio González[4], Manuel Fernández[7] and Noelia Vázquez on behalf of RENACER Study Group[8]. [1]Hospital General Hospitalet-Sant Joan Despí Moisès Broggi, Hospitalet Llobregat, Barcelona, Spain, [2]Hospital de Can Mises, Ibiza, Spain, [3]Hospital Universitario Lucus Augusti, Lugo, Spain, [4]Hospital General Universitario de Elche, Alicante, Spain, [5]Hospital Universitario de Valme, Sevilla, Spain, [6]Hospital La Ribera, Alzira, Valencia, Spain, [7]Hospital Universitario de Guadalajara, Guadalajara, Spain, [8]Hospital Universitario de Ceuta, Ceuta, Spain.

Background/Purpose: There's scant data of CertolizumabPEGol (CZP) in clinical practice. Study goal: assess efficacy and safety of CZP in RA patients at 3, 6,12-month (m), and clinical / serological variables that predict 12-m clinical CZP response.

Methods: Observational, retrospective study of RA patients (ACR 2010), 35 sites in Spain. Patients on CZP, either anti TNF naïve / after other Biological Therapies (BT) failure. Study approved by a local Ethics Committee. Efficacy variables: Tender Joint Count (TJC) and Swollen Joint Count (SJC) reductions, European League against Rheumatism (EULAR) Response, Simplified Disease Activity Index (SDAI) response, steroids dose, CRP, ESR. Safety variables: discontinuation due to side effects. Statistical analysis: SPSS v19.0. Comparative: Mann Whitney / Chi-square tests. Longitudinal: Friedman Cochran's test. Logistic regression analyses performed.

Results: 168 patients: 79.2% women, mean age 54.5 (±13.2), mean disease time 7.5 (±7.3), prior DMARD (25.6% none; 32.1% 1, 42.3% ≥2): MTX 55.4%, leflunomide 36.9%, gold 25.6%, SSZ 11.3%, HCQ 10.7%. Mean number (nr) prior DMARD: 1.4 (±1.2). Prior BT (54.2% none, 28.6% 1, 17.2% ≥2): etanercept 23.8%, adalimumab 19.0%, infliximab 16.1%, rituximab 6.5%, tocilizumab 5.4%, abatacept 4.2%, golimumab 3.0%. Mean nr prior BT 0.8 (±1.1). Mean time on CZP 9.8 m (±3.4), 93.5% induction dose. Concomitant treatment: 11.9% oral steroids, 24.4% DMARD, 50.0% DMARD + steroids (69.6% 1 DMARD, 4.8% 2 DMARDs).

Table 1: Basal, 3-m, 6-m, 12-m clinical variables

	Basal	3-m	6-m	12-m	P value
RF	70.8% (mean RF: 124.2 ± 183.2)				
Anti-Cyclic citrulinated Protein (CCP)	59.8% (mean CCP:275.1 ± 454.9)				
CRP	9.0 (±12.7)	5.7 (±11.7)	4.7 (±9.9)	4.6 (±9.9)	<0.001
ESR	32.3 (±25.3)	25.7 (±21.2)	23.7 (±21.9)	23.5 (±19.9)	<0.001
TJC	8.0 (±5.2)	4.7 (±5.3)	3.6 (±5.0)	3.3(±5.2)	<0.001
SJC	6.0 (±4.5)	3.1 (±4.2)	2.1 (±3.7)	2.2 (±3.9)	<0.001
Disease Activity Score (DAS28)	5.1 (±1.3)	4.0 (±1.6)	3.5 (±1.7)	3.4 (±1.7)	<0.001
DAS28 remission	4.2%	23.8%	35.7%	44.0%	
EULAR		19.6% / 29.8%	27.4% /38.7%	25.0% / 46.4%	
Moderate/Good Response					
SDAI	35.8 (±18.1)	22.1 (±20.7)	17.8 (±19.3)	17.1 (±19.6)	<0.001
Steroids (mg)	8.8 (±6.9)	6.6 (±5.7)	5.7 (±5.7)	4.8 (±5.2)	<0.001

19 patients had mild side-effects, 6 at 3-m (1 varicella zoster reactivation), 8 at 6-m (1 mild respiratory tract infection, that led to CZP withdrawn), 5 at 12-m (1 infectious otitis). 48 withdrawn (28.6%): 31 lack efficacy, 15 intolerance, 2 other causes, 11.9% 3-m and 16.7% 6-m. 120 patients (71.4%) went on CZP at 12-m visit.

Looking responders versus non responders for DAS28/EULAR Response/SDAI we saw some predictors of response ($p<0.05$): lower nr of prior DMARD / BT; higher CRP, ESR, TJC, SJC, DAS28, SDAI. No differences in BT-naive / monotherapy

Conclusion: CZP showed clear benefit in severe refractory to DMARD / BT RA patients with a significant reduction of CRP, ESR, TJC, SJC, DAS28. 75% patients achieved moderate/good EULAR response, either RF/antiCCP (+) or (−). 12-m predictors of response: CRP, ESR, nr of prior DMARD / BT, TJC, SJC, DAS28, SDAI. CZP was well tolerated, no serious side effects. On clinical practice, CZP showed benefit in 71% of RA after 12-m, even in a 45.8% of patients with prior antiTNF.

Risk Analysis of a First Adverse Event and Recurrent Infections during Biological Therapy in Chronic Inflammatory Arthritis. G. Avila[1], Arnald Alonso[1], Andrea Pluma-Sanjurjo[2], Carolina Diaz[2], Roxana Juverdeanu[2], María América López-Lasanta[1] and Sara Marsal[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]University Hospital Vall d'Hebron, Barcelona, Spain.

Background/Purpose: Biological therapies (BT) have significantly improved the prognosis of chronic inflammatory arthritis (CIA) patients. Although they are characterized by a good safety profile, the presence of adverse events (AE) might limit their use. Despite their importance, neither the distribution of AE during treatment nor the risk of a recurrent event has been adequately estimated. The **objective** of this study was to analyze the incidence, distribution in time and the risk of recurrence of infectious AE (IAE) in CIA patients during BT.

Methods: 290 CIA patients (i.e. rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis) treated with at least 1BT during the period between December '99 – March '13 were included. From all these patients a large retrospective clinical data set of 615 BTs could be collected.

The incidence rate (IR) was calculated as the total number of AE per 1,000 patients / year. The difference in the risk of an AE between the 3 CIA was analyzed using the Cox and Poisson regression models. To evaluate temporal distribution and recurrence of IAE, the IR was analyzed at multiple time intervals. Only those IAE with at least 10 recurrences were included.

The analysis of the recurrence was based on a regression model of Cox proportional hazards. Time to failure (TTF) was defined as the time interval between the initiation of the BT and the first IAE. For recurrent events, was defined as the time interval between a recurrent event and the previous one.

Results: A total of **1,361 AE** were found. Comparing the 3 CIA, the risk of a first AE was higher for RA, although this was not significant. The Cox and Poisson regression models showed a high degree of concordance between the 3 CIA.

738 IAE with at least 10 recurrences were identified. From these, 485 were respiratory infections (RI), 73 urinary infections (UI), 67 gastrointestinal infections (GII), 58 herpetic infections (HI) and 55 oral cavity infections (OCI).

The probability of a first **RI** was greatest during the first 48 wks of BT. When all RI (first event and recurrences) were considered, we found a homogeneous distribution over time. In the Cox model, we observed that RI was significantly associated with an increased risk of recurrence (p-value = 7.99e-03, HR = 1.08 [95% CI 1.2–1.14]).

UI showed a less homogeneous distribution over time and there was a greater risk of UI in the first 48 wks of treatment. The probability of recurrence was highly significant (p-value = 1.67e-10, HR = 1.96 [95% CI 1.59–2.41]).

The probability of a first **GII** showed a maximum in the first 12 wks and he risk of recurrence was not significantly (p-value =6.81e-02; HR=1.55 [95% CI 0.97–2.49]).

In the distribution of the **HI**, we found a maximum during the first 48 wks, and a significant risk of recurrence (p-value = 2.78E-03, HR = 1.91 [95% CI 1.25–2.91]).

The distribution of **OCI** showed two maxima, and the risk of recurrence was highly significant (p-value = 5.21e-06, HR [95% CI 1.53–2.92]).

Conclusion: In our series of Chronic Inflammatory Arthritis treated with BT we found no significant differences in the risk of a first AE between the three CIA. In the recurrence analysis, UI and OCI had a highly significant risk of recurrence, whereas the recurrence risk in GII was minimal.

Medium-Term Safety of TNF-Alpha Inhibitors in Rheumatoid Arthritis: A Meta-Analysis of Randomized Controlled Trials. Lucile Poiroux[1], Yannick Allanore[2], Andre Kahan[3] and Jerome Avouac[1]. [1]Cochin Hospital, Paris, France, [2]Rheumatology A, Paris Descartes University, Cochin Hospital, APHP, Paris, France, Paris, France, [3]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France.

Background/Purpose: TNF-a inhibitors have changed the prognosis of rheumatoid arthritis (RA). The number of molecules and the time of exposure have increased. However, few studies have compared the safety of the five TNF-alpha inhibitors between them, and their medium term safety. The aim of our study was to compare medium term safety (particularly death and severe infection) obtained from randomized controlled trials for the five TNF alpha inhibitors used in the treatment of RA.

Methods: A systematic review of articles published from January 2000 to January 2013 was performed using MEDLINE, EMBASE and COCHRANE

databases. We included randomized, controlled, double-blind trials, with a follow-up period of at least 6 months, comparing TNF-a inhibitors to placebo, with or without concomitant Methotrexate. The primary outcome measure was the occurrence of a serious adverse event, defined by the occurrence of death or of a severe infection (with the requirement of hospitalization). The MedCalc software was used for the statistical analysis.

Results: Among the 396 articles initially identified, 22 were finally selected. These articles included 6682 patients in the anti-TNF-a group (Adalimumab: 2507, Golimumab: 575, Certolizumab: 1512, Infliximab: 1087 and Etanercept: 1001) and 3607 in the placebo group. The duration of patient follow-up ranged from 24 to 78 weeks.

There was no excess of risk of serious adverse event (death or severe infection) in the TNF-a inhibitors compared to placebo (Odds Ratio OR: 1.14, 95% Confidence Interval CI: 0.91–1.44). Nevertheless, we noticed an increased risk of serious event under Certolizumab (OR: 2.06, CI: 1,35–3,15).

There was no increases risk of death in the TNF-a inhibitor group compared to the placebo group (OR: 1.27). We referenced 36 deaths among 6208 patients under TNF alpha inhibitors (0,58%) and 10/3282 deaths under placebo (0,30%). However, increased risk of severe infections in the TNF alpha inhibitor group was observed compared to the placebo group (OR: 1.66) with 192 serious infections among 5889 patients under TNF alpha inhibitors (3,26%) versus 63 serious infections among 3398 patients under placebo (1,85%). Sensibility analysis revealed that adalimumab had an increased risk of severe infection (OR: 2.10)

	Total	Adalimumab	Golimumab	Certolizumab	Infliximab	Etanercept
Death	1.27	2.27	2.02	1.19	0.47	1.28
(CI 95%)	0.71–2.25	0.84–6.16	0.22–18.19	0.27–5.18	0.16–1.40	0.22–7.24
Serious infections	1.66	2.10	2.47	3.47	1.59	0.75
(CI 95%)	1.24–2.23	1.28–3.46	0.93–6.54	0.94–12.78	0.87–2.90	0.40–1.41
SAE	1.14	0.91	1.82	2.06	1.13	0.80
(CI 95%)	0.91–1.44	0.68–1.23	0.45–7.29	1.35–3.15	0.80–1.59	0.57–1.12

Conclusion: This meta-analysis has been performed on a large number of patients and included the five TNF-a inhibitors currently available. It allowed an indirect comparison between the different molecules according to their medium-term safety. We did not find an increased risk of serious adverse events or deaths in patients treated with TNF-a inhibitors. However, we observed an increased risk of severe infections. Further studies aiming at the evaluation of the long-term safety are now needed to confirm these results.

Leflunomide Use Is Not Associated with an Increased Risk of Lung Disease in Rheumatoid Arthritis: A Meta-Analysis of Randomised Controlled Trials. Richard Conway[1], Candice Low[2], Robert J. Coughlan[1], Martin O'Donnell[1] and John J. Carey[1]. [1]Galway University Hospitals, Galway, Ireland, [2]St. James Hospital, Dublin, Ireland.

Background/Purpose: Leflunomide is an effective treatment for rheumatoid arthritis. An association between pulmonary adverse events, in particular interstitial lung disease, and leflunomide use has been reported. Incident respiratory events may result in cessation of leflunomide treatment. Clarification of its potential role in pulmonary disease is therefore of clinical importance.

Methods: We performed a systematic literature search of Pubmed and Cochrane databases with no date limits for double-blind randomised controlled trials of leflunomide versus placebo or active comparator agents in adults with rheumatoid arthritis. We evaluated the association between leflumonide use and pulmonary adverse events by performing a meta-analysis of the results. Studies with less than 50 subjects, of less than 12 weeks duration, or with no reporting of respiratory adverse events were excluded. Random effects meta-analysis using the Mantel-Haenszel method was used to assess total respiratory adverse events, infectious respiratory adverse events, non-infectious respiratory adverse events, pneumonitis, and death. **Results** were expressed as relative risks (RR) with 95% confidence intervals.

Results: Our literature search returned 884 results. A total of 8 studies, 4 with placebo comparators, met our inclusion criteria. Seven hundred and eight respiratory adverse events were documented in 4579 participants. Six cases of pneumonitis occurred, all in the comparator group. Four pulmonary deaths were reported, none in the leflunomide group. Leflunomide was not associated with an increased risk of total adverse respiratory events, RR 0.99 (95% CI 0.56–1.78), or infectious respiratory adverse events, RR 1.02 (95% CI 0.58–1.82). Leflunomide was associated with a decreased risk of non-infectious respiratory adverse events, RR 0.64 (95% CI 0.41–0.97).

Conclusion: Our study found no evidence of increased respiratory adverse events with leflunomide treatment.

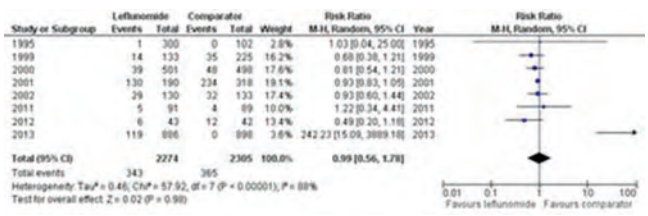

Figure 1: Forest Plot of Total Adverse Respiratory Events

Adverse Events and Infections in Patients with Rheumatoid Arthritis Treated with Conventional Drugs or Biologic Agents: A Real World Study. Christos E. Lampropoulos[1], Philippos Orfanos[2], Vasiliki-Kalliopi Bournia[3], Theofilos P. Karatsourakis[1], Clio P. Mavragani[4], Dimitrios Pikazis[1], Menelaos N. Manoussakis[5], Athanasios G. Tzioufas[1], Haralampos M. Moutsopoulos[6] and Panayiotis G. Vlachoyiannopoulos[3]. [1]School of Medicine, National University of Athens, Athens, Greece, [2]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National University of Athens, Athens, Greece, [3]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [4]School of Medicine, University of Athens, Athens, Greece, Athens, Greece, [5]School of Medicine, National University of Athens, Greece, Athens, Greece, [6]School of Medicine, University of Athens, Athens, Greece.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease with joint destruction and permanent disability. Biologic agents (BAs) offer a better outcome when disease is not adequately controlled by DMARDs. Nevertheless, many doubts still exist about the safety of BAs compared to classical treatment. Purpose of the study was to test the hypothesis that adverse events (AEs), including infections, are rather common in patients receiving BAs than in those with DMARDs.

Methods: Analysis of the medical records of patients with RA followed in a single outpatient clinic was performed. In total, 1403 adults (295 men, 1108 women) were included in the analysis (969 treated with DMARDs only, 434 with biologics). All AEs and infections were recorded and their severity was graded according to international criteria. Cox proportional-hazards models were performed to examine the association of treatment groups and other confounding factors with the risk of first AE or infection. Incident rates were calculated as number of events/100 person-years.

Results: The risk of first AE or infection, mild or serious, was significantly increased in patients with biologics (Figure 1, $p<0.001$). Hazard ratios ranged from 1.93 (95% CI: 1.59 to 2.34) for any AE to 5.92 (95% CI: 2.55 to 13.75) for serious infection (Table 1). Age, ESR >40mm/h and total steroid dose >500mg were significant detrimental risk factors. The risk for infection was equal across biologic agents, but infliximab and adalimumab were marginally significantly associated with AEs in general (Figure 2, $p<0.05$).

There were 519 AEs in the biologic group with an IR of 35.5 events/100 PY (IRR=2.24 95% CI: 1.96 to 2.55), as compared with 407 and 15.9 events/100 PY with DMARDs only. When only the follow-up time up until the first AE or infection in both treatment groups was counted in, the IRR for the biologic group was 2.14 for any first AE (95% CI: 1.78 to 2.58), 4.43 for first serious AE (95% CI: 2.83 to 7.09), 5.27 for any first infection (95% CI: 3.62 to 7.8) and 7.93 for first serious infection (95% CI: 3.60 to 19.83).

Conclusion: Biologic agents are associated with a higher frequency and severity of AEs and infections compared to conventional DMARDs.

Long Term Safety of Intravenous Golimumab and Comparison with Subcutaneous Golimumab in Rheumatoid Arthritis: Results through 2 Years. Rene Westhovens[1], Edward C. Keystone[2], Clifton O. Bingham III[3], Elizabeth C. Hsia[4], Lilianne Kim[4], Yiying Zhou[4], Alan M. Mendelsohn[4] and Michael E. Weinblatt[5]. [1]University Hospital KU Leuven, Leuven, Belgium, [2]Mount Sinai Hospital, University of Toronto, Toronto, ON, [3]Johns Hopkins University, Baltimore, MD, [4]Janssen Research & Development, LLC., Spring House, PA, [5]Brigham and Women's Hospital, Boston, MA.

Long Term Safety of Intravenous Golimumab and Comparison with Subcutaneous Golimumab in Rheumatoid Arthritis: Results through 2 Years

Background/Purpose: To describe the safety profile of IV GLM in RA (MTX nonresponders) from the Ph3 GO-FURTHER trial. AE rates of interest are indirectly compared to those observed in the SC GLM GO-FORWARD trial in a similar pt population.

Methods: In GO-FURTHER, pts with active RA despite MTX were randomized to MTX + IV PBO or GLM 2mg/kg at wks 0, 4, and q8wks. In GO-FORWARD, pts with active RA despite MTX were randomized to SC PBO+MTX or SC GLM 100mg+PBO, GLM 50 mg+MTX, or GLM 100 mg+MTX administered q4wks. Observed safety findings through wk 112 for GO-FURTHER and wk 104 in GO-FORWARD are reported; incidence rates/100 pt-yrs are reported for AEs of interest from data through the August 15, 2012 cut-off (120-day safety update) in GO-FURTHER and from the wk160 CSR in GO-FORWARD. Comparison of targeted safety events between IV and SC GLM are reported. Pts who received ≥1administration were included.

Results: Baseline demographic and disease characteristics were similar in GO-FURTHER and GO-FORWARD. 584 pts received IV GLM, with a mean follow-up of 95.9 wks. 434 pts received SC GLM, with a mean follow-up of 89.9 wks. Overall AEs observed in GO-FURTHER and GO-FORWARD are summarized (Table). Similar proportions of pts in GO-FURTHER (wk 112) and GO-FORWARD (wk 104) had an AE (79.1% and 89.4%, respectively), an SAE (18.2% and 22.6%, respectively), or discontinued due to an AE (7.0% and 9.4%, respectively). Infections/infestations were the most common type of AE in both trials. Rates of selected SAEs per 100 pt-years through the August 15, 2012 cut-off in GO-FURTHER and wk 160 in GO-FORWARD showed no difference in AE rates or significant SAEs between GLM IV and SC in RA pts previously treated with MTX with the exception of patients with ALT abnormalities (>1 – < 3 × ULN). Similar differences were noted through all ALT tertiles (≥3 – <5 × ULN; ≥5 × ULN). (Table). Incidence of nonserious infusion reactions (median 30 minute infusions) remained low regardless of infusion length, and no serious infusion reactions, requiring study discontinuation, were reported. NMSC (incidence/100 pt-yrs of f/u: 0.10[95% CI: 0.00,0.58] vs. 0.81 [95%CI: 0.37,1.54] for GLM IV vs GLM SC) and lymphoma rates were numerically lower in GO-FURTHER vs. GO-FORWARD.

Conclusion: Overall safety profile of IV GLM in pts with RA despite MTX observed through wk 112 in GO-FURTHER was similar to that for SC GLM in a similar pt population (GO-FORWARD). Rates/100 pt-yrs (through August 15, 2012 in GO-FURTHER and wk 160 in GO-FORWARD) for events of interest such as malignancies and serious infections in GO-FURTHER were comparable to or lower than rates in GO-FORWARD.

Overall AE summary: GLM-treated patients in GO-FURTHER (IV;through wk 112) and in GO-FORWARD (SC; through week 104)

	GO-FURTHER GLM IV 2 mg/kg + MTX	GO-FORWARD All GLM SC 50 mg +MTX or 100 mg +/− MTX
Pts treated/Mean duration of f/u (wks)	584/95.9	434/89.9
AE/Serious AE/D/c due to AE	79.1%/18.2%/7.0%	89.4%/22.6%/9.4%
Overall infection/Serious infection	49.1%/6.2%	67.5%/6.7%
Infusion or injection reactions	3.5%	8.3%

AEs of interest in pts receiving IV or SC GLM: Incidence per 100 pt-years of follow-up (95% CI)

	GO-FURTHER (IV)[a] (n= 584)	GO-FORWARD (SC)[b] (n=434)
Total pt/yrs of follow-up	958	1127
Deaths	0.52 (0.17, 1.22)	0.35 (0.10, 0.91)
Sepsis	0.42 (0.11, 1.07)	0.71 (0.31, 1.40)
Tuberculosis	0.31 (0.06, 0.92)	0.27 (0.05, 0.78)
Opportunistic Infections	0.42 (0.11, 1.07)	0.27 (0.05, 0.78)
Cellulitis	2.19 (1.36, 3.35)	3.28 (2.31, 4.52)
Postbaseline ALT ↑ (>1 to <3 × ULN)	98.86 (92.66, 105.36)	69.02 (64.26, 74.05)
Postbaseline ALT ↑ (≥3 to <5 × ULN)	3.76 (2.63, 5.20)	1.51 (0.88, 2.41)
Postbaseline ALT ↑ (≥5 × ULN)	2.30 (1.44, 3.48)	0.71 (0.31, 1.40)

Serious Infection Risk By Treatments and Types in Patients with RA. Kaleb Michaud[1], Sofia Pedro[1], Andre Kalil[2], Ted R. Mikuls[2] and Frederick Wolfe[1]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Recent studies provide conflicting results on the impact of DMARDs on the risk of serious infections for patients with RA. We examined these infection risks by type, site, and treatment in a real world setting.

Methods: Participants were followed biannually from 1998 through 2013 in a large US longitudinal observational study. Serious infections were defined as those requiring hospitalization or intravenous antibiotics, or led to death within a year after the patient's last observation. Infections were validated from hospitalization, physician, and death records. Infections were categorized as opportunist, by cause and by syndrome. Survival analysis methods (Cox regression, time to first infection using time-varying covariates and Andersen-Gill multiple failures model) were applied, both in a univariate and multivariate manner. Confounders included demographics, clinical status, disease severity and medications. DMARDs and biologics were grouped using different categorizations: methotrexate (MTX), non-MTX DMARDs (NMTX), anti-TNF (TNF), and no DMARD/biologic (nDB). Individual drugs included abatacept (ABA), adalimumab (ADA), etanercept (ETA), infliximab (INF), rituximab (RIT), and leflunomide (LEF). An at-risk window of 3 months was considered for all drugs (except RIT with 12 months).

Results: We had 21,727 RA patients participate, with 21% male, a mean (SD) age of 59.0 (13.7) yrs, and 1.7 (1.5) comorbidities. During 92,138 patient-yr follow-up, the treatment exposures included: prednisone (53%), MTX (61%, median 2.4 yrs), NMTX (53%, 1.9 yrs), TNF (50%, 1.5 yrs), and NTNF (8%, 1.4 yrs). There were 2530 serious infections of any type (69 opportunist, 881 bacterial, 114 viral, 43 fungal and 1048 were unable to classify). The most frequent by syndrome were pneumonia (1017), skin (424), and sepsis (367). From the univariate and multivariate analyses, no differences between treatments were found when compared to MTX monotherapy in any group of infections considered. Some exceptions were found: patients who were on INF seemed to be at a higher risk of any infection (HR: 1.29 (1.10–1.50)) and opportunistic infections (2.96 (1.38–6.33)). Patients who took ETA or INF were also at higher risk for skin infections (1.38 (1.04–1.38) and 1.32 (1.00–176), respectively) (Figure 1). When decomposing DMARDs into 5 classes, the results also didn't change but patients on LEF seemed to be at higher risk for bacterial infections (1.4 (1.12–1.75)), bone/joint (2.01 (1.37–2.94)) and skin (1.48 (1.11–1.95)). HCQ was protective for pneumonia (0.82 (0.69–0.98)).

Conclusion: Our preliminary results indicated little differences between treatments in risk of serious infections in RA. Next steps will include propensity scores to adjust for possible channeling and to adjust for previous infections and geographical region.

Efficacy and Safety of Etanercept in Rheumatoid Arthritis Patients over 75 Years Old. Satoru Kodama, Satoshi Ito, Akira Murasawa, Kiyoshi Nakazono and Daisuke Kobayashi. Niigata Rheumatic Center, Shibata, Japan.

Background/Purpose: Early introductions of biologics in early rheumatoid arthritis (RA) patients are well documented, but there are few reports of biologics use in established elderly RA patients. We used etanercept (ETN), which has a short half-life and was considered safe, for elderly RA patients who had many complications.

Methods: Out of 330 patients treated with ETN at Niigata Rheumatic Center from May 2008 to June 2013, clinical course and data of the patients who started ETN at 75 years old (YO) or older were analyzed. Tender joint counts (TJC) and swollen joint counts (SJC), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), matrix metalloprotease-3 (MMP-3), rheumatoid factor (RF), Disease Activity Score for 28-joint counts based on ESR (DAS28-ESR), simplified disease activity index (SDAI), and major adverse events were obtained from their medical records. The efficacy and safety of ETN was evaluated at 24 months.

Results: Forty five patients (17 males, 28 females), a mean age of 79.0 ±2.9 YO and a mean disease duration of 17.0±10.2 years were analyzed. Eighty four point four percent of them had complications such as hypertension, diabetes mellitus, osteoporosis, interstitial pneumonia, or amyloidosis. ETN was used at a dose of 20 mg/week in 1 patient, 25 mg/week in 31, 50 mg/week in 13. Twenty six percent of the patients did not inject by themselves and were injected by family or by the general practitioners. Prophylaxis of tuberculosis (TB), pneumococcal pneumonia (PP), pneumocystis jiroveci pneumonia (PCP) were done in 64%, 40%, and 62 % respectively. TJC, SJC, CRP, ESR, MMP-3 and RF decreased significantly as follows: TJC, 6.3±4.77 to 3.1±3.34 ($P < 0.01$); SJC, 5.1±4.57 to 2.1±2.53 ($P < 0.01$); ESR, 54.2±19.48 mm/h to 34.5±24.25 mm/h ($p < 0.01$); CRP, 4.3±3.19 mg/dL to 1.2±1.68 mg/dL ($p < 0.01$); MMP-3, 330.7±236.44 ng/mL to 212.7±123.81 ng/mL ($p < 0.05$); RF, 189.4±219.67 IU/mL to 117.5±140.38 IU/mL ($p < 0.05$); DAS28-4[ESR], 5.3±1.18 to 3.9±1.33 ($p < 0.01$); SDAI, 27.3±12.63 to 12.0±9.08 ($p < 0.01$) (Last Observation Carried Forward). Thirty four percent of the patients achieved remission or low disease activity score and 50% achieved them by SDAI. Adverse events occurred in 10 patients. Six patients stopped ETN and 4 out of them had infection. One patient (85YO) died due to TB and another (80YO) died due to PCP.

Conclusion: We considered that ETN is an effective end relatively safe treatment for elderly RA patients. Prevention of TB, PP and PCP should be done in all elderly patients treated with ETN.

Incidence of Opportunistic Infections in Rheumatoid Arthritis Treated with Biological Agents. Alejandro Gomez-Gomez, Zulema Rosales, Leticia Leon, Juan A Jover, Luis Rodriguez-Rodriguez and Lydia Abasolo. Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain.

Background/Purpose: With the expanding use of Biological Agents (BA), in particular TNF inhibitors, opportunistic infections (OI) are a major concern in Rheumatology. Our purposes were to describe the incidence of OI global and by periods in Rheumatoid Arthritis (RA), and comparing the risk of OI by BA.

Methods: We performed a retrospective longitudinal observational study from 2000 to 2013. We included subjects followed in our outpatient clinic, diagnosed with RA according to ACR criteria 87, whom started treatment with a BA [etanercept (ETN), golimumab (GOLI), certolizumab (CTZ), infliximab (IFX), adalimumab (ADA), rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ)]. Our primary endpoint was OI that involved the suspension of the BA. We consider OI when there was a positive culture (for Virus, Fungus, and bacterial) or compatible symptoms that responded to specific treatment. We also collected secondary variables: sociodemographic (age, sex); clinical (disease duration, type of BA, hospital admission, previous BA). We used survival techniques to estimate the incidence of OI, expressed per 1000 patient-year [CI 95 %]. The exposure time was defined from the start date of each BA to its suspension, loss of follow up or end of study (23/11/2013). We performed Cox regression models (adjusted by age, duration of RA, sex, calendar time and prior BA) to compare the risk of OI between each BA.

Results: 453 RA patients were included in the study; they started 853 different courses of BA treatment. Of these, 81% were women with a mean age at diagnosis of 52.4 ± 14 years. The median time from onset of BA until onset of OI was 1.7 years [0.48–2.8]. Except for one all patients with OI took steroids. The most frequently used drug was ADA (33%), followed by ETN (25%), IFX (19%) and RTX (14%). There were 33 OI [22 Virus (18 Herpes Zoster, 2 virus B reactivation, 1 Avian flu), 10 Fungus (Candida, 2 Aspergillus), and 1 Bacterian (Legionella)], 36% required hospitalization and 4 died (2 fungus infection, 1 Legionella and 1 virus B reactivation with a myelodisplasic syndrome). The global incidence of OI was 17.7 [12.5–24.8]. TZC had 1 OI, with a incidence of 68.1 [9,6–483,5], followed by RTX, with 4 OI, Incidence 22.2 [8.3 to 59]; ADA, with 14 OI, Incidence: 19.9 [11,8–33,6]; IFX with 9 OI, Incidence: 19.4 [10,1–37,3], and ETN with 5 OI, Incidence: 11.6 [4,8–27,9]. We not find statistical differences in the rate of OI between BA. Age was found a predictor of OI in the multivariate analysis.

Conclusion: The incidence of OI and its evolution over time in real life conditions is described. Incidence found was near 18 cases per 1000 patients -year. Four of them resulted in death. Incidence of opportunistic infections showed no variance during the years. We did not find statistical differences in the rate of OI between BA. Doctors using Biological Agents should be concerned about this problem and be aware for the detection and management of OI.

Risk of HBV Reactivation in Rheumatoid Arthritis Patients Undergoing Treatment with Newer Biological Dmards, Tocilizumab and Abatacept: A Single-Center Real Life Experience. Francesca De Nard[1], Vittorio Grosso[2], Monica Todoerti[1], Carlomaurizio Montecucco[3] and Roberto Caporali[3]. [1]University of Pavia, IRCCS Policlinico S. Matteo Foundation, Pavia, Italy, [2]University of Pavia, Foundation IRCCS Policlinico S. Matteo, Pavia, Italy, [3]Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico S.Matteo Foundation/University of Pavia, Pavia, Italy.

Background/Purpose: HBV infection represents a major issue in patients with rheumatoid arthritis (RA) undergoing biological disease-modifying anti-rheumatic drugs (bDMARDs) (1). While the risk of hepatitis reactivation under anti-TNF agents has been well described, experience with drugs as tocilizumab (TCZ) and abatacept (ABA) is still limited (2). Aim of this study is to retrospectively assess the risk of HBV reactivation in real-life RA patients treated with ABA and TCZ.

Methods: RA patients with a past HBV infection history ('chronic inactive carriers' with HBsAg+ and undetectable or <2,000 IU/mL viral load + normal liver function tests (LFT) and 'occult carriers' with only

HBcAb+) and treated with ABA or TCZ, have been retrospectively analyzed for the risk of 'viral re-activation' (rise in viral load≥1 log10 IU/mL compared with baseline values, or detection of previously undetected serum HBV-DNA) and/or 'viral hepatitis B' (increase in LFT and serum HBV-DNA, necroinflammation and/or fibrosis in liver biopsy) by regularly detecting HBsAg, HBV-DNA, LFT throughout follow-up.

Results: Out of a total of 125 RA patients, 17 (13,6%) were HbcAb+: 16 occult carriers (8 treated with ABA+8 treated with TCZ), and 1 chronic inactive carrier treated with ABA. Patients have been followed for a median time (IQR) of 1.2 (0.7–1.5) years. They were previously treated with a median (IQR) number of 2 (1–3) synthetic DMARDs (sDMARDs) and 0 (0–1) bDMARDs. The mean age (sd) was 54.7 (13.8) years, the median disease duration was 5.8 (1.8–7.6) years. Most patients were treated with concomitant methotrexate (8/9 in the ABA group, 5/8 in the TCZ group) and corticosteroids. In the ABA group, 1 patient with chronic HCV co-infection (HCV-RNA+) started lamivudine, due to LFT elevation (<2-fold ULN) occurring 2 months after ABA initiation; amelioration of LFT along with undetectable viral load occurred throughout 12 months of follow-up. 2 patients (1 occult carrier and 1 chronic inactive carrier) underwent lamivudine before ABA with no HBV-related adverse events; among the other 6 ABA patients not receiving lamivudine only 1 experienced a temporary positivization of viral load (85 UI/mL) without LFT elevation at 12 months of follow-up: spontaneous negativization of viral load was registered at 18 months. In the TCZ group, no patient received lamivudine with no HBV reactivation.

Conclusion: Despite limited to few patients and short follow-up, the use of ABA and TCZ in RA patients with past history of HBV infection seems relatively safe. However, periodic monitoring of liver function tests and viral load is mandatory. According to scientific literature, viral prophylaxis might be considered mainly in patients undergoing ABA. Further data are needed to clarify long-term safety issues.

Reactivation of Hepatitis B Virus in Patients with Rheumatoid Arthritis after Anti-TNF Therapy. Seung Min Jung[1], Hong Ki Min[1], Jung Hee Koh[1], Jin Young Kang[1], Jennifer Lee[1], Seung-Ki Kwok[1], Ji Hyeon Ju[1], Hyeok-Jae Ko[2], Kyung-Su Park[3], Ho-Youn Kim[1] and Sung-Hwan Park[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Daejeon, South Korea, [3]St. Vincent Hospital, SuWon Gyeonggi-do, South Korea.

Background/Purpose: Anti-TNF therapy was known to increase the risk of certain infection. There are only limited data about the reactivation of hepatitis B virus (HBV) after anti-TNF therapy. The study was aimed to investigate the clinical course of hepatitis B in patients with rheumatoid arthritis (RA) after the introduction of anti-TNF therapy.

Methods: We retrospectively reviewed to identify patients infected with HBV treated with TNF inhibitors between October, 2004 and September, 2013. For patients with HBV infection, the liver enzyme and the viral status were monitored. The HBV reactivation was defined according to the Korean guideline by hepatology.

Results: Of 536 patients who were treated with TNF inhibitors, 17 patients had comorbidities of HBV infection. Thirteen patients were treated with etanercept, three with adalimumab, and one with infliximab. Seven patients received pre-emptive antiviral prophylaxis before anti-TNF therapy: 4 with entecavir, 1 with telbivudine, 1 with tenofovir, and 1 with lamivudine. Among 17 patients with HBV infection, 4 (23.5 %) patients experienced the reactivation of HBV, which occurred in 3 patients without prophylaxis and 1 patient with lamivudine prophylaxis. In the latter case, YMDD mutation was identified and addition of adefovir resulted in virological response. The other three patients were treated successfully with entecavir or tenofovir. There was no subsequent events associated with HBV infection.

Conclusion: This study indicates the risk of HBV reactivation during anti-TNF therapy. Careful management is mandatory for patients who planned to be treated with TNF inhibitors.

Incidence of Clinical and Serological Lupus-like Disease during Anti-Tnfα-Treatment – a Two-Year Prospective Study in an Interdisciplinary Patient Cohort. Simon Julius Winkelmann[1], Rainald A. Zeuner[1], Dörte Schuldt[1], Johannes Bethge[1], Ulrich Mrowietz[2], Matthias Laudes[1], Stefan Schreiber[1] and Johann Schroeder[1]. [1]University of Kiel, Kiel, Germany, [2]Univ Schleswig-Holstein, Kiel, Germany.

Background/Purpose: TNFα-Inhibitors are the most widely used biological agents in rheumatic conditions or other chronic inflammatory diseases. Over the last ten years, the occurrence of lupus-like disease and the induction of antinuclear antibodies have been observed in more than 800 individuals receiving anti-TNFα-treatment worldwide. However, the exact incidence of serological changes and the frequency of associated clinical manifestations are unknown.

Methods: We conducted a single center, interdisciplinary prospective study on patients with RA, spondyloarthropathies and inflammatory bowel diseases who were elected for anti-TNFα-therapy as their first biological treatment. Clinical and serological parameters were collected before the first application and thereafter at six-monthly intervals. The evaluation included a clinical questionnaire and serological testing for ANA, dsDNA-antibodies and ANCA. We calculated the incidence rates based upon duration of drug exposure. The odds ratios within the subgroups were adjusted to the diagnosis or the compound with the lowest event rate, respectively.

Results: Between January 2011 and February 2014, 223 patients entered the study. The underlying diseases of these patients were RA (68), spondyloarthropathies (67), inflammatory bowel disease (84) and JIA (4). During the follow-up, 318 serum samples were collected, 117 of these were allotted to week 26, 89 to week 52, 51 to week 78 and 61 to week 104 of follow-up. – During the entire observation period, there was a continuous rise in ANA-titers and in the concentration of dsDNA-antibodies. The proportion of samples tested positive for ANA increased from 20 or 9.0% at baseline to 21 out of 56 or 37.5% respectively at week 104 ($p=0.001$). The proportion of samples with dsDNA-antibodies above the normal range (20 IU/ml) rose from none at baseline to 16 of 49 or 32.7% at the two year evaluation ($p=0.0002$), the average anti-dsDNA value increasing from 5.6 IU/ml to 18.5 IU/ml ($p=0.004$). These results were confirmed by a crithidia luciliae assay in 51.4% of these cases. 5 individuals or 2.5% of the study population additionally developed musculoskeletal symptoms assessed as lupus-like disease. These events required temporary termination of anti-TNFαtreatment and the application of corticosteroids. - When analyzing the impact of the various biologics and the co-medication, the highest seroconversion rate was observed in patients receiving infliximab (46.1%), followed by adalimumab (15.6%), certolizumab (8.2%) and etanercept (6.1%). In patients being treated with concomitant MTX (only rheumatic conditions were considered), the risk was lower (odds ratio 0.87) than in patients without MTX.

Conclusion: The present data confirm the capability of TNFα-inhibitors to induce both, clinically relevant lupus like disease and a high rate of seroconversion towards a lupus like antibody profile in a substantial proportion of patients. Our prospective study thus substantiates the hypothesis that these phenomena represent a systematic effect of TNFα-inhibitors, and that their incidence is higher than assumed by estimates based upon case reports.

Tofacitinib Improves Arterial Stiffness Despite up-Regulating Serum Cholesterol with Chronic Cardiovascular Disease in Methotrexate-Resistant Active Rheumatoid Arthritis Patients. a Cohort Study. Kensuke Kume[1], Kanzo Amano[2], Susumu Yamada[2], Toshikatsu Kanazawa[3], Hiroshi Komori[3], Kazuhiko Hatta[4], Kuniki Amano[5] and Noriko Kuwaba[6]. [1]hiroshima clinic, Hiroshima, Japan, [2]Hiroshima Clinic, Hiroshima, Japan, [3]hiroshima clinic, hiroshima, Japan, [4]Hatta Clinic, Kure, Japan, [5]Sky Clinic, Hiroshima, Japan, [6]Sanki Clinical Link, Hiroshima, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased cardiovascular (CV) risk. We should have strategies for primary cardiovascularprevention in RA. Tofacitinib (Tofa) could possibly play a role in up-regulating levels of serum cholesterol[1].But there is no evidence of CV risk management about Tofa. To examine the effect of Tofa plus methotrexate (MTX) on arterial stiffness with CV disease in MTX resistant RA patients in a cohort study design.

Methods: 18 RA patients with moderate to severe active disease despite MTX treatment (disease activity score: DAS28 >3.2) were received Tofa plus MTX. All patients have previous history of CV. Arterial stiffness was assessed with cardio-ankle vascular index (CAVI) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 24 weeks follow-up. Clinical data were collected at regular visits. CAVI is very similar to pulse wave velocity (PWV), and CAVI measures arterial wall stiffness independent of blood pressure and it is superior to brachial ankle PWV as an index of arterial stiffness[2]. No new all treatments(statin, low lipids drug, and etc.) were allowed.

Results: Treatment with Tofa attenuated the CAVI significantly from baseline to 24 weeks follow up(12.68 ± 1.77 and 10.48± 1.28%; p = 0.016). Treatment with Tofa attenuated the Aix@75 significantly from baseline to 24 weeks follow up(38.7 ± 8.6, 33.2 ± 3.6 %; p = 0.018). DAS 28-ESR score improved significantly from baseline to 24 weeks(5.11±1.33, 2.43±1.43: p=0.01). On the other hand, fasting serum total cholesterol TC was significantly increased from baseline to follow-up at 24 weeks (195±21.2mg/dL, 211±24.2mg/dL, p = 0.03). No patients suffered from new CV disease.

Conclusion: These findings suggest that combination therapy, Tofa with MTX not only reduced RA disease activity but also limited vascular damage despite up-regulating serum cholesterol with CV disease in patients MTX resistant active RA.

Assessment of Lipid Changes in Patients with Early Rheumatoid Arthritis Treated with Tofacitinib or Methotrexate over 24 Months. C. Charles-Schoeman[1], A. Dikranian[2], J. Taylor[3], B. Wilkinson[4], T. Jones[5], K. Kwok[6] and C. Nduaka[4]. [1]University of California, Los Angeles, CA, [2]San Diego Arthritis Medical Clinic, San Diego, CA, [3]Anderson Arthritis and Rheumatology Center, Meridian, MS, [4]Pfizer Inc, Groton, CT, [5]Pfizer Inc, Collegeville, PA, [6]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Post-baseline (BL) increases in mean low-density lipoprotein cholesterol (LDL-C) and high-density lipoprotein cholesterol (HDL-C) were observed in Phase 3 (Ph 3) studies of tofacitinib (mostly with background DMARDs). In the Ph 3, 24-month (mo) ORAL Start study (NCT01039688), methotrexate (MTX)-naïve patients (pts) treated with tofacitinib monotherapy had significant and clinically meaningful improvements in RA signs and symptoms, physical function, and inhibition of radiographic progression vs MTX-treated pts. Here, the lipid profile during tofacitinib monotherapy treatment over 24 mos was investigated in these MTX-naïve pts with RA.

Methods: Pts were randomized 2:2:1 to receive tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or MTX (mean dose by Mo 3, 18.5 mg/week). LDL-C, HDL-C, and triglyceride (TG) levels were measured at BL and Mos 3, 6, 9, 12, 18, and 24, and descriptive statistics provided. Categorical changes (defined by National Cholesterol Education Program Adult Treatment Panel III) in LDL-C, HDL-C, and TG levels from BL to maximum on-treatment values through Mo 6 were compared using shift analyses.

Results: 956 pts were treated: tofacitinib 5 mg BID, n=373; tofacitinib 10 mg BID, n=397; and MTX, n=186. With both tofacitinib doses, median increases in LDL-C, HDL-C, and TG levels were observed at Mo 3 (first time point for analysis) but generally stabilized thereafter (Fig 1). Median increases and decreases in LDL-C, HDL-C, and TG levels were observed with MTX treatment (Fig 1). The total cholesterol (TC)/HDL-C ratio remained unchanged from BL through Mo 24 in all treatment groups. Categorical increases in lipid profile (ie shifts from a lower to higher lipid category) from BL through Mo 6 in pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, or MTX, respectively, were reported in: 52.2%, 57.3%, and 27.7% of pts for LDL-C; 5.7%, 10.2%, and 1.1% of pts for HDL-C; and 24.0%, 21.6%, and 14.7% of pts for TG levels. A similar percent of pts in each treatment group had BL LDL-C <130 mg/dL (tofacitinib 5 mg BID: n=251/362 [69.3%]; tofacitinib 10 mg BID: n=277/391 [70.8%]; MTX: n=132/184 [71.7%]). A minority of these pts had maximum on-treatment LDL-C ≥160 mg/dL by Mo 6 (tofacitinib 5 mg BID: n=32/251 [12.7%]; tofacitinib 10 mg BID: n=38/277 [13.7%]; MTX: n=4/132 [3.0%]).

Conclusion: Tofacitinib monotherapy was associated with increases in LDL-C, HDL-C, and TG levels by Mo 3 (first time point measured) which generally stabilized thereafter. TC/HDL-C ratios were unchanged across all treatment groups. These changes were consistent with changes observed in the tofacitinib Ph 3 program. Most pts had LDL-C <130 mg/dL at BL and a minority of these had maximum on-treatment LDL-C ≥160 mg/dL by Mo 6.

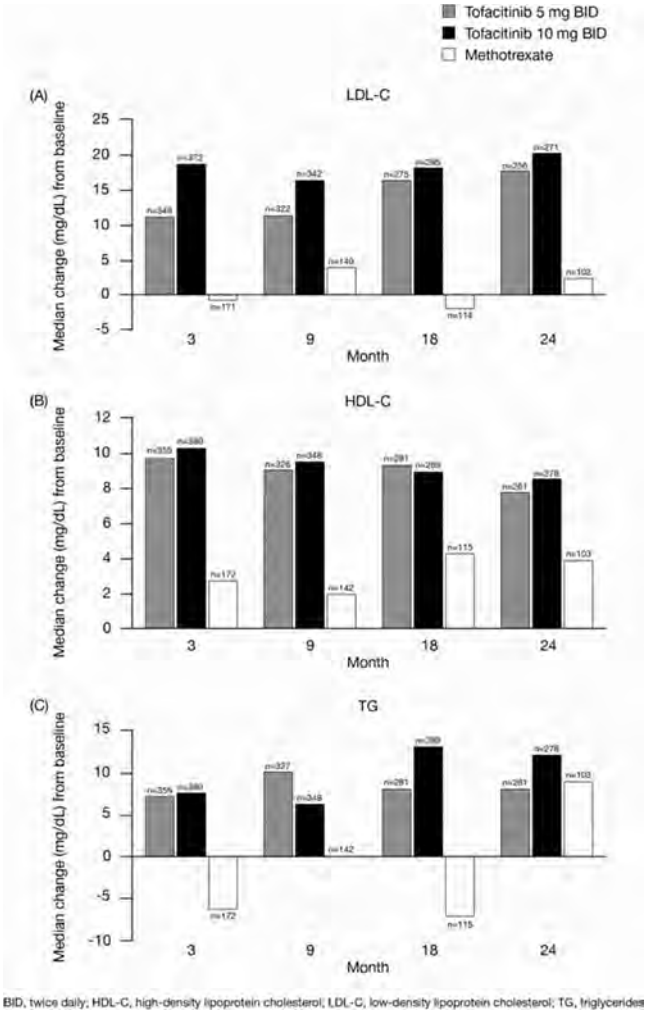

Fig 1. Median change (mg/dL) from BL in LDL-C (A), HDL-C (B), TG (C) at Mos 3, 9, 18, and 24 by treatment group

Increases in Serum Cholesterol with Baricitinib Treatment Are Associated with Favorable Changes in Apolipoprotein Content and with Improvement in DAS28-CRP in Patients with Rheumatoid Arthritis.

Joel M. Kremer[1], Mark C Genovese[2], Edward C. Keystone[3], Peter C. Taylor[4], Steven H. Zuckerman[5], Douglas E. Schlichting[5], Eric P. Nantz[5], Scott D. Beattie[5] and William L. Macias[5]. [1]Albany Medical College and the Center for Rheumatology, Albany, NY, [2]Stanford University Medical Center, Palo Alto, CA, [3]University of Toronto, Toronto, ON, [4]University of Oxford, Oxford, United Kingdom, [5]Eli Lilly and Company, Indianapolis, IN.

Background/Purpose: Treatment with baricitinib (bari), an oral inhibitor of JAK1/JAK2, demonstrated improvements in signs and symptoms of RA through 52 wks in a Phase 2b study[1]. Bari treatment also resulted in dose- and time-dependent changes in serum lipids detectable by Wk 2 and persisting through Wk 24 and was associated with increases in LDL particle size and HDL and VLDL particle numbers[2]. Increases in HDL, but not LDL cholesterol, correlated with decreases in CRP at Wk 12. Changes from baseline in serum cholesterol through 52 wks of bari treatment as well as changes in the apolipoprotein content of LDL, VLDL, and HDL particles with bari treatment at Wks 4 and 12 were evaluated. The relationship between cholesterol changes and measures of clinical efficacy was also explored.

Methods: Patients (pts) with RA were randomized to QD doses of placebo (PBO) (n=98) or bari 1 mg (n=49), 2 mg (n=52), 4 mg (n=52), or 8 mg (n=50) for 12 wks. Pts assigned to 2-, 4-, or 8-mg bari continued blinded treatment for an additional 12 wks. Pts who completed the 24-wk study could enter a 2-yr, open-label extension. Serum samples were collected through 52 wks for conventional lipid determinations (total cholesterol, LDL, HDL, and triglycerides). Apolipoprotein content was assessed at Wks 4 and 12 for PBO, 4-, and 8-mg bari groups. Pearson correlations and partial correlations, adjusted for assigned treatments, between changes in cholesterol and efficacy measures were evaluated at 12 wks.

Results: Pts treated with bari through 52 wks maintained a stable cholesterol and triglyceride profile with no further changes beyond Wks 12 and 24. Increases in apolipoprotein A-I, apolipoprotein B, and total apolipoprotein CIII were observed with 4- and 8-mg bari with no increase in LDL-associated apolipoprotein CIII. Bari treatment also demonstrated a significant reduction in HDL-associated SAA at the 4- and 8-mg doses compared to PBO while a significant reduction in Lp(a) was observed only in the 8-mg bari group (all $p<0.05$). These changes in apolipoproteins coincided with the increases in serum lipids apparent by Wk 4. In pts treated across all doses of bari, a significant correlation was observed between change in HDL cholesterol and absolute DAS28-CRP score at Wk 12 ($r=-0.33$, $p<0.001$) as well as the change from baseline to Wk 12 in the DAS28-CRP ($r=-0.29$, $p<0.001$). Specifically, pts achieving DAS28-CRP <2.6 and larger decreases in DAS28-CRP demonstrated larger increases in HDL cholesterol. No significant correlations were observed in the PBO arm between HDL and disease activity measures and no significant correlations were observed between disease activity and total cholesterol or LDL levels in the bari arms.

Conclusion: In addition to increases in serum cholesterol and lipoprotein particle number (HDL and VLDL) and size (LDL), there were changes in apolipoprotein content of these particles in pts treated with bari. The increase in HDL cholesterol with bari treatment correlated with an improvement in DAS28-CRP. Further studies are necessary to determine if these changes influence long-term cardiovascular outcomes.

Rosuvastatin Improves Arterial Stiffness in Patients with Inflammatory Joint Diseases.

Eirik Ikdahl[1], Silvia Rollefstad[1], Jonny Hisdal[2], Inge C. Olsen[1], Ingar Holme[3], Terje R. Pedersen[4], Tore Kvien[1] and Anne Grete Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Oslo University Hospital Aker, Oslo, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]University of Oslo, Oslo, Norway.

Background/Purpose: Arterial stiffness, as pulse wave velocity (PWV) and augmentation index (AIx) has emerged as early risk markers of cardiovascular disease (CVD) in patients with inflammatory joint diseases (IJD). In IJD patients, statin treatment has demonstrated a significant improvement in arterial stiffness. Furthermore, we have shown that statin treatment induced carotid plaque (CP) regression in IJD patients. However, the effect of statins on arterial stiffness in IJD patients with established atherosclerosis is still not elucidated. The aim of the present study was therfore to evaluate the effect of rosuvastatin on arterial stiffness in patients with IJD who had CP. We also evaluated the association between the change in arterial stiffness and change in inflammation markers, disease activity, low-density lipoprotein cholesterol (LDL-c), blood pressure (BP), CP height and intima-media thickness (IMT) after 18 months of rosuvastatin treatment.

Methods: The study population included 89 statin naïve patients with IJD (55 with rheumatoid arthritis, 23 with ankylosing spondylitis and 11 with psoriatic arthritis). All patients had B-mode ultrasound verified CP and received rosuvastatin therapy over 18 months to obtain LDL-c goals (<1.8mmol/L). The arterial stiffness variables PWV and AIx were measured prior to, and at the end of the study, using the Sphygmocor device. We used paired-samples t-tests to assess change from baseline, and regression analysis to assess the association between change in arterial stiffness and other outcome measures.

Results: Study population demographics are presented in table 1. After 18 months rosuvastatin therapy, a significant reduction in Aix was observed, from mean (SD) 27.9 (7.7) % to 26.2 (8.2) % ($p=0.026$). Furthermore, PWV decreased from 8.1 (1.6) m/s^2 to 7.8 (1.5) m/s^2 ($p=0.031$). In a logistic regression model where change in arterial stiffness was the dependent variable (defined as either increasing or decreasing related to baseline value), change in and exposure of systolic blood pressure during the study period influenced PWV significantly: odds ratio (95% CI): 1.06 (1.02, 1.09)($p=0.005$) and 0.97 (0.94; 1.00)($p=0.035$). Change in CP height and rosuvastatin dose predicted change in AIx 5.72 significantly: odds ratio (95% CI): (1.25, 26.25)($p=0.025$) and 1.22 (1.05, 1.41) ($p=0.009$).

Conclusion: This is the first clinical trial showing that rosuvastatin treatment improves arterial stiffness in IJD patients with atherosclerosis.

A Randomised Controlled Trial Evaluating the Effect of Humira upon Endothelial Function in ACPA Positive Rheumatoid Arthritis – an Interim Analysis. Stephen Oakley[1], Niloofar Esmaili[2], Gabor Major[2], David Mathers[3], Siva Ratnarajah[4], John van der Kallen[3], Mark Collins[4], Marc Toh[4] and John Glass[2]. [1]Hunter Medical Research Institute, Newcastle, Australia, [2]Newcastle Bone & Joint Institute, Newcastle, Australia, [3]Georgetown Arthritis Centre, Newcastle, Australia, [4]Private Practice, Newcastle, Australia.

Background/Purpose: Rheumatoid arthritis (RA) is associated with elevated cardiovascular (CV) risk not explained by traditional risk factors. Increased CV risk may develop prior to the onset of arthritis. Amongst RA patients Shared Epitope (SE) positivity is associated with increased CV mortality but it is unclear if this is mediated by inflammation. Observational studies suggest that TNF-inhibition improves endothelial dysfunction and lowers CV risk but RCT data are lacking. HEART-RA is a single-site RCT evaluating the effect of Humira upon endothelial function in ACPA positive RA.

Methods: ACPA positive RA patients with moderate disease activity were enrolled in a 24-week trial of Humira versus placebo on a background of usual care undergoing assessments of disease activity and endothelial function (reactive hyperaemic index - RHI) at baseline, 2, 4, 12 and 24 weeks. Serum lipids were evaluated when deemed appropriate by the treating clinician. Improvements RHI in Humira and placebo arms were compared by t test. Secondary analysis evaluated influences upon RHI by univariate analysis and multivariate time-series regression modelling.

Results: 23 subjects included 9 early (<6months) and 14 established RA underwent a total 138 assessments. 1 patient carried none, 10 one and 12 two SE. 12 patients (4 Humira and 3 placebo) withdrew after week 12 and were assessed open label at 24 weeks. HDL was available for 28 and LDL for 24. There were non-significant trends to greater RHI improvements in the Humira arm. Secondary analysis found better RHI in patients currently receiving Humira distinct from more general negative effects of higher disease activity and SE dose. Paradoxically ever-smokers had better RHI. Limited data suggested positive effects from HDL and negative from LDL.

Conclusion: Several disease-specific factors appear to contribute to endothelial dysfunction in RA. RHI is clearly better in patients receiving Humira distinct from the broader effects of disease activity. The paradoxical effect of smoking is not consistent with previous studies and is likely due to the small number of patients. However, negative effects of the SE are consistent with previous work. Furthermore, the effect appears to be quite distinct from inflammatory mechanisms seen in RA and introducing the possible role of antigen processing and lipid transport with implications for subjects with Pre-RA and therapies that that adversely influence lipids.

Input Variables	Mean RHI	Mean RHI	Raw Difference	t test p value	Adjusted Difference	Adjusted p value
Humira vs No Humira	2.23	2.11	0.12	0.016	0.19	0.041
3VDAS28CRP (<3.88 vs >3.88)	2.22	2.00	0.22	0.016	0.17	0.056
Shared Epitope (2 vs 0 or 1 copy)	2.20	2.04	0.16	0.080	0.25	0.045
Smoking (Ever versus Never)	2.20	1.79	0.24	0.001	0.44	0.004
Established vs Early RA	2.21	1.97	0.24	0.010	0.20	0.119
HDL Choilesterol (>1.20 vs <1.20)	2.23	2.06	0.17	0.448		Insufficient data
LDL Cholesterol (<3.00 vs >3.00)	2.13	2.07	0.06	0.226		Insufficient data

Do Patients with Congestive Heart Failure Treated with Biologics for RA Have a Lower Risk of Fatal Outcome of Serious Infections? Anja Strangfeld[1], Adrian Richter[1], Yvette Meissner[1], Matthias Schneider[2], Michael Zaenker[3], Wolfgang Ochs[4], Thomas Klopsch[5], Angela Zink[6] and Joachim Listing[1]. [1]German Rheumatism Research Center, Berlin, Germany, [2]Heinrich-Heine-University, Düsseldorf, Germany, [3]Immanuel Klinikum Bernau, Rheumatology Center Northern Brandenburg, Bernau, Germany, [4]Rheumatologist in private practice, Bayreuth, Germany, [5]Rheumatologist in private practice, Neubrandenburg, Germany, [6]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany.

Background/Purpose: Patients with multimorbid conditions are at high risk of developing serious infections (SI) and of premature mortality. TNF inhibitors increase the infection risk (1) in patients with rheumatoid arthritis (RA). However, they are likely to decrease all-cause mortality (2). We aimed to examine a) the infection risk and b) the outcome of SI in a group of patients at high mortality risk: RA patients with congestive heart failure (CHF).

Methods: We used data from the German biologics register RABBIT with 10,671 RA patients included at start of a synthetic or biologic DMARD (bDMARD) after at least one DMARD failure. In 242 patients, CHF was reported as comorbid condition at enrollment (NYHA grade III: 16%, NYHA IV: none). We investigated the incidence of SI in CHF patients compared to a matched control sample and the rest of the cohort. Age, sex and comorbidity (chronic lung disease, chronic kidney disease, hypertension) were used as matching criteria for the nested case control study. For 238 CHF patients exactly matching controls without CHF were found. Multiple logistic regression was applied to investigate the risk of fatal outcome of the first SI in CHF patients.

Results: Compared to the rest of the cohort (n=10,429), CHF patients were older (mean age 68 vs. 56), more frequently males (34% vs. 23%), at baseline they had a higher level of disease activity (DAS28: 5.9 vs. 5.2), considerably more comorbidities (e.g. chronic lung disease: 7% vs. 3%, kidney disease: 24% vs. 3%) and lower functional capacity (FFbH (mean % of full function): 44% vs. 63%). These patient characteristics predispose CHF patients to develop SI. Compared to the rest of the cohort, we observed a nearly five times higher incidence per 100 patient-years (PY) (16 [95%CI: 13, 19] vs. 3.4 [3.2, 3.6]). In addition we found a higher risk of fatal outcome of SI in CHF patients.

In the sample of 238 CHF patients with exact matched controls, the difference in incidence rates of SI in CHF patients vs. controls was considerably smaller: 13.0 [10.7;15.8] vs. 10.3 [8.2;13.0] per 100 PY.

In patients of the matched sample who developed SI we observed a significantly lower risk of fatal outcome in those who were treated with biologics at the time of the infection: The odds ratio for bDMARD treatment (adjusted for age, sex, CHF and physical function) was 0.4 [0.2, 0.96].

Conclusion: Patients with CHF are at increased risk of SI with a high lethality risk. Our data suggest that SI occurring in RA patients on biologic therapy tend to have a lower risk of fatal outcome.

Patient-Reported Outcomes from a Canadian Study of Patients Taking Methotrexate and Etanercept. J. Carter Thorne[1], Edward C. Keystone[2], Janet E. Pope[3], Melanie Poulin-Costello[4], Krystene Phan-Chronis[4] and Boulos Haraoui[5]. [1]Southlake Regional Health Centre, Newmarket, ON, [2]University of Toronto, Toronto, ON, [3]St Joseph Health Care, London, ON, [4]Amgen Canada Inc., Mississauga, ON, [5]Institut de rhumatologie de Montréal (IRM), Montréal, QC.

Background/Purpose: The Canadian Methotrexate and Etanercept Outcome Study (CAMEO) evaluated etanercept (ETN) monotherapy vs ETN plus methotrexate (MTX) in biologic-naïve patients with rheumatoid arthritis (RA) who had an inadequate response to MTX.

Methods: This phase 4, randomized, open-label, noninferiority study enrolled patients who had an inadequate response to MTX. All patients received ETN+MTX for 6 months; they were then randomized at month 6 to ETN monotherapy or remained on ETN+MTX for an additional 18 months. Patient-reported outcomes (PROs) were assessed at baseline and at 6, 12, 18, and 24 months and included the Short Form-36 (SF-36) Health Survey questionnaire (higher scores represent better health); Health Assessment Questionnaire Disability Index (HAQ-DI; 0=no disability to 3=severe disability), and pain based on visual analog scale (VAS; 0=no pain to 100=severe pain). The minimal clinically important difference (MCID) for the SF-36 physical and mental component scores is a change ≥2.5; for HAQ-DI is a change ≥0.22; and for the pain VAS is a change ≥10mm.

Results: Of 258 patients enrolled, 205 were randomized at month 6 to ETN (n=98) or ETN+MTX (n=107); 53 were not randomized. These PROs through month 24 are shown (Table). As expected, on average, PROs demonstrated improvements at 6 months, when all patients had been on ETN+MTX. From month 6 (randomization) to month 24, mean improvements were maintained in both treatment arms.

	All Patients (N = 258)	ETN (N = 98)	ETN+MTX (N = 107)
HAQ-DI, mean score (SD)			
BL		1.2 (0.7)	1.5 (0.5)

Efficacy and Safety of Tofacitinib Following Inadequate Response to Nonbiologic DMARD or Biologic DMARD. C. Charles-Schoeman[1], Gerd Burmester[2], P. Nash[3], C.a.F. Zerbini[4], S. Anway[5], K. Kwok[6], T. Hendrikx[7], E. Bananis[8] and Roy Fleischmann[9]. [1]University of California, Los Angeles, CA, [2]Charité – University Medicine Berlin, Berlin, Germany, [3]Rheumatology Research Unit, Nambour Hospital, Sunshine Coast and Department of Medicine, University of Queensland, Queensland, Australia, [4]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [5]Pfizer Inc, Groton, CT, [6]Pfizer Inc, New York, NY, [7]Pfizer BV, Capelle aan den IJssel, Netherlands, [8]Pfizer Inc, Collegeville, PA, [9]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Department of Medicine, Dallas, TX.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Here we compare the efficacy and safety of tofacitinib 5 mg and 10 mg twice daily (BID) vs placebo (PBO) in patients (pts) who had an inadequate response (IR) to nonbiologic/conventional synthetic DMARDs only (csDMARDs; biologic-naïve) and pts with an IR to previous anti- TNF drugs or other biologic DMARDs (biologic-IR pts).

Methods: Efficacy comparisons were performed on pooled data from 4 Phase (Ph) 2 and 5 Ph 3 randomized, controlled studies of tofacitinib in RA pts. Pts received tofacitinib 5 mg or 10 mg BID or PBO as monotherapy, or with background MTX or other csDMARDs. In this analysis, efficacy in biologic-naïve and biologic-IR subpopulations was assessed by American College of Rheumatology (ACR) 20/50/70, disease activity score (DAS)28-4(ESR [erythrocyte sedimentation rate]), Health Assessment Questionnaire-Disability Index (HAQ-DI), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI). Safety was assessed in pooled Ph 3 pts from 5 studies.

Results: A total of 1071, 1090 and 651 biologic-naïve pts were randomized to tofacitinib 5 mg BID, 10 mg BID and PBO, respectively. For biologic-IR pts, 259, 253, and 193 were randomized to tofacitinib 5mg BID, 10 mg BID and PBO, respectively. Baseline demographics and disease characteristics were similar between tofacitinib and PBO groups within subpopulations. Biologic-IR pts were heavier, with a higher proportion of white pts, had longer disease duration and had slightly greater disease activity at baseline compared with biologic-naïve pts. In both biologic-naïve and biologic-IR pts in the pooled Ph 2 and 3 studies, clinical response was significantly greater for tofacitinib 5 and 10 mg BID vs PBO; significantly more pts achieved low disease activity and remission with both tofacitinib doses vs PBO by DAS28-4(ESR), SDAI or CDAI (Table 1). Clinical response appeared numerically greater with biologic-naïve vs biologic-IR pts. Rates of safety events of special interest in pooled Ph 3 studies were generally similar between tofacitinib doses and subpopulations (Table 2). Confidence intervals (CI) for safety events were wide and overlapping for all events and treatment groups due to the limited sample size in PBO and biologic-IR groups.

Conclusion: Tofacitinib reduced signs and symptoms of RA in pts who were biologic-naïve and biologic-IR. Tofacitinib had a numerically greater clinical response in the biologic-naïve population compared with the biologic-IR population. The safety profile appeared similar between the pt subpopulations in Ph 3 studies.

Table 1. Efficacy responses at Month 3 (pooled Ph 2 and Ph 3 studies) within each subpopulation. All measures were significantly improved with tofacitinib 5 mg or 10 mg BID vs PBO ($p<0.05$)

Estimation of Cost per Effectively Treated Patients with Biologic Disease Modifying Anti-Rheumatic Drugs in US Veterans with Rheumatoid Arthritis. Grant W. Cannon[1], Chia-Chen Teng[1], Tao He[1], Jianwei Leng[2], Chao-Chin Lu[1], Derek Tang[3], Neel Shah[3], David J. Harrison[3] and Brian Sauer[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA and University of Utah, Salt Lake Citty, UT, [3]Amgen Inc., Thousand Oaks, CA.

Background/Purpose: An algorithm based on administrative claims data (in lieu of clinical measures) was validated using data from the Veteran's Affairs (VA) Rheumatoid Arthritis (RA) Registry (VARA). It can be used to evaluate effectiveness of biologic disease modifying anti-rheumatic drugs (DMARDs) and cost per effectively treated patient.

Methods: National VA pharmacy and administrative claims for US veterans initiating biologics (abatacept (ABA) (intravenously [IV]), adalimumab (ADA), etanercept (ETN), infliximab (INF), or rituximab (RIT)) from Jan 1, 2008 to Jan 1, 2011 were evaluated. Patients were included if they newly initiated biologic treatment ≥365days after VA enrollment and were followed for 1-year. Only biologics with ≥100 patients were evaluated.

Clinical effectiveness was estimated using an algorithm based on claims data. Patients who did not fail any of the six algorithm criteria; biologic dose escalation, switching biologics, adding a new non-biologic DMARD, receiving >1 intra-articular glucocorticoid injection, increasing glucocorticoid dose, or low treatment compliance (<80%) were categorized as effectively treated. Cost per effectively treated patient was calculated using annual medication and administration cost divided by the percentage of patients categorized as effectively treated.

Subgroup analyses stratified by age, smoking status, serologic status, and body mass index (BMI) were conducted.

Results: A total of 4,696 patients (mean age 61 years, 87% male) met all inclusion and exclusion criteria. Demographic characteristics were similar across groups. The percentage of patients categorized as effectively treated ranged from 25% to 33% and was higher for self-injected than IV biologics. Annual cost was higher for INF and RIT compared to ABA, ADA, and ETN.

Outcomes were similar across all subgroups other than gender. Men had higher drug cost, but a higher percentage were categorized as effectively treated and the cost per effectively treated patient was lower, ($40.7k vs. $57.5k). Cost per effectively treat patient was lower for current non-smokers, patients with positive rheumatoid factor, positive anti-cyclic citrullinated peptide antibodies (aCCP), and BMI ≥30, but the differences were not statistically significant.

Conclusion: In US veterans, the percentage of patients categorized as effectively treated using the algorithm was highest for ADA (33%) and ETN (32%) and the cost per effectively treated patient was lowest for ETN ($39.4k) and ADA ($41.5k). Male gender was associated with higher annual drug cost but lower cost per effectively treated patient.

Discontinuation of Biologics in Patients with Rheumatoid Arthritis after Achieving Low-Activity Disease Status. Moeko Ochiai, Eri Sato, Eiichi Tanaka, Eisuke Inoue, Ayako Nakajima, Shigeki Momohara, Atsuo

Taniguchi and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Several clinical trials have reported bio-free remission or discontinuation of biologic DMARDs; however, these findings have not been confirmed in a real-world setting. The aim of this study is to evaluate the discontinuation of biologics after achieving low -activity disease status among patients with rheumatoid arthritis (RA) undergoing treatment in daily practice.

Methods: Among 1,775 patients (infliximab [IFX], 418 patients; etanercept [ETN], 690 patients; adalimumab [ADA], 267 patients; tocilizumab [TCZ], 318 patients; and abatacept [ABT], 82 patients) who had been treated with biologics in our clinic between 2003 and 2012, we extracted data on 43 patients with RA (IFX, 26 patients; ETN, 9 patients; ADA, 4 patients; TCZ, 2 patients; and ABT, 2 patients) who discontinued biologics since their disease activity were well controlled. In these patients, DAS28 scores were $<$ 3.2 at the time of biologics discontinuation. Those 43 patients were divided into two groups (bio-free or bio-reuse) on the basis of biologic usage 1 year after discontinuation. Those 43 patients were also divided into bio-free success and bio-free failure groups on the basis of disease activity (DAS28 $<$ 3.2 or DAS28 $\geqq$ 3.2, respectively) 1 year after discontinuation. The clinical features of the patients at the time of initiation and discontinuation of biologics were compared between the bio-free and bio-reuse groups and between the bio-free success and bio-free failure groups.

Results: The percentages of patients who discontinued biologics due to well-controlled disease activity and in the bio-free success group among biologics users in our clinic were 2.4% (43/1775) and 1.4% (25/1775), respectively. The number of patients in the bio-free and bio-reuse groups was 34/43 (79.1% [IFX, n = 20; ETN, n = 8; ADA, n = 3; TCZ, n = 1; and ABT, n = 2) and 9/43 (20.9%), respectively. There were no significant differences between the two groups with respect to age (bio-free vs. bio-reuse [47.5 vs. 39.0 years]), disease duration (3.0 vs. 2.0 years), DAS28 (4.17 vs. 5.10), J-HAQ (0.75 vs. 0.56), dose of MTX (8.0 vs. 8.0 mg/week), and dose of glucocorticoids (4.0 vs. 0 mg/day) at initiation of biologics, or DAS28 at discontinuation of biologics (2.09 vs. 1.80), or duration of biologics use (591.5 vs. 851.0 days). In addition, most clinical features did not differ significantly between the bio-free success (n=25 [58.1%]; IFX, n = 13; ETN, n = 6; ADA, n = 3; TCZ, n = 1; and ABT, n = 2) and bio-free failure groups (n=18 [41.9%]). The median DAS28 at initiation of biologics was significantly lower in the bio-free success group than the bio-free failure group (3.95 vs. 5.04, *p=0.04*). The bio-free success group was significantly decreased the average dosage of glucocorticoid during the biologics use than that in the bio-free failure group (−3.0 vs 0 mg/day, *p=0.01*).

Conclusion: We showed that the 1-year discontinuation rate of biologics after achieving low-activity disease status was high (79.1%) in patients with RA being treated in an outpatient setting. A lower DAS28 score at initiation of biologics and decreasing the dose of glucocorticoid before discontinuation of biologics were important factors leading to bio-free success in patients with RA irrespective of biologic type.

Efficacy and Safety of Induction Therapy for Rheumatoid Arthritis with Simultaneous Administration of Methotrexate and Low-Dose Tacrolimus: A Retrospective Study. Takashi Nakanishi[1], Hideyuki Horikoshi[1], Reiko Takahashi[1], Kanami Tongu[2], Junko Nishioka[2], Fumihiko Kimura[1], Yuichi Nishioka[2] and Kenji Itoh[1]. [1]National Defense Medical College, Tokorozawa, Japan, [2]Nishioka Clinic for Rheumatic Diseases and Allergic Diseases, Kofu, Japan.

Background/Purpose: Additional administration of low-dose tacrolimus (LD-TAC) at 0.5–1.0 mg daily was reported to be quite effective for rheumatoid arthritis (RA) patients with inadequate response to methotrexate (MTX). This study evaluated the efficacy and safety of induction therapy with simultaneous administration of MTX and LD-TAC for RA.

Methods: Clinical records of 147 RA patients initially treated with MTX alone or MTX with LD-TAC were retrospectively analyzed. We classified the patients into the MTX monotherapy group (patients who continued to receive MTX alone during the entire investigation), LD-TAC add-on group (patients with inadequate response to MTX who initially received MTX monotherapy and then an add-on LD-TAC), and simultaneous combination group (patients who initially received concomitant administration of MTX and LD-TAC). Patients who needed to receive other disease-modifying antirheumatic drugs, biological agents, or prednisone $>$ 10 mg daily were excluded from the study. Treatment efficacy was evaluated every 12 weeks for 1 year from the initial treatment, using the Disease Activity Score in 28 joints and erythrocyte sedimentation rate (DAS28-ESR) and Boolean-based remission rate.All adverse events observed in each group were also evaluated.

Results: A total of 26, 18, and 28 patients in the MTX-monotherapy, LD-TAC add-on, and simultaneous combination groups, respectively, were evaluated. The initial DAS28-ESR scores were 4.73, 4.58, and 4.63, respectively. No differences in baseline patient characteristics were found between the groups, except the higher initial prednisone dose in the MTX-monotherapy group.Of the patients in the simultaneous combination group, 92.9% achieved low disease activity at the 48th week, which was a significantly higher rate than that for those in the MTX-monotherapy and LD-TAC add-on groups (65.4% and 66.7%, respectively; $p < 0.01$). The achievement rates for good response according to the DAS28-based European League of Associations for Rheumatology response and Boolean-based remission criteria were also significantly higher in the simultaneous combination group. In addition, the prednisone dose was lower in the simultaneous combination group than in the MTX monotherapy group at the 48th week.No significant difference in the incidence of adverse events was observed between the groups. No serious adverse event was observed during the study period.

Conclusion: This study demonstrates the efficacy and safety of induction therapy with simultaneous administration of MTX and LD-TAC for RA. Large-scale prospective cohort studies are required for a more precise understanding of the treatment.

Efficacy and Safety Study of a Sequential Therapy of Tocilizumab and, If Initially Inadequately Responded to Tocilizumab, Followed By Rituximab in Patients with Rheumatoid Arthritis and Inadequate Response to Traditional Disease Modifying Anti-Rheumatic Drugs. Thomas Dörner[1], Hans-Peter Tony[2], Gerd Burmester[1], Hendrik Schulze-Koops[3], Jörg Kaufmann[4], Peter Kästner[5], Herbert Kellner[6], Reiner Kurthen[7], Sylke Wagner[8], Marvin A. Peters[9] and Christoph Iking-Konert[10]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]University Clinic Wuerzburg, Wuerzburg, Germany, [3]University Clinic Munich, Munich, Germany, [4]Rheumatology Practice, Ludwigsfelde, Germany, [5]MVZ Out-patient Rheumatogy Unit Erfurt, Erfurt, Germany, [6]Specialist Practice for Rheumatology and Gastroenterology, Munich, Germany, [7]Rheumatology Practice, Aachen, Germany, [8]Practice for Internal Medicine specialized in Rheumatology, Halle, Germany, [9]Roche Pharma AG, Grenzach-Wyhlen, Germany, [10]University Clinic Hamburg-Eppendorf, Hamburg, Germany.

Background/Purpose: The MIRAI study evaluated a sequential exposure to 2 defined biologics under rigorous study conditions within a homogeneous population of biological naïve patients (pts) with moderate/severe active RA who inadequately responded to traditional DMARDs. This study investigated the early response to the IL-6 inhibitor tocilizumab (TCZ); non-responders to TCZ subsequently received 1 cycle of rituximab (RTX; anti-CD20 therapy).

Methods: We report the results of the final analysis (first-pat-in: MAR-2011; last-pat-out: FEB-2014) of MIRAI (NCT01332994), a German, multicenter, two-arm, open-label, phase-III-study. All pts received 4 TCZ infusions (8 mg/kg, q4w; 1st treatment period) until week 16. Partial responders (ΔDAS28 $>$1.2 or DAS28$\geq$2.6 and $\leq$3.2) received further 4 TCZ infusions (8 mg/kg, q4w); non-responders (ΔDAS28$\leq$1.2 and DAS28 $>$3.2) received subsequent RTX treatment (1g each at weeks 16 and 18). All pts with a 2nd treatment period (TCZ or RTX) completed study at week 32. Primary endpoint: pts in remission (DAS28 $<$2.6) at week 16 (expected 45%). Secondary endpoints: DAS28/ACR response at week 32, patient-reported outcomes, B-cells, adverse events (AE).

Results: 519 pts (ITT-Main/Safety; mean age: 56 years, females 67.8%) received TCZ in the 1st treatment period. 504 pts received concomitant DMARDs (mostly MTX, 365 pts). At week 8, a clinically relevant DAS28

reduction (>1.2) from baseline was seen in 81.5% of pts. At week 16, 222 pts (42.8%) were in remission and completed study, 213 pts received a 2nd TCZ period (ITT-TCZ2), only 27 non-responder initiated subsequent RTX (ITT-RTX). At week 32, 117 of 213 pts achieved remission under continued TCZ therapy, and 10 of 27 pts showed a clinically relevant DAS28 reduction from week 16 after 1 cycle RTX.

Total incidence of drug related AEs/SAEs: 38.3%/4.4%. Drug-related serious infections occurred in 10 pts (1.9%). One death possibly related to TCZ was reported (fall plus craniocerebral injury). No RTX related SAEs were reported.

Conclusion: Early response to TCZ was demonstrated by a rapid improvement of RA symptoms until week 16. Initially partial responders to TCZ benefited from a continued TCZ therapy. Notably, the proportion of TCZ non-responders was low (27 of 519 pts); about 1/3 of these pts clearly benefited from subsequent RTX therapy with lasting effects until week 66.

All patients (ITT-main/Safety), 1st treatment period TCZ: results from baseline to week 16

Patient Experience with Initiation of SQ and Oral MTX. Jeffrey R. Curtis[1], David Mackey[1], Noam Gerber[2], Aseem Bharat[1], Lang Chen[1], Fenglong Xie[1], Ben Nowell[2], Kenneth G. Saag[3] and Seth Ginsberg[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Creaky Joints/ Global Healthy Living Foundation, Upper Nyack, NY, [3]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Methotrexate is the anchor drug used for the treatment of rheumatoid arthritis (RA). Despite its prominent position in RA therapeutics, its real-world effectiveness may be influenced by a relative lack of tolerability or other side effects that physicians may not be aware of but that are bothersome to patients.

Methods: We conducted a prospective, compensated ($25), online survey among RA patients who were members of Creakyjoints, a large arthritis patient community. Eligible participants must have recently initiated a new biologic, SQ MTX, or oral MTX in the last 12 months and were uniquely assigned to one of these 3 exposure cohorts. Patients eligible for more than 1 cohort were assigned in the hierarchy above. **Results** were stratified by exposure cohort: SQ MTX, oral MTX, and biologic. Descriptive statistics were used to compare patient-reported side effects and tolerability related to MTX use, comparing SQ vs. oral formulations and referent to biologic initiation. Recruitment is still ongoing to an expected sample size of 550 pts and results are reported through June 5th, 2014.

Results: A total of 783 patients were screened for the survey, and 346 were eligible. Of these, 287 (83.0%) completed the survey, distributed to the biologic (n=175, including 85 initiating SQ biologics), SQ MTX (n=33), and oral MTX (n=79). Demographics were similar across treatment arms; overall, mean (SD) age was 47.91 (13.01) years, 90.2% women. Commonly-reported side effects were included in the table and showed differences between exposure groups in diarrhea, nausea, fatigue, and other adverse events. Pain initiating SQ biologics compared to SQ MTX reported greater pain, particularly with SQ etanercept and adalimumab compared to SQ MTX. The mean pain score (0–10 scale) for patients on SQ MTX was 2.18, lower than mean score for etanercept (4.21, $p = 0.002$) and adalimuamb (4.43, $p < 0.0001$). Patients reported a monthly co-payment of $0 with the following frequencies: oral MTX - 13%, SQ MTX – 0%, and biologic users - 23%; and monthly co-payments between $0 and $25: oral MTX – 61%, SQ MTX - 61%, and biologics - 30%.

Conclusion: Results: from this real-world RA patient cohort suggest that oral MTX is accompanied by many patient-reported side effects and tolerability problems that may be under-recognized by physicians. These may impact both treatment satisfaction and medication adherence that adding or switching to biologics or SQ MTX may attenuate.

Table: Patient Reported Side Effects and Tolerability Associated with use of Biologics and MTX

	Biologic N=175	SQ MTX N=33	Oral MTX N=79	P value for difference between the 3 treatments
Diarrhea	6 (3%)	3 (9%)	17 (22%)	<0.0001
Vomiting	7 (4%)	1 (3%)	5 (6%)	0.64
Other stomach problems	13 (7%)	2 (6%)	4 (5%)	0.77
Fatigue	42 (24%)	27 (82%)	42 (53%)	<0.0001
Malaise	26 (15%)	16 (48%)	26 (33%)	<0.0001
Mental fog	26 (15%)	13 (39%)	21 (27%)	0.002
Infection	22 (13%)	3 (9%)	4 (5%)	0.18
Any pain with injections	83/99* (84%)	20 (71%)	N/A	0.008

*limited to the 99 patients using SQ biologics

Biologic Discontinuation in Rheumatoid Arthritis: Experience from a Canadian Clinic. Denis Choquette[1], Louis Coupal[1], Marie-Claude Laliberté[2] and Olivier Desjardins[2]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]AbbVie, St. Laurent, QC.

Background/Purpose: Adherence and persistence to treatment are a cornerstone of treatment success in chronic diseases such as rheumatoid arthritis (RA). The purpose of this study was to describe biologic treatment discontinuation and assess the predictors of discontinuation in RA patients followed at a Canadian clinic.

Methods: In this prospective cohort study, adult patients included in the RHUMADATA computerized database with a diagnosis of RA and treated with at least one biologic agent since 2003 were selected. The RHUMADATA database includes clinical, laboratory and socioeconomic information of patients with rheumatic diseases followed at the *Institut de Rhumatologie de Montréal*, a rheumatology clinic in Montreal (Quebec, Canada). Patients were followed for three years after therapy initiation or until treatment discontinuation. Biologic therapies considered include abatacept, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, rituximab, tocilizumab, and anakinra. Treatment discontinuation was measured using pharmacy records. Time to discontinuation and predictors of treatment discontinuation were explored using Cox proportional hazards models.

Results: A total of 623 eligible patients were treated with at least one biologic. The average age was 53.2 years (SD=12.4), 77% were women and patients had been diagnosed for an average of 7.7 years. The average time on treatment for the first biologic agent was 1.7 years (SD=2.1). In all, 233 (37%), 326 (52%), 405 (65%), and 438 (70%) patients had stopped their first biologic treatment after 6, 12, 24, and 36 months, respectively. In time-to-event analyses (Cox proportional hazard models), type of work [part time vs. full time; hazard ratio (HR): 1.57; 95% confidence interval (CI): 1.05–2.34] and income [$20,000 to $40,000 vs. less than $20,000 (HR: 1.35; 1.01–1.80) and $80,000 to $100,000 vs. less than $20,000 (HR: 2.16; 1.23–3.80)] were significantly associated with biologic discontinuation over the complete treatment duration. The number of disease-modifying antirheumatic drugs (DMARDs) used (HR: 0.89; 0.80–0.99) and the use of methotrexate (yes vs. no; HR: 0.80; 0.64–0.99) were associated with a reduced risk of biologic discontinuation.

Conclusion: In this real-life Canadian study, high biologic discontinuation rates were observed over three years. This study also suggests that many clinical and socioeconomic variables are predictors of biologic therapy discontinuation in RA patients. These results may help design interventions aiming at improving treatment adherence in RA, a chronic and progressive disease.

Prediction of Successful Dose Reduction or Discontinuation of Adalimumab or Etanercept Using Serum Drug Levels and Antidrug Antibody Measurement. Noortje van Herwaarden[1], Chantal Bouman[1], Aatke van der Maas[1], Ronald F. van Vollenhoven[2], Johannes W.J. Bijlsma[3], Frank H.J. van den Hoogen[4], Alfons A. den Broeder[1] and Bart van den Bemt[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Unit for clinical therapy research (ClinTrid), Karolinska Institute, Stockholm, Sweden, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]Rheumatology Centre Sint Maartenskliniek and Radboud university medical center, Ubbergen (Nijmegen), Netherlands.

Background/Purpose: Dose reduction and discontinuation of TNF inhibitors (TNFi) is feasible in many rheumatoid arthritis (RA) patients, but leads to (temporary) worsening of disease activity in some patients. We evaluated the predictive value of baseline adalimumab and etanercept serum levels and antidrug antibodies for successful dose reduction or discontinuation in patients with RA and low disease activity.

Methods: Patients with RA and a stable low disease activity, included in the intervention arm of an 18 months randomised controlled trial (DRESS study) assessing non-inferiority of a dose reduction strategy of adalimumab or etanercept compared to usual care were analysed[1]. Dose was reduced by stepwise increasing the interval between injections every 3 months until flare or discontinuation of the TNFi. Serum levels of adalimumab or etanercept and antidrug antibodies were measured before start of dose reduction[2,3]. Receiver-operator-curves (ROC) and optimal cut-off drug serum levels were calculated. A sensitivity analyses was done for timing of serum sampling (days after last injection), per tertile. Sensitivity/specificity of anti-drug antibodies were calculated for successful discontinuation and for successful dose reduction separately.

Results: Data was available for 118 of 121 included patients. Mean DAS28-CRP at baseline was 2.2 (SD 0.6). At 18 months follow up TNFi could be stopped in 19% (95%CI 12–27) of patients, the interval increased in 44% (95%CI 35–53) and in 37% (95%CI 29–47) of patients no dose reduction was possible. Mean drug levels and anti-drug antibodies were not different per subgroup (table 1). ROC analyses showed no predictive value of drug levels for successful dose reduction or discontinuation (figure 1). Sensitivity analyses showed no influence of serum sample timing, with the exception of adalimumab trough level (last tertile) predicting successful dose reduction (AUC 0.86, 95% CI 0.58–1.00, optimal cut-off 7.8 μg/ml).

Anti-adalimumab antibodies were detected in 4 patients (10%), and were not predictive for successful discontinuation. No anti-etanercept antibodies were detected.

Conclusion: Adalimumab and etanercept serum levels and antidrug antibodies have no predictive value for successful dose reduction or discontinuation in RA patients with low disease activity, with a possible exception of adalimumab trough levels for predicting successful dose reduction.

Bio-naïve Patients with Rheumatoid Arthritis Benefit More from Abatacept Treatment Compared to Those Who Are Inadequate Responders to Other Biologics – Results from the National Swedish Rheumatology Quality Register. Carl Turesson[1], Leszek Stawiarz[2], Staffan Lindblad[2] and Saedis Saevarsdottir[3]. [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska institutet and Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Abatacept is a biological anti-rheumatic drug used in Rheumatoid Arthritis (RA). Data on patient characteristics, diagnosis, previous treatment and outcomes of abatacept have been collected in the Swedish Rheumatology Quality register (SRQ) which comprises the Swedish Biologics Register (ARTIS; Arthritis Treatment In Sweden), since the drug was first available in 2006. The objective of this study was to evaluate drug survival probability and short term outcome of abatacept in clinical practice for patients with RA, using a national register.

Methods: Observational data from the SRQ were collected for the period from April 1st, 2006 to May 20, 2014. Analyses were stratified by previous exposure to biologics, regardless of the cause of discontinuation. Kaplan-Meier survival analysis with right censoring and log-rank test of equality across strata were performed and Šidák multiple-comparison adjustments applied. EULAR good or moderate response rates at 6 and 12 months were calculated, and corrected for survival on drug using the Lundex method (proportion still on drug x proportion responding(1)).

Results: A total of 1291 patients with RA (1023 females, 79.2%) started abatacept treatment between April 2006 and May 2014. The mean age at start of abatacept was 59.2 years, and the median duration of RA was 11.2 years. Abatacept was prescribed as the first biologic treatment in 200 cases (15.5 %), after inadequate response (IR) to one other biologic in 349 cases (27.0 %) and after IR to ≥ 2 other biologics in 742 cases (57.5 %). The baseline disease activity was slightly lower in bio-naïve patients starting abatacept compared to those who had received one or ≥2 previous biologics (mean DAS28 5.01, 5.16 and 5.37 respectively). The bio-naïve patients treated with abatacept were older at baseline (mean 62.0 vs 60.6 and 57.8 years, respectively), and less likely to be female (71 % vs. 80 % and 81 %). Survival on drug was significantly longer in patients treated with abatacept as the first biologic compared to those previously exposed to 1 biologic (p=0.002) or ≥ 2 biologics (p=0.002). The corresponding estimated survival rates were 91%/77%/78% at 6 months and 75%/60%/62% at 12 months. There was no significant difference in drug survival between those with IR to one vs two biologics (p=0.94). After 6 months, among those still on treatment, a EULAR good or moderate response was achieved in 74 % of patients in the bio-naïve subset compared to 62 % among those with previous IR to one biologic, and 57 % among those exposed to ≥ 2 biologics. The Lundex corrected EULAR good/moderate responses were 67%/48%/45% at 6 months and 47%/41%/37% at 12 months.

Conclusion: In this observational study of RA patients treated with abatacept in clinical practice, a greater proportion of bio-naïve patients had a significant clinical response and remained on treatment compared to those with a previous IR to other biologic drugs. These results are compatible with reports from clinical trials, and indicate that a substantial number of RA patients treated with abatacept as their first biologic in clinical practice have a favorable outcome.

Tocilizumab Use in Patients with Rheumatoid Arthritis Having Failed One Previous Anti-TNF Agent: Comparison with Adalimumab, Etanercept and Infliximab. Denis Choquette[1], Marie-Pier Payette[1], Jean-Pierre Raynauld[1], Jean-Pierre Pelletier[2], Louis Bessette[3], Edith Villeneuve[1], Boulos Haraoui[1], Isabelle Fortin[4], Marie-Anaïs Rémillard[1], Diane Sauvageau[1] and Louis Coupal[1]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [3]Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, QC, [4]Centre de rhumatologie de l'est du Québec (CREQ), Rimouski, QC.

Background/Purpose: Tocilizumab, as an intra-venous agent, has been approved for rheumatoid arthritis (RA) in Canada in April 30th, 2010. It was the sixth approved agent after adalimumab, etanercept, abatacept, infliximab and rituximab. It has been demonstrated effective in the treatment of RA either in monotherapy or combo therapy after non-biologic or biologic DMARDS [1–3]. The goal of this analysis is to describe its effectiveness in patients with RA failing a first anti-TNF DMARDs and to compare its retention rate versus adalimumab, etanercept and infliximab in the same clinical situation.

Methods: All patients with RA having failed a first anti-TNF agents and subsequently exposed to tocilizumab after the 1stof January 2005 were extracted from the Rhumadata® database. 4 cohorts were created according to the time tocilizumab or the subsequent anti-TNF agents was introduced: One cohort of patients starting tocilizumab and 3 other cohorts starting either adalimumab, Etanercept or infliximab. Demographics and baseline characteristics including age, gender, disease duration, Rheumatoid factor and anti-CCP antibodies, CRP and ESR, previous failed treatment number, DAS 28 ESR and CDAI, HAQ-DI were included for each cohorts.

Results: The data from 259 patients prescribed either tocilizumab (53=20%), adalimumab (97=37%), etanercept (82=33%) or infliximab (27=10%) as a second biologic agent were extracted from the Rhumadata® registry and clinical database. Mosts subjects were female (75%) and the average age of cohort subjects was 58.2 (StD=14.3). Mean CRP and ESR were respectively 17.0 (StD=29.5) mg per L and 26.6 (StD=24.1) mm per hour. No clinically significant differences at baseline were observed between groups. The four year retention rates of tocilizumab, adalimumab, etanercept and infliximab as second line biologic agents were 44.3%, 27.2%, 37.1% and 34.0% respectively. Kaplan-Meier survival analysis revealed significant differences in the drug retention rates (logrank p=0.0249).

Conclusion: In RA patient having failed their first anti-TNF agent, tocilizumab, an Il-6 inhibitor, could be a more valuable alternative than cycling to a second anti-TNF agent.

Does a Higher Dose of Folic Acid Reduce Adverse Effects of Methotrexate in Rheumatoid Arthritis? a Randomized Controlled Trial. Varun Dhir[1], Amit Sandhu[1], Jasbinder Kaur[2], Nidhi Gupta[1], Prabhdeep Kaur[1], Ankita Sood[1], Aman Sharma[1] and Shefali Sharma[1]. [1]Postgraduate Institute of Medical Education and Research, Chandigarh, India, [2]Government Medical College and hospital Sector 32, Chandigarh, India.

Background/Purpose: There is good evidence that folic acid 5–10mg per week leads to reduction in methotrexate (MTX) toxicity in rheumatoid arthritis (RA). However, this data comes from old studies using a lower dose of MTX. There is limited data of folic acid doses with contemporary usage of MTX, i.e., when MTX is started at a high dose and rapidly escalated. We wondered whether a higher dose of folic acid i.e. 30mg per week (approx. 1:1 MTX) would be better, in this context, in reducing toxicity than 10 mg per week.

Methods: This was a single-center double-blind randomized controlled trial of 24 weeks duration. Included patients 18–75 years of age, who fulfilled 1987 ACR criteria for RA and had active disease (DAS28(3) >3.2). MTX was started at 15mg/week and escalated by 8 weeks to 25 mg/week. At 16 weeks, a new DMARD could be added on the physician's discretion. Folic acid was given at a dose of 10 mg (FA-10) or 30 mg per week (FA-30), as 6 identical tablets for every day of the week except the day of taking MTX. Patients were seen every 8 weeks. Co-primary endpoints were incidence of toxicity and change in disease activity by 24 weeks. Toxicity included undesirable symptoms (evaluated by questionnaire) and laboratory abnormalities (cytopenias: WBC<4000 or platelet<100x10^3/ul or transaminitis:

>2ULN). Disease activity was evaluated using modified disease activity score using 3 variables (DAS28(3)). In addition, HAQ, serum and RBC folate and MMP-3 were done at 0 and 24 weeks. Intention-to-treat and per-protocol analyses were performed. Trial # NCT01583959

Results: This study included 100 patients, having a mean±SD age of 44.3±10.9 years, disease duration of 4.8±4.7 years and DAS28(3) of 5.8±0.9. At enrolment 13 patients were on steroids and 4 on other DMARDs. FA-10 and FA-30 groups had 51 and 49 patients respectively, with similar baseline characteristics. Similar numbers of patients were lost to follow up (6,6). At 24 weeks, the mean±SD dose of MTX in both groups (22.8±4.4, 21.4±4.6mg/week) was similar (p=0.1). Leflunomide was added in 18 and 10 patients at 16 weeks and SSZ in 1 patient. Among patients with at least 1 follow up, there were no significant differences between groups in the frequency of undesirable symptoms or laboratory abnormalities. Lung toxicity was suspected in 2 patients in the FA10 group (Table 1). DAS28(3) declined similarly from baseline to 24 weeks (p=0.2) in FA10 (−1.1±1.0) and FA30 (−1.3±1.0) groups. At 24 weeks, serum folic acid was significantly (p<0.001) higher in FA30 (45.1±39.7) compared to FA10 group (20.4±17.1ng/ml), but there was no difference in RBC folate, HAQ and MMP-3.

Conclusion: We did not find any significant difference in toxicity or efficacy of MTX with higher dose of folic acid even when starting MTX at a high dose and escalating rapidly. The finding of 2 cases of suspected lung toxicity with folic acid 10 mg/week warrants larger studies.

Table 1: Frequency of MTX related toxicity in patients who had at least one follow up visit

	Folic acid 10 mg per week (N=47) N(%)	Folic acid 30 mg per week (N=46) N(%)	P value
Laboratory abnormalities			
Cytopenias	2 (4.3)	2 (4.3)	0.99
Transaminitis	20 (42.6)	21 (45.7)	0.76

Abatacept after Rituximab in Rheumatoid Arthritis. a Pan-European Collaboration of RA Registries. Axel Finckh[1], David Neto[2], M. Victoria Hernández[3], Florenzo Iannone[4], Elisabeth Lie[5], Helena Canhao[6], K Pavelka[7], Carl Turesson[8], Xavier Mariette[9], Merete Lund Hetland[10] and Jacques Gottenberg[11]. [1]Geneva University Hospital, Geneva, Switzerland, [2]University of Geneva, Geneva, Switzerland, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Reumatologia Universita e Policlinico di Bari, Bari, Italy, [5]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [6]Instituto de Medicina Molecular, Universidade de Lisboa, Lisbon, Portugal, [7]Institute of Rheumatology, Prague, Czech Republic, [8]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [9]Université Paris-Sud, Le Kremlin Bicêtre, France, [10]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark, [11]Strasbourg University Hospital, Strasbourg, France.

Background/Purpose: Some observations have suggested that the effectiveness of abatacept (ABA) may be decreased in rheumatoid arthritis (RA) patients (pts) who previously failed rituximab (RTX).(1) The objective of this study was to compare the effectiveness of ABA started after prior inadequate response (IR) to RTX (RTX-IR) versus prior IR to anti-TNF agents only (aTNF-IR) in routine care.

Methods: This is a pooled observational database analysis of 9 prospective registries of RA pts (Czech Republic, Denmark, France, Italy, Norway, Portugal, Spain, Sweden, Switzerland). We included all RA pts treated with ABA with information on prior use of specific bDMARDs and who experienced either a RTX-IR or a aTNF-IR. The primary outcome was drug retention of ABA, defined as the time between first and last administration plus one dispensation interval, and analyzed using a Cox proportional hazards model. A secondary endpoint was EULAR good or moderate response rate at one year, estimated by longitudinal interpolation and corrected for drug retention (Lundex(2)). All analyses were adjusted for potential confounders, such as calendar year, demographics, country, number of prior bDMARDs and other disease characteristics.

Results: We identified 1994 pts initiating ABA with 3105 pt-years of follow-up. Of these, 486 pts (24%) received ABA after failing RTX and 1508 pts (76%) after failing > 1aTNFs, but never RTX. RTX-IR pts had significantly higher disease activity at baseline, longer disease duration, more functional disability, more prior bDMARDs and used more concomitant glucocorticoids than had aTNF-IR pts. (Table)

Baseline characteristics*	RTX-IR (N=486)	aTNF-IR (N=1508)	p-value
Age, (yrs)	57	57	0.08
Female, (%)	84	82	0.41
DAS28	5.2	4.9	<0.001
Dis. Duration (yrs)	13.9	12.1	<0.001
HAQ	1.4	1.2	<0.001
BMI	26	26	0.91
CRP (mg/L)	24.8	22.7	0.11
ESR (mm/1h)	34	32	0.25
RF+, (%)	70	74	0.10
N° prior bDMARDs, med (IQR)	3[2–4]	2[1–2]	<0.001
Oral Glucocorticoid use, (%)	74	59	<0.001

* Values are the means, unless stated otherwise

The crude median retention time of ABA after RTX-IR was 1.65 y (IQR: 1.42 – 2.13) compared to 2.05 y (IQR: 1.87 – 2.27) after aTNF-IR (p = 0.11). After adjustment for potential confounders no difference between ABA retention rates was found (Hazard Ratio (HR) RTX-IR vs aTNF-IR: 1.00 (95%CI: 0.83 – 1.21)). Similar results were found when examining only ABA treatment discontinuations due to ineffectiveness (HR: 1.04 (95%CI: 0.84 – 1.29)). However, response rates at one year were slightly lower in pts with RTX-IR compared to pts with aTNF-IR (73% EULAR good or moderate responses versus 83% in aTNF-IR (p=0.001); Lundex-adjusted EULAR good or moderate response 45% versus 56% in aTNF-IR, p=0.003, respectively).

Conclusion: The results of this large pooled RA population of inadequate responders to bDMARDs suggest that the slightly decreased effectiveness of ABA in patients having experienced a RTX-IR may be largely driven by a selection of pts with more treatment refractory disease.

A Structured Approach for Comparative Benefit-Risk Assessment of Rituximab for the Treatment of Rheumatoid Arthritis. Ani John[1], George Quartey[1], Patricia B. Lehane[2], Nicole Mairon[3], Michael Schulte[3], Ashwini Shewade[1], Carol Chung[1] and Dominic Borie[1]. [1]Genentech, Inc, South San Francisco, CA, [2]Roche Products Ltd, Welwyn Garden City, United Kingdom, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland.

Background/Purpose: Rituximab in combination with methotrexate (MTX) is indicated for the treatment of adult patients with moderate to severe active rheumatoid arthritis (RA) who have an inadequate response to tumor necrosis factor therapies (TNF-IR). A structured systematic assessment of a drug's benefit-risk profile is useful to inform decisions at each developmental milestone, and could meaningfully inform multiple stakeholders, physicians, patients, payors and researchers on the trade-offs between benefits and risks during the lifecycle of a drug product. The objective of this post-hoc analysis

was to apply a structured descriptive approach to compare the benefit-risk profile of rituximab from the REFLEX 24-week placebo (PBO)-controlled trial and to produce a graphical representation of this profile in TNF-IR patients with RA.[1]

Methods: Presentations of data were based on the Benefit Risk Assessment Tool Framework developed for pharmaceutical benefit-risk decision-making in drug development and post-approval settings.[2,3] Key benefits and risks of rituximab were identified and organized in a hierarchical manner to construct a 'value tree' as a basis for potential treatment benefits and risks. Absolute differences in efficacy outcome measures and safety event rates between (rituximab+MTX) and (PBO+MTX) treated patients were calculated to summarize key benefit-risk metrics and then presented graphically in a descriptive manner.

Results: Key benefits of rituximab treatment in TNF-IR patients identified included measures of clinical response (ACR and EULAR response and DAS28-ESR) and patient-oriented outcomes (Health Assessment Questionnaire Disability Index [HAQ-DI]). Safety assessments included rates of overall adverse events (AEs), serious AEs, all infections and serious infections. Mean (95% CI) efficacy differences and adverse event rate differences between the rituximab and PBO arms of the 24-week trial were calculated and displayed in the **Figure**. Overall, patients receiving rituximab treatment demonstrated meaningful clinical and statistically significant improvement compared with PBO in ACR20/50/70 response rates, EULAR response rates, DAS28-ESR and HAQ-DI, with no meaningful differences in safety events including serious AEs and infections.[1]

Conclusion: A graphical representation of key benefits and risks was generated to present the positive benefit-risk profile of rituximab in TNF-IR patients with RA. Future applications of this structured approach could include interpretation of the benefit-risk profile of longer term outcomes and of subpopulations of patients with RA receiving rituximab or a similar structured assessment of other drugs in a consistent manner.

Trial of Six Weeks Interval of Tocilizumab Infusion in Patients with Rheumatoid Arthritis. Osamu Saiki, Hiroshi Uda and Koji Shigematsu. Higashiosaka City General Hospital, Higashiosaka, Japan.

Background/Purpose: For active rheumatoid arthritis (RA) patients with inadequate response to synthetic DMARDs, biologic agents, such as TNF inhibitor and IL-6 receptor inhibitor, are indicated. However, all biologics are very expensive, and, therefore all patients with high disease activities always can not receive biologics. Indeed, the interval of administration is fixed in most of biologics, but the interval is flexible in some biologics such as etanercept and infliximab. Tocilizumab (TCZ) is one of useful biologics, and the interval of TCZ infusion is fixed for 4 weeks. In the course of treating active RA patients by TCZ with 4 weeks interval, sometimes we experienced that longer interval was also effective. In preliminary study, we found that six weeks interval was effective in these patients. The present study is carried out to clarify the efficacy of six weeks interval of TCZ infusion in the patients with active RA.

Methods: The patients who showed inadequate response to DMARDs and the patients who showed inadequate response to biologics other than TCZ and who agreed with TCZ therapy of six weeks interval were enrolled in the present study. In addition to oral medicines, the patients were infused 8mg/kg of tocilizumab in every six weeks (SIWETO study). The clinical assessments and blood tests were also carried out in every 6 weeks. To the patients who did not achieve clinical remission by 6 weeks interval of TCZ, prednisolone (PSL) and/or methotrexate were added with increasing the dose. The patients who achieved clinical remission in 12 months were estimated as responder and others were as non-responders. We followed up the patients at least for 3 years.

Results: Total of 74 patients was enrolled in the present study. Male and female were 18 and 56 respectively. Forty-four patients achieved clinical remission with 6w interval, and the rest of the patients were non-responder. To the patients who did not achieve clinical remission with 6w interval, TCZ infusion with 5w or 4w interval was carried out. Nineteen patients achieved clinical remission by 5w interval and four patients by 4w interval, respectively. The rest of 7 patients could not achieve clinical remission by TCZ infusion. In 44 patients who achieved clinical remission with 6w interval of TCZ infusion, 10 patients were treated by TCZ alone without any oral medicines for rheumatoid arthritis and kept the condition throughout the observation and the rest of patients received either or both PSL (1 to 7.5 mg) and MTX (2 to 8mg). It is generally accepted in Japanese rheumatologist that the effective dose of MTX in Japanese is lower than that in Caucasian. Severe adverse events including tuberculosis and death were not found. The frequency of other adverse events of 6w interval of TCZ was less than those of regular use (4w interval).

Conclusion: The SIWETO study provides evidence that 6w interval of TCZ infusion is also effective in active rheumatoid arthritis patients. The finding of SIWETO study is quite useful for taking care of active rheumatoid arthritis patients, especially in financial aspects. The cost of 6 weeks interval of TCZ became two thirds of that of 4 weeks regular use.

Efficacy and Safety of Adalimumab Therapy in Japanese Patients with Rheumatoid Arthritis. Yosuke Hattori. National Hospital Organization Nagoya Medical, Nagoya, Japan.

HIGH RATE OF IMPROVEMENT IN SERUM MATRIX METALLOPROTEINASE-3 LEVELS AT 4 WEEKS PREDICT REMISSION AT 52 WEEKS IN RA PATIENTS WITH ADALIMUMAB THERAPY

Background/Purpose: Serum Matrix metalloproteinase-3 (MMP-3) is a specific inflammatory marker of the synovium in patients with rheumatoid arthritis (RA). Our aim in this study is to investigate whether serum MMP-3 is the predictor for remission in treatment for RA patients with biologics.

Methods: All RA patients (n=269) who underwent Adalimumab (ADA) treatment in the multicenter study group (Tsurumai Biologics Communication Registry; TBCR) were enrolled in this study. We analyzed 114 patients in continuation with ADA therapy for 52 weeks. We divided into 2 groups based on the improvement of serum level of MMP-3 and CRP: high rate of improvement (MMP-HR group) and low rate of improvement (MMP-LR group) in serum MMP-3 levels at 4 weeks.and: high rate of improvement (CRP-HR group) and low rate of improvement (CRP-LR group) in serum CRP levels at 4 weeks (Table1). We also divided into 2 groups based on the serum level of MMP-3 and CRP: high value (MMP-H group) and low value (MMP-LR group) in serum MMP-3 levels at 4 weeks, and: high value (CRP-H group) and low value (CRP-L group) in serum CRP levels at 4 weeks (Table2). We evaluated the rate of remission at 24, and 52 weeks in 2 groups.

Results: In patients continuing at 52 weeks, the rate of remission at 24 and 52 weeks in MMP-HR group is 56% and 60%, and MMP-LR group is 32% and 37%. The rate of remission at 24 and 52 weeks in MMP-HR group is significantly higher than in MMP-LR group (Fig.1). However, the rate of remission at 24 and 52 weeks had no significance in CRP-HR group and CRP-LR group (Fig.2).The rate of remission at 24 and 52 weeks in MMP-H group is 35% and 44%, and MMP-L group is 55% and 53%. The rate of remission at 24 weeks in MMP-L group is significantly higher than in MMP-H group (Fig.3). However, the rate of remission at 24 and 52 weeks had no significance in CRP-H group and CRP-L group (Fig.4). Moreover, the rate of remission at 24 and 52 weeks in MMP-(L and HR) group is very high (Fig.5). In patients continuing at 52 weeks, the best cut-off rate of improvement in MMP-3 at 4 weeks for determining remission at 52 weeks was 40% determined by ROC analysis (sensitivity: 47%, specificity: 83%, accuracy: 64%).

Conclusion: We considered that high rate of improvement in serum MMP-3 at 4 weeks can be useful for predicting the remission at 52 weeks in RA patients with ADA therapy.
