Methods: Memory B cell subsets were phenotypically analyzed for activation (expressions of CD95 and ki-67) and their isotype profile using 10 color flow cytometry at baseline, week 12 and week 24 during cytokine inhibition. Single B cell PCR approach was used to study isotypes specific Ig-receptors. Mann-Whitney U test was used for statistical analysis by using GraphPad Prism 5.

Results: Surface and intracellular staining of memory B cell subsets showed a significantly higher percentage of CD95 and ki-67 expression in RA ($n=60$) compared to healthy donors ($n=20$). During cytokine (IL-6 or TNF-α) inhibition, both CD95 and ki-67 expression was significantly reduced at week 12 and 24 in all 3 types of memory B cells. RA patients showed a significant relative expansion of DN IgD-/CD27- B cells with a mixture of IgA, IgG and IgM expression dominated by the IgG phenotype. During IL-6 receptor inhibition, IgA+ DN B cells decreased significantly from 25.1 (8.0–54.2) percent median (range) to 19.0 (4.8–51.1) at week 12 ($P= 0.0016$) and 20.5 (4.6–33.8) at week 24 ($P=0.0008$) respectively without any remarkable change in relative IgG+ and IgM+ B DN B cells. In the postswitch compartment, IgA+ and IgG+ postswitch B cells were not influenced during IL-6R inhibition. Isotype specific analysis of rearranged Ig-R sequences from DN B cells revealed that mutational frequencies were highest in IgA+ B cells followed by IgG+ and IgM+, respectively. During IL-6R inhibition, significantly reduced mutational frequencies in Ig-receptors of all DN isotypes at week 12, 24 and 1year ($p<0.0001$) were observed. Accordingly hotspot motif targeting was also decreased whereas CDR3 length increased during therapy.

Conclusion: Our study suggests that all three major memory B cell subsets are activated in RA which can be significantly reduced by IL-6R and TNF-α inhibition in vivo. DN B cells are expanded in RA and IL-6R inhibition resulted in a reduction of particularly IgA+ DN B cells. IL-6 inhibition leads to a reduced mutational frequency and hot spot targeting in IgA, IgG as well IgM DN Ig receptors. The results are in accordance with a specific effect on DN memory B cells by in vivo IL-6 receptor inhibition.

Explore Translational Pharmacokinetics/Pharmacodynamics Response/ Efficacy Relationship of a Novel Bruton's Tyrosine Kinase Inhibitor in Rat Collagen-Induced Arthritis Model. Jie Zhang-Hoover[1], Erica Leccese[1], Kalyan Chakravarthy[1], Ian Knemeyer[1], Jos Lommerse[1], Marianne Spatz[1], Francois Gervais[2], Raquel Sevilla[1], Jian Liu[3], Ronald Kim[3], Sachin Lohani[3], Kevin Matthew Maloney[3], Joseph Kozlowski[3] and Alexandra Hicks[1]. [1]Merck Research Laboratories, Boston, MA, [2]Merck & Co., Boston, MA, [3]Merck Research Laboratories, Rahway, NJ.

Background/Purpose: Abnormal B cell activation is an essential part of autoimmune inflammation. B cell depletion is proven to be an efficacious treatment in patients as well as in preclinical rodent rheumatoid arthritis models. Bruton's Tyrosine Kinase (BTK) is downstream of B cell receptor and critical in B-cell development and activation, making it a potential therapeutic target for autoimmune inflammatory diseases. Here we evaluated a novel and selective small molecule BTK inhibitor in disease mechanism and pharmacokinetics (PK)/pharmacodynamics (PD) models to understand the level and duration of compound exposure on activation biomarker PD effect that leads to efficacy.

Methods: Female Lewis rats were treated with the BTK inhibitor (3, 10, 30, 100 mg/kg PO QD) prophylactically starting from the day of immunization in the rat collagen induced arthritis (CIA) model. Disease severity was evaluated in life by measuring paw thickness and

clinical scores and terminal by micro-CT imaging of ankle and knee joints for bone erosion. The effect of the BTK inhibitor on B cells was evaluated by ex vivo whole blood B cell CD86 PK/PD assay. Blood was collected from rats at 0, 0.5, 4, 8, and 24 hours after compound dosing. B cells were stimulated in vitro in whole blood by crosslinking of BCR with dextran conjugated anti-IgD. Activation biomarker CD86 expression on B cells was quantified by flow cytometry. Rat plasma compound concentrations were determined by protein precipitation followed by liquid chromatography – tandem mass spectrometry. A PK/PD-CIA model was built linking the effect of compound exposure with CD86 biomarker expression in the ex vivo whole blood assay and paw inflammation in the rat CIA. PK was best described using a zero-order dissolvation linked with a first-order absorption compartment and a concentration dependent elimination rate. For CD86 expression a direct-effect model was used. Paw inflammation in the rat CIA modeling was performed based on the assumption that the biomarker PD effect drove the disease inhibition.

Results: The BTK inhibitor showed an exposure-dependent suppression of joint inflammation in the rat CIA model with an EAUC50 of 56 uM.h, and blocking of CD86 upregulation in ex vivo whole blood B cell biomarker activation assay (IC50= 918 nM). Micro-CT imaging revealed reduced bone erosion in both ankle and knee joints by the inhibitor, and the bone effect correlated well with the reduction on joint inflammation. The integrated PK/PD-CIA model was used to simulate the full range of target engagement by the inhibitor as measured by the CD86 assay. A good correlation between average CD86 inhibition over a 24 hour time period and the paw thickness inhibition in the rat CIA model was found. An average of 60% CD86 suppression led to a 90% suppression of disease development in the rat CIA model.

Conclusion: The selective and novel BTK inhibitor is efficacious in the rat CIA model. Pharmacological evaluation of compounds in disease mechanism and target pathway relevant PK/PD and efficacy models can provide valuable data in building a translational PK/PD/efficacy platform from preclinical *in vitro* and *in vivo* models to human diseases in drug discovery.

β2 Adrenoceptor Signal Is Augmented in B Cells in the Course of Arthritis to Increase IL-10. Georg Pongratz, Clemens Wiest, Madlen Melzer and Rainer Strraub. University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: Splenic B cells from collagen-induced arthritis (CIA) mice react to a β2-adrenoceptor (AR) stimulus with increased IL-10 production and adoptive transfer of these cells decreases disease activity. However, B cells from unimmunized mice do not adequately increase IL-10. Therefore, we test the hypothesis that sensitivity to catecholamines changes during CIA. Furthermore, we wanted to test if human peripheral blood B cells from osteoarthritis (OA) and rheumatoid arthritis (RA) patients also increase IL-10 following a β2-adrenergic stimulus.

Methods: FACS to determine AR pathway related proteins (β2-adrenoceptor, G-protein coupled receptor kinase (GRK) 2, phophorylated and unphosphorylated mitogen activated protein kinase p38, and cAMP responsive element binding protein (CREB)) in B cells at different timepoints during CIA. Unstimulated splenic B cells and B cells stimulated with terbutalin, a β2-AR agonist, were used. Human B cells were isolated from peripheral blood of patients with OA or RA and stimulated under different conditions with and without terbutalin. IL-10 protein level was determined by ELISA after 5 days of culture.

Results: In the course of CIA the percentage of β2-AR+ B cells increased and stayed above baseline (ANOVA $p<0.05$). In contrast, the mean fluorescence intensity (MFI) as measure for the number of receptors per cell remained unchanged. MFI for GRK2 decreased and stayed low from day 6 p.i. (ANOVA $p<0.0001$). The relative increase in phosphorylation of p38 (ANOVA $p<0.001$) and CREB (ANOVA $p<0.001$) following a β2-AR stimulus was augmented starting at day 18 p.i. with a maximum response at day 55 p.i. in the late phase of CIA. In human B cells, similar mechanisms are in place, because β2-AR stimulation of RA, but not OA B cells increased IL-10.

Conclusion: The current data show, that B cells become more sensitive to β2-AR stimuli in the course of CIA, possibly due to a decrease in GRK2 and increase in the percentage of β2-AR expressing splenic B cells. Increased catecholamine sensitivity might support B cell and IL-10 mediated anti-inflammatory mechanisms primarily in the late phase of CIA. A similar mechanism is observed in human peripheral B cells and might be used to improve treatment of autoimmune arthritis.

Microrna-155 As an Epigenetic Regulator of B-Cell Activation in Rheumatoid Arthritis: In Vivo and in Vitro Evidences. Stefano Alivernini[1], Barbara Tolusso[1], Silvia Canestri[1], Luca Petricca[1], Clara Di Mario[2], Elisa Gremese[1] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]Division of Pathology, Catholic University of the Sacred Heart, Rome, Italy.

Background/Purpose: MicroRNAs (miRs) are a novel class of post-transcriptional regulators. miR-155 was shown to be a regulator of B cell biology in haematological diseases as well as in myeloid cells in Rheumatoid Arthritis (RA). The regulation of the transcription factor PU.1 by miR-155 is required for the production of high-affinity IgG1 antibodies. The aim of this study was to investigate the expression of miR-155 in B cells of RA patients and its association with synovial inflammation.

Methods: 31 RA patients underwent ultrasound guided synovial tissue (ST) biopsy. ST samples were categorized through Hematoxiline and Eosine staining as diffuse or aggregate pattern. B cells from peripheral blood (PB) and matched synovial fluid (SF) of RA patients (n=19) and PB of healthy controls (HC) (n=10) were isolated by CD19+ microbeads (Mylteni). B-cell subsets were determined by Flow-Cytometry using IgD/CD27 classification and ZAP70 intracellular expression was assessed. IL-6 and BAFF levels in PB and SF were measured by ELISA. miR-155 expression was determined by qPCR on B cells from PB and SF and on ST of osteoarthritis (OA) (n=3), diffuse RA (n=5) and aggregate RA (n=5) patients. Finally, B cells from PB of HC (n=5) were isolated by CD19+ microbeads and cultured in RPMI with or without IL-6 (30 ng/ml), BAFF (20 ng/ml), IL-6+BAFF. Cells were collected after 24h, 48h and 72h to assess miR-155 and PU.1 expression by qPCR.

Results: 14(45,2%) RA patients showed an aggregate synovial pattern in ST. RA patients with an aggregate synovial pattern were more likely anti-CCP positive compared to RA patients with diffuse pattern ($p=0.05$). Moreover, anti-CCP plasma levels directly correlates with the synovial aggregate grade ($r=0.38$; $p=0.01$). IL-6 and BAFF levels were higher in SF than in PB of RA patients regardless to the synovial pattern ($p=0.001$ for both). CD19+/IgD-CD27- and CD19+/ZAP70+ cells were over-represented in PB of RA patients with an aggregate pattern ($p=0.05$ and $p=0.04$) compared to RA patients with a diffuse pattern. Moreover, anti-CCP+ RA patients showed higher percentages of CD19+/IgD-CD27- and CD19+/ZAP70+ in the PB ($p=0.01$ for both) compared to anti-CCP- RA patients. miR-155 was over-expressed in PB B-cells compared to HC ($p=0.0002$). miR-155 was over-expressed in SF B-cells compared to matched PB B-cells ($p=0.05$) in RA patients. Moreover, anti-CCP+ RA showed higher miR-155 expression in PB B-cells compared to anti-CCP- RA patients ($p=0.02$) and HC ($p=0.001$). miR-155 was over-expressed in ST of aggregate RA compared to diffuse RA ($p=0.03$) and OA ($p=0.03$) patients respectively. Finally, IL-6 and BAFF in vitro stimulation of healthy B-cells induced an overexpression of miR-155 after 72h of incubation ($p=0.04$ and $p=0.03$). Consistently PU.1 was down-regulated after in vitro stimulation ($p=0.01$ and $p=0.03$).

Conclusion: This study indicates that miR-155 is over-expressed in B-cells of RA patients and is associated to anti-CCP positivity and to an aggregate synovial pattern. IL-6 and BAFF, that are over-expressed in the SF environment, induce in vitro an over-expression of miR-155 in B-cells. Thus, miR-155 may represent a key regulator of B-cells in RA patients with an activated memory phenotype.

Pathogenic Role of CXC Chemokine receptor 3-Positive B Cells in Bone Destruction of Rheumatoid Arthritis. Yuri Hirosaki, Hiroaki Niiro, Shunichiro Ota, Naoko Ueki, Hirofumi Tsuzuki, Kumiko Noda, Siamak Jabbarzadeh-Tabrizi, Hiroki Mitoma, Yojiro Arinobu, Mitsuteru Akahoshi, Hiroshi Tsukamoto and Koichi Akarshi. Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan.

Background/Purpose: B cells can function as potent effector cells by production of autoantibody, immune complex formation and inflammatory cytokines. Clinical efficacy of B-cell depletion therapy underscores a pathogenic role of B cells in autoimmune diseases such as rheumatoid arthritis (RA). A recent study suggests that infiltrating B cells in the joints of RA express RANKL, which plays a key role in osteoclastogenesis and inflammatory bone loss. In the RA joints, abundant accumulation of B cells expressing chemokine receptor CXCR3 was also noted, however the role of these cells in bone destruction of RA remains to be established. In this study, we have sought to elucidate the relationship of RANKL- and CXCR3-expressing B cells and their role in osteoclast differentiation.

Methods: Levels of RANKL/CXCR3 mRNA and protein in B cells from peripheral blood of normal subjects and RA patients were evaluated using quantitative RT-PCR and flow cytometry, respectively. Highly-pure B cell subsets were isolated using cell sorter. To validate the functional significance of osteoclast differentiation, B cells were co-cultured with osteoclast precursor cells and the formation of tartrate-resistant acid phosphatase (TRAP)-positive cells were assessed thereafter.

Results: Without stimuli, freshly-isolated B cells only marginally expressed RANKL mRNA and protein. Combined stimulation of B cells with B-cell receptor (BCR) and CD40, mimicked as chronic inflammation stimuli, however, significantly induced RANKL expression. Among B cell subsets, switched-memory (CD27+IgD-) B cells, a normal counterpart of pathogenic B cells in the joints, expressed RANKL at the highest levels. Upon the same stimulation, the levels of joint-homing receptor CXCR3 increased from 30 to 80%, representing the state of activation, but not plasma cell differentiation. Switched-memory B cells of RA patients expressed higher levels of CD80/CD86 than that of healthy control. In addition, highly-activated switched-memory B cells expressing CD80/CD86 double-positive B cells from RA patients expressed RANKL and CXCR3 at higher levels than those from normal subjects. Consistent with these findings, these subsets induced osteoclast formation as assessed by TRAP staining compared with other B cell subsets.

Conclusion: Our current findings shed the light on a pathogenic role of switched-memory B cells in bone damage associated with RA via production of RANKL, and regulation of CXCR3-expressing B cells may provide a novel strategy for the treatment for this devastating disease.

Fibroblast-like Synoviocytes Inhibit Wnt Signaling Pathway By Secreting Dockcop-1. Satoshi Yamasaki and Eiji Sugiyrama. Hiroshima University Hospital, Hiroshima, Japan.

Background/Purpose: There is evidence of osteoclast activation in the inflamed joints of patients with rheumatoid arthritis (RA). Studies that focus on osteoblasts are not sufficient to illustrate the cell functioning in an RA joint. Osteoblast differentiation is regulated by complex environmental stimuli. Among them, Wnt family proteins are thought to promote osteoblast differentiation via stabilization of β-catenin and activation of TCF transcription. It is now known that the Wnt pathway is blocked with several soluble proteins such as Dockcop-1 (DKK-1) or Sclerostin (SOST). Fibroblast-like synoviocyte (FLS) is a unique articular resident cell and is a therapeutic target for RA, because the cell is believed to play a role in the joint destruction observed in this disease. In this study, we aimed to determine if FLS has an inhibitory effect on Wnt signaling.

Methods: FLS derived from RA patients (Articular Engineering, USA) was cultured in Dulbecco's modified Eagle's medium with 10% fetal bovine serum. Supernatants were collected from the FLS culture for 24 hours, with or without TNF-α (100 ng/ml, Millipore). The supernatants were added to U2OS culture after the transfection of TCF reporter plasmid, which contains Wnt/β-catenin responsive consensus sequence (Millipore), by using lipofectamine 2000 to monitor the activity of Wnt3a responsive promoter. Wnt3a (R&D) or lithium chloride (LiCl) was used to activate the Wnt signaling pathway. Anti DKK-1 antibodies were used to neutralize DKK-1 in uupernatants from the FLS. The DKK-1 productions from FLS were measured by ELISA after treatment with TNF-α (100 ng/mL), IL-6 (100 ng/mL) with soluble IL-6 receptor (100 ng/mL), or IL-17A (100 ng/mL) for 24 hours.

Results: Wnt3a (200 ng/mL) or LiCl (50 mM) clearly increased the luciferase activity, which was effectively suppressed by the addition of supernatants from the FLS culture. The supernatant from FLS treated with TNF-α exhibited a greater inhibitory effect on luciferase activity induced by Wnt3a or LiCl. The inhibitory effects were blocked by anti DKK-1 neutralizing antibodies. DKK-1 was detectable in the FLS culture medium by ELISA, and the concentrations of DKK-1 were higher in the FLS culture medium supplemented with TNF-α, but not with IL-6 or IL-17, compared to the control.

Conclusion: Our data suggests that FLS inhibits osteogenesis by inhibiting osteoblast differentiation, which is achieved by inhibition of the Wnt signaling pathway. DKK-1, an antagonist for Wnt signaling, is one of the soluble factors that might contribute to the inhibition of the Wnt signaling pathway by FLS. The inflammatory milieu may enhance the Wnt signal inhibition by FLS because TNF-α facilitates the secretion of DKK-1 from FLS. Detailed research is required for the clinical application of DKK-1 blockade in promoting bone regeneration in an inflamed joint of a patient with RA.

Global Transcriptome Analysis in Osteoarthritic Cartilage Reveals Significant Differential Gene Expression and Associations with Histologic Disease Progression. Matlock A. Jeffries[1], Madison Donica[1], Anand Annan[1], Michael Stevenson[1], Mary Beth Humphrey[1], Judith A. James[2] and Amr H. Sawalha[3]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]University of Michigan, Ann Arbor, MI.

Background/Purpose: Osteoarthritis (OA) is the leading cause of chronic disability affecting 40% of individuals over the age of 70 and costing $128 billion annually in the US alone. Little is known regarding changes in gene expression that occur regionally within these affected joints. Herein, we perform RNA-seq analysis of eroded and intact cartilage from human OA, and correlate transcript levels with histopathologic disease severity.

Methods: Six femoral heads were obtained at the time of hip arthroplasty for primary OA. Articular cartilage tissue samples were dissected from grossly affected and grossly normal areas of the same joints, flash frozen in liquid nitrogen, and RNA was extracted. A portion of these samples were also histologically examined for OA severity using modified Mankin scoring. Following confirmation of RNA quality (RIN value $\geq$6), samples were sequenced with the Illumina TruSeq system on a MiSeq sequencer. Raw data were analyzed and mapped using the GeneSifter software package. Genes with GeneSifter quality score $<$1.0 were excluded. For categorical analysis, EdgeR $p \leq 0.01$ with Benjamini-Hochberg $q \leq 0.1$ and expression ratios ≤ 0.83 or ≥ 1.2 between affected and normal tissues were considered significant. For correlations with histologic score, Pearson's $r > 0.75$ or < -0.75 with $p \leq 0.05$ were considered significant. Gene ontology and pathway analysis was performed using the Ingenuity IPA platform.

Results: Categorical analysis identified 43 overexpressed and 313 underexpressed genes in eroded compared to intact cartilage. Both under- and overexpressed genes were overrepresented in the fibroblastic growth factor (FGF) signaling pathway ($p=0.004$). *FGFR2* demonstrated an eroded to intact cartilage expression ratio of 0.46, was highly inversely correlated with OA histologic score severity ($r=0.92$), and is known to be hypermethylated in eroded OA cartilage. The WNT pathway genes, *WNT11* (ratio 0.27) and *WNT9A* (ratio 0.45), and the STAT3 pathway was also overrepresented, including both under- and overexpressed genes ($p=0.001$). A top predicted upstream regulator in differentially expressed genes was mir-9 ($p=0.005$), known to be associated with metalloproteinase production. Further, we

identified 176 genes positively and 1591 genes inversely correlated with histopathologic score. Among these, the NFAT pathway was highly overrepresented, including both positively and inversely correlated genes (24, p=0.002). The RIG-I innate immunity pathway was also overrepresented among inversely correlated genes (p=0.008), as were several genes related to chromatin remodeling (overall p=0.009: HDAC1, r=−0.89, MECP2 r=−0.78, RBBP4 r=−0.82, SAP130 r=−0.81, SIN3A r=−0.80).

Conclusion: Using RNA-seq we detected significant changes in gene expression in eroded compared to intact OA cartilage, as well as expression changes correlated with histologic disease progression in OA. Our data strongly suggest involvement of several signaling pathways, many of which are potential therapeutic targets for OA. This work reinforces the heterogeneity of the disease process and provides novel insights into OA pathogenesis.

Proteomic Analysis of Connexin 43 Reveals Novel Interactors Related to Osteoarthritis. Raquel Gago-Fuentes[1], Patricia Fernández-Puente[2], Paula Carpintero-Fernández[1], Jesus Mateos[2], Maria Dolores Mayan[1] and Francisco Javier Blanco[2]. [1]Cartilage Biology Research Group, Rheumatology Division, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Rheumatology Division, CIBER-BBN/ISCIII, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain.

Background/Purpose: We have previously reported that articular chondrocytes in tissue contain long cytoplasmic arms that physically connect two distant cells. Cell-to-cell communication occurs through connexin channels termed Gap Junction (GJ) channels, which achieve direct cellular communication by allowing the intercellular exchange of ions, small RNAs, nutrients and second messengers. The Cx43 protein is overexpressed in several human diseases and inflammation processes and in articular cartilage from patients with osteoarthritis (OA). An increase in the level of Cx43 is known to alter gene expression, cell signalling, growth and cell proliferation. The interaction of proteins with the C-terminal tail of connexin 43 (Cx43) directly modulates GJ-dependent and -independent functions. Here, we describe the isolation of Cx43 complexes using mild extraction conditions and immunoaffinity purification.

Methods: Cx43 complexes were extracted from human primary articular chondrocytes isolated from healthy donors and patients with OA. The proteomic content of the native complexes was determined using LC-MS/MS, and protein associations with Cx43 were validated using western blot and immunolocalisation experiments.

Results: We identified >100 Cx43-associated proteins including previously uncharacterised proteins related to nucleolar functions, RNA transport and translation. We also identified several proteins involved in human diseases, cartilage structure and OA as novel functional Cx43 interactors, which emphasised the importance of Cx43 in the normal physiology and structural and functional integrity of chondrocytes and articular cartilage. Gene Ontology (GO) terms of the proteins identified in the OA samples showed an enrichment of Cx43-interactors related to cell adhesion, calmodulin binding, the nucleolus and the cytoskeleton in OA samples compared with healthy samples. However, the mitochondrial proteins SOD2 and ATP5J2 were identified only in samples from healthy donors.

Conclusion: The identification of Cx43 interactors will provide clues to the functions of Cx43 in human cells and its roles in the development of several diseases, including OA.

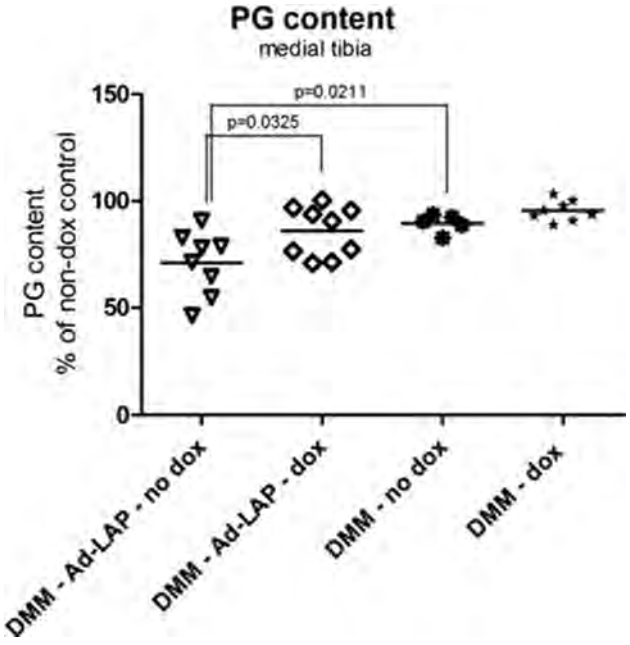
Elevated Levels of BMP2 Compensate for Loss of TGF-Beta in Articular Cartilage during Experimental Osteoarthritis. Esmeralda Blaney Davidson[1], Arjan van Caam[1], Arjen Blom[2], Elly Vitters[2], Miranda Bennink[1], Wim van den Berg[2], Fons van de Loo[1] and Peter van der Kraan[2]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: We have demonstrated that TGF-beta signaling via Smad2/3 is drastically reduced in articular cartilage (AC) with age and loss of Smad2/3-signaling predisposed AC for OA. We additionally showed that TGF-beta inhibition reduces the proteoglycan (PG) content in AC. During OA BMP2 is elevated in chondrocytes surrounding AC lesions. However, the effect of this BMP2 on AC is unclear. Therefore, we investigated whether elevated BMP-2 could counteract the loss of TGF-beta signaling during OA.

Methods: We made a unique transgenic mouse expressing human BMP2 under control of the Col2a1 promoter only when exposed to doxycycline (Col2a1-rtTA-BMP2). Functionality was tested on mRNA from AC, spleen and liver 72 hours after exposure to doxycycline- or standard diet (hBMP2 expression). We induced OA (DMM-model) while treating them with doxycycline- versus standard diet. To study the effect of losing TGF-beta activity, we intra-articularly injected an adenovirus overexpressing TGF-beta-inhibitor LAP (Ad-LAP). Four weeks after DMM induction knee joints were isolated for histology. OA was scored based on cartilage damage (adapted OARSI score, 0–30) and PG-content was measured with digital image analysis of Safranin O stainingin AC of the medial tibia.

Results: Doxycycline treatment clearly elevated hBMP2 mRNA in AC, but not in spleen and liver thereby confirming functionality of the transgenic mice. Doxycycline exposure in Col2a1-rtTA-BMP2 up to 8 weeks did not result in alterations in healthy AC. DMM induced a clear increase in OA-score (average of all DMM groups of 16.9 versus 2.5 in non-DMM), but this was not affected by elevated chondrocyte-specific BMP2. TGF-beta inhibition with LAP did not affect the OA-score either. However, TGF-beta inhibition during DMM significantly reduced the PG-content compared to DMM alone (18%). BMP2 did not affect the PG-content during DMM (figure). Nevertheless, the PG-depletion by inhibition of TGF-beta during DMM could significantly and nearly completely be counteracted by elevated chondrocyte-specific BMP2.



Conclusion: Our data show that in healthy AC and AC affected by OA in young animals BMP2 did not have detectible effects. However, when TGF-beta signaling was lost, a phenomenon occurring in aged individuals, this resulted in decreased levels of PG-content in AC during OA. In this setting, BMP2 compensated this PG loss. Therefore the elevated levels of BMP2 near OA lesions could be a reparative response of the AC, compensating age-related loss of TGF-beta signaling.

Histone Lysine Demethylase KDM6A Mediates Joint Destruction in Osteoarthritic Knees By Epigenetic Disturbance of SOX9 Promoter and Histone H3K27. Feng-Sheng Wang, Pe-Chin Chuang, Yi-Chih Sun, Yu-Shan Chen and Jih-Yangr Ko. Kaohsiung Chang Gung Memorial Hospital, Taiwan, Kaohsiung, Taiwan.

Background/Purpose: Intensive articular cartilage deterioration and synovial fibrosis in joints are prominently pathogenic features of osteoarthritic (OA) knees. Epigenetic reactions in joint microenvironments are linked to the incidence

of OA knees. Histone lysine demethylase KDM6A is an emerging epigenetic regulator cntributing to tissue development and remodeling. This study was undertaken to investigate the biological roles of KDM6A in joint integrity of OA knees and decipher the epigenetic actions of KDM6A on methylation statuses of master cartilage regulator SOX9 promoter and histone 3 lysine 27 (H3K27) and metabolism of cartilage and synovial matrices in OA knee joints.

Methods: Mice with collagenase-induced OA knees were weekly administered with KDM6A inhibitor GSK-J4 or vehicle for 12 weeks. Gait profiles, fluorescence probe 2-deoxyglucose uptake by inflammatory tissues, and subchondral bone microstructures were analyzed using Catwalk, near infrared fluorescence in vivo imaging and μCT. Quantitative RT-PCR, immunoblotting, methylation-specific PCR, and chromatin immunoprecipitation were performed to quantify mRNA, protein expression, methylation statuses and enrichments of SOX9 promoter and H3K27.

Results: Articular cartilage damage and synovial fibrosis were in conjunction with increased expression of KDM6A, KDM6B and decreased levels of SOX9 and methylated H3K27 in OA knee joints. Administration with KDM6A inhibitor GSK-J4 alleviated the deleterious effects of OA on gait characteristics (maximum contact intensity, area and print area of paws) and joint inflammation. It also improved subchondral bone microarchitecture (trabecular volume, thickness, number and cortical porosity) and bone mineral density of affected joints. Inhibition of KDM6A attenuated the adverse effects of OA on chondrogenic matrix expression, morphology and OARSI scores of articular cartilage, as well as mitigated nucleated cell infiltration, hypervascularization and fibrotic matrix accumulation in synovial compartments. Loss of KDM6A signaling restored methylation of CpG islands in SOX9 promoter and alleviated the OA-mediated inhibition of SOX9 mRNA transcription and protein levels. Treatment with KDM6A inhibitor also increased H3K27 methylation that reduced the enrichment of H3K27 to proximal promoter region of fibrogenic transcription factor AP-1 and profibrotic gene expression in injured joint tissues.

Conclusion: KDM6A induces SOX9 promoter and H3K27 hypomethylation that deregulates SOX9 and AP-1 actions on articular cartilage integrity and synovium homeostasis in the pathogenesis of OA knees. Inhibition of KDM6A ameliorates the OA-mediated epigenetic dysfucntion in cartilage and synovium, thereby protects aganist excessive joint remodeling. This study sheds emerging lights on epigenetic modulation of joint integrity in OA knees and highlights that pharmaceutical modulation of KDM6A actions has therapeutic potentials for preventing against OA-induced joint damage.

Interleukin-4 As Promising, Anti-Inflammatory Transgene for Gene Therapeutic Application in Joint Diseases. Annemarie Lang[1], Johannes Neuhaus[2], Moritz Pfeiffenberger[3], Erik Schroeder[4], Frank Buttgereit[4], Michael F. G. Schmidt[3] and Timo Gaber[5]. [1]Berlin-Brandenburg School of Regenerative Therapies (BSRT), Berlin, Germany, [2]Research Center of Medical Technology and Biotechnology, Bad Langensalza, Germany, [3]Institute of Immunology, Freie Universität Berlin, Berlin, Germany, [4]Charité University Medicine, Berlin, Germany, [5]Berlin-Brandenburg Center of Regenerative Therapies (BCRT), Berlin, Germany.

Background/Purpose: Interleukin- 4 (IL-4), a Th2-cell released immunomodulatory factor, has potent chondroprotective and anti-inflammatory properties able to inhibit the synthesis of IL-1β and TNFα, and to reduce the inflammation-induced mediators of cartilage breakdown (e.g.: NO, PGE2, MMPs). To optimize cartilage transplants for the application in patients with cartilage defects as a result of osteoarthritis (OA) or rheumatoid arthritis (RA) we developed a vector for the transgenic expression of IL-4 in chondrocytes under the "smart" control of the inflammation-activated cyclooxygenase- 2 promoter (pCox-2) which is inactive under non-inflammatory conditions. For effective translation to the clinic we use the horse as naturally occurring model since the disease in this species parallels the human form of OA.

Methods: The non-viral transfection of equine chondrocytes was optimized by comparing a range of different reagents as well as by different vector designs using the co-expression of the reporter gene GFP by flow cytometry. For further investigations, we used vectors containing Cox-2 and IL-4 in combination or alone. After transfection cells were stimulated using 100ng/ml Il-1β to mimic inflammation. Induction of Il-4 was validated on mRNA level and protein level by quantitative PCR, ELISA and Western Blot. To confirm the functional activity of transgenic IL-4 as well as simulation of inflammation we additionally analyzed Cox-2, IL-1β, IL-6, IL-8, MMP-3, MMP-9 and MMP-13 on mRNA level by quantitative PCR.

Results: The transfection efficiency was increased up to 44% by delivering a vector without IRES and using Turbofect (Fermentas). A plasmid vector including IL-4 as therapeutic gene under the control of pCox-2 was proven to be functional since it induced the production of high levels of IL-4 in cell culture supernatants and cell lysates. Furthermore, in the same cultures IL-1β IL-1β, IL-6, IL-8, MMP-3, MMP-9 and MMP-13 expression was significantly decreased whenever IL-4 was expressed.

Conclusion: Our study shows the promising impact of new generation gene therapy where the therapeutic transgenic target IL-4 will only be expressed if inflammatory mediators are present. IL-4 demonstrated chondroprotective and anti-catabolic potential *in vitro*. Translation into clinical practice: cartilage transplants containing autologous cells with the inflammation sensitive plasmid could exert therapeutic effects when placed close to the defective joint area. We are presently focusing on the application of the new plasmids in a 3D-*in-vitro*-OA-model including viral gene delivery systems. Eventually, *in vivo* studies and clinical trials are needed to substantiate the promising potential of our therapy concept.

1007

Markedly Increased Mesenchymal Stem Cell Activity in MRI Bone Marrow Lesions Compared with Non-Involved Bone in Osteoarthritic Hips. T Mark Campbell[1], Frederique Ponchel[2], Alexandro Gomez[3], Richard J. Hodgson[2], Dennis McGonagle[4], Philip G. Conaghan[5] and Elena Jones[3]. [1]The Ottawa Hospital Rehabilitation Centre, Ottawa, ON, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds, United Kingdom.

Background/Purpose: Multipotent mesenchymal stem cells (MSCs) are critical for bone and cartilage repair but the role of such cells *in vivo* in hip OA is poorly defined. Subchondral bone changes depicted as bone marrow lesions (BMLs) on MRI are intimately linked to joint remodelling and OA structural deterioration, suggesting potential aberrant MSC responses within such tissue. We hypothesised that deficiencies in native *in vivo* $CD45^-CD271^+$ MSC numbers and/or function contributed to BML pathophysiology and investigated BML and non-BML hip subchondral bone for numerical, topographic and *in vitro* functional differences.

Methods: Twenty femoral heads were obtained during total hip arthroplasty from subjects with primary hip OA that fulfilled the ACR criteria for hip OA. *Ex vivo 3T* MRI identified BML and non-BML regions from excised hips; one half was enzymatically treated to extract cells and the other half EDTA-decalcified to quantify trabecular bone area and cartilage thickness. Digital imaging was performed on 15 paired excisions using 92 manually defined morphologically homogenous regions containing cartilage and 188 regions containing only bone. The MSC frequency relative to total live cells was established using flow cytometry for the $CD45^-CD271^+$ phenotype. A colony forming unit-fibroblast (CFU-F) assay determined the number of MSCs per million cells. *In vitro* tri-lineage MSC differentiation assessed functional capacity of expanded $CD271^+$ cells. MSC topography was examined using anti-CD271 IHC.

Results: Regions with a normal appearance of cartilage were closely associated with non-BML excisions ($p=0.01$) compared to BML where most of the surface was damaged. Trabecular bone area was increased in BML regions ($p=0.001$). In 18/20 subjects, the proportion of native $CD45^-CD271^+$ MSC phenotype cells was higher in BMLs (Figure 1A, median 3.5-fold difference; $p<0.001$). This was confirmed using CFU-F assays (Figure 1B, 12/14 subjects, median 3.5-fold; $p=0.013$). Small differences were detected in MSC proliferation and mineralization capacities but not in their phenotype ($\diamond$95% $CD73^+CD90^+$). We observed abundant $CD271^+$ MSCs surrounding subchondral blood vessels near the cement line underlying cartilage lesions and in regions surrounding subchondral cysts, suggesting an accumulation and/or local proliferative MSC response to tissue injury (Figure 1C).

Conclusion: BMLs of OA femoral heads contain a higher proportion of MSCs with similar *in vitro* functional capacity compared to neighbouring

non-BML regions. Topographically, MSCs appear to be abundant in areas of active osteochondral repair and neo-angiogenesis. Despite this abundance, the *in vivo* MSC response is likely to be inadequate in the face of abnormal joint biomechanical stressing. These data advocate that, given their abundance, *in vivo* MSC repair-capacity optimization may be a target for future OA treatments.

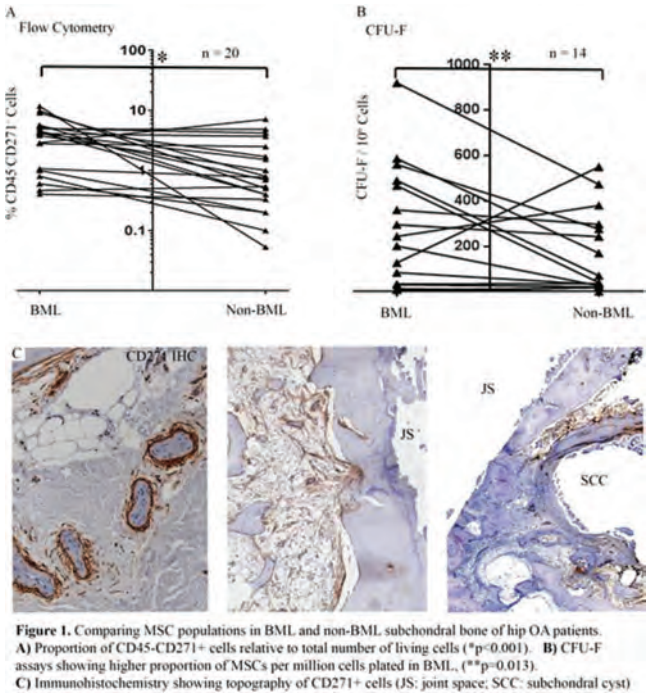

Figure 1. Comparing MSC populations in BML and non-BML subchondral bone of hip OA patients. **A)** Proportion of CD45-CD271+ cells relative to total number of living cells (*p<0.001). **B)** CFU-F assays showing higher proportion of MSCs per million cells plated in BML, (**p=0.013). **C)** Immunohistochemistry showing topography of CD271+ cells (JS: joint space; SCC: subchondral cyst)

Autophagy Activation Protects from Mitochondrial Dysfunction in Human Chondrocytes. Beatriz Carames[1], Paloma López de Figueroa[2], Martin Lotz[3] and Francisco J. Blanco[4]. [1]Cartilage Biology Group. Rheumatology Division, INIBIC–A Coruña, SPAIN, A Coruña, Spain, [2]Cartilage Biology group. Rheumatology Division, INIBIC-A Coruña, Spain, A Coruña, Spain,[3] The Scripps Research Institute, La Jolla, USA, La Jolla, CA, [4]Rheumatology Division, INIBIC-A Coruña, Spain, A Coruña, Spain.

Background/Purpose: Autophagy, is a key pathway of cellular homeostasis for removing damaged macromolecules and organelles, including mitochondria. Recent studies indicate that autophagy activation is defective in aging and osteoarthritis (OA), contributing to the cell death and tissue damage. In addition, there is increasing evidence that mitochondrial dysfunction plays an important role in OA pathogenesis. *The objective of this study is to determine whether activation of autophagy protects from mitochondrial dysfunction in human chondrocytes.*

Methods: Human chondrocytes were treated with Oligomycin (10 μg/ml), a mitochondrial respiratory chain (MRC) inhibitor of complex V. Mitochondrial function and cell death were evaluated by Flow Cytometry, Fluorescence Microscopy. Autophagy activation was analyzed by determination of LC3-II, a main marker of autophagy activation by Immunofluorescence and Western Blot. To investigate whether autophagy protects from mitochondrial dysfunction, autophagy was induced by mammalian target of rapamycin complex 1 (mTORC1) selective inhibitor Rapamycin (Rapa, 10 μM) and the dual mTORC1 and mTORC2 inhibitor Torin 1 (50 nM). Genetic deletion of Atg5 (siAtg5), a essential autophagy marker for autophagosome formation, was employed to evaluate the role of autophagy in mitochondrial dysfunction.

Results: Mitochondrial dysfunction was induced by treatment with Oligomycin, which significantly decreased mitochondrial membrane potential ($\Delta\Psi$m) (Oligo: 41.74 $\pm$ 7.59, expressed as % vs control; *.p $<$ 0.01). This was associated with increased intracellular ROS production (25.7 % vs. control; *p $<$ 0.001 compared to control condition) and mitochondrial superoxide generation (29.61 % vs. control; *p $<$ 0.001 compared to control condition). Furthermore, increased cell death by apoptosis was observed (Control: 11.35 $\pm$ 1.735; Oligo: 25.37 $\pm$ 6.767, *p$<$0.05 vs. control). Autophagy activation determined by LC3-II was increased at short incubation times, perhaps acting as an early response to stress and then decrease in a time dependent manner. To evaluate whether autophagy regulates mitochondrial dysfunction, chondrocytes were pretreated with Rapa and Torin 1 and then treated with Oligomycin. The results show an increase in LC3 expression compared to MRC inhibitor alone. Furthermore, autophagy inducers Rapa and Torin1 increased $\Delta\Psi$m (Rapa: 125.8 $\pm$ 20.74; Rapa $\pm$ Oligo: 108.5 $\pm$ 55.03 and Torin 1: 90.34 $\pm$ 9.17; Torin 1+Oligo: 98.19 $\pm$ 16.81; *p$<$0.05), decreased ROS production and reduced cell death (*p$<$0.05), suggesting a protective effect of autophagy activation on pharmacologically induced mitochondrial dysfunction. Importanly, blocking autophagy by siAtg5 showed a significant dysfunctional changes in the $\Delta\Psi$m and ROS production (*p$<$0.05), indicating the essential role of autophagy in mitocondrial function.

Conclusion: Our data highlight the role of autophagy as a critical protective mechanism against mitochondrial dysfunction. Pharmacological interventions that enhance autophagy may have chondroprotective activity in cartilage degenerative processes such as OA.

Regeneration of Articular Cartilage in Situ with Bone Marrow-Derived Mesenchymal Stem Cells. Cong-Qiu Chu[1], Xiaowei Zhang[2], Yuan K. Chou[2], Shili Wu[3], Camilo Avenano[3], Tom Caldwell[3], Brian Maniaci[3] and Yong Zhu[3]. [1]Oregon Health & Science Univ, Portland, OR, [2]Oregon Health & Science University, Portland, OR, [3]VivoScript, Inc, Costa Mesa, CA.

Background/Purpose: Regeneration of hyaline cartilage has been an attractive approach to cartilage repair and therapy of osteoarthritis (OA), but remains to be a challenge. SOX9 is a transcription factor belonging to the Sox (Sry-type HMG box) gene family and has been identified as a "master regulator" of chondrogenesis. We reported previously that a super positively charged cell penetrating SOX9 fusion protein (scSOX9) can induce bone marrow-derived mesenchymal stem cells (MSC) to differentiate into chondrocytes *in vitro*. Here we investigated the *in vivo* use of scSOX9 to promote hyaline cartilage regeneration *in situ* in combination with microfracture for articular cartilage repair in a rabbit model.

Methods: scSOX9) was generated by fusing SOX9 with a super positively charged green fluorescence protein. A 4 mm in diameter, full-thickness cartilage defect was created at the right femoral trochlear groove in New Zealand female rabbits. Microfracture was performed using a 0.9 mm Kirschner wire tapped into the subchondral bone to a depth of approximately 3 mm. Three microfracture holes were created within each full-thickness chondral defect in a triangular configuration. scSOX9 was administered at the site of mcrofracture via a bilayer collagen membrane. Cartilage repair was assessed at 8 weeks by gross morphology, histology and analysis of matrix component and was quantified using International Cartilage Repair Society (ICRS) macroscopic scale and ICRS Visual Histological Assessment Scale (ICRS-VHAS). High scores indicate high quality of repaired cartilage.

Results: After creation of cartilage defect, rabbits were divided into 4 groups (n=4 in each group) for treatment: Group 1, un-treated, Group 2, microfracture only, Group 3, microfracture plus scMyoD (a control protein for scSOX9) and Group 4, microfracture plus scSOX9. As shown in Table 1, microfracture plus scSOX9 significantly improved cartilage repair with nearly 100% defect area being covered with repaired tissue compared with 78% in Group 3, 80% in Group 2 and 18% in Group 1 respectively. Compared with all other groups, morphologically microfracture plus scSOX9 induced hyaline like cartilage which was well integrated with native cartilage and the repaired tissue showed highest intensity of Safranin O staining, indicating the highest density of proteoglycan.

Table 1. ICRS Macroscopic Scores and ICRS Visual Histological Assessment Scale

	ICRS Macroscopic Score	P value*	ICRS VHAS	P value*
Group 1	2.5 $\pm$ 0.5	$<$0.001	3 $\pm$ 1.5	$<$0.001
Group 2	7 $\pm$ 2.1	$<$0.05	14 $\pm$ 0.5	$<$0.005
Group 3	5 $\pm$ 2.3	$<$0.01	6 $\pm$ 3.2	$<$0.01
Group 4	12 $\pm$ 1.2		17 $\pm$ 1.5	

*p value indicated comparison of Group 4 with other groups.

Conclusion: This short term *in vivo* study demonstrated that when administered at the site of microfracture, scSOX9 was able to induce

reparative tissue with features of hyaline cartilage and significantly improved the outcome of cartilage repair by microfracture. These data suggest combination of microfracture with scSOX9 has great potential being translated into a therapy for cartilage repair and therapy for OA.

Catecholaminergic-to-Cholinergic Transition of Sympathetic Nerve Fibers in Arthritis and in a Co-Culture System of Sympathetic Ganglia in Vitro. Hubert Stangl[1], Hans Robert Springorum[2], Dominique Muschter[2], Susanne Graessel[2] and Rainer Straub[1]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital Regensburg, Regensburg, Germany, [2]Division of Experimental Orthopedic Surgery, University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: Sympathetic nerve fibers play an important role in bone and tissue homeostasis of joints. However sympathetic nerve fibers are able to switch their phenotype and respective neurotransmitter machinery from sympathetic to cholinergic. This transition was shown in developing sweat glands, in the periosteum and in failing heart tissue. This is crucial since strong anti-inflammatory effects have been described for the α7nicotinic acetylcholine receptor as well as for the cholinergic co-transmitter vasoactive intestinal peptide (VIP). We studied connective tissue obtained from the knee and finger joints of osteoarthritis (OA) and rheumatoid arthritis (RA) patients and tested possible transition requirements in an in-vitro model with murine sympathetic ganglia.

Methods: Knee synovial tissue samples obtained from 44 OA and 21 RA patients and connective as well as bone tissue samples from interphalangeal finger joints obtained from seven OA and five RA patients were stained for tyrosine hydroxylase (TH, noradrenergic fibers), vesicular acetylcholine transporter (VAChT, cholinergic fibers) and VIP (cholinergic fibers). Sympathetic ganglia were obtained from newborn C57Bl/6 mice and double-stained for TH and VAChT after a co-culture period of two days with osteoclast progenitors attained from the femoral and tibial bone marrow from adult healthy and arthritic mice. Supernatants from osteoclast progenitors were tested for possible transition factors. Whole RNA isolated from the respective osteoclast progenitors was screened via microarray analysis in order to identify possible candidate transition factors.

Results: In connective tissue sections from human finger joints, VAChT but not VIP positive cholinergic nerve fibers were more present in OA than in RA patients. In knee synovial tissue no significant difference in the appearance of cholinergic (VAChT and VIP) nerve fibers was found. The ratio of VAChT/TH immunoreactivity of sympathetic ganglia in coculture with osteoclast progenitors from healthy mice was elevated compared to experiments with osteoclast progenitors from arthritic mice. Leukemia inhibitory factor (LIF), a known transition factor from the glycoprotein 130 cytokine family, is present in low concentrations in supernatants from osteoclast progenitor cells but did not induce transition. Microarray analysis showed an upregulation of several candidate molecules (biglycan, fibronectin, LIF, periostin, tenascin-C, tensin-1, TIMP-1) in the transcriptome of osteoclast progenitors from healthy mice compared to arthritic ($n=3$ vs. 3, mean fold chance >2.0, $p<0.01$).

Conclusion: In humans and mice, catecholaminergic-to-cholinergic transition is possible in less inflamed tissue of the joint but not in highly inflamed arthritic tissue.

Fibroblast Growth Factor-2 and Its Receptor Antagonists in Osteoarthritis. Elina Nummenmaa, Mari Hamalainen, Teemu Moilanen, Katriina Vuolteenaho and Eeva Moilarnen. The Immunopharmacology Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland.

Background/Purpose: The fibroblast growth factor (FGF) family represents an interesting group of molecules which are involved in the regulation of connective tissue development and metabolism. FGF-18 has promising effects also in articular cartilage whereas FGF-2 seems to signal through different cellular receptors and its role in osteoarthritis (OA) remains unknown in many aspects. In the present study we investigated the presence and effects of FGF-2 in OA joints by assessing the associations of FGF-2 with cartilage degrading matrix metalloproteinase (MMP) enzymes and with the synthesis of the major cartilage matrix components aggrecan and collagen as well as by investigating the effects of FGF receptor antagonists.

Methods: Synovial fluid and cartilage samples were obtained from 97 OA patients undergoing total knee replacement surgery (60 females and 37 males, BMI 30.9 ± 0.6 kg/m^2, age 69.8 ± 1.0 years; mean $\pm$ SEM). FGF-2 concentrations in the synovial fluid and cartilage culture medium were measured by immunoassay. The effects of FGF-2 and its receptor antagonists on the production of MMP-1, MMP-13, aggrecan and collagen II were investigated in cultures of primary human OA chondrocytes. The study was approved by the Ethics Committee of Tampere University Hospital, Tampere, Finland and it was carried out in accordance with the Declaration of Helsinki. The patients gave their written informed consent, and their diagnosis was confirmed to fulfill the ACR classification criteria for osteoarthritis.

Results: FGF-2 was present in OA synovial fluid and released into the culture media from cartilage samples obtained from OA patients. Interestingly, FGF-2 concentrations correlated positively with the concentrations of MMP-1 ($r = 0.414$, $p < 0.001$) and MMP-13 ($r = 0.362$, $p < 0.001$) (Fig. 1) in the cultures of OA cartilage. Further, FGF-2 up-regulated the production of MMP-1 and MMP-13, and down-regulated the expression of aggrecan and collagen II, in human OA chondrocyte cultures. More importantly, FGF receptor antagonists AZD4547 and NVP-BGJ398 (10–300nM) down-regulated the production of MMP-1 and MMP-13 and up-regulated the expression of aggrecan and collagen II in a concentration dependent manner, and not only in the presence but also in the absence of exogenous FGF-2.

Conclusion: The present results suggest that, in contrast to its growth factor like effects in some other conditions, FGF-2 induces catabolic and anti-anabolic effects in osteoarthritis. Moreover, FGF-receptor antagonists showed promising beneficial effects on the balance of catabolic and anabolic mediators within OA cartilage.

Figure 1. Levels of FGF-2 released by human OA cartilage correlated positively with the levels of MMP-1 (A) and MMP-13 (B)

1012

Role of High Glucose Environment on Chondrocyte Activation and Characterization of Diabetic Osteoarthritic Cartilage: Toward Pathophysiological Delineation of Diabetes Mellitus-Related Osteoarthritis. Marie-Charlotte Laiguillon[1], Alice Courties[2], Xavier Houard[1], Martine Auclair[1], Alain Sautet[3], Bruno Fève[1], Jacqueline Capeau[1], Francis Berenbaum[2] and Jérémie Sellam[2]. [1]Sorbonne Universités, UPMC Univ Paris 06, UMRS 938 and Inflammation-Immunopathology-Biotherapy Department (DHU i2B), Paris, France, [2]AP-HP, Saint-Antoine Hospital, Rheumatology Department and DHU i2B, Paris, France, [3]AP-HP, Saint-Antoine Hospital, Orthopaedic Surgery Department, Paris, France.

Background/Purpose: Recent epidemiological studies have suggested an association between type 2 diabetes/hyperglycemia and osteoarthritis (OA) but experimental evidences are lacking (1). We aimed i) to decipher *in vitro* the impact of a high glucose environment on chondrocyte activation ii) to compare the production of pro-inflammatory mediators by OA cartilage explants derived from diabetic (db) or non-db patients.

Methods: Primary cultures of chondrocytes from new-born mice were stimulated for 24h and 72h with/without IL-1β (5 ng/mL) under a normal (5.5 mM) or a high (25 mM) glucose environment. Glucose uptake by cells was

analyzed by incorporation of radioactive 2-deoxyglucose. Osmotic stress was assessed by adding mannitol. Gene expression and release of pro-inflammatory mediators (IL-6, COX2/PGE_2) were analyzed by RT-qPCR, ELISA and EIA, respectively. Oxidative stress was assessed by the measurement of reactive oxygen species (ROS) by fluorescent DCFDA and production of NO by Griess reaction. To address the role of high glucose and oxidative stress on chondrocyte activation, cells were pretreated with cytochalasin B (1 μM), a glucose transporter inhibitor, or treated with a specific inhibitor of the polyol pathway (Epalrestat, 10 μM), a specific mitochondrial antioxidant (Mitotempo, 50 μM) or a NO synthase inhibitor (L-NAME, 5 mM). *Ex vivo*, pro-inflammatory mediators (IL-6, PGE_2) release in 24h-conditioned media of IL-1b- stimulated OA cartilage from db and non-db patients was measured by ELISA/EIA.

Results : *In vitro*, at 72h, the expression and release of IL-6 and COX2/PGE_2 were dramatically increased in the presence of IL-1β in high glucose as compared to normal glucose concentration by 5.6- and 3- [IL-6 mRNA and protein, respectively], 8- [Cox2] and 3.6-fold [PGE_2]) (n=5, p=0.03 for all analyzes). Glucose uptake was also transiently increased by IL-1β at 72h (n=3). Mannitol experiments ruled out the hypothesis of an osmotic stress due to high glucose (n=3). High glucose environment under IL-1β stress increased ROS and NO production (2.1- and 1.9-fold, respectively; n=5, p=0.04 and p=0.03). Cytochalasin B significantly decreased the induction of IL-6 mRNA (−40%; n=6, p=0.02). L-NAME significantly decreased the release of IL-6 and PGE_2 (−40% and -78%, respectively; n=5, p=0.04) as did Epalrestat (−49% for mRNA IL-6 and -55% for COX2; n=3), and as did Mitotempo (IL-6: -69% and COX2: -90%; n=2).

Conclusion : High glucose exposure sensitizes chondrocytes to IL-1b activation *via* increased glucose uptake, oxidative stress and polyol metabolic pathway leading to a sustained chondrocytic pro-inflammatory phenotype. Such results are in accordance with an increased sensitivity to inflammatory stress of OA cartilage of db patients. These results strengthen the hypothesis that diabetes could be a trigger for the initiation and/or the severity of OA.

1013

Mitochondrial Function Is Impaired in Human Knee Osteoarthritic (OA) Chondrocytes and Improved By Pharmacologic AMPK Activation Via SIRT1 and PGC-1α.

Ru Bryan[1], Yun Wang[2], Xianling Zhao[3], Martin Lotz[4] and Robert Terkeltaub[5]. [1]VA Medical Center/University of California San Diego, San Diego, CA, [2]VA Medical Ctr/UCSD, San Diego, CA, [3]VAMC, San Diego, CA, [4]The Scripps Research Institute, La Jolla, CA, [5]VA Medical Ctr/University of California San Diego, San Diego, CA.

Background/Purpose: Chondrocyte mitochondrial abnormalities have been identified in OA, and have the potential to mediate disease progression by promoting oxidative stress and inflammation-driven cartilage matrix catabolism. AMPK (AMP-activated protein kinase) and the NAD^+-dependent protein deacetylase SIRT1 are cellular energy bio-sensors recently implicated in cartilage tissue homeostasis. In chondrocytes, AMPK promotes expression of PGC-1α, a master regulator of mitochondrial biogenesis. SIRT1 also regulates PGC-1α through deacetylation, and AMPK can regulate SIRT1 activity. Hence, we tested the hypothesis that pharmacologic activation of AMPK improves mitochondrial function via SIRT1 and PGC-1α in human knee OA chondrocytes.

Methods: We studied cultured human knee chondrocytes from both normal and OA donors (passage 1) with and without the selective AMPK pharmacological activator A-769662, or overexpression of SIRT1 or PGC-1α via transfection. Phosphorylation and expression of AMPKa, expression of SIRT1, PGC-1α, acetylation status of PGC-1a, expression of mitochondrial transcriptional factor A (TFAM, a direct regulator of mitochondrial DNA replication and transcription), nuclear respiratory factor 1 and 2 (NRF1 and NRF2, stimulating transcription of TFAM), and oxidative phosphorylation (OXPHOS) were examined by Western blot analyses. Mitochondrial DNA copy number was determined by the ratio of cytochrome C oxidase I or II (*COX I* or *COX II*, mitochondrial-encoded gene) and 18S rRNA (nuclear gene) by quantitative PCR. Mitochondrial mass was assessed by Mitotracker Green FM staining. Oxygen consumption and intracellular ATP were measured.

Results: In comparison with normal chondrocytes, human OA chondrocytes (grade III and IV) exhibited reduced oxygen consumption (P=0.03), decreased intracellular ATP level (P=0.019), and less mitochondrial biogenesis indicated by decreased mitochondrial DNA content (P=0.001) and mitochondrial mass, decreased expression of NRF1, NRF2 and TFAM, as well as decreased expression of respiratory complexes I, II and III. These differences were linked to reduced phosphorylation of AMPKα and expression of SIRT1 and PGC-1α, and increased acetylated PGC-1α in OA chondrocytes. Stimulation of human OA chondrocytes with A-769662 increased phosphorylation of AMPKα and expression of SIRT1 and PGC-1α, and decreased acetylation of PGC-1α. A-769662 also increased oxygen consumption (p=0.003), intracellular ATP level (p=0.015), and mitochondrial biogenesis. Overexpression of SIRT1 or PGC-1α in chondrocytes also induced increased mitochondrial biogenesis.

Conclusion: Both mitochondrial oxidative phosphorylation and mitochondrial biogenesis are impaired in human knee OA chondrocytes. AMPK activation improved the observed impairments of mitochondria in OA chondrocytes, and did so via SIRT1 and PGC-1α.These findings provide a novel molecular mechanism by which pharmacologic activation of AMPK has translational potential to inhibit progression of cartilage degradation in OA via restoration of chondrocyte mitochondrial biogenesis and function.

1014

Harpagide, a Low Molecular Weight Natural Product, Suppresses IL-1â-Induced IL-6 Expression By Blocking the Activation of p38 MAPK and Transcription Factors CEBPâ and AP-1 in Primary Human Osteoarthritis Chondrocytes.

Abdul Haseeb[1] and Tariq Haqqi[2]. [1]Northeast Ohio Medical University (NEOMED), Rootstown, OH, [2]Northeast Ohio Medical University, Rootstown, OH.

Background/Purpose: There is growing evidence that shows the involvement of IL-6 in cartilage degradation during OA. Significant correlation between IL-6 levels in serum as well as synovial fluid and OA severity has been reported. IL-6 stimulates the expression of MMP-13 and inhibits the expression of type II collagen. Harpagide is a low molecular weight compound isolated from the secondary roots of *Harpagophytum procumbens (Hp)*. In the present study we used an *in vitro* model of inflammation in OA to investigated the therapeutic potential of Harpagide in OA.

Methods: Primary human chondrocytes were isolated from the non-affected cartilage obtained from OA patients who underwent total knee arthroplasty. Human OA chondrocytes were cultured and pre-treated with Harpagide (500 μM) and then cultured with and without IL-1β (5 ng/ml). Chondrocyte viability was assayed using Trypan blue exclusion assay. Secreted levels of IL-6 in the culture supernatants were quantified by ELISA. Total protein levels and phosphorylation levels of CEBPβ and AP-1 in human OA chondrocytes were measured by Western blot analysis using specific antibodies. Nuclear extracts were prepared and used to study the effect on the nuclear localization and activation of NF-κB, CEBPβ and AP-1 in OA chondrocytes by Western blotting and DNA binding activity. IL-6 mRNA levels were quantified using the TaqMan assays. Data were derived using Origin 6.1 software and $P<0.05$ was considered significant.

Results: Harpagide had no effect on OA chondrocyte viability *in vitro*.Treatment of primary human OA chondrocytes with IL-1β markedly stimulated the mRNA expression of IL-6 and protein secretion in the culture supernatants which was inhibited significantly (p<0.05) by pre-treatment with Harpagide. Harpagide did not inhibit the IL-1b-induced degradation of IκB and the activation of NF-κB but suppressed the IL-1β-triggered nuclear localization and activation of CEBPβ and AP-1 in human OA chondrocytes. There was a significant decrease in IL-1β-induced phosphorylation of CEBPβ, c-Fos and ATF-2 by Harpagide which also inhibited the IL-1β-induced enhancement in cytoplasmic levels of total c-FOS protein in OA chondrocytes. While there was a significant decrease in the nuclear levels of CEBPβ and c-Fos, there was no effect of pre-treatment of the cells with Harpagide on nuclear levels of NF-kB-p-65. Activation of p38 MAPK, which phosphorylates CEBPβ, ATF-2 and c-Fos resulting in their activation was significantly inhibited by Harpagide in human OA chondrocytes. Two small molecule inhibitors of p38MAPK (SB203580 and SB202190) also significantly inhibited the IL-1b-induced activation of p38-MAPK and the expression and secretion of IL-6 in human OA chondrocytes.

Conclusion: Taken together, the data presented here suggests that Harpagide may have a significant chondroprotective and OA suppressive effect by inhibiting the expression and production of IL-6. Importantly, we

also identify a novel mechanism of IL-6 suppression which bypasses the activation of NF-*kB*.These data provide strong evidence with mechanistic details in support of the possible use of Harpagide as a therapeutic choice to prevent/retard the progression of OA.

Mir-9/MCPIP1 Axis Mediated Regulation of IL-6 Expression in Osteoarthritis Chondrocytes. Tariq Haqqi[1], Abdul Haseeb[2] and Mohammad Shahidul Makki[2]. [1]Northeast Ohio Medical University, Rootstown, OH, [2]Northeast Ohio Medical University (NEOMED), Rootstown, OH.

Background/Purpose: Post-transcriptional regulation of cytokine expression is important for maintaining tissue integrity. MCPIP1 was identified as a novel protein, which destabilizes inflammatory cytokines mRNAs via their 3' UTR. IL-6 has recently gained attention because of its high levels in synovial fluid in Osteoarthritis (OA) and ability to induce high levels of MMP-13 in OA. In the present study we determined whether MCPIP1 regulates IL-6 expression and evaluated the role of miR-9/MCPIP1 axis in the regulation of IL-6 in human OA chondrocytes.

Methods: Human chondrocytes were prepared from OA cartilage by the enzymatic digestion. TaqMan assays were used for gene expression analysis using RNA isolated from cultured primary chondrocytes or from damaged or smooth regions of OA cartilage or RNA immunoprecipitation (RIP). RNA fluorescent *in-situ* hybridization (ISH) for *IL-6* and *MCPIP1* expression was performed using RNAScope. Transfection was done using Amaxa kit. Knockdown experiments were performed using Trisilencer-27 human siRNA. For RIP, lysates from IL-1b-stimulated chondrocytes were incubated overnight with anti-MCPIP1 antibody or with isotype control IgG followed by RNA purification.

Results: *MCPIP1* expression was low in damaged cartilage compared to smooth cartilage while the expression of IL-6 was high in damaged cartilage and low in smooth cartilage, suggesting that lower expression of MCPIP1 may be contributing to the excessive expression of IL-6 in OA. Expression of miR-9 predicted by TargetscanS to bind the seed sequence in MCPIP1 mRNA was high in damaged cartilage compared to smooth cartilage and was also upregulated by IL-1b in OA chondrocytes. Over expression of miR-9 mimic or inhibitor in OA chondrocytes altered the expression of MCPIP1 and IL-6. IL-1b-mediated induction of IL-6 was initially low in OA chondrocytes but was significantly accelerated 8 h post-stimulation. On the other hand, expression of MCPIP1 was high initially in IL-1b-stimulated OA chondrocytes but started to decline 8 h post-stimulation. Overexpression of wild type MCPIP1, but not of mutant MCPIP1, in OA chondrocytes reduced the expression of *IL-6* mRNA and protein significantly ($p<0.05$). Importantly siRNA-mediated knockdown of MCPIP1 elevated the *IL-6* mRNA expression in OA chondrocytes. TaqMan analysis of the immunoprecipitated mRNAs showed that anti-MCPIP1 antibody pulled down larger amount of *IL-6* mRNA than control IgG antibody did thus demonstrating the binding of MCPIP1 with IL-6 mRNA in OA chondrocytes.

Conclusion s: In this study for the first time expression of *MCPIP1* and miR-9 in human OA cartilage and chondrocytes is shown. The data also demonstrate miR-9/MCPIP1/IL-6 interactions and provide evidence of miR-9/MCPIP1 axis as an important regulator of IL-6 expression in OA.

Reduced Expression of Circadian Rhythm Genes in Human Osteoarthritis Cartilage: NR1D1 Suppression Alters Chondrocyte Response to IL-1β Stimulation. Ryuichiro Akagi[1], Kathleen M. Fisch[1], Oscar Alvarez-Garcia[1], Takeshi Teramura[1], Yuta Muramatsu[1], Masahiko Saito[2], Takahisa Sasho[3], Andrew I. Su[1] and Martin K. Lotz[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]Toho University Sakura Medical Center, Sakura, Japan, [3]Chiba University School of Medicine, Chiba, Japan.

Background/Purpose: NR1D1 is a negative regulator of BMAL1, a core clock gene that regulate circadian rhythmicity. Involvement of NR1D1 in inflammatory process has been reported, but data regarding its function in articular cartilage is limited. Since IL-1β induced inflammation is one of the key factors that disturb cartilage homeostasis and lead to cartilage degradation, we examined the function of NR1D1 in articular cartilage in relation to IL-1β stimulation.

Methods: RNA was extracted from human cartilage tissues harvested from normal and osteoarthritis (OA) knees (n=15 each), and expression levels of NR1D1 and BMAL1 mRNA were assessed by quantitative PCR. NR1D1 protein expression was confirmed by immunohistochemistry in normal and OA human cartilage, as well as in normal knees and knees with surgically induced OA of mice. To examine the circadian rhythmicity of gene expression in cultured chondrocytes isolated from normal human cartilage, chondrocytes were synchronized by dexamethasone and harvested at 4-hour intervals up to 48 hours for RNA and protein extraction. Chondrocytes were then treated with small interfering RNA (siRNA) for NR1D1 or BMAL1, followed by IL-1β stimulation to test the effect of knock down on response to IL-1β.

Results: Both NR1D1 and BMAL1 mRNA levels were significantly reduced in OA cartilage, compared to normal cartilage. NR1D1 protein was predominantly expressed in the superficial and upper-mid zone of normal cartilage, both in human and in mouse knees. The protein expression was reduced in OA cartilage, although high expression was observed in cluster cells. In surgically induced mice OA, NR1D1 protein expression was significantly reduced before cartilage loss occurred. In cultured human chondrocytes, a clear circadian rhythmicity was observed for NR1D1 and BMAL1 mRNA levels. NR1D1 expression was at its lowest level at T12 and T36, whereas highest expression was observed at T24 and T48. The expression pattern of BMAL1 displayed the reversed pattern. Treatment with siRNA significantly suppressed levels of both genes at all time points, but the rhythmic expression pattern was preserved. Increase in BMAL1 expression was observed at T24 and T48 after knocking down NR1D1, and decreased NR1D1 levels were observed at all time points after knocking down BMAL1. IL-1β treatment significantly induced IL6, COX2, iNOS, MMP13 and ADAMTS4. NR1D1 knock down further increased the expression levels of iNOS, MMP13 and ADAMTS4, while by contrast the IL-1 induction of IL6 and COX2 was blunted. Genome-wide sequencing of RNA from chondrocytes treated with NR1D1 siRNA identified 330 genes that were significantly different and this affected predominantly TGFβ signaling pathway and protein processing in endoplasmic reticulum (ER), as well as ER stress response.

Conclusion: NR1D1 and BMAL1 expression are reduced in OA cartilage. NR1D1 and BMAL1 present circadian rhythmicity in cultured chondrocytes with an opposite phase, indicating a bidirectional regulation between the two genes. Reduced expression of NR1D1 in chondrocyte leads to altered response to IL-1β stimulation, affects TGFβ signaling and ER function, thus suggesting an important role of NR1D1 in cartilage homeostasis.

BMP9-Induced pSmad1/5/8 Signaling and Chondrocyte Hypertrophy Are Effectively Inhibited By TGFβ1. Arjan van Caam, Esmeralda Blaney Davidson, Ellen W. van Geffen, Wim B. van den Berg and Peter M. van der Krraan. Radboud university medical center, Nijmegen, Netherlands.

Background/Purpose: Osteoarthritis is characterized by degradation of articular cartilage. TGFβ-superfamily signaling via Smad phosphorylation (pSmad) plays a crucial role in cartilage maintenance. Two distinct pSmad pathways exist: pSmad1/5/8 and pSmad2/3. pSmad2/3 induces matrix formation and protects cartilage against deleterious processes like chondrocyte hypertrophy and IL1-signalling. In contrast, pSmad1/5/8 is linked to chondrocyte hypertrophy and expression of the main cartilage degrading enzyme: MMP13. Recently a very potent pSmad1/5/8 inducing ligand has been identified: BMP9. BMP9 is produced by the liver and circulates in high levels. Over 60% of all BMP activity in serum can be attributed to BMP9, showing

the abundance of this BMP. In this study we investigated the effect of this potent pSmad1/5/8 inducing ligand, BMP9, on chondrocyte phenotype. Furthermore, because of pSmad2/3's importance in chondrocyte homeostasis, we studied the interaction between BMP9-signaling and TGFβ1-induced pSmad2/3 signaling.

Methods: In this study, primary bovine chondrocytes were used. BMP9-induced Smad phosphorylation was detected after 1 h and 2 h using Western Blot. Subsequently, BMP9-induced gene expression was measured up to 24 h using real time qPCR. Biological activity of pSmad2/3 was measured using the (CAGA)12-luc reporter assay, which produces luciferase in response to pSmad3. Cellular hypertrophy was investigated by culturing chondrocytes 1 week in the presence of growth factors and analyzing gene expression of hypertrophy markers.

Results: In primary bovine chondrocytes, BMP9 stimulation in doses upwards of 50 pg/ml induced pSmad1/5/8, which was reflected in expression of the Smad1/5/8 response gene bId1. Remarkably, BMP9 doses of 1 ng/ml and higher also induced pSmad2, but, expression of the pSmad3 response gene bSerpine1 was not induced. Co-stimulation of chondrocytes with BMP9 and a low dose TGFβ1 (0.1 ng/ml) reduced BMP9-induced pSmad1/5/8 and, surprisingly, enhanced TGFβ1-induced pSmad2. After 24 hours, this interaction was reflected in mRNA levels, as co-stimulation increased expression of the pSmad2/3 responsive genes: bSerpine1, bTgfb1 and bSmad7 and decreased expression of bId1. Furthermore, BMP9 also synergistically enhanced biological activity of TGFβ1 in the CAGA12Luc reporter assay. The uniqueness of this synergy between BMP9 and TGFβ1 was illustrated by co-stimulation of chondrocytes with TGFβ1 and two other BMPs important in chondrocyte biology: BMP2 and BMP7, which showed that both these BMPs do not synergize with TGFβ1 on Smad2/3p. As a more long term effect, BMP9 induced chondrocyte hypertrophy after one week of stimulation, as indicated by upregulation of Alkaline phosphatase and Col10a1, however addition of 0.1 ng/ml of TGFβ1 inhibited this BMP9-induced hypertrophy.

Conclusion: Our results show that BMP9 potently induces pSmad1/5/8 and its downstream gene expression in chondrocytes. In long term culture this results in induction of chondrocyte hypertrophy. However TGFβ1 can potently inhibit this hypertrophy. Possibly, this runs via the observed but yet unexplained pSmad2/3 enhancing interaction between both growth factors, which is unique for BMP9 compared to BMP2 or BMP7.

Monolayer Culture Induced the Expression of Zyxin-Related Protein 1 (ZRP-1), $\alpha_v\beta_3$integrin Complex and Leptin in Human Articular Chondrocytes. Edith Charlier[1], Olivier Malaise[1], Mustapha Zeddou[2], Sophie Neuville[1], Gaël Cobraiville[1], Philippe Gillet[3], William Kurth[3], Dominique de Seny[1], Biserka Relic[1] and Michel G. Malaise[1]. [1]GIGA Research - University of Liège - CHU of Liège, Liège, Belgium, [2]Department of Biology, Faculty of Sciences, University Mohamed I, Oujda, Morocco, [3]Orthopedic Surgery Unit-CHU of Liège, Liège, Belgium.

Background/Purpose: During Osteoarthritis (OA), chondrocytes loose their initial anabolic properties, undergoing morphological and biochemical modifications similar to those encountered during chondrocyte dedifferentiation. However, the molecular mechanisms underlying this process are poorly known. In order to understand the morphological changes, we interested in the expression of two molecules involved in actin cytoskeletal organization, namely Zyxin-related protein 1 (ZRP-1) and in regulation of cell interaction with the extracellular matrix (ECM), meaning the integrin complex $\alpha_v\beta_3$. Concerning the biochemical changes, we followed the expression of leptin, an OA-related adipokine, during chondrocytes dedifferentiation. We next assessed pathways potentially involved in its production, namely TGFβ and Wnt/β-catenin, since they are both involved in chondrocytes phenotype maintenance and OA development.

Methods: Human articular cartilage was obtained from macroscopically preserved areas within OA hip after prosthetic surgery. Isolated chondrocytes were cultured in monolayer during 14 days sothat dedifferentiation happen, shifting from round (day1) to fibroblastic-like (day 14) shape. Classical dedifferentiation and hypertrophic markers were assed by qRT PCR, ELISA or western blotting. ZRP-1 was detected by western blotting and $\alpha_v\beta_3$complex was vizualized by immunohistochemistry using LM609 antibody. Components of TGFβ and Wnt/β-catenin were detected by western blotting and involvement of these pathways in leptin production was investigated by stable lentiviral silencing of Smad1 and β-catenin.

Results: Chondrocytes monolayer culture induced typical *Sox9* and *COLIIA1* gene expression lost, as well as *COLIA1*, Runx-2 and MMP-13 gain. We found that ZRP-1 and $\alpha_v\beta_3$ complex expression came with dedifferentiation. Similarly, leptin was absent in primary chondrocytes whereas present in dedifferentiated chondrocytes, and significantly more under prednisolone. ALK1/ALK5 ratio was shifted during dedifferentiation, from high ALK5 and p-Smad2 expression in primary chondrocytes to high endoglin, ALK1 and p-Smad1/5 expression in dedifferentiated counterpart. Moreover, inactive GSK3β and correspondant active β-catenin were found in dedifferentiated chondrocytes, whereas absent from primary cells. Smad1 and β-catenin stable lentiviral silencing led to a significative decrease in leptin production by dedifferentiated chondrocytes.

Conclusion: ZRP-1, $\alpha_v\beta_3$ integrin complex, leptin expression and its associated signaling might represent novel markers for chondrocyte loss of primary phenotype.

Targeting the Bone-Driven Metabolic OA Phenotype By a Novel Dual Amylin Calcitonin Receptor Agonist, KBP-056. Ditte Reker, Sara Toftegaard Hjuler, Kim Andreassen, Morten Asser Karsdal, Kim Henriksen and Anner C. Bay-jensen.Nordic Bioscience, Biomarkers and Research, Herlev, Denmark.

Background/Purpose: Osteoarthritis (OA) may be segregated into different disease phenotypes based on disease drivers; cartilage damage, joint inflammation or subchondral bone remodelling. Each phenotype may require targeted treatments. Patients with a bone-driven OA may particularly benefit from a treatment with anti-resorptive and chondro-protective properties. Salmon calcitonin (sCT), a hormone acting through CT and amylin receptors, have in multiple preclinical models been demonstrated to improve bone homeostasis and attenuate joint destruction, in part through the anti-resorptive property. In addition, sCT have recently been shown to have a positive effect on obesity and diabetes, which may benefit certain OA subjects. Several Dual Amylin Calcitonin Receptor Agonists (DACRAs) were characterized through a larger screening program; KBP-056 was found to be particular interesting for OA, by showing higher potency for the receptors than sCT. The objective of this study was to investigate the *in vivo* effect of KBP-056 on bone and cartilage turnover, as well as metabolic health.

Methods: Male Sprague Dawley rats (Taconic, Ry, Denmark) were given HFD for 10 weeks before they were treated with defined doses of KBP-056 (0.625, 1.25, 2.5, 5, 10 ug/Kg) or vehicle as subcutaneous injections. Blood was collected from overnight fasted rats immediately at baseline, 3 and 24 hours after first treatment. Rats were treated for 8 weeks. Body weight was recorded weekly. Biomarkers of bone and cartilage degradation were assessed in the blood using the ELISAs CTX-I (bone resorption) and CTX-II (cartilage degradation). CTX-I and -II were reported as fold of baseline levels, as means with standard error of mean (SEM) and compared using two-way ANOVA assuming normal distribution. Significance levels; *P $<$ 0.05, **P $<$ 0.01, ***P $<$ 0.001. In addition, a similar study was performed using ovariectomy (OVX)-meniscectomy (MNX) Sprague Dawley rats.

Results: Serum levels of both CTX-I and -II decrease significantly 3 hours after treatment with KBP-056, even at the lowest dose tested ($P<0.05$, fig. 1). Moreover, a dose-dependent response by CTX-I still remained 24 hours after treatment, suggesting increased potency. KBP-056 caused a 19% vehicle-corrected weight reduction for two highest doses at the end of the experiment. A similar weight reducing effect was observed in OVX-MNX rats.

Conclusion: The data presented here clearly indicate a protective effect of KBP-056 on both bone and cartilage *in vivo*, when evaluated by biochemical markers. Furthermore, KBP-056 has demonstrated positive effects on metabolic health (cause a weight decrease), and may therefore represent a possible treatment opportunity for bone-driven OA, with an unhealthy phenotype (e.g. high BMI). Many further studies are needed to match the optimal treatment opportunity with the right OA patient for a personalized health care approach for OA.

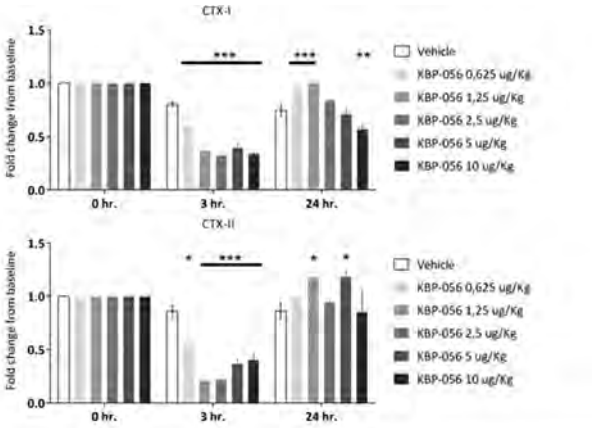

Figure 1. Acute CTX-I and -II response to KBP-056. High-fat diet Sprague-Dawley rats were subjected to a single subcutaneous injection with indicated treatments, and tail blood was collected at indicated timepoints. CTX-I and -II values of each rat were normalized to its baseline value (0 hr.). Values are means ± SEM of 5 replicate rats. Two-way ANOVA was used to compare each bar with its respective vehicle. *$P < 0.05$, **$P < 0.01$, ***$P < 0.001$.

Changes in Peripheral Blood Immune Cell Composition in Osteoarthritis. Agata Burska[1], Mark Campbel[2], Rafi Raja[2], Dylan White[1], Paul Emery[3], Philip G. Conaghan[4] and Frederique Ponchel[1]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Translational Research in Immune Mediated Inflammatory Diseases, the University of Leeds, Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., Leeds, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds, United Kingdom.

Background/Purpose: Healthy ageing and the occurrence of the common age-related disease osteoarthritis (OA) result from varying degrees of interaction between many determinants (genetic, lifestyle). Immunosenescence and inflammageing are features of the ageing immune system. Age-related abnormalities (loss of T-cell reactivity, development of autoantibodies, activation of inflammatory mechanisms) may be synergising with structural defects of the musculoskeletal system aiding the development of OA. We aimed to determine if abnormalities of blood immune cell composition are associated with OA, beyond the defects already associated with age.

Methods: Blood samples were collected from 120 healthy controls (age range 18–69) to establish variations associated with age and 120 OA (age range 49–80). We examined loss or acquisition of age-related changes in blood composition. 8-colours flowcytometry was performed to establish the frequencies of: CD4/CD8, B, NK-cells. Naïve and regulatory T and B-cell were subsequently analysed and cells with an abnormal phenotype identified in Rheumatoid arthritis is direct relation with inflammation (IRC phenotype).

Results: Flowcytometry was performed on all 240 samples (only 20 HC and 45 OA were analysed for B-cells) and demonstrated, as expected, very little change in lineage representation associated with age in health with: no change for NK, CD4, and B-cells, weak decline in CD8 (rho=−0.300, p=0.019) and increase in NKT (rho=0.315, p=0.012). In contrast phenotyping T and B-cells showed clear age-related changes with reduction of naïve CD4 T-cell (rho=0.817, p<0.0001). Regulatory T-cells increased (rho=0.401, p<0.0001) whereas B-reg reduced (rho= -0.658, p=0.002). IRC were not related to age.

In OA differences were observed. NK, CD4 and B cells were not related to age but in OA, NK cells were positively correlated (rho=0.350, p<0.0001), CD4 (rho=−0.318, P=0.001) and B-cells (rho=−0.260, p=0.006) negatively. The NKT correlation with age was maintained in OA (rho=0.296, p=0.002) but the CD8 relationship was lost. Naïve CD4 cells appeared to be particularly affected (see Figure 1 showing % of several subsets) with considerable increase in frequency. Treg were reduced in most patients irrespective of age. B-cell subsets were not particularly affected although the age-relationship for B-reg was lost. IRC were not increased with the exception of ~20 patients.

Conclusion: This analysis of the immune cell composition of the blood of OA patients suggests that immune dysfunction is present in OA above what is directly related to ageing. Immuno-senescence and inflammageing (as suggested by the increased frequency of IRC in some OA patents) may therefore play a role in OA in addition to their implication in healthy ageing.

Transthyretin and Amyloid in Cartilage Aging and Osteoarthritis. Yukio Akasaki[1], Oscar Alvarez-Garcia[1], Natalia Reixach[1], Joel Buxbaum[1], Yukihide Iwamoto[2] and Martin K. Lotz[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

Background/Purpose: Deposition of amyloid is a common aging-associated phenomenon and a key factor in the pathogenesis of several aging-related diseases. Osteoarthritis is the most prevalent joint disease and aging is its major risk factor. Although amyloid deposits appear to be a prevalent in OA-affected joints, their composition and effects on cell and tissue function are unknown. Transthyretin (TTR) is an amyloidogenic protein. Point mutations in the TTR gene cause of familial amyloidotic polyneuropathy and cardiomyopathy. Wild-type TTR can also assemble into amyloid deposits and this may be facilitated by oxidation, or the presence of sulfated glycosaminoglycans. This study addressed TTR deposition in aging and OA-affected knee cartilage and effects of TTR on chondrocyte function.

Methods: Amyloid deposition in normal and OA human knee cartilage was determined by Congo-red staining and polarized light microscopy. TTR in cartilage and synovial fluid was analyzed by immunohistochemistry and western blotting. TTR gene expression in chondrocytes was studied by quantitative PCR and RNA sequencing. Effects of wild type and mutant TTR were studied in normal human chondrocyte cultures with measurements of cell viability and OA-related gene expression.

Results: There was no amyloid deposition in young normal cartilage. In contrast, 58% (7/12) of aged normal cartilage and 100% (12/12) of OA cartilage samples had Congo red staining. TTR was detectable in all OA and a majority of aged but not in young normal cartilage and predominantly located at the cartilage surfaces. TTR is not produced by chondrocytes at substantial levels and synovial fluid levels are similar in normal and OA affected knees. In chondrocytes, TTR induces cell death, the expression of proinflammatory cytokines and extracellular matrix degrading enzymes. This was observed for the amyloidogenic but not for the non-amyloidogenic TTR mutant. Effects of TTR on cell viability and gene expression are mediated by activation of TLR4 signaling and MAP kinases.

Conclusion: These findings are the first to suggest that TTR amyloid deposition may not represent an inconsequential aging-related phenomenon but contribute to cell and extracellular matrix damage in articular cartilage.

Fibroblast-like Synovial Cells and Monocytes Team up in the Organization and the Dynamic Modelling of the Synovial Tissue. Ruth Byrne, Karolina von Dalwigk, Thomas Karonitsch, Gunter Steiner, Johannes Holinka, Reinhard Windhager, Josef Smolen, Hans Peter Kiener and Clemens Scheinecrker. Medical University of Vienna, Vienna, Austria.

Background/Purpose: The synovial lining tissue consists of fibroblast-like synoviocytes (FLS) and monocyte-derived macrophage-like synoviocytes (MLS) within a self-built meshwork of dense extracellular matrix (ECM) components. FLS are thought to direct ECM synthesis, assembly and degradation. Whether this requires their cognitive interaction with MLS and whether FLS themselves or the ECM network serve as guiding structures for MLS migration is incompletely understood. This tempted us to study the dynamics of synovial tissue modelling under steady state and inflammatory conditions using a three-dimensional in-vitro model of the synovial tissue.

Methods: Human FLS were prepared from synovial tissues obtained as discarded specimens following joint arthroplasty. CD14+ monocytes (Mo) were isolated from peripheral blood. FLS and Mo were labeled with fluorescent membrane dyes and cultured in spherical extracellular matrix micromasses with an average size of 1.5 mm for up to two weeks. Second harmonic generation (SHG) was used for the visualization of collagen fibers. For stimulation experiments, micromasses were cultured in medium containing 10 ng/ml of tumor necrosis factor (TNF). Cell migration was monitored in individual micromasses by real-time confocal/multi-photon microscopy.

Results: The formation of a FLS network was observed within 3–7 days and coincided with the detection of collagen fibers that colocalized with FLS. The majority of Mo was found to be in close contact with the FLS network with low tendency for migration. A minor fraction of Mo displayed a directed cell movement with an impressive maximum speed of up to 15 mcm/min. Rapid Mo migration occurred in intimate contact with FLS but did not necessarily follow FLS network boundaries. In addition, we observed the formation of Mo cell clusters that co-localized with collagen fibers in the absence of FLS. The addition of TNF i) increased the frequency and size of Mo cell clusters and ii) prolonged the overall mobility of Mo.

Conclusion: The 3D synovial tissue culture system allows for monitoring and analyzing the dynamics of synovial lining modelling. Both, FLS and Mo appear to cooperate in the organization of the synovial lining tissue with subtle migration patterns of Mo in relation to the organized synovial lining architecture. Ongoing experiments address molecular mechanism(s) of Mo – FLS interaction in order to identify potential targets for future therapeutic intervention in arthritis.

Chronic PTHrP Treatment Promotes Hypertrophic Differentiation and Inflammatory Gene Expression in Chondrocytes. Bin Wrang. Center for Translational Medicine, Department of Medicine, Thomas Jefferson University Medical College, Philadelphia, PA.

Background/Purpose: Parathyroid hormone-related protein (PTHrP) binds to the type 1 PTH receptor (PTH1R), a member of the superfamily of G protein-coupled receptors (GPCRs). Activation of PTH1R by PTHrP has been widely documented to maintain cartilage homeostasis. However, PTHrP also acts as a cytokine-like peptide and mediates multi-organ inflammation. PTHrP content is higher in osteoarthritis (OA) synovial fluid. Changes in PTHrP expression in a rabbit OA model indicate PTHrP involvement in late rather than early pathogenic events. Blockade of PTHrP prevents articular cartilage destruction in streptococcal cell wall-induced arthritis. Emerging data show that GPCRs play important roles in inflammation through Ga12/13-mediated NF-kappa B/cyclooxygenase 2 (*COX2*) signaling pathway. In present studies.the effects of chronic PTHrP treatment on hypertrophic differentiation and inflammatory gene expression in chondrocytes were investigated.

Methods: Mouse chondrogenic cells (ATDC5), which express PTH1R during their differentiation, were used to examine hypertrophic differentiation and inflammatory gene expression in response to chronic PTHrP treatment. ATDC5 differentiation was induced by addition of ITS (10 μg/ml insulin, 10 μg/ml transferrin, and 10 ng/ml sodium selenite) into the cell culture medium after cell confluence. The mRNA expression for hypertrophic differentiation and inflammatory genes was detected by quantitative real-time PCR. PTH1R activation was determined by measuring [^{3}H]-adenine incorporation for cAMP accumulation.

Results: The cartilage nodules in cultures of ATDC5 cells were formed by day 30 after ITS treatment. PTHrP (10 nM) initially inhibited ITS-induced expression of type 10 collagen a1 (Col10a1) and matrix metalloproteinase 13 (MMP13) (hypertrophic differentiation markers). However, the prolonged and sustained PTHrP increased Col10a1 and MMP13 expression in the late stage of differentiation (hypertrophic cells). Chronic PTHrP treatment enhanced the mRNA expression of *COX2*, but inhibited adenylyl cyclase activity in the late stage of differentiated chondrocytes.

Conclusion: These data suggest that chronic PTHrP treatment promotes a specific switch of PTH1R signaling from Gas to Ga12/13 to induce hypertrophic differentiation and increase inflammatory gene expression. Locally produced PTHrP in OA synovial fluid may have a pathogenic role in diseased cartilage.

Racial Differences in Biochemical Knee Cartilage Composition Between African American and Caucasian American Women with MR-Based T2 Relaxation Time Measurements – Data from the Osteoarthritis Initiative. Martin Kretzschmar[1], Ursula Heilmeier[2], Aihong Yu[3], Gabby B. Joseph[4], Felix Liu[5], Hans Liebl[3], Charles E. McChulloch[3], Michael C. Nevitt[6], Nancy E. Lane[7] and Thomas M Link[2]. [1]University of California, San Francisco, San Francisco, CA, [2]Musculoskeletal Quantitative Imaging Research, UCSF, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA, [4]University of California San Francisco, San FRancisco, CA, [5]University of California at San Francisco, San Francisco, CA, [6]UCSF (University of California, San Francisco), San Francisco, CA, [7]Center for Musculoskeletal Health, UC Davis School of Medicine, Sacramento, CA.

Background/Purpose: To determine whether knee cartilage composition differs between African-American and matched Caucasian-American women at risk for Osteoarthritis (OA) using in-vivo 3T MRI T2 relaxation time measurements.

Methods: Right knee 3 Tesla MRI studies of 200 subjects (100 African-American women, 100 Caucasian-American were selected from the Osteoarthritis Initiative Cohort and closely matched for age, BMI, Kellgren-Lawrence Scores (KL≤1), subcohort and clinical site. Knee cartilage was segmented and T2 maps were generated in five compartments (patella (PAT), medial and lateral femur (MF/LF), medial and lateral tibia (MT/LT)). Mean T2 relaxation time values per compartment and per whole joint cartilage were generated and analyzed spatially via laminar and grey-level-co-occurrence-matrix texture methods. Presence and severity of cartilage lesions per compartment were graded using a modified whole-organ magnetic resonance imaging score (WORMS). Statistical analysis employed paired t- and McNemar testing.

Results: Although African-American and matched Caucasian-Americans did not differ in their WORMS cartilage lesion score ($p=0.970$), African American women showed significantly lower mean T2 values than Caucasian-Americans in the whole knee cartilage ($p<0.001$), and in the subcompartments (LF: $p=0.001$, MF: $p<0.001$, LT: $p=0.019$, MT: $p=0.001$) and particularly in the superficial cartilage layer (whole cartilage: $p<0.001$, LF: $p<0.001$, MF: $p<0.001$, LT: $p=0.003$, MT: $p<0.001$). T2 texture parameters were also significantly lower in the whole joint cartilage of African-American women than in Caucasian-Americans (variance: $p=0.001$; contrast: $p=0.018$). In analyses limited to matched pairs with no cartilage lesions in a given compartment, T2 values remained significantly lower in African-Americans.

Conclusion: Using T2 relaxation time as a biomarker for the cartilage collagen network, our findings suggest racial differences in the biochemical knee cartilage composition between African-American and Caucasian-American women.

Leptin Production By Osteoarthritis Synovial Fibroblasts: Stimulation By Glucocorticoids and Mineralocorticoids through the Glucocorticoid Receptor and GILZ (Glucocorticoid-Induced Leucine Zipper) Protein. Olivier Malaise, Biserka Relic, Sophie Neuville, Edith Charlier, Dominique de Seny and Michel G. Malarise. GIGA Research - University of Liège - CHU of Liège, Liège, Belgium.

Background/Purpose: Osteoarthritis (OA) is a metabolic disorder for which leptin is playing a catabolic role on cartilage. In mice, obesity due to impaired leptin did not cause OA. *In vitro*, we have previously shown that OA synovial fibroblasts (SF) produced leptin, hypothesizing that they were also able to contribute to intra-articular levels of leptin. The glucocorticoid prednisolone strongly induced leptin and leptin receptor (Ob-R), suggesting a deleterious involvement in the metabolic component of OA.

Aldosterone, a mineralocorticoid, is found in OA synovial fluid and is involved in systemic metabolic regulation. First, we will study the mineralocorticoid's influence on leptin and Ob-R expressions, and determine whether leptin and Ob-R are glucocorticoid receptor (GR) or mineralocorticoid receptor (MR) dependent.

Glucocorticoid-Induced Leucine Zipper (GILZ) protein, induced by glucocorticoids, is an anti-inflammatory mediator in inflammatory models. Links with leptin are unknown, but GILZ's overexpression decreases adipogenic and enhances osteogenic differentiation, two processes associated to leptin. We will study GILZ's involvement in leptin expression.

Methods: Human SF were isolated from OA patients during knee surgery and treated with glucocorticoid (prednisolone), mineralocorticoid (aldosterone), GR agonist (Compound A, CpdA), GR antagonist (mifepristone), MR antagonists (eplerenone, spironolactone), TNF-α and TGF-β. SF were transfected with shRNA lentiviruses for GILZ and GR silencing. ELISA measured leptin and IL-6. Ob-R, GR, GILZ and GAPDH were analyzed by Western Blot.

Results:

(1) Prednisolone and aldosterone induced leptin and Ob-R through GR but not MR: mifeprisotone (GR antagonist), but not eplerenone or spironolactone (MR antagonists), reduced both prednisolone- and aldosterone-induced leptin and Ob-R. GR silencing with shRNA confirmed these results.

(2) GILZ was induced by prednisolone and aldosterone. Similarly to leptin, stimulations with GR or MR antagonists and GR silencing showed that both leptin and Ob-R inductions were GR-dependent: leptin and GILZ shared similar modulations. Moreover, CpdA and TGF-β, that did not induce GILZ in OA SF, did not induce leptin.

(3) GILZ was involved in prednisolone- and aldosterone-induced leptin and Ob-R, with a significant dose-response decrease when GILZ was down-regulated by shRNA.

(4) GILZ inhibition with shRNA did not modify the anti-inflammatory properties of prednisolone, with an unchanged endogenous or TNF-α-induced IL-6 reduction opposite to the control.

Conclusion:

(1) Both mineralocorticoids and glucocorticoids induced leptin and Ob-R in OA SF, suggesting a deleterious involvement of both corticosteroids in the metabolic component of OA. Synovial tissue could represent a new target for mineralocorticoids.

(2) Mechanistically, we propose a new role for GILZ in OA, with an involvement in corticosteroids-induced leptin and Ob-R. By contrast, GILZ did not seem significantly involved in the anti-inflammatory action of glucocorticoids in OA SF.

Monosodium Urate Monohydrate Crystals Induces the Expression of Ihh and MMP-13 in ATDC5 Cells: Implications in Osteoarthritis (OA) Development. Melissa Ramirez, Josh Potvin, Diana Ramirez and Anthony M. Reginrato. The Warren Alpert School of Medicine at Brown University, Providence, RI.

Background/Purpose: Cartilage damage is often observed in affected joints with advance gout[1]. Musculoskeletal ultrasound studies have highlighted the close relationship between monosodium urate (MSU) crystals and articular cartilage in patients with gout. The "double contour sign" is an hyperechoic band over the superficial layers of the articular cartilage that highlights the close relationship between MSU and cartilage[2]. The interaction between MSU crystal and chondrocyte may contribute to cartilage damage in gout[3]. The objective of this study was to investigate the effect of increasing concentrations of MSU crystals on chondrocyte function and differentiation.

Methods: Primary chondrogenic cell line (ATDC5) were cultured in a 1:1 mixture of DMEM/F12 medium containing 10% FBS, Insulin-Transferrin-Selenium and incubated with increasing concentrations of endotoxin-free MSU crystals at increasing concentrations (0.01, 0.025, 0.05 and 0.1 mg/ml) for 4, 7, and 14 days respectively. Purification of total cellular RNA for real time PCR was prepared from ATDC5 at different time points. Real-time quantitative PCR was performed on specific extracellular matrix genes, transcription factors and metalloproteinases. Alcian-blue and Alizarin red S staining was performed at selected time point of ATDC5 cells exposed to different MSU concentration.

Results: MSU crystals have a negative effect in the function and differentiation of ATDC5 chondrogenic cell lines. The ability of chondrocyte to produce matrix protein assessed by relative mRNA expression of aggrecan and type II collagen was reduced in chondrocytes following culture with MSU crystals and correlated with Alcian-blue staining. The expression of of chondrogenic gene expression was found to correlate with Runx 2. The expression of Ihh, and MMP-13 was increased and confirmed by western blotting (1-way ANOVA $p<0.05$). Furthermore, the expression of degradative enzymes such as Adamts4 and Adamts5 was also increased contributing to the cartilage degradative process.

Conclusion: Long-term culture of MSU crystals with chondrogenic cell line ATDC5 impairs the function and differentiation of chondrocytes. MSU crystals stimulate gene expression of Ihh and MMP-13 contributing to the development of osteoarthritis.

Hematopoietic Cell Kinase (HCK) As a Novel Regulator of Fibroblast-like Synoviocyte Function in RA. Ying Wang[1], Deepa Hammaker[2], David L. Boyle[3], Toshio Yoshizawa[4] and Gary S. Firestein[3]. [1]UCSD, La Jolla, CA, [2]University of California San Diego, La Jolla, CA, [3]University of California at San Diego School of Medicine, La Jolla, CA, [4]Ono Pharmaceutical Co., Ltd., Osaka, Japan.

Background/Purpose: Fibroblast-like synoviocytes (FLS) are key mediators of inflammation and joint damage in rheumatoid arthritis (RA) through the production of cytokines and matrix metalloproteinases (MMPs) as well as invasion into extracellular matrix. The search for potential kinases that target FLS for RA led to hematopoietic cell kinase (HCK) as a candidate target. HCK is a member of the Src tyrosine kinases and is primarily expressed by myeloid cells. HCK deficiency reduces the migration of M-CSF- and RANKL-induced murine bone marrow mononuclear cells in vitro, indicating that it might play a role in cell migration. However, its expression in mesenchymal cells is not defined, and nothing is known about HCK function in synoviocytes. To determine if HCK is a potential therapeutic target in RA, we evaluated HCK expression and function in RA FLS. These studies show that HCK is an inducible gene in RA FLS that regulates key pathogenic functions, thus allowing an inhibitor to target its effects primarily at sites of inflammation.

Methods: FLS were obtained from RA and osteoarthritis (OA) patients undergoing joint replacement surgery and used from passage 3 through 9. Three separate cell lines were studied for each experiment. To study HCK expression in FLS, RA and OA FLS were serum starved and treated with medium, IL-1β (2ng/ml) or TNF (50ng/ml) for various times. mRNA levels

were determined by qPCR. For functional studies, we used a novel selective small molecule HCK inhibitor, with an IC50 of approximately 7nM. IL-6 and MMP expression were measured by qPCR. MTT assays were performed to determine PDGF-induced proliferation. Apoptosis was induced by H2O2 stimulation and MTT assay. For cell migration, scratch assays were performed on PDGF-stimulated FLS monolayers. The data were analyzed using student's t test and one way ANOVA.

Results: HCK mRNA levels were very low under basal conditions in cultured FLS. IL-1 and TNF increased HCK expression, with maximal introduction at 24 hr by 734- and 65-fold, respectively. TNF-induced IL-6 expression was decreased by 39% in cells treated with 1 μM of the HCK inhibitor ($p = 0.025$). MMP3 expression was also inhibited by $50\pm15\%$ ($p = 0.03$) and $41\pm12\%$ ($p = 0.026$) after the stimulation with IL-1β and TNF, respectively. The small molecule HCK inhibitor (1 μM) significantly reduced PDGF-induced FLS growth by $93\pm32\%$ on day 3 ($n=3$ RA FLS, $p = 0.001$), and $81\pm19\%$ on day 7 ($p = 0.001$). The compound had no effect on H2O2-induced apoptosis, suggesting that the effect on cell growth was due to decreased proliferation rather than increased cell death. HCK inhibition impaired PDGF-induced migration by $83\pm31\%$ ($p = 0.04$).

Conclusion: HCK expressed was induced by IL-1β and TNF in RA FLS. HCK blockade decreased cytokine production, MMP production, proliferation, and cell migration in FLS. Because the gene is minimally expressed in resting cells, its main effect would be in cells at the site of inflammation. Therefore, HCK could be a promising therapeutic target for RA that can regulate pathogenic behavior in a site and event specific manner.

ADAM-10 Plays Monocyte Migration and Adhesion in Rheumatoid Arthritis Synovial Fibroblasts. Takeo Isozaki[1], Sho Ishii[2], Shinichiro Nishimi[2], Airi Maeoka[2], Mayu Saito[2], Nao Oguro[2], Shinya Seki[2], Yoko Miura[2], Yusuke Miwa[2], Koei Oh[3], Yoichi Toyoshima[3], Masanori Nakamura[3], Katsunori Inagaki[3] and Tsuyoshi Kasama[2]. [1]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [2]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [3]Showa University School of Med, Tokyo, Japan.

Background/Purpose: :A disintegrin and metalloprotease family proteins (ADAMs) have been reported to be involved in a number of inflammatory conditions. We previously reported that ADAM-10 mediated rheumatoid arthritis (RA) angiogenesis. In this study, we examine the expression of ADAM-10 in RA biological fluids and the role it plays in monocyte migration, cell adhesion, and proliferation.

Methods: ADAM-10 expression was determined in serum and synovial fluids (SFs) from normal (NL) subjects, osteoarthritis (OA) patients and RA patients using enzyme linked immunosorbent assay (ELISA). To determine expression of ADAM-10 on RA synovial fibroblasts, immunofluorescence was performed. To examine the role of ADAM-10 in RA synovial fluids (SFs), we performed THP-1 (human acute monocytic leukemia cell line) chemotaxis. To block the expression of ADAM-10, RA synovial fibroblasts were transfected with siRNA against ADAM-10. In order to determine that ADAM-10 mediates monocyte adhesion, ADAM-10 siRNA transfected RA synovial fibroblast adhesion assay was performed. To determine if ADAM-10 played a role in cell proliferation in the RA synovium, ADAM-10 siRNA-transfected RA synovial fibroblast proliferation assays were performed.

Results: The expression of ADAM-10 in RA serum was significantly higher compared to NL serum [mean $\pm$ SE; 450 $\pm$ 44 pg/ml ($n=90$) and 85 $\pm$ 33 pg/ml ($n=34$), respectively] and was correlated with a disease activity score of 28. ADAM-10 concentration in RA SFs was significantly elevated compared with that in OA SFs [(727 $\pm$ 144 pg/ml ($n=10$) and 255 $\pm$ 42 pg/ml ($n=7$), respectively]. ADAM-10 was expressed on RA synovial tissue lining cells and synovial fibroblasts. ADAM-10-depleted RA SFs showed a 56 $\pm$ 9% ($n=5$ patients) decrease in THP-1 migratory activity compared to sham-depleted controls. Adhesion of THP-1 to ADAM-10 siRNA-transfected RA synovial fibroblasts in response to tumor necrosis factor (TNF)-α was significantly decreased compared with control siRNA-transfected RA synovial fibroblasts. Finally, RA synovial fibroblasts transfected with ADAM-10 siRNA showed less proliferation in response to TNF-α at 2.5 ng/ml for 48 hours.

Conclusion: These data indicate that ADAM-10 plays a role in monocyte migration in RA and suggest that targeting ADAM-10 may provide a method by which to decrease inflammation and potentially treat other inflammatory diseases.

Anandamide and Related Eicosanoids Decrease the Production of Pro-Inflammatory Cytokines in Synovial Fibroblasts By a COX-2 Dependent Mechanism: Involvement of Calcium and TRP Channels. Torsten Lowin[1], Tanja Späth[2], Angelika Graeber[1] and Rainer Straub[3]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany, [2]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, Regensburg, Germany, [3]University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: Endocannabinoids are immunomodulatory lipid compounds that act on cannabinoid receptors type 1 and 2 but also on transient receptor potential (TRP) channels. Their action is terminated by FAAH, one major enzyme responsible for endocannabinoid degradation. COX-2, however, also degrades endocannabinoids, and products from this reaction are pro-inflammatory. This study studied a potential mode of action for the anti-inflammatory effects of endocannabinoids in synovial fibroblasts from RA and OA donors. Furthermore it is investigated how pro-inflammatory cytokines alter the responsiveness of synovial fibroblasts to (endo)cannabinoid ligands.

Methods: MMP-3 and cytokines were detected by ELISA. ERK 1/2, p38, CREB and cjun phosphorylation was assessed by proteome profiler analysis and cell-based ELISA. Cannabinoid receptors 1 and 2, TRPA1, TRPV1, and COX-2 were detected by western blotting and cell-based ELISA. The XCELLigence system was used to determine EC50 values for CB_1/CB_2/TRPV1/TRPA1 with/without cytokine stimulation.

Results: The endocannabinoid arachidonylethanolamide (anandamide, AEA) and related eicosanoids palmitoylethanolamide (PEA), oleoylethanolamide (OEA) and N-arachidonylglycine (NAGly) reduced TNF induced production of IL-6, IL-8 and MMP-3. The effects of AEA, PEA and OEA were significantly enhanced by addition of the COX-2 inhibitor nimesulide but not by FAAH inhibiton. The effects of all compounds tested were not inhibited by CB_1 or CB_2 antagonism but were blocked by TRPV1 and TRPA1 antagonists in RASFs and OASFs. In the case of AEA, COX-2 inhibition reversed the effects of TRPA1 antagonism. Quantification of CB_1, CB_2, COX-2, TRPV1 and TRPA1 revealed a significant stimulatory influence of pro-inflammatory cytokines and hypoxia on observed protein levels. Furthermore, high AEA concentrations ($>1\mu$M) induced cell death only when combined with the intracellular calcium chelating agent BAPTA-AM. Analysis of intracellular signaling pathways revealed an inhibitory effect of AEA on p38 and ERK1/2 phosphorylation after TNF stimulation.

Conclusion: Under hypoxic conditions, Endocannabinoids promote an anti-inflammatory phenotype in RASFs and OASFs by activating/desensitizing TRPV1 and TRPA1. As a consequence, MAP kinase signaling is reduced as demonstrated after AEA treatment. Furthermore, COX-2 and FAAH inhibition are necessary to fully exploit the therapeutic potential of endocannabinoids. This might be important in RA where low oxygen and abundant cytokine expression up-regulate COX-2 in the joint. In addition, pro-inflammatory cytokines increase the efficacy of endocannabinoids due to upregulation of target receptors.

ABT-122, a Novel Dual Variable Domain (DVD)-Ig™, Targeting TNF and IL-17, Inhibits Peripheral Blood Mononuclear Cell Production of GM-CSF and Decreases Lymphocyte Expression of CXCR4 in Healthy Subjects. Melanie Ruzek[1], Donna Conlon[1], Heikki Mansikka[2], Robert Padley[2] and Carolyn Cuff[1]. [1]AbbVie, Inc, Worcester, MA, [2]AbbVie, Inc, North Chicago, IL.

Background/Purpose: TNF and IL-17 contribute to the pathogenesis of several inflammatory disorders and are known to synergistically induce chemokines and cytokines, including chemokine (C-X-C motif) ligands 1 (CXCL1), 5 (CXCL5), and 8 (CXCL8), chemokine (C-C motif) ligand 2 (CCL2), IL-1b, IL-6, G-CSF, and GM-CSF. In addition, the CXCL12 chemokine receptor, CXCR4, is reported to be coordinately regulated by TNF and IL-17. As these factors play a role in the pathogenesis of several

autoimmune diseases, greater clinical responses in patients may be possible with dual neutralization of TNF and IL-17. ABT-122 is novel DVD-Ig™ molecule targeting both human TNF and IL-17 cytokines and is currently in clinical trials. The aim of this study was to determine the biologic response to ABT-122 in healthy volunteers based on known activities of TNF and/or IL-17 in humans.

Methods: Twenty-four healthy subjects were administered a single dose of ABT-122 (1.5 mg/kg subcutaneously) in a Phase I trial. PBMCs were collected prior to ABT-122 administration at baseline and at days 7, 15, 36, and 57 post dosing and cryopreserved. Thawed PBMCs were either analyzed directly by flow cytometry for chemokine receptors CXCR1, CXCR4, and CXCR5, or stimulated with LPS. Supernatants from the LPS cultures were analyzed by multiplex analysis (MAPx, Millipore EMD) for CXCL8, CXCL1, CXCL5, CCL2, IL-1b, IL-6, IL-10, G-CSF, and GM-CSF.

Results: A single dose of ABT-122 administered to healthy volunteers resulted in 4-fold lower production of GM-CSF through day 57 compared with baseline from LPS-stimulated PBMCs. CXCR4 expression also decreased on B cells, T cells, and monocytes at day 7 compared with baseline with average reductions of 54%, 41%, and 20%, respectively. Decreases in CXCR4 on B cells persisted to day 15 (24%) and day 36 (18%). As GM-CSF and CXCR4 are reported to be synergistically regulated by IL-17 and TNF, these results suggest dual neutralization by ABT-122. Consistent with known activities of anti-TNF agents in RA patients, there were 2.5-fold elevations in the anti-inflammatory cytokine IL-10 and significant 9–12% increases in CXCR5 expression on T cells following administration of ABT-122. Other chemokine/cytokine responses to LPS stimulation and expression of CXCR1 were unchanged after ABT-122.

Conclusion: The changes observed in expression of GM-CSF and CXCR4 in healthy subjects with dual neutralization of TNF and IL-17, demonstrate pharmacodynamic activity of ABT-122 DVD-Ig™ protein consistent with the known combinatorial activities of TNF and IL-17. Notably, the effects of ABT-122 on these analytes were demonstrated in healthy volunteers, thus these changes likely reflect modulation of the in vivo homeostatic activities of TNF and IL-17 in the absence of disease. These data further support the rationale that ABT-122 can be used to evaluate the therapeutic potential of dual IL-17 and TNF blockade in patients with disorders driven by these two cytokines.

Induction of Pro-Apoptotic Noxa Expression By Ursolic Acid Sensitizes Rheumatoid Arthritis Synovial Fibroblasts to Apoptosis: A Role of Mir-181a. Salahuddin Ahmed[1], Laura Walsh[2], Anil Singh[1], Maria Beamer[2], Kuladeep Sudini[2] and Douglas Leaman[2]. [1]Washington State University, Spokane, WA, [2]University of Toledo, Toledo, OH.

Background/Purpose: In rheumatoid arthritis (RA), the paucity of pro-apoptotic protein expression may significantly contribute to the resistance of synovial fibroblasts (FLS) to apoptosis. In the present study, we evaluated if inducing the expression of pro-apoptotic protein Noxa in RA-FLS using a potent anti-inflammatory pentacyclic triterpenoid uroslic acid (UA) triggers apoptosis and studied the underlying mechanism.

Methods: Effects of UA (2.5–10 μM) on human RA-FLS morphology and cell viability were determined by microscopy and a colorimetric MTT/SRB cell viability assays. Mechanism of UA's activity was modulated experimentally by using the siRNA or plasmid overexpression approaches. Epigenetic regulation of Noxa by microRNA-181a (mir-181a) was studied using the microarray and qRT-PCR methods. Apoptosis was measured by the cleavage of caspase-3 and poly-ADP-ribose polymerase (PARP). Western blotting was used to evaluate the apoptosis signaling mediators, Noxa, and Mcl-1 expression.

Results: UA (2.5–20 μM) decreased the cell viability of RA-FLS in a dose-dependent manner. Importantly, UA (10 μM) selectively induced Noxa expression within 3 h to ~2–3 fold in RA-FLS ($p<0.05$; $n=4$). Induction of Noxa led to the consequent downregulation of Mcl-1 expression and apoptosis by 24 h of UA treatment ($p<0.05$; $n=3$). The inhibition of Mcl-1 expression by UA resulted in the sensitization of RA-FLS to TRAIL-induced PARP cleavage and apoptosis. Overexpression of Noxa using a plasmid vector targeting Noxa was effective in making RA-FLS susceptible to apoptosis. Using a siRNA method to block Noxa expression, we found that the RA-FLS apoptosis-inducing activity of UA was significantly blocked suggesting that UA induced apoptosis in RA-FLS primarily through Noxa upregulation. Confirmatory studies using WT and Noxa−/− BMK cells showed that UA efficiently induced apoptosis in WT cells but had no effect in Noxa−/− counterparts ($p<0.01$; two independent experiments). Interestingly, transfection of stably expressing Noxa in Noxa−/− BMK cells restored the apoptosis inducing capability of UA. MicroRNA array analysis showed a significant decrease in RA-FLS mir-181a expression, a miRNA known to facilitate apoptosis, by ~30% as compared to the normal FLS ($p<0.05$). We also found that UA (5–10 μM) was capable of inducing mir-181a expression in RA-FLS as compared to the non-stimulated samples suggesting that UA-induced Noxa expression and consequent apoptosis in RA-FLS may be mediated epigenetically via upregulation of mir-181a.

Conclusion: Our novel findings indicate that inducing Noxa expression by UA in RA-FLS effectively induces apoptosis and this effect is partly mediated through mir-181a. Thus, developing therapeutic strategies that can selectively upregulate Noxa and/or modulate mir-181a to induce apoptosis in RA-FLS may have potential therapeutic application for the treatment of RA.

Neutralization of IL-17 Ameliorated Kidney Pathology Associated with Immune-Complex Mediated Autoimmune Glomerulonephritis. Partha Biswas[1], Kritika Ramani[1], Kelly Maers[1], Anna Huppler[2] and Sarah L. Gaffen[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Immune complex mediated autoimmune glomerulonephritis (AGN) is an often-fatal clinical manifestation of systemic lupus erythematosus. In recent years, pro-inflammatory cytokines in the nephritic kidney appear to contribute to the pathogenesis of AGN. The inflammatory cytokine network that drives renal pathology is poorly understood. IL-17, the signature cytokine of T-helper 17 (Th17) cells, which promotes autoimmune pathology in a variety of settings, is beginning to be identified in kidney diseases as well. However, the role of IL-17 and the consequence of blocking IL-17 in the pathogenesis of AGN have not been elucidated.

Methods: We took advantage of a prototypic mouse model of AGN, where glomerular injury is induced by generating an autoimmune response against rabbit anti-mouse glomerular basement membrane serum. In this model, development of AGN is an inevitable consequence of glomerular injury induced by immune-complex deposition, recapitulating many features of lupus nephritis. Accordingly, wild type (WT) and IL-17 receptorA$^{-/-}$ (IL-17RA$^{-/-}$) mice were subjected to AGN and evaluated for the development of kidney pathology over a period of 14 days. We also test the therapeutic efficacy of neutralizing IL-17 in AGN induced WT mice.

Results: We showed that IL-17RA signaling is critical for the development of renal pathology. Despite normal systemic autoantibody response and glomerular immune-complex deposition, IL-17RA$^{-/-}$mice exhibit diminished influx of inflammatory cells and kidney specific expression of IL-17 target genes correlating with disease resistance in AGN. IL-17 enhanced the production of pro-inflammatory cytokines and chemokines from tubular epithelial cells. Finally, we were able to show that neutralization of IL-17 ameliorated renal pathology in wild type mice following AGN.

Conclusion: These results clearly demonstrated that IL-17RA signaling significantly contributes to renal tissue injury in experimental AGN. Additionally, it also suggested that blocking IL-17-IL-17R signaling may be a promising therapeutic strategy for the treatment of AGN associated with SLE, which may have ramifications in other autoinflammatory kidney disorders.

Stat3 Promotes IL-10 Expression in SLE T Cells through *Trans*-activation and Chromatin Remodeling. Christian Hedrich[1], Thomas Rauen[2], Sokratis Apostolidis[3], Alexandros P. Grammatikos[4], Noe Rodriguez Rodriguez[4], Christina Ioannidis[3], Vasileios C. Kyttaris[4], José C. Crispin[4] and George C. Tsokos[5]. [1]Children's Hospital, Dresden, Germany, [2]BIDMC, Harvard Medical School, Boston, MA, [3]BIDMC, Boston, MA, [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [5]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: IL-10 is an immune-regulatory cytokine that is expressed by a wide range of cells and tissues. It plays a central role in the

regulation of the innate and adaptive immune system. IL-10 is elevated in the serum and tissues of patients with the autoimmune disorder systemic lupus erythematosus (SLE). SLE is characterized by autoantibody production, immune complex formation, and altered cytokine expression. Because IL-10 exhibits B cell-promoting effects, it has been suggested as a contributor to autoantibody production and tissue damage in SLE. In this study, we aimed to determine molecular events governing T cell-derived IL-10 expression in health and disease.

Methods: To achieve this, we forced the expression of the transcription factors Stat3 or Stat5, or inhibited them through siRNAs or chemical inhibitors in human T cells. Furthermore, *IL10* reporter constructs have been utilized to determine the relative contribution of Stat3/5 on specific regulatory elements in the *IL10* proximal promoter and an intronic enhancer. The influence of two major epigenetic events, DNA methylation and histone acetylation, on IL-10 expression has been determined using MeDIP or ChIP assays. Furthermore, we determined potential interactions between Stat transcription factors and the transcriptional co-regulator p300, using transfection systems, siRNA and chemical inhibition strategies, and proximity ligation assays.

Results: We link reduced DNA methylation of *IL10* regulatory regions with increased recruitment of Stat transcription factors. IL-10 is regulated by both Stat3 and Stat5 through their differential recruitment to the *IL10* promoter (Stat3) and an intronic enhancer (Stat5). Stat3 and Stat5 *trans*-activate regulatory elements and induce epigenetic remodeling of *IL10* through their interaction with the histone acetyltransferase p300. Of note, in T cells from SLE patients, activation of Stat3 is increased, resulting in enhanced recruitment to regulatory regions and competitive replacement of Stat5 at the intronic enhancer, subsequently promoting IL-10 expression.

Conclusion: Understanding the molecular events governing cytokine expression will provide new treatment options in autoimmune disorders, including SLE. The observation that altered Stat3 activation enhances IL-10 expression in T cells offers a potential target in the search for novel biomarkers and treatment options in SLE.

Therapeutic Potential of Targeting Sialic Acid Modified Receptors in Osteoarthritis. Maria Dolores Mayan[1], Paula Carpintero-Fernández[1], Raquel Gago-Fuentes[1], Marta Varela-Eirin[1], Gary S. Goldberg[2] and Francisco Javier Blanco[1]. [1]Cartilage Biology Research Group, Rheumatology Division, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Department of Molecular Biology, School of Osteopathic Medicine, Stratford, NJ.

Background/Purpose: Glycosylated proteins are essential components of the extracellular matrix (ECM) of cartilage and contribute to the maintenance of its function. A shift from a-2,6- to a-2,3-linked sialic acids of glycoproteins modifies the binding ability of proteins to substrates influencing cellular anchoring and affecting signal transduction. Intriguingly, the predominance of a-2,3-sialylation of chondrocytes glycoproteins was associated with the pathophysiology of rheumatic diseases including rheumatoid arthritis (RA) and osteoarthritis (OA). A highly O-glycolysated protein with $\alpha-2,3$-sialic acid, involved in the induction of inflammation and tissue repair, is the transmembrane mucin receptor named Podoplanin (PDPN). The present study aimed to assess the effect of specifically targets a-2–3-sialic acid residues with a lectin-based drug (MASL) on chodrocyte dedifferentiation and cartilage breakdown processes.

Methods: For immunofluorescence and immunohistochemistry assays, in situ cartilage was fixed and frozen immediately using Tissue-Tek O.C.T. and isopentanol in liquid nitrogen. Primary cells in monolayer culture were fixed with formaldehyde for optical microscopy assays. 4mm cartilage punches were prepared from cartilage explants that were cut in the operating room immediately after surgery and cultured in DMEM with 0.1% FCS. Chondrocytes were isolated from articular cartilage and cultured in DMEM with 15% FCS. Cell viability was evaluated by the colorimetric MTT assay. Cell adhesion and grown was assess with fibrinogen-coated well plates and Wound Healing Assay Kit. Reactive oxygen species levels were measured by DCFH-DA and by Flow Cytometry. RNA was isolated with TRIZOL® Reagent and analyzed by Real-Time RT-PCR.

Results: The treatment of chondrocytes with 400 and 720 nM of MASL did not affect cell viability, adhesion or growth. To mimic pathological conditions, cells and cartilage explants were treated with 5 μg/ml oligomycin. Treatment of chondrocytes with oligomycin did not affect cell viability but increased ROS levels over 10 fold and MMP3, IL-6 and COX2 mRNA levels over 3–10 folds. The treatment of cells with MASL effectively protected chondrocytes from ROS production when incubated in the presence of oligomycin. Moreover, oligomycin induced the expression of inflammatory cytokines including IL-6 and COX2, and this induction was reverted by treatment with nanomolar concentrations of MASL. 5 μg/ml of oligomycin for 7 days decreased safranin uptake and disrupted the ECM structure of cartilage punches as evidenced by ulceration increasing lacunae space. However, the presence of 400 nM of MASL prevented the cartilage destruction and inhibited COX2 and MMP3 induction by oligomycin treatment. Immunohistochemistry assays revealed that OA cartilage contained significantly higher levels of PDPN protein in comparison with cartilage from healthy donors.

Conclusion: This study demonstrates that physiologically relevant concentrations of MASL protect chondrocytes from detrimental effects of ROS, inflammatory cytokines and MMPs and preserve chondrocyte phenotype and articular cartilage structure under pathological conditions.

TNF-á Modulates the Expression of Circadian Clock Genes Via Calcium Signaling in Rheumatoid Synovial Cells. Kohsuke Yoshida[1], Nao Shibanuma[2], Teppei Hashimoto[3], Yoshiko Kawasaki[3], Naonori Hashimoto[1], Ayako Nakai[1], Kenta Kaneshiro[1], Koji Tateishi[4], Natsuko Nakagawa[4] and Akira Hashiramoto[3]. [1]Faculty of Health Sciences, Kobe University School of Medicine, Kobe, Japan, [2]Department of Orthopaedic Surgery, Kobe Kaisei Hospital, Kobe, Japan, [3]Department of Rheumatology, Kobe Kaisei Hospital, Kobe, Japan, [4]Department of Orthopaedic Surgery, Konan-Kakogawa Hospital, Kakogawa, Japan.

Background/Purpose: The mammalian clock genes including *Clock* (circadian locomotor output cycles kaput), *Bmal1* (brain and muscle Arnt-like protein 1), *Per* (Period) and *Cry* (Cryptochrome) regulate the circadian rhythm. We previously showed that arthritis was significantly accelerated in *Cry* knockout mice due to the activation of TNF-α (tumor necrosis factor a) transcription, and TNF-α inhibited the expression of *Per2* gene via D-box binding protein, such as *Dbp* (D site of albumin promoter binding protein), in rheumatoid synovial cells. Since the effect of TNF-α on expression of *Dbp* gene has been reported to be dependent on intra-cellular calcium signaling, we tried to elucidate the contribution of the calcium signaling on TNF-α-induced *Per2* inhibition in rheumatoid synovial cells.

Methods: Primary cultured rheumatoid synovial cells were synchronized upon incubation with 50% horse serum for 2 hours. Cells were treated with an intra-cellular [Ca^{2+}] chelator BAPTA-AM (25μg/mL) or a calcineurin inhibitor FK-506 (Tacrolimus; 0.25 to 25 μg/mL) for 60 min, and then stimulated with or without TNF-α (10 ng/mL) for 24 hours. Total RNA was extracted from synovial cells, and mRNA expression of D-box binding protein genes, including *Dbp*, *Hlf* (hepatic leukemia factor), *Tef* (thyrotroph embryonic factor) and *E4BP4* (E4-binding protein 4), were analyzed by real-time PCR. The viability of the synovial cells was determined using Cell Counting Kit-8.

Results: The mRNA expression of *Per2* was inhibited upon incubation with TNF-α in rheumatoid synovial cells, which was cancelled by BAPTA-AM treatment ($P < 0.05$), but not FK-506, suggesting that *Per2* inhibition by TNF-α could be induced via calcium signaling. Since *Dbp*, *Hlf*, *Tef* and *E4bp4* genes could transactivate and suppress the expression of *Per2* gene, respectively, we next examined the effect of BAPTA-AM on expression of these genes. As well as the result of *Per2*, the inhibition of *Dbp*, *Hlf* and *Tef* mRNA expression upon incubation with TNF-α were cancelled by BAPTA-AM treatment ($P < 0.05$). However, BAPTA-AM treatment did not affect the increase of *E4bp4* expression by TNF-α. In addition, the viability of the synovial cells was increased by stimulation with TNF-α, and this was reversed by treatment with BAPTA-AM ($P < 0.01$).

Conclusion: In rheumatoid synovial cells, TNF-α modulates the expression of *Dbp*, *Hlf*, *Tef* genes and then inhibits *Per2* gene via calcium signaling. Since *Per2* knockout mice exhibit increased resistance to apoptosis in thymocytes, our results suggest a novel role of TNF-α in the relationship between clock gene expression via calcium signaling and the anti-apoptotic character of rheumatoid synovial cells.

Synergism Between GM-CSF and IL-17 Causes Enhanced Joint Pathology Via the Production of IL-6 and IL-23. Annemarie E.M. van Nieuwenhuijze[1], Debbie M. Roeleveld[1], Birgitte Walgreen[1], Miranda Bennink[1], Monique M. Helsen[1], Liduine van den Bersselaar[1], Ian P. Wicks[2], Wim B. van den Berg[1], Fons A. van de Loo[1] and Marije I. Koenders[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Background/Purpose: T helper-17 (Th17) cells are important mediators of inflammatory diseases, and are the main pathogenic cell type in many animal models of autoimmunity. Recent studies highlight a surprising role for T-cell derived granulocyte-macrophage colony stimulating factor (GM-CSF) in the pathogenicity of Th17 cells. We examined the mechanism by which interleukin 17 (IL-17) and GM-CSF contribute to cartilage- and bone damage of synovial joints during experimental arthritis, and investigated their potential additive and synergistic effects to provide a rationale for combination therapy in auto-inflammatory conditions.

Methods: Collagen-induced arthritis (CIA) was elicited in DBA/1J mice. Neutralizing antibodies to IL-17 and/or GM-CSF were administered after onset of disease for 14 days. Arthritis progression was followed by macroscopic scoring of the paws (maximum score of 12 per mouse). In addition, the effect of local over-expression of IL-17 and/or GM-CSF was studied by adenoviral transfection in naïve knee joints. Joint pathology was studied by X-ray and histology, and Luminex and QPCR were performed to determine cytokine en chemokine expression.

Results: Combined therapeutic treatment of mice early after the onset of CIA ameliorated disease progression. Macroscopic joint inflammation was significantly reduced, from a total score of 5.6 ± 0.4 for mice treated with isotype control antibodies to 2 ± 0.6 for mice treated with combination therapy. Treatment with anti-IL-17 or anti-GM-CSF alone resulted in scores of 3.4 ± 0.5 and 3.5 ± 0.4, respectively. Simultaneous blocking of GM-CSF and IL-17 was also the most effective treatment in the prevention of radiological bone damage and histological cartilage destruction.

To provide further insight in local additive or synergistic effects of IL-17 and GM-CSF, overexpression of IL-17, GM-CSF or the combination was achieved with adenoviral vectors. Inflammatory infiltrate and cartilage- and bone damage developed in all groups from day 1 after adenoviral transfer, with the most severe effect observed in the combination group. On day 7, partial destruction of joint architecture was apparent in knee joints after combined overexpression of IL-17 and GM-CSF. Overexpression of GM-CSF alone induced IL-1β, which production was elevated by IL-17. Interestingly, overexpression of IL-17 alone caused a clear increase in synovial IL-6 production (179 ± 63pg/ml), which was dramatically enhanced in the co-presence of GM-CSF ($1{,}9\pm0{,}4$ng/ml). In addition, a strong synergistic effect of combined overexpression was seen on the Th17 differentiation factor IL-23.

Conclusion: Our results demonstrate that the combined presence of IL-17 and GM-CSF causes aggravated joint damage through synergistic effects on inflammatory mediators in the synovial joints. In view of the moderate success of therapeutic IL-17 or GM-CSF blockade in rheumatoid arthritis, combined inhibition of IL-17 and GM-CSF might be an interesting alternative option for RA patients that do not fully respond to inhibition of the separate cytokines.

Anti-MDA5 Antibody Associated Myositis Compared to DM Patient: A Distinct Muscular Pattern Associated with a shared IFN Signature. Yves Allenbach[1], Gaelle Leroux[2], Aude Rigolet[3], Baptiste Hervier[4], Nicolas Limal[5], Peter Hufnagl[6], Norman Zerbe[6], Thierry Maisonobe[7], Alain Meyer[8], Yurdagul Uzunhan[9], Kuberaka Mariampillai[10], Romain Gherardi[11], Serge Herson[10], Olivier Benveniste[1] and Werner Stenzel[6]. [1]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [2]DHU 2iB Internal Medicine Referal Center for Autoimmune diseases Pitie Hospital, Paris, France, [3]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, Paris, France, [4]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, PARIS, France, [5]Hôpital Henri Mondor, APHP, Creteil, France, [6]Charite Hospital, Berlin, Germany, [7]Pitie-Salpetriere Hospital, Paris, France, [8]University Hospital of Strasbourg, Strasbourg, France, [9]APHP Avicenne Hospital, Bobigny, France, [10]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University, Paris, France, [11]APHP Henri Mondor Hospital, Creteil, France.

Background/Purpose: Anti-MDA5 auto-antibodies are thought to be specifically associated with dermatomyositis (DM). Nevertheless anti-MDA5 auto-antibody positive patients ($MDA5^+$ DM) predominantly suffer from extra-muscular involvement with severe interstitial lung disease, and arthritis. Further, skin lesions may be atypical with skin ulcers and mechanics' hands. Importantly, clinical signs of myopathy are rather mild or absent and morphology and immunology of skeletal muscle tissue has not been studied yet. Thus, the previously described characteristic 'IFN signature' in classical DM may not be found in $MDA5^+$ DM patients. We aim to describe the histological pattern of the skeletal muscle and the intrinsic immune response $MDA5^+$ DM patients.

Methods: Muscle specimens were subjected to conventional staining and immunohistochemical analysis to describe muscle fibers, vessel morphology and inflammatory features. Morphometry of vessels was performed using imageJ software on digitally completely scanned slides and by electron microscopy. A panel of six interferon stimulated genes (ISGs) (*OAS1, OAS3, ISG15, MX1, RIG1 and MDA5*), involved in the IFN immune response were tested by quantitative PCR in muscle biopsie (results expressed as normalized fold change relative to a normal muscle). The median fold change of the six ISGs, was used to create an IFN score. **Results:** are compared to anti-MDA5 auto-antibody negative DM patients (based on ENMC criteria). Serum level of IFN-α was tested using a bioassay.

Results: In $MDA5^+$ DM patients ($n=9$) the mean MRC-score (five score) of the weakest muscular group was 4.5 ± 0.5 and CK levels were 498 ± 809 IU/l. Muscle biopsies ($n=10$) were analyzed compared to $MDA5^-$ DM patients ($n=7$). Histological analysis showed that anti-$MDA5^+$ patients did not present the classical feature of perifascicular fiber atrophy. Inflammation was focal in the perimysium and mainly perivascular but significantly less intense as it is shown by density scores of $CD45^+$ leukocytes (35.8 ± 28 vs. 5.9 ± 7.6 cells/mm^2, $p<0.05$). MHC-class I staining was also less intense and more focal compared to $MDA5^-$ DM patients who harboured a diffuse staining pattern with a perifascicular re-inforcement. $MDA5^+$ DM patients did not show signs of capillary loss since the capillary density was 279.9 ± 17.7/mm^2 vs. 340.9 ± 16.5/mm^2 ($p=0.05$) in $MDA5^-$ DM patients. In the same line the frequency of enlarged capillaries (diameter $>10\mu$m) was decreased $5.8\pm1.1\%$ vs. $13.9\pm2.5\%$. Tubulo-reticular formations were observed in only 50% of $MDA5^+$ patients, but in all cDM patients. In $MDA5^+$ DM patients a strong up-regulation of ISGs expression was observed with RQ values ranging from 74.5 ± 17.2 for *RIG* to 1107 ± 406 for *ISG15* even though, the IFN score was less increased than in controls (139.5 vs 634; $p=0.005$). Finally IFN-α serum levels were increased in all active $MDA5^+$DM patients ($n=2$).

Conclusion: These results show that myositis in patients with anti-MDA5 Ab positivity shows a distinct morphological pattern compared to $MDA5^-$ DM patients, but is associated with an IFN signature as well, underlining the importance of this pathway in the pathogenesis of both entities.

Macrophage-Fibroblast Crosstalk Pathways Amplify RA Joint Pathology. Laura T. Donlin, Jennifer Ding and Lionel B. Ivashrkiv. Hospital for Special Surgery, New York, NY.

Background/Purpose: Macrophages and synovial fibroblasts represent key cellular drivers of RA. The goal of this study was to define how the complex cellular programs of macrophages and fibroblasts crossregulate within an inflammatory setting and potentially perpetuate pathologic responses. Previously, we have shown that soluble synovial fibroblast products

suppress the macrophage TNF-induced Type I Interferon response. Here through a next-gen sequencing transcriptome analysis, we describe on a global scale how the macrophage TNF-a response is reshaped by synovial fibroblast factors, ultimately converting classic anti-inflammatory/resolution pathways into programs that feedback to support fibroblast growth and function. Furthermore, macrophages isolated directly from RA synovium indeed activate a subset of these gene expression networks, suggesting these macrophage-fibroblast crosstalk pathways represent novel therapeutic targets.

Methods: Human blood derived macrophages and human RA synovial fibroblasts were co-cultured in transwell plates and treated with TNF for 2 days. The transcriptomes of both cell types were analyzed by RNA sequencing (RNAseq). Pathway analysis programs identified macrophage responses specifically controlled by synovial fibroblasts, as well as identified candidate soluble crosstalk mediators. Cellular STAT3 activity was monitored by Western blot detection of phospho-STAT3 levels and by qPCR analysis of STAT3-dependent genes, while the soluble mediators responsible for inducing differential STAT3 responses were confirmed with neutralizing antibodies in the culture media.

Results: Synovial fibroblasts modified specific programs within the macrophage inflammatory response, impacting 30% of TNF-regulated genes. Pathway analysis demonstrated fibroblast factors largely transformed macrophage lipid programs and induced growth factor responses, including genes known to promote wound healing activities and growth of fibroblasts. Interestingly, while TNF-a alone induced an anti-inflammatory STAT3 response, TNF-a combined with fibroblast factors blocked this resolution response and instead diverted STAT3 activity towards mitogenic and metabolic pathways. Furthermore, initial analysis of synovial macrophages isolated directly from RA synovium revealed a subset of the crosstalk pathways identified in the in co-culture system including specific growth factor responses.

Conclusion: We propose the combination of inflammatory and fibroblast-derived factors found in the RA synovium drive macrophages into an unresolving novel macrophage phenotype that in part functions to feedback and support synovial fibroblast pathologic activity.

Interleukin-20 Is Triggered By TLR Ligands and Associates with Rheumatoid Arthritis Disease Activity. Ladislav Senolt[1], Klara Prajzlerova[1], Hana Hulejova[2], David Veigl[3], Karel Pavelka[1] and Jiri Vencovsky[1]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [2]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic, [3]1st Orthopaedic Clinic, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by persistent synovial inflammation and subsequent joint damage with systemic manifestations. Interleukin-20 (IL-20) has been previously identified as a pro-inflammatory cytokine that may be implicated in the pathogenesis of chronic inflammatory diseases, particularly RA (1). Recently, phase 2a trial (2) demonstrated that treatment with anti-IL-20 monoclonal antibody significantly reduced disease activity in seropositive patients with RA. Therefore, the aim of the current study was to characterize the role of IL-20 in patients with RA.

Methods: The levels of serum and synovial fluid IL-20 were measured by ELISA assay in 34 patients with RA (25 female) and 35 patients with OA (19 female). Disease activity was assessed based on the Disease Activity Score of 28 joints (DAS28). The expression of IL-20 in synovial tissue samples from patients with RA (n=5) and OA (n=7) were determined by immunohistochemistry. Secretion of IL-20 was analysed in human peripheral blood mononuclear cells (PBMCs) isolated from blood of patients with RA (n=8).

Results: The expression of IL-20 was significantly up-regulated in RA compared with OA synovial tissue, particularly in the lining (2.6±0.65 vs 0.93±0.19; p=0.003) as well as in the inflammatory infiltrates of the sublining layer (2.2±0.57 vs 0.37±0.36; p=0.005). The levels of IL-20 in synovial fluid were significantly higher in patients with RA compared to those with OA (86.3±87.5 vs 41.9±43.3 pg/ml; p=0.01). IL-20 production from PBMCs was induced by Poly I:C (TLR-3 ligand) (p<0.0001) and LPS (TLR-4 ligand) (p=0.0008), but not with pro-inflammatory cytokines such as TNFα (p=0.99) or IL-1 (p=0.74).

In contrast to local sites of inflammation, serum levels of IL-20 in RA patients were comparable to those in OA patients (41.7 ± 48.7 vs 32.3 ± 45.4 pg/ml; p=NS), and significantly correlated with DAS28 (r=0.581; p=0.001) and anti-CCP levels (r=0.362; p=0.045). When adjusted for anti-CCP levels, correlation with DAS28 remained still significant (r=0.540; p=0.002). Similarly, the levels of IL-20 in synovial fluid correlated with RA disease activity. In addition, the levels of IL-20 in synovial fluid were significantly higher in anti-CCP positive compared to anti-CCP negative patients with RA (122.3±104.1 and 45.9±35.8 pg/ml; p=0.008); this difference was however not paralleled by serum IL-20 levels (51±48.6 and 31.1±48.2 pg/ml; p=0.24).

Conclusion: Our data show that IL-20 is independently associated with RA disease activity and may be triggered by TLR ligands at local sites of inflammation. Association between IL-20 and anti-CCP levels may, at least partially, explain disease activity improvement after the treatment with anti-IL-20 monoclonal antibody in seropositive RA patients.

Dysregulated Serum Interleukin 16 Concentration Associated with Clinical Disease Activity in Patients with Rheumatoid Arthritis Is Efficiently Corrected By Immunological Intervention. Atsuko Murota[1], Katsuya Suzuki[1], Yoshiaki Kassai[2], Takahiro Miyazaki[3], Rimpei Morita[4], Akihiko Yoshimura[4] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Takeda Pharmaceutical Company, Fujisawa, Japan, [3]Takeda Pharmaceutical Company Limited, Kanagawa, Japan, [4]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: IL-16 is a chemoattractant factor that evokes massive infiltration of mononuclear cells in the synovial tissue in patients (pts) with rheumatoid arthritis (RA). IL-16 concentrations are elevated in RA synovial fluid and also sera. However, the effect of current pharmacological intervention on this key cytokine and its association with clinical outcome are not fully understood. The purpose of this study was to clarify the effects of various treatments on IL-16 and the role in RA pts.

Methods: The study enrolled consecutive RA pts who met the 1987 or 2010 RA classification criteria, as well as pts with primary Sjogren's syndrome (pSS) and healthy controls (HC). Serum IL-16 and other proteins' concentrations in these groups were measured by quantitative proteomics assay using nucleic acid aptamers. Levels of IL-16 in RA pts were measured at baseline and 12 weeks after treatment with MTX or three different biologics (infliximab (IFX), tocilizumab (TCZ), and abatacept (ABT)) by conventional ELISA. In biologics therapy, pts who started with MTX at baseline or whose MTX dosage was increased during the 12 weeks were excluded. Correlations between IL-16 concentrations and clinical parameters were statistically analyzed.

Results: Serum IL-16 concentration was significantly increased in pts with untreated active RA (n=28) compared to the HC (n=30, p<0.0001) and pSS (n=30, p<0.0001) groups. IL-16 was a positively and most correlated cytokine with serum MMP-3 (R=0.70, P=3.5E-05) in pts with untreated RA, but only weakly and negatively correlated with MMP-3 in pts with pSS (R=−0.31, p=0.095). IL-16 was significantly decreased during treatment for RA for 12 weeks in all 86 RA pts (Figure). On stratification, IL-16 was decreased in the MTX- (n=31), TCZ- (n=17) and ABT-treated (n=16)

groups, but did not change in the IFX-treated group (n=22). Regarding clinical disease activity, the decrease in IL-16 was positively associated with DAS28-CRP in the MTX (R=0.48, p=0.007), ABT (R=0.60, p=0.01), TCZ (R=0.52, p=0.06) groups. Furthermore, the decrease in IL-16 was positively correlated with a decrease in serum CRP in the MTX (R=0.48, p=0.007) and ABT (R=0.54, p=0.03) groups, which indicates a stronger association with CRP in the composite measure, except for the TCZ group. MMP-3 in the MTX, IFX and TCZ groups was also significantly decreased at 12 weeks. In contrast, the decrease in IL-16 with treatment was not correlated with that of MMP-3, unlike the case with untreated RA at baseline.

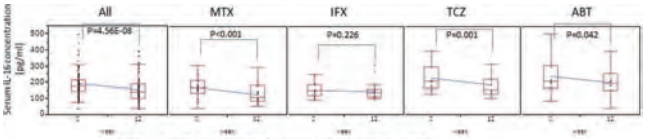

Figure. Serum IL-16 concentrations at baseline and 12 weeks.
MTX: methotrexate, IFX: infliximab, TCZ: tocilizumab, ABT: abatacept

Conclusion: Treatment with MTX, TCZ and ABT for active RA ameliorated the dysregulation of serum IL-16. This correction was correlated with decreases of clinical disease activity and CRP, except for TCZ, but not correlated with MMP-3. The directional change in serum IL-16 with different interventions, especially with TCZ, may indicate the need to revise molecular abnormalities in RA.

Imaging the Role of Chemoattractants in Inflammatory Arthritis. Yoshishige Miyabe, Thomas T. Murooka, Chie Miyabe, Nancy Kim, Thorsten R. Mempel and Andrew D. Lusrter. Massachusetts General Hospital, Charlestown, MA.

Background/Purpose: Inflammatory arthritis, including rheumatoid arthritis, is characterized by neutrophil recruitment into the diseased joint. Our previous studies and the work of others have demonstrated important roles for several neutrophil chemoattractant receptors, including the leukotriene B4 receptor, BLT1, the chemokine receptors CCR1 and CXCR2, and the complement receptor C5aR in a murine model of immune-complex mediated arthritis. However, the precise role for each chemoattractant in the process of neutrophil recruitment into the inflamed joint remains unclear.

Methods: Multiphoton intravital microscopy (MP-IVM) was used to study the migratory behavior of wild-type and chemoattractant receptor-deficient leukocytes in the joint in the K/BxN serum transfer model of inflammatory arthritis. LysM-GFP mice in which endogenous neutrophils and macrophages express GFP were also used in these studies. Following the transfer of arthritogenic serum, MP-IVM was performed to analyze neutrophil migratory behavior in the joint on day 1 (early phase of arthritis) and day 7 (established arthritis). We also analyzed the ability of WT and chemoattractant receptor-deficient neutrophils to enter the joint in short term adoptive transfer homing assays on days 1 and 7 following arthritogenic serum transfer using MP-IVM.

Results: Analysis of neutrophil migratory behavior revealed that the number of neutrophils adhering to blood vessels of the joint and subsequently infiltrating into the inflamed joint was markedly increased on day 7 following arthritogenic serum transfer in WT LysM-GFP mice, compared to day 1 following serum transfer and compared to control untreated WT LysM-GFP mice. In short term homing assays, both WT and BLT1-deficient neutrophils rolled along the joint vessels of WT and BLT1-deficient mice and on day 1 following serum transfer but did not adhere or enter the joint. In contrast, adoptive transfer of WT and BLT1-deficient neutrophils on day 7 following serum transfer into WT mice revealed that the number of BLT1-deficient neutrophils that adhered to and subsequently migrated into the joint was dramatically reduced compared to WT neutrophils. Furthermore, neither WT nor BLT1-deficient neutrophils entered the joints of BLT1-deficent host mice on days 1 or 7 following serum transfer.

Conclusion: BLT1 plays an important role in both the adhesion and transmigration of neutrophil across blood vesseles of the joint during immune complex induced arthritis.

IL-1β and TNF-α Promote Monocyte Viability through the Induction of GM-CSF Expression By Rheumatoid Arthritis Synovial Fibroblasts. Christelle Darrieutort-Laffite, Marie Astrid Boutet, Mathias Chatelais, Regis Brion, Frederic Blanchard, Dominique Heymann and Benoit Le Groff. INSERM, UMR 957, Nantes, France.

Background/Purpose: Macrophages and synovial fibroblasts (SF) are two major cells implicated in the pathogenesis of rheumatoid arthritis (RA). They can interact in the synovial micro-environment to drive inflammation and bone destruction. The aim of our work was to investigate the effects of SF on monocyte viability and differentiation and to determine which factors were implicated in these effects.

Methods: SF were isolated from synovial tissue of 9 RA patients and CD14+ cells were magnetically isolated from healthy donors by MACS technology. SF conditioned media were collected after 24 hours of culture with or without TNF-α or IL-1β. After 3 days of culture with RA SF conditioned media, monocyte survival was assessed using a WST-1 viability test. To study the involvement of M-CSF, IL-34 and GM-CSF, their expression was quantified in RA SF by qPCR, in RA synovial fluids by ELISA assay, and specific blocking antibodies were used in monocyte cultures. Macrophages polarization after culture with RA SF conditioned media was studied by flow cytometry. The cell surface markers analyzed were CD14, CD16, CD64 (M1), CD200R (M2a) and CD163 (M2c). A non-parametric test (Kruskall Wallis) was used to perform statistical analyzes.

Results: SF conditioned media significantly increased monocyte viability compared to cells cultured in medium alone ($p<0.001$). This effect was stronger when using conditioned media from IL-1β or TNF-α pre-stimulated SF. Monocyte viability was significantly increased compared to M-CSF (+29% ($p=0.05$) and +52% ($p=0.004$) for TNF-α and IL-1-β media respectively). M-CSF and IL-34 blocking antibodies, alone and in combination, had no effect on monocyte viability induced by SF conditioned media. In contrast, blocking GM-CSF resulted in a significant decrease in monocyte viability by 30% when added to the stimulated SF conditioned media ($p<0.001$). The expression of GM-CSF by RA SF was stimulated by TNF-α and IL-1β and GM-CSF levels in the synovial fluids were correlated with those of these two cytokines. Finally, studying the cell surface markers, we found no regulation of M1/M2 polarization when monocytes were differentiated in the presence of SF conditioned media.

Conclusion: SF conditioned media increased monocyte viability with a greater effect observed when SF were pre-stimulated with IL-1β or TNF-α and this effect was GM-CSF-dependent. However, cells cultured in the presence of conditioned media did not express specific M1 or M2 markers.

Identification of Putative Biomarkers and Molecular Mechanisms Associated with Adverse Tissue Reactions to Metal-on-Metal and Modular Neck Hip Implants. Ed Purdue, Gabrielle Wilner, Kritti Kolatat, Geoffrey H. Westrich, Friedrich Boettner, Seth Jerabek and Steven R. Goldrring. Hospital for Special Surgery, New York, NY.

Background/Purpose: Total hip replacement (THR) is a highly successful treatment for degenerative arthritis, alleviating pain and restoring joint function in the vast majority of patients. However, inflammatory reactions to polyethylene wear debris resulting in destruction of bone (osteolysis) can lead to implant loosening and revision surgery. To avoid the adverse effects of polyethylene wear products, metal-on-metal bearings were introduced. Recent studies, however, have revealed an alarming rate of early revision surgery related to the development of adverse local tissue reactions (ALTR)

characterized by extensive and rapid necrosis of soft tissue surrounding implants with metal-on-metal (MoM) or dual modular neck (DMN) designs. We have used chemokine/cytokine profiling of synovial fluid and serum and gene expression analysis of peri-implant tissue to identify biomarkers for early detection and to gain insights into the pathogenesis of ALTR.

Methods: Synovial fluid and serum was collected from ALTR and osteolysis patients at revision surgery, and cell-free aliquots were prepared and immediately frozen. Antibody arrays were used to identify selected chemokines and cytokines, and results confirmed by ELISA. For gene expression profiling, total RNA was prepared from peri-implant tissue using Trizol. RNA integrity was verified using an Agilent Bioanalyzer, and then subjected to microarray analysis (Affymetrix U133 2.0). Results: were verified using real time PCR.

Results: Synovial fluid from ALTR patients demonstrated elevated levels of several chemokines and cytokines compared to those seen in osteolysis patients, including the interferon gamma inducible chemokines MIG/CXCL-9 and IP-10/CXCL10. Levels of these factors were generally higher in the DMN ALTR patients than the MoM ALTR patients. More modest elevations of these chemokines were found in ALTR serum samples. Microarray analysis revealed a unique ALTR gene expression profile that was absent in arrays prepared from peri-implant tissues from patients with osteolysis. Pathway analysis identified a unique chemokine/interferon signature that mirrored the protein profile of synovial fluid.

Table 1 Mean (Standard Deviation) levels of selected proteins in the synovial fluid and serum (in pg/ml). p-values are for comparison to the osteolysis group.

	Protein	Osteolysis	ALTR–DMN	p-value (DMN)	ALTR–MOM	p-value (MoM)
Synovial Fluid	MIG	1,320 (1,901)	178,442 (120,107)	8.46 E-6	68,609 (68,867)	2.52 E-3
	IP-10	1,880 (4,304)	100,137 (78,158)	9.32 E-5	32,829 (30,575)	2.00 E-3
	IL-6	497 (786)	28,583 (28,481)	1.53 E-3	16,102 (21,768)	2.10 E-2
	IL-8	8,621 (12,820)	64,172 (58,125)	2.21 E-3	54,338 (41,930)	1.32 E-3
Serum	MIG	273 (163)	592 (315)	1.68 E-3	456 (279)	0.036
	IP-10	17.4 (9.8)	25.7 (29.5)	0.31	32.9 (31.0)	0.074

Conclusion: Expression profiling of peri-implant tissues from ALTR patients reveals a unique chemokine/cytokine gene signature. The corresponding gene products are detectible in synovial fluid and serum, indicating their potential utility as biomarkers for early diagnosis and monitoring of patients at risk for ALTR. In addition, pathway analysis reveals up-regulation of genes involved in lymphocyte trafficking and activation, providing insights into disease pathogenesis and importantly identifies potential therapeutic targets to prevent this devastating complication.

Novel Compound Cytokine Release Inhibitory Drug 3 (CRID3) Inhibits the NLRP3 Inflammasome in Rheumatoid Arthritis. Trudy McGarry[1], Mary Connolly[1], Rebecca C. Coll[2], Avril A. B. Robertson[3], Matthew A. Cooper[3], Luke A. O'Neill[2], Douglas J. Veale[1] and Ursula Fearon[1]. [1]Translational Rheumatology Research Group, Dublin, Ireland, [2]School of Biochemistry and Immunology, Dublin, Ireland, [3]The University of Queensland, Brisbane, Australia.

Background/Purpose: The NLRP3 inflammasome is a multi-protein complex activated in response to environmental pathogens. This results in caspase-1-dependant cleavage of pro-IL-1β and IL-18 to their active and mature form, induction of which leads to a variety of biological effects associated with infection, inflammation and autoimmunity. Cytokine Release Inhibitory Drug 3 (CRID3) is a novel inhibitory molecule thought to be active in the NLRP3 pathway. In this study, we examined the effects of Toll-like Receptor 2 on inflammasome activation and cytokine secretion. Furthermore, the role of CRID3 on the NLRP3 pathway in the RA joint was examined.

Methods: Rheumatoid Arthritis *ex vivo* synovial tissue biopsies were cultured in the presence or absence of synthetic Toll-like Receptor 2 agonist Pam3CSK4 (1 μg/mL). Expression of inflammasome component NLRP3 in addition to the pro and mature/active forms of IL-1β and IL-18 were assessed by Taqman PCR and ELISA. TLR-2-induced pro-inflammatory cytokine secretion (IL-6, IL-8, TNFα) was also assessed by ELISA. RA synovial biopsies were incubated in the presence or absence of CRID3 (100 nM), a novel inhibitory compound which is thought to act on or closely to NLRP3. Expression of NLRP3, IL-1β and IL-18 expression was analysed by Taqman PCR and ELISA. The effect of CRID3 on *ex vivo* pro-inflammatory cytokine secretion (IL-6, IL-8, TNFα) was also determined by ELISA.

Results: TLR2 stimulation significantly induced transcript levels of NLRP3 and pro IL-1β and IL-18 in RA *ex vivo* synovial tissue biopsies, a model which maintains cell-cell contact, preserves the synovial architecture and closely reflects the *in vivo* environment. Additionally, protein expression of IL-1β and IL-18 was increased in comparison to basal control. Pam3CSK4 significantly increased secretion of pro-inflammatory cytokines IL-6, IL-8 and TNFα. Incubation of synovial biopsies with CRID3 resulted in a decrease of pro IL1β, which was mirrored by a decrease in active IL-1β and NLRP3 expression. Spontaneous release of IL-6, IL-8 and TNFα were also reduced following CRID3 treatment.

Conclusion: TLR2 signalling induces NLRP3 activation in the RA joint, resulting in the secretion of inflammasome related cytokines IL-1β and IL-18. Additionally, we show for the first time that CRID3 is a novel compound which inhibits inflammasome activity in RA, and subsequent induction of pro-inflammatory pathways.

Tertiary Lymphoid Organ Developmental Program: Diversgent Paradigm of Lymphoid Organogenesis. Saba Nayar[1], Bridget Glaysher[2], Joana Campos[1], Jorge Caamano[1], David Withers[1], Kai Toellner[1], Sanjiv Luther[3], Mark Coles[4], Christopher Buckley[5] and Francesca Barone[1]. [1]University of Birmingham, Birmingham, United Kingdom, [2]University of York, york, United Kingdom, [3]Losanne University, Epalinges, Switzerland, [4]University of York, York, United Kingdom, [5]The University of Birmingham, Birmingham, United Kingdom.

Background/Purpose: Tertiary lymphoid organs (TLOs) represent the histological hallmark of many immune-mediated inflammatory diseases. TLOs are characterized by a functional leukocyte aggregation and network of lymphoid-like stromal cells (LLSc). LLSc express lymphoid chemokines (CXCL13, CCL19, and CCL21), survival factors (BAFF and IL-7), lymphoid markers and adhesion molecules (gp38, RANKL, ICAM-1 and VCAM-1) that locally support lymphocytes survival and organization in ectopic sites areas.

Methods: We have used a combination of in vitro and in vivo approaches in two models of TLO formation to address the dynamic of stromal cell activation within TLOs.

Results: and Conclusion: We demonstrated that the acquisition of this lymphoid phenotype by the non-activated resident stroma requires a multistep process, fundamentally different from that responsible of secondary lymphoid organ formation. We showed that early, during TLO formation, IL-4Rα engagement via IL-13 on quiescent tissue-resident fibroblasts induces LLSc priming and mediates the up-regulation of gp38 and lymphoid-associated adhesion molecules. Expansion of this activated lymphoid stroma requires IL-22/IL-22R mediated signaling. Lack of IL-22 or its receptor induces defective LLS proliferation, abrogation of CXCL13 expression and TLO involution. Finally we demonstrated that, similarly to secondary lymphoid organ, stabilization of the stroma to a functional lymphoid phenotype requires lymphocyte infiltration and lymphotoxin beta expression. This work highlights critical differences between the embryonic program responsible for SLO formation and the inflammatory development of TLOs and unveils novel potential targets for TLO targeting.

Modulatory Effect of Adiponectin on Apoptosis and Proliferation of Synovial Fibroblasts from Rheumatoid Arthritis Patients. Wei Yu[1], Wenfeng Tan[2] and Miaojia Zhang[3]. [1]The First Affiliated Hospital of Nanjing Medical University, nanjing, China, [2]the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China, [3]the first affliated hospital with nanjing medical univercity, nanjing, China.

Background/Purpose: We previously reported that adiponectin (AD) is highly expressed in the inflammatory joint of rheumatoid arthritis (RA)

patients and closely correlated with progressive bone erosion, but the mechanism remained largely unclear. Synovial fibroblasts from RA patients (RASFs) have been suggested a unique characteristic of resistance to apoptosis that contributes to synovial hyerplasia, synovitis and bone erosion in RA. In this study, we tested the role of AD on apoptosis and proliferation in primary RASFs.

Methods:RASFs was treated with PBS in the absence and presence of AD (0.1, 1 or 10 μg/ml) for 24 h to 72 h and the frequencies of apoptosis cells were measured by flow cytometry. CCK-8 and direct microscopic count were used to analyze the proliferation of RASFs after stimulated with AD. Real-time PCR was used to test the expression of Bcl-2, Bax, p53, CDK4, PCNA, IL-6, IL-8 and MMP-3 mRNA in RASFs. Western blot was used to test the protein expression of Bcl-2 and Bax and activation of signal transduction pathways.

Results: The frequencies of apoptosis cells were significant decreased in RASFs after AD stimulation. AD could promote proliferation of RASFs compared with untreated it. A markedly increased CDK4 and PCNA mRNA expression and a decreased level of p53 mRNA were observed in RASFs after treated with AD. The levels of IL-6, IL-8 and MMP-3 expression also obviously increased in RASFs upon AD stimulation. Western blot indicated that AD could rapidly triggered p-Akt and p-ERK activity and then induced Bcl-2, but decreased Bax expression in RASFs.

Conclusion: Our findings indicate that AD could affect apoptosis and proliferation of RASFs via Akt and ERK pathway, suggesting a critical role of AD on disease progression in RA.

Type I and II Interferon Signatures in Sjogren's Syndrome: Contributions in Distinct Clinical Phenotypes and Sjogren's Related Lymphomagenesis. Adrianos Nezos[1], Fotini Gravani[2], Efstathia K. Kapsogeorgou[3], Michael Voulgarelis[1], Haralampos M. Moutsopoulos[1], Mary K. Crow[4] and Clio Mavragani[1]. [1]School of Medicine, University of Athens, Athens, Greece, [2]General Hospital of Athens 'G.Gennimatas', Athens, Greece, [3]School of Medicine, National University of Athens, Greece, Athens, Greece, [4]Hospital for Special Surgery, New York, NY.

Background/Purpose: Both type I and II interferons (IFNs) have been implicated in the pathogenesis of Sjogren's syndrome (SS). We aimed to explore the contribution of type I and II IFN signatures in the generation of distinct SS clinical phenotypes including non-Hodgkin's lymphoma (NHL) development, a major SS complication.

Methods: Peripheral blood from SS patients (n=31), SS patients complicated by lymphoma (SSL, n=13) and healthy donors (HD, n=30) were subjected to real-time polymerase chain reaction for 3 interferon inducible genes (IFIGs) preferentially induced by type I IFN, 2 IFIGs preferentially induced by IFNγ as well as for IFNα and IFNγ genes. The same analysis was performed in minor salivary gland tissues (MSG) derived from 31 SS patients, 10 SSL patients and 17 sicca controls (SC).

Results: In peripheral blood and MSG tissues, overexpression of both type I and type II IFIGs was observed in SS patients versus HC and SC, respectively, with a predominance of type I IFN signature in peripheral blood and a type II IFN signature in MSG tissues. SS patients with salivary gland enlargement, lymphopenia, anti-Ro/SSA antibodies and hypergammaglobulinemia exhibited higher type I IFN scores in peripheral blood compared to their counterparts without those features. Hypergammaglobulinemia was also associated with increased type II IFN scores in peripheral blood. In MSG tissues derived from SSL patients we observed lower IFNα, but higher IFNγ and type II IFIG transcripts compared to both SS and SC. In ROC curve analysis, IFNγ/IFNα ratio in MSG tissues showed the best discrimination for lymphoma development, with an area under the curve of 0.88 (95% CI:0.72–1.00, p-value: 0.001).

Conclusion: Discrete expression patterns of type I and II IFN signatures might be related to distinct clinical SS features and SS related lymphomagenesis.

Oncostatin M Suppresses Activation of IL-17/Th17 Via Suppressor of Cytokine signaling3 (SOCS3) Regulation in CD4+ T Cells. Young Ok Jung[1], seon Yeong Lee[2], Sung Yeon Lee[3], Mi-La Cho[2] and Hea-Jin Son[4]. [1]Hallym University Kangnam Sacred Heart Hospital, Seoul, South Korea, [2]Catholic University of Korea, Seoul, South Korea, [3]Hallym University Sacred Heart Hospital, Gyeonggi-do, South Korea, [4]Rheumatism Research Center, Catholic Institutes of Medical Science, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: Oncostatin M (OSM) is a pleiotropic cytokine that belongs to the interleukin(IL)-6 group of cytokines. High level of OSM were detected in synoviums of rheumatoid arthritis (RA) patients but its exact role in arthritis perpetuation has not been elucidated. We evaluated the role of OSM in T helper 17(Th17) cell differentiation, the most important cells in arthritis development.

Methods: Collagen-induced arthritis (CIA) was induced in DBA/1J mice. IL-2 immune complex(IC) were injected intraperitoneally three times at 2days intervals before 1st immunization. Severity of arthritis was assessed by clinical scoring of arthritis. CD4+ T cells were isolated by MACS and incubated in Th17 differentiation condition with and without OSM. The levels of cytokines were measured using ELISA. To analyze intracellular cytokine were analyed by FACS. Subpopulations of T cells of spleens were assessed by confocal microscopy. The mRNA levels of OSM and signaling molecules were determined by RT-PCR and real time PCR. The protein levels were assessed by Western blot. Suppressor of cytokine signaling3 (SOCS3) small interfering RNA(siRNA) was transfected by using the Amaxa 4D-nucleofector X unit (Lonxa, Cologne, Germany).

Results: IL-2IC treatment reduced the clinical arthritis score and OSM and SOCS were increased in spleens of IL-21C treated mice. We observed that OSM suppressed Th17 cell differentiation and the levels of IL-17 and IL-21 were decreased in dose dependent manner in vitro. OSM time dependently increase the level of STAT3, STAT5 and SOCS3 in mRNA and protein levels. STA21, the STAT3 inhibitor abrogated the suppressive effect of OSM on Th17 differentiation. SOCS3 siRNA also abrogated the suppressive effect of OSM.

Conclusion: OSM was up-regulated spleens of IL-2IC treated mice. OSM suppressed the Th17cell differentiation and the inhibitory effects of OSM on Th17 cells were via SCOS3 regulation.

Bioactive TGF-β Is Present on Bovine Milk-Derived Exosomes: Consequences for Patients? Bartijn C.H. Pieters, Onno J. Arntz, Mathijs G.A. Broeren, Arjan van Caam, Peter M. van der Kraan, Marieke de Vries and Fons A.J. van de rLoo. Radboud university medical center, Nijmegen, Netherlands.

Background/Purpose: Development of rheumatoid arthritis (RA) is associated with different genetic and environmental factors. We postulate that cow milk could be such an environmental trigger and a recent prospective study of Lu *et al.* (Arthritis Care Res 2014;66(6):802–9) suggests that frequent milk consumption is associated with reduced OA progression in women. Human breast milk contains many components to promote development of neonatal immune competence, such as cytokines, antibodies and immune cells. More recently, exosomes were identified in both bovine and human breast milk. Exosomes are small vesicles recently rediscovered as an important part of intercellular communication. Milk exosomes are known to carry immunoregulatory microRNAs and cytokines, thereby enhancing the antimicrobial defense in newborns. It is however unknown whether exosomes are present in commercial milk and whether they are bioactive.

Methods: By differential ultracentrifugation, followed by ExoQuick isolation, we isolated exosomes from commercial milk. NanoSight analysis was performed to estimate vesicles size (Ø120nm) and concentration (approx.10^{10} exosomes per ml). The expression of milk-derived mRNA and miRNA was confirmed by RT-qPCR. Exosomes were acidified at a gastrointestinal pH2 to test their stability. Cellular uptake of PKH-67 labeled exosomes was analyzed by confocal microscopy and flow cytometry. TGFβ levels were measured with a CAGA-fLuc reporter construct. Naïve T cells were cultured for 5 days with an inflammatory cocktail in the presence of milk exosomes, to induce Th17 differentiation. RORγT and IL-17 expression levels were determined by RT-qPCR.

Results: We found clear levels of messenger- and miRNAs (e.g. miR-let-7a, 124a) in cow milk exosomes. Sucrose gradient followed by electron microscopy revealed an exosome-like morphology. We showed cellular uptake of exosomes *in vitro* by murine macrophages, splenic antigen presenting cells and non-phagocytic fibroblasts. To test the stability of these vesicles, we used a luciferase reporter assay to measure *in vitro* NFκB-activation. Acidification, up to gastric acid level kept the exosomes intact, and did not alter the inhibitory effect they had on NFκB-activation. Active TGFβ was detected using CAGA-fluc reporter cells and blocked by addition of anti-TGFβ1,2,3 antibodies. More importantly, incubation of naïve T cells with milk exosomes in the presence of an inflammatory cytokine cocktail induced significant Th17 differentiation.

Conclusion: We clearly showed that commercial milk contains stable exosomes, which are resistant to acidification. These vesicles can facilitate Th17 differentiation and could therefore play an important role in autoimmune diseases, such as rheumatoid arthritis. To our knowledge, this is the first study to show that commercial milk contains immunoregulatory exosomes with active TGFβ. Our data suggest that bovine milk-derived exosomes, carrying immunoregulatory cargo, could remain intact in the gastrointestinal tract and therefore reach the circulation. This warrants further research to determine their biological effect in both healthy individuals and patients with autoimmune diseases.

A Role for Purinergic Receptor Signalling in Basic Calcium Phosphate Crystal-Induced Inflammation. Clare C. Cunningham[1], Emma M. Corr[1], Geraldine M. McCarthy[2] and Aisling Dunne[1]. [1]Trinity College Dublin, Dublin 2, Ireland, [2]Mater Misericordiae University Hospital, Dublin 7, Ireland.

Background/Purpose: Basic calcium phosphate (BCP) crystals are uniquely associated with osteoarthritis (OA). They are found in the majority of affected joints and closely correlate with the extent of joint destruction, suggesting a pathogenic role in driving disease. They have been shown to induce pro-inflammatory cytokine production and activate synovial fibroblasts (SF) and articular chondrocytes, resulting in increased cell proliferation and matrix metalloprotease expression. These combined processes eventually lead to an imbalance in anabolic versus catabolic mediators of cartilage turnover and ultimately to extracellular matrix degradation. At the molecular level, BCP crystals were shown to activate protein kinase C, ERK1/2, MAP kinase and NF-κB in SF. Recent studies have demonstrated that both mechanical stress and activation of purinergic receptors drives the release of nucleotides such as ATP and UTP from osteocytes which then activate signalling pathways that can negatively impact bone remodelling. It has also been proposed that particulate matter such as alum and monosodium urate (MSU) crystals drive interleukin-1 production via ATP release and purinergic signalling. Furthermore, it has been reported that the P2Y6 receptor and its downstream signalling molecule phospholipase C (PLC) mediate the inflammatory responses induced by MSU crystals. In this study, we sought **1)** to determine whether BCP crystals induce the release of ATP from murine macrophages and **2)** to investigate the role of purinergic signalling in BCP-induced inflammation in order to identify novel targets for the treatment of BCP-related arthropathies, such as OA.

Methods: Murine macrophages were stimulated with BCP crystals over the course of 5 hours, and ATP release was measured using the ATPlite luminescence assay system. BCP crystals are known to drive IL-1β production in vitro. Therefore in order to investigate the role of purinergic receptors in BCP-induced cell activation, murine macrophages were primed with lipopolysaccharide, a toll-like receptor agonist prior to treatment with the broad-spectrum P2 receptor inhibitor oATP, the P2Y6-specific inhibitor MRS2578, or the PLC inhibitor U73122. Alternatively, siRNA was used to knock down the expression of P2Y6. The cells were then stimulated with BCP crystals and IL-1β production was quantified by enzyme linked immunosorbent assay (ELISA).

Results: We have found that physiological concentrations of BCP crystals (50μg/ml) induced the release of approximately 100 nM ATP by murine macrophages, a concentration sufficient to activate purinergic receptors. Inhibition of the P2Y6 receptor or PLC dose-dependently reduced IL-1β production following BCP stimulation, with full abrogation observed with the top dose of each inhibitor. Furthermore a 40% knockdown of the P2Y6 receptor led to an equal reduction in BCP-induced IL-1β production.

Conclusion: Based on these studies we propose that nucleotides released from BCP-activated cells act in an autocrine or paracrine manner via purinergic receptors to enhance BCP-induced inflammation. Released nucleotides may also act on neighbouring osteoblasts/osteoclasts to impact on bone remodelling.

Rates of Renal Remission with Immunosuppressives in Lupus Nephritis: A Systematic Review and Network Meta-Analysis. Jasvinder Singh[1], Ahmed Kotb[2], Alomgir Hossain[2], Amy Mudano[3] and George Wells[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Ottawa, Ottawa, ON, [3]The University of Alabama at Birmingham, Birmingham, AL, [4]University of Ottawa Heart Institute, Ottawa, ON.

Background/Purpose: To compare renal remission rates with immunosuppressives by performing a systematic review and network meta-analyses (NMA) of RCTs of lupus nephritis.

Methods: We performed a systematic review and NMA of randomized trials of patients with lupus nephritis, who were treated with immunosuppressant alone or in combination with other immunosuppressant or biologics (such as rituximab or belimumab) compared with another immunosuppressant with/without biologic or placebo. We compared the rates of complete renal remission or partial renal remission. Complete renal remission was usually defined as return to normal serum creatinine, urine protein $\leq$0.5 g/d, and inactive urinary sediment ($\leq$5 white blood cells per high-power field and $\leq$5 red blood cells per high-power field, and a reading of lower than 2+ on dipstick and absence of red cell casts). Partial remission was variably defined in the studies, with the most common definition of improvements in urinary parameters between 25–50%. Bayesian NMA were conducted. A binomial likelihood model, which allows for the use of multi-arm trials was used. Informed priors were assigned for basic parameters and odds ratios, as well as risk ratios and risk differences, and 95% credible intervals were modeled using Markov chain Monte Carlo methods. Brooks-Gelman-Rubin plots were used to assess model convergence. Model fit was examined using the deviance information criterion (DIC) and the residual deviance. The degree of inconsistency was assessed by comparing statistics for the deviance and deviance information criterion in fitted consistency and inconsistency models. In further sensitivity analyses, fixed effects models and models using vague priors were also conducted.

Results: 39 RCTs with 2,730 patients provided data; 35 were 2-arm RCTs and 4 were 3-arm RCTs. Comparisons showed that cyclophosphamide (CYC), mycophenolate mofetil (MMF), tacrolimus (TAC), cyclosporine (CSA) and MMF+TAC were superior to prednisone alone in achieving renal remission (**Table 1**). Compared to MMF, CYC HD and PRED were less likely to lead to renal remission. Compared to AZA, TAC and MMF+TAC were superior. MMF+TAC was superior to MMF-AZA, CYC-AZA, CYC HD, CYC LD MMF+RTX and LEF in leading to renal remission.

Conclusion: Our NMA compared the ability of immunosuppressive medications and combinations to lead to remission (complete and/or partial) in RCTs of patients with lupus nephritis. Comparative effectiveness of medications is now available to assist treatment decision-making, with the caveats of trial heterogeneity and indirect comparisons.

Table 1 Comparison of various drugs for the renal remission (complete or partial) in patients with lupus nephritis showing statistically significant results

Treatment	Reference	Odds Ratio (95% Credible Interval [CrI])	Relative Risk (95% CrI)	Risk Difference % (95% CrI)

Time Trends in Comorbidities Among Patients with Rheumatoid Arthritis Compared to the General Population. Cynthia S. Crowson, John M. Davis III, Brittny T. Major, Eric L. Matteson, Terry M. Therneau and Sherine E. Gabrriel. Mayo Clinic, Rochester, MN.

Background/Purpose: Rheumatoid arthritis (RA) related comorbidities are major determinants of morbidity and mortality. Little is known regarding the trends in these conditions. The purpose of our study was to examine whether the risk of comorbidities in RA patients has changed in recent years.

Methods: A population-based inception cohort of RA subjects who fulfilled 1987 ACR criteria for RA in 1980–2007 and a comparison cohort of subjects without RA of similar age and sex were assembled and followed until death, migration, or 7-1-2012. The presence of Charlson comorbidities (i.e., myocardial infarction, heart failure [HF], peripheral vascular disease [PVD], cerebrovascular disease, dementia, chronic obstructive pulmonary disease [COPD], ulcer, liver disease, diabetes mellitus, chronic kidney disease [CKD], and cancer) was ascertained by medical record review. Chi-square tests were used to assess trends in comorbidities present at baseline (i.e., RA incidence/index date) according to time period (1980–84 vs. 1995–2007) in each cohort. Cumulative incidence adjusted for competing risk of death was used to assess the risk of developing comorbidities during follow-up.

Results: The study included 813 RA patients and 813 non-RA subjects. Age and sex were similar in both cohorts and both time periods (mean age 56 [SD 16] years, 69% women). More patients with incident RA in the 1995–2007 time period had ≥1 Charlson comorbidity at baseline than those in the 1980–1994 time period (56% vs 44%; $p<0.001$). However, this trend was similar in the non-RA cohort (50% vs. 38%; $p<0.001$). Comorbidities that increased over time included cancer, CKD, COPD and liver disease in both cohorts, PVD and cerebrovascular disease in RA and HF in non-RA. However, among those with no comorbidities at baseline, the cumulative incidence of ≥1 Charlson comorbidity by 10 years later was lower among those with incident RA in the 1995–2007 time period than the 1980–1994 time period (22% vs. 27%; $p=0.008$), with similar findings for non-RA (17% vs. 25%; $p=0.03$). Considering both prevalent and incident comorbidities, there was no significant change over time in the cumulative incidence of ≥1 comorbidity at 10 years in the RA (76% in 1995–2007 vs. 71% in 1980–1994; $p=0.11$) or non-RA cohorts (67% in 1995–2007 vs. 64% in 1980–1994; $p=0.07$).

Conclusion: Although the prevalence of comorbidities at baseline was higher in more recent years in both the RA and non-RA cohorts, the rate of occurrence of new comorbidities has declined over time. This may indicate earlier recognition and improved management of comorbidities both in the RA and in the general population.

Co-Morbidity Is Associated with Disease Severity in Early Rheumatoid Arthritis. Christopher Sparks[1], Aleena Abdullah[1], Steven Zhao[2], Cristina Estrach[2] and Nicola Goodson[1]. [1]University of Liverpool, Liverpool, United Kingdom, [2]University Hospital Aintree, Liverpool, United Kingdom.

Background/Purpose: Co-morbidity has been shown to increase length of hospital stay and mortality in hospitalised patients. However, in early rheumatoid arthritis (eRA) co-morbidity may confound treatment response and affect disease severity measures (disease activity scores (DAS28) and health assessment questionnaire (HAQ)).

The study aims were to assess:

1) Whether self reported comorbidity correlates with baseline DAS28 & HAQ in an eRA cohort?

2) Does co-morbidity burden predict DAS28 remission and HAQ after 1yr of treatment?

Methods: At time of eRA diagnosis, patients completed a modified validated self-reported 14 item comorbidity questionnaire (1). Each co-morbidity item scores 1 point (maximum score 14). Use of treatment or associated impairment contributes to a weighted co-morbidity score (Maximum score 36). The number of comorbidity items were divided into 3 categories: low≤1, medium=2, & and high ≥3. Correlation between co-morbidity number and weighted score and DAS28 and modified mHAQ were assessed at baseline using Spearman's rank correlation.

Logistic regression (adjusting for age, gender, smoking, obesity, & seropositive status) were used to explore whether baseline co-morbidity:1) number & 2) weighted score, predicted 1yr DAS28 remission & high HAQ (defined as >1).

Results: 147 eRA patients, with symptom duration less than 12 months, mean age 58.1yrs & 67% female, had complete baseline and 1yr data. All were treated with synthetic DMARDS following a treat to target regime.

At baseline, comorbid disease was reported by 107 (72.8%) with median number of 1 [IQR 0, 3] comorbid conditions in addition to RA. The median weighted co-morbidity score was 2 [IQR 0, 3]. Patients reporting ≥2 co-morbidities had higher prevalence of high HAQ>1 and DAS28> 5.1. Modest correlation was observed between the number of co-morbidities and 1)DAS28- rho 0.23, ($p<0.05$) and 2)HAQ- rho 0.31($p<0.01$).

After 1 year, 77 (52.4%) achieved DAS28 1. Reporting 2 or more co-morbidities was associated with reduced rates of DAS28 remission and high HAQ score at 1 year (table 1). Increasing numbers of co-morbidity and use of the co-morbidity weighted scores did not increase the strength of association.

Table1:- Predictors of disease severity after 1 year

Comorbidity		n	DAS28<2.6 ORadj (95%CI)	1 year HAQ >1 ORadj (95%CI)
Number	0–1 (ref)	90	1.0	1.0
	2	23	0.35 (0.13, 0.94)	2.16 (0.63, 7.31)
	>=3	34	0.46 (0.19, 1.56)	5.16 (1.64, 16.24)
Weighted	0–1 (ref)	58	1.0	1.0
	2–3	44	1.31 (0.57, 3.03)	2.48 (0.79, 7.77)
	>=4	45	0.30 (0.12, 0.74)	4.11 (1.26, 13.3)

Conclusion: Self reported comorbid disease burden predicts disease activity and level of disability in an eRA cohort after 1 year of treatment. Weighting co-morbidity for severity and function do not increase the strength of association with 1 year outcomes in early RA. Adjusting for the confounding effects of co-morbidity is important when assessing response to treatment. Use of self reported co-morbidity questionnaires appear to be an acceptable method of quantifying co-morbidity in routine rheumatology outpatient departments.

Rheumatoid Factor, Not ACPA, Is Associated with Disease Activity in Rheumatoid Arthritis. Daniel Aletaha[1], Farideh Alasti[1] and Josef S. Smolen[2]. [1]Medical University of Vienna, Vienna, Austria, [2]PsAID taskforce, EULAR, Zurich, Switzerland.

Background/Purpose: To investigate the associations of rheumatoid factor (RF) and autoantibodies against citrullinated proteins (ACPA) with rheumatoid arthritis (RA) disease activity.

Methods: We analyzed the association of RF and ACPA on individual and composite measures of disease activity at baseline in four recent randomized controlled clinical trials (RCT) using stratified and matched analyses. Data included one RCT in early RA patients on rituximab, RTX; three on golimumab, GOL, in early and established populations.

Results: A total of 2118 patients were analyzed in the four studies. In both, the RTX and the pooled GOL cohorts, RF+ patients, regardless of ACPA status, had the highest levels of baseline disease activity, while ACPA+ patients had similar or lower disease activity than ACPA- patients, regardless of RF status (See Figure, using Simplified Disease Activity Index, SDAI).

When patients from the RTX trial were matched for the levels of ACPA, as well as for age, gender, and duration of RA (n=29), SDAI levels were 49.3±14.5 in the presence of high positive RF, and 42.3±12.7 in patients who were RF negative; this was the opposite for ACPA in patients matched for RF levels and the same covariates: high positive ACPA: 45.8±14.8; ACPA negative: 53.1±16.5 (p=0.025). These trends were supported in the respective analyses in the pooled GOL trials (RF high vs. neg.: SDAI of 36.8 vs. 33.1; ACPA high vs. neg.: 37.0 vs. 39.5), although the difference did not reach statistical significance.

Conclusion: The data suggest that the presence of RF rather than ACPA is related to higher disease activity. When matched for RF levels, ACPA had little influence on disease activity, if at all, with the tendency towards lower disease activity for ACPA+ patients.

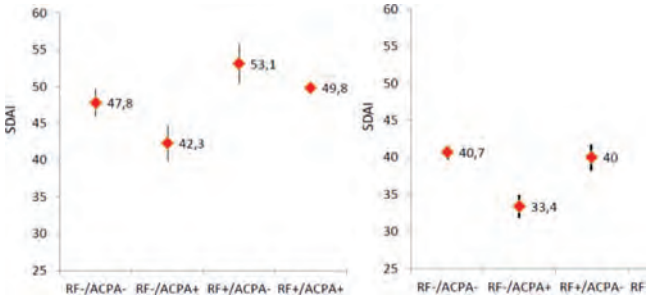

Figure. Simplified Disease Activity Index at baseline of the rituximab trial (left panel) or the pooled golimumab trials (right panel) by groups of RF/ACPA status.

Identifying Flare in Rheumatoid Arthritis (RA): Performance of the Flare-Assessment in RA (FLARE) Questionnaire in a US Population. Elena Myasoedova[1], Cynthia S. Crowson[1], Bruno Fautrel[2], Francis Guillemin[3], Eric L. Matteson[1] and Sherine E. Gabriel[1]. [1]Mayo Clinic, Rochester, MN, [2]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France, [3]Nancy University Hospital, Nancy, France.

Background/Purpose: Flare is an important aspect of rheumatoid arthritis (RA) patients' disease experience with a crucial impact on quality of life and well-being. The flare-assessment in RA (FLARE) questionnaire was developed for the detection of flares based on the joint symptoms and systemic impact of RA disease over the most recent 3 months. We aimed to assess the performance of FLARE questionnaire in relation to clinical and laboratory measures of RA disease activity/severity in RA patients.

Methods: Patients with RA (age≥18 yrs; 1987 ACR criteria) participating in an ongoing population-based cohort study completed FLARE, Bristol Rheumatoid Arthritis Fatigue (BRAF) questionnaires and Health Assessment Questionnaire (HAQ) with visual analogue scale for pain (VAS pain) on 100mm scale during a study visit (2012–2014), and submitted a blood sample for C-reactive protein (CRP) and Interleukin-6 (IL6) assessment. Retrospective medical records review was performed to collect prior history of flares (as per OMERACT 9 definition), as well as physician clinical assessment (PCA) and patient global assessment (PGA) of RA disease activity on 100mm scale for the most recent clinical visit prior to the study visit. The previously validated RA medical Records-Based Index of Severity (RARBIS) and Claims-based Index of RA Severity (CIRAS) were used to estimate RA severity based on the recent year of data on RA disease characteristics and medications. Pearson's correlation was used to examine relationships between the variables.

Results: The study included 160 RA patients (mean age 62.6 years; 74% female; mean RA duration 14.7 yrs). The mean standard deviation (SD) of the overall FLARE score was 2.47 (2.54) on 0–10 scale; 1.82 (2.43) for systemic subscale; 3.26 (3.08) for joint subscale. Mean (SD) CRP was 4.15 (5.8) mg/L; IL6 3.48 (5.52) pg/ml; HAQ 0.64 (0.62); VAS pain 28.6 (24.6). FLARE score overall and both subscales were statistically significantly correlated with BRAF, HAQ, VAS pain, IL6 and PGA, but not PCA (Table). CRP was significantly correlated with overall FLARE score and systemic, but not joint subscale. There was a statistically significant correlation of FLARE overall and its joint subscale with RARBIS, but not CIRAS. No significant correlation of FLARE was found with any history of prior flare. In a subset of patients (n=28) who had a clinical visit within 3 months of the study visit, being in a flare at that visit correlated with FLARE overall (r=0.41, p=0.03) and joint subscale (p=0.51, p=0.006), but not systemic subscale (r=0.26, p=0.18).

Conclusion: The FLARE score is highly correlated with other measures of RA patients' self-report, i.e. BRAF, HAQ, VAS pain and PGA; with systemic inflammatory markers, RARBIS and flare at the most recent visit. Our findings suggest that FLARE questionnaire may be a reliable tool for RA flare detection reflecting clinical and laboratory aspects of RA disease activity.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disabling disease with significant impact on the quality of life (QOL) of patients. Since clinical features are different in RA patients according to the disease course, various factors might be influence on the low QOL depending on the phase of the disease. We aimed to explore the associating factors for impairment on quality of life in either early RA or established RA patients.

Methods: A total of 5,361 RA patients in the KORean Observational study Network for Arthritis (KORONA) were included in this study. The EuroQol-5 dimension (EQ-5D) is a widely used generic QOL instrument, and it allows for negative utility values, which correspond to health states worse than death. We defined the worst QOL as EQ-5D score < 0, a state worse than death. We classified RA patients according to their disease duration: early RA patients (n=714) as patients whose disease duration was less than 1 year and patients with longer disease duration formed the established RA patients (n=4,647). The distribution of EQ-5D in both groups of early and established RA patients were compared, and the possible determinants for negative EQ-5D score in each group were explored using the logistic regression analyses.

Results: The average EQ-5D score was not different between early and established RA patients (0.69±0.26 vs. 0.68±0.27, p=0.19), and the proportions of the negative EQ-5D score were comparable in both groups.

(4.9% vs. 4.6%, p=0.76). The most important determinant for worst QOL in early RA patients was high functional disability (OR 17.3, CI 6.0–50.2). In addition, sleep disturbance (OR 1.02, CI 1.01–1.04) and fatigue (OR 1.04, CI 1.01–1.07) were another factors for worst QOL in early RA patients. In established RA patients, though the odds ratio was lower than early RA patients, high functional disability (OR 10.0, CI 7.1–14.3), sleep disturbance (OR 1.01, CI 1.00–1.01) and fatigue (OR 1.03, CI 1.02–1.04) were still associated with impairment on QOL. In addition, higher disease activity (OR 1.28, CI 1.08–1.51) increased risk for worst QOL but regular exercise (OR 0.66, CI 0.43–0.99) showed protective effect in established RA patients.

Conclusion: The functional disability, sleep disturbance and high fatigue level were significantly associated with the impairment on QOL in both early and established RA patients, while high disease activity had significant effects on the worst QOL only in patients with established RA. Regular exercise might have a protective effect against the impairment on QOL in established RA patients.

Table 1. Determinants of health state worse than death (EQ-5D<0) in early and established RA patients.

°°	Early RA (n=714)	Established RA (n=4,647)
Age	1.00 (0.95–1.06)	1.01 (0.99–1.03)

Work-Related Behavior and Experiences in Patients with Rheumatoid Arthritis.

Jutta G. Richter[1], Thomas Muth[1], Ralph Brinks[2], Tobias Koch[1], Peter Angerer[1] and Matthias Schneider[1]. [1]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [2]Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany.

Background/Purpose: Work-related behavior and experiences are discussed to be either risk factors or resources for individual‘s health. Diseases and related changing working conditions and/or experiences might have additional effects. The objective of the study was to describe work-related attitudes and to examine their relationship to clinical data and health in patients (pts) with rheumatoid arthritis (RA).

Methods: Self-reported (outcome) questionnaires were applied to RA pts and controls (c) not suffering from rheumatic diseases, both groups were capable for work. The ’AVEM’ questionnaire assesses eleven health relevant dimensions via 66 items and thus determines the personal attitude towards work, see Table 1. The dimensions (d) are attributable to three areas: work engagement (d 1–5), resistance to stress (again d 5; 6–8) and emotions accompanying occupation (d 9–11). Pts self-reported clinical data. Ethics committee approval had been obtained.

Results: 267 pts (85.0% female (f)) and 177 c (90.3% f) contributed data. Pts’ mean age was 47.7±10.0 (c 42.8±9.8) years, mean disease duration 9.0±8.0 years, and the mean HAQ 1.1±0.5 (c 0.4±0.1). 85.5% of the pts self-reported at least one comorbidity (range 0–8, c 45.2%, range 0–4). In pts 81.7% received at least one immunosuppressive medication (range 0–6), 43.8% steroids ≤7.5mg, 9.0% steroids >7.5mg and 61.4% NSAIDS.

AVEM scales are depicted in Table 1, RA pts scored significantly different to c in six dimensions. Pts scored similar to c in work engagement scales and resignation tendencies, but showed less capability for emotional distancing, lower balance and mental stability, lower satisfaction with work & life and lower experiences of social support. OR indicate whether pts of the T- group (see table 1) have an increased risk for lower self-rated health status compared to T+.

Table 1 AVEM dimensions in c and RA pts, *mean±standarddeviation (SD), T+ and T- Percentage of pts deviating > 1 SD from mean of c, + Wilcoxon test, # Fisher’s exact test

AVEM dimensions	c*	RA*	p-value+	T+	T−	OR	p-value#
1. Subjective significance of work	15.2 ± 5.0	16.0 ± 5.0	p>0.05	17.4	15.1	0.86	p>0.05
2. Professional ambition	16.5 ± 5.0	16.2 ± 4.9	p>0.05	12.8	16.7	2.42	p>0.05
3. Tendency to exert	17.9 ± 5.1	18.7 ± 5.2	p>0.05	17.7	14.2	0.48	p>0.05
4. Striving for perfection	21.8 ± 4.5	21.6 ± 4.5	p>0.05	12.3	15.0	0.42	p>0.05
5. Emotional distancing	20.6 ± 5.0	19.0 ± 5.1	0.0019	9.3	26.7	3.08	0.0295
6. Resignation tendencies	15.4 ± 4.2	16.0 ± 5.2	p>0.05	24.3	20.0	0.52	p>0.05
7. Offensive coping with problems	22.0 ± 3.3	20.7 ± 3.6	0.0003	9.6	30.4	2.23	p>0.05
8. Balance and mental stability	20.3 ± 4.3	19.2 ± 4.6	0.0194	12.4	28.3	3.73	0.0044
9. Satisfaction with work	22.4 ± 4.1	20.9 ± 4.5	0.0008	8.6	31.2	2.34	p>0.05
10. Satisfaction with life	22.9 ± 3.9	20.4 ± 4.4	0.0000	7.7	30.4	9.21	0.0000
11. Experience of social support	23.5 ± 4.3	22.5 ± 4.5	0.0266	11.2	24.4	2.74	0.0367

Conclusion: This is the first study applying AVEM to RA pts. Results detected domains that are potentially modifiable and should be considered in clinical management. Resistance to stress and emotional issues should be predominantly targeted. Further study analyzes will address correlations to other study parameters and confounding factors. Thus, appropriate strategies that promote healthy personal attitudes and equip pts with adequate supporting coping skills that prepare them for the challenges at their daily work might and should be developed.

Levels of Fatigue Are Dependent on Country of Residence in Rheumatoid Arthritis: An Analysis Among 3920 Patients from 17 Countries.

Monika Hifinger[1], Polina Putrik[2], Sofia Ramiro[3], Maxime Dougados[4], Laure Gossec[5], Andras Keszei[6], Ihsane Hmamouchi[7] and Annelies Boonen[2]. [1]University of Maastricht, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Amsterdam Rheumatology Center/ University of Amsterdam, Amsterdam, Netherlands, [4]Paris Descartes University, Paris, France, [5]Pierre et Marie Curie University, Paris, France, [6]Uniklinik RWTH Aachen University, Aachen, Germany, [7]Mohamed V Souissi University, Rabat, Morocco.

Background/Purpose: For patients with rheumatoid arthritis (RA), fatigue is an important aspect of disease which impacts quality of life. However the complex relationship between fatigue and either disease-related or external factors remains unclear. Country of residence as a surrogate for a variety of cultural, economic and linguistic aspects might play a role, but this has never been formally explored. The aim of the study was to investigate how country of residence influences level of fatigue in addition to socio-demographic and objective disease- characteristics.

Methods: Data from a multi-national study were used (COMORA). Fatigue was measured using 0–10 VAS scale. A multivariable linear regression model (outcome fatigue) was computed using manual forward selection. Contribution of socio-demographic factors (age, gender, education, marital status, work status), comorbidities (Wolfe-Michaud index), smoking status, clinical disease characteristics (tender and swollen joints (TJC, SJC), erosions in hands or feet (yes/no), erythrocyte sedimentation rate) and medication (all type of DMARDs, steroids and NSAIDs) was tested. Country of residence was added using the country with the highest level of fatigue (Netherlands) as reference. In a second step, sensitivity analyses were

developed replacing country of residence by country specific variables including gross domestic product (GPD), human development index (HDI), a climate indicator (latitude) and income inequality (gini index).

Results: 3920 patients from 17 countries (range: 30 to 411, mean age 56 years (SD 13), 82% female) were included. Mean fatigue across countries was 4.13 (SD 2.8). 32.8% of all patients had fatigue scores >5. In multi-variable regression, female gender (βf=1=0.70, CI 0.49/0.91) and a higher comorbidity score (β=0.32, CI 0.24/0.39) were associated with higher fatigue. TJC and SJC had limited influence on fatigue with higher contribution of TJC (βTJC=0.14, CI 0.12/0.16 and βSJC=0.05, CI 0.02/0.08). When adding individual countries, the contribution was significant and increased the overall model fit (Δ R2=0.08). Country differences in fatigue varied between -3.9 for Venezuela vs Netherlands (NL) and -0.6 (Italy vs NL) after adjustment for individual factors. When country was replaced by GDP, HDI, latitude or gini index, only GPD and HDI index contributed significantly. The overall model improvement was lower compared to country (R2 GDP=0.14, R2 HDI=0.18, R2 country=0.20). Interactions were not significant.

Conclusion: While individual demographics and objective clinical measures of disease have only a small influence on the experience of fatigue, the country of residence adds substantially. Economic and development status of the country only explain small parts of the variation among countries. More research is needed to identify these unknown aspects of RA related fatigue, e.g. cultural (attitudes, believes), linguistic or work related factors might play a role.

1059

Patients with RA from Wealthier Countries Perform Better on Clinical Disease Activity Measures, but Tend to Show Worse Person Reported Outcomes. Polina Putrik[1], Sofia Ramiro[2], Andras Keszei[3], Ihsane Hmamouchi[4], Maxime Dougados[5], Monika Hifinger[6], Laure Gossec[7] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [3]Uniklinik RWTH Aachen University, Aachen, Germany, [4]Mohamed V Souissi University, Rabat, Morocco, [5]Paris Descartes University, Paris, France, [6]University Hospital Maastricht, Maastricht, Netherlands, [7]Pierre et Marie Curie University, Paris, France.

Background/Purpose: Inequalities in health between low and high income countries are often reported, but it is not known whether clinical disease activity measures ("objective") and person reported outcomes ("subjective") follow the same patterns in patients with rheumatoid arthritis (RA). The objective of this study was to investigate the patterns in RA health outcomes ("objective" vs "subjective" outcomes) across countries with different level of socio-economic development.

Methods: Data from a cross-sectional multinational (17 countries) study COMORA was used. Contribution of gross domestic product (GDP) to clinical disease activity measures (DAS28, total joint count (TJC), swollen joint count (SJC), and erythrocyte sedimentation rate (ESR)) and person reported outcomes (Patient global assessment (PatGA) (0–10), fatigue (0–10), Physician global assessment (PhysGA) (0–10) and function assessed with health assessment questionnaire (HAQ) (0–3)) was explored. All models were adjusted for potentially relevant confounders, including age, gender, education and comorbidities (Wolfe-Michaud index). Models were computed with and without adjustment for current RA medication (steroids, NSAIDs and DMARDs). Additionally, models with person reported outcomes were adjusted for the presence of erosive disease, TJC, SJC, and ESR. GDP was dichotomized in low and high GDP countries (with a cut-off of 20,000 international dollars per capita (adjusted to purchasing power parity), which by data inspection was the one that discriminated best both groups).

Results: A total of 3920 RA patients from 17 countries (range 30–411) were included in COMORA (mean age 56 y.o. (SD13), 82% females). DAS28 varied between 5.3 (Egypt) and 2.6 (Netherlands), HAQ ranged between 0.7 (Taiwan) and 1.5 (Netherlands). Venezuela had the lowest average score on fatigue (1.7) and Netherlands scored on average highest on fatigue (5.0). In models adjusted for medication, low GDP countries had on average 0.94 higher DAS28, 2.84 and 1.85 higher scores on TJC and SJC, respectively, and 11.50 higher ESR compared to high GDP countries. At the same time, patients from low GDP societies had a 0.41 and 0.21 lower score on patient and physician global assessment, respectively and 0.96 lower score on fatigue compared to high GDP countries. HAQ was 0.14 higher in countries with low GDP (Table 1).

Table 1. Association between clinical disease activity measures and person reported outcomes with GDP

	Clinical disease activity measures				Person reported outcomes			
	DAS28	TJC	SJC	ESR	PatGA	Fatigue	PhyGA	HAQ
GDP (low vs. high) (Adjusted model,including medication)	0.94*	2.84*	1.85*	11.5*	−0.41*	−0.96*	−0.21*	0.14*
GDP (low vs. high) (Adjusted model, excluding medication)	0.97*	2.92*	1.75*	11.8*	−0.44*	−1.01*	−0.25*	0.11*

*p<0.05

Conclusion: Patients from countries with lower socio-economic welfare score worse on clinical measures of disease activity (DAS28 and its components), however, tend to score better on person reported outcomes (patient global assessment and fatigue) for the same level of objective disease activity. Cultural factors that may play a role in reporting of subjective outcomes should be further explored.

Musculoskeletal Surgeries and Procedures in Patients with RA: Results from a UK Retrospective Study. H Cawston[1], F Bourhis[1], T Le[2] and E Alemao[3]. [1]OptumInsight, Nanterre, France, [2]Bristol-Myers Squibb, Hopewell, NJ, [3]Bristol-Myers Squibb, Princeton, NJ.

Background/Purpose: Musculoskeletal surgeries and procedures substantially improve the quality of life of patients with RA, but represent an important burden in terms of medical costs. The aim of this study was to assess whether recent advances in RA treatment had an impact on long-term surgery rates in the UK.

Methods: A retrospective cohort study was conducted from 1997 to 2010, using Clinical Practice Research Database General Practice Online Data (GOLD) and Hospital Episode Statistics (HES) data. RA population was defined as all patients presenting with one or more RA read code after 01/01/1988 (index code), with no RA or juvenile RA codes before the RA index code. Patients were required to have a minimum of 12 months of data before the first RA code and to have no psoriatic arthritis-related codes over the entire period. Date of onset of disease was defined as date of first RA-related code. RA patients were matched 4:1 to non-RA patients based on their year of entry in the GOLD database, cardiovascular (CV) risk category (NCEP classification), CV treatment status, and a risk score measuring the probability of having RA. The index code of non-RA patients was defined as the date of observation closest to the index code of their matched RA patient. Surgeries such as total joint arthroplasties (TJA), non-TJA, TJA-associated procedures, as well as other orthopedic procedures were identified in HES and GOLD databases using operating procedure codes and read codes. Incidence rates (IRs) were estimated over the study period and by time since diagnosis in both cohorts. Time-to-first-surgery curves in all RA patients as well as stratified by terciles of CRP measured at diagnosis were based on Kaplan–Meier (KM) estimates. **Results:** Overall, 14,181 patients with RA were identified and matched to 49,935 non-RA patients. IRs in RA patients, relatively constant up to 2003, sharply increased in 2004 (IR=4.0/100 person-years; 95% CI: 3.5, 4.3) before a steady decrease was observed up to 2006 (3.1 [2.8, 3.5]). This trend was driven by TJAs, for which an IR of 2.7 (2.3, 3.0) was observed in 2010. Majority of TJAs involved the knee (43.5%) and hip (40.2%). However, IRs of all surgeries increased from 0.1 (0.0, 0.2) to 1.4 (1.3, 1.6) from 1997 to 2010 in non-RA patients. Based on the KM analysis, the probabilities of having a surgery at 3, 5 and 10 years were 5.5%, 8.6% and 17.3%, respectively. Patients in the higher tercile of CRP at diagnosis were at higher risk of first surgery than the two lower terciles (log-rank test between three groups: p=0.0007).

Conclusion: Decrease in the IRs of musculoskeletal surgeries in 2005/2006 could be attributed to greater availability of biologic therapies. However, these rates have not decreased in recent years, suggesting there is an unmet need for more effective therapies. CRP levels at diagnosis were associated with higher risk of surgeries, suggesting that therapies reducing CRP may be effective to further lower surgical rates.

1061

How Does Rheumatoid Arthritis Disease Activity Affect Development of Upper Cervical Lesions? a Retrospective Study of Cervical Spine X-Rays Combined with a Cohort Study in Rheumatoid Arthritis Patients.

Osamu Ishida[1], Katsunori Ikari[1], Eisuke Inoue[1], Atsuo Taniguchi[2], Shigeki Momohara[1] and H. Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: It is believed that 40% to 80% of patients with rheumatoid arthritis (RA) have cervical spine lesions. In particular, atlanto-axial subluxation (AAS) and vertical subluxation (VS) are clinically important. However, little is known about how disease activity and other factors are involved in their development. The aim of this study is to identify risk factors for upper cervical lesions in RA patients.

Methods: IORRA is a prospective observational cohort study of Japanese patients with RA established in 2000 at the Institute of Rheumatology, Tokyo Women's Medical University. Approximately 5,000 patients with RA are involved in each phase of the biannual survey. In our department, when RA patients schedule surgery, dynamic X-rays of the cervical spine are conventionally taken to assess instabilities in case tracheal intubation for general anesthesia is required. In this study, we evaluated these X-rays and investigated their relevance to the integrated data in the IORRA cohort study. Inclusion criteria were: (1) scheduled surgery in our department from 1 April 2010 to 31 March 2013, and (2) registration into the IORRA cohort study within 2 years from onset of RA. Fifty-seven patients were selected, with the following characteristics: women, 49 (85.9%); median onset age, 56 years; disease duration, 8.5 years; and DAS28, 4.3. Cervical X-rays were measured two times by one board-certified orthopedic surgeon and mean values were generally used. To assess AAS, the atlantodental interval (ADI) was measured, and for VS, the Redlund-Johnell method (R-J) was adopted. AAS was defined as ADI≧3mm; VS was defined as 34mm≦R-J in males, 29mm≦R-J in females. For statistical analysis, regression analysis was used for ADI and R-J, and logistic regression analysis was used for AAS and VS.

Results: Median ADI was 2.8mm, and R-J was 34mm. Twenty-seven patients had AAS (48.2%) and twelve had VS (21.4%). No significant correlation between ADI and R-J was observed ($\rho = -0.025$, $p = 0.8$). By univariate regression analysis, gender ($p = 0.004$), height ($p < 0.0001$), body weight ($p = 0.03$), total methotrexate dose ($p = 0.002$), and DAS28 maximum value ($p = 0.001$) and integrated value ($p = 0.003$) during the IORRA enrollment period were significantly relevant to R-J. Multivariate regression analysis revealed height ($\beta = 0.59$, 95%CI: 0.011–0.25, $p < 0.0001$) and maximum DAS28 ($\beta = -0.27$, 95%CI: -2.4- to -0.33, $p = 0.011$) to be significantly associated with R-J. No factors were significantly associated with ADI. By univariate logistic regression analysis, maximum DAS28 (OR=2.4, 95%CI: 1.3–5.2, $p = 0.01$) was significantly associated with VS. Total duration of biological drug use (OR=1.2, 95%CI: 1.0–1.6, $p = 0.04$) was also significantly associated with AAS, but this involved development and was not thought to be causal.

Conclusion: Higher RA disease activity appears to be a significant risk factor for VS development and severity, regardless of integrated value of disease activities. We suggest that RA disease activity should be tightly controlled to prevent development of upper cervical lesions, particularly VS.

Impact of Obesity on 1 Year Outcomes: Results from the Meteor Foundation International Rheumatoid Arthritis Cohort.

Christopher Sparks[1], Robert Moots[1], Eftychia Psarelli[1], Tom Huizinga[2] and Nicola Goodson[1]. [1]University of Liverpool, Liverpool, United Kingdom, [2]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Increased adiposity is associated with increased production of pro-inflammatory adipokines and raised inflammatory markers. As a result, standard disease activity scores (DAS) may be greater in obese rheumatoid arthritis (RA) patients, with important implications for their treatment in modern target based regimens. There is limited longitudinal evidence assessing the impact of obesity on DAS. We sought to investigate the influence of obesity on 1 year outcomes in a large international RA cohort.

Methods: Patients with a clinical diagnosis of RA with complete 6 and 12 month follow up from the METEOR Foundation International RA database were identified. The cohort was divided into early RA (eRA, disease duration <12 months) and established RA subgroups (disease duration ≥12 months). Patient demographics, DAS28, Health Assessment Questionnaire (HAQ) score and BMI were collected from the first recorded visit on the database. The cohorts were stratified into 4 categories by BMI: 1) Underweight <18.5, 2) Normal 18.5–24.9, 3) Overweight 25–29.9 and 4) Obese ≥30. Outcomes of interest were: good EULAR response (DAS28), low disease activity (DAS28 <3.2) and DAS28 remission (DAS28 <2.6) at follow up. Associations between BMI category and outcome measures at follow up (6 and 12 months) were explored using multivariate logistic regression analysis for both the eRA and established RA cohorts, adjusting for age, gender and smoking status.

Results: 1,525 patients with complete data were identified. Mean age was 53.2 (SD 13.2) and 78.8% were female. The eRA and established RA subgroups contained 641 and 884 patients respectively, with a similar distribution of BMI categories seen in both groups (mean BMI 26.8 (SD 5.6) and 26.8 (SD 5.07) respectively).

At baseline median DAS28 scores for each BMI category were similar to those described for this cohort previously.[1]Logistic regression analysis found no associations between overweight or obese BMI categories and clinical outcomes at 6 or 12 month follow up in the eRA subgroup. However, underweight patients had a lower probability of achieving low disease activity at 6 and 12 months (OR 0.24 (95%CI 0.07, 0.85) and OR 0.14 (95%CI 0.03, 0.62) respectively).

Analysis of the established RA subgroup identified obese patients to be significantly less likely to exhibit low disease activity at 6 and 12 month follow up, or disease remission at 12 months follow up (Table 1).

Table 1: Multivariate adjusted offs ratio (95% Confidence Intervals) for association between disease activity and BMI category for the established RA cohort.

Variable	Underweight (n=12)	Normal (r) (n=359)	Overweight (n=313)	Obese (n=200)
Good Response 6 months	0.42 (0.05, 3.37)	1.0	0.90 (0.60, 1.35)	0.59 (0.36, 0.97)
DAS28 <3.2 at 6 months	1.23 (0.38, 3.99)	1.0	0.83 (0.60, 1.13)	0.55 (0.39, 0.80)
DAS28 <2.6 at 6 months	0.62 (0.16, 2.38)	1.0	0.84 (0.60, 1.16)	0.48 (0.32, 0.72)
Good Response 12 months	0.39 (0.05, 3.15)	1.0	0.80 (0.54, 1.20)	0.97 (0.63, 1.52)
DAS28 <3.2 at 12 months	1.89 (0.55, 6.48)	1.0	1.12 (0.82, 1.53)	0.77 (0.54, 1.10)
DAS28 <2.6 at 12 months	0.97 (0.28, 3.38)	1.0	0.86 (0.62, 1.20)	0.62 (0.42, 0.92)

Conclusion: Obese patients with RA appear to respond to treatment, and achieve treatment goals within the first year following diagnosis. Outside of this period, obese patients are less likely to reach low disease activity or disease remission. These findings may have important implications for treatment objectives in modern target based regimens.

Management of Hyperlipidemia Among Patients with Rheumatoid Arthritis in the Primary Care Setting. Kashif Jafri[1], Lynne Taylor[1], Nehal N. Mehta[1], Melissa Nezamzadeh[1], Joshua Baker[2] and Alexis Ogdie[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Rheumatoid arthritis has been associated with an increased risk of cardiovascular morbidity and mortality. It is unclear, however, whether this knowledge has translated into improved screening and management of traditional cardiovascular risk factors such as hyperlipidemia in the primary care setting. The objectives of this study included 1) To determine the prevalence of screening for hyperlipidemia in patients with rheumatoid arthritis (RA) that are followed by primary care physicians; 2) To examine whether current Adult Treatment Panel (ATP) III guidelines for the initiation of lipid-lowering therapy are being followed in patients with RA, and 3) to assess whether proposed modifications to cardiovascular risk calculations change the percentage of RA patients with an indication for therapy.

Methods: A retrospective cohort study was performed among patients with RA in an academic medical center medical record database in the United States between 2005–2010. A validation study prior to initiation of the study demonstrated a positive predictive value of 96.7% for accurate capture of patients with RA using ICD-9 codes. Descriptive statistics were used to report the prevalence of screening and use of lipid-lowering therapy (LLT) among those with an indication for LLT. Factors associated with not receiving lipid screening were examined using logistic regression models. Finally, indication for and receipt of therapy were assessed following application of the European Union League Against Rheumatism (EULAR) recommended multiplier to the Framingham risk score.

Results: Among 1418 patients with RA followed by primary care physicians, lipid screening was ordered for 780 (55%) within the 3-year follow-up period. Patients under the age of 50 were significantly less likely to be screened whereas patients with diabetes, hypertension, chronic kidney disease, and obesity were more likely to be screened (**Table**). Of those with lipid results (N=419), 50 (12%) patients had an indication for LLT based on the ATP III guidelines. Among the 50 patients with an indication for LLT, 38 (76%) received therapy. Applying the EULAR multiplier only changed the indication for LLT in two patients.

Conclusion: Although patients with RA have an increased risk for cardiovascular disease, they are often not receiving optimal management of traditional cardiovascular risk factors, such as screening for hyperlipidemia. Nevertheless, once hyperlipidemia has been identified, most patients received the appropriate lipid-lowering therapy. The EULAR multiplier does not seem to have a measurable impact on clinical care, and new methods for assessing cardiovascular risk among patients with RA are needed.

Table. Logistic regression models for non-receipt of screening*

		Univariable OR (95%CI)	Final Multivariable Model* OR (95%CI)
Age (<50)		1.74 (1.38–2.19)	1.65 (1.30–2.10)
Sex (F)		1.08 (0.81–1.43)	
Race	Caucasian	Ref	
	Black or African American	0.76 (0.61–0.95)	
	Asian	1.26 (0.60–2.64)	
	Other or unknown	1.60 (1.04–2.48)	
Hypertension		0.30 (0.21–0.42)	0.40 (0.28–0.57)
Hyperlipidemia Diagnosis		0.17 (0.10–0.31)	
Diabetes mellitus		0.41 (0.31–0.53)	0.47 (0.36–0.63)
Obesity		0.37 (0.25–0.56)	0.44 (0.28–0.68)
Peripheral Arterial Disease		0.13 (0.02–1.06)	
Tobacco use (n=564)	Current smoker vs non-smoker or past-smoker	1.50 (1.00–2.23)	

Note that odds ratios (OR) refer to NOT receiving screening. For example, age <50 is associated with an increased risk of NOT receiving screening by a factor of 1.95. *c=0.65 for the association between predicted probabilities and observed responses for the final multivariable model.

Unique Profile of Cardiovascular Risk Factors in Rheumatoid Arthritis High-Risk Populations with Insufficient Risk Control. Ulf Müller-Ladner[1], Stefan Kleinert[2], Klaus Krüger[3], Bianca Wittig[4] and Rolf Hecker[4]. [1]Kerckhoff-Klinik GmbH, Abt. Rheumatologie und klinische Immunologie, Bad Nauheim, Germany, [2]Praxisgemeinschaft Rheumatologie-Nephrologie, Rheumatologische Schwerpunktpraxis, Erlangen, Germany, [3]Praxiszentrum St. Bonifatius, München, Germany, [4]Abbvie Deutschland GmbH & Co. KG, Wiesbaden, Germany.

Background/Purpose: More than 50% of premature deaths in patients with rheumatoid arthritis (RA) are due to cardiovascular disease (CVD). Both the cumulative burden of inflammation and the increased prevalence of conventional CVD risk factors contribute to this increase in CVD. CVD risk screening and management is therefore mandatory.[1]

Methods: A cross-sectional study was conducted to screen RA patients for CVD risk factors at rheumatology outpatient centers in Germany. Age, gender, smoking habits, blood pressure, and lipid levels were assessed, as well as medications, comorbidities, DAS28, CVD, and standard laboratory parameters. Using these parameters, a subset of patients was assigned to 3 high-risk CVD subgroups: patients with manifest CVD, patients with diabetes mellitus (DM; type 1 or 2), and, as the CVD mortality risk is a function of age, patients ≥70 years of age. Achievement of target values for CVD risk factors adopted from the European Society of Cardiology (ESC) and European League Against Rheumatism (EULAR) recommendations were compared within these groups.[1,2] Descriptive data analysis was performed without adjusting for confounders. The RA population without those risks was used as a comparator group and stratified into risk categories by the mSCORE model.[2]

Results: The comparator population included 866 patients with RA. High-risk subgroups included 146 RA patients with existing CVD, 111 RA patients with DM (28 aged ≥70 years) and 114 RA patients aged ≥70 years but without DM or CVD. 49% of the CVD patients had a previous myocardial infarction or stroke, 62% had coronary heart disease (CHD), and 22% had previous arterial occlusion events. Recommended target values for CVD risk factors were not achieved by a substantial number of patients even in the high risk populations. Depending on the subgroup, 40%–45% of the patients achieved low disease activity or DAS remission, 41%–63% reached the respective blood pressure target, and 0%–28% reached the low-density lipoprotein (LDL) cholesterol target (Table 1). Lipid target values were rarely achieved in high-risk populations. Only a minor fraction of patients received statin therapy; there was no difference in glucocorticoid use between the high-risk and comparator populations. 65% of the investigators stated that the EULAR recommendations for the management of CVD risk in RA influenced their diagnostic and therapeutic concept.

Conclusion: Target values for CVD risk factors are rarely achieved in high-risk RA patients in routine outpatient settings, reflecting the insufficient management of CVD risk.

Characteristics of Rheumatoid Arthritis Patients with and without Cardiovascular Diseases - Data from the Ontario Best Practice Research Initiative (OBRI). Kangping Cui[1], Binu Jacob[2], Janet E. Pope[3], Jessica Widdifield[4], Xiuying Li[2], Bindee Kuriya[5], Pooneh Akhavan[6] and Claire Bombardier[5]. [1]University Health Network/Toronto General Hospital Research Institute, Toronto, ON, [2]University Health Network, Toronto General Research Institute, Toronto, ON, [3]Schulich School of Medicine and Dentistry, Western University, London, ON, [4]Institute for Clinical Evaluative Science, Toronto, ON, [5]University of Toronto, Toronto, ON, [6]Mount Sinai Hospital/ University of Toronto, Toronto, ON.

Background/Purpose: Cardiovascular disease (CVD) is a major comorbidity and the leading cause of death among patients with rheumatoid arthritis (RA). The aim of this study was to compare the characteristics and patterns of medication use in RA patients with and without CVD.

Methods: Descriptive analyses were performed using physician and patient-reported data collected from the Ontario Best Practice Research Initiative (OBRI), a clinical registry of RA patients followed in routine care. CVD was defined as the presence of coronary artery disease (CAD), congestive heart failure (CHF), hypertension (HTN), arrhythmia, stroke, transient ischemic attack (TIA), and/or other heart disorders upon entering the registry (baseline). Patient demographics, clinical characteristics, socioeconomic status and treatment regimens were compared between patients with and without CVD at baseline using Chi-square and t-tests. Generalized linear regression models were used to estimate means for disease activity and functional status scores, adjusting for age, sex, smoking history, and socioeconomic factors.

Results: Among 2305 RA patients, 725 (31.5%) had CVD at baseline. Of those who had CVD, 562 (77.5%) had HTN, 68 (9.4%) had CAD, 21(2.9%) had arrhythmia, 10 (1.4%) had CHF, 9 (1.2%) had TIA, 5 (0.7%) had stroke, and 108 (14.9%) had other heart disorders. Patients with CVD were older (64.5 ± 10.1 vs. 54.2 ± 12.9 yrs, $p<0.0001$), and had longer RA disease duration (9.3 ± 10.7 vs. 8.3 ± 9.1yrs, $p<0.0001$). Male sex, low education and income, lack of private insurance, and smoking were also associated with the presence of CVD.

Positive rheumatoid factor (71.0% vs. 75.1%, $p<0.05$) was less prevalent in CVD patients. After adjusting for age, sex, income, education, insurance status, and smoking history, there were no significant differences in disease duration but CVD patients maintained higher disease activity (see table), measured by DAS28, CDAI, RADAI, tender joint count-28 (TJC), and erythrocyte sedimentation rate (ESR). Functional status measured by HAQ was worse in CVD patients. Extra-articular features (24.7% vs. 16.0%, $p<0.05$) were higher among CVD patients. CVD patients were less frequently treated with biologics (19.5% vs. 24.0%, $p<0.05$) and NSAIDS (34.9% vs. 48.6%, $p<0.05$) but did not differ in disease-modifying agents (DMARDs) and steroids usage compared with non-CVD patients.

Conclusion: RA patients with CVD have worse disease activity, more extra-articular features, and lower utilization of biologics and NSAIDS. The latter may be due to CVD risk with NSAIDs, but the lower utilization of biologics may require further investigation. Clarification on the CVD status of HTN patients is ongoing.

Disease Activity and Functional Status comparing RA patients with and without CVD

Disease Activity and Functional Status Measures	CVD (N = 725) Adjusted Mean*	SE**	Non-CVD (N = 1580) Adjusted Mean*	SE**	P-value*

Factors Associated with Recording of Rheumatoid Arthritis on Death Certificate. Emily Molina[1], Jose Felix Restrepo[2], Inmaculada Del Rincon[1], Daniel Battafarano[3] and Agustin Escalante[2]. [1]University of Texas Health Science Center, San Antonio, TX, [2]University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX.

Factors Associated with Recording of Rheumatoid Arthritis on Death Certificates

Background/Purpose: Death certificates can be used to study mortality due to a particular disease. However, rheumatoid arthritis (RA) often remains unreported in death certificates. We sought to determine to what extent RA is underreported and what demographic and clinical characteristics could predict mention of RA in the death certificate.

Methods: Between 1996 and 2009, we recruited 1,328 patients with RA that met the American College of Rheumatology criteria. Patients were followed prospectively. A rheumatologist assessed clinical characteristics of RA at each evaluation, including number of tender, swollen and deformed joints, presence of rheumatoid nodules, as well as Steinbroker classification and Charlson comorbidity index. Joint damage was determined by Sharp score, using hand radiographs taken from the most recent visit prior to death. Deaths were identified through family members, friends, neighbors, other physicians, obituaries and public death databases. We obtained state-issued death certificates and mapped causes of death to ICD9 codes. Standard bivariate analyses were conducted comparing patients with and without RA on the death certificate. A multivariable logistic regression model was performed to determine what variables were associated with recording RA.

Results: By December 2013, 323 deaths had occurred during 8,326 person-years of observation, for a mortality rate of 3.8 per 100 person-years [95% confidence interval (CI) (3.4, 4.3)]. Of the 308 death certificates we received, 61 (19.8%) mentioned RA on the death certificate. Only two of them recorded RA as the immediate cause of death. Bivariate analysis revealed that a greater number of deformities (mean ±SD = 17.6±9.0 vs. 14.4±9.4; $P=0.016$), higher Sharp score (mean ±SD = 192±132 vs. 138±112; $P=0.010$) and lower socioeconomic status (mean ±SD = 42.4±21 vs. 48.3±19; $P=0.041$) were each associated with recording RA on the death certificate. Place of death, presence of rheumatoid nodules, having health insurance or an autopsy were not associated with recording RA. Multivariable analyses revealed that an increased number of deformed joints [odds ratio (95% confidence interval) = 1.04 (1.00, 1.07); $P=0.04$], less comorbidity [OR (95%CI) = 0.87 (0.76, 0.99); $P=0.048$] and having a certified physician sign the certificate [OR (95%CI) = 3.56 (1.16, 10.8); $P=0.026$] were associated with listing RA on the death certificate.

Conclusion: In this RA cohort, a diagnosis of RA was not listed in the death certificate in 80% of patients who died. Patients with fewer comorbidities and more joint deformities were more likely to have RA reported. Studies that rely on death certificates may underestimate the mortality of RA and be biased toward patients with more severe RA and less comorbidities.

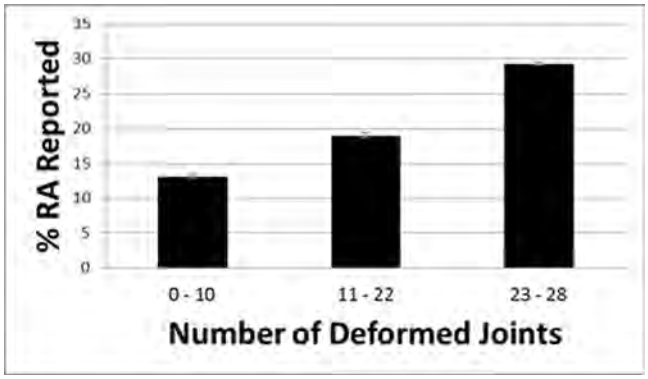

Figure 1. Percent death certificates reporting RA according to the number of deformed joints.

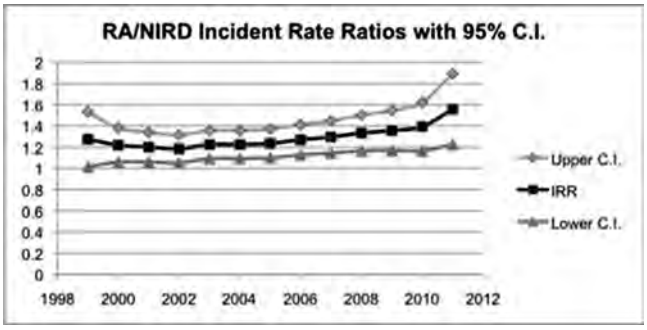
Mortality Trends in Rheumatoid Arthritis during the Biologic Era, 1998 to 2011. Bryant R. England[1], Harlan Sayles[2], Ted R. Mikuls[2] and Kaleb Michaud[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]National Data Bank for Rheumatic Diseases, Wichita, KS.

Background/Purpose: Rheumatoid arthritis (RA) has consistently been associated with increased mortality risk, a risk that appears to be linked with greater disease activity. Although there have been substantial recent improvements in treatment, particularly with the availability of biologic treatments, it is unknown whether these advances have translated into improved RA-related survival. The purpose of this study was to describe and compare the trends in mortality in patients with RA and non-inflammatory rheumatic diseases (NIRD) from 1998 to 2011.

Methods: Patients were enrolled in a longitudinal study and open cohort of US rheumatologist diagnosed rheumatic diseases. Patients with RA and NIRD (osteoarthritis, back pain, tendonitis; excluding fibromyalgia) were followed from 1998 through 2011. Death records were obtained through the US National Death Index. Standardized mortality ratios (SMR) were calculated each year adjusting for age, sex, race, and calendar year. To account for possible participation bias, the RA group was compared to another enrolled group (NIRD) known to have an SMR close to or slightly lower than 1. Incidence rate ratios (IRR) comparing RA and NIRD groups and 95% confidence intervals were calculated each year controlling for age, sex, smoking status, disease duration, and comorbidity.

Results: In the RA group, 3,604 deaths occurred over 145,510 person-years. In the NIRD group, 965 deaths occurred over 40,003 person-years. SMR increased abruptly in the first three years in both groups. Annual SMRs were consistently higher for patients with RA (median 1.44, range 0.42 – 1.78) than for those with NIRD (median 0.88, range 0.09 – 1.35). Following multivariate adjustment, RA-related mortality risk remained significantly higher than NIRD mortality risk, a relative risk that remained constant throughout the observation period (IRR mean 1.29, range 1.18 – 1.56) (Figure).



Conclusion: Despite important advances in treatment that have accompanied the availability of biologics, there has been no meaningful improvement in RA-related mortality over this time period. As a result, there has been no narrowing of the 'mortality gap' separating RA patients from patients with NIRD. Though caution is warranted in interpretation, it appears that this gap may actually be widening. To determine whether this trend continues will require additional follow-up.

Smoking-Related Mortality in Rheumatoid Arthritis: A Retrospective Cohort Study Using Electronic Medical Records. Rebecca M Joseph[1], Mohammad Movahedi[2] and Deborah PM Symmons[2]. [1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Smoking is a known risk factor for rheumatoid arthritis (RA) and there is evidence suggesting that many patients with RA continue to smoke. The proportion of patients with RA who smoke is therefore higher than the general population. Smoking is associated with several serious adverse events and so is likely to reduce life expectancy. The aim of this study was to examine the influence of smoking status on all-cause mortality in patients with RA.

Methods: Incident cases of RA were identified from a large UK primary care database using a validated algorithm. Patients were followed from their first code for RA until death, leaving their general practice or the last data collection date within the study window of March 1991 to January 2014. Read codes, codes for smoking cessation therapy and additional clinical information were used to define smoking status at baseline and as a time-varying exposure during follow-up. Smoking status was classified as non-, current or former. Date of death was available in the database. The Cox regression model was used to compare mortality rates between smoking categories, adjusting for gender and diagnosis date (pre/post January 2000). Age, cardiovascular disease (CVD), diabetes, depression, use of immunosuppressive DMARDs, any code for painkillers in the past 6 months and any code for respiratory infections, oral steroids, cardiovascular medication and antidepressants in the past year were included in the model as time-varying covariates. As the effect of smoking status was not constant over time, the interaction between smoking status and year of follow-up was also included in the model.

Results: 13154 adult RA patients were identified, of whom 12431 (94.5%) had a baseline smoking status recorded and were included in the analysis. 68.9% were female and the median age was 60.8 years (IQR 50.2, 71.0). At baseline, all covariates differed significantly between the smoking categories. Former smokers had the highest prevalence of CVD, diabetes, and respiratory infection whilst current smokers had the highest prevalence of depression. The total follow-up time was 75467 person-years and there were 1719 deaths, giving a crude mortality rate of 22.8 per 1000 person years. The crude mortality rate for smoking status at baseline was 19.8, 25.6 and 24.8 per 1000 person years for non-, current and former smokers respectively. In the adjusted models, using time-varying smoking status, the risk of mortality for current smokers was nearly 80% greater than that of non-smokers (hazard ratio 1.79 (95% CI 1.46, 2.20) (Table).

Current smoking status	Unadjusted hazard ratio (95% CI)	Adjusted hazard ratio (95% CI)
current (vs. non-smoker)	1.21 (1.06, 1.37)	1.79 (1.46, 2.20)
former (vs. non-smoker)	1.54 (1.38, 1.71)	0.96 (0.80, 1.16)
current (vs. former)	0.79 (0.70, 0.89)	1.86 (1.53, 2.27)

Conclusion: Current smoking significantly increases the risk of death at any time after RA diagnosis compared to both non- and former smokers. Adjusted risk of death is similar for former smokers and non-smokers. Stopping smoking prior to the development of associated comorbidities may therefore help to reduce the risk of smoking-related mortality.

Impact of Rheumatoid Arthritis on the Mortality of Patients Who Develop Cancer: A Population-Based Study. Pratibha Nayak, Ruili Luo, Linda Elting and Maria E. Suarez-Almarzor. The University of Texas, MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Comorbidity among cancer patients imposes additional risks for premature mortality. The specific effect of rheumatoid arthritis (RA) on survival among cancer patients is unknown. Our objective was to examine survival among cancer patients diagnosed with RA compared to patients without RA.

Methods: Patients diagnosed with colorectal, breast, prostate or non-small cell lung cancer between years 2001 to 2010 were identified from the Texas Cancer Registry and Medicare-linked databases, which includes all beneficiaries in Texas 65 years and older who develop cancer. Patients were divided into 3 groups on the basis of previous Medicare claims for RA (International Classification of Diseases, ICD-9 code 714): (i) those who had no hospital or outpatient Medicare RA (No RA); (ii) those who had at least one claim related to RA (1-RA), and those who had at least 2 - claims related to RA that occurred a minimum of 6 months apart (2-RA). The overall survival and 95% confidence intervals (95% CIs) were estimated for each of the cancer types (colorectal, breast, prostate and non-small cell lung), and compared between RA and no RA groups. Cox proportional hazards regression models were used to control for demographic factors, cancer stage, and other comorbid conditions. Comorbidity was evaluated using the Charlson's comorbidity index.

Results: The overall analytical sample consisted of 126,241 cancer patients, with a mean age of 75 years (breast 31,545; prostate 38,858;

colorectal 27,784; non-small cell lung 28,054). About 1.7% (n=2,095) had 1-RA claim and 1.1% (n=1,397) 2-RA claims. After adjusting for covariates, the hazard ratios for patients in the 2-RA group were 1.42 (95% CI, 1.20–1.68) for those with breast cancer, and 1.45 (95% CI, 1.16–1.80) among those with prostate cancer. Increased mortality risk was observed among patients with colorectal cancer 1.17 (95% CI, 0.996–1.36) with 2-RA to those without RA, however this was not statistical significant (p value, 0.056). No differences in survival were observed between patients with or without RA and non-small cell lung cancer, and survival in patients with this tumor was much shorter than for the other 3 cancers.

Conclusion: A 40% increase in mortality was found among patients with breast or prostate cancer who also had RA, compared to those without RA. Additional research is needed to determine whether the observed increases mortality risk is related to comorbid burden, or differential utilization of cancer or rheumatoid therapies in patients with both diseases.

Mortality Risk in Patients with Rheumatoid Arthritis Who Develop Non–Hodgkin's Lymphoma. Pratibha Nayak[1], Zaki Abou Zahr[2], Ruili Luo[1], Linda Elting[1] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: Patients with rheumatoid arthritis (RA) have greater risk of non-Hodgkin lymphoma (NHL) than the general population. A previous two-center study suggested that the rates of progression and relapse of patients with NHL and antecedent RA were better than those of patients with NHL alone, but that the overall risk of mortality was increased. The objective of this study was to conduct a population-based study of Medicare beneficiaries to compare the survival of patients with NHL and prior RA with that of patients with NHL alone.

Methods: We used for this study population-based data that links patients with cancer in the State of Texas (Texas Cancer Registry) with Medicare data in beneficiaries 65 years and older. The datafile has a case capture of over 95%. We included all Medicare-linked cases in the registry diagnosed with NHL (B cell, T cell, or not otherwise specified/unknown lineage) between 2001 and 2010. We classified each patient into one of three groups based on RA Medicare claims during the year prior to cancer diagnosis (International Classification of Diseases ICD 9, code 714): (i) 1-RA (having least one RA claim), (ii) 2-RA (having at least 2 hospital or outpatient claims, 6 or more months apart), and (iii) no-RA (having no claims related to RA). Cox proportional hazards regression models were used to compare overall survival among groups. Covariates included demographic variables, stage at diagnosis and comorbidity burden estimated using the Charlson's comorbidity index.

Results: 8,858 NHL patients were included, of whom 2.5% (n=226) had 1-RA claim and 2.3% (n=203) had 2-RA claims. Overall median survival for the cohort was close to 4 years. The hazard ratio (HR) for patients in the 1-RA group was 1.14 (95% CI, 0.95–1.37), and that for the 2-RA group was 1.04 (95% CI, 0.85–1.27), compared to that of patients without RA after controlling for demographics, and stage. The risk did not significantly change after including comorbidity in the models: 1-RA group HR=1.13, 95% CI, 0.94–1.36, and 2-RA group HR=1.04, 95% CI, 0.85–1.26. Comorbidity was an independent factor significantly associated with mortality such that having one additional comorbidity increased risk by 20% HR=1.20, (95% CI, 1.12–1.29), and having 3 or more comorbidities increased risk by more than 2 fold, HR=2.31 (95% CI, 2.01–2.43).

Conclusion: Having antecedent RA does not confer an independent mortality risk in NHL Medicare beneficiaries. However, patients with RA and NHL with other comorbidities can have decreased survival. Additional research should evaluate the risk associated with specific comorbid conditions, and whether this potential detrimental effect is from disease burden or differential use of cancer therapies.

What Is the Impact of Chronic Systemic Inflammation Such As Rheumatoid Arthritis on Mortality Following Cancer? Julia Simard[1], Sara Ekberg[2], Anna Johansson[3] and Johan Askling[4]. [1]Stanford School of Medicine, Stanford, CA, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, stockholm, Sweden, [4]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Emerging evidence links inflammation and immune-competence to cancer progression and outcome. The few studies addressing cancer survival in the context of systemic inflammation, such as rheumatoid arthritis (RA), have reported reduced survival without accounting for the underlying mortality risk in RA. Whether this increased mortality is a cancer-associated phenomenon, an effect of the decreased lifespan in RA, or a combination of both is unknown.

Methods: Using Swedish register data (2001–2009), we performed a cohort study of individuals with RA (N=34930), matched to general population comparators (N=169740), including cancers (N=12676) and deaths (n=14291). We restricted to adults with no history of malignancy between 40 and 84 years old at start of study. Using multivariable adjusted stratified Cox models we first estimated the overall association between RA and death for those with and without cancer during follow-up using age as the underlying timescale., and then stratified by cancer stage. We then estimated the effect of RA versus non-RA by cancer stage restricting to individuals with an incident cancer during follow-up. We also investigated how the RA effect varied by time since cancer diagnosis (0–2 years, 2–5 years, >5 years since diagnosis) These analyses looked at all-cause mortality for all cancers and specific sites (lung, colorectal, female breast, prostate, malignant melanoma, and lymphoma).

Results: In the absence of cancer, RA was associated with a doubled mortality rate (HR=2.1, 95%CI 2.0–2.2). In the presence of cancer, the effect of RA on mortality was lower (HR=1.2, 95%CI 1.1–1.3), but only for advanced stage cancers. For stages I and II the relative effect of RA on mortality was doubled (HR=2.0 and HR=2.1, respectively). These associations remained across time since cancer diagnosis, and were reasonably similar across sites.

Conclusion: Our results offer limited evidence that RA would potentiate the effect of cancer on the risk of death, at least not in cancers diagnosed at advanced stage. Instead, much of the increase in mortality in RA patients diagnosed with cancer seems to reside with effects of RA independently of the cancer.

Table 1. Hazard ratios of all-cause death as a function of RA, cancer, and cancer stage

Cancer	Stage at cancer diagnosis	HR (95% CI) comparing patients with vs. without RA
No	–	2.1 (2.0, 2.2)
Yes	All	1.2 (1.1, 1.3)
No	–	2.1 (2.0, 2.2)
Yes	Stage I	2.0 (1.5, 2.8)
Yes	Stage II	2.1 (1.4, 2.9)
Yes	Stage III	1.6 (1.3, 2.0)
Yes	Stage IV	0.9 (0.7, 1.0)
Yes	Missing	1.2 (1.1, 1.4)

Stratified Cox models stratified on cancer or cancer stage, and adjusted for age (as underlying timescale), birth year, sex, civil status, region of residence, education, history of chronic obstructive pulmonary disease, history of diabetes, history of ischemic heart disease, and history of cerebrovascular disease.

Table 2 Hazard ratios for RA vs. non-RA among individuals diagnosed with any cancer, stratified by time since cancer diagnosis and stage at cancer diagnosis.

		Time since cancer diagnosis		
	All years	*0–2 years*	*2–5 years*	*>5 years*
All stages	1.3 (1.2, 1.4)	1.3 (1.2, 1.4)	1.3 (1.1, 1.6)	1.8 (1.2, 2.7)
Stage I	2.3 (1.7, 3.2)	2.5 (1.7, 3.7)	2.1 (1.2, 3.5)	2.8 (0.7, 11.6)
Stage II	2.5 (1.6, 3.1)	2.3 (1.5, 3.6)	1.8 (0.9, 3.5)	5.0 (1.1, 22.6)
Stage III	1.4 (1.2, 1.8)	1.4 (1.2, 1.8)	1.6 (0.9, 2.9)	*
Stage IV	1.0 (0.8, 1.2)	1.0 (0.9, 1.3)	0.5 (0.3, 1.1)	4.3 (0.7, 25.8)
Missing	1.3 (1.2, 1.4)	1.3 (1.1, 1.4)	1.3 (1.1, 1.6)	1.5 (0.9, 2.5)

The stratified Cox model is stratified by cancer status or stage, and adjusted for time since diagnosis (as underlying timescale) and age at cancer diagnosis, sex, civil status, geographic region, education, and history of comorbid conditions. Presented as HR and 95% confidence intervals.

Sex Ratio of Offspring Born to Women with Lupus and Rheumatoid Arthritis. Elizabeth V. Arkema[1], Johan Askling[2], Jane Salmon[3] and Julia F. Simard[4]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Hospital for Special Surgery, New York, NY, [4]Stanford School of Medicine, Stanford, CA.

Background/Purpose: Women with SLE are at increased risk for pregnancy complications and specific autoantibodies may result in preferential loss of female offspring. Studies on the male to female (M:F) sex ratio of births in the SLE population have been contradictory. We used a large national population-based cohort of patients with SLE to determine whether the M:F ratio of births to mothers with SLE is different than the general population as well as a population of women with rheumatoid arthritis (RA) to estimate the ratio in another chronic inflammatory disease.

Methods: SLE was defined as ≥2 visits in inpatient or outpatient care (National Patient Register (NPR); 1969–2011) listing an SLE ICD code with ≥1 SLE-coded visit to a specialist. A sample of general population comparators was identified from the Total Population Register. Women with a delivery were identified from the Swedish Medical Birth Register (1973–2011). We used modified Poisson regression with robust sandwich estimators to calculate the risk ratio (RR) for having a male offspring associated with an SLE diagnosis adjusted for age, year and maternal country of birth. Our primary analysis was restricted to first singleton births only. In secondary analyses, we examined all births and restricted to live births only. We also examined antiphospholipid syndrome (APS) history in the SLE population using any ICD10 code before or at delivery, restricted to ≥1997 when the code was available. Lastly, we calculated the M:F ratio of offspring born to women with ≥2 RA-coded visits in the NPR with ≥1 visit to a specialist before delivery.

Results: We identified 604 women with SLE before their first delivery and 1289 singleton deliveries total to women with prevalent SLE. Maternal SLE at delivery had a lower proportion of male offspring compared to the general population. The RR for male offspring associated with SLE was 0.95 (95%CI 0.88, 1.04) for first births and 0.96 (95%CI 0.90, 1.01) for all singleton births (Table). RRs did not change with adjustment by age, year or country of birth. Results were similar among live births only and including multiples. Women with both APS and SLE had a lower odds of having a male child compared to the general population. We identified 1136 women with prevalent RA at first delivery and 2674 singleton deliveries total. The M:F ratio in RA was not significantly different than the general population (first birth RR=0.96 (95%CI 0.91, 1.02), all births OR=0.99 (95%CI 0.95, 1.03)).

Conclusion: We observed a lower proportion of male offspring born to women with prevalent SLE at delivery compared to the general population, which was not statistically significant. We observed a significantly lower odds of male offspring born to women with SLE and APS when all births were considered. In this large study using similar techniques to identify patients as that of a group in Canada, we did not confirm their findings of a male dominance in offspring.

Table 1: Maternal characteristics and M:F sex ratio among deliveries in Sweden, 1973-2011, comparing mothers with SLE at delivery to mothers from the general population restricted to singleton births

	First births			All births

Prescription Medication Trends in Medicaid-Enrolled Pregnant Women with Rheumatoid Arthritis, Psoriasis, and Systemic Lupus Erythematosus.

Rishi Desai[1], Krista Huybrechts[2], Brian Bateman[2], Helen Mogun[2], Sonia Hernandez-diaz[3] and Seoyoung C. Kim[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard School of Public Health, Boston, MA.

Background/Purpose: Little is known about the trends of medication use in pregnant women with autoimmune disorders. The objective of the current study was to examine the prevalence and trends of oral steroids and immunomodulatory drug use in pregnant women with rheumatoid arthritis (RA), psoriasis, and systemic lupus erythematosus (SLE).

Methods: A cohort of pregnant women with RA, psoriasis, or SLE was identified using data from the Medicaid Analytical eXtract for the period of 2000–2007. The following 3 classes of medications were identified using prescription dispensing data for these patients; 1) oral steroids, 2) non-biologic disease modifying anti-rheumatic drugs (nbDMARDs), and 3) biologic DMARDs. The proportion of women with RA, psoriasis, and SLE exposed to these medications in the following time-windows were reported, 1) 3 months pre-last menstrual period (LMP), 2) first trimester, 3) second trimester, and 4) third trimester. Trends in the use were also evaluated by calendar year.

Results: A total of 1,734 pregnant women with RA, 2,932 with psoriasis and 2,392 with SLE enrolled in Medicaid from 46 states and Washington, DC were identified. During the 3 months pre-LMP, 16.8% of women with RA used oral steroids, 11.9% used nbDMARDs, and 4.3% used biologics. During pregnancy, the use of steroids showed modest reduction in women with RA compared to 3 months pre-LMP use **(Figure)**. However, the use of nbDMARDs showed a marked reduction during the 1st, 2nd and 3rd trimesters with 7.8%, 2.9%, and 2.6% of women with RA using these agents during these periods, respectively. Similarly, the use of biologics in women with RA also decreased during pregnancy. In women with psoriasis, 6.3% used oral steroids, 0.8% used nbDMARDs, and 1.4% used biologics during the 3 months pre-LMP period. During pregnancy, use decreased for all the three classes of medications. In women with SLE, 16.7% used oral steroids, 14.9% used nbDMARDs, and 0.6% used biologics during the 3 months pre-LMP. Use of steroids was increased moderately during pregnancy compared to 3 months pre-LMP use, but a lower proportion of women used non-biologic and biologics during pregnancy in the SLE cohort. No meaningful time trends were observed in use of these three classes of medications during pregnancy between 2000 and 2007.

Conclusion: We observed reduced use of non-biologic and biologics in women with RA, psoriasis, and SLE during pregnancy compared to before pregnancy. This reduced use may be due to lowered disease activity during pregnancy or fetal safety concerns related to the use of these agents. Oral steroids were the most commonly used therapy in all three populations at all the stages of pregnancy. Given this high use, future research evaluating the safety of steroids in pregnancy is warranted.

A Meta-Analysis of the Risk of Venous Thromboembolism in Inflammatory Rheumatic Diseases.

Jason J. Lee[1] and Janet E. Pope[2]. [1]University of Western Ontario, London, ON, [2]St Joseph Health Care, London, ON.

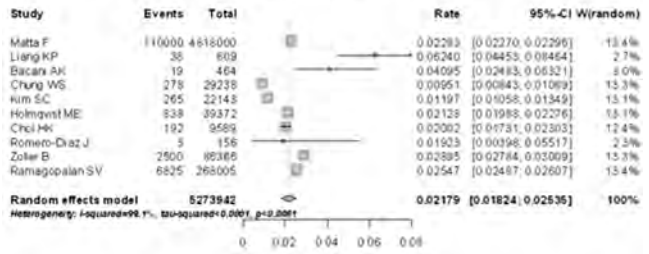
Background/Purpose: We performed a meta-analysis investigating the risk of developing deep vein thrombosis (DVT) and/or pulmonary embolisms (PE) in patients with inflammatory arthritis, vasculitis, and connective tissue diseases (CTD) [SLE, Sjogren's syndrome, inflammatory myositis and systemic sclerosis (SSc)].

Methods: PubMed, Embase, Cochrane Databases, and Medline were searched identifying full text English publications in adults related to rheumatologic inflammatory diseases and VTE. Data regarding rates of DVTs and PEs were extracted. Using random effects models, pooled estimates for VTE in individual and pooled diseases compared with matched populations where possible. Studies were excluded if VTEs were in the setting of pregnancy, postoperative outcomes or solely antiphospholipid antibody syndrome.

Results: Most of the 3,929 studies were excluded due to lack of rate or incidence of VTE. Twenty studies remained for analysis. Eight studies of RA identified 5,273,942 patients and 891,530,181 controls with a cumulative incidence of 2.18% (95% CI: 1.82–2.54%) and an odds ratio of 2.23 (95% CI: 2.02–2.47) compared to age and sex, matched population. Six studies included 36,582 SLE patients with a cumulative incidence of 8.24% (95% CI: 6.27–10.22%); three Sjogren's syndrome studies (N=16,180) demonstrated a VTE cumulative incidence of 2.62% (95% CI: 2.15–3.10%); four studies of inflammatory myositis (N=8,245) yielded a VTE cumulative incidence of 4.03% (95% CI: 2.38–5.67%), SSc and ANCA vasculitis rates (3 studies each) were 3.82% and 8.51% respectively. The figure shows VTEs in RA as an example.

Conclusion: Inflammatory rheumatologic diseases studied were all associated with high rates of VTEs, more nearly three times higher than the general population. Identification of those at risk is important. We cannot determine from these studies what the risk is when inflammation is effectively treated.

(a) Cumulative Incidence of VTEs in patients with RA



(b) Cumulative Incidence of VTEs in RA compared to matched control population presented as Odds Ratio

Risk of High-Grade Cervical Dysplasia and Cervical Cancer in Women with Systemic Lupus Erythematosus on Immunosuppressive Drugs. Candace H. Feldman, Jun Liu, Sarah Feldman, Daniel H. Solomon and Seoyoung C. Kim. Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Human papillomavirus (HPV) is the most common sexually transmitted disease in the US and the main cause of high-grade cervical dysplasia and cervical cancer. Prior studies suggest an increased risk of cervical cancer in women with systemic lupus erythematosus (SLE), however the relationship with immunosuppressive drugs (ISDs) is not well studied. We compared the risk of high-grade cervical dysplasia and cervical cancer among women with SLE receiving hydroxychloroquine (HCQ) to those on ISDs in a nationwide database. We hypothesized that the risk of cervical dysplasia and cervical cancer would be increased among ISD users.

Methods: We utilized US commercial insurance claims data (2001–2012) to conduct a cohort study to examine the incidence rates (IR) of high-grade cervical dysplasia or cervical cancer in women who initiated ISDs or HCQ for SLE. The index date was defined as the dispensing date of the first ISD or HCQ after ≥2 diagnoses of SLE (ICD-9 code 710.0). We required patients to have ≥365 days of continuous enrollment prior to the index date without use of ISDs or HCQ. We assessed baseline covariates during this period. We defined the outcome, high-grade cervical dysplasia or cervical cancer, using a validated claims-based algorithm with a positive predictive value of ≥81%. We also determined the number of gynecologic visits and procedures during follow-up. To control for potential confounders including age, comorbidities, HPV vaccination, corticosteroid use, additional medications, and healthcare utilization, initiators of ISDs were matched to HCQ initiators using propensity scores with a 1:1 ratio.

Results: Among 2,451 propensity score-matched pairs of women with SLE, the median age was 46 years, the mean follow-up was 1.15 (SD 1.38) years, and the overall follow-up was 5,622 person-years. The IR of high-grade cervical dysplasia or cervical cancer per 1,000 person-years was 4.70 in ISD initiators and 1.89 in HCQ initiators (**Table**). There were 14 cases of high-grade cervical dysplasia or cervical cancer in the ISD group and 5 cases in the HCQ group for a hazard ratio of 2.47 (95% CI: 0.89–6.85). The number of outpatient gynecologic visits (Rate ratio [RR] 0.93, 95% CI: 0.81–1.07) and gynecologic procedures (RR 1.13, 95% CI: 0.98–1.44) was not significantly different between the two groups.

Conclusion: Among women with SLE, initiation of ISDs may be associated with a greater, albeit not statistically significant risk of high-grade cervical dysplasia or cervical cancer compared to HCQ alone. Given the rare nature of cervical cancer and the prolonged latency period, further studies with extended follow-up are needed to confirm this finding.

Table 1. Risk of high-grade cervical dysplasia or cervical cancer among women with SLE who initiated immunosuppressive drugs* versus hydroxychloroquine in a propensity score-matched analysis**

	Immunosuppressive drugs* (N=2,451)				Hydroxychloroquine (N=2,451)			
	Event	Person-years	IR+ (95%CI)	HR (95% CI)	Event	Person-years	IR+ (95%CI)	HR (95% CI)
High-grade cervical dysplasia or cervical cancer	14	2,976	4.70 (2.78–7.94)	2.47 (0.89–6.85)	5	2,646	1.89 (0.79–4.54)	Ref.

*Immunosuppressive drugs include: methotrexate, azathioprine, cyclosporine, cyclophosphamide, mycophenolate mofetil, tacrolimus, abatacept, rituximab and belimumab
**The propensity score model includes age, sex, calendar year, comorbidities, HPV vaccination, being sexually active, sexually transmitted diseases, other comorbidities, medication use including oral contraceptives and corticosteroids, Pap test, HPV DNA test, and other health care utilization factors
+IR is per 1,000 person-years

1076

U.S. Geographic Trends in the Distribution and Treatment Practices of Juvenile Systemic Lupus Erythematosus: An Analysis of the Childhood Arthritis and Rheumatology Research Alliance Registry. Jennifer M.P. Woo[1], Ornella J. Rullo[1], Deborah K. McCurdy[2] and The CARRA Registry Investigators[3]. [1]University of California, Los Angeles, Los Angeles, CA, [2]UCLA Division of Pediatric Rheumatology, Los Angeles, CA, [3]Childhood Arthritis and Rheumatology Research Alliance, Durham, NC.

Background/Purpose: The treatment of juvenile systemic lupus erythematosus (jSLE) often requires complex medication regimens in order to address the different disease manifestations. Despite the limited number of medications approved for the treatment of jSLE, standardized treatment protocols have been slow to emerge. Identification of regional and temporal variations in medication usage in jSLE can help to establish more unified treatment practices.

Methods: Demographic and clinical data were collected for jSLE patients (diagnosis <18 years of age) enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry between 2009 and 2012. Individuals identified as being diagnosed and starting treatment prior to 2007 (Cohort 1; C1; n = 285) or as being diagnosed and treated between 2007 and 2012 (Cohort 2; C2; n = 284) were used to evaluate temporal changes in treatment practices by region. Regions were identified based on U.S. Census definitions and inclusion in a region was determined by the U.S. Census 3-digit zip code tabulation area (ZCTA) prefix of the area in which the patient resided at the time of symptom onset.

Results: Of the 925 jSLE enrolled in the CARRA Registry by July 2012, 809 (87%) had geographic data available and were included in the spatial analysis. This cohort was further separated based on year of diagnosis and duration of jSLE treatment, resulting in groups C1 and C2. Although the population distribution of jSLE varied among U.S. Census regions, C1 and C2 population sizes within a region were similar. Both demonstrated comparable female-to-male ratios (~3–4:1), ACR criteria counts, and ACR functional scores at worst disease (Table 1).

At symptom onset, approximately 90% of CARRA Registry patients lived in ZCTAs within 50 miles of a CARRA Registry pediatric rheumatology center. Glucocorticoid, non-biologic, biologic, and NSAID use in jSLE varied by region, however, comparison of C1 and C2 suggests an overall decrease in steroid and NSAID use and an increase in use of biologic and non-biologic

medications (Fig 1). Furthermore, C2 jSLE required significantly fewer medications compared to C1 (4.4 vs 5.7, respectively; $p<0.01$).

Conclusion: The heterogeneous nature of jSLE and regional variation in medication usage may have impacted the development of standardized treatment practices. Importantly, however, the overall number of required medications, glucocorticoids and NSAIDs in particular, has decreased across the U.S. Subsequently, regional and temporal variations may reflect the recent trend towards the standardization of medication practices in jSLE.

Table 1. Demographics and characteristics of spatial analysis cohort and temporal cohorts

	Spatial Analysis Cohort	Cohort 1 (Diagnosis & treatment prior to 2007)	Cohort 2 (Diagnosis & treatment 2007–2012)
n (% of enrolled CARRA jSLE; N = 925)	809 (87)	246 (27)	260 (28)
Female-to-Male ratio	644:165 (3.9:1)	185:61 (3.0:1)	211:49 (4.3:1)
Age of disease onset (years); mean	12.4	10.7*	13.3*
Disease duration prior to diagnosis (years); mean	0.56	0.53	0.51
ACR criteria count; mean	4.1	4.1	4.1
ACR functional class at greatest disease†; mean	2.3	2.4	2.3
Medication count; mean	5.0	5.7*	4.4*
Medication count excluding glucocorticoids; mean	4.0	4.6*	3.1*
Health insurance (%)	94.7	95.5	93.1
Household income; median	25–49K	25–49K	25–49K

*Values compared between C1 and C2; $p < 0.01$.
†ACR functional class is a physician scored measure of disease morbidity; scaled from 1 to 4 with 1 representing "completely able to perform usual activities" to 4 representing "Limited in ability to perform usual self-care activities"

A Real-World Characterization of US Patients with "Moderate-to-Severe" Systemic Lupus Erythematosus. Vibeke Strand[1], Jennifer Johnson[2], Carl Vandeloo[3], Catrinel Galateanu[3] and Steve Lobosco[2]. [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]Adelphi Real World Ltd., Macclesfield, United Kingdom, [3]UCB Pharma, Brussels, Belgium.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, inflammatory disease which can impact on patients' Health-Related Quality of Life (HRQoL). This analysis was designed to characterize US SLE patients classified by physicians as having "moderate-to-severe" disease, and to assess their burden of disease compared with those with "mild" disease severity.

Methods: Data were extracted from the multi-sponsor Adelphi 2013 Lupus Disease-Specific Program, a multinational survey of clinical practice. US physicians completed Patient Record Forms (PRFs); disease severity was based on physician assessments. Patients self-reported data including EQ-5D and Work Productivity and Activity Impairment Index for SLE (WPAI-Lupus), which were included in Patient Self-Completion Records (PSCs).

Results: PRFs and PSCs were collected from 97 rheumatologists. Of 498 patients, disease severity was classified as "mild" in 355 (71%), and "moderate-to-severe" in 139 (28%) (severity was not specified in 4 patients [1%]). Physician assessment of disease severity was predominantly based on affected organs/symptoms (considered most important by 37% and 40% of rheumatologists, respectively). Only 11% reported test results/clinical assessments as a determinant of SLE severity, with no single disease activity index widely used in clinical practice; 68% rheumatologists reported using their own systematic assessment. Physician assessment of disease severity and control of disease activity were imperfectly correlated: disease activity was controlled in 54% of patients with "moderate-to-severe" disease severity, and partially controlled or uncontrolled in 29% of patients with "mild" disease severity. "Moderate-to-severe" patients initially presented with greater disease severity and organ involvement (13% had skin-only SLE at diagnosis), and more flares per 12 month period (Table), than "mild" patients. Compared to "mild" severity, "moderate-to-severe" SLE severity was associated with a greater impact on HRQoL, which was comparable to rheumatic conditions including rheumatoid arthritis and psoriatic arthritis (Table). Fewer "moderate-to-severe" patients were employed, and a higher proportion required care providers (Table). For both "mild" and "moderate-to-severe" patients, obesity was one of the most common associated comorbidities; the proportion of "moderate-to-severe" patients affected was over double that of "mild" patients (Table).

Conclusion: "Moderate-to-severe" SLE severity was associated with a greater burden of disease than patients with "mild" severity. Data show that disease severity is not consistently assessed in US clinical practice and is a multifaceted concept, imperfectly correlated with control of disease activity. Thus, there is a need for a simple, universal tool to accurately assess SLE disease activity, as well as severity, to inform physician and patient decisions regarding treatment.

Table: Characteristics of patients with "Mild" and "Moderate-to-severe" SLE disease severity

	"Mild" patients n = 355	"Moderate-to-severe" patients n = 139

Work-Related Behavior and Experiences in Patients with Systemic Lupus Erythematosus. Jutta G. Richter[1], Ralph Brinks[2], Thomas Muth[1], Tobias Koch[1], Peter Angerer[1] and Matthias Schneider[1]. [1]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [2]Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany.

Background/Purpose: Work-related behavior and experiences are discussed to be either risk factors or resources for individual's health. Diseases and related changing working conditions and/or experiences might have additional effects. The objective of the study was to describe work-related attitudes and to examine their relationship to

clinical data and health in patients (pts) with systemic lupus erythematosus (SLE).

Methods: Self-reported (outcome) questionnaires including clinical data were applied to SLE pts and controls (c) not suffering from rheumatic diseases, both groups were capable for work. The 'AVEM' questionnaire assesses eleven health relevant dimensions via 66 items and thus determines the personal attitudes towards work, see Table 1. The dimensions (d) are attributable to three areas: work engagement (d 1–5), resistance to stress (again d 5; 6–8) and the emotions accompanying occupation (d 9–11). Ethics committee approval had been obtained.

Results: 252 pts (95.6% female (f)) and 177 c (90.3% f) contributed data. Patients' mean age was 40.1±9.4 (c 42.8±9.8) years, mean disease duration 10.5±7.3 years, mean HAQ 0.8±0.4 (c 0.4±0.1). 86.0% reported at least one comorbidity (range 1–10, c 45.2%, range 0–4). 77.4% received at least one immunosuppressive medication (range 0–3). 40.5% were on steroids <7.5mg, 16.3% on steroids >7.5mg, 32.1% took NSAIDS.

AVEM scales are depicted in Table 1, SLE pts scored significantly different to c in eight dimensions. Pts showed higher scores for 4 of 5 work engagement scales, less capability for emotional distancing, higher resignation tendencies, lower satisfaction with life and lower experiences of social support. OR indicate whether pts of the T- group (see table 1) have an increased risk for lower self-rated health status compared to T+.

Table 1. AVEM dimensions in c and SLE, *mean±standarddeviation, T+ and T- Percentage of pts deviating > 1 SD from mean of c, + Wilcoxon test, # Fisher's exact test

AVEM dimensions	c*	SLE*	p-value+	T+	T−	OR	p-value#
1. Subjective significance of work	15.2 ± 5.0	16.5 ± 5.2	0.0080	19.8	14.0	0.70	p>0.05
2. Professional ambition	16.5 ± 5.0	17.5 ± 5.6	p>0.05	23.0	16.7	1.07	p>0.05
3. Tendency to exert	17.9 ± 5.1	19.8 ± 5.3	0.0004	28.0	9.6	0.12	0.0002
4. Striving for perfection	21.8 ± 4.5	22.7 ± 4.2	0.0448	21.7	13.8	0.30	0.0135
5. Emotional distancing	20.6 ± 5.0	18.7 ± 5.3	0.0007	8.3	27.7	4.37	0.0099
6. Resignation tendencies	15.4 ± 4.2	16.9 ± 4.9	0.0023	29.2	10.6	0.42	p>0.05
7. Offensive coping with problems	22.0 ± 3.3	21.0 ± 3.7	0.0098	10.5	23.8	1.69	p>0.05
8. Balance and mental stability	20.3 ± 4.3	18.6 ± 4.9	0.0006	12.2	32.8	2.06	p>0.05
9. Satisfaction with work	22.4 ± 4.1	21.6 ± 4.4	p>0.05	13.8	24.3	3.54	0.0084
10. Satisfaction with life	22.9 ± 3.9	20.3 ± 4.5	0.0000	8.4	30.3	9.93	0.0001
11. Experience of social support	23.5 ± 4.3	22.2 ± 4.7	0.0069	12.7	27.9	4.80	0.0014

Conclusion: This is the first study applying AVEM to SLE pts. Results detected domains that are potentially modifiable and should be considered in clinical management. Pts work engagement, resistance to stress and emotional issues should be predominantly targeted. Further study analyzes will address correlations to other study parameters and confounding factors. Thus, appropriate strategies that promote healthy personal attitudes and equip pts with adequate supporting coping skills that prepare them for the challenges at their daily work might and should be developed.

1079

Prevalence of Cardiac Arrhythmias in Systemic Lupus Erythematosus. Gihyun Myung, Lindsy J. Forbess, Mariko L. Ishimori, Sumeet Chugh, Daniel Wallace and Michael H. Weisrman. Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Cardiovascular disease is a major cause of death among systemic lupus erythematosus (SLE) patients. Although the prevalence of atrial fibrillation (0.5–1%) and QT prolongation (7%) is well studied in the general population, little is known regarding arrhythmias in SLE. The aim of this project is to determine the prevalence of arrhythmias in a SLE population.

Methods: We retrospectively reviewed electrocardiograms (ECGs) of SLE patients seen in inpatient, outpatient and emergency department settings over a 10-year time frame at a single academic center. Abnormal ECG findings were confirmed by an electrophysiologist. ECGs were categorized as abnormal if arrhythmias or QT prolongation (QTc ≥460ms for women; ≥450ms for men) were present. Sinus bradycardia, 1st degree AV block, and sinus tachycardia were not considered arrhythmias but were recorded. Arrhythmias were also ascertained through review of ICD9 codes for the subset of SLE patients with available ECGs.

Results: Of 1,139 SLE patients, 235 had available ECGs. 160 were white (68%), 33 black (14%), 27 Asian (12%), and 15 Hispanic (6%). 217 were female (92%), 18 (8%) male, and the average age was 52 ± 15 (average ± SD). Through ECG review, 6% had tachyarrhythmias (3% with atrial fibrillation) and 17% had QT prolongation (Table 1). None had bradyarrhythmias. Through ICD9 code examination, more had tachyarrthythmias (15%), including atrial fibrillation (9%), compared with direct ECG review. 35 of 53 abnormal ECGs (66%) were obtained in the inpatient setting, 11 (21%) in the outpatient setting, and 7 (13%) in the emergency department. The most common ECG indication was chest pain (12% of abnormal and 16% of normal ECGs).

Conclusion: Sinus tachycardia was the most common ECG finding among our SLE patients. Compared to the general population, our SLE patients had a higher prevalence of atrial fibrillation and QT prolongation. This is likely an underestimation of the true arrhythmia prevalence, given that review of ICD9 codes revealed an even higher rate of tachyarrhythmias compared to direct ECG review. As QT prolongation was common in our SLE patients, it is important to be vigilant about drug interactions and the electrophysiologic effects of various medications, such as antibiotics, in these patients. Further prospective study of arrhythmias, their outcomes, and underlying causative factors (such as medication use and disease severity) in SLE patients is warranted.

Table 1. Prevalence of Arrhythmias in SLE patients after Review of ECGs and ICD9 codes

	Type of Review, N (%)	
Arrhythmia	ECG, N=235	ICD9 Code, N=235
Tachyarrhythmia	13 (6)	35 (15)
Atrial fibrillation	7 (3)	21 (9)
Atrial flutter	2 (1)	6 (3)
Atrial tachycardia	2 (1)	8 (3)
Supraventricular tachycardia	2 (1)	3 (1)
Paroxysmal ventricular tachycardia	0 (0)	8 (3)
QT Prolongation	40 (17)	4 (2)
Sinus Tachycardia	42 (18)	Not Available
Sinus Bradycardia	34 (14)	Not Available
1st Degree AV Block	6 (3)	3 (1)

Stroke Risks Among U.S. Medicaid Recipients with Systemic Lupus Erythematosus, 2000–2006: Racial and Ethnic Variation. Medha Barbhaiya[1], Jose A. Gomez-Puerta[2], Hongshu Guan[1], Daniel H. Solomon[1], Joanne M. Foody[3], Graciela S. Alarcon[4] and Karen H. Costenbader[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, Boston, MA, [3]Division of Cardiovascular Medicine, Brigham and Women's Hospital, Boston, MA, [4]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: SLE patients are at increased stroke risk, but racial/ethnic variation in risk has not been examined in a population-based study. We examined risks by race/ethnicity among SLE patients in Medicaid, the US medical insurance program for the poor. We investigated whether differential loss to follow-up and variation in mortality between racial/ethnic groups influenced Cox regression model estimates.

Methods: From the Medicaid Analytic eXtract (MAX) 2000–2006, containing all billing claims for patients from 47 U.S. states and Washington D.C., we identified patients 18–65 with prevalent SLE (≥3 SLE ICD-9 codes of 710.0, >30 days apart) and/or lupus nephritis (additional >2 codes for nephritis, renal insufficiency or failure). The index date was the date when SLE or lupus nephritis definition was met. We extracted age, sex, US region, calendar year, zip code area-based socioeconomic status (SES). Baseline comorbidities and SLE-specific risk index (Ward M, *J Rheum*, 2000) were from ICD-9 and CPT codes until index date. Within inpatient claims, ICD-9 codes identified fatal and non-fatal, ischemic and hemorrhagic strokes (PPV 83%, Andrade SE, *Pharmacoepi Drug Saf*, 2012). Stroke incidence rates (IR) per 1,000 person-years with 95% CIs were calculated for each racial/ethnic group. Multivariable-adjusted Cox regression models calculated cause-specific hazard ratios (HRcs) for stroke from index date through end of follow-up, censoring for death or loss to Medicaid follow-up, adjusting for covariates (**Table**). We also used Fine and Gray proportional hazards models

to calculate subdistribution HRs (HRsd), accounting for competing risks of death and loss to follow-up, adjusting for the same covariates.

Results: Of 42,221 SLE patients, 39,320 (93%) were female and 6,467 (15%) had lupus nephritis. Mean age at baseline was 38.13 (SD 12.29); 38% lived in the South, 23% in the West, 20% in the Northeast and 20% in the Midwest. Blacks represented 40%, Whites 38%, Hispanics 15%, Asian 5%, and Native Americans 2%. IRs were 10.02 (95% CI 9.44–10.64) per 1,000 person-years for all SLE patients, and 17.03 (95%CI 15.11–19.20) per 1,000 person-years for all lupus nephritis patients. After multivariable adjustment, Blacks had higher stroke risks (HRcs 1.31) than Whites. (**Table**) This risk remained similarly elevated in competing risks models (multivariable HRsd 1.36). Among lupus nephritis patients, stroke risks among Blacks vs. Whites were also high (multivariable HRsd 1.57). Stroke risks among other racial/ethnic groups did not significantly differ from those in White patients.

Conclusion: Among US Medicaid SLE and lupus nephritis patients, stroke IRs were high. After adjusting for sociodemographic and clinical factors, Blacks compared to Whites with SLE had 36% increased risks and those with lupus nephritis had 57% increased risks. Accounting for competing risks did not substantially affect these estimates.

Table Incidence Rates and Adjusted Subdistribution Hazard Ratios for Stroke Hospitalization among Medicaid patients with SLE in the US, from 2000-2006, by Race and Ethnicity

Race/Ethnicity	Total individuals	Number of events	Person-years	IR* (95% CI)	Multivariable-Adjusted Proportional Hazards HRcs (95% CI)¥	HRsd (95% CI)¥
White	16,219	352	40,204	8.76 (7.89–9.72)	1.0 (Ref)	1.0 (Ref)
Black	16,956	538	42,091	12.78 (11.74–13.91)	**1.32 (1.18–1.48)**	1.36 (1.17–1.59)
Asian	1,880	41	5,525	7.42 (5.46–10.08)	1.14 (0.87–1.50)	1.26 (0.89–1.80)
Hispanic	6,489	114	16,495	6.91 (5.75–8.30)	1.01 (0.85–1.20)	0.95 (0.75–1.20)
Native American	677	17	1,653	10.29 (6.40–16.55)	1.32 (0.90–1.93)	1.38 (0.82–2.33)

*IR=Incidence rate, events per 1,000 person-years.
¥HRcs=Cause-specific hazard ratio from Cox proportional hazards model; HRsd=Sub-distribution hazard ratio from Fine and Gray proportional hazards competing risks model. Multivariable models adjusted for age, sex, U.S. region of residence, calendar year, area-based SES, and baseline comorbidities (including history of angina, coronary artery bypass graft, coronary atherosclerosis, percutaneous coronary intervention, hypertension, smoking, obesity) and SLE-specific risk adjustment index.

Prediction of Mortality Risk Related to Cerebrovascular Accidents in Patients with Systemic Lupus Erythematosus (SLE) vs Anti-Phospho-Lipid-Antibody (aPL) syndrome. Khushboo Sheth[1], Tapan Mehta[1], Sonam Puri[1], Ronak Soni[2] and Kathan Mehta[3]. [1]University of Connecticut, Farmington, CT, Farmington, CT, [2]Government Medical College, Surat, India, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, Pittsburgh, PA.

Background/Purpose: It is well-established that patients with co-existent Systemic Lupus Erythematosus (SLE) and Anti-Phospho-Lipid-Antibody (aPL) syndrome are at increased risk of cerebrovascular accidents (CVA). Many studies have described that incidence of stroke is significantly higher in SLE and aPL syndrome; However, both these conditions may overlap. Hence, in this nation-wide study, after controlling the potential confounders we studied the individual impact of either condition (SLE and aPL syndrome) on mortality related to CVA.

Methods: We queried the Healthcare Cost and Utilization Project's (HCUP) Nationwide Inpatient Sample (NIS) between 2004 and 2010 and separated the hospitalizations due to or with stroke using ICD 9 diagnostic codes previously established by HCUP. Among this population, we examined the patients with SLE and patients with aPL syndrome and compared their risk of mortality to the all stroke population using the logistic regression model. The model was controlled for confounders which included age, sex, atrial fibrillation, chronic kidney disease, diabetes mellitus, rheumatoid arthritis, chronic rheumatic heart disease and diseases of endocardium. Using SAS 9.2, survey procedures were used to identify multivariate predictors of stroke.

Results: A total of 1,799,560 (weighted N= 8,874,475) who were hospitalized with stroke were available for analysis out of which 6,890 (weighted N= 33,882) had SLE and 13,769 (weighted N=68,069) had aPL syndrome. On univariate analysis, patients with SLE had 4.43%mortality as compared to 4.35% in patients without SLE ($p = 0.47$); and patients with aPL syndrome had 11.37% mortality as compared to 4.3% in patients without aPL syndrome ($p<0.001$). After controlling for confounders mentioned above, com-morbid SLE had no impact on in-hospital mortality (Odds Ratio (OR)=0.93, Confidence Interval (CI)=0.81–1.06, $p = 0.2888$). Whereas, co-morbid aPL syndrome was associated with significantly increased risk of in-hospital mortality (OR= 2.77, CI=2.59–2.97, $p < 0.0001$), in patients with stroke.

Table 1: Multivariable predictors of mortality in the study population for stroke (N=1,799,560)

Variables	Model OR with 95% CI	P value
Age	1.017 (1.015–1.019)	<0.0001
Female Gender	1.065 (1.046–1.084)	<0.0001
Race(African American vs Caucasian)	1.122 (1.088–1.157)	<0.0001
CCI	1.213 (1.203–1.223)	<0.0001
Systemic Lupus Erythematosus	0.929 (0.810–1.065)	0.2888
Antiphosholipidantibody syndrome	2.772 (2.590–2.968)	<0.0001
Chronic Kidney Disease	2.064 (1.998–2.132)	<0.0001
Atrial fibrillation	1.921 (1.878–1.964)	<0.0001
Diseases of endocardium	0.791 (0.764–0.819)	<0.0001
Rheumatic heart disease	0.762 (0.720–0.806)	<0.0001
Rheumatoid Arthritis	0.718 (0.665–0.776)	<0.0001
Scleroderma	1.284 (0.999–1.650)	0.0508
Diabetes Mellitus	0.580 (0.566–0.594)	<0.0001
Teaching Hospital Status	1.175 (1.116–1.237)	<0.0001

*CCI = Charlson Co-morbidity Index.

Conclusion: Though SLE and aPL Syndrome overlap significantly, we found in our analysis that after controlling the significant confounders, SLE alone is not an independent risk factor for increasing mortality risk among the CVA population. Whereas, aPL Syndrome is an independant predictor of increased risk of mortality in patients with CVA.

1082

Risk of Intra Cranial Hemorrhage among Patients with Anti-Phospho-Lipid-Antibody (aPL) syndrome vs Systemic Lupus Erythematosus (SLE) in Stroke Population: A Nationwide Analysis. Tapan Mehta[1], Khushboo Sheth[1], Ronak Soni[2], Sonam Puri[1] and Kathan Mehta[3]. [1]University of Connecticut, Farmington, CT, Farmington, CT, [2]Government Medical College, Surat, India, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, Pittsburgh, PA.

Background/Purpose: Central nervous system involvement is common in Systemic Lupus Erythematosus (SLE) and was first described in 1873. Though ischemic involvement is more common than Intra-Cerebral Hemorrhage (ICH) in SLE, hemorrhagic involvement is more life threatening and disabling. Several studies have shown that SLE patients with ICH present with higher frequency of Anti-Phospho-Lipid-Antibody (aPL) syndrome. In our study we tried to investigate if SLE or aPL syndrome independently predicts risk of ICH in CVA.

Methods: We queried the Healthcare Cost and Utilization Project's (HCUP) Nationwide Inpatient Sample (NIS) between 2004 and 2010 and separated the hospitalizations due to or with stroke using ICD 9 diagnostic codes previously established by HCUP. Among this population, we examined the patients with SLE and patients with aPL syndrome and compared their risk of ICH to the all stroke population using the logistic regression model. The model was controlled for confounders which included age, sex, atrial fibrillation, chronic kidney disease, diabetes mellitus, rheumatoid arthritis, chronic rheumatic heart disease and diseases of endocardium. Using SAS 9.2, survey procedures were used to identify multivariate predictors of stroke.

Results: A total of 1,799,560 (weighted N= 8,874,475) who were hospitalized with stroke were available for analysis out of which 6,890 (weighted N= 33,882) had SLE and 13,769 (weighted N=68,069) had aPL syndrome. On univariate analysis, among patients with SLE 1.41% developed ICH as compared to 1.29% in patients without SLE ($p = 0.06$); and among patients with aPL syndrome 3.5% developed ICH as compared to 1.28% in patients without aPL syndrome ($p<0.001$). After controlling for confounders mentioned above, co-morbid SLE was associated with decreased risk of having ICH (Odds Ratio (OR)= 0.68, Confidence Interval (CI)=0.53–0.89, $p < 0.0039$) in patients with stroke. Whereas, co-morbid aPL was associated with increased risk of having ICH (OR= 1.93, CI=1.72–2.17, $p<0.0001$), in patients with stroke.

Table 1: Multivariable predictors of ICH in the study population for stroke (N= 1,799,560)

Variables	Model OR with 95% CI	P value

Age	0.984 (0.982–0.985)	<0.0001
Female Gender	1.039 (1.001–1.079)	0.0434
Race(African American vs Caucasian)	1.154 (1.083–1.229)	<0.0001
CCI	1.097 (1.081–1.113)	<0.0001
Systemic Lupus Erythematosus	0.683 (0.528–0.885)	0.0039
Antiphosholipidantibody syndrome	1.932 (1.716–2.176)	<0.0001
Chronic Kidney Disease	0.909 (0.864–0.955)	0.0002
Atrial fibrillation	1.583 (1.512–1.658)	<0.0001
Diseases of endocardium	0.706 (0.658–0.757)	<0.0001
Rheumatic heart disease	0.857 (0.774–0.948)	0.0028
Rheumatoid Arthritis	0.778 (0.679–0.891)	0.0003
Scleroderma	0.744 (0.428–1.294)	0.2951
Diabetes Mellitus	0.631 (0.606–0.656)	<0.0001
Teaching Hospital Status	2.252 (2.024–2.507)	<0.0001

*CCI = Charlson Co-morbidity Index.

Conclusion: In addition to the understanding of increased risk of CVA in SLE and aPL Syndrome patients, further understanding of the nature of the cerebrovascular disease can influence treatment strategies. Our study showed that SLE patients are at decreased risk of hemorrhagic stroke in comparison to general stroke population. However, aPL Syndrome patients are at increased risk of hemorrhagic stroke in comparison to general stroke population. This suggests that aPL component of the disease spectrum predisposes the patients to ICH.

The Relation of Step Length to MRI Features of Osteoarthritis in the Patellofemoral Joint: The MOST Study. Joshua Stefanik[1], K. Douglas Gross[2], David T. Felson[2], Jingbo Niu[1], Daniel K. White[2], Ali Guermazi[2], Frank Roemer[3], C.E. Lewis[4], Neil A. Segal[5], Michael Nevitt[6] and Cara Lewis[1]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Klinikum Augsburg, Augsburg, Germany, [4]University of Alabama at Birmingham, Birmingham City, AL, [5]University of Iowa, Iowa City, IA, [6]UCSF, San Francisco, CA.

Background/Purpose: Patellofemoral joint (PFJ) osteoarthritis (OA) is a common source of pain and there is little evidence for rehabilitation treatment. Gait retraining treatments are effective in reducing pain in younger individuals with patellofemoral pain. Compared to self-selected step length, increased step length is related to increased PFJ stress. If step length affects PFJ stress, then individuals with a longer step length may be at increased risk of PFJ disease. The purpose of this study was to investigate the relation of step length to prevalent/worsening structural damage in the PFJ.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded cohort study of 3,026 individuals with or at risk for knee OA. Participants had MRI of their knee and two musculoskeletal radiologists assessed cartilage morphology and bone marrow lesions (BMLs) in the PFJ at the 60 and 84-month study visit. Spatial-temporal gait parameters were collected using the Gaitrite system at the 60-month visit. Step length was measured as the distance from heel center of footprint to heel center of previous footprint from the other foot. Step length was divided into quintiles and we determined the relation of step length to **prevalent** full-thickness cartilage loss and BMLs in PFJ subregions using logistic regression with generalized estimating equations, adjusting for age, sex, BMI and leg length (measured from long limb films from center of femoral head to center of talus). Because knee pain from structural damage could cause a person to shorten their step length and reduce PFJ stress, in order to examine causal effects of step length, we determined the relation of step length to **incident** cartilage loss and BMLs from 60 to 84-months in PFJ subregions without any cartilage loss or BMLs at 60-months. In secondary analyses we normalized step length by leg length and and also removed knees with frequent knee pain at 60 months.

Results: 4212 patellar and anterior femur subregions from 1132 knees were included. The mean age and BMI at the 60-month visit were 66.9 (±7.5) years and 29.6 (±4.7) kg/m^2, respectively, and 62% were female. While subregions in knees with the longest step length had the lowest *prevalence* of full-thickness cartilage loss, there was no association when adjusting for potential confounding variables. There was no association between step length and *incident* PFJ cartilage loss. Compared to subregions in knees with short step length, those with the longest step length were associated with 0.72 (0.52, 0.98) times the odds of *prevalent* BMLs in the PFJ (Table). There was no association between step length and *incident* BMLs. Similar results were seen in the secondary analysis.

Conclusion: Cartilage loss and BMLs were most common in knees with short step length but there was no relation of step length to worsening of cartilage or BMLs longitudinally. Individuals may shorten their step length to reduce PFJ stress.

Obesity Is a Risk Factor for Depression in Systemic Lupus Erythematosus (SLE). Patricia P. Katz[1], Stephanie Rush[2], Laura Trupin[2], Jennifer Barton[2], Gabriela Schmajuk[2], Jinoos Yazdany[2], Chris Tonner[2] and Mary Margaretten[2]. [1]University of California, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: General population studies have found significant relationships between obesity and depression, including identifying obesity as a risk factor for onset of depression. In SLE, rates of depression are high, and depression can be a neuropsychiatric manifestation of SLE. The role of obesity as an independent risk factor for depression in SLE has not been studied. In this analysis, we examine the risk of depression onset for obese and non-obese women with SLE.

Methods: Analyses use data from the Lupus Outcomes Study (2004–2014) obtained through annual structured telephone interviews. All participants have physician-confirmed SLE. Depressive symptoms were measured with the Center for Epidemiologic Studies Depression scale (CESD). Possible and probable depression were estimated using validated SLE-specific cut-points (20 and 24, respectively). Body mass index (BMI) was calculated from self-reported height and weight, and obesity was defined using a validated SLE-specific BMI cut-point of ≥26.8. (A sensitivity analysis also examined the standard BMI obesity cut-point of 30.) Cox proportional hazard models were used to estimate the risk of becoming depressed associated with obesity at baseline. Models were calculated for both possible and probable depression. Multivariate analyses adjusted for age, race (white non-Hispanic vs. other), baseline disease activity (Systemic Lupus Activity Questionnaire, SLAQ), current smoking, prednisone use, and baseline functioning (SF-36 Physical Component Score). Only women were included in the analysis because the number of men was relatively small. Women who had BMI <18.5 or who met the depression criterion at baseline were excluded from analysis.

Results: Data from 718 women were available for analysis, of whom 32 had BMI<18.5. At baseline, 211 met the criterion for possible depression (CESD ≥ 20) and 171 for probable depression (CESD ≥ 24), leaving 471 and 515 in the analyses for possible and probable depression, respectively. BMIs ranged from 18.6 — 54.9. Mean follow-up time was 9 years (range 2–11 years). In the analysis for possible depression, 31.6% of those who were not obese became depressed, compared to 48.1% of those who were obese (table). The adjusted HR (95% CI) for possible depression associated with obesity was 1.56 (1.15, 2.11). In the analysis of probable depression, 25.9% of those not obese became depressed compared to 42.6% of those who were

obese. The adjusted HR (95% CI) for probable depression was 1.69 (1.23, 2.30). Using the standard BMI cut-point for obesity yielded similar results.

Conclusion: Obesity appears to be a risk factor for development of depression among women with SLE, even after controlling for disease activity and other relevant factors. This is a clinically important finding, as obesity is modifiable, and reducing obesity is likely to lead to additional health benefits such as reduced cardiovascular disease.

Risk of depression onset associated with obesity* among women with SLE

	Possible depression (CESD ≥20)	Probable depression (CESD ≥24)
Total n for analysis	471	515
Obese at baseline	38.9%	39.2%
Became depressed		
Not obese	31.6% (91)	25.9% (81)
Obese	48.1% (88)	42.6% (86)
Multivariate HR (95% CI) for obesity†	1.56 (1.15, 2.11)	1.69 (1.23, 2.30)

Women who met criteria for depression at baseline were excluded.
* Obesity defined as BMI ≥ 26.8.
† HR = Hazard ratio. Multivariate model adjusted for age race, baseline disease activity (SLAQ), smoking, and baseline physical functioning.

Trajectories and Predictors of Physical Activity over Two Years in Rheumatoid Arthritis. Ingrid Demmelmaier[1], Alyssa B. Dufour[2], Birgitta Nordgren[1] and Christina H. Opava[1]. [1]Karolinska Institutet, Huddinge, Sweden, [2]Hebrew SeniorLife & Boston Univ, Boston, MA.

Background/Purpose: Although physical activity is crucial for managing symptoms and comorbidities in rheumatoid arthritis (RA), the majority of the RA population does not reach recommended health-enhancing physical activity levels. Longitudinal studies are scarce and more knowledge is needed about predictors of different patterns of physical activity over time in large RA samples. The aim was to, within a large well-defined sample of persons with rheumatoid arthritis, identify and describe groups demonstrating different trajectories of physical activity over two years and to identify baseline predictors for being in each specific group.

Methods: This longitudinal study used data from the Swedish Quality Registries and a questionnaire covering sociodemographic, disease-related, psychosocial and physical activity variables. Physical activity was assessed by the International Physical Activity Questionnaire as total weekly hours of vigorously intense activity, moderately intense activity and walking. A total of 2752 participants responding to at least two out of three questionnaires at baseline, 12 months and 24 months were aged 18–75 years, diagnosed with RA according to the ACR criteria and independent in daily living (Stanford Health Assessment Questionnaire ≥ 2.0). K-means cluster analysis was used to identify three trajectories of hours of weekly physical activity. Multinomial logistic regression was used to identify predictors of trajectory membership. Multiple imputation was used to impute missing data in potential predictors, which included sociodemographic, disease-related, psychosocial and physical activity variables.

Results: We identified three patterns of physical activity: The "Stable High" group performed on average 25 hours of physical activity per week (n=272), the "Decreasing" group went from 22 to eight hours per week (n=564) and the "Stable Low" performed three hours of physical activity per week (n=1916). Predictors of being in the "Stable High" group versus the other two groups were male gender and already established health-enhancing physical activity at baseline. Increased age predicted being in the "Decreasing" group versus the other two groups. Predictors of being in the "Stable Low" group versus the other two groups were female gender, more activity limitation, lower self-efficacy for exercise and not having established health-enhancing physical activity at baseline. For detailed results, see Table 1.

Conclusion: The results indicate that physical activity levels are still low in the RA population. Different trajectories of physical activity over time exist and are possible to identify, with each trajectory being associated with a unique set of predictors. Modifiable predictors to improve physical activity include activity limitation and self-efficacy for exercise.

Table 1 Baseline predictors of being in the Stable High (n = 272), Decreasing (n = 564) and Stable Low (n = 1916) physical activity groups. Odds ratios (OR) with 95% confidence intervals (CI)

Baseline predictors	Stable High vs Stable Low OR (95% CI)	Stable High vs Decreasing OR (95% CI)	Decreasing vs Stable Low OR (95% CI)

The Effect of Foot Pain on Mobility Disability in Older Adults: The Framingham Foot Study. Alyssa B. Dufour[1], Patricia P. Katz[2], Yvonne M. Golightly[3], Arunima Awale[4] and Marian T. Hannan[5]. [1]Hebrew SeniorLife, Harvard Medical School & Beth Israel Deaconess Medical Center, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [4]Hebrew SeniorLife, Boston, MA, [5]Institute for Aging Research, Hebrew SeniorLife, Dept. of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: While lower extremity function is thought to affect mobility, little is known of the influence of foot structure or function upon mobility limitations. We evaluated the associations of foot structure and foot function with mobility limitations in community-dwelling older men and women.

Methods: Framingham Foot Study participants (2002–2008) with performance measures of mobility limitations were included in this cross-sectional analysis. Mobility limitations was assessed using the Short Physical Performance Battery (SPPB), a composite of 3 timed performance tests (4-meter walk (s), chair stands (s), and balance test) with each test scored on a scale of 0 to 4 (total score range 0–12, higher score = better function). Previously, SPPB scores have predicted physical limitations, disability and mortality. We dichotomized SPPB as 1–9 to indicate mobility limitations and 10–12 as good mobility. We also examined quartiles of chair stand and walk time. Foot function while walking (pronated, supinated, normal) and weight-bearing arch structure (low, high, normal arch) were defined using a Tekscan matscan pressure system. Age, sex, body mass index (BMI; <30, ≥ 30 kg/m^2), current smoker (y/n) and depression (CES-D scale) were also obtained. Sex-specific multivariate logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (CI) for the association between foot structure and function with mobility limitations, adjusting for factors above.

Results: In 556 men and 700 women, average age was 70 yrs ($\pm$10.8) and BMI was 28 ($\pm$5.2). 16% had mobility limitations, 30% had high arched and 27% had low arched foot structure; 33% had pronated and 27% had supinated foot function. Foot function was not associated with mobility limitations. In women only, low arched foot structure was associated with increased odds of mobility limitations (SPPB; OR=2.27, p=0.005) after adjustment (Table). No associations were seen between foot structure or function and chair stand time (ORs= 0.8–1.1, all p>0.4). In quartiles of walk time, men in the 3rd quartile, compared to the lowest (fastest), were less likely to have a high arch foot structure (OR=0.53) and supinated foot function (OR=0.51). Women with a low arched foot were less likely to be in the 4th quartile (slowest walkers) compared to the fastest walkers and women with a pronated foot function were more likely to be in the 3rd quartile of walking speed compared to the fastest walkers.

Conclusion: Specific components of foot structure and function were associated with mobility limitations in our study, albeit with inconsistent patterns between men and women. Given these results, future work might examine specific regions of foot pressures and time-integral measures in order to drill down to biomechanical mechanisms.

Table. Odds Ratios and 95% Confidence Intervals for the Association* between SPPB and Quartiles of Measured Walk Time with Foot Structure and Foot Function in Men and Women of the Framingham Foot Study.

				Men	Women
SPPB (1–9 versus 10–12)	Foot Structure	High Arch		0.59 (0.31, 1.12)	0.783 (0.45, 1.37)

The Prevalence of Knee Arthritis and Associated Self-Reported Limitation of Activity in Chinese Populations. Xu Tang Sr., Ke TAO, Qiang LIU, Xu WU, Zheng Ming Cao and Jian Hao rLin. Arthritis Institute, People's Hospital, Peking University, Beijing, China.

Background/Purpose: To estimate the prevalence of knee arthritis and assess the association between knee arthritis and self-reported limitation of activity in Chinese Populations.

Methods: Populations: China Health and Retirement Longitudinal Study (CHARLS) is a population-based longitudinal survey among Chinese retired populations. Persons age ≥45 years and their spouse were interviewed in 450 randomly selected communities among China during 2011–2012.

Questionnaire and physical examination: The questionnaire and physical examination were used in this survey. Trained health professionals went door to door to administer the survey questionnaires and physical examination. We applied the information of "gender, age, living area, height, weight, self-reported knee pain and diagnosis of arthritis/rheumatism by a physician in the past" for the advanced analysis of knee arthritis prevalence. "Does the respondents have any difficulty in running or jogging about 1 km?/ walking 1 km?/ walking 100 meters?/ getting up from a chair?/ climbing upstairs?/ kneeling?" was employed for self-reported limitation assess.

Knee arthritis definition: We defined knee arthritis as "if one reported had knee pain and had a diagnosis of arthritis/rheumatism by a physician in the past".

Statistical analysis: The prevalence of knee arthritis by population groups was calculated, and the association between knee arthritis and the self-reported limitation of activity was assessed. Logistic regression analysis was used for statistical analysis.

Results: In 17708 participants (men: 47.9% vs women: 52.1%), the overall prevalence of knee arthritis was 9.1%, with women 1.9 times higher than men (95% CI 1.70–2.17, P<0.01). The prevalence of knee arthritis in the rural areas was approximately twice as much as urban regions in China (95% CI 0.46–0.60, P<0.01). The current knee arthritis structure of Chinese residents had been separated by a geographic structure (Qinling Mountains-Huaihe River Line) into two clusters: the South and North, and populations in South China had knee arthritis around 1.5 times the number of those in North China (95% CI 1.36–1.73, P<0.01). Along with the growth of the age and BMI (body mass index), the percentages of knee arthritis climbed gradually (P<0.01). Considering "running/walking distance, getting up from a chair, climbing upstairs or kneeling", subjects with knee arthritis had more difficulty in self-reported limitation (P<0.01).

Conclusion: The prevalence of knee arthritis in China is moderate, with women, populations in the rural area and geographic structure (South China) all the influencing factors of morbidity. It also indicates that growth of age and BMI contributes to the increase of knee arthritis rate and knee arthritis and self-reported limitation of activity demonstrates great association. This study provides a fundamental demographic profile for prevalence of knee arthritis and better to understand the knee arthritis and associated self-reported limitation of activity in Chinese populations.

Socioeconomic Disparities in Health Outcomes Among Individuals with, or at Risk for, Osteoarthritis from the United States: Data from the Osteoarthritis Initiative. Antoine A. Baldassari[1], Todd Schwartz[1], Rebecca J. Cleveland[1], Joanne M. Jordan[2] and Leigh F. Callahan[3]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Socioeconomic disparities in health outcomes among people with osteoarthritis are well documented, with some key limitations: existing studies limit their analyses to few outcome variables at a time and often evaluate socioeconomic status (SES) as a dichotomous exposure. As a result, there remains substantial uncertainty regarding the extent and nature of those health inequities. The data from the Osteoarthritis Initiative (OAI) allow us to comprehensively assess socioeconomic disparities in health outcomes within a large group of individuals at risk for or diagnosed with knee osteoarthritis.

Methods: This study includes 4081 OAI participants with full data on demographics, SES and health behaviors. Health outcomes included SF-12 measures of physical (PCS) and mental (MCS) health, the Center for Epidemiological Studies Depression scale (CESD), Western Ontario and McMaster Universities Arthritis Index (WOMAC) subscales for disability, pain and stiffness, Knee Injury and Osteoarthritis Outcome Scores (KOOS) for function and quality of life, and the amount of time needed to complete 20m and 400m walks. Our analyses focused on baseline measurements and used ordinary least squares regressions to evaluate the associations of health indicators with categories of family income and education, included separately and then simultaneously. All analyses were adjusted for race, sex and age, and standard errors were clustered by study site. Linear trends were assessed across income and education categories using linear contrasts.

Results: 58% of sample respondents were women, 18% self-identified as African-Americans, and the mean age was 61 years. Participants had an average BMI of 29kg/m^2, and nearly half (45%) ever smoked. 30% of all sample participants held a graduate degree and 24% reported family earnings over $100,000/year. There were graded associations of education and income with each of the health outcome measures, adjusted for age, race and sex (Table 1), with the exception that individuals who only partially attended graduate school experienced worse self-reported health than those with a college degree but no postgraduate schooling. Further adjustments for pack-years smoked, body mass index, alcohol use, comorbidities, marital status, current employment and study site did not substantially change the associations, while education and income remained independently associated with health outcomes when simultaneously included in models (Data not shown).

Conclusion: The health of OAI participants varied strongly according to their SES, in a gradient pattern of worsening health with lower levels of income and education. This may be the most comprehensive study of the health socioeconomic gradient in a population with OA or at risk for OA. Differences were not explained by health behaviors, and further studies should explore pathways related to the patterns described herein.

Table 1: Differences in adjusted means (from reference)[1] for the associations of education and income with health outcome measures in the Osteoarthritis Initiative (N=4081), in separate ordinary least squares regression models adjusted for age, race, and sex

Trajectories of Disability over Time Among Patients with Systemic Sclerosis. Sarah D. Mills[1], Rina S. Fox[1], Shadi Gholizadeh[1], Scott C. Roesch[1], Murray Baron[2], Marie Hudson[3], Russell Steele[3], Brett D. Thombs[3] and Vanessa L. Malcarne[4]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]McGill University, Montreal, QC, [3]Jewish General Hospital, Montreal, QC, [4]San Diego State University, San Diego, CA.

Background/Purpose: Systemic Sclerosis (SSc) is often associated with disability, which worsens over time. However, there is considerable heterogeneity in the rate of patients' disability progression. The aim of the present study was to identify homogenous subpopulations of SSc patients with distinct trajectories of change in disability over a three-year period.

Methods: The sample included patients with limited and diffuse SSc (N = 1,125) participating in the Canadian Scleroderma Research Group Registry. As part of the Registry, patients are scheduled for annual follow-up visits. Patients with and without follow-up visits were included to account for potentially informative patient drop out. Growth mixture modeling (GMM) with robust maximum likelihood estimation was completed to identify groups of patients with distinct trajectories of disability over a three-year period, as measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI; range: 0 (no disability) – 3 (severe disability)). Multinomial logistic regression was used to identify baseline sociodemographic and clinical variables that predicted membership in the latent growth trajectory classes.

Results: Considering fit indices (AIC, sBIC, BLRT) and substantive interpretation (class proportions, entropy), the GMM analysis identified three distinct groups of patients based on their disability trajectories. Class 1 was comprised of 53.4% of the total sample, and Classes 2 and 3 were comprised of 35.3%, and 11.2% of the total sample, respectively. Based on trajectories of HAQ-DI scores the groups were named: Minimal Disability-Increasing (Class 1; baseline HAQ-DI:. 27), Moderate Disability-Stable (Class 2; baseline HAQ-DI: 1.20), and Severe Disability-Stable (Class 3; baseline HAQ-DI: 2.04). In Class 1, HAQ-DI scores increased by. 12 over three years. Patients in Class 3 had more finger ulcers, more breathing problems, and more gastrointestinal problems than patients in Class 2 or Class 1. In addition, patients in Class 3 were of older age, had shorter disease duration, and were more likely to be female and have diffuse disease than patients in Class 1. Patients in Class 2, when compared to Class 1, had more finger ulcers, breathing problems, and severe Raynaud's phenomenon, and were more likely to be older, female, and have diffuse disease.

Conclusion: Disability trajectories are not uniform across patients with SSc. Overall, patients with low baseline disability scores and disability progression had fewer finger ulcers, breathing problems, and gastrointestinal problems, less severe Raynaud's phenomenon, were of younger age, male, had longer disease duration, and limited disease in comparison to the moderate and severe disability groups. The moderate and severe disability groups did not report significant disability progression, suggesting that for at least some patients with SSc, disability may reach a peak and then remain stable overtime.

Association of Objectively Measured Physical Activity and Metabolic Syndrome Among Adults with Osteoarthritis in the United States. Shao-Hsien Liu[1], Charles Eaton[2] and Kate Lapane[3]. [1]Clinical and Population Health Research Program, Graduate School of Biomedical Science, University of Massachusetts Medical School, Worcester, MA, [2]Departments of Family Medicine and Epidemiology, Warren Alpert Medical School, School of Public Health, Brown University, Providence, RI, [3]Department of Quantitative Health Sciences, University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Metabolic syndrome increases the risk of osteoarthritis (OA). The accumulation of components of the metabolic syndrome is associated with a gradual increase in the risk of development and progression of knee OA. Physical activity may be a viable strategy to decrease the prevalence of metabolic syndrome. Studies examining physical activity among persons with OA are limited by self-reported data and the definitions are varied. The purpose of this study is to investigate the association between objectively-measured physical activity and metabolic syndrome among a nationally representative sample of adults with OA.

Methods: Using cross-sectional data from the 2003–2006 National Health and Nutrition Examination Survey, we identified 385 adults with OA who had physical activity measured with the Actigraph AM-7164 accelerometer worn over the right hip on an elasticized belt. Accelerometers provide a reliable and sensitive measure for the duration and intensity of bodily movement. As such, the activity counts derived from accelerometers were used to differentiate overall physical activity levels: 1) sedentary (>100 counts/min); 2) light physical activity (100 to 759 counts/min; 3) lifestyle (760 to 2019 counts/min); and 4) moderate to vigorous activity (≥2020 counts/min). Metabolic syndrome was defined using the National Cholesterol Education Program Adult Treatment Panel III standards. Logistic regression models estimated the relationship of quartile of daily minutes for each activity type to odds of metabolic syndrome adjusted for confounders and weighted for the complex survey design.

Results: Metabolic syndrome was present in 48.0% and of those, 11.2% met the physical activity guidelines of 150 minutes per week of moderate/vigorous activity. The proportion of sedentary time of total wear time, daily duration in light, lifestyle, or moderate to vigorous physical activity was associated with cluster components of metabolic syndrome. Relative to the lowest quartile of light activity, those in the highest quartile had reduced odds of metabolic syndrome (adjusted odds ratio (aOR) >296.3 versus ≤212.3 minutes/day : 0.43; 95% Confidence Interval (CI): 0.23 to 0.83; aOR 256.1–296.3 versus ≤212.3 minutes/day : 0.77; 95% CI: 0.30 to 1.97;aOR 212.4–256.0 versus ≤212.3 minutes/day : 1.43; 95% CI: 0.88 to 2.31; p-value for linear trend = 0.01).

Conclusion: Increased light physical activity was inversely associated with prevalence of metabolic syndrome among adults with OA. Effective interventions to encourage individuals with OA to increase light activity during daily living are warranted.

Skeletal Muscle Fat and Its Association with Physical Function and Physical Activity in Adults with Rheumatoid Arthritis. Samannaaz S. Khoja[1], Bret Goodpaster[2] and Sara R. Piva[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Sandford Burnham Medical Research Institute, Lake Nona in Orlando, FL.

Background/Purpose: Systemic inflammation in RA not only affects joints, but also body composition. People with RA tend to have lower lean body mass and higher body fat compared to healthy persons. Fat is also present inside the muscle, but little is known about how these fat depots are affected in RA, and their role in physical function. Skeletal muscle fat can potentially interfere with muscle fiber function and metabolic activity, and thus can be hypothesized to affect physical function. The aim of this study was to explore the association of skeletal muscle fat with outcomes of physical function and physical activity in persons with RA.

Methods: This was a cross-sectional, secondary analysis of baseline data from a study in adults diagnosed with RA as per the ACR criteria. Skeletal

muscle fat was quantified as the average muscle attenuation (MA) of the mid-thigh region, and was obtained through bilateral computed tomography (CT) imaging. MA values range from 0 to 100 Hounsfield units; higher values represent greater muscle density and thus, lower fat content. Physical function measures consisted of quadriceps maximum isometric strength, single leg balance time (up to 30 seconds), and the number of seconds taken to perform functional tasks such as chair rise (five times), ascend one flight of stairs, and walk four meters. Physical activity was captured with the SenseWear Armband, and time spent in moderate level activities (≥ 3 metabolic equivalent-MET) over 7 days was calculated. Bivariate correlations were used to test the associations of mid-thigh MA with physical function and physical activity. Separate hierarchical regression models were used to assess the contribution of mid-thigh MA to each physical function and physical activity measure after controlling for body mass index (BMI), quadriceps strength and quadriceps area.

Results: Study sample consisted of 60 subjects with RA, of which 82% were female, with average age and BMI of 59 ± 10 years and 31.2 ± 7.2 kg/m^2, respectively. Average RA duration was 15 ± 10 years and disease activity levels were moderate (mean DAS-28 score 4 ± 1.3). MA was inversely correlated with time to ascend one flight of stairs, and walk four meters; and directly correlated with time spent in physical activity (≥ 3 MET), and single leg stance. After adjusting for BMI, quadriceps strength and area, MA continued to contribute significantly to the variability in stair climb time, single leg balance time and physical activity time ≥ 3 MET (Table).

Conclusion: Higher skeletal muscle fat predicts lower physical function and physical activity. The contribution is above and beyond that of body size, and muscle strength and area. The mechanism by which skeletal muscle fat affects physical function is not clear, and perhaps muscle properties beyond its size and torque production need to be considered and investigated in future studies.

Table. Correlations between Muscle Attenuation, Physical Function and Physical Activity Outcomes

Outcome Variables	Correlations with MA (Spearman's rho)	Contribution of MA after adjusting for BMI, quadriceps strength and quadriceps area		
		β-coefficient	R^2 change	p-value
Quadriceps Isometric strength, *Newton-meters*	**.454***	–	–	–
Chair rise time, *sec*	−.244	.083	.005	.594

Does Arthritis Status Predict Starting or Stopping Work over a 2-Year Period? Kristina A. Theis[1], Miriam Cisternas[2] and Louise Murphy[1]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]MGC Data Services, San Diego, CA.

Background/Purpose: Employment is linked to prosperity, identity, and the ability to contribute to society. Lower employment is well documented among adults with arthritis, but less is known about trajectories of stopping or starting work and subgroups particularly at risk for not working. Our purpose was to describe longitudinal patterns in work stopping and starting among three groups of U.S. adults ≥18 years: 1) those with no arthritis (arthritis$^-$), those with arthritis but no arthritis-attributable work limitation (AAWL-), and those with arthritis and AAWL (AAWL+).

Methods: We analyzed data for those in the 2009 National Health Interview Survey (an ongoing nationally representative survey of the U.S. civilian, noninstitutionalized population) Sample Adult Core who were subsequently followed for 5 rounds in the 2010–2011 Medical Expenditures Panel Survey (n=24,870; response rate=57.2%). AAWL+ was "yes" to: "Do arthritis or joint symptoms now affect whether you work, the type of work you do, or the amount of work you do?" Among those working in 2009, we examined baseline characteristics (sociodemographic [age, sex, race/ethnicity, education], chronic health condition, and job) and estimated risk of **stopping work** with hazard ratios (HR) and 95% confidence intervals (CIs) using unadjusted and multivariable adjusted models for the 3 groups; among those not working in 2009, we used the same methods to examine **starting work**.

Results: At baseline, the proportion working was substantially lower among those with AAWL+ (28.6%; 95% CI=26.1–31.1) compared with AAWL- (47.3%; 45.1–49.4) and arthritis$^-$ (66.9%; 66.0–67.8). A significantly higher proportion with AAWL+ (24.2%; 21.7–26.5) had not finished high school compared with AAWL- (13.6%; 12.3–14.8) and arthritis$^-$ (14.2%; 13.5–15.0), and more of those with AAWL+ (39.5%; 37.0–42.0) had high functional limitations compared with AAWL- (8.5%; 7.6–9.4) or arthritis$^-$ (2.1%; 1.8–2.3). Multivariable adjusted HRs for ***stopping*** work (referent: arthritis$^-$) were 1.1 (0.8–1.6) for AAWL- and 2.0 (1.4–3.1) for AAWL+ (unadjusted HRs were virtually identical). Multivariable adjusted HRs (referent: arthritis$^-$) for ***starting*** work were 1.1 (0.7–1.7) for AAWL- and 0.5 (0.3–0.9) for AAWL+; unadjusted HRs were 0.4 [0.2–0.6] for AAWL- and 0.3 [0.2–0.6] for AAWL+.

Conclusion: Over two years of follow-up, the presence of AAWL+ was a substantial and significant risk factor for stopping work (HR = 2.0) and not starting work (HR=0.5), even after adjusting for baseline differences, including characteristics (e.g., low educational attainment) associated with not working. Those with AAWL- followed the same pattern as those with arthritis$^-$. For starting work, adjustment attenuated arthritis effects only among AAWL-, whereas AAWL+ consistently identifies a unique group of individuals at risk for increased work loss and reduced work entry over time. Identification of AAWL+ may be a useful indicator for offering clinical, public health, job accommodation, and other interventions to retain and gain employment.

Female Sexual Function in Fibromyalgia. Maria Julieta Gamba[1], Claudia Uña[1], Alicia Igel[1], Fernando Eraña[1], Maritza Vidal[1], Gimena Gómez[2], Griselda Redondo[1], Maria Celina de la Vega[1], Estella Chiuzzi[1], Augusto Martin Riopedrer Sr.[1], Maria Ines de la Barrera[1], Norma Villa[1], Dario Mata[1], Alba Russo[1] and Osvaldo Daniel Messina[1]. [1]HOSPITAL ARGERICH, BUENOS AIRES, Argentina, [2]Hospital Argerich, Buenos Aires, Argentina.

Background/Purpose: Fibromyalgia (FM) is a common condition in young and middle-aged women, which is mainly characterized by diffuse chronic pain and is associated with other manifestations such as fatigue, unrefreshing sleep, stiffness, anxiety and depresión[1]. Recent studies have evaluated that chronic pain syndrome and related manifestations could have a negative impact on sexual function of these patients, as well as psychophysical abuse history could act as potential triggers of FM. **OBJECTIVE:** Assess sexual function in women with FM and correlate with tender points count, clinical severity, anxiety, depression, chronic fatigue and history of physical and psychological violence.

Methods: A case-control study. Between 03/01/12 and 06/30/12 were included consecutively: women >18 years diagnosed with FM according to ACR criteria '90, and healthy controls >18 years, without history of violence. We excluded patients with other causes of chronic pain disorders and psychotic disorders. We recorded: sociodemographic data, education, employment and menopausal status and sexual function by **Female Sexual Function Index**[2] (FSFI: self-administered questionnaire that assesses six domains). In the FM group tender points count, duration of disease, medication, psychological care, presence of chronic fatigue (by **Fukuda Criteria**), clinical severity **(FIQ-Spanish version)**, depression **(HADS)**, and history of physical or psychological violence **(Screening Questionnaire of Violence)**[3] were assessed. We used Chi^{2}test, Student t test and Mann-Whitney test, and Spearman correlation coefficient (significant $p \leq 0.05$).

Results: We included 52 patients in the FM group and 52 in the control group. Median age: 50 ± 9.2 and 47 ± 10 years, respectively. FM Group: Medium evolution time: 60 months, mean pain points: 15 ± 3, FIQ median: 67.8 (28–86). 73.1% received medication for FM and 44.2% demanded psychological care. Patients with FM showed <level education ($p = 0.001$) and <work activity level ($p < 0.001$). 56% had chronic fatigue, 35% depression and 75% had a history of personal violence. The most common link with the aggressor was, the current partner in cases of psychological violence (28.1%) and former partners for physical violence (31.25%).We found significant impaired sexual function vs controls (median FSFI total: 17.2 (1.2–33.3) vs. 29.4 (1.2–36), $p < 0.001$) and the difference persists analyzing each domain of the FSFI. Having violence history generated a tendency to

lower values of FSFI (no statistical significance). No correlation was found between values of FSFI and the other analyzed variables

Conclusion: Our patients with FM had impaired sexual function compared to control group. Physical and psychological violence were frequent but weren't related with sexuality function.

Work Productivity and Healthcare Utilization in Patients with Fibromyalgia and Comorbid Depression Taking Antidepressant Medication. Jaren Landen[1], Claire Burbridge[2], Elizabeth Masters[3], Pritha Bhadra Brown[3], Joseph Scavone[1], Birol Emir[3], Richard Vissing[4], Andrew Clair[3] and Lynne Pauer[1]. [1]Pfizer Inc, Groton, CT, [2]Pfizer Ltd, Walton Oaks, United Kingdom, [3]Pfizer Inc, New York, NY, [4]Pfizer Inc, Louisville, KY.

Background/Purpose: Patients with fibromyalgia (FM) experience pain, sleep disruption, fatigue, and other symptoms that limit activity, impacting work productivity and increasing healthcare utilization. Here, we describe the burden of FM on work productivity and healthcare utilization in patients with FM taking antidepressant medication for their comorbid depression.

Methods: Patients from 38 centers in the United States, Europe (Italy, Spain), and Canada were enrolled in a phase 3 study of pregabalin efficacy and safety (NCT01432236). Patients with FM aged ≥18 years were taking a stable dose of a single selective serotonin reuptake inhibitor or serotonin/norepinephrine reuptake inhibitor for their comorbid depression for ≥2 months prior to randomization. FM-related work productivity and healthcare utilization were assessed at randomization. Work productivity over the preceding 7 days was measured using the Work Productivity and Activity Impairment:Fibromyalgia Symptoms (WPAI:FMS) questionnaire, a self-reported measure of FM-related absenteeism (work time missed), presenteeism (impairment while working), overall work impairment (absenteeism plus presenteeism), and activity impairment (impairment of regular activities other than work). Absenteeism, presenteeism, and overall work impairment were measured for employed individuals only. Each score is expressed as a percentage, higher scores indicating less productivity and greater impairment. Healthcare utilization related to FM in the preceding 3 months was measured using a self-reported Healthcare Utilization Assessment questionnaire that captured: number of healthcare professional (HCP) visits, hospitalizations, and emergency room (ER) visits; use of physical treatments and supplements; time other people spent providing help with activities of daily living without receiving payment; and out of pocket expenses for physical treatments, supplements, prescription and non-prescription medications, and professional services to assist with activities of daily living.

Results: 193 patients were evaluated at randomization. FM-related work productivity scores (mean ± SD) in the preceding 7 days were: absenteeism 15.2 ± 25.4% (n = 86), presenteeism 54.0 ± 21.5% (n = 83), overall work impairment 58.0 ± 23.4% (n = 82), and activity impairment 65.0 ± 18.8% (n = 193). In the preceding 3 months, the total number (mean ± SD) of HCP visits related to FM was 5.0 ± 6.6. There were no hospitalizations but 12 (6.2%) patients visited the ER. 67 (34.7%) and 61 (31.6%) patients used physical treatments and supplements, respectively. The number of hours (mean ± SD) other people spent providing help without payment was 50.4 ± 98.1. In patients who incurred out of pocket expenses in the preceding 3 months, total (mean [range]) expenditure was $US 307.12 (0–5,300; n = 110), EUR 410.43 (0–2,485; n = 49), and $CAN 211.26 (0–1,000; n = 19).

Conclusion: FM affects work productivity and regular activities other than work in patients with FM taking antidepressant medication for their comorbid depression. In these patients, FM is associated with substantial healthcare utilization, and generates considerable out of pocket expenses.

Treatment of Fibromyalgia with Neurostimulation: A Randomized, Double-Blinded, Sham-Controlled Trial. R. Michael Gendreau[1], Donald Deering[2], Judith Gendreau[3] and Jeffrey Hargrove[1]. [1]Cerephex Corporation, Los Altos, CA, [2]St. Joseph Mercy Oakland, Pontiac, MI, [3]Gendreau Consulting, LLC, Poway, CA.

Background/Purpose: NeuroPoint is a medical device designed to provide noninvasive brain stimulation using a proprietary approach to deliver very low energy levels to deep brain structures. NeuroPoint provides a therapy referred to as "reduced impedance noninvasive cortical electrostimulation" (RINCE). An initial feasibility study of 77 patients diagnosed with fibromyalgia (FM) was conducted between 2006 and 2008. The current pilot study was designed to further evaluate the safety and efficacy of RINCE therapy in the treatment of FM.

Methods: A total of 46 patients selected using the ACR 1990 FM criteria were enrolled in a single site, 12-week, double-blind, sham-controlled trial. Patients were randomized (1:1:1) to receive 24, 16 or 0 RINCE stimulations over a 12 week period. Due to an additional, unintended 60 Hz stimulation signal that was originally present in the system, 8 of 15 patients randomized to 0 treatments (Sham) received a form of stimulation. The final disposition was:

Group/	# Treatments	# Patients
A	24	15
B	16	16
C	0	7

Outcome measures included a 24-hour and 7-day recall pain VAS, Fibromyalgia Impact Questionnaire (FIQ-R), Patient Global Impression of Change (PGIC), and assessment of sleep, mood and neurocognitive changes.

Results: Completion rates were excellent with 45 of 46 patients completing all 12 weeks of scheduled treatments. At the 3 month landmark endpoint, patients treated with 24 RINCE stimulations were statistically improved on VAS pain relative to the sham group (MMRM LS Mean change from baseline −31.8 vs −8.3 mm, p=0.009). Pain responder analyses, defining a responder as 50% improvement from baseline, also favored RINCE but did not reach statistical significance due to small numbers (5 of 15 vs 1 of 7, p=NS). Likewise, PGIC responder analyses where a responder is defined as "Much Improved" and "Very Much Improved", also favored RINCE (8 of 15 vs 1 of 7, NS). Additional outcome measures generally favored RINCE as well: 7 day pain recall (VAS MMRM LS Mean contrast −22.9, p=0.013); FIQ-R total score (−24.5 vs −13.6, p=0.11); Neurocognitive functioning—MASQ improvement: −8.64 vs +2.43 (p=0.083); MCS cognition: −8.37 vs +0.09 (p=0.10); MCS mental clutter: −12.90 vs +0.44 (p=0.005). In addition, the Beck Depression Inventory and a modified Jenkins sleep questionnaire both numerically favored RINCE, but did not achieve statistical significance. Consistent with classification as a "non-significant risk" device, the adverse event profile of RINCE was very encouraging. The most common adverse event reported as potentially related to therapy was headache, reported by 3 patients out of 39 who received some form of stimulation therapy (8%). All other event reports were at rates of no more than 2 patients (5%), and were consistent with the underlying fibromyalgia.

Conclusion: Despite the very small control group of 7 patients, the benefit/ risk ratio of RINCE therapy with NeuroPoint appears highly favorable. This pilot study encouraged the sponsor to initiate a large, well powered pivotal trial in fibromyalgia.

1096

Fibromyalgia Patients Who Have More Symptoms at Their Initial Office Visit Tend to Have a Worse Clinical Course. Robert S. Katz[1], Ben J. Small[2], Alexandra Small[3] and Hannah Bond[4]. [1]Rush Medical College, Chicago, IL, [2]MacNeal Hospital, Berwyn, IL, [3]University of Illinois College of Medicine, Chicago, IL, [4]Rheumatology Associates, Chicago, IL.

Background/Purpose: Patients with the fibromyalgia syndrome (FMS) experience pain, insomnia, fatigue, and memory/concentration problems. But

some fibromyalgia patients also have many additional somatic symptoms. We surveyed our patients with fibromyalgia to determine if those patients with many physical symptoms, in addition to the core FMS complaints, tended to have more challenging clinical courses, a poor response to treatment and more disabling limitations.

Methods: Patients from a rheumatology office practice were studied. We reviewed the charts of fibromyalgia patients and counted the number of symptoms from a list of 92 medical complaints as part of a form provided by the American College of Rheumatology. The total number of symptoms was recorded from the patient's initial visit. We then compared the number of symptoms to the patient's most recent office visit, a patient update form which includes patient recorded visual analog scales for health status in general, pain, fatigue, concentration, sleep, and also a HAQ activity questionnaire.

Results: 66 patients in this study met the 2010 ACR criteria for FMS, the number of symptoms varied from 6 to 55, with a mean number of symptoms 21.5. We found a relationship between the number of somatic symptoms and the patient's status with regard to pain, fatigue and overall health and HAQ scores. Those patients with 19 or more symptoms tended to have worse ability to perform activities and higher levels of pain and fatigue. (See table.)

Number of Symptoms	Mean HAQ	Mean Pan VAS	Mean Fatigue VAS	General Health Status VAS
less than 19 symptoms	2.18	5.11	5.04	4.79
19 or more symptoms	4.42	7.11	7.13	6.66

Conclusion: FMS **p**atients with many somatic symptoms tend to have a worse course with higher levels of pain, fatigue, insomnia, and fibrofog as well as higher HAQ scores,, indicating diminished physical functioning. FMS patients with a somatoform clinical picture tend to have a more challenging clinical course.

Can We Help Identify Learning Disabilities in Fibromyalgia Patients? Robert S. Katz[1], Lauren Kwan[2] and Jessica L. Polyak[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: A previous study (ArthRheum;S10:956) has shown that Fibromyalgia syndrome (FMS) patients may have learning disabilities. Experts in the field have identified seven types of learning disabilities. We queried FMS patients about the types of learning disabilities they might have.

Methods: 111 patients meeting the 2010 ACR criteria for Fibromyalgia, followed in a rheumatology office practice, were asked to fill out a questionnaire listing multiple questions and problems relating to learning disabilities. Based on responses, tentative classifications of specific learning disabilities were made from the following classifications: dyslexia, dysgraphia, dyscalculia, central auditory processing disorder, non-verbal learning disorder, visual processing disorder, and aphasia/dysphasia/global aphasia.

Results: According to FMS patients responses to a questionnaire, possible categories of learning disabilities were: 48.6% central auditory processing disorder; 36.9% dysphasia/global aphasia disorder; 34.2% visual processing disorder; 35.1% dyscalculia; 29.7% dysgraphia; 26.1% dyslexia; and 25.2% non verbal learning disorder.

Conclusion: Although a tentative diagnosis of a learning disability needs to be confirmed by a learning disability expert, these findings suggest that fibromyalgia patients may have multiple types of learning disabilities. The most common learning disability was central auditory processing disorder, an auditory disability causing difficulty processing verbal information and interpreting speech. It is possible that learning disability specialists could help FMS patients improve their performance at school and work.

Clinical Efficacy of the High-Concentration Capsaicin Patch for the Treatment of Carpal Tunnel Syndrome. Olga Sleglova[1] and Marek Hakl[2]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]Pain Department Faculty Hospital Saint Anna, Brno, Brno, Czech Republic.

Background/Purpose: Carpal tunnel syndrome (CTS) is a clinical syndrome manifested by signs and symptoms of irritation of the median nerve at the level of the carpal tunnel in the wrist. CTS is the most frequent pressure neuropathy. The conservative treatments for chronic neuropathic pain that currently exist are only moderately effectively. Oral pharmaceuticals for neuropathic pain have significant side effects, and treatment efficacy tends to be modest. The use of topical analgesics allows direct application of medications to the area of pain. Capsaicin causes a brief initial sensitization followed by a prolonged desensitization of the local pain nerves. This occurs through stimulation of the transient receptor potential vanilloid-1 (TRPV1) expressing pain nerve fibers. Capsaicin dermal is an adhesive patch containing a high concentration (8 %) of synthetic capsaicin. It has not been studied yet in patients with CTS.

Methods: The patients with clinically and electrophysiologically confirmed CTS, indicated for the treatment of highly concentrated capsaicin 8% patch due to neuropathic pain, were included in the study. The aim of the study was to determine the proportion of patients who achieve at least a 30% reduction in pain intensity on the Numeric Pain Rating Scale (NPRS) compared with baseline. There were also observed absolute and percentage decline in the scale of NPRS and prior and concomitant medications. Patients were monitored in four visits - before treatment of capsaicin patch and after 3, 6 and 12 months of application. On all visits were evaluated clinical status, monitored the intensity of pain and quality of life. The intensity of pain was evaluated using a range of intensity of pain – NPRS. Quality of life was assessed using the EQ-5D questionnaire.

Results: Altogether, 30 patients (four male) with symptomatic CTS were included in this study between April 2012 and April 2014. Capsaicin dermal patch reduced NPRS scores from baseline 6.3 points to 4.3 points after 3 months treatment ($p < 0.001$). 71 % of patients experienced at least a 30% reduction of pain intensity measured with NPRS score, 64 % of patients had at least a 50% reduction of pain intensity. The quality of life assessed by EQ-5D questionnaire improved significantly from 0.51 to 0.69 (three months after patch administration, $p < 0.001$). The consumption of concomitant medication decreased from 81% of patients at baseline to 52% after 3 months. Pain intensity decreased and EQ-5D questionnaire improved significantly gradually during the visits after 6 and 12 months. NPRS scores decreased after 12 months to 3.4 points. Capsaicin dermal patch was well tolerated. The most common adverse events were transient, mostly mild, application reaction in 8% of patients.

Conclusion: Capsaicin in the form of 8% dermal patch is a new treatment for peripheral neuropathic pain in patients with CTS. This study showed a high therapeutic efficacy, excellent tolerability and a significant improvement in quality of life, persisting for 12 months after administration.

Which Stresses Bother Fibromyalgia Patients Most? Robert S. Katz[1], Alexandra Small[2] and Jessica L. Polyak[3]. [1]Rush Medical College, Chicago, IL, [2]University of Illinois College of Medicine, Chicago, IL, [3]Rheumatology Associates, Chicago, IL.

Background/Purpose: Fibromyalgia patients identify stress as a factor in aggravating their pain and other symptoms. We administered a questionnaire to fibromyalgia patients to try to identify a difference between various kinds of stress and the effect on fibromyalgia symptoms.

Methods: Patients in a fibromyalgia office practice completed a questionnaire including various types of stresses: family, financial, job, health issues, marital, other. All patients met the 2010 ACR criteria for the diagnosis of fibromyalgia.

Results: 91 patients responded regarding which stresses affect their fibromyalgia the greatest.

As expected, concern regarding health issues was the greatest stress, (6.64), followed by family stress (5.81), job stress (5.55), money stress (4.69), and marital stress (4.01).

Conclusion: Stress is reported by many fibromyalgia patients as aggravating their symptoms. Aside from health related concerns, family and job stress had the highest visual analog scale ratings as to the impact on fibromyalgia pain and related symptoms. Sometimes the rheumatologist or nurse needs to act as a psychotherapist, allowing the patient to ventilate and to discuss symptoms, but also areas of stress. Understanding the impact of

various stresses on fibromyalgia symptoms may assist clinicians in dealing with patients who have fibromyalgia.

System Review: The Most Common Symptoms of Fibromyalgia Patients Other Than Pain, Fatigue, Insomnia, and Cognitive Dysfunction. Robert S. Katz[1] and Jessica L. Polyak[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: Fibromyalgia patients are somatically sensitive. The frequently complain of symptoms other than the core ones used for the diagnosis- pain, fatigue, poor sleep and cognitive problems. We queried fibromyalgia patients as to which symptoms they commonly experienced.

Methods: We administered a questionnaire to fibromyalgia patients meeting the 2010 ACR criteria. Included was a checklist of symptoms called System Review, from the American College of Rheumatology, copyright 1999.

Results: 82 fibromyalgia patients completed the questionnaire. The most frequent symptoms reported other than pain, fatigue, poor sleep and cognitive changes were headaches 39 patients (47.6%), dry eyes 37 patients (45.1%), dry mouth 37 patients (45.1%), easy bruising 27 patients (32.9%), anxiety 25 patients (30.5%), ringing in the ears 21 patients (25.6%), dizziness 21 patients (25.6%), night sweats 21 patients (25.6%), weight gain 20 patients (24.4%), and constipation 20 patients (24.4%). Aside from these top 10 symptoms, also commonly reported were double or blurred vision 19 patients (23.2%), rash 19 patients (23.2%), color changes in hands/feet 19 patients (23.2%), runny nose 18 patients (22.0%), nausea 18 patients (22.0%), mouth sores 17 patients (20.7%), shortness of breath 17 patients (20.7%), and depression 17 patients (20.7%).

Conclusion: Fibromyalgia patients commonly have symptoms other than pain and fatigue. Non-rheumatologists, who see patients with fibromyalgia with some of the symptoms listed above, such as tinnitus, dizziness, blurred vision, mouth sores, shortness of breath, etc., may not think to link them to fibromyalgia, but they are common in this illness.

Numbness and Tingling: Neurological Symptoms in Fibromyalgia. Robert S. Kratz. Rush Medical College, Chicago, IL.

Background/Purpose: Fibromyalgia patients may present with localized or diffuse paresthesias. Some patients have are concerned about the possible diagnosis of multiple sclerosis and other neurological disorders. Neurologists are hesitant to use the term fibromyalgia in patients with paresthesias.

Methods: We administered a questionnaire to office patients who met the 2010 ACR criteria for the diagnosis of fibromyalgia. Included were questions on presence and location of paresthesias. Location: right arm.left arm, right leg, left leg, right side of body, left side of body, right side of face, left side of face, whole body. If numbness and tingling were present, were the symptoms constant, intermittent, frequent?

Results: 95 patients with fibromyalgia completed the questionnaire. 53 of the 95 patients (55.7) answered positively to the question "Do you have numbness and tingling?" The mean age of the patients was 51.9 years; 83F and 12M.

The paresthesia's were considered to be diffuse (more than 2 areas of the body) in 21 patients (22.1%) and limited in 32 patients (33.6%).

Patients responded that the paresthesia's were constant in 21 patients (22.1%), intermittent in 42 patients (44.2%). 28 patients responded that numbness and tingling was frequent (29.4%).

Conclusion: 22.1% of this sample of fibromyalgia patients, taken from a rheumatology office practice, complained of diffuse paresthesias. Neurologists and Primary Care Physicians need to be aware that paresthesia's are common in fibromyalgia.

Anxiety in Fibromyalgia Patients. Robert S. Katz[1] and Frank Leavitt[2]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: In fibromyalgia (FMS), it is normal to expect people burdened with the uncertainty of unresolvable medical issues to face a certain amount of anxiety. A high number of medical and anxiety symptoms are seen in FMS; however, the normal reaction hypothesis may not fully explain the linkage. Another possibility is that anxiety levels differ in FMS relative to other medical conditions and may even promote the progression of medical symptoms. The purpose of this study is to determine if anxiety in FMS differs from other rheumatic disorders after adjusting for illness intensity.

Methods: The study was comprised of 191 patients seen in a rheumatologic practice. Of these, 79 had FMS and 112 had Non-FMS rheumatic disease. Diagnosis was based on ACR criteria. The two samples were closely matched on age (FMS: 51.2 ± 12.0 vs. 51.9± 15.9); the FMS sample had slightly less education (FMS: 14.8 ± 2.1 vs. 15.5 ± 2.0). The 0.7 year difference between means was significant ($p < 0.05$).

Patients were administered the 9-item Anxiety scale of the Profile of Mood States, and the Symptom Review section of the 1999 American College of Rheumatology Patient Forms. On the Anxiety scale, participants rated the anxiety variables listed in Table 1 on a 5 point scale, with 0= not at all and 4 = extremely. The anxiety score is the sum of the ratings. The system review is a symptom checklist covering 13 organ systems. Illness intensity is the number of symptoms endorsed as significantly affecting the individual.

Results: The mean anxiety levels of patients on the 9 items are shown in Table 1. FMS patients scored higher on 8 of the 9 anxiety items. As a whole, anxiety was significantly higher in FMS patients (12.7 ± 9.4 vs. 7.7 ±6.3; $p<0.001$). The score of 7.7 in the non-FMS group is in the normal range of healthy individuals (normative mean: 8.2±6.0). Illness intensity was also significantly higher in FMS participants (16.7± 11.8 vs. 8.7± 8.5: $p <0.001$). An analysis of covariance was used to subtract by statistics the effects of a higher number of medical symptoms on anxiety. Difference in anxiety remained significant after the affects of the number of medical symptoms endorsed was removed ($p<0.01$).

Conclusion: Results of the analysis of covariance essentially eliminates the greater number of medical problems in FMS as an explanation for the higher level of anxiety in FMS. With symptom intensity eliminated, the results could be read as suggesting that patients with FMS are more anxiety prone than other rheumatic disease patients.

However, more needs to be *learned about the source of higher anxiety in FMS, since competing explanations are present. For example, the argument could be made* that unexplained malfunctions of the body could in and of themselves be catalysts for excessive worry and higher levels of anxiety. Undoubtedly patients with FMS have a greater number of medically unexplained problems.

Analgesic and Anti-Hyperalgesic Effects of Deep Dry Needling Therapy in Fibromyalgia Patients. B. Casanueva[1], P. Rivas[2], R. López-Mejías[3], F. Genre[3], J. Llorca[4] and M. A. González-Gay[3]. [1]Rheumatologist. Rheumatology Service at the Specialist Clinic of Cantabria, Santander, Spain, [2]Physical Therapist. Specialist Clinic of Cantabria, Santander, Spain, [3]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain, [4]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain.

Background/Purpose: Patients with fibromyalgia (FM) complain of widespread chronic pain from deep tissues including muscles. Previous research highlights the relevance of impulse input from deep tissues for clinical FM pain. Deep dry needle stimulation is an invasive treatment modality used in the management of musculoskeletal pain. Its efficacy has been confirmed in the management of myofascial trigger points, acute and chronic low back pain, and chronic whiplash. To determine if blocking abnormal impulse input with deep dry needling stimulation of tender point may decrease hyperalgesia and clinical pain in FM patients.

Methods: 120 patients that fulfilled the ACR 1990 criteria for FM were enrolled into a prospective controlled study of 12 week. Patients were randomly split into two groups: The control group (CG), 56 women and 4 men, who continued their treatment, and the deep dry needling group (DNG), 54 women and 6 men, who apart from continuing their medical treatment, also underwent weekly one-hour session of deep dry needling over 18 FM tender points for a 6-week-period. Study variables included pressure hyperalgesia as well as clinical pain. Patients were assessed at the start (at week 0), at the end of the 6-week intervention period (end of intervention), and were

again evaluated 6 week later (at week 12 after the onset of the study). Study questionnaires and protocol were approved by the Ethical Committee of the regional health authority. All statistical analyses were performed with de software Stata 12/SE (Stata Corporation, College Station, TX, US). P values < 0.05 were considered significant.

Results: 60 patients were randomly assigned to the CG and 60 to the DNG. A total of 100 (83.3%) patients completed the study: 50 (83.3%) in the CG and 50 (83.3%) in the DNG. The mean ± SD age of participants was 53.5 ± 11.1 years, and the average reported in Fibromyalgia Impact Questionnaire (FIQ) was 73.1. At the beginning of the program (week 0), there were only significant differences between groups in age (56.2 in DNG versus 50.8 in the CG, p: 0.01) and McGill Pain Questionnaire (MPQ) (39.1 in DNG versus 42.4 in the CG, p: 0.03). At the end of the intervention (week 6), DNG showed reduction in the FIQ (p: 0.02), VAS of pain (p: 0.002), pain of SF-36 (p: 0.0007), MPQ (p: 0.02), Pain Catastrophizing Scale (PCS) (p: 0.02), activity engagement of Chronic Pain Assessment Questionnaire (CPAQ) (p: 0.008), pain intensity of Brief Pain Inventory (BPI) (p: 0.03), pain interference of BPI (p: 0.01), myalgic score (p: 0.0005), number of tender points (p: 0.0004), and pressure pain threshold (p: 0.002). Six weeks after the end of the treatment, DNG still showed significant differences in the FIQ (p: 0.03), VAS of pain (p: 0.01), pain of SF-36 (p: 0.01), MPQ (p: 0.02), PCS (p: 0.03), activity engagement of CPAQ ($p = 0.01$), pain intensity of BPI (p: 0.04), pain interference of BPI (p: 0.01), number of tender points (p: 0.0008), myalgic score (p: 0.00001) and pressure pain threshold (p: 0.0004).

Conclusion: These results suggest that deep dry needling of tender points can reliably reduce clinical FM pain, and that peripheral input is required for the maintenance of mechanical hyperalgesia of these patients.

1104

Utility of the 2010 ACR Diagnostic Criteria for Fibromyalgia for Pediatric Patients with Juvenile Fibromyalgia. Tracy Ting[1], Kimberly Barnett[2], Anne Lynch-Jordan[2] and Susmita Kashikar-Zuck[2]. [1]Cincinnati Children's Hosp, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Juvenile Fibromyalgia (JFM) is a chronic condition characterized by widespread musculoskeletal pain, fatigue, poor sleep and significant morbidity. Currently, a classification of JFM is based upon one of two published criteria – the 1990 American College of Rheumatology (ACR) criteria for adult fibromyalgia (FM) or the 1985 Yunus and Masi pediatric criteria. Both require a manual tender point examination that is controversial, not routinely or consistently applied by clinicians, and may be influenced by patient anxiety about the procedure. The newer 2010 ACR criteria allows for the use of a validated tool that excludes the use of the tender point exam and includes a clear scoring algorithm for consistency in screening and diagnosis of FM. However, these criteria were developed for adult FM patients and it is not clear whether they can be applied in pediatric populations. The aim of this study was to examine the utility of the new 2010 ACR criteria for pediatric patients with JFM in comparison to the ACR 1990 and Yunus and Masi classification criteria.

Methods: Participants were patients (ages 11–17) with primary JFM diagnosed by a rheumatologist or pain physician ($N=44$, $M_{age}=15.02$) and age and gender matched controls (MC) with localized pain conditions, e.g., abdominal pain, headaches, limb pain ($N=44$, $M_{age}=15.05$). Physicians completed a form indicating which set of criteria they used to make a JFM diagnosis (ACR 1990 or Yunus and Masi). The ACR 2010 Widespread Pain Index (WPI), regarding which body locations were painful and Symptom Severity (SS) checklist of associated somatic symptoms were administered by a trained assessor. Total scores for the WPI and SS tools were computed and the ACR 2010 algorithm was used to determine diagnosis of JFM. Also, t-tests were conducted to compare the two groups on number of pain locations and number of symptoms endorsed.

Results: The Yunus and Masi criteria were used the most often (93.2% of the time) by physicians to classify JFM and the ACR 1990 criteria were used far less (6.8%). When the 2010 criteria were applied, 83.7% of patients diagnosed with active JFM by their primary rheumatologist met the ACR 2010 criteria. However, approximately 11.4% of controls with localized pain were also classified as having JFM. JFM participants reported significantly more pain locations and associated symptoms than MC ($p<.01$).

Conclusion: Preliminary results indicate that the 2010 adult FM ACR Criteria may be a useful tool to screen for JFM in an adolescent population with JFM. The WPI and SS tools that comprise the 2010 criteria are brief and easy to administer and the tender point is not required. Therefore, the ACR 2010 criteria allow for more widespread application and potentially earlier identification of JFM in pediatric practices. However, confirmation of the clinical diagnosis by a specialty trained physician is still recommended. Further validation studies with larger samples to test the sensitivity and specificity of the measure are needed.

The Effectiveness of Mirror Therapy in Patients with Adhesive Capsulitis. Mehmet Cetin Baskaya[1], Cem Ercalik[2], Ozlem Kir Karatas[1] and Tiraje Tuncer[1]. [1]Akdeniz University School of Medicine, Antalya, Turkey, [2]Sisli Etfal Hospital, Istanbul, Turkey.

Background/Purpose: To investigate the efficacy of mirror therapy (MT) combined with conventional physical therapy on shoulder range of motion (ROM), pain and quality of life in the patients with adhesive capsulitis.

Methods: Thirty patients who had painful and limited 1/3 of shoulder ROM for 2 –12 months and were diagnosed as adhesive capsulitis included in this randomised single blind controlled trial(RCT). Patients who had neurological disorders, cervical radiculopathy, rotator cuff ruptures, calcific tendinitis/bursitis, tumoral lesions, humerus fracture, history of intraarticular injections within 3 months, and previous physical therapy programme within 6 months were excluded. Patiens were randomised into two groups: 15 patients (12 female, 3 male, mean age 59.8±10.6) randomised as mirror group and 15 patients (9 female, 6 male, mean age 54.4±7.6) as control group. 10 session of physical therapy programme (TENS, infrared, ultrasound, codman exercises, shoulder ROM and streching exercises and home programme for 20 minutes twice a day) was applied both groups. After each physical therapy session, mirror therapy group performed ROM exercises(flexion, abduction, internal and external rotation for 30 times once a day) while watching unaffected shoulder movements with reflected side of the mirror. Control group performed active ROM exercises (flexion, abduction, internal and external rotation for 30 times once a day) with non- reflected side of the mirror (The mirror has been placed midline of the patient's body while exercises were performed). Patients were evaluated for pain (VAS with shoulder movement), function(UCLA), quality of life (SF-36) and active - passive ROM with goniometer before and after treatment.

Results: There was no significant difference between the groups according to age and disease duration. After treatment, pain in the mirror group was found significantly less than the control group ($p<0,05$). Shoulder function scores were significantly higher than the control group ($p<0,05$). Post-treatment measurements of active flexion, active abduction, passive flexion, passive abduction in the mirror group significantly were better than the control group ($p<0,05$). Physical functioning, physical and emotional role functioning and pain parameters of SF-36 were found better in mirror therapy group than the control group after the treatment. When we compared each group before and after treatment, we found that statistically significant reduction in shoulder pain and statistically significant improvements in shoulder function, active-passive ROM measurements and quality of life after treatment.

Conclusion: Mirror therapy combined with physical thearapy programme seems to be an effective treatment to reduce pain and to improve shoulder function, shoulder ROM and quality of life in the patients with adhesive capsulitis. In our opinion, mirror therapy which is a cheap, easy appliable and reliable method should be added to standart physical therapy programme in adhesive capsulitis.

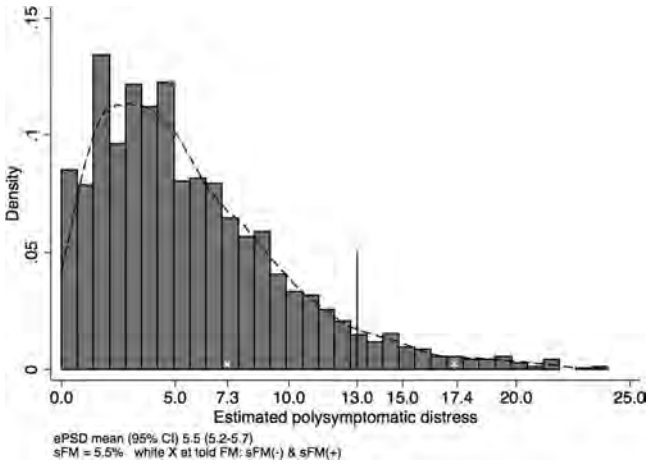
Most Patients Diagnosed with Fibromyalgia By Physicians Do Not Have Fibromyalgia: The 2012 National Health Interview Survey Fibromyalgia Study. Brian Walitt[1], Richard Nahin[2], Robert S. Katz[3], Martin J. Bergman[4] and Frederick Wolfe[5]. [1]MedStar Health, Washington, DC, [2]National Institutes of Health, Bethedsa, MD, [3]Rush Medical College, Chicago, IL, [4]Taylor Hospital, Ridley Park, PA, [5]National Data Bank for Rheumatic Diseases, Wichita, KS.

Background/Purpose: Although criteria exist for fibromyalgia (FM) diagnosis, little is known about how FM diagnosis is applied and understood by physicians and patients in the US population. The 2012 National Health Interview Survey (NHIS) is the largest US population-based health survey. We examined the relation between self-reported physician FM diagnosis, polysymptomatic distress (PSD), demographics and selected symptoms captured in the NHIS.

Methods: The NHIS asked participants about receiving a FM diagnosis from a physician along with questions about joint pain and somatic symptoms. We developed NHIS FM/PSD definitions by administering germane NHIS questions and the modified 2010 ACR criteria to 415 consecutive rheumatology patients in 2 clinics. After applying these definitions to the NHIS, we estimated a PSD score (ePSD) and set a surrogate FM diagnosis (sFM) at ePSD $\geq$ 13. Because of differences in questions and administration between the ACR criteria and the NHIS, the current data should be considered approximate.

Results: The ePSD distribution in the NHIS is shown in Figure 1. Using population derived survey weights in a sample of 2,680 participants, 4.8% reported being told they had FM (FM+); 5.6% met the criteria for sFM (sFM+).Table 1 shows the subjects stratified by told FM and sFM status. Of FM (+) subjects, 83.0% were sFM (-). Subjects that were FM (+) but sFM (-) were similar to the non-FM population but with modest increases in ePSD, not working, and lifetime depression (Table 1). In addition, they were generally white (82.1%) and female (91.0%). FM (-) but sFM (+) subjects were less often white (69.1%) or female (66.8%). Women were more likely to report being told they had FM (odds ratio 9.6) but not as likely to meet sFM criteria (odds ratio 2.1).

Conclusion: More than 80% of subjects in NHIS who report being told by physicians they have FM do not satisfy sFM criteria. Among these subjects, more are female and non-minorities than in those satisfying sFM criteria. In addition, FM (+) individuals are generally indistinguishable from the non-FM population (FM -), but are less likely to be employed and more likely to report functional limitations and a lifetime history of depression. The cause for over-diagnosis is likely multi-factorial, but may include physician misdiagnosis, access to health care, personal beliefs, and socio-cultural ideas about FM engendered by academic and industry messaging. Regardless, our current medical approach to FM/PSD results in 3.9% of minimally symptomatic Americans reporting themselves labeled as "sick". These results have important public health implications.



Group	Category %	Mean ePSD score	% White	% Female	% High School graduate	% Not working	% Functional limitations	% Lifetime depression
Not told FM, Not sFM	93.3	4.7	75.8	51.6	75.8	47.1	63.4	21.9
Told FM, Not sFM	3.9	7.3	82.1	91.0	82.1	73.5	73.7	42.1
Not told FM, +sFM	1.9	15.7	69.1	66.8	69.1	73.7	91.7	63.2
Told FM, +sFM	0.8	17.4	89.6	83.0	89.6	78.4	100.0	58.2

A Strong Association Between Memory Loss and Word Finding Difficulties in Fibromyalgia. Robert S. Katz[1] and Frank Leavitt[2]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: A core feature of fibromyalgia (FMS) is cognitive dysfunction. The predominant clinical manifestations is memory loss; however impaired word retrieval frequently referred to as word finding difficulty sometimes unfolds in the clinical situation as the central patient focus. The purpose of this study is to build a more precise picture of cognitive dysfunction in FMS by examining the linkage between memory loss and word finding deficits and its relation to the severity of cognitive dysfunction.

Methods: Participants were 191 patients seen in a rheumatologic practice. Of these, 79 had FMS and 112 had Non-FMS rheumatic disease. Diagnosis was based on ACR criteria. The two samples were closely matched on age (FMS: 51.2 $\pm$ 12.0 vs. 51.9$\pm$ 15.9); the FMS sample had slightly less education (FMS: 14.8 $\pm$ 2.1 vs. 15.5 $\pm$ 2.0). The 0.7 year mean difference was significant ($p < 0.05$). Data on memory loss and word finding difficulty were collected by questionnaire. Data on 8 cognitive skills and 8 aspects of mental clarity were derived from the Mental Clutter Scale that was filled out by each participant.

Results: Compared to Non-FMS patients, patients with FMS were more likely to report memory loss (69.6%) [55 of 79] to (25.0%) [28 of 112] $p<0.001$ and word finding difficulties (69.6%) [55 of 79] to (23.2%) [26 of 112] p.<001. Within the FMS sample, 89.1% [49 of 55) of those with memory loss reported word finding difficulty, whereas 67.9% [19 of 28] of those in the Non-FMS with memory loss reported word finding difficulty ($p<0.001$). In respect to total samples, memory loss and word finding difficulty were coupled in 62.0% [49 of 79] of the FMS sample and in 17.0% [19 of 112] of the Non-FMS sample ($p<0.001$).

Results: of cognitive functioning as assessed by the 16 item Mental Clutter Scale show that cognitive difficulties are substantially skewed toward patients with FMS (Table 1). Compared to Non-FMS, those with FMS endorse a higher level of disturbance on the 8 of the 8 cognitive skills, and on 7 of the 8 aspects of mental clarity.

Conclusion: Cognitive difficulty varies widely depending upon the type of rheumatic disease. Patient with FMS appear to carry a considerably higher risk for memory loss and word finding difficulties than individuals with other rheumatic disease. The memory loss-FMS relationship is well established and has played a central role in cognitive studies to date; whereas the role of word finding difficulty has been largely unappreciated.

Memory loss and word finding difficulties co-occur in FMS to an unusual degree. Cases in which these cognitive difficulties are coupled to the experience of multiple concurrent cognitive difficulties and greater mental fog as reflected by a high level of disturbance in 7 aspects of mental clarity.

At this stage, it is unclear why the cognitive picture is worse when memory loss and word finding difficulties co-occur in FMS or what mechanisms bind them together.

Table 1. Comparison of Rheumatic Patients With (FMS) and Without (Non-FMS) Fibromyalgia Who Endorse Both Memory Loss and Word Finding Difficulties on the Cognitive and Mental Clarity Subscales of the Mental Clutter Scale.

	Fibromyalgia (n = 49)	Non-Fibromyalgia (n = 19)
Concentration*	6.4 $\pm$ 2.6	4.5 $\pm$ 2.0**
Memory	6.5 $\pm$ 2.2	4.6 $\pm$ 2.2**
Staying Focused	6.2 $\pm$ 2.3	4.7 $\pm$ 2.5**
Multitasking	6.3 $\pm$ 2.5	4.5 $\pm$ 3.1**
Expressing Yourself	5.6 $\pm$ 3.0	4.0 $\pm$ 2.1*
Thinking Clearly	5.7 $\pm$ 2.2	4.2 $\pm$ 2.4*
Perceptual Clarity	5.3 $\pm$ 2.3	4.0 $\pm$ 2.5*
Mental Speed	6.2 $\pm$ 2.3	4.6 $\pm$ 2.4*
Spaciness‡	5.4 $\pm$ 2.9	3.4 $\pm$ 2.2*
Looking at life through a haze	4.7 $\pm$ 3.0	2.9 $\pm$ 2.4*
Confusion	4.3 $\pm$ 2.8	3.5 $\pm$ 2.5
Cluttered thinking	5.5 $\pm$ 2.7	3.9 $\pm$ 3.1*

Understanding Baseline Clinical Characteristics May be of Use in Considering the Response to Pregabalin in FM Patients with Comorbid Depression. Lynne Pauer[1], Jaren Landen[1], Pritha Bhadra Brown[2], Joseph Scavone[1], Richard Vissing[3] and Andrew Clair[2]. [1]Pfizer Inc, Groton, CT, [2]Pfizer Inc, New York, NY, [3]Pfizer Inc, Louisville, KY.

Background/Purpose: In a prior study in fibromyalgia (FM) patients taking an antidepressant for their comorbid depression, pregabalin (PGB) significantly reduced pain severity (treatment difference compared with placebo [95% CI], –0.61 [–0.91 to –0.31]). However, the effect of patients' baseline clinical characteristics on the treatment response to pregabalin has not previously been examined.

Methods: In the randomized, placebo (PBO)-controlled, 2-way crossover study, patients with FM aged ≥18 years taking a single antidepressant for their comorbid depression were randomized 1:1 to PGB (300 or 450 mg/d)/PBO or PBO/PGB. Treatment was for two 6-week periods, separated by a 2-week taper/washout. Antidepressant medication (SSRI or SNRI) was continued throughout the study. Endpoint mean pain scores (by 11-point numeric rating scale) were pooled from the two treatment periods. In this analysis, the effect of the following baseline clinical characteristics on endpoint mean pain scores was examined: pain severity (moderate, pain score of 4 to ≤7; severe, 7 to 10); depression diagnosis (major depressive disorder [MDD] or depression not otherwise specified [NOS]); prior or no prior opioid use; and Hospital Anxiety and Depression Scale-Anxiety (HADS-A) or -Depression (HADS-D) score (0–21 scale). Variables were analysed as fixed factors in a linear mixed effects model including sequence, period, and treatment as fixed factors, and subject within sequence and within subject error as random factors.

Results: A total of 193 patients were included in the analysis; 181 received ≥1 dose of PGB and 177 PBO. Mean age was 50.1 years and 93.3% of patients were female. Mean (median) pain, HADS-A, and HADS-D scores at baseline were 6.7 (6.9) 8.3 (8.0), and 8.0 (8.0), respectively. Endpoint mean pain scores were significantly lower ($P < 0.05$) with PGB compared with PBO (treatment difference, 95% CI) irrespective of patients having: moderate (–0.62, –1.06 to –0.17; n = 104) or severe (–0.53, –0.93 to –0.14; n = 89) pain; diagnosis of MDD (–0.73, –1.22 to –0.24; n = 84) or depression NOS (–0.54, –0.94 to –0.13; n = 101); prior (–0.70, –1.35 to –0.05; n = 44) or no prior opioid use (–0.53, –0.88 to –0.19; n = 149); HADS-A score <8 (–0.55, –1.08 to –0.02; n = 86) or ≥8 (–0.67, –1.04 to –0.31; n = 107); or HADS-D score <8 (–0.93, –1.44 to –0.42; n = 85). However, while there was a trend towards improvement with pregabalin in patients with HADS-D score ≥8, this was not significant (–0.31, –0.67 to 0.06; $P = 0.098$; n = 108).

Conclusion: In patients with FM taking an antidepressant for comorbid depression, pregabalin significantly improved mean pain scores irrespective of baseline pain severity, depression diagnosis, prior opioid use, or HADS-A score. This study has important clinical implications in that pregabalin improved pain in FM patients with a wide range of baseline clinical characteristics.

Disclosure: L. Pauer, Pfizer Inc., 1, Pfizer Inc., 3; **J. Landen**, Pfizer Inc, 3, Pfizer Inc, 1; **P. Bhadra Brown**, Pfizer Inc, 3, Pfizer Inc, 1; **J. Scavone**, Pfizer Inc., 1, Pfizer Inc., 3; **R. Vissing**, Pfizer Inc, 3, Pfizer Inc, 1; **A. Clair**, Pfizer Inc, 3, Pfizer Inc, 1.

Impact of Age on Symptom Severity and Disease Management at Fibromyalgia Diagnosis. Emmanouil Rampakakis[1], Mary-Ann Fitzcharles[2], Peter A. Ste-Marie[2], John S. Sampalis[1] and Yoram Shir[2]. [1]JSS Medical Research, Montreal, QC, [2]McGill University Health Centre, Montreal, QC.

Background/Purpose: Population studies indicate that older persons experience more pain generally. Fibromyalgia (FM) affects persons of all ages, with previous studies on the impact of age on symptom severity reporting conflicting findings. Jiao et al. reported worse symptoms for younger patients[1], whereas Cronan et al. reported that increasing age was associated with reduced FM symptomatology.[2] The aim of this analysis was to describe the association between age at FM diagnosis and patient and clinical characteristics among Canadian patients in routine clinical care.

Methods: A cohort of FM patients prospectively followed at a tertiary care multidisciplinary clinic was included in the analysis. Demographic and disease severity measures included: pain visual analog scale (VAS), patient global assessment (PGA), Health Assessment Questionnaire (HAQ), Pain Disability Index (PDI), Pain Catastrophizing Scale (PCS), FIQ, MPQ, anxiety and depression by Arthritis Impact Measurement Scale (AIMS). General linear models and logistic regression were used to assess the association between age and, continuous or categorical, respectively, patient or disease parameters at baseline.

Results: The cohort comprised 248 patients with a mean ± SD age 47.89 ± 10.34 years, disease duration 10.84 ± 9.80 years, and 91.13% female. Baseline values were: pain VAS 6.52 ± 2.29, PGA 6.58 ± 2.23, FIQ 66.97 ± 16.82, HAQ 1.19 ± 0.61, MPQ 40.82 ± 15.22, PDI 37.69 ± 14.44, PCS 29.39 ± 12.17, AIMS anxiety 6.34 ± 1.84, AIMS depression 4.91 ± 1.84, with a mean medication count of 2.38 ± 1.67 per patient.

Increased age was associated with significantly ($P<0.001$) longer pain duration ($B=0.34$; i.e. increased duration of pain by 0.34 years for each additional year of age) and lower odds of having allodynia ($OR=0.97$; $P=0.037$). Furthermore, increased functional disability was observed in older patients as evidenced by the higher HAQ scores ($B=0.01$; $P=0.007$). However, no significant association was observed with pain severity, PDI, PCS, PGA, FIQ, MPQ, anxiety and depression. Older patients were more likely to be treated with tranquilizers ($OR=1.03$; $P=0.039$), with a statistical trend towards more analgesics ($OR=1.03$; $P=0.096$) but less antidepressant use ($OR=0.98$; $P=0.091$). No significant differences were observed for other treatments, cigarette smoking, or substance abuse.

Conclusion: Although older age at baseline was associated with significantly longer duration of pain, no significant differences in disease parameters were observed based on age; the only exception being HAQ which was worse among older patients. Patient management differed based on age without, however, reaching statistical significance. Further study is necessary to establish whether response to treatment is associated with age.

The Comparative Efficacy of Kinesio Taping and Local Injection Therapy in Patients with Subacromial Impingement Syndrome. Hamit Goksu[1], Pinar Borman[2] and Figen Tuncay[3]. [1]Ankara Training and Research Hospital, Ankara, Turkey, [2]University of Hacettepe Faculty of Medicine, Ankara, Turkey, [3]Ahi Evran University, Kirsehir, Turkey.

Background/Purpose: The aim of this study was to compare the therapeutic effects of kinesio taping (KT) and local subacromial injection in patients with subacromial impingement syndrome (SIS) with regard to pain, range of motion (ROM) and disability.

Methods: Sixty-one patients with subacromial impingement syndrome were enrolled into the study. Demographic and clinical characteristics including age, sex, duration of disease were recorded. The patients were randomized into two treatment groups receiving either a single corticosteroid and local anesthetic (LA) injection, or kinesio taping performed three times by intervals of 3 day. Visual analog scale (VAS) was used to assess pain intensity, shoulder abduction, flexion and rotation range of motion (ROM) degrees were recorded and Shoulder Pain and Disability Index (SPADI) was performed to evaluate functional disability, before treatment, at the first and fourth weeks after therapies. Both groups were educated for home exercise programme.

Results: Forty-eight female and 13 male patients (mean age, 42.4+6.48 years; mean disease duration, 2.35+0.79 months) were included in the study. There were no differences between the groups regarding demographic variables on entry to the study. Pain, functional outcome measures were determined to have improved significantly in both groups at the end of therapies at first and fourth weeks, but these improvements were more significant in the injection group than in kinesio taping group. The improvements in pain at rest, shoulder abduction degrees, and SPADI scores at first and fourth weeks were statistically higher in injection group than in kinesio taping group.

Conclusion: We imply that single dose subacromial injection and three times of kinesio taping by 3 day intervals have favorable effects on pain and functional status in the early period (up to one month) of subacromial impingment syndrome. Although the improvement in pain intensity at rest, abduction ROM measures and disability were better with local injection, KT may be an alternative non-invasive method for patients suffering from subacromial impingement syndrome in the early period.

The Effect of High Intensity Laser Therapy in the Management of Myofascial Pain Syndrome of the Trapezius: A Double Blind, Placebo-Controlled Study. Umit Dundar, Utku Turkmen, Hasan Toktas, Ozlem Solak and Alper Ulasli. Afyon Kocatepe University, Faculty of Medicine, Afyonkarahisar, Turkey.

Background/Purpose: Myofascial pain syndrome (MPS) of the trapezius muscle is one of the main causes of neck pain**.** In this randomized, double blinded study, we planned to evaluate the effects of high-intensity laser therapy (HILT) in female patients with chronic MPS of the trapezius muscle**.**

Methods: The female patients with the diagnosis of MPS of the trapezius muscle, were enrolled in the study and assigned to two groups**.** HILT group (group1) was treated with HILT and exercise. Sham therapy group (group2) received placebo HILT and exercise**.** The patients were assessed for pain, cervical active range of motion, disability and quality of life**.** Evaluations were performed before treatment (week 0) and after treatment (week 4 and week 12).

Results: Both groups showed significant improvement for all parameters at week 4 and week 12. However, comparison of the percentage changes of parameters both at week 4 and week 12 relative to pretreatment values showed that improvement in pain scores, neck disability index and physical functioning, role limitations due to physical functioning, bodily pain, general health perceptions, social functioning and role limitations due to emotional problems subparts of SF-36 were better in HILT group.

Conclusion: As a result, it is concluded that HILT is an effective therapeutic method in the treatment of patients with chronic MPS of the trapezius muscle**.**

Key words: Myofascial pain syndrome**,** high-intensity laser therapy**,** exercise**,** pain, disability, quality of life**.**

Cognitive Symptoms in Fibromyalgia Patients Compared with Rheumatoid Arthritis Patients. Robert S. Katz[1], Ben J Small[2], Alexandra Small[3] and Susan Shott[4]. [1]Rush Medical College, Chicago, IL, [2]MacNeal Hospital, Berwyn, IL, [3]University of Illinois College of Medicine, Chicago, IL, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: Many fibromyalgia symdrome (FMS) patients report impaired mental function (fibrofog.) We compared FMS and RA patients with respect to symptoms of impaired cognition.

Methods: 211 office patients with either FMS (150; 130 women and 20 men; mean age 51±12) and RA (61; 45 women and 16 men; mean age 55±15) completed a questionnaire about symptoms of impaired mental function, rated as 1 = never, 2 = occasionally, 3 = sometimes, 4 = mostly, and 5 = always. The two-sided Mann-Whitney test was done to compare FMS and RA patients with respect to these ratings, using a 0.05 significance level.

Results: Compared to RA patients, FMS patients had significantly worse ratings for inability to recall known words (1.9 ± 1.0 vs. 1.4 ± 0.6, p = 0.001), inability to write an idea down (1.5 ± 1.0 vs. 1.2 ± 0.4, p = 0.017), mistaking numbers that look similar (1.5 ± 0.8 vs. 1.2 ± 0.4, p = 0.034), inability to retain patterns when adding, subtracting, multiplying, or dividing (1.6 ± 1.0 vs. 1.2 ± 0.6, p = 0.02), distraction by background noises (2.3 ± 1.3 vs. 1.7 ± 1.0, p = 0.002), difficulty following directions (1.9 ± 1.1 vs. 1.4 ± 0.6, p = 0.005), trouble following conversations (1.7 ± 0.9 vs. 1.3 ± 0.6, p = 0.006), becoming disruptive in conversations (1.4 ± 0.8 vs. 1.2 ± 0.5, p = 0.027), misremembering spelling of familiar words (1.7 ± 0.9 vs. 1.4 ± 0.7, p = 0.009), losing place while reading (2.0 ± 1.1 vs. 1.6 ± 0.8, p = 0.03), difficulty expressing thoughts verbally (2.0 ± 1.1 vs. 1.5 ± 0.8, p = 0.001), poor reading comprehension (1.9 ± 1.1 vs. 1.4 ± 0.8, p = 0.003), frustration when speaking (1.8 ± 1.1 vs. 1.3 ± 0.6, p = 0.003), and difficulty concentrating (2.5 ± 1.2 vs. 1.8 + 1.0, p < 0.001).

Conclusion: FMS patients had median ratings for cognitive function that were significantly worse than patients with RA. FMS patients report significantly more symptoms of impaired concentration and mental fog. Fibrofog is a troubling problem for many fibromyalgia patients.

Mayor Trocanter Painful Syndrome. Treatment with Hyaluronic Acid Versus Triamcinolone Acetonide Injections. A Comparative Study. Asuncion Acostar Sr.[1], Arturo Rodriguez de la Serna[2], Berta Magallares[2] and Gary Sterba Sr.[3].[1]Hospital Santa Creu i Sant Pau, Barcelona, Spain, [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]rheumatologist, miami, FL.

Background/Purpose: Painful syndrome of the mayor trochanter (MTPS). The treatment includes intra-bursal injections with cortico-steroids.Steroids. Estimate the efficacy of the treatment with hyaluronic acid injections in comparison to injections with triamcinolone acetonide in a follow up time of 1,3 and 6 months.

Methods: Random double blind clinical study. The patients were recruited of the consult injection clinic of the rheumatic diseases. Inclusion: MTPS confirmed by physical exam/ Pain that persist at least 1 month in spite of treatment/Fulfillment of the informed content. Exclusion: coxo-femoral intra-articular pathology. The more symptomatic side was evaluated. First group intrabursal injection 40 mg of triamcinolone acetonide.Second group intra-bursal injection 60 mg of hyaluronic acid depot. Technique: spinal syringe 22 g in a maximal pain point. Non steroidal anti-inflammatory was not permitted and paracetamol was permitted. Variables: Analog visual scale espontaneous pain and pain upon palpation at baseline, 1, 3 and 6 months. Likert scale of interference of pain in activities at baseline, Likert scale of pain resolution and treatment satisfaction at baseline, 1, 3 and 6 months. Statistical Analysis age, pain VAS palpation: average and standard deviation. Sex and Likert scales: frequency and percentage. Chi-square/fisher exact test: category variables. T student test for independent data. To analyze the progression in the VAS:ANOVA. A non-inferiority analysis:treatment with hyaluronic acid is non inferior that the treatment with triamcinolone acetonide. SPSS 18.

Results: 52 patients, 2 arms: 4 lost in the triamcinolone acetonide group. 1 lost in the group with hyaluronic acid. Final sample 22pts triamcinolone acetonide group, 25 hyaluronic acid group. F/M:87.2/12.8%. VAS on palpation (was less than one point and considered irrelevant) in any case better results (barely) in the group with hyaluronic acid than in the group with triamcinolone acetonide. No statistically significant differences in the interference of pain in the activities at baseline. Analysis of the variance: the progression of spontaneous pain VAS 1, 3 and 6 for the group effect P=0,756, The interaction effect P=0,433. Time effect P<0,001 (both therapies reduce pain). Analysis of the progression of pain to VAS palpation. The group effect P=0,241. The interaction effect P=0,639. Time effect P<0,001 (Both therapies reduce pain). Non-inferiority analysis: The treatment with hyaluronic acid is non inferior to the treatment with triamcinolone acetonide. No secondary adverse effect.

Conclusion: MTPS treatment with hyaluronic acid injections is not inferior to the treatment with triamcinolone acetonide injections at 6 month. In specific cases like in diabetic patients or where corticosteroid have been unsuccessful or are contraindicated, hyaluronic acid injections is a therapeutic alternative.

Clinical Effectiveness of Exercise and Corticosteroid Injection for Subacromial Impingement Syndrome: A Randomised Controlled Trial. Edward Roddy[1], Reuben Ogollah[1], Irena Zwierska[1], Praveen Datta[2], Alison Hall[1], Elaine Hay[1], Sue Jackson[2], Martyn Lewis[1], Julie Shufflebotham[3], Kay Stevenson[2], Danielle van der Windt[1], Julie Young[1] and Nadine Foster[1]. [1]Keele University, Keele, United Kingdom, [2]University Hospital of North Staffordshire, Stoke-on-Trent, United Kingdom, [3]Staffordshire and Stoke-on-Trent Partnership Trust, Stoke-on-Trent, United Kingdom.

Background/Purpose: Subacromial impingement syndrome (SIS) is the most common cause of shoulder pain. It is commonly managed by exercise and corticosteroid injection yet how these are best-delivered is uncertain. The SUPPORT trial investigated whether better outcomes in pain and function are achieved with (1) physiotherapist-led individualised, supervised and progressed exercise rather than a standardised advice and exercise leaflet, and (2) ultrasound (US)-guided subacromial corticosteroid injection rather than unguided injection.

Methods: Study design was a 2×2 factorial randomised controlled trial. Adults with SIS were recruited from community musculoskeletal services and randomised equally to one of four treatment groups: (1) US-guided steroid

injection and physiotherapist-led exercise, (2) US-guided steroid injection and an exercise leaflet, (3) unguided steroid injection and physiotherapist-led exercise, or (4) unguided steroid injection and an exercise leaflet. Outcomes were collected at 6 weeks, 6 months and 12 months by postal questionnaire. The primary outcome measure was the Shoulder Pain and Disability Index (SPADI), compared at 6 weeks for the injection interventions and 6 months for the exercise interventions. Secondary outcomes included SPADI pain and disability subscales, current shoulder pain intensity, patient's global impression of change, and pain self-efficacy. 250 participants were required to detect a small-moderate effect size (0.4) in SPADI for the two main comparisons. Analysis was by intention-to-treat.

Results: 256 participants were recruited (48% male, mean age 54 years), 64 to each treatment group. Response rates for the primary outcome were 94% at 6 weeks, 88% at 6 months and 80% at 12 months.

Greater mean improvement in total SPADI score was seen with physiotherapist-led exercise than with the exercise leaflet at 6 months and 12 months: 3.02 (95%CI −3.00, 9.03) at 6 weeks, 9.48 (95%CI 3.30, 15.65) at 6 months, and 6.64 (95%CI 0.33, 12.96) at 12 months. Physiotherapist-led exercise led to greater mean improvement in SPADI pain subscale at 6 and 12 months, and in SPADI disability subscale at 6 months but not at 12 months. At 12 months, the physiotherapist-led exercise group showed a greater reduction in current shoulder pain intensity, stronger self-efficacy beliefs and more frequent patient reporting of being much or completely better.

Within-group improvement in total SPADI was seen in both injection groups but there were no significant between-group differences at any time-point: 2.99 (95%CI −3.03, 9.00) at 6 weeks, 3.38 (95%CI −2.79, 9.56) at 6 months, and −1.50 (95%CI −7.82, 4.82) at 12 months. There were no differences in secondary outcome measures between the injection groups at any time-point.

There was no significant interaction effect of combined US-guided injection and physiotherapist-led exercise at the primary endpoints of 6 weeks and 6 months.

Conclusion: Physiotherapist-led exercise in patients with SIS leads to greater improvements in pain and function than providing a standardised advice and exercise leaflet. Ultrasound-guidance confers no additional benefit over unguided corticosteroid injection.

The Effects of Mulligan's Mobilization with Movement Techniques in Patients with Lateral Epicondylitis. Aycan Cakmak[1], Elcin Dereli[1] and Dilsad Sindel[2]. [1]Istanbul Bilgi University, School of Health Sciences, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: The aim of this study was to investigate the effects of Mulligan's mobilization with movement (MWM) technique in the management of pain and improvement of functional status in patients with lateral epicondylitis (LE).

Methods: A total of 40 patients with LE were randomly assigned to two groups. The MWM group (n=20) was treated with MWM technique, exercise and cold therapy. The patients in control group (n=20) received only exercise and cold therapy. The physical therapy sessions were applied in our clinics five times a week for two weeks (total number: 10). All physical therapy sessions were supervised by the same investigator. We used the Visual Analogue Scale (VAS) to assess the intensity of pain. Moreover, the intensity of pain and functional disability were evaluated by the Patient-rated Tennis Elbow Evaluation (PRTEE) Questionnaire. Both dynamometer and pinchmeter were used to assess muscle strength of the hand. Muscle strength of elbow and wrist were evaluated by the manual muscle testing method. All outcome measures were conducted at baseline and repeated immediately after treatment (post-treatment), and at 1- and 3-month follow-up assessments. To compare the difference between two groups, we used the Mann-Whitney U test (α=0.05).

Results: There was a significant decrease in VAS scores during activity scores in MWM group at post-treatment (p=0.001), 1-month (p<0.001) and 3-month (p=0.040) assessments compared with the control group. Moreover, there was a significant decrease in VAS scores at night in MWM group (p=0.024) and significant increase in pain-free grip strength (p=0.002) at post-treatment assessment compared with the control group. The PRTEE-Pain Subscale scores decreased significantly in MWM group at post-treatment (p<0.001), 1-month (p<0.001) and 3-month (p=0.001) assessments compared with the control group. For all other outcome measures, there was no statistically significant difference between the two groups at all assessment intervals (p>0.05).

Conclusion: Mulligan's MWM techniques may be effective in reducing pain and improving in grip strength in patients with LE.

Mindfulness Is Associated with Sleep Quality Among Patients with Fibromyalgia. Yuan Zhang[1], Lori Lyn Price[2], Nani Morgan[3], Lucas Morgan[4] and Chenchen Wang[2]. [1]University of Massachusetts Lowell, Lowell, MA, [2]Tufts Medical Center, Boston, MA, [3]University of Hawaii, Honolulu, HI, [4]University of Massachusetts, Honolulu, HI.

Background/Purpose: Mindfulness is the ability to observe, describe, or be aware of present moment experiences without judgment or reactivity. Previous literature suggests that mindfulness-based interventions may be effective in reducing chronic pain and depression experienced among patients with fibromyalgia. Additionally, fibromyalgia patients commonly experience sleep disturbance, which at least partially attributes to chronic pain and depression. Therefore, we hypothesize that mindfulness could be associated with fibromyalgia patients' sleep quality, and the effect may be explained through reducing symptoms of chronic pain and depression.

Methods: We conducted a secondary analysis of baseline data from a randomized controlled trial comparing Tai Chi and aerobic exercise among patients with fibromyalgia. Patients completed the Five Facet Mindfulness Questionnaire (FFMQ), a 39-item, self-report questionnaire; scores ranging 39–195, with higher scores representing higher levels of mindfulness. Participants also completed the Beck Depression Inventory Second Edition (BDI-II), PROMIS Pain Interference, PROMIS Sleep Disturbance, and Pittsburgh Sleep Quality Index (PSQI). Pearson correlations were run to examine the associations of mindfulness with sleep quality and disturbance, chronic pain, and depression. Multivariate linear regressions were run to examine the predicting effect of mindfulness on sleep quality and disturbance. Chronic pain and depression were then separately introduced into the regressions to test their potential mediating effects.

Results: This study included 160 fibromyalgia patients with an average age of 51.9 years, primarily female (92%). Patients reporting higher levels of mindfulness tended to report better sleep quality (r=−0.25, p<0.01) and less sleep disturbance (r=−0.27, p<0.01), as well as lower chronic pain (r=−0.36, p<0.01), and less depression (r=−0.57, p<0.01)). Patients reporting higher levels of chronic pain or depression tended to report worse sleep quality (r=0.42 & r=0.43, p<0.01) and more sleep disturbance (r=0.42 & r=0.32, p<0.01). The linear regression modeling reported that mindfulness significantly predicted sleep quality and disturbance (Table 1). The association between mindfulness and sleep quality/disturbance was partially mediated through chronic pain and depression (Table 1).

Conclusion: Mindfulness may be associated with fibromyalgia patients' sleep quality, and the effect could possibly be explained through affecting the symptoms of chronic pain and depression. Longitudinal studies are needed to further evaluate whether improvement in mindfulness are associated with improvement in sleep quality of fibromyalgia patients.

Table 1. Linear Regression Models for the Predicting Effect of Mindfulness on Sleep Quality/Disturbance and the Mediating Effect of Chronic Pain and Depression

	Sleep quality (PSQI)			Sleep Disturbance (PROMIS)

Fibromyalgia Patients Taking Opioids Have Low Self-Efficacy and High Pain Catastrophizing but No Reduction in Pain or Improvement in Activity. Joseph Adu[1], Cecilia P. Chung[1], Li Alemo Munters[1], Leon Darghosian[1], Rebecca Spitz[2], Dana Dailey[2], Barbara Rakel[2], Kathleen Sluka[2] and Leslie J. Crofford[1]. [1]Vanderbilt University, Nashville, TN, [2]University of Iowa, Iowa City, IA.

Background/Purpose: Fibromyalgia (FM) is a chronic disease of unknown etiology characterized by diffuse pain leading to fatigue, unrefreshing sleep and mood disturbances. The Fibromyalgia Activity Study with Tens (FAST) is a randomized controlled multicenter trial designed to evaluate the efficacy of Transcutaneous Electrical Nerve Stimulation (TENS) for FM. We have found that at baseline, approximately 40% of patients enrolled in FAST have been prescribed chronic opioids. Data supporting opioid efficacy for FM is lacking and they are not recommended by professional societies. The purpose of this study is to compare the baseline characteristics of FAST participants who are taking opioids to those who are not.

Methods: Patients screened for FAST (n = 44) wore ActiGraph wGT3X-BT accelerometers for 7 days prior to each visit and were evaluated by pre-randomization baseline data. These included the Demographic Health History questionnaire, the Fibromyalgia Impact Questionnaire-Revised (FIQR), the Short-form-36 Health Survey (SF-36), the Brief Pain Inventory (BPI), the Pain Self-Efficacy Questionnaire (PSEQ), the Pain Catastrophizing Scale (PCS), and others. These results were compared between patients separated into a non-opioid vs. opioid classifications (n = 25 vs. n = 19). These data were analyzed using two-sample Wilcoxon rank-sum (Mann-Whitney) test and Fisher's exact test with significance set at $P \leq 0.05$.

Results: There were no significant differences between the two groups in terms of age, sex, race, education, income level, marital status, years diagnosed with FM, smoking history, and activity level as measured by actigraphy. FIQR scores, the main disease activity measure for FAST, between non-opioid and opioid users (median: 55.6; IQR: 49.5–63.6 vs. 53.1; 47.9–75.6; $P = 0.17$), and the SF-36, a quality of life measure, did not differ across domains except for General Health, which was lower in opioid patients (median: 38.9; IQR: 34.2–43.7 vs. 33.2; 26.1–38.9; $P = 0.05$). Patients in the opioid group had significantly lower ratings on the PSEQ (median: 25.5; IQR: 14.0–34.0 vs. 37.0; 25.5–49.5), which assesses patients' confidence to accomplish specific tasks despite concurrent pain ($P = 0.01$). In addition, PCS total scores, which measure negative thoughts experienced during pain, were significantly higher in the opioid group (median: 22.0; IQR: 13.0–35.0 vs. 10.5; 6.0–23.0; $P = 0.02$), although pain severity was not significantly different based on BPI.

Conclusion: These data suggest an association between opioid use, pain catastrophizing and low levels of pain self-efficacy. The reasons for these associations are not clear, but it is possible that patients with these characteristics are more likely to be prescribed opioids. There is no evidence that patients on opioids have improved disease activity or better health outcomes than those not on opioids.

Olecranon Bursitis Is Often Hemorrhagic and Responds to Steroid Injections. Kyriakos A. Kirou and Naveed Chaudrhry. Hospital for Special Surgery, New York, NY.

Background/Purpose: Olecranon bursitis is a common presentation to an outpatient rheumatology practice. The differential diagnosis includes crystalline bursitis (gout and pseudogout), inflammatory bursitis due to systemic arthritis such as rheumatoid arthritis, infectious, and hemorrhagic. We have observed a larger than expected percentage of hemorrhagic olecranon bursitis in our practice and wanted to report our experience with this entity and its management.

Methods: We systematically looked for the ICD9 diagnosis code 726.33 in our academic rheumatology outpatient practice from 2011–2014. We recorded the patents demographic information, as well as clinical examination findings, bursa fluid analysis, and response to glucocorticoid injections. We defined inflammatory cases when the tissues around the swelling were erythematous and hot and the synovial fluid was inflammatory (>2,000 WBC with predominance of PMN). Non-inflammatory cases were defined when none of the above were present. A bursitis was defined as infectious when a culture was positive and possibly infectious when culture was negative but there were no crystals in the fluid. Hemorrhagic bursitis was identified when the bursa fluid had the appearance of pure blood. A bursa was defined as large when its diameter was >5 cm (larger than golf ball), intermediate when its diameter was 2.5–5 cm and small when its diameter was <2.5 cm.

Results: We identified 9 patients. Of those, 6 were non inflammatory in appearance. All of them proved to be hemorrhagic and negative for infection on culture. The remaining 3 were inflammatory, but no crystals were identified in the fluid under polarizing microscopy. The fluid was yellow opaque in 2 of those cases and in one case there was only 1 drop of blood which was hemorrhagic in appearance. The 6 hemorrhagic cases were injected with depomedrol 40 mg and five had a dramatic response within few days-few weeks. We had no follow up in 1 patient. Of 3 inflammatory cases, one had a documented infection with MSSA, another one responded well to antibiotics, and another was lost to follow up. Of note, all of our patients were males with an average age of 54 (range: 32–72), relatively high BMI (average 30.5 with range: 21–45). Of the 6 hemorrhagic cases, 4 were large and 2 intermediate in size. Two of the inflammatory cases were small and one large. One out of 6 hemorrhagic bursa patients was on warfarin and another on dabigatran.

Conclusion: Hemorrhagic bursitis is not uncommon and should be suspected when there is no inflammation on examination. Middle age men, especially those with higher BMIs, and perhaps those on anticoagulation appeared to be at higher risk for this entity. Our experience suggests that an injection with glucocorticoids is an effective treatment strategy and leads to resolution or marked improvement within few days-few weeks.

Comparison High Intensity Laser Therapy and Wrist Splint in the Treatment of Lateral Epicondylitis. Ekrem Akkurt[1], Halim Yilmaz[1], Ali Salli[2], Selman Parlak[3], Gulten Karaca[1] and Sami Kucuksen[4]. [1]MD, Konya, Turkey, [2]MD, Konya, Turkey, [3]MD, Konya, Turkey, [4]MD, Konya, Turkey.

Background/Purpose: Lateral epicondylitis (LA), also known as tennis elbow, is a quite common disease with a prevalence of 1.7% and mostly seen between 3rd and 6th decade of life.

Methods: 67 elbows diagnosed with lateral epicondylitis were divided randomly into two groups as HILT (33,9 and as wrist splint (34). 33 wrists were treated for 5 sessions weekly for two weeks. The remaining elbows, 34, were recommended to wear wrist splints for 6 subsequent weeks. The aim of this study is to compare the efficacy of HILT and wrist splint treatment. Patients were evaluated before and in 6th week of post treatment period using visual analogue scale for pain (VAS) during activity and resting, Disabilities of the Arm, Shoulder and Hand (DASH) Score, hand grip strength test (HGST), and Short Form 36 (SF-36).

Results: Out of the 60 patients, 14 male and 46 female with a mean age of 46,28 ± 9,44. The pretreatment and 6th week scores of the HILT patients were as follows: VAS activity 8,33±1,97, 6,03±2.35 VAS resting 5,75±3,27, 2,72±2.41, DASH 53.40±22, 38.33±17.10, HGST 15.49±9.95, 21,52±13,18, SF 36 physical component 35.35±17,72, 66,74±15,75, and SF 36 mental component 46,43±17.31, 62,16±17,93 and of the wrist splint group as the following: VAS activity 7,77±2,34, 6,14±3,20, VAS resting 4,67±3,10, 2,79±3.01, DASH 44,68±16,03, 30.49±17.52, HGST 17,19±7,66, 20,81±8,11, SF 36 physical component 36,70±15,13, 50,42±18,93, and SF 36 mental component 38,62±15,57, 52,33±18,72.

The VAS activity, resting, DASH, HGST, SF36 physical, and SF36 mental component scores of both groups revealed significant improvements on comparing their pretreatment and 6th week score. Except the SF physical component scores, none of these variables were statistically significant when the HILT and wrist splint groups were compared. The statistical difference was in favor of the HILT group.

Conclusion: The findings of the present study suggest that both HILT and wrist splints are reliable, safe, and effective treatment options in LE patients. Although HILT has been determined to be more effective in increasing functional capacity, both groups revealed almost equally positive outcomes, in the short and long term considering pain, functional status and quality of life.

The Relationship Between Tender Points and Disease Severity in Patients with Fibromyalgia. Oya Ozdemir[1] and Fitnat Dincer[2]. [1]Hacettepe University Faculty of Medicine, Ankara, Turkey, [2]Hacettepe University, Faculty of Medicine, Ankara, Turkey.

Background/Purpose: The aim of this study was to investigate the relationship between tender point examination and disease severity in patients with a diagnosis of fibromyalgia according to the 1990 American College of Rheumatology criteria.

Methods: Sixty three consecutive female patients, with a mean age of 43.8±10.5 years, were included to the study. Digital palpation of tender points was performed by the same physician (OO), after then total tender point count (TPC) and myalgic score (rated as 0=no pain, 1=mild pain, 2=a verbal exclamation of pain, 3=withdrawal or flinching) were calculated. In order to assess the disease severity, Fibromyalgia Impact Questionnaire (FIQ) was used.

Results: The median duration of symptoms was 3.0 years (range, 0.5–20). The mean of total TPC and myalgic score were 14.7±2.5 and 25.3±8.0, respectively. The mean of FIQ total score was found to be 63,2±15.9. Both TPC and myalgic score do not correlate with the patients' age and symptom duration. We have found no statistically significant correlation between total TPC and FIQ (p=0.070). However, there was a positive correlation between total myalgic score and FIQ (p=0.035, r=0,267).

Conclusion: As an indicator of disease severity, calculating the total myalgic score appears to be more informative than the TPC in female patients with fibromyalgia.

The mtDNA Haplogroups Influence the DNA Methylome of Articular Chondrocytes. Ignacio Rego-Perez[1], Juan Fernández-Tajes[1], Mercedes Fernandez Moreno[1], Angel Soto-Hermida[1], María Eugenia Vázquez-Mosquera[1], Estefanía Cortés-Pereira[1], Maria Tamayo[2], Sara Relaño-Fernandez[1], Alejandro Mosquera[2], Natividad Oreiro-Villar[1], Carlos Fernandez-Lopez[1], Jose Luis Fernandez[2] and Francisco J. Blanco Garcia[1]. [1]Servicio de Reumatología. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain, [2]Departamento de Genética. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain.

Background/Purpose: Mitochondria and DNA methylation play a main role in the development of Osteoarthritis. The aim of this work is to analyze the influence of the mitochondrial background on the DNA methylome of articular chondrocytes.

Methods: DNA methylation profiling was performed using the Infinium HumanMethylation27 beadchip. Previously, cartilage isolated DNA from 41 cartilage samples (13 from haplogorup J and 20 from haplogroup H) was bisulfite-modified using EZ DNA methylation kit and hybridized according to the manufacturerxs instructions. DNA methylation M-values were obtained and further compared between haplogroups using ANOVA and adjusting for cofounder effects of age, gender and disease status. Bonferroni post-hoc analysis was performed for analysing haplogroup pairwise differences. Enrichment in biological process and molecular function was tested by means of IPA (Ingenuity Pathway Analysis) software (Qiagen). All statistical analyses were conducted in R software.

Results: ANOVA analysis showed a total of 1926 CpG probes with a p-value under 0.05 (Figure 1); bonferroni post-hoc analysis allowed us to identify 538 significant probes (adjusted p-value < 0.05) between haplogroup H and haplogroup J; of these, 451 were more methylated in J and 87 were less methylated in J in relation to the most common haplogroup H.

A CpG site in the promoter region of fucosidase, alpha-L-1 (FUCA1) gene was the most differentially methylated probe between H and J groups, being the most methylated in haplogroup J; on the contrary, a CpG site located in the promoter region of homeobox D3 (HOXD3) gene, the second most differentially methylated probe between H and J groups, was the less methylated in haplogroup J, compared with the most common haplogroup H.

Among the most significant altered canonical pathways obtained with IPA software, those involving apoptosis signalling (p=0.013) and inflammatory response (p=0.0048) stand out. Besides, an enrichment of several pathways involved in TGF-β signalling (p=0.0107), iNOS signalling (p=0.0011), BMP signalling (p=0.0044), Protein kinase A signalling (p=0.0071), MAPK signalling (p=0.016) or PI3K signalling (p=0.0074) were also revealed. It is noteworthy that, to a greater or lesser extent, these pathways are involved in the OA process.

Conclusion: The mitochondrial genetic background seems to modify the nuclear epigenome of articular chondrocytes. Some of the altered pathways, mainly enhanced in carriers of the haplogroup H, have been previously described to be involved in the etiology of OA. The role played by the mtDNA haplogroups on Spanish patients with OA could be mediated by this particular epigenetic profile.

Transmitocondrial Cybrids: A Tool to Study the Role of mtDNA Haplogroups in OA Pathogenesis. Mercedes Fernandez Moreno[1], Tamara Hermida-Gómez[2], Angel Soto-Hermida[1], Juan Fernández-Tajes[1], María Eugenia Vázquez-Mosquera[1], Estefanía Cortés-Pereira[1], Sara Relaño-Fernandez[1], Natividad Oreiro-Villar[1], Carlos Fernandez-Lopez[1], Esther Gallardo-Perez[3], Rafael Garesse[3], Ignacio Rego-Perez[1] and Francisco J. Blanco Garcia[1]. [1]Servicio de Reumatología. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain, [2]Grupo de Bioingeniería Tisular y Terapia Celular (CBTTC-CHUAC). CIBER-BBN/ISCIII. Servicio de Reumatología. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de Coruña (CHUAC). SERGAS. Universidade de A Coruña, A Coruña, Spain, [3]Departamento de Bioquímica, Instituto de Investigaciones Biomédicas, Madrid, Spain.

Background/Purpose: Mitochondria play an important role in the OA pathogenesis. mtDNA haplogroup J is significantly associated with a lower risk of OA in northwest Spanish populations. Transmitochondrial cybrids,

that carry the same nuclear background and different mitochondrial variants, are optimal cellular model to study mitochondrial biology and function. This cellular model excludes variations from the nuclear genome in the cellular activity. The aim of this work is to test the real role of mtDNA haplogroups in cellular activity, using cybrids with mtDNA haplogroup H and J and analyzing several parameters implicated in the OA process.

Methods: Cybrids were developed using the 143B.TK$^-$ rho-0 cell line and platelets from healthy (without OA) and OA donors with mtDNA haplogroups H and J. The metabolic status was evaluated by measuring both lactic acid production and glucose consumption. The respiration was evaluated with a high resolution respirometry (Oroboros). The ATP levels were obtained by luciferase reaction. The expression levels of genes implicated in inflammation (COX-2 and iNOS), Metalloproteinases (MMP-1, 3 and 13) and MnSOD, were evaluated by RT-PCR. The ROS production and percentage of apoptotic cells were measured by Flow Cytometry (mean fluorescence intensity).

Results: Cybrids carrying the mtDNA haplogroup J show higher lactic acid production (62.22 mg/ml and 52.71 mg/ml; $p<0.05$) and 20% higher of glucose consumption than H cybrids, therefore being more efficient using glucose vie glycolysis, In addition, J cybrids show lower levels of ATP (0.027nmol ATP/mg protein) than H (0.033nmol ATP/mg protein), and higher values of oxygen consumption (36.92 nmmol/ml for J cybrids and 9.97 nmmol/ml for H cybrids). H cybrids had significantly higher levels of total ROS (203.30 for H cybrids and 131.26 for J) and mitochondrial ROS (47.36 and 36.87 respectively). MnSOD expression in basal conditions was higher in cybrids H than J (2-fold) and IL-1β stimulation (5 ng/ml 24 hours) showed 2-fold increase of MnSOD in J cybrids compared to H. The analysis of inflammatory process showed that the basal expression levels of COX-2 and iNOS were higher in H than in J (H expressed 4-fold COX-2 than J; iNOS was 1.5-fold). Basal expression of MMP-1, 3 and 13 was higher in cybrids H than J. The percentage of cell in spontaneous apoptosis was similar between cybrids H (3.76%) and J (5.78%). The use of staurosporine (0.2μM, 2 hours) to induce apoptosis showed a 7-fold increase of apoptosis in H cybrids.

Experiments performed in OA cybrids confirm the metabolic differences between H cybrids and J cybrids, as well as the higher susceptibility of H cybrids than to undergo apoptosis.

Conclusion: H and J cybrids have different metabolic behavior (J are more glycolysis dependent than H). Cybrids J have a lower ATP production, lower inflammatory response and produce less reactive species of oxygen. Cybrids J are less susceptible to undergo apoptosis. All these results offer a real rationale for why haplogroup J is associated with lower risk of OA.

Impact of Genes Modulating Serum Low-Density Lipoprotein Cholesterol Levels on Progression of Joint Destruction in Japanese Patients with Rheumatoid Arthritis. Shinji Yoshida[1], Katsunori Ikari[1], Koichiro Yano[1], Yoshiaki Toyama[2], Atsuo Taniguchi[3], Hisashi Yamanaka[1] and Shigeki Momohara[3]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) have a higher prevalence of dyslipidemia than healthy individuals. Since RA is a chronic inflammatory disease, an inflammatory response may be partly involved in the pathogenesis of dyslipidemia. Recently, low-density lipoprotein (LDL) cholesterolemia has been reported to be a risk factor for radiographic progression of joint destruction. Several genetic risk loci for progression of joint destruction have been identified so far. However, the genetic predisposition factors have not yet been elucidated. The purpose of this study was to evaluate impact of genetic variants modulating serum LDL cholesterol (LDL-C) levels on progression of joint destruction in Japanese patients with RA.

Methods: This study included 1,005 Japanese patients with RA for whom Sharp/van der Heijde scores (SHS) of hands were available at a disease duration of 5 years. DNA samples of the subjects were obtained from the Institute of Rheumatology Rheumatoid Arthritis cohort study (IORRA) DNA collection. All of the patients who donated DNA samples consented to participate in this study as approved by the Tokyo Women's Medical University Genome Ethics Committee, and satisfied the American College of Rheumatology 1987 revised criteria for the classification of RA. Thirteen single nucleotide polymorphisms (SNPs) in the 8 loci influencing serum LDL-C concentrations in the Japanese population were selected and genotyped in the DNA samples: rs611917, in *SORT1*; rs693, rs7575840, and rs515135, in *APOB*; rs3846662, in *HMGCR*; rs662799, in *BUD13-APOA1-APOA5*; rs838867, in *SCARB1*; rs1532624, and rs2303790, in *CETP*; rs688, and rs1433099, in *LDLR*; rs429358, and rs7412, in *APOE-C1*. Multivariate linear regression analyses were performed to examine the association of each SNP with radiographic progression of joint destruction in the first 5 years after onset of RA, calculated as SHS of hands at the 5-year disease duration. Adjustments were made for gender, age of onset, anti-citrullinated peptide status, and year of disease onset. All SHS were log-transformed to obtain a normal distribution.

Results: Multivariate linear regression analyses revealed that the minor allele of rs662799 in *BUD13-APOA1-APOA5* was associated with progression of joint destruction in the recessive model ($P=0.04$). However, the association could not reach the level of the significance after Bonferroni correction for multiple comparisons. The other SNPs showed no association (Table 1).

Conclusion: We could not confirm the association between genes modulating serum LDL-C levels and progression of joint destruction in Japanese patients with RA. Our results indicated that rs662799 in *BUD13-APOA1-APOA5* might be a risk factor for progression of joint destruction, but further studies would be required to confirm the association.

Genome-Wide Profiling of DNA from Cartilage Reveals Regions Differently Methylated in Osteoarthritis Patients. Guangju Zhai[1], Ming Liu[2], Yuhua Zhang[1], Patricia E. Harper[1], Erfan Aref-Eshghi[2], Glynn Martin[3], Andrew Furey[3], Roger Green[1], Guang Sun[4] and Proton Rahman[5]. [1]Discipline of Genetics, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [2]Memorial University, St. John's, NF, [3]Department of Surgery, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [4]Discipline of Medicine, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [5]Memorial University of Newfoundland, St. John's, NF.

Background/Purpose: Osteoarthritis (OA) represents the most common form of arthritis and has substantial clinical and economic impact. Evidence supports that DNA methylation plays a significant role in OA. The aim of the study was to identify differentially methylated loci for OA using an epigenome-wide association approach.

Methods: Cartilage samples were collected from 14 patients who underwent total hip joint replacement due to primary OA and 16 hip fracture patients who do not have evidence of hip OA. DNA was extracted from the cartilage samples and methylation profiling was performed using the Illumina Infinium HumanMethylation 450k chip, which measures about 480,000 different CpG sites covering 96% of RefSeq genes. It provides comprehensive gene region coverage, targeting multiple sites including the promoter, 5' UTR, 1st exon, gene body and 3' UTR. The methylation level at each CpG site was measured by β values varying from 0 (no methylation) to 1 (100% methylation).

Results: We found 18 individual CpG sites significantly associated with OA, with a mean difference in methylation level of >10% and a p value < 10^{-4}. Six of them were hypermethylated and 12 were hypomethylated in OA patients. Nine of them are located within genes and other 9 are intergenic. Two genes – COL8A1 and CDKN2C have been reported recently using the same approach as ours and the other 16 CpG sites are novel. ATG7 involving in autophagic pathway and CLCN7 causing osteopetrosis are novel promising candidates for OA.

Conclusion: We confirmed the recently reported association of COL8A1 and CDKN2C methylation with OA and identified 16 novel DNA methylation loci for OA, providing new insight into the pathogenesis of OA. Confirmation study with large sample size is underway.

The Mitochondrial Genome Influences the Risk of Incident Knee OA. DATA from the Osteoarthritis Initiative. Angel Soto-Hermida[1], Ignacio Rego-Pérez[1], Juan Fernández-Tajes[1], Mercedes Fernandez Moreno[1], María Eugenia Vázquez-Mosquera[1], Estefanía Cortés-Pereira[1], Sonia Pértega-Díaz[2], Natividad Oreiro-Villar[1], Carlos Fernandez-Lopez[1] and Francisco J. Blanco Garcia[1]. [1]Servicio de Reumatología. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain, [2]Unidad de Epidemiología Clínica y Bioestadística. Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain.

Background/Purpose: Previous studies by our group showed a significant influence of the mtDNA haplogroups on both radiographic progression and cartilage integrity of knee OA patients from the Osteoarthritis Initiative (OAI). The aim of this study is to analyze the influence of the mitochondrial variants on the risk of incident knee OA in patients with pre-radiographic OA of the OAI.

Methods: We assessed the mtDNA haplogroups in 2374 Caucasian samples of the OAI to analyze their influence on incident knee OA. Incidence of knee OA was defined as a KL score <2 at baseline and a KL≥2 at 4 years follow-up of the same knee. We also included individuals with unilateral KOA, since they were at risk of developing incident OA at the other knee. Statistical analyses included chi-square contingency tables and logistic regression models considering age, gender, body mass index (BMI), contralateral knee OA and mtDNA variants as variables of interest. Further, the area under the receiving operative characteristic (ROC) curve (AUC) of the model was also calculated.

Results: After 4 years of follow-up, a total of 214 patients developed incident knee OA, meanwhile 1323 did not. The rest of patients (n=837) had a KL score≥2 at baseline in both knees, therefore did not meet the selection criteria and were subsequently excluded from further analyses. Patients belonging to mtDNA cluster HV were significantly overrepresented in the incident knee OA group (OR=1.395; CI=1.044–1.8636; p=0.024) meanwhile patients in cluster TJ were less represented in the incident group (OR=0.692; CI=0.466–1.026;p=0.065). The logistic regression model showed that female gender (p<0.001), higher BMI (p<0.001) and contralateral knee OA (p<0.001) were risk factors to develop incident OA; additionally, OA patients in cluster HV were at higher risk for incident knee OA than patients in cluster TJ (p=0.016). The AUC of this regression model was 0.707

Conclusion: The mitochondrial genome contributes to the development of incident knee OA. The assignment of the mtDNA haplogroups could be used as complementary genetic biomarkers to predict the risk of incident knee OA.

As Xubias, 15006 A Coruña, Spain, A Coruña, Spain.

Background/Purpose: In this study we have identified proteins differentially abundant in the serum of Osteoarthritis (OA) patients comparing four different progressive pathological grades using mass spectrometry and iTRAQ technique for relative quantification. Our final aim is to establish a panel of biomarkers useful to predict the pathology in pre-radiological stages (early Osteoarthritis biomarkers), but also for its handling and the developing of trials of treatment in radiological stages (late Osteoarthritis biomarkers).

Methods: 15 individual samples for each condition (OA Grade 0, pre-radiological stage Grade I, and radiological stage grades II-III and IV) were pooled in three groups with the aim of reducing the contribution of individual extreme values. After enrichment in the low-abundant protein fraction, the pooled samples were subjected to in-solution digestion, followed by iTRAQ labelling following manufacturer instructions and Reverse Phase peptide separation in a LC system (Agilent 1200). Fractions were again separated in a nanoLC system (Tempo, Eksigent) automatically deposited on a MALDI plate and analyzed by MSMS in a 4800 MALDI-TOF/TOF system (ABSciex). Relative quantitative analysis was done using ProteinPilot software (ABSciex) and modulated proteins were analyzed with String 9.0 software.

Results: We have detected two big sets of serum proteins modulated in the early pre-radiological OA process. Serum levels of apolipoproteins are altered when comparing Grade I vs. Grade 0. Specifically, apolipoprotein E and apolipoprotein B-100, that mediates the binding, internalization, and catabolism of lipoprotein particles are accumulated in Grade I samples. Furthermore, up to six components of the complement, a group of proteins involved in immune response and inflammation are decreased in serum in early OA grades. Among them, complement component 5 -C5-, that have been recently identified as key player of the OA process, is much less abundant in any OA grade in comparison to Grade 0. Proteins previously described as putative biomarkers by our group and others, like histidine-rich

glycoprotein, gelsolin and decorin, are also modulated in our study, but at later radiological stages -Grade II/III and Grade IV *vs.* Grade I and Grade 0-.

Conclusion: Our results indicate that early pathological grades of the OA process are linked to an imbalance in the metabolism and, specifically, in the lipid metabolism. Altered serum levels of apo-lipoproteins could be used, in combination with other 'dry' biomarkers, as an indicator for early OA process and to detect the pathology in pre-radiological stages. Furthermore, the lower serum levels in the OA grades detected for the complement component 5 -C5-, strongly support recent *in vivo* data indicating that a decrease of this protein is linked to the development of the disease.

Table 1: Summary of the results

Main proteins modulated in pre-radiological OA Grade I vs. OA Grade 0 (Healthy controls)	*Ratio GI/G0*	*p-value*	*Main proteins modulated in late OA Grade IV vs. pre-radiological OA Grade I*	*Ratio GIV/GI*	*p-value*
Apolipoprotein E	2.25	0.02	Zinc-alpha-2-glycoprotein	5.43	0

Mass Spectrometry Imaging Revealed Potential Lipid Chondrogenic Biomarkers for Cell-Based Therapy in Cartilage. Beatriz Rocha[1], Berta Cillero-Pastor[2], Gert Eijkel[2], Valentina Calamia[1], Lucia Lourido[1], Carolina Fernández-Costa[1], Patricia Fernandez-Puente[1], Jesus Mateos[1], Cristina Ruiz-Romero[1], Ron MA Heeren[2] and Francisco J. Blanco Garcia[1]. [1]Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatologia. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). As Xubias, 15006., A Coruña, Spain, [2]AMOLF, Amsterdam, Netherlands.

Background/Purpose: Recent studies highlight the importance of lipid metabolism in the modulation of chondrogenesis. Specifically, the positive chondrogenic effect of acid ceramidase, which is necessary to maintain the metabolic balance of several bioactive lipids, during the chondrogenesis of mesenchymal stem cells (MSCs) has been demonstrated. Therefore, knowledge on the distribution and modulation of lipids during chondrogenesis could be highly valuable to improve MSC-based cartilage therapies by the discovery of new chondrogenic markers. In this work, mass spectrometry imaging (MSI) has been employed to characterize the spatial distribution of lipids in human bone marrow MSCs (hBMSCs) during the first steps of their chondrogenic differentiation.

Methods: hBMSCs micromasses obtained from 3 osteoarthritic donors and collected at day 2 and 14 of chondrogenesis were gelatin-embedded and cryo-sectioned into thin sections for MSI. Samples were then sprayed with matrix and analyzed by matrix-assisted laser desorption ionization (MALDI)-MSI to obtain the lipid profiles. Statistical methods such as PCA and discriminant analysis were used for data interpretation. Lipid images were generated with Biomap software. Data were confirmed by Real-Time PCR analyses.

Results: Analysis of hBMSCs micromasses at days 2 and 14 of chondrogenesis by MALDI-MSI led to the identification of 20 different intact lipid species, including fatty acids, sphingolipids and phospholipids (Table 1). Among the lipid classes identified, we found phosphatidylcholines and sphingomyelins levels decreased during chondrogenic differentiation (Figure 1). These data suggest that hBMSCs mobilize the SMs in order to produce secondary metabolites such as sphingosine-1-phosphate and ceramides that are necessary for their differentiation towards chondrocytes. In addition, a clear up-regulation of 4.74-fold was found for sphingosine kinase 1 ($p<0.05$) at day 14 when compared to day 2, supporting the low expression of SMs intact species at day 14 of chondrogenesis.

Conclusion: The data compiled herein are undoubtedly useful for a better understanding of the molecular processes that occur during the differentiation of these cells towards cartilage-like tissues. In addition, the differential lipid profiles described in our study might serve as useful differentiation markers for the development of cell-based therapies for cartilage repair. In fact, the loss of SM during chondrogenesis might be used as a novel chondrogenic marker.

TABLE 1 Lipid profiles of hBMSCs undergoing chondrogenesis after MALDI-MSI analysis.

m/z peak	Lipid assignment	Condition
303.2	Arachidonic acid	Day 14
327.2	Docosahexaenoic acid	Day 14
723.5	SM (d18:1/16:1)	Day 2
725.5	SM (d18:1/16:0)	Day 2
729.5	SM (d18:1/18:1)	Day 2
739.5	PC (16:0/18:1-N(CH_3)$_3$)	Day 2
750.5	PE (18:0/20:4)	Day 14
767.5	SM (d18:1/19:0)	Day 2
778.5	ST (d18:1/16:0)	Day 14
790.5	PC (18:0/18:0)	Day 2
794.5	PE (18:0/22:4)	Day 14
798.5	PC (16:0/18:1)	Day 2
800.5	PC (34:0)	Day 2
819.5	PG (18:1/22:6)	Day 14
824.5	PC (36:2)	Day 2
826.6	PC (18:0/18:1)	Day 2
832.5	PC (18:4/20:0)	Day 2
853.6	SM (d18:1/24:0)	Day 2

Regulation of PIWIL4 By Histone Modifications in Rheumatoid Arthritis. Lenka Pleštilová[1], Niharika Gaur[1], Mária Filková[2], Borbala Aradi-Vegh[1], Ladislav Senolt[3], Adrian Ciurea[1], Renate E. Gay[4], Jiri Vencovsky[3], Michel Neidhart[5], Steffen Gay[5] and Astrid Juengel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich Schlieren, Switzerland, [2]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [3]Institute of Rheumatology and Clinic of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [4]Zurich University Hospital, Zurich, Switzerland, [5]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Analog to miRNAs that bind to argonaute proteins to suppress gene expression, a new group of non-coding RNAs piwi-interacting RNAs (piRNAs, 26–31 nt) build complexes with the argonaute-family members "P-element induced wimpy testis" (PIWI)-like proteins to repress retrotransposons in germ cells. In somatic cells a high expression of the PIWIL proteins was associated with cancer.

The aim of our study was to analyse the expression and regulation of PIWIL proteins in synovial cells and in peripheral blood mononuclear cells (PBMC) from patients with rheumatoid arthritis (RA) focusing on the regulation of PIWIL4 by histone methylation and acetylation.

Methods: Expression of PIWIL mRNA was analysed by TaqMan RealTime-PCR and normalised to HPRT1 in synovial fibroblasts (SF) and synovial tissues (ST) from RA and osteoarthritis (OA) patients (n=5 each). PIWIL4 protein expression was analysed by Western blot.

RASF and OASF (n=5–12) were stimulated or not for 24 hours with Poly(I:C) (10ug/ml), LPS (100ng/ml) or TNFα (10ng/ml) in combination with IL1β (1ng/ml). RASF (n=3–6) were treated or not with the DNA methylation inhibitor 5-Azacytidine (5-AZA, 1uM, 7 days), the histone deacetylase inhibitor Trichostatin A (TSA, 1uM, 24h), the histone methylation inhibitor 3-Deazaneplanocin A (DZNep, 2.5uM, 48h) or with the methyl donor Betaine (50mM, 14 days).

After silencing PIWIL4 we assessed proliferation by cell counting. We analysed expression of PIWIL4 mRNA in PBMC isolated from patients with RA, systemic lupus erythematosus (SLE), axial spondyloarthritis (axSpA) and from healthy controls (HC, n=6–12 each).

Results: PIWIL2, 3 and 4 but not PIWIL1 could be detected in both RA and OASF without significant changes (RA/OA mean dCt=3.87/2.83, 9.50/12.32, 2.63/3.21). A high expression of PIWIL4 was also found in ST of patients with RA and OA (mean dCt=3.59/2.91).

Levels of PIWIL4 mRNA were further enhanced by Poly(I:C) in both RASF and OASF 2.9-fold (p=0.003)/3.4-fold (p=0.013); LPS 2.1-fold (p=0.026)/2.6-fold (p=0.025) and TNFα in combination with IL1β 1.9-fold (p=0.003)/1.7-fold (p=0.007). However, on the protein level no induction of PIWIL4 expression could be detected.

Treatment of RASF with 5-AZA did not regulate PIWIL4 expression, treatment with TSA down-regulated PIWIL4 mRNA to 0.4-fold (p=0.003); DZNep to 0.7-fold (p=0.026) and Betaine treatment caused 1.4-fold induction of PIWIL4 mRNA (p=0.043).

PIWIL4 silencing in RASF significantly decreased mRNA expression of the histone deacetylase HDAC1 (to 0.6-fold, p=0.0003), but not HDAC2 or HDAC3. Furthermore PIWIL4 silencing decreased cell proliferation in RASF stimulated with TNFα and IL1β by 30% (p=0.034).

In PBMC of patients with RA the expression of PIWIL4 was higher than in HC (mean dCt=2.18 vs. 2.64, $p<0.05$), but lower than in patients with SLE (mean dCt=1.42, $p<0.001$). There was no difference between RA and axSpA patients (mean dCt=2.30).

Conclusion: We have demonstrated that PIWIL4 expression is regulated by inflammatory cytokines and epigenetic modifications with functional consequences on proliferation suggesting a role of PIWIL4 in the activation of synovial fibroblasts in RA.

***FCGR2A* Polymorphism and Response to Anti-TNF Treatment in Rheumatoid Arthritis.**

G. Avila[1], Jesús Tornero[2], Antonio Fernandez Nebro[3], Francisco Blanco[4], Isidoro Gonzalez-Alvaro[5], Juan D. Cañete[6], Joan Maymo[7], Javier Ballina[8], Benjamin Fernandez Gutierrez[9], Alejandro Olivé[10], Hector Corominas[11], Alba Erra[12], Raül Tortosa[1], María América López-Lasanta[1], Adrìa Aterido[1], Antonio Julia[1] and Sara Marsal[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]Hospital Universitario Guadalajara, Guadalajara, Spain, [3]Hospital Regional Carlos Haya, Biomedical Research Institute of Malaga (IBIMA), Malaga, Spain, [4]Complejo Hospitalario Juan Canalejo, A Coruña, Spain, [5]Hospital Universitario de La Princesa, Madrid, Spain, [6]Hospital Clínic de Barcelona, Barcelona, Spain, [7]Hospital del Mar, Barcelona, Spain, [8]Rheumatology Department. Hospital Universitario Central de Asturias, Oviedo, Spain, [9]Department of Rheumatology, Hospital Clínico San Carlos, Madrid, Spain, [10]Hospital Universitario Germans Trias i Pujol, Badalona, Spain, [11]Hospital de Sant Joan Despí Moisès Broggi, Barcelona, Spain, [12]Hospital Sant Rafael, Barcelona, Spain.

Background/Purpose: TNF-α inhibitors have significantly improved the prognosis of patients with Rheumatoid Arthritis (RA). Despite this, approximately 30% of patients fail to achieve a satisfactory clinical response. One of the main challenges of personalized medicine in RA is being able to predict those patients that have an increased likelihood of not responding to anti-TNF therapies so that such patients can be selected for other biological therapies. Recently, evidence for a specific association of the non synonymous SNP in *FCGR2A* with infliximab response has been reported. The aim of our study was to replicate this genetic association in an independent cohort of patients with RA.

Methods: A total of 348 RA patients treated with TNF-alpha inhibitors (i.e. Infliximab n=126, Adalimumab n=95, Etanercept n=127) were genotyped for *FCGRA* H131R polymorphism (i.e. rs1801274). Response to anti-TNF therapies was measured at 12–14 weeks of therapy using the EULAR response criteria. Association of clinical and epidemiological variables to treatment response was analyzed using linear model regression. Good and moderate responders were merged in a single responder group and association analyses were performed using logistic regression.

Results: The clinical characteristics of the RA patient cohorts according to anti-TNF treatment are shown in Table 1. We found a significant association ($P=0.05$) between smoking status (actual and past smokers vs non-smokers) and response to anti-TNF agents. No other clinical or epidemiological variable showed an association to treatment response. We found a significant association of *FCGR2A* SNP rs1801274 with treatment response in Adalimumab-treated patients ($P=0.01$, OR (95%CI) = 0.32(0.18–0.83)) but not in Infliximab ($P=0.3$) or Etanercept-treated patients ($P=0.82$). Including smoking status as a covariate of rs1801274 association with treatment response showed no evidence of confounding ($P_{FCGR2A} = 0.01$).

Conclusion: We have found, for the first time a specific association of *FCGR2A* with the response to Adalimumab in RA at 3 months of therapy. The lack of validation of the previous specific association of *FCGR2A* with Infliximab could be due to the low effect size of the genetic association or to differences between patient cohorts. Finally, we have also found a positive association with smoking and the response to anti-TNF agents.

Table 1 Epidemiological and Clinical Features of the Study Cohort

Feature	All (n=348)	Infliximab (n=126)	Adalimumab (n=95)	Etanercept (n=127)

Background/Purpose: Systemic Sclerosis (SSc) is a polygenic autoimmune disease (AID) characterized by fibroblast dysregulation. It shares some genetic bases with other AIDs, as evidenced by autoimmune gene pleiotropism. Fibroblast dysregulation can be also observed in Primary Biliary Cirrhosis (PBC), another polygenic AID, which can be associated with SSc in the so called Reynold's Syndrome. The present study was undertaken to investigate whether single nucleotide polymorphisms (SNPs) identified by a large GWAS in PBC might contribute to SSc susceptibility by a cross-disease approach.

Methods: Sixteen PBC susceptibility SNPs were genotyped in a total of 1,616 SSc patients and 3,621 healthy controls all of whom were of European Caucasian origin.

Results: We observed an association between *PLCL2* rs1372072 (OR=1.23 [95% CI 1.12–1.33] $P_{adj}=7.22\times10^{-5}$, *NF-kB* rs7665090 OR=1.16 [95% CI 1.06–1.25], $P_{adj}=0.01$, and *IRF8* rs11117432, OR=0.75 [95% CI 0.67–0.86], $P_{adj}=2.50\times10^{-4}$ with SSc susceptibility. We subsequently queried associations according to the main subtypes and found that

rs1372072 and rs11117432 were associated with the limited cutaneous subgroup (P_{adj}=0.001 and P_{adj}=0.003, respectively) and that rs7665090 was conversely associated with the diffuse cutaneous subset (P_{adj}=0.007). We then looked for genotype – phenotype correlations by measuring mRNA expression of PBMC, obtained from patients (n=39) and controls (n=24), and observed that the *IRF8* protective allele was associated with decreased IFIT1 expression reflecting type 1 interferon signature. We investigated gene interactions between the 3 associated SNPs that revealed an epistatic interaction between *NF-kB* and *IRF8* SNPs (OR=0.56 [95% CI 0.00–0.74], $P=4\times10^{-4}$). Interestingly, we observed that the effects of *IRF8* and *NF-kB* were only observed in patients carrying the susceptibility allele from both genes.

Conclusion. By a cross disease approach querying pleiotropic genes, we identified 2 new susceptibility genes for SSc and confirmed *IRF8* locus. We also identified functional effects of *IRF8* variant affecting interferon signature and that an interaction between *IRF8* and *NF-kB* genes might play a role in SSc susceptibility.

Identification of Genetic Variants Associated with Response to Adalimumab Plus Methotrexate in Patients with Early Rheumatoid Arthritis. Alla Skapenko[1], Hendrik Schulze-Koops[1], Viswanath Devanarayan[2], Kenneth Idler[3], Feng Hong[4], Josef S. Smolen[5], Arthur Kavanaugh[6], Hartmut Kupper[7] and Jeffrey F. Waring[3]. [1]University of Munich, Munich, Germany, [2]AbbVie Bioresearch Center, Worcester, MA, [3]AbbVie Inc., North Chicago, IL, [4]AbbVie Bioresearch Center, Worchester, MA, [5]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [6]University of California San Diego, La Jolla, CA, [7]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

Background/Purpose: For patients with rheumatoid arthritis (RA) who fail to attain remission or low disease activity after 6 months of methotrexate (MTX) treatment, TNF inhibitors should be considered for patients with a high risk of aggressive disease. The objective was to identify genetic variants associated with response to adalimumab (ADA)+MTX in patients with early RA.

Methods: OPTIMA was a 78-week, multicenter, randomized, double-period, double-blind study in which patients were randomized 1:1 to combination therapy with ADA+MTX or MTX alone for the first study period of 26 weeks. Enrolled patients were invited to participate in a genetic sub-study and asked to provide written, informed consent. 384 variants in genes previously shown to be associated with RA or treatment response were assayed using the Illumina BeadXpress GoldenGate Assay. Changes in the 28-joint disease activity score (DAS28) from baseline to 26 weeks and the total Sharp score (TSS) following 26 weeks of treatment were assessed for association with allele status using genotypic tests.

Results: A total of 413 patients randomized to ADA+MTX were included in the genetic sub-study. Three SNPs within the APOH gene were significantly associated with a response to ADA+MTX (Table). APOH (b2-GPI) has been shown to stimulate macrophages and to produce TNF-a in a TLR4-dependent manner, and some studies have suggested that RA patients display increased levels of autoantibodies against b2-GPI. Additionally, eight SNPs within the MAP2K6 gene, which has been shown to be activated in RA, were significantly associated with a response to ADA+MTX. Other SNPs within genes that have been associated with RA susceptibility or treatment response to TNF-a inhibitors, such as ABCB1, IL21, and STAT4, also showed an association with ADA+MTX treatment. For some genes, such as APOH and MAP2K6, multiple SNPs were identified, suggesting that haplotype analysis could identify stronger associations. In addition, SNPs within TRAF6/RAG1, APOH, and CDK6 were also associated with a change in TSS (DTSS ≥0.5).

Table. SNPs Significantly Associated with Treatment Response to ADA+MTX

Gene	SNP	Additive AA vs Ab vs bb (p-value)	Additive AA vs Ab vs bb False Discovery Rate (q-value)	Dominant Major AA vs Ab + bb (p-value)	Dominant Major AA vs Ab + bb False Discovery Rate (q-value)	Dominant Minor AA + Ab vs bb (p-value)	Dominant Minor AA + Ab vs bb False Discovery Rate (q-value)

STAT4	rs12327969	0.023	0.49	NS	NS	NS	NS

NS, not significant.

Conclusion: Genetic polymorphisms in genes such as ABCB1, APOH, MAP2K6, and STAT4 were shown to associate with ADA+MTX response in the OPTIMA study. These results may prove useful for the development of future diagnostic tests or personalized therapeutics for combination therapy treatment with ADA+MTX.

A Novel Epigenetic Mark, Histone H1 Fucosylation, Orchestrates Macrophage Differentiation and Plasticity By Remodeling the Enhancer Landscape in Rheumatoid Arthritis. Jun Li[1], Keith Giles[2], Parastoo Azadi[3], Mayumi Ishihara[3], PingAr Yang[1], Qi Wu[1], Bao Luo[1], David M. Spalding[4], James A Mobley[5], S. Louis Bridgesr Jr.[1], Hui-Chen Hsu[1] and John D. Mountz[1].[1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Stem cell Institute, Birmingham, AL, [3]University of Georgia, Complex Carbohydrate Research Center, Athens, GA, [4]University of Alabama at Birmingham, Division of Clinical Immunology & Rheumatology, Birmingham, AL, [5]University of Alabama at Birmingham, Comprehensive Cancer Center Mass Spectrometry/Proteomics Facility, Birmingham, AL.

Background/Purpose: There is an imbalance of inflammatory M1 vs. anti-inflammatory M2 macrophages (MΦs) in rheumatoid arthritis (RA). The epigenetic codes underlying this M1 dominating pathogenesis in RA have not been well established. Our studies have demonstrated that terminal fucosylation, adding a fucose to the glycan termini by fucosyltransferases is a hallmark of M1 MΦs. A terminal fucosylation inhibitor, 2-Deoxy-D-galactose (2-D-gal), precluded the differentiation of M1 MΦ and skewed them to an M2 phenotype, resulting in suppression of collage II-induced arthritis. The purpose of the study is to investigate how terminal fucosylation regulates MΦ plasticity by modulating the epigenetic landscape.

Methods: Mouse bone marrow derived M1 and M2 MΦs were differentiated by GM-CSF and M-CSF respectively. Ulex Europaeus Agglutinin I [UEA 1, recognizing terminal Fucα(1–2)Gal] pull down coupled to liquid chromatography mass spectrometry (LCMS) was performed to identify the fucosylated proteins in M1 MΦs. Histone H1 was purified from mouse M1 MΦs by using high salt/acid extraction and SDS-PAGE. N-linked glycans on histone H1 was released by in gel PNGase F digestion, followed by permethylation and analyzed by MALDI/TOF-MS and NSI-FT-MS. MS/MS and MS3rd were further carried out to sequence the fucose moieties. Chromatin immunoprecipitations (ChIPs) were performed using anti-H3K4me1 and H3K27ac, followed by next generation sequencing (illumina HiSeq 2500). ChIP-Seq data were aligned to build version mm9 of mouse genome using Bowtie, and regions of enrichment were identified by the MACS peak-finding algorithm. A *p* value threshold of enrichment of $1\times10^{-9}$was used.

Results: Decreased chromatin condensation was observed in M1 compared to M2 macrophages by chromatin staining, which is reversed by 2-D-gal. This suggested that histone H1, a chromatin packing regulator, might be the fucosylated target. Indeed, MS analysis revealed that H1 (Q value 117.5), but not H2A, H2B, H3 and H4 (Q value 15.2, 6.1, 5.1 and 0), is the key protein that is highly fucosylated in M1 MΦs. Terminal fucose moieties and 23 distinct N-glycans were further identified on histone H1 from mouse M1 MΦs by MS analysis. ChIP-seq revealed that active enhancers, characterized by the co-enrichment of H3K4me1 and H3K27ac, exhibited a significantly higher activity at the M1 signature gene loci (including *Irf5, Tnf, Il12, Ifng,* and *H2 loci*) in M1 compared to M2 MΦs. Importantly, inhibition of H1 fucosylation in M1 MΦs by 2-D-gal dramatically reduced the enhancer activity at these loci to a level that is comparable to or even lower than that of M2 macrophages; On the other hand, 2-D-gal promoted the enhance

activity at the M2 signature gene loci, including *Arg1*, in M1 MΦs. Gene transcription was verified by illumina WG-6 gene array.

Conclusion: Histone H1 fucosylation is a novel chromatin mark. It regulates macrophage subset plasticity and determines their identities by dynamically interacting with histone H3 and modulating the enhancer activity at the M1and M2 signature gene loci. These processes can be reversed by the fucosylation inhibitor, which is a potential biologic agent that acts at the epigenetic level to reshape the inflammatory MΦs and reestablish immune homeostasis in RA.

Genetic Variants Influencing Joint Damage in Mexican Americans and European Americans with Rheumatoid Arthritis. Rector Arya[1], del Rincon Inmaculada[1], Vidya S Farook[2], Jose Felix Restrepo[1], Deidre A Winnier[1], Marcel J Fourcaudot[1], Daniel Battafarano[3], Satish Kumar[2], Marcio AA de Almeida[2], Joanne E Curran[2], Christopher P Jenkinson[1], John Blangero[2], Ravindranath Duggirala[2] and Agustin Escalante[1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Texas Biomedical Research Institute, San Antonio, TX, [3]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX.

Background/Purpose: Joint damage in rheumatoid arthritis (RA) has been shown to be heritable, but knowledge on specific genetic determinants of joint damage in RA is limited. We have used the ImmunoChip array to examine whether genetic variants with relevance to susceptibility to multiple autoimmune diseases including RA, influence variation in joint damage in Mexican Americans (MA) and European Americans (EA) with RA.

Methods: We recruited 720 MA and 424 EA patients with RA from public, private, military and VA rheumatology clinics. Joint damage was quantified using a radiograph of both hands and wrists, scored for erosions and joint-space narrowing using Sharp's technique. The Sharp scores were transformed using inverse normalization to approximate a normal distribution for the subsequent association analyses. To identify ethnic outliers, principal components (PCs) were derived using EIGENSTRAT principal component analysis. We conducted association analyses with the transformed Sharp score as a quantitative trait and single nucleotide polymorphism (SNP) genotypic (i.e., autosomal SNPs) data obtained from the Immunochip in both MA and EA samples using the program PLINK. We used the linear regression additive genetic model which included covariates age, sex, and the first two principal components (PC1 and PC2) to adjust for potential population stratification influences.

Results: After excluding SNPs due to the following reasons: stringent quality control, admixture and cryptic relationship inference analyses, and SNPs with minor allele frequency below 1%, our Sharp score association analyses involved 127,563 and 128,387 autosomal SNPs in MA and EA, respectively. Both phenotypic and genotypic data were available for 666 MAs and 407 EAs. In MAs, the 15 SNPs with the strongest association with joint damage were located in chromosomes 1, 5, 9, 17 and 22 with p-values ranging from $p < 1 \times 10^{-5}$ to $p \leq 1 \times 10^{-6}$ including the best associated SNP rs7216796 ($\beta \pm SE = -0.25 \pm 0.05$, $p = 6.23 \times 10^{-6}$ within the *MAP3K14* gene on chromosome 17. In EAs, there were 28 SNPs from chromosomes 1, 4, 6, 9, and 21 with strong p-values ranging from $p < 1 \times 10^{-5}$ to $p \leq 1 \times 10^{-6}$, showing associations with joint damage. The best associated SNP was rs59902911 ($\beta \pm SE = 0.86 \pm 0.17$, $p = 1.01 \times 10^{-6}$) in the *CARD9* gene on chromosome 9. Aside from the above population-specific association signals, we also found evidence for several loci influencing joint damage in both MAs and EAs. However, none of the association signals found in our study reached the Bonferroni-adjusted significance level.

Conclusion: We identified novel loci that influence variation in joint damage on chromosomes 17 (*MAP3K14*) and 9 (*CARD9*) strongly associated with joint damage in MAs and EAs with RA, respectively. We also found several ethnic-specific and shared loci showing suggestive associations with joint damage in MAs and EAs. These novel findings, observed in MAs and EAs, may provide new insights into the genetic architecture of joint damage in RA.

Role of NOD2 Pathway in Sarcoidosis Cases with Characteristics of Blau Syndrome. Gerard Dumancas[1], Indra Adrianto[1], Albert M. Levin[2], Michael C. Iannuzzi[3], Benjamin A. Rybicki[2] and Courtney Montgomery[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Henry Ford Health System, Detroit, MI, [3]SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: Blau syndrome (BS) is a rare autosomal dominant, autoinflammatory syndrome characterized by the clinical triad symptoms of symmetric arthritis, dermatitis, and granulomatous recurrent uveitis, similar to that of early onset sarcoidosis. The phenotype of the disease has proven to be more complex than initially thought but most commonly involve cutaneous and arthritis manifestations. Eye disease is rarely the presenting symptom but significant visual impairment has been observed in 46% of patients. Polymorphisms in the nucleotide oligomerization domain 2 *(NOD2)* are known to be associated with susceptibility to BS, Crohn's disease and sarcoidosis. Studies have shown that dysregulation of *NOD2* signaling is involved in the pathogenesis of a variety of inflammatory disorders and has been implicated in the development of autoimmune disease, allergy, and asthma. As such, the goal of our study was to investigate the involvement of the *NOD2* pathway genes by selecting sarcoidosis cases that presented with disease similar to BS in African Americans (AAs) and European Americans (EAs).

Methods: Our AA case-case analysis comprised 51 AA sarcoidosis cases with positive skin and bone/joint involvement (~35.3% also have eye involvement), and 255 AA sarcoidosis cases without any skin and bone/joint involvement. Our EA case-case analysis consisted of 27 EA sarcoidosis cases with positive skin and bone/joint involvement (~14.8% have eye involvement), and 135 EA sarcoidosis cases without any skin and bone/joint involvement. Genotyping was performed at the Oklahoma Medical Research Foundation (OMRF) using the Illumina HumanOmni1-Quad array and imputed using IMPUTE2/gtool. Quality control included removal of SNPs with call rate $< 80\%$ and Hardy-Weinberg proportion tests $P < 0.001$. We evaluated 5,362 SNPs in AAs and 2,639 SNPs in EAs from 30 genes within the *NOD2* pathway. Single-marker association test was performed using EMMAX adjusted for sex as a covariate.

Results: We observed novel significant associations in a *TAB1* variant in AAs (rs35506409) and *TAB2* variants (rs111447766, rs111576955, rs76778446, and rs79995379) in EAs passing Bonferroni thresholds ($P < 3.46 \times 10^{-5}$ in AAs; $P < 1.12 \times 10^{-4}$ in EAs). *TAB1* is involved in kinase activator activity while *TAB2* is involved in polyubiquitin binding molecular functions. Cursory analysis using BioGPS of these genes confirmed their high expression in retina, CD4+ T cells, and CD8+ T cells of human tissues. Previous studies have shown that TAB1 has been found to play a role in skin homeostasis, wound repair, and oncogenesis. Further, both *TAB1* and *TAB2* genes have been found to be redundantly involved in lipopolysaccharide-induced *TAK1* activation in macrophages, and that deletion of either *TAB1* or *TAB2* results in macrophage death.

Conclusion: Our genetic study of the key players in the *NOD2* pathway identified novel genetic associations in *TAB1* in AAs and *TAB2* in EAs. These findings will give insight into the genetic etiology of BS in adult sarcoidosis cases among AAs and EAs.

Genes Involved in Cartilage Synthesis and Risk to Knee Osteoarthritis. Abhishek Mishra Sr., Rajeshwar Srivastava II, Divya Sanghi III, Ajai Singh IV and Devendra Parmarr V. King George's Medical University,, Lucknow, India.

Background/Purpose: Osteoarthritis (OA), characterized by gradual loss of articular cartilage in the joint, is a leading cause of disability among the elderly people. Though the etiology and pathogenesis of OA is obscure. Several studies have suggested that OA is not only related with aging, calcium and vitamin D deficiency; OA risk is also associated with several genetic susceptibility loci. The aim of this study to elucidate the genetic background of osteoarthritis.

Methods: In a case-control study; 500 cases with knee osteoarthritis (KOA) and an equal number of age matched healthy controls were included. Cases were diagnosed using the ACR guidelines for KOA. Blood were drawn for DNA, RNA and lymphocyte isolation. PCR-RFLP method, TaqMan

assay were carried out to identify the SNPs. Total RNA isolated from whole blood of healthy controls and patients suffering from KOA were analyzed for ESR- α, CALM-1 and GDF-5 mRNA by quantitative reverse transcriptase-PCR. ESR- α, CALM-1 and GDF-5 protein level were detected by western blot analysis in control and cases from peripheral blood lymphocytes. The haplotype analyses were carried out using Haploview software. All statistical analysis was performed with the SPSS software.

Results: The variant genotype of ESR- α, CALM-1 and GDF-5 genes were found to be present at relatively higher frequency in cases than the controls. Risk increased in cases that carried combination of variant genotypes of ESR α (Btg-AA) and GDF-5 (TT); CALM-1 (ApeKI-TG) and GDF-5 (TT); CALM-1(ApeKI-TG) and ESR α (Btg-AA) resulting in 4–6 fold elevated risk to KOA. The haplotype C-G-G and T-G-G of ESR- α gene reduced the risk to OA. In contrast the haplotype T-G-C containing variant of all three polymorphism of CALM-1 gene was over represented in the cases, increasing the risk to 3 fold. A significant association of this variant genotype was also found with clinical scores of KOA (VAS, WOMAC). RT-PCR data revealed that mRNA expression of GDF-5, ESR-α and CALM-1 in OA patients downregulate significantly 0.3, 0.64 and 0.48 -fold in blood when compared with the controls respectively. Protein Expression of GDF-5 was significantly decreased 0.24-fold in cases. Similar to that observed in GDF-5, westernblot analysis revealed that expression of ESR-α and CALM-1 proteins were also found to be decreased in lymphocyte.

Conclusion: This study demonstrate that polymorphism in genes involved in the development, maintenance and repair of bone and cartilage such as GDF-5, CALM-1and ESR- α modify the susceptibility to knee OA. Several fold higher risk was found in cases carrying haplotype of variant alleles of CALM-1 gene. Likewise, several folds increase in risk in individuals with variant genotype of GDF-5 with ESR- α (BtgI) or CALM-1 and ESR- α (BtgI) or CALM-1 and GDF-5 have further demonstrated that the importance of gene-gene interection in the development of knee OA. In addition, our data of gene expression by q-PCR and protein expression by western blotting of GDF-5, CALM-1 and ESR-α also suggest the relevance of these genes in pathophysiology of OA patients.

Transcriptional Heterogeneity of the *SLC2A9* Gene Encoding the GLUT9 Urate Transporter. David B. Mount[1], Tony R. Merriman[2], Eli A. Stahl[3], Hyon K Choi[4] and Asim Mandal[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of Otago, Dunedin, New Zealand, [3]Mt Sinai School of Medicine, New York City, NY, [4]Boston University School of Medicine, Boston, MA.

Background/Purpose: Variation in *SLC2A9*, which encodes the urate transporter GLUT9, is the major *single* genetic determinant of serum uric acid (SUA); however, the causal variant(s) within *SLC2A9* have not been identified. Two distinct N-terminal isoforms, GLUT9a, (540 residues) and GLUT9b (511 residues), are generated by alternative 5' ends. Our aim was to characterize the 5' end of *SLC2A9*to further understanding of how variation in this gene affects SUA.

Methods: 5' untranslated region (UTR) exons, alternative splicing, and transcriptional start sites were identified by database mining, 5'-RACE PCR, and RT-PCR. GLUT9 cDNA expression constructs were characterized by ^{14}C-urate uptakes in *Xenopus*oocytes. Promoter analysis utilized the dual luciferase system.

Results: Seven novel 5' UTR exons were identified, with substantial alternative splicing; in GLUT9b only exon 2, containing the start codon, is spared from alternative splicing. Alternative splicing that deletes coding exons 3 +/− 4 was also identified, in both GLUT9a and GLUT9b transcripts. Exon 3 is a cassette exon encoding most of transmembrane domain 1 (TM1) and part of the first, glycosylated extracellular loop. Surprisingly, GLUT9b constructs with deletion of exon 3 were functional (GLUT9b-delta3), generating urate uptakes that were 10-fold higher than that of control *Xenopus*oocytes. Western blotting indicated that GLUT9b-delta3 protein is not glycosylated, presumably due to altered topology of the first extracellular, glycosylated loop.

A single GLUT9a transcriptional start site was identified, flanking exon 1a. Luciferase constructs for this promoter were highly active in multiple cell lines, with a minimal promoter construct of ~200 bp. Four GLUT9b start sites were identified, including one ~35 kb 5' of exon 1b flanking a novel 5' UTR exon. Only 2 out of 4 GLUT9b promoters were functional, with substantially lower activity than the GLUT9a promoter.

Using the publically available Atherosclersis Risk in Communities Study dataset a major urate-increasing haplotype (freq=0.50) was identified spanning the promoter elements, in addition to two related urate-lowering haplotypes (freq=0.21) with the remaining haplotypes not significantly associated with urate levels.

Conclusion: There is substantial transcriptional heterogeneity in SLC2A9, with seven new 5' UTR exons and at least four transcriptional initiation sites. Alternative splicing that removes exon 3 generates functional GLUT9 urate transporters, despite removal of TM1. The single GLUT9a promoter is strongly active in luciferase assays, whereas only 2 out of 4 GLUT9b promoters are weakly active. Relating these effects to genetic control of urate will increase understanding of the molecular basis of renal uric acid secretion.

Multiway Transcriptomic Analysis of Monocyte-Derived Dendritic Cells Discriminates Effects of Disease and of HLA-B27 in Spondyloarthritis. Emmanuel Chaplais[1], Alice Talpin[2], Félicie Costantino[1], Clémence Desjardin[1], Nelly Bonilla[2], Ariane Leboime[3], Roula Said Nahal[4], Franck Letourneur[2], Jacques Sébastien[2], Gilles Chiocchia[5], Maxime Breban[1] and Henri-Jean Garchon[1]. [1]INSERM U987, Faculté des Sciences de la Santé Simone Veil, Montigny-le-Bretonneux, France, [2]INSERM U1016, Cochin Institute, Paris, France, [3]Rheumatology Division, Ambroise-Paré Hospital AP-HP, Boulogne-Billancourt, France, [4]Service de Rhumatologie, Hopital Ambroise Pare, Boulogne-Billancourt, France, [5]INSERM U987, UFR des Sciences de la Santé, Montigny-le-Bretonneux, France.

Background/Purpose: Spondyloarthritis (SpA) etiology is largely multifactorial with a genetic component dominated by the long-known strong association with the HLA-B27 allele. This allele, however, is not sufficient for the disease to occur. Whereas dendritic cells are believed to play a key role in SpA pathogenesis, the precise mechanisms underlying disease development and particularly the role of HLA-B27 remain poorly understood. To shed light on the genes involved, we carried out a transcriptome analysis of dendritic cells from patients and healthy controls, also accounting for HLA-B27.

Methods: Transcriptomic profiles of monocyte-derived dendritic cells (MD-DCs) were obtained from 23 HLA-B27+ SpA patients, and from 44 controls (23 HLA-B27+ and 21 HLA-B27-). MD-DCs were stimulated or not with endotoxin for 6 or 24 hrs. We used the Affymetrix Human Gene 1.0 ST platform. Analysis of differentially expressed (DE) genes was conducted with LIMMA considering both the disease and the HLA-B27 status (p-value $<$ 5%), followed by quantitative gene set enrichment analyses (quSAGE) and functional pathway annotation.

Results: We performed three comparisons to identify DE genes related to HLA-B27 or SpA status, thus generating three lists: A, including 800 DE genes between HLA-B27+ SpA patients and HLA-B27- healthy controls; B, including 673 DE genes between HLA-B27+ controls and HLA-B27- controls; and C, including 466 DE genes between HLA-B27+ patients and HLA-B27+ controls. Subtracting A–B left 656 genes, of which 68 are in list C, thus yielding a robust list of genes affected by SpA and filtering out irrelevant genes affected by HLA-B27. The most significantly DE gene was procollagen C-endopeptidase enhancer 2 (PCOLCE2), which was overexpressed in patients compared to both HLA-B27- (Fold Change = 2.35, P = 9×10-4) and HLA-B27+ (FC = 3.57, P = 2.7×10-6) controls. This gene codes for an enhancer of bone morphogenic protein-1 (BMP1) that facilitates the cleavage of procollagen and apolipoproteins. QuSAGE and functional annotation revealed that DE genes and gene sets associated with SpA were mainly related to lipid biosynthesis, autophagy, and ribosomal units.

Conclusion: Our study identified a list of MD-DC genes and functions that differ between SpA and controls after controlling for HLA-B27 and involve major pathways, including lipid synthesis, autophagy and ribosomal function. The most striking DE gene, PCOLCE2 is known to interact physically with BMP1, an enzyme that is implicated in ossification and cartilage formation. BMP1 loss-of-function mutations can cause osteogenesis imperfecta. Thus, it is conceivable that a mechanism of gain-of-function of BMP1 signalling pathway could be implicated in the SpA pathogenic process.

Vasoactive Intestinal Peptide (VIP) Genetic Variants Determine VIP Serum Levels and Could be Used As a Prognosis Biomarker. Amalia Lamana[1], Iria Valino-Seoane[2], Luis Rodriguez-Rodriguez[3], Javier Leceta[2], Yasmina Juarranz[2], Ana M. Ortiz Garcia[1], Carmen Martinez-Mora[4], Benjamín Fernández-Gutiérrez[3], Isidoro González-Alvaro[5], Rosa P Gomariz[2] and Rosario Garcia-Vicuña[5]. [1]Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain, [2]School of Biology. Universidad Complutense de Madrid, Madrid, Spain, [3]Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain, [4]School of Medicine. Universidad Complutense de Madrid, Madrid, Spain, [5]Hospital Universitario de La Princesa. IIS La Princesa, Madrid, Spain.

Background/Purpose: VIP has shown immunoregulatory properties in assays performed with human or murine cells. VIP has demonstrated a therapeutic effect in a murine model of collagen-induced arthritis. We recently reported that low VIP serum levels (sVIP) were associated to a worse clinical course in patients with early arthritis despite receiving a more intense treatment.

Purpose: determine whether genetic variants of VIP lead to variations in sVIP.

Methods: Princesa Early Arthritis Register Longitudinal (PEARL) study includes patients with early arthritis in which demographic, clinical, laboratory, therapeutic and radiological data are collected for 5 years follow-up (baseline, 6, 12, 24 and 60 months). Biological samples are obtained at each visit. sVIP had been measured in a previous study (Martinez et al. 2014). 11 patients with the highest and 9 patients with the lowest sVIP were selected for sequencing of VIP gene. Primers were designed to produce overlapping amplicons covering the promoter, exons and introns. We used BigDyeDirect sequencing Kit and performed capillary electrophoresis on a 3500xL Genetic Analyzer (Applied Biosystems [AB]). 16 single nucleotide polymorphisms (SNPs) were differentially expressed in patient groups with extreme sVIP. Rs3823082, rs35643203, rs71575932, rs7755568 and rs688136 were selected for validation (trend statistical significance [$p<0.2$] in population $n=20$). **Results** were validated in 457 patients (80% female, median age 54 [interquartile range 42–66], 60% RA, 40% undifferentiated arthritis) from PEARL study through RT-PCR and specific Taqman probes (AB). Fisher's exact test was applied to determine the significance level in the distribution of genotypes between patients with low and high sVIP. Kruskal-Wallis test was used to assess potential differences in sVIP between SNPs genotypes. To determine the effect of SNPs on disease activity, cumulative DMARD treatment and radiological progression, we fitted 3 multivariate analysis using generalized estimating equations for repeated measures. Statistical analysis was performed using Stata 12.1 for Windows.

Results: In the whole population, the minor allele frequency was 23.2% for rs3823082, 6.5% for rs35643203, 7.5% for rs71575932, 6.8% for rs7755568 and 34% for rs688136. Patients with at least one minor allele for rs35643203, rs71575932 or rs7755568 ($p=0.015$; being these SNPs in linkage disequilibrium) and those carrying the TT genotype of rs3823082 ($p=0.07$) showed significantly lower sVIP, and these genotypes showed an additive effect ($p=0.003$). Patients homozygous for the minor allele of rs688136 showed a slight trend to higher sVIP ($p=0.27$). Patients carrying one minor allele for rs35643203 and being homozygous for the T allele of rs3823082 displayed higher DAS28 along the follow-up if they were ACPA negative ($p=0.07$), required more intensive DMARD treatment ($p=0.028$) and showed higher radiological progression ($p=0.007$). Patients with CC genotype of rs688136 showed a trend to lower disease activity ($p=0.17$).

Conclusion: In our PEARL population genetic variants of VIP associated with low serum levels of this peptide may be a biomarker of severe disease in EA patients.

***TACR1* rs3771863 Single Nucleotide Polymorphism Is a Genetic Risk Factor for *Sicca* Syndrome in Fibromyalgia Patients.** L. Rodriguez-Rodriguez[1], Jose Ramon Lamas[2], Juan A Jover[1], Sara Baena[1], Antonio Collado[3], Javier Rivera[4] and B. Fernández-Gutiérrez[1]. [1]Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain, [2]Hospital Clinico San Carlos, Madrid, Spain, [3]Hospital Clínic de Barcelona, Barcelona, Spain, [4]Instituto Provincial de Rehabilitación, Madrid, Spain.

Background/Purpose: Fibromyalgia (FM) is a condition characterized by chronic widespread pain associated to multiple symptoms, including fatigue, sleep disturbances, cognitive dysfunction, and depressive episodes. In recent years, many candidate gene association studies have been designed and carried out to identify the genes associated with FM. However, the study of the genetic factors associated to disease severity or to the presence of coexisting comorbidities, and therefore, potentially useful as predictors of disease outcome, is a relatively unexplored field. The aim of the study was to analyze in FM patients the genetic risk factors involved in the presence of syndromes and symptoms associated with this disease, and/or severity.

Methods: We included Spanish Caucasian patients diagnosed with FM according to 1990 ACR criteria. Fist, we used a discovery cohort (DC) of 564 patients, recruited from 15 centers throughout the Spanish geography. Subsequently, we used a replication cohort (RC) of 397 patients from the DNA Bank for Genetic Research in FM and Chronic Fatigue Syndrome of the FF Foundation and from the National DNA Bank (Salamanca, Spain). In the DC we studied the association between 320 single nucleotide polymorphisms (SNPs), located in 22 loci, and the presence of symptoms and syndromes associated with FM (depression, headache, sleep disorders, myofascial syndrome, irritable bowel syndrome, chronic fatigue, vertiginous syndrome, chronic cystitis, and sicca syndrome) and disease severity, using the FIQ (Fibromyalgia Impact Questionnaire) and the HADS (Hospital Anxiety and Depression Scale). In the RC, we studied those SNPs and those variables that were associated in the discovery cohort. As the dependent variables were dichotomous or continuous, linear or logistic regressions were performed, respectively, to study the genetic association, using an additive model of effects. The odds ratio (OR), with 95% confidence intervals [95% CIs], was used to assess the strength of association between genotypes and the main dichotomous variables. Analyses were adjusted for sex and time from the onset of pain symptoms. P values were adjusted for the number of main variables and a cutoff of 0.05 was established to select those SNPs to replicate in the RC. DC and RC results were pooled using meta-analysis techniques. P value was corrected considering the number of linkage disequilibrium blocks in which the analyzed SNPs were included.

Results: In the DC, we observed 10 SNPs with an adjusted p-value lower that 0.05: rs4760750, rs4760816, rs2171363 (associated to sleep disturbances), rs174696, rs10171225, rs3771863 (associated to sicca syndrome), rs2422148, rs2216307 (associated to vertigo), and rs12654778, rs10434128 (associated to HADS depression). After replication in the RC and pooling the results from both cohorts, only the rs3771863 variant, from the *TACR1* gene, showed a significant association with a lower risk of sicca syndrome (adjusted OR 0.56 [95% CI 0.42 – 0.76], $p = 0.00022$).

Conclusion: *TACR1* gene could play a role in the development of sicca syndrome in FM patients.

Association of Polymorphisms on *OPG*, *RANK* and *RANKL* with ACPA Presence and Erosions: Results of a Meta-Analysis on 1570 Rheumatoid Arthritis Patients from 3 French Cohorts. Adeline Ruyssen Witrand[1], Sara Scaramuzzino[2], Delphine Nigon[1], Cédric Lukas[3], Yannick Allanore[4], Olivier Vittecoq[5], Thierry Schaeverbeke[6], Jacques Morel[7], Jean Sibilia[8], Anne Cambon-Thomsen[2], Alain G. Cantagrel[9], Philippe Dieude[10] and Arnaud Constantin[1]. [1]CHU Purpan - Hôpital Pierre-Paul Riquet, Toulouse, France, [2]University Paul Sabatier, Toulouse, France, [3]Hopital Lapeyronie, Montpellier, France, [4]Department of Rheumatology, University Paris Descartes and Cochin Hospital, Paris, France, [5]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France, [6]Bordeaux University Hospital, Bordeaux, France, [7]Hôpital Lapeyronie, Montpellier, France, [8]University Hospital of Strasbourg, Strasbourg, France, [9]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [10]Hopital Bichat Claude Bernard, Paris, France.

Background/Purpose: Rheumatoid Arthritis (RA) is a multifactorial complex disease characterized by the presence of anti-citrullinated peptides antibodies (ACPA) and joints erosions. The mechanisms of bone erosions in RA are mediated by the RANK-RANKL-Osteoprotegerin (OPG) system. Some single nucleotide polymorphisms (SNPs) on *RANK*, *RANKL* and *OPG* genes have been previously associated with RA susceptibility. The aim of this study was to assess the association between 1 SNP on *RANK* (rs8086340), 3 SNPs on *RANKL* (rs7984870, rs7325635, rs1054016) and 1 SNP on *OPG*(rs2073618) and ACPA presence or joint erosions.

Methods: *Patients:* the study was based on 3 French cohorts: ESPOIR cohort ($n=632$ early RA patients, 76% of females, mean age: 50 years,

ACPA+: 49%, presence of erosions in 36,6%), RMP cohort (n=249 early RA patients, 75% of females, mean age: 50 years, ACPA+: 73%, presence of erosions in 39%) and FRAGC-PRI cohort (n=689 long-standing RA patients, 76% of females, mean age: 61 years, ACPA+: 62%, presence of erosions in 68%). *Genotyping:* the 5 SNPs located on *RANK, RANKL* and *OPG* were genotyped by Kbiosciences (GB). *Statistical analysis:* The proportion of patients with ACPA presence or presence of erosions were compared according to the allele carriage of each SNP by a Chi square test for each cohort separately. A meta-analysis on the 3 cohorts assessing the risk of ACPA presence or the risk of erosions according to the allele carriage of each SNP was performed using Mantel-Haenszel method.

Results: were expressed as Odds ratios (OR) and 95% confidence intervals (95%CI). Correction for multiple tests was performed using Bonferroni method (significance set at p=0.005).

Results: After meta-analysis performed on the 3 cohorts, 1 SNP located on *RANKL* had a protective effect against ACPA presence after Bonferroni correction: G allele of rs7325635 carriage: OR=0.63 [0.47–0.86], p=0.003, whereas the 2 other SNPs were not significantly associated with ACPA presence when Bonferroni correction was applied (G allele of rs1054016 carriage: OR=0.67 [95%CI: 0.49–0.91], p=0.01, G allele carriage of rs7984870: OR=0.71 [0.54–0.93], p=0.01). Furthermore, the SNP located on RANK had also a protective effect on ACPA presence: C allele of rs8086340: OR=0.64 [0.50–0.81], p=0,0003. However, these SNPs were not significantly associated with the risk of erosions. The SNP located on *OPG* was significantly associated with a protection against erosions after Bonferroni correction: G allele carriage of rs2073618: OR=0.68 [0.52–0.88], p=0.004.

Conclusion: This meta-analysis performed on 3 French cohorts identified 1 SNP located on *RANKL*, 1 SNP located on *RANK* associated with protection against ACPA presence and 1 SNP located on *OPG* associated with protection against erosions in RA.

Comparisons of Quality of Life, Resource Use and Physical Functioning in RA Patients Classified As High, Moderate or Low Risk for Rapid Radiographic Progression. E Alemao[1], S Joo[2], P Allison[3], M Al[4], M Rutten-van Molken[4], S Banerjee[1], C Iannaccone[5], M Frits[5], N Shadick[5], M Weinblatt[5] and KP Liao[5]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Hopewell, NJ, [3]University of Pennsylvania, Philadelphia, PA, [4]Erasmus University, Rotterdam, Netherlands, [5]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: We developed and validated a prognostic model to identify subjects with elevated risk of rapid radiographic progression (RRP). The objective of this study was to compare differences in quality of life (QoL), resource use and clinical outcomes at 12 months in patients classified with high, moderate and low baseline risk of RRP by the prognostic model.

Methods: In a longitudinal cohort of RA patients with clinical and radiographic data in an outpatient setting, we applied the prognostic model to calculate the baseline probability of RRP. Variables to determine the probability of RRP in the prognostic model included seropositivity, body weight, disease duration, DAS28 (CRP) and total Sharp score. Based on the calculated probability of RRP, patients were categorized into low risk (probability 0 to 0.25), moderate risk (0.25 to 0.75) and high risk (>0.75) of RRP. The categorization was based on visual inspection of probability plots. QoL outcome measured by EQ5D, healthcare resource use (nursing home visits, home healthcare visits, surgeries, durable medical equipment use, hospitalization and ER visits) and clinical outcome of physical functioning measured by mHAQ at 12 months were compared by baseline RRP risk groups of low, moderate and high using analysis of variance for continuous variables and Chi-square test for categorical variables.

Results: In the RA cohort, 942 (72.6%) patients had adequate data to calculate RRP. Of these, 414 (43.9%) were classified as low, 477 (50.6%) as medium and 51 (5.4%) as high risk of RRP at baseline. Patients in the low-risk group when compared with those in the moderate- and high-risk groups tended to be younger, have a lower number of swollen or tender joints (mean [SD] 9.4 yrs [11.5], 19.8 [14.2], 33.1 [12.9], respectively), and less likely to be treated with a biologic DMARD. Patients in the low- versus high-risk groups had higher QoL, lower resource use and higher physical functioning at 12 months (Table).

Table: QoL, Resource Use and Physical Functioning at 12 Months in Patients at Low, Moderate and High Baseline Risk of RRP

Outcomes	Low Risk of RRP	Moderate Risk of RRP	High Risk of RRP
EQ5D, mean (SD)**	0.83 (0.14)	0.79 (0.15)	0.72 (0.19)
ER visits, % of pts*	23.4	25.1	38.2
Nursing home visits, % of pts*	2.4	2.7	14.6
Home healthcare visits, % of pts*	4.8	13.5	36.0
Surgeries, % of pts*	15.4	25.4	38.2
DME use, % of pts*	21.0	33.2	58.4
Hospital visits, % of pts*	13.3	20.4	37.1
mHAQ, mean (SD)**	0.39 (0.42)	0.65 (0.50)	0.72 (0.19)

*p<0.05 based on Chi-square test; **p<0.05 based on analysis of variance.

Conclusion: Patients categorized as having high risk of future RRP at baseline (compared with moderate and low risk of RRP) had worse outcomes at 12 months for QoL, resource utilization and physical functioning. These findings suggest that therapies are needed to improve QoL and resource utilization in these high-risk patients.

Healthcare Costs Associated with Serious Infections Among Biologic-Naïve Rheumatoid Arthritis Patients Initiating First-Line Biologic Treatment. S Johnston[1], S Kelly[2], A Nadkarni[2], K Wilson[1], B Limone[1] and M Hochberg[3]. [1]Truven Health Analytics, Bethesda, MD, [2]Bristol-Myers Squibb, Plainsboro, NJ, [3]University of Maryland School of Medicine, Baltimore, MD.

Background/Purpose: The risk of serious infections can vary across biologics. For example, in the 2-year AMPLE trial, serious infections occurred in 3.8% of SC abatacept-treated patients and 5.8% of adalimumab-treated patients. In the 1-year ATTEST trial, serious infections occurred in 1.9% of IV abatacept-treated patients and 8.5% of infliximab-treated patients. Little is known about the healthcare costs associated with serious infections. This study quantified real-world healthcare costs associated with serious infections among biologic-naïve RA patients initiating first-line biologic treatment. **Results** were used to estimate serious infection costs in a hypothetical cohort of RA patients treated with abatacept, adalimumab or infliximab based on data from AMPLE and ATTEST.

Methods: Retrospective, observational cohort study based on US administrative claims data. Study patients initiated first-line biologic treatment (abatacept, adalimumab, etanercept, certolizumab, golimumab, or infliximab) between January 1 2008 and September 1 2012 (initiation=index), were aged ≥18 years, had continuous insurance enrollment for 12 months before (baseline) and 12–24 months after (follow-up) the index date, had no baseline biologic treatment, and had ≥2 baseline medical claims with an International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) diagnosis code for RA (714.0x). Published algorithms and medical coders were consulted in compiling a list of ICD-9-CM diagnosis codes for serious infections. Patients were identified as having experienced a serious infection if they incurred a hospitalization with a primary diagnosis indicative of a serious infection. The cost of serious infections, measured during follow-up, included the cost of the serious infection hospitalization, follow-up outpatient medical claims with diagnoses of the same serious infection, and anti-infective medications.

Results: The samples included 19,412 patients with 1 year of follow-up and 11,699 patients with 2 years of follow-up: in both samples, mean age was 53 years and 77% were female. Over the 1-year and 2-year follow-ups, 3.4% (n=669) and 6.2% (n=720) of patients experienced a serious infection, respectively. The most common serious infection was pneumonia. The total mean (median) cost of serious infections per patient experiencing a serious infection was $19,072 ($10,439) in the 1-year and $21,021 ($11,306) in the

2-year groups. Applying the serious infection cost estimate to the 2-year AMPLE and 1-year ATTEST trial findings in a hypothetical cohort of 1000 biologic-naïve patients, the 2-year expected cost of serious infections per 1000 biologic-naïve patients would be $798,811 for SC abatacept (3.8%*$21,021*1000) and $1,219,237 for adalimumab; and the 1-year cost would be $362,371 for IV abatacept and $1,697,420 for infliximab.

Conclusion: In this pharmacoeconomic study of biologic-naïve RA patients initiating biologic treatment, serious infections were associated with substantial healthcare costs over 1- and 2-year periods. Biologic treatments that are associated with lower infection risk may confer important cost savings related to serious infections.

1143

Preferences of Biologic Treatment Characteristics Among Rheumatoid Arthritis Patients Who Are Current Biologic Therapy Users. David M. Kern[1], Angela E. Williams[2], Ozgur Tunceli[1], Bingcao Wu[1], Judy Stephenson[1], Laura Horne[3] and Alfred Sackeyfio[4]. [1]HealthCore, Inc., Wilmington, DE, [2]MedImmune, LLC, Cambridge, United Kingdom, [3]AstraZeneca, Wilmington, DE, [4]AstraZeneca, Manchester, United Kingdom.

Background/Purpose: To identify the most and least important characteristics of rheumatoid arthritis (RA) treatment according to patients currently on biologic therapy.

Methods: From the HealthCore Integrated Research Environment, RA patients (ICD-9-CM: 714.0x) ≥18 years old with ≥1 claim for a biologic therapy between 5/1/2012 and 7/31/2013 were identified. All eligible patients were targeted to complete a survey measuring their quality of life, RA treatment history, treatment satisfaction, and treatment preferences, among other measures. The Maximum Difference Scaling Instrument (MaxDiff) was used to determine what characteristics of RA treatments (e.g., efficacy; side effects; costs; how, when, and where the medication is administered) were most and least important to the patients. A MaxDiff score <100 denotes characteristics that are less important to the patient, while a score >100 signifies characteristics of higher importance.

Results: There were 9,802 patients meeting all study criteria, of which 219 completed a patient survey. Survey patients were 56 years old on average, 82% were female, 89% were white, and 51% had at least a 4-year college degree. 29% of patients were currently taking etanercept, while the next most common treatments were adalimumab (22%), infliximab (17%), and abatacept (12%).

The MaxDiff results identified that the 3 most important characteristics of RA treatment were related to the efficacy of the treatment: 'Keeps my disease from getting worse' (MaxDiff score = 209), 'Improves my physical abilities' (199), and 'Reduces Pain' (195). 'Potential side effects' (117) and 'How long treatment effects last' (102) were neither relatively important or unimportant to the patients surveyed, while 'How quickly (within a few weeks)' treatment works (70) and 'Personal costs' (67) were seen as less important. The least important characteristics were those that identified the 'how', 'when', and 'where' of treatment administration: 'How treatment is given (oral, injection, IV, etc.)' (15), 'How often treatment must be taken' (13), and 'Where treatment is given (home, doctor's office, hospital, etc.)' (13). Results were consistent across groups based on their current biologic therapy.

A separate question found that 75% of patients would like to take their medication at home if it were possible; however, the MaxDiff results show that relative to efficacy this is not a priority for patients. Additionally, when asked why patients stopped taking prior biologic therapy the statement 'I didn't feel that the drug was working' was cited as a major reason 66% of the time, more than any other reason. 'I don't like needles' and 'I don't like infusions' were cited as major reasons for stopping therapy just 1% and 3% of the time, respectively; while the cost of treatment and side effects were a major reason 12% and 21% of the time, respectively.

Conclusion: The effectiveness of RA treatment is the most important attribute according to patients currently treated with biologic therapy, while administration characteristics were seen as relatively unimportant. Reducing symptoms, improving physical abilities, and slowing disease progression should be considered as primary outcomes in studies comparing RA treatments.

Economic Implications for Policies Regarding Triple Therapy Use in Patients with Rheumatoid Arthritis. Nick Bansback[1], Diane V. Lacaille[2], Daphne Guh[3], Kamran Shojania[1] and Aslam H. Anis[3]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada/University of British Columbia, Richmond, BC, [3]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC.

Background/Purpose: Recent randomized controlled trials in rheumatoid arthritis (RA) patients have determined that a strategy of first adding the two Disease Modifying Anti-Rheumatic Drugs (DMARDs) sulfasalazine and hydroxychloroquine to methotrexate (a combination known as Triple Therapy) is neither inferior nor less safe than first adding anti-TNF drugs in patients with active disease despite methotrexate. The implication is that inexpensive triple therapy should be initiated prior to expensive biologic therapy. In this study we examine historical biologic and Triple Therapy use in British Columbia (BC), Canada over the past 10 years. We sought to estimate the potential savings in expenditures if Triple Therapy use had been more prevalent, and project potential future cost-savings.

Methods: We examined a population-based cohort of all BC patients with a rheumatologist diagnosis of RA identified from administrative data. We selected prevalent RA cases who used a biologic for the first time between 2001 and 2010 and examined their prior DMARD history from prescription billing data. For each year, we calculated the proportion of patients that had used Triple Therapy, the average drug prices, and the average duration patients remain on Triple Therapy. Since not all patients can use Triple Therapy, we conducted a series of scenarios which estimated the cost that would have been saved if a higher proportion of patients had used Triple Therapy.

Results: In total, we examined 2726 RA patients who started their first biologic over the time period. Triple therapy use prior to biologic therapy has increased over time, from 15.2% in 2001 to 24.4% in 2010. The average duration patients remained on triple therapy was 1.13 years. Of the $62million spent on patients first year of biologics, a scenario where 80% of patients would have received triple therapy instead would have resulted in cost savings to BC of $47.3 million over the 10 year period (figure 1). Assuming similar patterns of triple therapy use across Canada, projections suggest future cost-savings of over $12 million per year if triple therapy is used in 80% of patients prior to biologic use. Various sensitivity analyses are performed.

Conclusion: Higher utilization of Triple Therapy will require a willingness for rheumatologists to prescribe it, and a willingness for patients to use it. With the benefit of hindsight, higher use of Triple Therapy prior to biologic initiation would have released a substantial amount of pharmaceutical spending to alternative treatments. Importantly, with less than 25% of patients currently receiving triple therapy prior to a biologic, there is still a considerable potential for future savings. Strategies such as academic detailing and patient decision aids may be good investments if they can change treatment choices.

Evaluation of Biologic Treatment Patterns, Clinical Outcomes, and Healthcare Resource Utilization Post-Tumor Necrosis Factor Inhibitor Discontinuation in Rheumatoid Arthritis. J. Harnett[1], D. Wiederkehr[1], R. Gerber[2], D. Gruben[2], A. Koenig[3] and J. Bourret[3]. [1]Pfizer Inc, New York, NY, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA.

Background/Purpose: For rheumatoid arthritis (RA) patients (pts) with inadequate response to a TNF inhibitor (TNFi), limited evidence exists from observational studies and indirect comparisons of randomized trials to support switching to a nonTNFi vs another TNFi. These exploratory analyses evaluate clinical outcomes and healthcare resource use (HCRU) after switching from a TNFi to another TNFi or nonTNFi biologic across 2 de-identified real world data sources.

Methods: Pts (≥18 years) with ≥2 outpatient or 1 inpatient visit for RA (ICD-9: 714.xx) and (1) HCP-reported TNFi discontinuation and switch to a biologic or conventional DMARD (cDMARD) within 180 days in Humedica EHR database (1/07-7/13) or (2) switched from TNFi to another biologic (or 1 pt to tofacitinib) in Truven Marketscan® claims database (2010–2013) were included. Pts had continuous enrollment/follow-up ≥6 months (mo) before and ≥12 (claims) or 18 (EHR) mo after discontinuation. EHR cohort was followed for 18-mo all-cause HCRU and change in patient-reported pain scores (0–10 on provider-determined scales; ≥30 days pre-/post-switch). Claims cohort was evaluated for subsequent biologic switching and RA-related HCRU costs. Multivariable analyses evaluated the impact of switching to a TNFi vs nonTNFi on RA-related costs.

Results: Of 2799 pts who discontinued a TNFi (47% etanercept, 28% adalimumab, 21% infliximab, 4% other) in the EHR cohort, reasons were lack of efficacy (14%), AE/other clinical reason (16%), cost (6%), or unknown (65%). Following discontinuation, 21% switched to another biologic (67% TNFi) and 11% to cDMARD. In the claims cohort, 68% switched to another TNFi, of whom 43% switched again vs 28% of those first switched to a nonTNFi biologic. Among EHR pts with pre-/post-switch pain scores, TNFi (n=58), nonTNFi biologic (n=19), or cDMARD (n=55) switchers had mean (standard deviation [SD]) pain reductions of 0.72 (3.12), 1.11 (2.87), and 0.42 (3.88), respectively. Office visits comprised the largest HCRU category in the 18 mo after switching; mean (SD) number: 42.7 (34.5), 57.6 (47.3), and 38.4 (33.3) for TNFi, nonTNFi, or cDMARD switchers, respectively. Nearly half (n=7.2) the difference in office visits with TNFi vs nonTNFi was associated with biologic administration procedures. Unadjusted mean (SD) RA-related costs were $27544 ($21100) for TNFi vs $44742 ($30743) for nonTNFi switchers. Including biologic administrations without RA diagnosis (TNFi, $389; nonTNFi, $1126), most (79%) of the mean cost differences were attributed to outpatient visits, followed by prescriptions (18%). Biologic administration visits accounted for 89% of outpatient cost differences. NonTNFi therapy was associated with 32% higher total RA-related costs in adjusted analyses ($p<0.0001$).

Conclusion: NonTNFi switchers were less likely to switch again and had greater pain reduction vs TNFi switchers (in a small subset). NonTNFi switchers had higher all-cause HCRU and RA-related costs, largely due to in-office administration. NonTNFi therapies that do not require in-office administration may reduce switching and costs. Disease outcomes and financial consequences of clinical decision-making warrant future prospective structured research.

1146

Cost-Effectiveness of Adalimumab for Rheumatoid Arthritis in Germany. Christian Gissel[1], Georg Götz[1], Holger Repp[1] and Uwe Lange[2]. [1]Justus-Liebig-University Giessen, Giessen, Germany, [2]Justus-Liebig-University Giessen, Kerckhoff-Clinic, Bad Nauheim, Germany.

Background/Purpose: In Germany, Rheumatoid Arthritis (RA) can be treated with TNF-α inhibitors after the failure of conventional disease-modifying antirheumatic drugs like Methotrexate. The clinical use of TNF-α inhibitors grew from 2 % of treated RA patients in 2000 to 20 % in 2008. In 2012, Adalimumab was the most popular TNF-α inhibitor and the best selling drug in the German statutory health insurance system with net expenditure of € 581 mn. We aim to analyze the determinants of cost-effectiveness of Adalimumab and Methotrexate combination therapy for the treatment of RA in Germany.

Methods: We set up an individual patient sampling lifetime model to simulate 10,000 hypothetical patients. Health benefits are recorded in terms of quality-adjusted life years (QALYs). Quality of life is derived from patients' Health Assessment Questionnaire (HAQ) scores. Initially, patients can achieve one of three responses according to American College of Rheumatology (ACR) criteria or fail the therapy. Each ACR response is associated with an initial improvement in functional status. In each cycle, treatment might be discontinued due to loss of efficacy or adverse events. The patient is then switched to the next available treatment or palliative care. In the Adalimumab simulation arm, we add Adalimumab and Methotrexate combination therapy to the treatment algorithm after failure of both Methotrexate monotherapy and conventional triple therapy. Extensive sensitivity analysis investigates the effects of baseline age and functional status, cost and health effects discounting, methods for estimating quality of life and time horizon.

Results: In the base case, patients gain 7.07 QALYs with conventional synthetic therapy and 9.92 QALYs if Adalimumab combination therapy is added to the treatment algorithm. The incremental cost-utility ratio (ICUR) is € 24,492 based on German list prices. If mandatory rebates and taxes are deducted for international comparison, the ICUR is only € 17,277. Adalimumab combination therapy lowers indirect costs from € 162,698 to € 134,363. From a societal perspective, the ICUR based on total costs is € 14,550 (€ 7,335 after deducting taxes and rebates). Sensitivity analyses shows that Adalimumab combination therapy becomes a dominant treatment option for younger baseline populations, i.e. Adalimumab is both more effective and less expensive for baseline age 30 due to savings in indirect costs. The biggest increase in ICURs can be seen if the simulation period is limited. If the maximum simulation period is limited to 10 years, ICURs double compared to a lifetime perspective.

Conclusion: Cost-effectiveness of Adalimumab combination therapy in Germany compares favorably to analyses in other countries. Our lifetime simulation model shows that a sufficiently long simulation horizon is necessary to capture the complete range of possible outcomes and the associated longterm benefits of biological treatment. If a lifetime perspective is chosen, the most important determinant of cost-effectiveness is savings in indirect costs. Adalimumab combination therapy is most cost-effective for societies with high indirect costs like Germany.

1147

Economic Implications of Flares Among Patients with Early Rheumatoid Arthritis (RA). James Signorovitch[1], Keith Betts[1], Vishvas Garg[2] and Yanjun Bao[2]. [1]Analysis Group, Inc., Boston, MA, [2]AbbVie Inc., North Chicago, IL.

Background/Purpose: Government mandated dose tapering and withdrawal of biologic treatments for RA after achievement of sustained disease control is currently observed in Taiwan, the Netherlands, Denmark and the Czech Republic, among other countries. A recent systematic review reported that flares of RA signs and symptoms are associated with the withdrawal of biologics.[1] This study quantifies the direct, indirect, and total costs associated flares among early RA patients (pts) withdrawing biologics after achieving low disease activity (LDA).

Methods: Pts from the OPTIMA trial[2] who were re-randomized to methotrexate (MTX) monotherapy in Period II after achieving LDA on adalimumab plus MTX combination therapy at week 26 (re-randomization baseline [RBL]) were included (N = 102). Two definitions of flare were proposed: i) Change at visit week [VW] from RBL in Disease Activity Score (DAS) 28 >0.6 and DAS 28 >3.2, and, ii) Change in Health Assessment Questionnaire (HAQ) >0.22 and HAQ ≥0.5 in pts with HAQ <0.5 at RBL. Pts who met the definitions at any VW were considered as having flares. HAQ scores were assessed i) at VW of flare for pts who had flares and ii) at the last VW for pts who had no flares. Average annual direct medical and indirect costs were calculated based on the mapping between HAQ scores and published 2005 German costs.[3] Costs were inflated to 2012 values and differences in average annual costs were assessed between pts with and without flares. **Results** were converted to currencies in the Netherlands, Denmark, Taiwan, and the Czech Republic using standard currency conversions.

Results: Among pts who discontinue biologics after achieving LDA, 34% (35/102) experience flares according to the DAS definition, and 25% (19/76) experience flares according to the HAQ definition. Both the average annual medical cost and indirect cost for pts with flares were higher compared to those for pts without flares across all four countries regardless of which flare definition is used (Table 1). The incremental cost of flares based on the DAS28 and HAQ flare definitions were € 7,163 and € 10,190 for Germany/

Netherlands, DKK 53,483 and DKK 76,081 for Denmark, TWD 301,385 and TWD 428,729 for Taiwan, and 196,498 Kč and 279,525 Kč for the Czech Republic, respectively.

Conclusion: Flares after biologic withdrawal in early RA patients who achieved LDA are found to be costly based on the HAQ-costs mapping as published. Real world direct assessment of the consequences of biologic withdrawal is recommended to further the understanding of this practice.

Table 1: Direct, Indirect and Total costs for RA patients with disease flares

Country	DAS Change > 0.6 and DAS > 3.2		HAQ Change > 0.22 and HAQ >=0.5 for HAQ< 0.5 at baseline	
	DAS Flare	Non-DAS Flare	HAQ Flare	Non-HAQ Flare

Evaluation of a Methodological Approach to Determine Timing of Rheumatoid Arthritis Disease Onset Using Administrative Claims Data.

Jie Zhang[1], Fenglong Xie[2], Lang Chen[2], Jeffrey D. Greenberg[3] and Jeffrey R. Curtis[2]. [1]Univ. of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]New York University School of Medicine, New York, NY.

Background/Purpose: The identification of patients with recent-onset rheumatoid arthritis (RA) is often desirable to create inception cohorts of patients. We evaluated an approach to identify the timing of RA onset using administrative claims data from public (Medicare) and commercial health plans.

Methods: The study sample consisted of RA patients participating in Corrona, a large North American RA registry, linked to administrative medical and pharmacy claims data from Medicare (2006 to 2011) or a U.S. commercial health plan (2005–2012). We estimated year of RA onset in the claims data using several algorithms that were based on the following factors: 1) different ICD-9 diagnosis code for RA (e.g. 714.0, 714.2, and 714.81. vs. 714.X, code from physician visit claim vs. any claim); and 2) length of observable time in the health plan (>1 vs. > 2 years) preceding the first diagnosis code for RA, with exclusions for use of any disease modifying anti-rheumatic drugs. We compared the estimated year of RA onset using the claims-based algorithms to that recorded by rheumatologists in the Corrona registry (gold standard). We reported accuracy as a positive predictive value (PPV), calculated if the year of RA onset from the claims data agreed (+- 1 year) with that documented in Corrona. We conducted a subgroup analysis limited to patients whose disease duration was 2 years or less at their first Corrona rheumatologist visit to improve the reliability of disease onset ascertainment by reducing recall bias and misclassification of the gold standard.

Results: In the main analysis, using ICD-9 codes 714.0, 714.2, 714.81 from a physician visit, the PPVs for accurately classifying year of RA onset ranged from 62% to 68%. When ICD-9 codes 714.x from any type of claim were used, PPVs were higher, ranging from 67% to 100%. In subgroup analysis of patients with more recently diagnosed RA, PPVs were much higher, ranging from 91–100%.

Conclusion: Claims-based algorithms can be used with high validity to identify patients with recent onset RA. Additional research will focus on reasons and opportunities to reduce misclassification of disease onset.

Table: PPVs of claims-based algorithms to identify recent onset RA compared to gold standard of rheumatologist report

Claims-Based Algorithm	Look Back Period	Medicare		Commercial Health Plan	
		Total N	PPV	Total N	PPV
All Patients					
714.0, 714.2, 714.21 on physician claim	>=365 days	144	62%	21	67%
	>=730 days	84	68%	12	67%
714.xx from any claim	>=365 days	182	67%	34	71%
	>=730 days	93	77%	12	100%
Patients with year of RA diagnosis within 2 years from time of physician ascertainment*					
714.0, 714.2, 714.21 on physician claim	>=365 days	120	91%	24	100%
	>=730 days	80	91%	15	100%
714.xx from any claim	>=365 days	139	94%	22	91%
	>=730 days	73	92%	15	93%

*The purpose of the subgroup analysis is to identify patients whose year of onset is less likely to be biased due to recalling events occurred a long time ago

1149

Novel Adherence Measures for Infusible Therapeutic Agents in Rheumatoid Arthritis.

Roxanne Meyer[1], Michael Ingham[2], Joseph Tkacz[3], Brenna Brady[3] and Charles Ruetsch[4]. [1]Janssen Scientific Affairs, Horsham, PA, [2]Janssen Services, LLC, Horsham, PA, [3]Health Analytics, LLC, Columbia, MD, [4]Health Analytics LLC, Columbia, MD.

Background/Purpose: Adherence is under consideration for quality reporting in a number of disease states. Published data on adherence of biologics reveal a wide range of calculation methods. Biologics administered via infusion do not lend themselves to the typical measures of adherence, such as the medication possession ratio (MPR) or proportion of days covered (PDC). The purpose of this study was to investigate a number of newly constructed proxies for medication adherence across two of the more commonly prescribed infusible biologic agents: infliximab (IFX) and abatacept (ABA).

Methods: Using the Optum™ Clinformatics™ database of insured individuals, IFX (n = 417) and ABA (n = 431) members who were continuously eligible for benefits one-year post-induction were selected for adherence analyses. New measures of medication adherence were designed for calculation over the maintenance phase of treatment (Table 1). For both IFX and ABA, the fourth dose constitutes the beginning of maintenance. Maintenance infusions are recommended every eight weeks for IFX and every four weeks for ABA. The total study measurement period was one year, beginning with the induction infusion, though only maintenance infusions were subjected to adherence measures. As a reference, mean maintenance intervals were also calculated for both groups.

TABLE 1. New Measures of Medication Adherence

Adherence Measure	Abbreviation	Definition
Patients w/Refill Gap ≥ 20%:	PtRG ≥ 20%	total number of patients who show at least one refill gap ≥ 20% based on labeling guidelines for maintenance treatment
Cumulative Amount of Time w/Refill Gap ≥ 20%:	CATRG ≥ 20%	summation of all refill gaps days ≥ 20% based on the days supply value
Cumulative Time Off Treatment:	CToTx	summation of all infusion interval gaps > 0 days
Days of Uninterrupted Use:	DoUU	length of time from index date to the first refill gap ≥ 10% based on the days supply value
Observed Vs. Expected Re-Fill Ratio:	OvERR	actual infusions in measurement period/expected infusions in measurement period
Repeated Observations of Under-Use:	ROoUU	total number of refill gaps ≥ 10% based on the days supply value

Variance in Time Between Re-Fill beyond expected interval	ViTBR	all infusion interval gaps categorized as either 0–7 days, 8–14 days, 15–21 days, >21 days
Persistence/Time to Discontinuation:	PT:D	Number of days between index date and the appearance of a gap in treatment ≥ 90 days + recommended number of days in a maintenance interval (or until the end of measurement year)

Results: Mean maintenance intervals approximated recommended guidelines. IFX patients had a mean observed infusion interval (MOII) of 53 days (recommended 56 days) while ABA patients demonstrated a MOII of 33 days (recommended 28 days). ABA patients had a significantly greater amount of CToTx than IFX patients (78.56 vs 61.08 days), and a significantly shorter number of DoUU (164 vs 286 days). ABA patients had a significantly lower OvERR than IFX patients (0.73 vs 0.97), and were over 3 times as likely as IFX patients to show a PtRG ≥ 20% (68.4% vs 20.63). The ROoUU was more than 4 times higher for ABA than IFX patients (1.91 vs 0.42), while the CATRG≥20% was also higher for ABA patients (32.23 days) compared to IFX patients (20.63 days). Finally, the ViTBR for 0–7 days was lower for ABA patients than IFX patients (88.2% vs 93.2%). All measured adherence outcomes were significantly different between groups ($p < 0.001$).

Conclusion: This study piloted a number of measures designed to assess infusion adherence. Results indicated more favorable adherence outcomes for IFX-treated patients compared to ABA patients. Substantial differences may result from assumptions made regarding days' supply and calculation methods for adherence when using medical claims. Quality reporting should include all details for days' supply assumptions and calculation methods. Future studies should examine the relationship between these new measures of adherence and more clinically relevant endpoints and/or cost outcomes to determine if they possess any predictive utility.

Marked Differences in Euro-Qol-5-Dimensions Preference Sets Based on Hypothetical or Experience Based Valuation. Anna Cooper, Johan A. Karlsson and Anders Gürlfe. Lund University, Faculty of Medicine, Lund, Sweden.

Background/Purpose: Health related quality of life (HRQoL) can be expressed as utility, a value anchored at 0 (death) and 1 (perfect health, forming the basis for health economic evaluations. Utilities are determined by means of a generic instrument such as Euro-QoL-5-Dimensions (EQ-5D), a questionnaire rating mobility, self-care, usual activities, pain/discomfort and anxiety/depression on a 3-level scale. Each set of responses made by the individual constitutes a "health state", which is translated into a utility score by means of a a preference set (weights) from a reference population. Many preference sets are available based on hypothetical valuations (ratings of health states described), and the use of different weights may result in varying utility scores for the same "health state". Recently, Swedish (SE) weights were developed using experience based valuations (rating onexs own health), and we intended to compare these to the standard, hypothetically-derived UK weights.

Methods: Demographics, core set variables, EQ-5D and a PASS question (present state considered acceptable by patient) from patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondarthritis (SpA), including ankylosing spondylitis in southern Sweden, treated with biologics, were entered into a database. EQ-5D utility employing UK and SE weights were calculated for those with complete baseline data (n=360), and the cut-off for utility PASS was determined by ROC-curves.

Results: Baseline characteristics are shown in Table 1 and PASS cut-offs in Table 2.

Conclusion: PASS does not vary appreciably between arthritis diagnoses or over time. As expected, SE utilities (experience based) are higher than UK (hypothetical). This holds true both for baseline utilities and PASS cut-off values. This difference must be accounted for in health economic evaluations and when comparing studies using different EQ-5D preference sets.

Barriers and Facilitators of a Career in Research Among Rheumatologists in the United States. Alexis Ogdie[1], Sheila Angeles-Han[2], Una Makris[3], Amanda Nelson[4], Ami Shah[5], Yihui Jiang[1], J. Michelle Kahlenberg[6], Eyal Muscal[7], Flavia V. Castelino[8], Amit Golding[9] and Alfred Kim[10]. [1]University of Pennsylvania, Philadelphia, PA, [2]Emory University School of Medicine, Atlanta, GA, [3]Dallas VA Medical Ctr, Dallas, TX, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]John Hopkins University, Baltimore, MD, [6]University of Michigan, Ann Arbor, MI, [7]Texas Children's Hospital, Houston, TX, [8]Massachusetts General Hospital, Boston, MA, [9]Baltimore VA and University of Maryland School of Medicine, Baltimore, MD, [10]Washington Univ School of Med, Saint Louis, MO.

Background/Purpose: Development of young rheumatology investigators is critical to the future of rheumatology. Beyond funding, the specific barriers to maintaining a career in rheumatology research remain unclear. The objective of this study was to determine the perceived barriers and facilitators to a career in rheumatology research.

Methods: A web-based survey was conducted among the domestic ACR membership from Jan-Mar 2014. Inclusion criteria were current or previous fellowship in rheumatology, ACR membership, and an available email address. Non-rheumatologist members were excluded. The instrument was developed by the Early Career Investigator subcommittee using a Delphi method to identify and distill facilitators and barriers to a career in research for inclusion in the survey. The survey also assessed demographics, research participation, and free text response for ways in which the ACR could support young investigators. After excluding incomplete surveys and duplicates, demographics were summarized. The chi-squared test was used to assess differences in rating of barriers and facilitators by category of respondents (e.g., young investigators, mentors, fellows, and R01 recipients). Free text comments were analyzed by content analysis using NVivo software.

Results: Among 5,448 ACR domestic members, 502 responses were obtained (9.2% response rate). After exclusions (38 incomplete, 2 duplicates, 32 non-rheumatologists), 430 responses were analyzed. Demographics and types of research represented are shown in the **Table.** The most highly ranked barrier and facilitator of a career in research was funding. Other common barriers were clinical workload, insufficient protected time, lower salary, and lack of institutional research infrastructure. Current fellows were more likely to report difficulty establishing a niche as an important barrier (34% vs 22%, p=0.04) and mentors were significantly less likely to report personal finances as an important barrier (21% vs 39%, p=0.004). Facilitators included protected research time, outstanding mentors, institutional

support, as well as personal skills or traits such as hard work, resilience, initiative, persistence and passion for the job. Personal skills were significantly more often cited by recipients of an R01 than other groups (71% vs 49%, p=0.001). Evaluation of free text comments revealed few additional themes including gender issues and lack of flexibility to allow part-time work to care for children.

Conclusion: To our knowledge, this is the first study to examine barriers and facilitators to a career in rheumatology research from the perspectives of young investigators, established investigators, mentors, and fellows. Knowledge of such barriers and facilitators may assist in designing interventions to support young investigators during vulnerable points in their career.

Table. Demographics of Survey Participants (N=430)

Current Position	Adult Rheumatologist	309 (72%)

Euroqol-5-Dimensions Utility Gain in Rheumatoid Arthritis, Treated with Abatacept, Rituximab, Tocilizumab or Tumor Necrosis Factor Inhibitors. Anders Gülfe[1], Johan A. Karlsson[1] and Lars-Erik Kristensen[2]. [1]Lund University, Faculty of Medicine, Lund, Sweden, [2]Lund University, Faculty of Medicine, Malmö, Sweden.

Background/Purpose: We have earlier demonstrated that EuroQoL-5-Dimensions (EQ-5D) utility improves rapidly after commencement of tumor necrosis factor inhibition (TNFi) in rheumatoid arthritis (RA) and other arthritides, and that it is fairly stable for up to 7 years in those remaining on therapy(1). The development of utility over time in RA treated with other biologics is not well known.

Methods: Demographics, core set data, EQ-5D and data on drug treatment for patients with established RA on biologics from southern Sweden were retrieved from an observational database. Diagnosis was as by the treating rheumatologist, and has been shown to comply with 1987 ACR criteria in >95% of cases. Time frame was Jan 2006 – March 2014. EQ-5D utilities based on the British weights were computed and means and plotted over time.

Results: There were 2418 patients treated with Abatacept (ABA), Rituximab (RTX), Tocilizumab (TOZ) or tumor necrosis factor inhibitors (TNFi) with utilities at treatment start (Table 1). Patients lacking baseline EQ-5D (n=913) did not differ appreciably from the main cohort (data not shown). TNFi patients had shorter disease duration and fewer previous DMARDs than patients on ABA, RTX or TOC, as these drugs were seldom started in bio-naïve patients. EQ-5D utility development over time is shown in Figure 1.

Conclusion: Despite starting at very low mean utilities, patients receiving ABA and TOC display rapid utility gains similar to TNFi although at a lower level, reflecting more longstanding and treatment resistant disease. As compared to the other biologics, the utility gain after commencement of RTX therapy starts at a level similar to TNFi (perhaps more bio-naïve patients with recent malignancy or other contraindications to TNFi) but is more gradual. Such differences may influence the area under the curve and thus accumulation of quality-adjusted life years. The continuing improvement observed in all groups may partly reflect a selection of patients responding and thus adhering to therapy.

Area of Residence and Socio-Economic Factors Significantly Affect Access to Biological Therapy for Rheumatoid Arthritis Patients in Romania. Catalin Codreanu[1], Corina Mogosan[2], Ruxandra Ionescu[3], Ioan Ancuta[4], Magda Parvu[5] and Simona Rednic[6]. [1]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [2]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [3]Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania, [4]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [5]Colentina Clinical Hospital, Bucuresti, Romania, [6]University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Background/Purpose: Clinical trials have proven the efficacy of biological therapy for rheumatoid arthritis (RA) worldwide. However, high costs have set boundaries to their use, especially in developing countries. Whereas in Europe, there are countries without any biological reimbursed, other countries have a more liberal prescription, regardless of the RA duration and previous therapy. To be eligible for biologics, in Romania, patients with active RA must be non-responders to at least two synthetic DMARDs; up to date four biological products are reimbursed: infliximab, etanercept, adalimumab, rituximab. The aim of the study is to evaluate patient's accessibility to biological therapy on a national scale (41 counties and Bucharest, i.e. the capital) and the correlation with socio-economical indicators for each region.

Methods: Observational study carried out in 41 counties and Bucharest. Data was gathered from the Romanian Registry of Rheumatic Diseases, while the socio-economic indicators were extracted from the yearbook of the National Institute for Statistics (EUROSTAT).

Results: The sample enrolled data of 4507 RA patients (4267 being treated with biologics and 240 being eligible for biologics). The mean age was 56.69 yrs (+−12.07), 85.24% women, 67.80% live in urban residences, with a mean RA duration of 12 yrs. 80.20% (n=3614) of patients had access to biologics in their county of residence, whereas 19.80% (n=893) of patients were treated elsewhere. The group treated outside of their county of residence come from areas with high deficit of physicians (1.67 physicians/1000 inhabitants, compared to 3.24 physicians/1000 inhabitants, for the group treated locally) and with a decreased welfare (GDP/inhabitant: 6634.83 €, compared to 4891.02 €, $p<0.001$). The total number of rheumatologists working in a county varies from none (7 counties do not have any rheumatologist) to 75 (in Bucharest). There is a positive correlation between areas with better living conditions and the number of local working rheumatologists ($r=0.54$, $p<0.01$). Patients living in urban areas (70.20%) have significantly greater access to biologics in their county of residence compared to patients living in rural environments (29.7%), most of them being forced to travel in order to be taken into care by a rheumatologist. The patients' age does not impact on their access to biological therapy. On a national scale, the majority of RA patients who are treated outside their county of residence chose the capital, Bucharest: 53.73% [805/1498] of patients treated in Bucharest came from a different geographical area.

Conclusion: In Romania, the accessibility of RA patients to biological therapy greatly varies according to the socio-economic situation of their county of residence. Living in an area with a low socio-economic status significantly decreases the patients' chances of getting treated with biologics compared to other national counties, even when therapeutic protocols are equal and equitable.

Increasing Discrepancies Between Physician Assessment of Disease Activity and Patient Global Health in Germany Between 2000 and 2012. Dörte Huscher[1], Katinka Albrecht[2], Katja Thiele[2], Sascha Bischoff[2], Andreas Krause[3], Susanna Späthling-Mestekemper[4], Siegfried Wassenberg[5] and Angela Zink[1]. [1]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Immanuel Krankenhaus Berlin, Berlin, Germany, [4]Praxis für Innere Medizin/Rheumatologie, München, Germany, [5]Fachkrankenhaus, Ratingen, Germany.

Background/Purpose: We have seen remarkable achievements in disease control (DAS28) in rheumatoid arthritis in the past decade. They were, however, not accompanied to the same degree by improvements in patient reported outcomes. To evaluate whether the relationship between patient global health and physician assessment of disease activity, both measured on numerical rating scales 0–10, has changed in the last decade and if these changes differ between diagnoses or depend on sex, age, disease duration or education.

Methods: Patients recorded in the National Database of the German Collaborative Arthritis Centres between 2000 and 2012 for whom both physician and patient assessments were available were evaluated. The percentages of patients assessing their global health worse than the physician rated disease activity were analysed for rheumatoid arthritis (RA, on average n≈6,554 each year), ankylosing spondylitis (AS, n≈1,079), psoriatic arthritis (PsA, n≈1,191), systemic lupus erythematodes (SLE, n≈800) and polymyalgia rheumatica (PMR, n≈489) with regard to sex, age, disease duration and education.

Results: In 2000, patient ratings were on average 0.9–1.6 scores worse than physician ratings. These differences further increased by 0.4–1.2 score units until 2012. In 2000, patient ratings at least one score worse than physician ratings were found in 62–65% of patients with RA, AS, PsA and PMR, and in 53% of patients with SLE. We saw an increase in poorer patient ratings by 12–16% for all diagnoses but AS (+7%) between 2000 and 2012. Male patients showed a stronger increase in discrepant ratings over time. Patients aged up to 40 had a higher agreement between physicians and patients than older patients. Poorer patient ratings were more frequent in patients with longer disease duration and lower education. The higher rates with both increasing age and disease duration are probably also reflecting the burden of co-morbid conditions. When analysing by logistic regression which parameters predict a poorer patient than physician rating, calendar year played a significant role in all diagnosis groups after adjusting for sex, age, disease duration and education.

Conclusion: The discrepancies between patient and physician ratings have increased over the past decade for various diagnoses. In addition to a rising importance of quality of life in public perception in recent years, in times of almost universal internet access this might also reflect the better informed patient with higher expectations. These changes should be taken into account when comparing patient reported outcomes over long periods. In general, our findings underline the need to consider carefully the patient view when assessing treatment outcomes.

Economic Impact of Frequent Gout Flares in a Managed Care Setting. Robert Jackson[1], Aki Shiozawa[1], Erin Buysman[2], Aylin Altan[2], Stephanie Korrer[2] and Hyon K Choi[3]. [1]Takeda Pharmaceuticals International, Inc, Deerfield, IL, [2]Optum, Eden Prairie, MN, [3]Boston University School of Medicine, Boston, MA.

Background/Purpose: Gout is the most common inflammatory arthritis in the US. For most patients, excruciatingly painful gout attacks ("flares") are the major clinical burden of the disease. The goal of this study was to assess the association of flare frequency with economic outcomes including all-cause and gout-related health care costs to better understand the economic benefit of reducing flare frequency.

Methods: This cohort study used administrative claims data from a large US health plan of commercially insured and Medicare Advantage enrollees. Patients were identified based on medical and pharmacy claims for gout between January 2009 and April 2012. The 12 months prior to the index gout

claim was used to assess baseline confounders. Gout flares were assessed in the 12 months following the index gout claim based on diagnoses for gout or joint pain followed within 7 days by claims for NSAIDs, colchicine, corticosteroids, or joint aspiration/drainage. Flare frequency, gout treatments, and all-cause and gout-related health care costs were assessed in the 12 months following the index gout claim. Patient characteristics and economic outcomes were compared between patients with infrequent flares (0–1 flares in the 12-month follow-up period) to those with 2 flares or ≥3 flares. Generalized linear models were used to adjust for potential confounders.

Results: Our study included 102,703 patients; 89,201 had 0–1 flares, 9714 had 2 flares, and 3788 had ≥3 flares. Demographic and baseline characteristics did not appear to be meaningfully different among these groups (Table). After adjusting for potential confounders, patients with 2 or ≥3 flares had significantly higher mean all-cause and gout-related total health care costs compared to those with 0–1 flares. Adjusted all-cause costs were $11,786, $12,625, and $15,328 in those with 0–1, 2, and ≥3 gout flares, respectively ($p=0.012$ comparing 0–1 flares to 2 flares; $p<0.001$ comparing 0–1 flares to ≥3 flares). Adjusted gout-related costs were $1,804, $3,014, and $4,363, in those with 0–1, 2, and ≥3 gout flares, respectively ($p<0.001$ comparing 0–1 flares to 2 or ≥3 flares).

Conclusion: The economic implications of frequent gout flares are significant, particularly when comparing patients with infrequent flares (0–1 flares per year) to those with 2 or ≥3 flares. Gout-related costs were 67% higher in those with 2 flares and nearly 150% higher in those with ≥3 flares compared to those with infrequent flares. This suggests significant cost benefit to a disease management plan with a goal of reducing flare frequency to fewer than 2 per year. Future research should consider costs beyond those related to health care utilization and include costs from other sources such as missed work and loss of worker productivity.

Table. Demographics and Baseline Patient Characteristics by Flare Frequency

	0-1 Flares	2 Flares	≥3 Flares
N	89,201	9714	3788

Satisfaction with Rural Rheumatology Telehealth Service. Katherine Poulsen[1], Lynden Roberts[2], Catherine Millen[3], Umayal Lakshman[3] and Petra Buttner[4]. [1]Queensland Health, Brisbane, Australia, [2]James Cook University, Melbourne, Australia, [3]Queensland Health, Mount Isa, Australia, [4]James Cook University, Townsville, Australia.

Background/Purpose: To assess patient satisfaction with the rheumatology telemedicine service provided to a rural town in northern Australia.

Methods: A prospective, questionnaire-based exploratory study of patients seen in Mount Isa rheumatology telemedicine clinics during 2012 was done. Control groups included patients travelling over 3 hours to be seen face-to-face in Townsville, and patients seen face-to-face in Mount Isa. A 5-point Likert scale was used to explore themes of communication, confidentiality, physical examination, rapport, medication safety and access.

Results: This study evaluated 107 rheumatology outpatients (49 telemedicine, 46 face-to-face Townsville, 12 face-to-face Mount Isa). Patients seen in Mount Isa travelled a median of 3km for telemedicine and 5km for face-to-face appointments. The face-to-face Townsville control group travelled a median of 354km. New patients comprised 14% of consultations. Satisfaction with themes related to quality-of-care was high with over 90% selecting 'agree' or 'strongly agree' to these questions. Comparing models of care, there were no significant differences in the rates of those selecting 'strongly agree' across questions, apart from a single question related to rapport which favoured the Mount Isa face-to-face model ($p=0.018$). When asked whether they would rather travel to Townsville than participate in a telemedicine consultation, 63% of patients selected 'disagree' (17%) or 'strongly disagree' (46%).

Conclusion: These results suggest that patients are satisfied with a rheumatology telemedicine service, and may prefer this alternative to extensive travelling. Evaluation in other settings is recommended before generalizing this finding.

1157

Delay in Diagnosis from Onset of Symptoms By More Than One Year in 31% of Patients with Different Rheumatic Diseases in Australia. Isabel Castrejón[1], Kathryn A. Gibson[2] and Theodore Pincus[1]. [1]Rush University Medical Center, Chicago, IL, [2]Liverpool Hospital, Liverpool, Australia.

Background/Purpose: Early treatment is regarded as critical for optimal clinical outcomes in patients with inflammatory rheumatic diseases. However, delayed diagnosis is recognized in many rheumatic diseases. We studied possible delay in diagnosis in routine care in a rheumatology teaching hospital in 2013, using a simple 1-page form completed by the rheumatologist.

Methods: All patients seen in the study setting complete a multidimensional health assessment questionnaire (MDHAQ) at each visit in the waiting area before seeing the rheumatologist. The rheumatologist completes a complementary doctor form (RHEUMDOC). RHEUMDOC includes entry of 3 possible rheumatic diagnoses, queried for year of onset of symptoms and year of diagnosis. For this study, patients were classified into 4 groups according to diagnosis: rheumatoid arthritis (RA), osteoarthritis (OA), other inflammatory diseases (INF), and other non-inflammatory diseases (NON); differences between groups were compared using Wilcoxon rank sum tests.

Results: Among 211 patients seen between February and December 2013, 145 (69%) reported establishment of a diagnosis within one year, including 81% with RA, 55% with OA, 70% with other INF, and 57% with other NON (Table). The delay in RA was significantly less than in OA ($p=0.0046$). Nonetheless, 10% of RA patients received a diagnosis 1–5 years, and 8% >5 years, after symptom onset. Among all patients, 13% of RA patients received a diagnosis 1–5 years after onset of symptoms, and 18% after more than 5 years after onset of symptoms.

		Number of patients in each group according to interval from onset of symptoms to diagnosis		
Diagnosis	Number of patients	<1 year N (%)	1–5 years N (%)	>5 years N (%)
RA	59	48 (81%)	6 (10%)	5 (8%)
OA	45	25 (55%)	10 (22%)	10 (22%)
Other INF	86	60 (70%)	8 (9%)	18 (21%)
Other Non-INF	21	12 (57%)	4 (19%)	5 (24%)
Total	211	145 (69%)	28 (13%)	38 (18%)

Conclusion: A delay from onset of symptoms to definitive diagnosis remains an important problem in rheumatic diseases. Delay in diagnosis more than 1 year is more common in patients with diseases other than RA, but remains in more than 30% of all patients and 19% of RA patients. Identification of specific contributors to this delay could inform education of both patients and physicians regarding the importance of early diagnosis and treatment, and health policy resources to facilitate timely management of rheumatic diseases.

A Patient Survey Study of Zoledronic Acid Utilization and Factors Associated with Persistence. Deborah T. Gold[1], Stuart L. Silverman[2], Benjamin J. Chastek[3], Lung-I Cheng[4], Alyssa Goolsby Hunter[3], John C. White[3], Damon Van Voorhis[3] and Bradley S. Stolshek[4]. [1]Duke University Medical Center, Durham, NC, [2]OMC Clinical Research Center, Beverly Hills, CA, [3]Optum Life Sciences, Eden Prairie, MN, [4]Amgen, Inc., Thousand Oaks, CA.

Background/Purpose: Persistence with osteoporosis therapies is associated with clinical outcomes. The goal of this study is to examine patient-reported persistence with zoledronic acid, a once-yearly bisphosphonate infusion, and to assess the factors associated with non-persistence with zoledronic acid therapy.

Methods: A cross-sectional study of patients affiliated with a large US health plan was conducted via a mailed survey. The Optum Research Database was used to identify female patients receiving a zoledronic acid infusion (index date) 13–19 months prior to the November 2013 survey administration. Patients were required to be age 50 or older at index date with continuous enrollment in medical and pharmacy benefits and an osteoporosis diagnosis in the 6 months prior to the index date. Patients who received the index infusion in a long-term care institution or had a diagnosis of Paget's disease or cancer during the 6-month pre-index period were excluded. Data collection included a pilot-tested patient survey to assess patient clinical and demographic characteristics, experiences associated with index zoledronic acid therapy (e.g., side effects and barriers to treatment), knowledge of osteoporosis and zoledronic acid therapy, attitudes toward medication, and availability of support for disease and therapy management. Mailed survey administration followed the Dillman tailored design method. Survey data were collected from November 2013 to January 2014. The chi-squared test was used to examine the differences in survey responses between patients who did and did not receive a follow-up infusion.

Results: Of the 391 surveys sent to patients identified for the survey, 111 returned the survey (response rate = 32.0%). The mean (SD) age of the respondents was 62.2 (7.4). Among the respondents, 55 (49.6%) reported having received their follow-up zoledronic acid infusion in the previous 6 months. The differences in demographic characteristics were not statistically significant between those who did and did not receive a follow-up infusion. Those who received a follow-up infusion were more likely to report having had a discussion with the physician regarding the need to return for additional infusions compared with those who did not return (98.2% vs. 83.9%; p=0.016). Patients who scheduled a follow-up appointment to receive another dose at the time of the initial infusion (n=27) were more likely to receive a follow-up infusion (74.1%) than those who did not schedule (43.6%) (p=0.006). Similarly, patients who reported having been contacted by the physician's office about scheduling their next infusion (n=61) were more likely to receive a follow-up infusion (60.7%) than those who were not contacted (36.7%) (p=0.013).

Conclusion: Results from the survey study show that half of the patients on zoledronic acid therapy for osteoporosis reported receiving a follow-up infusion 13 to 19 months after the index infusion. Higher follow-up infusion rates were seen among patients who discussed the need to return for additional infusions with their physicians, scheduled a follow-up appointment for a follow-up infusion at the time of the index infusion, or received contact from the physician's office about scheduling their next infusion.

Long-Term Quality of Life, Productivity Impairment, Disease Severity and Health Care Costs in Relation to Functional Impairment in Ankylosing Spondylitis Patients in the Czech Republic. Liliana Sedova[1], Monika Urbanova[2], Jiri Stolfa[3], David Suchy[4], Andrea Smrzova[5], Tomas Mlcoch[6], Jiri Klimes[7] and Tomas Dolezal[7]. [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology Prague, Prague, Czech Republic, [3]Charles University Prague, Prague, Czech Republic, [4]University hospital Plzen, Plzen, Czech Republic, [5]University hospital Olomouc, Olomouc, Czech Republic, [6]Institute of Health Economics and Technology Assessment, Prague, Dominica, [7]Charles University, Prague, Czech Republic.

Background/Purpose: To describe the quality-of-life (QoL), productivity impairment, clinical indicators and health care costs in relationship to functional status described by Bath Ankylosing Spondylitis Functional Index (BASFI) in ankylosing spondylitis (AS) patients in three-year follow-up. These are follow-up results; the first visit was presented in ACR 2013.

Methods: This is a prospective multicenter non-interventional observational study with AS patients in 4 specialized centers for treatment of rheumatic diseases in the Czech Republic. A three-year follow-up with 6 months period between each time point observation is ongoing. The data presented here comes from the first visit and three subsequent visits (i.e. time 0, 6, 12 and 18 months). The demographic, clinical, QoL and productivity data were directly collected from patients. Health care consumption was assessed retrospectively reviewing individual patient's medical record. Clinical data were described by ASDAS-CRP, QoL measured by EuroQol questionnaire (EQ-5D), work impairment by Work Productivity and Activity Impairment (WPAI) with respect to BASFI categories. Patients were stratified according to their BASFI into 10 categories. Within health care consumption directly related to AS, we focus on medication, out-patient & in-patient care, complement, examination and out-of pocket expenses. Health care expenditures are presented as average yearly costs per patient. Patients were analyzed as the whole cohort and specifically by the presence of biologic treatment.

Results: 291 patients with AS were registered at the first visit, 218 on biological drugs, mean age was 44.3 years, mean time from diagnoses was 13.6 years, 26.1% were female. With higher functional impairment, described by BASFI, there is a trend in age increase, increase in time from diagnosis, percentage of work impairment and also decrease in percentage of work-active patients. There is also deterioration in clinical impairment (ASDAS-CRP) and QoL observed with higher BASFI. See the results in table 1 & 2; values presented as mean, n.a.-not applicable.

Conclusion: Patients with worse functional impairment revealed more significant impairment of their QoL, work productivity and revealed also worse clinical outcomes and higher costs (in non-biologic treated patients). There is a trend of decreasing number of work active patients who are not on biologics. For patients not treated with biologics, BASFI is a very good cost predictor.

Annual Real-Practice Costs of Biologics for 200 Cases with Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis Treated By *Tight Control* and *Treat to Target* Strategy Permitting Dose Reduction. Bernd Raffeiner[1], Costantino Botsios[2], Michele Ragazzi[3] and Ernesto De Menis[4]. [1]Rheumatology-General Hospital Bolzano, Bolzano, Italy, [2]Rheumatology-Hospital San Valentino Montebelluna, Montebelluna, Italy, [3]Pharmacy-Hospital San Valentino Montebelluna, Montebelluna, Italy, [4]Internal Medicine-Hospital San Valentino Montebelluna, Montebelluna, Italy.

Background/Purpose: To investigate annually real-practice costs of biologic therapy for rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) cohort treated by *tight control* and *treat to target* strategy permitting dose reduction in Italian local health centre.

Methods: 200 Italian patients in treatment with biologic therapy including all five TNFα inhibitors (adalimumab, ADA; certolizumab, CER; etanercept, ETA; golimumab, GOL; infliximab, IFX), abatacept (ABA), tocilizumab (TCZ) and anakinra (ANK) adhering to local health centre Asolo, in northeast of Italy counting population of 250.000 people, were investigated. ABA and TCZ were used as second and third biologic line. 127 were affected from RA, 39 from PsA and 34 from AS. All patients were controlled every 3 months for low disease activity or remission following EULAR criteria (DAS 28-CRP $<$ 2.6 or ASDAS $<$ 1.3). After achieving sustained remission for at least 12 months doses of biologics were reduced and maintained when activity permitted it. Real-practice costs were supplied by payment bureau of local health centre for the year 2013. Costs for eventual concomitant DMARDS, NSAIDs, steroids and other pain killers were excluded. Periods of treatment stops because of justified or unjustified causes were included.

Results: Clinical remission by *tight control* and *treat to target* strategy was achieved in 81 RA (63.7%), 26 PsA (66.6%) and 22 AS (64.7%) patients. Dose reduction was very frequent for RA (49.6%), PsA (69%) and AS (44%); and significantly more frequent in patients treated with ETA (69.6%) than ADA (30.2%). Dose reduction was infrequent for the other biologics and beyond first biologic line. Total annual costs of biologics for the year 2013 were € 1.463.470, mean costs per patient per year were € 7.317. Mean annual costs per patient per year were € 5.736 for ETA, € 6.511 for CER, € 6.876 for ANK, € 7.867 for IFX, € 8.485 for TCZ, € 8.563 for GOL, € 9.285 for ADA and € 9.404 for ABA.

Conclusion: a) Clinical remission was achieved by *tight control* and *treat to target* strategy in high number of patients with RA, PsA and AS; b) Dose reduction was very frequent in real-practice conditions; c) This was especially possible during ETA and first line biologic treatment; d) Permitting dose reduction importantly decreased expected annual costs for biologics in real-practice conditions.

The Price of a Positive Test: Is It Worth the Cost? Lara H. Huber, Kristen Morella, Natasha M. Ruth and Murray H. Parsso. Medical University of South Carolina, Charleston, SC.

Background/Purpose: The ACR Choosing Wisely Campaign top 5 lists highlight the appropriate use of autoantibody testing, thereby reducing unnecessary spending. Positive antinuclear antibodies (ANA) are one of the most common reasons for referral to pediatric rheumatology clinics. The prevalence of positive ANAs in the pediatric population ranges from 3 – 36%. ANAs are useful when used for confirmation of a suspected diagnosis and for risk stratification of a known diagnosis, but ANAs are often inappropriately used to screen for autoimmunity resulting in positive tests with unclear clinical significance. We hypothesize that a large amount of health care dollars are spent on laboratory and radiographic tests related to a positive ANA and that general pediatricians are more likely to order an ANA than pediatric rheumatologists when confronted with the same clinical scenario.

Methods: We conducted a retrospective chart review of new patients referred for a positive ANA to the pediatric rheumatology clinic at our institution from July 1, 2010 through June 30, 2011. We recorded findings from the history and physical examination, any studies ordered prior to and at the time of the rheumatology visit, and the final diagnosis. The history, physical examination, and baseline laboratories were reviewed by 2 pediatric rheumatologists, 3 pediatric hospitalists, and 2 ambulatory pediatricians blinded to the final diagnosis, ANA titer, and other studies. The reviewers indicated whether they would have ordered an ANA. A list of gross charges for the studies was obtained from the laboratory and department of radiology at our institution.

Results: Seventy-five patients were identified. The total charges equaled $195,402 with a mean of $2,605 per patient. Only 5 patients had a primary rheumatologic disease. Two patients had lupus, 2 had JIA, and 1 had UCTD. Hypermobility was the most common diagnosis, and 24% of patients had a negative ANA on repeat testing. There was a significant difference in the total charges per patient based on the final diagnosis (primary rheumatologic disease vs. other diagnosis, $p = 0.0499$). The interrater reliability between all 7 reviewers was fair with an intraclass correlation coefficient of 0.303; it was moderate between rheumatologists with a kappa statistic of 0.478. There was not a significant difference between the number of ANAs ordered by the 3 groups. The responses for the patients with a rheumatologic disease were analyzed. The rheumatologists agreed on ordering an ANA for all these patients, but there was disagreement among the general pediatricians.

Conclusion: ANAs are useful when used appropriately, but they generate large amounts of unnecessary spending if used inappropriately. Most patients with a positive ANA did not have an autoimmune disease bringing into question the necessity of the initial ANA test. When comparing the utilization of ANAs between pediatric rheumatologists and general pediatricians, there was not a significant difference in the number of tests ordered; however, the rheumatologists more accurately identified patients with a rheumatologic disease.

Patterns of Use of Long-Term (> 5 Years) Oral Bisphophonate Prescription Among Primary Care Providers and Rheumatologists for the Treatment of Osteopenia and Osteoporosis in a Veteran Population. Mathilde Pioro[1], Stephanie Ogorzaly[2] and Maya Mattar[3]. [1]Cleveland Veterans Affairs Medical Center, Cleveland, OH, [2]Cleveland Veterans' Affairs Medical Center, Cleveland, OH, [3]University Hospitals Case Medical Center, Cleveland, OH.

Background/Purpose: Osteoporosis is a widely prevalent but underrecognized condition. Oral bisphosphonates are considered first-line treatment of osteoporosis in men and women however long term use is associated with potential adverse effects. In patients taking bisphosphonates for at least 5 years, it is generally recommended that the need for continued bisphophonate therapy be reevaluated and a drug holiday be considered.

Methods: We conducted a computerized retrospective cohort study of all veterans, male and female $>$ 50 years of age at the Cleveland VA Medical Center receiving a prescription for an oral bisphosphonate for greater than 5 years. Medication compliance was determined by a medication possession ratio (MPR) greater than 0.8 over 5 years (MPR= total number of days supplied/total number of days since first fill). We excluded patients receiving bisphosphonates for Paget's disease or an indication other than osteoporosis/osteopenia (ICD9 codes 733.00, 733.90,733.01, 733.02). We identified whether prescribers were rheumatologists or primary care providers. We reviewed laboratory testing for serum 25 (OH) D3 at any time during bisphosphonate therapy, and VA pharmacy prescriptions for Calcium and Vitamin D supplementation. Chart review of clinical notes and radiology reports was performed to determine if baseline and follow-up bone mineral densitometry (BMD) were obtained and documented.

Results: 100 patients met inclusion criteria, 78 male and 22 female, mean age 76 years (range 50–96). The diagnosis was osteoporosis in 54%, osteopenia in 21%, and not documented in 23%. The most commonly prescribed bisphosphonate was alendronate (71%). The duration of bisphosphonate therapy ranged from 5 to 14 years (mean 8 years).

	Prescription of oral bisphosphonate by rheumatologist		Prescription of oral bisphosphonate by primary care provider	
Number of patients (total N=100)	n=5	%	n=95	%
Documentation of BMD at initiation of bisphosphonate	4	80	44	46.3
Documentation of follow-up BMD	5	100	37	38.9
Glomerular filtration rate $<$ 30 ml/min	0	0	3	3.2
Serum level of 25(OH)D3	5	100	60	63.1
Active order for Calcium	5	100	71	74.7
Active order for Vitamin D	5	100	72	75.7

Conclusion: The large majority (95%) of patients on long-term bisphophonate therapy in this veteran population were managed by PCPs rather than

rheumatologists (5%). In comparison to patients managed by rheumatologists, patients managed by PCPs had low frequency of BMD documentation at initiation of therapy and in follow-up, suboptimal measurement of serum 25(OH)D3, and suboptimal Calcium and vitamin D supplementation. Our study was limited by possible use of non-VA Calcium and Vitamin D supplementation, and possible use of non-VA BMDs in patients living in areas distant from the medical center. Future studies should be directed to educational outreach to PCPs and use of computerized clinical reminders at the time of prescription renewal.

Disclosure: M. Pioro, None; **S. Ogorzaly**, None; **M. Mattar**, None.

1163

Predictors of Cholesterol and Lifestyle Discussions in Rheumatoid Arthritis Visits: Impact of Perceived RA Control and Comparison with Other Prevention Topics. Christie M. Bartels[1], Joanna Wong[2], Heather Johnson[1], Katya Voelker[3] and Maureen Smith[1]. [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Tufts University School of Medicine, Boston, MA, [3]Univ of Wisconsin School of Medicine and Public Health, Madison, AA.

Background/Purpose: Experts recommend discussing modifiable cardiovascular disease (CVD) risk factors in RA visits. We examined the predictors of discussions about cholesterol and or lifestyle (weight, diet, exercise) in RA visits among patients eligible for improved cholesterol control, and compared them to other prevention topics: vaccination, bone health. We hypothesized that cholesterol/lifestyle discussions would depend on perceived RA control at a given visit.

Methods: Electronic health records were used to identify RA patients with uncontrolled cholesterol who received primary and rheumatology care in a health system with 3 rheumatology clinics (2004–2011). Those with diabetes, CVD, chronic kidney disease with low density lipoprotein (LDL) cholesterol >100 mg/dL and without such conditions whose LDL exceeded 130 mg/dL had visit notes reviewed by trained abstractors until LDL control or censoring for loss of continuity, death, or end of data. "RA control" was defined as stated by a rheumatologist in the visit note. We used logistic regression to calculate the odds ratios (OR) and 95% confidence intervals reflecting RA control as a predictor of cholesterol/lifestyle or other prevention discussions after controlling for sociodemographics, comorbidity (ACG score), and clinic.

Results: 1785 abstracted RA visits showed a mean age 60 years, 84% female, 93% white, 10% smokers, and mean BMI was 30.2 (SD 7.3). Prevalent CVD was noted in 18%, diabetes 15%. Overall 37% of visits reported controlled RA, and 31% discussed either cholesterol or lifestyle (13% cholesterol). As hypothesized, perceived RA control at a visit increased the odds of cholesterol/lifestyle discussion at that visit (OR 1.54, 1.21–1.98; Table 1). Other predictors of cholesterol/lifestyle discussions included single marital status, Medicaid, higher ACG score and hyperlipidemia codes or medications. In contrast, black race, non-English language, tobacco use, obesity and chronic kidney disease (CKD) predicted lower odds of such discussions. RA control was not predictive of vaccine or bone health discussions which showed less variation. Obese patients had lower odds of any prevention discussions. Clinic effects were significant for cholesterol and vaccine discussions but not bone health (data not shown). Limitations of our study include a visit note level analysis, which may not reflect care over several visits or without documentation, and use of subjective "RA control" definitions, although this may reflect usual care.

Conclusion: Perceived RA control predicted higher odds of cholesterol/lifestyle discussions, but not vaccine or bone health discussions. Concerning low discussion rates in at-risk patients with tobacco use, obesity, chronic kidney disease, and black race and clinic variation call for improved quality guidelines and systematic practices to address modifiable CVD risk factors in RA visits.

1164

Inequity: Level of Education Is Associated with Access to Biologic Dmards Even in a Country with Highly Developed Social Welfare (Norway). Polina Putrik[1], Sofia Ramiro[2], Elisabeth Lie[3], Andras Keszei[4], Desirée van der Heijde[5], Robert Landewé[6], Tore K. Kvien[3], Till Uhlig[3] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Uniklinik RWTH Aachen University, Aachen, Germany, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Biologic DMARDs (bDMARDs) have greatly improved the outcome of rheumatoid arthritis (RA). Investigating possible inequities in access to bDMARDs across socio-economic factors is important, and such analyses could provide clinicians and healthcare decision makers with useful information. The objective of the study was to explore whether there are differences in initiation rates of a first bDMARD across age, gender and educational status among RA patients.

Methods: Data from the Norwegian NOR-DMARD study (collected between 2000–2012) was used. Only patients who were DMARD naïve at entrance into the study were included in the analyses. The first prescription of any bDMARD was the event of interest. In order to assess impact of education, age and gender on time to first bDMARD, two Cox regression models were built using a manual forward step-wise modelling strategy. Models were adjusted for potential clinical confounders (DAS28, erosive disease, physician global assessment, HAQ, rheumatoid factor, disease duration, and comorbidities) and year of baseline visit. The first model included baseline predictors; the second was a time-varying model accounting for clinical information of all other visits between study inclusion and either start of bDMARD or censoring. Interactions between education and either year of baseline visit or age were tested.

Results: In total, 2005 patients were included (mean age at baseline 55 yrs, 68% females), and 368 patients received a bDMARD in the time of the period of observation (mean time to bDMARD 2.6 yrs). In both models, the socio-economic factors age and education were significant predictors of time-till-prescription (prescription of a first bDMARD), with lower hazard ratios (HR) for lower education and older age (Table). Education and age consistently and significantly contributed to the access to first bDMARD. Effect of lower education was more pronounced in later years (HR low vs. high education= 0.17 and 0.34 in patients who entered the cohort in 2008–2011, in time-varying and baseline models, respectively).

	Time-varying Cox regression model	Baseline predictors Cox regression model
	Hazard ratio [95% CI]

2008–2011		

*p<0.05, ** not included in the final model

Conclusion: Well-educated and younger patients apparently have potentially decisive advantages with regard to access to expensive treatments, even a country with highly developed welfare like Norway. A stronger effect of education in later years might be explained by changes in prescription practice and social trends towards longer education, pointing at increasing health gaps between education groups. Findings are relevant as the impact of age and education on access might result in avoidable adverse impact on health.

Evaluation of Symptom Control Among Treated Gout Patients in the United States, United Kingdom, and Germany. Robert Morlock[1], Chris Storgard[1], Vernon F. Schabert[2], Augustina Ogbonnaya[2], Pierre Chevalier[3], Dionne Hines[2] and Sulabha Ramachandran[4]. [1]Ardea Biosciences, San Diego, CA, [2]IMS Health, Alexandria, VA, [3]IMS Health, Vilvoorde, Belgium, [4]AstraZeneca, Wilmington, DE.

Background/Purpose: Gout affects approximately 1–4% of the population in developed Western countries. The hallmark signs of gout are elevated serum uric acid (SUA) level, episodes of painful inflammatory arthritis (flares), and tophi. Despite treatment with urate lowering therapies (ULT), e.g., xanthine oxidase inhibitors, a significant proportion of patients continue to have elevated SUA, recurrent flares, or tophi. This study aimed to estimate the rate of gout control among ULT treated established gout patients in the United States (US), United Kingdom (UK), and Germany (DE).

Methods: A longitudinal panel study was conducted using IMS' PharMetrics Plus database linked with outpatient laboratory results (US), Disease Analyzer (DE) databases, and the Clinical Practice Research Datalink-Hospital Episode Statistics (UK) from Jan 1, 2009 to Dec 31, 2011. Patients were required to have evidence of established gout (treated with ULT or eligible for ULT based on American College of Rheumatology guidelines) between Jan 1, 2009 and Dec 31, 2009; aged ≥18 years on index date (Jan 1, 2010); and have SUA results for outcome assessment at continuous follow-up in their respective databases throughout the observation period. ULT treatment was defined as having ≥60 days' supply of consecutive therapy any time during the baseline period (calendar year 2010). Gout symptom control was defined as SUA <6 mg/dL, ≤1 flare, and no tophi, and was measured at any time during the outcome assessment period (calendar year 2011).

Results: A total of 1,765 (US), 3,594 (UK), and 17,486 (DE) patients met the patient selection criteria and the ULT treatment definition in the respective databases. The mean (SD) age of the patients was 54.5 (9.6), 64.6 (12.3), and 69.2 (11.0) years in the US, UK, and DE, respectively. Most patients were male (US: 89.2%; UK: 85.6%; DE: 70.3%). Of the comorbidities evaluated at baseline, hypertension and hyperlipidemia were the most common in the US (64.9% and 54.8%, respectively) and DE (73.8% and 54.0%, respectively), while hyperlipidemia (51.6%) was the most common in the UK. Overall, 40.9%, 49.6%, and 41.1% of patients treated with ULT in the US, UK, and DE, respectively, achieved gout symptom control. When baseline ULT treatment was evaluated among controlled and uncontrolled patients, allopurinol was the predominant treatment in all 3 countries (US: N=1,575; UK: N=3,466; DE: N=16,684). Of those treated with allopurinol in the respective databases, 43.6% (US), 51.2% (UK), and 41.5% (DE) were controlled patients. Fewer patients were treated with febuxostat (US: N=76; UK: N=15; DE: N=61); and of those treated with febuxostat in the respective databases, 39.5% (US), 33.3% (UK), and 36.1% (DE) were controlled patients.

Conclusion: Overall, less than half of patients treated with ULT achieved gout symptom control, with the vast majority of patients in this study treated with allopurinol. New treatment options might be needed to improve outcomes/gout control for some patients. Further investigation is also necessary to understand factors that impact gout symptom control among treated patients.

5 Year Budget Impact Analysis of Biosimilar Infliximab for the Treatment of Rheumatoid Arthritis in UK, Italy, France and Germany. JiSeon Kim[1], JungAn Hong[1] and Alex Kudrin[2]. [1]CELLTRION HEALTHCARE, INCHEON, South Korea, [2]CELLTRION, Inc., Incheon, South Korea.

Background/Purpose: Biosimilar infliximab has been approved by EMA based on comparable quality, safety and efficacy profile to infliximab for the management of inflammatory autoimmune disorders including rheumatoid arthritis (RA), ankylosing spondylitis (AS), Crohn's disease, ulcerative colitis (UC), psoriatic arthritis (PsA), and psoriasis. Recent studies have shown considerable potential savings through the use of biosimilars for the investigated classes of biological drugs, for instance, the first generation biosimilar filgrastim which decreased the treatment cost by its introduction in oncology field.

Methods: We aimed to evaluate the budget impact of the introduction of biosimilar infliximab in treatment of Rheumatoid arthritis from the payer and the patient perspectives by using an Excel based budget-impact model over a five-year time horizon. The model calculated patients eligible for infliximab treatment based on the total population, annual population growth rate and prevalence of RA in 4 major EU countries; UK, Italy, France, and Germany. The acquisition cost of comparator infliximab was assumed not to change after the introduction of biosimilar mAb. The price of the biosimilar infliximab is currently unknown, therefore three different discount scenarios (10%, 20%, and 30%) were applied to evaluate the budget impact. Market uptake growth rate was also varied in each of the scenarios at 20%, 30%, and 40%, respectively. The market share was assumed to be 25% in the first year in all scenarios.

Results: The total budget saving for the 10% price discount scenario for all four countries for 2015, 2016, 2017, 2018, and 2019 was € 12,880,000, € 15,450,000, € 18,560,000, € 22,260,000, and € 26,710,000, respectively. The total budget saving for the 20% price discount scenario for 2015, 2016, 2017, 2018, and 2019 was €25,750,000, €33,490,000, €43,550,000, € 56,610,000, and € 73,600,000, respectively. The total budget saving for the 30% price discount scenario for 2015, 2016, 2017, 2018, and 2019 was € 38,630,000, € 64,630,000, € 75,740,000 €106,050,000, and € 148,470,000, respectively. The total budget saving over the five year period (2015 –2019) for all four countries was € 95,860,000, €233,000,000, and € 433,520,000 for the 10%, 20%, and 30% price discount scenarios, respectively.

Conclusion: The introduction of the biosimilar infliximab as a treatment option for patients with Rheumatoid arthritis could achieve substantial cost savings. In the scenarios tested, the total 5 year saving across UK, Italy, France and Germnay ranged from € 96 million to € 433 million.

A Description and Comparison of Treatments for Low Back Pain in the United States. Elizabeth G. Salt, Yevgeniya Gokun, Anna Kerr and Jeffery Talbrert. University of Kentucky, Lexington, KY.

Background/Purpose: Low back pain (LBP) affects 67% to 84% of persons residing in industrialized countries, and is a significant source of lost productivity, disability, and increased health care costs (treatment costs estimated at $90 billion). Both pharmacologic (i.e., opioids-"fair" evidence to support use) and non-pharmacologic (i.e., exercise therapy-"good" evidence) treatments are recommended for LBP management. Because the prevalence of LBP and opioids use (p=.0014) differs between the U.S. Census Regions, we compared the treatments used for LBP and their related costs between regions.

Methods: De-identified patient health claims data from persons with LBP (ICD-9 codes-724.2 [lumbago]) along with treatments received (CPT codes-97001 [physical therapy {PT}]) and medication records was extracted from a large commercially insured dataset (January 1, 2007-December 31, 2009) (N=1,630,438). After using descriptive statistics to describe the sample and the frequency of received LBP treatments, we used Pearson's Chi-Squared Test of Independence to compare therapy and medication usages among the different regions.

Results: An opioid was used by 49.8% (n=812,479) of this sample while nonpharmacologic therapies were rarely used (8%-psychological therapies; 19%-exercise therapies; 12%-PT). Opioids had the lowest standardized cost ($16);

anti-convulsants (n=49,073) had the highest standardized cost ($452). The median costs for non-pharmacologic treatments are variable ($5,526-surgical procedures vs. $40-hot/cold packs). We found significant differences in the medications and therapies used in the U.S. Census Regions ($p <$ .0001; Figure 1).

Conclusion: There is a lack of adherence to treatment recommendations for LBP and significant differences in the receipt of various LBP treatments per U.S. Census Region. Further research is needed to explore this discrepancy.

Usng an Advanced Clinician Practitioner in Arthritis Care Trained Physiotherapist and a Standardized Electronic Medical Record Triage Assessment Tool to Detect Inflammatory Arthritis and Initiate Dmards Earlier in a Community Rheumatology Office Setting. Vandana Ahluwalia[1] and Tiffany Larsen[2]. [1]William Osler Health Center, Brampton, ON, [2]Headwaters Health Care Centre, Orangeville, ON.

Background/Purpose: An experienced Advanced Clinician Practitioner in Arthritis Care (ACPAC) trained physiotherapist with advanced directives using a standardized Electronic Medical Record (EMR) triage tool conducted a 15 minute assessment on patients with suspected inflammatory arthritis. We evaluated the time from referral to the initiation of Disease Modifying Antirheumatic Drug (DMARD) therapy in those patients who had been triaged and confirmed to have inflammatory arthritis (IA).

Methods: Patients were referred by local primary care physicians to a solo community rheumatology practice. The rheumatologist triaged the paper referrals, and those with suspected inflammatory arthritis were selected to be initially seen by the ACPAC physiotherapist (ACPAC triage model). Patients in whom the physiotherapist suspected inflammatory arthritis were given a workup with laboratory and x-ray testing as per advanced directives. These patients were then booked as priority to see the rheumatologist. The average number of days from referral to the initiation of DMARDs was determined for those patients confirmed to have a diagnosis of IA. A retrospective chart review using the rheumatologists EMR was conducted on new referrals that were seen solely by the rheumatologist (Traditional triage model) and suspected to have IA. The time from referral to the initiation of DMARDs was determined was also determined for this group.

Results: One hundred and twenty-one patients were triaged by the ACPAC physiotherapist prior to the assessment by the rheumatologist. Forty eight patients (40%) were diagnosed with IA and 31 patients were started on a DMARD. Twenty-nine patients (93.5%) were started on a DMARD at the first Rheumatology visit, and two patients (6.5%) were started on a DMARD on the second Rheumatology visit. The average number of days from referral to Rheumatology visit for patients with IA was 73 days. The average number of days from the referral to initiation of DMARDs was 75 days. We compared these findings to patients from a retrospective chart review using the Traditional Triage Model. One hundred and ten charts were retrospectively reviewed on patients with suspected IA. There were 53 patients (48%) diagnosed with IA and forty-three patients were started on a DMARD. Fifteen patients (35%) started on a DMARD at the first Rheumatology visit, and 28 patients (65%) started on a DMARD at the second Rheumatology visit. In this group, the average number of days from referral to Rheumatology visit was 84 days. The average number of days from the referral to the initiation of DMARDs was 125 days.

Conclusion: The utilization of an ACPAC trained physiotherapist with advanced directives to triage suspected inflammatory arthritis referrals prior to a Rheumatology assessment resulted in an earlier initiation of DMARDs with the majority of patients starting a DMARD at the first Rheumatology visit. This approach may serve as a model for other settings in which there is a need for health human resources in musculoskeletal care.

Hippocampal Atrophy Is Associated with Anti-NR2 Antibodies in Patients with Systemic Lupus Erythematosus and Primary Sjögren's Syndrome. Maria B Lauvsnes[1], Mona K Beyer[2], Jan T Kvaløy[1], Ole J Greve[1], Simone Appenzeller[3], Erna Harboe[1], Anne B Tjensvoll[1], Lasse G Gøransson[1] and Roald Omdal[1]. [1]Stavanger University Hospital, Stavanger, Norway, [2]Oslo University Hospital, National Hospital, Oslo, Norway, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Antibodies against the NR2 subtype of the NMDA-receptor (anti-NR2 antibodies) are detected in patients with systemic lupus erythematosus (SLE) and primary Sjögren's syndrome (SS). It is known from murine lupus models that these antibodies can cause hippocampal atrophy and cognitive impairment when they gain access to the brain. Reduced hippocampal volumes have been described in both SLE and primary SS patients; but a link between anti-NR2 antibodies and hippocampal atrophy has never been described in humans until now.

Methods: A population-based cohort of 50 SLE (all fulfilling the ACR criteria) and 50 primary SS patients (all fulfilling the AECG criteria) were clinically examined and cerebral MRI scanning performed. Anti-NR2 antibodies were measured in cerebrospinal fluid (CSF). We applied the SPM8 software and compared hippocampal volumes between patients with and without anti-NR2 antibodies.

Results: 16 % of the SLE patients and 12 % of the primary SS patients had anti-NR2 antibodies in CSF. Patients with anti-NR2 antibodies had less grey matter in their hippocampi compared to patients without these antibodies. There were no differences in grey matter volumes in other areas of the brain. Hippocampal grey matter volumes did not differ between the two total groups of SLE and primary SS patients, and there were no statistical significant interactions between groups and anti-NR2 antibodies. No effect on hippocampal volumes were found for presence of anti-phospholipid antibodies, disease duration, or present use of corticosteroids.

Conclusion: Less hippocampal grey matter is observed in SLE and primary SS patients with anti-NR2 antibodies compared to those without these antibodies. This indicates that anti-NR2 antibodies may cause neuronal death in humans, as previously demonstrated in mice with autoimmune disease.

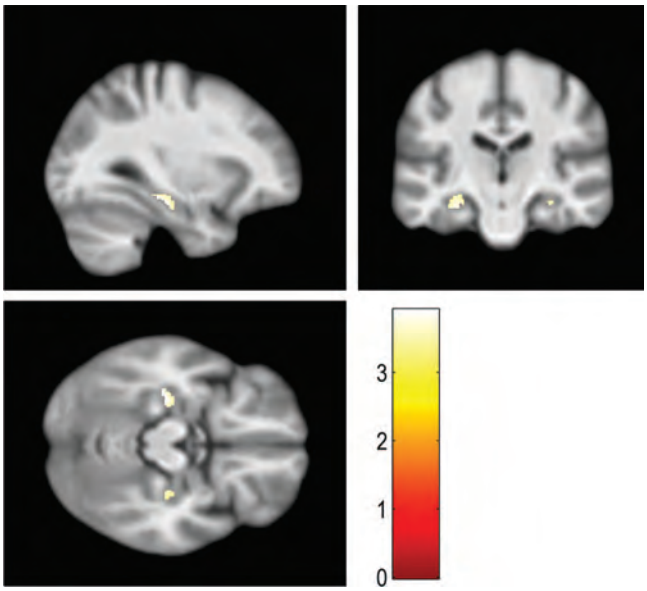

Figure 1: Clusters of voxels with GM loss in patients with anti-NR2 antibodies ($p < 0.05$, FWE corrected). The cluster color represents the statistical significance of GM decrease according to the gradation of the color bar.

Neurological Complications during Anti-TNF Therapy: A Prospective Imaging and Electrophysiological Study. Evripidis Kaltsonoudis[1], Anastasia Zikou[2], Paraskevi V. Voulgari[3], Spyridon Konitsiotis[4], Maria Argyropoulou[5] and Alexandros A. Drosos[6]. [1]Rheumatologist, Ioannina, Greece, [2]Lecturer of Radiology, Ioannina, Greece, [3]Associate Professor of Rheumatology, Ioannina, Greece, [4]Associate Professor of Neurology, Ioannina, Greece, [5]Professor of Radiology, Ioannina, Greece, [6]Professor of Medicine/Rheumatology, Ioannina, Greece.

Background/Purpose: The aim was to investigate the frequency of neurological adverse events in patients with rheumatoid arthritis (RA) and spondylarthropathies (SpA) treated with tumor necrosis factor (TNF) α antagonists.

Methods: Seventy-seven patients eligible for anti-TNFα therapy were evaluated. There were 36 patients with RA, 41 with SpA (24 psoriatic arthritis [PsA] and 17 with ankylosing spondylitis [AS]). All patients had a complete physical and neurological examination. Brain and cervical spine magnetic resonance imaging (MRI) and neurophysiological tests were performed in all patients before the initiation of anti-TNFα therapy and after a mean of 18 months or when clinical symptoms and signs indicated a neurological disease. Exclusion criteria included hypertension, diabetes mellitus, dyslipidemia, heart arrhythmias, atherothrombotic events, vitamin 12 and iron deficiency, head and neck trauma and neurological surgeries.

Results: Two patients did not receive anti-TNFα therapy because brain MRIs at baseline revealed lesions compatible with demyelinating diseases. Thus, 75 patients received anti-TNFα (38 infliximab, 19 adalimumab and 18 etanercept). Three patients developed neurological adverse events. A 35-year-old man with PsA after 8 months of infliximab therapy presented with paresis of the left facial nerve and brain MRI showed demyelinating lesions. Infliximab was discontinued and he was treated with pulses of corticosteroids recovering completely after two months. The second patient was a 45-year-old woman with RA who after 6 months of adalimumab therapy presented with optic neuritis. The third patient was a 50-year-old woman with AS, whom after 25 months of infliximab therapy, presented with tingling and numbness of the lower extremities and neurophysiological tests revealed peripheral neuropathy. In both patients anti-TNF were discontinued and they improved without treatment after 2 months. The rest of our patients showed no symptoms and MRIs showed no abnormalities.

Conclusion: Neurological adverse events after anti-TNFα therapy were observed in our patient. The estimated rate of neurological complications is 4% (3/75). Brain MRI and neurophysiological tests are essential tools to discriminate neurological diseases.

Disclosure: E. Kaltsonoudis, None; **A. Zikou**, None; **P. V. Voulgari**, None; **S. Konitsiotis**, None; **M. Argyropoulou**, None; **A. A. Drosos**, None.

1171

Diffusion–weighted Magnetic Resonance Imaging (MRI) of Wrist and Hands in Patients with Rheumatoid arthritis –reproducibility and Correlation with Conventional MRI. Misbah Khurram[1], Jakob M. Møller[1], Mikkel Østergaard[2], Henrik Thomsen[1], Bo Jannik Ejbjerg[3], Merete Lund Hetland[4] and Signe Møller-Bisgaard[3]. [1]Department of Radiology, Copenhagen University Hospital Herlev, Copenhagen, Denmark, [2]Copenhagen Center for Arthritis Research, Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [3]Department of Rheumatology, Slagelse Hospital, Slagelse, Denmark, [4]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup Hospital, Glostrup, Denmark.

Background/Purpose: The aim of this study was to investigate the performance of diffusion-weighted imaging (DWI) in detecting high signal intensity areas (HSIA), as potential signs of bone inflammation, in wrist and metacarpophalangeal (MCP) joints of rheumatoid arthritis (RA) patients, in comparison with short tau inversion recovery (STIR) MRI images.

Methods: 26 patients with RA in clinical remission underwent MRI including DWI (with apparent diffusion coefficient (ADC) maps), T1-weighted (T1w) and STIR images. 13 were rescanned after 4 months. STIR scans were scored for bone marrow edema (BME) according to Outcome Measures in Rheumatoid Arthritis Clinical Trials (OMERACT) Rheumatoid Arthritis Magnetic Resonance Imaging scoring system (RAMRIS) and DWI scans were scored for absence (0) or presence (1) of HSIA in bone marrow. STIR and DWI images were reviewed separately by one reader and ADC values were calculated in each of 21 bones in the wrist and MCP joints. For calculation of ADC, regions of interest (ROIs) were drawn, which covered the maximal possible subcortical bone areas, including both areas with high and with normal signal, avoiding erosions (method A). Furthermore, in DWI positive areas, ROIs were also placed within the HSIA (method B). ADC values were divided into 4 groups based on STIR and DWI scores as seen in the table below and nonparametric tests were used to compare groups. The reproducibility of the scores was analyzed by kappa (k) values, intra-class correlation coefficient (ICC), and smallest detectable difference (SDD) and change (SDC).

Results: STIR showed more positive lesions (132 HSIA (=bone marrow edema)) than DWI (50 HSIA) ($p<0.001$ Fisher's exact test). Mean ADC of "STIR-only" (STIR+/DWI-) positive lesions ($318\pm172\times10^{-3}mm^2/s$ was significantly lower than lesions, where both STIR and DWI were positive (STIR+/DWI+; $894\pm486\times10^{-3}mm^2/s$) ($p<0.001$; Mann-Whitney U test). ADC-values increased with increasing STIR scores (see table).The median ADC, in DWI positive areas, with method A ($759.5\times10^{-3}mm^2/s$) was slightly lower than the median ADC with method B ($846\times10^{-3}mm^2/s$) (p-value 0.048; Wilcoxon signed rank test). There was no statistically significant difference between baseline and 4 months follow-up scans in any parameters ($p=0.9$, 0.8 and 0.2 for STIR, DWI and ADC respectively; Wilcoxon signed rank test).The intraobserver agreement was good to excellent using STIR ($k=0.80$) and DWI ($k=0.76$), respectively (baseline). The intraobserver ICC of ADC measurements was 0.85. Intraobserver SDD of ADC at baseline was $60\times10^{-3}mm^2/s$, whereas intraobserver SDC between baseline and 4 months follow up was $108\times10^{-3}mm^2/s$.

Conclusion: DWI, including ADC measurements, in bones of patients with RA were highly reproducible and may partially reflect BME on STIR MRI. Further studies are needed to investigate if the method is useful for monitoring treatment response and/or predicting disease progression.

Table: ADC values stratified by STIR and DWI assessments

	Number of ROIs	Mean (SD)	Median (IQR)	Range	Mann-Whitney U test: P values		
					STIR+/DWI−	STIR−/DWI+	STIR−/DWI−
STIR+/DWI+	47	894(486)	790(589–1114)	203–2315	<0.001	0.533	<0.001
STIR+/DWI−	86	318(172)	303(216–397)	95–1071		<0.001	0.004
STIR−/DWI+	3	684(94)	666	600–786			0.003
STIR−/DWI−	364	258(111)	235(178–317)	67–705			
Only DWI+ area ADC (method B ROI)	50	957(424)	846(662–1119)	286–2315			
					Mann-Whitney U test: p value		
					STIR 1	STIR 2	STIR 3
STIR 0	367	262(117)	237(180–317)	67–786	>0.001	>0.001	>0.001
STIR 1	98	392(280)	315(218–479)	95–1588		0.002	>0.001
STIR 2	17	690(401)	618(390–898)	203–1813			0.045
STIR 3	17	1074(603)	1007(680–1410)	227–2315			

STIR+/− and DWI+/−: High intensity signal detected/not detected on STIR and diffusion-weighted MRI sequences, respectively; STIR 0,1,2,3: Scores of bone marrow edema on STIR sequence by using RAMRIS system; ROIs: regions of interest; SD: standard deviation; IQR: interquartile range.

Assessing the Validity and Reliability of a Novel MRI Semi-Automated Algorithm for Quantifying Bone Loss in the Hand. Matthew Jessome[1], Isabel Rodrigues[1], Michael Tomizza[1], Joshua Barbosa[1], Melissa XP. Koh[1], Karen Beattie[2], William G. Bensen[2], Raja Bobba[2], Alfred Cividino[2], Patrick D. Emond[2], Karen Finlay[3], Chris Gordon[2], Lawrence Hart[2], George Ioannidis[2], Erik Jurriaans[3], Maggie Larche[2], Arthur Lau[2], Naveen Parasu[3], Ruben Tavares[2], Stephen Tytus[2], Hao Wu[1] and Jonathan D. Adachi[2]. [1]McMaster University, Hamilton, ON, [2]St Joseph's Healthcare Hamilton, Hamilton, ON, [3]Hamilton Health Sciences, Hamilton, ON.

Background/Purpose: Efficient and accurate evaluation of erosive damage to the MCP joints in RA patients is desirable in both clinical trials and clinical practice. The novel software *Early Erosions in Rheumatoid Arthritis* (EERA) hybridizes region growing and level-set segmentation algorithms, and can be used by a novice reader to semi-automatically quantify bone erosion volumes of the MCP joints captured by MRI. The objectives of this study were firstly to compare EERA to the Outcome Measures in Rheumatology Clinical Trials RA MRI score (RAMRIS), which is an established tool for evaluating erosive damage, and secondly to assess the inter- and intra-rater reliability of EERA.

Methods: Magnetic resonance images were acquired of both hands of 71 RA patients from a single rheumatology clinic at baseline and 2 years follow-up using a 1T magnet, 100mm cylindrical transmit and receive coil, and a 3D spoiled gradient echo sequence. Images were randomly distributed to 4 blinded musculoskeletal radiologists trained in RAMRIS. RAMRIS erosion scores for the 2nd through 5th MCP joints of both hands were evaluated and summed. A separate reader trained in EERA, but otherwise inexperienced with conventional quantification techniques, used EERA to evaluate and sum the volume of bone loss (in mm^3) of the 2nd through 5th MCP joints of these same images. To assess reliability, a random subset of 20 images was evaluated by 2 additional novice readers similarly trained in EERA. All 3 readers scored these 20 images a second time after 72 hours. Spearman's correlations were calculated to compare EERA and RAMRIS cross-sectionally and longitudinally, and intra-class correlation coefficients, ICC (2,1) with 95% confidence intervals (CI) were used to assess EERA reliability.

Results: Of the 71 participants [female: 78%, Caucasian: 72%, age: mean (standard deviation) 56.5 (12.8)yr, DAS28-ESR: 4.39 (1.42), symptom duration: 5.5 (5.7)yr], 52 (73%) were imaged at 2 years follow-up. EERA detected erosions in 43 (61%) participants, whereas RAMRIS detected erosions in 65 (92%) participants. The mean baseline erosion volume per participant was 63.4mm^3 (129.7mm^3), and mean baseline RAMRIS erosion score per participant was 10.8 (10.9). A Spearman's rho=0.450 ($p<0.001$) showed moderate correlation between EERA erosion volumes and RAMRIS erosion scores at baseline, with similar correlation at 2 years follow-up (rho=0.496, $p<0.001$). The 2 year mean change in EERA erosion volume was 1.2mm^3, and volume changes did not correlate significantly with 2 year RAMRIS erosion score changes ($p=0.505$). EERA reliability was excellent between all 3 raters, with an inter-rater reliability ICC of 0.945 (95% CI 0.887 to 0.959). Intra-rater reliability ICCs of 0.993 (95% CI 0.982 to 0.997), 0.979 (95% CI 0.949 to 0.992), and 0.933 (95% CI 0.834 to 0.973) were achieved for each reader.

Conclusion: EERA erosion volumes evaluated by a novice reader exhibited moderate correlation with RAMRIS erosion scores evaluated by trained radiologists. The excellent reliability of EERA suggests that it may have practical utility in a clinical setting, and future assessment of responsiveness is warranted.

Magnetic Resonance Imaging of Inflammatory Severity and Cartilage Damage of Finger Joints in Rheumatoid Arthritis. Dr. Philipp Sewerin[1], Dr. Christoph Schleich[2], Anja Mueller-Lutz[1], Prof. Dr. Benedikt Ostendorf[1], Christian Rubbert[1], Dr. Christian Buchbender[1], Prof. Dr. Matthias Schneider[2], Prof. Dr. Gerald Antoch[1] and Dr. Falk Miese[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: To assess the association of inflammation severity and cartilage damage measured by delayed gadolinium-enhanced magnetic resonance imaging of the cartilage (dGEMRIC) of metacarpophalangeal (MCP) joints in patients with rheumatoid arthritis (RA).

Methods: 43 patients with RA according to ACR/EULAR classification criteria [age 52.9 ± 14.5 years, range: 18 – 77 years; disease duration 2.9 ± 4.9 years, range: <0.5 – 19 years; Disease Activity Score of 28 joints (DAS28) 3.7 ± 1.5] were included in this study. All study participants received 3T MRI scans of the metacarpophalangeal joints of the second and third finger. Cartilage composition was assessed with dGEMRIC. The severity of synovitis was scored according to the RAMRIS synovitis subscore (range: 0–3) by two readers in consensus. In the cases with identical synovitis subscores in MCP 2 and 3, two radiologists decided in consensus on the joint with more severe synovitis and the joint with less severe synovitis. To test the association of inflammation severity and cartilage damage and in order to eliminate inter-patient confounders, each patient's MCP 2 and 3 were dichotomized into the joint with more severe synovitis versus the joint with less severe synovitis for a paired Wilcoxon test of dGEMRIC value. The study was approved by the local ethics committee and written informed consent was obtained from all patients prior to the MR examination.

Results: dGEMRIC value of MCP with more severe synovitis was 369 msec ± 137, dGEMRIC value of MCP with less severe synovitis was 421 msec ± 129. RAMRIS synovitis subscore of the joint with more severe synovitis was 2.51 (range: 1–3), synovitis subscore of the joint with less severe synovitis was 1.86 (range: 0–3). There was a significant difference of dGEMRIC value (median of difference: 47.12, CI [16.6; 62.76]) between the dichotomized MCPs ($p = 0.0001$). There was a significant correlation between dGEMRIC value and RAMRIS synovitis grading of the joint with more severe synovitis ($r = 0.5$; $p < 0.05$) and the joint with less severe synovitis ($r = 0.33$; $p < 0.05$).

Conclusion: Our data concur with the concept that synovitis severity is associated with cartilage damage. The local inflammatory status on a joint level correlated significantly with the extent of cartilage degradation.

Evaluating MRI-Detected Tenosynovitis of the Hand and Wrist in Early Arthritis. W.P. Nieuwenhuis, A. Krabben, W. Stomp, T. W. J. Huizinga, D. M. van der Heijde, J.L Bloem, M. Reijnierse and A.H.M. van der Helm-van rMil. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Magnetic resonance imaging (MRI) is a sensitive method to detect local inflammation in rheumatoid arthritis (RA), visualizing synovitis, bone marrow edema and tenosynovitis. The prevalence of MRI-detected tenosynovitis and the diagnostic value in early arthritis are unclear. This study aimed to identify the frequency of MRI-detected tenosynovitis at the metacarpophalangeal (MCP) and wrist joints in early arthritis and the association with RA and severity features within RA.

Methods: 178 early arthritis patients underwent unilateral 1.5T extremity-MRI at baseline. The MCP and wrist-joints were scored using the RA MRI scoring (RAMRIS) system extended with Haavardsholms tenosynovitis score. 69 patients fulfilled the 2010 RA classification criteria during the first year and were compared with the other patients. Within RA-patients com-

parisons were made for anti-citrullinated-peptide-antibody (ACPA) positivity and for radiographic progression during year-1.

Results: 65% of all patients had MRI-detected tenosynovitis. RA-patients had tenosynovitis more often than non-RA patients (75% versus 59%, p=0.023). The flexor tendons at MCP-5, the extensor tendons at MCP-2 and MCP-4 and extensor compartment-I of the wrist were more frequently affected in RA than in other diagnoses (odds ratio's 2.8 (95% confidence interval (CI) 1.2–7.0), 9.1 (95% CI 1.9–42.8), 14.2 (95% CI 1.7–115.9), 4.0 (95% CI 1.4–11.1) respectively). These associations were independent of local MRI-detected synovitis. Specificities were all ≥82%. Within RA, tenosynovitis-scores were not associated with ACPA-positivity or radiographic progression.

Conclusion: MRI-detected tenosynovitis is common in early arthritis. The flexor tendons at MCP-5, the extensor tendons at MCP-2 and MCP-4 and the first extensor compartment of the wrist are more often affected in RA, independent of local synovitis.

1175

Association of Hand MRI Findings with the Level of Plasma Cytokines in Patients with Newly Diagnosed Rheumatoid Arthritis. Yasushi Kondo, Yuko Kaneko, Hiroaki Sugiura, Shunsuke Matsumoto, Naoshi Nishina, Masataka Kuwana, Masahiro Jinzaki and Tsutomu Takeurchi. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Magnetic resonance imaging (MRI) is a very useful modality that can directly visualize both inflammatory and structural changes of affected joints in patients with rheumatoid arthritis (RA). On another front, cytokines have pleiotropic and strong effector functions in inflammatory response and play an important role in pathogenesis of RA joints. However, it is still unclear MRI findings can reflect dynamic features of cytokines in RA.The aim of this study is to examine the association with hand MRI findings scored using Outcome Measures in Rheumatology (OMERACT) RA MRI scoring (RAMRIS) system and plasma cytokine levels in patients with RA.

Methods: In total of 98 newly diagnosed, untreated consecutive RA patients in our cohort (SAKURA study) were included. MRI of dominant wrist and finger joints were evaluated for synovitis, osteitis, tenosynovitis, JSN and bone erosions according to the latest OMERACT RAMRIS. MR images were assessed by 2 experienced radiologists independently, and the mean of their scores were used in the analysis. Ten cytokines including IL-6, VEGF, IL-1β, TNF-α, IL-8, GM-CSF, IFN-γ, IL-10, IL-12p70 and IL-2 in patients' plasma were measured by electrochemiluminescence assay. Clinical and laboratory data were collected from their charts. The associations between RAMRIS scores and cytokine levels were examined by Spearman's Rank Correlation Coefficient. The agreement of the two MRI readers was tested intraclass correlation coefficient (ICC).

Results: Seventy-seven (80.2 %) patients were female, 69 (71.9%) were positive for anti-CCP, and the median age and symptom duration were 59 years and 3.5 months, respectively. Mean disease activities score (DAS) 28 was 4.80. The median scores of RAMRIS were 5.75 for synovitis, 5.00 for osteitis, 4.00 for bone erosion, 2.50 for tenosynovitis and 1.00 for JSN. The ICCs of these scores were approximately 0.90 for all. RAMRIS synovitis and tenosynovitis scores were significantly correlated with DAS28, pain, global and evaluator Visual Analog Scale and Health Assessment Questionnaire-Disability Index. While RAMRIS synovitis, osteitis and tenosynovitis scores significantly correlated with plasma IL-6 ρ=0.410, p<0.001; ρ=0.381, p<0.001; ρ=0.337, p=0.001, repectively) and VEGF (ρ=0.296, p=0.003,; ρ=0.323, p=0.001; ρ=0.268, p=0.008, respctively), RAMRIS osteitis and bone erosion scores were significantly correlated with plasma IL-1β (ρ=0.221, p<0.031; ρ=0392, p<0.001). TNF and the other cytokines were not correlated with any RAMRIS score although IL-8 tended to correlate with osteitis score. In patients with anti-CCP antibody positive the correlations between RAMRIS synovitis and plasma levels of IL-6 and VEGF were more significant.

Conclusion: In newly diagnosed RA patients, synovial, bone and tendon inflammatory changes of hand MRI may reflect the high level of plasma IL-6 and VEGF, and plasma IL-1β may be associated with MRI bone involvements.

Feasibility and Clinical Implication of Radiocarpal Cartilage $T_{1\rho}$ MR Imaging in Rheumatoid Arthritis. Valentina Pedoia[1], Favian Su[1], Andrew J. Burghardt[1], Jonathan Graft[2], John B. Imboden[2], Mary Nakamura[3], Ursula Heilmeier[1], Thomas M Link[1] and Xiaojuan Li[1]. [1]Musculoskeletal Quantitative Imaging Research, UCSF, San Francisco, CA, [2]Division of Rheumatology, UCSF, San Francisco, CA, [3]SFVAMC/UCSF, San Francisco, CA.

Background/Purpose: Rheumatoid arthritic (RA) disease progression and anti-rheumatic treatment efficacy have traditionally been monitored by evaluation of radiographs. However, MRI has emerged as a more sensitive tool to depict synovial and articular inflammatory changes in early and low disease activity that are not radiographically evident. In particular, $T_{1\rho}$ MRI allows the detection of early-stage cartilage damage[1]. There are no prior reports of using $T_{1\rho}$ to evaluate cartilage composition changes in the wrist of RA patients. In this study we assessed the feasibility of wrist cartilage $T_{1\rho}$ mapping in RA patients and the association of $T_{1\rho}$ values with RA MRI scoring (RAMRIS).

Methods: The wrists of 5 RA patients (55.2 ± 13.3 yrs.,4 fem., DASCRP28: 3.72 ± 2.26, RA) and two healthy subjects (27 ± 4 yrs., 1 fem.) were scanned on a 3T MR scanner (GE, Healthcare) using the standard imaging protocol recommended by the OMERACT group and a coronal $T_{1\rho}$ (time of spin-lock = 0/10/20/50 ms; spin-lock frequency = 500Hz, resolution $0.21\times0.21\times3$ mm)^2. For both volunteers, scan/re-scan data were acquired after repositioning. Radiocarpal joint cartilage was segmented semi-automatically in the lunate, scaphoid and radius. Lunate, scaphoid and radius bones were automatically segmented using active contours initialized by the cartilage segmentations. The individual bone masks were used to perform piecewise rigid registration between the 4 echo images. Reliability measurements were computed as coefficients of variation (CV). MRI wrist images were scored using the OMERACT RA MRI Scoring (RAMRIS) system[3]. Joint space narrowing (JSN), bone erosion and bone marrow edema-like lesion (BMEL) scores were correlated with $T_{1\rho}$.

Results: The mean scan/re-scan $T_{1\rho}$ CVs were 1.48%, 3.60% and 5.62% for the lunate, scaphoid and radial cartilage. The overall CV was 3.59%. In Tab. 1, the mean cartilage $T_{1\rho}$ values and MRI scores are reported. Strong linear correlations were found between the overall $T_{1\rho}$ values and both BMEL (R^2 = 0.87, p<0.01) and erosion scores (R^2 = 0.95, p<0.01). Fig. 1 shows FSE T2 IDEAL sequence and the corresponding $T_{1\rho}$ map of representative RA cases with high $T_{1\rho}$ (43.2 ms) and low $T_{1\rho}$ (36.9 ms).

Conclusion: We demonstrated excellent in vivo reproducibility of MRI $T_{1\rho}$ quantification in wrist cartilage. Despite the small sample size, the results obtained demonstrate the feasibility of using $T_{1\rho}$ to study the progression of cartilage damage and response to therapy in the wrist of RA patients.

Evaluation of a Simplified Version of the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) Comprising 5 Joints (RAMRIS5). Dr. Philipp Sewerin[1], Dr. Christoph Schleich[2], Dr. Christian Buchbender[1], Dr. Falk Miese[1], Dr. Ralph Brinks[3], Prof. Dr. Matthias Schneider[2], Prof. Dr. Gerald Antoch[1] and Prof. Dr. Benedikt Ostendorf[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany, [3]Univ Duesseldorf, Düsseldorf, Germany.

Background/Purpose: Semi-quantitative measurement of inflammatory pathologies of the hand in magnetic resonance images (MRI) is a mandatory, but time-consuming task for MRI controlled studies in Rheumatoid Arthritis (RA). The objective of this study was to evaluate a simplified version of the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) reduced to five joints of the hand (RAMRIS5).

Methods: 94 patients with rheumatoid arthritis (62 female; age 59 ±12 years, range 25 – 83 years; disease duration 60 ± 90 months (median: 22 months, first quartile: 7 months, third quartile: 66 months) from the REMISSION PLUS study cohort who had complete files on C-reactive protein (CRP) levels and Disease Activity Score of 28 joints (DAS28) and complete MRI of the clinical dominant hand at baseline and after one year under anti-rheumatic therapy (follow-up time 12.5 ± 1.1 months) in a dedicated extremity MRI scanner at 0.2T were included in this retrospective study. MR images were scored according the RAMRIS criteria by two readers in consensus. Spearman correlations of the RAMRIS sum-score, subscores for RAMRIS of the metacarpophalangeal joints (RAMRISMCP), wrist (RAMRISWrist) and a reduced score comprising the MCP 2 and 3, capitate bone, triquetral bone, distal ulna were assessed. Additionally, Spearman correlations of MRI scores, CRP levels and DAS28 were calculated.

Results: There was a strong correlation between RAMRIS5 and the RAMRIS sum-score for all patients ($r = 0.87$, $p < 0.001$) at baseline and follow up ($r = 0.87$, $p < 0.001$). Among the subscores there was a significant correlation between RAMRIS5 and RAMRISMCP (baseline: $r = 0.66$, $p < 0.001$; follow-up: $r = 0.74$, $p < 0.001$) as well as between RAMRIS5 and RAMRISwrist (baseline: $r = 0.72$, $p < 0.001$, follow-up: $r = 0.69$, $p < 0.001$) at baseline and follow up. The correlation between RAMRIS5 and CRP (baseline: $r = 0.21$, $p < 0.05$; follow-up: $r = 0.03$, $p = 0.76$) or DAS28 (baseline: $r = 0.17$, $p = 0.11$; follow-up: 0.31, $p < 0.01$) were weak, similarly as observed for conventional RAMRIS (for CRP baseline: $r = 0.29$, $p < 0.01$; follow-up: $r = 0.10$, $p = 0.34$; for DAS28 baseline: $r = 0.20$, $p = 0.05$; follow-up: $r = 0.32$, $p < 0.01$).

Conclusion: RAMRIS5, a modified shorter RAMRIS score based on five joints of the hand is a viable tool for semi-quantitative assessment and monitoring of joint damage in RA. This abbreviated score might reduce the time needed for image analysis in MRI-controlled studies in RA and facilitate the use of MRI in studies on therapy response assessment in RA.

Novel Quantification of MRI Provides a More Sensitive Outcome Measure Than Ramris. Michael A. Bowes[1], Gwenael Guillard[1], Eleanor Gill[1], Graham R. Vincent[1], Elizabeth Hensor[2], Jane E. Freeston[3], Edward M. Vital[3], P. Bird[4], Paul Emery[3] and Philip G. Conaghan[5]. [1]Imorphics Ltd, Manchester, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., United Kingdom, Leeds, United Kingdom, [4]Combined Rheumatology Practice, Sydney, Australia, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds, United Kingdom.

Background/Purpose: There is increasing need for sensitive, objective outcome measures in rheumatoid arthritis (RA). MRI is more sensitive than clinical examination and X-rays, using a semi-quantitative score (OMERACT RAMRIS). The objective was to use statistical shape models (SSMs) to identify RA pathology, and compare rates of change with RAMRIS in a RA population treated with a biologic therapy.

Methods: MR images of the hand were acquired from 45 established, active (mean (SD) DAS28 = 5.4(1.1), seropositive) RA patients who received a single cycle of rituximab at 0 months in an open label study. DAS28 improved by mean (SD) 1.7(1.4). Subjects were imaged at 0,3,6,9 & 12 months. Hand bones were segmented using SSMs; resulting bone surfaces were used to quantify erosion and oedema (inside bone), synovitis and 3D joint space width (3DJSW, outside bone). RAMRIS scoring was performed by a single experienced reader blinded to time point. Multilevel linear regression analysis was used to model changes over time. Quantitative values were adjusted for differences in scale using total bone area at baseline. Observations were nested within patients; random slopes for time were included. Non-linear changes were modelled with polynomial terms. Likelihood ratio (LR) tests were used to compare nested models. Accuracy of automated segmentation was examined using point-to-surface distance between automated and manually segmented bone surfaces.

Results: Quantitative synovitis decreased over time; the extent of the change varied between patients (Table 1). By contrast, there was no change over time in RAMRIS synovitis. There was no change in quantitative or RAMRIS erosion and no inter-patient variation. In some patients there was evidence of cubic change in quantitative oedema; with relatively rapid change between 0 and 3m. There was no evidence of changes in RAMRIS oedema. There was strong evidence of change over time for 3DJSW (LR test chi-square=22.0, $p<0.001$), though the result was complex, with the most responsive patient showing increase in joint space width, while others showed a decrease. Mean accuracy of automatically generated bone surfaces was 0.2 mm (Table 2); 90th percentile 0.44 mm.

Conclusion: Fully automatic quantitative analysis of RAMRIS measures is now practical, and showed change for synovitis and oedema where RAMRIS did not. 3DJSW is a novel measure that needs careful interpretation as it includes more than one type of change. Quantitative analysis depends upon accurate and automatic identification of all hand bones; these results show excellent accuracy of around 1/3 pixel.

Table 1: Change in quantitative and RAMRIS measures

Quantitative RA MRI feature (ln-transformed)	Synovitis	Erosions	Oedema
Change: per month	−2.70 (−4.82, −0.58), p=0.013	0.07 (−0.99, 1.13), p=0.898	2.79 (−1.19, 6.76), p=0.169
Change: per month squared	n/a	n/a	0.06 (−0.43, 0.55), p=0.810
Change: per month cubed	n/a	n/a	−0.12 (−0.26, 0.01), p=0.073
LR test for change model*	chi-sq=21.9, p<0.001	chi-sq=0.0, p=0.992	chi-sq=19.3, p=0.004
Pseudo-R^2 for time	0.34	0.00	0.43
RAMRIS (sqrt transformed)			
Change: per month	−0.87 (−2.84, 1.11), p=0.388	0.23 (−1.14, 1.59), p=0.746	−0.75 (−2.42, 0.92), p=0.378
LR test for change model*	chi-sq=2.2, p=0.331	chi-sq=8.7, p=0.068	chi-sq=0.78, p=0.679
Pseudo-R^2 for time	0.08	0.00	0.01

chi-sq = Chi-square; ln = natural logarithm; LR = likelihood ratio test; sqrt = square root
* Random slopes model compared to unconditional means model

Table 2: Accuracy of automated search

Bone	Mean point-to-surface distance (mm)	90% point-to-surface distance (mm)
Capitate	0.15	0.33
Hamate	0.14	0.31
Lunate	0.19	0.42
M2_dist	0.22	0.48
M2_prox	0.21	0.50
M3_dist	0.21	0.48
M3_prox	0.18	0.42
M4_dist	0.19	0.41
M4_prox	0.14	0.31
M5_dist	0.17	0.36
M5_prox	0.19	0.46
P2_prox	0.27	0.61
P3_prox	0.24	0.54
P4_prox	0.19	0.42
P5_prox	0.20	0.46
Radius	0.24	0.54
Scaphoid	0.21	0.47
Trapezium	0.18	0.40
Trapezoid	0.14	0.31
Triquetrum	0.18	0.39
Ulna	0.26	0.56
	0.20	0.44

Voxel size was 0.47 × 0.47 × 0.45 mm. Note mean accuracy is typically around 1/3 of a voxel, and 90th percentile is still typically sub-voxel

Efficacy of Tocilizumab in Patients with Rheumatoid Arthritis: Sequential Evaluation Using Whole-Body Magnetic Resonance Imaging. Michihito Kono[1], Shinsuke Yasuda[1], Kazumasa Ohmura[1], Tomoko Fukui[1], Sanae Shimamura[1], Ikuma Nakagawa[1], Atsushi Noguchi[1], Haruki Shida[1], Toshiyuki Watanabe[1], Yuka Shimizu[1], Takashi Kurita[1], Kenji Oku[1], Toshiyuki Bohgaki[1], Olga Amengual[1], Tetsuya Horita[1], Keita Sakamoto[1], Tamotsu Kamishima[2] and Tatsuya Atsumi[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Faculty of Health Science, Sapporo, Japan.

Background/Purpose: Magnetic Resonance Imaging (MRI) has been established as a useful modality to evaluate synovitis, bone edema, and bone erosion in patients with rheumatoid arthritis (RA). Most of previous MRI studies in RA, however, have focused their evaluation only on finger, wrist, or knee joints. In daily clinical practice for RA, we use whole-body MRI technique to validate effect of anti-rheumatic drugs. The purpose of this study was to clarify the efficacy of tocilizumab (TCZ) in patients with RA using this technique.

Methods: A total of 21 consecutive RA patients on TCZ in our department between 2008 and 2014 were included in this retrospective study. Contrast whole-body MRI (1.5T) was performed before and one year after the initiation of TCZ. MR images were assessed by one experienced radiologist without any clinical information. Hand joints were evaluated according to RA MRI score (RAMRIS) and the other joints (atlantoaxial, shoulder, hip, and knee joints) were scored in the modified RAMRIS for this study.

Results: Mean age was 54.7 years old and mean duration of the disease 2.7 years. Of the subjects, 67% were on methotrexate and 24% had a history of other biologics agents. Mean DAS28-ESR at baseline was 5.04. After one year, clinical remission was obtained in 76%, 57% and 57% by DAS28-ESR, CDAI and SDAI, respectively. TCZ treatment led to improvement (Figure) in whole-body synovitis score ($p < 0.01$, paired t-test) from baseline (mean ± S.D; 32.6 ± 15.2) to one year (22.2 ± 11.0), as well as in whole-body bone edema score ($p < 0.01$, Wilcoxon signed-rank test) from baseline (median [range]; 11 [1–45]) to one year (3 [0–15]). Whole-body MRI-bone-erosion-score was improved in six patients and deteriorated in 11 patients. Whole-body synovitis score ($p = 0.03$, t-test) was identified as one of the poor prognostic factors for development of whole-body MRI-bone-erosion. Changes in RAMRIS synovitis score of hands did not correlate with those in modified RAMRIS synovitis score of other joints in whole-body MRI ($r = 0.34$, $p = 0.13$), as in the cases of bone edema score ($r = 0.01$, $p = 0.96$) and of MRI-bone-erosion-score ($r = -0.13$, $p = 0.57$).

Conclusion: TCZ exhibited significant efficacy and improvement in synovitis and bone edema. Changes in synovitis, bone edema, or erosion detected by hand MRI did not correlate with those of other joints in whole-body MRI. Whole-body MRI may be a potent tool to evaluate the inflammation and structural damage of the joints in RA independent of traditional hand MRI.

Dynamic Magnetic Resonance Imaging in the Assessment of the Response to Certolizumab Pegol in Rheumatoid Arthritis Patients: Results from a Phase IIIb Randomized Study. Mikkel Østergaard[1], Mette Bjørndal Axelsen[1], Lennart T.H. Jacobsson[2], Christopher Schaufelberger[2], Michael Sejer Hansen[3], Johannes W.J. Bijlsma[4], Anna Dudek[5], Maria Rell-Bakalarska[6], Fabienne Staelens[7], Robert Haake[8], Britt Sundman-Engberg[9] and Henning Bliddal[10]. [1]Copenhagen Center for Arthritis Research, Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [2]Department of Rheumatology and Inflammation Research, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Department of Rheumatology, Gentofte Hospital, Copenhagen, Denmark, [4]University Medical Center Utrecht, Utrecht, Netherlands, [5]Medica Pro Familia, Warsaw, Poland, [6]Rheuma Medicus, Warsaw, Poland, [7]UCB Pharma, Brussels, Belgium, [8]UCB Pharma, Raleigh, NC, [9]UCB Pharma, Stockholm, Sweden, [10]The Parker Institute, Department of Rheumatology, Frederiksberg, Denmark.

Background/Purpose: Magnetic resonance imaging (MRI) can detect early joint inflammation with high sensitivity, without use of radiation. The MARVELOUS study (NCT01235598), using the OMERACT RA MRI scoring system (RAMRIS), previously established 16 weeks (wks) as the earliest time point at which certolizumab pegol (CZP) had a statistically significant reduction on synovitis and bone edema.[1] To further evaluate efficacy of CZP on synovitis, dynamic contrast-enhanced MRI (DCE-MRI) parameters were examined on proximal interphalangeal (PIP) joints 2–5 (PIP 2–5), metacarpophalangeal (MCP) joints 2–5 (MCP 2–5), and PIP 2–5 and MCP 2–5 joints combined (PIP+MCP 2–5).

Methods: A total of 41 patients (pts) with active RA despite DMARD therapy and ≤1 biological therapy were randomized 2:1 to CZP, or 2 wks placebo followed by CZP (PBO-CZP). 40 were treated (27 CZP, 13 PBO-CZP), 36 completed Wk16 (24 CZP, 12 PBO-CZP). The approved CZP dose was administered: CZP loading dose 400mg every 2 wks (Q2W) Wks 0–4 for CZP pts or Wks 2–6 for PBO-CZP, followed by CZP 200mg Q2W to Wk16. The DCE-MRI parameters Initial Rate of Enhancement (IRE), Maximum Enhancement (ME; % increase compared to pre-contrast) and Number of voxels with Plateau and Washout Pattern (Nvox) were used to quantify contrast-enhanced MRIs. Data were analyzed using Dynamika software (Image Analysis, UK) by an experienced reader blinded to time, pt identity and treatment group who manually performed precise outlining of regions of interest at each joint for all 6 acquired time points (Wks 0, 1, 2, 4, 8, 16). Each DCE-MRI parameter was analyzed for PIP 2–5, MCP 2–5, and PIP+MCP 2–5. Intrareader variability (intraclass correlation coefficients [ICCs]) was assessed.

Results: There were statistically significant changes from baseline at Wk16 in the CZP group for PIP 2–5 in median IRE (−0.009; p=0.024) and median ME (−0.33; p=0.021), and for MCP 2–5 and PIP+MCP 2–5 in median Nvox (−235.0; p=0.025 and -421.5; p=0.015, respectively). Changes at Wk8 were not statistically significant, precluding earlier timepoint testing (Table 1). For PBO-CZP vs CZP comparisons at Wks 1 and 2, 3 of the 9 (ME for MCP 2–5 and PIP+MCP 2–5, Nvox for MCP 2–5) had nominal p-values <0.05 at Wk1. However, no nominal p-values were <0.05 at Wk2. The complete set of results is displayed in Table 2. All parameters had very good intrareader reliability (ICC>0.90).

Conclusion: Statistically significant improvements in dynamic MRI variables were observed at Wk16 following initiation of CZP therapy, despite small sample size. Dynamic MRI results were consistent with primary analysis (RAMRIS scoring).[1] Thus, both conventional MRI RAMRIS and DCE-MRI criteria confirmed efficacy of CZP in reducing joint inflammation in RA pts.

Effects of Tofacitinib on Bone Marrow Edema, Synovitis, and Erosive Damage in Methotrexate-Naïve Patients with Early Active Rheumatoid Arthritis (Duration ≤2 Years): Results of an Exploratory Phase 2 MRI Study.

Philip G. Conaghan[1], M. Østergaard[2], C. Wu[3], D. van der Heijde[4], F. Irazoque-Palazuelos[5], P. Hrycaj[6], Z. Xie[7], R. Zhang[7], B.T. Wyman[7], J.D. Bradley[7], K. Soma[7] and B. Wilkinson[7]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds, United Kingdom, [2]Copenhagen Center for Arthritis Research, Glostrup, Denmark, [3]BioClinca Inc., Newark, CA, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Servicio de Reumatología, Hospital Angeles Mocel, Mexico City, Mexico, [6]Poznan University of Medical Sciences, Poznan, Poland, [7]Pfizer Inc, Groton, CT.

Background/Purpose: Inflammation of the synovium and in particular the bone marrow, as assessed by magnetic resonance imaging (MRI), have been identified as prognostic indicators of structural joint damage in patients (pts) with rheumatoid arthritis (RA).[1] Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of RA. Inhibition of structural damage has been shown using conventional radiography in pts receiving tofacitinib for moderate to severe RA.[2] Here we explore the effects of tofacitinib, with or without methotrexate (MTX), on tissue inflammation and progression of structural damage in early RA using highly-sensitive MRI endpoints.

Methods: This was an exploratory, Phase 2, randomized, double-blind, parallel group, multicenter study (NCT01164579) in MTX-naïve adult pts with early active RA (duration ≤2 years) and evidence of clinical synovitis in an index wrist or metacarpophalangeal (MCP) joint. Pts were randomized 1:1:1 to receive tofacitinib 10 mg twice daily (BID) + MTX, tofacitinib 10 mg BID + placebo (PBO), or MTX + PBO, for 1 year. MTX was titrated, if tolerated, from 10 mg once weekly for the first month to 20 mg weekly by Month 2. Change in synovitis, bone marrow edema (BME), and erosions were assessed in the wrist and MCP joints using OMERACT RAMRIS. Co-primary endpoints: change from baseline (BL) in synovitis at Month (M) 3, and change from BL in BME at M6. Evaluable pts were assessed using a mixed effect model for repeated measures to evaluate endpoints (statistical significance at 10% [2-sided] level). Scoring was performed by one centralized reader blinded to time point and treatment.

Results: Of 109 pts randomized and treated (Table 1), most were female and Caucasian. Disease duration was consistent with early RA (Table 1). Mean age, disease activity, and RAMRIS were similar across treatment groups at BL (Table 1). More pts from the tofacitinib + MTX and tofacitinib + PBO groups completed the study (n=28, n=27, respectively) vs the MTX + PBO group (n=21). Synovitis improvements were observed in all groups; while improvements were numerically greater in both tofacitinib groups vs MTX + PBO, statistically significant differences were not consistently observed across assessment time points. Mean BME improvements were statistically greater in both tofacitinib groups vs MTX + PBO at M6 (primary), M3 and M12. Significantly less erosive damage was seen in both tofacitinib groups vs MTX + PBO at M6 and M12.

Conclusion: These results provide evidence of a reduction in tissue inflammation using assessments identified as positive prognostic factors for radiographic joint damage. The greater magnitude of improvement in BME and inhibition of erosive damage measured by MRI is consistent with the established effect of tofacitinib on inhibiting radiographic structural damage.

Do Patients with Active RA Also Have Inflamed Atherosclerotic Plaques on PET-MRI? Sarah Skeoch[1], Heather Williams[1], Penny Cristanacce[1], Jacqueline James[2], Paul Hockings[3], Yvonne Alexander[4], John Waterton[1] and Ian N. Bruce[5]. [1]University of Manchester, Manchester, United Kingdom, [2]Central Manchester University Hospitals Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Chalmers University of Technology, Gottenburg, Sweden, [4]Manchester Metropolitan University, Manchester, United Kingdom, [5]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Inflammation plays a key role in the progression and destabilisation of atherosclerotic plaque in the general population. In RA, inflammation is thought to accelerate atherosclerosis and may lead to a more unstable plaque phenotype. ^{18F}-Fludeoxyglucose PET-CT (FDG-PET-CT) is a nuclear imaging technique which can be used to quantify carotid plaque inflammation. Histology studies have shown that FDG-uptake correlates with macrophage content of plaque and it has been used to identify vulnerable lesions and evaluate the effects of statins. We hypothesised that patients with active arthritis would have carotid plaque inflammation on FDG-PET and that plaque inflammation would correlate with the degree of disease activity using the DAS-28 score.

Methods: Patients with active arthritis (DAS-28>3.2), who had evidence of carotid plaque on ultrasound, were invited to have MRI then an FDG-PET-CT scan of the carotid arteries. Those on statins, or those with a history of cancer or recent infection, were excluded.

Following MRI scans performed on a 3 Tesla scanner, patients subsequently attended for a PET-CT within 2 weeks. FDG tracer was injected after a 6 hour fast. The scan was performed 2 hours after injection. Patients were positioned in a specialist head support to mimic MRI position. Mandible to sternal notch distance was also measured to ensure similar positioning during the 2 scans.

T1-weighted sequences from the MRI and PET-CT images were co-registered, then a region of interest (ROI) was drawn round the plaque. FDG uptake in the ROI was measured by a physicist, blinded to clinical information. The tissue activity was divided by the injected activity per kilo to give a maximum standardised uptake value (SUV^{max}). Descriptive and non-parametric statistical analyses were performed.

Results: 12 patients underwent MRI and FDG-PET-CT, 8 of whom were female. The median (IQR) age and disease duration was 59.5 (56.5, 64.5) and 11 (5.5, 25) years, respectively. The median DAS-28 score was 4.52 (4.32, 5.13) and 10 patients were rheumatoid factor and/or ACPA positive. No patients had a history of arterial disease, 2 had hypertension, 1 had dyslipidaemia and 2 were smokers.

The median plaque thickness was 2.5 (2.3, 2.8) mm and all had less than 70% stenosis. All subjects had plaque inflammation on PET-MRI, median (range) SUV^{max} was 2.14 (1.46, 6.11). An example of a PET-MRI can be seen in figure 1. There was no significant correlation with SUV^{max} and DAS28 or erythrocyte sedimentation rate ($r=0.126$, $p=0.70$ and $r=-0.15$, $p=0.63$ respectively).

Conclusion: Plaque inflammation was demonstrated in all subjects, despite the cohort having no history of cardiovascular disease and relatively small lesions. Larger longitudinal studies are required to further investigate the relationship between disease activity and plaque inflammation and to study the effects of inflammation on plaque progression.

Validation of the Omeract Psoriatic Arthritis Magnetic Resonance Imaging Score for the Hand and Foot in a Randomized Placebo-Controlled Trial. Daniel Malm[1], P. Bird[2], Frédérique Gandjbakhch[3], Philip Mease[4], Pernille Bøyesen[5], Mikkel Østergaard[6], Charles G. Peterfy[7] and Philip G. Conaghan[8]. [1]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [2]Combined Rheumatology Practice, Sydney, Australia, [3]Groupe Hospitalier Pitie Salpetriere, Paris, France, [4]Swedish Medical Center and University of Washington, Seattle, WA, [5]Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [6]Copenhagen Center for Arthritis Research, Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [7]Spire Sciences LLC, Boca Raton, FL, [8]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds, United Kingdom.

Background/Purpose: The joint involvement in psoriatic arthritis (PsA) is heterogeneous, and inflammation is seen in both axial and peripheral joints, including the small joints of the hands and feet. The quickly evolving treatment options increase the requirements for developing efficient measures for assessing the treatment response. MRI can visualize the inflammatory components of PsA as well as features reflecting bone damage. The objective of this randomized controlled trial (RCT) was to assess the course during treatment, reliability and responsiveness to change of the Psoriatic Arthritis Magnetic Resonance Imaging Score (PsAMRIS) in hand and foot.

Methods: Forty PsA patients randomized to either placebo or abatacept in an RCT had MRI of either a single hand (n=20; all MCP, PIP and DIP joints) or foot (n=20; all MTP joints and the 1st interphalangeal joint) at baseline and after 6 months. Axial, T1-weighted, pre-contrast images, axial and coronal 3D post-contrast fat suppressed images, coronal and sagittal fat suppressed T2-weighted images and coronal short-tau inversion recovery (STIR) images were acquired. Images were scored blindedly, twice, by 3 readers according to the OMERACT PsAMRIS (synovitis, tenosynovitis, periarticular inflammation, bone oedema, bone erosion and bone proliferation). Change over time was assessed using Wilcoxon signed-rank test. Smallest detectable change (SDC) and intraclass correlation coefficient (ICC) were used for assessment of intrareader (single measure; SmICC) and interreader (average measure; AvmICC) reliability.

Results: Inflammatory features improved numerically but non-significantly in the abatacept group but not the placebo group (table 1). Baseline intrareader intraclass correlation coefficients (ICC) for all features were good (≥0.50) to very good (≥0.80) for all or some readers in hand and

foot. Baseline interreader ICC was good (ICC 0.72–0.96) for all features, except periarticular inflammation and bone proliferation in the hand and tenosynovitis in the foot (ICC 0.25–0.44). Intra- and interreader ICC for change scores varied. SDC was overall low (table 2). Guyatt's responsiveness index (GRI) was high for inflammatory features in the hand and metatarsophalangeal joints of the foot (GRI 0.67–3.13) (bone oedema not calculable). Minimal change and low prevalence may explain low ICC and GRI for bone damage.

Conclusion: PsAMRIS showed overall good intrareader agreement in the hand and foot and the inflammatory features were responsive to change, suggesting that PsAMRIS is a valid tool for MRI assessment of hands and feet in PsA clinical trials.

Table 1

	Total scores, mean (range)			
HAND	**Placebo**		**Abatacept**	
PsAMRIS features (Range of total score)	**Baseline**	**Change**	**Baseline**	**Change**
Synovitis (0–42)	7.2 (6.0 to 9.1)	−0.2 (−0.2 to −0.2)	7.1 (5.6 to 9.1)	−1.3 (−3.1 to 0.0)
Flexor tenosynovitis (0–42)	3.1 (2.1 to 4.8)	0.1 (−0.4 to 0.6)	3.7 (2.8 to 4.2)	−1.4 (−2.2 to −0.5)

Subclinical Inflammation in Psoriatic Patients with No History of Psoriatic Arthritis: An Assessment By Magnetic Resonance Imaging. David Simon[1], Francesca Faustini[1], Matthias Englbrecht[1], Arnd Kleyer[1], Roland Kocijan[2], Judith Haschka[1], Sebastian Kraus[1], Axel J. Hueber[1], Michael Sticherling[1], Georg Schett[1] and Jürgen Rech[1]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]St. Vincent Hospital, Vienna, Austria.

Background/Purpose: Six to 39% of patients with cutaneous psoriasis (PSO) can develop psoriatic arthritis (PsA). The transition from skin disease to joint involvement is only partially characterized. Advanced imaging can depict signs of subclinical joint involvement. The present study analyzes the prevalence of hand-MRI signs of inflammation in PSO patients without clinical history of synovitis, dactylitis and enthesitis and no positive CASPAR criteria at any time, but evidence of bone proliferative changes on high resolution peripheral computed tomography (HR-pQCT) of the dominant hand.

Methods: PSO patients underwent HR-pQCT (Scanco Medical, Switzerland) and 1.5T MRI (Siemens, Germany) of the dominant hand. HR-pQCT focused on the metacarpophalangeal (MCP) joints 2 and 3. Imaging analysis searched for erosions and new bone formation (bony spurs) with a periarticular location. MRI of the whole hand was conducted to detect osteitis, synovitis, tenosynovitis of the flexor tendon, periarticular inflammation at the MCP, PIP and DIP regions of the 2nd to 5th finger, according to the definitions of key pathologies provided for the PsAMRIS scoring system. Patients participated after signing informed consent. The study was conducted upon approval by the local ethic committee and the National Radiation Safety Agency (BfS).

Results: Images were acquired from 55 PSO patients (36.4% female) of mean age 49.5±11.5 y, mean disease duration 15.2±15.4 y and mean PASI score of 6.2±8.0. The most prevalent subtype was psoriasis vulgaris (73%), while nail psoriasis was present in 51 % and scalp involvement in 29%. On HR-pQCT erosions were found in 29% of patients, while all showed new bone formation. On MRI, 26 patients (47%) showed at list one of the mentioned signs of MRI detectable inflammation. In detail, osteitis was found in 6 patients (11%), while synovitis in 21 (38%); tenosynovitis and periarticular inflammation were detected each in 2 patients (4%). In the total sample, partial correlations (controlling for the influence of age and disease duration) between periarticular bone changes observed on HRp-QCT and osteitis as well as synovitis on MRI did not show any significant relations.

Conclusion: MRI signs of inflammation can be found in patients with cutaneous psoriasis without a history of arthritis. No evident relation seems to link these signs to bony changes observed on HR-pQCT. Longitudinal assessment of inflammation might provide deeper insight into the relationship between inflammation and changes in bone microstructure before the onset of clinical signs of arthritis.

Feature of Fatty Deposition in Sacroiliac Joints in Ankylosing Spondylitis Patients Seen By MRI. Zaiying Hu[1], Qing Lv[2], Xiaohong Wang[1], Zetao Liao[3], Zhiming Lin[3] and Jieruo Gu[3]. [1]Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [3]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China.

Background/Purpose: Fatty deposition (FD) is often seen in ankylosing spondylitis (AS) patients in the sacroiliac joints (SIJs). Magnetic Resonance Imaging (MRI) is a useful equipment to detect FD. The feature of FD of AS patients is seldom reported. We planned to investigate the feature of FD in SIJs in AS patients seen by MRI that may help in diagnosing.

Methods: This was a retrospective study. MR images of SIJs of 353 AS patients and 224 non-spondyloarthritis (SpA) patients were read by a radiologist and a rheumatologist without knowing the history of patients. FD were recorded and compared between two groups.

Results: Totally 1154 SIJs were studied and FD were recorded in 611 (52.95%) of them. FD was significantly more often to be seen in AS group than in non-SpA group (71.95% vs. 22.99%, $p<0.01$). There was no difference of positive FD rate between the left SIJs and the right SIJs either in AS group (left vs. right = 70.82% vs. 73.9%, $p>0.05$) or non-SpA group (24.11% vs. 21.88%, $p>0.05$). FD was more frequently seen in the upper half than the lower half SIJs in AS group (79.89% vs. 64.02%, $p<0.01$). The ilium bones were with more FD than the sacrum bones in AS group (83.85% vs. 60.06%, $p<0.01$). The rate of FD was of no difference between the upper and the lower half SIJs or between the ilium and sacrum bones in non-SpA group (both $p>0.05$). In AS group, the rate of FD was of no difference between patients under 25 years old (n=191) and over 45 years old (n=25) (70.68% vs. 76%, p=0.58). In non-SpA group, the rate of FD was significantly higher in patients over 45 years old (n=58) than under 25 years old (n=54) (53.45% vs. 7.41%, $p<0.01$).

Conclusion: Our study found that fatty deposition was much more often to be seen in AS patients than non-SpA subjects. FD appeared more in the upper half and ilium bones and did not depend much on age in AS patients.

1186

Prevalence of MRI Spinal Lesions Typical for Axial Spondyloarthritis in Patients with Inflammatory Back Pain. Manouk de Hooge[1], Jean-Baptiste Pialat[2], Antoine Feydy[3], Monique Reijnierse[1], Pascal Claudepierre[4], Alain Saraux[5], Maxime Dougados[3] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Hôpital Edouard Herriot, Lyon, France, [3]Descartes University, Cochin Hospital, Paris, France, [4]Henri Mondor Teaching Hospital, Creteil, France, [5]CHU de la Cavale Blanche, Brest Cedex, France.

Background/Purpose: A cut-off value of ≥3 inflammatory lesions was suggested by the ASAS/OMERACT group, as positive MRI of the spine (MRI-spine). Moreover, fatty lesions on MRI-spine are associated with axial Spondyloarthritis (axSpA). In this study the aim was to determine the prevalence of inflammatory (BME) and fatty lesions on MRI-spine in patients (pts) with and without axSpA.

Methods: Pts aged 18–50 with inflammatory back pain (≥3 months, [2]3 years) from 25 participating centers in France were included in the DESIR-cohort (n=708). All available baseline MRIs were independently scored by 2 well-calibrated readers, blinded to any other data. In case of disagreement, an experienced radiologist served as adjudicator. BME and fatty lesions typical for axSpA were scored when visible on ≥2 consecutive slices. Prevalence of MRI lesions was calculated based on several cut-offs and lesions were considered present if 2/3 readers agreed.

Results: All pts with symptom onset <45 yrs with MRI-spine (n=549) were included in the analyses. Pts fulfilling the ASAS criteria could either fulfill both arms, only the imaging arm or only the clinical arm. The first 2 groups were subdivided; pts with radiographic sacroiliitis (mNY+) & sacroiliitis on MRI (MRI+), pts with mNY+ & no sacroiliitis on MRI (MRI-), pts without radiographic sacroiliitis (mNY-) & MRI+. BME lesions occur in all different subgroups of the ASAS criteria and in pts without axSpA (table). The prevalence in no SpA group (which can be seen as false positives) is only 6.1%. With a cut-off ≥2 BME lesions false positives drop below 5% while the prevalence in the ASAS axSpA groups is still reasonable. Especially prevalence in pts with mNY+ & MRI+ is very high; 61.9% (both arms positive) and 43.8% (imaging arm only positive). Fatty lesions are seen slightly less often seen in all patient groups. However the same trend is seen as with BME lesions; Even with cut-off ≥1 the prevalence in no SpA group is low (5.5%), with cut-off ≥2 false positives drop below 5% and again pts with mNY+ & MRI+ have the highest percentage of spinal fatty lesions.

Conclusion: In a low percentage of pts without axSpA BME and fatty lesions is found indicating that spinal BME and fatty lesions are specific for patients with axSpA. These lesions are especially prevalent in pts with sacroiliitis on imaging. In this cohort, a cut-off ≥2 or ≥3 BME lesions and similarly ≥2 or ≥3 fatty lesions discriminate best between pts with and without axSpA.

	ASAS axSpA							
	Both arms positive:			Imaging arm only positive:			Clinical arm positive	No SpA

1187

Scoring of Spinal Lesions Compatible with Axial Spondyloarthritis on MRI in Clinical Practice By Local Radiologist or Rheumatologist in Desir; Comparison with Central Reading. Manouk de Hooge[1], Jean-Baptiste Pialat[2], Monique Reijnierse[1], Désirée van der Heijde[1], Pascal Claudepierre[3], Alain Saraux[4], Maxime Dougados[5] and Antoine Feydy[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Hôpital Edouard Herriot, Lyon, France, [3]Henri Mondor Teaching Hospital, Creteil, France, [4]CHU Brest and EA 2216, UBO, Brest, France, [5]Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: In clinical practice radiologists and rheumatologists assess whether lesions compatible with axial SpondyloArthritis (axSpA) are present on spinal MRI. The objective was to compare the results of local readings (LocR) to centralized reading (CentR) as external standard of BME and structural lesions on MRI-spine, in patients (pts) with inflammatory back pain (IBP).

Methods: Pts aged 18–50 with recent IBP (≥3 months, [2]3 years) from 25 participating centers in France were included in the DESIR-cohort (n=708). All available baseline MRIs-spine were scored on BME and structural lesions as present, absent or doubtful by the local radiologist/rheumatologist who might have access to clinical data. In addition, 2 well-calibrated centralized readers independently scored the same MRIs for BME lesions and structural lesions (fatty lesions, erosions and (bridging) syndesmophytes). In case the centralized readers disagreed, an experienced radiologist served as adjudicator. Agreement between CentR and LocR was calculated excluding the cases assessed as doubtful by LocR (kappa κ).

Results: BME/structural lesions were in 492/492 pts scored by a radiologist, 206/205 by a rheumatologist and in 32/32 pts by both. The k agreement between LocR and CentR was 0.27 for BME lesions and 0.13 for structural lesions. For radiologists, $\kappa=0.36$ for BME, and $\kappa=0.15$ for structural lesions. For rheumatologists $\kappa=0.006$ for BME and $\kappa=0.12$ for structural lesions.

Overall, local specialists are highly overrating positive findings: 42.3% and 85.7% of the positive MRIs for BME are scored negative by the central read (radiologists and rheumatologist respectively). Similarly findings for structural lesions: 48.4% and 70% of MRIs positive for structural lesions are scored normal by central reading.

Conclusion: Both local radiologists, but especially rheumatologists overrate the presence of BME lesions and structural lesions on MRI of the spine compared to trained central readers. These results do not even take doubtful cases into account.

BME lesions		LocR (rheumatologist)		
		Positive	Negative	Doubt
CentR	Positive	4	20	21
	Negative	24	126	11
		LocR (radiologist)		
		Positive	Negative	Doubt
	Positive	30	29	58
	Negative	41	304	30

Structural lesions		LocR (rheumatologist)		
		Positive	Negative	Doubt
CentR	Positive	6	26	7
	Negative	14	146	6
		LocR (radiologist)		
		Positive	Negative	Doubt
	Positive	16	87	21
	Negative	15	338	15

1188

Reproducibility of Magnetic Resonance Imaging Diffusion Weighted Imaging in Axial Spondyloarthritis Patients and Healthy Subjects. Jakob M. Møller[1], Inge Juul Sorensen[2], Mikkel Ostergaard[3], Henrik Thomsen[1], Ole Rintek Madsen[4] and Susanne Juhl Pedersen[3]. [1]Department of Radiology, Copenhagen University Hospital Herlev, Copenhagen, Denmark, [2]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [3]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [4]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark.

Background/Purpose: Diffusion weighted imaging (DWI) is a magnetic resonance imaging (MRI) technique where the image contrast is dependent on the diffusion of the extracellular free water molecules. DWI is widely used in oncology imaging, but only few papers address DWI in spondyloarthritis (SpA). From DWI the apparent diffusion coefficient (ADC) can be calculated and hence the diffusion in a region of interest (ROI) can be quantified. The water diffusion reflects the cellularity and thus it may be used as a quantification of inflammatory cells. The aim of the study was to measure the reproducibility of DWI in SpA patients and healthy subjects.

Methods: 25 SpA patients (13 females, mean age 36.1 years (SD 9.6); 12 males, mean age 42.3 (SD10.8) and 24 healthy subjects (13 females, mean age 42.7 (SD 13.2); 11 males, mean age 45.3 (SD 7.5)) were MRI examined at 1.5T two times with a mean interval of 6.8 days (SD 0.9). A 5mm (gap 1.2mm) sagittal single-shot echo-planar imaging DW sequence with four b values (0;50;500;800) and a resolution of 2mm × 1.65mm was performed on Th6 to L5. ADC maps were calculated based on all b values. The MRIs were anonymized and read in random order without information on time point and clinical data. On ADC maps 50mm^2 circular ROIs were placed in each vertebral corner just inside cortex. ADC was measured on the sagittal slice in the middle of the spine and on the adjacent slice to the right and left to the middle. ADCs from the four ROIs were pooled. Another ROI was placed in the right and left pedicle and in the spinous process from L1 to L5. The inter-reader variability was measured by intra-class correlation coefficient (ICC). Intra-reader variability was measured by a second reading of the examinations at time point (TP) 2.

Results: Overall ICC of the vertebral bodies between TP1 and TP2 was 0.80 (95% CI: 0.77–0.83). At TP1, ICC between the right and middle slice was 0.89 (95% CI: 0.87–0.90) and between left and middle slice 0.89 (95% CI: 0.87–0.90). Intra-reader reliability was 0.94 (95% CI: 0.93–0.95). For the right pedicle ICC was 0.44 (95% CI: 0.33–0.54), for the left pedicle 0.49 (95% CI: 0.39–0.58), for the spinous processes 0.20 (95% CI: 0.07–0.32). Table 1 provides ICCs for each vertebral body.

Table 1. Inter-reader and intra-reader ICCs for each vertebral body.

	Inter-reader Reliability	Intra-reader Reliability		Inter-reader Reliability	Intra-reader Reliability
T6	0.64 (0.39–0.80)	0.83 (0.70–0.90)	T12	0.76 (0.60–0.86)	0.96 (0.93–0.98)
T7	0.58 (0.33–0.75)	0.92 (0.86–0.96)	L1	0.85 (0.75–0.91)	0.97 (0.94–0.98)
T8	0.39 (0.11–0.62)	0.75 (0.59–0.85)	L2	0.91 (0.84–0.95)	0.97 (0.95–0.98)
T9	0.57 (0.32–0.75)	0.94 (0.89–0.97)	L3	0.91 (0.84–0.94)	0.99 (0.98–0.99)
T10	0.49 (0.23–0.69)	0.95 (0.91–0.97)	L4	0.81 (0.67–0.89)	0.98 (0.96–0.99)
T11	0.77 (0.55–0.89)	0.98 (0.94–0.99)	L5	0.79 (0.65–0.88)	0.96 (0.93–0.98)

Table 1: ICC (95% CI) measurements per vertebral body.

Conclusion: MR DWI is overall a reproducible imaging sequence performed in the sagittal plane. The reproducibility is better in the lumbar spine compared to lower thoracic spine. Pedicles and spinous proceses are not reliably imaged by DWI.

Conventional Magnetic Resonance Imaging (MR) and Hybrid 18F-Fluoride Positron Emission Tomography MRI (18F-F- PET/MRI) of the Spine and the Sacroiliac Joints – a Detailed Description of Pathologic Signals in Patients with Active Ankylosing Spondylitis. Xenofon Baraliakos[1], Dr. Christian Buchbender[2], Prof. Dr. Benedikt Ostendorf[2], Verena Ruhlmann[3], P. Heusch[4], F. Miese[4], K. Beiderwellen[5], Matthias Schneider[6], G. Antoch[7] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Univ. Duesseldorf, Düsseldorf, Germany, [3]Univ Duisburg-Essen, Medical Faculty, Duisburg, Germany, [4]Univ Duisburg-Essen, Medical Faculty, Essen, Germany, [5]Univ Dusseldorf, Medical Faculty, Duesseldorf, Germany, [6]MNR-Klinik, Düsseldorf, Germany, [7]Univ Dusseldorf, Medical Faculty, Dusseldorf, Germany.

Background/Purpose: PET is a nuclear imaging technique that depicts functional processes within the body based on gamma rays. The biologically active molecule used for PET is the bone-seeking agent ^{18}F labeled Fluoride (^{18}F-F). The concentrations of tracer reflect tissue metabolic activity of regional bone perfusion and bone remodeling. We tested the performance of integrated 18F-Fluoride positron emission tomography and magnetic resonance imaging (PET/MRI) of the whole spine and the sacroiliac joints and compared bone marrow edema (BME) and structural (fat deposition, FD) and metabolic findings (18F-F) in patients with active ankylosing spondylitis (AS).

Methods: 13 AS patients (6 male, 7 female, mean age 37.8±11.4 years, all BASDAI>4, no anti-TNF treatment) underwent a 3-Tesla MRI and integrated PET/MRI 40 minutes after injection of a mean dose 157 MBq of 18F-Fluoride of their whole spine and the SIJs. Two readers scored all images independently and the lesions where both readers showed agreement were considered for analysis. Inflammatory activity (bone marrow edema, BME), structural lesions (fat deposition) and focal 18F-Fluoride uptake were recorded on the level of a vertebral quadrant (VQ) or SIJ-quadrant (SQ), where one VQ and SQ consisted by 4 VQs (superior anterior and posterior and inferior anterior and posterior).

Results: Acquisition of whole-spine 18F-F PET/MRI including the SIJ was successful in all patients. There was excellent agreement in the reading of the two readers. For the SIJ, a total of 104 SQs could be analyzed by MRI and PET/MRI and 44.2% showed BME, while FD 42.3% and 18F-F in 46.2% SQs. BMD without FD was found in 60.9%, the majority with concomitant 18F-F. In comparison, FD alone without BME was found in 59.1% SQs and in those, parallel 18F-F was seen in only 7.7% SQs. The combination of BMD/FD was found in 17.3% SQs and in those, parallel 18F-F uptake was seen 72.2% SQs. For the spine, a total of 1,196 VQs could be analyzed and 9.9% showed BME, while FD was found in 18.2% and 18F-F 5.4% VQs. BME without FD was found in 41.5% and in those, parallel 18F-F was seen in 14.3% VQs. In comparison, FD without BME was found in 68.3% VQs and in those, 18F-F was 8.7% VQs. Finally, the combination BME/FD was found in 5.8% VQs and in those, 18F-F uptake 40.6%. The highest mean SUVmax per lesion was found in both the SIJ (28.1 ±13.5) and the spine (25.7 ±21.1) in in SQs or VQs with a combination of BME and FD.

Conclusion: In this first study on hybrid 18F-F-PET/MRI of active AS patients we show that rather BME than chronic changes is associated with osteoblastic activity. The combination of BME and FD showed the highest 18F-F uptake, confirming our previous finding that this is the strongest predictor of future syndesmophyte formation.

Osteoarthritis-like Changes Are Present in the Tibia and Femur 1 Year Following ACL Reconstruction. Valentina Pedoia[1], Drew A. Lansdown[2], Musa Zaid[1], Charles McCulloch[3], C. Benjamin Ma[2] and Xiaojuan Li[1]. [1]Musculoskeletal Quantitative Imaging Research, UCSF, San Francisco, CA, [2]Department of Orthopedic Surgery, UCSF, San Francisco, CA, [3]Department of Epidemiology and Biostatistics, San Francisco, CA.

Background/Purpose: Statistical Shape Modeling (SSM) is a promising tool that has the ability to characterize complex shapes in a brief feature vector. The application of SSM in 2D imaging is widely used, though 3D MRI application is still a challenge. Injury of the anterior cruciate ligament (ACL) is a high risk factor for developing post-traumatic osteoarthritis (OA). The aim of this study is to analyze the longitudinal shape changes of the tibia and femur in patients with ACL injuries using a novel MR-based SSM algorithm. We hypothesized that distinct shape changes are present one year following ACL injury.

Methods: Bilateral knees were scanned using a 3T MRI scanner (GE Healthcare) for 15 patients (29.3 ± 4.2 yrs, 5 female) with ACL injuries prior to surgical reconstruction, and at 6 and 12 months after reconstruction. 10

controls (30.5 ± 5.2 yrs, 3 female) with no history of knee injuries underwent MR imaging at baseline and 12 months later. The imaging protocol included sagittal T_2 fast spin-echo (FSE) images with TR/TE = 4000/49.3 ms, resolution 0.39×0.39×1.5 mm, slice spacing of 1.5 mm. The SSM is extracted individually from the segmentation of tibia and femur. Each principal component analysis (PCA)'s mode of the model describes a different aspect of the bone shape. Starting from the mean mode's vector we can return to the space domain after the perturbation of a single mode. This method allows for the identification of the specific shape feature that is described in each mode. The first 20 modes were analyzed. The difference in mode values between baseline, 6-month, and 12-month follow-up were compared to the changes in the control knees from baseline to 12 months. Unpaired t-tests were used to compare longitudinal changes in ACL-injured and control knees, with significance set at alpha less than 0.05.

Results: The variation in Mode 10 for the tibia from baseline to 12 months is significantly different between injured (19.46 ± 28.83) patients and controls (−11.68 ± 22.18). The change in Mode 10 in the injured group occurs primarily in the second 6 months, as the variation between 6 and 12 month is 18.17± 33.31, which is significantly different as well. The variation of the same mode in the first 6 months is not significantly different (1.29 ± 22.18). A decrease of this mode is related with an expansion and elevation of the lateral tibial plateau.

The variation in Mode 12 for the femur from baseline to 6 months and 12 months is significantly different between injured patients (6 months: 15.28 ± 28.67, 12 month 21.67 ± 21.86) and controls (−4.85 ± 17.79). The change Mode 12 in the injured group occurs primarily in the first 6 months. A decrease of the mode value is related to a flattening of the lateral femoral condyle, and to an increase of the height in the intercondylar notch.

Conclusion: In this study the longitudinal shape changes in the femur and tibia in ACL patient was analyzed. The observed expansion and elevation of the lateral tibial plateau is similar to previously observed radiographic changes in patients with OA. Significant differences are also observed in the shape of the lateral femoral condyle following ACL injury. This novel methodology may lead to the development of imaging biomarkers for post-traumatic OA.

The Kimriss Bone Marrow Lesion Score in Patients with Osteoarthritis of the Knee Correlates with WOMAC Pain Status Using Target-Lesion Based Scoring Methodology; Data from the Osteoarthritis Initiative. David McDougall, Jacob Jaremko, RG Lambert and Walter P. Maksymowrych. University of Alberta, Edmonton, AB.

Background/Purpose: Inflammatory components of osteoarthritis including bone marrow lesions (BML) may be a target for therapy. Limited literature quantifies the relation of these markers on MRI with respect to pain and dysfunction in hip osteoarthritis. We sought to correlate the extent of BML using a validated scoring methodology, the Knee Inflammation MRI Scoring System (KIMRISS), with a validated pain score, WOMAC, in patients with hip osteoarthritis. In KIMRISS a score of 0 (no BML) or 1 (BML present) is assigned to each region of bone in each slice using a customized grid overlay with regions each approximately 1 cm × 1 cm in size; a higher KIMRISS BML sum score directly represents a larger volume of BML.

Methods: Data for these analyses are from the OAI public use data set(s). MRI scans at enrolment and 1 year follow-up were evaluated in 80 patients for BML score by two readers using KIMRISS methodology. The WOMAC pain score was available for each patient at the same time points. We assessed association of BML status and change scores with WOMAC pain status and change scores using correlation (Pearson chi square) and by multivariate regression adjusted for age, sex, Kellgren-Lawrence grade, and baseline scores for WOMAC pain.

Results: The volume of BML correlated highly with both WOMAC pain score (chi-square 0.86 $p < 0.0001$) and change in WOMAC pain score between enrolment and 1 year (chi-square 0.84 $p < 0.0001$)

Conclusion: KIMRISS BML score correlates highly with pain in patients with hip osteoarthritis, and was highly responsive to change. KIMRISS offers an alternative approach for scoring bone marrow lesions in knee osteoarthritis that is designed to be easily learned and can potentially be automated in future.

Erosions Detected By Magnet Resonance Imaging in Patients with Juvenile Idiopathic Arthritis (JIA) Are True Erosions As Visualized By Computed Tomography. Stephanie Finzel[1], Georg A. Schett[1] and Nikolay Tzaribachev[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Pediatric Rheumatology, Bad Bramstedt, Germany.

Background/Purpose: Chronic arthritis occurs relatively frequent in childhood. Patients with polyarticular disease might have a destructive disease course and thus a worse outcome. In adult rheumatology MRI is known to detect erosions in early stages. In children little is known about changes in bone structure during the course of JIA and thus erosions detected by MRI are discussed controversially. (1–3)

To test, whether MRI erosions in patients with chronic arthritis are true erosions as detected by conventional computed tomography (CT).

Methods: Six children (all female) with a median age of 14 years, 4 with polyarthritis, 1 – psoriatic arthritis and 1 with systemic sclerosis were identified as having both MRI and CT of the same wrist during retrospective chart review. The median disease duration was 4 years. All patients with treated with sq methotrexate and NSAR.

A descriptive statistical approach was chosen due to the relatively low number of patients.

Results: Overall 55 surfaces were evaluated both in MRI and CT; in MRI 9 erosions were detected by MRI and 19 by CT. In MRI erosions were localized in the Os capitatum and hamatum, whereas in CT erosions were found in all carpal bones despite the scaphoid as well as in the 2nd through 4th proximal metacarpal bone. Of the 9 erosions detected in MRI, 5 were confirmed as being true bone erosions in CT and 4 MRI erosions were detected as vessel channels in CT. Widths in MRI varied from 1.50–3.50mm, and depths from 2.00–4.00mm. In CT widths ranged from 0.57–3.07mm, and depths from 0.95–3.24mm. Due to contrast agent artifacts, no physiological vessel channels could be detected, whereas in CT 254 vessel channels were found. Visualization of os pisiforme was difficult in MRI because of soft tissue and signal of immature bone.

Conclusion: Erosions in the bone of patients with chronic arthritis vizualised by MRI relate to pathological cortical defects as detected by conventional CT. Our findings suggest that these pathological CT-alterations represent either premature or manifest bone erosions identical to those in adult bone. Given the irradiation dose of conventional CT, future imaging studies are needed in order to evaluate the significance of novel CT-techniques with lower irradiation load such as HR-pQCT for use in juvenile chronic arthritis.

Diagnostic value of Contrast-Enhanced MR-Angiography in diagnosing large Vessel Vasculitis. Sabine Adler, Marco Sprecher, Harald Bonel, Thorsten Klink and Peter M. Villirger. University Hospital Bern, Bern, Switzerland.

Background/Purpose: Diagnosis of large-vessel vasculitis (LVV) remains difficult despite clinical and serological signs and symptoms. Detection by histology might be unavailable in exclusive thoracic or abdominal involvement. PET-scans rarely are ready to be used in every-day practice and CT-scans might miss vascular affections. The value of easily accessible, contrast-enhanced MR-angiographies has only rarely been described.

Methods: Between 2005 and 2012 we investigated 76 patients (44 females, 32 males, aged 18–82 years, mean age 64.5 years) with clinical and serological suspicion of LVV by contrast-enhanced MR-angiography (MRA). Gadolinium was used as contrast-medium. Twenty-nine patients underwent both thoracic and abdominal MRA, 32 patients had thoracic and 15 patients abdominal MRA only. Additional histologies of the temporal arteries were performed in 22 patients. MRAs were independently reviewed by two radiologists. Correlations were measured for clinical, serological, histological and radiological parameters.

Results: LVV was diagnosed by MRA in 20/76 patients with 13/20 being abdominal and 7/20 thoracical vasculitides. Out of those, nine patients showed both thoracical and abominal LVV. Interobserver agreement regarding LVV correlated in all but one patient. Diagnoses other than LVV were fibrosis in 36/76 patients, vascular stenosis in 2/76 and arterial dissection in another 2/76 patients. The remaining 10/76 patients showed no vascular abnormalities. In 7/22 biopsied patients, histology was positive for temporal arteritis; 2 out of those 7 patients had additional LVV. Neither erythrocyte

sedimentation rate (ESR) nor C-reactive protein (CRP) showed significant differences regarding patients with or without LVV.

Conclusion: Occult LVV can be detected by MRA despite negative serological and/or histological parameters. MRA enables distinguished diagnosis and therefore initiation of tailored immunosuppression in LVV and allows for follow-up investigations in order to control therapeutic success.

Cofilin-1 Is a ROS Sensor in Regulating the NLRP3 Inflammasome. Yong Hwan Park, Daniel L. Kastner and Jae Jin Crhae. National Human Genome Research Institute, Bethesda, MD.

Background/Purpose: NLRP3 (NOD-like receptor family, pyrin domain containing 3) has a pivotal role in nucleating inflammasome, cytoplasmic multiprotein complexes that mediate the maturation of the proinflammatory cytokines interleukin-1β (IL-1b) by activating caspase-1. Mutations in the gene encoding NLRP3 cause a series of autoinflammatory disease, cryopyrin-associated periodic syndromes (CAPS). It has been reported that generation of reactive oxygen species (ROS) is one of the major NLRP3 inflammasome activating factor. However, the molecular mechanism of relationship between change of cellular redox state and NLRP3 inflammasome activation has not been elucidated. Here we show that cofilin-1, a redox sensitive actin binding protein, is involved in NLRP3 inflammasome activation.

Methods: Mouse bone marrow derived macrophages (BMDMs) were obtained by differentiating bone marrow progenitors from tibial and femoral bone with M-CSF for 7 days. Inflammasome activation experiments were performed in two stages, initial LPS priming for 3 h and then inflammasome activation for 30 to 50 min by replacing the medium with RPMI 1640 medium supplemented with activators (ATP or nigericin). Inflammasome activation was analyzed by Western blotting of secreted interleukin-1b (IL-1b). The lysates from BMDMs or PT67 cells transiently transfected with expression constructs for the wild-type (WT) or various deleted forms of NLRP3 were immunoprecipitated with anti-cofilin-1 antibody.

Results: When the NLRP3 inflammasome is activated, not only activated IL-1b but also inflammasome components, such as ASC and caspase-1 are secreted. We found that cofilin-1 is also secreted along with IL-1b from the LPS-primed BMDMs when the cells are treated with ATP, a NLRP3 inflammasome activator. In addition, knockdown of *cofilin-1* reduces inflammasome activation in response to ATP, which suggests that cofilin-1 has an important role for the activation of the NLRP3 inflammasome. Cofilin-1 directly interacts to the nucleotide-binding domain (NBD) of NLRP3 protein. However, when the cells are stimulated with the NLRP3 inflammasome activators, ATP or nigericin, cofilin-1 is oxidized and dissociated from NLRP3. Indeed, the interaction of cofilin-1 with NLRP3 is increased significantly when the oxidation sites of cofilin-1 are substituted from cysteine to alanine. Finally, we found that NLRP3 inflammasome activation is attenuated when WT cofilin-1 is replaced with the oxidation-resistant mutant cofilin-1.

Conclusion: Taken together, these results suggest that cofilin-1 is a key component in regulating the activation of the NLRP3 inflammasome in response to ROS. Furthermore, since cofilin-1 is an actin binding protein that depolymerizes and severs actin filaments, and is able to translocate into mitochondria during oxidative stress condition, our finding about the interaction of cofilin-1 with NLRP3 provides an important molecular mechanism for the mitochondrial localization of the NLRP3 inflammasome.

Activation of the nlrp3 Inflammasome By an Endogenous TLR2 Ligand in Rheumatoid Arthritis. Mary Connolly, Trudy McGarry, Monika Biniecka, Douglas J. Veale and Ursula Fearron. Translational Rheumatology Research Group, Dublin, Ireland.

Background/Purpose: The inflammasome is a large multiprotein complex which plays a key role in innate immunity by mediating the production of pro-inflammatory cytokines interleukin-1β (IL-1β) and IL-18. The most characterised inflammasome is nlrp3, activation of which results in numerous biological effects associated with infection, inflammation and autoimmune processes. While the inflammasome has traditionally been thought to regulate infection and inflammation, impaired mitochondrial metabolism may mediate this process. In this study we examined the interplay between the inflammasome and mitochondrial function following TLR2 activation.

Methods: Mitochondrial mutagenesis was assessed by Random Mutation Capture Assay. Reactive oxygen species were measured by cellular detection assay. Primary RASFC and whole ex vivo synovial tissue were stimulated with a TLR2 agonist, PAMCSK, in the presence of absence of N-Acetyl Cysteine (NAC). IL-1β and IL-18 expression was examined by PCR. Nlrp3 expression was assessed by real-time PCR and western blot. To establish whether A-SAA activates TLR, human embryonic kidney (HEK) -TLR2 or -TLR4 cells were cultured in the presence of A-SAA and NFκB luciferase activity was examined. In parallel, the effect of A-SAA on RASFC function was examined in the presence of a specific neutralising anti-TLR2 mAb (1μg/ml) and matched IgG isotype control Ab (1μg/ml). RASFC proliferation, adhesion, chemokine expression, migration and invasion were assessed by proliferation assays, flow cytometry, Taqman PCR, ELISA, wound repair and transwell assays.

Results: PAM3CYSK4 significantly induced mitochondrial mutagenesis and reactive oxygen species in RA synovial explants cultures and fibroblasts ($p<0.05$). TLR2 activation increased transcript levels of inflammasome and pro-inflammatory mediators including IL-1, IL-18 and nlrp3. Furthermore, activation of TLR2 induced IL-6, IL-8, IL-1, IL-18 at a protein level, effects which were significantly inhibited in presence of NAC, an ROS inhibitor (all $p<0.05$). Additionally, we demonstrated that A-SAA is an endogenous TLR2 ligand since it induced TLR2 mediated NF-κB lucifearse activity ($p<0.05$), with no effect observed for NFκB in HEK-TLR4 cells. A-SAA significantly induced NLRP3 mRNA and protein expression. In parallel, A-SAA induced RASFC proliferation, ICAM-1 expression, invasion and migration, all of which were significantly inhibited in the presence of anti-TLR2 (all $p<0.05$), further confirming its role as an endogenous TLR2 ligand.

Conclusion: TLR2 induces mitochondrial dysfunction which plays a key role in the regulation of downstream inflammasome activation. TLR2-induced pro-inflammatory effects in RA may be mediated by endogenous secretion of A-SAA from the synovium at the site of inflammation.

Inflammation Develops in a Toll-like Receptor 9-Independent Manner in Experimental Arthritis and Rheumatoid Arthritis. Julie Mussard[1], Matthieu Ribon[1], Gaelle Clavel[2], Marie-Christophe Boissier[3] and Patrice Decker[1]. [1]INSERM UMR 1125, Li2P, University Paris 13, Sorbonne Paris Cité and Rheumatology Department, Avicenne Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), Bobigny, France, [2]Fondation Ophtalmologique A. De Rothschild, Paris cedex 19, France, [3]INSERM UMR 1125, Li2P, University Paris 13, Sorbonne Paris Cité, Bobigny, France.

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory disease of unknown etiology. Toll-like receptor (TLR) 9 recognizes pathogen-derived DNA and even self DNA under certain circumstances. Interestingly, environmental factors and especially bacterial infections have been suggested to favor RA development. In addition, TLR9 might also recognize damage-associated molecular patterns (DAMP) in RA. Since the involvement of TLR9 in RA remains unclear, we have investigated whether TLR9 is necessary for disease development in a mouse model of RA and we have analyzed TLR9 expression in samples from patients and controls.

Methods: Disease development was followed in the collagen-induced arthritis (CIA) mouse model. The impact of TLR9 was evaluated by comparing wild-type (WT) mice and TLR9-knockout (KO) true littermates. Arthritis was followed by clinical score evaluation. Inflammation and bone destruction were estimated by histology. Anti-collagen antibody, C3a and blood cytokine levels were measured by ELISA and Luminex. B and T lymphocytes as well as neutrophils were analyzed by flow cytometry. Osteoclastogenesis was analyzed by culturing bone marrow cells with M-CSF and RANKL and then counting TRAP-positive multinucleated cells by microscopy. Moreover, TLR9 expression was analyzed ex vivo by flow cytometry on whole blood from healthy donors and RA patients.

Results: We clearly show for the first time that TLR9 is not crucial in inflammatory arthritis. Indeed, TLR9 is not required for arthritis development in CIA as TLR9-KO mice strongly developed clinical arthritis. Accordingly, WT and KO mice produced similar levels of anti-collagen antibodies. As a control, we verified that WT and KO mice responded to complete Freund's adjuvant. Moreover, inflammation and joint destruction were observed in both WT and TLR9-KO mice and at a similar level. In agreement with those observations, no statistically significant difference was noted between WT and KO mice regarding the percentage or the activation of lymphocytes and neutrophils in the blood, spleen and lymph nodes. Osteoclastogenesis and complement activation (the latter being estimated by C3a production) are similar in WT and TLR9-KO CIA mice. Importantly, TLR7 does not compensate TLR9 deficiency in vivo as there is no TLR7 over-expression in TLR9-deficeint mice. The impact of TLR9 on cytokine secretion in vivo is currently being analyzed. In human samples, we have shown that leukocytes from healthy donors and RA patients express endosomal and cell surface TLR9 at the same extent and accordingly TLR9 expression is not correlated with disease activity in patients.

Conclusion: This is the first demonstration that TLR9-KO mice clearly develop arthritis. Immune cells from RA patients do not over-express TLR9 in comparison to healthy donors. Our results thus suggest that TLR9 does not play a crucial role in inflammatory arthritis development in the CIA model and that there is no intrinsic abnormal TLR9 expression in RA patients. This also suggests that TLR9 is not strongly involved in the recognition of DAMP in RA.

Febuxostat Inhibits Monosodium Urate Crystal-Induced IL-1beta Secretion and Cell Death Via ROS- and Intracellular ATP-Dependent Pathways. Johji Nomura[1], Nathalie Busso[2], Mizuho Tamura[1], Tsunefumi Kobayashi[1] and Alexander So[2]. [1]Teijin Pharma Limited, Tokyo, Japan, [2]Centre Hospitalier Universitaire Vaudois, University of Lausanne, Lausanne, Switzerland.

Background/Purpose: In gout, monosodium urate (MSU) crystals trigger acute inflammation. MSU has been reported to activate NLRP3 inflammasome via ROS-dependent pathways, which result in IL-1beta secretion and cell death. To date, we have shown that febuxostat, a potent inhibitor of xanthine oxidoreductase (XOR), inhibits crystal-induced IL-1beta secretion and cell death in activated macrophages. In this study, we examined its inhibitory mechanisms. **Methods:** Bone marrow-derived macrophages were primed, incubated with febuxostat and stimulated with MSU. IL-1beta in the supernatant, intracellular ATP, mitochondrial ROS and membrane potential were analyzed. **Results:** MSU treatment resulted in the production of mitochondrial ROS as well as IL-1beta secretion, and led to decreased intracellular ATP (iATP) levels and depolarization of mitochondrial membrane potential. All these intracellular mechanisms were inhibited by febuxostat. Accordingly, Mito-TEMPO, a mitochondria-targeted antioxidant, inhibited IL-1beta secretion by decreasing mitochondrial ROS production; in addition, artificially decreased iATP induced IL-1beta secretion and depolarization of membrane potential in activated macrophages. **Conclusion:** These results suggested that MSU induces IL-1beta and cell death via two pathways: 1) mitochondrial ROS formation, 2) iATP reduction and mitochondrial dysfunction. Both pathways can be inhibited by febuxostat, suggesting that XOR inhibition not only decreases uric acid level in the blood but also suppresses crystal-induced inflammation.

Prolactin Is Locally Produced in the Synovium of Patients with Inflammatory Arthritic Diseases and Promotes Macrophage Activation. Man Wai Tang[1], Samuel Garcia[2], Danielle M. Gerlag[2], Kris A. Reedquist[3] and Paul P. Tak[4]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]University of Cambridge, Cambridge & GlaxoSmithKline, UK, Stevenage, United Kingdom.

Background/Purpose: The sex hormone prolactin (PRL) has immunomodulatory properties, can be produced by immune cells, and elevated PRL serum levels have been reported in rheumatoid arthritis (RA) patients. Here we examined synovial expression of PRL and PRL receptor (PRLR) in patients with inflammatory arthritis, their expression in polarized macrophages from patients and healthy donors, and the effects of PRL on macrophage activation.

Methods: PRL levels in paired synovial fluid (SF) and peripheral blood of RA (n=19), psoriatic arthritis (PsA, n=13) and gout (n=11) patients were measured using an immunofluorescent metric assay. PRL mRNA expression was measured in synovial tissue (ST) of RA (n=25), PsA (n=11) and gout (n=12) patients, and in macrophages differentiated in RA, PsA, spondyloarthritis (SpA) and gout SF by qPCR. PRLR protein expression was determined in ST of RA (n=19), PsA (n=15) and osteoarthritis (OA, n=9) patients by immunohistochemistry and detected in specific cell types by immunofluorescence. IL-6 production by IFN-y and IL-10 -differentiated macrophages following stimulation with CD40L or TNF in the absence or presence of PRL was measured by ELISA.

Results: PRL protein levels were similar in serum and SF of RA, PsA and gout patients, as was mRNA expression in RA, PsA and gout ST. Of interest, PRL mRNA expression significantly correlated with clinical disease parameters in PsA (DAS28, R=0.729, P=0.017) and RA (ESR, R=0.424, P=0.049). PRL expression was also detected in monocyte-derived macrophages from RA patients, and significantly higher ($P \leq 0.01$) in healthy donor macrophages differentiated in pooled SF of RA and PsA compared to SpA and gout SF. In RA SF-differentiated macrophages PRL production was increased by CD40L or IgG stimulation but not LPS or TNFα.

Median (IQR) PRLR expression was significantly higher ($P<0.05$) in RA [0.06 (0.00–0.33)] and PsA [0.18 (0.00–1.67)] ST compared to OA [0.00 (0.00–0.02)], and there was no significant difference in PRLR expression between (pre/postmenopausal) females and males, independently of disease. PRLR expression was mainly colocalized with $CD68^+$ macrophages and vWF^+ endothelial cells. In vitro, PRLR was prominently expressed in IFN-y and IL-10 polarized monocyte-derived macrophages compared to macrophages polarized in GM-CSF, M-CSF or RA SF. In these macrophages, PRL stimulation significantly enhanced IL-6 production in response to TNFα or CD40L.

Conclusion: Our results provide the first evidence that PRL is produced locally in the synovium of patients with inflammatory arthritis, and contributes to the activation of macrophages in the presence of other inflammatory stimuli.

Alarmins S100A8/S100A9 Aggravate Osteophyte Formation in Experimental Osteoarthritis and Predict Osteophyte Progression in EARLY Human Osteoarthritis in the Dutch Check Cohort. Rik Schelbergen[1], Wouter de Munter[1], Martijn van den Bosch[1], Floris Lafeber[2], Annet Sloetjes[1], Thomas Vogl[3], Johannes Roth[3], Peter M. van der Kraan[1], Arjen B. Blom[1], Wim B van den Berg[1] and Peter L. van Lent[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Institute of Immunology University of Muenster, Muenster, Germany.

Background/Purpose: The main pathological feature of osteoarthritis (OA) is degradation of the articular cartilage. Other important hallmarks include subclinical inflammation of the synovium and ectopic formation of new bone and cartilage at the ligaments or joint margins, termed osteophytes. Alarmins S100A8 and S100A9 are major products of activated macrophages regulating cartilage damage and synovial activation during murine and human osteoarthritis (1) (OA).

In the current study we investigated whether S100A8 and S100A9 are involved in osteophyte formation during experimental OA and if S100A8/A9 predicts osteophyte progression in early human OA.

Methods: OA was elicited in S100A9 −/− and wild-type C57Bl/6 mice in two experimental models that differ in degree of synovial activation. Osteophyte size, S100A8, S100A9 and VDIPEN expression was measured on histology. Chondrogenesis was induced in murine mesenchymal stem cells (MSCs) in the presence of S100A8. Levels of S100A8/A9 were determined in plasma of early symptomatic OA patients of the CHECK cohort study and osteophyte size measured at baseline and after 2 and 5 years.

Results: S100A8 and S100A9 protein levels in the synovial lining and serum coincide with osteophyte development in collagenase-induced OA

(CIOA), in which synovial activation is high. Osteophyte size was drastically reduced in S100A9 −/− mice on day 21 and 42 of CIOA, in the medial collateral ligaments (58% and 93% reduction) and at medial femur and tibia (62% and 67% reduction). In contrast, osteophyte size was not reduced in S100A9 −/− mice during destabilized medial meniscus OA, in which synovial activation is scant. One explanation for the reduced osteophyte size in S100A9−/− mice may be a direct effect of S100-proteins on chondrogenesis. During *in vitro* chondrogenesis using murine MSCs, S100A8 caused a marked increase in MMP-3 mRNA and VDIPEN expression (as measure for MMP activity) as well as a strongly altered morphology, indicating increased remodeling allowing for larger osteophytes. Interestingly, early symptomatic OA patients of the CHECK study with osteophyte progression after two and five years had significantly elevated S100A8/A9 plasma levels at baseline, while CRP, COMP and ESR were not higher.

Conclusion: S100A8/A9 aggravate osteophyte formation in experimental OA with high synovial activation and may be used to predict osteophyte formation in early human OA.

Plasma Levels of Pattern Recognition Molecules of the Lectin Pathway Are Altered in SLE Patients. Anne Troldborg[1], Steffen Thiel[1], Magdalena Janina Laska[1], Bent Deleuran[2], Jens Christian Jensenius[1] and Kristian Stengaard-Pedersen[2]. [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease where the Complement System plays a key role in the pathogenesis. The objective of this pilot study was to measure the levels of the pattern recognition molecules of the Lectin Pathway: mannan binding lectin (MBL), collectin-L1 (CL-L1), and the three ficolins in plasma of patients with SLE and compare the plasma levels to a group of age and gender matched healthy controls. Further, we analyzed for associations between the plasma levels and SLE disease activity score and characteristic SLE manifestations.

Methods: Plasma was obtained from a cross-sectional cohort of 58 SLE patients. We collected prospectively demographic and clinical data including ACR classification criteria and SLE disease activity index score (SLEDAI). For comparison, blood samples were collected from 65 age and gender matched healthy blood donors. Plasma levels of MBL, CL-L1, M-ficolin (Ficolin-1) and H-ficolin (Ficolin-3) were measured using Time Resolved Immuno-Flourometric Assay (TRIFMA) developed at our own lab. Plasma levels of L-ficolin (Ficolin-2) were measured by ELISA (Hycult Biotech , the Netherlands). Mann-Whitney test were used for comparison of plasma levels of the proteins in patients and controls and Spearman correlation analysis was used for correlation analysis. p values < 0.05 were considered statistically significant.

Results:

RESULTS	SLE Patients (n=58) Mean plasma conc. ng/ml (SD)	Healthy Controls (n=65) Mean plasma conc. ng/ml (SD)	Difference between means ng/ml (SD)	Mann-Whitney P value
MBL	1003 (±821)	1137 (±1157)	219,5 ± 183,5	0,5204
CL-L1	771 (±145)	937 (±191)	165,5 ± 30,84	<0,0001
M-ficolin	356 (±231)	564 (±266)	214,1 ± 46,96	<0,0001
L-ficolin	2649 (±1031)	2554 (±998)	94,97 (±192,5)	0,6116
H-ficolin	23998 (±10397)	16387 (±4927)	7611 (±1450)	<0,0001

Mean plasma levels of CL-L1 and M-ficolin were significantly lower and H-ficolin significantly higher in patients with SLE compared to healthy controls ($p<0.0001$). A statistical significant difference between plasma levels of H-ficolin in SLE patients with lymphopenia compared to the non-lymphopenic patients was found ($p=0.0434$). A relatively higher level of CL-L1 in the subgroup of SLE patients with discoid rash was statistically significant ($p=0.0364$). Otherwise, analysis showed no statistically significant association between characteristic disease manifestations or SLEDAI score on one side and plasma level of MBL, CL-L1, M-ficolin, L-ficolin and H-ficolin on the other hand.

Conclusion: The plasma concentrations of several of the pattern recognition molecules of the Lectin Pathway were significantly altered in a cross-sectional co-hort of SLE-patients showing low levels of CL-L1 and M-ficolin and high levels of H-ficolin. In the subgroup of patients with lymphopenia, this manifestation was associated with a high level of H-ficolin. The association with a key element of the clinical picture, lymphopenia, may indicate a pathogenic role of Ficolin-3 in SLE.

A limitation of the study is small SLE subgroups.

Hypoxia Modulates Peptidyl Arginine Deiminase 4 Activity and Neutrophil Extracellular Trap Formation. Akif A. Khawaja[1], Charis Pericleous[1], Luke W. Thomas[2], Margaret Ashcroft[2], Joanna C. Porter[3] and Ian Giles[1]. [1]Centre for Rheumatology, University College London, London, United Kingdom, [2]Centre for Cell Signalling and Molecular Genetics, University College London, London, United Kingdom, [3]Centre for Inflammation and Tissue Repair, University College London, London, United Kingdom.

Background/Purpose: RA is an autoimmune rheumatic disease characterised by ACPA, endothelial dysfunction, platelet activation, synovial hyperplasia and hypoxia in affected joints. ACPA recognise citrullinated proteins, generated by the activity of peptidyl arginine deiminase (PAD)-2/4, however the source of these autoantigens is unknown. Neutrophil extracellular traps (NETs) play a critical role in the innate immune response and have been identified in serum and synovial fluid of patients with RA. NETs require PAD-4 for their generation and are also a source of citrullinated proteins. NET formation is enhanced by integrin engagement, interactions with activated platelets, and other stimuli but the effects of hypoxia upon their generation are unknown. Therefore, we hypothesise that hypoxia modulates the cellular interactions leading to enhanced NETosis and the externalisation of citrullinated autoantigens in RA.

Methods: Human umbilical cord endothelial cells (HUVEC) were grown in hypoxia (1% oxygen, equivalent to 7.6 mmHg) to mimic conditions found in the RA joint or normoxia (21% oxygen, 159.6 mmHg) in the presence or absence of TNF-α or lipopolysaccharide (LPS). Expression of PAD-4 and citrullinated histone H3, a PAD-4 target, were measured by western blot, and levels of surface adhesion molecules, intercellular adhesion molecule (ICAM)-1, ICAM-2, vascular cell adhesion molecule (VCAM)-1 and E selectin, were measured by FACs. Neutrophils were isolated from whole blood donated by healthy volunteers. Cell adhesion assays were performed in which binding of 2',7'-bis-(2-carboxyethyl)-5-(and-6)-carboxyfluorescein, acetoxymethyl ester (BCECF-AM) labelled neutrophils to HUVEC monolayers was measured using a fluorescent plate reader. A capture ELISA was established and validated to compare NET release between experimental conditions.

Results: Culture of HUVEC under hypoxia increased PAD-4 expression by 13.5% (1.2 fold) with levels of citrullinated histone H3 elevated by 1415.3% (15 fold). Hypoxia modulated both basal expression of ICAM-1, ICAM-2, VCAM-1 and E selectin as well as on stimulation with TNF-α or LPS. Hypoxia also increased neutrophil adhesion to HUVEC monolayers from 3+/−3.1% to 47+/−12.0% of total cells added ($p=0.0002$). NET formation of phorbol 12-myristate 13-acetate (PMA)-stimulated neutrophils was elevated under hypoxia compared to unstimulated controls (49.6% vs. 58.4%, $p<0.01$). Co-culture experiments demonstrated enhanced NETosis of PMA-stimulated neutrophils cultured with HUVEC compared to neutrophils cultured alone under normoxia ($p<0.05$).

Conclusion: We have shown that hypoxia modulates: PAD-4 expression; citrullination of histone H3; adhesion molecule expression in HUVEC; neutrophil adherence to HUVEC monolayers; and NET release. Furthermore, co-culture of neutrophils with HUVEC under normoxia elevates NET production on stimulation. Given that these processes are all relevant to the pathogenesis of citrullinated antigens in RA, further experiments are currently underway to dissect the modulatory effects of hypoxia on NETosis and investigate the effects of ACPA positive RA-IgG upon these cellular conditions.

Type I Interferon Promotes Inflammatory Cytokine Production By Inhibiting Mir-146a Maturation in SLE. Bo Qu[1], Jianchang Cao[2], Feifei Zhang[2] and Nan Shen[2]. [1]Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China, [2]Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), Shanghai, China, Shanghai, China.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by the uncontrolled inflammation along with over produced inflammatory cytokines, among which type I interferon (IFN) is recognized as a crucial pathogenic factor. The expression of miR-146a, which plays a key role in negatively controlling both the innate and adaptive immune responses, is reduced in the peripheral blood cells of SLE patients and accounts for the overactivated inflammatory responses in SLE. However, the mechanism of the reduction of miR-146a is still not fully understood. Not only are miRNAs regulated at the transcriptional level, their biogenesis consists of complex posttranscriptional processing that is affected by many factors, some of which are indicated to be associated with autoimmune diseases and can even be regulated by IFN. In this study, we tested whether the key pathogenic cytokine of SLE, type I IFN, is responsible for the dysregulation of miR-146a through regulating its posttranscriptional processing.

Methods: Gene expression was measured with RT-qPCR, northern blotting, or western blotting. MCPIP1 expression was knocked down in THP1 cells with a lentivirus encoding a short hairpin RNA targeting MCPIP1. Gene expression data for IFN-inducible genes, MCPIP1, and miR-146a in the peripheral blood cells of SLE patients was used in the correlation analysis.

Results: The pretreatment of THP1 cells with type I IFN attenuated the induction of miR-146a by LPS. Further investigation revealed that this phenomenon happened at the posttranscriptional level, along with downregulated pre-miR-146a, but not pri-miR-146a or its original unspliced transcript. We then demonstrated that the expression of MCPIP1, which is reported to limit miR-146a maturation by antagonizing the function of DICER1, was enhanced by type I IFN. Knocking down the expression of MCPIP1 abolished the inhibition of miR-146a and alleviated the enhancement of the expression of inflammatory cytokines by type I IFN. Finally, we demonstrated that MCPIP1 expression was elevated in the peripheral blood cells of SLE patients and its expression correlated positively with the IFN score and negatively with the level of miR-146a.

Conclusion: Our data suggest that elevated type I IFN inhibits the maturation of miR-146a and contributes to the reduction of miR-146a via MCPIP1 in SLE patients, providing new insights into the mechanisms by which the overproduction of type I IFN in SLE patients amplifies inflammation and even destroys immune tolerance. This knowledge may lead to more-specific therapeutic approaches, targeting downstream effectors of type I IFN. Our findings also indicate that the posttranscriptional regulation of miRNA maturation may be involved in the pathogenic process of SLE and may account for the dysregulated inflammatory gene expression in this disease.

NK/NKT Cells from Early and Definite Systemic Sclerosis Patients Show Different Immunological Responses after IL-2 Stimulation. Marta Cossu[1], Lenny van Bon[1], Stefan Nierkens[2], Alessandro Santaniello[3], Lorenzo Beretta[4] and Timothy Radstake[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University Medical Centre Utrecht, Utrecht, Netherlands, [3]Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, [4]Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy.

Background/Purpose: The innate immune system may be implicated in the fibrotic processes of systemic sclerosis (SSc); to date little has been done to unravel the immunological events that take place in earlySSc (EaSSc) and definite SSc patients prior to the onset of fibrosis. To this end, we evaluated the response of CD56+ cells (NK/NKT) cells to different stimuli with the potential to trigger immune responses in the early phases of the disease before the onset of fibrosis.

Methods: CD56+ NK/NKT cells were isolated from 22 EaSSc (LeRoy and Medger criteria, e.g. Raynaud phenomenon (RP) + either SSc-specific nailfold videocapillaropic changes and/or SSc-specific autoantibodies and no other manifestations of SSc) and from 13 definite SSc patients (ACR/EULAR 2013 criteria) without evidence of fibrotic features. Cells were stimulated for 24 hours with Toll-Like receptor (TLR) agonists (Pam3CSK4, Poly(I:C), R848) and human recombinant IL-2 and IFNα. Levels of IFNγ, TNFa, IL-6, IL-10, IL-4, IL-13, IL-17, IL-22, IL-8, GM-CSF, RANTES, MIP-1a were measured in cell-free supernatants using a validated multiplex immunoassay based on Luminex technology. Differences in analytes concentrations between groups were tested via the Mann-Withney's test. We then used the radial coordinate visualization method (Radviz™), a projection-based visualization technique, to represent high dimensional data into the orthogonal space to provide an interpretation of the joint effect of cellular responses on the disease status. The best projection is chosen and validated via the VizRank method.

Results: No single analyte could differentiate NK/NKT responses between groups. Joint-effect analysis via VizRank sorted out meaningful results for NK/NKT-products after IL-2 stimulation. The best Radviz™ representation considering 4 simultaneous attributes is represented in the Graph. This projection had an accuracy to correctly classify patients on the basis of GM-CSF, RANTES, IL-10 and IL-8 levels equal to 82.9%. When these molecules are jointly considered, the decision boundary between EaSSc and definite SSc patients is clearly marked; most definite SSc lie close to the GM-CSF and far from IL-8 anchor points (e.g have higher GM-CSF levels and low IL-8 levels); on the other hand, most EaSSc patients lie far from the RANTES and close to the IL-10 anchor points (e.g. have low RANTES and high IL-10 levels).

Conclusion: We showed that NK/NKT cells from EaSSc and definite SSc patients present distinct immunological patterns after stimulation with IL-2 and that these patterns accurately differentiate these groups of patients.

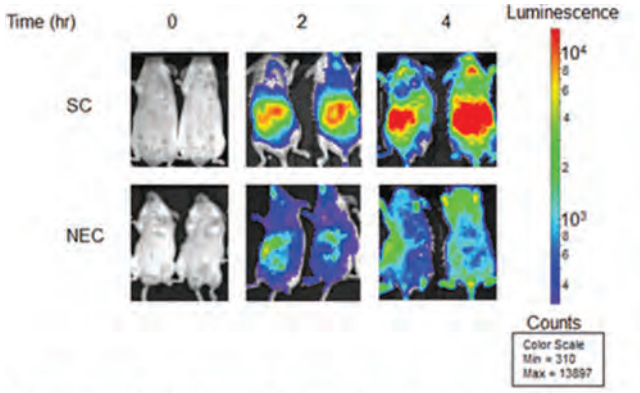
Oral Administration of Nano-Emulsion Curcumin in Mice Suppresses Inflammatory-Induced NFkB Signaling and Macrophage Migration. Nicholas A. Young[1], Michael Bruss[1], Mark Gardner[1], William Willis[1], Xiaokui Mo[1], Giancarlo Valiente[1], Yu Cao[2], Zhongfa Liu[2], Lai-Chu Wu[1] and Wael N. Jarjour[1]. [1]The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University Wexner Medical Center, columbus, OH.

Background/Purpose: The major obstacles to successful use of curcumin as an anti-inflammatory agent are its low solubility in water and rapid metabolism, which both translate to poor systemic bioavailability. To protect against metabolism and to enhance accessibility systemically, we have previously reported a novel formulation of nano-emulsified curcumin (NEC) that increases relative bioavailability by over 10-fold. In this study, we validated the bioactivity of NEC *in vivo* and characterized the associated mechanisms of immunosuppression.

Methods: Since curcumin has been shown to inhibit NFkB activation, we used BALB/C-Tg(NFkB-RE-luc)-Xen mice, which contain a firefly luciferase reporter gene under the control of kB responsive elements. Mice were treated with identical concentrations of curcumin in aqueous suspension (SC) or NEC by oral gavage and subsequently challenged with LPS. Acute systemic inflammation was measured and quantitated on the Xenogen *in vivo* imaging system (IVIS 200). Whole blood was collected for flow cytometry and serum was analyzed by ELISA. Acute peritonitis was induced in BALB/C mice by thioglycollate injection with and without NEC administration by oral gavage; peritoneal lavages were isolated for flow cytometry. Scratch assays to measure cell migration were performed on a human cells.

Results: Treatment with NEC significantly reduced LPS-induced inflammation relative to SC, as measured by IVIS detection of NFkB activity. Flow cytometry of peripheral blood indicated that circulating monocytes were reduced with administration of NEC and levels of LPS receptors TLR4 and RAGE were down-regulated on the surface of cells. Induction of monocyte chemoattractant protein (MCP)-1 secretion by LPS stimulation was significantly reduced with NEC administration. While macrophage recruitment was significantly reduced with NEC administration in thioglycollate-induced peritonitis, levels of T-cells and B-cells were not affected. Scratch assays to measure *in vitro* cell migration showed that curcumin significantly inhibited responses in both THP-1 cells and primary human macrophages.

Conclusion: In this study, we establish a novel system to screen and validate curcumin-derived drugs for longitudinal analysis *in vivo*. Furthermore, our results validate NEC as a candidate for future therapeutic studies and demonstrate that curcumin can suppress inflammation by selectively inhibiting macrophage migration via NFkB and MCP-1 inhibition.



LPS-induced NFκB reporter gene expression is suppressed with nano-emulsion curcumin (NEC) in mice when compared to equivalent concentration of suspension curcumin (SC). Transgenic BALB/C-Tg(NFκB-RE-luc)-Xen mice were treated with NEC or SC by oral gavage prior to LPS injection and imaged 0 h, 2 h, and 4 h. Representative whole body bioluminescent images are shown.

Expression of Lectin-like Transcript 1, the Ligand for CD161, in Rheumatoid Arthritis. Paulina Chalan[1], Johan Bijzet[2], Minke G. Huitema[1], Bart-Jan Kroesen[1], Elisabeth Brouwer[1] and Annemieke M.H. Boots[1]. [1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Precursor Th17 lineage cells expressing CD161 are implicated in rheumatoid arthritis (RA) pathogenesis. CD4+CD161+ T cells were found to accumulate in RA synovial fluid (SF) and tissue (ST) where they may acquire a non-classical T-helper 1 phenotype. The endogenous ligand for CD161 is lectin-like transcript 1 (LLT1). Previously, the LLT1-CD161 interaction was reported to co-stimulate T cell effector functions and to enhance IFN-γ production. This prompted us to investigate whether LLT1 is upregulated in arthritic joints. To that end we investigated the presence and identity of LLT1-expressing cells in RA synovial fluid and synovial tissue.

Methods: Paired samples of peripheral blood (PB) and SF mononuclear cells (n=14) and digested ST cells (n=4) from late-stage rheumatoid arthritis patients were analyzed for LLT1 expression by flow cytometry. Cell suspensions were stained with fluorochrome labeled anti-human LLT1, CCR2, CD14, HLA-DR, CD1a, CD16, CD163, CD1c, CD141, CD62L, CD86, CD303. Cells were analyzed using an LSR II flow cytometer and data analysis was performed with Kaluza® analysis software. Paraffin-embedded ST sections (n=6) were used for the immunohistochemical detection of LLT1. To further characterize LLT1 expressing cells, consecutive tissue sections were stained with the antibodies recognizing macrophage marker CD68, T cell marker CD3 and B cell marker CD20.

Results: In rheumatoid arthritis SF LLT1 expression was found upregulated in a subset of monocytes with a more differentiated, mature phenotype. In RA ST, LLT1-expressing cells were detected in the lining layer, sublining layer and in areas with lymphoid infiltrates. The LLT1 staining pattern overlapped with the CD68 (macrophages) staining pattern. Flow cytometric analysis of digested ST confirmed that LLT1 is expressed on CD68+ cells.

Conclusion: This is the first study showing that surface-expressed LLT1 is present in arthritic joints in RA. The finding of LLT1 expression by macrophages in synovial tissue suggests potential crosstalk with CD161+ T-cells. Ligation of CD161-LLT1 on CD4 T cells and macrophages respectively, may contribute to modulation of their function at the level of the joint.

Low Dose Colchicine Anti-Inflammatory Effects Are Transduced By AMP-Activated Protein Kinase (AMPK). Ru Bryan[1], Robert Terkeltaub[2] and Yun Wang[3]. [1]VA Medical Center/University of California San Diego, San Diego, CA, [2]VA Medical Ctr/University of California San Diego, San Diego, CA, [3]VA Medical Ctr/UCSD, San Diego, CA.

Background/Purpose: AMPK is a master metabolic energy regulator, whose tissue activity drops in response to nutritional excesses, alcohol consumption, and in obesity, metabolic syndrome and diabetes, and high levels of soluble urate. In addition to its anti-inflammatory effects, AMPK activity promotes microtubule stabilization. Therefore, we tested the effects of AMPK activation on urate crystal-induced inflammatory responses, and the hypothesis that AMPK activation transduces the capacity of the microtubule stabilizing agent colchicine to limit gout-like inflammation.

Methods: We studied bone marrow derived macrophages (BMDMs) from AMPKα1 knockout (KO) and wild type (WT) mice, and human monocytic THP-1 cells, and assessed a low concentration (10 nM) of colchicine achieved by "low dose regimens" for both prophylaxis and treatment of gout in humans. We examined expression and phosphorylation (activation) of AMPKa and of LKB1, the major upstream activating kinase for AMPK. We also assessed negative regulators of AMPKα phosphorylation (phosphatases 2A and 2C), and parameters of NLRP3 inflammasome activation and of macrophage inflammatory M1 to anti-inflammatory M2 polarization (iNOS, arginase, respectively). We studied acute MSU crystal-induced inflammation *in vivo*in subcutaneous air pouches.

Results: Colchicine (10 nM) increased AMPKα and LKB1 phosphorylation in cultured macrophage lineage cells, but phosphatases 2A and 2C were unchanged. Colchicine (10 nM) enhanced protein expression of total AMPKα translationally in BMDMs. Furthermore, colchicine (10 nM) promoted

macrophage polarization toward anti-inflammatory M2 phenotype by increasing ratio of arginase (M2-like) to iNOS (M1-like) mRNA expression. Colchicine partially but significantly inhibited caspase-1 cleavage and IL-1β maturation, as well as release of IL-1β and CXCL1 in response to MSU crystals in WT but not AMPKα1 KO BMDMs. Hence, manifold anti-inflammatory effects of colchicine were AMPK-dependent. Last, acute gout-like inflammation (neutrophil infiltration) were attenuated by pharmacologic AMPK activation in WT ($p<0.01$ compare to non-treated mice, 95% CI of difference: -5.9 to -0.9), but were enhanced in AMPKα1 KO mice ($p<0.001$ compared to WT mice, 95% CI of difference: 1.6 to 5.6) *in vivo*.

Conclusion: AMPK transduced multiple low dose colchicine anti-inflammatory effects *in vitro*, including promotion of M2 macrophage polarization, inhibition of NLRP3 inflammasome activation and reduction of IL-1β and CXCL1 release. Moreover, AMPKα1 knockout significantly enhanced model acute gout-like inflammation. Our results reveal a novel molecular mechanism of action for colchicine, and suggest that decreased AMPK activation triggered by certain nutritional excesses and co-morbidities may heighten the inflammatory potential of deposits of urate crystals. Hence, colchicine, and other pharmacologic AMPK activators currently in the clinic for other conditions (methotrexate, salicylates, high dose aspirin, metformin), may have the potential to enhance efficacy of anti-inflammatory prophylaxis and treatment of gouty inflammation.

Novel Role of Liver X Receptor Alpha (LXRα) in the Attenuation of TLR Signalling: Implications in Congenital Heart Block. Susmita Bagchi[1], Mark Halushka[2], Robert M. Clancy[1] and Jill P. Buyon[1]. [1]New York University School of Medicine, New York, NY, [2]John Hopkins Pathology, Baltimore, MD.

Background/Purpose: Anti-SSA/Ro associated congenital heart block provides a unique opportunity to examine the effector arm of immunity and define the molecular mechanisms that link maternal antibodies and the inflammatory cellular response. Based on an agnostic survey of transcripts from macrophages stimulated by immune complexes (IC) containing anti-Ro, 60kD Ro, and ssRNA-hY3, risk and protective genes were recently compiled. Two highly significant candidates in the injury spectrum, one enhancing - interleukin 6 (*IL6)*, and one attenuating - liver X receptor alpha (*NR1H3 or* LXRα), which has been shown to decrease NFkB-induced expression, were identified. Accordingly, this study was initiated to determine the potential functional significance of these candidates; specifically, whether LXRα expression influences TLR7/8 ligation and downstream NF-kB–dependent cytokine release underlying both overt inflammation and the transition to established fibrosis.

Methods: The approach included both in vitro and in vivo studies. The former employed TLR7/8 stimulated human macrophage cells (THP1) and peripheral blood macrophages in the presence and absence of a LXRα ligand, and the latter used immunohistochemistry of autopsy tissue from the heart of a fetus dying with CHB and an age matched control.

Results: As expected, exposure of THP-1 cells and isolated macrophages to a LXRα ligand, GW3965 (10 μM), resulted in the upregulation of its receptor LXRα mRNA (10 ± 1.25 vs 1, $N=4$). In addition, LXRα expression was likewise increased in hY3-transfected macrophages (14 ± 6.1 vs 1), confirming results obtained by the previous microarray data (gene name *NR1H3*). Increased protein expression of LXRα following either GW3965 or hY3 alone was confirmed using anti-LXRα antibodies in immunofluorescence and permeabilized FACS (whole cells, digitonin treated, respectively). To identify whether an increase of LXRα expression might alter proinflammatory hY3-induced transcripts, macrophages were simultaneously treated with hY3 and GW3965. As expected, hY3 treatment increased IL-6 mRNA expression compared to untreated cells or those treated with GW3965 alone (transcript normalized to GAPDH, 2.04, 1.03 and 0.83, respectively). In a cotreatment approach, we addressed whether the provision of ligand and upregulation of its receptor would impact the hY3-stimulated expression of IL-6. There was a 65% reduction in IL6 transcripts in macrophages treated with hY3 and GW3965 compared to hY3 alone ($N=2$) suggesting that ligand binding to receptor (but not increase of receptor alone) is a sufficient stimulus to trigger a sustained anti-inflammatory response. Immunohistochemistry of a heart from a fetus dying with CHB revealed focal expression of LXRα in proximity to the AV nodal region in areas containing calcified myocytes. In contrast, as assessed in the control heart, healthy myocytes did not express LXRα.

Conclusion: These data support the novel identification of a link between TLR7 activation and expression of a potential anti-inflammatory checkpoint, LXRα. In vitro and in vivo approaches suggest that LXRα may represent a thwarted attempt to forestall a smoldering hY3-driven inflammatory milieu.

Cholesterol Loading Induces Neutrophil Extracellular Traps, and Atorvastatin Attenuates This Effect. Ming-Lin Liu[1], Muhammad Bashir[2], Kevin Williams[3] and Victoria Werth[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]Philadelphia V.A. Hospital, Philadelphia, PA, [3]Temple University School of Medicine, Philadelphia, PA.

Background/Purpose: Neutrophils are the most common white blood cell, but their role in autoimmune and cardiovascular diseases has been underestimated. As part of host defense, neutrophils release granule proteins and chromatin DNA into the extracellular space to form neutrophil extracellular traps (NETs). Recent studies reported the presence of NETs in atherosclerotic lesions, and NETs promote thrombosis. Moreover, pharmacological inhibition of NET formation through peptidyl-arginine deiminase blockade can reduce atherosclerosis and arterial thrombosis in mice. Hypercholesterolemia is the underlying cause of atherosclerotic cardiovascular disease. Nevertheless, the effects of cholesterol loading on NET formation and the relevant cellular mechanisms have not been investigated.

Methods: Primary neutrophils were isolated from healthy donors by sequential centrifugation with Histopaque 1077 and 1119. Cultured human HL-60 cells were differentiated into neutrophil-like cells with 1.2% DMSO. Cholesterol was delivered to primary and HL-60 neutrophils as a water-soluble complex with meythl-β-cyclodextrin (MCD, Chol/MCD), which is widely used to modify the cholesterol content of cultured cells without potentially confounding effects from receptor engagement. Cells were fixed and then stained with Sytox Green, which indicates exposed nucleic acids. Formation of NETs was assessed with a fluorescence microplate reader and by fluorescence microscopy. To study the effects of atorvastatin on NET formation, selected plates were pretreated with this agent before exposure to Chol/MCD.

Results: We found that Chol/MCD loading could induce NET formation in a time- and dose-dependent manner in primary neutrophils [4491 ± 60 RFUs (relative fluorescent units) for control without Chol/MCD, 6553 ± 206 RFUs with 12.5 μg/ml Chol/MCD, and 9297 ± 223 RFUs with 25 μg/ml Chol/MCD, mean$\pm$SEM, $P<0.001$ by ANOVA], and in HL-60 neutrophils, detected with a fluorescence microplate reader. Both findings were confirmed by examination of the NET structure with fluorescent microscopy. Importantly, pretreatment of neutrophils with low or lower dose (10 or 25 μM), but not high dose (75 μM), atorvastatin, significantly attenuated cholesterol-induced NETosis in vitro.

Conclusion: Our studies indicated that cholesterol loading can induce neutrophil extracellular trap formation in vitro. Low-dose atorvastatin can attenuate cholesterol-induced NETosis. Our preliminary results indicate a potential role of hypercholesterolemia in NET formation and a potential beneficial role for statins.

Anti-Scavenger Receptor Autoantibodies Disrupted Marginal Zone Macrophage Integrity Via *Bruton's Tyrosine Kinase*. Hao Li[1], Qi Wu[1], PingAr Yang[1], Zheng Wang[1], Jun Li[1], Bao Luo[1], Jeffrey C. Edberg[1], Hui-Chen Hsu[1], John D. Mountz[1] and Robert P. Kimberly on behalf of PROFILE investigators[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Ibrutinib, a Btk kinase activity inhibitor, is a novel inhibitor under development for autoimmune disease therapy. We have shown that Btk was significantly upregulated in spleen MΦs of lupus prone BXD2 mice that spontaneously develop high titers of autoantibodies (auto-Abs). As loss of control on Btk expression in myeloid cells has been implicated previously to cause mislocation and loss of marginal zone macrophages (MZMs), a critical apoptotic bleb clearance barrier, in the spleen, the purpose of the present study is to determine a possible pathogenic

role of autoAbs to disrupt MZM integrity throught upregulating Btk activity in MZMs. The implication of these results in human systemic lupus erythematosus (SLE) was further studied.

Methods: Purified polyreactive monoclonal antibodies isolated from the spleen of BXD2 mice were screened for their reactivity to MZM specific scavenger-receptors including MZRCO and SR-A. AutoAbs that are either reactive or non-reactive to anti-MARCO/anti-SR-A were individually administered to recipient B6 mice to evaluate the pathogenic effects on MZMs. Confocal microscope analysis and FACS analysis were carried out to quantitate the percentage of MZMs in the spleen and evaluate the expression of phospho-Btk (pBtk). ELISA was carried out to determine the autoAb titers.

Results: In BXD2 mice, elevated anti-MARCO/anti-SR-A autoAbs in the sera correlated with the loss of MZMs in the spleens. Different purified monoclonal autoAbs were administrated into normal B6 mice. Disruption of MZMs was only observed when recipient mice were administered with polyreactive autoAbs that exhibit high reactivity to both MARCO and SR-A. In these mice, there was gradual induction of *pBtk* in the MZMs. Increased pBtk was also observed in MZMs of BXD2, and this induction can be efficiently blocked via early global inhibition of endogenous apoptosis using a pan-caspase inhibitor, z-VAD. Delivery of Ibrutinib either systemically or via an Ibrutinib-*l*iposome strategy to target MZM specifically, prevented MZM loss and attenuated autoantibodies mediated glomerulonephritis in autoAb administrated B6 or BXD2 mice. Surprisingly, anti-MARCO/anti-SR-A autoantibody administration also induced the reduction of MZMs in the spleen of $Fc\gamma r^{-/-}$ or $C3^{-/-}$mice, suggesting that autoAb mediated MZM loss is not related to either antibody-dependent cell-mediated cytotoxicity (ADCC) or complement-dependent cytotoxicity (CDC). In SLE patients, higher serologic levels of anti-MARCO autoAb titers exhibited significant positive correlation with the development of end-stage-renal disease (ESRD). Loss of MZMs was also identified in SLE patient spleens.

Conclusion: The present study suggests a novel autoAb-mediated systemic autoimmune disease mechanism based on the induction of pBtk in MZMs to break a critical barrier that is crucial to clear apoptotic debris in the spleen. The present study further suggests the potential to develop anti-MARCO/anti-SR-A into a novel biomarker for apoptosis clearance defects and development of ESRD in human SLE.

The Role of the Transcription Factor cAMP Responsive Element Binding Protein 1 in Lipopolysaccharide-Induced Tolerance. Kerstin Klein[1], Renate E. Gay[2], Christoph Kolling[3], Lih-Ling Lin[4], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Zurich University Hospital, Zurich, Switzerland, [3]Schulthess Clinic, Zurich, Switzerland, [4]Inflammation and Remodeling Research Unit, Pfizer, Cambridge, MA.

Background/Purpose: In macrophages, repeated stimulation of Toll-like receptor (TLR) 4 leads to adaptation of signaling pathways and epigenetic modifications resulting in a tolerant state of the cell which protects inflamed tissues from damage. We have recently shown that in contrast to macrophages, rheumatoid arthritis synovial fibroblasts (RASF) lack these protective mechanisms and keep on secreting inflammatory cytokines and matrix degrading metalloproteinases also after repeated stimulation with LPS. The objective was to investigate mechanisms behind tolerizable and non-tolerizable effects in RASF.

Methods: RASF were treated with LPS (100 ng/ml). 24h after the initial stimulation, cells were re-stimulated with LPS (10 ng/ml) for another 24h. The expression levels of IL6, IL8, CXCL10, matrix metalloproteinases (MMP) 1 and MMP3, as well as RIG1 and OAS1 were analyzed by quantitative Real-time PCR or ELISA. Nuclear factor-κB (NF-κB) and activator protein-1 (AP-1) promoter activities in RASF (n=4) were evaluated by Dual-Luciferase reporter assays after repeated stimulation with LPS. RASF (n=8) were transfected with siRNAs targeting cAMP responsive element binding protein 1 (CREB1) or scrambled siRNAs as control prior to stimulation with LPS (100 ng/ml, 24h). Activation of CREB1 after repeated LPS stimulation was analyzed in nuclear extracts (n=2) using p-CREB1 antibodies.

Results: RASF (n=10) maintained their production of IL6 after repeated TLR4 stimulation (single stimulation: 13.2 ± 5.8 ng/ml, double stimulation: 12.4 ± 7.1 ng/ml). A lack of tolerizable effects of RASF was also found for MMP1 and MMP3, whereas the interferon-responsive genes OAS1, RIG1, MDA5 and CXCL10 were tolerizable. RASF (n=5) secreted 531 ± 385 pg/ml CXCL10 after a single LPS stimulation and 111 ± 97 pg/ml CXCL10 after double stimulation ($p<0.05$). Reporter gene activities for NF-κB and AP-1 were similar in single and double stimulated RASF, excluding potential differences in the activation of these transcription factors as underlying mechanisms for tolerizable/non-tolerizable effects in RASF. Silencing of CREB1 reduced the LPS-induced expression levels of the tolerizable genes CXCL10 (x-fold: ctrl 54.8 ± 64.9; siCREB1 34.5 ± 42.9; $p<0.05$), OAS1 (x-fold: ctrl 24.0 ± 21.1; siCREB1 15.6 ± 15.2, $p<0.05$) and RIG1 (x-fold: ctrl 14.8 ± 12.1; siCREB1 10.1 ± 8.6, $p<0.05$), whereas LPS-induced expression levels of the non-tolerizable genes IL6, IL8, MMP1 and MMP3 were not affected. Similar effects of CREB1 silencing were obtained when secreted protein levels of LPS-induced CXCL10, IL6, IL8, MMP1 and MMP3 where measured. The phosphorylation of CREB1 was not changed by LPS double compared to single stimulation indicating that CREB1 activation was not impaired by double stimulation.

Conclusion: The expression of tolerizable genes in RASF is dependent on the transcription factor CREB1. Based on the fact that CREB1 activation is not altered by repeated LPS stimulation, epigenetic modifications on target gene promoters that effect the recruitment of CREB1 to promoters are likely to contribute to tolerization effects seen in RASF.

Gene Expression Profile in Muscle Tissue before and after Immunosuppressive Treatment in Patients with Myositis. Joan Raouf[1], Ingela M. Loell[2], Yi-Wen Chen[3], Rongye Shi[4], Inger Nennesmo[5], Helene Alexanderson[6], Maryam Dastmalchi[7], Marina Korotkova[8], Kanneboyina Nagaraju[9] and Ingrid E. Lundberg[10]. Background/Purpose: Autoimmune muscle diseases such as polymyositis (PM) and dermatomyositis (DM) are characterized by infiltration of inflammatory cells, production of cytokines and chemokines, as well as the expression of major histocompatibility complex (MHC) class I on skeletal muscle fibers. Patients are conventionally treated with high doses of glucocorticoids in combination with additional immunosuppressive drugs. Nevertheless, many patients have persisting muscle weakness even after prolonged treatment.

Objectives: To investigate the effect of conventional immunosuppressive treatment on gene expression profiling in skeletal muscle biopsies from patients with PM and DM, taken before and after treatment in order to develop further understanding of molecular mechanisms that might contribute to the persisting compromised function.

Methods: Biopsies (*vastus lateralis muscle)* from six newly diagnosed, untreated patients with PM (n=2) or DM (n=4) before and after a median of 8.5 months of immunosuppressive treatment were examined by gene expression microarray analysis. Functional associations were analyzed by using Ingenuity Pathway Analysis. Tissue sections from corresponding biopsies were evaluated for MHC class I molecule expression, inflammatory infiltrates, and signs of fiber regeneration/degeneration. Selected genes that displayed changes in expression were validated by western blot (WB).

Results: Evaluation of the biopsies taken after a median of 8.5 months of treatment showed MHC class I staining in muscle fibers, presence of CD3 positive cells (low in general with few positive cells scattered throughout the tissue) and CD68 positive cells (frequent but also ranging from scattered

mononuclear cells to infiltrates). By microarray analyses alterations were observed in the overall gene expression in muscle tissue. As expected most of the genes related to immune response such as interferon (IFN) pathway and inflammasome (e.g. AIM-2 and Caspase-1) were down-regulated. In addition alterations were seen in the expression of genes involved in muscle tissue remodeling suggesting protein breakdown as well as muscle regeneration (e.g. by up-regulation of the FKBP5 gene which encodes the protein important in basic cellular processes involving protein folding/trafficking). Validation of changes in gene expression by WB confirmed changes in protein expression; AIM-2 ($p=0.044$) and Caspase-1 ($p=0.035$) were significantly down-regulated, while FKBP5 ($p=0.020$) was up-regulated after chronic glucocorticoid treatment.

Conclusion: Together, these data indicate that during conventional immunosuppressive treatment of myositis patients transcriptional modifications in genes involved in muscle tissue inflammation and remodelling are taking place and their changes could be validated by changes in protein expression. The alteration indicate that besides the beneficial down-regulation of inflammatory pathways there are signs of protein breakdown which may have a negative consequence in muscle repair and may contribute to a defect recovery of muscle strength that may be seen in patients with PM/DM despite immunosuppressive treatment.

Behcets Disease in Females Due to Mutation in NEMO, the NF-Kb Essential Modulator. Alex Wessel[1], Spiros Vonortas[2], Jevgenia Zilberman-Rudenko[3], Richard Siegel[4] and Eric Hanson[5]. [1]NIH, Bethseda, MD, [2]NIH, NIAMS, Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [4]NIAMS, NIH, Bethesda, MD, [5]National Institute of Health, Bethesda, MD.

Background/Purpose: Behçet's disease (BD) is a chronic multi-system inflammatory disorder associated clinically with oral and genital ulceration, uveitis, erythema nodosum, and other inflammatory disease. The cause of BD is unknown. A current hypothesis is that an autoinflammatory reaction in individuals with a permissive genotype may arise due to altered cellular signal transduction events and hence altered immune cell function. This reaction may be triggered in these individuals due to infectious agents or microbes not generally considered pathogenic. The family of NF-kB transcription factors are activated in various signaling pathways involved in microbial sensing, immunity, and inflammatory disease. Previously, a case of familial Behcets was described in two females harboring a mutation in the C-termial Zinc finger domain of NEMO, the NF-kB essential modulator, a key regulator of NF-kB activation.

Methods: We evaluated female patients diagnosed with Behcets disease who harbor mutation in the NEMO C-terminus, in addition to those with mutation affecting another ubiquitin binding domain. Patient mononuclear cells in addition to patient-mutation-reconstituted NF-kB reporter T cell lines were stimulated with TNF, Toll-like Receptor (TLR) ligands Flagellin and LPS, in addition to anti-CD3/CD28, and PMA/Ionomycin. Gene expression, cytokine production and biochemical assays including co-immunoprecipitation of endogenous proteins implicated in the regulation of NF-kB activation were performed to characterize signaling and cellular responses.

Results: Mutation leading to premature truncation of the C-terminal Zinc finger in females is associated with a BD phenotype. NF-kB activation by reporter assay in cells harboring the patient mutation reveals enhanced NF-kB activation in response to TNF and TLR5 stimulation compared to the response seen in cells harboring other NEMO mutation not associated with BD. Cytokine production by capture assay indicates LPS induced IL-1b, TNF and GMCSF were approximately 2-fold increased compared to unrelated control, whereas other cytokine responses were normal or reduced. Co-immunoprecipitation studies following cell stimulation with TNF reveal impaired stabilization of the NF-kB negative regulator A20 at the receptor in cells harboring the patient mutation.

Conclusion: These results illustrate that single gene defects may lead to phenotypes observed in complex genetic disease. Molecular characterization of the altered signaling resulting from NEMO mutation may yield important insights into more common rheumatic disease such as BD.

Absence of Hormone Responsive Estrogen Receptor Alpha Reduces the Activation of Plasmacytoid Dendritic Cells in Lupus Prone Mice. Jennifer L. Scott[1], Melissa A. Cunningham[1], Osama S. Naga[1], Jackie G. Eudaly[1], Jena R. Wirth[2] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects women at a 9 to 1 ratio compared to men. To further understand mechanisms underlying the female predominance our laboratory is investigating the role of estrogen receptor alpha (ERα) in SLE disease development. In lupus-prone mice, absence of hormone responsive ERα increased survival and decreased glomerulonephritis despite no effect on autoantibody production or renal immune complex deposition. To explain this protective effect, we hypothesized ERα deficiency impacts innate immune responses and in particular plasmacytoid dendritic cell (pDC) function. Our previous work showed ERα deficiency reduced the bone marrow derived dendritic cell (DC) toll-like receptor (TLR) mediated type I Interferon response. To determine the significance of the reduced dendritic cell interferon response in disease development we investigated the impact of ERα deficiency on spleen pDC activation state *ex vivo* in pre-disease lupus-prone mice.

Methods: We measured the number, maturation state, and activation state of pDCs *ex vivo* from the spleens of pre-disease (12 to 14 week old) WT and hormone responsive ERα deficient female lupus-prone mice (NZM2410) using flow cytometry. pDCs were identified as singlets, live, $CD11b^{-}B220^{+}SiglecH^{+}$. Activation markers measured included MHC class lI, CD40, and pDC-TREM. Ly49Q expression was used as the marker to identify fully mature pDCs. We also measured activation of the bone marrow derived pDCs, sorted as live, $CD11b^{-}$, $B220^{+}$, and $CD11c^{+}$, after TLR 9 stimulation *in vitro*.

Results: ERα deficiency reduced the activation state of spleen pDCs from pre-disease lupus-prone mice. The frequency of spleen pDCs expressing the activation markers MHC class II and pDC-TREM was reduced by ERα deficiency ($n=20$, $p=0.002$, $p=0.06$). This finding was specific to lupus-prone prone mice. We did not detect any alteration in the frequency of activated pDCs between WT and ERα deficient age and sex matched C57BL/6 mice. To determine if the reduced frequency of activated pDCs was the result of ERα deficiency mediated alterations in pDC maturation or Toll-like receptor (TLR) responsiveness, we measured pDC maturation state *ex vivo* and TLR responsiveness *in vitro* in pDCs from WT and ERα deficient lupus-prone mice. ERα deficiency did not affect the maturation state of spleen pDCs, as measured by Ly49Q expression. However, ERα deficiency reduced TLR 9 mediated activation of bone marrow derived pDCs. After stimulation with TLR 9 ligand, a greater frequency of pDCs from WT mice expressed MHC class II and pDC-TREM compared to ERα deficient pDCs ($n=8$, $p=0.002$, $p=0.002$).

Conclusion: Our findings suggest the absence of hormone responsive ERα reduces *in vivo* pDC activation state by impairing pDC responsiveness to TLR ligands in lupus-prone mice. These findings may explain the protective role of hormone responsive ERα deficiency in SLE.

Oxidative Stress from Use of Allopurinol - Is There a Reason for Patients with Gout to Take Vitamin C? Lisa K. Stamp[1], Peter T. Chapman[2], John L. O'Donnell[3], Irada Khalilova[1], Rufus Turner[1] and Anthony Kettle[1]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]Canterbury Health Laboratories, Christchurch, New Zealand.

Background/Purpose: During acute gout attacks neutrophils are activated and release a number of pro-inflammatory cytokines and enzymes. One of these enzymes is myeloperoxidase (MPO), which we have previously shown to be elevated in the circulation of patients with acute gout. Furthermore, MPO was associated with increased oxidation of urate as demonstrated by the increased concentration of allantoin in the plasma of these patients. Thus, oxidative stress is a feature of acute attacks of gout. Allopurinol is the most commonly used urate

lowering therapy. It is rapidly metabolised by aldehyde oxidase to oxypurinol as well as superoxide and hydrogen peroxide. Oxypurinol exerts most of its inhibitory effects on xanthine oxidoreductase. In our previous work, allopurinol use was also associated with an increase in allantoin, indicating that it increases oxidative stress. The aim of this study was to determine the effects of allopurinol on plasma ascorbate (vitamin C), because its levels are sensitive to oxidative stress.

Methods: Patients with gout and a serum urate >0.36mmol/L were recruited. Twenty patients already receiving allopurinol were randomised to either increase the dose of allopurinol or commence vitamin C 500mg/d. Twenty patients not receiving urate lowering therapy were randomised to either start allopurinol or vitamin C 500mg/d. Plasma ascorbate, allantoin, myeloperoxidase, oxypurinol and serum urate were measured at day 0 and week 8.

Results: As expected at day 0, the 20 patients receiving allopurinol had significantly lower serum urate compared to those not on allopurinol (0.44 vs 0.54 mM $p<0.001$). Use of allopurinol was also associated with significantly lower plasma ascorbate levels (38.8 vs 56.7 μM $p=0.03$) and higher MPO levels (29.4 vs 18.0 μM $p<0.001$) at day 0. There was a non-significant increase in serum allantoin.

In the 10 patients who commenced allopurinol there was a significant reduction between day 0 and week 8 in serum urate (0.57 vs 0.41 mM $p=0.0003$) and plasma ascorbate (54.2 vs 28.1 μM $p=0.003$) and an increase in plasma allantoin (2.6 vs 3.0 μM $p=0.04$). Plasma MPO was not affected by allopurinol. There was a significant negative correlation between plasma oxypurinol and plasma ascorbate concentrations ($r=-0.54$, $p<0.0004$). For the 10 patients who stayed on their original dose of allopurinol, supplementation with vitamin C increased plasma vitamin C (48.4 vs 68.1 μM $p=0.01$) but had no effect on either urate or allantoin levels.

Conclusion: These results suggest that allopurinol promotes oxidative stress thereby depleting plasma ascorbate. Supplementation with vitamin C can increase plasma ascorbate in patients on allopurinol. The clinical significance of oxidative stress and low plasma ascorbate remains to be determined but our results indicate there may be a reason other than urate lowering for patients with gout to take vitamin C.

Circulating Mediators of Bone Remodeling in Patients with Tophaceous Gout. Ashika Chhana[1], Opetaia Aati[1], Gregory Gamble[1], Karen E. Callon[1], Anthony Doyle[1], Mark Roger[2], Fiona M. McQueen[1], Anne Horne[1], Ian R. Reid[1], Jillian Cornish[1] and Nicola Dalbeth[1]. [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand.

Background/Purpose: Disordered bone remodeling has been implicated in the development of bone erosion in tophaceous gout. The function of bone cells in the skeleton is regulated by a number of factors, including soluble mediators that influence osteoclast and osteoblast function. The aim of this study was to determine the relationship between bone erosion and circulating mediators of bone remodeling in people with tophaceous gout.

Methods: One hundred patients with tophaceous gout were prospectively recruited from rheumatology outpatient clinics. Bone erosion at articular sites was assessed by two readers in conventional computed tomography (CT) scans of the feet using a validated semi-quantitative erosion score, and in plain radiographs (XR) of the hands and feet using a modification of the Sharp-van der Heijde score. Readers were blinded to all clinical details, including laboratory results. Hip, spine and total body bone mineral density (BMD) was also measured. The following soluble mediators of bone remodeling were measured in serum by ELISA: osteoprotegerin (OPG, a soluble decoy receptor for RANKL), sclerostin (an osteocyte-derived Wnt inhibitor), dickkopf-1 (DKK-1, a Wnt inhibitor), and fibroblast growth factor-23 (FGF-23, an osteocyte-derived regulator of phosphorous and vitamin D).

Results: CT bone erosion scores positively correlated with circulating OPG concentrations ($r=0.22$, $p=0.03$), and negatively correlated with sclerostin concentrations ($r=-0.29$, $p=0.003$). Similar correlations were observed for XR erosion scores for OPG ($r=0.30$, $p=0.002$), and sclerostin ($r=-0.21$, $p=0.04$). Neck of femur BMD negatively correlated with OPG concentrations ($r=-0.34$, $p=0.001$), and positively correlated with sclerostin concentrations ($r=0.24$, $p=0.02$). Similar relationships were observed for total body BMD. No relationship was observed between bone erosion scores or BMD, and DKK-1 or FGF-23 concentrations. In linear regression analysis, OPG and sclerostin were independently associated with CT erosion score ($p=0.005$ for OPG and $p=0.003$ for sclerostin, R^2 for model 0.16, $p<0.0001$). Similarly, OPG and sclerostin were independently associated with neck of femur BMD ($p=0.002$ for OPG and $p=0.04$ for sclerostin, $R^2$for model 0.13, $p=0.001$). These relationships persisted after adjusting for eGFR.

Conclusion: In people with tophaceous gout, circulating OPG and sclerostin levels are independently associated with both central and peripheral bone loss. The direction of the associations does not support a direct role for bone-remodeling factors in pathogenesis of bone erosion, but may reflect compensatory or repair mechanisms to maintain bone homeostasis at both central and peripheral sites.

The Relationship Between Serum Homocysteine, Uric Acid and Renal Function in Chronic Gouty Patients: 2 Year Follow-up Results. Eun-Hye Park, Sang Tae Choi and Jung-Soo Srong. Chung-Ang University College of Medicine, Seoul, South Korea.

Background/Purpose: Hyperhomocysteinemia is one of the important factors for the endothelial cell damage and also a risk factor for cardiovascular events. Gout is known to be associated with cardiovascular disease (CVD) as well. Although both hyperhomocysteinemia and gout are related to CVD, the only few cases about serum homocysteine (Hcy) in gouty patients have been reported. In this study, we investigated the associations between serum Hcy level and the other parameters including serum uric acid level, renal function, and cholesterol profiles in chronic gouty patients with longitudinal follow-up data.

Methods: Ninety-one male patients with chronic gout and 97 age-matched healthy male controls were included in this study, and the average age of each was 51.19 $\pm$ 15.08 and 51.57 $\pm$ 17.01 years old, respectively. Among them, 33 patients with gout and 39 healthy controls underwent follow-up tests for Hcy levels with 24.00 $\pm$ 9.12 months on average. Serum Hcy levels were measured by a competitive immunoassay using direct chemiluminescent. The estimated glomurular filtration rate (eGFR) was calculated using modification of diet in renal disease equation, and then chronic kidney disease (CKD) was defined as an eGFR below 60 ml/min/1.73m^2.

Results: In the serum uric acid level, there was no significant difference between chronic gouty patients and controls (6.15 $\pm$ 2.23 mg/dL vs 5.82 $\pm$ 1.22 mg/dL, $p = 0.214$). In contrast, gouty patients showed significantly higher levels in serum Hcy than those in controls (13.96 $\pm$ 4.05 μmol/L vs 12.67 $\pm$ 3.51 μmol/L, $p = 0.022$). In patients with chronic gout, serum Hcy level was negatively correlated with eGFR (γ= -0.413, $p < 0.001$), while it was uncorrelated with serum uric acid levels or cholesterol profiles. Serum Hcy levels were not different between the groups treated with allopurinol and with benzbromarone. When we observed the follow-up results in chronic gouty group, the change of serum Hcy level was positively correlated with the change of serum creatinine level ($\gamma = 0.560$, $p < 0.001$), and negatively correlated with the change of eGFR ($\gamma = -0.556$, $p < 0.001$). However the change of serum Hcy level was uncorrelated with the changes of uric acid level or the lipid profiles. The chronic gouty patients with CKD showed significantly higher serum Hcy level than those without CKD (17.45 $\pm$ 4.68 μmol/L vs 13.15 $\pm$ 3.46 μmol/L, $p < 0.001$), and the follow-up result also showed similar tendency (19.12 $\pm$ 4.29 μmol/L vs 15.69 $\pm$ 5.73 μmol/L, $p = 0.059$). In multiple linear analyses, serum Hcy level was affected by eGFR (β = -0.385, $p< 0.001$), however, was not affected by the serum uric acid level.

Conclusion: Serum Hcy level was elevated in chronic gouty patients than in controls. The change of serum Hcy level was negatively correlated with the change of eGFR. Hyperhomocysteinemia in chronic gouty patients was related with decreased renal function, and was not with serum uric acid or lipid profiles.

The Random Urine Uric Acid to Creatinine Ratio As a Predictor of 24-Hour Urine Uric Acid Excretion in Gout Patients. Sang Tae Choi, Jung-Soo Song and Eun-Hye Prark. Chung-Ang University College of Medicine, Seoul, South Korea.

Background/Purpose: Gout is an inflammatory disease resulted from an increased body pool of uric acid. The measurement of 24-hour uric acid excretion is important to evaluate the disease status as well as to select the

kind of uric acid lowering agents. However, 24-hour urine collection is inconvenient, and frequently unreliable due to errors in collection. The average person excretes approximately 1 g/day creatinine, and thus a lot of studies showed that the random urine protein to creatinine ratio was well correlated with 24-hour urine protein excretion rate. In this study, we investigated the utility of the random urine uric acid to creatinine ratio for predicting 24-hour urine uric acid excretion in gouty patients.

Methods: The cross-sectional study included 37 gouty patients without any use of uric acid lowering agents. The average age was 47.7 ± 17.7 years old and 34 out of 37 were male patients. 24-hour urine collections of the patients were conducted to the evaluate uric acid excretion and renal function. Random urine uric acid and creatinine specimens were obtained from all participants at the day when 24-hour urine collection was conducted. The creatinine clearance (CCr) was measured from the 24-hour urine collected sample, and chronic kidney disease was defined as the CCr levels below 60 ml/min/1.73m^2.

Results: The mean of 24-hour uric acid excretion was 602.4 ± 236.0 mg, and those of serum uric acid levels and CCr values were 7.31 ± 1.31 mg/dl and 100.9 ± 33.2 ml/min/1.73m^2, respectively. Random urine uric acid to creatinine ratio was closely correlated with the absolute and log transformed 24-hour urine uric acid excretions ($\gamma = 0.450$, $p = 0.005$;$\gamma = 0.474$, $p = 0.003$, respectively). In the linear regression analysis, the amount of absolute 24-hour urine uric acid excretion was estimated by 0.812 × (random urine uric acid to creatinine ratio) + 290.466 ($R^2 = 0.450$, $p = 0.005$). The correlation between random urine uric acid to creatinine ratio and 24-hour urine uric acid excretion was also found in the patients with chronic kidney disease ($\gamma = 0.900$, $p = 0.037$).

Conclusion: Random urine uric acid to creatinine ratio showed positive correlation with the absolute and log transformed 24-hour urine uric acid excretions. The random urine uric acid to creatinine ratio would be a good predictor of 24-hour urine uric acid excretion in gouty patients.

The Reduction of Serum Uric Acid Level Might Prevent Atherosclerosis in Mice. Yoshitaka Kimura[1], Tamiko Yanagida[2], Akiko Onda[2], Hajime Kono[2], Maki Takayama[2], Kurumi Asako[2], Akiko Okamoto[2], Hirotoshi Kikuchi[2] and Toshihiro Nanki[3]. [1]The University of Tokyo, Tokyo, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan, [3]Teikyo University, Tokyo, Japan.

Background/Purpose: Excess amount of uric acid in human body causes acute inflammation, gout. In addition, uric acid is identified as a danger signal and is implicated in playing roles in chronic inflammatory processes. Recently several retrospective studies have reported that serum uric acid might be one of the independent risk factors of atherosclerosis. However there has been no prospective study showing the association of serum uric acid level and atherosclerosis. It's not still clear whether uric acid progresses atherosclerosis. Using the transgenic mice expressed uricase, an uric acid hydrolytic enzyme, we investigated the reduction of serum uric acid level could prevent atherosclerosis in mice.

Methods: We prepared uricase transgenic mice based in C57BL/6 mice. They expressed the urcase secreted to extracellular space and their serum uric acid level were decreased. We bred Uricase^{Tg} mice with LDL receptor deficient or apolipoprotein E deficient mice to develop LDLR$^{-/-}$Uricase^{Tg} mice or ApoE$^{-/-}$Uricase^{Tg} mice, respectively. LDLR$^{-/-}$Uricase^{Tg} mice, ApoE$^{-/-}$Uricase^{Tg} mice and control mice (LDLR$^{-/-}$ mice and ApoE$^{-/-}$ mice) at 6 weeks of age received high-fat diet for 16 weeks. Then their hearts and aortas were removed at 22 weeks of age. Aortic sinuses of these mice were fixed and sliced into 8 micrometer. We measured atherosclerosis area of each slice and computed volume of lesions of aortic sinus. Aortas of these mice were stained with oil red O and measured area of atherosclerosis lesions. We calculated ratio of the lesion area to whole aortic area.

Results: The volumes of atherosclerosis lesions in aortic sinuses of LDLR$^{-/-}$Uricase^{Tg} (0.158±0.016 mm^3) [n=17] were smaller than that of LDLR$^{-/-}$ (0.231±0.017 mm^3) [n=12] [p=0.0049]. There were no significant differences between ApoE$^{-/-}$Uricase^{Tg} (0.227±0.022 mm^3) [n=15] and ApoE$^{-/-}$ (0.292±0.032 mm^3) [n=7] [p=0.11]. The ratio of area of atherosclerosis in aorta was 7.4±1.2 % in LDLR$^{-/-}$Uricase^{Tg} [n=14], 8.1±0.9% in LDLR$^{-/-}$[n=24], 6.0±0.8% in ApoE$^{-/-}$Uricase^{Tg} [n=15] and 5.3±0.6% in ApoE$^{-/-}$ [n=7]. There were little differences between each group (LDLR$^{-/-}$Uricase^{Tg} vs LDLR$^{-/-}$Uricase^{Tg} [p=0.63], ApoE$^{-/-}$Uricase^{Tg} vs ApoE$^{-/-}$ [p=0.63]).

Conclusion: Although there was a discrepancy between atherosclerosis prone strains, the results showed that the reduction of serum uric acid level by expressing secretable uriase may inhibit the progression of atherosclerosis.

Lack of Gene-Diuretic Interactions on Risk of Incident Gout: The Nurses' Health Study and Health Professionals Follow-up Study. Ying Bao[1], Tony R. Merriman[2], Gary Curhan[3], Eli A. Stahl[4], David B. Mount[1], Robert M. Plenge[1], Peter Kraft[5] and Hyon K Choi[6]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of Otago, Dunedin, New Zealand, [3]Harvard Medical School, Boston, MA, [4]Mt Sinai School of Medicine, New York City, NY, [5]Program in Molecular and Genetic Epidemiology, Harvard School of Public Health, Boston, MA, [6]Boston University School of Medicine, Boston, MA.

Background/Purpose: Diuretics, particularly thiazide and loop diuretics, increase the risk of gout, likely through urate transporters (e.g., OAT4) and volume depletion promoting urate reabsorption. As the prevalence of hypertension is remarkably high in gout patients (74% in the US general population), diuretic use is commonly encountered in gout care as a first line anti-hypertensive agent. A recent analysis based on 108 self-reported incident cases of gout in the Atherosclerosis Risk in Communities (ARIC) Study has reported that diuretic-induced gout occurs only among those with a genetic predisposition to hyperuricemia (*Ann Rheum Dis* 2013). If confirmed, those genes could potentially be used to predict gout from diuretic use, a first line agent for hypertension and congestive heart failure.

Methods: We examined the potential interaction between urate genes and diuretic use in relation to the risk of incident gout in 6788 women from the Nurses' Health Study (NHS) and 4012 men from the Health Professionals Follow-up Study (HPFS). Two genetic risk scores (GRS) were created from common urate SNPs for eight previously known genes (GRS8, used by the ARIC study above) as well as for 29 genes (GRS29, a new score incorporating additional novel genes). We ascertained incident gout cases using the American College of Rheumatology survey criteria. We used Cox proportional hazards models for associations and interactions of interest.

Results: Our study included 310 and 674 confirmed cases of incident gout in the NHS and HPFS cohorts, respectively. In the NHS, compared with no thiazide or loop diuretic use, their use was associated with a multivariate RR of 1.97 (95% CI 1.32 to 2.93) among those with a GRS8 below the median and 2.33 (95% CI 1.73 to 3.13) for those with a GRS8 above the median (p for interaction = 0.21) (**Table 1**). The corresponding RRs according to GRS29 categories were 1.89 (95% CI 1.28 to 2.79) for below the median and 2.39 (95% CI 1.77 to 3.24) for above the median (p for interaction = 0.33). Similarly, two previously purported genes, SLC2A9 (GLUT9) and SLC22A11 (OAT4), showed no significant interactions (p for interactions > 0.05). Corresponding analyses in the HPFS showed no significant interactions (**Table 1**) (all p values for interaction > 0.28). Further, the lack of interaction persisted in our analyses when limited to those with hypertension in both cohorts, except for SLC22A11

among women, which showed a significant interaction but in the opposite direction to that in the recent ARIC study.

Conclusion: These prospective studies based on a large number of incident cases of confirmed gout indicate that individuals with a genetic predisposition for hyperuricemia are not at an increased risk of developing diuretic-induced gout as compared with those without such a predisposition. These findings do not support the potential utility of these genes to assess gout risk in relation to diuretic use.

Table 1 Relative Risk for Incident Gout According to Diuretic Use and Genetic Urate Score Based on 8 Urate SNPs (GRS8) and 29 Urate SNPSs (GRS29)

Higher Inflammatory Response in Elderly Patients during Gout Attack.

Ji Ae Yang[1], Jae Hyun Lee[1], Eun Young Lee[2], Eun Bong Lee[1], Yeong Wook Song[3] and Jin Kyun Park[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University College of Medicine, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Clinical experiences suggest that gout attacks in elderly patients are accompanied by stronger systemic inflammatory response including fever, higher C-reactive protein (CRP) and erythrocyte sediment ratio (ESR) as compared those in younger patients. As such, it is often difficult to differentiate them from septic arthritis, leading to frequent use of empiric antibiotics and unnecessary diagnostic and therapeutic joint surgery. To define whether gout attacks are accompanied by stronger systemic inflammatory response with age.

Methods: In this retrospective study, medical records of patients who were evaluated for a possible gout attack between January 2000 and April 2014 were examined. The presence of fever (>37.8°Æ), levels of C-reactive protein (CRP) and erythrocyte sediment ratio (ESR) on attack were compared between young (<50 years), middle aged (50- 65 years) and elderly patients (>65 years).

Results: Gout attacks were observed in 188 patients with 34 young, 54 middle aged and 100 elderly patients. Baseline characteristics of three groups differed; elderly patients had more comorbidities including diabetes mellitus ($p<0.001$), hypertension ($p<0.001$), coronary artery disease ($p=0.015$), cerebrovascular accident ($p<0.001$), and cancer ($p=0.031$) as compared other groups. The elderly patients had a low body mass index (BMI) (24.60 ± 4.65, 24.55 ± 3.30, 23.27 ± 3.12, $p=0.041$ by ANOVA) and longer disease duration (2.76 ± 5.16, 4.20 ± 6.13, 6.58 ± 9.23 years, $p=0.028$ by ANOVA).

Fever was more often present in the elderly patients (17.6% in young vs. 29.6% in middle aged vs. 50.0% in elderly, $p=0.001$ by chi-square test). Although numbers of involved joints during attacks did not differ between groups ($p=0.656$), CRP and ESR levels during gout attack increased significantly with age (Figure 1).

Conclusion: Since gout attacks in elderly patients are accompanied by stronger systemic inflammatory response, often resembling sepsis or septic arthritis, it is crucial to correctly diagnose them as gout so that unnecessary invasive diagnostics including joint lavage and prolonged antibiotic treatment can be avoided.

Key words: gout, age, elderly, fever

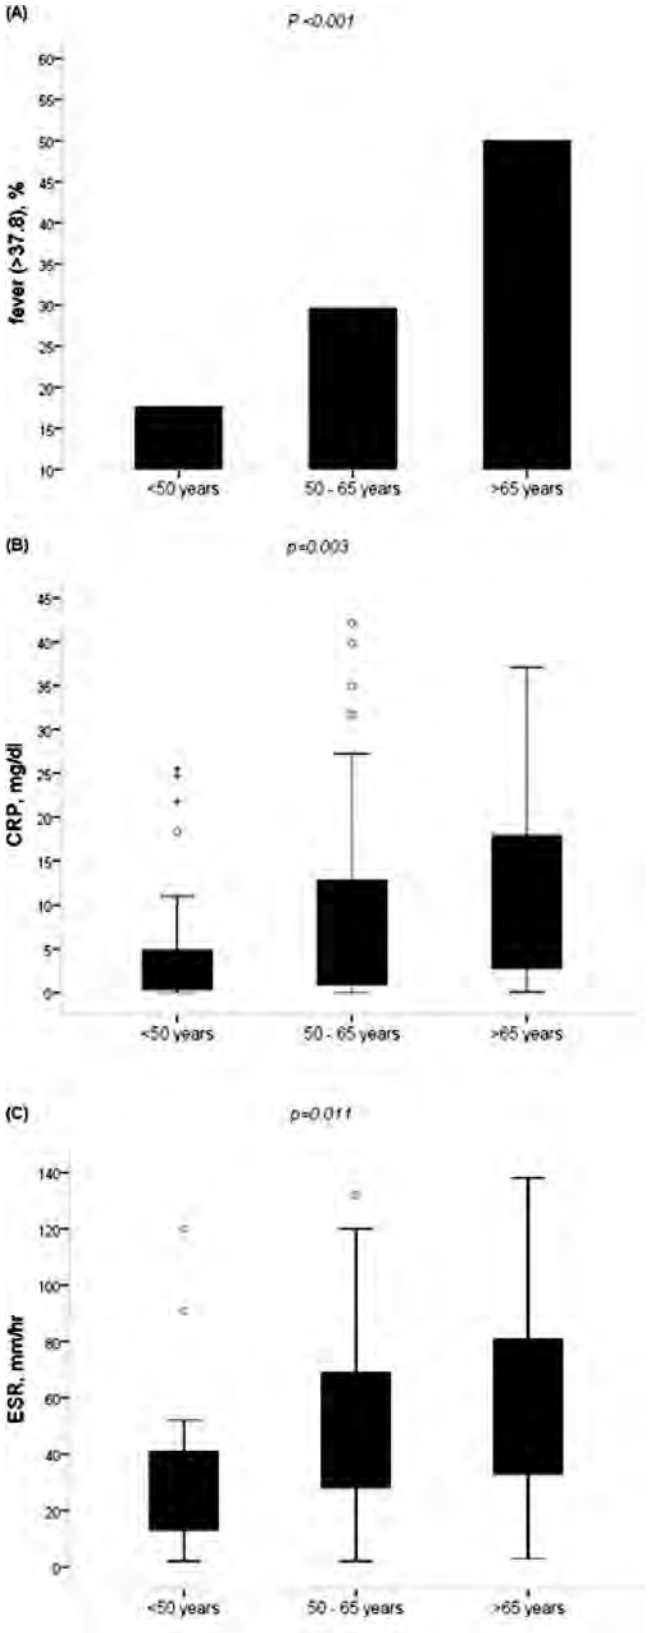

Figure 1. Differences in characteristics on gout attack among young (<50 years), middle aged (50 - 65 years) and elderly patients (>65 years). (A) Percentage of patient with fever (>37.8) (B) C-reactive protein (CRP) (C) Erythrocyte sedimentation ratio (ESR) were significantly higher in the elderly group.

1221

Serum Uric Acid As an Independent Risk Factor on Progression of Chronic Kidney Disease in Gout Patients with Uric Acid Lowering Agent. Young Hyup Lim[1], Eun-Jung Park[1], Seulkee Lee[2], Hemin Jeong[3], Hyungjin Kim[4], Jinseok Kim[1], Jaejoon Lee[3], Hoon-Suk Cha[5] and Eun-Mi Koh[5]. [1]Department of Medicine, Jeju National University Hospital, Jeju University School of Medicine, Republic of Korea, Jeju, South Korea, [2]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, Seoul, South Korea, [3]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [4]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, Seul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Background/Purpose: Hyperuricemia is particularly common in patients with chronic kidney disease (CKD). Its role, however, as a risk factor for renal outcomes of CKD is debated. This aim of study was to evaluate long-term effect of serum uric acid (SUA) level on progression of CKD in gout patients with uric acid lowering treatment.

Methods: All patients who had a first visit for gout with CKD at Samsung Medical Center between 1995 and 2003, and follow-up until December 2012 or expired during follow-up period were included and retrospective analyzed. CKD was defined as an estimated glomerular filtration rate (GFR) of < 60 mL/min/1.73m^2 via MDRD Study equation more than 3 months. All serum creatinine and matched SUA taken during follow-up period were analyzed by using Mixed effect model to determine the effect of SUA level on renal outcome.

Results: One-hundred eleven gout patients with CKD were observed. The mean age of the patients at diagnosis of gout was 51.3 and mean follow-up duration was 13 years. Baseline eGFR and serum creatinine were 47.7 mL/min/1.73m^2 and 1.62 mg/dL, respectively. Maintaining the SUA below 6 mg/dL showed protective effect on serum creatinine and eGFR compared with SUA more than 6 mg/dL ($p < 0.0001$ and $p = 0.02$, respectively). Mixed effect model demonstrated that the protective effect on renal outcome with maintaining the SUA below 6 mg/dL was statistically significant after adjusting baseline age, follow-up time, hypertension, diabetes mellitus, history of cardiovascular disease, obesity, and intrinsic renal disease ($p < 0.0001$). Hypertension, diabetes mellitus and follow-up time were independently associated with progression of chronic kidney disease ($p < 0.001$, $p < 0.001$ and $p < 0.001$, respectively). In particular, for every 1 mg/dL increase of the SUA, serum creatinine revealed to be increased 0.02 mg/dL when the SUA is more than 6 mg/dL ($p < 0.0001$).

Conclusion: Our long term follow-up data demonstrated the SUA level was associated with progression of CKD in gout patients. Maintaining of SUA level below 6 mg/dL would be essential to protect renal function in gout patients with CKD.

1222

Suppressive Effect of Butyrate on Monosodium Urate (MSU) Crystal-Induced IL-1 beta Production Is Mediated Via Inhibition of Class I Histone Deacetylases. Maartje Cleophas[1], Tania Crisan[2], Heidi Lemmers[3], Helga Toenhake-Dijkstra[2], Gianluca Fossati[4], Tim Jansen[2], Charles Dinarello[5], Mihai Netea[2] and Leo Joosten[2]. [1]Radboud Unversity Medical Center, Nijmegen, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands, [3]Radboud Univeristy Medical Center, Nijmegen, Netherlands, [4]Italfarmaco, Cinisello Balsamo, Italy, [5]University of Colorado, Denver, CO.

Background/Purpose: Gouty arthritis is triggered by endogenously formed monosodium urate (MSU) crystals. MSU crystals alone are unable to induce cytokine production and therefore a second stimulus is needed to induce the release of active interleukin (IL)-1β, the dominant cytokine in acute gout. Toll-like receptor (TLR) ligands such as LPS or saturated free fatty acids (FFA) can provide such a second signal and stimulate transcription of pro-IL-1β. In contrast to FFA, which can act as second signal for MSU-mediated cytokine production, the short-chain fatty acid butyrate has many anti-inflammatory effects. One of the possible mechanisms involved is inhibition of histone deacetylases (HDACs). Here, we explored the effects of butyrate on MSU/FFA-induced cytokine production and its inhibition of several specific HDACs.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from healthy donors or gouty arthritis patients and stimulated for 24 hours with MSU and palmitic acid (C16.0) in the presence or absence of butyrate or the synthetic HDAC inhibitors. Cytokine responses were measured with specific ELISAs and quantitative PCR. Effects on HDAC activity were measured with a fluorimetric cellular assay kit.

Results: Butyrate decreased C16.0/MSU-induced production of IL-1b, IL-6, and IL-8, as well as the transcription of IL-1b mRNA. Similar results were obtained when PBMCs isolated from gout patients were exposed to butyrate and C16.0/MSU. Butyrate selectively inhibited class I HDACs, but the strongest inhibition was found for HDAC8. However, the selective HDAC8 inhibitor ITF-A did not decrease ex-vivo C16.0/MSU-induced IL-1b production. The pan HDAC inhibitor Panobinostat and the HDAC inhibitor ITF-B significantly decreased C16.0/MSU-induced IL-1b production. Interestingly, the dose-response curves of butyrate and ITF-B are very different between PBMC's stimulated with C16.0/MSU or with LPS.

Conclusion: Butyrate and ITF-B have in common that they both inhibit class I HDACs and potently inhibit C16.0/MSU-induced IL-1b production. ITF-B also inhibits HDAC10 and -11, but the effect on C16.0/MSU- and LPS-induced IL-1b production is strikingly similar to that of butyrate. Therefore we conclude that the effect of butyrate on C16.0/MSU-induced cytokine production is mediated through class I HDAC inhibition. In contrast to the high concentrations of butyrate needed for cytokine suppression, synthetic HDAC inhibitors show potent anti-inflammatory effects at low concentrations. These novel HDAC inhibitors could be effective in the treatment of acute gout. Moreover, the use of specific HDAC inhibitors could even improve the efficacy and reduce any potential adverse effects.

1223

Enhancement of Proinflammatory Cytokine Production By Uric Acid in Human Cells Via Down Regulation of IL-1Ra. Tania Crisan[1], Maartje Cleophas[2], Heidi Lemmers[3], Helga Toenhake-Dijkstra[1], Mihai Netea[1], Tim Jansen[1] and Leo Joosten[1]. [1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Radboud Unversity Medical Center, Nijmegen, Netherlands, [3]Radboud Univeristy Medical Center, Nijmegen, Netherlands.

Background/Purpose: Gout is an autoinflammatory disease characterized by the deposition of monosodium urate (MSU) crystals in the joints of hyperuricaemic patients and subsequent attacks of severe gouty arthritis. Major lines of research investigating the proinflammatory effects of uric acid have been mainly focusing on MSU crystal-induced processes that come into role once uric acid reaches supersaturation. However, some indications exist that uric acid can directly have pro-inflammatory effects. In this study we investigate the effects of high uric acid exposure on the cytokine production of primary human immune cells upon stimulation with MSU crystals and synergizing agents.

Methods: Peripheral blood mononuclear cells (PBMCs) were harvested from gout patients and healthy volunteers. Cells were pre-treated with uric acid, allantoin or left untreated for 24h and then subjected to 24h stimulation with TLR2 or TLR4 ligands in the presence or absence of MSU. Cytokine production was assessed using specific sandwich ELISA kits. mRNA levels were measured using quantitative real-time PCR.

Results: MSU crystals stimulation alone did not induce detectable levels of IL-1β or IL-6 neither in patients nor in controls, however, synergy was present between MSU and Pam3Cys or LPS. Of high importance, higher levels of IL-1β and IL-6 were seen in patients compared to controls. An enhanced pro-inflammatory cytokine production was also observed when cells were specifically pretreated with uric acid, together with a significant down regulation of IL-1Ra but not IL-10. This observation correlated with mRNA levels for these cytokines observed in uric acid pre-treated cells.

Conclusion: In this study we propose a mechanism in which high uric acid concentrations might influence inflammatory responses by facilitating IL-1β production in immune cells. We show that a mechanism for the amplification of IL-1β consists in downregulation of IL-1Ra production that has the role of counterbalancing IL-1β auto-induction loop. As a consequence, patients having hyperuricaemia could be at risk of exhibiting increased vulnerability upon encounter of acute inflammatory stimuli and this might induce enhanced states of inflammation.

Pegloticase for Tophus Debulking: Comparison of Dual Energy Computerized Tomography (DECT), Musculoskeletal Ultrasound (MSK-US) and Topographic Caliper Measurement for Assessing Debulking Rate. Dodji Modjinou[1], Elaine Karis[2], Soterios Gyftopoulos[3], Jonathan Samuels[4], Robert T. Keenan[5], Daisy Bang[6], Kristen Lee[4], Svetlana Krasnokutsky-Samuels[6], Daria B. Crittenden[7] and Michael H. Pillinger[7]. [1]NYU/HJD, New York, NY, [2]pending, pending, NY, [3]NYU Langone Medical Center/NYU Hospital for Joint Diseases, New York, NY, [4]NYU Langone Medical Center, New York, NY, [5]Duke University, Durham, NC, [6]NYU School of Medicine, New York, NY, [7]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Pegloticase is approved for lowering serum urate (sUA) in chronic refractory tophaceous gout (CRTG), but the rate of tophus resolution is not well defined, in part owing to limitations of measurement techniques. DECT permits 3-dimensional reconstruction and volumetric assessment of tophi, but comparisons between DECT and other imaging modalities are limited. We conducted an n-of-1 pilot study comparing DECT, MSK-US and surface caliper measurement to assess the rate of tophus debulking during pegloticase treatment.

Methods: A 32-year old male with a 10 year history of CRTG underwent a 13-infusion, twice-monthly course of pegloticase 8 mg, with sUA assessment prior to each infusion. Monthly caliper measurements of 3 index tophi, photographs and MSK-US imaging (gray scale, 18 mHz probe) every 3 months, as well as DECT and X-Rays (pre-/post-treatment) of the hands and feet were performed and compared.

Results: 8 tophi were noted on physical exam of the hands and feet, with 3 selected as index tophi. Whereas physical exam identified 4 tophi on the right hand, DECT revealed 15; whereas X-ray identified a single erosive lesion in the right hand, DECT identified 4 more in the feet. Pegloticase persistently lowered the patient's sUA to <0.5 mg/dL. Caliper measurements at the start and end of treatment revealed 73, 60, & 63% reductions of the index tophi, while MSK-US showed 29, 80, and 41% reductions of the same tophi, respectively. In contrast, DECT revealed 100% resolution of all 3 index tophi, and resolution/improvement of all other tophi identified. Initial DECT images revealed a composite tophus volume of 2,170 mm^3 on the right hand and 900mm^3 on the left; each decreased to 130 $mm^3$by study completion. On caliper measurement, the size of the index tophi fluctuated over time despite overall reduction. On MSK-US, some individual tophi appeared to "soften" and expand initially, followed by overall size reduction.

Conclusion: Pegloticase rapidly reduced all tophi assessed. While all assessment modalities were informative, correlation between them was poor, probably relating to the fact that calipers and MSK-US measure tophus area in non-congruent, perpendicular planes, whereas DECT measures volume. As previously reported, DECT identified occult urate deposition not visible on physical exam. Interestingly, tophi may fluctuate in size, even transiently increasing, during the process of resolution, revealed on ultrasound as tophus "softening" and loss of structure. Moreover, DECT imaging indicated that some urate deposits fully resolved even as their visible/palpable lesions persisted, possibly because of persistence of soft tissue swelling and/or fibrosis. We conclude that urate resorption begins early in the course of pegloticase therapy, but may be hard to recognize because of fluctuating volumes. While all imaging modalities have value, DECT is superior for identifying total (including occult) urate deposition, assessing absolute volume of deposits, and confirming urate resolution, even when soft tissue swelling persists. DECT may therefore be particularly valuable for determining the end point of pegloticase therapy.

Clinical Presentation and Cytokine Production Abnormalities in a Cohort of Patients Carrying NLRP12 GENE Variants. Antonella Insalaco[1], Luigi Raganelli[2], Manuela Pardeo[2], Virginia Messia[2], Denise Pires Marafon Jr.[2], Francesca Romana Lepri[2], Elisa Pisaneschi[2], Claudia Bracaglia[1], Valeria Gerloni[3], Rebecca Nicolai[2], Elisabetta Cortis[4], Fabrizio De Benedetti Sr.[1] and Giusi Prencipe[1]. [1]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, Italy, [3]Istituto Ortopedico Gaetano Pini, Milano, Italy, [4]Santa Maria della Stella Hospital, Orvieto, Italy.

Background/Purpose: The NLRP12 related autoinflammatory disorder (NLRP12-RD) is a rare autosomal dominant disease, caused by mutations in the NLRP12 gene.Clinical manifestations are extremely heterogeneous. We describe clinical features and inflammatory response of a cohort of patients carrying different NLRP12 variants, some of which not yet described as being associated with NLRP12-RD.

Methods: Twelve caucasian patients(6 males)carrying NLRP12 variants were identified. Blood samples obtained from 9/12 NLRP12 patients and from 7 active Juvenile idiopathic arthritis(JIA) patients were stimulated ex vivo with 1 mg/ml of Zymosan for 22h. Whole blood RNA analysis was also performed, using a human immune array(TaqMan® Human Immune Array from Applied Biosystems),containing 92 genes typically involved in the immune response.

Results: The median age at symptoms onset was 11,4 months(IQR 4,6–35,2)and the median of disease duration was 6,8 years(IQR 4,1–11). Sequencing of NLRP12 gene in the 12 patients revealed 5 heterozygous mutations:F402L(n=6),G448A(n=1),H304Y(n=1),R1030G(n=1) and G39V(n=1). Two patients were homozygous for NLRP12 variants:F402L and G39V. In 6/12 variants of NLRP3 were also found:Q703K(n=4) and V198M(n=2). All patients had symptoms consistent with a recurrent inflammatory syndrome:11/12 presented recurrent episodes of skin lesions,11/12 arthralgia,10/12 recurrent fever episodes,8/12 arthritis,10/12 headache,11/12 fatigue,5/12 conjunctivitis,7/12 recurrent abdominal pain and lymphadenopathy,5/12 oral aphthosis,4/12 thoracic pain and 2/12 sensorineural deafness. During the attacks 5/12 patients showed increased acute phase reactants. In 5/12 patients anakinra was administered because of the severity of phenotype and the persistence of elevated acute phase reactants. In 2 of these 5 patients lack of efficacy led withdrawal of anakinra and introduction of tocilizumab with good response. In vitro cytokine release studies, performed in 9 patients, showed that the production of IL-6 and TNF-α was significantly higher in patients carrying the NLRP12 variants compared to patients with JIA (IL-6:2841$\pm$1682 ng/ml and 1496$\pm$982.4 ng/ml versus 498.8$\pm$338.7 ng/ml and 226.6$\pm$111.8 ng/ml respectively;p=0.0002 and p=0.007)and even higher in homozygous patients;no significant difference in IL-1β production was found(2134 $\pm$ 1026 ng/ml versus 1527$\pm$930.3 ng/ml, p=0.29). Whole blood RNA samples collected from 5 NLRP12 patients were compared to 6 whole blood RNA samples collected from healthy controls comparable for age. At basal level, we did not find significant differences in the expression of 92 genes evaluated.

Conclusion: Our data in vitro and in vivo suggest that these NLRP12 variants are pathogenic. The role played by the concomitant presence of the NLRP3 variants remains to be clarified, though an effect in modifying the disease phenotype cannot be excluded. Our data also confirm the clinical and functional heterogeneity of NLRP12 related disorder, a condition often misunderstood. Furthermore, although the small number of patients treated, our data suggest that inhibition of IL-6 may be effective in NLRP12-related disorder.

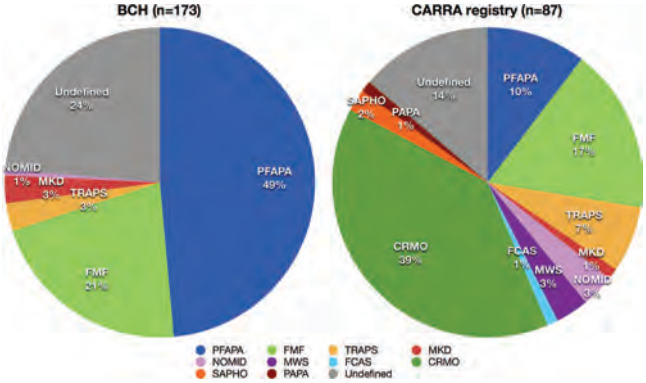
Studying Patients with Autoinflammatory Diseases: The Past, Present, and a Perspective for the Future. Jonathan S. Hausmann[1], Catherine Biggs[2], Donald P. Goldsmith[3] and Fatma Dedeoglu[4]. [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]St Christopher's Hospital for Children/Drexel College of Medicine, Philadelphia, PA, [4]on behalf of CARRAnet Investigators, Palo Alto, CA.

Background/Purpose: Autoinflammatory diseases (AIDs) are uncommon disorders characterized by recurrent episodes of systemic and organ-specific inflammation. Because of their rarity, finding large numbers of patients to study has been challenging. This project will compare the results of a retrospective chart review of patients with AIDs at a single academic medical center, with those of participants within the Childhood Arthritis and

Rheumatology Research Alliance (CARRA) Registry, a multicenter observational pediatric rheumatic disease registry in North America.

Methods: Patients with a clinical or genetic diagnosis of AID were included in this study. A retrospective chart review was conducted at Boston Children's Hospital (BCH) from 2002–2012. Charts were identified by keywords and billing codes related to AIDs and recurrent fevers. We also conducted a cross-sectional study of children with AIDs enrolled in the CARRA registry from May 2011 to December 2013.

Results: At BCH,173 subjects with AIDs were identified. In the CARRA registry, of 9,523 subjects enrolled, 87 patients were classified as having AIDs. The frequency of diagnoses are found in Figure 1.



Conclusion: Using the traditional methodology of a single-center retrospective chart review, we described the patients with AIDs seen at BCH, and estimated the frequency of various AIDs within this population. This research required little cost and relatively little time. Limitations included incomplete documentation in some cases, and the variety of AIDs identified was limited.

The CARRA registry, on the other hand, was a modern, multicenter effort that allowed enrollment of patients from multiple sites at a faster rate, and with a greater variety of diagnoses. However, this registry required significant financial investments in technology and operational costs. The fact that PFAPA, the most common pediatric AID, represented a minority of subjects within the CARRA registry suggests that physicians enrolled a select number of patients, possibly due to the time required for the consent, enrollment, and data-uploading processes.

Integration of registries into the patient's electronic health records will potentially minimize the current barriers to research. In addition, we believe that online patient communities can also contribute valuable information. In future studies, we plan to empower and engage patients with AIDs through social media to collaborate in the design and implementation of research studies. Our efforts could exponentially expand the number of patients available to participate in research, and help our understanding of these complex disorders.

Cryopyrinopathy with a Myeloid-Specific *NLRP3* Mutation. Patrycja Hoffmann[1], Qing Zhou[2], Amanda Ombrello[2], Anne Jones[2], Beverly Barham[2], Ivona Aksentijevich[1] and Daniel L. Kastner[1]. [1]National Human Genome Research Institute, Bethesda, MD, [2]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Background/Purpose: To identify the cause of disease in an adult patient who presented with recurrent fevers and urticaria which responded to IL-1 inhibition with anakinra. She was negative for *NLRP3* mutations based on conventional sequencing.

Methods: A 52 year-old perimenopausal pediatrician presented to the NIH with new-onset episodes of urticarial rash, fever, chills, fatigue, arthralgia, and myalgia. A skin biopsy revealed neutrophilic infiltrates. She recalled a similar urticarial rash as a child, which resolved at puberty. Prior treatments included colchicine, prednisone, IVIG, antihistamines, H2 blockers, high dose aspirin, and hydroxychloroquine, without significant benefit. The patient was started on anakinra 100 mg daily, and eventually increased to 300 mg daily. Frequency and duration of flares and diagnostic biomarkers, including CRP, ESR, and WBC, were recorded before starting anakinra and for eleven years afterwards. Whole-exome sequencing, targeted deep resequencing of *NLRP3* in peripheral blood and buccal cells, and mutational screening in subcloned amplicons from skin fibroblasts, buccal cells, and flow-sorted monocytes, granulocytes, T lymphocytes, and B lymphocytes, was performed to interrogate the possibility of somatic mutations in *NLRP3*.

Results: Prior to starting anakinra, flares occurred every 2–3 days lasting less than 24 hours. A stress-induced erythematous rash was the predominant symptom during flares, along with constitutional symptoms, arthralgia, and myalgia. During flares the CRP was elevated at 16.5 mg/L, and the WBC was slightly elevated at 9.860 K/uL. After starting anakinra, there was immediate resolution of rash, constitutional symptoms and normalization of inflammatory markers. WBC also normalized at 5.060 K/uL. Whole- exome sequencing identified a previously reported CAPS-associated mutation, p.Tyr570Cys, with a mutant allele ratio of 15% in whole blood. Targeted deep sequencing of *NLRP3* in blood and buccal cells demonstrated similar levels of mosaicism, but only in the peripheral blood. We then analyzed 192 colonies each from subcloned amplicons derived from monocytes, granulocytes, T lymphocytes, B lymphocytes, fibroblasts, and buccal cells. This confirmed the presence of the mosaic mutation at a ratio similar to the exome data in monocytes and granulocytes but not in lymphocytes, cultured fibroblasts, or buccal cells.

Conclusion: To our knowledge this abstract represents the first report documenting lineage-specific *NLRP3* mosaicism, established by subcloning amplicons from six different cell types. The patient's initial presentation of urticarial rash before puberty and reoccurrence during menopause along with constitutional symptoms, arthralgia and myalgia was not classic for Muckle-Wells syndrome, however the clinical presentation was suggestive of a cryopyronpathy. The molecular demonstration of lineage-specific *NLRP3* mosaicism, taken together with the clinical response to anakinra, confirm the diagnosis of cryopyrinopathy, and underscore the emerging role of massively-parallel sequencing in clinical diagnosis.

1228

Involvement of the IFN-Õ Pathway in a Patient with Candle Syndrome Carrying a Novel Variant of PSMB8 Gene. Antonella Insalaco[1], Giusi Prencipe[1], Manuela Pardeo[2], Virginia Messia[2], Andrea Masotti[2], Cristina de Min[3], Claudia Bracaglia[1], Rebecca Nicolai[2], Ivan Caiello[1] and Fabrizio De Benedetti Sr.[1]. [1]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, Italy, [3]Novimmmune S.A., Plan-Les-Ouates, Geneva, Switzerland.

Background/Purpose: Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) syndrome is a newly described autoinflammatory disease. We describe clinical phenotype and cytokine profile of our patient.

Methods: A 10 years-old young girl presented at 10 months of age with recurrent fever, hepatosplenomegaly and nodular erythematous skin lesions; she progressively developed lypodistrophy, arthralgia, arthritis and edema of eyelids. Skin biopsy showed features of lobular panniculitis. Laboratory tests showed persistent elevated acute phase reactants with anemia, recurrent leucopenia, thrombocytopenia and hypogammglobulinemia. Immunological and cytogenetic studies performed on bone marrow were normal. Subsequently, the patient developed nephrotic syndrome. Renal biopsy revealed a minimal change glomerulopathy responsive to high-dose glucocorticoid. Response to hydroxychlorochine, colchicine, cyclosporine-A, and anakinra was unsatisfactory. Complete sequencing of TNFRSF1A and MVK genes showed no mutations. Analysis of the PSMB8 (proteasome subunit β type 8) gene revealed the presence of c.220A>T p.(T74S) variant in heterozygotic status that has never been reported before. In order to assess the dysregulated inflammatory response, we evaluated the cytokine profile in patient's sera using the Luminex multiplexing assay. Whole blood RNA analysis was also performed using a human immune array (TaqMan® Human Immune Array from Applied Biosystems), containing 92 genes typically involved in the immune response.

Results: Serum samples (n=4) were collected during the last two years. We found high levels of IFNγ (mean $\pm$ S.D.: 115.3 pg/ml $\pm$ 64.21), of IFNγ inducible protein 10 (IP-10, also called CXCL10) (1641$\pm$ 892.5 pg/ml) and of IFNγ inducible protein 9 (IP-9, also called CXCL11) (582.9$\pm$ 335.6 pg/ml) and especially of CXCL9, also known as monokine induced by γ-interferon (MIG) (18161$\pm$ 6405 pg/ml), compared to healthy controls or pediatric patients with sJIA during active disease. Two whole blood RNA samples collected from our Candle patient were compared to 6 whole blood RNA samples collected from healthy controls comparable for age. We obtained results consistent with those obtained by serum cytokine measurement: IFNγ, CXCL10 and CXCL11 mRNA expression were significantly increased compared to healthy controls (1.88, 32.7 and 4.1 fold higher

respectively). We also found that the expression of the HLA-DRB1, a gene whose expression is known to be induced by IFNγ, was markedly upregulated (> 100.000 fold increase) compared to healthy controls.

Conclusion: we describe a typical CANDLE clinical phenotype in the absence of biallelic mutations of PSMB8 gene. The presence of high levels of IFNγ and of IFNγ related chemokines points to a major pathogenic role of the IFNγ pathway, which appears to be similar to what has been recently reported in CANDLE (Liu et al). The pathogenic role of the variant T74S remains to be elucidated:a potential role is suggested by its presence in a patient with a classical phenotype and with a dysregulation of the IFNγ pathway, taking also into account that this variant is close to the know pathogenic mutation T75M.

Is NOD2-Associated Autoinflammatory Disease Remotely Related to Familial Mediterranean Fever or Continuum of It? Min Shen, Bo Shen and Qingping Yao Cleveland Clinic, Cleveland, OH.

Background/Purpose: NOD2-associated autoinflammatory disease (NAID) is a newly described autoinflammatory disease characterized by periodic fever, dermatitis, polyarthritis, gastrointestinal and sicca symptoms. It is genotypically associated with NOD2. Its clinical phenotype may superficially resemble familial Mediterranean fever (FMF). We report a case series to illustrate the similarities and differences between these two autoinflammatory diseases.

Methods: Three patients with NAID or FMF were cared for by the authors between 2012 and 2014, and their phenotypes and genotypes were retrospectively studied. Genetic testing for MEFV and NOD2 mutations was performed.

Results: The clinical phenotypes and genotypes of these patients are summarized (Table). Patient 1 presented with recurrent fever, abdominal pain/diarrhea, chest pain, and arthralgia since the age of 5 years. Her symptoms responded well to colchicine, and FMF was diagnosed in the presence of heterozygous K695R. Patient 2 is the niece of patient 1 and presented with symptoms since the age of 17 years and shared the similar phenotypes with her aunt except the presence of recurrent erythematous patches of the skin and longer lasting gastrointestinal symptoms. FMF was suspected, but she had a transiently mild response to colchicine. Genetic testing identified the NOD2 mutations IVS8+158 and R702W and negative MEFV. NAID was diagnosed with a complete response to oral sulfasalazine. Patient 3 is a man and presented with recurrent fever and abdominal pain/diarrhea since the age of 17 years, with mild response to colchicine. Genetic testing identified heterozygous M694V in the MEFV and NOD2 mutation IVS8+158.

Conclusion: Both NAID and FMF appear similar phenotypically, but they are distinct. The symptoms can last longer than 3 days, and spongiotic dermatitis is common in NAID, whereas erysipelas-like erythema with sparse infiltrate on the lower extremities is a feature of FMF. NAID does not respond to colchicine. Both MEFV and NOD2 genes are located on chromosome 16 and share similar gene structures. This case study suggests that these two diseases could be remotely related.

Efficacy of Interleukin-1 Targeting Drugs in Familial Mediterranean Fever Patients. Pinar Cetin[1], Ismail Sari[1], Betul Sozeri[2], Ozlem Cam[2], Merih Birlik[1], Fatos Onen[1], Nurullah Akkoc[1] and Servet Akar[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Ege University School of Medicine, Izmir, Turkey.

Background/Purpose: Familial Mediterranean fever (FMF) is an autosomal-recessive autoinflammatory disorder characterized by recurrent episodes of fever accompanied by sterile peritonitis. The most devastating complication of FMF is the development of secondary amyloidosis which has a potential risk for developing end stage renal disease. However cholchicine is the most effective treatment regimen in FMF patients, 5–10% of patients are refractory. However, there are several drugs being tested in this group of patients. The most promising group of drugs appears to be the anti-IL-1 therapies. The objective of this study is to demonstrate the efficacy of anakinra and canakinumab in FMF patients who followed up in our outpatient clinics.

Methods: In this study we included 20 cholchicine resistant FMF patients (16 adults and 4 children) diagnosed according to the Tel–Hashomer or Sheba Medical Center criteria, who are receiving anti-IL-1 treatments (anakinra n= 12 or canakinumab n= 8). A retrospective review of medical records of anti-IL-1 recipients was performed. The main clinical characteristics of these patients and their genotypes for MEFV gene and the evolution after anti-IL-1 were recorded laboratory response was evaluated with erythrocyte sedimentaion rate(ESR) and C-reactive protein (CRP).

Results: The median age of patients was 23 (14–50), the median disease duration was 16 years (4–46) and the median follow up time in clinic was 12 years (1–26). 16 were homozygous for the M694V mutation. Attacks per month and year were significantly decreased after anti IL-1 theraphy $p < 0.05$ (Table 1). The median follow-up of the anakinra and canakinumab patients were 14 (4–36) and 18 (4–25) months respectively ($p = 0.51$). All patients were also receiving background colchicine with a median dose of 1.5 mg. there is a trend towers a decreasing dose of colchicine after anti-IL-1. Acute phase responses were aslo significantly decreased after IL-1 treatments ($p < 0.05$, Table 1). Besides the effectiveness on acute attacks we also noted significant decreases in proteinuria in patients with amyloidosis (9 gr to 3.7 gr/day in the adult and 25.6 mg/m^2/hour to 12 mg/m^2/hour in the pediatric patient). In a median 16 months of follow-up there were only one serious adverse event (pneumonia) in a patient receiving anakinra therapy However, after antibiotic treatment we resumed treatment in this patient.

Conclusion: In this study we revealed that 95% of our colchicine-resistant patients responded to the anti-IL-1 targeting agents. These drugs tolerated well and only one patient had serious adverse events during the 16 months of follow-up. We also noted significant ameloration of proteinuria in amyloidosis patients. IL-1 receptor antagonists anakinra and canakunimab seem to be safe and effective treatment options in colchicine-refractory FMF patients.

Table 3: Number of attacks and acute phase protein levels before and after anti-IL-1 treatment

	Attacks/mo (Before treatment)	Attacks/mo (After treatment)	*p*	Attacks/year (Before treatment)	Attacks/year (After treatment)	*p*

Hospital Sant Joan de Déu. Universitat de Barcelona, Barcelona, Spain, [9]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [10]University of Siena, Siena, Italy, [11]Bicêtre Hospital, University of Paris SUD, Paris, France, [12]Istituto Giannina Gaslini, Genova, Italy, [13]Hopital Tenon, Paris, France, [14]Centre Multisite Romand de Rhumatologie Pediatrique, Lausanne, Switzerland, [15]University Hospital Tuebingen, Tuebingen, Germany, [16]University College London Medical School, London, United Kingdom, [17]Radboudumc, Nijmegen, Netherlands, [18]The Hospital for Sick Children, Toronto, ON, [19]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel, [20]Deptartment. of Pediatric Rheumatology, Hacettepe University, Ankara, Turkey.

Background/Purpose: Familial Mediterranean Fever (FMF) is a disease that starts in childhood and can lead to significant morbidity. In 2013, an initiative called SHARE (Single Hub and Access point for pediatric Rheumatology in Europe) has been launched for children and young adults with rheumatic diseases. For FMF, attention was focused on genetics. The aim of the SHARE recommendations in FMF is to provide a diagnostic tool for inexperienced pediatric rheumatologists to cope with FMF in their clinical practice. This is possible through a correct interpretation of the diagnostic value of *MEFV*mutations in predicting FMF phenotype.

Methods: An expert committee was instituted, consisting of pediatric rheumatologists, and search terms for the systematic literature review were defined. Two independent experts scored articles for validity and level of evidence. Recommendations derived from the literature were evaluated by an online survey. Those with less than 80% agreement during the online survey were reformulated. Subsequently, all recommendations were discussed at a consensus meeting using the nominal group technique. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 3386 articles, of which 25 considered relevant and therefore scored for validity and level of evidence. 17 articles were scored valid and used in the formulation of the recommendations. 8 recommendations were finally accepted with 100% agreement after the consensus meeting (Table 1). Topics covered for diagnosis were: clinical versus genetic diagnosis of FMF; genotype-phenotype correlation; genotype-age at onset correlation; silent carriers and risk for amyloidosis; role of the specialist in FMF diagnosis.

Conclusion: The SHARE initiative provides recommendations for the diagnosis of FMF and thereby facilitates improvement and uniformity of care.

FMF Recommendations

1. FMF is a clinical diagnosis, which can be supported but not excluded by genetic testing.
2. Consider patients homozygotes for M694V at risk of developing, with very high probability, a severe phenotype.
3. FMF patients carrying two of the common mutated alleles (homozygotes or compound heterozygotes), especially for M694V mutation or mutations in the position 680 to 694 on exon 10, must be considered at risk of having a more severe disease than those carrying only one mutated allele (heterozygotes).
4. The E148Q variant is common, of unknown pathogenic significance and as the only MEFV variant does not support the diagnosis of FMF.
5. Patients homozygous for M694V mutation are at risk for an early onset disease.
6. Individuals, homozygous for M694V, who are not reporting symptoms, should be evaluated and followed closely in order to consider therapy.
7. For individuals with two pathogenic mutations for FMF who don't report symptoms, if there are risk factors for AA amyloidosis (such as country of origin, family history and persistently elevated inflammatory markers) treatment and close follow-up should be considered.
8. Consultation with an autoinflammatory disease specialist may be helpful, in order to aid in the indication and interpretation of the genetic testing and diagnosis.

Canakinumab Therapy in Patients with Familial Mediterranean Fever. Serdal Ugurlu, Emire Seyahi, Gulen Hatemi, Aysa Hacioglu, Fatma Nihan Akkoc and Huri Ozdogan. Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: According to a recent pilot study Canakinumab reduced the frequency of attacks in 9 patients with Familial Mediterranean Fever (FMF) resistant to colchicine with no apparent side effects(1). We present our experience with Canakinumab in FMF patients resistant or intolerant to colchicine.

Methods: The charts of the patients with FMF who were on Canacinumab were evaluated retrospectively with regard to response and safety.

Results: There were 30 patients with FMF (16 F/14 M) receiving canakinumab for various indications. Here we report 28 (15 F/13 M) who had at least 3 injections. Six patients had concomitant diseases such as psoriasis (1), ankylosing spondylitis (3), polyarteritis nodosa (1), ankylosing spondylitis and polyarteritis nodosa (1). The indications for canakinumab (150mg/mo) were insufficient response to colchicine in 15 (>1 attack/month), amyloidosis in 6, injection site reaction to anakinra in 5, oligospermia in one and myopathy in one patient, both being adverse effects of colchicine. The mean age of the patients was 34,67 ± 13,45 years, the disease duration was 16,75 ± 9,42 years, the mean injection number was 7,00 ± 3,62 and the mean duration of canakinumab therapy was 10,98 ± 6,06 months. Twenty of the patients had no attacks after canakinumab, six patients' attack frequency was reduced more than %50 while two patient's attack frequency did not change. In 6 cases with FMF amyloidosis, proteinuria decreased in 2 (from 15020 mg/dl to 910 mg/dl, and from 6135 mg/dl to 4610 mg/dl), increased in 2 (from 1700mg/dl to 4700mg/dl and from 5001 mg/dl to 7061 mg/dl), and did not change in the other 2. Eleven of the 24 patients with severe myalgia and calf pain unresponsive to colchicine treatment, improved significantly on canakinumab. According to patient global assessment the mean score decresed from 7,9 ± 2,6 to 2.1 ± 2.9 ($p<0.001$). Canacinumab was stopped because of remission (no attacks at least for 3 months) in 5 and for pregnancy demand in one. The treatment was also stopped in the patient with oligospermia after being fertile, and he is without attacks for 5 months. Attacks recurred after 4, 6, 12 months from discontinuation of the therapy in 3 patients, and 3 patients are attack-free for 5, 6 and 13 months till now. None of the patients had injection site reactions. The patient with psoriasis reported a flare in psoriatic plaques, which responded to local treatment. Therapy was discontinued temporarily in one patient who developed mild leucopenia, which did not recur on a 2-monthly regimen. Treatment was switched to another biological agent in 2 patients with amyloidosis because of increasing proteinuria. One other patient with amyloidosis whose proteinuria was stable, developed lichen planus lesions and the treatment had to be stopped. One patient had pnomonia, also he is attack-free for three months untill last dose.

Conclusion: Canacinumab is effective in controlling the attacks in patients with inadequate response to colchicine. In a selected group of FMF patients, Canacunimab may serve as a treatment alternative with a favorable side effect profile. For better understanding the drug's efficacy and safety in the long term there is a need for controlled trials.

Tocilizumab (TCZ) in the Treatment of AA Amyloidosis in Patients with Familial Mediterranean Fever. Huri Ozdogan, Serdal Ugurlu, Aysa Hacioglu, Yasaman Adibnia and Vedat Hamuryudan. Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: AA amyloidosis is the major long-term complication of various chronic inflammatory diseases like rheumatoid arthritis, ankylosing spondylitis, FMF and other autoinflammatory syndromes. Treatment of the underlying disease decreases the frequency of this complication however if it develops there is no established treatment of AA amyloidosis. Recently there are few reports pointing out that tocilizumab (TCZ), an anti IL-6 agent may be effective in controlling resistant AA amyloidosis.

We aim to demonstrate our data on the effect of TCZ in patients with AA amyloidosis secondary to FMF.

Methods: The follow-up data of FMF patients with histologically proven AA amyloidosis, treated with TCZ (8 mg/kg per month) is evaluated by assessing the changes in creatinine, creatine clearance, the amount of 24-hour urine protein, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) values measured before and throughout the treatment period. Adverse and side effects of the treatment were closely monitored.

Results: TCZ was given to 13 patients (8 female, 5male) with AA amyloidosis secondary to FMF who were also on Colchicine (2.28 mg± 0.48 mg/day). Two patients had coexisting ankylosing spondylitis, one had systemic lupus erythematosus and one other had Crohn's disease. The mean age was 36.46±9.96 years, while the mean disease duration of FMF was

23.15±7.65 years and of amyloidosis was 4.52±4.98 years. The mean follow-up period on TCZ treatment was 8.76 ± 5.59 months. The mean creatinine levels decreased from 1.21±0.93 mg/dl to 1.05 ± 0.65 mg/dl (p = 0.001), mean creatine clearance increased from 102.34±53.95 ml/min to 109.08±60.23 ml/min (p <0.001). Renal function was impaired in 3 of the 13 patients which improved significantly on TCZ therapy (serum creatinine from a mean of 2.64±0.57 mg/dl to 1.97±0.46 mg/dl, p=0.018; creatinin clearence from a mean of 36.2±4.51 to 45.3±5.55ml/min, p=0.005). The median of 24-hour urinary protein excretion for the whole group was reduced from 3038.5 mg/dl (IQR 1827–7061) to 1155mg/d (IQR 802–4707) (p=0.013). A significant decrease in acute phase reactants was also recorded. The mean level of CRP was reduced from 19.43 ±18.75 mg/l to 3.87±4.8 mg/dl (p=0.004) as the mean ESR was reduced from 45.41±26.68 mm/h to 27.63 ± 29.25 mm/h (<0.001).

Twelve of the patients did not experience any FMF attack under TCZ treatment. In one patient TCZ was switched to canakinumab because of an increase in the frequency of attacks associated with erysipelas-like erythema and no decrease in proteinuria. One other patient with FMF and AS had 2 attacks of acute sacroiliitis during the follow-up. Increased blood pressure (220/120 mm Hg) was noted 5 days after the single infusion in one patient who was an illicit user of synthetic cannabinoid. TCZ was stopped in one other patient with underlying SLE and APLS who developed ishemic chest pain after the 12th infusion.

Conclusion: TCZ improves the acute phase response and the renal function impaired by amyloidosis secondary to FMF. Among this patient group TCZ treatment is well tolerated and not associated with serious side effects. Further studies are warrented to test the efficacy and safety of TCZ in AA amyloidosis secondary to FMF as well as other inflammatory conditions.

Periodic Fever Syndromes in an Academic Medical Center. Mark Cervinski[1] and Daniel Albert[2]. [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]The Dartmouth Institute for Health Policy and Clinical Practice, lebanon, NH.

Background/Purpose: Most published clinical data on this rapidly evolving group of diseases are from highly specialized centers and do not reflect what is commonly seen in academic rheumatology practices. This retrospective case series examines the breadth and phenotypic variation seen in our medical center over the last two years.

Methods: Case acquisition was acheived by three methods: review of ICD 9 code for periodic fever (277.31 -Famillial Mediterranean Fever); laboratory test requests for periodic fever genetic screening; and, clinic records.

Results: 30 cases were obtained. The age range was 2m to 54 years old. 13 were female, 17 male. All but 3 were seen by a rheumatologist. Of the rheumatology patients 1 was cared for by an adult only rheumatologist and 1 by a rheumologist who predominantly cares for adult patients and the remainder (25) by a rheumatologist who cares for children (DA). 11 patients had the periodic fever, apthous stomatitis, pharyngitis, adenopathy syndrome (PFAPA) and all responded to abortive therapy with prednisone 1–2mg/kg at the onset of symptoms. 9 patients had an unknown syndrome predominantly abdominal pain and fever with a negative screen for common mutations associated with Familial Mediterrean Fever and other periodic fever syndromes (GeneDX). 5 patients with the Tumor Necrosis Factor Receptor Associated Periodic Syndrome (TRAPS) were diverse ranging from asymptomatic relatives to classical presentiations including fever, abdominal pain, myalgias, arthritis and conjunctivitis. Only one of TRAPS patients received Entanercept and had a partial response but developed systemic lupus when given infliximab.Two of the three Familial Mediterranean patients responded to colchicine. The single patient with Hyper IgD Syndrome (HIDS) did not respond to either prednisone or anakinra. One child is a compound heterozygote with a mutation in the CIAS1 gene and the MEFV gene. This patient presented with urticaria, abdominal pain, and fever reflecting an overlap syndrome as did one of the othe FMF patients.

Conclusion: Patients with Periodic Fever Syndromes have a variable clinical presentation and response to therapy and are predominantly cared for by rheumatologists. Familiarity with these disorders is essential for trainees and practicing rheumatologists. Expertise in pediatric rheumatology is useful to distinguish these patients from those with systemic juvenile rheumatoid arthritis and to appropriately treat this population that predominantly present in childhood.

Recovery of Renal Function after Corticosteroid Therapy for IgG4-Related Kidney Disease. Takako Saeki[1], Mitsuhiro Kawano[2], Ichiro Mizushima[2], Motohisa Yamamoto[3], Yoshifumi Ubara[4], Hitoshi Nakashima[5], Yoko Wada[6], Tomoyuki Ito[1], Hajime Yamazaki[1], Ichiei Narita[6] and Takao Saito[5]. [1]Nagaoka Red Cross Hospital, Nagaoka, Japan, [2]Kanazawa University Hospital, Kanazawa, Japan, [3]Sapporo Medical University School of Medicine, Sapporo, Japan, [4]Toranomon Hospital, Tokyo, Japan, [5]Fukuoka University, Fukuoka, Japan, [6]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background/Purpose: In our earlier study of IgG4-related kidney disease (IgG4-RKD), we found that renal dysfunction, which was mostly attributable to IgG4-related tubulointerstitial nephritis, was significantly improved at 1 month after the start of corticosteroid therapy, but reached a plateau thereafter, and renal atrophy developed in many patients (Saeki, et al. Kidney Int 2013). Little is known about the appropriate initial corticosteroid dose for induction therapy or the long-term renal outcome in IgG4-RKD with renal dysfunction.

Methods: This retrospective cohort analysis evaluated the recovery of renal function during the initial 1 month of corticosteroid therapy, and the long-term course of renal function after treatment, in 41 patients with confirmed IgG4-RKD in whom the eGFR before corticosteroid treatment had been less than 60 ml/min. The patients were collected from 16 collaborating institutions in Japan between 2004 and 2013, and divided into two groups (group L, initial prednisolone dose <0.6 mg/kg/day; group H, >0.6 mg/kg/day).

Results: Among the patients, 88% were male, and the mean age at the time of diagnosis of renal disease was 66.6±9.3 years. Renal pathology data were available for 38 of the 41 patients, and all of them had the tubulointerstitial features characteristic of IgG4-RKD. One patient with renal failure in group L showed no recovery of renal function and maintenance hemodialysis became necessary within 1 month after the start of treatment. Except for this patient, eGFR data at 1 month after treatment were available for 31 patients (group L 17; group H 14). The initial prednisolone dose was 0.47±0.12 mg/kg daily in group L and 0.84±0.16 mg/kg daily in group H, being significantly lower (P<0.001) in the former. There was no significant inter-group difference in patient age, sex or pretreatment eGFR. In both groups, the pretreatment eGFR was significantly improved at 1 month after the start of corticosteroid therapy [30.5±15.7 to 41.8±14.9 ml/min in group L (p<0.05) and 32.7±13.8 to 46.6±17.0 mi/min in group H (p<0.05)], and the degree of improvement showed no significant inter-group difference. Fifteen of the 41 patients were followed up for over 36 months (39 – 210 months, median 56 months), and all of them had been maintained on low-dose prednisolone (5.1 ± 2.1 mg daily) at the last review. No patient showed progression to end-stage renal disease, and there was no significant difference in eGFR at the last review (45.1 ±11.3 ml/min) in comparison to that at 1 month after the start of treatment (42.5 ±12.8 ml/min).

Conclusion: In IgG4-RKD, prednisolone 0.5 mg/kg daily is sufficient for induction therapy, and the recovery of renal function during the first month of this treatment can be maintained for a long period on low-dose corticosteroid maintenance therapy.

IgG4 Immunostaining Is Common but Not Specific in Orbitbal Inflammatory Diseases. James T. Rosenbaum[1], Amanda Wong[2], Patrick Stauffer[2], Megan Troxell[3], Donald Houghton[2], Dongseok Choi[3], Christine Harrington[2], David Wilson[2], Hans Grossniklaus[4], Roger Dailey[2], John Ng[2], Eric Steele[2], Patrick Yeatts[5], Peter Dolman[6], Valerie White[6], Craig Czyz[7], Jill Foster[7], Deepak Edward[8], Hind Alkatan[8], Don Kikkawa[9], Bobby Korn[9], Dinesh Selva[10], Gerald Harris[11], Michael Kazim[12], Payal Patel[12] and Stephen R. Planck[2]. [1]OHSU, Portland, OR, [2]Oregon Health & Science University,

Portland, OR, [3]Oregon Health and Science University, Portland, OR, [4]Emory University, Atlanta, GA, [5]Wake Forest University, Winston-Salem, NC, [6]University of British Columbia, Vancouver, BC, [7]Ohio State Univeristy, Columbus, OH, [8]King Khaled Eye Hospital, Riyadh, Saudi Arabia, [9]University of California, San Diego, San Diego, CA, [10]Royal Adelaide Hospital, Adelaide, Australia, [11]Medical College of Wisconsin, Milwaukee, WI, [12]Columbia University, New York City, NY.

Background/Purpose: IgG4-related disease is an emerging clinical entity which frequently involves tissue within the orbit. In order to appreciate the implications of IgG4 immunostaining, we analyzed gene expression and the prevalence of IgG4- immunostaining among subjects with orbital inflammatory diseases.

Methods: We organized an international consortium to collect orbital biopsies from 109 subjects including 22 with no known orbital disease, 42 with nonspecific orbital inflammatory disease (NSOI), 27 with thyroid eye disease (TED), 12 with sarcoidosis, and 6 with granulomatosis with polyangiitis (GPA). Lacrimal gland and anterior orbit adipose tissue biopsies were immunostained for IgG4 or IgG secreting plasma cells. RNA transcripts were quantified by Affymetrix microarrays.

Results: None of the healthy controls or subjects with TED had substantial IgG4 staining. Among the 63 others, the prevalence of significant IgG4-immunostaining ranged from 11 to 39% depending on the definition for significant. IgG4 staining was detectable in the majority of tissues from subjects with GPA and less commonly in tissue from subjects with sarcoidosis or NSOI. The detection of IgG4+ cells correlated with inflammation in the lacrimal gland based on histology. Subjects with NSOI and IgG4 staining did not have multisystem disease. IgG4 staining tissue expressed an increase in transcripts associated with inflammation, especially B cell-related genes. Functional annotation analysis confirmed this.

Conclusion: IgG4+ plasma cells are common in orbital tissue from patients with sarcoidosis, GPA, or NSOI and do not consistently indicate a multisystem disease. Even using the low threshold of 10 IgG4+ cells/high powered field, IgG4 staining correlates with increased inflammation in the lacrimal gland based on histology and gene expression.

Retroperitoneal Fibrosis and IgG4 Disease: Response to Immunosuppressive Therapy - a Single Centre Retrospective Study. Shirish Sangle[1], Pamela Lutalo[2], Louise Nel[3], James Pattison[3], Tim OBrien[4] and David P. D'Cruz[1]. [1]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom, [2]King's College London School of Medicine, London, United Kingdom, [3]Guy's and St Thomas' Hospital NHS Foundation Trust, London, United Kingdom, [4]Guy's and St Thomas' Hospital NHS Trust, London, United Kingdom.

Background/Purpose: A retrospective observational study of patients with IgG4 related disease and retroperitoneal fibrosis.

Methods: Retroperitoneal fibrosis (RPF) is a rare chronic inflammatory condition which may be associated with IgG4 disease. Thirty nine patients diagnosed with idiopathic RPF were retrospectively analysed at Guy's and St Thomas' Hospitals, London, England. All patients' data regarding clinical presentation, markers of inflammation, immunoglobulin subsets, autoantibody profiles, imaging and histopathology was collected. Comprehensive Diagnostic Criteria (CDC) for the diagnosis of IgG4 disease was applied to all patients.

Results: The study included 24 Caucasian, 9 African and 6 Asian patients. There were 19 female and 20 male patients. The median age of the patients was 54 years (range 38 – 80). The majority presented with ureteric obstruction (n=18) and 12 of these patients had renal failure. Clinical features included periaortitis (n=8), periaortic masses (n=6), left kidney atrophy (n=1), atheroma (n=1), lung cavitations (n=1), polymyalgia rheumatica (n=1), 1 patient had RPF diagnosed after a positive PET scan, 1 patient had RPF and a malignancy, and 1 patient developed RPF after methysurgide.

Laboratory markers of inflammation were significantly elevated in IgG4 related RPF. The median ESR was 28 (5 – 91) mm per hour and CRP was 26 (6 – 200) mg/l. The mean ESR=56mm/hr (S.D 28) in IgG4RPF was higher versus non-IgG4 RPF mean ESR=29mm/hr (S.D 27) [p=0.008]. IgG4 RPF, mean CRP=51mg/l (S.D 39) versus non-IgG4 RPF, mean CRP=31 mg/l (S.D 29) [p=0.04]. Immunoglobulin IgG subclass analysis showed higher IgG4 levels in IgG4 RPF, mean IgG4=0.96g/l (S.D 0.8) compared to non-IgG4 RPF, mean IgG4=0.44g/l (S.D 0.3) [p=0.05]. There were no statistically significant differences between IgG3, IgG2 and IgG1 levels in the IgG4 RPF and non-IgG4 RPF patients. Seven patients had elevated IgG4 levels. Thirty seven patients had biopsies, 7 had confirmed diagnosis and 4 had a probable diagnosis of IgG4 RPF based on IgG4 plasma cells and fibrosis in biopsy specimens. None of the patients diagnosed with IgG4 RPF had positive serology for ANA, dsDNA, ENA or ANCA. Seventeen patients had FDG-PET-CT scans of which 12 showed active inflammation, 5 with IgG4 RPF had positive scans. Therapeutic interventions included corticosteroids (n=28), immunosuppressants: azathioprine, methotrexate, ureteric stents (n=12), ureterolysis (n=4), and nephrectomy (n=2). Median corticosteroid dose was 20 mgs (0 - 40)/day. The median ESR 11 (3–63) mm/hour and CRP was 6 (5–70) mg/l improved after treatment. The median IgG4 levels dropped from 7.44 to 0.37 gm/l. Four patients had post therapy FDG-PET-CT scans and 3 (1 with IgG4 RPF) had reduced activity. Clinical improvement was reported in 72% of the patients (n=28), 1 patient deteriorated but declined Rituximab. Fifteen patients had a confirmed diagnosis of IgG4 disease based on CDC criteria.

Conclusion: IgG4 disease may be considered in patients with retroperitoneal fibrosis and periaortic lesions. FDG-CT-PET imaging is useful diagnostically and response to corticosteroids and immunosuppressant therapy is favourable.

1238

Proportion of Peripheral Plasmacytoid Dendritic Cells and Plasmablasts Reflects Disease Activity in IgG4-related Disease. Mitsuhiro Akiyama[1], Katsuya Suzuki[1], Yoshiaki Kassai[2], Takahiro Miyazaki[2], Rimpei Morita[3], Akihiko Yoshimura[3] and Tsutomu Takeuchi[4]. [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [2]Takeda Pharmaceutical Company Limited, Kanagawa, Japan, [3]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan, [4]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Immunoglobulin (Ig) G4-related disease (IgG4-RD) is a recently recognized fibro-inflammatory disease with multi-organ system involvement. Affected patients frequently have a history of bronchial asthma and allergic rhinitis. The reported pathogenesis of IgG4-RD describes the clear involvement of excessive Th2 cells and regulatory immune reaction in addition to plasma cells 1). However, peripheral immune cell phenotype, which reflects disease status, has not been comprehensively evaluated. Our aim was to definitively determine peripheral blood cell abnormalities and their correlation with disease activity in patients with IgG4-RD.

Methods: Peripheral blood samples were obtained from active untreated IgG4-RD patients (n=11) and healthy controls (n=16). Comprehensive immunophenotyping assay with information on activation status was done by multi-color flow cytometry, and the proportion of peripheral blood mononuclear cells (PBMCs), including T cells (naïve/memory, Th1/2/17, Treg, and Tfh), B cells (naïve/memory, plasmablast, Breg), monocytes (classical, intermediate, non-classical) and dendritic cells (myeloid, plasmacytoid), and their activity status were precisely defined. Disease activity was measured using the IgG4-RD responder index (RI). Statistical analysis was done using the Mann-Whitney U test and Spearman rank correlation coefficient test.

Results: The proportion of plasmablasts (CD19+CD20−CD27+CD38+), memory Th2 cells (CD3+CD4+CXCR3-CCR6-CD45RA-), Tregs (CD3+CD4+CD25+CD127low), Tfh (CD3+CD4+CXCR5+), and mDCs (CD3-CD19-CD14-HLA-DR+CD1c+CD303-) in peripheral blood was significantly increased in IgG4-RD patients compared with HC, whereas the proportion of pDCs (CD3-CD19-CD14-HLA-DR+CD1c-CD303+) was significantly decreased. Interestingly, the proportion of pDCs in total DCs was negatively correlated with IgG4-RD RI (r=−0.778, p=0.005) while the proportion of plasmablasts in CD19+cells was positively correlated with RI (r=0.701, p=0.016). Further, the increased proportion of plasmablasts was positively correlated with serum IgG4 level (r=0.718, p=0.013)

while the decreased proportion of pDCs tended to be negatively correlated with the number of affected organs ($r=-0.518$, $p=0.061$).

Conclusion: Our comprehensive analysis identified distinct proportional changes in PBMCs in IgG4-RD. In particular, the decrease in pDCs and increase in plasmablasts were strongly linked with disease activity. These combined measurements are expected to be clinically useful surrogate cell markers. This newly identified decrease in circulating pDCs may be involved in the pathogenesis in IgG4-RD via the recently described role in the enhancement of Th2 response 2).

Is Lymphocytic Sialadenitis IgG4-Related? Nathalie Shehwaro[1], Murielle Hourseau[1], Thomas Papo[2] and Karim Sacre[3]. [1]University Paris-7, APHP, Bichat Hospital, Paris, France, [2]Bichat Hospital, Paris, Paris, France, [3]University Paris-7, INSERM U699, APHP, Bichat Hospital, Paris, France.

Background/Purpose: To assess the prevalence of IgG4-related disease among patients with lymphocytic sialadenitis on labial salivary gland biopsy.

Methods: All labial salivary gland biopsies (LSGB) performed in a French University Hospital Center over a one-year period (2012) were retrospectively screened. IgG4 immunostaining was performed on all LSGB showing lymphocytic sialadenitis defined by a Chisholm score ≥3. Histopathological criteria for IgG4-related disease according to international criteria and final diagnosis associated with lymphocytic sialadenitis were analyzed in all cases.

Results: Three hundred and fifty patients had a labial salivary gland biopsy (LSGB). Among them, 79 (23%) had a lymphocytic sialadenitis. Mean age was of 55.5±15.7 years old. Female/Male Sex ratio was 3.2/1. LSGB was performed because of sicca symptoms in most cases (48/79, 60.8%). Only one (1/79, 1.3%) LSGB showed histopathological features of IgG4-related disease in a patient who otherwise displayed obvious extra-salivary features of IgG4-related disease. Overall, the diagnoses associated with lymphocytic sialadenitis were Sjögren's syndrome (29/79, 36.7%), other autoimmune disorders (besides Sjogren's syndrome) (17/79, 21.5%), idiopathic pulmonary fibrosis (5/79, 6.3%), sarcoïdosis (3/79, 3.8%), B-cell hemopathy (3/79, 3.8%), hepatitis C infection (2/79, 2.5%), unclassified arthritis (1/79, 1.3%), idiopathic uveitis (1/79, 1.3%), multiple sclerosis (1/79, 1.3%) and tuberculosis (1/79, 1.3%). In 15 cases (19%), no diagnosis could be obtained despite extensive work-up. Of note, IgG4 staining was negative in all patients with unexplained lymphocytic sialadenitis.

Conclusion: The prevalence of IgG4-related disease among patients with lymphocytic sialadenitis on LSGB is very low. Systematic IgG4 immunostaining has no diagnostic value in patients with lymphocytic sialadenitis. On the other hand, lip biopsy, by being simple and safe, can be useful for a definite diagnosis when IgG4-related disease is suspected.

Palma de Mallorca., Palma de Mallorca, Spain, [18]Hospital Universitario 12 de Octubre, Madrid, Spain, [19]Rheumatolgy Unit. Hospital Jerez, Jerez, Spain, [20]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: Adult-onset Still's disease (AOSD) is frequently refractory to standard therapy. Anakinra (ANK), an interleukin-1 (IL-1) receptor antagonist, has demonstrated efficacy in single cases or in small series of AOSD. We assessed the efficacy of ANK in a large series of AOSD patients.

Methods: Multicenter retrospective open-label study of 41 patients with AOSD from 19 hospitals. ANK was used due to lack of efficacy to standard synthetic immunosuppressive drugs and some cases also due to lack of adequate response to at least 1 biologic agent.

Results: 41 Patients (26 women/15 men) had a mean age of 34.4±14 years and a median [interquartile range- IQR] AOSD duration of 2.2 [1–24] years before ANK onset.

Besides oral steroids, patients had previously received the following drugs: Methotrexate (32 patients), Leflunomide (7), Etanercept (10), Infliximab (9) and Adalimumab (6). ANK standard dose was 100 mg/sc/day.

At ANK onset, the most frequent clinical manifestations were joint manifestations (n=36), fever (n=32) and cutaneous manifestations (n=24). Abnormality of laboratory parameters was generally observed at that time: high C reactive protein (CRP) (n=37), high erythrocyte sedimentation rate (ESR) (n=32), leukocytosis (n=27) or anemia (n=23). ANK yielded rapid and maintained clinical and laboratory improvement (TABLE). After one year of ANK therapy, joint manifestations had decreased from 87.8% to 29.6%, fever from 78% to 7.4%, cutaneous manifestations from 58.5% to 3.7%, anemia from 56.1% to 0%, hepatomegaly and/or splenomegaly from 31.7% to 3.7% and lymphadenopathy from 26.8% to 0%. Also, a dramatic reduction of laboratory markers of inflammation including CRP, ESR and ferritin was achieved. The median [IQR] dose of prednisone was also reduced from 20 [0–100] mg/day at ANK onset to 2.5 [0–40] at 12 months. After a median [IQR] follow-up of 15.5 [1–206] months, the most important side effects were cutaneous rash (n=8), mild leukopenia (n=3), myopathy with elevation of muscle enzymes (n=1), respiratory infection by *Pseudomonas Aeruginosa* and gluteal abscess (n=1), herpes zoster (n=1), phalanx osteomyelitis (n=1) and urinary tract infection (n=2).

Conclusion: ANK is associated with rapid and maintained clinical and laboratory improvement, even in cases that are refractory to other biologic agents. However, joint manifestations seem to be more refractory than systemic manifestations.

Table

	Baseline N=41	Month 1 N=41	Month 3 N=37	Month 6 N=32	Month 12 N=27

Efficacy of Tocilizumab Therapy in Korean Patients with Adults Onset Still's Disease: Multicenter Retrospective Study of 20 Cases. Jin Ju Kim[1], Joo Hyun Lee[2], Chang-Nam Son[3], Hyoun-Ah Kim[4], Kwang-Hoon Lee[5], Sang Tae Choi[6], Eun Young Lee[7], Ki Chul Shin[7], Hoon-Suk Cha[8] and Dae-Hyun Yoo[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Ilsan Paik Hospital, Inje University, Goyang, South Korea, [3]Keimyung University School of Medicine, Daegu, South Korea, [4]Ajou University School of Medicine, Suwan, South Korea, [5]Dongguk University Ilsan Hospital, Goyang, South Korea, [6]Chung-Ang University College of Medicine, Seoul, South Korea, [7]Seoul National University College of Medicine, Seoul, South Korea, [8]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Background/Purpose: Adult onset Still's disease (AOSD) is a rare inflammatory disorder of unknown etiology. Refractory cases to conventional therapy require biologic agents. Although IL-1 targeting therapy is very effective, but tocilizumab (TCZ), an anti-interleukin-6 receptor monoclonal antibody may be an effective agent especially in the countries where anti-IL-1 therapy is not easily available. In this study, we assessed the efficacy of TCZ in multicenter retrospective fashion.

Methods: We retrospectively collected clinical data of AOSD patients who were treated with in Korea. The response to TCZ was defined as decreased modified Pouchot's score more than 2 score with decreased acute phase reactants compared to initial treatment of TCZ at least two consecutive months.

Results: Patients (15 women/5 men) had a mean age of 42.5± 18.8 years and the age of diagnosis was 37.3 ±21.2years old. The mean disease duration before TCZ treatment was 40.7 ± 33.6 months. Ten patients (52.6%) had polycyclic systemic pattern and 9 patient had chronic articular pattern, but 1 patient was no classified due to short disease duration.

Immune modulating agents before TCZ therapy were as follows: methotrexate (n=18), leflunomide (n=12), cyclosporine (n=9), azathioprine (n=8) and hydroxychloroquine (n=7). Biologic agents before TCZ therapy were etanercept (n=7), infliximab (n=4), adalimumab (n=3), abatacept (n=2) and anakinra (n=1). At TCZ onset, the most frequent clinical manifestations were: joint manifestations (80.0%), rash (50.0%), myalgia (35.0%), fever (25.0%) and sore throat (25.0%) (Table 1). The baseline laboratory parameters such as leukocytosis, ESR, CRP and serum ferritin showed high level (Table 1). The mean dose of TCZ was 7.8 mg/kg (4–8 mg/kg) per 4 weeks and mean duration of TCZ administration was 7.9 ± 6.7 months. The 90.0% of patients showed clinical and laboratory improvement after TCZ therapy (Table 1). The median dose of prednisolone was also significantly reduced from17.1± 10.1 mg/day at TCZ onset to 7.5 ± 3.9 mg/day at 12months (Table 1).

The 35% of patients had side effects during TCZ treatment as follows: leukopenia (n=2), hypertension (n=2), alopecia (n=2), pneumonia (n=1). Four patients (20%) relapsed after 5.0 ± 3.6 months of discontinuation of TCZ.

Conclusion: TCZ was effective in Korean AOSD patients refractory to conventional therapy and/or other biologic agents. Larger and prospective study is needed for further investigation.

Table 1. Change of clinical manifestations and laboratory parameters before and after TCZ treatment

	Baseline (N=20)	After 6 months (N=12)	After 12 months (N=7)
Fever (n, %)	5, 25.0	0, 0	1, 14.3
Sore throat (n, %)	5, 25.0	1, 8.3	0, 0

Switching Biologic Agents in Refractory Adult-Onset Still's Disease: Efficacy and Safety in a Cohort of 20 Patients at a Single Referral Center. Giulio Cavalli[1], Stefano Franchini[1], Corrado Campochiaro[1], Elena Baldissera[2], Lorenzo Dagna[3] and Maria Grazia Sabbadini[3]. [1]Vita-Salute San Raffaele University, Milan, Italy, [2]Clinical immunopathology and advanced medical therapeutics, San Raffaele Scientific Institute, Milan, Italy, [3]Vita-Salute San Raffaele University, Milano, Italy.

Background/Purpose: No data is available on the long-term clinical outcome of Adult-Onset Still's Disease (AOSD) patients treated with biological drugs, nor on the efficacy and safety of switching biologics in the management of refractory cases. We aimed to evaluate the efficacy and safety of switching biological agents in a large, monocentric cohort of 20 patients with refractory AOSD.

Methods: Twenty Italian AOSD patients treated with biological agents were followed-up at our Institution for at least 24 months. For each case we retrospectively evaluated the disease course, the efficacy of treatment, and the potential adverse effects. Efficacy was evaluated as "Complete response" (CR: absence of articular and systemic manifestations, normalization of inflammatory indexes, >50% reduction in the corticosteroid dosage); "Partial response" (PR: clinical improvement without normalization of inflammatory markers, nor >50% reduction in the dose of steroids); or "Treatment failure" (TF: persistence/worsening of disease manifestations, persistent elevation of inflammatory markers, or need for an increased dose of corticosteroids despite 2 months of treatment).

Results: The median duration of follow-up was 5 years. In 12 patients a single biological drug induced a clinical response. Five patients were switched to a different biologic because of lack of efficacy. In 3 patients, a third biologic was necessary to achieve disease control. Biologics eventually determined a clinical response in all patients. Anakinra was used in all 20 patients; etanercept, tocilizumab and adalimumab was used in 6, 4, and 1 patient, respectively. Sixteen patients responded to anakinra (80%; CR 70%; PR 10%). Four patients (20%) did not respond to anakinra, and of these three responded to tocilizumab, and one responded to adalimumab. Etanercept was used unsuccessfully in six patients. Patients with systemic manifestations showed better responses than patients with chronic articular disease ($p<0.05$). Overall, biologic agents determined a significant reduction in the dose of the associated therapy with corticosteroids ($p<0.0001$) and DMARDs ($p<0.05$). Three patients experienced herpes zoster reactivation.

Conclusion: Biological agents represent a pivotal therapeutic resource for AOSD patients refractory to conventional treatment. Although the biologic drug of choice may prove ineffective, switching between biologics ultimately resulted in a clinical response in all patients without significant adverse effects, hence the importance of pursuing a tailored treatment approach. Although IL-1 blockade with anakinra represents the mainstay of treatment, IL-6 blockade may be more effective in patients with chronic articular involvement. Both anakinra and tocilizumab were more effective than TNF-α blockers. Patients with SD are more likely to respond favorably to biologics than patients with CAD. Different pathogenic mechanisms underlying SD and

CAD, or the development of irreversible articular damage in CAD, may account for the differences in response to treatment.

Macrophage Activation Syndrome Complicating Adult Onset Still's Disease - Single Center Experience and Literature Review. Aleksander Lenert and Qingping Yao. Cleveland Clinic, Cleveland, OH.

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is a life threatening complication typically associated with hematologic malignancies and infections. HLH, also referred to as macrophage activation syndrome (MAS), has been recognized to complicate adult onset Still's disease (AOSD) and systemic lupus erythematosus. Due to paucity of reported cases, there is no clear consensus concerning treatment recommendations and outcomes.

Methods: We performed a retrospective study of 5 patients with MAS complicating AOSD at the Cleveland Clinic over the past 7 years. All 5 patients underwent bone marrow biopsy. We also reviewed a total of 77 cases from various published reports and identified 49 cases with definitive evidence of MAS and with complete data. Our cohort and the historical data were compared and analyzed.

Results: We identified 5 cases (4 female, 1 male) for our cohort that satisfy both criteria for AOSD and MAS, with 3 cases simultaneously presenting with MAS and AOSD. Mean age at diagnosis of MAS was 35.8 years and mean follow-up was 14.4 months. All patients had fever, arthralgias, typical rash, and leukocytosis, with lymphadenopathy in 3/5 and sore throat in 2/5 consistent with AOSD. These patients also had MAS, with lung involvement in 2/5, renal insufficiency in 2/5 and shock in 1/5. There was significant hepatic dysfunction in all, but only 1/5 had hepatomegaly. One patient had superimposed histoplasmosis. All patients had bi-cytopenia. Besides systemic glucocorticoids, 4/5 patients received Anakinra and 2 of the patients received combination treatment with Cyclosporine. All 5 patients survived with a mean follow-up of 14.4 $\pm$ 15 months. We also reviewed 49 cases (34 female, 15 male) for the literature cohort. Mean age at diagnosis of MAS was 39.9 years and mean follow-up was 17.2 months. Compared with the historical data, the levels of ferritin and hepatic dysfunction were similarly higher, and triglycerides were less elevated in our cohort, while fibrinogen was normal in both. Soluble IL-2 receptor level was significantly higher as well.

Conclusion: MAS can be a serious complication of AOSD and may coexist with its onset. In conjunction with literature, this study of a relatively largest case series suggests that treatment with a triple combination of an IL-1 receptor antagonist, a calcineurin inhibitor and systemic glucocorticoids may have favorable outcomes.

The Prevalence of Malignancy in Adult-Onset Still's Disease. Rupal Chavda[1], Melissa R. Bussey[2], Rodney Tehrani[1] and Rochella A. Ostrowski[1]. [1]Loyola University Medical Center, Maywood, IL, [2]Division of Rheumatology, Loyola University Medical Center, Maywood, IL.

Background/Purpose: Adult-onset Still's disease (AOSD) is a systemic inflammatory disease of unknown etiology. It is characterized by high fever, evanescent salmon-colored rash, sore throat, liver dysfunction, lymphadenopathy, hepato-splenomegaly, arthritis, and leukocytosis. Although most inflammatory disorders have a known risk of malignancy there is a lack of published data regarding the risk of malignancy in AOSD. There are multiple case reports suggesting the presence of AOSD or an AOSD-like syndrome in the setting of various solid tumors (breast, lung, renal and thyroid cancer) and hematological malignancies (leukemia and lymphoma). To date, there are no published studies of the relationship between AOSD and cancer. We conducted a retrospective observational study to identify an association between AOSD and malignancy.

Methods: A chart review was performed of patients 18 years of age and older who were diagnosed with AOSD based on Yamaguchi criteria between January 1, 2006 and June 30, 2013 at Loyola University Medical Center. Patients with known infection, pre-existing malignancy, or other rheumatic disorders at the time of diagnosis of AOSD were excluded. Patient charts were reviewed for a subsequent diagnosis of cancer.

Results: From January 2006 to June 2013 twenty-one cases of AOSD were identified. Of these cases, eight fulfilled Yamaguchi criteria for definite AOSD while one was diagnosed with probable AOSD (Table 1). The median age was 38 years (range 18–63 years) and median follow up was 25 months (1-72 months). One patient was subsequently diagnosed with Hodgkin's lymphoma at 7 months follow up. Another patient was diagnosed with non-small cell lung cancer (NSCLC) at 3 months follow up and then acute myeloid leukemia (AML) at 19 months follow up.

Conclusion: In our case series of 9 patients followed over a median period of 25 months, we noted 1 case of Hodgkin's lymphoma, 1 case of AML and 1 case of NSCLC. The National Cancer Institute reports the incidence of Hodgkin's lymphoma as 2.7 per 100,000 and the incidence of leukemia as 13.0 per 100,000 per year. The incidence reported for all lung cancers is 49.2–66.8 per 100,000 per year. The observed incidence of Hodgkin's lymphoma, AML and NSCLCA in our case series is many times higher. Although the association between AOSD and malignancy has been rarely reported, careful screening for malignancy in patients diagnosed with AOSD may be warranted. Additional studies of association between AOSD and malignancy are needed to further explore the relationship between these diagnoses.

Table 1. Cases of Definite and Probable Adult Onset Still's Disease

Case	Age	Sex	Criteria Met	Ferritin (ng/mL)	ALT/AST (IU/L)	WBC (K/UL)	Malignancy

1245

Long Term Outcome of Infliximab in Severe and Refractory Systemic Sarcoidosis: Report of 16 Cases. Catherine Chapelon[1], David Saadoun[1], Lucie Biard[2], Matthieu Resche-Rigon[3], Baptiste Hervier[4], Nathalie Costedoat-Chalumeau[5], Aurélie Drier[6], Jean-Marc Léger[7] and Patrice Cacoub[8]. [1]DHU 2iB Internal Medicine Referal Center for Autoimmune diseases Pitie Hospital, Paris, France, [2]Hôpital St Louis, Biostatistics, Paris, France, [3]Hopital Saint-Louis, Paris, France, [4]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, PARIS, France, [5]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [6]Hôpital Pitié-Salpêtrière, Neuroradiology, Paris, France, [7]Hôpital Pitié-Salpêtrière, Neurology, Paris, France, [8]Groupe Hospitalier Pitié Salpétrière, Service de Médecine Interne, DHU i2B, Paris, France.

Background/Purpose: Infliximab (IFX) appears to be effective in refractory sarcoidosis. However, data are lacking regarding its efficacy in severe sarcoidosis (i.e. with cardiac and/or neurological involvement).

Methods: Retrospective single-center study including 16 unselected consecutive patients with biopsy proven, severe, and resistant sarcoidosis, who were treated by infliximab (3 or 5 mg/kg at 0, 2 and 6 weeks, then every 8 weeks) between 2005 and 2013.

Results: Following IFX therapy we observed an improvement in 92% of cases, with a marked decrease of the severity score [median score 6 (3–12) vs. 2 (1–8), $p<0.0001$] and trend toward steroid sparing effect [12.5 (0–40) vs. 8.5 mg/d (0–30), $p=0.11$] between baseline and the end of follow-up, respectively. Regarding the index organ response, we observed a remission of cardiac and central nervous system involvements in 4 out of 4 and 11 out 12 cases, respectively. Thirty-eight percent of patients experienced a relapse. After a median follow-up of 57 months (2 to 91), we observed 7 (44%) infectious complications, 1 paradoxical cutaneous granuloma and 1 leucoen-

cephalopathy. Infectious complications were mostly observed in male [6/7 (86%), p=0.06], with a longer duration of steroids (108 vs. 39 months, p= 0.11) and immunosuppressant use prior IFX (42 vs. 24 months, p = 0.08) compared to their negative counterpart, respectively.

Conclusion: IFX was efficient in severe and refractory sarcoidosis. Infectious complications were frequent and occurred mainly in male patients with longer duration of steroids and immunosuppressant use prior IFX.

1246

Assessment of Protective Factors of Bone Mineral Density in a New Orleans Sarcoidosis Population. McCall Walker[1], Harmanjot K. Grewal[2], Adam Janot[3], Mary Yu[4], Sophia Cenac[5], Matthew R. Lammi[6] and Lesley Ann Saketkoo[4]. [1]LSUHSC School of Medicine, New Orleans, LA, [2]Louisiana State University Health Sciences Center, New Orleans, LA, [3]Virginia Commonwealth University –Medical College of Virginia, Charlottesville, VA, [4]Louisiana State University Health Sciences Center, New Orleans, LA, [5]Louisiana State University Health Science Center, New Orleans, LA, [6]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA.

Background/Purpose: Sarcoidosis often involves pathological dysregulation of dependent factors of bone metabolism, e.g. calcitriol/calcium, and administration of high dose glucocorticoids (GCs) leading to low bone mineral density (LBMD). Traditional risk factors for LBMD include advancing age, female sex, low body mass index (BMI), smoking, white race and GCs. LBMD in sarcoidosis is presumed but not yet described.

Methods: A retrospective chart review of biopsy-diagnosed patients with sarcoidosis for > 1 year extracted and compared variables of prevalence, age (at chart review), sex, race, smoking status and designation of LBMD defined as osteopenia or osteoporosis with a T-score of ≤ -1 on DXA. Calculations were performed by non-parametric analyses using Fisher's exact for categorical data and Mann Whitney tests for continuous variables.

Results: 269 charts were reviewed and 109 had documentation of biopsy. Of these 109, 61 patients (86.9% Black) had documentation of DXA, 38 (62.3%) with LBMD (30 with osteopenia and 8 with osteoporosis). Although patients with BMI ≥ 30 had a significantly lower incidence of LBMD vs. those with BMI <30, LBMD incidence exceeded reported in CDC data for overweight subjects. No differences (table) were seen in incident LBMD in patients age ≥ vs < 65, in ever vs never smokers (no significant age difference between groups), nor in males vs females (despite females being significantly older than males with median 54 and 48 respectively).

Table 1. Comparison of Factors Influencing Bone Mineral Density within a New Orleans Sarcoidosis Population

	Low BMD	Normal BMD	Odds Ratio	p Value
% ≥65 Years Old	26% (10/38)	9% (2/23)	3.75 (95% CI 0.74 to 18.96)	0.11
% Male	13% (5/38)	26% (6/23)	0.43 (95% CI 0.11 to 1.61)	0.30
% BMI ≥30	18% (7/38)	52% (12/23)	0.21 (95% CI 0.06 to 0.66)	0.01
% Smoker	32% (12/37)	55% (12/22)	0.40 (95% CI 0.14 to 1.19)	0.11

Conclusion: Factors protective against LBMD in the general population were not demonstrated in this retrospective sarcoidosis predominantly black cohort. A lower risk of LBMD was not conferred by age < 65, male gender, or non-smoking status. While BMI appeared to confer protection, the prevalence in obese sarcoidosis patients supersedes that in CDC reported data. These trends suggest an abnormal signal of incident LBMD in this population differing from the general population. Lack of uniformity of documentation inherent in retrospective methods limits the assessment of important associative and causative influences such as duration and dose of GCs, biomarkers of bone metabolism (e.g. calcium, calcitriol, etc) and fracture risk which will be examined in our prospective sarcoid registry. Nevertheless these findings are important and support increased vigilance in GC use and perhaps consideration to initiate GC sparing agents earlier in the disease course, as well as routine DXA screening in sarcoidosis.

1247

The Prevalence of Sacroiliitis and Spondyloarthritis in Patients with Sarcoidosis. Senol Kobak[1], Fidan Sever[2], Ozlem Ince[2] and Mehmet Orman[3]. [1]SIFA UNIVERSITY, Izmir, Turkey, [2]Sifa University, Izmir, Turkey, [3]Associated Professor, Izmir, Turkey.

Background/Purpose: Sarcoidosis is a chronic granulomatous disease, which can involve different organs and systems. Coexistence of sarcoidosis and spondyloarthritis has been reported in numerous case reports. **Purpose:** To determine the prevalance of sacroiliitis and spondyloarthritis in patients previously diagnosed with sarcoidosis, and to investigate any possible relation with clinical findings.

Methods: Forty-two patients with sarcoidosis were enrolled in the study. Any signs and symptoms in regard to spondyloarthritis (i.e. existence of inflammatory back pain, gluteal pain, uveitis, enthesitis, dactylitis, inflammatory bowel disease, psoriasis) were questioned in details and biochemical tests were evaluated. Sacroiliac joint imaging and lateral heel imaging were performed in all patients. The existence of active sacroiliitis was confirmed by magnetic resonance imaging of sacroiliac joint with short time inversion recovery (STIR) method.

Results: Sacroiliitis was found in 6 of the 42 (14.3%) sarcoidosis patients and all of these patients were female. The average age of the patients with sacroiliitis was 55 years, while the average duration of the disease was 17.8 months. Common features of the disease in these six patients were inflammatory back pain as the major clinical complaint, stage 2 sacroiliitis as revealed by radiological staging and the negativity of HLA B-27 test.These six patients with sacroiliitis were diagnosed as spondyloarthritis according to the criteria of ASAS and of ESSG.

Conclusion: We found spondyloarthritis in patients with sarcoidosis at a higher percentage rate than in the general population (1–1.9%). Controlled trials involving large series of patients are required for the confirmation of the data.

Serologic and Clinical Overlap Between Sarcoidosis and the Rheumatic Autoimmume Diseases. Sabrina Qazi and Marie Claire Maroun. Wayne State University, Detroit, MI.

Background/Purpose: Sarcoidosis is a systemic inflammatory disorder of unknown etiology, characterized pathologically by noncaseating epithelioid cell granulomas, primarily affecting the lungs, the eye, the skin, and the lymphatics. Musculoskeletal manifestations and the immunologic profile in sarcoidosis may mimick those seen in the rheumatic autoimmune diseases. Hyperglobulinemia and autoantibodies including rheumatoid factor [RF] and anti-nuclear antibodies [ANA] have been reported. Citrullination is a post-translational modification of proteins, in which the amino acid arginine is enzymatically converted to citrulline. Citrullinated peptides can be found at the site of chronic inflammation and, in the appropriate genetic setting, can elicit an autoimmune response. Anti-cyclic citrullinated peptide antibodies [ACPA] are thought to be a new and more specific marker than RFs in rheumatoid arthritis [RA] and have been added to the new RA classification criteria. The occurrence of ACPA in sarcoidosis has not previously been described.

Objectives: The aim of this study was to investigate the serologic profile, in particular the serum RFs, ANAs and ACPA in patients with sarcoidosis attending the rheumatology and/or pulmonary clinics.

Methods: We retrospectively reviewed the charts of 73 patients with the diagnosis of sarcoidosis and recorded the clinical manifestations and the immunological profile including ANA, RF, and ACPA.

Results: Forty one percent of patients with sarcoidosis [30/73] had a positive ANA, with titers ranging from weakly positive [1/40] to high positive [1/1280]. RF and ACPA were not available on all patients. RF was found in 22 % of patients [13/59] while ACPA was found positive at moderately elevated titers in 8% of patients [2/24] in the absence of RA. One patient with RA with positive CCP was excluded from the analysis. One patient had Sjogren syndrome and one had systemic lupus erythemathosus. In addition, 22% of the patients had sarcoid arthropathy.

Conclusion: ANAs, RFs and ACPA were found in sarcoidosis patients at titers within the range found in the rheumatic ADs. ACPA was present in 8% of sarcoidosis patients in the absence of RA. We suggest that investigation of the autoantibody signatures responsible for the serologic overlap between sarcoidosis and the rheumatic ADs, especially ACPA may be of great interest

since, since inflammation is central in the immune-pathogenesis of sarcoidosis.

Hospitalario Universitario A Coruña, A Coruña, Spain, [7]Hospital Virgen de la Arrixaca. Murcia. Spain, Murcia, Spain, [8]Hospital Universitario de Donostia. San Sebastián. Spain, San Sebastián, Spain, [9]Hospital Virgen de las Nieves. Granada, Granada, Spain, [10]Hospital Regional Universitario (Carlos Haya). Málaga. Spain., Málaga, Spain.

Background/Purpose: To evaluate the clinical response and safety of Tocilizumab (TCZ) in a series of patients with non-infectious uveitis refractory to other biologic drugs.

Methods: Multicenter study of patients studied in the Uveitis Units of 14 hospitals from Spain. All patients had experienced inadequate response to at least one biologic agent. Intraocular inflammation, macular thickness, visual acuity, steroid sparing effect and immunosuppression load score were the outcome variables. Comparisons were made between baseline and 1st week, 1st month, 6th month and 1st year.

Results: We studied 31 patients/58 affected eyes (7 men/24 women) with a mean age of 31.7±17.2 years (range 8–70). Uveitis was bilateral (n=27 cases) or unilateral (n=4). The pattern of ocular involvement was anterior uveitis (n=11 cases), panuveitis (n=6), posterior (n=4), intermediate (n=3), panuveitis+ retinal vasculitis (n=3), retinal vasculitis without uveitis (n=2) and panuveitis+retinal vasculitis+papillitis (n=1). Uveitis was acute (n=1), chronic (n=26) or recurrent (n=4).

The main underlying diseases were: Juvenile Idiopathic Arthritis (n=13), Behçet disease (n=5), idiopathic uveitis (n=5), Birdshot retinopathy (n=3), idiopathic retinal vasculitis (n=2), spondyloarthritis (n=2) and rheumatoid arthritis (n=1).

Besides oral steroids and before TCZ onset they had received: intraocular corticosteroids (n=21), intravenous. methylprednisolone pulses (n=9), methotrexate (n=25), cyclosporine A (n=20), azathioprine (n=3), other synthetic immunosuppressive drugs (n=9), adalimumab (n=25), infliximab (n=12), etanercept (n=7), abatacept (n=6), rituximab (n=2), golimumab (n=2) and anakinra (n=1). TCZ was started because of inefficacy (n=28) and/or toxicity (n=3) to other biologics. TCZ was used as monotherapy (n=10) or in combination with methotrexate (n=12), leflunomide (n=4), cyclosporine A (n=4) and mycophenolate (n=1). After one year of TCZ therapy all the following variable improved statistically ($p<0.05$) **(TABLE): a)** mean best corrected visual acuity (from 0.46±0.3 at baseline to 0.58±0.3); **b)** anterior chamber cells and vitreous inflammation (from 58% and 60% of eyes, to 15.3% and 34%, respectively); **c)** cystoid macular edema (OCT>300 μm) (from 66.6% to 21%); **d)** the mean OCT (from 389.1±197.2 to 261.8±46.1 μm); and **e)** the median [IQR] dose of prednisone (from 30 [10–90] to 5 [0–5] mg/day). A non-statistically reduction in the mean of the immunosuppression load score (from 6.3±5.1 to 4.2±3.3, p=0.6) was also observed.

After a mean follow-up of 13.4±9.5 months the more important side-effects observed were bullous impetigo (n=1), mild thrombocytopenia (n=1), pneumonia (n=1) and infusional reaction (n=1).

Conclusion: Our results indicate that TCZ is an effective and safe therapy for patients with non-infectious uveitis refractory to other biologic agents.

Table.

	Basal Patients (n) active eyes (%)	1 week active eyes (%)	1 month active eyes (%)	6 months active eyes (%)	1 year active eyes (%)
Anterior chamber cells	21 58%	46.66%*	21.7%*	17.6%*	15.3%*

Spain, Albacete, Spain, [11]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: To evaluate the clinical response and safety of golimumab (GLM) in a series of patients with non-infectious uveitis refractory to other anti-TNFα drugs.

Methods: Multicenter study of 29 patients with uveitis that was refractory to previous standard synthetic immunosuppressive drugs and at least 1 anti-TNFα drug. GLM was given at the standard dose of 50 mg/sc/month. The main outcome measures were degree of anterior and posterior chamber inflammation, visual acuity, and macular thickness.

Results: A total of 29 patients (44 affected eyes) (21 men/8 women) with a mean age of 34.6±9.5 years (range 11–48) were studied. Uveitis was bilateral (n=15 cases) or unilateral (n=14). The pattern of ocular involvement was anterior uveitis (n=19), panuveitis (n=6) and intermediate, anterior+intermediate, anterior+posterior and intermediate+posterior (one case each). Uveitis was acute (n=1), chronic (n=16) or recurrent (n=12).The underlying diseases were spondyloarthritis (n=9), psoriatic arthritis (n=5), juvenile idiopathic arthritis (n=4), Behçet disease (n=4), sarcoidosis (n=3), uveitis associated with HLA-B27 and ulcerative colitis (n=1), undifferentiated arthritis (n=1), pars planitis (n=1) and Vogt-Koyanagi-Harada (n=1).

Besides oral steroids and before GLM onset they had received: intraocular corticosteroids (n=11), intravenous pulses of methylprednisolone (n=6), methotrexate (n=23), cyclosporine A (n=6), azathioprine (n=7), adalimumab (n=17), infliximab (n=15), abatacept (n=2) and certolizumab (n=1). GLM was started because inefficacy (n=27) and/or toxicity (n=2) to other biologics. GLM was used as monotherapy (n=11) or in combination with methotrexate (n=10), azathioprine (n=4), leflunomide (n=2), and mycophenolate (n=2).

After one year of GLM therapy all the following variables improved significantly ($p<0.05$)**(TABLE): a)** The mean best corrected visual acuity (from 0.68±0.3 at baseline to 0.75±0.3); **b)** anterior chamber and vitreous inflammation (from 62.7% and 40.4% of eyes, to 12.5% and 0% respectively); **c)** Cystoid Macular Edema (OCT>300 μm), (from 50% to 0%), **d)** the mean OCT (from 318.9±76 to 244.2±43.2 μm); and **d)** the mean dose of prednisone (from 24±20.1 to 7.7±7.6 mg/day). After a mean follow-up of 13.1±8.5 (range 2–30) months the most important side-effects observed were Injection site erythema (n=3) and herpes zoster (n=1).

Conclusion: Our results suggest that GLM may be an effective and safe treatment for patients with uveitis refractory to other anti-TNFα drugs.

Efficacy of Certolizumab in Patients with Refractory Uveitis to Other Biologic Therapy. Study of 7 Cases. Montserrat Santos-Gómez[1], Victor Llorens[2], Marina Mesquida[2], Ricardo Blanco[1], Vanesa Calvo-Río[1], Olga Maíz[3], Ana Blanco[3], Maite Sainz de la Maza[2], Alfredo Adan[2], Leyre Riancho-Zarrabeitia[1] and Miguel A. González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [2]Hospital Clinic. Barcelona. Spain, Barcelona, Spain, [3]Hospital Universitario de Donostia. San Sebastián. Spain, San Sebastián, Spain.

Background/Purpose: Anti-TNF-α therapy may be useful in cases of uveitis refractory to standard synthetic immunosuppressive drugs. Infliximab (IFX) and adalimumab (ADA) are the biologic agents more frequently used. To our knowledge information on Certolizumab Pegol (CZP) in patients with uveitis is scarce. Due to this, we assessed the efficacy of CZP in a series of patients with uveitis refractory to other anti-TNF-α drugs.

Methods: Study from 3 tertiary referral centers that included patients with uveitis that had been refractory to previous standard synthetic immunosuppressive and at least 1 anti-TNF-α drug. For the inclusion in the assessment a follow-up of at least 6 months was required.

Outcome was measured according to SUN criteria (Jabs et al. 2005) for anterior chamber inflammation (0 to 4+) and scale (0 to 4+) for vitreous haze (Bloch-Michel 1997). Best corrected visual acuity (BCVA) was measured by Snellen charts and converted to logarithm (LogMAR) (Jabs 2005). Macular thickness was defined by OCT.

Results: We studied 7 patients (14 affected eyes) (4 men/3 women) with a mean age of 42.4±8.8 years. The main underlying diseases were: Behçet disease (3 cases), idiopathic retinal vasculitis (1 case), ankylosing spondylitis (1 case), psoriatic arthritis and Crohn's disease (1 case) and relapsing polychondritis (1 case). All patients suffered from long-lasting chronic-relapsing ocular inflammation with a median evolution time until CZP onset of 108 (range 68–302) months.

The 1st biological drug was IFX. It was changed to ADA because of serious adverse events (n=3) or loss of efficacy (n=4). However, ADA was withdrawn in all these cases because of inefficacy (n=6) or lupus-like reaction (n=1)]. Afterward, 3 patients were switched to golimumab (GLM) and 1 to etanercept (ETN) **(TABLE).** Due to inefficacy, all 7 patients were switched to CZP that was administered at the standard dose (induction dose of 400 mg q2w for 4 weeks followed by 200mg q2 w for maintenance). After a mean follow-up of 10.4±4.8 months since CZP onset, 5 (71.4%) patients achieved remission and 4 of them could withdraw oral prednisone. Mean logMAR visual acuity improved significantly from 0.41±0.48 at baseline to 0.34±0.45 at first month ($p=0.03$) and remained stable since then. Macular edema was present in 4 eyes (3 patients) at baseline. The mean OCT decreased from 328.3±96.5 microns at baseline to 303.1±81.8 at final visit ($p=0.099$). CZP was well tolerated in all cases and no adverse event was observed during follow-up.

Conclusion: CZP can be an alternative to other anti-TNF-α agents in patients with refractory uveitis.

Table

case	sex/age	anatomical pattern	etiology	previous non-biologic immunosuppressive drugs	previous biologic immunosuppressive
1	M/34	panuveitis	Behçet disease	CyA	IFX, ADA, GLM
2	M/38	panuveitis	Ankylosing spondylitis	CyA, MTX	IFX, ADA, GLM
3	F/33	anterior uveitis	Psoriatic arthritis & Crohn's disease	CyA, AZA	IFX, ADA
4	F/51	panuveitis	Behçet disease	CyA, AZA, MTX	IFX, ADA
5	F/37	posterior uveitis	Idiopathic retinal vasculitis	AZA, MTX	IFX, ADA
6	M/53	anterior uveitis + scleritis	Relapsing polychondritis	MTX	IFX, ADA, ETN

Spain, Valencia, Spain, [3]Hospital Universitario San Cecilio. Granada. Spain, Granada, Spain, [4]Hospital de Cruces. Bilbao. Spain, Bilbao, Spain, [5]Hospital Dr. Peset. Valencia. Spain, Valencia, Spain, [6]Hospital Doctor Negrín. Las Palmas de Gran Canaria. Spain, Las Palmas de Gran Canaria, Spain, [7]Hospital Universitario de Basurto. Bilbao. Spain, Bilbao, Spain, [8]Hospital Universitario de Donostia. San Sebastián. Spain, San Sebastián, Spain, [9]Hospital Infanta Sofía. San Sebastián de los Reyes. Spain, Madrid, Spain, [10]Hospital Clínico San Carlos. Madrid. Spain, Madrid, Spain, [11]Hospital Universitario La Fe. Valencia. Spain, Valencia, Spain, [12]Hospital de León. Spain, León, Spain.

Background/Purpose: Treatment with high-dose intravenous methylprednisolone (IVMP) pulse therapy has proved to be effective in different inflammatory conditions. Since severe ocular inflammation can lead to rapid and irreversible structural and functional eye damage, we aimed to assess the efficacy of IVMP pulse therapy as a remission induction therapy in patients with severe ocular inflammation.

Methods: Multicenter study of patients with severe ocular inflammation attended at 11 Uveitis Units from Spain. All patients were treated with IVMP pulse therapy for 2–5 consecutive days. MP dose ranged from 0.25 to 1 gram per day. Patients were evaluated at baseline and on days 2–5, 7, 15 and 30 after treatment with IVMP.

Results: 104 patients (59 women/45 men; mean age of 42.27±14.42 years [range 8–76 years]) with severe ocular inflammation were included in the study. The most frequent underlying conditions were: idiopathic uveitis (n=21), Vogt-Koyanagi-Harada (n=26), Behçet disease (n=19), spondyloarthritis (n=4), Sjögren syndrome (n=2), psoriatic arthritis (n=2) and multiple Sclerosis (n=2). All the patients had active and severe intraocular inflammation at baseline. The inflammatory ocular patterns were: panuveitis (n=61), posterior uveitis (n=35), anterior uveitis (n=3), scleritis (n=3) and intermediate uveitis (n=2). Bilateral ocular involvement was observed in 65 patients (62.5 %). Following IVMP pulse therapy inflammation in the anterior chamber, vitritis and visual acuity experienced rapid and statistically significant improvement. It was already seen 2 days after the onset of IVMP therapy. However, improvement of retinal vasculitis, choroiditis/chorioretinitis and macular edema was achieved more gradually, reaching statistical significance from the first week. Optical coherence tomography (OCT) showed a macular thickening ($>250\mu$) in 90 eyes at baseline, with normalization in 30 % of the affected eyes at day 15 and in 50 % of the affected eyes at day 30 ($p<0.05$). IVMP pulse therapy was well tolerated without remarkable side effects.

Conclusion: Treatment with IVMP pulse therapy decreases rapidly the ocular inflammation, leading to an improvement of all the ophthalmological measurements without important side effects.

Anakinra – a Promising New Therapy for Idiopathic Recurrent Pericarditis. Sonia Jain[1], Charat Thongprayoon[2], Raul Espinosa[1], Sharonne Hayes[1], Kyle Klarich[1], Kevin Moder[3], Nandan Anavekar[1], Jae Oh[1] and Eric L. Matteson[4]. [1]Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN, [2]Mayo clinic, Rochester, MN, [3]Division of Rheumatology, Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Rochester, MN.

Background/Purpose: Idiopathic recurrent pericarditis (IRP) is a debilitating condition that can be recalcitrant to conventional therapy. Some patients develop steroid dependency with the attendant risks of systemic side effects and increased future recurrence. Anakinra is a recombinant human interleukin-1 receptor antagonist that reduces systemic inflammatory responses. The aim of this study was to evaluate the therapeutic role of anakinra in a series of adult patients with IRP refractory to conventional therapy.

Methods: We retrospectively studied consenting patients with treatment refractory IRP who received anakinra, between January 2009 and November 2013. None of the patients had an identified systemic inflammatory rheumatic disease. The primary end points were symptom resolution and steroid discontinuation.

Results: Nine patients were followed for a median of 16.8 (IQR 1.3–24) months. Study subjects were predominantly female (7 [78%]) with a median age of 53 (IQR 38 – 58) years. All 9 patients had failed maximum tolerated doses of NSAIDs, colchicine and prednisone (median dose 20 mg [IQR 15 – 22.5]). Additionally, 2 patients (22%) were on hydroxychloroquine, 2 (22%) on azathioprine and 1 (11%) on methotrexate. Primary symptom was chest pain in 9 (100%), with concurrent dyspnea in 5 (56%) patients. Symptom duration prior to anakinra initiation was 24 (IQR 13 – 71) months. Indication for anakinra was steroid sparing agent in 7 (78%) and symptom control in 2 (22%) patients. The dosage was 100 mg once daily via subcutaneous injection. Baseline left ventricular ejection fraction was 62% (IQR 59% - 67%). Echocardiographic findings include pericardial effusion in 3 (33%), pericardial thickening in 6 (67%), and constrictive physiology in 4 (44%). Pericardial enhancement on cardiac MRI was seen in 7 (78%) patients. All 9 patients (100%) had prompt symptom improvement with complete resolution in 8 (89%) and partial resolution in 1 (11%) patient. At last follow up, all (100%) patients had discontinued NSAIDs and colchicine, 5 (56%) patients discontinued and 4 (44%) had reduced prednisone dosage. 4 out of 5 patients (80%) discontinued concomitant immunsuppressive agents. 1 patient remained on low dose hydroxychloroquine. All patients remained on anakinra at the end of follow up. The only reported side effect was transient injection site reaction in 4 (44%) patients. In 2 (22%) patients, attempted anakinra weaning was unsuccessful due to symptoms flare after 6 weeks.

Conclusion: Anakinra is an effective alternative agent for the management of steroid dependent IRP. It can provide remarkable symptomatic amelioration, avoid steroid dependency, and is associated with minimal side effects.

Anakinra for the Management of Resistant Idiopathic Recurrent Pericarditis in Adults. Dimitrios Vassilopoulos[1], Panagiotis Vasileiou[1], Christos Koutsianas[1], Katerina Antonatou[2], Christina Tsalapaki[1], Dimitrios Pectasides[1] and George Lazaros[2]. [1]University of Athens Medical School, Athens, Greece, [2]Hippokration General Hospital, Athens, Greece.

Background/Purpose: Recurrent idiopathic pericarditis is currently considered as an auto-inflammatory disorder which is frequently either resistant to standard therapy (with NSAIDs, colchicine or corticosteroids-CS) or requires long term treatment with high doses of CS. Interleukin-1 (IL-1) inhibition has shown encouraging results in pediatric cases and a few adult cases. The aim of our study was to explore the efficacy and safety of anakinra in adult patients with recurrent idiopathic pericarditis.

Methods: In this open label study, ten patients with idiopathic recurrent pericarditis were included. All were resistant and/or intolerant to previous treatment with aspirin and/or NSAIDs, colchicine and CS while two (20%) had failed azathioprine therapy. Patients were initially treated with daily subcutaneous injections of anakinra (100 mg) with gradual tapering of the administered dose. Recurrences as well as adverse events were recorded in all patients during the follow-up period (24 $\pm$ 16 months).

Results: Among the 10 patients included (5 females/5 males, mean age = 42 $\pm$ 18 years, mean disease duration=37 $\pm$ 22 months), the mean number of recurrences despite standard therapy was 8 $\pm$ 3.7 while the baseline mean daily dose of prednisolone was 14.1 $\pm$ 7.9 mg. All patients treated with anakinra demonstrated a rapid clinical response with resolution of symptoms and normalization of CRP (mean time=5.9 $\pm$ 2.3 days). All patients receiving CS at baseline (n=8) were able to gradually discontinue them (mean time to discontinuation = 53 $\pm$ 44 days). Among 7 patients who discontinued anakinra, 5 (70%) relapsed after a mean time of 18 $\pm$ 9 days; in 4/5, anakinra was restarted leading again to clinical remission while one was successfully treated with NSAIDs and colchicine. One patient discontinued therapy due to transient elevation of aminotransferases while 6 (60%) demonstrated mild skin reactions at the injection site.

Conclusion: Our study shows that IL-1 inhibition with anakinra is a highly efficacious, safe and steroid-sparing strategy for treatment-resistant recurrent idiopathic pericarditis in adults. Further studies are needed to clarify the appropriate dose and duration of therapy in these patients.

Pathogenic Role of Tyrosyl–Transfer RNA Synthetase in Anti-Synthetase Syndrome. Yuko Okamoto[1], Yasuhiro Katsumata[1], Yasushi Kawaguchi[1], Manabu Kawamoto[1], Ken Iwaki[2], Miki Miyanokoshi[2], Keisuke Wakasugi[2], Koji Tahara[3], Kaori Ito[3], Hiroaki Hattori[3], Takahisa Gono[1], Masanori Hanaoka[1], Tomoaki Higuchi[1], Hidenaga Kawasumi[1] and Hisashi Yamanaka[4]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]BML, Saitama, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Autoantibodies directed against the aminoacyl transfer RNA (tRNA) synthetases are associated with myositis, arthritis, Raynaud's phenomenon, mechanic's hands, fever, and interstitial lung disease, clinically referred to as anti–synthetase syndrome. Targoff and his colleagues reported a case with an autoantibody to tyrosyl–tRNA synthetase (TyrRS) with features of anti–synthetase syndrome at the 2005 ACR meeting. At the 2013 ACR meeting, we reported three more patients with anti–TyrRS autoantibodies in the setting of anti–synthetase syndrome using other assays than previously reported methods: enzyme–linked immunosorbent assay, Western blot, and immunoprecipitation assay. In addition, one of the authors of this abstract reported that TyrRS can be split into two fragments with distinct chemotactic activities: an interleukin-8 (IL-8)–like cytokine, and an

endothelial-monocyte-activating polypeptide II (EMAP II)–like cytokine (*Science*. 1999). We aimed to further elucidate the pathogenic role of TyrRS in anti–synthetase syndrome.

Methods: Previously defined anti–TyrRS antibody–positive patients with features of anti–synthetase syndrome were the study subjects. Anti–TyrRS antibody–positive and control sera were tested for the ability to inhibit TyrRS aminoacylation by preincubation of the enzyme source with the sera. Recombinant human TyrRS and histidyl–tRNA synthetase (HisRS; Jo–1) proteins were generated. Peripheral blood mononuclear cells (PBMCs) were isolated from heparinized whole blood of an anti–TyrRS or an anti–HisRS antibody–positive patient by density gradient centrifugation. Then, PBMCs were cultured and stimulated with TyrRS, HisRS, or phytohemagglutinin (PHA). Antigen–specific cell proliferation was analyzed using tetrazolium salt as a chromogenic indicator for nicotinamide adenine dinucleotide (NADH). Immunohistochemical analyses were performed to determine if the corresponding chemokine receptors were upregulated in frozen muscle tissue from an anti-TyrRS antibody–positive patient using primary mouse anti–human mAbs and peroxidase-conjugated anti–mouse IgG Fab'.

Results: Anti–TyrRS sera significantly inhibited the *in vitro* enzymatic function of TyrRS (aminoacylation of $tRNA^{Tyr}$) compared with normal control serum. In the cell proliferation assay using PBMCs from an anti–TyrRS patient, the O.D. values of the TyrRS–stimulated cells were significantly higher than in those of the unstimulated cells and HisRS–stimulated cells. Immunohistochemical analyses demonstrated that C–C chemokine receptor type 1 (CCR1) and type 2 (CCR2) which are the receptor of IL–8, and type 3 (CCR3) which is the receptor of EMAP II, were expressed in degenerating muscle fibers, vascular endothelial cells, and infiltrating mononuclear cells in muscle tissue from an anti–TyrRS antibody–positive patient.

Conclusion: This study showed that the anti–TyrRS sera can function as an enzyme inhibitor. TyrRS may also play some pathogenic roles in anti–synthetase syndrome by recruiting leukocytes to inflammatory cites and eliciting adaptive immune responses.

Background/Purpose: Anti Jo-1 antibodies are the main marker of the antisynthetase syndrome (As), a connective tissue disease chiefly characterized by arthritis (A), myositis (M) and interstitial lung disease (I). These manifestations may occur concomitantly but incomplete clinical pictures have been described. Aim of this study is to further characterize clinical presentation and course of anti Jo-1 positive As

Methods: Data from multicentre, multinational series of patients diagnosed with anti Jo-1 positive As were retrospectively collected and analyzed. Anti Jo-1 antibodies were tested in all cases by commercially available ELISA techniques.

Results: 146 patients were included (Table 1). Median follow up was 91 months (IQR 40.25–153.75). At the onset, a complete clinical picture (AMI) was present in 26 patients (18%). Seventy-two patients (49%) had monosymptomatic presentation (A 36, 24.5%; M 20, 14%; I 16, 11%), 19 AM (13.5%), 19 MI (13.5%) and 10 AI (7%). Arthritis was the most frequent feature at the onset, the only detectable in 24.5% of patients. Many patients meet the 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA). Rheumatoid factor, anti citrullinated peptide antibodies and RA typical radiographic erosions were not a rare finding. Time from clinical onset to diagnosis was longer in incomplete forms ($p<0.001$). During the follow up, 69 patients (57.5%) developed additional features (median time to progression: 17 months, IQR 7.5–43.5). Progression rate was significantly higher in patients with single feature onset (57/72) with respect to those with two features (12/48) ($p<0.001$). At the last follow-up, 69 patients (47%) had AMI, 23 (15.5%) AM, 23 (15.5%) MI, 16 (11%) AI, 8 (5.5%) I, 4 (3%) A and 3 (2%) M. Twenty-five patients (17.5%) died, 7 (5%) due to As progression. First line treatment was based on corticosteroids (140 patients, 96%) and immunosuppressants (112, 77%; hydroxychloroquine, HCQ, 30; methotrexate, MTX, 24; IV cyclophosphamide, CYC, 20; cyclosporine, Cys, 20; azathioprine, AZA, 17; mycophenolate mofetil, MMF, 4; tacrolimus, TC, 3; other not listed). Globally, MTX was prescribed in 58 patients (40%, 22 withdrawn for side effects/ineffectiveness), Cys in 47 (32%, 10), AZA 36 (24.5%, 21), CYC 34 (23%, 23), HCQ 34 (23%, 21), MMF in 17 (11.5%, in 5), TC in 9 (6%, 5)

Conclusion: The diagnosis of anti Jo1 positive As may be delayed in incomplete forms, which are the vast majority at presentation. Joint involvement may be very similar to RA, adding further challenges to differential diagnosis. Clinical picture evolution is common in patients presenting with incomplete forms and it may occur even after several years from disease onset. Treatment appears heterogeneous and with high drop-out rates in both first and second line. This suggests the need of better strategies supported by specific recommendations.

A New Multianalyte Assay for Detection of Dermatomyositis-Specific Autoantibodies Undetectable By Commercially Available Immunoassays. Masataka Kuwana, Yuka Okazaki and Tsutomu Takeuchi. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The disease expression of dermatomyositis (DM) is highly variable among patients, ranging form those with severe muscle weakness in the absence of internal organ involvement to those with clinically amyopathic DM (CADM) complicating fatal rapidly progressive interstitial lung disease. A series of serum autoantibodies have been identified in DM patients, and are useful in diagnosis as well as disease subsetting. These are antibodies to aminoacyl tRNA synthetase (ARS), including Jo-1, EJ, OJ, PL-7, PL-12, and KS, Mi-2, melanoma differentiation-associated gene 5 (MDA5), transcription intermediary factor-1 (TIF1)-γ, NXP2, SAE, and Ku. These antibodies are detectable by immunorecipitation (IP) assays for RNA and protein components, which require a complicated procedure with cultured human cell lines and a radioisotope. Recently, a novel enzyme-immunoassay (MESACUP anti-ARS test; MBL) has been developed for detection of 5 different anti-ARS specificities together (Jo-1, EJ, PL-7, PL-12, and KS), and a multianalyte line-blot assay that detects Mi-2, Ku, PM-Scl, Jo-1, SRP, PL-7, PL-12, EJ, OJ (Myositis Profile 3 EUROLINE, EUROIMMUN) is commercially available. However, many DM-specific antibodies are still undetectable by these convenient assays. In this study, we have developed a new multianalyte assay for detection of DM-specific antibodies undetectable by current commercial assays, using a principle of IP combined with immunoblots (IB).

Methods: We enrolled 116 patients with DM, including 52 with CADM, who were diagnosed at our institution between 2000 and 2013. DM-specific antibodies were first identified using IP assays and the MESACUP anti-ARS test. Patients' sera negative by the MESACUP test were further applied to a multianalyte IP/IB assay, in which native autoantigens were isolated by IP technique, followed by IB probed with a mixture of monoclonal or polyclonal antibodies specific to Mi-2 (240kDa), TIF1γ (155kDa), OJ (150kDa), NXP2 (145kDa), MDA5 (140kDa), SAE (90kDa), and Ku (80kDa). Identification of individual antibodies was based on the molecular sizes of the immunoreactive bands. In some sera, DM-specific specificities were also measured by the EUROLINE.

Results: DM-specific antibodies were detected in 101 (87%) patients by IP assays. These included MDA5 in 26, Jo-1 in 14, TIF1γ in 14, EJ in 10, PL-7 in 7, PL-12 in 7, OJ in 6, NXP2 in 6, Mi-2 in 4, Ku in 3, SAE in 2, and U1RNP in 2). The MESACUP anti-ARS test was positive in 38 (33%) patients who were completely matched to those positive for Jo-1, EJ, PL-7, or PL-12 by IP assays. When 78 sera negative by the MESACUP test were further subjected to the multianalyte IP/IB assay, results obtained by IP assays and the IP/IB assay were identical in terms of Mi-2, TIF1γ, OJ, NXP2, MDA5, SAE, and Ku (sensitivity and specificity 100%). We also applied 51 sera positive for Mi-2, Ku, Jo-1, PL-7, PL-12, EJ, or OJ to the Euroline, resulting in a false-negative result in all 6 anti-OJ-positive sera and a false-positive result of Ku in 3 sera.

Conclusion: Multianalyte IP/IB assay is a convenient and reliable method useful for detection of a full panel of DM-specific autoantibodies when it is combined with the commercial MESACUP test.

Enzyme-Linked Immunosorbent Assays for Detection of Anti-Transcriptional Intermediary Factor-1 Gamma and Anti-Mi-2 Autoantibodies in Dermatomyositis: Utility and Crossreactivity. Manabu Fujimoto[1], Akihiro Murakami[2], Shunsuke Kurei[2], Akiko Kuwajima[3], Yasuhiro Fujisawa[1], Atsushi Kawakami[4], Michiaki Mishima[5], Shinji Sato[6], Mariko Seishima[7], Takafumi Suda[8], Tsuneyo Mimori[9], Kazuhiko Takehara[10] and Masataka Kuwana[11]. [1]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Medical & Biological Laboratories Co., Ltd, Nagaya, Japan, [3]Medical & Biological Laboratories Co.,Ltd., Nagoya, Japan, [4]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [5]Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, Japan, [6]Tokai University School of Medicine, Isehara, Japan, [7]Gifu University Graduate School of Medicine, Gifu, Japan, [8]Hamamatsu University School of Medicine, Hamamatsu, Japan, [9]Kyoto Univ Grad Schl of Med, Kyoto, Japan, [10]Kanazawa University, Kanazawa, Japan, [11]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Anti-transcriptional intermediary factor 1 (TIF-1) and anti-Mi-2 antibodies (Abs) are myositis-specific autoantibodies (MSA) selectively detected in dernatomyositis (DM) patients. Anti-TIF-1 Ab is frequently found in juvenile DM and cancer-associated adult DM. Anti-Mi-2 Ab is predominantly detected in patients with classic DM with favorable prognosis. TIF-1 and Mi-2 proteins share similar molecular structures and amino acid sequences, suggesting a potential crossreactivity. In this study, we have established enzyme-linked immunosorbent assays (ELISAs) for anti-Mi-2 and anti-TIF-1γ Abs, and have assessed their utility and crossreactivity.

Methods: Serum samples were obtained from 242 patients with idiopathic inflammatory myopathy (IIM) who were followed up at 8 medical centers across Japan. IIM patients included 104 with classic DM, 68 with clinically amyopathic DM (CADM) and 70 with polymyositis. Serum samples from 190 patients with other connective tissue diseases (CTDs) including 45 with rheumatoid arthritis, 67 with systemic lupus erythematosus, 43 with systemic sclerosis, 20 with mixed connective tissue disease, 8 with Sjögren's syndrome, and 7 with others, and 123 healthy individuals were also assessed.

Full-length TIF-1γ and Mi-2β proteins were produced by a baculovirus expression system. Purified proteins were respectively coated on ELISA plates, on which serum antibody levels were examined. To assess the crossreactivity, partial-length Mi-2β proteins with or without mutations were produced and processed similarly, before subjected to ELISA.

Results: Cutoff levels for anti-TIF-1γ and anti-Mi-2 ELISAs were calculated using Receiver Operating Characteristic analysis based on the results from the gold standard IP assay of 242 IIM samples. When compared with IP assay, anti-TIF-1γ ELISA showed 100% sensitivity and 100% specificity, while anti-Mi-2 ELISA showed 100% sensitivity and 99.6% specificity.

Anti-TIF-1γ Ab was positive in 30 (28.8%) with classic DM and 4 (5.9%) with CADM, whereas 14 (13.5%) with classic DM, but none with CADM, were positive for anti-Mi-2 Ab. Anti-TIF-1γ and anti-Mi-2 Abs were both positive in 2 (1.1%) with CTDs other than IIM, respectively. Of 30 anti-TIF-1γ positive DM patients, 23 (67.6%) and 5 (14.7%) had malignancy and interstitial lung disease (ILD), respectively. By contrast, 3 (21.4%) had malignancy in 14 anti-Mi-2 positive DM patients, but none had ILD. Both Abs were negative in normal subjects.

Although no samples positive for anti-Mi-2 Ab exceeded the cutoff level of anti-TIF-1γ Ab, they showed substantially higher levels than those negative for anti-TIF-1γ Ab. ELISA analyses after absorption with various truncated Mi-2 proteins with and without inserted mutations identified that anti-Mi-2 Ab weakly crossreacted with the 896–903 amino acid sequence (ggdllcce) within a Plant Homeo domain of TIF-1γ protein, due to the sequence homology with Mi-2β protein (458–465, ggellccd).

Conclusion: The current study demonstrates the utility of newly established ELISAs for anti-TIF-1γ and anti-Mi-2 Abs, which can serve as easier detection systems for routine testing. Developing these ELISAs needs attention to crossreactivity of anti-Mi-2 Ab with TIF1 antigen.

A Multi-Center Study for Validation of a New Assay for Anti-Melanoma Differentiation-Associated Gene 5 (MDA5) Autoantibody. Shinji Sato[1], Akihiro Murakami[2], Akiko Kuwajima[3], Kazuhiko Takehara[4], Tsuneyo Mimori[5], Atsushi Kawakami[6], Michiaki Mishima[7], Takafumi Suda[8], Mariko Seishima[9], Manabu Fujimoto[10] and Masataka Kuwana[11]. [1]Tokai University School of Medicine, Isehara, Japan, [2]Medical & Biological Laboratories Co., Ltd, Nagaya, Japan, [3]Medical & Biological Laboratories Co.,Ltd., Nagoya, Japan, [4]Kanazawa University, Kanazawa, Japan, [5]Kyoto Univ Grad Schl of Med, Kyoto, Japan, [6]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [7]Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, Japan, [8]Hamamatsu University School of Medicine, Hamamatsu, Japan, [9]Gifu University Graduate School of Medicine, Gifu, Japan, [10]Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [11]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Anti-Melanoma Differentiation-Associated Gene 5 (MDA5) antibody is found specifically in patients with dermatomyositis (DM). This autoantibody is associated with clinically amyopathic DM (CADM) and rapidly progressive interstitial lung disease (RP-ILD) especially in eastern Asian population. An association between anti-MDA5 antibody titer measured by in-house enzyme-linked immunosorbent assay (ELISA) and disease activity has been also reported. Recently, we have established an ELISA system for detection of anti-MDA5 antibody for clinical practice use.

Objectives: To verify utility of our anti-MDA5 ELISA in a multi-center study.

Methods: Sera and clinical information were obtained from 432 patients with connective tissue disease (CTD) and 154 with Idiopathic interstitial pneumonia (IIP), who were followed at 8 participating hospitals. CTD patients included 104 with classic DM, 68 with CADM, 70 with polymyositis (PM), 43 with systemic sclerosis, 67 with systemic lupus erythematosus, 45 with rheumatoid arthritis, 20 with mixed connective tissue disease, 8 with Sjögren syndrome, and 7 with other CTD. IIP was defined as interstitial lung disease of unknown cause, in which patients did not fulfill classification criteria for any specific CTD or vasculitis. A healthy control included 123 volunteers. Anti-MDA5 ELISA utilized a recombinant protein encompassing the entire amino acid sequence of MDA5, which was expressed and purified using a baculovirus expression system. Antibody levels were shown in an index, which was calculated by optical density (OD) at 450 nm according to the following formula: (sample OD – blank OD/positive reference OD – blank OD) $\times$ 100. Immunoprecipitation (IP) assay was also conducted in patients with PM/DM (including classic DM, CADM, and PM). Comparisons between two groups were made using the chi-square test.

Results: Of 242 PM/DM samples, 10 (9.6%) with classic DM and 46 (67.6%) with CADM were positive for anti-MDA5 antibody by the gold standard IP assay. When a cutoff of the anti-MDA5 ELISA was set at 32 index based on receiver operating characteristics curve analysis in comparison with results of IP assay, analytical sensitivity and specificity of the ELISA were 98.2% and 100%, respectively. The ELISA showed an extremely high specificity, since anti-MDA5 antibody was detected in none of the patients with other CTD (including PM), those with IIP, or healthy controls. RP-ILD was more frequently found in classic DM/CADM patients with anti-MDA5 than in those without (83.6% versus 14.5%, $P < 0.001$).

Conclusion: This multi-center study has confirmed that a newly established ELISA for anti-MDA5 antibody is as efficient as the IP assay. This system enables easier and wider use in the detection of anti-MDA5 antibody in patients suspected to have DM and/or RP-ILD.

The Early Use of Cyclosporine Is Beneficial for Long-Term Prognosis in Patients of Polymyositis/Dermatomyositis-Associated Interstitial Lung Disease with Anti- Synthetase Antibodies. Yuji Hosono[1], Ran Nakashima[2], Yoshitaka Imura[2], Naoichiro Yukawa[2], Hajime Yoshifuji[2], Takaki Nojima[3], Koichiro Ohmura[2] and Tsuneyo Mimori[2]. [1]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Kyoto University Graduate School of Medicine, Kyoto, Japan, [3]Hiroshima University Hospital, Hiroshima, Japan.

Background/Purpose: Interstitial lung disesases (ILD) is the most common cause of mortality in polymyosotis (PM) and dermatomyositis (DM). Cyclosporine had been reported to improve clinical outocome in some patients with PM/DM and associated ILD. However, the efficiencies and longterm prognosis depending on the time of administration are still unclear. Here, we intended to investigate the benefits of early use of cyclosporine in PM/DM-associated ILD with antibodies (Ab) against aminoacyl-tRNA synthetase.

Methods: Clinical data and serum samples were collected from 144 adult Japanese patients with PM/DM who visited our department from January 2005 to December 2013. Patients who were treated with cyclosporine within 3 months from the initial treatment with high dose glucocorticoids were defined as early use group. Myositis-specific Abs (MSAs) were screened using the RNA immunoprecipitation assay. Kaplan-Meier survival analysis was applied to compare overall mortality rates.

Results: Sixty eight patients (33 with PM and 35 with DM) were positive for anti- synthetase Ab positive (25 anti-Jo-1, 14 anti-PL-7, 13 anti-EJ, 7 anti-PL-12, 5 anti-OJ, and 4 anti-KS). Among them, 64 patients (94%) had ILD. Among PM/DM associated ILD patients, 11 (17%, 6 with PM and 5 with DM) were cyclosporine early use group. Twenty-one (32%, 7 with PM and 14 with DM) were treated after more than 3 month from initial treatment and 32 (50%, 18 with PM and 14 with DM) were not treated with cyclosporine. The 15-year survival rate of early use group was significantly higher than that of delayed use of cyclosporine and non-combination with cyclosporine groups ($P<0.05$ by log-rank test). Three of 11 (27%) of early use group did not show any exacerbation of ILD after the treatment, while none of delayed group ($P<0.05$). There were no significant differences in age, sex, duration of diseases, rates of each anti-synthetase Ab, and requirement of intravenous cyclophosphamide pulse therapy among each group. One of 2 in early use group needed no longer home oxygen therapy within first year from the initial treatment, whereas none of other groups.

Conclusion: Our study showed significant survival benefits of cyclosporine use at early stage in PM/DM-associated ILD with anti- synthetase Ab. The introduction of combination therapy with cyclosporine and high dose glucocorticoids at early stage for ILD in PM/DM patients should be strongly recommended.

Pulmonary Arterial Hypertension in Patients with Anti-PM-Scl Antibody. Hiromichi Tamaki, Colin O'Rourke and Soumya Chatterjee. Cleveland Clinic, Cleveland, OH.

Background/Purpose: Patients with anti-PM-Scl antibody (PM-Scl) can present with several different phenotypes: polymyositis (PM), dermatomyositis (DM), systemic sclerosis (SSc), scleromyositis, or sclero-dermatomyositis. Pulmonary arterial hypertension (PAH) may be a disease manifestation of patients with PM-Scl but the association has not been rigorously examined and the association between its clinical manifestations and PAH is not clear, especially with PAH confirmed on right heart catheterization (RHC).

The association of PAH in systemic sclerosis is well established. Recent discoveries of effective medications to treat PAH, especially in patients with SSc have been encouraging and have important implications for other "autoimmune rheumatic disease"-associated PAH. It is not clear whether similar recommendations should apply to patients with PM-Scl.

Methods: All patients screened for PM-Scl between October 1999 and April 2014 were evaluated through our electronic medical record (EMR) system and patients with positive PM-Scl were identified. The patients' demographics, rheumatologic diagnoses (PM, DM, SSc, scleromyositis, or sclero-dermatomyositis), co-existing auto-antibodies, RHC variables, skin manifestations related with dermatomyositis, and presence of CT defined interstitial lung disease (ILD) were extracted from their EMR retrospectively. The primary outcome of this study was to compare the prevalence of RHC-confirmed PAH among patients with PM-Scl to that in the general population and also to that in SSc. The secondary outcomes were to explore possible predictors of PAH among these patients including presenting phenotypes or co-existing auto-antibodies.

Results: PM-Scl was detected in 42 patients; 32 (76.2%) were female. Mean age at diagnosis of their rheumatologic condition was 45.1 years and that of PM-Scl detection was 51 years. Five patients had RHC proven PAH [11.9% (95% confident interval 4.0% - 25.6%)], of whom 2 had moderate (mean pulmonary artery pressure (PAP) 41–55 mmHg) and 3 had mild PAH (mean PAP 25–40 mmHg). Compared to a previously documented prevalence of PAH in the general population of 0.0015%, this study found a significantly higher rate of PAH in patients with PM-Scl (1). However, the rate (11.9%) did not differ significantly from a previously documented prevalence of PAH in SSc patients (7.8%) (2). Of all PM-Scl positive patients 27 had ILD, of whom 4 also had PAH. There was a significant association between phenotype and PAH ($P=0.003$). In our cohort, all patients with PAH were associated with either DM or sclero-dermatomyositis phenotypes. There was no significant association of co-existing autoantibodies in these PAH patients.

Conclusion: Patients with PM-Scl have a higher prevalence of PAH than that in the general population, and should be screened for it at baseline and periodically thereafter. In our cohort PAH was seen in those presenting with a clinical phenotype of DM or sclero-dermatomyositis.

Mechanisms of Muscular Necrosis in Auto-Immune Myopathies Associated with Anti-Signal Recognition Particle and Anti-3-Hydroxy-3-Methylglutaryl-Coenzyme a Reductase Antibodies: Pathogenic Role of Auto-Antibodies. Yves Allenbach[1], Aude Rigolet[2], Bruno Eymard[3], Tanya Stojkovic[3], Anthony. Behin[3], Pascal Laforet[3], Peter Hufnagl[4], Norman Zerbe[4], Thierry Maisonobe[5], Kuberaka Mariampillai[3], Serge Herson[3], Olivier Benveniste[1] and Werner Stenzel[4]. [1]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [2]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, Paris, France, [3]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University, Paris, France, [4]Charite Hospital, Berlin, Germany, [5]Pitie-Salpetriere Hospital, Paris, France.

Background/Purpose: Necrotizing auto-immune myopathies (NAM) are a group of acquired idiopathic inflammatory myopathies characterized by severe muscle weakness and no or mild extra-muscular involvement. Definition of NAM is based on morphological features including fiber necrosis with no or few inflammation. Anti-SRP and anti-HMGCR auto-antibodies are specifically associated with NAM. However, to date data concerning histological features of anti-SRP or anti-HMGCR auto-antibody positive NAM patients (SRP^+ or $HMGCR^+$ NAM) are rare and mechanisms involved in fiber necrosis are totally unknown. We aim to describe the histological pattern of the skeletal muscle of a large series of SRP^+ or $HMGCR^+$NAM patients and to analyze mechanisms involved in muscle necrosis.

Methods: Fiber necrosis was detected on combined dystrophin stain and eosin counterstaining. Fiber necrosis were manually counted and normal fibers were automatically counted using imageJ software on digitally completely scanned slides. For immunohistochemical analysis, cell density was measured. **Results** are compare to a myositis group of anti-Jo-1 auto-antibody positive patients. A panel of immune mediators was tested by quantitative PCR in muscle biopsies (expressed as normalized fold change relative to normal muscle).

Results: The percentage of fiber necrosis is higher ($3.2\pm2.5\%$) in SRP^+ NAM patients ($n=22$) compared to $1.6\pm1.5\%$ in $HMGCR^+$ NAM patients ($n=19$) ($p=0.02$) and $1.6\pm2.5\%$ in Jo-1+ patients ($n=17$) ($p=0.007$). Amount of necrosis is not different in $HMGCR^+$ NAM patients vs. $Jo1^+$ patients but $80.7\pm6.7\%$ of necrosis occurs in perifasciuclar region in Jo-1^+ patients ($25.3\pm2.8\%$ in NAM; $p<0.001$). T cells and $CD8^+$ T cells densities are higher in Jo-1^+ patients (33.2 ± 7.9 cells/mm^2 and 22.3 ± 24.6 cells/mm^2) compared to NAM patients (10.2 ± 2.3 and 4.1 ± 6.0 cells/mm^2; $p=0.001$) but 17.7% of NAM patients harbored significant T cells infiltrates (>20 cells/mm^2). A diffuse MHC-I expression was observed in 22.7% of NAM patient vs. 87% in Jo1+ patients ($p<0.001$). In NAM patients T cells, $CD8^+$ T cell densities are correlated with amount of necrosis ($r=0.5$ and $r=0.4$; $p<0.01$) and an up-regulation of *IFN-γ* gene expression is observed in NAM patients (SRP^+ ($n=7$) and $HMGCR^+$($n=7$)).

On the other hand, a Th-2 immune polarization is observed in SRP^+ ($n=7$) and $HMGCR^+$ ($n=7$) NAM patients attested by the up-regulation of *STAT6*expression (11.5 ± 5.1). In the same line 95.2% of NAM patients harbor complement membrane attack complex (C5b-9) deposits with $13.8\pm16.1\%$ of muscle fibers decorated by C5b-9. Sarcolemmal C1q and IgG deposits are observed in all tested NAM patients ($n=3$).

Conclusion: SRP^+ and $HMGCR^+$ NAM patients present mostly a NAM pattern with a randomly distributed necrosis (contrary to Jo-1^+ patients) more pronounced in SRP^+ patients. Nevertheless a subgroup of patients presents inflammatory infiltrates which could be involved partly in muscular necrosis. In addition the Th-2 immune response with signs of classical complement pathway activation suggests the pathogenic role of auto-antibodies.

Evidence for the Involvement of NK Cells in Antisynthetase Syndrome. Baptiste Hervier[1], Yves Allenbach[2], Mikael Perez[3], Hervé Devilliers[4], Fleur Cohen-Aubart[5], Zahir Amoura[6], Werner Stenzel[7], Isabelle Cremer[3], Olivier Benveniste[2] and Vincent Vieillard[1]. [1]INSERM UMR-S 1135, UPMC, Paris, France, [2]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [3]INSERM & UPMC, Paris, France, [4]CHU de Dijon, Dijon, France, [5]Pitié-Salpêtrière Hospital, APHP, Paris, France, [6]Pitié-Salpêtrière Hospital (AP-HP), Paris, France, [7]Charite Hospital, Berlin, Germany.

Background/Purpose: Antisynthetase syndrome (aSS) is characterized by the association of interstitial lung disease and myositis with anti-tRNA-synthetase autoantibodies. Its pathogenesis remains unknown, especially regarding the involvement of innate immune cells, including natural killer (NK) cells. Here, we describe the first phenotypic and functional characterization of NK cells in this context.

Methods: A total of 20 patients with inactive and active aSS were included (women/men =9, median age =50 years), and compared to 20 healthy controls. Freshly isolated NK cell phenotype was performed by Flow cytometry. Polyfunctionality assays were performed to measure degranulation and intracellular production of TNFa and IFNg, spontaneously or after stimulation by interleukin(IL)-12 and IL18, in the presence of K562 target cells. The presence and the localization of NK cells in primary human specimens of lung ($n=3$) and muscle ($n=3$) target tissue were studied by immunohistochemistry, using anti-NKp46 monoclonal antibody.

Results: NK cells from inactive patients showed normal phenotype, whereas active aSS revealed a differentiated NK cell profile, as indicated by a increased level of CD57 ($p=0.09$) and ILT2 ($p=0.016$) associated with decreased CD161 ($p=0.052$) and NKp30 ($p=0.009$), compared to healthy donors. This is consistent with the inability of circulating NK cells of active aSS patients to produce IFNγ ($p=0.0017$) after IL12 plus IL18 stimulation, compared to healthy controls. More importantly, our in-depth analysis reveals that NKp30 down-modulation strongly correlated with the loss of NK cell functions (Spearman coefficient $r=0.57$, $p=0.009$), and could be a surrogate marker of aSS activity. Histological studies reveal for the first time the presence of small numbers of NK cells in the muscles, as well as a massive infiltration of NK cells inside the lungs of aSS patients.

Conclusion: Taken as a whole, NK cell phenotypic and polyfunctional changes as well as infiltration of target tissue argue for an involvement of NK cells in aSS pathogenesis.

1264

Analysis of Clinical Manifestations and Myositis-Specific Autoantibodies Associated with Severity of Physical Dysfunction after Treatment for Polymyositis and Dermatomyositis. Hidenaga Kawasumi[1], Takahisa Gono[1], Yasushi Kawaguchi[1], Yasuhiro Katsumata[1], Hisae Ichida[1], Akiko Tochimoto[1], Masanori Hanaoka[1], Yuko Okamoto[1], Sayuri Kataoka[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Half of all polymyositis (PM)/dermatomyositis (DM) patients suffer from muscle weakness after initial treatment. Therefore, many patients with PM/DM have trouble with daily living even after disease activity has been adequately controlled. However, details regarding the clinical factors that are associated with the disability of physical function after treatment in PM/DM remain unclear. The aim of our study was to clarify the clinical manifestations and myositis-specific autoantibodies (MSA) that are associated with the severity of physical dysfunction after treatments in PM/DM.

Methods: In the present study, Seventy seven patients who were diagnosed with PM, DM or clinically amyopathic DM (CADM) were retrospectively enrolled. They were admitted to our hospital from December 1991 to February 2013 because of initial treatment for PM/DM/CADM. Diagnoses were made based on the criteria of Bohan and Peter or those of Sontheimer. We obtained clinical data from their medical records, including age of disease onset, gender, and disease duration. We also obtained laboratory data prior to initial treatment, such as CK, LD, antinuclear

antibodies and MSA, the content of treatment, and the presence of relapse. We evaluated the physical dysfunction of each patient after treatment from August to October 2013 using the Japanese version of the Health Assessment Questionnaire Disability Index (J-HAQ-DI). We retrospectively analyzed the clinical data prior to the initial treatment as predictors for the severity of physical dysfunction after treatment.

Results: Of the 77 patients with PM/DM/CADM, the median age of disease onset was 46 years old, and 79% of the patients were female. The numbers of PM, DM, and CADM cases were 40, 30, and 7, respectively. Anti-a*minoacyl*-tRNA synthetase antibody (anti-ARS), anti-melanoma differentiation-associated gene 5 antibody (anti-MDA5), and anti-signal recognition particle antibody (anti-SRP) were identified in 25, 7, and 9 patients, respectively. Anti-Mi-2, anti-TIF1-γ, and anti-NXP-2 were also identified in a few patients. The median dose of prednisolone (PSL) at the initial treatment was 50 mg/day. The median of J-HAQ-DI score after treatment was 0.125 (range 0–2.75). In a multivariate analysis, the age of disease onset (t value=4.72, $p<0.0001$), female status (t=2.80, $p<0.01$), and the initial doses of PSL (t=1.83, $p=0.073$) were associated with the severity of the J-HAQ-DI score after treatment. The serum levels of CK prior to treatment, the presence of mPSL pulse therapy, and the relapse of the diseases were not associated with the severity of the J-HAQ-DI scores after treatment. From the viewpoint of MSA, anti-SRP positivity was associated with more severe physical dysfunction after treatment than other MSAs. However, anti-MDA-5-positivity was associated with better physical function after treatment than other MSAs.

Conclusion: The age of disease onset, gender, and the initial dose of PSL were significant factors associated with the severity of physical dysfunction after treatment in PM/DM. The clarification of MSA is useful for predicting the prognosis of physical function after treatment in PM/DM.

1265

Diabetes and Atorvastatin Are Potential Risk Factors for Statin-Associated Myopathy with Autoantibodies Against 3-Hydroxy-3-Methylglutaryl-Coenzyme a Reductase. Pari Basharat[1], Arash Lahouti H.[1], Andrew L. Mammen[1], Iago Pinal-Fernandez[1], Tanmayee Bichile[2], Thomas E. Lloyd[3], Sonye K. Danoff[1], Livia Casciola-Rosen[2] and Lisa Christopher-Stine[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins, Baltimore, MD.

Background/Purpose: The idiopathic inflammatory myopathies (IIM) comprise a group of autoimmune disorders that target skeletal muscle. Some IIM cases may be associated with an autoantibody against 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), especially in statin exposed patients. The purpose of our study was to characterize the disease course, prevalence of comorbidities and detailed statin history in HMGCR antibody positive (HMGCR +) IIM patients, as compared to statin exposed HMGCR antibody negative (HMGCR -) IIM patients. We also aimed to distinguish differences between statin exposed vs statin naive HMGCR + patients.

Methods: From 5/1/02 to 1/31/14, 1687 suspected myopathy patients evaluated at the Johns Hopkins Myositis Center were enrolled in a longitudinal study. Serum and DNA samples were available for 1083 patients. Patients were included in our analysis if they met Bohan and Peter (B and P) criteria for definite/probable polymyositis or dermatomyositis. HMGCR autoantibodies were tested for via immunoprecipitation and ELISA. Patients in the comparator group were selected from the large cohort of myositis patients if they were HMGCR-, fulfilled the aforementioned B and P criteria, and had a documented statin history including exact statin name, dose, and start/stop dates. We performed a retrospective chart review from time of first clinic visit until 01/31/2014 or last clinical encounter.

Results: There were 77 HMGCR+ patients, 19 statin naïve. Data was compared between 58 statin exposed HMGCR+ IIM patients and 39 statin exposed HMGCR- IIM patients. HMGCR+ patients were slightly older (mean age 59.9 vs 55; p=0.013) but otherwise had similar baseline characteristics. HMGCR+ patients had higher mean creatine kinase (CK) values ($p<0.001$), and greater hip flexor weakness at presentation (p=0.002) and over time. Distal weakness was more prevalent in HMGCR– patients (p=0.023). IVIG (p=0.036) and Rituximab (p=0.018) were used more in HMGCR+ patients. More HMGCR– patients had interstitial lung disease (ILD) (p=0.003). There was no difference in the prevalence of dysphagia. HMGCR+ patients had a higher prevalence of non-steroid induced type II diabetes (p=0.002). There was a higher prevalence of cancers in the HMGCR+ group (10 patients), although not statistically significant (p=0.775). More patients in the HMGCR+ group were exposed to atorvastatin ($p<0.001$). Adjusted for HMGCR antibody status, multiple regression showed no significant association between individual statins and measures of CK and proximal weakness. HMGCR- patients exposed to statins > 1 year had slightly increased arm abduction weakness at presentation. Statin naïve HMGCR+ patients were significantly younger than statin exposed HMGCR+ patients and received less Rituximab and IVIG, although results for IVIG were not statistically significant. Four statin naïve HMGCR+ patients had a history of cancer.

Conclusion: Compared to statin exposed HMGCR- patients, statin exposed HMGCR+ patients had a higher prevalence of type II diabetes, a high number of cancers, increased exposure to atorvastatin prior to symptom onset, less prevalence of ILD, and greater treatment with IVIG and Rituximab.

1266

Anti-MDA5 Is Associated with Rapidly-Progressive Interstitial Lung Disease and Poor Survival in U.S. Patients with Amyopathic and Myopathic Dermatomyositis. Siamak Moghadam-Kia[1], Chester V. Oddis[1], Shinji Sato[2], Masataka Kuwana[3] and Rohit Aggarwal[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Tokai University School of Medicine, Isehara, Japan, [3]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Clinically amyopathic dermatomyositis (CADM) is a subset of dermatomyositis (DM) presenting with the characteristic rash(es) of DM without objective muscle weakness. Asian studies report that anti-MDA5 autoantibody (autoAb) in CADM is associated with interstitial lung disease (ILD), particularly rapidly-progressive ILD (RPILD). These associations have not been established in U.S. myositis patients. The goals of our study were to determine the association of anti-MDA5 autoAb with ILD, RPILD and survival in U.S. patients with CADM and DM.

Methods: A cohort of CADM patients were matched (gender and age) 1:1 with classic DM controls. CADM was defined by a DM rash without objective muscle weakness for at least 6 months after rash onset with no or minimal abnormalities of serum muscle enzymes, electromyography or muscle biopsy. We collected clinical, laboratory, radiographic and survival data on the CADM and DM cohorts. Anti-MDA5 autoAb was measured by serum ELISA on both groups. ILD was defined by fibrosis on imaging studies and RPILD by the acute onset and rapid worsening of dyspnea or severe radiographic ILD/fibrosis within 3 months from the onset of respiratory symptoms. Kaplan-Meier and Cox proportional hazard model was used for survival analysis. Chi-square test and Student's t-test was used for other associations.

Results: We identified 61 CADM patients and 61 age and gender matched DM controls. There were 62% and 64% females, 92% and 87% Caucasians, with a mean (SD) age of 48.2 (16.9) and 44.8 (17.6) in the DM and CADM cohorts, respectively. Anti-MDA5 frequency was similar in CADM (13.1% [8/61]) and DM (13.1% [8/61]) as was ILD (CADM: 31.1% [19/61], DM: 26.2% [16/61]) or RPILD (CADM: 8.2% [5/61], DM: 5% [3/61]), p = NS]. Anti-MDA5 positivity was significantly associated with ILD as 50% (8/16) of MDA-5+ subjects had ILD vs. 25.5% (27/106) of MDA-5- subjects (p=0.043). Anti-MDA5 was strongly associated with RPILD ($p<0.001$). Among 8 anti-MDA5+ patients with ILD, 7 had RPILD leading to early death in 5; whereas, only one MDA5- patient had RPILD (1/106). Anti-MDA5 positivity was significantly associated with poor survival (Figure 1, p=0.007), but the presence of ILD or CADM was not predictive of survival. RPILD had a very poor prognosis with hazard ratio (HR) of 28 (CI: 9–86, $p<0.001$). Multivariate analysis suggested that anti-MDA5 positivity predicted survival (HR [C.I.] = 7 [2–23], p=0.001) even after controlling for diagnosis (CADM vs. DM), age at diagnosis, gender, ethnicity, smoking, and ILD (p=0.002).

Conclusion: CADM is not associated with anti-MDA5 or ILD in U.S. DM patients. Anti-MDA5 has a similar frequency in CADM and DM and is significantly associated with ILD, RPILD, and poor survival in U.S. DM patients.

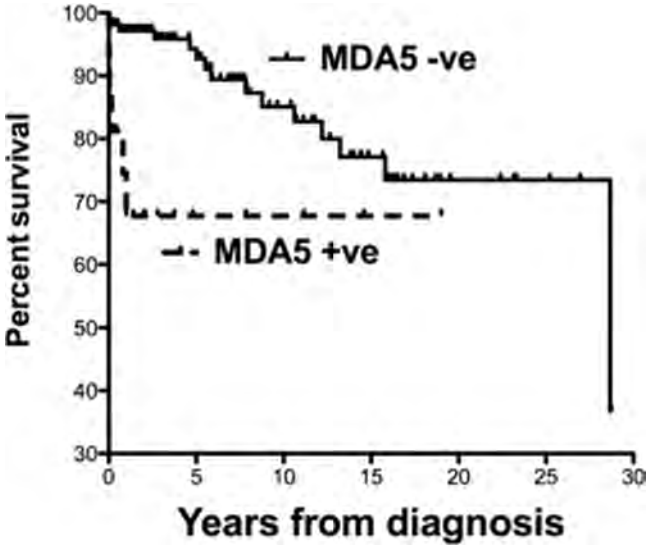

Figure 1. Kaplan-Meier survival curve for anti-MDA5 positive and negative patients (p-value=0.007).

Are Anti-SRP Auto-Antibodies Specific for Myositis? Samantha Rodriguez-Muguruza, Ines Lozano, Jaume Coll, Maria Lourdes Mateo, Susana Holgado, Eva Martínez-Cácerez and Alejandro Olivé Marqués. Hospital Universitari Germans Trias i Pujol, Barcelona, Spain.

Background/Purpose: Myositis-specific auto-antibodies (Ab) include those directed against aminoacyl-tRNA synthetases (ARS), signal recognition particle (SRP) and nuclear helicase Mi-2. Anti-SRP Ab are among the most abundant and best characterized myositis-specific Ab. Patients diagnosed with myositis associated with anti-SRP Ab are mainly associated with aggressive disease and poor prognosis and are refractory to glucocorticoids/To determine the clinical features, serological features and long-term prognosis among patients with anti-SRP Ab.

Methods: We retrospectively analyzed 8 patients with positive anti-SRP Ab, detected between 2000 and 2013 in our hospital (Tertiary, referral: 850,000 inhabitants). Medical records of patients with polymyositis (PM) or dermatomyositis according to the Bohan and Peter criteria, and patients with anti-cytoplasmic Ab, were reviewed regardless of diagnosis. Past and current status were assessed from hospital records. A post-questionnaire, personal interview and electromyography (EMG) test were performed in patients without myositis. Anti-nuclear Ab and anti-tissue Ab (AMA, LC, LKM) were tested at diagnosis by indirect immunofluorescence on Hep-2000 cells (Immunoconcepts®) and in-house tissue, respectively. Myositis-specific Ab: anti-ARS (Jo-1, PL7, PL12) and anti-SRP were tested by immunoblot (Orgentec®). In addition, levels of creatine kinase (CK) were measured by turbidimetry (Roche®).

Results: Patients with anti-SRP Ab were 6 Caucasians and 2 north-African women, mean age 63 years; three (37.5%) had PM (1 associated with systemic sclerosis). At diagnosis, muscle weakness was severe in 2 patients (defined as < 3 of manual muscle strength testing), associated with dysphagia and respiratory muscle involvement. Season of onset of muscle weakness: 2 in spring and 1 in winter. All 3 patients were treated with glucocorticoids; 2 required immunosuppressive agents (methotrexate, azathioprine, rituximab or intravenous immunoglobulin). Histological study of biceps brachii showed histological changes consistent with necrotising myopathy with scarce inflammatory cells. Five (62.5%) patients showed no features of myositis after a follow-up of 6 months to 3.5 years; 4 had a normal EMG and normal CK levels. Their diagnoses were: rheumatoid arthritis, Sjögren′s syndrome, autoimmune hepatitis, and primary biliary cirrhosis (pure and associated with systemic sclerosis). There were no deaths or history of malignancy among the 8 anti-SRP patients.

Race/Age (years)	Diagnosis	Treatment	EMG	CK U/L (maximum)	Other Ab
North african/36	Autoimmune hepatitis	Azathioprine	N/A	40	Ro52, La
White/65	Primary biliary cirrhosis, sarcoidosis	Ursobilane	Normal	42	M2
White/69	Primary biliary cirrhosis, systemic sclerosis	Ursobilane	Normal	72	M2, Cep B
White/83	Rheumatoid arthritis	Azathioprine, prednisone	Normal	37	Anti-CCP antibodies, ANA Homogenous Pattern 1/640
White/74	Sjogren′s Syndrome	No	Normal	41	Ro 52, Ro 60, La
North african/46	PM	Methotrexate, azathioprine, prednisone, Ig, Rituximab	Polymyositis	3000	Ro 52, La
White/80	PM	Methotrexate, prednisone	Polymyositis	2339	No
White/58	PM, systemic sclerosis	Prednisone	Polymyositis	1100	Ro52, SP100

N/A not available.

Conclusion: Although anti-SRP remains a specific Ab for PM, it is occasionally detected in patients with other rheumatic diseases and autoimmune hepatitis in the absence of myositis.

Study of Autoantibodies in a cohort of Mexican patients with idiopathic inflammatory myopathies. Yelitza Gonzalez-Bello[1], Miguel Angel Ortiz-Villalvazo[2], Ignacio Garcia-Valladares[1], Gabriel Medrano-Ramírez[3], José E. Navarro-Zarza[4], Lilia Andrade-Ortega[5], Arnulfo Nava-Zavala[1], Gerardo Orozco-Barocio[1], Marco Maradiaga-Ceceña[6], Marvin Fritzler[7] and Ignacio Garcia-De La Torre[8]. [1]Hospital General de Occidente, Zapopan, Jal., Mexico, [2]Hospital Civil de Guadalajara, Guadalajara, Jal., Mexico, [3]Hospital General de Mexico de la Secretaría de Salud, Mexico City, Mexico, [4]Hospital General de Chilpancingo, Chilpancingo, Gro., Mexico, [5]CMN 20 Noviembre ISSSTE, Mexico City, Mexico, [6]Hospital General de Culiacan de la Secretaría de Salud, Culiacan, Sin., Mexico, [7]University of Calgary, Calgary, AB, [8]Universidad de Guadalajara, Guadalajara, Jal., Mexico.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of autoimmune disorders characterized by muscle inflammation, progressive weakness with a combination of clinical, electromyography and laboratory findings, which includes the expression of autoantibodies. In the last few years there has been an increasing interest to study IIM in different geographic populations. The objective of the study was to identify ANA, the myositis specific antibodies (MSA) and the myositis associated antibodies (MAA) in a cohort of Mexican IIM patients.

Methods: Serum samples from 77 IIM patients were collected from five participating centers in Mexico. ANA were detected by indirect immunofluorescence (IIF) on HEp-2 cells (Antibodies Inc., Davis, CA., USA). MSA and MAA were tested by two different methods: Luminex ENA (FIDIS: Thera-Diag, Paris, France) kit (ALBIA), and EUROLine Autoimmune Inflammatory Myopathies 15 Analyte kit (Euroimmun, Luebeck, Germany, line immunoassay).

Results: Of the 77 IIM patients, 55 (71%) had dermatomyositis (DM), 13 (17%) polymyositis (PM) and 9 (12%) juvenile dermatomyositis (JDM). The mean age was 40 years (6–69 years), 67 (87%) were female. The frequency of ANA by IIF was 81%, the most common IIF patterns were homogeneous and speckled representing close to 60%, the second most common pattern was cytoplasmic speckled 13% and then nucleolar 10%, 37% had the highest end point titer of 1:5,120.

By LIA the frequency of MSA was: Mi-2β (40.2%), Jo-1 (18.1%), SRP (5.2%), PL-12 and Mi-2α (3.9%), Anti-PL-7 (2.6%), Anti-EJ (1.3%) and Anti-OJ (0%). The most frequent MAA tested by LIA was PM/Scl-75 (12.9%), followed by Ku and TIF-1-gamma (9%), and MDA-5 (7.8%); with less than 4% attributed to PM/Scl-100, NXP-2 and SAE-1. Ro52/TRIM21 (16.9%) was detected by FIDIS ALBIA. Of the 16.9% of positive Ro52/TRIM21 patients, 30% were also positive for Jo-1 (LIA), and 54% for Mi-2β (LIA).

Conclusion: This is the first study of MSA and MAA in a cohort of Mexican IIM patients from 5 different centers. We observed a high prevalence of IIF ANA (81%) which is consistent with some previous reports. Homogeneous and speckled pattern represented approximately

60% of the ANA and the second most common pattern was cytoplasmic and nucleolar (13 and 10%, respectively). Regarding the analysis of the MSA and MAA we found an increased prevalence of anti-Mi2 antibodies (32.5%) an autoantibody typically associated with DM which was even higher frequency (~40%) when the two α and β isoforms of anti-Mi2 were analyzed. This is in contrast to many other geographic studies were anti-synthetase antibodies tend to be the most common IIM autoantibody. The most common MAA antibody was anti-Ro52/TRIM21, an autoantibody that has been associated with pulmonary fibrosis and polyautoimmunity. It is worth noting that up to 46% of the positive Ro52/TRIM21 patients did not share any MSA or MAA which may indicate that it is an independent marker in IIM sera.

Epidemiology and Characteristics of Antisynthetase Syndrome in the African Descent Population of Martinique. Christophe Deligny[1], Maryvonne Dueymes[2], Serge Arfi[1], José Zécler[2], Maia Forgues[3], Véronique Dehlinger[4], Michel DeBandt[5], Lauren Brunier-Agot[5], Remi Bellance[5], Isabelle Lamaury[6], Nadege Cordel[6], Nicolas Baillet[7], Gilbert. Cadelis[8], Georges Jean Baptiste[9] and Katlyne Polomat[5]. [1]Centre hospitalier Universitaire de Fort de France, Fort de France, Martinique, [2]Centre Hospitalier Universitaire de Fort de France, Fort de France, Martinique, [3]Centre Hospitalier Andre Rosemon, Cayenne, French Guiana, [4]Centre Hospitalier universitaire de Fort de France, Fort De France - Martinique, Martinique, [5]Centre Hospitalier universitaire de Fort de France, Fort de France, Martinique, [6]Centre Hospitalier universitaire de Guadeloupe, Pointe à Pitre, Guadeloupe, [7]Centre Hospitalier de la Basse Terre, Basse Terre, Guadeloupe, [8]Cnetre Hospitalier Universitaire de Guadeloupe, Pointe à Pitre, Guadeloupe, [9]Centre Hospitalier Universitaire de Fort de France, Fort de France, Guadeloupe.

Background/Purpose: There is no population based epidemiologic studies of antisynthetase syndrome (ASS). We described characteristics and epidemiology of this disease in Martinique, populated by an African descent population.

Methods: Incidence was calculated including incident cases prospectively identified from 2006 to 2013 by 3 sources in Martinique: (1) competence center for rare systemic autoimmune diseases, (2) national referral center for rare neuromuscular disorders, (3) the only respiratory medicine department, all located in the academic hospital of Fort de France. We included to describe biological and clinical characteristics, more patients from the rheumatology, internal medicine and respiratory medicine units of the 2 others French American regions (Guadeloupe and French Guiana). Inclusion criteria were: presence of one of the antisynthetase antibodies associated to muscular, rheumatologic involvement or interstitial lung disease.

Results: In the 3 regions, 41 patients (all of African descent) were found (31 from Martinique, 6 from Guadeloupe and 5 from French Guiana): 31 females, 10 males. The mean age at diagnosis was 44.1 yo (range: 25–82). Three patients were lost to follow up (none in Martinique) and 5 deceased (2.06 dead/100 patients-year). The mean follow up time was 72.3 months. Fifty one percent had anti-Jo1 antibody, 44% anti-PL12, 5% anti-PL7. Initially, the clinical picture was: 15% and 57% muscular ($p< 0.05$), 60 and 38% pulmonary ($p>0.05$), 50 and 23.8% rheumatologic ($p> 0.05$) for anti-PL7/PL12 and anti-Jo1 respectively. Cumulative characteristics in 41 patients showed: Interstitial lung disease 82.9% (PL7/12: 90%, Jo1: 76.2%; $p> 0.05$), arthritis 63.4% (PL7/12: 65%, Jo1: 62.9%; $p>0.05$), mechanic hands 51.2% (PL7/12: 36.8%, Jo1: 71.4%, $p>0.05$), fever 51.2% (PL7/12: 60%, Jo1: 42.9%; $p>0.05$). Clinical myopathy was found for 43.9% (PL7/12: 25%, Jo1: 61.9%; $p< 0.05$) and 56.1% were considered as amyopathic (34.1%; PL7/12: 45%, Jo1: 23.8%) or clinically amyopathic (22%; PL7/12: 30%, Jo1: 14.3%). Main histologic patterns at the chest CT scan were: non specific interstitial pneumonia (52.9%), usual interstitial pneumonia (23.5%), cryptogenic organizing pneumonia (5.9%), diffuse alveolar damage (3%). Myocarditis was present in 3 patients. Associated diseases were: rheumatoid arthritis (5), Juvenile idiopathic arthritis (1), systemic sclerosis (1), antiphospholipid syndrome (1), Evans syndrome (3). Pulmonary hypertension was found in 4 patients and responsible for 3 of the 5 deaths. Eighteen patients were considered as incident cases in Martinique during the 2006–2013 period, allowing a mean annual incidence of $5.3/10^6$ (PL7-12: 2.5; Jo1: 3.1). In December 31, 2013, the prevalence of ASS in Martinique was $67.5/10^6$(PL7/12: 30; Jo1: 37.5).

Conclusion: We provide the first population based epidemiology of ASS, moreover in an African origin population. We confirm the elevated proportion with anti-PL7/12 close to anti-Jo1 in our black patients from the French West Indies. This initial clinical profile, frequently mimicking infectious pneumonia with fever and high blood c reactive proteine level without clinical myopathy, can explain difficulties in the diagnosis.

1270

Distinctive Muscle Histopathological Features of Anti-Synthetase Syndrome. Baptiste Hervier[1], Yves Allenbach[2], Lenaig Mescam-Mancini[3], Thierry Maisonobe[4], Werner Stenzel[5], Aude Rigolet[6] and Olivier Benveniste[2]. [1]Pitié-Salpêtrière Hospital, APHP, Paris, France, [2]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [3]University hospital, Grenoble, France, [4]Pitie-Salpetriere Hospital, Paris, France, [5]Charite Hospital, Berlin, Germany, [6]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, Paris, France.

Background/Purpose: As supported by recent studies, anti-histidyl tRNA synthetase (anti-Jo1) antibodies are specific for clinico-biological features and outcomes. Though, anti-Jo1 synthetase syndrome is a clinical distinct entity among idiopathic inflammatory myopathies and among other anti-synthetase syndromes, its pathological features are poorly described.

Methods: This study was performed to define the histological characteristics of the associated myopathy, as well as to immunophenotype the inflammatory infiltrates, in a series of 53 anti-Jo1-positive patients with antisynthetase syndrome.

Results: Myopathic changes in myofibers were observed with predominant perifascicular topography: these changes included a characteristic peripheral necrosis (66%), or atrophy (45%). A perimysial fragmentation, seen with a trichrome coloration or with histoenzymological stain for alkaline phosphatases was commonly noted (90%). C5b9 membrane-attack-complex staining showed a sarcolemmal perifascicular expression in 57% of the biopsies. Human-leucocyte antigen class-I (HLA I) expression was enhanced at the periphery of the fascicles in 60% of the cases. A perimysial inflammatory infiltrate was present in 90 %, extending to endomysium in 83 %.

Conclusion: This largest study to date is highlighting that anti-Jo1 synthetase syndrome is a distinct histological entity within the spectrum of myositis, with a particular perifascicular necrotizing involvement, associated with a perimysial fragmentation, and a striking membrane-attack-complex perifascicular sarcolemmal expression.

1271

Myocarditis in Antisynthetase Syndrome. Céline Dieval[1], Olivier Benveniste[2], Christophe Deligny[3], Alain Meyer[4], Guillaume Lefevre[5], Yoland Schoindre[6], Aude Rigolet[7] and Baptiste Hervier[8]. [1]Rochefort Hospital, Rochefort, France, [2]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [3]CHU Fort de France, Fort de France, France, [4]University Hospital of Strasbourg, Strasbourg, France, [5]CHRU Lille, Lille, France, [6]DHU 2iB Internal Medicine Referal Center for Autoimmune diseases Pitie Hospital, PARIS, France, [7]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, Paris, France, [8]Pitié-Salpêtrière Hospital, APHP, Paris, France.

Background/Purpose: Antisynthetase syndrome (aSS) corresponds to an overlapping inflammatory myopathy identified by different myositis specific autoantibodies (directed against tRNA-synthetases). Myocardial involvement in this condition is poorly described.

Methods: From a 342 aSS patient registry, nine cases of myocarditis were identified on the basis of an unexplained increased in cardiac troponin I levels associated with either suggestive cardiac magnetic resonance imaging (MRI) findings, normal coronary artery explorations, and/or positive endomyocardial biopsy.

Results: The prevalence of myocarditis in aSS is 2.6% (n=9) and was not linked to any autoantibody specificity: anti-Jo1 (n=5), anti-PL7 (n=3) and anti-PL12 (n=1). Myocarditis was an inaugural presentation in 44% of the

cases and was asymptomatic (n=1) or revealed by an acute (n=4) or subacute (n=4) cardiac failure. Of note, myocarditis was always associated with an active myositis. When performed (n=8), cardiac MRI revealed a late hypersignal in the T_1-images in 87% of the cases (n=7). Four patients (44%) required intensive care. Seven patients (78%) received dedicated cardiotropic drugs. Steroids and at least one immunosuppressive drug were given in all cases. After a median follow-up of 23 months (range 2–51), six (67%) patients recovered whereas three (33%) developed chronic cardiac insufficiency. No patient died.

Conclusion: The prevalence of myocarditis in aSS is similar to that reported in other inflammatory myopathies. Although it has a relatively good prognosis, myocarditis is a severe condition and should be carrefully explored in active aSS patients.

Myositis-Specific and Myositis Associated Autoantibodies in Indian Patients with Inflammatory Myositis. Puja Srivastava, Ramnath Misra, Able Lawrence, Amita Aggarwal and Vikas Agarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Recently, idiopathic inflammatory myositis (IIM) has been categorised into distinct subsets based on myositis specific autoantibodies (MSA) and myositis associated autoantibodies (MAA). However, there is little data on prevalence of these autoantibodies from Indian subcontinent. Hence, we studied the prevalence and clinical associations of MSAs and MAAs in Indian patients with IIM.

Methods: Clinical data and sera were collected from patients with IIM (November 2012-May 2014). Sera were analysed for antibodies against SRP, Mi2, Jo1, PL 7, PL 12, EJ, OJ, Ro 52, Ku, Pm-Scl75 and PM-Scl 100, using line immunoblot assay (Euroimmune).

Results: During 18 months there were 124 patients with IIM. ANA positivity was found in 84 (68.9%). The distribution of different autoantibodies in different subset is given below:

Parameter	DM	PM	CTD assoc. IIM	JDM	Total
Number	**55**	**25**	**22**	**22**	**124**
Female: Male	40:15	24:1	22:0	11:11	97:27
Mean age	34.4	35.2	34.4	10.1	30.4
Mean disease duration	8.3+11.2	11.4+16.7	7.6+7	20.6+25.1	10.9
Myosits specific antibodies (number positive)					
Mi2	21	2	1	2	26
SRP	3	1	1	1	6
Anti-Jo1	3	6	0	5	14
Other Anti-synthetase	7	3	2	3	15
Myositis associated antibodies (number positive)					
Ro52	14	11	15	5	45
Ku	7	1	2	3	13
PM-Scl 100	1	1	2	1	5
PM-Scl 75	3	4	3	3	13
All antibody negative					
	13	**5**	**5**	**10**	**33**

Thirty eight (30.6%) patients had two autoantibodies and 7(5.6%) patients had 3 autoantibodies.

Anti-Jo1 showed positive association(r= 0.31) while anti-Mi2 showed negative association (r= −0.26) with anti-Ro52 antibody. Anti-Mi2 antibodies were strongly associated with adult DM ($p< 0.0001$) as well as it was associated with decreased risk for ILD (p=0.001) and increased risk for pharyngeal weakness (p=0.006). ILD and mechanics hands were strongly associated, both with anti-Jo1and anti-synthetase antibodies ($p<0.0001$). Four of the six patients with anti-SRP antibody had poor response to multiple drugs.

Conclusion: Higher prevalence of anti-Mi2 is probably related to higher proportion of patients with DM. We found absence of ILD in patients with anti-Mi2 antibody suggesting that it may protect against ILD. In Indian population also anti-synthetase antibodies are associated with ILD and anti-SRP with poor response to treatment.

1273

Assessment of the Effect of Rituximab in the Treatment of Interstitial Lung Disease associated with the Antisynthetase Syndrome. Tracy Doyle[1], Juan Osorio[2], Eduarda Nilo DeMagaldi[3], Rachna Madan[4], Fernanda Cabral[5], Ivan Rosas[2] and Paul Dellaripa[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard Medical School, Boston, MA, [4]Brigham and women's Hospital, Boston, MA, [5]Brigham and women's Hospital, boston, MA.

Background/purpose: To assess clinical outcomes including pulmonary function and radiographic imaging in patients with ILD and the antisynthetase syndrome who were treated with Rituxan (RTX).

Methods: We retrospectively identified all patients at one institution with the antisynthetase syndrome who presented with ILD and were treated with RTX. Data regarding demographics, serologic status, muscle disease, concomitant steroid use, pulmonary function testing and chest CT scans were assessed before and after the use of RTX. Serial assessments with PFTs were performed using standardized methods. Two radiologists independently evaluated axial chest CT scans using a standardized scoring system (Oda et al. Respiratory Research 2014, 15:10) and made a subjective assessment of the type of ILD pattern at 0 and 6 months and the scores of the two radiologists were averaged.

Results: 12 patients were identified who were treated with RTX for the anti-synthetase syndrome. Anti-synthetase antibodies were identified in all patients (5 PL-12, 4 Jo-1, 3 PL-7). 11 patients (92%) were females and the mean age was 54. Three patients (25%) had been smokers. The diagnosis of antisynthetase syndrome followed the diagnosis of ILD in 8 patients (67%) by a mean of 4.5 years. 7 of the patients had myositis. In 9 cases (75%), the principal indication for use of RTX was recurrent or progressive ILD due to failure of other agents. Mean time to initiation of RTX after identification of ILD was 5.4 years. One patient discontinued RTX in this time due to anaphylaxis. One patient proceeded to lung transplant, and 2 patients had serious gastrointestinal complications requiring surgery but subsequently resumed RTX.

Comparing pre and post RTX PFTs at 3–12 months for the 10 patients with adequate follow-up, FVC% and TLC% were stable or improved in 70% and 80% of subjects, and DLCO% increased in 38% [Table 1]. The average individual change was 12%, 13%, and −6%, respectively. CT score was stable or improved in 83% of subjects where followup CT was available. Eight CTs were consistent with non specific interstitial pneumonia (NSIP) and 2 had components of both cryptogenic organizing pneumonia (COP) and NSIP. Steroid dose decreased in 88% of subjects with an average decrease in dose of 6mg.

Conclusions: Use of RTX was well tolerated in the majority of patients who had ILD and the anti-synthetase syndrome. Stability or improvement in pulmonary function or CT imaging was seen in most patients. RTX may play a therapeutic role in patients with ILD associated with the antisynthetase syndrome and further clinical investigation is warranted.

Table 1: Comparison of pre and post RTX pulmonary function test measurements, CT scan score at 0 and 6 months, and prednisone dose (mg/d) with individual values and % change

	FEV1%	FVC%	TLC%	DLCO%	CT Score	Prednisone Dose
Average Pre-RTX	55.3	55.6	42.3	39.8	171.9	19 mg
Average Post-RTX	62.3	62.6	63.5	45.9	162.7	12 mg

ACR/ARHP Poster Session B
Osteoarthritis - Clinical Aspects: Epidemiology and Pathogenesis
Monday, November 17, 2014, 8:30 AM–4:00 PM

1274

Patients with Osteoarthritis Do NOT Have Increased Risk of Cardiovascular Disease in Ullensaker Community in Norway. Silvia Rollefstad[1], Ingvild Eeg[1], Ida K. Haugen[1], Inge C. Olsen[1], Nina Østerås[1], Barbara Christensen[1], Hilde Berner Hammer[1], Lars Nordsletten[2], Bård Natvig[3], Tore K. Kvien[1] and Anne Grete Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Oslo University Hospital, Oslo, Norway, [3]Oslo University, Oslo, Norway.

Background/Purpose: Controversies exist regarding whether patients with osteoarthritis (OA) have an increased risk of cardiovascular (CV) disease. Our aim was to evaluate the CV risk in a population-based OA cohort.

Methods: The **M**usculoskeletal pain in Ullensaker **ST**udy (**MUST**) is a cross-sectional investigation comprising a thorough clinical examination, recording of CV risk factors in addition to radiographic evaluation of hands, hips and knees of persons with self-reported OA (The MUST-Heart study). Of the 604 persons examined, 438 fulfilled the ACR classification criteria for OA in the hand, knee and/or hip joints. The study population was divided into: 1) generalized OA, defined as bilateral hand OA or involvement of > 3 out of 6 sites (bilateral hand/hip/knee); 2) focal OA; or 3) non-OA. CV risk was calculated by the SCORE algorithm for persons without CV disease, not using lipid lowering and/or antihypertensive medication (OA n=200 and non-OA n=87). An estimated CV risk < 5% for a fatal myocardial infarction coming 10 years is defined as low to medium risk, while > 5% is the cut off for initiation of CV preventive pharmacotherapy. Comparisons between groups were done by using independent samples T-test, Mann Whitney-U and χ^2.

Results: The median CV risk for patients with OA [1.40 (IQR 0.65, 2.92)] was significantly higher compared to non-OA [0.99 (IQR 0.52, 1.92)] (p=0.02). The difference in the CV risk was related to higher age (p <0.001), but not to total cholesterol (p=0.07), systolic blood pressure (p=0.13) or to the OA diagnosis. Only 17/200 (8.5%) of the OA patients and 3/87 (3.4%) of the non-OA persons had a CV risk > 5% (p=0.12) (Table). The presence of established CV disease was comparable for those with (n=72/438, 16.8%) and without OA (n=34/166, 21.1%) (p=0.23). Dividing the OA group into focal and generalized OA, did not reveal any further differences regarding estimated CV risk or CV disease compared with non-OA. Inflammatory biomarkers (erythrocyte sedimentation rate and C-reactive protein) were in the normal range for the whole study population, with no difference between OA and non-OA (p=0.30 and 0.10, respectively) (Fig 1a&b).

Conclusion: Inhabitants with OA in a Norwegian municipality had an overall low risk of CV disease and did not have higher prevalence of established CV disease compared to non-OA.

Figure 1a

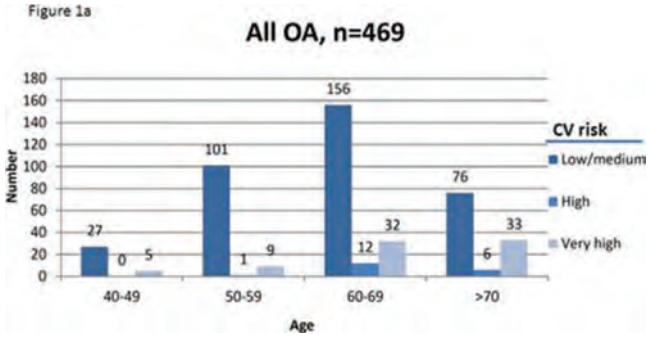

Figure 1b

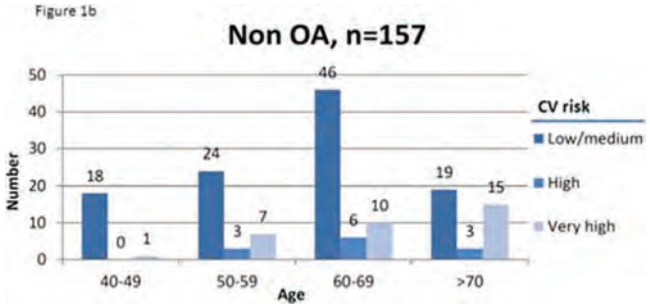

Table. Patient characteristics

	OA	Non-OA	P-value
Number	469	157	–

Association Between Cardiometabolic Disorders and Hand Osteoarthritis Severity: A Cross-Sectional and Longitudinal Study. Alice Courties[1], Jérémie Sellam[1], Francis Berenbaum[1], Emmanuel Maheu[1], Yoann Barthe[2], Fabrice Carrat[2] and Christian Cadet[3]. [1]AP-HP, Saint-Antoine Hospital, Rheumatology Department and DHU i2B, Paris, France, [2]Saint-Antoine Hospital, Inserm UMRS_1136, UPMC Univ Paris 06, AP-HP, Paris, France, [3]Private office, Paris, France.

Background/Purpose: Obesity and metabolic disorders increase the risk of hand osteoarthritis (HOA)**.** This study aimed to determine i) clinical and radiographic features associated with HOA symptoms and structural severity ii) factors associated with HOA progression.

Methods: This is an ancillary study from an international 3-year, randomized, placebo-controlled phase III trial designed to evaluate strontium ranelate on the X-ray progression of knee OA (SEKOIA trial). A clinical assessment at baseline and at 3 years was performed. Hand radiographs were scored by 2 reproducible readers (ICCs >0.8) for Kellgren-Lawrence (KL) and Verbruggen anatomical phase (Verb) scores. We included subjects with radiographic HOA defined by at least 2 joints with KL≥2. Symptoms were assessed using the overall Australian/Canadian (AUSCAN) score (normalized at 300) and the criterion hand pain and Functional index for HOA (FIHOA) ≥5. Radiographic HOA severity at baseline was assessed by global KL and Verb scorings. The longitudinal analysis was performed on the placebo group only to avoid potential biases due to a treatment effect. The clinical and radiographic progressions were defined as the changes of AUSCAN, KL or Verb scores between baseline and endpoint. Baseline age, gender, body mass index (BMI), clinical features and cardio-metabolic parameters were included in a multivariate linear or logistic regression model.

Results: At baseline, 869 subjects (72 % women) with mean ± SD age of 64 ± 7 years and BMI 29.6 ±4.7 kg/m^2 had radiographic HOA. Multivariate analyses indicated that AUSCAN level was associated with menopause (p<0.0005), depression (p<0.01), a history of ischemic cardiopathy (p<0.05) and radiographic severity (p<0.0005) (**Table**). A similar association was found for "FIHOA ≥ 5 and pain" criterion (p<0.05 for all analyses). Accumulation of metabolic factors (hypertension, dyslipidemia, diabetes mellitus and obesity (BMI ≥30 kg/m^2) was associated with the AUSCAN score (β=5.5 [0.3;10.9]; p<0.05). Radiographic severity was associated with age, obesity, menopause as well as knee KL grade after adjustment on confounders (Table). Similar associations were found for Verb score (p<0.05 for all

analyzes). 307 HOA patients from the placebo group were followed for a mean duration of 31.5 ± 8.5 months. Obesity independently predicted Verb score variation (β=−1.3 [−2.2;−0.45]; p<0.01). Baseline KL score was the main factor associated with radiographic progression (KL or Verb). Baseline AUSCAN score was the main factor associated with subsequent clinical progression (β=−0.39 [−0.05;−0.03]; p<0.0001).

Conclusion: In HOA, obesity and ischemic cardiopathy are associated with structural damages and symptoms respectively. Such results further delineate the metabolic OA phenotype.

Table. Factors associated with baseline HOA symptoms and radiographic severity. NT: not tested, NS: not significant

	Corrected AUSCAN score		Hand KL score	
Average (± SD)	95.4 ± 79.9		21.4 ± 13.1

Hyperglycemia and Risk of Osteoarthritis. Mona Walimbe[1], Ann V. Schwartz[1], Irina Tolstykh[1], Charles E. McCulloch[1], David T. Felson[2], Cora E. Lewis[3], Neil A. Segal[4], Michael C. Nevitt[1] and Nancy E. Lane[5]. [1]UCSF (University of California, San Francisco), San Francisco, CA, [2]Boston University School of Medicine, Boston, MA, [3]The University of Alabama at Birmingham, Birmingham, AL, [4]University of Iowa, Iowa City, IA, [5]Center for Musculoskeletal Health, UC Davis School of Medicine, Sacramento, CA.

Background/Purpose: Osteoarthritis (OA) is reported to be more prevalent in individuals with diabetes mellitus (DM). Potential etiologies include advanced glycation endproducts, which reduce cartilage integrity, and obesity which increases the mechanical load on the knee. We further explored the relationship of abnormal glucose metabolism and incident knee OA in a community based cohort with 84 months of follow up.

Methods: The Multicenter Osteoarthritis Study Group (MOST) is an NIH-funded longitudinal study of risk factors for knee OA in people age 50–79 years, with or at high risk of knee OA. Subjects were eligible for this ancillary study if they did not have RKOA at baseline (Kellgren and Lawrence (KL) grade <2 bilaterally). Subjects were excluded if they lacked follow up knee radiographs or if their baseline blood sample was not available. A random sample diverse in baseline body mass index (BMI) of 1000 subjects (out of 1280 eligible subjects) was selected. Fasting glucose (Unical DxC 800 Auto-analyser (Beckman Coulter, Fullerton, CA, USA) and free insulin (Luminex Milliplex Analyzer Model XYP 100/200 S, Austin, Texas) levels at baseline were measured on all subjects. Subjects were categorized as DM based on any of the following: self-report DM, use of anti-diabetic medications or a fasting glucose at baseline of > 126 mg/dL. The outcome was the cumulative incidence of RKOA between baseline and the 84-month follow-up visit, defined by either a KL grade > 2 or total knee replacement. Knee-level pooled binary regression analysis was performed in men and women separately. GEE (to account for within-subject correlation) was used to obtain risk ratios (95% CI) for incidence of RKOA predicted by: fasting glucose, insulin resistance (measured by homeostatic model assessment - insulin resistance (HOMA-IR)) and diabetes status. Subjects who were taking insulin were excluded from models in which insulin resistance was analyzed.

Results: Among the 1000 subjects (mean age 61+/−7.8 years, 58% women, mean BMI at baseline 29.1+/−4.9 kg/m^2), there were 107 subjects with DM. DM subjects were more likely to be male, non-white and have higher BMI. Over the 84 months of follow-up, incidence of RKOA did not differ between diabetics compared to non-diabetics. In men, both elevated fasting glucose and HOMA-IR were associated with an increased risk of incident RKOA, but this effect did not persist after adjustment for BMI. In women, HOMA-IR levels were associated with a decreased risk of incident RKOA after adjustment for BMI. (Table)

Conclusion: DM at baseline was not associated with incident RKOA in this cohort. However, insulin resistance in women may be protective against the development of RKOA once the effect of high BMI is accounted for. This finding needs to be replicated in additional studies.

Table: Risk Ratio for Incident Knee Osteoarthritis, stratified by sex

	WOMEN 580 subjects/1160 knees/278 events Risk Ratio (95% CI) and p-values		MEN 420 subjects/840 knees/137 events Risk Ratio (95% CI) and p values

Retinal Arteriolar Narrowing and Incidence of Knee Replacement for Osteoarthritis: A Prospective Cohort Study. Sultana Monira Hussain[1], Yuanyuan Wang[1], Jonathan E Shaw[2], Dianna J Magliano[2], Tien Yin Wong[3], Anita Wluka[1], Stephen Graves[4], Robyn J Tapp[5] and Flavia Cicuttini[1]. [1]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [3]Singapore Eye Research Institute, Singapore, Singapore, [4]Australian Orthopaedic Association National Joint Replacement Registry, Adelaide, Australia, [5]The University of Melbourne, Melbourne, Australia.

Background/Purpose: Epidemiological studies suggest that macrovascular disease is involved in the pathogenesis of osteoarthritis (OA) possibly through reduced nutrition to the joint. However, the role of the microcirculation in the pathogenesis of OA remains unclear. The retinal vasculature provides a unique window to assess the microcirculation noninvasively and directly. This study examined the association between retinal vascular caliber and incidence of knee replacement for OA.

Methods: 1,838 participants of the Australian Diabetes, Obesity and Lifestyle Study - a population-based, national prospective cohort study, had retinal vascular caliber measured in 1999–2000 using a nonmydriatic digital fundus camera and a validated computer-based program. Participants were aged >40 years at joint replacement data collection commencement. The incidence of knee replacement for OA during 2002–2011 was determined by linking cohort records to the Australian Orthopaedic Association National Joint Replacement Registry. Cox proportional hazard regression models were used to estimate the hazard ratio (HR) and 95% confidence interval (CI) for the incidence of knee replacement due to OA associated with retinal vascular caliber, with age as the time scale. Follow-up for joint replacement (calculation of person-time) began 1 January 2002, and ended at the date of first knee replacement for OA or date of censoring. Retinal vascular caliber was standardized so that HR represents the effect of a one-standard-deviation difference in caliber. Retinal vascular caliber was also categorized into tertiles based on the analysis sample. The widest tertile was used as the referent category. Each analysis was adjusted for sex and body mass index (BMI), and further adjusted for physical activity, HbA1c, and cardiovascular risk factors (systolic blood pressure, total cholesterol and microalbuminuria).

Results: 77 participants underwent knee replacement for OA. At baseline, these participants had narrower retinal arteriolar calibre than those who did not need knee replacement (166.1±24.8μm vs. 174.3±24.5μm, p=0.004). Narrower retinal arteriolar caliber was associated with an increased risk of knee replacement (HR 1.25, 95%CI 1.00–1.56, per 1 standard deviation decrease in retinal arteri-

olar caliber); and participants with arteriolar caliber in the narrower two-thirds of the cohort had twice the risk of knee replacement compared with those in the widest one-third (HR 2.00, 95%CI 1.07–3.74, p=0.03) after adjustment for sex, BMI, physical activity and HbA1c. Further adjustment for the cardiovascular risk factors did not change the associations. There was no association for retinal venular caliber.

Conclusion: Persons with narrower retinal arteriolar caliber had a higher risk of knee replacement for OA, suggesting a role of microvascular disease in the pathogenesis of knee OA.

Association of Low Birth Weight and Preterm Birth with the Incidence of Knee and Hip Arthroplasty for Osteoarthritis. Sultana Monira Hussain[1], Yuanyuan Wang[1], Anita Wluka[1], Jonathan E Shaw[2], Dianna J Magliano[2], Stephen Graves[3] and Flavia Cicuttini[1]. [1]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [3]Australian Orthopaedic Association National Joint Replacement Registry, Adelaide, Australia.

Background/Purpose: Low birth weight and preterm birth have been associated with adverse adult outcomes including hypertension, insulin resistance, cardiovascular disease and reduced bone mass. It is unknown whether low birth weight and preterm birth affect the risk of osteoarthritis (OA). This study aims to examine whether low birth weight and preterm birth were associated with the incidence of knee and hip arthroplasty for OA.

Methods: 3,604 participants of the Australian Diabetes, Obesity and Lifestyle Study - a population-based, national prospective cohort study who reported their birth weight and history of preterm birth and were aged more than 40 years at the commencement of arthroplasty data collection. The incidence of knee or hip arthroplasty for OA during 2002–2011 was determined by linking cohort records to the Australian Orthopaedic Association National Joint Replacement Registry. Cox proportional hazard regression models were used to estimate the hazard ratios (HR) and 95% confidence interval (CI) for knee or hip arthroplasty due to OA associated with low birth weight and preterm birth. Follow-up for arthroplasty (i.e. calculation of person-time) began in January 1, 2002, and ended at the date of first arthroplasty for OA or date of censoring. Each analysis was adjusted for age, sex, and body mass index (BMI), in model 1, as these are established risk factors for arthroplasty for OA. In model 2, the analyses were further adjusted for hypertension, diabetes, smoking status and physical activity. To test whether associations of low birth weight and preterm birth with arthroplasty risk were modified by obesity (BMI $\geq$ 30 kg/m^2) and sex, interactions were fitted, and tested using the likelihood ratio test.

Results: One hundred and sixteen participants underwent knee arthroplasty and 75 underwent hip arthroplasty for OA. Low birth weight (yes vs. no, HR 2.04, 95% CI 1.11–3.75, p=0.02) and preterm birth (yes vs. no, HR 2.50, 95% CI 1.29–4.87, p=0.007) were associated with increased incidence of hip arthroplasty independent of age, sex, BMI, education level, hypertension, diabetes, smoking and physical activity. No significant association was observed for knee arthroplasty.

Conclusion: Although these findings will need to be confirmed, they suggest that individuals born with low birth weight or preterm are at increased risk of hip arthroplasty for OA in adult life. The underlying mechanisms warrant further investigation.

Disclosure: S. M. Hussain, None; **Y. Wang**, None; **A. Wluka**, None; **J. E. Shaw**, None; **D. J. Magliano**, None; **S. Graves**, None; **F. Cicuttini**, None.

Pre-Operative Musculoskeletal Comorbidities Limit Improvement in Functional Outcomes and Hip Pain in Total Hip Arthroplasty Patients. Scott Pascal, David Ayers, Wenjun Li, Leslie Harrold, Jeroan Allison and Patricia D. Franklin. University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Identifying clinical factors predictive of total hip arthroplasty (THA) outcomes is valuable for clinicians and patients to make a data-driven surgical decision. While factors such as age, weight, and medical comorbidities have been shown to affect post-operative pain and/or functional gains following THA, musculoskeletal comorbidities have not been investigated. We evaluated whether lumbar pain and pain in the knees and non-operative hip joints predict poorer 6 month pain relief and functional gain.

Methods: Data were collected from 2,848 patients enrolled in FORCE-TJR, a national prospective cohort of patients who underwent a primary unilateral total hip replacement due to osteoarthritis. Data including patient demographics, medical comorbidities, emotional health (SF/MCS), low back pain (Oswestry), pain in both hips and knees (HOOS/KOOS pain score), and pre-operative and post-operative function (SF/PCS) were collected pre-operatively and six months post-operatively. Post-THA pain relief and functional gain were analyzed using descriptive statistics as well as linear mixed regression models, in relation to musculoskeletal comorbid conditions and traditional patient and clinical factors.

Results: This cohort was 59% female, with a mean age of 65.4 years and mean BMI of 28.9 (kg/m$\hat{2}$). Out of the 2,848 patients, 992 (34.8%) reported moderate to severe low back pain pre-operatively. In addition, 264 (9.3%) reported moderate to severe pain in at least two non-operative hip or knee joints. After adjusting for gender, age, BMI, emotional health and medical co-morbidities, moderate to severe pre-THA back pain and pain in one or more non-operative hip or knees was significantly correlated (p<0.001) with a smaller improvement in hip pain and function after THA. Additionally, the greater the number of nonsurgical hip and knee joints with pain pre-operatively, the stronger the negative effect on pre-to-6 month post-THA gain in pain and function outcomes.

Conclusion: The presence of low back pain and pain in non-operative hip and knee joints has a significant negative impact on post-THA pain relief and functional outcome. In addition to traditionally reported clinical factors (i.e. age, weight and medical co-morbidities) the burden of musculoskeletal co-morbidity is an important consideration in predicting post-THA gains.

Relationship of Buckling and Knee Injury to Pain Exacerbation in Knee Osteoarthritis: A Web-Based Case-Crossover Stud. Isabelle Zobel[1], Tahereh Erfani[2], Kim Bennell[3], Joanna Makovey[2], Ben Metcalf[3], Jian Sheng Chen[4], Lyn March[2], Yuqing Zhang[5], Felix Eckstein[6] and David J. Hunter[2]. [1]Institute of Bone and Joint Research, Kolling

Institute, University of Sydney, St Leonards, Australia, [2]Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia, [3]University of Melbourne, Melbourne, Australia, [4]University of Sydney Institute of Bone and Joint Research, St Leonards, Australia, [5]Boston University School of Medicine, Boston, MA, [6]Paracelsus Medical University, Salzburg, Austria.

Background/Purpose: Knee osteoarthritis (OA) pain is neither constant nor stable and exacerbations of pain are disabling. We examined whether knee injury and buckling (giving way) are triggers for exacerbation of pain, also defined as flare, in persons with symptomatic knee OA.

Methods: We conducted a web-based case-crossover study with all data collected via the Internet. Participants with painful radiographic knee OA were recruited and followed at 10-day intervals for 3 months (control periods). Participants were instructed to additionally record knee pain exacerbations during the 3 months interval. Pain exacerbation was defined as an increase of ***20mm from baseline on*** VAS knee pain score (VAS 0–100). Information about triggers occurring during ***"control periods***" (without pain exacerbation) and ***"hazard periods"*** (immediately preceding the pain exacerbation) was collected. We collected data on potential triggers by asking for acute knee injuries in the previous seven days. Similarly we asked about knee buckling events, defined as giving way in the previous two days (i.e., date of pain exacerbation for hazard period, and date of data assessment for control periods). The relationship of knee injury and buckling to the risk of pain exacerbation was examined using conditional logistic regression models.

Results: Of the 297 participants (women: 61%, mean age: 62 years, mean BMI: 29.3 kg/m^2) recruited, 157 (53%) had both hazard and control periods and were included in the data analysis. Sustaining a knee injury increased the likelihood of experiencing a pain flare (odds ratio (OR) 10.2; 95% CI 5.4, 19.3) compared to no injury (Table). An event of knee buckling increased the likelihood of experiencing a pain exacerbation (OR 4.0; 95% CI 2.6, 6.2) compared to no buckling and the risk increased with a greater number of buckling events (for ≥ 6 buckling events, OR 20.1; 95%CI 3.7, 110).

Table. Association of knee injury and risk of knee pain exacerbation

Knee injury	Case periods	Control periods	Odds ratio (95%CI)
No	329	820	
Yes	71	31	10.2 (5.4, 19.3)
Association of knee buckling and risk of knee pain exacerbation.			
No	259	743	1.0 (referent)
Yes	141	108	4.0 (2.59, 6.18)
Number of episodes			
1	64	54	3.5 (2.0, 6.0)
2–5	66	50	4.1 (2.4, 7.0)
≥6	11	4	20.1 (3.7, 110)

Conclusion: Knee injury and buckling are associated with knee pain exacerbation. Reducing the likelihood of knee injury and buckling through avoidance of particular activities and/or appropriate rehabilitation programs may decrease the risk of pain exacerbation.

1281

Knee Pain and a Prior Injury Are Associated with Increased Risk of a New Knee Injury: Data from the Osteoarthritis Initiative.

Jeffrey B. Driban[1], Grace H. Lo[2], Lori Lyn Price[1], Charles Eaton[3], Bing Lu[4] and Timothy E. McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [3]Center for Primary Care and Prevention, Memorial Hospital of Rhode Island, Providence, RI, [4]Brigham and Women's Hospital, Foxboro, MA.

Background/Purpose: A knee injury increases the risk for early-onset osteoarthritis (OA) and accelerated knee OA progression but little is known about risk factors for injuries among adults. Knee pain and a history of knee injury may be key risk factors because both can lead to altered joint biomechanics. Therefore, we explored if knee pain or a history of knee injury was associated with a knee injury in the subsequent 12 months.

Methods: We conducted longitudinal knee-based analyses among participants in the Osteoarthritis Initiative, a longitudinal observational study. We included both knees of all participants who attended baseline and had at least one follow-up visit with complete data. Our first set of exposures were knee pain (frequency and severity) at baseline, 12-month, 24-month, and 36-month visits. We defined frequent knee pain as pain on most days of a month in past 12 months. Knee pain severity was based on the WOMAC pain subscale, which we dichotomized as no-to-little pain (0 to 2) or knee pain (≥ 3). Another exposure was a history of injury, which we defined as a self-reported injury at any time prior to baseline, 12-month, 24-month, or 36-month visits. The outcome was self-reported knee injury during the past year at 12-month, 24-month, 36-month, and 48-month OAI visits. We conducted secondary analyses based on the bilateral absence or presence of knee OA at baseline, which we defined as Kellgren-Lawrence Grade ≥ 2. We evaluated the association between knee pain or history of injury (in both knees) and a new knee injury within 12 months of the exposure by performing repeated measures random intercept models to adjust for correlations within person observations over time and between knees. Analyses were adjusted for sex, age and body mass index at each visit.

Results: The baseline characteristics of the samples are presented in Table 1. In our primary analyses, individuals who reported frequent knee pain or an injury in either knee were more likely to experience a new knee injury in the following 12 months (Table 2) than individuals without frequent knee pain or prior injury. These findings were supported when we evaluated knee pain severity and in our secondary analyses. The only exception was that a history of a contralateral knee injury was not related with a new knee injury among those without radiographic OA at baseline.

Conclusion: Knee pain and a history of injury are associated with new knee injuries in the following 12 months. This may identify a group of people at higher risk for accelerated knee OA. It may be beneficial for individuals with knee pain or a history of injury to participate in injury prevention programs.

Table 1. Descriptive Baseline Characteristics of the Study Samples in Primary and Secondary Analyses

	Full OAI Cohort (n = 4,435)	ROA at Baseline (n = 1,443)	No ROA at Baseline (n = 1,863)
Age (years, mean (sd))	61.2 (9.2)	63.0 (8.8)	59.2 (9.0)
Body mass index (kg/m^2, mean (sd))	28.6 (4.8)	30.2 (5.0)	27.2 (4.5)

Systemic Pain Modulation Is Related to Body Perception in People with Knee Osteoarthritis. Jennifer Stevens-Lapsley[1] and Andrew Kittelson[2]. [1]UCD Physical Therapy Program, Aurora, CO, [2]University of Colorado Denver, Aurora, CO.

Background/Purpose: Cortically mediated changes in body perception have been linked to a variety of chronic pain conditions, including knee osteoarthritis (OA). However, associations between body perception and pain neurophysiology have yet to be examined, and the role of body perception in the etiology or mechanisms of chronic pain remains largely unknown. Therefore, the purpose of this study was to assess measures of cortical body representation in a population of people with knee OA, to determine the relationship with physiological measures of pain sensitivity and systemic pain modulation.

Methods: Forty-six people with knee OA (68% female, average age = 65.0 ± 8.5 years) were assessed in this cross-sectional study. Measures of body perception included an assessment of motor imagery performance (via a right-left lower extremity recognition task), an assessment of tactile acuity (two-point discrimination threshold) at the knee joint, and an assessment of knee size perception. To assess perception of knee size, a single photograph for each participant, capturing both of the participant's lower extremities. This photograph was then digitally manipulated to make either the right or left knee appear larger or smaller than reality. An array of images containing several of these manipulations (ranging from 85% to 115% of the original size) was displayed to the participant, who was instructed to select the most accurate representation. The relative size of the more painful knee was selected for analysis. Pain sensitivity was assessed by measuring pressure pain threshold (PPT) at the medial knee joint. Conditioned pain modulation (CPM), via a cold pressor paradigm, was performed at the forearm to assess endogenous analgesic pathways. Bivariate Pearson correlation coefficients were then determined between measures of cortical body representation and measures of pain neurophysiology.

Results: Although motor imagery performance and tactile acuity appeared weakly related to each other ($r=-0.24$, $p=0.08$), no significant associations were found between either of these measures and any measure of pain neurophysiology. Perception of knee size was not related to PPT but was significantly associated with CPM, such that participants with higher capacity for descending analgesia tended to overestimate the size of the more painful knee ($r=0.56$, $p=<0.0001$).

Conclusion: For the first time, this study provides evidence linking a specific measure of pain neurophysiology to body perception. Descending analgesia may affect a person's overall perception of the knee joint, with potential functional sequelae deserving of further study. Alternatively, abnormalities in knee perception may contribute to diminished capacity for endongenous pain inhibition, thereby exacerbating pain. Regardless of the direction of the relationship, a relatively simple assessment of knee size perception could allow clinicians to identify people with deficits in systemic pain modulation who may require alternative treatment approaches.

Sensitivity to Change of Patient Preference Outcome Measures for Pain in Trials of Patients with Knee Osteoarthritis. Matthew J. Parkes, Michael J. Callaghan, Terence W. O'Neill and David T. Felson. University of Manchester, Manchester, United Kingdom.

Background/Purpose: A variety of pain and function instruments are often measured in osteoarthritis (OA) clinical trials. Instruments with maximal sensitivity to change are preferred as the primary measure in trials. Shown to be sensitive to change in rheumatoid arthritis, patient preference instruments, in which a patient nominates a painful activity to track, have not been tested in OA trials. Ideally, to compare the sensitivity to change of outcome measures, trials with a positive result need to be studied. We compared the sensitivity to change of pain and function self-report outcomes in 2 OA trials that reported statistically significant improvements in pain/functional status outcomes.

Methods: We used data from a controlled trial of a knee brace (BRACE; n = 126) and an uncontrolled trial of intraarticular steroid injection (TASK; n = 120). For both trials, eligible subjects had to meet ACR criteria for knee OA and have significant knee pain. In addition to completing KOOS and WOMAC questionnaires, and questions about overall knee pain, subjects were asked to nominate an activity that commonly caused them knee pain, and to rate pain during that activity throughout the trial. Standardised response means (SRMs) were generated for multiple time points in both trials, in the active treatment group alone, and comparing treatment to control, where possible. Additionally, we tested correlations between the study outcomes and an anchor variable: a 5-point likert scale of patient-perceived change in pain, using ordinal regression to determine the odds of an improvement in pain for a 1 SD increase in each pain outcome.

Results: Both trials reported a positive effect of the intervention on pain and function. Pain on nominated activity visual analogue score (VAS) produced SRMs that were at least as high as other pain outcomes, and usually higher (table 1). Sensitivity to change of the other outcomes was less consistent. Patient perceived improvement in pain was more strongly associated with pain on nominated activity than the other pain or function outcomes (table 2).

Conclusion: Pain on nominated activity may be an extremely sensitive outcome for OA trials, and appears more strongly associated with perceived pain improvement than other currently used outcome measures.

Table 1: Standardised Response Means (SRMs) for the TASK and BRACE Trials

Outcome	BRACE Study - 6 week active vs. control treatment difference: SRMs	BRACE Study - 6 week active treatment only: SRMs	BRACE Study - 12 week active treatment only: SRMs	TASK Study - Change at 1 week after intra-articular steroid: SRMs
Pain on nominated activity VAS	−0.31	−0.85	−0.95	−1.13
Pain in last week VAS	−0.25	−0.86	−0.73	−1.07
Global pain VAS	–	–	–	−0.51
KOOS pain subscale	−0.16	−0.53	−0.73	−1.12
KOOS symptom subscale	−0.20	−0.62	−0.61	−0.94

1285

Prevalence of Risk Factors for Gastrointestinal Side Effects of Drugs for the Treatment of Pain in Rheumatic Diseases and the Provision of Gastroprotective Treatment – Results of a Large Non-Intervention Study. Gustavo Citera[1], Edgardo Smecuol[2], Alberto Millán[3], Manuel Robles[4] and Ruben Mantilla[5]. [1]Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Hospital Municipal de Gastroenterología, Buenos Aires, Argentina, [3]Hospital Universitario de Caracas, Caracas, Venezuela, [4]Centro Médico Toluca, Toluca, Mexico, [5]Clínica de Artritis y Rehabilitación (CAYRE), Bogota, Colombia.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are the long established first-line treatment for the management of pain associated with rheumatic diseases but carry a risk of gastrointestinal (GI) disturbance. The recognized GI risk factors are age >60 years; concomitant use of acetylsalicylic acid (ASA), oral corticosteroids or anticoagulants; previous history of ulcer, bleeding, or dyspepsia; and use of two NSAIDs or high dose of one NSAID. Evidence-based guidelines recommend the concomitant use of gastroprotective agents (GPAs) in NSAID users with one or more risk factors. Current evidence suggests that a significant proportion of patients at risk for GI events do not receive a GPA.

Methods: The RATIONAL study was conducted in Asia, Russia and Latin America and had an observational, multicenter, cross-sectional design to evaluate the prevalence of GI risk factors in patients with osteoarthritis (OA), rheumatoid arthritis (RA) and ankylosing spondylitis (AS). The single study visit was part of standard practice. Patients were aged >21 years with a documented diagnosis of RA (ACR/EULAR 2010 criteria), OA (ACR 1991 criteria) or AS (New York 1984 criteria or ESSG 2002 criteria) and had taken at least one dose of NSAIDs in the 15 days before enrolment. Information collected included NSAID treatment over the year preceding the study visit, GPA use, and occurrence of any of a defined range of GI events.

Results: The distribution of rheumatic disorders in the 5373 patients was OA 2996 (55.8%), RA 1882 (35.0%), AS 283 (5.3%), and a combination of these 212 (3.9%). One or more GI risk factors were present in 87.7% of patients. The prevalence of individual risk factors and treatment with GPAs is shown in the Table 1. GPA use in patients aged ≥60 years or concomitantly using anticoagulants was close to the study average (57.9%). A modest numerical increase from this mean value was observed in patients taking concomitant ASA (63.8%) or high doses of an NSAID (64.1%). A greater numerical increase in this percentage was seen for all of the other risk factors with values of 96.6% and 93.3% for those with histories of GI complications and GI ulcer, respectively. There was a strong preference for using proton pump inhibitors as the class of GPA and the most commonly used individual treatment was omeprazole (36.4% of total patients).

Table 1: Prevalence of risk factors

	Risk factor present		Receiving a GPA	
Risk factor	n	%	n	%
Any risk factor	4711	87.70	3112	57.9
Age ≥60 years	2627	48.89	1534	58.4
Concomitant ASA	564	10.64	360	63.8
Concomitant corticosteroids	1202	22.37	850	70.7
Concomitant anticoagulants	87	1.64	53	60.9
History of complicated ulcer	45	2.08	42	93.3
History of GI complications	405	7.50	28	96.6
History of dyspepsia	569	26.34	501	88.0
High dose NSAID	1206	22.45	773	64.1
More than one NSAID	21	0.39	15	71.4

Conclusion: Risk factors that appeared to influence the provision of treatment with a GPA were those related to a previous history of GI-related symptoms or events and concomitant use of corticosteroids. Most of the other risk factors appeared to have little influence on the prescription of a GPA. Although 87.8% of the study population had one or more GI risk factors, only 57.9% received any form of GPA. Age does not appear to be recognized as a risk factor for GI symptoms and GPAs are under prescribed. **Study identifier [NCT01577563]**

The Natural Course of Physical Function in People with Symptomatic Knee Osteoarthritis: Data from the Osteoarthritis Initiative. Britt Elin Øiestad[1], Daniel White[2], Ross Booton[3], Jingbo Niu[3], Yuqing Zhang[4], James C. Torner[5], Cora E. Lewis[6], Michael C. Nevitt[7], Michael P. Lavalley[3] and David T. Felson[4]. [1]Oslo University Hospital, 0407 Oslo, Norway, [2]Boston Univ School of Med, Boston, MA, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]University of Iowa, Iowa City, Iowa City, IA, [6]The University of Alabama at Birmingham, Birmingham, AL, [7]UCSF (University of California, San Francisco), San Francisco, CA.

Background/Purpose: Longitudinal studies of people with knee osteoarthritis (OA) have reported stable or improved physical function, contrary to the progressive degenerative nature of OA. The early improvement may be from regression to the mean, because subjects enroll when they are in pain. Limitations to current studies are exclusion of subjects with missing data, and of total knee replacements (TKRs). Little is known when including imputation of missing values and pre-TKR physical function data. The aim of this study was to describe physical function over 7 years among subjects with symptomatic knee OA before and after imputation of missing values, and inclusion of pre-TKR physical function values.

Methods: Participants from the Osteoarthritis Initiative (OAI) with symptomatic knee OA at baseline were included, excluding those with hip replacement, those that died, and with TKR at baseline. We defined symptomatic knee OA when at least one knee showed Kellgren and Lawrence grade >1 by x-ray and pain on most days the last month. WOMAC physical function (pf) (0–68) was assessed annually over 7 years in clinic visits. We set the post-TKR values to missing. For all, missing WOMAC-pf values were imputed using the multiple imputation method. For the TKR group, time from the last clinic visit prior to TKR was regressed on WOMAC-pf using a fitted LOESS curve. Then, new predicted WOMAC-pf values were assigned to the existing pre-TKR values, to provide values close to the actual time of the TKR. Mixed effect models were used to compare original WOMAC-pf values against adjusted values (after imputation and prediction of pre-TKR values) (grey vs. red lines in the figure).

Results: Of 4344 eligible people in OAI, 1065 (24.5%) had symptomatic knee OA at baseline (age: 61.3±8.9 years, women: 58.4%, BMI: 30.3±5.0). There were 163 unilateral and 45 bilateral TKRs (19.5%). There was no significant difference in WOMAC-pf between original values and adjusted values, although incorporating data on missing and predicted pre-TKR values left WOMAC-pf worse on average (figure, red and grey lines), and created a larger sample followed over time than original analyses in which pre-TKR and missing values were excluded.

Conclusion: Physical function over time is sensitive to missing values when excluding people who go through TKR and missing clinic visits. Including imputation of missing visit and adjusted pre-TKR values better depicts physical function in persons with symptomatic OA, and permits the evaluation of function in many persons left out of current studies.

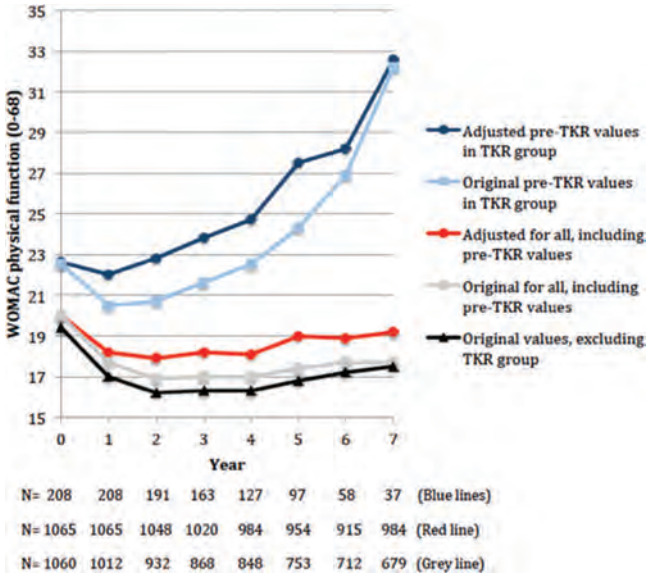

Figure. WOMAC physical function over 7 years among people with symptomatic knee osteoarthritis.

1287

Patient Perspective of the Main Health Concerns and Needs of Living with Hand Osteoarthritis. Mariko L. Ishimori[1], Geraldine Racaza[1], Mellissa Withers[2] and Michael Weisman[1]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]UCLA, Los Angeles, CA.

Background/Purpose: Hand OA (HOA) is associated with substantial pain, joint stiffness, functional impairment and disability, and cosmetic concerns. Data regarding patients' perspective on living with these consequences is limited. We aimed to explore the experiences of HOA patients of different phenotypes and explored their perspectives in the symptom, function and aesthetics domains.

Methods: Unrelated patients ≥ 45 years of age with clinical and radiographic idiopathic HOA (distal interphalangeal (DIP) and/or carpalmetacarpal (CMC) joints) from our registry were recruited and consented for a 45-minute, face-to-face semi-structured interview by a trained medical anthropologist to assess symptom, function and aesthetics domains. Interviews were audiotaped and interviewer notes and tapes were reviewed using a content analysis approach.

Results: 14 (11 women and 3 men) patients were interviewed. 10 of 14 were ≥ 60 years with a median age of 70 years. 5 had erosive disease, of whom 3 also had CMC involvement, 3 had CMC only disease, 6 had non erosive HOA, of whom 4 had CMC disease as well.

Most participants (13 of 14) had dull, aching pain (median score=6 out of 10 with 0=none and 10=maximum possible) and stiffness. Many described different adaptations to address pain, discussed their fears of future disease progression and their reluctance to medication for HOA, and accepted pain as part of the aging process. The participants claimed the worst part of having HOA was decreased functionality and potential loss of independence (median score=5). They discussed how HOA limited daily activities, hobbies, and work, leading to frustration. Those with HOA in multiple joint areas reported the most limitations; those with DIP joint involvement reported worse function vs. those with CMC only disease. Whether it was erosive or non-erosive did not make much difference.

Participants rated how much the appearance of their hands affected them (median score=2). Most related HOA to aging However, of those bothered by their appearance (all female), they reported being very troubled.

Important issues of concern to the patients also emerged and were discussed openly – coping strategies, self-reliance and personal strength, lessons learned, and worry and fears for the future, given this chronic illness. They also commonly articulated their desire to receive more counseling and information, including non-medical healing approaches, from their rheumatologists.

Conclusion: Patients with more joint area involvement suffered the most functional loss. IP involvement led to more severe functional limitations compared to CMC OA but erosive disease did not compound functional disability. Patients experienced frustration over functionality loss and potential loss of future independence since many either experienced or anticipated living alone. Other areas of concern not traditionally assessed or considered by physicians, including coping, lessons learned from the disease, fears for the future, and desire for non-drug approaches were identified. Understanding the impact of HOA on patient perception may identify new opportunities for targeted intervention outside of traditional methods.

1288

Older Adults with Osteoarthritis Do Not Have an Increased Risk of Cognitive Impairment. Bansari Gujar[1], Ann Gruber-Baldini[1], Mona Baumgarten[1], William Hawkes[1], Michael C. Nevitt[2], Kristine Yaffe[2], Tamara Harris[3] and Marc C. Hochberg[1]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]UCSF (University of California, San Francisco), San Francisco, CA, [3]National Institute on Aging, National Institutes of Health, Bethesda, MD.

Background/Purpose: A prior study showed an association between osteoarthritis (OA) and increased mortality from dementia. Recent preclinical studies suggest a possible association between OA and the development of dementia. The objective of this analysis was to determine if older adults with OA have a higher risk of cognitive impairment (CI).

Methods: We used data from the Health Aging and Body Composition (HABC) study, a multicenter prospective cohort study of community dwelling adults, ages 70–79, to determine if participants with OA at baseline (self-reported OA or OA defined by HABC prevalent disease algorithm) have an increased risk of developing CI. CI was defined as a Modified Mini-Mental State examination (3MS) score<80. Participants with 3MS scores of <80 at baseline were excluded. Baseline and year 3, 5, 8, and 10 scores were analyzed.

Results: There were 2577 participants with 3MS scores of >=80 at baseline (n=1277 with OA, n=1300 without OA)**.** The OA group had more women (54% vs 44%, p<0.001), higher baseline CES-Depression scores (4.9 SD 5.4 vs 4.2, SD4.9, p=0.003) and hypertension (46% vs 40%, p=0.028).There was no significant difference in development of CI after 9 years amongst those with OA (n=165, 12.9%) versus without OA (n=197, 15.1%). $\chi^2(1, n= 2577) = 2.66$, $p > 0.10$. The results of the multiple variable logistic regression analysis (adjusted for age, race, education and gender) suggest a protective effect that did not reach statistical significance (odds ratio= 0.8; 95% CI 0.6–1.0; P-value = 0.10). There was no significant association between baseline OA and the development of CI at the 3, 5, 8 and 10 year time points. No differences were found upon sensitivity analysis using race and education adjusted cut-points for 3MS scores.

Conclusion: These results do not support the hypothesis that there is a causal association between OA and CI.

Disclosure: B. Gujar, None; **A. Gruber-Baldini**, None; **M. Baumgarten**, None; **W. Hawkes**, None; **M. C. Nevitt**, None; **K. Yaffe**, None; **T. Harris**, None; **M. C. Hochberg**, None.

Classification of Osteoarthritis Phenotypes By Metabolomics Analysis. Weidong Zhang[1], Sergei Likhodii[2], Yuhua Zhang[1], Erfan Aref-Eshghi[1], Patricia E. Harper[1], Edward Randell[2], Roger Green[1], Glynn Martin[3], Andrew Furey[3], Guang Sun[4], Proton Rahman[5] and Guangju Zhai[1]. [1]Discipline of Genetics, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [2]Department of Laboratory Medicine, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [3]Department of Surgery, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [4]Discipline of Medicine, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, [5]Memorial University of Newfoundland, St. John's, NF.

Background/Purpose: Osteoarthritis (OA) is a group of heterogeneous conditions consisting of different subgroups or phenotypes that continuously evolve, eventually leading to common clinical manifestations. Identifying OA subphenotypes and uncovering their different mechanisms of pathogenesis is of fundamental importance for the development of appropriate therapies and diagnostic tools. The aim of the study was to identify metabolic markers that can classify OA patients into subgroups.

Methods: A case-only study design was utilized in this study. Patients undergoing total hip/knee joint replacements due to primary OA were recruited and their synovial fluid samples were collected during their joint surgeries. Metabolic profiling was performed on the synovial fluid samples by the targeted metabolomics approach using the Biocrates AbsoluteIDQ p180 kit. Various analytic methods including principal component analysis (PCA), hierarchical clustering (HCL) method, and partial least squares discriminant analysis (PLS-DA) were utilized to identify metabolic markers for classifying subgroups of OA patients. Potential confounders such as age, sex, body mass index (BMI), and comorbidities were considered in the analysis.

Results: A total of 80 OA patients were included in the study. 38 were males and 42 were females with an average age of 65.2 ± 8.7 years. Two distinct patient groups, A and B, were clearly identified. Patients in group A had significant higher concentration on 39 acylcarnitines in their synovial fluids than the patients in group B. Patients in group B were further subdivided into five subgroups, i.e., B1-1, B1-2-1, B1-2-2, B2-1 and B2-2. The corresponding metabolites that contribute to the grouping were 14 amino acids, 24 glycerophospholipids, 12 acylcarnitines and 1 biogenic amine. The grouping was not associated with any known confounders including age, sex, BMI, and comorbidities. The possible biological processes involved in these clusters are carnitine, lipid, and collagen metabolism, respectively.

Conclusion: The study demonstrated that OA consists of metabolically distinct subgroups. Identification of these distinct subgroups will help to unravel the pathogenesis and develop targeted therapies for OA.

Knee Osteoarthritis Progression Is Predictable By Genetic Polymorphisms. Results from a Multicenter Association Study. Francisco J Blanco[1], Ingrid Möller[2], Nerea Bartolome[3], Marta Artieda[3], Diego Tejedor[3], Antonio Martínez[4], Eulàlia Montell[5], Helena Martínez[5], Marta Herrero[5] and Josep Vergés[5]. [1]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Instituto Poal de Reumatología., Barcelona, Spain, [3]Progenika Biopharma, a Grifols Company, Derio, Bizkaia, Spain, [4]Progenika, a Grifols Company, Derio, Bizkaia, Spain, [5]Pharmascience Division, Bioiberica S.A., Barcelona, Spain.

Background/Purpose: Single Nucleotide Polymorphisms (SNPs) are inherited genetic variations that can predispose or protect individuals against clinical events. Osteoarthritis (OA) has a multifactorial etiology with a strong genetic component. Genetic factors influence not only knee OA onset, but also disease progression. The aim of the Arthrotest study was to develop a genetic prognostic tool to predict radiologic progression towards severe disease in primary knee OA (KOA) patients.

Methods: Cross-sectional, retrospective, multicentric, association study with Spanish KOA patients. 595 patients from 31 sites were selected. Inclusion criteria: Caucasian patients aged ≥40 years at the time of diagnosis of primary KOA (according to the ACR criteria), for whom two anteroposterior X-rays were available, one corresponding to the time of OA diagnosis with Kellgren-Lawrence grade 2 or 3 and the other to the end of the follow-up period. Patients who progressed to KL score 4 or were referred for total knee replacement in ≤ 8 years since the diagnosis were classified as progressors to severe disease. A unique expert viewer measured radiologic progression from all X-rays. A candidate gene study analyzing 774 SNPs was conducted. SNP genotyping was performed with Illumina Golden gate technology or KASPar chemistry. Clinical variables of the initial stages of the disease (gender, BMI, age at diagnosis, OA in the contralateral knee and OA in other joints) were registered as potential predictors. Univariate analysis was done to identify associations between the baseline clinical variables or SNPs and KOA progression. SNPs and clinical variables with an association of $p<0.05$ were included on the multivariate analysis using forward logistic regression.

Results: 282 patients fulfilled DNA and X-ray quality control criteria (220 in the exploratory cohort and 62 in the replication cohort). The univariate association analysis showed that one of the clinical variables and 23 SNPs were significantly associated to KOA severe progression in the exploratory cohort ($p<0.05$). The predictive accuracy of the clinical variable was limited, as indicated by the area under the ROC curve (AUC=0.66). Combining only genetic variables, a predictive model with a good accuracy (AUC=0.78) was obtained. When genetic variables were added to the clinical model (full model) the prediction of KOA progression was improved and the AUC increased to 0.82. The predictive ability for KOA progression of the full model was confirmed on the replication cohort (two-sample Z-test $p=0.190$). The full final model developed combines the clinical variable age at KOA diagnosis and 8 SNPs (rs2073508, rs10845493, rs2206593, rs10519263, rs874692, rs7342880, rs12009 and rs780094 – located in GCKR2 gene -). Interestingly, a new association between GCKR2 gene (previously shown to be associated with elevated diabetes type II risk) and OA was first found in this study.

Conclusion: Genetic polymorphisms predict radiologic progression more precisely than clinical variables. An accurate prognostic tool to predict primary KOA progression has been developed based on genetic and clinical information from OA patients.

Relationships Between Inflammation, Disease Severity and Synovial Fluid Calcium Crystals Detected By Scanning Electronic Microscopy in Early Osteoarthritis. Paola Frallonardo[1], Francesca Oliviero[1], Luca Peruzzo[2], Leonardo Tauro[1], Anna Scanu[1], Mariagrazia Lorenzin[1], Augusta Ortolan[1], Leonardo Punzi[1] and Roberta Ramonda[1]. [1]University of Padova, Padova, Italy, [2]Institute for Geosciences and Earth Resources IGG-CNR, Padova, Italy.

Background/Purpose: The presence of calcium crystals (CC) in synovial fluid (SF) of osteoarthritis (OA) is a well known and frequent feature (1). However, their role in the pathogenesis of OA is still unclear and matter of discussion, in particular as regard the local inflammation (2). The objective of the study was to evaluate the presence of the most common CC, calcium pyrophosphate (dehydrate) (CPP) and basic calcium phosphate (BCP), in SF of the symptomatic knee OA (KOA, particularly in early disease stage (<1year) and to investigate their association with local infiammation, disease activityand severity.We performed an ultrasensitive analysis of SF crystals using the scanning electron microscopy (SEM) and the routinary method by compensated polarized ligth microscopy (CPLM) and alizarin red staining.

Methods: Seventy-four (48 F, mean age 64.85±9.33 yrs, range 50–89 yrs) consecutive outpatients attending theRheumatology Unit, University of Padova with symptomatic KOA (according to the American College of Rheumatology criteria) underwent knee arthrocentesis. After optical and CPLM, the SF was analysed by SEM. Total white blood cell (WBC) count was performed and a cut-off of total WBC was established in $< 1000/mm^3$. Patients' medical history, clinical features (WOMAC, Lequense and VAS) X-ray findings (Kellgren & Lawrence), ultrasound and power Doppler (PD) signal values were also assessed.

Results: CPP crystals were identified in 32.4% by CPLM and in 31.1% by SEM. Alizarin was positive in 36.5% of the samples. BCP were found in 13.5% by SEM. CPP and BCP crystals were simultaneously positive in 8.1% of the samples by SEM.

The study population was divided into three groups depending on disease duration (group A <1 yr; group B 1–5 yrs; group C > 5 yrs). The SF volume ($p=0.0008$) was significantly different in the group A with respect to B and C groups. The SF WBC was higher during the early stages of disease (group A), although not significant, with respect to B and C groups. Moreover, the presence of CC in group A correlated significantly with SF WBC ($p=0.048$) and % of PMN ($p=0.033$) with respect to those without CC in the same group.

PD resulted positive in 43.24% of all the patients, 62.5% of these were CC+ according to SEM ($p<0.0001$).

Conclusion: The presence of CC in SF, also when detected in early OA stages, was associated with a higher degree of local inflammation, so suggesting that they may play a role of in eliciting an inflammatory reaction, which may be crucial in OA pathogenesis.

Synovitis Characteristics and Associated Intra-Articular Pathology in a Cohort of Patients Undergoing Meniscectomy for Meniscal Tear. Marta Favero[1], Giovanni Trisolino[2], Antonello Lazzaro[3], Mary B. Goldring[4], Steven R. Goldring[5], Elisa Assirelli[6], Claudio Iacobellis[7], Augusto Cigolotti[8], Assunta Pozzuoli[3], Ambrogio Fassina[8], Ermanno Martucci[2], Leonardo Punzi[9], Andrea Facchini[6] and Eleonora Olivotto[6]. [1]Rheumatology Unit, Padova, Italy, [2]Reconstructive Hip and Knee Joint Surgery, Bologna, Italy, [3]Orthopaedic Clinic, Padova, Italy, [4]Tissue Engineering Repair and Regeneration Program, Hospital for Special Surgery and Weill Cornell Medical College, New York, NY, [5]Hospital for Special Surgery, New York, NY, [6]Laboratory of Immunorheumatology and Tissue Regeneration/RAMSES, Bologna, Italy, [7]UOC of Orthopaedic and Traumatology, Padova, Italy, [8]Surgical Pathology and Cytopathology Unit, Department of Medicine, University of Padova, Italy, Padova, Italy, [9]University of Padova, Padova, Italy.

Background/Purpose: Previous epidemiologic studies have established that there is a strong relationship between meniscal tear and the risk for subsequent development of osteoarthritis (OA). Though not normally considered a classical inflammatory arthropathy, OA is often associated with low-grade synovitis. In patients with OA, synovial inflammation is one factor associated with risk of progression of structural joint deterioration and symptoms. The aims of the study were to characterize the synovial features in patients undergoing partial meniscectomy for meniscal tear.

Methods: The study was conducted in the context of a three-year project funded by the Italian Ministry of Health (Ricerca Finalizzata - Giovani Ricercatori - project code: GR-2010-2317593), which maintains extensive records of preclinical, intraoperative and post-operative data so far for 58 patients who have undergone meniscectomy for both degenerative and traumatic meniscal tear. Synovial biopsies were collected in suprapatellar area during arthroscopic surgery and processed for histology. Synovial features of

inflammation were assessed using an histological synovial scoring based on perivascular mononuclear cell infiltration as follows: grade 0=none, grade 1=mild (0–1 perivascular aggregates per low-power field); grade 2=moderate (>1 perivascular aggregate per low power field with or without focal interstitial infiltration); grade 3=marked aggregates (both perivascular and interstitial) (Scanzello CR, Arthritis Rheum. 2011). The following clinical data were collected: age, sex, BMI, date of injury and time to surgery, pre-operative VAS and KOOS, 3–6 months KOOS and meniscal tear characteristics and/or cartilage pathology. Cartilage damage was assessed intra-operatively using the Outerbridge scoring system.

Results: In the series of 58 patients, males were predominant (72%) with median ages of 43.6 and 50 years, respectively. Meniscal tear were traumatic in 50% of patients. KOOS at 3–6 months after meniscectomy statistically improved compared with the baseline ($p<0.0001$). No association was observed between traumatic or degenerative meniscal tear and age, BMI, KOOS, frequency of cartilage defects or macroscopic synovitis score. Of 26 suprapatellar synovial biopsies H&E stained: 15 exhibited mild synovial inflammation, 7 moderate, 1 marked. Cartilage defects were observed in 48 patients (82,7%). 35 patients had multiple cartilage defects, while 13 exhibited only a single focal chondral lesion. Outerbridge scores were distributed as follows: grade I (7 patients), grade II (13 patients), grade III (16 patients) and grade IV (12 patients). The grade of cartilage defects correlated with synovial inflammation assessed by histological scoring ($r=0{,}500$; $p=0{,}009$) and both patients age and BMI.

Conclusion: In our study, we observed an high percentage of low-grade synovitis (88%), and/or cartilage defects (82,7%) in patients undergoing partial meniscectomy for meniscal tear. Microscopic synovial inflammation correlate with the grade of cartilage defect confirming that synovitis play a role in the progression of the disease.

1293

Identification of an Inflammation-Driven Phenotype of Osteoarthritis By Quantification of Synovial Inflammation *Ex Vivo* and in Serum from Patients.

Cecilie F. Kjelgaard-Petersen[1], Anne Sofie Siebuhr[1], Kristian Kjaer Petersen[2], Lars Arendt-Nielsen[2], Thomas Eskehave[3], Hans Christian Hoeck[3], Ole Simonsen[4], Thorbjørn Christiansen[5], Line Lindhardt Egsgaard[6], Morten A. Karsdal[1] and Anne C. Bay-jensen[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Center for Sensory-Motor Interaction, Aalborg, Denmark, [3]Center for Clinical and Basic Research (CCBR), Aalborg, Denmark, [4]Frederikshavn Hospital, Frederikshavn, Denmark, [5]Gentofte University Hospital, Gentofte, Denmark, [6]Aalborg University, Aalborg, Denmark.

Background/Purpose: Osteoarthritis (OA) is a multifaceted degenerative joint disease, where inflammation of the synovial membrane leads to accelerated joint destruction, resulting in elevated release of matrix metalloproteinase (MMP)-mediated type I and III collagen degradation fragments, C1M and C3M. The aim of the study was to investigate if C1M and C3M were associated with joint inflammation in OA, by i) measuring the release of the biomarkers in response to pro-inflammatory factors in an *ex vivo* human OA synovial explant model and ii) investigate the level of the biomarkers in patients in association with radiographic and inflammatory knee OA.

Methods: *Synovial membrane explants (SME);* Synovial membrane from 4 OA patients undergoing total knee replacement at Gentofte Hospital, Denmark, were cultured as SMEs (30±2mg) for 3 weeks with media alone (w/o), 10 ng/mL TNFα, IL-1β or TGFβ-2, or metabolic inactivated. Supernatant was collected 3 times a week and stored at -20°C. In-house neo-epitope biomarkers; C1M, C3M, and active MMP-3 were assessed by ELISA. MMP-2 and -9 were detected by gelatin zymography. *Knee OA cohort:* A cross-sectional study including 332 subjects with knee pain; 52% women, mean age: 65 (8.4) years; BMI: 28 (4.4). Patients were divided into 4 groups based on Kellgren-Lawrence (KL) score Mild; KL 0, (n=12), Moderate: KL 1+2 (n=202); Severe: KL 3+4 (n=57); and Terminal OA (n=61). The degree of inflammation was evaluated by VAS pain and level of hsCRP. C1M and C3M were measured in serum. The study was approved by The Ethical Committee of Northern Jutland.

Results: *SME:* C1M and C3M were increased (10 and 100-fold, respectively) at day 7 in response to TNFα compared to w/o (C1M: $p<0.05$, C3M: $p<0.0001$). IL-1β showed similar pattern. TGFβ-2 did not affect C1M or C3M. Activated MMP-9 and activated MMP-3 ($p<0.0001$) was increased in SMEs treated with IL-1β or TNFα throughout the study for SMEs, while activation of MMP-2 was not affected. *Knee OA cohort*: Serum C1M were significant elevated in the Terminal group compared to the Moderate ($p<0.0001$) and Severe OA ($p<0.01$) groups, but no significant difference in serum C3M. Patients with inflammatory OA (high hsCRP and pain) had a higher level of C1M and C3M as compared to non-inflammatory patients (table). There was no difference in KL between the two groups.

Conclusion: In OA patients with the same KL score, C1M and C3M were significantly higher in those with an inflammation-driven phenotype. C1M and C3M were released from the SMEs upon treatment with the pro-inflammatory cytokines IL-1β and TNFα, but not TGFβ-2, which indicates that C1M and C3M are direct measures of synovial turnover and inflammation. This was supported by the detection of active MMP-3 and -9, which act down-stream of the cytokines and up-stream of the biomarkers. These biomarkers may be part of the identification of the important and possibly treatable inflammation-driven OA phenotype.

Table

	Non-inflammatory OA		Inflammatory OA		
	Mean	*95%-CI*	*Mean*	*95%-CI*	*P value*

Gender Differences in the Lupus Nephritis Biomarkers in Children.

Khalid Abulaban[1], Hermine Brunner[2], Michael Bennett[1], Shannen L. Nelson[1], Jun Ying[3] and Prasad Devarajan[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Cincinnati, Cincinnati, OH.

Background/Purpose: Lupus nephritis (LN) is frequently associated with a poor long-term prognosis. The non-invasive traditional measures of LN (LN-TM) currently used to monitor LN have limited responsiveness to change. Though the discovered and initially validated promising LN biomarkers (i.e. the LN-Panel) accurately reflect LN activity & chronicity as seen on kidney biopsy, and can forecast LN flares, however, there remains an important unknown in regards whether the LN-Panel biomarkers are influenced in their levels by patient gender. The objective of this study is to assess the gender and age specific differences in the levels of the LN-Panel biomarkers and to establish normative values of the combinatorial biomarkers in healthy children.

Methods: Urine concentrations of the LN biomarkers Neutrophil gelatinase associated lipocalin (NGAL), Monocyte chemoattractant protein-1 (MCP1), Ceruloplasmin (CP), Alpha1-acid glycoprotein (AGP), Transferrin (TF)and Lipocalin-like prostaglandin-D Synthase (LPDGS) were measured by nephelometry or ELISA in select male and female pediatric LN patients. All the biomarkers were logarithmically transformed and standardized to urinary creatinine concentration. Student t test was used to compare means of the LN panel biomarkers between female and male active LN patients. A fixed effect model was used to compare means after adjusting for differences in clinical measures of LN activity using the Renal SLEDAI domain scores. P value of <0.05 was considered statistically significant.

Results: In a sample of 64 females and 12 males with childhood LN, the means of urinary MCP-1 was significantly elevated in females compared to males (table 1). Also the means of urinary LPGDS was significantly elevated

in 27 female patients who had histological feature of Epimembranous deposits compared to 6 males (table2). There were also significant gender differences in select LN Panel biomarkers when looking at the activity and chronicity of LN on kidney biopsy (see Table 3).

Conclusion: This study supports that there are gender differences in select LN-Panel markers. Also these differences can be seen with certain type of underlying histological features of LN.

Table 1: Gender related differences in LN-Panel with LN adjusted for differences in clinical measures of LN activity using the Renal SLEDAI domain scores

*Type of Biomarker**	*Biomarker*	*Female (n=64)*	*Male (n=12)*	*P-value*

Childhood-Onset Systemic Lupus Erythematosus: Short-Term Treatment Response Rates in Proliferative Lupus Nephritis. Andrea Human[1], Simon Yu Tian[2], Earl D. Silverman[3] and Deborah M. Levy[1]. [1]The Hospital for Sick Children and University of Toronto, Toronto, ON, [2]The Hospital for Sick Children, Institute of Medical Science, University of Toronto, Toronto, ON, [3]The Hospital for Sick Children, Toronto, ON.

Background/Purpose: Proliferative Lupus Nephritis (PLN) occurs in up to 50% of patients with childhood-onset systemic lupus erythematosus (cSLE). PLN is a significant source of morbidity and can lead to end-stage renal disease. Our objectives were to examine rates of complete and partial response to treatment in the first year in a large multiethnic cohort using non-cyclophosphamide induction strategies.

Methods: A single-centre retrospective cohort study at the Hospital for Sick Children examined partial and complete response rates at 6 and 12 months following the diagnosis of biopsy-proven PLN (WHO Class III or IV) in cSLE patients. Patients with PLN and concomitant Class V lupus nephritis were included. Urine protein/creatinine ratio (uPCR) and serum creatinine (Cr) were used as core renal parameters. Urinary sediment was not included due to lack of available data. Criteria for complete (CR) and partial response (PR) were adapted from the American College of Rheumatology consensus guidelines, and from the outcome measures defined in Wofsy et al (Table 1). All data were collected prospectively on standardized clinic forms and maintained in a clinical database. Demographic, clinical, pathologic and laboratory data were analyzed. As therapeutic options have evolved over the past 30 years, results were stratified into two treatment eras, the 1st era when prednisone and azathioprine (aza) were routinely used in the first year, and the 2nd era when prednisone and mycophenolate mofetil (MMF) were more commonly used.

Table 1: Renal Response Definitions

Complete Response	For patients with abnormal Cr, - Normalization of Cr For patients with normal Cr, - Maintenance of a normal Cr within 50% of baseline value uPCR <25g/mol
Partial Response	For patients with abnormal Cr, - Normalization of Cr OR 50% improvement in Cr For patients with normal Cr, - Maintenance of a normal Cr within 50% of baseline value For patients with uPCR >300 (nephrotic range) at baseline, - Reduction in uPCR to <300 For patients with uPCR ≤300 - Reduction in uPCR by 50% to final uPCR<100 OR normalization of uPCR <25g/mol

Results: 155 patients had biopsy-proven PLN between 1983–2013. Mean age at PLN diagnosis was 12.6±3.4 years old, and 80% were female. The cohort's ethnic heritage was 38% Asian, 28% Caucasian, 19% Black, and 15% other. 47 (30%) patients had class III, 85 (55%) had class IV, 5 (3.2%) had III/V, and 11 (7.1%) had class IV/V. 34 (22%) patients developed acute renal failure. Other phenotypic features included malar rash (71%), arthritis (74%), fever (65%), and photosensitivity (28%). At baseline, mean C3 was 0.72, and mean C4 was 0.11. Overall, 61% had CR and 15% had PR at 6 months, while 68% had CR and 7.5% had PR at 12 months (see Table 2 for complete results). We found that the rate of CR at 6 and 12 months was significantly higher in Era 1 (aza) than in Era 2 (MMF).

Table 2: Response rates

	Overall (1983–2012) (N=150)	**ERA 1 (1983–2002) (N=86)**	**ERA 2 (2003–2012) (N=64)**	**p-value**
Complete response @ 6 mo (N, %)	92 (61)	59 (69)	33 (52)	0.04
Complete response @ 12 mo	101 (68) (n=149)	64 (76)	37 (59) (n=63)	0.04
Partial response @ 6 mo	23 (15)	10 (12)	13 (20)	0.17
Partial response @ 12 mo	12 (7.5) (n=149)	4 (4.6)	8 (13) (n=63)	0.13

Conclusion: The majority of patients showed a complete response to treatment at 6 months, with 68% of patients demonstrating complete response by one year. Partial response rates at both 6 and 12 months were comparatively lower. Interestingly, CR rates at 6 and 12 months were higher in the aza-prednisone era as compared to the MMF-prednisone era.

Pulse- Pediatric Update on Lupus in South Africa: Epidemiology and Management. Laura Lewandowski[1], Laura Schanberg[1], Nathan Thielman[2] and Christiaan Scott[3]. [1]Duke University Medical Center, Durham, NC, [2]Duke Hubert Yeargan Center for Global Health, Durham, NC, [3]Red Cross War Memorial Children's Hospital, Cape Town, South Africa.

Background/Purpose: In developed nations, SLE is more common and severe in people of African extraction than in Caucasians; however, the epidemiology of SLE in Africa is largely undetermined. Historically, the incidence of SLE in Africa was presumed to be low, but recent studies challenge this theory. In general, children present with higher disease activity, require more therapy, and accrue more organ damage than adult-onset patients. Although African children with SLE may be at high risk for poor outcomes, little research has investigated this population. We have initiated the first prospective study of this high risk pediatric SLE (pSLE) population. Here, we

report the initial findings of the South African pSLE patients (PULSE cohort).

Methods: We conducted a retrospective chart review of pediatric and adult rheumatology and nephrology patients seen at 2 centers in Cape Town, South Africa from 1988–2014 meeting American College of Rheumatology criteria for pSLE. Patient age, gender, race, and presenting features were recorded for the PULSE cohort and compared to previously described pSLE cohorts in South Africa and worldwide.

Results: Initial review of patients yielded 68 patients (age 12.2; 83% female). The racial distribution was 65% colored, 26% black, 3% white, and 3% Asian/Indian. A much larger proportion of patients in our cohort are of colored or black race compared to a previously published South African cohort. Most patients presented with severe lupus nephritis (LN) (renal biopsy performed in 49%)). Of patients with LN, 83% presented with ISN class IV or higher. Pediatric LN cohorts from developed nations report 6–7% progressing to end stage renal disease (ESRD), and reports from developing nations report 8–12%. Within the cohort, 13% went on to develop ESRD requiring transplant, strikingly higher than previously reported cohorts. Our cohort had severe disease at diagnosis (mean SLEDAI 20.4), compared to previously reported pSLE cohorts (SLEDAI 4-13). Also, the PULSE cohort had end organ damage with 63% of the cohort having a SLICC score >0 (mean SLICC 1.9), compared to only 23% in a previously reported US cohort of 221 pSLE patients.

Table 1. Demographic Information

	PULSE cohort South Africa 2014 n=68	Faller cohort (South Africa, 2005) n=36	APPLE cohort (USA, 2010) N=221
Average age (years)	12	11.5	15.7
Median Age (years)	12.2	Not reported	15.5
% Female	83	61	83
% Colored	65	14	Not reported
% Black	26	38	27 (African Am)
% Indian/Asian	3	1	13
% White	3	42	51

Table 2. International Society of Nephrology/ Renal Pathology Society 2003 Classification of Lupus Nephritis

Class of Lupus Nephritis	PULSE cohort South Africa 2014 N=32	Toronto Cohort N=43
I Minimal Change	0 (0%)	0 (0%)
II Mesangial	3 (9%)	10 (23%)
III Focal Proliferative	2 (6%)	11 (26%)
IV Diffuse Proliferative	17 (53%)	17 (40%)
V Membranous	7 (21%)	5 (11%)
VI Advanced Sclerosis	3 (9%)	Not Reported

Conclusion: The PULSE cohort is the largest registry of pSLE patients in Africa to date. Preliminary findings show these children present with high disease activity and progress to end organ damage at higher rates than pSLE cohorts in developed nations.

Safety and Efficacy of Rituximab in Pediatric Lupus and Other Rheumatic Diseases. Ajay Tambralli[1], Timothy Beukelman[2], Randy Q. Cron[2] and Matthew L. Stoll[2]. [1]University of Rochester, Rochester, NY, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Rituximab (RTX) is a chimeric monoclonal antibody that specifically targets CD20 positive B cells and is used successfully for a variety of pediatric rheumatologic conditions. One pediatric autoimmune disease for which RTX has gained particular interest is systemic lupus erythematosus (SLE). Herein, we report on the safety and effectiveness of use of RTX in 104 subjects with a variety of pediatric autoimmune diseases, with a focus on SLE.

Methods: This was a retrospective study of children treated by 1 or more pediatric rheumatologists at Children's of Alabama (CoA) with at least 1 course (2 doses of 750 mg/m^2, maximum of one gram, 2 weeks apart) of RTX between August 1, 2007 and April 1, 2014. To evaluate effectiveness, we documented for all patients the MD Global assessment of disease activity and corticosteroid dosage at baseline (just prior to RTX) and at 12 months of follow-up. For SLE patients, we additionally documented complement levels, ESR, CBC, creatinine, albumin, urine protein, and anti-DNA levels. For safety outcomes, we documented infusion reactions and severe adverse events. Comparisons were performed with the Student's t-test.

Results: 104 children were included in the study. The single most common diagnosis was SLE (n = 50), and the next most common diagnosis was dermatomyositis (n=11). In total, 464 RTX infusions were administered during the study period. A total of 251.4 person-years of follow-up was available (median 2.4 years; range 1 month – 6.4 years.) Among patients with one-year follow-up data available, mean daily corticosteroid dose decreased from 29.8 ± 25.7 mg to 8.7 ± 13.1 mg (n = 98; $p < 0.001$) and mean MD global assessment of disease activity decreased from 34.4 ± 19.2 to 15.7 ± 12.3 (n = 88; $p < 0.001$). Among SLE patients with data available at 12 months of follow-up, significant improvements were observed in corticosteroid dosage and MD global assessment of disease activity, as well as in multiple SLE-associated markers of disease activity (Table.) Overall, RTX was well-tolerated. There were no infusion reactions requiring emergent intervention. The incidence of hospitalized infections among the cohort as a whole (83.5/1,000 person-years) and among the 50 SLE patients (92.2/1,000 person-years) is similar to previous studies of children with SLE treated with cyclophosphamide. One patient died after transition to adult care.

Conclusion: RTX can be safely administered to children with a variety of rheumatic conditions and appears to contribute to decreased disease activity and steroid burden.

Table. Effectiveness data among 48 SLE patients with at least 12 months of follow-up

Variable	Baseline	12 months	p-value, Student's t-test
Corticosteroid dose (n = 48)	31.7 ± 23.4	8.8 ± 12.1	<0.001
C3 (n = 29)	70.4 ± 39.8	115 ± 41.8	<0.001
C4 (n = 29)	11.6 ± 11.5	25.6 ± 15.9	<0.001
ESR (n = 47)	57.4 ± 37.7	37.2 ± 28.4	0.005
Hemoglobin (n = 48)	10.9 ± 1.6	12.0 ± 1.4	<0.001
Creatinine (n = 48)	1.0 ± 2.0	0.84 ± 1.1	0.143
Albumin (n = 48)	3.7 ± 0.76	4.2 ± 0.51	<0.001
Urine pr : cr (n = 40)	0.96 ± 2.0	0.75 ± 1.8	0.548
dsDNA (n = 37)	860 ± 3300	85 ± 301	0.128
Physician global (n = 41)	35.2 ± 19.2	14.3 ± 12.1	<0.001

Macrophage Activation Macrophage Activation Syndrome: A Severe and Frequent Manifestation of Acute Pancreatitis in Childhood-Onset Compared to Adult Systemic Lupus Erythematosus Patients. Natali W. Spelling[1], Carini I. Otsuzi[1], Diego L. Barros[1], Mariana A. da Silva[1], Rosa M. R. Pereira[1], Lucia M. A. Campos[1], Eduardo F. Borba[1], Eloisa Bonfá[1] and Clovis A Silva[2]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Acute pancreatitis (AP) is a rare and severe manifestation of childhood-onset systemic lupus erythematosus (cSLE) and adult SLE (aSLE) patients. Macrophage activation syndrome (MAS) is reported in lupus patients, however the comparisons of specific clinical and laboratorial features of MAS in cSLE and aSLE populations with AP were not performed. Therefore, the aim of this study was to analyze in a large population of cSLE and aSLE patients the rare group of AP and MAS.

Methods: A retrospective study included 362 cSLE and 1,830 aSLE patients followed in the same University Hospital. AP was defined according to the presence of abdominal pain or vomiting associated with an increase of pancreatic enzymes (3X) and/or pancreatic radiological abnormalities. MAS was diagnosed according to preliminary diagnostic guidelines, requiring the presence of at least one clinical and two laboratorial criteria. Bone marrow aspirate to assess macrophage hemophagocytosis was evaluated when available. Demographic data, clinical features, SLEDAI-2K, SLICC/ACR-DI and treatment were also assessed.

Results: A higher frequency of AP was observed in cSLE compared to aSLE [12/362 (3.3%) vs. 20/1830 (1.1%), p=0.003], with similar AP duration [22(6–60) vs. 15(4–90) days, p=0.534]. MAS was significantly higher in the former group (85% vs. 30%, p=0.003) and four of them had

macrophage hemophagocytosis. cSLE patients had higher SLEDAI-2K at AP diagnosis [22(8–41) vs. 10(0–40), p=0.007], fever (p=0.002), anti-dsDNA antibodies (p=0.002) and death by MAS complication (31% vs. 0%, p=0.017) than aSLE. No differences were evidenced in glucocorticoid use in both groups (p=0.394). Further analysis of MAS patients showed that the median of ferritin [1804(28–24,511) vs. 409(25–4,282) ng/ml, p=0.041], aspartate aminotransferase (AST) [121(23–1,156) vs. 30(13–1,446) U/L, p=0.018] and triglyceride [285 (163–526) vs. 172(61–357) mg/dL, p=0.005] were significantly higher in AP patients with MAS compared those without this complication. Fever (94% vs. 38%, p=0.001), leucopenia (82% vs. 19%, p=0.0001), thrombocytopenia (65% vs. 19%, p=0.013), hypertriglyceridemia (87% vs. 42%, p=0.037) and hyperferritinemia (93% vs. 37%, p=0.011) were also more frequently observed in AP patients with *versus* without MAS. Of note, acute infections were alike in both groups (p=0.438).

Conclusion: This study provides novel data demonstrating that MAS occur in the majority of cSLE with AP with a higher mortality compared to aSLE. In addition, we identified in AP patients, a cluster of MAS clinical and laboratorial parameters more associated with this complication.

A Cross-Sectional Study of Mental Health Symptoms and Mental Health Care in Pediatric SLE/MCTD Patients and Their Peers. Andrea Knight[1], Michelle Vickery[1], Pamela Weiss[1], Knashawn Morales[2] and Ron Keren[2]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Mental health problems are prevalent in pediatric systemic lupus erythematosus (SLE). We aimed to compare the rates of mental health problems and mental health services use for children and adolescents with SLE and mixed connective tissue disease (MCTD) to healthy peers and those with other chronic disease.

Methods: In a cross-sectional analysis, 40 children and adolescents with SLE/MCTD were matched according to sex and age with 40 healthy and 40 type 1 diabetic controls. Subjects were consecutively recruited and consented at outpatient clinic visits. We screened for symptoms of depression, suicidal ideation and anxiety using the Patient Health Questionnaire 9 (PHQ-9) and the Screen for Child Anxiety Related Disorders (SCARED), respectively. We also assessed for use of mental health services in the previous 12 months by parent report. We used matched pair analysis to compare the rate of mental health symptoms, and the Fisher's exact test to compare rates of mental health services use among the groups.

Results: Mental health symptoms were prevalent in all groups with 33% (13) of SLE/MCTD, 30% (12) of healthy controls and 43% (17) of diabetic controls screening positive for any symptom. Compared to the 10% prevalence of depression symptoms in the healthy controls, there was a trend towards higher prevalence in the SLE/MCTD group at 23% (RR=2.3, 95%CI 0.8–6.6) and statistically higher prevalence in the diabetes group at 30% (RR=2.5, 95%CI 1.2–5.3). Compared to the 5% prevalence of suicidal ideation in the healthy controls, there was a trend towards higher prevalence in the SLE/MCTD group at 18% (RR=3.5, 95%CI 0.7–16.8) and in the diabetes group at 18% (RR=2.5, 95%CI 0.9–7.3), but these were not statistically significant. There was no difference in depression and suicidal symptoms between the SLE/MCTD and diabetes groups. Anxiety was prevalent among all groups, but there was no difference between the groups. In those with any symptom, previous mental health care had been obtained in none (0/12) of the healthy controls, 23 % (3/13) of the SLE/MCTD and 53% (9/17) of the diabetes groups. Compared to healthy controls, the diabetes group had a statistically significant higher rate of mental health care in those with symptoms (p=0.003), but there was no difference for the SLE/MCTD group (p=0.12). There was no statistically significant difference in mental health care rates between SLE/MCTD and diabetic patients with symptoms (p=0.14).

Conclusion: Mental health symptoms were common in pediatric SLE/MCTD patients and their peers, but there was a trend towards more frequent depression and suicidal ideation in the SLE/MCTD and diabetes groups, implicating chronic disease as a risk factor for these symptoms. The majority of those with symptoms had no previous mental health care, although those with diabetes had a significantly higher rate of mental health care compared to healthy peers. Further study of the risk factors for mental health problems in chronic illness and factors affecting mental health care may improve overall care for pediatric SLE/MCTD patients.

Subclinical Right Ventricle Systolic Dysfunction By Two-Dimensional Speckle-Tracking Echocardiography in Childhood-Onset Systemic Lupus Erythematosus Patients. Gabriela N Leal[1], Kellen F Silva[1], Camila M. P. França[1], Alessandro C. Lianza[2], José L. Andrade[1], Lucia M. A. Campos[1], Eloisa Bonfa[1] and Clovis A Silva[3]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]University of São Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Evaluation of right ventricle (RV) systolic function by standard echocardiogram remains a challenge because of the complex geometry of this chamber. Recently, two-dimensional Speckle-tracking derived strain (2DST) was proven to have a better accuracy in detecting subtle RV dysfunction in children with congenital heart diseases, however this new technique was not systematically studied in childhood-onset SLE patients. Therefore, the aim of this study was to evaluate strain imaging by 2DST in cSLE patients and healthy controls and possible association of RV dysfunction with demographic data, clinical manifestations, laboratory and treatment.

Methods: A cross-sectional study was conducted at our Pediatric Rheumatology Unit from September 2012 to September 2013. Exclusion criteria were heart failure, congenital heart disease, pericardial effusion, history of infectious myocarditis or pulmonary obstructive diseases and poor quality echocardiographic imaging. Thirty-five cSLE patients and 33 healthy volunteers were submitted to standard echocardiogram, and 2DST. Conventional parameters included: RV diastolic diameter (RVDD), tricuspid annular plane systolic excursion (TAPSE), tricuspid annular systolic wave velocity (S), Tei index and the presence of pulmonary hypertension (velocity of tricuspid regurgitation jet>2.5m/s). 2DST analyzed global systolic longitudinal strain and strain rate of RV. Demographic data, clinical features, SLEDAI-2K, SLICC/ACR-DI and treatment were also assessed.

Results: The median current age was similar in cSLE patients and controls (14.75 vs. 14.88 years, p=0.62). Standard echocardiogram analysis revealed that cSLE patients had a significant increase RVDD (14.65±3.68 mm/m^2 vs. 12.31±2.43 mm/m^2, p=0.031) and Tei index compared to controls [0.49 (0.3–0.96) vs. 0.32 (0.22–0.45), p<0.0001]. They also had reduced S wave velocity [0.13 (0.09–0.2) vs. 0.16 (0.13–0.23)m/s, p<0.0001] and TAPSE (1.84±0.26 vs. 2.59±0.41cm, p<0.0001). Four patients had mild pulmonary hypertension. Further evaluation of function by 2DST showed that RV longitudinal peak systolic strain was significantly reduced in cSLE (−24.5±5.09 vs. −27.62±3.02%, p=0.003). The same finding was observed with the exclusion of four patients with mild pulmonary hypertension (−24.62 ± 4.87 vs. −27.62 ± 3.02, 0.0041, p=0.0041). RV longitudinal peak systolic strain was positively correlated with TAPSE (r=+0.49, p=0.0027) and negatively correlated with Tei index (r=-0.34, p=0.04) in cSLE patients. Further analysis of cSLE patients revealed higher frequencies of neuropsychiatric manifestations (39% vs. 0%, p=0.007) and antiphospholipid antibodies (55% vs. 18%, p=0.035) in those with reduced strain (≤ −23.7%) compared to high strain values (>−23.7%). No differences were evidenced in demographic data, disease activity/damage and treatments (p>0.05).

Conclusion: This is the first study to identify, using a more accurate methodology, subclinical RV systolic dysfunction in cSLE patients. The novel association of asymptomatic cardiac dysfunction with neuropsychiatric manifestations and antiphospholipid antibodies may suggest a common underlying mechanism.

Trabecular Bone Impairment Assessed By HR-pQCT in Juvenile-Onset Systemic Lupus Erythematous with Vertebral Fractures. Juliane Paupitz, Glauce Lima, Valéria Caparbo, Henrique Fuller, Eloisa Bonfa and Rosa M R Pereira. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: The three-dimensional evaluation of bone by HR-pQCT has the advantage to provide assessment to not only bone density, but also to a noninvasive evaluation of bone structure and bone strength. Information about changes in bone microarchitecture in juvenile-onset SLE (JoSLE) with and without fractures is lacking and they may improve future strategies of therapy and prediction of fracture risk in these patients. The objective of this study was, therefore, to analyze bone microarchitecture in JoSLE with and without vertebral fractures(VF).

Methods: Twelve consecutive JoSLE female patients with VF according to Vertebral fracture assessment (VFA) by dual-energy X-ray absorptiometry (DXA) were selected and compared to 44 female JoSLE patients without VF. Demographic, anthropometric, clinical and laboratory data were recorded by interview and electronic chart review. Bone microarchitecture was evaluated by High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) at the distal radius.

Results: Patients with and without VF had comparable age (18.0±2.73 vs. 18.5±3.35 years, p=0.0636), BMI (23.03±4.39 vs. 23.15±3.45 kg/m^2, p=0.927), disease duration (58.25 ± 45.03 vs. 71.39 ± 48.57 months, p=0.403), SLEDAI (4.14±4.04 vs. 4.73±5.92, p=0.744), CG cumulative dose (8602.71±8484.15 vs. 6291.54±6737.18 mg, p=0.454), current GC dose (16.04±14.44 vs. 15.97±19.75 mg/day, p=0.990), maximum GC dose (34.17±26.53 vs. 29.20±31.35 mg/day, p=0.466) and 25-hydroxyvitamin D (22.25 ± 6.93 vs. 23.38 ± 6.90 ng/ml, p=0.610). In spite of these comparable parameters, Table 1 illustrates significant differences in HR-pQCT in distal radius findings in the two groups of patients analyzed. Patients with vertebral fractures had reduced density parameters, particularly related to D100 (p=0.011) and D trab (p=0.024), suggesting a predominant trabecular bone involvement. Structural evaluation in patients with VF revealed a significant reduction in BV/TV (p=0.023) and Tb.Th (p=0.033), both parameters associated with trabecular organization. Finally, a significant decrease in apparent modulus was observed in patients with VF (p=0.018) indicating a bone strength impairment of VF group.

Table 1: Density and Structural parameters of distal radius assessed HR-pQCT in JoSLE patients with and without vertebral fractures

The Psychological Impact on Health-Related Quality of Life in Childhood-Onset Lupus. Jordan T. Jones, Natoshia Cunningham, Jennifer L. Huggins, Susmita Kashikar-Zuck and Hermine I. Brunner. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Childhood-onset lupus (cSLE) is a chronic autoimmune disease and its effect on health-related quality of life (HRQoL) has not been fully established, but, disease activity alone does not solely account for the impact on HRQoL. Gaps in the literature exist around the impact of potentially modifiable factors (pain, sleep, fatigue, pain coping, mood, anxiety) in relation to HRQoL. Disease activity measures are often unrelated to psychological factors associated with cSLE. Chronic disease and its related psychological factors can impair participation in developmentally appropriate activities in adolescents, leading to chronically poor HRQoL. *Objectives* of this study were to evaluate psychological factors in patients with cSLE and the degree of HRQoL impairment in cSLE due to psychological factors commonly associated with chronic diseases.

Methods: As part of an ongoing study, a population-based cohort of cSLE patients (n= 20; 8 – 18 years) followed at Cincinnati Children's Hospital were asked to complete brief measures of *pain* (Pain visual analog scale[Pain VAS]), *sleep* (Adolescent Sleep Wake Scale), *fatigue* (PedsQL Multidimensional Fatigue Scale), *pain coping* (Pain Coping Efficacy questionnaire, Pain Catastrophizing questionnaire), *mood* (Children's Depression Inventory [CDI1]), *anxiety* (Screen for Child Anxiety Related Disorders [SCARED]), and *HRQoL* (PedsQL Generic Core scale and Rheumatology Module). Measures of disease activity (Systemic Lupus Erythematosus Disease Activity Index [SLEDAI], and physician completed visual analog scale of cSLE disease activity [MD Global, 0–10; 0=inactive]) were also obtained.

Results: Subjects were 90% female with mean age of 15.5 years (SD 1.5) and mean SLEDAI score of 7.8 (SD 6.1). Of the subjects, 60% had fatigue and more than minimal pain (Pain VAS ≥ 3), and 40% reported often feeling rested the next morning. Also, 25% had clinically significant anxiety symptoms (SCARED ≥ 25), and 30% had mild-to-moderate depressive symptoms (CDI1 ≥ 10). The average HRQoL score for cSLE patients was well below the reported healthy mean, and the presence of fatigue, anxiety, and decreased mood correlated highly with HRQoL (Pearson's r > 0.70). Conversely, none of the HRQoL measures correlated with SLEDAI score or MD global (r< 0.25; see **Table 1**). Regression demonstrated HRQoL was most impacted by fatigue (p <0.05) when evaluating all factors concurrently.

Conclusion: cSLE is often associated with decreased HRQoL, despite comprehensive treatment provided at a tertiary pediatric rheumatology center. Our data suggests that psychological aspects of health (pain, mood, fatigue and anxiety) contribute substantially to diminished HRQoL in cSLE patients, whereas, measures of cSLE activity are not related to HRQoL outcomes. Psychological factors, and especially fatigue, need to be addressed to achieve optimal health outcomes with cSLE.

Imundo[14], Tracey Wright[15], David Witte[16], Jun Ying[17], Prasad Devarajan[1] and Hermine I. Brunner[7]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Ohio State University College of Medicine, Columbus, OH, [3]Anne & Robert H Lurie Childrens Hospital of Chicago, Chicago, IL, [4]Emory University School of Medicine, Atlanta, GA, [5]BC Children's Hospital and University of British Columbia, Vancouver, BC, [6]Cincinnati Children's Hospital Medical Center, c, OH, [7]Cincinnati Children's Hospital Medical Center, Cincinnati,

OH, [8]University of Chicago Hospitals, Chicago, IL, [9]Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [10]Cohen Children's Medical Center, Lake Success, NY, [11]Riley Hospital for Children, Indianapolis, IN, [12]Case Medical Center, Cleveland, OH, [13]Children's National Medical Center, Washington, DC, [14]Columbia University Medical Center, New York, NY, [15]UT Southwestern Medical Center, Dallas, TX, [16]Cincinnati Children's Hospital, Cincinnati, OH, [17]University of Cincinnati, Cincinnati, OH.

Background/Purpose: LN is common in childhood-onset Systemic Lupus Erythematosus (cSLE). Kidney biopsies are impractical to assess the course of LN given their invasiveness and cost. Therefore, traditional laboratory measures [GFR, complement levels, anti-dsDNA antibodies, serum creatinine and urinary protein/creatinine ratio] are used and several clinical indices [Systemic Lupus International Collaborating Clinics Renal Activity Score (SLICC-RAS), renal domain score of the BILAG (BILAG-R) and SLEDAI (SLEDAI-R)] have been developed: The objective of this study was to validate these traditional non-invasive measures of LN activity in cSLE, using histological activity & severity of LN as criterion standard.

Methods: The traditional laboratory measures were measured in 83 children with LN at time of the kidney biopsy. The biopsy specimens were rated by a single nephropathologist for LN severity as per International Societies for Nephrology & Renal Pathology (ISN/RPS) class, the NIH glomerular activity Index (GLAI; range 0-24) and the tubulointerstitial activity index (TIAI, range 0–21). For the statistical analysis, LN severity is categorized as Class I/II vs. III/IV vs. V; GLAI score ($\leq$10 vs. $>$10), or TIAI score ($\leq$5 vs. $>$5) in fixed effect models and logistical models, respectively.

Results: Of the 83 kidney biopsies, 12%, 60% and 28%, of the patients had class I/II, III/IV and V, respectively. The median scores of the GLAI and TIAI are summarized (Table 1). SLEDAI-R and SLICC-RAS, but not BILAG-R was positively associated to the ISN/RPS classification (Table 2). In particular, higher SLEDAI-R and serum creatinine level and lower GFR level was found in patients with LN inflammatory activity (GLAI $>$ 10 or TIAI $>$5). Similar patterns were also noticed in patients with ISN/RPR Class III/IV being compared against those with ISN/RPR Class V.

Conclusion: Of the currently used measures to assess LN in routine daily practice, the SLEDAI-R and the GFR appears to best reflect inflammatory LN activity in both the glomerulus and the interstitium of pediatric populations.

Table 1. Summary of GLAI, TIAI and ISNPR CLASS in cSLE Cohort

Score	Stat Type	Statistics
GLAI score	Median (range)	6 (0, 22)
	Freq (%) of score$>$10	27/71 (38.0%)
TIAI score	Median (range)	4 (0, 11)
	Freq (%) % of score$>$5	14/55 (25.5%)
ISNPR CLASS	I/II	10 (12.05%)
	III/IV	50 (60.24%)
	V	23 (27.71%)

Development of an Index to Non-Invasively Quantify Lupus Nephritis Chronicity in Children. Khalid Abulaban[1], Michael Bennett[1], Marisa Klein-Gitelman[2], Stacy P. Ardoin[3], Kelly A. Rouster-Stevens[4], Lori B. Tucker[5], Kasha Wiley[6], Shannen Nelson[7], Karen Onel[8], Nora G. Singer[9], Kathleen M. O'Neil[10], B Anne Eberhard[11], Lawrence K. Jung[12], Lisa F. Imundo[13], Tracey Wright[14], David Witte[15], Jun Ying[16], Prasad Devarajan[1] and Hermine I. Brunner[7]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Anne & Robert H Lurie Childrens Hospital of Chicago, Chicago, IL, [3]Ohio State University College of Medicine, Columbus, OH, [4]Emory University School of Medicine, Atlanta, GA, [5]BC Children's Hospital and University of British Columbia, Vancouver, BC, [6]Cincinnati Children's Hospital Medical Center, c, OH, [7]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [8]University of Chicago Hospitals, Chicago, IL, [9]Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [10]Riley Hospital for Children, Indianapolis, IN, [11]Cohen Children's Medical Center, Lake Success, NY, [12]Children's National Medical Center, Washington, DC, [13]Columbia University Medical Center, New York, NY, [14]UT Southwestern Medical Center, Dallas, TX, [15]Cincinnati Children's Hospital, Cincinnati, OH, [16]University of Cincinnati, Cincinnati, OH.

Background/Purpose: The current gold standard for assessing chronic changes in Lupus Nephritis (LN) is a kidney biopsy interpreted using the International Societies for Nephrology & Renal Pathology (ISN/RPS) Classification. However, kidney biopsies are invasive, costly and unsuited for close surveillance of LN. The objective of this study was to develop a non-invasive Index to measure LN chronicity or damage, considering both traditional measures of LN (LN-TM) and recently discovered renal biomarkers (RBM).

Methods: In this ongoing prospective study, 70 children with LN were studied at the time of the kidney biopsy for the LN-TM [GFR, anti-dsDNA antibodies, urinary protein/creatinine ratio] and the urine concentrations of the RBM (see Table 1) were measured. Histological findings were rated by a single nephropathologist who provided the NIH chronicity index (NIH CI; range 0–12) which served as the Criterion Standard. Prior to statistical analysis, RBM levels were normalized by urine creatinine and logarithmically transformed. NIH-CI scores ranged from 0 to 12. LN damage was categorized as low (NIH-CI $<$3) or moderate (NIH-CI $>$3). LN-TM and the RBM that showed significance in univariate logistic analysis at a p-value$<$0.20 were considered in exploratory stepwise multivariate logistical regression models as candidate predictors, using the NIH CI as dependent variable (outcome) to assess the combinatorial character of the candidate predictors.

Results: The means and percentages of the values of the LN-TM and RBM levels are summarized (Table1). Based on multivariate logistical regression modeling levels of TGFB, NGAL and GFR (or serum creatinine) but not protein excretion (urinary protein/creatinine ratio) were found to be combinatorial biomarkers of LN damage. Results on the RBM liver-type fatty acid binding protein (LFABP), Kidney Injury Molecule-1 (KIM1) and the receiver operating characteristic curve analyses will be presented.

Conclusion: NGAL, TGBF and GFR are good potential components for Children a Lupus Nephritis Index for Damage (C-LID) to non-invasively measure chronic histological changes in LN in the glomeruli, interstitium and tubules. Further studies with larger numbers of patients are required for further evaluation and confirmation of our finding.

Table 1. Comparisons of LN biomarkers between NIH CI Groups

LN biomarkers	NIH CI Score $<$ 3	NIH CI Score $\geq$ 3	p
Protein/ Cr ratio*	1.85 (1.32, 2.59)	3.73 (1.94, 7.18)	0.065

Adiposity and Adipokines Are Associated with Insulin Resistance in Pediatric Systemic Lupus Erythematosus. Leandra Uribe Woolnaugh[1], Tracey Wright[1] and Gloria Vega[2]. [1]Children's Medical Center, Dallas, TX, [2]UTSouthwestern Medical Center, Dallas, TX.

Background/Purpose: Traditional risk factors for cardiovascular disease do not fully account for the increase in atherosclerosis in SLE. Insulin resistance (IR) and other metabolic derangements are considered a harbinger of cardiovascular disease Specific factors related to SLE including immune dysregulation and chronic inflammation are also important and may, in part, be mediated by adipocytokines. The relationship between body composition and cardiometabolic risk factors is not well characterized in children with chronic illness including pediatric SLE. The study's objective was to evaluate the association of body composition measures, inflammation, and insulin resistance a cohort of pediatric SLE.

Methods: This cross sectional study examined metabolic parameters, including adiponectin, leptin and hsCRP, and body composition, using dual x-ray absorptiometry to measure whole body lean and fat mass, in 33 children with SLE and 27 healthy controls. All SLE subjects met ACR criteria for diagnosis. Sex- specific BMI z scores (BMIZ), fat mass index (FMIZ) and lean mass index z scores (LMIZ) relative to age were calculated using national reference data. Multi-variable linear regression was used to determine the relationship of IR and SLE and predictors of IR within the SLE subjects.

Results: FMIZ (0.5 vs −0.6; p=0.001) was significantly greater in SLE, with no difference in LMIZ. High sensitivity-c reactive protein (hs-CRP) (4.4 vs 1.1; p=0.04), homeostasis model assessment of insulin resistance (HOMA-IR) (6.4 vs 3.5; p=0.006), measured leptin (40.8 vs 12.9; p=0.0001), and leptin/kg of body fat (1.5 vs 0.7; p<0.001) were significantly greater in SLE. While there was no difference in measured adiponectin, the adiponectin/leptin ratio was greater in controls compared to SLE (2.7 vs 1.1; p=0.03). After adjustment for age, gender, ethnicity and tanner stage, hs-CRP (β=3.9 (1.3–6.4); p=0.004) was significantly associated with IR in SLE. FMIZ (β=1.1 (0.2–2.1); p=0.02), was the significant body composition measure, and leptin/kg of body fat (β=2.3 (0.2–4.4); p=0.03), the most significant metabolic parameter, associated with IR in SLE. Cumulative prednisone dose was not associated with IR.

Conclusion: In this cohort, SLE subjects demonstrated cardiometabolic risk factors with elevated leptin and leptin/kg of body fat and decreased adiponectin/leptin ratio. IR was more common in SLE with adiposity, leptin, and inflammation as the crucial determinants of this association. Further studies are needed to evaluate the use of adipocytokines as biomarkers of cardiovascular disease in this vulnerable population.

Outcome of Lupus Nephritis in Children Less Than 12 Years Old from North-India. Anju Gupta, Bonnie Abujam, Deepti Suri, Amit Rawat and Surjit Singh. Postgraduate Institute of Medical Education and Research, Chandigarh, India.

Background/Purpose: Studies on lupus nephritis in young children below 12 years of age from developing countries are limited. This study looks at long-term outcome in North-Indian children.

Methods: This was a single-center retrospective study from a University referral hospital that provides subsidized treatment. Children seen in the center during the last 25 years were included if they had been diagnosed with systemic lupus erythematosus (as per the ACR 1997 criteria) and lupus nephritis (proteinuria >500mg/day or hematuria (>5RBC/HPF) or any cellular cast) before their 12thbirthday. Initial presentation, laboratory data and treatment received was obtained from the file. Renal biopsy data was classified as per the WHO classification. The primary endpoint was survival with functioning kidneys (absence of death or ESRD). Patients were followed up till January 2012. Kaplan-Meier analysis was used for survival and log-rank test was used to compare different classes. *Definitions used:* Chronic kidney disease = elevated serum creatinine (>1.5mg/dl) for atleast 3 months. End-stage renal disease = need for renal replacement therapy > 3 months.

Results: This study included 72 children (F: M 3.2:1). The mean± SD age at onset of lupus was 9.3±2.4 years and the duration of disease before presentation was 9.2±12.6 months. Majority of the children (76%) had nephritis at presentation. Renal biopsy was done in 54 children. The histological class was class II in 9, class III in 1, class IV in 35 and class V in 7. Biopsy was not done in the remaining 18 patients due to poor general condition in 7, ongoing anticoagulation in 5, thrombocytopenia, uncontrolled hypertension and refusal by caregivers in 2 children each. The most common induction treatment was monthy pulses of cyclophosphamide (6–12 pulses) followed by maintenance with azathioprine or quarterly pulses of cyclophosphamide. At 1 year of follow up, 11 (15%) children had died (all in 1st admission), 11 (15%) were lost to follow up, 36 (50%) were in complete remission and 5 each (6.9%) were in partial remission and active disease. Data for 4 children at 1 year could not be retrieved. Another 11 (15%) children died after the 1st year. The common causes of mortality was infection, disease activity and renal failure. (Table 1). The mean duration of follow up was 4 ± 4.4 years (0.2–20 years) with a total follow up of 287 patient years. Survival with functioning kidneys was seen in 71% at 3 years, 68% at 5 years and 60% at 10 years. There was no difference in survival among various histological classes.

Conclusion: We found a majority of young children presented with lupus nephritis. There was a high mortality at initial presentation. The long term outcome is still much lower as compared to those from the developed nations. Majority of deaths occur in the initial presentation due to infections, severe disease activity and renal failure.

Table 1: Causes of death

	Total	Initial visit	Later
Septicemia	7	7	0
Severe disease activity	3	3	–
End stage renal disease	4	–	4
Disseminated kochs with shunt malfunction	2	–	2
Pulmonary thromboembolism	2	–	2
Hypertensive Intracranial bleed	1	–	1
Myocarditis with left ventricular failure	1	1	–
Unknown cause (died at home)	2	–	2
Total	22 (30)	11	11

Monitoring of Mid-Interval Plasma Levels of Mycophenolic Acid in Pediatric Lupus Nephritis Patients. Joyce S Hui-Yuen[1], Kristi Truong[2], Liza Mariel Bermudez-Santiago[1], Amy J. Starr[3], Andrew Eichenfield[4], Lisa F. Imundo[3] and Anca Askanase[3]. [1]Morgan Stanley Children's Hospital of New York Presbyterian, Columbia University Medical Center, New York, NY, [2]St John's University, Queens, NY, [3]Columbia University Medical Center, New York, NY, [4]Children's Hosp of New York, New York, NY.

Background/Purpose: Mycophenolate mofetil (MMF) is often used to treat lupus nephritis (LN) and extra-renal lupus in children with SLE. Plasma levels of mycophenolic acid (MPA) are used in clinical practice to determine absorption of MMF and compliance. However, data are equivocal in the use of plasma MPA levels as a measure of efficacy or a predictor of prognosis in pediatric LN patients. This study was initiated to evaluate the use of MPA levels in routine care of children with LN.

Methods: This is a retrospective study of pediatric LN patients treated with MMF. Data were collected on demographic and disease characteristics, concomitant medications, and treatment outcomes. Complete renal remission (CR) was defined as proteinuria <500mg/24h, and no other clinical manifestations of renal disease. Mid-interval MPA plasma levels were drawn

during routine follow-up. Calculated steady-state concentrations can predict plasma MPA levels at peak, trough, or any time during the dosing interval. Steady-state levels of MPA were calculated using basic pharmacokinetics and compared to routine mid-interval plasma MPA levels. Student t-tests were used when appropriate.

Results: We describe 17 patients with pediatric lupus nephritis treated with MMF that have plasma MPA levels available from our cohort. The mean duration of SLE was 5 years, and LN was 3.3 years. Ten LN patients were in CR at the time of this study, 5 had mixed proliferative/membranous nephritis and 5 had proliferative disease alone. All 7 patients not in CR had some component of membranous LN. MMF was dosed at 600mg/m^2/dose for all patients. The mean dose of corticosteroids was 23.75mg prednisone equivalent/day in patients in CR compared with 62.5mg prednisone equivalent/day in patients with persistent disease (p=0.06). The mean mid-interval levels of MPA were 1.69 ug/ml (range <0.5 to 8 ug/ml) in patients in CR and 2.04 ug/ml (range <0.5 to 6 ug/ml) in patients with persistent active disease (p=NS). Of note, 3 patients in each group had undetectable MPA levels. Based on dose, the calculated mid-interval steady-state level was 13.62 ± 3.67 mg*h/L and did not reflect the observed mid-interval levels.

Conclusion: This is the first study to investigate the correlation between mid-interval levels of MPA and predicted steady-state serum levels in patients with lupus nephritis. Our data suggest a large inter-individual variability but also clearly raise concerns about compliance with MMF regimens and emphasize the need to more precisely monitor MPA levels with peak, trough, and area-under-the-curve, as well as the need to discuss with patients and families the reason(s) for non-compliance.

Disclosure: J. S. Hui-Yuen, None; **K. Truong**, None; **L. M. Bermudez-Santiago**, None; **A. J. Starr**, None; **A. Eichenfield**, None; **L. F. Imundo**, None; **A. Askanase**, None.

1308

Antinucleosome Antibodies As Potential Diagnostic and Prognostic Biomarkers in Childhood Onset Systemic Lupus Erythematosus. Thaschawee Arkachaisri, Joo Guan Yeo, Justin Hung Tiong Tan, Sook Fun Hoh, Lena Das and Jing Yao Leong. KK Women's and Children's Hospital, Singapore, Singapore.

Background/Purpose: The role of antinucleosome antibodies (ANuA) in the immunopathogenesis of SLE is evident. ANuA was shown to be a good, if not better than anti-dsDNA antibody, diagnostic and prognostic biomarkers in adult SLE pts of different ethnicities. Such evidence is scarce in childhood onset SLE (cSLE). We aim to explore the role of ANuA as potential diagnostic and prognostic biomarker in our ASEAN cohort.

Methods: 68 cSLE pts (onset < 18) were recruited and 55 pts with 180 pt-visits with complete clinical data/blood samples were studied. Disease activity (DA) indices: SLEDAI-2K, SLAM and BILAG were recorded. Anti-dsDNA, ANuA (H1-stripped) and anti-C1q were measured by ELISA. Pts were evaluated at 1–3 mo intervals depending on DA. Pts were grouped into 3 DA groups: no activity (ID), minimal DA (MD) = mild DA with no treatment change or DA with improvement from previous visit and active DA (AD) = new case or flare or persistent DA/refractory to treatment. 72 JIA, 6 JDM, 5 MCTD/UCTD, 11 vasculitides, 5 ANA-positive and 17 other inflammatory conditions composed 116 controls (female 45%, median age (IQR) 13.6 (10.3–16.6)). Descriptive statistics were used to describe data. Mann-Whitney/Kruskal-Wallis tests were used to compare data and Spearman's rho for correlation studies.

Results: 55 cSLE (84% female) with median age of 15.9 (14.4–18.2) and median disease duration of 54.7 (29.4–76.2) mo were included. Majority were Chinese and Malay (38%, 33%). Hematologic disorder (98%), arthritis (58%), malar rash (47%) and renal disease (44%) were among most common manifestations. All cSLE had positive ANA at onset. The median (IQR) of SLEDAI-2K, SLAM and BILAG for each disease activity groups were as follows: ID-2.0 (0.0–2.0), 1.0 (0.0–3.0), 1.0 (0.0–1.0); MD-4.0 (3.0–8.0), 3.0 (2.0–4.0), 2.0 (2.0–4.0) and AD-8.0 (4.0–12.0), 6.0 (3.0–9.0), 5.0 (3.0–12.0). ANuA titers among cSLE disease groups and controls were shown in Figure 1. Diagnostic property and correlation studies were shown in Table 1. ANuA level did not fluctuate with renal DA (p=0.601) or associated with the presence of nephritis (p=0.58), so did anti-dsDNA Ab (p=0.587). ANuA showed good and reasonable diagnostic properties, moderate – strong correlations with laboratory parameters but rather weak correlation with DA indices.

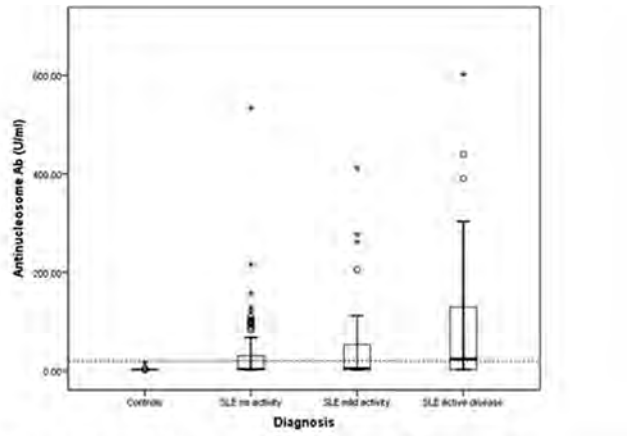

Figure 1 Antinucleosome antibody level distribution among disease group, normal < 20 U/ml
p-value: cSLE vs. Controls (p < 0.001); ; cSLE no activity vs. controls (p<0.001); cSLE min activity vs. active disease (p=0.002); cSLE no activity vs. min activity (p=0.983); cSLE min activity vs. active disease (p=0.073)

Table 1.

Antinucleosome antibodies (ANuA) as diagnostic biomarkers*

Properties	%	95% confidence interval
Sensitivity	66.67	46.04–83.48
Specificity	100.00	96.87–100.00
+ Likelihood ratio (+LR)	NA as specificity 100.00%, very large	
− Likelihood ratio (−LR)	0.33	0.20–0.57
+ Predictive value (+PPV)	100.00	81.47–100.00
− Predictive value (−PPV)	92.80	86.77–96.65
Diagnostic odd ratio (DOR)	NA as specificity 100.00%, very large	

Antinucleosome antibodies (ANuA) in cSLE and controls

Parameters	cSLE (n=180)δ	Controls (n=116)
ANuA titers (nil < 20 U/ml)		
No activity (n=106) ‡	3.57 (2.01–30.63)	
Minimal activity (n=23) ‡	5.47 (1.83–53.48)	1.79 (1.59–1.99)
Active disease activity (n=51) ‡	24.14 (2.57–129.64)	
ANuA and	Correlation coefficients (*rho*)	p value
ESR	0.461	<0.001
CRP	0.140	0.065
C3	−0.581	<0.001
C4	−0.479	<0.001
Anti-dsDNA	0.865	<0.001
Anti C1q Ab	0.558	<0.001
SLEDAI	0.338	<0.001
SLAM	0.188	0.012
BILAG	0.074	0.324

*Controls n=116, cSLE n=27 (20 active disease + 7 newly diagnosed).
‡Minimal activity = mild activity with no therapeutic intervention or activity with improvement from previous visit.
Active disease activity = New case or flare or persistent activity/refractory to treatment
δpatient-visits.

Conclusion: ANuA has a good diagnostic property with high specificity and high PPV suggesting that it could be a compliment biomarker in cSLE diagnosis. The levels fluctuated with DA with moderate - strong correlation with lab parameters despite weak correlation with clinical index, for which a larger validation study is needed.

Does Anti-C1q Antibody Have Diagnostic and Prognostic Roles in Childhood – Onset Systemic Lupus Erythematosus? Thaschawee Arkachaisri, Joo Guan Yeo, Justin Hung Tiong Tan, Sook Fun Hoh, Lena Das and Jing Yao Leong. KK Women's and Children's Hospital, Singapore, Singapore.

Background/Purpose: Biomarkers proven to be effective in aSLE patients may not directly apply to cSLE unless validation is done. Existing

evidences have shown immunopathogenic roles of C1q and anti-C1q antibody (aC1qA) in SLE both in vitro and in vivo. The latter are strongly associated with the development of lupus nephritis especially in aSLE but evidences of its role in cSLE are rare. We aim to explore the role of aC1qA in our Southeast Asian cSLE cohort in regard to its diagnostic and prognostic properties as our proof-of-concept study.

Methods: Sixty-eight cSLE patients were recruited and 55 patients with 180 patient-visits with complete clinical data/blood samples were studied. Disease activity indices including SLEDAI-2K, SLAM and BILAG were recorded. Anti-dsDNA, antinucleosome Abs (ANuA, H1-stripped) and aC1qA were measured by ELISA. Patients were evaluated at 1–3 mo intervals depending on their disease severity. Patients were grouped into 3 disease activity groups: no activity (ID), minimal activity (MD) = mild activity with no therapeutic intervention or activity with improvement from previous visit and active disease activity (AD) = new case or flare or persistent activity/ refractory to treatment. 72 JIA, 6 JDM, 5 MCTD/UCTD, 11 vasculitides, 5 ANA-positive and 17 other inflammatory conditions composed 116 controls (female 45%, median age (IQR) 13.6 (10.3–16.6) years). Descriptive statistics were used to describe data. Mann-Whitney/Kruskal-Wallis tests were used to compare data and Spearman's rho for correlation studies.

Results: 55 cSLE (84% female) with median age of 15.9 (14.4–18.2) yrs and median disease duration of 54.7 (29.4–76.2) mo were included. Majority were Chinese and Malay (38% and 33%). Hematologic disease (98%), arthritis (58%), malar rash (47%) and renal disease (44%) were among most common manifestations. All patients had ANA positivity at onset. Fig 1 shows significant differences in AC1qA levels between controls vs. cSLE and among disease activity groups ($p < 0.001$). Table 1 reveals strong diagnostic properties of aC1qA. aC1qA was also associated with the presence of nephritis ($p=0.034$). Correlation analysis showed moderate to good correlations with ESR, C3, C4, anti-dsDNA and ANuA and SLEDAI.

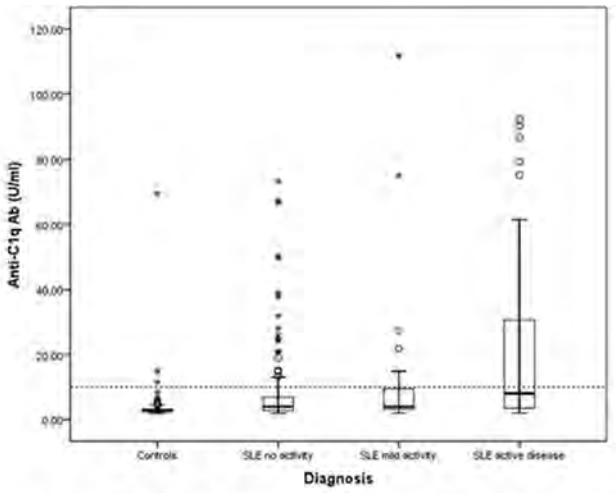

Figure 1 Anti-C1q antibody level distribution among disease group, normal < 10 U/ml. p-value: cSLE vs. Controls ($p < 0.001$); cSLE no activity vs. controls ($p<0.001$); cSLE min activity vs. active disease ($p=0.158$); cSLE no activity vs. min activity ($p=0.456$); cSLE min activity vs. active disease ($p=0.001$).

Table 1.

Anti-C1q antibody as diagnostic biomarker*

Properties	%	95% confidence interval
Sensitivity	48.15	28.67–68.05
Specificity	97.41	92.63–99.46
+ Likelihood ratio	18.62	5.70–60.80
− Likelihood ratio	0.53	0.37–0.77
+ Predictive value	81.25	54.35–95.95
− Predictive value	88.98	82.20–93.84
Diagnostic odd ratio (DOR)	35.13	

Anti-C1q antibody (aC1q) in cSLE and Controls

Parameters	cSLE (n=180)δ	Controls (n=116)
aC1q titers (nil < 10 U/ml)		
No activity (n=106)**	4.03 (2.78–6.97)	2.81 (2.46–3.27)
Minimal activity (n=23)**	4.01 (3.25–9.50)	
Active disease activity (n=51)**	8.05 (3.53–30.85)	

aC1q and	Correlation coefficients (*rho*)	p value
ESR	0.321	<0.001
CRP	0.011	0.886
C3	−0.573	<0.001
C4	−0.486	<0.001
Anti-dsDNA Ab	0.596	<0.001
Antinucleosome Ab	0.558	<0.001
SLEDAI	0.473	<0.001
SLAM	0.276	<0.001
BILAG	0.235	0.002

*Controls n=116, cSLE n=27 (20 active disease + 7 newly diagnosed).
**Minimal activity = mild activity with no therapeutic intervention or activity with improvement from previous visit.
Active disease activity = New case or flare or persistent activity/ refractory to treatment.
†Median (IQR).
δpatient-visits.

Conclusion: Our initial findings showed a strong diagnostic and possible, prognostic properties of aC1qA in our cSLE cohort. The presence of aC1qA was associated with lupus nephritis and its levels seem to fluctuate with global, if not only renal disease activity. A longer term and prospective study is needed to validate these initial findings in our region.

Predicting Macrophage Activation Syndrome in Pediatric Systemic Lupus Erythematosus Patients at Diagnosis. Maya Gerstein[1], Roberto Ezequiel Borgia[1], Brian Feldman[1], Deborah M. Levy[2], Sharon Sukhdeo[3], Susanne M. Benseler[4], Lawrence W.K. Ng[1], Mohamed Abdelhaleem[1], Earl D. Silverman[1] and Linda T Hiraki[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children and University of Toronto, Toronto, ON, [3]The Hospital For Sick Children, Toronto, ON, [4]Alberta Children's Hospital, University of Calgary, Calgary, AB.

Background/Purpose: It can be difficult to differentiate macrophage activation syndrome (MAS) from active pediatric systemic lupus erythematosus (pSLE). However, this differentiation is in determining correct treatment decisions. The purpose of this study is to generate a decision tree for the recognition of MAS in newly diagnosed pSLE and test the performance of these proposed criteria in an independent pSLE cohort.

Methods: A retrospective cohort study of consecutive patients requiring admission to SickKids Hospital with newly diagnosed, active pSLE between January 2002 and July 2007 (training cohort) was performed. All patients met ≥4 /11 ACR criteria. Data collection on: 1) Clinical features including fever, CNS dysfunction, splenomegaly, hepatomegaly and hemorrhage; 2) laboratory parameters; CBC, ESR, CRP, C3, C4, ferritin, AST, ALT, LDH, albumin, bilirubin, triglycerides, LDL, HDL, urea, creatinine, sodium, coagulation parameters including INR, PTT, fibrinogen and D-Dimer, and soluble IL-2 receptor (sIL-2R) and CD163. Patients were assigned to one of 2 cohorts exclusively (MAS/non-MAS). Putative predictor variables were compared between cohorts. A decision tree analysis for diagnosis of MAS in pSLE was constructed using recursive partitioning, and decision rules were subsequently applied to an independent cohort of newly diagnosed, active pSLE diagnosed and admitted to SickKids between July 2007 and July 2013 (testing cohort) to determine the sensitivity and specificity of the proposed criteria

Results: The training cohort consisted of 56 pSLE patients: 9 (16%) diagnosed with MAS and 47 non-MAS patients. Splenomegaly was more common in the non-MAS cohort, with no other differences in clinical characteristics between cohorts. Of all the available laboratory data, ALT ≥ 45 units/L, neutrophils $< 1.65 \times 10^3/mm^3$ and ferritin ≥ 836 μg/L identified 55% of the patients with MAS ($R^2 = 0.75$) with 100% specificity. The testing cohort consisted of 9 (20%) MAS and 32 non-MAS pSLE patients. The proposed thresholds for ALT, neutrophil count and ferritin demonstrated a sensitivity of 67% and specificity of 94% in discriminating MAS from nonMAS patients.

Conclusion: None of the clinical features differentiated pSLE patients with and without MAS. Using all laboratory data proposed to be elevated in MAS and decision tree analysis demonstrated that ALT, neutrophil count and ferritin had excellent specificity and adequate sensitivity for distinguishing MAS from active SLE at diagnosis in the both the testing and validation

cohorts. This is a first step in improved recognition of MAS among pSLE patients. Future analyses are planned to further refine methods in distinguishing these two groups.

Lupus Nephritis in Mexican Children. María del Rocío Maldonado-Velázquez, Enrique Faugier, Fernando Garcia-Rodriguez, Paola Lara, Angel Flores, Javier Tomala-Haz and Diego Salinas-Encinas. Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico.

Background/Purpose: Incidence and disease pattern of childhood-onset systemic lupus erythematosus (SLE) is reported to differ among ethnic groups. Lupus nephritis (LN) strongly affects the outcome in children with LES systemic lupus erythematosus (SLE). There are lack of data on the clinical course, long-term outcome and predictors of disease progression in mexican children. This study reports the results and outcomes of a cohort of Mexican patients with LN.

Methods: To describe lupus nefritis pattern and follow-up of a cohort of 61 Mexican children with SLE in the Hospital Infantil de Mexico Federico Gomez during a 18-month period in 2013–2014. Descriptive data, parametric, non parametric statistics and Kaplan-Meier graphs was used to analyze disease remission.

Results: The mean age at diagnosis was 12.4 years (SD = 2.6), most of them was female (85%) and 51 (83%) presented nephritis at the time of LES diagnosis. The mean plasma creatinine was 0. 8 (SD 0.4) and 24 (39%) patients presented with nephritic syndrome. Renal function was reported with a median proteinuria 41 mg/m2TBS/h (0 - 735) and 53 (86.9%) presented with positive urinary sediment. Complement was diminished in the most of the patients. Class IV LN was the most prevalent (62%).

Treatment was based on cyclophpsphamide IV pulses alone or combined with oral either azathioprine or MMF. The patients completed a mean follow-up of 8 months, 26 (42.6%) patients were in complete remission and 15 (24.6%) were in partial remission. Two patients needs to move to rituximab treatment.

Mean time to remission (either complete or partial) was 9 months (SD 0.6) and the best outcome was related with class II LN (Figure, P =.013).

Conclusion: The current study provides outcome data on a mexican pediatric population with LN and underlines the importance of prescribing appropriate induction treatment to all children, also we identify that class II LN presents the best outcome in our patients.

Features, Treatment and Outcome of Macrophage Activation Syndrome in Pediatric Systemic Lupus Erythematosus. Roberto Ezequiel Borgia[1], Maya Gerstein[1], Deborah M. Levy[2], Earl D. Silverman[1] and Linda T Hiraki[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children and University of Toronto, Toronto, ON.

Background/Purpose: Macrophage activation syndrome (MAS) is a life-threatening inflammatory complication of pediatric systemic lupus erythematosus (pSLE). There are few reports of the presentation, treatment and outcome of MAS in pSLE. Our objective is to describe the presentation and treatment of pSLE-MAS patients seen at a single tertiary centre.

Methods: Our retrospective review included all patients seen at the Hospital for Sick Children, Toronto, diagnosed with pSLE (≥ 4/11 ACR classification criteria) and MAS (by Pediatric Reumatologist expert opinion) between January 2002 and December 2012. We collected data on: 1) Demographics: Sex, ethnicity, age of diagnoses; 2) MAS clinical features (fever, hepatosplenomegaly, lymphadenopathy, hemorrhages, CNS involvement); 3) SLE ACR classification criteria; 3) Additional laboratory, pathological and genetic parameters including autoantibodies and bone marrow aspiration (BMA); 4) Treatment; 5) Frequency of hospitalization, PICU admission and death.

Results: We identified 34 patients diagnosed with pSLE and MAS. The majority were female (70%). The most common SLE features were malar rash, arthritis and anti-dsDNA antibodies (Table). Mean age at SLE diagnosis was 13.4 years (SD: 3.0), the average interval between SLE and MAS diagnosis was 1.5 months (SD: 0.54), with the majority (76%) of patients diagnosed with MAS concomitantly with their SLE diagnosis. 4 patients had documented concomitant infections: 2 bacterial, 1 EBV and 1 HSV1.

All patients had fever (Table). 6/23 patients (26%) who underwent BMA demonstrated hemophagocytosis. Targeted gene sequencing of HLH genes perforin and syntaxin 11 was performed in 5 patients with the only abnormality a silent heterozygous polymorphism in perforin coding region detected in one patient. All patients were treated with corticosteroids with the majority (59%) receiving IV pulse of methylprednisolone (average 3 pulses/patient). Concomitant medications: IVIG in 59%, calcineurin inhibitor in 32%, and etoposide in 6%. All the patients required hospital admission, 6 required PICU admission and there were no deaths from MAS.

Conclusion: To our knowledge this is the largest cohort of patients with diagnosis of MAS in pSLE reported in a single center. We observed that MAS is most likely to develop concomitantly with pSLE diagnosis. The majority of the patients were successfully treated with corticosteroids and IVIG with complete recovery in all.

Comorbidity Patterns in Children with Juvenile Idiopathic Arthritis and Systemic Lupus Erythematosus: The Childhood Arthritis and Rheumatology Research Alliance Registry. Marc D. Natter[1], Mei-Sing Ong[2], Kenneth D. Mandl[1], Laura Schanberg[3], Yukiko Kimura[4], Norman Ilowite[5] and the CARRA Registry Investigators. [1]Children's Hospital Boston, Boston, MA, [2]University of New South Wales, Sydney, Australia, [3]Duke University, Durham, NC, [4]Hackensack Univ Medical Ctr, Hackensack, NJ, [5]Children's Hospital Montefiore, Bronx, NY.

Background/Purpose: Knowledge of co-occurring disease processes (comorbidities) is important for understanding disease pathogenesis, refining disease classifications, developing appropriate screening and prevention strategies, and determining overall burden of disease. We analyze prevalence and patterns of comorbidities in children with JIA and SLE in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry.

Methods: We analyzed cross-sectional data from the CARRA Registry across 60 sites between 2010 and 2013. Patterns of comorbidities in children with JIA and SLE were assessed. Network analysis of disease co-occurrence was carried out to identify clusters of comorbidities that are likely to present in the same individual.

Comorbidities were present and captured (1 or more) for subjects in the registry according to disease type:

JIA: uveitis, fibromyalgia, sarcoid, autism, autoimmune hepatitis, autoimmune thyroiditis, celiac disease, cerebral palsy, congenital heart disease, cystic fibrosis, type 1 diabetes (T1D), type 2 diabetes (T2D), malignancy, immunodeficiency, asthma, Down syndrome, demyelinating disorder, seizure, pulmonary hypertension, psoriasis, IBD, interstitial lung disease.

SLE: chronic vasculitis, autoinflammatory disease, uveitis, fibromyalgia, sarcoid, autism, autoimmune hepatitis, autoimmune thyroiditis, celiac disease, cerebral palsy, congenital heart disease, cystic fibrosis, T1D, T2D, malignancy, immunodeficiency, asthma, Down syndrome, demyelinating disorder, coronary heart disease.

Results: 6,150 children with JIA and 1,067 children with SLE were enrolled in the CARRA registry. 20.5% of JIA and 11.5% of SLE patients had at least 1 comorbidity (Table 1). Multiple co-occurring co-morbidities were individually much less common (0.6% or less), including in known associations (e.g. JIA with Down's syndrome and hypothyroidism or congenital heart disease).

Conclusion: The prevalence of comorbidities in children with JIA and SLE in the CARRA Registry is in accordance with ranges reported in other studies. We analyzed multiple co-occurring co-morbidities, including a network clustering analyses, which showed established and potential associations that are candidates for further evaluation in larger, population-based data sets.

Table 1. Number of comorbidities in JIA and SLE patients

	Frequency (%)	
Number of Comorbiditics	**JIA* (n=6,150)**	**SLE # (n = 1,067)**
1	1153 (18.7)	118 (11.1)
2	95 (1.5)	3 (0.3)
3	8 (0.1)	1 (0.1)
4	4 (0.1)	
At least one	1258 (20.5)	120 (11.5)

*Comorbidities considered included: uveitis, fibromyalgia, sarcoid, autism, autoimmune hepatitis, autoimmune thyroiditis, celiac disease, cerebral palsy, congenital heart disease, cystic fibrosis, type 1 diabetes, type 2 diabetes, malignancy, immunodeficiency, asthma, Down syndrome, demyelinating disorder, seizure, pulmonary hyertension, psoriasis, inflammatory bowel disease, interstitial lung disease.
Comorbidities considered included: chronic vasculitis, autoinflammatory disease, uveitis, fibromyalgia, sarcoid, autism, autoimmune hepatitis, autoimmune thyroiditis, celiac disease, cerebral palsy, congenital heart disease, cystic fibrosis, type 1 diabetes, type 2 diabetes, malignancy, immunodeficiency, asthma, Down syndrome, demyclinating disorder, coronary heart disease.

Table 2. Summary of comorbidity patterns

Comparison of the Utility and Validity of Three Scoring Tools to Detect Skin Disease in Patients with Juvenile Dermatomyositis.

Raquel Campanilho-Marques[1], Beverley Almeida[2], Katie Arnold[1], Kiran Nistala[3], Clarissa A Pilkington[2] and Lucy R Wedderburn[1]. [1]UCL Institute for Child Health, London, United Kingdom, [2]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [3]University College London, London, United Kingdom.

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare condition affecting 3 children/million/year. Muscle and skin involvement are key features. The muscle symptoms are frequently the main initial focus: formal measures (Childhood Myositis Assessment Scale - CMAS and Manual Muscle Test - MMT8) exist to routinely and accurately assess this component of the disease. However the involvement of skin, and its assessment, is a vital aspect. The abbreviated Cutaneous Assessment Tool (CAT) encompassing active skin disease and skin damage, Disease Activity Score (DAS) and Myositis Intention to Treat Activity Index (MITAX), both with skin components, have all been suggested to measure skin disease in JDM; however the optimal tool is unknown. The aim was to compare 3 tools for assessment of skin disease in JDM and correlate them with the physician's 10cm skin visual analogue scale (physician's skin VAS) to define which tool best assesses skin disease.

Methods: Patients recruited to the UK JDM Cohort & Biomarker Study who fulfil Bohan-Peter criteria for JDM were included. Each patient was assessed for skin disease using the CAT, DAS, MITAX and an overall physician's skin VAS. Markers of muscle disease (CMAS, MMT8, CK U/L), inflammatory markers (CRP mg/L and ESR mm/hr) and overall physician's global score were also recorded. Spearman's correlations (rs) were used to correlate categorical and continuous variables and a relationship >0.75 was considered strong. A p-value <0.05 was considered significant.

Results: Between 2012 and 2014, 67 JDM patients were assessed. 59.7% were female. The mean (±SD) age of the patients was 9.86 ±3.37 years, with mean age at diagnosis 6.59 ±3.42 years and mean disease duration of 3.26 ±3.08 years. The skin section of the DAS had the strongest correlation with the physician's skin VAS (Table 1). The skin section of the MITAX and the CAT activity scores were significantly correlated with the physician's skin VAS. DAS skin, MITAX skin and CAT Activity scores were all negatively correlated with CMAS and MMT8 scores; no significant correlations were noted with the CK. DAS skin scores were significantly correlated with both the CRP and ESR, while the MITAX skin was significantly correlated only with the ESR, and CAT Activity only with the CRP.

Table 1. Spearman's correlation between items shown as r_s and corresponding p value

	Skin VAS n=67	CMAS n=67	MMT8 n=67	CK n=52	CRP n=55	ESR n=54
DAS skin	r_s 0.795 p<0.001	r_s −0.443 p<0.001	r_s −0.424 p<0.001	r_s 0.176 p 0.212	r_s 0.280 p 0.039	r_s 0.311 p 0.022
MITAX skin	r_s 0.594 p<0.001	r_s −0.404 p 0.001	r_s −0.453 p<0.001	r_s 0.177 p 0.210	r_s 0.208 p 0.127	r_s 0.281 p 0.040
CAT Activity	r_s 0.623 p<0.001	r_s −0.471 p<0.001	r_s −0.428 p<0.001	r_s 0.157 p 0.267	r_s 0.300 p 0.026	r_s 0.164 p 0.235

Conclusion: These data demonstrate the potential application of using a skin assessment tool to evaluate and monitor skin involvement in JDM patients. It also demonstrates that the DAS skin section appears to be the best of the tools using the physician's skin VAS as the gold standard. The DAS skin tool was concise, quick to use and easy to score.

1315

Cross-Sectional Evaluation of Hydroxychloroquine (HCQ) Therapy in Children with Juvenile Dermatomyositis (JDM) Enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry.

Yonit Sterba[1], Dawn Wahezi[2] and For the CARRA investigators[3]. [1]Montefiore Medical Center, Bronx, NY, [2]Children's Hospital at Montefiore, Bronx, NY, [3]Duke Children's Hospital, Durham, NC.

Background/Purpose: Hydroxychloroquine is an antimalarial agent commonly used in the treatment of rheumatologic diseases. Data on the use of HCQ in JDM is limited, primarily based on anecdotal experience and two small, retrospective reviews. As a result, there is no current consensus on the utility of HCQ in the management of JDM. Our objective was to investigate the use of HCQ in JDM using a large, national, multi-center registry.

Methods: Subjects meeting Bohan and Peter criteria for definite or probable JDM were enrolled into the CARRA registry between 2010 and 2013. Cross sectional analysis of data regarding demographics, disease characteristics, measures of disease activity, diagnostic assessments, medications and long term complications were examined. Bivariate analysis was performed evaluating the use of HCQ with clinical variables of interest. Variables with biologic relevance or statistically significant associations (p<0.25) were selected for inclusion into a multivariate logistic regression model examining independent predictors of HCQ use.

Results: Baseline information was available for 604 patients. Information on HCQ treatment was available for 565 patients (93.5%). 295 (52.2%) patients had current or prior treatment with HCQ and 270 (47.8%) patients had never been treated with HCQ. In bivariate analysis, an association was found between the use of HCQ and age at first rheumatology visit (p=0.02), disease duration (p<0.001), abnormal CHAQ (p=0.001), symmetric proximal muscle weakness (p=0.002), large joint arthritis (p=0.002), malar erythema (p=0.04) and calcinosis (p=0.012). In multivariate analysis,

patients with symmetrical proximal muscle weakness or an abnormal CHAQ score were less likely to be on HCQ therapy; whereas patients with any rash (malar erythema, Gottron's sign, heliotrope rash, V-sign or shawl sign), calcinosis or arthritis had a higher likelihood to be on current or prior HCQ therapy (Table 1).

Table 1. Multivariable model using logistic regression predicting use of HCQ (n=496)

	Odds ratio [95% Confidence interval]	p-value
Symmetrical muscle weakness	0.46 [0.28–0.74]	0.002
Abnormal CHAQ	0.66 [0.44–0.99]	0.044
Calcinosis	1.93 [1.08–3.45]	0.027
Rash	1.65 [1.11–2.46]	0.014
Arthritis	1.56 [1.05–2.31]	0.027

Conclusion: The CARRA registry represents one of the largest ongoing multi-center JDM registries. This data aids our understanding of which clinical characteristics may predict HCQ use in JDM. Prior evidence in other rheumatologic conditions suggests that HCQ improves arthritis and skin manifestations. As expected, patients with these characteristics were more likely to be on HCQ. Patients with muscle weakness and abnormal CHAQ were less likely to be on HCQ. We speculate these patients had a more severe disease course and likely treated with aggressive immunosuppression. Due to the design of this study as a cross-sectional analysis, we are unable to determine the causal association of these results. Further longitudinal data is needed to examine the benefits of HCQ in these patients.

Gaslini, Genova, Italy, [17]Istituto Giannina Gaslini, Genova, Italy, [18]NIEHS, NIH, Bethesda, MD, [19]Charles University, Prague, Czech Republic, [20]Istituto Giannina Gaslini, Genoa, Italy.

Background/Purpose: Preliminary definitions of improvement (DOIs) for juvenile dermatomyositis (JDM) combining IMACS or PRINTO core set activity measures (CSMs) have been used as a responder index in clinical trials. However, these DOIs defined only minimal clinical improvement and are in need of further validation.

Methods: Using natural history study data, JDM experts rated patient profiles containing IMACS or PRINTO CSMs and achieved consensus (≥ 70% agreement) in 98% (247 minimal, 174 moderate and 84 major improvement). Conjoint analysis was performed on forced-choice surveys (by using 1000Minds software) administered to myositis experts. Candidate DOIs based on changes in core set measures (CSMs) were generated as follows: A) 23 published DOIs were retested; B) 436 DOIs developed using expert survey and variations of published DOIs; C) 56 DOIs derived from logistic regression analysis; D) 6 DOIs derived from a conjoint analysis survey that yielded scores with different levels of improvement in different CSMs; E) 8 DOIs drafted by combining changes in each CSM with respective conjoint analysis weights; and F) 194 DOIs drafted by applying weights from conjoint analysis to the base DOIs. Relative and absolute % change DOIs were tested. The consensus patient profiles were then used to test DOIs for their validity, including sensitivity, specificity, kappa, OR and area under the curve (AUC). High performing DOIs were externally validated using Rituximab in Myositis (RIM) trial data (N=48) and PRINTO JDM (n=139) trials.

Results: The 14 highest performing candidate DOIs with AUC ≥ 0.90 in profile data for minimal, moderate and major improvement, and comparable results in the RIM trial, were discussed among 12 JDM experts for their performance characteristics and clinical face validity at a consensus conference using Nominal Group Technique (NGT). Many DOIs had significant discriminant validity in the PRINTO trial. A final ranking of the pediatric experts' top DOIs yielded 92% consensus for a conjoint analysis hybrid model DOI using absolute % change in CSMs with different cut points for minimal, moderate and major improvement (Table 1). NGT discussion with the pediatric and adult working groups yielded consensus (91% agreement) in use of this hybrid DOI for adult DM/PM and JDM.

Conclusion: A conjoint analysis-driven hybrid definition with a continuous score of improvement based on absolute % change in CSMs with different cut points for minimal, moderate and major improvement was selected by a data- and consensus-driven process as a final DOI to be used for JDM and adult DM/PM clinical trials. ACR and EULAR funding support was received for this project, and their approval will be sought for these as new criteria for clinical response.

1317

Anti-p155/140 Autoantibodies and Selected Features at Illness Onset Are Associated with a Chronic Course of Illness in the Juvenile Idiopathic Inflammatory Myopathies. G. Esther A. Habers[1], Adam M. Huber[2], Gulnara Mamyrova[3], Ira Targoff[4], Chantal Boonacker[5], Marco van Brussel[1], Frederick W. Miller[6], Lisa G. Rider[6] and Annet van Royen-Kerkhof[7]. [1]Child Development and Exercise Center, Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, Netherlands, [2]IWK Health Centre, Halifax, NS, [3]George Washington University, Washington, DC, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands, [6]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD, [7]University Medical Centre Utrecht - Wilhelmina Children's Hospital, Utrecht, Netherlands.

Background/Purpose: Three types of disease courses can be distinguished in patients with juvenile idiopathic inflammatory myopathies (JIIM), namely monocyclic (M), polycyclic (P), and chronic (C). This study explored the association of demographics, clinical onset features and myositis autoantibodies with disease course in a large JIIM cohort.

Methods: In the present study, we included 365 patients with JIIM (295 dermato-, 28 poly-, and 42 overlap myositis) which were enrolled into IRB-approved studies in the US and Canada and had a disease duration >2 years from diagnosis. Blood samples and physician questionnaires with demographics and clinical onset features were obtained. Myositis autoantibodies were determined by immunoprecipitation and blotting methods. Follow-up was performed through medical record review. The disease course classification was: M - no active disease and off medication within 2 years of diagnosis (n=88); P - disease recurrence after definite remission (n=86); and C - persistent disease or continuation of medication for >2 years (n=191). Parameters with $p<0.10$ in univariate analysis were analyzed by multinomial logistic regression.

Results: Factors significant only in univariate analysis were cuticular overgrowth (M < P and C), V- and/or shawl-sign rash (M and P < C), contractures (P < C and M), photosensitivity (M < C), dyspnea at rest (P < C), palpitations and/or syncope (M and C < P), geoclimactic zone, and anti-Ro autoantibodies (M < C). Abnormal aldolase was more frequent in P compared to M and C, but not included in multivariable analysis due to missing values. Two different multinomial logistic regression analyses with non-overlapping parameters were performed (see Table 1 for results). Myositis -specific and -associated autoantibodies were more frequent in P and C than in M, with the anti-p155/140 autoantibody as the most significant ($p<0.0001$). Documented infections within 6 months prior to illness onset were also more frequent in the P and C compared to M. P had less early illness signs and symptoms (=lower clinical symptom score) compared to M and C. A more severe illness onset was present in C compared to M and P. Compared to M, mucous membrane involvement was less frequent in C and distal weakness was less frequent in P and C. Weight loss was more frequent in C compared to P.

Conclusion: Myositis -specific and -associated autoantibodies (especially the anti-p155/140 autoantibodies) and selected features at illness onset were associated with a chronic course of illness in patients with JIIM. These findings suggest that certain predictors of poor prognoses can be identified that might influence treatment options at illness onset.

Illness Onset Features and Misdiagnosis in Juvenile Idiopathic Inflammatory Myopathies (JIIM) Differ Among Clinical and Autoantibody (Ab) Subgroups. Gulnara Mamyrova[1], Lan Wu[2], Adam Huber[3], Ira N. Targoff[4], Frederick W. Miller[2] and Lisa G. Rider[2]. [1]George Washington University, Washington, DC, [2]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD, [3]IWK Health Centre, Halifax, NS, [4]Veterans Affairs Medical Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: To evaluate features of JIIM clinical and Ab subgroups at illness onset.

Methods: Physician-completed questionnaires illness onset features were reviewed in 465 JIIM pts (381 juvenile dermatomyositis [JDM], 33 polymyositis, [JPM], and 51 JIIM associated with other autoimmune diseases [JCTM]) meeting probable or definite Bohan and Peter criteria. Myositis Abs were tested by standard immunopreciptation and blotting methods. Univariate analysis was performed using GraphPad Prism 5.0.

Results: The first weakness was proximal in all clinical and Ab subgroups (86–90%). Gottron's papules were most often the first rash in JDM and JCTM (48% and 47%), followed by heliotrope (45% and 29%), and malar rash (30% and 14%). Gottron's papules were also the first rash in 57% of pts with anti-p155/140, 50% of anti-Mi2, 40% of anti-MJ and 32% of pts with anti-ARS Abs ($P < 0.04$). Heliotrope was most often the first rash in pts with anti-MJ (52%) and anti-ARS (47%). Both Gottron's papules and heliotrope were present at diagnosis in 72% of JDM and 58% of JCTM pts. Gottron's papules or heliotrope alone were seen in 18% and 9% of JDM pts at diagnosis, yet 1.7% of JDM patients did not have either rash at diagnosis. 81% of pts with anti-p155/140 Abs had both Gottron's and heliotrope at diagnosis. Rash before weakness was seen in 54% of JDM and 74% of JCTM pts. Weakness before rash was seen in 23% of JDM and 14% of JCTM pts; 23% of JDM and 12% of JCTM pts developed rash and weakness simultaneously. Rash before weakness was observed in 73% of pts with anti-p155/140, 67% of anti-Mi2, 39% of anti-MJ, and 39% of anti-ARS Ab pts ($P <0.04$). Weakness before rash was observed in 33% of anti-ARS, 31% of anti-MJ, 17% of anti-Mi2 and 12% of anti-p155/140 pts ($P < 0.02$). All JIIM pts had a median delay to diagnosis of 4.1 mo and JCTM pts had delay of 7.1 mo ($P < 0.03$); pts with anti-p155/140 had a median delay of 4.8 mo, anti-ARS 6.6 mo, and anti-SRP Abs 2.0 mo between first symptom and diagnosis. The median time between rash and diagnosis was 2.5 mo in JDM, 6.1 mo in JCTM, 4.0 mo in anti-p155/140 and 1 mo in anti-ARS Ab groups ($P < 0.007$). Twenty-three percent of JIIM pts had one and 5.7% had ≥ 2 misdiagnoses. Common misdiagnoses included infections (9.6%), other autoimmune diseases (4.6%), musculoskeletal (2.4%) and dermatologic conditions (17.6%), neurologic diseases (1.5%), and psychologic disorders (0.7%). JPM and pts with anti-SRP Abs were often misdiagnosed with hepatitis (15.2–28.6%) and neurologic conditions (9.1%) including Guillain-Barre (3–14%). Pts with JDM and JCTM, including those with p155/140 and MJ Abs, were often misdiagnosed with other skin conditions (11–21%), including eczema (11–21%).

Conclusion: JIIM clinical and Ab groups vary in their type of rash and weakness and misdiagnosis at illness onset. Most present with rash before weakness, and with Gottron's papules first. Better recognition of these varied presentations of illness should enhance recognition of JIIM phenotypes and help decrease delay in diagnosis and therapy.

Safety of Rituximab in Treating Pediatric Rheumatologic Disease. Arunima Agarwal[1], Anusha Ramanathan[2] and Rhina Castillo[3]. [1]Children's Hospital of Los Angeles, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA, [3]Childrens Hospital Los Angeles, Los Angeles, CA.

Background/Purpose: Rituximab is a chimeric human/murine monoclonal antibody directed against the B cell specific antigen CD20. There is growing evidence that suggests Rituximab may also influence T cell immu-

nity and thus predispose patients to opportunistic infections by this mechanism as well. Rituximab use, both as monotherapy and in combination with other immunosuppressants, is increasing in the pediatric population. Data regarding infection associated with Rituximab is limited and inconsistent. The most concerning side effect is the development of progressive multifocal leukoencephalopathy (PML), a fatal condition which has been reported rarely with Rituximab use. This study seeks to report adverse events associated with Rituximab use in the pediatric rheumatologic population.

Methods: A retrospective chart review of 20 pediatric patients with rheumatologic disease followed at Children's Hospital Los Angeles between January 2007 and April 2014 was conducted. All patients received Rituximab and incidence of infection was assessed for a follow-up period of 6 months to 7 years following first Rituximab course.

Results: The majority of patients were female (55%) and Hispanic (70%), with 3 African American, 2 Caucasian and 1 Asian patient. The most common diagnoses were lupus (35%), dermatomyositis (30%), or overlap syndrome (20%). Sixty percent of patients received only one course of Rituximab and most (65%) received high dose glucocorticoids concurrently with their first course of Rituximab. Other immunosuppressants included methotrexate (55%), cyclophosphamide (CYC) (15%, with an average cumulative dose of 6g/m2), and anti-TNF therapy (15%). One patient each was on concurrent therapy with cyclosporine or azathioprine. There were 15 total infections in 9 patients during a mean follow up of 16.2 months (range 6 to 45 months) occurring on average 4.5 months (range 1 to 19 months) following Rituximab. Two infections (bacterial pneumonia and cellulitis) requiring hospitalization occurred in one patient who had received CYC as well. The remainder of infections were minor, 11 required outpatient antibiotics and 2 self-resolved. The majority of infections (87%) occurred in patients with lupus or an overlap syndrome. Only 1 patient developed prolonged hypogammaglobulinemia requiring supplemental IVIG. There were no cases of infusion related adverse events or PML in this cohort.

Conclusion: Overall the occurrence of significant adverse events following Rituximab was low in this pediatric cohort. Serious infections may be increased in those receiving combination therapy with CYC. Larger studies are needed to determine the attributable risk for infection from Rituximab alone versus that associated with underlying diagnosis or combination therapy. However, our results suggest that Rituximab use is safe and well-tolerated in a variety of pediatric rheumatologic conditions.

Analysis of Risk Factors for Thrombosis in Pediatric Patients with Systemic Lupus Erythematosus. Kyla D. Driest[1], Mollie S. Sturm[2], Sarah H. O'Brien[2], Charles H. Spencer[3] and Stacy P. Ardoin[4]. [1]OSU Pediatrics, Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Nationwide Childrens Hospital, Columbus, OH, [4]Ohio State University College of Medicine, Columbus, OH.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a higher thrombotic risk compared to the general population, and arterial and venous thromboses impart substantial morbidity and mortality. Few studies have focused on thrombotic risk within the pediatric SLE (pSLE) population. We sought to better characterize the risk factors for thrombosis in patients with pSLE utilizing the Childhood Arthritis & Rheumatology Research Alliance (CARRA) registry.

Methods: The CARRA registry contains 979 patients with pSLE. Pediatric SLE patients with a history of thrombosis were compared to those with no history of thrombosis. A history for thrombosis was defined as any patient within the SLE registry who had a history of arterial or venous thrombotic event as reported by the treating pediatric rheumatologist. For continuous variables, the Wilcoxon Mann-Whitney test was used to compare groups. In the case of categorical variables, univariate logistical regression was used to calculate odds ratios (OR). Patients with missing outcome data were excluded from analysis. Statistical Analysis System software 9.3 (SAS Institute Inc., Cary, NC, USA) was used to perform statistical analysis.

Results: Of the 979 patients in the registry, 974 had data recorded for thrombosis and were included in the analysis. The majority of these patients were female (82.4%), non-Hispanic (72.8%) and white (44.7%). Of the 974 patients, 24 (2.5%) had history of arterial thrombosis and 35 (3.6%) of venous thrombosis. Odds ratios for thrombosis were calculated for gender, ethnicity, BMI, race, Raynaud's phenomenon, vasculitis, avascular necrosis (AVN), renal disease, positive antiphospholipid antibody (APLA), thrombocytopenia, and hydroxychloroquine use. Utilizing a p value of < 0.05 as significant, the odds ratios of having a thrombotic event were significantly higher in patients with vasculitis [3.11, 95% CI: (1.60, 6.01)], history of AVN [3.08, 95% CI: (1.24, 7.67)], or APLA [3.03, 95% CI: (1.45, 6.36)]. Odds ratios for other variables were not statistically significant.

Conclusion: Our study of 974 patients with pSLE including 59 with a history of thrombotic event suggests that pSLE patients with a history of vasculitis, positive APLA, and AVN are at a greater risk for thrombotic events than those without. Odds ratios for gender, race, ethnicity, hydroxychloroquine use, renal disease, history of Raynaud's phenomenon, and thrombocytopenia were not found to be statistically significant within this subset of patients.

A Pilot Study to Evaluate the Feasibility of Conducting Juvenile Localized Scleroderma Comparative Effectiveness Treatment Studies. Suzanne C. Li[1], Kathryn S. Torok[2], Mara L Becker[3], Fatma Dedeoglu[4], Polly J. Ferguson[5], Robert C. Fuhlbrigge[6], Gloria C. Higgins[7], Sandy D. Hong[8], Maria F. Ibarra[3], Ronald M. Laxer[9], Thomas G. Mason II[10], Elena Pope[11], Marilynn G. Punaro[12], C. Egla Rabinovich[13], Katie G. Stewart[12] and Brian Feldman[11]. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [3]Children's Mercy Hospital, Kansas City, MO, [4]Boston Children's Hospital, Boston, MA, [5]University of Iowa Carver College of Medicine, Iowa City, IA, [6]Brigham and Women's Hospital, Boston, MA, [7]Nationwide Childrens Hosp, Columbus, OH, [8]U of Iowa Children's Hosp, Iowa City, IA, [9]The Hospital for Sick Children, University of Toronto, Toronto, ON, [10]Mayo Clinic Rochester, Rochester, MN, [11]The Hospital for Sick Children, Toronto, ON, [12]Texas Scottish Rite Hospital, Dallas, TX, [13]Duke Univ Med Ctr, Durham, NC.

Background/Purpose: Juvenile localized scleroderma (jLS) often causes severe morbidity in the developing child, including growth defects and disfigurement. Optimal therapy is not known. The LS Children's Arthritis and Rheumatology Research Alliance (CARRA) subgroup has been working towards improving long-term outcome for these patients. Towards this end, we have developed standardized treatment regimens based upon best available evidence and consensus methodology (consensus treatment plans, CTPs), and clinical tools to use in comparative effectiveness treatment studies. We are currently conducting a pilot study to evaluate the feasibility of conducting jLS comparative effectiveness treatment studies. Additional analyses will include evaluating performance characteristics of developed tools.

Methods: Fifteen physicians from 10 CARRA centers have been conducting a prospective observational cohort study of jLS subjects initiating systemic immunosuppressive treatment. Inclusion criteria include diagnosis of jLS by pediatric rheumatologist or dermatologist, and presence of active disease according to delineated activity criteria generated by the group. Exclusion criteria include treatment with methotrexate (MTX) within prior 3 months or corticosteroids (CS) within prior 2 weeks. Subjects were treated with one of three MTX-based CTPs (MTX alone, MTX with intravenous CS (IV CS), or MTX with oral CS), determined by treating physician, and evaluated at 6 visits over 1 year. At the start of the study, a workshop meeting was held to standardize evaluation.

Results: The target enrollment (50 subjects) was reached. All sites enrolled subjects, with enrollment taking approximately 23 months to complete following study initiation at the first site. Subjects were enrolled in all 3 CTPs, with half enrolled in MTX + IV CS CTP. Over 40% of subjects deviated from their initial treatment regimen, with persistent activity a frequent reason. Over 80% of subjects agreed to participate in the optional sample collection and banking sub study.

Study Subject Features	
Gender	35 Females (73%)
Age at study entry, median (range)	12.7 yr (3 – 21 yr)
Race	43 White
	1 Black
	2 Asian
	2 unknown
Ethnicity	39 non-Hispanic: 9 Hispanics
Treatment Regimen	12 (25.5%)
MTX alone	24 (51%)
MTX+intravenous CS	11 (23%)
MTX + oral CS	

Number who deviated from starting CTP among subjects who completed at least 2 study visits	15/34 (44%)
Agreed to participate in sample collection	38/46 (82%)
Completed 1 year of study visits	13 (26%)
Dropped out from study	2 (4%)

Conclusion: This is the first study to explore the feasibility of conducting comparative effectiveness treatment studies in jLS. We achieved our target enrollment of 50 subjects, with subjects enrolled in all 3 standardized treatment regimens. Biological samples have been collected from the majority of subjects, which will enable future translational studies. This study will enable us to evaluate and refine clinical tools needed for treatment studies based upon study data, and identify issues related to conducting jLS treatment studies. Further analyses of these data once completed will also include clinical effectiveness and tolerability of the 3 different treatment regimens in LS subjects.

Cardiopulmonary Involvement in Juvenile Systemic Sclerosis: Development of Recommendations for Screening and Investigation. Ivan Foeldvari[1], Clare Pain[2], Tamás Constantin[3], Eileen Baildam[4], Christian Beyer[5], Michael Blakley[6], Dana Nemkova[7] and Clarissa A Pilkington[8]. [1]Department of Pediatric Rheumatology, Hamburger Zentrum für Kinder und Jugendrheumatologie, Hamburg, Germany, [2]University Children′s Hospital, Liverpool, United Kingdom, [3]University Childrens Hospital, Budapest, Hungary, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]Pediatric Cardiology, Hamburg, Germany, [6]Indiana University School of Medicine and Riley Hospital for Children at IU Health, Indianapolis, IN, [7]Pedaitric Rheumatology, Prague, Czech Republic, [8]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom.

Background/Purpose: There are currently no agreed recommendations on how to investigate children for cardiopulmonary involvement in Juvenile Systemic Sclerosis (JSSc). The aim of screening is to detect disease early to facilitate early aggressive therapy and improve outcomes. Cardiopulmonary involvement is the leading cause of death in JSSc and cardiopulmonary involvement at diagnosis incurs a worse outcome (1). Most deaths occur early in the disease course (1, 2).

Objectives: To develop recommendations for investigation of cardiopulmonary in JSSc, based on paediatric evidence and where this was lacking, consensus expert agreement.

Methods: Members of the PRES Scleroderma Working Group were invited to participate; additionally a paediatric cardiologist were invited. A nominal group technique was used. 75% consensus was defined as agreement.

Results: Table 1 shows the recommendations for screening for cardiopulmonary and GI involvement at baseline and at defined time points from diagnosis. Other recommendations agreed by the group which are relevant at any stage in the disease course are as follows:

1. If there are any concerns or signs of pulmonary hypertension then right heart catheterisation should be undertaken.

2. Any child with exertional chest pain or abnormality on 24hr ECG should undergo exercise ECG (if old enough to comply).

3. Those with worsening PFTS or clinical deterioration should have HRCT thorax repeated sooner (particularly, FVC <70% or DLCO <80% or drop in values by 20% of baseline).

Recommendations are based on low grade evidence and in the most part from expert consensus opinion with extrapolation from adult studies

Table 1. Recommendations for screening for cardiopulmonary and GI involvement in JSSc at baseline and follow-up (75% consensus defined as agreement)

Cardiopulmonary	**Baseline**	
	All patients should undergo:	
	- BP	
	- 12 lead ECG	
	- 24 hour ECG	
	- ECHO with Doppler	
	- Cardiac MRI with gadolinium	
	- HRCT thorax	
	- PFT with DLCO	
	- 6MWT	
	Follow-up screening (for first 5 years from diagnosis)*	
	6 monthly	12 lead ECG
		ECHO with doppler
		6MWT
		PFT with DLCO
	Annual	24hr ECG
	At 3 years	Repeat HRCT

Conclusion: JSSc has a significant mortality particularly early on in the disease course. The objective of an aggressive screening program is to identify cardiopulmonary and GI involvement at a stage which may be amenable to treatment. The recommendations developed by this group aim to standardise care and improve outcomes in this rare disease.

1323

Gastrointestinal Involvement in Juvenile Systemic Sclerosis: Development of Recommendations for Screening and Investigation. Ivan Foeldvari[1], Clare Pain[2], Tamás Constantin[3], Eileen Baildam[4], Henning Lenhartz[5], Michael Blakley[6], Dana Nemkova[7] and Clarissa A Pilkington[8]. [1]Department of Pediatric Rheumatology, Hamburger Zentrum für Kinder und Jugendrheumatologie, Hamburg, Germany, [2]University Children′s Hospital, Liverpool, United Kingdom, [3]University Childrens Hospital, Budapest, Hungary, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]Wilhelmstift, Hamburg, Germany, [6]Indiana University School of Medicine and Riley Hospital for Children at IU Health, Indianapolis, IN, [7]Pedaitric Rheumatology, Prague, Czech Republic, [8]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom.

Background/Purpose: There are currently no agreed recommendations on how to investigate children for gastrointestinal (GI) involvement in Juvenile Systemic Sclerosis (JSSc). The aim of screening is to detect disease early to facilitate early aggressive therapy and improve outcomes. GI involvement at diagnosis incurs a worse outcome (1). Most deaths occur early in the disease course (1, 2).

Objectives: To develop recommendations for investigation of GI involvement in JSSc, based on paediatric evidence and where this was lacking, consensus expert agreement.

Methods: Members of the PRES Scleroderma Working Group were invited to participate; additionally a paediatric cardiologist and paediatric gastroenterologist were invited. A nominal group technique was used. 75% consensus was defined as agreement.

Results: Table 1 shows the recommendations for screening for GI involvement at baseline and at defined time points from diagnosis. Other recommendations agreed by the group which are relevant at any stage in the disease course are as follows:

1. Oesophageal dilatation should be assessed on any HRCT thorax performed.

2. If any concerns regarding bleeding such as chronic anaemia, consider upper GI endoscopy.

3. Any patient with nausea, vomiting, abdominal pain, bloating, diarrhoea or poor weight gain should undergo a hydrogen breath test for bacterial overgrowth.

4. Consider dietetic or gastroenterology review to assess nutritional intake and status.

5. Any patient with significant persistent GI symptoms including poor weight gain should be referred to a paediatric gastroenterologist.

Table 1. Recommendations for screening for GI involvement in JSSc at baseline and follow-up (75% consensus defined as agreement)

Gastrointestinal	**Baseline**	
	All patients should have a barium swallow to assess for dysmotility or stricture and 24 hour pH monitoring for GORD and progress to upper GI endoscopy if any abnormality detected	
	Follow-up	
	Every 3 years or sooner if worsening lung involvement and/or worsening GI symptoms	Upper GI endoscopy Barium swallow 24 hours pH monitoring

*screening guidelines are based on asymptomatic patients. However, children may need more frequent monitoring depending on clinical status and abnormalities detected on previous.

Conclusion: JSSc has a significant mortality particularly early on in the disease course. The objective of an aggressive screening program is to identify GI involvement at a stage which may be amenable to treatment. The recommendations developed by this group aim to standardise care and improve outcomes in this rare disease.

1324

Predictors of Disease Relapse in Juvenile Localized Scleroderma. Kathryn S. Torok[1], Katherine Kurzinski[2] and Christina Kelsey[3]. [1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]University of Pittsburgh/UPMC, Pittsburgh, PA.

Background/Purpose: Localized scleroderma (LS) is an autoimmune disease characterized by inflammation of the skin and underlying tissue leading tissue damage including atrophy, dyspigmentation, and fibrosis. More recent literature supports childhood-onset LS as a chronic relapsing condition which may cause significant physical and psychological disability into adulthood. Often, initial control of the disease is obtained using systemic therapy regimens including methotrexate (MTX) combined with a corticosteroid (CS). For unknown reasons, patients may exhibit a relapse of LS activity following a period of disease remission. This study was designed to evaluate the clinical characteristics of patients exhibiting LS flares after an initial disease response (inactive disease) to a standardized MTX and CS regimen with the goal of identifying predictors of LS activity relapse.

Methods: Pediatric-onset LS patients at a single scleroderma center with at least 2 years of follow-up and three or more clinical visits were included in the analysis. Clinical data, including patient demographics, laboratory parameters, and treatment regimens were evaluated. Flare of LS was defined as a relapse of disease activity from inactive disease, as determined by the modified Localized Scleroderma Severity Index (mLoSSI) and the Physician Global Assessment of Disease Activity. Chi-square and Fisher's Exact test were used to compare rates of categorical variables, and independent sample t-tests were used to compare continuous variables between groups ($\alpha < 0.05$).

Results: Seventy-seven patients were followed for greater than two years and 35 patients (46%) were found to experience LS flare after an initial response to MTX and CS. Demographic and laboratory data are summarized in Table 1. Patients that flared were significantly older at age of onset and were more likely to be ANA positive. Unexpectedly, flare patients were less likely to have an extracutaneous manifestation (ECM).

Table 1. Patient characteristics

	Flare (n=35)	No Flare (n=42)	p-value
Gender, n (%)			
Female	26 (74)	28 (62)	0.23
LS Subtype, n (%)			
Circumscribed Superficial	10 (29)	11 (26)	1
Circumscribed Deep	4 (11)	4 (10)	1
Generalized Morphea	6 (17)	4 (10)	0.5
Linear Trunk/Limb	20 (57)	22 (52)	0.81
Linear Face	3 (9)	9 (21)	0.21
Mixed Morphea	6 (17)	6 (14)	0.76
Pansclerotic Morphea	—	2 (4.5)	0.76
Eosinophilic Fasciitis	—	1 (2)	1
Age Onset (years), mean (SD)	**10.0 (3.9)**	**6.7 (3.7)**	**<0.001**
Time Onset to Diagnosis (mos), mean (SD)	13.8 (18.5)	22.4 (31.4)	0.16
Follow-up Duration (years), mean (SD)	4.3 (2.0)	4.9 (2.8)	0.34
Laboratory Evaluation, n (%)*			
ANA Positive	**18/30 (60)**	**8/33 (24)**	**<0.01**
ssDNA Positive	13/32 (41)	18/39 (46)	0.81
AHA Positive	9/31 (29)	17/39 (44)	0.23
CPK Elevated	10/34 (29)	8/37 (22)	0.59
Aldolase Elevated	13/32 (41)	9/34 (27)	0.21
Extracutaneous Manifestation (ECM), n (%)			
At least 1 ECM	**10 (28)**	**23 (55)**	**0.02**
Joint Contractures	8 (23)	15 (35)	0.22
Arthritis	2 (5.7)	1 (2.4)	. . .
Dental	. . .	4 (9.5)	. . .
Uveitis	. . .	1 (2.4)	. . .
Limb length discrepancy	1 (2.9)	4 (9.5)	0.37
Limb circumference difference	6 (17)	8 (19)	0.83

*Laboratory parameters not obtained for all patients.

Conclusion: Our assessment of a cohort of LS patients has shown older age at onset of disease and ANA positivity to be potential risk factors for reactivation of disease. ANA positivity may reflect a higher propensity for immune system reactivity after disease remission, and older onset might indicate that the immune system is more developed, hindering a sustained the effect of treatment. Surprisingly, the presence of joint contractures and other accepted measures of LS severity do not seem to represent an inherent risk of flare after disease remission. A possible explanation may be closer patient follow-up and adherence to medication regimen given physician's judgment of more severe disease when an ECM is present. We suggest that these risk factors, ANA positivity and older age of onset, serve as indicators for more extensive treatment or follow-up to avoid disease flare in at-risk LS patients.

G. Russo[14], Claudia Saad-Magalhaes[15], Natasa Toplak[16], Angelo Ravelli[17], Nico Wulffraat[18], Ivan Foeldvari[19] and Francesco Zulian[2]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University of Padua, Padua, Italy, [3]Pediatric Rheumatology Unit. Hospital Sant Joan de Déu. Universitat de Barcelona, Barcelona, Spain, [4]University Children′s Hospital, Ljubjana, Slovenia, [5]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [6]University of Adelaide, Adelaide, Australia, [7]University Childrens Hospital, Budapest, Hungary, [8]The Children's Hospital Westmead, Sydney, Australia, [9]Charles University, Prague, Czech Republic, [10]University Cerrahpasa Faculty of Medicine, Istanbul, Turkey, [11]Universidade F Rio De Janeiro, Rio De Janeiro, Brazil, [12]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [13]University Medical Centre Utrecht - Wilhelmina Children's Hospital, Utrecht, Netherlands, [14]Hospital de Pediatria Garrahan, Buenos Aires, Argentina, [15]Faculdade de Medicina de Botucatu, Botucatu, Brazil, [16]University Medical Center, Ljubliana, Slovenia, [17]Istituto Giannina Gaslini and University of Genova, Genova, Italy, [18]Wilhelmina Children's Hospital/ UMC Utrecht, Utrecht, Netherlands, [19]Department of Pediatric Rheumatology, Hamburger Zentrum für Kinder und Jugendrheumatologie, Hamburg, Germany.

Background/Purpose: Juvenile Localized Scleroderma (JLS) and Juvenile Systemic Sclerosis (JSSc) form a group of rare pediatric diseases that can lead to significant morbidity. Evidence-based guidelines are sparse and management is mostly based on physician's experience. In 2012, a European initiative called SHARE (Single Hub and Access point for pediatric Rheumatology in Europe) was launched to optimize and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. Purpose: to provide evidence based recommendations for diagnosis and treatment of Juvenile Scleroderma.

Methods: Evidence based recommendations were developed using the European League Against Rheumatism (EULAR) standard operating procedure. An expert committee was instituted, consisting of pediatric rheumatologists and experts in Juvenile Scleroderma. The expert committee defined search terms for the systematic literature review. Two independent experts scored articles for validity and level of evidence. Recommendations derived from the literature were evaluated by an online survey. Those with less than 80% agreement during the online survey were reformulated. Subsequently, all

recommendations were discussed at a consensus meeting using the nominal group technique. Recommendations were accepted if more than 80% agreement was reached.

Results: The literature search yielded 1550 articles for JLS and 8562 for JSSc, of which 52 and 37, respectively (25 for diagnosis and 27 for treatment of JLS, 21 for diagnosis and 16 for treatment of JSSc) were considered relevant and therefore scored for validity and level of evidence. 42 articles (15 for diagnosis and 14 for treatment of JLS, 6 for diagnosis and 7 for treatment of JSSc) were scored valid and used in the formulation of the recommendations. Eleven recommendations for diagnosis and 7 for treatment were suggested in the online survey on JLS. Ten recommendations for diagnosis and 6 for treatment were accepted with more than 80% agreement after the consensus meeting. Six recommendations for diagnosis and 5 for treatment were suggested in the online survey on JSSc. Six recommendations for diagnosis and 4 for treatment were accepted with more than 80% agreement after the consensus meeting. Topics covered for diagnosis and for treatment are showed in *Table 1*.

JLS

DIAGNOSIS		TREATMENT	
Disease activity assessment and response to therapy	*Clinical scores*	Topical treatment	*Medium-dose UVA1 phototherapy*
	Thermography		*Imiquimod*
	Ultrasounds	Systemic treatment	*Corticosteroids*
Disease severity and damage assessment	*Clinical scores*		*Metotrexate*
Extra-cutaneous involvement (articular, musculoskeletal, neurological, ophtalmological, dental, maxillo-facial)	*Clinical assessment*		*Mychophenolate mofetil*
	Musculoskeletal MRI		
	Brain MRI		

JSSc

DIAGNOSIS		TREATMENT	
Disease severity and damage assessment	*Clinical scores*	Skin and lung involvement	*Mychophenolate mofetil*
Skin involvement	*Clinical scores*	Vascular involvement	*Bosentan*
Lung involvement	*Pulmonary function tests*	Progressive and refractory disease	*Autologous stem-cell transplantation*
	Serological markers		
Raynaud's phenomenon	*Capillaroscopy*	Ineffective treatments	*D-penicillamine*

Conclusion: The SHARE initiative provides recommendations for diagnosis and treatment for Juvenile Scleroderma and thereby facilitates improvement and uniformity of care throughout Europe.

Transition of Care and Long-Term Outcomes of Juvenile Systemic Sclerosis during Adulthood: Results from a French Single-Center Case-Control Study. Francois-Xavier Mauvais[1], Brigitte Bader-Meunier[2], Alice Berezne[3], Guillaume Bussone[4], Christine Bodemer[5], Loïc Guillevin[6], Pierre Quartier[2] and Luc Mouthon[6]. [1]INSERM U1151 / CNRS 8253, PARIS, France, [2]IMAGINE Institute, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [3]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [4]Hopital Cochin, Paris, France, [5]Hôpital Necker-Enfants Malades, Paris, France, [6]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: To describe the transition of care from Pediatric to an adult Internal Medicine department and long-term outcomes of patients with juvenile-onset SSc.

Methods: Twenty patients with SSc diagnosed before the age of 17 and previously followed in Pediatric departments were included. The control group comprised 60 patients randomly selected from all patients with a SSc diagnosed after 18 years old, matching by sex and disease duration.

Results: In the juvenile-onset group, 16/20 (80%) patients were female and 11/20 (55%) presented a diffuse SSc. Mean age for diagnosis was 11.9 years (5.1–15.9). One patient had anti-centromere, 4/20 (20%) anti-Scl70 and 1/20 (5%) anti-U1RNP autoantibodies.

While juvenile-onset patients had a significantly higher incidence of calcinosis (9/20 (45%) vs 12/60 (20%); $p=0.04$), they had a lower incidence of interstitial lung disease (4/20 (20%) vs 32/60 (53.3%); $p=0.01$) compared to the adult-onset group.

At the time of last follow-up, mean disease duration was 14.2 ± 13.1 years. Survival rate was lower among the juvenile-onset group but this difference was not significant (17/20 (85%) vs 57/60 (95%); $p=0.16$). Bowel involvement had a significantly higher incidence (11/20 (55%) vs 6/60 (10%); $p<0.001$) in the juvenile-onset group as well as calcinosis (13/20 (65%) vs 15/20 (25%); $p<0.02$) compared to the adult-onset group. Juvenile-onset patients had received significantly more steroids $>$ 15mg/d (11/20 (55%) vs 7/60 (11.7%); $p<0.001$) and methotrexate (10/20 (50%) vs 8/60 (13.3%); $p=0.002$). No significant difference could be observed regarding biological parameters between the two groups.

Only one patient in the juvenile-onset group had a major impact on quality of life, with a significant delay in his education and a depressive syndrome. Factors associated with a poor prognosis in juvenile-onset SSc were lung fibrosis and pericarditis.

Conclusion: At the time of transition of care to adult structures, patients with juvenile-onset SSc present with important musculoskeletal damages and lower incidence of lung involvement than patients with adult-onset SSc.

Decreased CD3-CD16CD56+ Natural Killer Cell Counts Are Associated with Disease Activity in Children with Orbital Myositis. Melissa R. Bussey[1], Gabrielle A. Morgan[2], Maria C. Amoruso[2], Bahram Rahmani[3] and Lauren M. Pachman[4]. [1]Division of Rheumatology, Loyola University Medical Center, Maywood, IL, [2]Stanley Manne Children's Research Institute, affiliated with Ann & Robert H. Lurie Children's Hospital of Chicago, Cure JM Myositis Center, Chicago, IL, [3]Department of Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Orbital myositis (OM), an inflammatory disease affecting the extra-ocular muscles, typically presents in the third decade. It more commonly affects females and is extremely rare in children. Pediatric orbital inflammatory disorders account for 6–17% of the total orbital inflammatory disorders and OM specifically makes up about 8% of pediatric orbital inflammatory disease. Because of the rarity of pediatric OM, many questions remain unanswered and specific laboratory markers of disease activity have not yet been identified, often resulting in a protracted course. The objective of this study is to describe the course of OM in children and to identify potential reliable indicators of disease activity.

Methods: After obtaining IRB approval, a retrospective review was performed of all patients with a diagnosis of OM presenting between 2006 and 2012 to the Cure-JM Program of Excellence of The Ann and Robert H. Lurie Children's Hospital of Chicago. Duration of untreated disease (DUD) was defined as time, in months, from onset of first symptoms to the date of the first medication. Data for muscle enzymes, neopterin, and absolute level of CD3-CD56/16+ natural killer cells (NK) via flow cytometry were determined using standard methods in the Diagnostic Immunology Laboratory. In addition, frozen sera were tested for immunoglobulin G 4 (IgG4) levels.

Results: Of the 4 cases, 2 were female and all were Caucasian; the mean age of onset of the first symptom was 14.4 ± 1.2 years, and the mean DUD was 0.28 ± 0.26 months. One child was seen after diagnosis, treatment, and resolution of disease. At diagnosis/first visit of the 3 active children, muscle enzymes were tested and the means are as follows ($n=3$ except where noted): CPK: 97.3 ± 44.2, aldolase: 8.5 ± 2.8 ($n=2$), ALT: 13 ± 2.8 ($n=2$), AST: 21.3 ± 2.9, LDH: 176 ± 52.4. Their mean WBC was 10.4 ± 1.3 ($n=2$), mean ESR 6 ± 4, mean neopterin: 6.3 ± 0.14 ($n=2$); mean Von Willebrand Factor Antigen: 133 ± 14.1 ($n=2$). The mean for IgG4 was 87.7 ± 66 (normal range=8–89 mg/dl). The mean NK was 96.7 ± 28.7 at diagnosis/first visit of the 3 active subjects (lower limit of normal =138) which increased to normal range 163 ± 57.2 with resolution of active disease. Computed tomography studies with contrast document involvement of left superior oblique, right superior oblique, left medial rectus, left lateral rectus, and right lateral rectus muscles in the 4 children. Only 1 child had multiple orbital muscles involved concomitantly. Treatment was initiated with high dose intermittent pulse methylprednisolone supplemented by daily oral prednisone (0.5 mg/kg) on non-IV day as well as methotrexate ($n=2$) and other steroid-sparing agents. Three of the 4 children returned to normal baseline after treatment completion. The fourth child was followed in another part of the country.

Conclusion: OM does occur in children and disease activity was not associated with creatine kinase, aldolase, neopterin, sedimentation rate, or C reactive protein values, which typically remained within normal range. In contrast, initially decreased absolute NK trended toward normal ranges as the inflammation improved. We speculate that this lymphocyte subset may contribute to the inflammatory myopathy.

Modulation of Natural IgM-Autoantibodies to Oxidative Stress-Related Neo-Epitopes on Apoptotic Cells in Newborns of Mothers with Anti-Ro Autoimmunity. Caroline Grönwall[1], Robert M. Clancy[1], Lelise Getu[1], Don L. Siegel[2], Joanne Reed[1], Jill P. Buyon[1] and Gregg J. Silverman[1]. [1]New York University School of Medicine, New York, NY, [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Background/Purpose: At birth, the human immune system expresses substantial circulating levels of polymeric IgM that include autoantibodies to oxidation-associated epitopes on apoptotic cells. This study addressed whether the neonatal IgM-repertoire may be affected by exposure to anti-Ro/La IgG-autoantibodies of maternal origin, which in some offspring leads to development of neonatal lupus.

Methods: Levels of IgM-specificities were compared in 43 healthy adults, and in umbilical cord blood (CB) from 31 unaffected newborns of non-autoimmune mothers and 103 newborns of mothers from the Research Registry for Neonatal Lupus. All mothers enrolled in the Registry have IgG anti-Ro (Ro60 and/or Ro52). In this cohort, 56 fetuses developed cardiac neonatal lupus, 4 neonates had rash, while 40 were clinically unaffected. Sandwich ELISA used phosphorylcholine (PC16)-BSA, malondialdehyde (MDA)-BSA or Ro60, with anti-IgM detection.

Results: IgM-antibodies to oxidation-associated MDA-determinants were relatively more highly represented in control newborns compared to adults (IgM anti-MDA/total IgM 7.2±3.6 CB vs 1.0±0.6 adults) while the ratio IgM anti-PC/total IgM was lower (2.7±1.7 vs 10.7±5.6, $p<0.0001$). CB levels of IgM anti-MDA directly correlated with IgM binding to apoptotic cells. In neonates exposed to IgG anti-Ro, total IgM and IgM anti-Ro60 were significantly elevated compared to control neonates (41±39 RU/ml vs 27±18, $p=0.008$; 218±203 RU/ml vs 129±115 RU/ml, $p=0.003$, respectively). Similarly, the ratio of IgM anti-Ro60 was higher in these newborns compared to controls (8.6±9.6 vs 5.0±2.8, $p=0.001$). No correlation between IgM and IgG anti-Ro60 or RF IgM in CB could be detected. In contrast, the proportion of IgM anti-MDA was significantly lower in CB from neonates exposed to IgG anti-Ro60 mothers compared to controls (4.8±4.7 vs 7.2±3.6, $p=0.004$). Neither the development of heart block, nor the disease status of the mothers, was associated with differences in neonatal IgM levels.

Conclusion: These findings document the relative dominance in the neonate of specificities of IgM-autoantibodies to oxidation-associated neo-determinants associated with protective properties in other settings. These data suggest that early immune development of the natural IgM-repertoire may become imprinted by maternally transferred anti-Ro60 IgG-autoantibodies.

1329

Comparison of Clinical and Serological Features of Childhood Sjögren Syndrome Based on the Presence or Absence of Parotitis. Jay Mehta[1], Namrata Singh[2] and Scott Lieberman[3]. [1]Children's Hospital at Montefiore/Albert Einstein College of Medicine, Bronx, NY, [2]University of Iowa, Iowa City, IA, [3]University of Iowa Children's Hospital, Iowa City, IA.

Background/Purpose: Sjögren syndrome is a complex autoimmune disease that affects lacrimal and salivary glands with the potential to cause damage to other organs. Diagnosis of childhood Sjögren syndrome (cSS) is currently based on expert opinion due to the lack of child-specific diagnostic criteria. Children do not typically present with sicca symptoms characteristic of adult Sjögren syndrome. While they most commonly present with recurrent parotitis, some children present with other organ involvement in the absence of parotitis. The goal of this study was to compare clinical and serological profiles of cSS patients presenting with or without parotitis as a first step towards defining cSS diagnostic criteria.

Methods: We reviewed cSS cases from a single center as well as those in the published English literature with individual patient data. We collected available data on sicca symptoms, serologies (ANA, anti-SSA/B, RF), lacrimal and salivary gland function, imaging, and histopathology as well as extraglandular clinical features. For analyses of laboratory, serologic, imaging, pathology, and functional data, cases were excluded if specific data were not explicitly reported.

Results: We reviewed 26 cases of cSS diagnosed and followed at The Children's Hospital of Philadelphia and 196 cases in the literature that contained information on individual children. Parotitis status was clearly indicated for 162 cases which were considered further. Parotitis was a main feature in presentation in 131 (81%) cases. Comparing the cases with parotitis ($n=131$) to those without ($n=31$), there were no differences in sex (78% and 87% female, respectively, $P=0.448$) or positive serologies: 87% and 90% ANA+, respectively ($P=0.768$), 72% and 61% RF+ ($P=0.405$), 86% and 90% SSA+ ($P=0.761$), 69% and 64% SSB+ ($P=0.649$). 53% of children had sicca symptoms regardless of parotitis status ($P=1$). Among extraglandular features, children without parotitis developed more joint symptoms (58% vs. 33%, $P=0.012$), CNS symptoms (32% vs. 7%, $P=0.0003$), Raynaud Phenomenon (16% vs. 5%, $P=0.048$), and renal tubular acidosis (16% vs. 4%, $P=0.032$). Non-significant extraglandular features included fever, rash, lymphadenopathy, fatigue, other renal manifestations, myositis, vaginal dryness, serositis, and transaminitis.

Conclusion: While the majority of childhood Sjögren syndrome (cSS) patients have parotitis, a significant percentage do not. Those who do not differ in their clinical features, with a significantly higher incidence of joint symptoms, RP, renal tubular acidosis, neuromyelitis optica, and all CNS manifestations. A large majority of all cSS patients have positive ANA and/or anti-SSA/B, and the serologic profiles do not significantly differ based on parotitis status. Thus, testing for ANA and anti-SSA/B is warranted in the diagnostic workup of any child suspected of having Sjögren syndrome, especially in patients who do not present with parotitis. Given the selection bias inherent in this approach, development of cSS-specific diagnostic criteria are needed for future prospective studies to better characterize the prognosis and optimal therapies for this potentially devastating disease.

The Efficacy of a Multidisciplinary Intervention Strategy for the Treatment of Benign Joint Hypermobility Syndrome (BJHS) in Childhood. a Randomised, Single Centre Parallel Group Trial. Peter Bale[1], Vicky Easton[2], Holly Bacon[2], Emma Jerman[3], Kate Armon[2] and Alex J Macgregor[2]. [1]University of East Anglia, Norwich, United Kingdom, [2]Norfolk and Norwich University Hospital, Norwich, United Kingdom, [3]Occupational Therapist, Norwich, United Kingdom.

Background/Purpose: Joint hypermobility is common in childhood and can be associated with musculoskeletal pain and dysfunction. Current management is delivered by a multidisciplinary team but evidence of efficacy is limited. This clinical trial aimed to determine whether a structured multidisciplinary intervention resulted in improved clinical outcomes compared with standard care.

Methods: A prospective randomised, single centre parallel group trial comparing an 8-week individualised multidisciplinary intervention programme with current standard management (advice and a physiotherapy appointment). Children and young people (CYP) were assessed for pain, function, coordination and strength at baseline, 3 and 12 months.

Results: 119 CYP, aged 5 to 16 years, with symptomatic hypermobility were randomised to receive targeted multidisciplinary intervention (I) ($n=59$) or standard management (S) ($n=60$). Of these, 105 were followed to 12-months. There was a significant improvement in child and parent reported pain, coordination and strength. However, no added benefit could be shown from the intervention (Table 1). The number of CYP showing significant pain reduction (>=40%) was 27 (50.0%) (I) vs 21 (41.1%) (S). Those pain free at 12 months were 29 (56.9%) (I) vs 20 (45.5%) (S). The response was independent of the degree of hypermobility.

Conclusion: This is the first RCT to compare a structured multidisciplinary intervention with standard care in symptomatic childhood hypermobility. The study demonstrates significant improvement among subjects but no additional benefit from targeted intervention. The findings emphasise the benefit of information and physiotherapy, but highlight the difficulty in demonstrating subtle benefit from specific interventions without better tools for case definition and outcomes assessment.

Table 1. The rate of change in primary and secondary outcomes over 12 month follow-up period, this data includes analysis from multilevel modelling

Outcome variable	Baseline score (SD)	Rate of change over 12 months (95% CI)			
		Intervention group		Control group	
Child pain assessment (Wong-Baker Faces pain scale), (0–5, zero is the best) n=103	2.31 (1.55)	−1.42	(−1.78 to −1.06)	−1.31	(−1.75 to −0.85)
Parent observed pain assessment (0–100 VAS, zero is the best) n=105	35.90 (26.46)	−6.09	(12.90 to 0.73)	−6.22	(−13.62 to 1.18)
Child health assessment questionnaire (CHAQ) (0–3, zero is the best) n=104	0.82 (0.63)	+0.02	(−0.12 to 0.16)	−0.03	(−0.13 to 0.64)
Child health 9 dimensional utility (CHU9D) (0–1, zero is the worst) n=104	0.85 (0.11)	+0.02	(−0.01 to 0.04)	+0.002	(−0.02 to 0.03)
Movement assessment battery for children (M-ABC) (0–100, zero is the worst) n =104	34.56 (28.61)	+2.60	(−2.92 to 8.11)	+8.51	(3.17 to 13.86)
Grip Strength (Dynamometer) n= 104	57.29 (28.30)	+4.55	(0.16 to 8.94)	+6.75	(2.85 to 10.66)

Factors Associated with Pain in Children with Hypermobility - a Pilot Study. Susan Maillard[1], Clarissa Pilkington[1], Richard Howard[1], Christine Liossi[1] and Suellen Walker[2]. [1]Great Ormond Street Hospital NHS Foundation Trust for Children, London, United Kingdom, [2]Great Ormond Street Hospital NHS Foundation Trust for Children, London, United Kingdom.

Background/Purpose: To explore the relationships between the degree of musculoskeletal pain, pain associated with disability and quality of life and how they are affected by having hypermobile joints.

It is now recognised that the symptoms that are common in young people with hypermobile joints are not necessarily linked to the range of movement presented and that the variation between young people has a very biopsychosocial complexity to it.

Methods: Young people aged between 8–14 were recruited from the paediatric rheumatology based Non-Inflammatory Musculoskeletal Pain Clinic at Great Ormond Street Hospital over a 12 month period. They were assessed using biomechanical measures (muscle strength and degree of hypermobility), sensory processing using Quantitative Sensory Testing and psychological measures of anxiety, depression and pain coping styles using validated questions. Full Ethics approval was granted.

Results: 30 children were recruited (18 female: 12 male); mean age 11.08 with 77% being Caucasian. The mean Beighton score was 6.79/9. All patients reported pain mainly affecting lower limbs with an average score of 49/100 VAS. Degree of hypermobility did not have any impact. Reduced muscle strength was associated with increased pain and reduced quality of life. Other measures were compared to the norms for healthy children. Children with hypermobility appeared to demonstrate increased depression, negative mood, anhedonia and increased anxiety. They demonstrated reduced quality of life specifically with school, emotional well being, physical health and psychosocially. The subjects also had reduced sensitivity to touch including hot and cold.

Conclusion: The pain experienced by children with hypermobile joints is complex and includes biomechanical, sensory, psychological and social factors. This pilot study is planned to be expanded into a multi-centred project depending upon funding.

1332

From Social Support to Information Sharing, How Are Persons with Rheumatoid Arthritis Using Disease-Specific Facebook Communities? a Content Analysis. Cheryl Crow and Kristin Jones. Samuel Merritt University, Oakland, CA.

Background/Purpose: High perceived social support is associated with better quality of life and lower rates of depression for persons with rheumatoid arthritis (Minnock, et al 2003 and Zyrianova, et al, 2006), yet pain, fatigue and the invisible nature of the disease can lead to social isolation. Disease-specific Facebook communities have become thriving, accessible platforms for information sharing and social support. However, little is understood about the content of patient engagement on this medium.

Methods: The 4 largest patient-driven Facebook community pages devoted to rheumatoid arthritis were identified. Text from 10 sequential "wall posts" from May-June 2013 by members each community and ensuing discussion posts were thematically coded and aggregated into a database. Multiple codes were allowed for each post. Members self-identified as persons with rheumatoid arthritis, loved ones, caregivers, or did not specify. Providing advice, sharing a personal story and providing support were predominant themes. Content coded as "providing advice" and "personal story" was further categorized based on areas of occupation according to the Occupational Therapy Practice Framework. Patient-provider interactions were coded under "Health Management and Maintenance" and then further sub-categorized to be of relevance to rheumatology professionals.

Results: 1066 posts were thematically coded. In 73% of posts, information was provided (44% of which involved a personal story, 29% of which involved advice). In 20% of posts, support was provided. Instrumental activities of daily living (such as home, medical and financial management) were the most frequently discussed topics. Health management was the most frequently discussed instrumental activity of daily living (which included pain management, medication management, nutrition and fitness, and patient-provider interactions).

Conclusion: Participants primarily use rheumatoid arthritis-specific Facebook pages to share stories, advice and support about health management and maintenance. While this medium allows for many potential positive effects such as increased social support and the sharing of effective daily living strategies, potential drawbacks include frequent medical advice given by individuals with unknown qualifications. It would behoove healthcare professionals to understand and address the role of this medium in social participation for their clients.

Bridging the Social Support Needs Gap for African American Women with Systemic Lupus Erythematosus through the Chronic Disease Self-Management Program. Charmayne M. Dunlop-Thomas[1], Hannah Cooper[2], Terrika Barham[1] and Cristina M. Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Emory Unversity, Atlanta, GA.

Background/Purpose: Social support is instrumental in the mental and physical well-being of people with systemic lupus erythematosus (SLE). Research has demonstrated that strengthening social ties can potentially reduce the negative influences of biology, genetics and environment. For instance, positive social integration has been found to be associated with both reduced mortality and improved health outcomes in people with SLE. This study assessed the social support needs among a socioeconomically disadvantaged cohort of African American women with SLE and investigated the ways in which a low-cost high-impact chronic disease self-management program (CDSMP) met these needs.

Methods: Participants were validated SLE patients receiving care at a lupus clinic at a public hospital. Qualitative data were gathered via focus groups with 27 of the 45 participants who completed the CDSMP, and with one-on-one interviews with two CDSMP leaders. The purport of focus groups and interviews was to gain insight into the acceptability of the CDSMP and the relevance and usefulness of its components. In addition, we surveyed

participants regarding the number of close relatives and friends, and CDSMP satisfaction.

Thematic analysis methods were used to analyze qualitative data; codes were developed using the data and the study's theoretical framework, including Cohen's definitions of social relationships and resources. Descriptive statistics were used to analyze survey data. Data sources and methodologies were triangulated.

Results: Six key themes emerged that depicted the types of social support needs: mental health (stress, depression, coping), personal empowerment (motivation), person-centered (care, "self-love"), interpersonal relationships, communication, and physical health (exercise, nutrition, pain management, stress). Survey data showed an average CDSMP satisfaction score of 4.8 (range 4 [agree] to 5 [strongly agree]). The most frequent memorable program opportunities were learning, personal support, and interpersonal interactions, respectively. There was no significant change in the numbers of close relatives and friends before and after the program. The emotion- and problem-focused channels of the CDSMP offered the supportive resources to satisfy participant needs. The data and methodological triangulation demonstrated a consistency across data sources and approaches.

Conclusion: This qualitative study provided a greater understanding of the role of social support among African American women with SLE and the ways in which the CDSMP might help develop, enhance and utilize supportive resources. Healthy social relationships were found to have significant impact in SLE women's ability to cope with stress and self-manage this disease. The influences of stress were revealed in both the mental health and physical health themes. The CDSMP offered the resources needed to enhance resilience, healthy behaviors, and overall well-being.

Social Support and Suicidal Ideation in Systemic Lupus Erythematosus: Georgians Organized Against Lupus Cohort. Charmayne M. Dunlop-Thomas[1], Gaobin Bao[1], S. Sam Lim[2] and Cristina M. Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Division of Rheumatology, Atlanta, GA.

Background/Purpose: Social support (SS) is instrumental in the mental and physical well-being of people with systemic lupus erythematosus (SLE). Moreover, SS contributes to overall health by providing a buffer from the adverse effects of stress. This is especially salient for people with SLE who may experience a wide-range of physical and psychological disease stressors. These stressors combined with other risk factors can contribute to suicidal ideation (SI). We examined the impact of perceived social support on suicidal ideation in SLE patients from the Georgians Organized Against Lupus (GOAL) Cohort.

Methods: We examined cross-sectional data from the GOAL Cohort, a large population-based cohort of validated SLE patients from metropolitan Atlanta, Georgia. GOAL participants responded to a variety of validated self-administered tools on health outcomes. The Systemic Lupus Activity Questionnaire assessed disease activity. The Patient Health Questionnaire-9 assessed depression severity, including the presence and duration of SI during the preceding two weeks. The emotional support question from the Behavioral Risk Factor Surveillance System assessed the perceived adequateness of SS received. Those who responded positively for SI were further contacted, provided with depression management resources, and probed for current SS resources. Logistic regression was used to examine the factors associated with SI.

Results: Of 600 SLE participants studied (93.3% women, mean age 48.8 [SD 12.8], 78.3% Black, mean disease duration 16 years [SD 9.6], and 68% uninsured), the average PHQ-9 score was 7.8 (SD 6.2), indicating mild to moderate depression. SI was present in 67 (11%) of GOAL participants. Significant differences were found in SS received, disease activity and poverty level between participants with and without SI.

Among the 67 with SI, only 23.4% reported visiting a psychologist, psychiatrist, or mental health counselor during the past 12 months. Thirty-one with SI were contacted. Many depended on family, friends or support groups (35%), or pastors, counselors, or physicians (25%) for SS. Moreover, 40% reported having no SS resource.

Conclusion: In a population-based cohort with large numbers of minorities and uninsured, depression was highly prevalent, with a significant proportion contemplating suicide. After controlling for other risk factors, such as socio-demographics and disease status, those with perceived inadequate social support, living in poverty, or with greater disease activity were at higher risk for SI. Further development and recognition of SS resources to which SLE patients can be referred are warranted, especially in socioeconomically disadvantaged communities.

Factors Associated with Suicidal Ideation in SLE

	Univariable		Multivariable	
Characteristics	**Odds Ratio**	**P Value**	**Odds Ratio**	**P Value**

Early Birds Versus Night Owls: Morning/Evening Preference and Its Association with Sleep Problems, Fatigue, and Emotional Well-Being Among RA Patients. Alyssa Wohlfahrt[1], Jing Cui[2], Michelle A. Frits[1], Christine K. Iannaccone[1], Jonathan S. Coblyn[1], Michael E. Weinblatt[1], Nancy A. Shadick[3] and Yvonne C. Lee[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Brigham and Women's Hospital/Harvard University, Cambridge, MA.

Background/Purpose: Over 60% of rheumatoid arthritis (RA) patients report sleep problems. Previous studies suggest that chronotype (the preferred time of day when individuals are active and alert), sleep problems, pain and emotional well-being are intimately linked. In the normal population, evening chronotype (preference for activity in the evenings) is associated with poor sleep, pain, and depression. This study examines the association between chronotypes and measures of sleep, pain and emotional well-being among RA patients with sleep problems.

Methods: Cross-sectional data were analyzed from 191 RA patients who participated in a substudy on sleep and morning/evening preference, within a large RA registry. Inclusion criteria included RA patients with sleep problems (Medical Outcomes Study (MOS) Sleep Problems Index II score > 35). Between March and June 2012, subjects were mailed the Horne-Ostberg Morningness-Eveningness Questionnaire (MEQ). The Multidimensional Health Assessment Questionnaire (MDHAQ), the 5-item Mental Health Index (MHI-5) and the MOS Sleep Scale were completed during the subjects' annual study visit. Multivariable linear regression models, adjusted for age, sex, serology, and disease activity (DAS28-CRP), were used to determine the association between chronotype and sleep problems, pain and emotional well-being. Scores for morning and intermediate chronotypes were compared to scores for evening chronotypes.

Results: Mean age was 61.0 ± 11.3 years. 162 (84.8%) were female. Mean DAS28-CRP was 2.90 ± 1.29. 43 (22.5%) exhibited a morning preference. 67 (35.1%) exhibited an evening preference, and 81 (42.4%) were intermediate chronotypes. Evening chronotypes reported significantly longer sleep duration (6.8 hours vs. 6.1 hours, $p = 0.01$) than intermediate chronotypes (Table). Although not statistically significant, evening chronotypes reported the lowest sleep adequacy scores (34.5 vs. 37.1 for intermediate and 41.9 for morning chronotypes) and the highest somnolence scores (34.4 vs. 31.8 for intermediate and 28.9 for morning chronotypes). Evening chronotypes also had the lowest mean scores on the MHI-5 (69.3 vs. 71.6 for

intermediate and 77.3 for morning chronotypes). Both morning and evening chronotypes had similar scores on the MOS Sleep Disturbance Scale (45.0 versus 45.8), MDHAQ Fatigue Scale (53.6 vs. 53.0) and MDHAQ Pain Scale (40.6 vs. 37.5).

Conclusion: In contrast to the general population, RA patients with an evening preference did not report worse emotional health or higher pain and fatigue, compared to intermediate or morning chronotypes. RA patients with evening chronotypes did report sleeping more hours than subjects with morning or intermediate chronotypes, despite similar sleep adequacy scores. Additional studies are needed to determine whether morning/evening preference can be used to identify subgroups of RA patients at increased risk for sleep problems. Table. Adjusted mean values for sleep, fatigue, pain and emotional well-being among RA patients with clinically significant sleep problems.

Clinical Characteristic	Morning* (N = 43)	Intermediate* (N = 81)	Evening 71.6 (p=0.51)
Sleep Quantity (hours)	6.4 (p=0.26)	6.1 (p=0.01)	6.8
Sleep Adequacy (0-100 scale, higher = better sleep adequacy)	41.9 (p=0.11)	37.1 (p=0.49)	34.5
Somnolence Scale (0-100 scale, higher = more somnolence)	28.9 (p=0.25)	31.8 (p=0.51)	34.4
Sleep Disturbance Scale (0-100 scale, higher = more disturbance)	45.0 (p=0.86)	48.5 (p=0.52)	45.8
MDHAQ Fatigue Scale (0-100 scale, higher = more fatigue)	53.6 (p=0.93)	52.2 (p=0.87)	53.0
MDHAQ Pain Scale (0-100 scale, higher = more pain)	40.6 (p=0.60)	39.7 (p=0.65)	37.5
Mental Health Index - 5 (0-100 scale, higher = better emotional well-being)	77.3 (p=0.07)	71.6 (p=0.51)	69.3

*P values are for comparison between morning chronotypes and evening chronotypes and the comparison between intermediate chronotypes and evening chronotypes.

Associations of Physical and Mental Factors with Outcome Expectations for Exercise in a Clinical Trial. Shaoyu Chang, Lori Lyn Price, Jeffrey Driban, William F. Harvey and Chenchen Wrang. Tufts Medical Center, Boston, MA.

Background/Purpose: In exercise intervention trials, higher outcome expectancy can predict stronger adherence. Such expectancy is known to be associated with gender, age, marital status, physical and mental health, and self-efficacy. However, it remains unclear whether specific disease conditions may help discriminate high expectancy individuals from those with moderate expectancy when screening participants for clinical trials. This study aimed to explore whether physical and mental health factors are associated with outcome expectations for exercise among patients with knee osteoarthritis (KOA) participating a large clinical trial.

Methods: We conducted a secondary analysis of baseline data from a randomized clinical trial comparing physical therapy and Tai Chi among individuals with KOA defined by the American College of Rheumatology criteria. We assessed expectancy for exercise with a 9-item Outcome Expectations for Exercise (OES) questionnaire, which utilizes a 5-point scale where a higher value indicates stronger expectation for a positive outcome. Participants reported the degree of pain and physical function through the WOMAC questionnaire. They also reported their confidence in coping with chronic pain through the Chronic Pain Self-Efficacy Scale (CPSS). A single reader scored radiographs for KL grades. We assessed participants' mental status with the Beck II scale and PROMIS anxiety inventory.

OES was analyzed as a binary variable (<4 versus ≥ 4). The physical and psychological parameters were analyzed as tertiles. Separate logistic regression models were performed to evaluate the relationship between OES and each of the physical and psychological parameters, controlled for age, gender, and BMI. Statistical significance was set at $p<0.05$.

Results: The 282 participants in the trial were 69% female; 51% white and 35% African American; aged 59.7±10.4 years (mean ± SD); and 51% with a low KL score (0–2), 22% with a moderate KL score (3), and 27% with a high KL score (4). Table 1 shows the odds ratio of higher OES for the six physical and psychological parameters after adjustment for age, gender, and BMI. We found that Beck II score and self-efficacy were significantly associated with OES.

Conclusion: The participants with worse depression symptoms and lower confidence in coping chronic pain tended to have lower outcome expectations. We observed trends that more severe self-reported symptoms and worse radiographic KOA severity were associated with higher outcome expectancy, although the statistical tests failed to reach significance. Such relationship may be confirmed by a larger sample size. Our results showed that in the clinical trials settings, high outcome expectancy populations may be identified through physical and psychological measurements, though further research is needed to determine their predictive ability.

Table 1. Odds ratios for high outcome expectations (OES ≥4) by physical and psychological parameters

Variable	Tertile	OR (95% CI)	Global p-value	p-value
WOMAC Pain	Best	Reference	0.2328

Mindfulness Is Associated with Symptom Severity and Pain Impact in Patients with Fibromyalgia. Emily Wolcott[1], William F. Harvey[1], Lori Lyn Price[1], Jeffrey B. Driban[1], Nani Morgan[2], Lucas Morgan[1] and Chenchen Wang[1]. [1]Tufts Medical Center, Boston, MA, [2]University of Hawaii, Honolulu, HI.

Background/Purpose: Mindfulness is attention to and awareness of present experiences (e.g. physical sensations, emotions, thoughts) in a nonjudgmental way. Initial evidence suggests that increased mindfulness may be associated with less pain intensity and catastrophizing among some people with chronic pain. However, this has not been confirmed among people with fibromyalgia. We evaluated whether greater mindfulness is associated with less pain and severity of associated symptoms in people with fibromyalgia.

Methods: We performed a secondary analysis of baseline data from a randomized clinical trial comparing Tai Chi to aerobic exercise in fibromyalgia patients as defined by the ACR criteria. At their baseline evaluation, subjects completed the Five Facet Mindfulness Questionnaire (FFMQ), a 39-item, self-report questionnaire that measures five facets of mindfulness: observing, describing, acting with awareness, non-judging, and non-reacting to inner experience. Higher scores in each facet indicate higher levels of mindfulness. Subjects also completed validated symptom measures including the PROMIS Pain Impact Short Form (PROMIS pain), Symptom Severity Scale, and the revised Fibromyalgia Impact Questionnaire (FIQR).We calculated Pearson's correlation coefficients to assess associations between mindfulness and measures of fibromyalgia pain impact and symptom severity. We determined an overall mindfulness score by calculating a mean of the five facets for each participant. We also completed a multivariate regression analysis to control for age, gender, body mass index, and education.

Results: Our analysis included data from rounds 1–4 (160 participants) with a mean age of 51.9 (SD=12.2) years; 92% women, mean BMI 29.5 kg/m^2, and 83% completed at least some college. Higher global mindfulness scores were associated with lower symptom severity and pain intensity as measured by the PROMIS Pain, Symptom Severity, and FIQR (see table). These relationships were also significant for most of the sub-facets of mindfulness with the exceptions of observing and non-reacting. Mindfulness

remained independently associated with PROMIS pain, Symptom Severity, and FIQR after adjusting for confounders.

Conclusion: Our results suggest that greater mindfulness is associated with less pain impact and severity of associated symptoms in people with fibromyalgia. Thus, mindfulness-based interventions may have the potential to improve the way those with fibromyalgia relate to their symptoms, by increasing non-judgmental acceptance of their experience, resulting in a reduction of their perception of pain intensity. Longitudinal studies are in progress to assess whether the cultivation of mindfulness alters the severity and prevalence of associated symptoms and experience of pain in people with fibromyalgia amongst those with other chronic pain disorders.

Table 1: Association between the Facets of Mindfulness and Measures of Symptom Severity and Pain Impact

	Correlations with Fibromyalgia Pain Impact and Severity		
FFMQ Variable (range; m±sd)	**PROMIS Pain r (p-value)**	**Symptom Severity r (p-value)**	**FIQR r (p-value)**

Correlates of Body Image Dissatisfaction in Patients with Limited and Diffuse Systemic Sclerosis. Rina S. Fox[1], Sarah D. Mills[1], Shadi Gholizadeh[1], Erin L. Merz[1], Scott C. Roesch[2], Philip J. Clements[3], Suzanne Kafaja[3], Dinesh Khanna[4], Daniel E. Furst[3] and Vanessa L. Malcarne[2]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]San Diego State University, San Diego, CA, [3]University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [4]University of Michigan Health System, Ann Arbor, MI.

Background/Purpose: Little research has evaluated body image dissatisfaction (BID) in Systemic Sclerosis (SSc). What has been conducted shows that BID is common and associated with worse psychosocial functioning. Additionally, age, upper-body telangiectasias, fingertip-to-palm distance, and facial skin involvement have been shown to be associated with Dissatisfaction with Appearance and Social Discomfort, two components of BID. However, it remains unclear if these factors relate to BID in the same way across disease classification (i.e., limited versus diffuse disease). Because limited and diffuse patients may have very different physical disease manifestations, the current study aimed to determine if sociodemographic and medical correlates of BID differed for patients with limited versus diffuse SSc, and identify which variables related to the two components of BID for each disease classification.

Methods: Participants were adults participating in the UCLA Scleroderma Quality of Life Study with rheumatologist-diagnosed limited (n = 101) or diffuse (n = 82) SSc. The Brief-Satisfaction with Appearance Scale (Brief-SWAP), which is comprised of two subscales measuring Dissatisfaction with Appearance and Social Discomfort, evaluated BID. The present analysis 1) examined if the relationships of sociodemographic (i.e., age, gender, race, education, and marital status) and medical (i.e., disease duration, presence of telangiectasis, presence of hyper/hypo-pigmentation, and facial, hand/finger, forearm, and leg/foot skin involvement) variables to the Brief-SWAP subscales were equivalent for limited and diffuse SSc, and 2) identified which of these variables were associated with each of the two Brief-SWAP subscales. Structural Equation Modeling evaluated both of these research questions. Both statistical and practical indicators of model fit were considered.

Results: There were similarities and differences in how sociodemographic and medical variables related to BID for limited versus diffuse SSc (S-Bχ^2 [143] = 181.42, p =. 02; RMSEA =. 06, CFI =. 91, SRMR =. 06). Greater Dissatisfaction with Appearance was associated with younger age (b = -.02, SD =. 01) and being unmarried (b = -.64, SE =. 30) for limited patients, and with younger age (b = -.02, SE =. 01) and increased finger/hand skin involvement (b =. 69, SE =. 15) for diffuse patients (ps <. 05). Greater Social Discomfort was associated with younger age (b = -.02, SE =. 01) and being unmarried (b = -.46, SE =. 22) for both subtypes (ps <. 05).

Conclusion: Both sociodemographic (i.e., age, marital status) and medical (i.e., finger/hand skin involvement) variables were related to BID. This is consistent with prior research and underscores the complex nature of BID in SSc. The present analysis suggests that young, unmarried patients may be at greatest risk for BID across disease subtypes. However, these factors may be more important for patients with limited disease, and finger/hand skin involvement may also be important for patients with diffuse disease. These findings can inform development of optimal, targeted interventions to diminish BID in SSc.

Is Psychological Status Related to Symptom Experience in Behçet's Syndrome? Robert Moots[1] and Sophie Campbell[2]. [1]University of Liverpool, Liverpool, United Kingdom, [2]Aintree University Hospital, Liverpool, United Kingdom.

Background/Purpose: Little is known about the impact of Behçet's Syndrome (BS) within the UK. The recent establishment of National Centres of Excellence now allows a systematic and holistic investigation of both physical and psychological effects of BS. This study investigates the relationship between disease characteristics and psychological status reported by attendees at one Centre.

Methods: Psychological questionnaires measuring depression, anxiety, pain, fatigue and condition intrusion were sent to all patients with a diagnosis of BS and attending a Behçet's Centre of Excellence (N=106). Associations between psychological scores and responses from the Behçet's Disease Activity Index (BDAI), a subjective measure of BS symptoms, were analysed using Spearman's correlation.

Results: Response rate was 51%. A high proportion of patients scored above the clinical cut off for depression (88.9%) and anxiety (74.1%). High levels of pain, fatigue and condition intrusion were also recorded. Female patients reported higher scores on all measures. On average, 4 out of 12 active BS symptoms were reported.

Overall, whilst psychological scores and BDAI responses indicated statistically significant positive correlations, associations were only moderate or low.

Surprisingly of the 12 BS symptoms measured by the BDAI, headache, arthralgia, arthritis, nausea, diarrhoea and erythema were significantly associated with higher psychological scores with no association between psychological scores and mouth ulcers, genital ulcers or skin pustules. Certain symptoms domains were not reported to be present by the majority of patients, notably eye, nervous system or major vessel problems, reflecting the spectrum of disease observed in the UK.

Table 1. Summary of results

Psychological Measure	Spearman's rho[a] (p-value)	Headache[b]	Skin Pustule[b]	Arthralgia[b]	Mouth Ulcer[b]	Genital Ulcer[b]	Arthritis[b]	Nausea[b]	Diarrhoea[b]	Erythema[b]

WSAS Total	0.428 (0.001)	0.060	0.914	**0.037**	0.060	0.900	**0.008**	**<0.001**	0.305	**0.021**

1. Rank correlation coefficient for the association between BDAI Total Score and psychological scores.
2. Mann-Whitney U test.

Conclusion: Whilst high levels of psychological morbidities were present within this UK BS cohort, psychological status was not strongly associated with BS symptoms. Surprisingly, many symptoms typically associated with BS and usually considered to be most debilitating (e.g. mouth and genital ulcers or eye problems), were not associated with increased psychological scores, whereas symptoms generally though to be less significant (eg headache, nausea, pain, diarrhoea) were more closely associated with poorer psychological status.

Choosing Subserologies Wisely: An Opportunity for Rheumatologic Healthcare Resource Savings. David Bulbin[1], Alicia Meadows[1], Sandi Kelsey[1], Harold Harrison[1] and Alfred E. Denio[2]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA.

Background/Purpose: In March 2013, the American College of Rheumatology published its Top 5 List of Things Physicians and Patients Should Question as part of the American Board of Internal Medicine's Choosing Wisely campaign. First on the list was "Don't test ANA subserologies without a positive ANA and clinical suspicion of immune-mediated disease." Previously, we examined positive subserologies when the ANA was negative, and were surprised to find that rheumatologists were frequently ordering subserologies when the ANA was negative. The present study was undertaken to elucidate the extent of this ordering pattern and understand the providers' rationales. The ultimate goal is to develop a quality improvement program to support cost effective utilization of subserologies.

Methods: We conducted a retrospective study of the Geisinger Health System that includes 2198 providers; 342 in primary care and 14 in rheumatology. We looked at the incidence of subserologies ordered simultaneously with an ELISA ANA when the ANA result was normal. Data from 2011–2012 was collected via the Sunquest lab system and EPIC electronic health record. Subserologies included were ELISA dsDNA, Anti-Smith/RNP, SSA/SSB, SCL70 and JO1 antibodies. Since anti-Smith/RNP, SCL70, and dsDNA should be negative when the ANA screen is negative, those testing instances represent unnecessary utilization. A six question survey was sent to providers who ordered ANA negative subserologies more than twice in an attempt to determine the providers' ordering rationale and to ascertain if they had quality improvement educational preferences. Finally, a cost analysis was done totaling the allowed reimbursement of unnecessary subserology tests based on the Medicare fee schedule.

Results: 22596 ANA tests were ordered from 2011–2012. 2246 ANA's were ordered at the same time as subserologies when all tests were negative (9.4%). 32.8% were ordered by Rheumatologists.

Out of 440 unique ordering providers, 183 ordered testing more than twice. 130 were sent the survey and 47 completed it. The primary reasons for ordering ANA's in conjunction with subserologies were an unclear diagnosis based on history and physical (16) and patient convenience (7). Providers were asked about opportunities for quality improvement. 10 preferred monetary incentives, 18 were interested in educational materials, 28 favored reflex testing, and 10 would want training through the EHR.

In our cost analysis we found that, excluding SSA/SSB and Jo-1, the estimated total cost of subserologies ordered with a negative ANA from 2011–2012 was $39,091.

Conclusion: In the Geisinger Integrated Health System, Rheumatologists frequently did not choose subserologies wisely. No specialty was immune from ordering ANA's and subserologies simultaneously. Responding physicians were most receptive to educational materials and reflex testing to help eliminate superfluous subserologies. If reflex testing had been available in 2011–2012, Geisinger would have saved close to $40,000 in unnecessary tests. We will be implementing an ANA/reflex subserology option combined with directed provider education about ordering patterns to improve utilization.

Choosing Not so Wisely: The Tale of Antinuclear Antibody Testing. Tejas Sheth[1] and David Alcid[2]. [1]Albert Einstein College of Medicine / Yeshiva University, Bronx, NY, [2]Drexel University College of Medicine / St Peter's University Hospital, New Brunswick, NJ.

Background/Purpose: Choosing Wisely campaign aims to promote evidence based care that is truly necessary and not duplicative. ACR has furnished guidelines for use of ANA and ANA subserologies (ANAS)[1]: First, repeat testing of ANA is not indicated in patients with established diagnosis of SLE. Second, ANAS should not be ordered along with initial ANA testing. Third, ANA should not be used as a screening test in patients with nonspecific symptoms. The study objective was to identify occasions where ANA testing does not reflect high-value, cost-conscious care.

Methods: All patients having ANA test done at St Peter's Hospital lab from 4/1/2012 to 3/31/2014 were included. Retrospective chart review was done for demographics, indication of testing and outcomes. Inferential analysis and logistic regression were done by SAS 9.0.

Results: Total 851 patient encounters were found with mean age of 46.9 years and M:F ratio of 1:3.3. In 91 encounters, ANA testing was done despite a history of SLE. In 223 encounters, ANAS were ordered along with initial ANA. Of 223 ANAS ordered, only 15 were positive; all of which had positive ANA results. Female patients (OR 2.92, 95% CI 1.86–4.59) and those with history of autoimmune disease (AID) (OR 6.76, 95% CI 4.37–10.44) were more likely to have a positive ANA result. Patients with history of AID (OR 7.87, 95% CI 1.72–35.95) and those with a positive ANA results ($p<0.001$) were more likely to have positive ANAS. Age (OR 0.99, 95% CI 0.98–1.01) and location of patient ($p=0.48$) did not show association with ANA results. ANA testing ordered in family medicine, pediatrics and gastroenterology were more likely to have negative results (OR 2.61, 2.3 and 5.04 respectively) as compared to rheumatology. Follow up visits were available in 587 encounters; on 12 occasions (2.07%) a positive ANA result translated in a change in management.

Conclusion: A significant amount of clinically done ANA testing does not reflect high value care and is associated with significant economic burden (>150,000 USD/yr).

Improving Serologic Testing for Antiphospholipid Antibodies in Patients with Systemic Lupus Erythematosus. Arshad Mustafa[1], Kara Prescott[2], Una Makris[2] and E. Blair Solow[3]. [1]UT Southwestern Medical Center at Dallas, Dallas, TX, [2]Dallas VA Medical Ctr, Dallas, TX, [3]UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: Antiphospholipid antibodies (APL) in patients with Systemic Lupus Erythematosus (SLE) are common. Persistent positivity is known to increase the risk of thrombosis and pregnancy morbidity and predicts early damage in patients with SLE. Testing for APL is part of the American College of Rheumatology (ACR) and the Systemic Lupus International Collaborating Clinics (SLICC) immunologic criteria for SLE. The purpose of the Quality Improvement (QI) project was to determine the percentage of SLE patients in whom APL were checked before and after intervention at the Parkland Rheumatology Clinic—the largest urban safety net hospital in Dallas, Texas.

Methods: Initially, 150 Parkland Rheumatology charts with an International Classification of Disease (ICD)-9 code of 710.0 were selected at random and reviewed for the presence of APL (lupus anticoagulant, anticardiolipin, and beta 2 glycoprotein I). Patients who met the ACR or SLICC classification criteria were included. APL testing done before July 2012 was recorded. Charts with ≥ 2 APL were counted as "Yes" and < 2 APL were counted as "No". The intervention consisted of a 6 month education period focusing on the impact of APL in SLE. This consisted of a series of case presentations and journal club by the fellows, guest speakers with expertise on Antiphospholipid Syndrome, and a QI related SLE-APL literature review. Verbal reminders were made to the providers on their clinic days. Subsequently, another 150 Parkland charts with an ICD-9 code of 710.0 were selected at random and reviewed for the presence of APL. Patients not seen in the clinic after July 2012 were excluded, as changes after intervention could not be applied to these patient's charts. Fisher's exact test was used to investigate the change in APL testing in SLE patients before and after the intervention.

Results: Pre-intervention data showed that in 95 (64%) charts APL were checked, and in 54 (36%) charts APL were not measured. Post-intervention, in 93 (77%) charts, APL were checked and in 27 (23%) charts APL were not measured, see Figure. The intervention was significant for a change in APL testing in SLE patients by the providers ($p = 0.02$).

Conclusion: Routine APL testing in patients with SLE is often overlooked. It is important to identify APL in SLE patients for diagnostic, therapeutic and prognostic purposes. In this QI project provider education significantly improved the testing for APL in patients with SLE. Future interventions include ongoing education strategies and creating rheumatology template notes with smartphrases in the electronic medical record.

A Quality Improvement Initiative to Improve Pneumococcal Vaccination Rates in Immunosuppressed Patients. Melissa Bussey[1] and Rochella A. Ostrowski[2]. [1]Division of Rheumatology, Loyola University Medical Center, Maywood, IL, [2]Loyola University Medical Center, Maywood, IL.

Background/Purpose: Patients with autoimmune diseases are at increased risk of complicated infections, and immunomodulating treatment regimens further enhance this risk. Many of these infections, including influenza, invasive pneumococcal disease, herpes zoster, and human papillomavirus, are vaccine preventable. The Centers for Disease Control (CDC), American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) recommend pneumococcal vaccination for patients who are immunosuppressed. Despite these clear recommendations, studies have shown pneumococcal vaccination rates ranging from only 19–54% in immunosuppressed populations. The aim of this study was to evaluate the effect of an educational intervention and distribution of a pocket vaccination guide on pneumococcal vaccination rates in an academic rheumatology practice.

Methods: Six attending rheumatologists in an academic setting were selected to receive the intervention in the form of an oral PowerPoint presentation and a pocket-sized guide containing CDC guidelines for vaccination, ACR recommendations regarding the use of vaccines in patients with rheumatoid arthritis, and the most recent recommendations for the pneumococcal vaccine including indications for the pneumococcal conjugate vaccine (PCV13). The rates of immunosuppressed patients being up-to-date with pneumococcal vaccination were assessed pre- and post-intervention over a one month time period (August 2012 and August 2013). Up-to-date vaccination status was defined as any one vaccine dose over age 65, any one dose in the last 5 years, or any 2 prior doses 5 years apart. Only patients age 18 and older on immunosuppressive therapy who were being seen on a follow up basis were included. Patients receiving rituximab were excluded as it is thought to decrease vaccine efficacy. Chi-square test and logistic regression were used to analyze the data (STATA 11.0).

Results: Among all providers, 171 immunosuppressed patients were seen in the pre-intervention time period and 190 in the post-intervention time period. 19.9% of eligible immunosuppressed patients were up-to-date with their pneumococcal vaccination pre-intervention as compared to 31.6% post-intervention ($p=0.003$) with an odds ratio of 1.85 (95% CI 1.11–3.01)[Table 1]. This increase remained significant when adjusting for site of clinic and provider. Among patients less than 65 years old, up-to-date vaccination status increased from 7.9% pre-intervention to 25.9% post-intervention ($p<0.0005$). Vaccination practices varied widely among providers.

Conclusion: A QI strategy involving an educational session along with distribution of a pocket-sized vaccination guide significantly increased the rate of being up-to-date with pneumococcal vaccination among immunosuppressed patients in our academic rheumatology practice.

Electronic Medical Record-Based Best Practice Alert Used By Clinical Staff Improved Pneumococcal Vaccination and Documentation Among Immunosuppressed Rheumatoid Arthritis Patients. Heena Sheth, Larry W. Moreland, Hilary J. Peterson and Rohit Aggarrwal. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: The Centers for Disease Control and American College of Rheumatology guidelines recommend pneumococcal vaccination for all immunosuppressed patients, specifically those taking disease modifying antirheumatic drugs (DMARDs) or biologic agents. Despite these guidelines, the rates of pneumococcal vaccination are very low in RA patients. The aim of this study was to improve the rate of administration and documentation of pneumococcal vaccine in rheumatoid arthritis (RA) patients taking DMARDs and biologic agents at rheumatology outpatient clinics.

Methods: An automated electronic medical record (EMR)-based best practice alert (BPA) intervention was designed to be used by clinical staff and to provide user-friendly interface to remind, document and order pneumococcal vaccine for eligible patients. EMR determined the eligibility of the patients at the time of rooming by medical assistant (MA) or nurse, and the BPA appeared for eligible patients. MA confirmed eligibility, documented prior vaccination or patient refusals and ordered the vaccine using the BPA if the patient agreed. Physicians reviewed and verified orders, and the patient either received the vaccination or a written prescription based on clinic/patient preferences. If the patient was unsure, the BPA was passed on to the physician for further discussion. The process continues at each visit until patient is vaccinated or documentation occurs. The study was designed as a pre- and post-intervention comparison. Clinical staff and physicians were educated on the guidelines and intervention. Patient education about vaccination was performed during clinic visit, and educational material was also provided. Eligibility for pneumococcal vaccine was all RA patients on immunosuppressant medications (DMARDs or biologics) who have not completed pneumococcal vaccination. Vaccination and documentation rates for the pre-intervention period (July 2012-June 2013) were compared with post-intervention period rates (2/17/2014 – 5/17/2014) using chi square test.

Results: 3285 and 1949 patients were analyzed for baseline and intervention data, respectively. Demographic characteristics were similar in both groups. Vaccination and documentation rates increased significantly from 44.4% and 51.4% in pre-intervention phase to 50.8 % and 58.4%, respectively within 3 months of intervention phase ($p<0.0001$). Approximately 3% of patients refused vaccination, and for 4% of patients, physicians noted deferral during both study phases.

Conclusion: Pneumonia vaccination administration rates in immunosuppressed patients with RA are low. Implementation of an automated EMR and clinical staff-based BPA intervention significantly improved vaccination rates without the need for considerable physician input. The project is ongoing and will become standard of practice in our rheumatology clinics.

1345

Improving Pneumococcal Immunization Rates for Patients on Immunosuppressant Medications at an Academic Rheumatology Clinic. Lauren Dudley, Stephen Liu, Krista Merrihew, Jocelyn Verrill and Lin Brrown. Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Background/Purpose: Patients with rheumatologic diseases are frequently placed on immunosuppressant medications which increase their risk of developing *Streptococcus pneumoniae* infections. The Advisory Committee on Immunization Practices recommends that all immunosuppressed adults receive the 13-valent pneumococcal conjugate vaccine (PCV-13) followed by the 23-valent pneumococcal polysaccharide vaccine (PPSV-23) but many specialty clinics lack processes of care that facilitate immunization. The objective of this study was to improve pneumococcal immunization rates for patients on immunosuppressant medications in the adult rheumatology clinic.

Methods: Immunization rates for PCV-13 and PPSV-23 were defined as the proportion of visits in which patients were up to date on their immunization. Data obtained from the electronic health record from May 2011 to April 2014 was analyzed using statistical process control methods. Rates over time were tracked using p-charts. Semi-structured interviews were performed with clinic staff to map the processes for immunization and create cause-and-effect diagrams. Interventions consisted of staff and provider education, a standardized process for obtaining immunization histories and a standing order permitting clinical support staff to order and administer immunizations via a protocol.

Results: At baseline, there was no standardized process for assessing immunization histories or providing immunizations in the clinic. Barriers included provider knowledge gaps, uncertainty regarding whether specialists or primary care providers should immunize, missing immunization records, lack of reminders and lack of time. The interventions resulted in statistically significant increases in the PCV-13 immunization rate from 3.0% to 33.3% (p-value < 0.001) and the PPSV-23 immunization rate from 58.1% to 64.9% (p-value < 0.001).

Conclusion: Rheumatologists place many patients on immunosuppressant medications rendering them high risk for infection yet many clinics have not incorporated immunizations into their standard processes. Standing orders combined with education should be considered as a potential intervention.

1346

Leveraging Electronic Health Records to Improve Vaccination Rates for Patients with Rheumatoid Arthritis. David W Baker, Tiffany Brown, Ji Young Lee, Diana S Sandler, David T Liss, Amanda Ozanich, Elizabeth Harsha Strong, Alpa Patel and Eric M. Ruderrman. Northwestern University, Chicago, IL.

Background/Purpose: Vaccination rates among patients with rheumatoid arthritis (RA) remain low. Improving these rates is important, as RA patients are inherently immunocompromised and frequently treated with immunosuppressives. To address this, we implemented a multifaceted, system-level intervention to improve pneumococcal (PVX) and zoster (ZVX) vaccination rates among patients with RA that was designed to make clinicians aware of their low vaccination rates, improve processes at the point of care (i.e., during a visit), and use panel-management strategies to contact patients between visits.

Methods: This study was conducted at an academic medical center in Chicago, IL. The study cohort included all adults seen in the faculty practice plan's rheumatology clinic with a diagnosis of RA. Our intervention had 3 main components: (1) clinicians received quarterly performance reports of the PVX and ZVX rates for their RA patients, generated from EHR data; (2) EHR clinical decision support best practice alerts (BPAs), designed to alert clinicians and facilitate PVX and ZVX administration at the point of care, and; (3) outreach to patients needing vaccination via mail or secure electronic messaging through the EHR patient portal, regardless of whether they had in-person clinic visits. Study BPAs allowed clinicians to either link to a standing order set for vaccination at the time of the visit, document why vaccination was inappropriate, or write a prescription for the patient to receive ZVX elsewhere. We assessed vaccination rates monthly from baseline in October 2013 through May 2014 using EHR data. For this interim analysis we assessed the statistical significance of differences in vaccination rates pre- and post-intervention.

Results: The study cohort included 1255 eligible patients. At baseline 293 (23.3%) had received PVX, and this increased to 524 (41.8%) at follow-up ($p<0.001$). An additional 11 (0.9%) patients had a documented medical exception for why PVX was not administered, and 53 (4.2%) had a documented refusal. At baseline, 35 (2.8%) patients had received ZVX, and at follow-up 63 (5.0%) patients had received ZVX at clinic or received a prescription to receive ZVX elsewhere ($p<0.01$). During follow-up, 99 (7.9%) patients had a documented medical exception and 44 (3.5%) had a documented patient exception (refusal or financial barrier) for ZVX.

Conclusion: Vaccination rates increased substantially following implementation of this multifaceted intervention. However, the rate of PVX remained much lower than rates we have achieved for PVX using similar interventions in a primary care clinic, and ZVX rates remained quite low. The reasons for these suboptimal vaccination rates are unclear, but could be due to rheumatologists' limited time to discuss prevention with patients or beliefs that vaccination is the responsibility of primary care providers. Alternatively, our results could be due to clinical confusion following the recent publication of new PVX recommendations, and uncertainty regarding ZVX administration in immunocompromised patients under age 60. Future research should seek to identify and overcome barriers to vaccination in this patient population.

1347

Understanding Vaccination Rates Among Patients with Rheumatoid Arthritis. Diana S Sandler, Eric M. Ruderman, Tiffany Brown, Ji Young Lee, Amanda Ozanich, David T Liss and David W Barker. Northwestern University, Chicago, IL.

Background/Purpose: Vaccinations are important for patients with rheumatoid arthritis (RA) who may receive immunosuppressive therapies that increase their risk of infection. The Advisory Committee on Immunization Practices (ACIP) recommends all adults receive annual influenza vaccination (INFVX), patients with immunocompromising conditions such as RA receive pneumococcal vaccine (PVX), and adults age 60 and older receive zoster vaccine (ZVX). However, rates of these vaccinations among RA patients are suboptimal. Using data from electronic health record (EHR) among our RA patients in 2012, 41% of patients had ever received PVX, 19% had received INFVX during 2011–2012 season (this may be low due to incomplete EHR capture), and 2% had ever received ZVX. We conducted a telephone survey among RA patients to assess self-reported vaccination status and to understand patient vaccination behavior and attitudes.

Methods: We recruited randomly selected RA patients in an academic practice from July to September 2013. Eligible participants were identified by EHR query with diagnosis of RA, at least one rheumatology visit in each of the previous two years, were 18+ years of age, and listed English as preferred language. Chart review confirmed diagnosis of RA. The 10 minute survey included: (1) Patient self-reported receipt of INFVX, PVX, and ZVX; (2) Attitudes about these vaccines, reasons for unvaccinated status if applicable and; (3) Provider recommendations about these vaccines. For patients that reported ever receiving INFVX, we asked if they had been vaccinated during the previous year's flu season (2012–2013).

Results: Participants' (n=102) mean age was 57.8 (SD=14.5), 85.3% were female, 67.3% were white and 85.2% reported taking immunosuppressive medication. The vast majority of participants (90.2%) reported having *ever*received INFVX; 79.4% reported receipt of INFVX during the 2012–2013 flu season. Approximately half of participants (53.9%) reported receipt of PVX, and only a few (7.8%) reported receipt of ZVX. When participants, regardless of vaccination status, were asked "How important do you think it is get vaccinations to prevent infections?" 78.5% felt it was at least somewhat important to get vaccinations; 14.7% thought vaccines were not important at all. 74.5% of respondents reported being told they had an increased risk of infection, but only 63.7% recalled being told the importance of vaccines by providers. 96.1% participants reported that their provider had recommended INFVX, but only 16.7% reported that ZVX had been recommended. The most common reason patients gave for not receiving PVX and ZVX was that it had not been recommended to them.

Conclusion: Academic rheumatology patients with RA reported very high levels of INFVX, low rates of PVX, and very poor ZVX uptake. The majority of participants thought vaccinations are at least somewhat important and the most common reason for not receiving vaccination was lack of provider recommendation. Further research is needed to investigate system-level barriers to vaccination, including reasons for inadequate provider recommendations and the impact of evidence-based provider-level interventions on vaccination rates.

Improvement in Herpes Zoster Vaccination and Documentation for Rheumatoid Arthritis Patients Using Electronic Medical Record. Heena Sheth, Siamak Moghadam-Kia, Rayford June, Hilary J. Peterson, Davi Sa Leitao, Larry W. Moreland and Rohit Aggarwal. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Despite increased risk of herpes zoster (HZ) in rheumatoid arthritis (RA) patients on immunosuppressive medication, American College of Rheumatology guidelines on HZ vaccination in RA and availability of HZ vaccine that decreases the risk of infection, the rates of vaccination against HZ in RA are very low. The aim of this study was to improve the rate of vaccination and e-record documentation of HZ vaccine in RA patients at high risk for HZ in rheumatology outpatient clinics.

Methods: This study evaluated HZ vaccination and documentation for RA patients using pre- and post-intervention data. All RA patients aged ≥ 60 years were considered eligible for HZ vaccine if they were on or starting DMARDs or starting a biologic agent or steroid >20 mg

equivalent of prednisone >3 months. Clinical staff and physicians were educated in vaccine guidelines and planned intervention. Intervention was an electronic medical record (EMR)-based best practice alert (BPA), which is a user friendly system for ancillary staff and physician with integrated vaccine eligibility verification, documentation and vaccine order capability at the time of patient visit. The BPA appeared for eligible patients upon opening the EMR, prompting the medical assistant or nurse to document vaccination status and order HZ vaccine if the patient agreed. The physician subsequently reviewed and confirmed the order. BPA was passed to physician if a patient was unsure. The pre-intervention phase included all eligible RA patients who were seen at the Rheumatology Clinics between 7/1/2012 – 6/30/2013. The intervention phase data was collected for 3 months after implementation of BPA system. Reasons like patient refusal or physician deferral were also documented. The proportion of patients vaccinated and documented among all eligible patients pre- and post-intervention was compared using chi-square tests.

Results: 1846 RA patients were analyzed for pre-intervention (baseline) data (76% female, 90% white, mean age of 72 years) and 1267 patients for the post-intervention data (76% female, 82% white, mean age of 71 years). Overall vaccination rate increased from 9.9 to 15.7% p=0.001, and documentation rate increased from 30.1 to 44.8% p<0.0001. Academic clinic vaccination rate improved from 12.4 to 24.3% p=0.003, documentation rate from 32 to 44% p=0.04. Community clinic vaccination rate improved from 8.6 to 14.5% p=0.0008; and documentation rate increased from average 25.2 to 35.6% p=0.014 (Figure 1). There was 4.4% patient refusal while 15.7% patients had documented physician deferral. The process was automated using EMR and user-friendly interface for ordering and documentation of vaccination without much increase in physician burden.

Conclusion: EMR-based BPA at the time of patient encounter and physician education intervention resulted in significant increase in HZ vaccination and documentation rates in RA patients.

Figure 1. Rates of HZ vaccination and documentation in 2 academic and 10 community clinics before and after use of EMR-based BPA and education intervention.

1349

A Decision Support Tool to Improve Herpes Zoster Vaccination Rates Among Patients Starting Biologic Medications.

Sara Schoenfeld[1], Eli Miloslavsky[1], Weihong Yang[1], Naina Rastalsky[1], Mollie Carruthers[1], Zachary Wallace[1], Traci Powers[1], Marcy Bolster[2] and Deborah Collier[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA.

Background/Purpose: Herpes zoster infection causes serious morbidity and mortality in immunocompromised patients. Vaccination reduces the risk of zoster infection by up to 40% among patients with autoimmune disease and is recommended for patients aged 60 or above before starting immunosuppressive treatment. We implemented an electronic medical record based zoster vaccine decision support tool to improve vaccination rates among patients prescribed but not yet started on biologic medications.

Methods: We incorporated a zoster vaccine screening tool into the mandatory prior authorization (PA) process required for prescribing biologic Disease Modifying Anti-Rheumatic Drugs (DMARDs) across a multicenter rheumatology practice at a tertiary care academic medical center. The revised electronic PA form included a zoster section with decision support prompts to screen each patient's appropriateness for the vaccine and to facilitate referral for the vaccine.

Process and outcome measures were analyzed during a 9 month period. The process measure assessed whether physicians accurately completed the zoster section of the PA form. The outcome measure assessed whether patients actually received the zoster vaccine. As a comparison group we used zoster immunization data derived from chart reviews of 123 patients over age 60 prescribed biologic medications in the same rheumatology unit during the 12 month period before implementation of the zoster screening decision support tool.

Results: During the 9 month period following the intervention, 119 PA forms with the zoster section were filled out for patients starting a biologic medication. The form was filled out correctly in 114/119 cases (Figure 1a). Prior to implementation of the zoster section on the PA form, 86/123 patients over age 60 who were prescribed a biologic were eligible for the vaccine without a contraindication. Of these 86 patients, 25% received the vaccine (Figure 1b). After the intervention, 41 of 119 patients prescribed a biologic were age-appropriate for the zoster vaccine, of whom 29 had one of the pre-defined contraindications to receiving the vaccine. Of the 12 age-eligible patients without contraindications, 42% received the vaccine (Figure 1c).

Conclusion: Incorporating a zoster immunization decision support tool in an electronic PA form for biologic medications was a successful method of prompting physicians to screen patients requiring biologic DMARD therapy for the zoster vaccine. After the support tool was implemented, a greater percentage of age-appropriate patients without a contraindication received the vaccine. Vaccination rates could be further improved by addressing a number of barriers including cost and logistical vaccine administration hurdles as well as by considering zoster screening prior to initiating a nonbiologic DMARD or prednisone.

Practice What You Preach? Suboptimal Guideline Adherence By Rheumatologists in Patients with Rheumatoid Arthritis. Nienke Lesuis[1], Ronald van Vollenhoven[2], Marlies Hulscher[3] and Alfons den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]The Karolinska Institute, Stockholm, Sweden, [3]Radboud University Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Tight control based treatment principles of rheumatoid arthritis (RA) are superior to usual care and therefore recommended in many (inter)national guidelines.[1–3] Unfortunately guideline adherence to these guidelines has often been shown to be suboptimal in clinical practice.[4,5] As this is mainly described in clinical trials and pre-defined cohorts, we aim to assess RA guideline adherence in daily practice. In addition, we will also explore potential determinants of guideline adherence.

Methods: In this retrospective, single-center observational study, all adult RA patients with a first outpatient clinic visit at the Sint Maartenskliniek (SMK) between September 2009 and March 2011 were included, either new RA patients or second opinions. Data from all visits in the first year of treatment were collected by manual chart revision. Afterwards, for every single visit guideline adherence to 7 indicators was assessed. The indicators were based on evidence-based national and local RA guideline recommendations (issued in 2009) and concerned diagnostic, therapeutic and follow-up decisions. To assess potential determinants of guideline adherence, all rheumatologists working at the SMK in March 2011 received a set of questionnaires about personality traits, propensity towards cognitive bias, thinking styles and knowledge about guideline content. Furthermore, demographic and disease characteristics of the patients were collected during the chart revision.

Results: A total of 994 patient visits for 137 RA patients were reviewed (mean age 59 years ± 14.1; 67% female; disease duration 4.9 years ± 8.5; 85% rheumatoid factor and/or anti-CCP positive). Guideline adherence varied between 21 and 72%, with referral to the physician assistant as worst scoring indicator and referral to a specialized nurse as best scoring one (see table 1). Both are routine measures implemented at our centre in order to facilitate frequent systematic follow-up. Patients and physician characteristics were analysed for relations with guideline adherence, preliminary analyses found two associations. In patients never seen by a rheumatologist before intervals between visits were more often correct and X-rays were more frequently made if more treatment options were available.

Table 1: Guideline adherence percentages

Indicator		Adherence percentages *[lowest – highest score rheumatologists]*
	Diagnostics	
1)	X-rays of hands, feet and thorax within the first three visits	54.7 [29.0–100.0]
	Treatment	
2)	Therapy change in case of moderate to high disease activity	65.6 [46.7–84.4]
3)	Prescription of conventional and biological DMARDs in agreement with the local preferential sequence	23 [0–50.0]
	Follow-up and shared care	
4)	Referral to a specialized nurse within the first three visits	71.5 [43.0–100.0]
5)	Referral to a physician assistant (PA) or nurse practitioner (NP) within the first year of treatment	21.2 [0–50.0]
6)	Regular outpatient clinic visits combined with a nurse visit for DAS28 assessment (clinimetric center)	35.5 [9.3–70.5]
7)	Correct intervals between regular outpatient clinic visits	21.3 [11.1–44.3]

Conclusion: Guideline adherence to the seven recommendations varied between 21 and 72%. This indicates that there is still room for improvement with regard to guideline adherence. Guideline adherence seems only marginally related to factors on patient- or clinician level. Therefore, adherence is more likely to be guided by a complex interplay of facilitators and barriers.

1351

Assessment of ACR Endorsed Quality Indicators in Rheumatoid Arthritis Patients – a Quality Improvement Initiative. Puneet Bajaj, Erik Anderson, Siddharth Raghavan, Asha Patnaik and Heidi Ropprelt. Stony Brook University Medical Center, East Setauket, NY.

Background/Purpose: Quality assessments are being increasingly used for quality improvement, accountability, and performance based incentives. The current research regarding quality of care provided to rheumatoid arthritis (RA) patients, although limited, does identify gaps and variations in several domains of care.

The American College of Rheumatology (ACR) has endorsed seven RA quality indicators (QI), which we used to access the quality of care provided to RA patients at our institution.

Methods: A retrospective chart review was performed on patients identified by the ICD9 code for RA (714.0) entered by a Rheumatologist between 1/1/09 to 8/31/13. We excluded patients whose records were not available and those without a definitive diagnosis of RA.

Our clinic began consistently applying the Multi-Dimensional Health Assessment Questionnaire for assessment of disease activity and functional status in June 2009; therefore, we only included patients seen in our clinic between 1/1/2010 and 12/31/2012. We adhered to specifications for inclusion and exclusion criteria endorsed by the ACR regarding the seven RA QI. In addition, we excluded patients being considered for initial DMARD therapy or undergoing management for worsening disease, who were lost to follow-up. P-values were calculated using Chi-Squared Test.

Results: A total of 356 patients were included. 87.9% (N=58) of eligible patients had documentation of TB screening. Measurement of disease activity and functional status rose significantly each year from 2010 to 2012 (72.8 to 94%, $p < 0.0001$ and 70.8% to 93.3%, $p < 0.0001$ respectively). None of the patients had documentation of disease prognosis. Documentation of a glucocorticoid management plan was done in 60% (N=5) of the patients who required it. 48.9% (N=174) of patients either did not take glucocorticoids or received glucocorticoids but did not meet the criteria to require a management plan. 98.8% (N=328) of eligible patients were treated with a DMARD. 61% (N=215) of patients on a DMARD required intervention for increased disease activity, of which 100% received it.

Conclusion: The majority of patients had documentation of TB screening. Our assessment of disease activity and functional status improved significantly over time, likely due to increasing provider awareness of quality metrics. Although most patients were stratified and treated as per disease severity, their prognosis was not documented. Only a small percentage of our patients met the criteria requiring a glucocorticoid management plan, thus limiting our assessment of this quality indicator. Our clinic had excellent adherence to treatment with DMARDs, as well as managing worsening disease.

A limitation of our study was a lack of electronic medical records (EMR), which may have negatively impacted data collection. As a result, actual rates of adherence may have been higher than those measured.

Better adherence to guidelines and documentation is required, especially with regards to assessment and classification of disease prognosis, which could be achieved through provider education. In addition, an automated EMR reminder to obtain TB screening upon ordering a biologic treatment may further improve documentation of this QI.

Rheumatoid Arthritis (RA) Disease Activity Assessment and Population Management Processes Used By Clinician Rheumatologists. Anne Winkler[1], James Mossell[2], Edmund MacLaughlin[3], Drew Johnson[4] and J. Timothy Harrington[5]. [1]Winkler Medical Practice LLC, Springfield, MO, [2]Arthritis & Osteo Center of South GA, Tifton, GA, [3]Edmund L. MacLaughlin LLC, Cambridge, MD, [4]Crescendo Bioscience, Inc., South San Francisco, CA, [5]Joiner Associates LLC, Madison, WI.

Background/Purpose: Timely disease activity assessment (DAA) and population management (PM) are known to reduce the burdens of chronic diseases**,** including RA. Currently, the measures and processes being used by clinician rheumatologists for managing RA are poorly documented. Our purpose is to survey DAA and PM processes across a cohort of clinician rheumatologists as a starting point for improving RA management and outcomes in these practices.

Methods: The Rheumatoid Arthritis Practice Performance (RAPP) Project is a voluntary collaboration of US clinician rheumatologists whose goal is to improve RA management, and to document our performance. Most invited to participate are multi-biomarker disease activity test users. To date, 97 physicians from 91 practices have attended quality improvement project kick-off meetings, and each has completed a baseline survey regarding their DAA and PM processes. Their aggregated responses are reported here.

Results: Participants represent all regions of the United States and differing practice environments: solo (33), single specialty (35), and multi-specialty group/integrated system practices (20). RA patients managed per rheumatologist derived from practice billing systems vary from 112 to 1800, self-reported patient visits/day from 12 to 80, and new patients/week from 0 to 32. Forty-six % have mid-level providers sharing in RA management, 91% have an electronic medical record (38 different brands), and 35% have any RA disease registry capability. DAAs used are highly variable, and often multiple. (Table 1) Composite DAA use varies from none (25%), to RAPID3 (39%), DAS28 (18%), CDAI (20%) and SDAI (2%). Disease activity documentation in medical records includes a non-numeric impression (active/controlled)(63%), 0–10 Physician Global (23%), composite score (11%), or other (3%).

Conclusion: 1. Practices vary in RA population size, office work flows, staffing, and DAAs utilized. 2. Use of composite disease activity measures is limited, with the majority documenting a binary, active/controlled clinical impression. 3. PM processes (analytic disease registries and team management) are used infrequently. 4. These results indicate opportunities to improve practice performance and RA disease outcomes in rheumatology practices.

Integrating Collection of Rheumatoid Arthritis Disease Activity and Physical Function Scores into an Academic Rheumatology Practice to Improve Quality of Care. Vladimir Chernitskiy[1], Andre DeVito[2], Naama Neeman[2], Niraj Sehgal[2], Jinoos Yazdany[1] and Andrew J. Gross[1]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA.

Background/Purpose: The default design of our institutions' electronic health record (EHR)(Epic Systems) was not optimally structured to systematically collect quality metrics for rheumatic disease management such as disease activity and physical function measures. Our goal was to implement a Quality Improvement (QI) program for care of patients with RA that could easily be incorporated into routine clinical practice. By optimizing EHR technology to provide relevant and timely data analysis reports, we hypothesized that we would create reproducible, actionable population management solutions for providers caring for patients with RA.

Methods: With the assistance of information technology (IT) technicians at our institution, we created "documentation flowsheets" in our EHR with the following fields: Patient Global Activity score, Provider Global Activity Score, Tender Joint count, Swollen Joint count, and ESR. This allowed the automatic calculation of Clinical Disease Activity Index (CDAI) as well as DAS28-ESR. Providers and clinic staff collaborated to enter data into flowsheets for each RA patient visit. Provider could review scores in real time for individual patients and track scores over time in a flowsheet. Data was collected and analyzed on a monthly basis for individual providers as well as the entire practice and was disseminated to the Rheumatology faculty with full transparency.

Results: Over the first six months of data collection for this project we observed continuous improvement in all RA documentation metrics. There was steady improvement in documentation of disease activity measures. CDAI scores were documented in 80.9% of visits 6 months into this project, compared to 56.5% of visits at study initiation. Patient global assessment was documented in 85.4% of visits vs. 68.5% at baseline. DAS28-ESR scores were documented at a lower frequency, 40.4%, due to lack of availability of ESR results to physicians at the time of the patient visit, but rates improved compared to the start of the study (21.7%).

In the final month of data collection, among RA patients with documented disease activity, 54.1% had CDAI scores of $\leq$10.0 indicating low level of disease or remission, where as 19.4% had high levels of disease activity (CDAI $>$22). We could not determine if there was an overall improvement in RA disease activity level in our patients over the six months of data collection due to large variation in distributions of patient disease activity from month to month.

Conclusion: Effective implementation of an RA QI Program is challenging but achievable. In addition to technical tools and having the right personnel involved (e.g. physician champions, IT programmers and report writers, analysts and clinic manager and clinic support staff), successful implementation requires strong buy-in from providers. This can be accelerated by objective documentation and analysis to identify areas needing improvement, and then providing this feedback to providers. In the future we plan to assess whether systematic documentation of disease activity can lead to improved patient outcomes.

1354

Improving the Measurement of Disease Activity for Patients with Rheumatoid Arthritis: Validation of an Electronic Version of the Routine Assessment of Patient Index Data (RAPID 3). Ruthie May Chua[1], John Mecchella[2] and Alicia Zbehlik[3]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Geisel School of Medicine at Dartmouth, Hanover, NH, [3]The Dartmouth Centers for Health and Aging, The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH.

Background/Purpose: Quantitative measures of disease activity are associated with improved outcomes for patients with rheumatoid arthritis (RA), but many rheumatologists continue to rely on non-quantitative assessments. The Dartmouth-Hitchcock Medical Center (DHMC) electronic health record (EHR) does not currently support patient-reported outcome measures (PROMs) to assess RA activity that can be searched and aggregated for patient care, research, or system-based quality improvement. The Routine Assessment of Patient Index Data 3 (RAPID 3) is a validated PROM which evaluates physical function, pain and global health. To integrate the RAPID 3 into routine clinical practice, an electronic version was built to allow patients to complete the RAPID3 through the EHR. Because we could not replicate the exact visual presentation of the RAPID 3 in the EHR, the aim of this study was to demonstrate equivalence between the electronic RAPID 3 and the validated paper version.

Methods: From March to June 2014, patients in the Rheumatology clinic age $\geq$ 18 years with seropositive or seronegative RA were identified. All participants were active users of the web-based patient portal of the EHR. The electronic RAPID 3 was sent via the patient portal to each participant 1 week prior to their appointment. Patients were notified electronically and by phone to complete the survey. The RAPID 3 paper version was administered on the day of their clinic visit. The first 50 patients to complete both versions were included. The EHR automatically calculates and interprets the disease activity score (scale 0–30: $>$12 high; 6.1–12 moderate; and 3.1–6 low; $\leq$3 remission). Paper surveys were scored manually. A paired *t*-test was used to compare samples with p values of $\leq$0.05 considered significant. The study was exempt from review by the Committee for the Protection of Human Subjects at Dartmouth College.

Results: Of the 50 patients included in the study, 33 (66%) were female and the average age was 58.8 years ($\pm$12.27). An average of 4.2

days passed between the assessments. The mean total RAPID 3 scores for the paper and EHR versions were 9.57(SD±6.45) and 9.75 (SD±6.46) respectively. There were no statistically significant differences between the mean total RAPID3 of the paper and electronic versions (p=0.46), or each component score (table 1).

Table 1. Comparison of paper and EHR versions of RAPID3.

	Mean (±Standard Deviation)		paired *t*-test p value
	Paper	EHR	
Physical Function	1.87 (1.91)	1.85 (1.83)	0.85
Dress yourself	0.40 (0.64)	0.42 (0.67)	0.36
Get in and out of bed	0.46 (0.61)	0.34 (0.59)	0.41
Lift full cup or glass to mouth	0.20 (0.53)	0.18 (0.56)	0.37
Walking outdoors on flat ground	0.40 (0.67)	0.40 (0.67)	0.50
Wash and dry your entire body	0.42 (0.64)	0.48 (0.68)	0.36
Bend down to pick up clothing from floor	0.48 (0.68)	0.50 (0.68)	0.50
Turn regular faucet on and off	0.20 (0.53)	0.20 (0.53)	0.50
Get in and out of a car, bus, train or airplane	0.54 (0.65)	0.50 (0.58)	0.23
Walk two miles or three kilometers, if you wish	1.20 (1.18)	1.20 (1.20)	0.46
Participate in recreational activities and sports	1.28 (1.03)	1.34 (1.08)	0.37
Pain Score	3.86 (2.64)	4.03 (2.65)	0.27
Patient Global Assessment	3.84 (2.75)	3.87 (2.80)	0.65
Total	**9.57 (6.45)**	**9.75 (6.46)**	**0.46**

Conclusion: There was no significant difference in responses between the electronic and paper versions. The electronic RAPID3 (built in an Epic system v2010) can and should be included in the care of all RA patients without interrupting clinic flow, and will facilitate research and systems-based practice improvement.

Population Management of Rheumatoid Arthritis (RA) in Rheumatology Practices: A Quality Improvement Project. David Sikes[1], Gary Crump[2], Kathleen Thomas[3], Alex Bangs[4] and J. Timothy Harrington[5]. [1]Florida Medical Clinic PA, Zephyrhills, FL, [2]Rheumatology Associates - Louisville, Louisville, KY, [3]Community Rheumatology, Noblesville, IN, [4]Crescendo Bioscience, Inc, South San Francisco, CA, [5]Joiner Associates LLC, Madison, WI.

Background/Purpose: Population management (PM) is required for reducing the burdens of chronic diseases, including RA. PM depends on standardizing disease activity assessment (DAA) and coordinating care for the entire disease population, as well as for individuals within this context. Our purpose is to implement PM for RA within rheumatology practices by optimizing DAA to define controlled, low, moderate, and high disease activity cohorts; to focus resources on those patients with the highest needs; and to document our delivery of care and outcomes.

Methods: The Rheumatoid Arthritis Practice Performance (RAPP) Project is a rapidly growing voluntary collaboration of U.S. clinician rheumatologists (current N = 94) who manage more than 50,000 RA patients in total, based on ICD-9 diagnoses. Patients are being enrolled in an analytic RA disease population registry from practice billing records, and RAPP physicians are reporting their preferred disease activity measures, including CDAI, RAPID3, DAS28, SDAI, Physician Global Assessment, and/or a multi biomarker disease activity score. Monthly Population Reports are provided that include 1) patients registered (N) and % ever assessed, 2) % with controlled-low DAA within 7 months, 3) % with moderate-high DAA within 4 months, and 4) %'s with controlled, low, moderate, and high disease activity. Working lists are also provided of patients lacking timely DAA (Report numbers 1, 2, and 3), and those with high disease activity (number 4). Practices are managing their DAA care gaps and high disease activity cohorts, and implementing these population management processes through clinical process improvement projects.

Results: Aggregated data from the baseline Population Reports for the first 26 fully enrolled registries are included in this abstract using multi-biomarker assay results. Other encounter-based disease activity measures are being added currently. The total patients enrolled = 16,979 (Median = 594/physician). At least one DAA is documented for 58% of the total (Median/physician = 69%). Forty-seven % of the controlled-low disease activity cohort has been assessed within 7 months, as has 29% of the moderate-high disease activity cohort within 4 months. The population disease activity distribution includes 21% with controlled-low, 39% with moderate, and 40% with high RA disease activity.

Conclusion: 1. These PM capabilities identify care gaps in DAA and disease control that were not identified previously. 2. Timely DAA and tracking of population measures are known to support improved care and disease activity outcomes.

1356

Collaboration Between a Third Party Payer and Community Rheumatologists to Create a Clinical Pathway for the Treatment of Rheumatoid Arthritis to Assure Proper Use of Biologics and Quality of Care. Alan K. Matsumoto[1], Herbert S. B. Baraf[1], Bruce Feinberg[2], Phil Miller[3] and Daniel Winn[3]. [1]Arthritis & Rheumatism Associates, PC, Wheaton, MD, [2]Cardinal Health, Dublin, OH, [3]CareFirst BlueCross, Baltimore, MD.

Background/Purpose: Use of biologic agents for the treatment of rheumatoid arthritis continues to grow rapidly, with the cost of these agents putting a significant strain on health care budgets. Although rheumatologists and third party payers share the goal of ensuring quality of care for RA patients, rheumatologists fear potential limitation of access to biologics due to cost while third party payers are concerned about the rising expenses associated with the use of these agents. New models of healthcare delivery stress the relationship of cost to quality and improved outcomes. This results in adversarial and inefficient procedures between physician and insurer. Treatment pathways have been suggested as a means to address these issues.

Methods: At the request of CareFirst/Blue Cross and Cardinal Health, we organized a committee of 12 community based rheumatologists to create a treatment pathway for RA patients based on published evidence and community standard of care. CareFirst did not participate in the specific details of the pathway in accordance of the belief that structure should be driven by community standards. Practices that reached 80 % compliance with the program were offered increased reimbursements to offset the cost of data collection and program compliance. Compliance was judged as follows. All patients insured by CareFirst with the RA ICD-9 code of 714.0 were required to be entered into the pathway. Patient visits were required at a minimum of every 3–6 month intervals with a Clinical Disease Activity Index (CDAI) measure recorded at each visit. The use of a non -biologic DMARD (methotrexate unless contraindicated) was mandated for 3 months prior to initiation of first biologic therapy. Indication and dosing of biologics were to be within the package insert guidelines but no specific biologic agent was preferred by the pathway. Site of infusion was required to be non-hospital based. Patients were not required to change biologics for ongoing disease activity, but biologics could not be initiated, switched or increased if the patient was in CDAI remission. Data was captured using a real time iPad based tool.

Results: Over the first 12 months, 80 physicians from 37 practices in the mid Atlantic were recruited and 1800 patients were entered into the pathway. Over 90% of patients were on compliant pathways and 74 % of practices reached compliance. Over 70% of patients were in remission or low disease activity by CDAI measurement. Biologic switches were infrequent. Within the program, site of infusion was more likely non-hospital based.

Conclusion: To our knowledge this is the first collaboration between rheumatologists and a third party payer to create a Rheumatoid Arthritis treatment pathway to assure proper biologic use and assess outcomes. We believe this is a powerful model to assess and improve cost and effectiveness of treatment strategies for rheumatoid arthritis.

1357

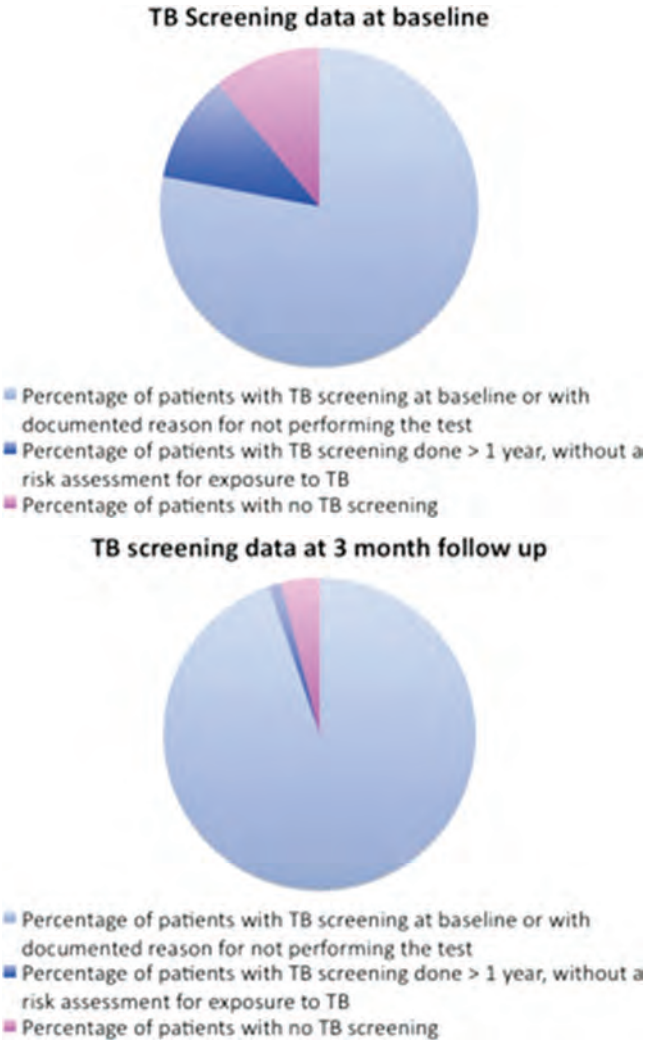
Improving Compliance for Tuberculosis Screening for Patients on Biologics in Rheumatology Clinics. Shraddha Jatwani, Rajani Rudrangi, Karan Jatwani, Vijaya Murthy, Rashmi Maganti, Rex McCallum and Emilio Gonzarlez. University of Texas Medical Branch, Galveston, TX.

Background/Purpose: Biologics are used commonly for patient with autoimmune diseases. These agents have ensured important efficacy advantages in the treatment of inflammatory rheumatic diseases. All biologics have been associated with risk of infections. The risk of serious infections has been reported to increase 1–2–1.8 times for patients on tumor necrosis factor inhibitors (TNFi) compared to patients on conventional agents. The risk of tuberculosis (TB) has been reported to increase manifold, up to 12 to 35 times. American College of Rheumatology (ACR) recommends that all patients on biologics should be screened for risk of latent TB infection (LTBI) either with tuberculin skin test (TST) or interferon-release assays (IGRAs), regardless of risk factors for LTBI.

With this Quality improvement exercise, we aim to improve compliance with TB screening in patients receiving biologics to a target of 90% over 3 months.

Methods: We generated an EMR query to review pre-intervention screening rates of patients on biologics from 3 university clinics over 6 months (July-December 2013). A list of 104 such patients was created. Chart review for these 104 patients was performed to determine adequacy of TB screening defined by presence of a documented TB screening, either PPD or Quantiferon gold TB test, within 1 year of last clinic visit. At baseline, TB screening had been performed in 78% of patients. To improve compliance, as an intervention, we conducted conferences with providers to educate them on the guidelines and our current performance. Nurses were educated through emails. Monthly email follow-up reminders were also sent to the providers and nurses. At 3 months a follow up chart review was conducted for 152 patients in the same three clinics, who had received prescriptions of biologics between March-June 2014 to determine effect of provider education on compliance with TB screening.

Results: Educational conferences and emails were well received by providers and nurses. At follow up after 3 months, the target was achieved in all clinics, with compliance rates for TB screening at 94.7% across board.



Conclusion: Developing methods to improve quality will become even more relevant in future. In this study, we demonstrated provider education makes a difference in implementation of guidelines for TB screening in patients receiving biologics. This was achieved in relatively short period of time. A similar strategy can be implemented in other subspecialty clinics like dermatology and gastroenterology where biologics are also being used.

A Systematic Analysis of the Safety of Prescribing Anti-Rheumatic Immunosuppressive and Biologic Drugs in Pregnant Women.

Sonia Panchal[1], Julia Flint[2], Maud van de Venne[3], Madeline Piper[4], Alice Hurrel[2], Joel Cunningham[2], Mary Gayed[5], Karen Schreiber[6], Subha Anthanari[7], Mohamed Nisar[7], David Williams[2], Munther Khamashta[8], Caroline Gordon[5] and Ian Giles[2]. [1]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom, [2]University College London, London, United Kingdom, [3]North Bristol NHS Trust, Bristol, United Kingdom, [4]Ysbyty Ystrad Fawr, Aneurin Bevan Health Board Wales, Wales, United Kingdom, [5]The Medical School, University of Birmingham, Birmingham, United Kingdom, [6]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [7]Burton Hospitals NHS Foundation Trust, Burton-upon-Trent, United Kingdom, [8]Guy's and St Thomas' NSH Foundation Trust, London, United Kingdom.

Background/Purpose: The use of anti-rheumatic drugs in pregnancy is often complicated by concerns over their potential for adverse effects. Given that rheumatic diseases often affect women of childbearing age and may flare during pregnancy, the safety (or otherwise) of anti-rheumatic drugs and immunosuppressant's are of particular importance. Practice has relied on information based mainly on experimental and animal studies. Human data is limited to inadvertent exposure described in case reports/series and population registries. Previous systematic reviews have identified risks with various anti-rheumatic drugs and biologics. This systematic review is an update on the consensus papers on anti-rheumatic drugs, biological agents and reproduction published in 2006/8.

Methods: A systematic search from 2006–2013 of PubMed, Embase, Cochrane, Lactmed and the UK Tetarology Information Services was carried out using MESH and free terms for drug, rheumatic disease and pregnancy. Review articles and non-English language papers were excluded.

Results: The search strategy identified 352 papers with original pregnancy outcome data.

Table 1. illustrates pregnancy outcomes for the immunosuppressant and biologic therapies.

Table 1 Pregnancy outcomes for rheumatological drugs

Drug	No. of pregnancies exposed to drug	Live births related to exposed drug (min)*	Spontaneous 1st trimester loss (min)	Spontaneous 2nd/3rd trimester loss (min)	Major Malformations (min)§	Minor malformations (min)§	Level of evidence
Prednisolone	771	565	23	35	39	3	C
Methotrexate	12	10	2	0	4	5	D
Leflunomide	77	78	0	0	7	63#	D
Sulphasalazine	12	12	1	0	2	0	D
Azathioprine	320	269	32	7	12	5	C
HCQ	212	230	15	0	29	7	B
MMF	17	18	0	0	19	5	D
Ciclosporin	136	135	1	1	6	0	D
Cyclophosphamide	10	7	2	1	1	0	D
Adalimumab	122	110	6	1	5	1	D
Etanercept	19	16	1	1	1	0	D
Infliximab	130	120	11	2	1	2	D
Group aTNFi$^{\Delta}$	215	160	39	5	1	4	D
Abatacept	3	1	1	0	0	0	D
Certolizumab	10	12	0	0	0	0	D

$^{\Delta}$Combination antiTNFi (infliximab, etanercept, adalimumab, certolizumab)*Includes twin pregnancies. #No increased risk of minor malformations compared to control group §Major & minor malformations meet the EUROCAT criteria for congenital anomalies

Conclusion: Evidence from this systematic review supports the compatibility of hydroxychloroquine, azathioprine, sulphasalazine and steroids in pregnancy. Increasing evidence of compatibility was found from pregnancies exposed (mostly at conception or during the first trimester) to anti-TNF alpha drugs that do not show an appreciable increase in the number of spontaneous

miscarriages and congenital malformations. Further registry data is required for biologic drugs, before the safe use of these drugs can be advocated throughout pregnancy.

1359

Care of Women with Rheumatological Conditions during Family Planning and Pregnancy. Megan E. B. Clowse[1], Munther Khamashta[2], Daphnee S. Pushparajah[3] and Eliza Chakravarty[4]. [1]Duke University Medical Center, Durham, NC, [2]The Rayne Institute, London, United Kingdom, [3]UCB Pharma, Brussels, Belgium, [4]OMRF, Oklahoma City, OK.

Background/Purpose: Rheumatological diseases often affect women of reproductive age and can impact pregnancy outcomes. There is a need to understand how patients (pts) are managed by their rheumatologists. We investigate the treatment pathway and care of women with rheumatological conditions who become pregnant.

Methods: Two online surveys, one in rheumatologists and one in pts, were undertaken. Surveys were conducted in the US, UK, Germany and Mexico. Rheumatologists were questioned on the last three pts who they have consulted whilst being pregnant or considering becoming pregnant. Rheumatologists were questioned on pts with rheumatoid arthritis (RA) and lupus. Pt survey included women with RA who had been pregnant in the past 2 years. Pts were questioned on their interactions with rheumatologists and obstetrics/gynaecology physicians (OBGYN).

Results: 30 rheumatologists completed the physician survey. 57 RA pts completed the pt survey. Rheumatologists were aware of the pt's intention to become pregnant in 70% of pts. When planning their pregnancy 44% of pts consulted with their rheumatologist and 51% with their OBGYN. On learning they were pregnant 33% of pts consulted with their rheumatologist and 61% with their OBGYN. For rheumatologists the majority of initial visits occurred prior to pregnancy (70%). During pregnancy rheumatologists saw 43% of pts once a month or more, 42% every trimester and 14% only once during pregnancy. 83% of pts reported that rheumatologists were very influential on how they managed their pregnancy. For OBGYN, this figure was 87%. The majority of pts rated the level of information reliability on managing disease from both rheumatologists and OBGYNs as very reliable. A treatment plan related to management of RA or pregnancy was initiated by rheumatologists for 56% of pts. 51% of pts reported they had a treatment plan in place prior to pregnancy. 60% of rheumatologists made treatment changes in anticipation of or during pregnancy. When considering treatment switches during pregnancy, rheumatologists increased steroid use and decreased biologic use (Table). For rheumatologists, the most common reason for switch was the pt requesting a change due to medication concerns (43%).

Conclusion: The involvement of rheumatologists in the management of women with rheumatological conditions who are planning to become or are pregnant is high, and they have substantial influence on how pts manage their pregnancy. The patients had a high level of interaction with both rheumatologists and OBGYN throughout the journey. This emphasizes the importance of cross-collaborative care and the sharing of information between specialists involved in the management of women with rheumatological conditions during family planning and pregnancy.

Table: Treatment switches in pregnant women

	Rheumatologists (N=30)	
	Before Switch	**After Switch**
Steroids	35%	43%
DMARDs	76%	35%
No treatment	0%	24%
NSAIDs	33%	13%
Other treatment	0%	13%
Anti-TNF biologic	28%	0%
Non-anti-TNF biologic	7%	2%

Response to question: Thinking about your last three patients who have consulted you whilst being pregnant or considering becoming pregnant, what treatment change did you make during pregnancy? Please indicate the product before and after the switch. If you stopped the treatment without switching the patient to another product, you don't need to indicate a product in the "after switch" column.

1360

Monitoring Methotrexate and Leflunomide Treatment for Liver Toxicity: the Kaiser Permanente Experience. Robert Goldfien[1] and Lisa Herrinton[2]. [1]Kaiser Permanente, Richmond, CA, [2]Kaiser Permanente, Oakland, CA.

Background/Purpose: Methotrexate (MTX) and Leflunomide (LEF) are widely prescribed to treat rheumatologic and other diseases. Each has the potential to cause liver injury in some patients. Current guidelines recommend regular monitoring of either ALT or AST every 2–3 months even in patients on a stable, long-term dose. Adherence to monitoring guidelines has not been reported for a large, community-based population. As part of a quality improvement project, we assessed adherence to monitoring guidelines as well as practices used by rheumatologists to assure monitoring.

Methods: First, we queried the clinical databases of Kaiser Permanente Northern California to identify all patients who had received 2 or more prescriptions of MTX or LEF, with at least 1 prescription dispensed in the previous 6 months. Adherence to guidelines was defined as having a result for ALT or AST in the 90 days prior to data collection. Second, to assess knowledge of guidelines, as well as clinical prescribing and monitoring practices, we surveyed 40 rheumatologists.

Results: We identified 8,276 Internal Medicine patients on MTX/LEF. Among the rheumatologists, the rate of adherence ranged from 62.3 to 94.6% (weighted mean, 82.3%) (Figure). Survey of the rheumatologists (87.5% response) revealed that all were knowledgeable of guidelines, all prescribed ≤3 month supply of medication, 94% used standing laboratory orders, and 71% did not refill prescriptions in patients without an ALT or AST in the prior 3 months.

Conclusion: Despite use of an electronic health record, knowledge of monitoring guidelines, and efforts to assure adherence, we observed significant variation in monitoring liver toxicity in a community rheumatology practice. Our results underscore the need for more effective tools and workflows that integrate prescribing with monitoring. Such solutions, implemented at the system level, would have wide applicability for drugs used across a range of diseases and specialty areas.

1361

Rheumatologists' Attitudes on Cardiovascular Risk and Lipid Screening in Patients with Rheumatoid Arthritis at an Academic Medical Center. Ashwini Komarla and Alexis Ogrdie. University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Cardiovascular (CV) disease is a major cause of morbidity and mortality in the rheumatoid arthritis (RA) population. Thus, the recognition and management of cardiovascular risk factors in patients with RA is especially important. Despite increased awareness of this risk, recent data suggests that adherence to both primary and secondary prevention strategies is low in the RA population compared to other high risk groups (e.g. diabetics). The objective of this study was to assess rheumatologists' perceptions of screening for and treating hyperlipidemia (HLD) and CV risk factors in patients with RA to inform the development of quality improvement initiatives.

Methods: In this qualitative study, all University of Pennsylvania rheumatologists were contacted with an email link to an online survey. The survey, administered via REDCap, included 15 questions assessing attitudes towards lipid screening and CV risk in RA. Answers were deindentified. The

chi-squared test was used to examine the association between respondent characteristics and attitudes.

Results: Of 28 survey invitations, 24 (85.7%) were returned. All respondents felt there was either a high (N=14) or moderate (N=10) risk of CV disease in RA. Rheumatologists' perceptions of their practice are given in the Table. Seventeen (70.8%) respondents did not believe that primary care physicians (PCPs) are aware of the increased CV risk in RA. Eighteen (75%) believed that both rheumatologists and PCPs should screen for HLD in patients with RA; the remainder felt that PCPs are responsible. Female physicians were more likely to report that both rheumatologists and PCPs should be responsible for screening for HLD (p= 0.03). Nearly all respondents (87.5%) felt that PCPs should be responsible for treating HLD. When asked to rank the clinically most useful approach to estimating CV risk in RA among 3 options, 17 of 21 respondents ranked "CAD equivalent like diabetes mellitus" as their first choice. The most commonly mentioned barriers to screening were time (N=11), patient complexity (N=6), and forgetting or needing a prompt (N=4). An electronic health record (EHR) reminder was the most commonly mentioned idea for increasing HLD screening in rheumatology and primary care practices (N=11).

Conclusion: All respondents believed that there is at least a moderately increased risk of CV disease in RA. Most believed that PCPs are not aware of the increased risk, but the majority also believed that PCPs should be responsible for treating HLD. Quality improvement strategies to bridge this disconnect are needed. Several barriers to screening were identified. Respondents recommended using an EHR prompt to increase screening for HLD and improve recognition of CV risk.

Table. Rheumatologists' Perceptions of Their Own Practice

Question	Total Respondents - n (%)
Do you routinely check lipids in your patients with RA?	
Never	1 (4.2)
Almost Never	5 (20.8)
Sometimes	8 (33.3)
Most of the Time	9 (37.5)
Always	1 (4.2)
Do you routinely initiate treatment of hyperlipidemia in your patients with RA?	
Never	4 (16.7)
Almost Never	11 (45.8)
Sometimes	8 (33.3)
Most of the Time	1 (4.2)
Always	0
Do you regularly counsel your RA patients about the increased risk for cardiovascular disease?	
Never	1 (4.2)
Almost Never	1 (4.2)
Sometimes	6 (25.0)
Most of the Time	12 (50.0)
Always	4 (16.7)
How comfortable do you feel in counseling about diet and exercise in your patients with RA and hyperlipidemia?	
Not at all comfortable	1 (4.2)
Somewhat comfortable	6 (25.0)
Very comfortable	17 (70.8)
How comfortable do you feel initiating medication therapy for hyperlipidemia?	
Not at all comfortable	2 (8.3)
Somewhat comfortable	12 (50.0)
Very comfortable	10 (41.7)

ACR/ARHP Poster Session B
Rheumatoid Arthritis - Clinical Aspects: Comorbidities, Treatment Outcomes and Mortality
Monday, November 17, 2014, 8:30 AM–4:00 PM

1362

Impact of Rapid Attainment of Stringent Measures of Efficacy in Rheumatoid Arthritis on Patient-Reported Outcomes. EA Alemao[1], S Joo[2], S Banerjee[1], P Emery[3] and M Weinblatt[4]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Hopewell, NJ, [3]University of Leeds, Leeds, United Kingdom, [4]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Treatment guidelines in RA recommend that therapies aim to reach a target of remission or low disease activity (LDA) and that these targets should be reached in 3–6 months (mths). This timeframe is based on 'expert opinion' rather than empirical data. Our objective was to evaluate the benefits of rapid (within 3 mths) vs later attainment of stringent measures of efficacy (SME) such as ACR/EULAR remission criteria (SDAI ≤3.3, CDAI ≤2.8), LDA (DAS <2.6), and ACR70 on pt-reported outcomes (PROs) in pts with RA in a randomized controlled trial.

Methods: Data were analyzed from a Phase IIb study evaluating SC anti-IL-6 monoclonal antibody clazakizumab (CLZ) with or without MTX in pts with moderate-to-severe RA and inadequate response to MTX. Pts were randomized equally to CLZ 25, 100 or 200 mg with MTX every 4 wks; CLZ 100 or 200 mg monotherapy every 4 wks; MTX alone; or adalimumab with MTX every 2 wks. 'Rapid' attainment of SME (DAS28 [CRP] <2.6, ACR70, SDAI ≤3.3 and CDAI ≤2.8) was based on attaining SME within 3 mths. Pts attaining SME between 3 to 6 mths and after 6 mths were considered 'intermediate' and 'late' respectively. PROs evaluated during the 12-mth follow-up period included physical functioning using HAQ-DI, quality of life (QoL) using the Short Form-36 Health Survey (SF-36) (physical component summary [PCS] and mental component summary [MCS]), and pain and fatigue using visual analog scales. Mixed models were used to estimate both fixed and random effects of independent variables on the outcome measures.

Results: A total of 418 pts were included in the analysis; average age was 50.4 yrs and 83.5% were females. At 12 wks ('rapid' group), 33.3%, 22.7%, 12.2% and 11.2% had attained DAS28 (CRP) <2.6, ACR70, SDAI ≤3.3 and CDAI ≤2.8, respectively. Between 12 and 24 wks ('intermediate' group) these values were 17.5%, 16.0%, 12.4% and 12.7%, respectively; and after 24 wks ('late' group) they were 18.2%, 20.8%, 19.6% and 18.9%, respectively. Baseline characteristics between groups were similar. Pts who attained DAS28 (CRP) <2.6 or ACR70 early ('rapid' group) had significantly better HAQ, SF-36 PCS, pain and fatigue scores at Wk 48 than those who attained DAS28 (CRP) <2.6 or ACR70 later ('late' group); the mean differences (delta) between the 'rapid' vs 'late' group were higher than the thresholds for minimum clinically important differences for these outcomes. Directionally similar results were observed for those attaining SDAI ≤3.3 and CDAI ≤2.8 rapidly vs late, although the results did not meet statistical significance due to small numbers of pts. There was no consistent pattern in PROs between the 'rapid' vs 'intermediate' group (Table).

Outcome	D DAS28 (CRP) <2.6 'rapid' vs 'late'	p-value	D ACR70 'rapid' vs 'late'	p-value
HAQ	**–0.37**	**0.0085**	**–0.60**	**<0.0001**
SF-36 PCS	**3.5**	**0.0007**	**3.4**	**0.0011**
SF-36 MCS	2.2	0.1073	2.2	0.1261
Pain	**–16.4**	**<0.0001**	**–14.4**	**<0.0001**
Fatigue	**–15.5**	**<0.0001**	**–13.6**	**<0.0001**
	D **DAS28 (CRP) <2.6 'rapid' vs 'intermediate'**	**p-value**	D **ACR70 'rapid' vs 'intermediate'**	**p-value**
HAQ	0.02	0.8731	–0.10	0.4489
SF-36 PCS	0.5	0.6113	0.2	0.8336
SF-36 MCS	1.5	0.2963	–1.0	0.4942
Pain	**–6.8**	**0.0046**	–4.0	0.0939
Fatigue	**–6.6**	**0.0113**	–4.1	0.1192

Conclusion: Pts with rapid attainment of SME (including treatment guideline targets) tend to benefit more in the longer term in physical functioning, QoL, pain and fatigue than those attaining these measures much later; the findings are mixed for those attaining SME in the intermediate 3–6 mths time period.

Psychosocial Comorbidities Are Independently Associated with Subclinical Atherosclerosis in Rheumatoid Arthritis. Ying Liu[1], Moyses Szklo[2], Karina Davidson[1], Joan Bathon[3] and Jon Giles[1]. [1]Columbia University Medical Center, New York, NY, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Columbia University, New York, NY.

Background/Purpose: Rheumatoid arthritis (RA) is associated with higher rates of cardiovascular disease (CVD) and subclinical atherosclerosis as well as psychosocial comorbidities, which themselves are associated with CVD. We explored if psychosocial comorbidities differentially contribute to CVD risk in individuals with RA compared with non-RA controls.

Methods: Data were derived from a longitudinal cohort study of subclinical cardiovascular disease in RA and non-RA controls. Using validated scales, psychosocial comorbidities (depression, chronic life stressors, anxiety/anger, social support, discrimination/hassles) were assessed. Differences in the associations of psychosocial measures with measures of subclinical atherosclerosis [coronary artery calcium (CAC) assessed using computed tomography and carotid intimal-media thickness (IMT)/plaque assessed using ultrasound] were explored using multivariable regression models incorporating RA x psychosocial variable interaction terms. Models were adjusted for relevant unbalanced demographic variables, CVD risk factors, and markers of RA activity/inflammation.

Results: 195 RA patients [mean age=59 ± 9 years, 61% female; 87% Caucasian; median RA=9 years; mean DAS28=3.65 ± 1.1] were compared with 1073 controls. RA participants had a higher prevalence of psychosocial comorbidities (depression and personal health, job, and total stress) compared with controls. In RA, per-unit higher Spielberger trait anxiety scores and the presence of caregiver stress were associated with an increased adjusted odds of CAC>100 units (Table). Per-unit higher Spielberger trait anger scores and Center for Epidemiologic Studies Depression scores were also associated with an increased odds of CAC>100 after adjustment (Table), although these effects were diminished with adjustment for anxiety. All associations were preserved after adjusting for markers of inflammation (IL-6 and CRP) and were only observed in RA patients, but not controls (adjusted interaction term p-values 0.001–0.077). Having job stress was associated with an increased frequency of carotid plaque [adjusted OR=3.21 (p=0.019)], and increasing social support was associated with lower internal carotid IMT (adjusted p=0.024) in RA participants, but not in controls.

Conclusion: Depression, stress, anger/anxiety and social support may affect CVD risk, specifically in RA patients, by promoting atherosclerosis. Because the impact of these factors on atherogenesis may be accentuated in RA compared with the non-RA population, screening and treatment of psychosocial comorbidities may help reduce the known increased burden of CVD in RA.

Table. Adjusted Associations of Psychosocial Variables with Moderate to Severe Coronary Arterial Calcification (CAC>100) Among 195 RA Patients Compared with 1073 non-RA Controls

	Anger			Anxiety			CES-D			CES-D≥ 16 units			Caregiver Stress

Accelerated Diastolic Dysfunction in Premenopausal Women with Rheumatoid Arthritis. Yune-Jung Park[1], JiHee Kim[2], Ki-Jo Kim[3], Wan-Uk Kim[4], Chul-Soo Cho[5], Kyung-Su Park[6] and Ki-Dong Yoo[2]. [1]St. Vincent's Hospital, The Catholic University of Korea, Suwon, South Korea, [2]Division of Cardiology, Department of Internal Medicine, St.Vincent's Hospital, The Catholic University of Korea, Suwon, Republic of Korea, Suwon, South Korea, [3]St. Vincent's Hospital, The Catholic University of Korea, Suwon, South Korea, [4]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [5]Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [6]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: Disturbances of diastolic function precede systolic heart failure and, although clinically silent, represent the earliest sign of cardiac involvement. Diastolic dysfunction is associated with age, female, and hypertension. However, little is known about the age-specific incidence rates and risk factors for diastolic dysfunction in patients with rheumatoid arthritis (RA).

Methods: We used standard two-dimensional/Doppler echocardiography to screen for the presence of diastolic dysfunction in 61 patients with RA (mean [±SD] age, 48.1±7.9 years) and 107 healthy subjects (47.3±9.4 years). All participants were premenopausal women with no history of hypertension. Diastolic dysfunction was defined as impaired relaxation with or without increased filling pressures.

Results: The two groups were similar with respect to age (P=0.269). Patients with RA had significantly higher LV mass index, LV filling pressure, and lower E/A velocity than controls. All patients had preserved ejection fraction (EF ≥50%). Diastolic dysfunction was more common in patients with RA at 47% compared with 26% in the controls (P=0.004). Women with RA in the 30- to 49- year age group were over 3.5 times more likely to have diastolic dysfunction than those of similar age in the control group (OR=3.54; 95% CI 1.27 to 9.85). Among patients with RA, high CRP levels were independently associated with diastolic dysfunction even after adjustment for cardiovascular risk factors (P=0.009).

Conclusion: In premenopausal women with RA, diastolic dysfunction is much more common and the age at onset is reduced. Early screening of myocardial function may provide an opportunity for preventing future cardiovascular disease.

ARE Erosions a Disappearing Feature in Rheumatoid Arthritis (RA)? Joint Damage in Patients with EARLY RA at 10 YEARS after Diagnosis. Juha Asikainen[1], Kalevi Kaarela[2], Heidi Mäkinen[3], Hannu Kautiainen[4], Pekka Hannonen[5], Tuomas Rannio[6] and Tuulikki Sokka[1]. [1]Jyvaskyla Central Hospital, Jyväskylä, Finland, [2]Jyväskylä Central Hospital, Jyväskylä, Finland, [3]Tampere University Hospital, Tampere, Finland, [4]Medcare Oy, Äänekoski, Finland, [5]Jyväskylä Central Hospital, Jyvaskyla, Finland, [6]Kuopio University Hospital, Kuopio, Finland.

Background/Purpose: Treatment of rheumatoid arthritis (RA) has improved during the last decade. Also importance of regular monitoring has been emphasized. Our objective was to study the extent of radiographic joint damage in an early RA cohort at 10 years after diagnosis.

Methods: Our early RA cohort includes 990 patients from a single clinic with a clinical diagnosis of early RA in 1997 – 2004. Radiographs of hands and feet were taken at a 10 year follow-up visit and were analyzed according to the Larsen score (0–100) including MCP I-V, wrists, and MTP II-V. Patients were treated with the T2T strategy by a multidisciplinary care for 2 years with follow-up visits at 5 and 10 years.

Results: Baseline characteristics of 990 patients were: the mean (SD) age 57(16) years, 67% female, 61% seropositive (RF/CCP+ any time over 10 years) and median (IQR) duration of symptoms before diagnosis 6(3, 12) months; 657(66%) patients were available for a 10 year follow up. Reasons for non-attendance among 333 patients included death (52%), high age, multi-comorbidity or institutionalization (10%), moving from the area (12%); 8% declined, 4% were lost to follow-up and 14% miscellaneous reasons. Thus, radiographs were available in 657 patients (66% seropositive); serology of one patient was missing.

At 10 years, erosions were present in 48% (314/656) patients including 61%(266/435) seropositive and 22% (48/221) seronegative patients. Among seropositive patients, Larsen score was >=10% of theoretical maximum in 28%(121/435) patients, <10% of max in 33%(145/435) patients, and 39% (169/435) remained non/erosive; for seronegative patients the corresponding figures were 5%(11/221), 17%(37/221) and 78%(173/221), respectively. The mean (SD) and median (IQR) Larsen score in seropositive patients was 7.8 (11) and 4.0 (1.0, 10), and in seronegative patients 2.0 (4.0) and 0 (0. 3).

In seropositive patients, the 10-years Larsen score declined over time while in seronegative patients erosiveness remained low and stabile (figure).

Over 10 years, all patients had been taking csDMARDs, 83% had been taking systemic glucocortikoids, and 20% bDMARDs.

Conclusion: Larsen score remained low over 10 years and erosion rates decreased over time.

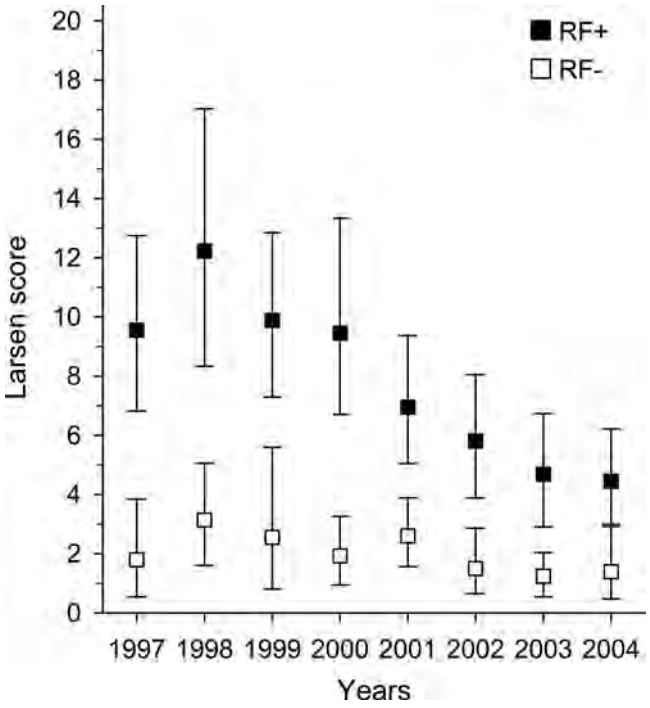

Figure. Larsen score (0–100) in seropositive and negative patients with early RA diagnosed 1997–2004 at 10 years after diagnosis. Mean with bootstrap type 95 per cent confidence intervals.

Outcomes of Interstitial Lung Disease Associated with Rheumatoid Arthritis in High Volume Referral Centers. Megan Krause[1], Amish Dave[2], Cynthia S. Crowson[1], Arun K. Chandran[1], C. John Michet[1], Paul F. Dellaripa[2] and Eric L. Matteson[1]. [1]Mayo Clinic, Rochester, MN, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: To describe the characteristics and morbidity and mortality impact of interstitial lung disease in rheumatoid arthritis (RA).

Methods: A retrospective review was performed at 2 high volume tertiary medical centers identifying patients with clinician determined RA associated interstitial lung disease (RA-ILD) in 1998–2012. Data regarding demographics and disease characteristics of RA, including serologic status and erosions, were collected. Features of pulmonary disease, including successive radiographic findings and pulmonary function test (PFT) results, were abstracted. Kaplan-Meier methods and Cox models were used to estimate survival rates and examine risk factors for mortality.

Results: A total of 119 patients were identified with RA-ILD (55% women; mean age at RA diagnosis 56.6 [range: 13.1–84.8] years; 63% former/current smokers; 75% rheumatoid factor positive). Cyclic citrullinated antibodies were tested in 92 (79%) and present in 71/92 (77%). Erosive disease was present in 32 patients (30%). The mean time from RA diagnosis to ILD diagnosis was 9.4 [−10.9–43.0] years. The mean follow-up time after ILD diagnosis was 3.5 [0.0–15.0] years. Over follow-up, 51 patients (44%) required supplemental oxygen. On repeat PFT, the mean percent predicted were 76.1% [40–148] for total lung capacity (TLC), 70.5% [32–141] for forced vital capacity (FVC), 70.0% [25–135], for forced vital capacity in one second (FEV1) and 51.9% [6–95] for diffusion capacity for carbon monoxide (DLCO). 33 patients died with cause of death attributed to pulmonary disease in 21%. One-year survival rate was 78% (95% confidence interval (CI) 71–86%) with 5 year survival only 41% (95% CI 32–52%**)**. The most common types of ILD were usual interstitial pneumonia (UIP; 44 [37%]) and nonspecific interstitial pneumonia (NSIP; 42 [35%]). Survival rates did not differ for those with UIP compared to those without (5 year survival rate 44% vs 40%; p=0.45; **Figure**). In patients with UIP compared to those without, the initial percent predicted DLCO (p=0.02) and the last available percent predicted TLC, FVC, FEV1, and DLCO were all significantly lower (p=0.003, 0.005, 0.02, 0.02, respectively). In patients without UIP, the first FEV1, both absolute volume and percent predicted, were associated with mortality (p=0.027 and p=0.007, respectively, adjusted for age and sex).

Conclusion: In this large cohort, ILD is an important complication of RA with a very high mortality rate in the first 5 years following diagnosis. The most common RA-ILD diagnoses were UIP and NSIP, and contrary to previously published data, there was no survival difference between these two groups. Earlier in disease, a lower diffusion capacity may identify UIP RA-ILD compared to non UIP RA-ILD. Further research is required to identify risk factors and biomarkers for this extraarticular manifestation of RA.

Figure. Kaplan-Meier Survival Curve for Patients with UIP (solid line) and without UIP (dashed line)

Cardiovascular Morbidity and Associated Risk Factors in Spanish Patients with Chronic Inflammatory Rheumatic Diseases Attending Rheumatology Clinics. Santos Castañeda[1], Maria Auxiliadora Martin[2], Carlos González-Juanatey[3], Javier Llorca[4], María Jesús García Yébenes[2], Sabina Pérez-Vicente[5], Jesús Sánchez Costa[2], Federico Diaz-Gonzalez[6], Miguel A. González-Gay[7] and CARMA Project Collaborative Group[2]. [1]Hospital Universitario de La Princesa, IISP, Madrid, Spain, [2]Sociedad Española de Reumatología, Madrid, Spain, [3]Hospital Universitario Lucus Augusti. Cardiology Division, Lugo, Spain, [4]School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), Santander, Spain, [5]Unidad de Investigación de la Sociedad Española de Reumatología, Madrid, Spain, [6]Servicio de Reumatologia.Hospital Universitario de Canarias, La Laguna, Spain, [7]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain.

Background/Purpose: The prevalence of cardiovascular disease (CVD) in chronic inflammatory rheumatic diseases (CIRD) is higher than in the general population. Recent studies have emphasized that tight control of the disease leads to a reduction in the rate of CVD in patients with rheumatic diseases. However, the prevalence of CVD in patients with CIRD and low disease activity is not well established. Thus, the aim f this study was to establish the cardiovascular (CV) morbidity and associated risk factors for CV disease (CVD) in Spanish patients with chronic inflammatory rheumatic diseases (CIRD) with low disease activity and unexposed individuals attending rheumatology clinics.

Methods: Analysis of data from the baseline visit of a 10-year prospective study (CARdiovascular in rheuMAtology-CARMA-project) that includes a cohort of patients with CIRD [rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA)] and another cohort of matched individuals without CIRD attending outpatient rheumatology clinics from sixty-six hospitals in Spain. Prevalence of CV morbidity, CV risk factors and systematic coronary risk evaluation (SCORE) assessment were analyzed.

Results: 2,234 patients (775 RA, 738 AS and 721 PsA) and 677 unexposed subjects were included.

Patients had low disease activity at the time of recruitment. PsA patients had more commonly classic CV risk factors and metabolic syndrome features than did the remaining individuals.

Prevalence of CVD was higher in RA (10.5%) than in AS (7.6%), PsA (7.2%) and unexposed individuals (6.4%). A multivariate analysis adjusted for the presence of classic CV risk factors and disease duration revealed a

positive trend for CVD in RA (OR=1.58; 95%CI=0.90–2.76; p=0.10) and AS (OR=1.77; 95%CI=0.96–3.27; p=0.07). Disease duration in all CIRD groups and functional capacity (HAQ) in RA were associated with an increased risk of CVD (OR=2.15; 95%CI=1.29–3.56; p=0.003). Most patients had a moderate CV risk according to the SCORE charts.

Conclusion: Despite recent advances in the management of CIRD, incidence of CVD remains increased in Spanish subjects with CIRD attending outpatient rheumatology clinics. It is of particular relevance that almost half of them were receiving biological therapy and most patients had low disease activity at the time of assessment.

Are Tender Joints Better Than Synovitis to Predict Structural Damage in Rheumatoid Arthritis? Peter Cheung[1], Karine Mari[2], Valerie Devauchelle[3], Jacques Bentin[4], Sandrine Jousse-Joulin[5], Maria-Antonietta d'Agostino[6], Gérard Chales[7], Isabelle Chary-Valckenaere[8], Fabien Etchepare[9], Philippe Gaudin[10], Xavier Mariette[11], Alain Saraux[12] and Maxime Dougados[13]. [1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [2]RCT, Lyon, France, [3]Brest university medical school, EA 2216, Lab Ex, INSERM, IGO, UBO and CHU de la Cavale Blanche,, Brest, France, [4]CHU-Brugmann, Brussels, Belgium, [5]CHU Brest, Brest, France, [6]Versailles-Saint Quentin en Yvelines University, Boulogne-Billancourt, France, [7]CHR - Hopital Sud, Rennes, France, [8]Nancy University Hospital, Nancy, France, [9]AP-HP, La Pitié-Salpétrière Hospital, Rheumatology Department, Paris-VI University, Paris, France, [10]Hopital Sud Grenoble, Echirolles, France, [11]Paris-Sud University, Paris, France, [12]CHU Brest and EA 2216, UBO, Brest, France, [13]Université Paris René Descartes and Hôpital Cochin, Paris, France.

Background/Purpose: Longitudinal studies indicate that synovitis can predict subsequent structural damage in rheumatoid arthritis (RA) but the clinical relevance of tenderness is unclear. The aim is to evaluate the predictive validity of tenderness for subsequent structural damage in RA, with synovitis as the comparator.

Methods: *Study design*: 2-year prospective study. *Patients*: Active RA (1987 ACR criteria) requiring anti-TNF. *Data collected*: For each patient, 32 joints were evaluated (2 wrists, 10 MCP, 10 PIP, 10 MTP) for tenderness and clinical synovitis, followed by blinded US assessment for synovitis in B-mode and Power Doppler (PDUS), at baseline and after 4 months of anti-TNF. X-rays of hands and feet were performed at baseline and 2 years. Radiographic progression: occurrence/worsening in structural damage (bone erosion/joint space narrowing) at 2 years compared to baseline. *Analysis*: The ability of baseline tenderness or synovitis to predict radiographic progression of the same joints at 2 years was compared using odds ratio, OR with 95% confidence interval, through generalized estimating equation adjusted for within patient correlation, age, gender, disease duration, baseline DAS28 and initial structural damage.

Results: Fifty-nine out of the 77 recruited patients had completed the 4 months of the study with radiographic evaluation at 2 years (female: 81%, age 56±12 years, rheumatoid factor positive: 73%). Radiographic progression was observed in 9% of the 1888 evaluated joints (16% of the 118 wrists, 7% of the 590 MCP, 8% of the 590 PIP, and 11% of the 590 MTP). Baseline tender joints were the least predictive for radiographic progression at 2 years (OR=1.53 [1.02; 2.29] p=0.04) when compared to synovitis (clinical OR=2.08 [1.39; 3.11] p<0.001 or PDUS OR=1.80 [1.20; 2.71] p=0.005 respectively) (Figure 1). Tender joints with presence of synovitis, was predictive of radiographic progression (OR=1.89 [1.25, 2.85] p=0.002) while non-tender joints with no synovitis was negatively predictive (OR=0.57 [0.39, 0.82] p=0.003) (Figure 2).

Conclusion: Clinical or US synovitis is more predictive than tenderness to predict subsequent structural progression. Co-existence of tenderness and synovitis at the level of an individual joint would suggest the need for either local/systemic treatment to prevent subsequent structural damage.

Figure 1. The predictive ability of baseline tenderness for radiographic progression at 2 years compared to synovitis

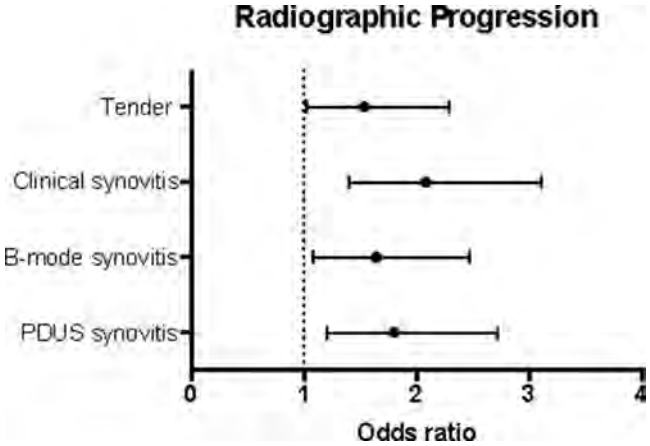

Figure 2. Predictive ability of tenderness with/without synovitis to predict radiographic progression

Predictors of Deterioration in Subjective Cognition: Results from a Rheumatoid Arthritis (RA) Observational Cohort Study. Christine K. Iannaccone[1], Jing Cui[2], Jonathan S. Coblyn[1], Michael Weinblatt[3] and Nancy A. Shadick[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital/Harvard University, Cambridge, MA.

Background/Purpose: Previous studies have suggested that RA confers an increased risk for worsened cognition later in life compared with the general population. Research in dementia has also indicated that the presence of subjective cognitive complaints may be a sensitive indicator of cognitive decline. Little is known about the inflammatory, psychological, and functional predictors of worsening subjective

cognitive complaints among patients with RA. Less is known about the relative contribution of how a change in these risk factors may affect an RA patient's perceived cognitive function.

Methods: We analyzed data from BRASS, a longitudinal RA cohort study. The data collection includes joint exams, serological analyses, and patient reported outcome measures collected annually from 2003–2014. Patients were asked to report the degree of their cognitive complaints concerning their memory, concentration, and word-finding difficulties (Table). In univariate analyses, we assessed known predictors for cognitive complaints (age, gender, ethnicity, education, CV Risk (Desai et al, 2012)) and computed variables that measured the past year's change (MDHAQ depression, MDHAQ fatigue, MDHAQ sleep, exercise level (METS), DAS28-CRP3, corticosteroid use) in relation to a worsening of cognitive complaints. Univariate factors ($p<0.10$), sociodemographic variables and the CV risk score were then entered into a multivariate backwards elimination mixed model to assess their impact on the degree of cognitive complaints.

Results: There were a total of 1126 subjects with at least two annual visits used in this analysis. Univariate analyses revealed that an increase in MDHAQ depression, fatigue, and corticosteroid use as well as a decrease in sleep quality and exercise level were associated with worsened cognitive complaints at follow-up. The multivariate mixed model that adjusted for sociodemographic variables and the CV risk score showed only that worsening MDHAQ depression, fatigue and increased corticosteroid use were associated with an increase in cognitive complaints one year later (Table). Neither a change in DAS28-CRP3 score nor exercise level impacted the degree of reported cognitive complaints.

Conclusion: Cognitive difficulties in RA are sensitive to a worsening of psychological factors such as depression but also to a change in corticosteroid use and fatigue. In this analysis disease activity measures do not appear to influence subjective cognitive complaints over time. Future studies of cognition difficulties in RA patients should focus on whether corticosteroid use and fatigue levels may be markers of subclinical disease activity that may drive patients to more likely reflect upon cognitive difficulties.

Clinical and Psychological factors predicting an increase is subjective cognitive complaints

Multivariate Mixed Model*	β coefficient	Standard Error	P-Value
Age (continuous)	−0.001	0.002	0.64
Sex (Female or not)	−0.100	0.059	0.09
CV Risk Score (0–9)	−0.004	0.013	0.76

The Association of Body Mass Index (BMI) and Radiographic Progression of Joint Disease in Rheumatoid Arthritis (RA). Christine K. Iannaccone[1], Jing Cui[2], K P Liao[1], Jonathan S. Coblyn[1], Michael Weinblatt[3] and Nancy A. Shadick[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA, [3]Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital/Harvard University, Cambridge, MA.

Background/Purpose: Previous studies suggest that lower BMI is associated with progression of radiographic joint damage in RA but little is known about the biological role BMI plays in radiographic joint damage and research outcomes of the association have varied. Whether the association of BMI and radiographic joint damage may be mediated by disease activity variables is currently unknown. Using a cohort of RA patients, this study aims to examine the relationship between BMI and radiographic joint damage and disease activity.

Methods: We analyzed data from a longitudinal RA cohort study. The data collection included joint examinations, blood draws and patient reported outcome measures over 10 years. Hand and wrist radiographs were acquired at baseline and 2 years and scored by the van der Heijde-modified Sharp score method (vdHSs) (n=543). We created a dichotomous outcome variable for radiologic progression; defining patients with radiographic progression as having a change of ≥ 10 units in total vdHSs over two years. We conducted univariate analyses to assess predictors of radiographic joint damage progression that included age, gender, BMI group (underweight BMI $<20 kg/m^2$, normal BMI 20–24.9 kg/m^2, overweight BMI 25–29.9 kg/m^2, obese BMI $\geq 30 kg/m^2$ (Baker et al, 2011)), DAS28-CRP4, anti-TNF use and anti-CCP status. For our primary analysis, we constructed a multivariate logistic regression model to study the effect between BMI and radiographic progression.

Results: We studied 543 patients with a mean age (SD) of 57.6 (12.7) years and a mean disease duration of 14.4 (12.2) years. Eighty-three percent were female and 68.3% were anti-CCP+; 69 (12.7%) of the patients had progression of joint damage. In the univariate analysis, BMI (group), anti-CCP+, and DAS28-CRP4 were all associated with radiographic joint damage, but age, gender and anti-TNF use did not show any association. The multivariate logistic regression analyses showed that patients who were underweight or normal weight had a significantly increased odds (OR=4.85, 95%CI 1.76–9.05; OR=3.99, 95%CI 1.76–9.05) of having radiographic progression compared to patients who were obese. Having a higher DAS28-CRP4 score was associated with greater odds of having radiographic joint damage (Table).

Conclusion: We found that lower BMI was associated with radiographic joint damage progression in RA, independent of disease activity. Further work is necessary to understand the biological role BMI plays in radiographic joint damage progression, as well as the involvement of inflammation in the relationship between BMI and progression of joint disease in RA.

Association of BMI and radiologic progression of joint disease in RA

Multivariate Logistic Regression Model*	Odds Ratios	Confidence Intervals
BMI (underweight vs. Obese)	**4.85**	**1.34–17.53****
BMI (Normal vs. Obese)	**3.99**	**1.76–9.05**
BMI (Overweight vs. Obese)	1.65	0.68–4.02
DAS28-CRP4 (continuous)	**1.28**	**1.08–1.51**

1371

Impact of Metabolic Syndrome (MetS) on Rheumatoid Arthritis Disease Activity. Federico Parra-Salcedo[1], Irazú Contreras-Yáñez[2], Daniel Elías-López[3], Carlos A. Aguilar-Salinas[3] and Virginia Pascual-Ramos[2]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán., Mexico City, Mexico.

Background/Purpose: The purpose of the study was to describe prevalence and components (c) of MetS in a cohort of early RA, to compare it with data from matched controls and to investigate MetS impact on disease activity.

Methods: The study population was a prospective cohort of early RA (95% satisfying 2010 ACR/EULAR criteria) initiated in 2004. At baseline, 2 months-apart for the first 2 years and thereafter at least six-months-apart, patients had complete medical evaluations that included height, weight and blood pressure, standardized rheumatic evaluations and assessments of

comorbidity and treatment; at 6 months fixed intervals, fasting serum glucose (GLU), triglycerides (TRG), HDL-Cholesterol (HDL) and acute reactant-phase were performed. Data from a local database of healthy controls randomly selected and matched were used.

MetS was defined according to 3 sets of criteria (ATP-III, AHA/NHLBI, IDF) and body mass index (BMI) ≥30 was used as a surrogate of the waist circumference criteria-c. Sustained remission (SR) was defined according to ACR/EULAR 2012 criteria and lasting ≥ 6 months.

The study was approved by the internal review board. Written informed consent was obtained.

Appropriated statistics was used. All statistical tests were 2-sided and evaluated at the 0.05 significance level.

Results: Up to March 2014, 162 patients were included in the cohort, of whom 160 had complete baseline data; they were more frequently middle-aged females (142 □S, [mean±SD] years of age: 38.1±12.8), RF+ (81.3%), ACCP+ (83.8%) and had high disease activity; comorbid conditions were present in 82 patients (51.3%). Patients were treated with conventional DMARDs.

Prevalence of MetS at the baseline evaluation varied (depending on the criteria applied) from 11.3% to 17.5% in RA patients and was similar to that in controls (vs. 13.8% to 18.8%). Distribution of MetS c varied from 64–100% for BMI-c, 93–96% for TRG-c, 94–96% for HDL-c, 21–22% for systolic blood pressure-c and from 28–54% for GLU-c.

During follow-up (69.2±36.8 months), 108 patients had at least ≥ 1 sustained remission state at (median) 14 months of study entry and remained in remission for 16 months; of them, 20.4% had MetS and no differences were seen between patients with/without MetS regarding remission related outcomes.

Up to last follow-up, 39 patients (34.5%) developed incidental MetS (out of 113 baseline MetS-free patients). Annual incidental rate decreased after the third year of follow-up. Patients who developed incidental MetS were older, more frequently menopause females, had higher BMI, had more cumulative disease activity and disability previous incidental MetS and developed more frequently erosive disease than their counterparts. In the Cox regression analysis, cumulative DAS28 (OR: 1.81, 95% CI: 1.346–2.433, p=0.000) and baseline BMI (OR: 1.131, 96% CI: 1.035–1.236, p=0.007) were the only predictors for incidental MetS (X^2=28.8%).

Conclusion: MetS prevalence in a cohort of early RA patients was similar to that from matched controls and varied from 11 to 18%. Cumulative disease activity and higher BMI were risk factors for incidental Mets. Disease activity control in RA patients may additionally impact comorbid conditions.

Prevalence of Cardiovascular Disease in US Veterans with Rheumatoid Arthritis and Hepatitis C Infection.

Ruchika Patel[1], Ted R. Mikuls[2], J. Steuart Richards[3], Grant W. Cannon[4], Gail S. Kerr[5], Lisa A. Davis[6], Liron Caplan[7] and Joshua F. Baker[8]. [1]University of Pennsylvania and Philadelphia VA Medical Center, Philadelphia, PA, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]Washington DC VA and Georgetown University, Washington, DC, [4]Salt Lake City VA and University of Utah, Salt Lake City, UT, [5]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [6]Denver VAMC and Univ of Colorado School of Medicine, Aurora, CO, [7]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [8]University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Chronic hepatitis C (HCV) and rheumatoid arthritis (RA) have both been associated with higher cardiovascular disease (CVD) in US veterans. Whether the presence of both conditions compounds the risk of CVD remains unknown. We compared the prevalence of CVD in RA patients with and without HCV.

Methods: In this cross-sectional study, 97 out of 1952 (5%) RA subjects were identified with HCV within the Veterans Affairs Rheumatoid Arthritis (VARA) registry by the presence of at least one diagnosis (ICD9) code for chronic HCV. This was validated by chart review in a subset of 28 RA patients, of which 25 (89%) were identified as HCV-antibody positive. At enrollment, the presence of cardiovascular disease (composite of myocardial infarction, percutaneous coronary intervention, coronary artery bypass graft, stroke, heart failure, and peripheral vascular disease) was determined using previously validated algorithms based on ICD9 codes and Current Procedural Terminology codes. Step-wise multivariable logistic regression models assessed differences in the prevalence of CVD, adjusting for factors known to be associated with CVD in RA.

Results: At enrollment, HCV-positive RA patients were younger, were more likely to be African-American, were more likely to smoke, had a lower body mass index (BMI), and had shorter disease duration **(Table 1).** RA disease characteristics between the two groups were similar, though HCV-positive patients were less likely to be prescribed methotrexate and had higher disease activity scores. CVD was less prevalent in the HCV-positive RA patients [24 (25%) vs. 729 (39%)]. There was no difference noted in the prevalence of other comorbidities (type 2 diabetes, chronic kidney disease, or hypertension). LDL, HDL, and triglyceride levels were similar between groups **(Table 1)**. After adjusting for age, sex, race, smoking, BMI, comorbidities, disease duration, and RA therapies, the prevalence of CVD was lower in the HCV-positive RA group [OR 0.58 (0.33–0.99) p=0.05]. In multivariate regression logistic models performed in a subset of 942 subjects with available data and adjusting for DAS28 scores, these associations were no longer significant [OR 0.55 (0.28–1.09), p=0.09 (**Table 2**)], although the point estimate remained similar.

Conclusion: Patients with concomitant RA and chronic HCV appear to have a lower odds of prevalent CVD at enrollment compared to those with RA alone. It might be hypothesized that comorbid HCV infection modulates chronic systemic inflammation by altering known atherogenic pathways.

Physical Function of Patients with RA Varies Importantly Across Countries, and These Differences Are Not Attributed to GDP: Results from Multi-National Study with 17 Countries. Polina Putrik[1], Sofia Ramiro[2], Andras Keszei[3], Ihsane Hmamouchi[4], Maxime Dougados[5], Till Uhlig[6], Tore K. Kvien[6] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Amsterdam Rheumatology Center, University of Amsterdam & Hospital Garcia de Orta, Almada, Portugal, Amsterdam, Netherlands, [3]Uniklinik RWTH Aachen University, Aachen, Germany, [4]Mohamed V Souissi University, Rabat, Morocco, [5]Paris Descartes University, Paris, France, [6]Diakonhjemmet Hospital, Oslo, Norway.

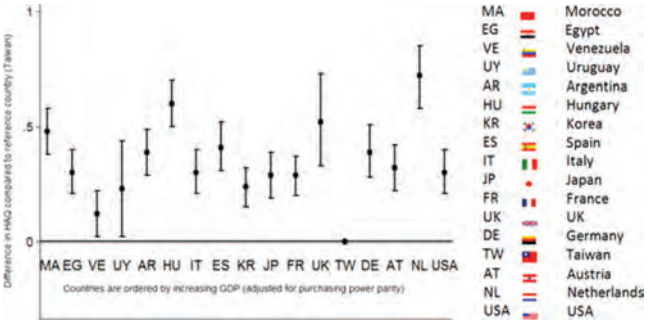
Background/Purpose: Physical function is an important outcome in RA and is essential for patients' quality of life. Is has not yet been sufficiently explored whether country level differences in reported function exist, and whether they interact with individual level factors. The objective of this study was to understand which individual or country level socio-economic factors contribute to functional status of RA patients.

Methods: Data from a cross-sectional multinational (17 countries) study (COMORA) was used. Contribution of age, gender, education, employment to function (as measured by the HAQ) were explored, adjusting for potential confounders. Adjusted differences (Bonferroni correction) between countries were tested. Taiwan was chosen as the reference (country with lowest mean HAQ). Further, country was replaced by gross domestic product (GDP) (low vs high GDP), and contribution of socio-economic welfare was investigated. Improvement in R-square of the two models that included either country or GPD was compared. Interactions between (1) education (2) age and (3) gender with country and GDP were tested.

Results: A total of 3920 RA patients from 17 countries (range 30 to 411) were included in COMORA. Mean age was 56 y.o. (SD13), 82% females, 35% and 39% had primary and secondary education, respectively. Mean HAQ was 1.0 (range 0.7 (Taiwan) – 1.5 (Morocco)). Gradients in HAQ across individual socio-economic factors were seen for education and gender but not age, after adjusting for individual disease characteristics and disfavouring low educated (β=0.16 vs high educated) and females (β=0.11 vs males). Final model was adjusted for comorbidities (Wolfe-Michaud index), total joint count, swollen joint count, erythrocyte sedimentation rate, and marital status. Country differences in HAQ varied from 0.11 (Venezuela) to 0.74 (Netherlands) compared to Taiwan, after adjustment for individual factors (Figure 1). Low GDP countries had 0.11 higher score on HAQ compared to high GDP countries. Contribution of country to R-square (model fit) was 0.05 and of GDP 0.01 (negligible). Interactions were either not statistically significant or not clinically relevant after stratification.

Conclusion: Among socio-economics factors, female gender and low education were independently associated with worse physical function after adjusting for individual disease characteristics. While substantial differences in HAQ exist between countries, socio-economic welfare did not explain these differences. Other cultural factors should be examined. Awareness of existing inequalities is a first step towards clinical and policy actions to reduce them.

Figure 1. Difference in HAQ score between countries, adjusted for confounders.



Disclosure: P. Putrik, None; **S. Ramiro**, None; **A. Keszei**, None; **I. Hmamouchi**, None; **M. Dougados**, None; **T. Uhlig**, None; **T. K. Kvien**, None; **A. Boonen**, None.

1374

A Comparison of the Risk for Cardiovascular Event in Patients with Rheumatoid Arthritis Treated with Biologic Disease Modifiers and Patients Treated with Methotrexate Only. Majed Khraishi[1] and Rana Aslanov[2]. [1]Nexus Clinical Research, St John's, NF, [2]Memorial University of Newfoundland, St.John's, NF.

Background/Purpose: We aimed to investigate whether the 10-year cardiovascular risk (CV) differs between patients with RA treated with Biologic Disease Modifiers (BDMARDs) and Methotrexate (MTX) and with MTX only.

Methods: Patients with RA receiving MTX and BDMARDs were prospectively followed-up from January 2011 to March 2014. Cardiovascular risk was assessed using the Framingham Risk Score (CCS 2009 Guidelines) and compared between cohorts. The presence of traditional CV risk factors was ascertained at the baseline and at every six months of observation up to 24 months.

Results: From 515 patients enrolled at the baseline, 15 patients dropped out of the study. Total 500 patients (75.2% females) with median age 57 years (Q1-Q3=50–65) were prospectively followed for at least 24 months. The mean (SD) age at RA diagnosis was 46.7 (13.5) years with the mean (SD) duration of RA symptoms 10.0 (8.6) years. Overall, females were significantly younger (p (95%CI)=0.016 (0.6–5.7)) while more males were obese (61.3% vs. 49.5%, p=0.023). Forty (8.0%) patients with documented MI and 12 (2.4%) patients with TIA/Stroke had their CV events prior to the study. Twelve patients (2.4%) experienced MI during the observation period with median age for males 68 years and for females 75 years. Significant differences in age, disease duration and activity indices were detected between cohorts. However, no significant changes were found in gender distribution, smoking status, and mean Atherogenic Index (AI) values. RA patients treated with MTX were older at the time of RA diagnosis and enrollment into the study but with significantly shorter duration of disease. 50.2% of patients were treated by Prednisone; 95.8% by MTX. 10-year CV risk was strongly correlated with Prednisone (r=0.122, p=0.006) and MTX only (r=0.178, p<0.001) therapy, and with total number of comorbidities in RA patients (r=0.569, p<0.001). Men had a significantly higher risk for CV event than women at the baseline and 24 months later.

	BASELINE		14.8 (9.0)	24-MONTH		
	MTX	BIO + MTX	P (95%CI)	MTX	BIO + MTX	P (95%CI)
CRP	7.0 (15.5)	14.7 (28.1)	<0.001 (−11.9-(−3.4))	5.5 (8.6)	8.4 (13.9)	0.009 (−5.1-(−0.7))
DAS28	3.1 (1.1)	4.0 (1.2)	<0.001 (−1.1-(−0.7))	2.8 (1.1)	3.4 (1.2)	<0.001 (−0.8-(−0.4))
CDAI	11.9 (9.4)	18.1 (10.0)	<0.001 (−8.0-(−4.5))	9.9 (7.4)	13.6 (9.7)	<0.001 (−5.2-(−2.0))
HAQ	0.7 (0.9)	1.1 (0.8)	<0.001 (−0.6-(−0.3))	0.6 (0.7)	1.0 (0.8)	<0.001 (−0.5-(−0.3))
TC	4.1 (1.9)	3.3 (2.6)	<0.001 (0.4–1.2))	3.8 (2.0)	3.5 (2.5)	0.107 (−0.1–0.7)
HDL-C	1.2 (0.7)	1.1 (1.2)	0.656 (−0.1–0.2)	1.2 (0.7)	1.2 (1.1)	0.703 (−0.2–0.1)
LDL-C	2.5 (1.3)	1.7 (1.4)	<0.001 (0.6–1.1)	2.2 (1.3)	1.2 (1.3)	<0.001 (0.8–1.2)
AI (TC/HDL-C)	3.7 (1.2)	3.6 (1.9)	0.408 (−0.2–0.5)	3.4 (1.1)	3.3 (1.4)	0.434 (−0.2–0.4)
10-year CV Risk	14.8 (9.0)	12.3 (99.3)	0.003 (0.9–4.2)	13.7 (8.6)	11.8 (8.9)	0.016 (0.4–3.5)

Conclusion: Our findings demonstrated significant difference in the 10-year cardiovascular risk at 24 months between the two treatment modalities. The combination of BDMARDs and MTX treatment modality seems to be more beneficial in the reducing patients' risk for CV events. Intensive treatment of chronic inflammation positively affects both patients' arthritis and their RA-dependent CV risk.

Educational Level and Not Ethnicity an Important Determinant of Disease Progression in Patients with Rheumatoid Arthritis. Sharon Dowell[1], Gail S. Kerr[2], Yusuf Yazici[3], Christopher Swearingen[4], Mercedes Quinones[5], Luis R. Espinoza[6], Edward L. Treadwell[7], Theresa Lawrence-Ford[8], Yvonne Sherrer[9], Angelia Mosley-WIlliams[10], Ignacio Garcia-Valladares[11], Rodolfo Perez Alamino[12], Chunqiao Luo[13], Akgun Ince[14], Adrian Godoy[1] and John Amatruda[1]. [1]Howard University, Washington, DC, [2]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [3]New York University School of Medicine, New York, NY, [4]University of Arkansas, Little Rock, AR, [5]Howard University Hospital, Washington, DC, [6]LSU Medical Center, New Orleans, LA, [7]East Carolina University, Greenville, NC, [8]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [9]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [10]Detroit VAMC, Detroit, MI, [11]Hospital General de Occidente, Zapopan, Jal., Mexico, [12]LSUHSC, New Orleans, LA, [13]University of Arkansas for Medical Sciences, Little Rock, AR, [14]St. Louis University, St. Louis, MO.

Background/Purpose: Formal educational level is often used as a surrogate for socioeconomic status and in patients with rheumatoid arthritis (RA), low levels have been associated with greater morbidity and worse disease outcomes. Yet, the role of formal educational level and its impact on meaningful clinical response (MCR) in ethnic minorities with RA is unknown**.** We evaluated the correlation of educational level with meaningful clinical response in ethnic minorities with RA.

Methods: Ethnic Minority RA Consortium (EMRAC) patients with at least one follow up visit were assigned to three educational level categories: high school only (HS), high school with some college, and college graduates. Comparisons between educational categories of demographic (age, gender, race, tobacco use), RA disease status (RF, ACPA, nodules/erosions), and RA treatment (prednisone, DMARD, biologics [anti-TNF, other]) variables were performed between these groups. The frequency of MCR (DRAPID3 [−3.6]) at 3, 6, and 12 months was also evaluated between educational groups.

Results: EMRAC patients (n= 723) with approximately 10 months of follow-up were evaluated (Table 1.). HS patients were significantly older, with longer disease duration and follow-up than those with advanced educational levels. HS patients also had higher baseline RAPID3 scores ($p < 0.001$). Overall, few patients achieved MCR and there was no difference in the frequencies of MCR between education categories at 3, 6 and 12 months. However, in multivariate analyses adjusted for, age, ethnicity, disease duration, and baseline RAPID3 scores, of those who did not achieve MCR, there were more HS patients with significant disease progression (RAPID3 D+0.2) versus college (RAPID3 D-0.5) and college graduates (RAPID3D-0.6)($p = 0.02$).

Conclusion: Regardless of race or ethnicity, RA patients with low formal education levels are at risk of disease progression. In clinical practice, this category of patient needs to be identified early, and focused interventions such as self-efficacy and health literacy instituted in order to improve disease outcomes.

Angiographic Pattern Among Rheumatoid Arthritis Patients Who Are Hospitalized Due to Acute Coronary Syndrome. Marie Holmqvist[1], Ängla Mantel[2], Tomas Jernberg[3], Stefan James[4], Solveig Wållberg-Jonsson[5] and Johan Askling[6]. [1]Clinical Epidemiology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden, [3]Department of medicine, Section of Cardiology, Karolinska University Hospital, Stockholm, Sweden, [4]3Department of Cardiology and Uppsala Clinical Research Center, Uppsala University, Uppsala, Sweden, [5]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umeå, Sweden, [6]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: We aimed at investigating and to compare the angiographic pattern of stenoses in patients with rheumatoid arthritis (RA) and general population comparators hospitalized due to acute coronary syndrome (ACS). This was done in a population which we have previously shown to be at increased risk for ACS, at increased risk of death following first event of ACS, and with more severe ACS events than the general population [1]. Our purpose was to investigate whether differences in angiographic findings could explain the more severe ACS phenotype.

Methods: Using nationwide Swedish registries, a cohort of individuals with established RA and general population individuals matched on sex, year of birth, area of residency and educational level were identified between 2006 and 2009. They were followed for a year to identify all cases hospitalized with a first time ACS and admitted to a coronary intensive care unit (CICU). For those with ACS who underwent angiography, the occurrence and extent of coronary stenoses were compared using logistic regression models. Analyses were stratified by diagnosis resulting in coronary angiography (non-ST-elevation myocardial infarction [NSTEMI], ST-elevation myocardial infarction [STEMI]), and adjusted for age and sex. The overall analyses were adjusted for age, sex, and diagnosis.

Results: 1135 RA patients and 3184 general population individuals were hospitalized with ACS during follow-up. Of those, 743 (65%) RA patients and 2203 (69%) general population comparators were admitted to a CICU within ±10 days of the event. 531 (71%) of those RA patients and 1683 (76%) of those general population comparators underwent angiography in conjunction with the ACS event. After adjusting for diagnosis resulting in angiography the adjusted OR for undergoing angiography was 0.84 (95% confidence interval [CI] 0.69, 1.02). Mean age at angiography was 70 years in both groups. 58 % of the RA patients and 53 % of the general population were women. STEMI was a more common indication for investigation in RA (45%) than in the general population (36%). RA patients were more likely to have three-vessel disease than the general population, even after adjusting for diagnosis, age, and sex, OR 1.53 (95% CI 1.04, 2.26). When stratified by indication, we noted an increased risk of having any stenosis, and for three-vessel disease for those with STEMI and for those with NSTEMI. All ORs are found in the table below.

Conclusion: RA patients with ACS seem to have more stenoses and a more unfavourable angiographic pattern than the general population with ACS. This, however, is seen regardless of indication for investigation and therefore does not seem to offer a ready explanation for the more severe presentation of ACS seen in RA.

Table. Odds ratios (OR) and 95% Confidence Intervals (CI) comparing findings on angiography in RA patients and general population comparators. Normal findings are used as reference group in all models.

	Overall OR (95% CI) Adjusted for age, sex, and diagnosis	NSTEMI OR (95% CI) Adjusted for age, sex	STEMI OR (95% CI) Adjusted for age, sex
Any stenosis	1.18 (0.88–1.59)	1.12 (0.80–1.56)	1.50 (0.79–2.85)
Any main stem	1.22 (0.76–1.96)	1.10 (0.63–1.93)	1.76 (0.67–4.61)
One vessel, not main stem	1.12 (0.81–1.55)	1.02 (0.70–1.49)	1.40 (0.72–2.72)
Two vessels, not main stem	1.12 (0.78–1.60)	0.99 (0.64–1.52)	1.65 (0.81–3.38)
Three vessels, not main stem	1.53 (1.04–2.26)	1.44 (0.91–2.28)	1.97 (0.92–4.24)

Anti-Citrullinated Peptide Antibody Titers and the Prevalence of Interstitial Lung Disease in Patients with and without Rheumatoid Arthritis. Chase Correia[1], Melissa R. Bussey[2], Brittany Panico[1], Rong Guo[1] and Rochella A. Ostrowski[3]. [1]Loyola University Medical Center, Chicago, IL, [2]Division of Rheumatology, Loyola University Medical Center, Maywood, IL, [3]Loyola University Medical Center, Maywood, IL.

Background/Purpose: Rheumatoid arthritis (RA) is a multisystem inflammatory disease characterized by a symmetric, destructive polyarthritis. Interstitial lung disease (ILD) is an extra-articular manifestation that occurs in 7.7% of RA patients and confers a poor prognosis. The anti-citrullinated peptide (anti-CCP) antibody has a specificity of greater than 90% for RA and is associated with worse articular outcomes. Four studies have evaluated the association between anti-CCP and ILD in RA patients with contradictory results. Furthermore, there are no published observations of an association between the extent of the anti-CCP titer elevation and the prevalence of ILD. The objective of this study is to determine whether the anti-CCP titer is associated with the prevalence of ILD in patients with and without RA.

Methods: A chart review was performed of all adult patients with anti-CCP testing between January 1, 2007 and December 31, 2012 at a single academic hospital. Patients were excluded if they had any of 12 other exposures or conditions known to cause ILD. Patients meeting inclusion criteria were divided into four groups based on anti-CCP titers: 0–4 U/mL (negative titer), 5–149 U/mL (low titer), 150–299 U/mL (moderate titer), and 300 U/mL or greater (high titer). Charts were reviewed to determine a diagnosis of RA by a rheumatologist or American College of Rheumatology (ACR) 2010 criteria, a diagnosis of ILD by imaging, relevant laboratory analysis, and treatment of RA. Fisher's exact test and logistic regression were used to compare the prevalence of ILD in the anti-CCP titer groups and to adjust for potential confounders.

Results: 2,030 patients met inclusion criteria, and 334 of these patients were diagnosed with RA by a rheumatologist or 2010 ACR criteria. Among all patients tested for anti-CCP, a progressively higher prevalence of ILD was associated with each anti-CCP titer group ($p<0.0001$) (Figure 1). However, the association was diminished when adjusting for age, C-reactive protein (CRP), tobacco use, and a diagnosis of RA (odds ratio: 1.18, 95% confidence interval: 0.78–1.78). In patients diagnosed with RA, there was a similar progression in the prevalence of ILD as anti-CCP titers increased, although this finding did not achieve statistical significance ($p=0.18$).

Conclusion: An increasing prevalence of ILD was observed in patients with higher levels of anti-CCP titers, regardless of a diagnosis of RA. However, additional factors, particularly age and disease activity represented by CRP, may influence these findings. To our knowledge, this is the first study to evaluate the relationship of increasing anti-CCP titers and ILD prevalence. Larger investigations are essential to better define the role of anti-CCP in the development of ILD and to determine whether higher anti-CCP titers further augment the risk of developing ILD.

The Impact of Rheumatoid Arthritis Activity and Medications on Pregnancy Outcomes. Megan E. B. Clorwse. Duke University Medical Center, Durham, NC.

Background/Purpose: While rheumatoid arthritis (RA) has historically improved in pregnancy, recent studies suggest the improvement may not be dramatic now that we are able to control the disease better outside of pregnancy. TNF inhibitors are now routinely continued during pregnancy for women with inflammatory bowel disease (IBD) because active IBD is associated with pregnancy morbidity. The link between RA activity and pregnancy outcomes.however, is less clear. We sought to explore the role that RA activity and medications play in pregnancy outcomes.

Methods: Pregnancies in women with RA from a prospective registry were reviewed to determine the extent that RA activity and medications in the 1st and 2nd trimesters impacted pregnancy outcomes. Disease activity was divided into 2 levels based on the worst DAS-CRP3 and/or physician's global assessment in the first 24 weeks of pregnancy. Chi-square and non-parametric tests were used for univariate analysis. A general estimating equation was used in multivariate analysis to account for multiple pregnancies in some women.

Results: A total of 31 pregnancies in 25 women with RA or JIA were enrolled in the registry before 24 weeks gestation. Seven pregnancies were in women with JIA and 24 with adult-onset RA. Two ended with first trimester miscarriages; both in women with low RA activity without prednisone or TNF inhibitor exposure, but one took methotrexate in pregnancy. Of the remaining 29 pregnancies, 15 (51.7%) had RA that was either mild or in remission throughout the 1st and 2nd trimesters and 14 (48.3%) had RA that was moderately to severely active during this period. 6 of 29 (20.7%) live births had poor outcomes: 4 with preterm delivery, 1 with preeclampsia, and 1 with preterm preeclampsia.

The rate of Sulfasalazine (SSZ), hydroxychloroquine (HCQ), and TNF inhibitor use was not statistically different for women with low vs high RA activity. Women with high RA activity, however, were more likely to take prednisone (57.1% vs 13.3%, $p=0.02$).

Significantly more women with preterm birth and/or preeclampsia had moderate/severe RA in early pregnancy (see table). While not statistically significant, more pregnancies with poor outcomes were exposed to prednisone and fewer to TNF inhibitors early in pregnancy. SSZ and HCQ were not associated with pregnancy outcomes. Methotrexate was associated with preterm birth.

A logistic regression model demonstrated that lower RA activity and use of a TNF inhibitor in the 1st and 2nd trimesters were associated with term birth without preeclampsia. Taking prednisone in the first half of pregnancy did not appear to impact pregnancy outcomes.

Conclusion: In this era of treat-to-target management of RA, our paradigm for RA pregnancy management may need adjusting. By controlling RA activity with medications considered relatively safe in pregnancy, we may be able to improve both the pregnancy experience and pregnancy outcomes.

Table: RA activity and medications in the 1st and 2nd trimesters of pregnancy for live births:

	All Live Births	Full term delivery without preeclampsia	Preterm delivery and/or preeclampsia	p-value
Number of live births	29	23 (79.3%)	6 (20.7%)	
Moderate/severe RA	14 (45.2%)	8 (34.8%)	6 (100%)	0.006
Physician's Global Assessment	63.7 (22.6)	Mean 69.9 (SD 20.1) Range: 25–100	Mean 40 (SD 15.2) Range: 20–60	0.005
Any prednisone use	10 (34.5%)	6 (26.1%)	4 (66.7%)	0.143
Prednisone dose	9.5mg (5.37)	10mg (SD 6.89) Range: 2.5–20mg	8.75mg (SD 2.5) Range: 5-10mg	0.83
Sulfasalazine	7 (24.1%)	6 (26.1%)	1 (16.7%)	0.55
Hydroxychloroquine	13 (44.8%)	11 (47.8%)	2 (33.3%)	0.44
Methotrexate	2 (6.9%)	0	2 (33.3%)	0.037

Studies on Ageing and the Severity of Radiographic Joint Damage in Rheumatoid Arthritis. L. Mangnus[1], H.W. van Steenbergen[1], E. Brouwer[2], E. Lindqvist[3], M. Reijnierse[1], P.K. Gregersen[4], S. M. Rantapää-Dahlqvist[5], D. M. van der Heijde[1] and A. H. M. van der Helm- van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]Lund University, Lund, Sweden, [4]The Feinstein Institute for Medical Research, Manhasset, NY, [5]Umeå University, Umeå, Sweden.

Background/Purpose: The Western population is getting older; consequently the proportion of elderly persons presenting with Rheumatoid Arthritis (RA) is increasing. We studied whether age is associated to the severity of RA at presentation and during the disease course, measured using radiographic joint damage.

Methods: Relationship between age and structural damage was studied in 7,232 radiographs of hands and feet of 1,879 RA-patients included in five European and North-American cohorts (Leiden EAC, Groningen, Lund, Umeå, Wichita). Within 702 early RA-patients included in the Leiden EAC between 1993–2006 associations between age and joint space narrowing (JSN) and erosions were evaluated separately; secondly mediation analyses were performed to explore whether the association of age with joint damage was mediated by symptom duration at diagnosis, swollen joint count (SJC), tender joint count (TJC), CRP or ACPA. Finally, 56 RA-patients included in the Leiden EAC between 2010–2012 underwent 1.5 Tesla MRI of the most symptomatic hand and foot at baseline and radiographs at baseline and after 1 year. The MRI-inflammation score (RAMRIS-synovitis plus bone marrow edema) was evaluated.

Results: In all cohorts, age at diagnosis was positively associated with more severe joint damage at baseline and during follow-up. A meta-analysis of these cohorts revealed that per year increase in age, patients had 2.6% (β1.026 $p<0.001$) more joint damage. Both JSN and erosion-scores correlated with age; pearson correlation coefficients were significantly stronger for erosion-scores than for JSN-scores (r 0.38 versus 0.29, $p=0.006$). Structural damage in PIP, CMC-1 and MTP-1 joints increased with age, however a similar increase was observed in wrist, MCP and MTP(2–5)-joints. Together this suggests that the association of joint damage with age cannot be totally explained by osteoarthritis. Age at diagnosis was associated with a shorter symptom duration (β0.99, $p= 0.011$), a lower odds on ACPA-positivity (OR 0.98 $p<0.001$) and was not associated with the SJC or TJC. Older age was positively associated with CRP (β1.016, $p<0.001$) but in a multivariate analysis including age and CRP, CRP was not associated with radiographic damage (β1.00, $p=0.14$). Therefore, symptom duration, ACPA and regular measures of inflammation did not mediate the association between age and joint damage. Finally, we questioned whether subclinical inflammation was a mediator. Age was significantly associated with the severity of MRI-detected inflammation when adjusted for CRP and SJC (β1.018, $p=0.027$). The effect size of the association between age and joint damage reduced after including MRI-inflammation in the analysis (from β1.032, $p=0.004$ to β1.025, $p=0.021$, adjusted for CRP and SJC), suggesting partial mediation.

Conclusion: RA-patients with a higher age at diagnosis had more severe joint damage at the time of diagnosis and during the disease course. This effect was partially explained by more severe subclinical joint inflammation at higher age. To what extend the remaining part of the effect is caused by disease-specific processes or is related to 'normal ageing' needs to be explored in further studies.

Patient Global Impression of Change for Patient Reported Outcomes in Rheumatoid Arthritis: Impact of Comorbidities. Pankaj Bansal[1], Aneet Kaur[1], Horace Spencer[1] and Nasim A. Khan[2]. [1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR.

Background/Purpose: Understanding patient's perspective of minimally clinically important difference (MCID) in health (or disease) status is important to improve patient-centered clinical care and planning and interpretation of clinical trial results. The aim of this study was to estimate mean changes in patient reported outcomes (PROs) and a PRO-based composite index [Routine Assessment of Patient Index Data 3 (RAPID3)] and assess the impact of comorbidities on MCID in rheumatoid arthritis (RA) patients.

Methods: A retrospective study of RA patients receiving routine clinical care at a single academic center from 2009 to 2012 was conducted. Eligibility criteria were a board-certified Rheumatologist diagnosed RA and ≥ 2 Rheumatology clinic visits. A patient completed questionnaire is part of routine clinical practice and includes patient's global impression of change compared to their last Rheumatology clinic visit on a 5-point Linkert scale (much better, somewhat better, about the same, somewhat worse, much worse). Data on socio-demographics; RA characteristics; PROs [functional status by Multi-Dimensional Health Assessment Questionnaires (MDHAQ); pain, patient's global assessment (PTGL) by 21-point Numeric Rating Scale; RAPID3; and comorbidities were extracted in standardized manner from medical records. Comorbidity burden was quantified by a composite comorbidity score (range: 0–9) [1] and categorized as low (0–1), moderate (2–3) and high (>3). Random effects analysis of variance models were used to assess the association between change in disease characteristics and PGIC classification. Since each subject may have multiple observations in the data, a random effects term was included to account for the correlation among observations from the same subject.

Results: Data on 155 patients [125 (80.6%) females; 112 (72.3%) white; median (interquartile range, IQR) age of 58 (50–66) years; RA duration 6 (1.4–9.8) years; seropositive 76.5%] were available for analysis. 46 (29.7%), 64 (41.3%), and 45 (29%) patients had low, moderate and high comorbidity burden respectively. Table shows the estimated mean of the study measures. Negative values means improvement in scores compared to prior Rheumatology visits. For each PRO and RAPID3 there was strong interaction with comorbidity burden. In general patients with low comorbidity burden have higher threshold for change for MCID than those with moderate to high comorbidity burden (Table).

Conclusion: Comorbidities have strong influence on RA patient's assessment of change of their health status. Comorbidities need to be considered when interpreting MCID.

	Somewhat better	About the same	Somewhat worse
MDHAQ (0-10)*			
Low comorbidity burden	−0.51	0.09	2.45
Moderate comorbidity burden	−0.43	−0.36	0.73
High comorbidity burden	−0.79	−0.34	−0.31
Pain (0-10)*			
Low comorbidity burden	−1.82	0.64	1.95
Moderate comorbidity burden	−0.34	−0.43	0.87
High comorbidity burden	−0.35	−0.13	0.41
PTGL (0-10)*			
Low comorbidity burden	−0.51	0.09	2.45
Moderate comorbidity burden	−0.43	−0.36	0.73
High comorbidity burden	−0.79	−0.34	−0.31
RAPID3 (0-30)*			
Low comorbidity burden	−2.85	0.76	4.43
Moderate comorbidity burden	−1.81	−0.97	1.94
High comorbidity burden	−1.15	−0.62	0.24

* P value < 0.001 for interaction of the variable with comorbidity burden.

Subaxial Cervical Spine Involvement in Symptomatic Rheumatoid Arthritis Patients: Comparison with Cervical Spondylosis. Helena Borrell[1], Javier Narváez[2], Jose Antonio Narvaez[3], Marta Serrallonga[4], Carmen Gomez Vaquero[1], Eugenia de Lama[1], Javier Hernandez Gañan[3] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [3]Hospital Universitari de Bellvitge - IDIBELL, Barcelona, Spain, [4]Institut de Diagnostic per la Imatge (IDI), Centre Bellvitge, Barcelona, Spain.

Background/Purpose: To investigate the frequency, location, nature, and clinical significance of subaxial involvement (below C1-C2) in a series of patients with rheumatoid arthritis (RA) and symptomatic involvement of the cervical spine.

Methods: Forty-one patients with RA were studied with cervical spine MRI. A comparative study of the incidence of the different types of subaxial lesions was also performed with respect to 41 age- and sex-matched patients with symptomatic cervical spondylosis.

Results: Stenosis of the spinal canal was found at the subaxial level in 85% of RA patients, and at the atlantoaxial level in 44%. The comparative study with cervical spondylosis revealed significant differences in the type and frequency of subaxial lesions (Table 1). In RA patients, subaxial stenosis seems to be the consequence of both the inflammatory activity of the disease (multilevel vertebral subluxations, inflammatory involvement of cervical spine ligaments, interapophyseal synovitis, bone marrow edema involving the vertebral plates and the interapophyseal joints, spinous process damage, and acquired vertebral blocks) and mechanical-degenerative changes (discopathy and ligamentum flavum hypertrophy).

Unconditional logistic regression analysis was used to identify MRI parameters of subaxial spine involvement associated with the development of

neurological dysfunction (Ranawat class II or III). Evidence of alterations in the signal intensity of the spinal cord was the only independent risk factor found for the development of neurological dysfunction (p=.01; OR=11.43), increasing the risk 11-fold. There was a trend toward statistical significance for spinal cord compression (p=.06; OR=3.95). The presence of stenosis of the subaxial spinal canal without evidence of cord compression did not achieve statistical significance (p=.17). These data suggest that neurological manifestations correlate poorly with MRI findings at this level.

Table 1. Frequency of subaxial lesions in patients with RA and Spondylosis.

	RA patients N = 41	Spondylosis N = 41	p value
Stenosis of the subaxial canal	85%	27%	0.0000003
Spinal cord compression	34%	0%	0.0001
Alteration in signal intensity of the spinal cord	27%	0%	0.0003
Bone marrow edema involving the vertebral plates and the interapophyseal joints	27%	2%	0.003
Inflammatory involvement of cervical spine ligaments (interspinal ligaments and/or ligamentum nuchae)	32%	0%	0.0002
Interapophyseal or facet joint synovitis	17%	0%	0.012
Synovitis of the uncovertebral joints	0%	0%	–
Spinous process damage (sharpening, erosions, sclerosis or fusion)	7%	0%	NS
Pannus formation	0%	0%	–
Discopathy (disk bulging or disruption and/or herniation)	90%	98%	NS
Ligamentum flavum hypertrophy	66%	22%	0.0001
Degenerative spinal osteophytosis	71%	78%	NS
Vertebral subluxation	24%	5%	0.026
Vertebral ankylosis	24%	2%	0.007
Sclerosis and/or hypertrophy of the interapophyseal joints	0%	49%	0.000001
Sclerosis and/or hypertrophy of the uncovertebral joints	0%	17%	0.0012

NS = not significant.

Conclusion: Subaxial stenosis seems to be the consequence of both the inflammatory process and mechanical-degenerative changes. Despite its frequency, it was not usually related to the occurrence of myelopathy symptoms, not even in cases with MRI evidence of spinal cord compression. These data seem to indicate a notable behavioral adaptation of this segment.

The Longitudinal Course of Fatigue in Rheumatoid Arthritis – Results from the Norfolk Arthritis Register. Katie L Druce[1], Gareth T Jones[1], Gary J. Macfarlane[1], Suzanne M. Verstappen[2] and Neil Basu[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Fatigue is common and burdensome in Rheumatoid Arthritis (RA). Though RA fatigue progression varies significantly between individuals, to date, published analyses have only considered average changes in fatigue. The aim of the current study was to determine if it is possible to distinguish participants who follow distinct trajectories of fatigue reporting over time and thus potentially inform to whom specific management should be targeted.

Methods: Participants from the Norfolk Arthritis Register (NOAR), a long-term inflammatory polyarthritis (IP) inception cohort, who met 1987 ACR RA criteria reported levels of fatigue (0–100mm visual analogue scale (VAS)) at recruitment and annually thereafter for four years. Among those with clinically relevant fatigue at recruitment (VAS≥20mm), changes in fatigue were calculated over the four years of follow-up; clinically significant improvements were defined as ≥10mm. Latent fatigue trajectory groups were determined using sex-stratified group-based trajectory modelling. Baseline variables (demographic, clinical and patient-reported) were compared between identified groups using descriptive statistics (p<0.05 considered significant).

Results: In 338 participants (30.2% male), there were only small average improvements in fatigue from recruitment to one (6.0mm, SD 26.9) and four years later (5.5mm, 29.3), yet improvements were clinically significant for 45.2% and 56.0% of participants at these follow-ups, respectively. The best fitting models revealed two fatigue trajectories in men (improved, and moderate-high), and three trajectories in women (as the male group, plus an additional 'High' trajectory (Figure 1)).

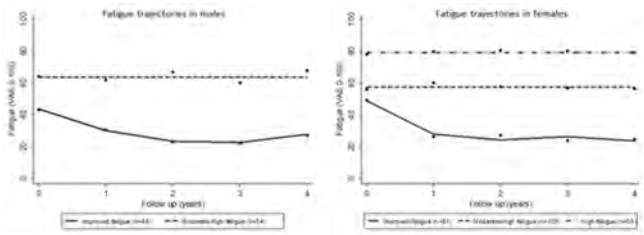

Figure 1. Fatigue trajectories in males (left) and females (right).

To determine the characteristics of those likely to benefit from fatigue-specific interventions, baseline variables were compared between those who improved and all other participants ('non-improved'). In both sexes, non-improvers reported significantly poorer scores for disability, pain, fatigue and sleep problems, at baseline. Female non-improvers were significantly younger, reported more disease activity and use of antidepressants and NSAIDs. Whereas, in males, the use of analgesics at recruitment was greater among non-improvers; as was the proportion of patients unable to work due to illness.

Conclusion: Among a group of patients who, on average, show only small improvements in fatigue, significant variation in fatigue progression exists. At presentation, it is possible to identify and characterise sub-groups of patients who do not improve. Such patients are most likely to require early and targeted interventions, to alleviate fatigue.

Disease Characteristics and RA Development in Undifferentiated Arthritis: A 2-Year Follow-up Study of 413 Patients with Arthritis of Less Than 16 Weeks Duration. Gina Hetland Brinkmann[1], Ellen Sauar Norli[1], Tore K. Kvien[1], Anne Julsrud Haugen[2], Lars Grøvle[2], Halvor Nygaard[3], Cathrine Thunem[4], Maria Dahl Mjaavatten[1] and Elisabeth Lie[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Østfold Hospital Trust, Fredrikstad, Norway, [3]Lillehammer Hospital of Rheumatic Diseases, Lillehammer, Norway, [4]Telemark Hospital, Skien, Norway.

Background/Purpose: Correct identification of the subset of patients with undifferentiated arthritis (UA) who will develop rheumatoid arthritis (RA) is important to enable initiation of appropriate treatment. Our objectives were to compare baseline characteristics and treatment of UA patients developing vs. not developing RA according to the 2010 ACR/EULAR RA classification criteria (UA-RA vs. UA-non RA) over a 2-year follow-up period, and to investigate the relationship between clinical RA diagnosis and fulfilment of the RA criteria in these patients.

Methods: Patients (18–75 years old) with ≥1 swollen joint of ≤16 weeks duration were from 2004 included in a multi-center longitudinal observational study and followed for 2 years with examinations at 0, 3, 6, 12 and 24 months. Patients with arthritis due to trauma, septic arthritis, crystal arthritis and osteoarthritis were excluded. Mann-Whitney U test, independent samples T test and chi-square test were used to compare baseline characteristics between UA-non-RA and UA-RA patients.

Results: 1119 patients were included during the period 2004–2010 (mean (SD) age 46(15) years, 55% females, median ((25, 75 perc) duration of joint swelling 34(13, 66) days). Patients with a clinical diagnosis of a rheumatic disease other than RA, and those without available anti-CCP/RF or follow-up data were excluded. Consequently, 663 patients were eligible for the current analyses, and 250 (37%) of these patients fulfilled the 2010 ACR/EULAR RA classification criteria at baseline. Among the remaining 413 patients, who were denoted UA, 27 patients (7%) were classified as RA during follow-up. 21/27 (78%) of these UA-RA patients fulfilled the criteria within the first 6 months. 58/386 patients (15%) of patients started DMARDs (3 patients started biologics for diagnosis of AS, RA and UA, respectively) vs. 16/27

(59%) in the UA-RA group (3 patients on biologics, all with clinical RA diagnosis) ($p<0.001$). In both groups approx. 2/3 of those started on DMARDs did so within the first 3 months and were mostly started on methotrexate. 22/386 (6%) of all the UA-non-RA were given a clinical diagnosis of RA during follow-up (19 of these patients were anti-CCP and RF negative).

Comparison of baseline characteristics between the UA-non-RA and UA-RA patients

		UA-non-RA (n=386)	UA-RA (n=27)	P-value
Age, mean (SD)		46.6 (14.8)	51.3 (13.8)	0.11
Female gender, n (%)		**207 (53.6)**	**20 (74.1)**	**0.039**
Duration of joint swelling, days, median (25, 75 perc.)		31 (10,66)	30 (14,60)	0.75
Body mass index, mean (SD)		25.9 (4.4)	26.2 (4.4)	0.707

	1 point	**n=99**	**n=2**	
	0 points	**n=30**	**n=1**	

***Standard 66-swollen joint count plus hips**

Conclusion: Among 413 patients with UA of ≤16 weeks duration only 7% fulfilled the 2010 RA classification criteria during 2 years of follow-up. Female gender, positive RF and/or ACPA, shoulder arthritis and number of involved joints were among the factors associated with RA development while ankle arthritis was more common in UA-non-RA patients. Some patients (mostly RF and/or ACPA negative) were given a clinical diagnosis of RA despite not fulfilling the criteria, but the proportion was low (6%).

Fibromyalgia and Its Effect on Treatment Response in Early Rheumatoid Arthritis Patients. Josefina Durán Santa Cruz[1], Bernard Combe[2], Jingbo Niu[1], Nathalie Rincheval[3], Cécile Gaujoux-Viala[4] and David T. Felson[1]. [1]Boston University School of Medicine, Boston, MA, [2]Hôpital Lapeyronie, Montpellier, France, [3]Institut Universitaire de Recherche Clinique, Montpellier, France, [4]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France.

Background/Purpose: Fibromyalgia (FM) occurs commonly in patients with rheumatoid arthritis (RA) and its effect on treatment response is unknown. In this study we aimed to evaluate if patients with RA and concomitant FM have an impaired response to treatment measured by traditional activity scores.

Methods: Patients from the ESPOIR cohort were analyzed. This prospective cohort included 813 patients with early arthritis not initially receiving disease-modifying antirheumatic drugs (DMARDs). We defined FM at baseline using Pollard et al. (Rheumatology (Oxford) 2010;49:924–928) validated criteria of tender joint count at least 7 higher than swollen joint count (72% sensitivity and 98% using ACR 1990 FM criteria as gold standard). Among the 697 patients who met RA classification (either ACR 1987 or ACR/EULAR 2010) criteria, we studied two groups, one with and the other without FM. The following endpoints were compared at 6, 12 and 18 months using a mixed linear regression model: 28-joint Disease Activity Score (DAS28), Simple Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI) and the Health Assessment Questionnaire. In addition attainment of low disease activity (LDA) (DAS28<3.2) and remission (DAS28<2.6, SDAI<3.3, CDAI<2.8) at these timepoints were analyzed using a log binomial regression.

Results: At baseline, patients with FM (n=120) had a higher DAS28, SDAI, CDAI and HAQ than patients with isolated RA (n=548). While they started out higher, DAS28 and other disease activity scores improved to a similar extent as in the isolated RA group. However, scores remained consistently higher among FM patients. (see figure) Achievement of LDA and of remission was significantly less likely in subjects with FM and few would have met treat to target goals.

Conclusion: Patients with FM and RA have a similar response to treatment according to a decrease in indexes of disease activity but may miss the target of remission or low disease activity.

Table 1. Comparison of rheumatoid arthritis activity scores and radiologic scores over follow up according to the presence of fibromyalgia

	FM	No FM	Difference in scores	P value*
DAS 28	3.50	3.05	0.45	<0.0001
SDAI	16.09	11.54	4.55	<0.0001
CDAI	14.98	10.75	4.23	<0.0001

What Discriminates Best Flares in Rheumatoid Arthritis (RA)? a Subanalysis of the Strass Treatment Tapering in RA Study. Agnès Danré[1], Bruno Fautrel[2], Toni Alfaiate[3], Thao Pham[4], Jacques Morel[5], Emmanuelle Dernis Labous[6], Philippe Gaudin[7], Olivier Brocq[8], Elisabeth Solau-Gervais[9], Jean-Marie Berthelot[10], Jean Charles Balblanc[11], Xavier Mariette[12], Florence Tubach[13] and Laure Gossec[14]. [1]La Pitié Salpêtrière, Paris, France, [2]Pitie Salpetriere Hospital, Paris, France, [3]APHP, Hospital Bichat, Paris, France, [4]Sainte Marguerite Hospital, Marseille, France, [5]Hôpital Lapeyronie, Montpellier, France, [6]Ch Du Mans, Le Mans, France, [7]Hopital Sud Grenoble, Echirolles, France, [8]Hospital of Princesse Grâce de Monaco, Monaco, France, [9]University Hospital of Poitiers, Poitiers, France, [10]CHU Nantes (Nantes University Hospital), Nantes, France, [11]Ch de Belfort, Belfort Cedex, France, [12]University Hospital, Le Kremlin Bicetre, Paris, France, [13]Universite Paris Diderot, Paris, France, [14]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Flares in rheumatoid arthritis (RA) are a patient-perceived increase of disease activity which might be particularly important to assess in the context of treatment tapering. However, there is little data on what patient-perceived flares really encompass. In a treatment tapering study, STRASS, patients were asked about flares, and many validated outcomes were collected.

The objective was to explore the discrimination properties of different validated outcomes for flares, by comparing these outcomes between visits where patients self-reported flares, and visits without flares, in the STRASS tapering study.

Methods: The STRASS study was a step-down randomized trial (ref). Patients had RA, were treated with adalimumab or etanercept for ≥12 months, and were in DAS 28-remission (DAS≤2.6) for ≥6 months. Patients were randomized to either the "spacing"(S) arm (where the TNF blocker was tapered gradually) or the "maintaining"(M) arm, over 18 months. Flares were evaluated through a patient-reported questionnaire every 3 months, asking: "Concerning the last 3 months, did you experience symptoms of a relapse of RA?". RA outcomes, including HAQ, patient global assessment, SF36, pain, tender joint count, swollen joint count, ESR and CRP were compared between visits with flares and visits without. Cohen's effect size was calculated for indicative purposes, without adjustment on these repeated measures. Effect size is considered high when above 0.8.

Results: In all, 137 patients were included in STRASS, 64 and 73 in the S and M arms respectively: age (mean±SD) 55±11 yrs, females 78%, RA duration 9±8 years. Over the 18 months of the study, the mean number of visits where the patient reported at least one flare (out of a possible total number of visits of 6 visits) was 1.87±1.74, with 2.44±1.68 visits with flares in the S arm, and 1.37 ±1.65 visits with flares in the M arm (p=0.0001). Overall, 55 patients (88.7%) in the S arm and 40 patients (55.6%) in the M arm reported flares at least once. Comparisons between visits at which patients reported flares, and visits without, showed statistically significant differences concerning all the outcomes, with effect sizes comprised between 0.27 [0.12–0.42] and 1.09 [0.94–1.25] (table). The highest effect sizes were observed for patient global assessment and SF36 PCS, and the lowest for ESR.

Conclusion: Patient-perceived flares are frequent during treatment tapering. Patient-reported outcomes discriminated better between visits with versus without flares, than physician measures or biology. More work is needed on the concept of flares.

Ref: Fautrel B et al. Arthritis Rheum 2013; 65: S1150.

Table:

	Visits with patient-reported flares. N=256	Visits without patient-reported flares. N=684	Indicative effect size [95% CI]
Patient global assessment 0–10	2.92 ± 2.41	1.11 ± 1.07	1.09 [0.94-1.25]
SF36 PCS	42.28 ± 8.86	49.70 ± 7.66	−0.91 [−1.13–−0.70]
Tender joint count	4.14 ± 5.73	0.97 ± 2.71	0.78 [0.63-0.94]
Swollen joint count	2.00 ± 3.12	0.41 ± 1.03	0.77 [0.62-0.92]
HAQ	0.67 ± 0.66	0.37 ± 0.53	0.56 [0.35-0.77]
SF36 MCS	43.77 ± 9.96	48.43 ± 10.05	−0.52 [−0.73–−0.30]
CRP, mg/l	5.73 ± 8.96	3.00 ± 3.68	0.44 [0.29-0.59]

Disease Flares during 10 Year Follow-up in Patients with Rheumatoid Arthritis Are Associated with Joint Damage Progression and Disability.

I.M. Markusse[1], L. Dirven[1], Y.P. Goekoop-Ruiterman[2], P.a. van der Lubbe[3], A.J. Peeters[4], P.J.S.M. Kerstens[5], W.F. Lems[6], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]HAGA hospital, The Hague, Netherlands, [3]Vlietland Hospital, Schiedam, Netherlands, [4]Reinier de Graaf Gasthuis, Delft, Netherlands, [5]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [6]VU Medical Center, Amsterdam, Netherlands.

Background/Purpose: Disease flares frequently occur in patients with rheumatoid arthritis (RA). It has been suggested that these may spontaneously remit, in which case targeted treatment including intensification at the time of a flare could entail overtreatment. We investigated the occurrence and outcomes of flares during long-term follow-up in early RA patients who were treated to target over 10 years.

Methods: In the BeSt study, which enrolled 508 patients, targeted treatment aimed at a disease activity score (DAS) ≤2.4. A flare was defined from the second year of follow-up onwards as a DAS >2.4 *and* an increase in DAS of ≥0.6 from the previous DAS, regardless of the height of the previous DAS, measured during 3-monthly visits. Of 480 patients sufficient follow-up data were available to apply this definition. Functional ability (health assessment questionnaire, HAQ) during a flare was compared to functional ability during the absence of a flare with a linear mixed model (LMM). Visual analogue scales (VAS) (increase of ≥20mm between two visits, yes/no) and radiographic progression (Sharp van der Heijde score; increase ≥0.5 during 1 year, yes/no) were analysed similarly with a generalized LMM.

Results: The incidence of flares was 7 – 11% per visit during year 2 to 4 of follow-up, and 4 – 6% per visit during the later years of follow-up. During year 2 to year 10, 321/480 patients (67%) experienced at least one flare with a median (interquartile range) frequency of 4 (2 – 8) times. At the time of a flare, functional ability decreased with a mean difference of 0.25 in HAQ (p<0.001). During a flare, the odds ratio (95% confidence interval) for an increase of ≥20mm in VAS compared to the previous visit was 8.8 (7.3 – 9.8), 9.6 (7.2 – 9.7) and 5.6 (4.8 – 6.6) for patient's assessment of disease activity, pain and morning stiffness, respectively, compared to the absence of a flare. The odds ratio for developing radiographic progression in a year a flare occurred was 1.7 (95% confidence interval 1.1 – 2.8), compared to a year without a flare. In patients without any flare during follow-up, median (IQR) radiographic progression from baseline to year 10 was 1.3 (0.0 – 3.1). The more flares occurred, the higher progression rates were observed: median (IQR) SHS progression was 2.3 (0.5 – 9.6), 3.0 (0.0 – 10.0) and 4.3 (0.5 – 20.1) in patients who experienced 1, 2 and ≥3 flares during follow-up, respectively (p=0.005). A similar dose response relation was shown for functioning; in patients without any flare during follow-up, median (IQR) HAQ was 0.0 (0.0 – 0.5) at year 10, and was 0.4 (0.0 – 0.9), 0.6 (0.1 – 0.9) and 0.8 (0.4 – 1.3) in patients with 0, 1, 2, or ≥3 flares during follow-up, respectively (p<0.001).

Conclusion: Disease flares in rheumatoid arthritis are associated with short term deterioration in functioning and pain as well as radiographic damage progression, and show a dose response relation with long term functional disability and joint damage. The incidence of flares was low, and with a treatment strategy targeted at DAS≤2.4, the frequency of flares further decreased over time. This suggests that the disease may become more indolent in the majority of patients.

Radiographic Progression Differs Between Trajectory Clusters Defined By DAS28 Scores in Early Rheumatoid Arthritis.

Cheryl Barnabe[1], Ye Sun[2], Gilles Boire[3], Carol Hitchon[4], Edward C. Keystone[5], J. Carter Thorne[6], Boulos Haraoui[7], Jeffrey R. Curtis[8], Désirée van der Heijde[9], Diane Tin[10], Janet E. Pope[11] and Vivian P. Bykerk[12]. [1]University of Calgary, Calgary, AB, [2]Mount Sinai Hospital, Toronto, ON, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]University of Manitoba, Winnipeg, MB, [5]University of Toronto, Toronto, ON, [6]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [7]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [8]The University of Alabama at Birmingham, Birmingham, AL, [9]Leiden University Medical Ctr, Leiden, Netherlands, [10]Southlake Regional Health Centre, Newmarket, ON, [11]Western University, London, ON, [12]Hospital for Special Surgery, New York, NY.

Background/Purpose: Group-based trajectory modeling defines clusters of individuals in observed data with similar disease trajectories. We have previously defined five distinct trajectories in early rheumatoid arthritis based on DAS28 scores. Our objective was to examine radiographic progression in these defined clusters.

Methods: Patients were assigned to mutually exclusive trajectories by their DAS28 scores over 24 months. Patients with baseline and follow-up radiographs (n=601) were included in this analysis and baseline demographics did not differ from the larger cohort (n=1,568). Radiographs were scored with the van der Heijde modification of the Sharp score (vdHSS). ANOVA with the Bonferroni correction was applied to test for mean differences in baseline and follow-up vdHSS between clusters. Paired t-tests were applied to

test differences in mean total vdHSS between baseline and last follow-up by cluster group. Pearson's chi-squared test was used to identify differences between clusters in the proportion of patients with vdHSS progression (≥3.5 units/year) and rapid progression (≥5 units/year).

Results: Clusters (Cl) were characterized as: Cl-1 (n=163, 27%) began in high disease activity and achieved remission; Cl-2 (n=121, 20%) began in moderate or low disease activity and achieved remission; Cl-3 (n=158, 26%) began in moderate disease activity and achieved low disease activity; Cl-4 (n=132, 22%) began in high disease activity and achieved moderate disease activity; and Cl-5 (n=27, 5%) began and remained in high disease activity. At 24 months, patients in Cl-5 were more frequently on biologics (35%) and steroids (38%) but were less frequently on methotrexate monotherapy (18%), despite earlier use of DMARD combination therapy (43% at 3 months) relative to other clusters. The overall mean baseline vdHSS score was 5.3 units (SD 8.4) with progression of 2.8 units annually (95%CI 2.4–3.2, p<0.001); 43% of the cohort had no change in radiographic scores in follow-up. Clusters differed in baseline and follow-up scores for joint space and total vdHSS but not erosions, with Cl-4 and Cl-5 experiencing the worst radiographic progression by 3.6 units annually (95%CI 2.5–4.6) and 4.4 units annually (95%CI 1.1–7.7) respectively (Table 1).

Table 1. Baseline and Mean Change in van der Heijde Sharp Scores over 24 months in Early Rheumatoid Arthritis, Overall and by Trajectory Cluster

	Erosion Score		Joint Space Score		Total vdHSS	
	Baseline	Change	Baseline	Change	Baseline	Change
	Mean (SD)	Difference (95%CI, p value)	Mean (SD)	Difference (95%CI, p value)	Mean (SD)	Difference (95%CI, p value)
OVERALL n=601	2.1 (3.8)	1.4 (1.2-1.7, p<0.001)	3.3 (6.1)	1.4 (1.1-1.6, p<0.001)	5.3 (8.4)	2.8 (2.4-3.2, p<0.001)
Cluster 1(HDA to REM) n=163	1.8 (4.2)	1.0 (0.6-1.4, p<0.001)	2.1 (3.9)	1.1 (0.7-1.6, p<0.001)	3.9 (6.8)	2.1 (1.4-2.9, p<0.001)
Cluster 2(LDA to REM) n=121	2.0 (3.4)	1.5 (1.0-2.0, p<0.001)	3.0 (4.7)	1.3 (0.9-1.7, p<0.001)	5.0 (6.7)	2.7 (2.0-3.5, p<0.001)
Cluster 3(MDA to LDA) n=158	2.2 (3.9)	1.5 (1.0-2.0, p<0.001)	3.7 (6.1)	1.1 (0.7-1.5, p<0.001)	5.9 (8.8)	2.6 (1.8-3.4, p<0.001)
Cluster 4(HDA to MDA) n=132	2.4 (3.6)	1.8 (1.2-3.1, p<0.001)	4.6 (8.8)	1.8 (1.2-2.3, p<0.001)	7.0 (11.0)	3.6 (2.5-4.6, p<0.001)
Cluster 5(HDA) n=27	1.2 (2.0)	1.7 (−0.1-3.6, p=0.065)	2.3 (4.7)	2.7 (0.9-4.5, p=0.0054)	3.5 (5.4)	4.4 (1.1-7.7, p=0.0107)

Legend: HDA high disease activity; REM remission; LDA low disease activity

Cl-4 and Cl-5 had the highest proportion of progressors (24 and 26% respectively) compared to the other clusters (range 14–19%) although not statistically significant (p=0.204) and Cl-5 was characterized by all patients being rapid progressors.

Conclusion: We have defined five clinical disease trajectories in early rheumatoid arthritis. The cluster defined by patients beginning and remaining in high disease activity have the lowest baseline radiographic scores but the highest propensity for radiographic progression despite aggressive therapy. This highlights the importance of defining patient prognosis at baseline and immediately optimizing therapy to prevent functional decline.

Background/Purpose: Early and sustained remission has become the ultimate goal in early arthritis patients. The aim of our study was to estimate the prevalence of clinical, sustained and drug free remission in patients with early arthritis, and to explore possible predictive factors of remission.

Methods: We included a cohort of DMARDs naïve patients with diagnosis of early rheumatoid arthritis (RA) or undifferentiated arthritis (UA) of less than 2 years of disease duration. Data was collected every 3 months, including sociodemographic characteristics, functional status, disease activity and medication. Remission was defined according to 2010 ACR/EULAR criteria. We selected four outcomes: Clinical Remission, Drug-Free Remission, steroids-Free Remission (Patients receiving DMARDs but not corticosteroids) and Sustained remission (patients who in the last follow up visit were still in remission). Time to outcome was assessed from date of baseline visit to the date of remission or last follow-up. Kaplan-Meier product limit method was used to estimate probability of each outcome. Patients were stratified according to initial and final diagnosis: UA-UA, UA-RA and RA-RA, respectively. Groups were compared with the log-rank statistic. Cox proportional hazards (PH) models were fit to determine possible predictors of remission including gender, age, disease duration, HAQ, DAS28, rheumatoid factor and baseline diagnosis.

Results: A total of 684 patients were included: UA-UA=125 (18%), UA-RA= 127 (19%) and RA-RA= 432 (63%). Mean follow-up was 21 ± 16 months (1228 patients-year). Baseline DAS28 and HAQ were 5.2 ± 1.3 and 1.2 ± 0.8, respectively. Mean age was 51 ± 15 years, 81% were female and 62% had positive rheumatoid factor. The mean disease duration was 7 ± 6 months. At baseline, 625 (98%) of patients were not in remission. During follow-up 36% achieved clinical remission at a median time of 12 months. Only 54% of these patients continued in sustained remission (median follow-up after first remission= 17 months). Steroids-free remission and Drug-free remission were achieved in 21% and 13%, respectively. The overall probability of remission per patients-year of follow-up were 0.29, 0.13, 0.07; for clinical, steroids-free and drug-free, respectively. There were no differences in rate of remission between different diagnosis groups. On multivariate analysis, male gender and baseline diagnosis of RA were associated with higher probability of remission (HR=1.70, p=0.001 and HR=1.43, p=0.03, respectively), while higher HAQ-score and longer disease duration were associated with lower probability of remission (HR=0.77, p=0.01 and HR=0.95, p=0.001; respectively).

Conclusion: In our cohort 36% of patients with early arthritis achieved clinical remission; however half of them relapse during follow-up. Only one in every ten patients reached drug free remission. A short disease duration, lower disability, male gender and initial diagnosis of RA were associated with higher probability of remission.

Osteophytes Increase the Ambiguity of Clinical Evaluation of Joint Swelling in Rheumatoid Arthritis. Peter Mandl, Paul Studenic, Gabriela Supp, Tanja A. Stamm, Martina Sadlonova, Michaela Ernst, Stefanie Haider, Daniel Aletaha and Josef Smorlen. Medical University of Vienna, Vienna, Austria.

Background/Purpose: It is recommended that a joint be classified as clinically swollen if this swelling is beyond doubt. However in clinical practice the evaluation of joint swelling in patients with rheumatoid arthritis (RA) is often hindered by joint deformity, secondary osteoarthritis (OA) or adiposity. The aim of this study was to evaluate the ambiguity and reliability of clinical swollen joint assessment in patients with RA.

Methods: Clinical joint swelling was evaluated in 2 cohorts of consecutive RA patients with at least 1 swollen joint. In Cohort A (n=20) a conventional 28 swollen joint count (SJC) was performed on the same day by 2 independent, blinded examiners. In Cohort B (n=28) the same examiners performed a modified 28 SJC in which joints were graded as either definitely swollen, non-swollen or doubtfully swollen (defined as a joint where swelling can not be excluded or confirmed due to limited evaluation attributed to the physical characteristics of the joint). In addition a standard grey-scale (GS) and Power Doppler (PD) ultrasonographic evaluation (US) was performed by a sonographer blinded to clinical data in Cohort B patients. Presence/absence of GS synovitis, PD signal, erosion and osteophytes were recorded.

Results: A total of 1316 joints were clinically evaluated in 48 RA patients (89% women; mean(±): age: 59.4 (12.1) years, disease duration: 12.5 (8.1) years, SDAI: 10.74 (8.9)) in 2 cohorts. Eighty-five percent (24 out of 28) of patients in Cohort B had at least 1 doubtfully swollen joint, with a maximum number of 4 doubtful joints/patient. The top joints with doubtful swelling were the wrist, knee, MCP3 and MCP1 joint. Interobserver reliability, evaluated by intraclass correlation coefficient in Cohort A for the conventional SJC and in Cohort B for the modified SJC was 0.80 (95% confidence interval (95%CI) 0.77–0.83) and 0.83 (95%CI: 0.81–0.85) respectively. Agreement between the 2 examiners for definitely swollen and doubtfully swollen joints was 65% and 16% respectively. Doubtfully swollen joints were more often GS ($p<0.001$) and PD positive ($p<0.001$) as compared to non-swollen joints (80% vs. 54% and 26% vs. 12% respectively) and had more frequently osteophytes on US than either swollen ($p=0.021$) or non-swollen joints ($p=0.003$) (11% vs. 4.5/4.5% respectively). Erosions were more commonly detected in swollen joints than in doubtfully swollen or non-swollen joints (4.8% vs. 1.8/2.2%) (Table 1). No association was found between body mass index and the number of doubtfully swollen joints.

Conclusion: A modified SJC including doubtfully swollen joints is characterized by similar interobserver reliability as the conventional SJC. Agreement between 2 blinded examiners was low for the evaluation of doubtful swelling. Doubtfully swollen joints had significantly more osteophytes on US suggesting a relationship between ambiguity of swelling and secondary OA in patients with RA.

Table 1: Summary of logistic regression for the dichotomized outcomes (yes/no) grey scale (GS), Power doppler (PD), erosions, and osteophytes. Tested independent variables: doubtfully swollen joints (DSJ) versus either non-swollen joints (NSJ) or swollen joints (SJ); OR: odds ratio

	Regression coefficient	Standard error	p	95% Confidence Interval for Odds Ratio		
				Lower	OR	Upper
GS						
DSJ vs. NSJ	1.45	0.374	<0.001	2.05	4.26	8.87
DSJ vs. SJ	0.68	0.520	0.188	0.18	0.51	1.40
PD						
DSJ vs. NSJ	1.10	0.316	<0.001	1.62	3.02	5.61
DSJ vs. SJ	−1.48	0.368	<0.001	0.11	0.23	0.47
Erosions

Heterogeneity in Cardiovascular Risk Factors, Event Rates and RA Disease Characteristics Among Patients with Rheumatoid Arthritis Across 10 Countries - Implications for CV Risk Assessment. Atacc-RA Collaborative Grroup. University of Umeå, Umeå, Sweden.

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease (CVD). CVD risk scores for the general population do not accurately predict CVD events in RA. Heterogeneity of traditional CV risk factors and RA characteristics across various countries may be associated with varying impacts on CVD events. We compared the impact of traditional CV risk factors and RA characteristics on CVD outcomes in RA patients from 10 countries.

Methods: RA cohorts from 13 rheumatology centers in UK.Norway, Netherlands, US, Sweden, Greece, South Africa, Spain, Canada and Mexico were compared. Data on CV risk factors and RA characteristics were collected at baseline for each cohort; CVD outcomes were collected prospectively using standardized definitions. Cox models with random effects for center were used to compare the impact of CV risk factors and RA characteristics on CVD events. Traditional CV risk factor effects were adjusted for age and sex; RA characteristic effects were adjusted for age, sex and CV risk factors.

Results: 5685 RA patients without prior CVD were included (mean age: 55 [SD: 14] years, 76% female). During a mean follow-up of 6.1 years (31155 person years), 476 patients developed CVD events. RA duration varied by center: 4 with early RA (<1 year), 7 established (mean 9–13 years) RA and 2 with both. Mean age varied from 37 to 61 years (younger in the early RA cohorts - $p<0.001$); females varied from 66% to 90% ($p<0.001$). 2 cohorts consisted of Hispanics, the rest Caucasians. CVD event rates varied across countries (range of 5 year CVD event rate: 0.8 – 7.5%) with the lowest observed in Norway and UK and the highest in South Africa, Netherlands, US-Mayo and Sweden. Age effects were fairly consistent (hazard ratios [HR] ranged from 1.6–1.8 per 10 year increase in age), but male sex varied from no effect to a doubled effect (HR=1.0–2.3). Varied effects were also seen for current smoking (HR=1.1–2.1), hypertension (HR=0.6–2.0), total cholesterol: high-density lipoprotein ratio (HR=0.9–1.2) and diabetes mellitus (HR=0.7–2.8). Effects were also varied for RA characteristics, including rheumatoid factor and/or anti-citrullinated protein antibody seropositivity (HR=0.7–1.4), disease activity score [DAS28] (HR=0.9–1.2) and RA disease duration (HR=0.7–1.1 per 10 years).

Conclusion: Major heterogeneity exists in CVD event rates and in the effects of traditional CV risk factors and RA characteristics on CVD outcomes among patients with RA across different countries. Generation of a CVD risk score that will be widely applicable for patients with RA must address this inherent heterogeneity. Efforts are underway to do this.

Weight Loss and Risk of Death in Rheumatoid Arthritis. Joshua Baker[1], Erica Billig[1], Grant W. Cannon[2], Liron Caplan[3], Vikas Majithia[4] and Ted R. Mikuls[5]. [1]University of Pennsylvania, Philadelphia, PA, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT, [3]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [4]University of Mississippi Medical Center, Jackson, MS, [5]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Low body mass index (BMI) has been linked to greater mortality among patients with Rheumatoid Arthritis (RA). Weight loss has also been associated with a greater risk of death among the elderly. The purpose of this study was to determine if weight loss is a predictor of death in RA.

Methods: Our sample consists of 1634 subjects from the Veterans Affairs Rheumatoid Arthritis (VARA) Registry. Dates of death were identified through review of the VA Computerized Patient Record System. BMI was

extracted within 14 days of each visit and the change in BMI from the previous visit was determined. BMI category and weight change were considered time-varying. Weight loss at each visit was defined as a decrease in BMI of 1 kg/m^2 from the preceding visit. Rate of loss (per 1 year) was defined as the change BMI from the preceding visit divided by the preceding interval length. Potential confounding co-variables associated with mortality in this cohort were identified. Cox proportional hazard models were used to assess associations between time-variant and time-invariant predictors of survival including the change in BMI and the rate of decline in BMI from the preceding visit adjusting for age, gender, race, BMI, diabetes, cardiovascular disease, chronic obstructive pulmonary disease, chronic kidney disease, smoking, and current use of methotrexate, prednisone, and anti-Tumor Necrosis Factor (TNF-α) medications.

Results: Among 1634 subjects (280 deaths, 8102 patient-years, 17,057 unique observations), weight loss of 1 kg/m^2 of BMI occurred in 2,308 observation periods (13.5%). Weight loss over the preceding interval was associated with an increased risk of subsequent death [HR: 2.00 (1.54, 2.60) p<0.001] (Table 1). In a subset of 1520 subjects with available data (223 deaths, 6650 patient-years), weight loss remained associated with an increased risk of death after further adjusting for CRP [HR 1.78 (1.33, 2.38) p<0.001] (full model not shown). In similar models, a rate of weight loss of >1 kg/m^2 of BMI over a 6-month period was associated with a greater risk of death [HR: 1.74 (1.31, 2.32) p<0.001] while a slower rate of weight loss was not associated with an increased risk compared to those who did not lose weight [HR: 0.94 (0.70, 1.27) p=0.7].

Conclusion: Recent weight loss, particularly a loss of more than 1 kg/m^2 of BMI (approximately 3.1 kg on average) over a 6-month period, is an independent predictor of death in RA. Changing weight may be a marker of poor functional status, poor nutrition, ongoing inflammation, and/or underlying malignancy and may help risk-stratify patients for more aggressive interventions.

Predictors of Long-Term Changes in Body Mass Index in Rheumatoid Arthritis. Joshua Baker[1], Grant W. Cannon[2], Said Ibrahim[3], Candace Haroldsen[4], Liron Caplan[5] and Ted R. Mikuls[6]. [1]Philadelphia VA Medical Center, Philadelphia, PA, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT, [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [4]University of Utah, Salt Lake City, UT, [5]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [6]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Low body mass index (BMI) is a risk factor for poor long-term outcomes in rheumatoid arthritis (RA). Low BMI in RA has been speculated to reflect weight loss due to the greater resting energy expenditure among subjects with more active and severe RA. We determined predictors of change in BMI in RA, and specifically examined whether greater disease activity was associated with weight loss over time.

Methods: Subjects from the Veterans Affairs RA Registry (VARA) (n=1396) were studied. Information on inflammatory markers, presence of erosions, and smoking status were extracted from the VARA database. VARA participants without longitudinal data were excluded (n = 349) but were similar in age, gender, race, and enrollment BMI (data not shown). BMI was extracted from the vital signs package from VA electronic medical records within 14 days of each visit date. VA pharmacy records were queried to identify prescriptions for specific RA therapies within 1 month of each visit. Robust Generalized Estimating Equations (GEE) regression models determined independent associations between pre-hypothesized clinical variables and change in BMI (or odds of weight loss >1 kg/m^2) over the subsequent observation period. Variables were either time-varying (log-transformed C-Reactive Protein [lnCRP] and medication use) or time-invariant (baseline CCP seropositivity, erosive disease, and smoking status).

Results: Increasing age, current smoking, and the presence of erosions at baseline were associated with lower BMI (all p<0.001). On average, weight decreased over time [β: −0.017 (−0.029, −0.0052) p=0.005]. Higher ln(CRP), current smoking at baseline, greater baseline BMI, and older age were associated with greater reductions in BMI over the subsequent observation period (Table 1) (all p<0.01). Higher ln(CRP), current smoking, greater baseline BMI, and older age were also associated with a greater risk of weight loss over the subsequent observation period (Table 1) (all p<0.01). Methotrexate use was associated with a lower risk of weight loss (p=0.002). The use of prednisone and the use of anti-TNF therapies were not associated with change in BMI or the risk of weight loss.

Conclusion: Greater age, greater inflammatory activity, and current smoking are associated with weight loss in RA. The weight loss (and lack of weight gain) among subjects with inflammation may be due to the greater resting energy expenditure and catabolism seen with the active inflammatory process. While methotrexate was associated with a decreased risk of weight loss, there were no consistent associations between other RA medications and changes in weight.

Table 1: GEE in linear and logistic regression models evaluating independent predictors of the change in BMI and the risk of weight loss over the subsequent observation period.

	Change in BMI (kg/m^2) (N=1396; Obs= 10707)		Risk of Weight Loss (≥ 1 kg/m^2) (N=1396, Obs=10707)	
	β (95% CI)	P	OR (95% CI)	P Value
Age (per 1 year)	−0.0070 (−0.0090,−0.0051)	<0.001	1.01 (1.00,1.02)	0.001

Periodontal Disease and Its Impact on Structural Joint Damage in a Rheumatoid Arthritis Peruvian Population. Rocio V. Gamboa-Cardenas, Manuel F. Ugarte-Gil, José Quiñones, Francisco Zevallos-Miranda, Fiorella Lazo, J. Mariano Cucho-Venegas, Risto A. Perich-Campos, Jose L. Alfaro-Lozano, Mariela Medina-Chinchon, Zoila Rodriguez-Bellido, Hugo Torrealva and Cesar A. Pastor-Asurrza. Hospital Guillermo Almenara, EsSalud, Lima, Peru.

Background/Purpose: Periodontal disease (PD) or periodontitis is currently considered an epigenetic determinant of both occurrence and severity of Rheumatoid Arthritis (RA). Common pathophysiological mechanisms like the migration of osteoclasts and secretion of pro-inflammatory cytokines, would occur in RA and PD but it has not been determined if the severity of

PD influence on joint damage (JD). The aim of the study was to demonstrate that a more severe PD is independently associated with a greater JD in RA patients.

Methods: A cross sectional study. RA was defined using the 1987 ACR criteria. Patients should not have other autoimmune disease and they were older than 18 years at time of diagnosis. We excluded patients with less than 4 teeth, serious or local ongoing infections, oral cancer or precancerous lesions; inpatients, pregnant, diabetic patients, severe Sjögren syndrome and local antibiotic or gingival hyperplasia associated drug users were also excluded. We applied a personal interview, physical examination, laboratory analysis and review of medical records to assess factors associated with JD. An assessment of periodontal attachment loss and panoramic dental X ray were done. To determine diagnosis and severity of PD the American Academy of Periodontology criteria were applied. Two categories were defined mild PD and moderate/severe PD. All dental assessments and radiographs were interpreted by three odolontologist blinded to JD. A blinded investigator to clinical RA and PD status determined JD scoring hands/feet radiographs according to Sharp VDH method. The association of PD severity and JD was determined using student's T test, after that a multivariable linear regression model adjusted for age, tobacco, gender, rheumatoid factor (RF), anticitrullinate protein antibody (ACPA), disease duration, socioeconomic status (SES) using Graffar scale, disease activity (DAS28CRP), functional status (MDHAQ) and quality of life (SF36) was performed to determined persistence of the associations. SPSSv21.0 statistical package was used.

Results: 213 patients were evaluated, 192 (90.1%) were women, mean (SD) age was 59.55 (12.59) years, disease duration was 15.14 (11.74) years, SES were more frequently medium / medium low (31.5% and 36.6% respectively); 79.3% were ACPA positive, mean ACPA title was 679.23 uM/L, mean DAS28PCR was 3.85 (1.24). 2.3% and 14.6% were current or past smokers. Erosion, joint space narrowing and total Sharp VDH scores were 41.25 (49.02), 64.65 (42.30) and 105.81 (88.44) respectively; 94 (44.1%) patients had mild PD and 119 (55.9%) patients had moderate/ severe PD. In multivariable analysis PD severity (adjusted for age, SES, tobacco, gender, RF, ACPA, disease duration, DAS28PCR, MDHAQ and SF36) was independently associated with a higher score join narrowing space (β:21.47, p =0.008) and total SharpVDH scores (β:17.78, p=0.029). Erosions and PD severity did not remain associated (β:18.17, p=0.085).

Conclusion: A more severe PD impacts on structural joint damage independently of other known associated factors. A routine periodontal evaluation and monitoring could be useful for better outcomes in RA patients.

Low Vitamin D Level Is Not Associated with Increased Risk of Cardiovascular Disease in Rheumatoid Arthritis Patients. Tarun S. Sharma[1], Xiaoqin Tang[2], Deepak Vedamurthy[1], Jonida Cote[3] and Androniki Bili[3]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Geisinger Health System, Danville, PA.

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of death in patients with Rheumatoid Arthritis (RA). Vitamin D deficiency is prevalent in RA and it has also been shown to be related to disease activity in some studies which is attributed to its immunomodulatory properties. There have been increasing reports of an inverse relationship between vitamin D levels and CVD risk in the general population but no studies in the RA population. The aim of this study was to evaluate the association between Vitamin D levels and CVD risk in RA.

Methods: A retrospective cohort of adult patients with RA (defined as ICD-9 714.0 twice by a rheumatologist) within a tertiary health system and with primary care physician within the health system from 1/1/2001 to 10/31/2013 was constructed (n=1459). Patients with prevalent diagnosis of CVD at the time of RA diagnosis (n=127) or those without available vitamin D levels (n=410) were excluded. Vitamin D level was analyzed as both a continuous and dichotomous variable with level <20 ng/ml defined as "deficient" and ≥20 ng/ml "sufficient" vitamin D level groups. Primary outcome was independent physician adjudicated incident CVD defined as a composite of CAD, stroke, transient ischemic attack or peripheral vascular disease. Data was censored for death or end of the study period and vitamin D levels closest to the censoring point were captured. Poisson regression models were used to calculate the relative risk (RR) for CVD between the deficient and sufficient vitamin D level groups. Cox regression models were used to calculate the hazard ratios (HR) for CVD between the two vitamin D groups. The models were adjusted for age, gender, BMI, smoking, RF and ACPA positivity, LDL, NSAID, corticosteroid, DMARD, statin and TNF inhibitor use. The study was designed to have an 80% power to detect a minimum HR for incident CVD of 2.5 between the two groups.

Results: 921 RA patients were included. Patients were 80.5% women, 96.9% Caucasian, with mean age of 58 years and BMI 30.4 kg/m^2. Median time from vitamin D level measurement to CVD events was 2.7 years. There were 128 patients in the deficient and 793 patients in the sufficient vitamin D level groups with mean vitamin D levels of 14.3 ng/ml and 36.8 ng/ml respectively. There were 88 incident CVD events with an Incidence Rate (IR) of 14.8/1000 patent years; of these events, 19 were in the deficient and 69 in the sufficient vitamin D groups with Incidence Rate Ratio (IRR) of 1.43 (0.84–2.43, p=0.19) for CVD between the groups. In the multivariate fully adjusted Cox model, the HR for incident CVD events was 1.30 (95% CI 0.78–2.15 p=0.32) between the two groups. When treating vitamin D as a continuous variable, the HR for incident CVD was 0.99 (95% CI 0.97–1.004, p=0.14) between the deficient and sufficient vitamin D level groups.

Conclusion: In this study, vitamin D level <20 vs. ≥20 ng/ml was not associated with increased risk of incident CVD in patients with RA. However, the study was powered to detect a minimum of double the risk between the vitamin D groups and may have missed an association of smaller magnitude.

Disease Activity Is Associated with Insulin Resistance in Early Rheumatoid Arthritis. Androniki Bili[1], Debra Webb[2], Cynthia Matzko[2], Andrea Berger[3], Eric D. Newman[1], Thomas P. Olenginski[1], David M. Pugliese[4], Maria Butterwick[5], Lisa L. Schroeder[1], Thomas M. Harrington[1], Jonida Cote[1], Lyudmila Kirillova[1], Susan Mathew[1], Tarun Sharma[1], H. Lester Kirchner[1], Jon Giles[6] and Mary Chester M. Wasko[7]. [1]Geisinger Health System, Danville, PA, [2]Geisinger Medical Center, Danville, PA, [3]Center for Health Research, Geisinger Health System, Danville, PA, [4]Geisinger Health System, Wilkes-Barre, PA, [5]Geisinger Specialty Group, Wilkes-Barre, PA, [6]Columbia University Medical Center, New York, NY, [7]Temple University School of Medicine, Pittsburgh, PA.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic disease that manifests mainly with articular symptoms, but the main cause of death is cardiovascular disease (CVD). Chronic inflammation is thought to contribute both directly to CVD as well as indirectly to cardiometabolic risk factors such as insulin resistance, atherogenic lipid profile and sarcopenic obesity, all features of chronic active RA. Data on the presence of these risk factors in newly diagnosed RA are scarce but need to be defined so that they can be addressed if present in early disease. The aim of the present study was to examine the association of disease activity with cardiometabolic risk factors in newly diagnosed RA.

Methods: Patients are participants in an ongoing study that compares the effect of a treat to target strategy vs. usual care on cardiometabolic comorbidities in RA. For the present study, baseline patient data were analyzed in a cross-sectional design. Participants had RA based on 2010 ACR classification criteria with symptoms < 2 years; were DMARD and biologic-naïve (except hydroxychloroquine); took corticosteroid equivalent of prednisone ≤10 mg daily; had clinical disease activity index >10, and did not have known diabetes. Disease activity was assessed by the disease activity score (DAS)28 and disability by the Modified Health Assessment Questionnaire (MHAQ). The primary outcome was insulin resistance as assessed by the 2 hour glucose tolerance test (GTT). Secondary outcomes were high density lipoprotein cholesterol (HDL-c) and body composition measurements by DXA (Hologic), including android/gynecoid ratio, appendicular lean mass (kg/m^2) and appendicular lean mass/height^2. The associations between DAS28 and MHAQ with the outcome variables were evaluated using linear regression analysis, both unadjusted and adjusted for age, gender and BMI. All outcome variables were analyzed as continuous. Pearson's partial correlation coefficient was used to estimate the strength of the associations.

Results: Of the 33 participants, 64% were female, with mean age 50 years, 70% RF positive, 53% ACPA positive, with median BMI 30.3 kg/m^2 and median DAS28 4.5. In the unadjusted model, DAS28 was positively associated with insulin resistance (p=0.01). In the adjusted model, the Pearson partial correlation was 0.3777 (p = 0.05). There was no association of the DAS28 with HDL or body composition measures. MHAQ was inversely associated with HDL (p= 0.05) in the unadjusted analysis but this

association lost significance in the adjusted model. There was no association of the MHAQ with insulin resistance or body composition measures. As expected, age and female gender were inversely associated with appendicular lean mass.

Conclusion: In early RA, higher disease activity was associated with increased insulin resistance, a risk factor for CVD. Our findings underscore the importance of addressing cardiometabolic comorbidities in early RA to minimize disease-related morbidity and mortality.

Assessment of Pulmonary Function in Rheumatoid Arthritis Patients Attending Rheumatology Clinics in Nairobi,Kenya. Irene Biomdo[1] and Omondi G. Oyoo[2]. [1]Ministry of Health,Kenya, Nairobi, Kenya, [2]University of Nairobi, Nairobi, Kenya.

Background/Purpose: Pulmonary involvement is frequent and among the most severe extra-articular manifestations of Rheumatoid arthritis (RA) ranking as the second cause of mortality in this patient population. Rheumatoid arthritis can affect the lung parenchyma, airways and pleura. Pulmonary complications are directly responsible for 10–20% of all mortality in RA patients. Spirometry is becoming increasingly available in Kenya and could be used in peripheral areas to screen and monitor for pulmonary function abnormalities in well characterized patient populations such as those with RA. Abnormalities detected by pulmonary function tests may precede symptoms by years and lead to early diagnosis of pulmonary fibrosis in rheumatoid arthritis and hence intervention.

Objective: To determine the prevalence of pulmonary function abnormalities in Rheumatoid arthritis patients attending Rheumatology Clinics in Nairobi.

Methods: Rheumatoid arthritis patients who fulfilled the study inclusion criteria were recruited. Sociodemographic characterictics and respiratory symptoms were assessed using Lung Tissue Research Consortium questionnaire (LTRC) and RA disease activity was established by Disease Activity Score (DAS28). Pulmonary function tests were then done using Spirolab 111 according to the American thoracic society recommendations.

Results: One hundred and sixty six RA patients were recruited; the male to female ratio was 1:9.3, with a median age of 47 years. The overall 6 month prevalence of pulmonary function abnormalities was 38.5% as measured by Spirometry and all our patients did not carry any prior pulmonary disease diagnosis. The predominant ventilatory defect was Obstructive pattern at 20.4%, followed by Restrictive pattern at 16.8% and least common being a mixed picture at 1.2%. Factors that were shown to be independently associated with pulmonary function abnormalities were age and RA disease activity. Respiratory symptoms that were predictive of PFTs abnormalities were cough, increased frequency of chest colds and illnesses and phlegm.

Conclusion: High prevalence of pulmonary function abnormalities was observed. Respiratory symptoms, older age and ongoing disease activity can identify patients in greatest need of further pulmonary evaluation.

1397

Impact of Corticosteroid Use on Remission Sustainability and Infection Rates Among Rheumatoid Arthritis Patients in Remission While on Infliximab: Treatment Implications Based on a Real-World Canadian Population. Boulos Haraoui[1], Algis Jovaisas[2], William G. Bensen[3], Rafat Faraawi[4], John Kelsall[5], Sanjay Dixit[4], Jude Rodrigues[6], Maqbool Sheriff[7], Emmanouil Rampakakis[8], John S. Sampalis[8], Allen J Lehman[9], Susan Otawa[9], Francois Nantel[9] and May Shawi[9]. [1]Centre Hospitalier de l'Université de Montréal, Montréal, QC, [2]University of Ottawa, Ottawa, ON, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]McMaster University, Hamilton, ON, [5]The Mary Pack Arthritis Centre, Vancouver, BC, [6]Clinical Research and Arthritis Centre, Windsor, ON, [7]Nanaimo Regional General Hospital, Nanaimo, BC, [8]JSS Medical Research, Montreal, QC, [9]Janssen Inc., Toronto, ON.

Background/Purpose: The Canadian Rheumatology Association[1] recommends that addition of corticosteroids (CS) should be considered only for the shortest period possible in rheumatoid arthritis (RA) patients treated with a traditional or biologic DMARD based on the patient's clinical status. The aim of this analysis was to examine the effect of chronic systemic CS treatment at different doses on the incidence of infections in RA patients treated with IFX in a real-life setting. The impact of CS use on the sustainability of remission was also assessed.

Methods: BioTRAC is an ongoing, Canadian, prospective, registry of rheumatology patients initiating treatment with IFX or golimumab as first biologics or after having been treated with a biologic for less than 6 mos. RA patients treated with IFX who were enrolled between 2002 and 2012 were included. Cox regression was used to examine the time-dependent association between systemic CS dose (no CS, ≤5 mg, >5 mg) and the incidence of first infection, while adjusting for possible confounders, and to assess the sustainability of remission.

Results: 838 RA patients were included in the analyses. Mean (SD) age of the patient cohort was 56.6 (13.5) yrs and mean (SD) duration since diagnosis was 10.5 (9.8) yrs. At initiation of treatment, 38.2% of patients were treated with a systemic CS. After a mean (SE) follow-up of 51.3 (1.7) mos, 310 infections were reported for 19.7% of patients (19.6 /100 PYs). Among these, the majority (90.0%) were non-serious infections. Multivariate survival analysis using Cox regression showed that, upon adjusting for enrolment period, age, disease duration, number of steroid administrations, and HAQ-DI, the hazard ratio (HR) (95%CI) for acquiring an infection was 2.48 (1.24–4.98) in patients treated with high dose (>5 mg) CS compared to patients not receiving CS. Treatment with low dose CS was also associated with an increased hazard for infection (HR (95%CI) = 2.12 (0.97–4.66)) which did not reach statistical significance. Consistent with previous studies, increased HAQ-DI (HR (95%CI) = 1.51 (1.15–1.92)) and disease duration (HR (95%CI) = 1.01 (1.00–1.03)) were also identified as significant predictors. CS use was continued in 15% of cases despite the achievement of remission (DAS28-CRP: 15.2%; CDAI: 15.7%). Survival analysis did not show a significant positive effect of steroid use on sustainability of remission [$HR_{DAS28\text{-}CRP}$ (95%CI) = 1.40 (0.95–2.06); HR_{CDAI}(95%CI) = 1.19 (0.75–1.88)].

Conclusion: Treatment with systemic CS was associated with an increased hazard ratio for acquiring an infection upon adjusting for possible confounders. Despite the achievement of remission, steroid use was continued in 15% of cases without having an impact on sustainability of remission. We show that treatment with systemic CS is an independent predictor of infection in patients treated with anti-TNF agents and suggest that the use of concomitant medications should be considered in the interpretation of safety data.

Spontaneous Regression of Methotrexate (MTX)-Related Lymphoproliferative Disorder Correlates with Lymphocyte Restoration after MTX Withdrawal. Shuntaro Saito[1], Yuko Kaneko[1], Katsuya Suzuki[1], Michihide Tokuhira[2] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical Center, Saitama Medical University., Saitama, Japan.

Background/Purpose: Lymphoproliferative disorder (LPD) is a rare complication with rheumatoid arthritis (RA) patients treated with methotrexate (MTX). It is known that not little proportion of these LPD shows spontaneous regression by MTX withdrawal without chemotherapy. This study is to identify factors by which the spontaneous regression of MTX-LPD can be predicted.

Methods: All 32 RA patients regarded as being complicated with MTX-LPDfrom 2007 to2013in our institution were studied. We analyzed the patients who had been observed after the withdrawal of MTX without chemotherapy. The comparisons of continuous values were examined by student t-test.

Results: Five patients were given chemotherapy after the diagnosis of MTX-LPD, so we analyzed the remaining 27 patients in this study. Baseline characteristics of 27 patients were following: median age, 65 years old,

female, 82%, duration of MTX administration, 7.5 years, RA duration, 11.9 years. In these patients, MTX was withdrawn without any additional treatment, and LPD was assessed during the follow up (median 5 weeks, range: 3–12 weeks). Seventeen patients were pathologically diagnosed as LPD and 10 were highly suspected of LPD with imaging tests. Spontaneous regression observed in 19 patients with 3 achieving complete remission (CR) and 16 partial remission (PR). Three patients were stable disease (SD) and 5 were progressive disease (PD).

We focused on the time course changes in absolute number of lymphocytes at the MTX withdrawal and at the time of follow-up assessment. In CR/PR group, the number of lymphocytes were decreased at the MTX withdrawal (median 510/μL, range:87–1045), but restored at the time of follow-up assessment (median 1409/μL, 900–2969). In SD/PD group, the patients could be classified into 2 groups; 3 of low lymphocytes (median 426/μL, 255–578) and 5 of high lymphocytes (median 1725/μL, 1165–2438). However in both groups the lymphocyte counts did not change after follow up duration. Therefore, the ratio between the number of lymphocytes at the MTX withdrawal and at the time of follow-up assessment was significantly higher in PR/CR group than SD/PD group (3.73 vs 0.96, p=0.02). There was no significant difference of follow up duration between 2 groups (median 4 vs 5.5 weeks, p=0.46).

Same tendency were observed in histologically diagnosed 17 patients. The outcomes were 2 CR, 11 PR, and 4 PD, and lymphocytes ratios were 4.07 in CR/PR group and 0.65 in SD/PD group (p=0.04).

Of 17 histologically defined LPDs, 15 had information on Epstein Barr virus encoded small RNA (EBER). EBER positivity was relatively higher (9/11, 81%) in PR/CR group and lower (2/4,50%) in SD/PD group, but difference was not statistically significant (p=0.261).

Conclusion: Careful observation of the changes in the number of lymphocytes may predict the LPD spontaneous regression after the withdrawal of MTX.

Proteinase K-like Serine Protease PCSK9 Influence on the Dyslipidemia and Endothelial Dysfunction Observed in Rheumatoid Arthritis Patients.

Esmeralda Delgado-Frias[1], Ivan Ferraz-Amaro[2], Vanesa Hernandez-Hernandez[3], A.M. de Vera-Gonzalez[4], A.F. Gonzalez-Rivero[5], Miguel A. González-Gay[6] and Federico Diaz-Gonzalez[7]. [1]Servicio de Reumatología.Hospital Universitario de Canarias, La Laguna. Tenerife., Spain, [2]Servicio de Reumatologia. Hospital Universitario de Canarias, Tenerife, Spain, [3]Servicio de Reumatologia.Hospital Universitario de Canarias., La Laguna. Tenerife, Spain, [4]Servicio de Laboratorio Central.Hospital Universitario de Canarias., La Laguna. Spain, Spain, [5]Servicio de Laboratorio Central. Hospital Universitario de Canarias., La Laguna. Tenerife., Spain, [6]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [7]Servicio de Reumatologia.Hospital Universitario de Canarias, La Laguna, Spain.

Background/Purpose: Proteinase K-like serine protease PCSK9 binds the low-density lipoprotein (LDL) receptor at the surface of hepatocytes, thereby preventing its recycling and enhancing its degradation in endosomes/lysosomes, resulting in reduced LDL-cholesterol clearance. Therefore, gain-of-function in PCSK9 lead to higher levels of LDL-cholesterol and increased risk of cardiovascular disease. The objective is to investigate how PCSK9, one of the molecules involved in the metabolism of LDL-cholesterol, is expressed in patients with rheumatoid arthritis (RA) and its potential relationship with the dyslipidemia and the endothelial dysfunction observed in these patients.

Methods: Plasma PCSK9 concentrations and brachial artery flow-mediated dilation (FMD) by ultrasound were measured in 115 patients with RA and 101 matched controls. A multivariable analysis adjusted for standard cardiovascular risk factors, disease activity and lipids, including LDL cholesterol, was performed to evaluate the relation of PCSK9 on RA dyslipidemia and endothelial dysfunction compared to controls.

Results: FMD was higher in controls when compared to RA patients (8.5 [95%CI 4.5–15.6] vs. 5.3 [0.0–9.2] mm, p=0.00). In the univariate analysis, RA patients tended to have lower levels of total cholesterol(p=0.08), LDL(p=0.18) and apolipoprotein A1(p=0.15), although statistical significance was not reached. PCSK9 levels were not different between patients and controls even adjusting for comorbidity or disease activity. PCSK9 tended to be correlated with LDL cholesterol in patients and controls, but statistical significance was not reached. Nevertheless PCSK9 was positively correlated with apolipoprotein B in RA patients (beta coef. 0.06 [0.02–0.09] x10 ng/ml, p=0.00) but not in controls. Disease activity score DAS28, both considering as continuous (766 [100–1432] ng/ml, p=0.03) or categorical -low, moderate, high and very high- (832 [82–1583] ng/ml, p=0.03) was correlated with PCSK9 levels. Therefore, higher DAS28 was associated with greater PCSK9 concentration. When RA patients were split in tertiles according to PCSK9 values we observed that patients which were more commonly included in the third tertile, showed the higher values of FMD. Therefore, in RA patients, as FMD increased we observed that the risk of having PCSK9 values included in the third tertile compared to that of being in the first tertile was statistically significant multiplied by OR 0.98 ([0.82–0.99],p=0.04). However, this association was not found in controls.

Conclusion: PCSK9 concentrations are associated with disease activity scores and endothelial dysfunction in RA patients. The role of PCSK9 in RA related dyslipidemia and cardiovascular risk needs further investigation.

Risk of Venous Thromboembolic Events in Patients with Rheumatoid Arthritis: A Meta-Analysis of Observational Studies.

Michelle Avina[1], Sally Choi[1], Sharan Rai[2], Hyon K Choi[3] and Mary De Vera[4]. [1]Arthritis Research Centre of Canada/University of British Columbia, Richmond, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]Boston University School of Medicine, Boston, MA, [4]University of British Columbia, Vancouver, BC.

Background/Purpose: Venous thromboembolism (VTE), which includes both deep vein thrombosis (DVT) and pulmonary embolism (PE), is the third most common vascular event after myocardial infarction and stroke. Several studies have investigated the risk of VTE among patients with rheumatoid arthritis (RA), a chronic and disabling disease associated with systemic inflammation. Our objective was to perform a meta-analysis of studies evaluating the risk of DVT and PE in patients with RA.

Methods: We systematically searched MEDLINE (1946–2013) and EMBASE (1974–2013) databases for studies that reported the risk of VTE in patients with RA. Our search strategy employed Medical Subject Headings (MeSH terms) together with keywords for unindexed concepts relating to the themes of RA and VTE. Eligibility criteria were: 1) original data from cohort or case-control studies; 2) pre-specified RA; 3) clearly defined VTE outcomes; 4) relative risk (RR), odds ratio (OR), or hazard ratio (HR), and corresponding 95% confidence intervals (CI); 5) sex- and age-matched comparison group; and 6) English language. We calculated weight-pooled summary estimates of RRs for VTE outcomes using the random effects model. The robustness of the results was evaluated using a jack-knife sensitivity analysis (i.e., removal of a single study from the baseline group of studies). All analyses were done using HePIMA software.

Results: Our search strategy yielded 86 articles, and we identified an additional 2 citations through a hand-search of relevant bibliographies. After applying the eligibility criteria, we identified 8 studies with a total of 479,452 RA patients for inclusion in the meta-analysis. We identified 7 cohort studies (of which one reported results for three separate cohorts) and 1 case-control

study. Overall, pooled estimates for VTE, DVT and PE were significantly increased (**Table 1 and Figure 1**). The estimates remained statistically significant in the jack-knife sensitivity analysis with the point estimates ranging from 1.58 to 1.72 and the corresponding 95% CIs >1 in all cases except for DVT.

Conclusion: The risk of new VTE events is increased in RA patients compared to age- and sex-matched controls. However, there exist a paucity of data on the risk of PE and DVT. These findings support increased vigilance of VTE complications and potential risk-factor intervention among RA patients.

Table 1. Pooled estimates on the risk of VTE events in Rheumatoid Arthritis

Events	No. of Studies	Pooled RR (95% CI)
VTE	8	1.64 (1.42,1.89)
DVT	3	2.06 (1.14,3.74)
PE	4	1.92 (1.85,1.99)

Higher-Order Neuropsychological Deficits Are Frequent and Occur Early in RA and SLE: The Impact of Basic Processing Abilities on Psychological Well-Being. Giorgia Dimitraki[1], Georgia Ktistaki[1], Emmanouil Papastefanakis[1], Antonis Fanouriakis[2], Irini Gergiannaki[2], George Bertsias[2], Nikolaos Kougkas[2], Argyro Repa[2], Evangelos Karademas[1], Prodromos Sidiropoulos[2] and Panagiotis Simos[1]. [1]University of Crete, Rethymnon, Greece, [2]University of Crete, Heraklion, Greece.

Background/Purpose: Deficits in higher-order cognitive abilities (episodic memory, executive functions) have been reported in patients with chronic inflammatory disorders, albeit inconsistently. We investigated whether such deficits are associated with impairments in basic cognitive processes (short-term memory, visuomotor speed) and premorbid verbal intelligence, and their potential impact on psychological well-being in newly diagnosed rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Methods: Patients with RA (N=84, age: 54.1±9.1 years, education: 9.1±4.1 years, DAS28: 3.9±1.4) or non-neuropsychiatric SLE (N=60, age: 43.8±9.7 years, education: 12.1±3.7 years, SLEDAI: 3.6±2.7), diagnosed within the last 3 years, were administered a battery of standardized tests of short-term memory (Digits Forward and Digits Reverse tasks), episodic memory (Auditory Verbal Learning Test [AVLT]), executive functions (Stroop Color-Word Naming, General Ability Measure for Adults [GAMA], Controlled Oral Word Association Test [COWAT], Trail Making Test [TMT] B), visuomotor processing speed (TMT A). Premorbid verbal capacity was estimated using the Peabody Picture Vocabulary Test (PPVT-R). Scores were evaluated against age- and education-adjusted Greek population norms. The Hospital Anxiety and Depression Scale (HADS) was used to assess symptoms of impaired mood.

Results: Compared to population norms, RA patients had significantly lower average scores on short term memory, immediate and delayed episodic recall, phonemic fluency, problem solving ability, visuomotor speed and set-shifting ability ($p<0.002$). SLE patients had significantly reduced performance on short-term memory, immediate and delayed episodic recall, visuomotor speed and set-shifting ability ($p<0.003$). Cognitive impairment (defined as performance ≥1.5 SD below the population mean on ≥3 indices) was found in 15.5% and 21.3% of RA and SLE patients respectively, and was not significantly affected by medical comorbidities or disease activity. Notably, impairments on higher-order cognitive abilities in patients were explained by deficits in verbal IQ, short-term memory and visuomotor speed. Both clinical variables (number of physical symptoms experienced, β-coefficient = 3.63, $p=0.002$) and processing speed ($\beta=2.59$, $p=0.035$) significantly contributed independently to the intensity of depression symptoms experienced by patients.

Conclusion: A wide range of cognitive domains was affected in a significant proportion of patients with newly diagnosed RA and SLE. Deficits in higher-order complex memory and executive tasks were largely due to impaired basic cognitive abilities and had an adverse impact on patients' psychological well-being. Emergence of cognitive defects early in the course of RA and SLE suggests common etiopathogenesis possibly linked to underlying disease processes (including inflammation) and/or administered treatments.

1402

Parameters of Periodontitis Correlate with Anti-Citrullinated Protein Antibodies and *P. Gingivalis* Antibody Titers in Patients with Early or Chronic Rheumatoid Arthritis. Sheila L. Arvikar[1], Hatice Hasturk[2], Marcy B. Bolster[1], Deborah S. Collier[1], Alpdogan Kantarci[2] and Allen C. Steere[3]. [1]Massachusetts General Hospital, Boston, MA, [2]Forsyth Institute, Cambridge, MA, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Emerging evidence suggests that periodontitis and periodontal pathogens, such as *Porphyromonas gingivalis* (*Pg*), may be an environmental trigger for rheumatoid arthritis (RA). We found that antibodies to *Pg* are increased in a subset of untreated early RA patients and correlate with anti-citrullinated protein antibodies (ACPA). As a next step, we are evaluating periodontal disease in our RA patients. We report here findings of periodontitis in the first 23 patients who have completed formal dental examinations.

Methods: 23 RA patients, 15 with new-onset disease and 8 with chronic RA, completed standardized dental examination performed by a single periodontist. All patients met the 2010 ACR/EULAR criteria for RA. 20 age- and gender-matched healthy subjects without periodontitis or RA were also enrolled. Dental parameters for assessment of periodontitis per the Centers for Disease Control criteria included pocket depth (PD), gingival margin, bleeding on probing (BOP) measured at 6 sites per tooth, and clinical attachment loss (CAL). Serum *Pg* IgG antibodies were measured by ELISA. The dental examiner was blinded to joint and laboratory findings.

Results: Typical of RA cohorts, the patients were predominantly female (87%) with median age of 48. The majority (61%) was seropositive for ACPA, 43% were positive for rheumatoid factor (RF), and they had a range of disease activity. None were current smokers, but 10 previously smoked. All but one patient received routine dental care with cleanings every 6 months.

Of the 23 patients, 10 (43%) had gingivitis, a precursor of periodontitis, 9 (39%) had periodontitis, and only 4 patients (17%) had healthy periodontal tissue. Compared with the 20 healthy subjects, the 23 RA patients had significantly increased pocket depth ($P<0.000001$), CAL ($P=0.001$), and BOP ($P=0.0001$). There were no differences in dental parameters between former vs. never smokers.

In the 23 patients, ACPA levels correlated directly with CAL ($P=0.03$), the most significant determinant of periodontal disease, and with BOP ($P=0.05$). In addition, dental parameters correlated with ESR values ($P=0.04$) and tended to correlate with RF ($P\leq0.09$) and disease activity (DAS-28-ESR, swollen and tender joint counts) ($P\leq0.1$).

Six of the 23 patients (26%) had elevated serum *Pg* IgG antibodies. All 6 patients with positive *Pg* antibodies had periodontitis, while no patient with gingivitis or normal periodontal tissue had elevated *Pg* antibodies ($P<0.001$). Finally, *Pg* antibodies strongly correlated with all dental parameters including pocket depth ($P<0.0001$), BOP ($P=0.003$), and CAL ($P=0.02$).

Conclusion: Most of our patients with early and chronic RA had gingivitis or periodontitis on formal examination, although they received regular dental care. Parameters of periodontitis correlated significantly with ACPA, supporting a role for periodontal disease in RA pathogenesis. As *Pg* antibodies correlate strongly with periodontitis, these may be useful biomarkers in screening for periodontal disease in RA patients. Finally, periodontitis

tended to correlate with RA disease activity, supporting a role for periodontal disease evaluation and treatment in a subset of RA patients.

1403

Psychosocial Impact of Rheumatoid Arthritis Patients on Their Family Members. Sang Wan Chung[1], Ji Ae Yang[2], Eun Ha Kang[1], Yun Jong Lee[1] and You Jung Ha[1]. [1]Division of Rheumatology, Department of Internal Medicine,Seoul National University Bundang Hospital, Seongnam, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory arthritis that can cause pain and functional disability, and RA patients have a higher risk of psychiatric disorders, especially depression. However, disability and socioeconomic burden of RA patients can also contribute to psychosocial wellbeing of their family members. To date, several studies have been conducted for evaluation of the burden of caregivers in chronic disease such as stroke and dementia, however, the burden of family members of RA patients has not been evaluated. In this study, we conducted a population-based analysis to examine the psychosocial characteristics of family members of RA patients in comparison with the general population and to evaluate the psychosocial impact of RA patients on their family members.

Methods: From the Fifth Korea National Health and Nutrition Examination Surveys (KNHANES V) (2010–2012) dataset, we identified 452 RA patients and then selected family members of these patients who were aged 20 years or older (n=515). The control group was sampled from members of families without RA patient with matching for sex and age (n=1,545).

We compared the psychosocial characteristics between family members of RA patients and control group. Also, serial conditional logistic regression models were performed to evaluate the association of psychosocial impact with the presence of RA patient after adjustment of covariants.

Results: The mean age was 51.9 ± 18.8 years and sixty percent were male in our study population. Family members of RA patients were more employed (63.6% vs. 60.2%, $p = 0.037$), and had higher household income ($p = 0.037$) compared with sex and age-matched control subjects. No significant differences were observed in comorbidities between two groups.

Family members of RA patients had a significantly higher level of stress (29% vs. 24.3%, $p = 0.046$), history of depression (17.3% vs. 11.9%, $p = 0.004$). The presence of a RA patient in the family showed significant association with history of depression (odds ratio, 1.60; 95% confidence interval, 1.19 to 2.16; $p = 0.002$), after adjustment for household income, education level, and employment status.

Conclusion: Family members of RA patients have higher level of stress and they are more susceptible to depression. Our findings suggest that physicians or rheumatologists who treat RA patients should pay more attention to psychosocial burden of their family members.

Table 3. Multivariate (adjusted) analyses of factors influencing psychosocial status of the study population

Presence and Significance of Anti-CCP Antibody in Patients with Interstitial Lung Disease with and without Clinically Apparent Rheumatoid Arthritis. Muhammad Imran[1], Shanley O'brien[2], Mark Hamblin[2] and Mehrdad Maz[1]. [1]University of Kansas Medical Center, Kansas City, KS, [2]Kansas University Medical Center, Kansas city, MO.

Background/Purpose: Interstitial lung disease (ILD) can be idiopathic or associated with underlying etiologies including rheumatoid arthritis (RA). The purpose of this study is to determine the presence and significance of anti-CCP (and RF) in patients with ILD, whether or not they meet the diagnostic criteria for RA; supporting the notion that ILD as an extra articular manifestation of RA can develop prior to articular symptoms and that anti-CCP antibodies can be a prognostic marker for development of ILD in RA.

Methods: This is a retrospective chart review of 160 patients with ILD to identify and compare patients without articular manifestations whom had CCP antibodies (with or without RF) to those who met the diagnostic criteria for RA. The data was abstracted from patients seen at the University of Kansas Medical Center Pulmonary ILD Clinic between January 2008 to June 2014. Each subject had serologic studies, pulmonary function testing (PFT), and thoracic computed tomography scan as part of the routine clinical evaluation.

Results: Of the 160 patients, RF and/or anti-CCP were measured in 125 patients (78%). Of these 125 patients, 55 patients (44%) who had ILD along with positive RF and/or anti-CCP were identified. Of these 55 patients, only 4 patients who had ILD and anti-CCP positivity (median 94.7, range 36–138) did not have articular manifestations of RA, 3 of whom were male and one was female. The 3 male patients had a mean age of 65 at the time of diagnosis of ILD and only one had a history of smoking. The female patient was a 53 y/o cocaine abuser who also had a p-ANCA titer at 1:1280, MPO >8, and PR3 (0.4). One female patient died within 6 years of diagnosis of ILD and never developed articular manifestations of RA; the remaining 3 patients have not developed articular symptoms of RA yet. Nine patients with ILD had a positive RF but negative anti-CCP without articular findings of RA. Majority of these patients were female, and most were former cigarette smokers. However, 6 of these 9 patients had elevated ANA (> 1:640) without features of a connective tissue disease. Among patients with ILD and RA, a positive anti-CCP antibody (28 patients) had a strong association with ILD ($x^2 = 8.526$, $p=0.0035$). Of these patients who had PFTs, 73% (30 of 41) already had moderate to severe restrictive lung disease or a severe impairment in diffusing capacity at the time of initial pulmonary evaluation.

Conclusion: Our data indicates that the majority of patients with ILD and positive RF and/or anti CCP antibody in the ILD Clinic met the diagnostic criteria for RA. Consistent with other reports, there was a strong association with presence of anti-CCP antibody and development of interstitial lung disease. These findings highlight the prognostic value of anti-CCP antibody in patients with RA who may be at increased risk of developing ILD. Hence, it is reasonable for CCP positive RA patients to undergo routine screening and surveillance for early detection and management of ILD at the time of diagnosis and thereafter. Further investigation and prospective studies are needed to fully assess the implications of a positive anti-CCP and RF in patients with ILD without articular manifestations of RA.

1405

Five-Year Changes in Myocardial Structure and Function in Patients with Rheumatoid Arthritis. John M. Davis III[1], Grace Lin[1], Jae Oh[2], Cynthia S. Crowson[1], Terry M. Therneau[1], Eric L. Matteson[1] and Sherine E. Gabriel[1]. [1]Mayo Clinic, Rochester, MN, [2]Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.

Background/Purpose: Patients with rheumatoid arthritis (RA) suffer an increased risk of heart failure not explained by traditional cardiovascular risk factors. Previously, we have shown that these patients have a high prevalence of abnormal left ventricular (LV) diastolic dysfunction and altered ventricular

geometry. The objective of this study was to evaluate longitudinal changes in LV structure and function in patients with RA.

Methods: A prospective longitudinal study of patients with RA from our community population-based inception cohort was performed. RA was defined according to the 1987 classification criteria. Patients were seen at study baseline (2007 – 2009) and approximately 5 years later (2012 – 2014). For each participant, a registered diagnostic cardiac sonographer performed pulse wave and tissue Doppler echocardiography according to a standardized research protocol. LV diastolic function parameters were analyzed according to guidelines and criteria of the American Society of Echocardiography. Medical records were reviewed to ascertain demographics, cardiovascular risk factors, and RA disease characteristics. Changes in the echo parameters between baseline and 5 years were tested using paired t-tests.

Results: A total of 137 patients to date have been studied at the 5-year time point. The mean age was 58.4 years, disease duration 9.6 years, and 76% were female. The E/e' ratio increased from 8.7 to 10.9 ($p<0.001$), consistent with increasing filling pressures of the left ventricle (Table). The left atrial volume index increased from 25.6 to 34.3 ($p<0.001$). The LV mass index and relative wall thickness decreased over time. On average, there was no biologically relevant change in the ejection fraction over time.

Measurement	Baseline Mean (SD)	5 Years Mean (SD)	Mean Difference	P-value
LV ejection fraction, %	62.0 (5.8)	61.2 (4.6)	−0.8 (6.3)	0.13
E velocity, m/s	0.69 (0.17)	0.7 (0.17)	0.01 (0.17)	0.53
A velocity, m/s	0.43 (0.1)	0.71 (0.21)	0.28 (0.25)	<0.001
Tissue Doppler e', m/s	0.08 (0.02)	0.07 (0.02)	−0.02 (0.02)	<0.001
E/A ratio	1.7 (0.4)	1.1 (0.4)	−0.6 (0.6)	<0.001
E/e' ratio	8.7 (2.9)	10.9 (3.9)	2.2 (3.4)	<0.001
Left atrial volume index, mL/m^2	25.6 (5.4)	34.3 (8.7)	8.6 (7.9)	<0.001
LV mass index, gm/m^2	80.7 (14.9)	77.3 (18.4)	−3.4 (17.5)	0.06
Relative wall thickness	0.40 (0.07)	0.36 (0.07)	−0.04 (0.08)	<0.001

Conclusion: In this sample of patients with RA, clinically significant worsening in cardiac structure and function occurred during 5 years of follow-up, including progression of diastolic dysfunction. Additionally, decline in the LV mass index was observed, which contrasts the expected increased LV mass associated with diastolic dysfunction (hypertrophy). Future work is necessary to compare these findings to age-related changes in the general population in order to better understand the significance of the results with respect to the risk of future heart failure.

1406

Comorbidity in Rheumatoid Arthritis. It Is Feasible to Record Concomitant Medical Conditions and Multi-Morbidity in Observational Research Studies. Can This be Extended to Routine Clinical Settings? Elena Nikiphorou[1], Sam Norton[2] and Adam Young[3]. [1]University of Hertfordshire, Hatfield, United Kingdom, [2]King's College London, London, United Kingdom, [3]ERAS, St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: Comorbidity in RA can delay diagnosis and influence treatment decisions. It is known to affect RA outcomes, and can confound data analysis. Most RA observational cohort studies have used either the generic and weighted Charlson Comorbidity Index (CCI), one of few validated tools but complicated and designed for medical inpatient settings, or non-standardised but simple comorbidity counts. We have previously reported on the feasibility of the latter and its value in assessing impact of comorbidity on survival and function [ref]. There is currently no standardised, uncomplicated and validated instrument for recording and collecting comorbidity data which is relevant to contemporary and routine rheumatology practice. Is it feasible to measure comorbidity in daily rheumatology practice? The purpose of the study is to evaluate the feasibility of a simple method based on ICD10 systems (chapters) to measure comorbidity in RA.

Methods: Clinicians involved in a UK inception observational cohort study of RA (the Early RA Study, ERAS, n=1465, median follow up 10yrs) completed a simple and specific outcome form at regular intervals which included indicating the presence or not of the main ICD10 systems (n=15), with space to add details as free text (completed in 91%).

Results: More than 90% of all comorbidities reported covered 10 systems in order of frequency – Non Cardiac Vascular (to comply with WHO classification), Cardiovascular, Endocrine, Gastro Intestinal & Hepatic, Respiratory, Psychiatric, Malignancies, Renal, Dermatology, Opthalmology. As musculoskeletal and extra articular RA conditions would be managed within the specialty, these were identified and remained as a separate group and not part of this analysis. 75% of all individual comorbidities recorded in the ICD10 systems included only 20 specific medical conditions, and the most common 2–3 specific conditions in each ICD10 system made up most (70–80%) of each system. For the other less common systems, there was a wider range of individual conditions of roughly equal frequencies. At least one comorbidity at baseline, 3, 5 & 10yr follow up was present in 21%, 40%, 50% and 78% respectively based on a simple numeric score, compared to weighted CCI of 11%, 27%, 36%, 52%. Mean scores were 0.21, 0.53, 0.72, 1.08 and 0.13, 0.4, 0.55, 0.86 respectively, with modest correlations since they measure different aspects: Spearman's rho of around 0.72. Kappa statistics were 19.3, 25.1, 24.6, 22.9 respectively. Multiple morbidity can be measured from ICD10 (>1 major condition) and was present in <1%, 11%, 17% & 29% at baseline, 3, 5, 10yrs.

Conclusion: This study has shown the feasibility of collecting comorbidity data in a relatively simple way using standard definitions, and its value in identifying multi-morbidity. It is this latter group with complex disease that requires prompt identification, multiple speciality input and coordination of patient care routine clinical settings.

1407

Low HAQ and Pain Predict Patient Perceived Remission in Rheumatoid Arthritis Patients Receiving MTX or Anti-TNF-Alpha Treatment. Paul Studenic[1], Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: The induction of remission is the primary target of RA therapy. Failing to achieve the patient global estimate of disease activity criterion (PGA<=1cm) has been shown to be the primary cause hindering patients to be classified as being in remission. Here, we aimed to determine factors that predict achieving the PGA criterion of remission in RA patients in usual clinical care.

Methods: We selected patients from a longitudinal RA database, who started MTX monotherapy or TNFi treatment in combination with MTX or leflunomide and had at least 6 months of follow-up. In univariate analysis, we tested core-set variables to identify candidate predictors of patient perceived remission (PGA≤1cm), which we then subjected to multivariate logistic regression analysis for the outcome: PGA≤1cm.

Results: Data of 172 patients receiving MTX (82% female, 65% rheumatoid factor positive, mean SDAI: 18.5±12.3) and of 112 patients on TNFi (82% female, 62% rheumatoid factor positive, mean SDAI: 19.7±13.3) were used for analysis. After 6 month of treatment 70% of those receiving MTX and 55% of the TNFi group were in a state of remission or low disease activity, based on the SDAI. Forty-seven percent of MTX and 34% of TNFi patients evaluated their PGA as being ≤1cm. Seventy-four percent of MTX and 58% of TNFi treated patients who had PGA≤1cm had also an evaluator global assessment of ≤1cm. The overlap of patient perceived remission and remission by SDAI was 49% in the MTX group and 46% in the TNFi group.

Univariate analyses in MTX treated patients showed an association of pain, HAQ scores, and TJC with the outcome PGA≤1cm. In the multivariate logistic regression model, the odds ratio (OR) was 0.46 for baseline HAQ (**Table**) and 0.98 for pain as predictors for achieving remission after 6 months of treatment. Higher HAQ and pain scores therefore lead to a lower odds for achieving PGA ≤1cm.

Patients with an improvement in HAQ within the first 3 month have a 3.5 (CI: 1–13) times higher odds to achieve PGA≤1cm after 6 months of treatment than patients who report a worsening in HAQ, which corresponds to a probability of 23% versus 8% to achieve PGA≤1cm.

In patients receiving TNFi-therapy, baseline HAQ (OR: 0.31) and pain (OR: 0.98) were shown to be predictive, i.e. a patient with a baseline HAQ of

1.25 or a pain score of 50mm has a 20% probability of achieving PGA remission, whereas a baseline HAQ of 0.5 or a pain score of 20mm coincides with a 40% probability.

Table: Summary of the multivariate logistic regression model for the outcome PGA≤1cm

		Regression coefficient	Standard error	p	95% Confidence Interval for Odds Ratio		
					Lower	OR	Upper
MTX	**Baseline HAQ**	−0.77	0.36	0.034	0.23	0.46	0.94
	Baseline pain	−0.02	0.01	0.026	0.96	0.98	1.00
	Constant	0.18	0.35	0.611		1.19	
TNFi	**Baseline pain**	−0.03	0.01	0.022	0.95	0.98	0.99
	Baseline HAQ	−1.16	0.41	0.004	0.14	0.31	0.70
	Constant	0.87	0.41	0.036		2.39	

Conclusion: We demonstrated here that patients with poor function or high pain levels are likely to fail patient reported remission, as shown here for the patient global variable, which is part of the established remission criteria. These findings were independent of the treatment regimen. Improvement in function enhances the chances for achieving patient perceived remission after 6 months of DMARD treatment.

Inflammatory Biomarkers, Sleep Quantity and Sleep Quality in Rheumatoid Arthritis. Alexander Fine[1], Michelle A. Frits[2], Jing Cui[3], Christine K. Iannaccone[2], Jonathan S. Coblyn[2], Michael E. Weinblatt[2], Nancy A. Shadick[4] and Yvonne C. Lee[2]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Womens Hospital, Boston, MA, [4]Brigham and Women's Hospital/Harvard University, Cambridge, MA.

Background/Purpose: Sleep problems affect over 60% of rheumatoid arthritis (RA) patients. However, little is known about the association between sleep problems and inflammatory pathways in RA. In the general population, studies have shown that sleep problems are associated with elevations in inflammatory biomarkers, notably CRP and the inflammatory cytokines, TNF-a and IL-6. The goal of this study was to examine the cross-sectional association between biomarkers associated with RA disease activity and sleep quantity and quality in patients with RA.

Methods: 208 patients in a RA registry were enrolled in a substudy on sleep and psychosocial distress. All subjects completed the Medical Outcomes Study (MOS) Sleep Scale. Of these 208 patients, 189 also had 12 biomarkers of disease activity (EGF, VEGF-A, leptin, IL-6, SAA, CRP, VCAM-1, MMP-1, MMP-3, TNFRI, YKL-40 and resistin) measured using a quantitative multiplex immunoassay. Biomarkers with non-normal distributions were transformed. The primary independent variables were the individual biomarkers and a composite disease activity score, calculated according to a validated algorithm. The primary dependent variables were sleep quantity (in hours) and sleep quality, measured by the MOS Sleep Problems Index II (0–100 scale with 100 indicating greater sleep problems). Linear regression models were used to examine the association between biomarkers and sleep quantity and quality, adjusted for age, sex, RA disease duration and RF or anti-CCP seropositivity. To elucidate the impact of TNF inhibitors on this association, secondary analyses were performed including an indicator variable for TNF inhibitor use. Using the Bonferroni correction for multiple comparisons, the threshold for significance was set at $p < 0.002$.

Results: The study population (N = 189) included 85.2% women. The average age was 58.2 ± 11.2 years. The average DAS28-CRP was 2.95 ± 1.29. 17.5% were taking corticosteroids. 59.8% were taking non-biologic disease-modifying anti rheumatic drugs, and 54.0% were taking TNF inhibitors. 61.9% were either RF or anti-CCP positive. After adjustment for multiple comparisons, neither the composite disease activity score nor the individual biomarkers of disease activity were significantly associated with sleep quantity or the MOS Sleep Problems Index II (Table). Similarly, neither the composite disease activity score nor the individual biomarkers were significantly associated with sleep quantity or the MOS Sleep Problems Index II in secondary analyses including TNF inhibitor use as an indicator variable.

Conclusion: Contrary to previous studies in the general population, no associations were observed between inflammatory biomarkers and measures of sleep quantity and quality in this cross-sectional study of established RA patients. These findings suggest that RA disease activity may not be the primary driver of sleep problems in RA.

Table. Adjusted associations between biomarkers of RA disease activity and sleep quantity and sleep quality, measured using the Medical Outcomes Study Sleep Scale.*

Biomarkers	Sleep Quantity(n=174)		Sleep Quality(n=176)	
	b	*P*	b	*P*
Composite score	0.01	0.42	−0.04	0.68
ln CRP	−0.05	0.48	−0.55	0.61

Pregnancy Outcomes after Exposure to Certolizumab Pegol: Updated Results from Safety Surveillance. Megan E. B. Clowse[1], Douglas C. Wolf[2], Frauke Förger[3], John J. Cush[4], Amanda Golembesky[5], Laura Shaughnessy[5], Dirk De Cuyper[6], Kristel Luijtens[6], Sarah Abbas[7] and Uma Mahadevan[8]. [1]Duke University Medical Center, Durham, NC, [2]Atlanta Gastroenterology Associates, Atlanta, GA, [3]Inselspital, University of Bern, Bern, Switzerland, [4]Baylor Research Institute and Baylor University Medical Center, Dallas, TX, [5]UCB Pharma, Raleigh, NC, [6]UCB Pharma, Brussels, Belgium, [7]UCB Pharma, Paris, France, [8]UCSF Medical Center, San Francisco, CA.

Background/Purpose: Certolizumab pegol (CZP) is a PEGylated Fc-free anti-TNF approved for the treatment of RA, CD, psoriatic arthritis (PsA) and ankylosing spondylitis (AS). The objective was to provide an updated analysis of pregnancy outcomes in rheumatic patients (pts) after CZP exposure, with a focus on RA pregnancies, from clinical trial and spontaneous post-marketing reports. Concomitant medications and disease activity are also reported from clinical trials.

Methods: The UCB Pharma global safety database was searched for all medically confirmed cases of pregnancy through 28 March 2013. The number of live births, spontaneous miscarriages and elective terminations for neonates exposed to CZP (maternal/paternal exposure) was examined. Congenital abnormalities, neonatal deaths, maternal demographics, disease activity and concomitant medications were also investigated.

Results: 309 CZP-exposed pregnancies were reported: 285 maternal exposure, 24 paternal. For maternal exposure pregnancies, the most common underlying maternal conditions were CD (190/285) and RA (52/285), with the remaining 43/285 for other indications (including AS and PsA). Pregnancy outcomes were available for 190 of 285 pregnancies: 42 in women with RA, 124 in CD and 24 in other rheumatic indications. Pregnancy outcomes, where reported, are shown in Table 1. Maternal disease activity in women with RA are shown in

Table 2. Common concomitant medications in all pregnancies are shown in Table 3. 5 congenital anomalies were reported, in 4 neonates, among all maternal exposure live births (n=132): vesicoureteric reflux; congenital morbus hirschsprung disease and club foot; right aortic arch with aberrant left subclavian artery; mild unilateral hydronephrosis on antenatal ultrasound (healthy at birth). None were considered related to CZP by the treating physicians. A single neonatal death was reported after maternal exposure in one of a set of twins with gestation <26 weeks.

Conclusion: Updated analysis of pregnancy outcomes after exposure to CZP supports previous reports[1] suggesting no apparent impact of maternal CZP exposure on pregnancy outcomes. Additional prospective data are required to better evaluate the safety of CZP in pregnancy and the role of concomitant medications and disease activity.

Low Rates of Cardiovascular Risk Factor Modification Among High-Risk Rheumatoid Arthritis Patients: Barrier to Cardiovascular Prevention Strategies?

Kimberly P. Liang[1], Rohit Aggarwal[1], Juan (June) Feng[2], Jason Lyons[2], Heather Eng[2], Stephen R. Wisniewski[2], Melissa Saul[3], Douglas P. Landsittel[4], Douglas W. Chew[1], Aryan Aiyer[5] and Larry W. Moreland[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]University of Pittsburgh, School of Medicine, Pittsburgh, PA, [4]University of Pittsburgh, Center for Health Care Research Data Center, Pittsburgh, PA, [5]University of Pittsburgh Medical Center, Pittsburgh, PA.

Background/Purpose: Despite higher risk of cardiovascular disease (CVD) in rheumatoid arthritis (RA), systematic cardiovascular (CV) prevention strategies are lacking. Recent guidelines for CV risk modification rely on documentation of traditional risk factors to estimate 10-year CV risk scores. Our primary objective was to quantify, by utilizing electronic medical records (EMR), the frequency of CV risk factors in a prospective longitudinal RA cohort, as well as use of CV medications, including statins, angiotensin-converting enzyme inhibitors (ACE-i), or angiotensin-receptor blockers (ARB). We also sought to determine the rates of CV risk factors and CV medication use in the subset of RA patients with 2 or more 'high risk' disease features, i.e., seropositivity for rheumatoid factor or anti-cyclic citrullinated peptide, disease duration >10 years, or severe extra-articular manifestations (ExRA).

Methods: Utilizing the EMR, we identified presence of hypertension (HTN), hyperlipidemia (HL), diabetes mellitus (DM), family history, and personal history of CVD, as defined by ICD-9 codes, as well as body mass index (BMI) >30 kg/m^2 (obesity), uncontrolled HTN (blood pressure [BP] ≥150/90 mm Hg for those aged ≥60 years; and BP ≥140/90 mm Hg for those aged <60 years), and current/ever smoking status. We defined use of any statin, ACE-I, or ARB if listed on EMR's medications. Severe ExRA was defined by ICD-9 codes for pericarditis, pleuritis, Felty's syndrome, vasculitis, neuropathy, scleritis/episcleritis, or glomerulonephritis. Merging EMR data with ongoing prospective RA Comparative Effectiveness Research (RACER) database, frequencies were calculated for each of the CV risk factors and medications in a subset of active RACER subjects from enrollment up to October 2013.

Results: A total of 934 active RACER subjects were identified among 1039 enrolled. Table 1 shows prevalence of CV risk factors. Only 14.7% were taking any statin, 26.3% any ACE-i, and 14.1% any ARB. Out of 675 subjects with complete data, 317 (47.0%) had at least 2 'high-risk' RA disease features that increase their estimated 10-year CV risk score. Of this subgroup, 259 (81.7%) had one or more CV risk factors, yet only 57 (18.0%) were treated with any statin, and 138 (43.5%) were treated with any ACE-i or ARB.

Conclusion: Among RA patients with available EMR data for traditional CV risk factors, a majority had modifiable obesity, HL and HTN (including uncontrolled). Yet, only a minority were treated with statins, ACE-I, or ARB. These data suggest that CV risk factor management is suboptimal in RA patients, even in the subgroup of RA patients with 'high-risk' disease features. The low rates of CV risk factor modification are potential barriers to optimizing CV preventive strategies in RA. Future studies are needed to improve work flows using EMR for CV risk factor documentation and to help modify them in this high-risk population.

Table 1: Prevalence of CV Risk Factors Reported in EMR in RACER Cohort. Analysis of 934 active RACER patients (out of 1039 patients) from enrollment up to October 2013

Psychological Distress over Time in Early Rheumatoid Arthritis: Results from a Longitudinal Study in an Early Arthritis Cohort. Bernard Combe[1], Nathalie Rincheval[2], René-Marc Flipo[3], Philipe M. Goupille[4], Jean-Pierre Daurès[2] and JP Boulenger[5]. [1]Hôpital Lapeyronie, Montpellier, France, [2]Institut Universitaire de Recherche Clinique, Montpellier, France, [3]Hopital R Salengro CHRU, Lille CEDEX, France, [4]Hopital Trousseau, Tours, France, [5]La Colombiere Hospital, Montpellier, France.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease with frequent psychological comorbidities, of which depression and anxiety are 2 common manifestations. We aimed to identify predictive factors of psychological distress in a large prospective cohort of very early RA patients.

Methods: ESPOIR (Etude et Suivi des POlyarthrites Indifférenciées Récentes) is a multicentre, longitudinal and prospective cohort study of patients with early arthritis (< 6-month disease duration). The study sample comprised 641 patients with very early RA according to the 2010 ACR/EULAR RA criteria from the ESPOIR cohort. Psychological distress was assessed over 3 years by the Mental Health Inventory 5 questionnaire, at different timepoints (baseline, 6, 12, 18, 24 and 36 months). Logistic regression with a Generalized Estimating Equation (GEE) model was used to analyse the association of disease variables and risk of psychological distress.

Results: At baseline, 46.9% of RA patients were screened as positive for psychological distress. Over 3 years, psychological distress decreased significantly, with a prevalence of 25.8% at 36 months. The Health Assessment Questionnaire–Disability Index (HAQ-DI) score was the most important factor predicting psychological distress over 3 years (odds ratio 1.81 [95% confidence interval 1.13–2.91] to 3.66 [2.07–6.45]). On GEE analysis, other significant variables predicting psychological distress included female sex (p= 0.0117), low educational level (p=0.0047), family income (p= 0.0138 or 0.0385) and occupation of employee according to national classification of socio-professional categories (p= 0.0096). Low (< median) patient and physician global assessment of disease activity or DAS28-CRP ≤ 3.2 were protective for risk of psychological distress. Finally, risk of psychological distress was increased during the first year after diagnosis (OR 1.31 [1.04–1.72] to 1.95 [1.44–2.84]. Baseline biological and radiological variables and treatment regimen were not associated with distress.

Conclusion: Psychological distress in very early RA is frequent and the HAQ-DI score is a predictor of depression and anxiety in these patients. Psychological evaluation in patients with early RA is important for further individual psychiatric diagnosis and management.

1412

Sarcopenia and Its Impact on Disability in Rheumatoid Arthritis, a Pilot Study. Meltem Alkan Melikoglu[1] and Kazim Senel[2]. [1]Ataturk University Faculty of Medicine, Erzurum, Turkey, [2]Ataturk University Medical School, Erzurum, Turkey.

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased morbidity and mortality due to several metabolic deteriorations one of which is sarcopenia. The aim of this cross-sectional pilot study was to investigate sarcopenia in patients with RA and to evaluate its relation to the disability assessment.

Methods: Forty female patients with RA and age-gender and body mass index (BMI) matched 40 healthy controls were included. Demographic data, pain, morning stiffness duration, disease activity score (DAS28), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and the Health Assessment Questionnaire (HAQ) were evaluated. Body compositions were assessed with whole body dual energy X-ray absorptiometry. We compared the appendicular appendicular skeletal muscle mass (ASM) and skeletal muscle mass index (SMI) of patients to their healthy matches. Also possible correlations between SMI and the disease characteristics and HAQ score were investigated. The independent samples t test and the Pearson's correlation test were used to evaluate the data.

Results: The mean age of the patients and controls were 48,29 ±8,34 and 46.21±6.90 years, respectively. The BMI values, percentages of obese, overweigth and healthy weight subjects were similar in patient and control groups. However, ASM and SMI calculations were found to be significantly lower in patients with RA than those in controls (p<0,05). The percentage of sarcopenia was significantly higher in patients with RA than that in their age-gender and BMI similar healthy matches (20% and 7%; respectively; p<0,05). Although there were no significant correlation between SMI and age, disease duration, morning stiffness, pain, DAS28 levels and laboratory investigations, a significant negative correlation was determined between SMI and HAQ score in patients with RA (p<0,05).

Conclusion: We demontrated lower SMI values and higher sarcopenia ratios in patients with RA than their age-gender and BMI similar healthy matches. Also, independetly from other disease characteristics, the inverse correlation between SMI and HAQ scores found in our study may contribute the understanding of the impact of the process on the disability of the patients.

The Prevalence of Renal Impairment in Patients with Rheumatoid Arthritis. Marion Coudercr Sr.[1], Martin Soubrier[2], Bruno Pereira[3], Aurelien Tiple[4], Melanie Gilson[5], Bruno Fautrel[6], Sophie Pouplin[7], Emmanuelle Dernis Labous[8], Laure Gossec[9], Cécile Gaujoux-Viala[10] and Maxime Dougados[11]. [1]Chu G.Montpied, Clermont Ferrand, France, [2]CHU G.-Montpied,

Clermont-Ferrand, France, [3]Clinical research department, Clermont-Ferrand, France, [4]CHU, Clermont-Ferrand, France, [5]CHu Grenoble, Grenoble, France, [6]Pitie Salpetriere Hospital, Paris, France, [7]Rouen University Hospital, Rouen, France, [8]Ch Du Mans, Le Mans, France, [9]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France, [10]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France, [11]Université Paris René Descartes and Hôpital Cochin, Paris, France.

Background/Purpose: To assess the prevalence and associations of renal dysfunction in patients with rheumatoid arthritis (RA).

Methods: COMEDRA is a French nationwide cross-sectional multicentre study on comorbidities in RA. Renal function was assessed from the estimated glomerular filtration rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) equation. RA characteristics, risk factors for renal dysfunction (cardiovascular risk factors, medications) were collected in all participants.

Results: 931 of the 970 recruited patients, were analysed (female gender: 79.6%, age: 57.8 years, disease duration: 11.1 years, DAS28-erythrocyte sedimentation rate: 3.1). About 9 % of patients had an eGFR<60 ml/min/1.73m^2 and 9.9% of the patients had proteinuria (defined by positive dipstick testing). In the univariate analysis, age ($p<0.001$), the presence of hypertension ($p<0.001$), systolic blood pressure ($p=0.03$), and Framingham Risk score ($p<0.001$) were associated with an eGFR<60ml/min/1.73m^2. Renal dysfunction was not associated with gender ($p=0.35$), disease duration ($p=0.91$), disease activity (as assessed by DAS28-ESR: $p=0.14$), NSAID use ($p=0.77$), disease severity (erosions [$p=0.9$], joint replacement [$p=0.6$]) or RA medications ($p=0.14$). Two multivariate analysis models were constructed: Model A, without the Framingham risk score which showed that age (OR: 1.05; 95%CI [1.03–1.09]) and hypertension (OR: 2.5, 95%CI [1.5–4.3]); were predictive of an eGFR <60 ml/ min/1,73m^2; Model B, which showed that the Framingham risk score was predictive of low eGFR (OR 1.06, 95%CI [1.03–1.09]).

Conclusion: Renal impairment is relatively common in RA and is associated with cardiovascular risk factors such as age, hypertension and the Framingham risk score but not with disease activity or severity.

Investigation of the Association Between Gastroesophageal Reflux Disease and Clinical Factors in Patients with Rheumatoid Arthritis. Katsushi Ishii[1], Yuichi Mochida[1], Yuki Ozawa[1], Naoto Mitsugi[1] and Tomoyuki Saito[2]. [1]Yokohama City University Medical Center, Yokohama, Japan, [2]Yokohama City University School of Medicine, Yokohama, Japan.

Background/Purpose: Gastroesophageal reflux disease (GERD) is caused by the abnormal reflux of the gastric contents into the esophagus. Many risk factors are considered as a cause of GERD. Nonsteroidal anti-inflammatory drugs (NSAIDs) consumption is regard as one cause of the development of GERD; but, there are few reports regarding the relationship between NSAIDs consumption and the development of GERD. NSAIDs are commonly used to control pain, inflammation related to patients with rheumatoid arthritis (RA). Therefore, the prevalence of GERD in RA may be high because of high rate of NSAIDs consumption. However, there are few reports regarding as the development of GERD in RA. The purpose of this study was to examine the prevalence of GERD in RA. We also investigate the association between GERD and clinical factors in RA.

Methods: We investigated 378 outpatients with RA (70 males, 308 females). Three rheumatologist of orthopaedic surgery examined all patients. The presence or absence of GERD was evaluated by using GerdQ questionnaire. It is well known that GerdQ can be used to diagnose GERD with an accuracy similar to that of the gastroenterologist. When heartburn or acid regurgitation symptoms are observed more than once a week, the patients are diagnosed with GERD. The correlation between GERD and clinical factors such as age, sex, height, weight, BMI, disease duration, DAS28/DAS28-CRP/SDAI, Pt-VAS, and medication drugs (NSAIDs, steroid, bisphosphonate, and gatroprotective agents) were analyzed.

Results: The GERD symptoms were observed in 96 of these 378 patients (25.4%). SDAI and patient's VAS were significantly higher in the GERD positive group than in the GERD negative group ($p<0.05$). DAS28 and DAS28-CRP were higher in the GERD positive group than in the GERD negative group, but these differences did not reach statistical significances. There was no statistical correlation between the presence or absence of GERD symptoms and the presence or absence of taking NSAIDs, steroid, and bisphosphonate.

Conclusion: The prevalence of GERD in RA (25.4%) was higher than that in the Japanese healthy population (7.6–10.6%). The prevalence of GERD in RA was high and associated with Pt-VAS. Therefore, we should pay attention to the complication of GERD when the evaluation of disease activity of RA.

Differential Gender Impact in the Quality of Life of Patients with Rheumatoid Arthritis. Comprehensive Study Including Clinical, Comorbidity and Psicho-Social Variables. Elena Aurrecoechea[1], Jaime Calvo-Alen[2], Graciela S. Alarcon[3], Gerald McGwin[4], Maria Luisa Diez Lizuain[5] and Javier Llorca[6]. [1]Hospital Sierrallana. Torrelavega, Torrelavega, Spain, [2]Hospital de Sierrallana. Torrelavega. Spain, Torrelavega, Spain, [3]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, [4]Rheumatologist, Birmingham, AL, [5]MD, Torrelavega, Spain, [6]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain.

Background/Purpose: To evaluate whether gender portends a differential impact in the outcome of RA in terms of quality of life (QOL) and which type of variables may cause such effect.

Methods: Seventy female and 70 male RA unselected patients followed in our division were cross-sectionally evaluated according to a pre-established protocol. It includes: medical history review, standardized measurements of disease severity (biological parameters, DAS28 activity index, HAQ index, modified Sharp-van der Heidje scoring method) as well as specific tools to assess comprehensively different psychological and disease related behavior and coping aspects (The Beck Depression Scale, The ISEL questionnaire for social support, The illness behavior abnormalities using the Illness Behavior Questionnaire (IBQ),The Rheumatology Attitude Index, and the level of disease with the Self-efficacy Questionnaire). QOL was assessed by the SF-36 questionnaire. Univariate and multivariate analyses were performed to examine the different contribution of these variables in both genders in the final outcome of the disease assessed in terms of QOL.

Results: Both groups were homogeneous regarding to age at diagnosis (49.92+13.43 vs 52.94+13.63; $p=0.189$), disease duration (2472.48+2236.46 vs2441.62+2220.26 days; $p=0.93$), disease activity by DAS28 (3.81+1.49 vs 3.5+ 1.43, $p=0.21$), functional impairment by HAQ (0.89+ 2.61 vs 0.22+0.96, $p=0.04$) or radiologic damage by SVH score (24.6+48.4 vs men 22.1+ 27.7; $p= 0.71$). Regarding to comorbidity, men had a higher prevalence of ischemic heart disease (1.43% vs 11% $p=0.029$), chronic pulmonary obstructive disease, COPD (2.86% vs17.14% $p=0.005$), and conversely women had higher prevalence of osteoporosis (18.57% vs 5.71, $p=0.02$ and received more frequently anti-resortive therapy (15.71% vs 5.71%, $p=0.056$). Regarding to psychological variables, women presented significant higher scores in the Beck scale (10.78+7.52 vs 7.83+ 6.85, $p=0.016$) and numerically worse IBQ results (11.91+6.07 vs 10.55+ 5.88, $p=0.181$); not finding differences in the rest of studied physochological and behavioral variables. A greater impairment in the physical functioning (PF) subscale of SF36 was observed among female patients (57.78 + 22.11 vs 67.30 + 22.75; $p=0.01$). In the different models of multivariate analyses performed, Beck Scale ($p=0.000$), and the presence of osteoporosis ($p=0.000$) remained independently associated with the SF36 results.

Conclusion: Female RA patients have lower levels of quality of life than their male counterparts. Psychological variables as a higher level of depressive symptoms and, maybe, a worse disease related behavior as well as a higher incidence of osteoporosis plays a major role in this result, rather than pure biological disease related variables. This fact should be taken into account in the management of these patients.

Analysis of Cardiac Involvement in Patients with Amyloid a (AA) Amyloidosis Due to Rheumatoidarthritis. Daisuke Kobayashi[1], Satoshi Ito[1], Satoru Kodama[1], Akira Murasawa[1], Ichiei Narita[2] and Kiyoshi Nakazono[1]. [1]Niigata Rheumatic Center, Shibata, Japan, [2]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is one of the major causes of amyloid A (AA) amyloidosis. The major organs affected are the kidneys and gastrointestinal (GI) tract. Although cardiac amyloidosis is the principal cause of death in patients with amyloid L amyloidosis, significant cardiac involvement in AA amyloidosis is thought to be rare. On the other hand, the survival rate of hemodialysis patients with AA amyloidosis associated with RA has been shown to be low, and our previous study revealed that cardiac failure accounted for more than half of the mortality in these patients. The purpose of this analysis was to clarify the cardiac involvement and its clinical significance in patients with RA-associated AA amyloidosis.

Methods: Twenty-seven RA patients (4 males, 23 females) with AA amyloidosis who were followed up at Niigata Rheumatic Center between April 2007 and March 2014 were enrolled. Each patient fulfilled the 1987 American College of Rheumatology criteria for RA. All patients had undergone GI tract biopsies, and had been confirmed to have reactive AA amyloidosis by pathological examination. The patients' background data and echocardiographic features were analyzed retrospectively. Differences were assessed by Mann-Whitney U test*, Fisher's exact test#, and log rank test**, and differences at $p < 0.05$ were considered statistically significant.

Results: The median age was 71 [range, 48–89] yr, the period between the onset of RA and echocardiographic examination was 20 [2–41] yr, and the period between the onset of AA amyloidosis and echocardiographic examination was 1007 [20–6458] day. Echocardiography showed that the left ventricular (LV) posterior wall thickness was 11.0 [7.4–17.0] mm, with an interventricular septal thickness of 10.5 [5.5–14.2] mm, and an ejection fraction (EF) of 72.1% [32.3–85.4%]. Thirteen patients with LV wall thickness exceeded 11.0 mm were assigned to a LV hypertrophy (LVH) group, and their clinical features were compared with a normal group (n=14). Fatalities in the LVH group vs normal group were 7 vs 0 at two year after echocardiography and 9 vs 2 at the last observation. Kaplan-Meier survival curves showed a significant association with reduced survival in the LVH group (p=0.039**). There were no significant differences between the LVH group and the normal group at the baseline in terms of patient age (p=0.512*), duration of RA (p=0.627*), serum albumin level (p=0.92*), estimated glomerular filtration rate (eGFR) (p=0.094*), disease activity score in 28 Joints based on erythrocyte sedimentation rate (p=0.19*), modified Health Assessment Questionnaire score (p=0.77*), and echocardiogram EF (p=0.21*). Patients in the LVH group had a higher systolic blood pressure (133 [116–160] vs 120.5 [110–142] mmHg, p=0.039*), in spite of higher usage of antihypertensive agents (12 vs 3, respectively, $p<0.001$#). Although the LVH group appeared to have a lower eGFR, there was no significant difference in survival rate between the patients whose eGFR was under 45 ml/min/1.73 m^2 (n=12) and the others (n=15) (p=0.52**).

Conclusion: Thickening of the LV wall is a notable cardiac feature of patients with AA amyloidosis and is strongly suspected to contribute to their poor prognosis.

Red Cell Distribution Width: A Measure for Cardiovascular Risk in Rheumatoid Arthritis Patients? Sobia Hassan[1], Maria Antonelli[2] and Stanley P Ballou[3]. [1]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, [2]Case Western Reserve University School of Medicine at MetroHealth Medical Center, Cleveland, OH, [3]MetroHealth Medical Center / Case Western Reserve University, Cleveland, OH.

Background/Purpose: Red cell distribution width (RDW) is a measure of the variation in red blood cell size reported on the automated complete blood count. Although traditionally used to differentiate between causes of anemia, elevated RDW has recently been found to predict cardiovascular (CVS) risk and outcome in patients with and without heart disease. RDW may be a marker for the inflammation that drives CVS risk.

Supporting an inflammatory link, RDW has been shown to correlate with disease activity and inflammatory markers in conditions such as Bechet's, inflammatory bowel disease, rheumatoid arthritis (RA) and systemic lupus erythematosus.

RA is a chronic inflammatory condition with an increased risk of CVS disease. We hypothesized that RA patients with elevated RDW levels would experience greater burden of myocardial infarction (MI).

Methods: Utilizing a secure cloud based platform, Explorys, we searched de-identified patient data from multiple US healthcare systems between the years 1999 to 2014. Patients with a diagnosis of RA were identified by CCP and/or RF positivity. To exclude the influence of anemia only patients with Hb>12 mg/dl were included. Patients were stratified into a high (≥15.6 %) RDW group if they ever had an RDW > 15.6% and a low RDW group (<13.5% and excluding any patient with prior episode of RDW 15.6%). The proportion of patients with a diagnosis of MI in each RDW group was collected.

For comparison, patients were divided into a high and low CRP group (≥ 2.5 and ≤ 0.8 mg/dl) and a high and low ESR group (≥50 and ≤30 mm/hr) and MI data was collected.

Statistical comparison between high and low laboratory test groups was performed with chi square and odds ratios were calculated.

Results:

Table 1: Proportion of patients with RA who have had MI

	N with MI/Total N (%)	N with MI/Total N (%)	*p*-value
RDW	High RDW (>15.6%) 1410/11250 (11)	Low RDW (<13.5%) 1320/21990 (6)	<.0001
ESR	High ESR (>50mm/hr) 710/5480 (13)	Low ESR (<30mm/hr) 1120/22490 (5)	<.0001
CRP	High CRP (>2.5 mg/dL) 630/5380 (10)	Low CRP (<0.8mg/dL) 580/11700 (5)	<.0001

The total cohort of patients with RA from the database was 35 890; of which 2 810 had an MI.

The proportion of RA patients with MI was significantly increased in the high compared to low RDW, ESR and CRP groups (results depicted in Table 1).

The odds of MI was more likely in the high verses low RDW (OR 2.1, 95% CI 1.9 to 2.3), ESR (OR 2.6, 95 % CI 2.4–2.9) and CRP (OR 2.4, 95% CI 2.1 to 2.7) groups.

Conclusion: In keeping with previous findings in RA patients, elevated levels of ESR and CRP were associated with increased risk of MI. Elevated levels of RDW in RA patients also appear to indicate an increased risk of MI. RDW is a widely available laboratory parameter that may be useful as a measure for CVS risk in RA.

We propose that in addition to elevated ESR and CRP, elevated RDW levels in RA patients should prompt physicians to aggressively screen and treat their patients for modifiable CVS risk factors, in addition to treating RA inflammation.

1418

Prevalence of Vitamin D Deficiency in Rheumatoid Arthritis (RA). Stella Cecchetti[1], Martin Soubrier[2], Pilar Galan[3], Bruno Pereira[4], Gael Mouterde[5] and Maxime Dougados[6]. [1]CHU Gabriel Montpied, 63000, France, [2]CHU G.-Montpied, Clermont-Ferrand, France, [3]Université Paris 13, Sorbonne Paris Cité, Paris Cité, France, [4]Clinical research department, Clermont-Ferrand, France, [5]Hopital Lapeyronie, Montpellier, France, [6]RAID working group for EULAR, Zurich, Switzerland.

Background/Purpose: Serum levels of vitamin D (VitD) are usually inversely correlated with RA activity. However, the prevalence of VitD deficiency does not appear to differ from that of the general population. Hypertension (HT) and low levels of HDL-cholesterol (HDL-c) –two cardio-

vascular (CV) risk factors with an increased prevalence in RA – are inversely correlated with VitD levels. The objectives were to determine the prevalence of VitD deficiency in RA patients versus a control population, and detect correlations between VitD levels and RA disease activity and/or characteristics, and between VitD levels and CV risk factors.

Methods: The COMEDRA study evaluated the impact of a visit with a nurse on the management of comorbidities in RA patients. VitD and lipids assays were performed in all patients. Controls were from the SU.VI.MAX cohort and were matched for gender, age, latitude and season during which samples were taken for assay. VitD deficiency was defined as VitD<10 ng/ml and VitD insufficiency as VitD between 10 and 29.9 ng/ml (VDI).

Results: 894 patients (79.3% women) with an average disease duration of 11.2 years [6.3 – 19.1] were analyzed. RA was erosive in 73.3% of patients and 83.9% had positive RF or anti-CCP antibodies. The DAS28-ESR was 3.0 ± 1.3. 630 patients (70.4%) were treated with biologic therapy and 341 (38.1%) received glucocorticoids (5.5 ± 5.7 mg/day). BMI was 25.1 ± 4.8. SBP was 124.9 ± 16.5 mmHg, and DBP 75.6 ± 11.4 mmHg. Total cholesterol was 2.2 ± 0.5 g/l, LDL-c was 1.3 ± 0.4 g/l, HDL-c was 0.7 ± 0.2 g/l. 147 patients (16.4%) were smokers and 52 (5.8%) were diabetic. VitD levels were in the normal range in 362 patients (40.5%), whereas 501 patients (56.0%) had VitD insufficiency and 31 (3.5%) had VitD deficiency. Comparison of 861 RA patients with 861 matched controls revealed that the RA patients had a lower prevalence of VitD insufficiency (RA: 480 (55.8%) vs. controls: 508 (59%); p=0.04) and of VitD deficiency (RA: 31 (3.6%) vs. controls: 45 (5.23%); p=0.04).

Among RA patients, males had a higher frequency of VitD insufficiency (117 (63.3%) vs.: 384 (54.2%); p=0.04) and VitD deficiency (8 (4.3%) vs.23 (3.2%); p=0.04 in males vs females respectively). There was no difference according to latitude, but the prevalence of VitD insufficiency and VitD deficiency were higher in springtime. Univariate analysis found an inverse correlation between VitD levels and RA activity defined by DAS28-CRP (p=0.02), SDAI (p=0.05) and CDAI (p=0.05), but only a trend for DAS28-ESR (p=0.08). No correlation was found with antibody status or with treatments. VitD levels were inversely correlated with BMI (p<0.001) but not with blood pressure, total-c, LDL-c, HDL-c or diabetes.

Conclusion: This study confirms that VitD is inversely correlated with RA activity and BMI but not with other CV risk factors. The prevalence of VitD deficiency was lower than in the control population, which could be explained by the fact that RA patients more frequently received VitD supplementation.

Rituximab Use in Patients with Rheumatoid Arthritis-Associated Interstitial Lung Disease and Other Connective Tissue Disease-Associated Interstitial Lung Disease: A Single Center Experience.

Sandra Chartrand[1], Jeffery J. Swigris[2], Lina Peykova[2] and Aryeh Fischer[2]. [1]Hôpital Maisonneuve-Rosemont, Montreal, QC, [2]National Jewish Health, Denver, CO.

Background/Purpose: Small series have suggested that rituximab (RTX) may be effective as rescue-therapy for connective tissue disease-associated interstitial lung disease (CTD-ILD). We sought to describe our center's experience of the outpatient use of RTX in patients with a diverse spectrum of CTD-ILD.

Methods: We identified all patients with CTD-ILD who (1) received at least one cycle of RTX as an outpatient between January 2008 and May 2014, (2) had at least one thoracic HRCT scan, and (3) pulmonary function testing pre- and post-initial RTX treatment. We extracted data from the medical record for the following: demographics, concurrent immunosuppressive medications, pulmonary function and thoracic imaging, RTX-associated side effects, infection history, and discontinuation rate. We analyzed the % predicted forced vital capacity (FVC%) closest to pre- (mean 131.8±204.6 days) and post-initial RTX administration (mean 121.7±97.2 days). T-tests were used for continuous variables analysis and Fisher's exact test was used for contingency table analysis.

Results: The cohort comprised 24 subjects with a diverse spectrum of CTD-ILD.

Table 1: Clinical characteristics

	All patients (n=24)	RA patients (n=15)
Age, years (mean±SD)	61.3±10.4	62.9±10.3
Female, n (%)	15 (62.5)	10 (66.7)
Race, n (%)		
White	21 (87.5)	14 (93.3)
Afro-American	2 (8.3)	1 (6.7)
Asian	1 (4.2)	0 (0.0)
Past smokers, n (%)	8 (33.3)	5 (33.3)
Current smokers, n (%)	1 (4.2)	1 (4.2)
Pack-year (mean±SD)	27.1±9.5	29.7±6.8
Expired, n (%)	1 (4.2)	0 (0.0)
Diagnosis, n (%)		
RA	15 (62.5)	15 (100.0)
Idiopathic inflammatory myositis (IIM)	3 (12.5)	
IIM+RA	2 (8.3)	
Systemic sclerosis	3 (12.5)	
Suggestive CTD-ILD	1 (4.2)	
Rheumatic disease duration, years (mean±SD)	9.5±9.1	11.6±10.0
ILD duration, years (mean±SD)	3.0±2.8	2.5±2.1
RTX regimen		
RA protocol	22	14
Vasculitis protocol	2	1
Concurrent corticosteroid-sparing agent, n (%)		
Mycophenolate mofetil	8 (33.3)	3 (20.0)
Methotrexate	4 (16.7)	4 (26.7)
Leflunomide	1 (4.2)	1 (6.7)
Azathioprine	1 (4.2)	1 (6.7)
Intravenous immunoglobulin	1 (4.2)	0 (0.0)
Cyclophosphamide	1 (4.2)	0 (0.0)
Thoracic HRCT patterns, n (%)		
NSIP	11 (45.8)	7 (46.7)
NSIP+OP	5 (20.8)	1 (6.7)
NSIP+UIP	1 (4.1)	1 (6.7)
UIP	4 (16.7)	4 (26.7)
LIP	1 (4.1)	1 (6.7)
Unclassifiable diffuse lung disease	2 (8.3)	1 (6.7)

There was no change in mean FVC% pre- and post-initial RTX cycle (71.3±18.6 vs. 71.6±17.9, p=0.87). Post-RTX, in 9 subjects (38%) FVC% improved (4 by >10%), and in 15 subjects (63%) FVC% declined (3 by >10%). In the 15 subjects with RA, FVC% was unchanged (70.4±20.2 vs. 74.5±19.7, p=0.18). Post-RTX, in 9 RA subjects (60%) FVC% improved (4 by >10%), and in 6 subjects (40%) FVC% declined (1 by >10%). In those without RA (n=9), FVC% declined significantly (72.7±15.4 vs. 66.8±12.8, p=0.015; 3 by >10%).

Pre- and post-RTX change in FVC% were 4.2±17.4 in RA vs. −8.6±7.2 in non-RA (p=0.025). RA subjects were also more likely to have improved FVC% (p=0.0068).

Sixteen (67%) subjects were on a concomitant corticosteroid-sparing medication. Thirteen (54%) were on prednisone at RTX initiation (mean dosage 10.2±16.2 mg) and 9 (38%) remained on prednisone at 6 months post-RTX (mean dosage 5.6±11.0 mg) (p=0.27).

Five infectious episodes (2 upper respiratory tract infections, 2 lower respiratory tract infections and 1 disseminated Herpes Zoster infection) occurred in 5 different subjects within 6 months post-initial RTX cycle. An additional 11 infectious episodes (mostly upper or lower respiratory tract infections) occurred in 5 of 12 subjects that received more than 1 RTX cycle (mean observation period of 35.6±19.3 months and 66 RTX cycles).

Conclusion: Treatment of RA-ILD and other forms of CTD-ILD with RTX was associated with variable effects on pulmonary physiology and our series suggests a possible beneficial role for RTX in RA-ILD. RTX treatment was associated with modest corticosteroid sparing effects and a sizeable number of post-infusion infections. RTX warrants prospective study to better assess its role in managing RA-ILD and other CTD-ILD.

Non-Use of Glucocorticoid and Osteoarthritis Absence As Predictors of Clinical Remission in AR. Salvador Loredo-Alanís[1], David Vega-Morales[2], Mario Garza-Elizondo[1], Mario Garcia-Pompermayer[3], Roberto Negrete-López[1], Daniel Treviño-Montes[1] and Diana Flores-Alvarado[2]. [1]Servicio de Reumatología, Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico, [2]Hospital Universitario UANL, Monterrey, Mexico, [3]Servicio de Reumatología, Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterey, Mexico.

Background/Purpose: The clinical evaluation of Rheumatoid arthritis (RA) is accomplished with compound indexes allowing better clinical decision. Clinical remission nowadays is an attainable target in the management of RA patients. Clinical remission associated factors are under investigation.

Objetive: Determine which factors are associated with clinical remission by CDAI in a RA population (ACR/EULAR 2010).

Methods: From a rheumatologic diseases cohort in a University Hospital we made an observational, descriptive, retrospective and cross-sectional study of 361 patientes with RA. We analized variables such as demographics, rheumatoid factor, Anti-Cyclic Citrullinated Peptide antibodies, erythrocyte sedimentation rate, C-reactive protein, treatment, clinical activity, visual analog scale, comorbidities, extra-articular manifestations and temporality of RA. CDAI was calculated. Remission was defined with a CDAI score of 2.8.

Results: 361 patients were evaluated. Female sex was predominant (97.7%). Mean age was 51.4. Clinical remission was found in 40.2%. When patients with and without clinical remission were compared, we found significant differences in: non use of prednisone (p 0.0001), use of Non-steroidal anti-inflammatory drugs (NSAIDs) (p 0.012), use of tramadol (p 0.0001), absence of osteoarthritis (p 0.33) and BMI <25Kg/m2 (p 0.017). In multivariate analysis factors associated with reach clinical remission were: Non use of oral steroids (p 0.0001, OR 3.39 IC 2.05–5.63) and absence of osteoarthritis (p 0.025, OR 1.8, IC 1.007–3.048). It was found a negative association to reach clinical remission with use of NSAIDs (p 0.008, OR 0.292, IC 0.117–0.73) and use of tramadol (p 0.003, OR 0.107, IC 0.024–0.47).

Conclusion: According to our study the presence of OA in patients with RA is a factor that decreases the CDAI specificity for detecting clinical remission. This possibly related to the score given by the patient to the visual analog scale and the presence of painful joints secondary to OA, but not inflamed by RA activity. It is therefore important that clinicians consider these factors when evaluating clinical remission in RA.

Preclinical Interstitial Lung Disease in Early Rheumatoid Arthritis. Javier Narváez[1], Alejandro Robles Perez[2], Maria Molina Molina[2] and Joan Miquel Nolla[2]. [1]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [2]Hospital Universitario de Bellvitge, Barcelona, Spain.

Background/Purpose: Early detection and treatment of interstitial lung disease (ILD) in patients with rheumatoid arthritis (RA) may ameliorate disease progression. The objective of the present study was to: *1)* study the frequency of asymptomatic preclinical ILD in early RA patients, in order to determine how early the lungs are affected in the disease and establish whether it is clinically advantageous to systematically screen asymptomatic patients for this complication; and *2)* study the potential association of anti-citrullinated peptide antibody (ACPA) positivity with RA-ILD.

Methods: Observational prospective study of a cohort of early RA patients (joint symptoms < 2 years) who did not present respiratory symptoms and were included in an ILD screening program via baseline chest radiograph and complete pulmonary function tests (PFT). In patients with lung abnormalities in the chest radiograph or any restriction or impaired diffusion, defined as < 80% of predicted forced vital capacity (FVC) and diffusing lung capacity for carbon monoxide (DLCO) respectively, the study was completed with a high-resolution computerized tomography scan (HRCT) of the chest.

Results: Forty patients (30 women) were included in the study, with PFR alterations detected in 18 (45%). All cases had a DLCO < 80% of predicted (mean 68%; range 43% to 78%), without significant reduction in the FVC values. The HRCT detected abnormalities in only 7 of these 18 patients: 1 radiographic pattern suggestive of non-specific interstitial pneumonia (NSIP); 1 radiographic pattern of respiratory bronchiolitis-associated interstitial lung disease (RB-ILD); the other 5 had bronchiectasis in the absence of fibrosis, emphysema or pulmonary nodules**.** In 11 patients with DLCO alterations, the HRCT was normal, and in none of these cases could the alteration be attributed to the presence of anemia.

A significant inverse correlation between ACPA levels and baseline DLCO was found. We also observed, a significant association between the severity of disease activity as measured by DAS28-CRP and baseline DLCO values.

Conclusion: Asymptomatic preclinical ILD, which is detectable by restrictive abnormalities in PFT (mainly, DLCO < 80% of predicted), is common (45%) among patients with early RA. PFT screening may be indicated for such patients since early detection of these alterations could change the course of the lung disease if risk factors (such as smoking or environmental exposures) are avoided, infections are prevented and drugs for RA treatment are selected that are less harmful to the lung. Our data also support a relationship between high ACPA levels and the occurrence of RA-ILD.

Demographic Differences in Health Related Information Technology Use Among Patients with Rheumatic Diseases. David Mackey[1], Aseem Bharat[1], Lang Chen[1], Ben Nowell[2], Liana Fraenkel[3], Peter J. Embi[4], Kenneth G. Saag[5], James Willig[1], Seth Ginsberg[2], Ruth McConnell[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Creaky Joints/Global Healthy Living Foundation, Upper Nyack, NY, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [4]The Ohio State University, Columbus, OH, [5]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Use of the Internet and mobile technologies can be a valuable resource for patients with rheumatic diseases who are seeking health-related information, allowing patients to track health longitudinally, and/or engage with similar patients or their clinicians. However, such technologies may have a limited penetrance among certain demographic groups defined by older age, non-Caucasian race, and lower education and income. We evaluated use and ownership of information technologies among patients in a rheumatology clinic to assess their use of these technologies, and assess any differences based on patients' characteristics.

Methods: Starting in 2014 (with ongoing recruitment), we approached adult patients from two rheumatology outpatient clinics at a large academic medical center to participate in a descriptive survey, administered either on paper or electronically (iPad tablet) according to patient preference. The survey included questions derived from the Pew Internet Survey regarding 1) ownership of a smartphone; 2) use of the Internet for health-related information in the last 12 months; and 3) willingness to electronically exchange medical information with their healthcare provider. Additional data included information about demographics and socioeconomic status. These three outcomes were examined according to various demographic and socioeconomic status (SES) categories.

Results: Among 195 patients approached to take the survey, 171 (87%) completed the survey, 24 (12%) refused, and 2 (1%) failed to complete it. Among complete responders, 82% were women, 75% were white, with median age 56 years, and 77% had at least some college education. The gender and race distribution was similar between respondents and those who refused.

Age older than 65, lower education, and lower income were associated with less smartphone ownership, less use of the Internet for health-related reasons, and a lower willingness to share electronic health information with their healthcare provider (Table). In contrast, sex and race were not strongly associated with these outcomes. However, even for patient groups with less access to or use of technologies for health reasons, more than 50% of patients reported ownership or willingness to use IT.

Conclusion: Based upon this sample of rheumatology patients, older age, lower education and lower household income were associated with less use of the Internet and information technology for health reasons. However, at least half of patients in these demographic and SES categories had access to these technologies. Given these results, it is reasonable to expect that technolgical solutions that address the health information needs of patients with rheumatic diseases can reach a broad patient population.

Table: Factors associated with Healthcare-related Internet use and Technology

	Total responders N=171	Owns a Smartphone	Accessed the Internet for a health-related search	Willing to exchange medical information electronically
Age				
< 40	33	91%~	79%*	79%*
40–55	49	92%~	82%*	82%*
55–65	43	71%~	86%*	57%*

Cardiovascular Risk Estimation in Rheumatoid Arthritis: What Is Missing in Traditional Risk Estimators? Gulsen Ozen, Murat Sunbul, Pamir Atagunduz, Haner Direskeneli, Kursat Tigen and Nevsun Inranc. Marmara University School of Medicine, Istanbul, Turkey.

Background/Purpose: Cardiovascular (CV) disease is one of the major causes of mortality in rheumatoid arthritis (RA). Although the CV risk in RA is well-recognized, detection of high risk patients and prevention of CV disease are still major challenges. We aimed to determine which CV risk estimation index is better in RA patients and to determine the factors that may improve CV risk estimation in RA.

Methods: Two-hundred and ten consecutive RA patients without history of CV disease or diabetes mellitus were assessed. Systematic Coronary Risk Evaluation (SCORE), 2013 American College of Cardiology/American Heart Association (ACC/AHA) 10-year atherosclerotic CV disease risk (ASCVD), QRisk II indices and their modified versions (mSCORE, mASCVD, mQRisk II) according to EULAR recommendations were calculated. All patients were evaluated with carotid ultrasonography (US). Carotid intima-media thickness (cIMT) > 0.90 mm and/or carotid plaques were used as the gold standard test for subclinical atherosclerosis and high CV risk (US+). Retrospectively, along with disease characteristics, DAS28 scores, ESR and CRP values of each visit during the entire follow-up of RA patients were recorded and average DAS28, ESR and CRP were calculated.

Results: The study cohort consisted of 210 RA patients (F/M= 169/41, mean age 52.5±11.4) with a mean disease duration of 11.1±7.0 years. The EULAR multiplier factor was used in 95 (45.2%) patients. The mean mSCORE was 1.6±2.5%, mASCVD risk was 5.8±7.1%.and mQRisk II was 9.8±9.6%. Eleven (5.2%), 61 (29%) and 80 (38.1%) patients were defined as having high CV risk (mSCORE≥5%, mASCVD≥7.5%, mQRiskII≥10%) according to mSCORE, mASCVD and mQRisk II, respectively. Concerning US results, 50 (23.8%) patients had either cIMT> 0.90 mm or carotid plaques. The mASCVD and mQRisk II indices better identified US+ patients, that 29 (58%) and 30 (60%) of the US+ patients were in high risk group according to mASCVD and mQRisk II, respectively. Whereas only 8 (16%) of the US+ patients were in high risk group according to mSCORE ($P<0.0001$). However mASCVD and mQRisk II still failed to identify 42% and 40% of US+ patients. When traditional risk factors and disease characteristics of US+ and US- patients were compared, it was found that US+ patients were older at diagnosis, had higher average DAS28 scores, average ESR and CRP levels. Impaired fasting glucose was also higher in US+ patients along with similar rates of biologic treatment, steroids and NSAIDs (Table 1).

Conclusion: EULAR recommendation for CV risk assessment, SCORE, seems inadequate even after modification according to RA characteristics. On the other hand QRisk II and ACC/AHA 10-year ASCVD risk indices are better in estimating CV risk in RA patients. However, still additional modifications, like age at disease onset, cumulative disease activity and inflammatory biomarkers are required to fully identify high-risk RA patients.

Table 1. Characteristics of US(+) and US(–) RA patients

	US(+) (n=50)	US(–) (n=160)	*P* Value

Bone Erosions in Patients with RA: Exploring the Impact of the Anatomy of Interest on the Relationship Between MRI and X-Ray Erosion Detection. Michael Tomizza[1], Isabel Rodrigues[1], Matthew Jessome[1], Joshua Barbosa[1], Karen Beattie[2], William G. Bensen[2], Raja Bobba[2], Alfred Cividino[2], Patrick D. Emond[2], Karen Finlay[3], Chris Gordon[2], Lawrence Hart[2], George Ioannidis[2], Erik Jurriaans[3], Melissa Koh[1], Maggie Larche[2], Arthur Lau[2], Naveen Parasu[3], Ruben Tavares[2], Stephen Tytus[2], Hao Wu[1] and Jonathan D. Adachi[1]. [1]McMaster University, Hamilton, ON, [2]St Joseph's Healthcare Hamilton, Hamilton, ON, [3]Hamilton Health Sciences, Hamilton, ON.

Background/Purpose: Detection of bone erosions in patients with RA is critical in clinical practice, with treatment initiation and effectiveness largely based on limiting erosive progression. While studies have compared the use of MRI and x-ray for the assessment of erosive damage, the potential influence of the anatomy of interest is not always considered. Given that the joints assessed by researchers and clinicians vary and may contribute to differences in the ability of MRI and x-ray to identify erosions, this study focused on describing the relationship between these two modalities while taking into account the anatomy of interest.

Methods: This was a cross-sectional study. For each participant, MRI scans of both hands (bilateral MCP 2–5 joints) and x-ray scans of the hands, wrists, and feet were acquired. A 1.0T MRI scanner with a 100-mm cylindrical coil was used and multiple sequences were obtained, including T1-weighted images for erosion detection. On x-ray, the conventional erosion definition was applied and three imaging projections were used: posteroanterior, oblique, and lateral. Four radiologists used the RA-MRI scoring system (RAMRIS) and the van der Heijde-modified Sharp scoring system (vdHSS) to semi-quantitatively evaluate the MRI and x-ray images, respectively. For statistical analysis, interval data (RAMRIS) and ordinal data (vdHSS) were classified by erosion presence (yes/no).

Results: A total of 488 joints from 122 hands of 65 RA patients were included in this analysis [median (interquartile range) age: 59.0 (49.0–66.0) years, sex: 83.1% female, ethnicity: 61% Caucasian, symptom duration: 4.3 (2.6–7.0) years, Rheumatoid Factor positivity: 70.8%, Disease Activity Score (DAS28): 4.5 (3.3–5.7), Clinical Disease Activity Index (CDAI): 62.3 (32.7–91.6)]. 331 individual MCP 2–5 joints were assessed as having erosions on MRI (67.8%), while 134 erosions were detected in the same joints on x-ray (27.5%). MCP 2–5 joints of the hand were also grouped together for analysis. Overall, 2.1-fold the MCP 2–5 joint sets with erosions on x-ray had erosions on MRI.

Per common joint imaged, 2.6- to 8.0-fold the erosions detected on x-ray were detected on MRI. At the patient level of analysis, bilateral MRI of the MCP 2–5 joints resulted in the detection of erosive disease in 1.1-fold the number detected on x-rays of the hands, wrists, and feet. Limiting MRI to the dominant MCP 2–5 joints, the proportion of patients with erosive disease was 66% of the frequency detected on x-rays of the hands, wrists, and feet; the same frequency detected on x-rays of the feet alone; and 1.3-fold the frequency detected on x-rays of the hands and wrists.

Conclusion: Practically, the results suggest that the relative performance of the two imaging modalities is highly dependent on the anatomy imaged. Technologically, the findings demonstrate the enhanced capacity of MRI to detect erosions per joint imaged. The ability of a single MRI scan of the dominant hand to identify more patients with erosive disease than x-rays of both hands and wrists emphasizes the clinical value of MRI as a tool for detecting and monitoring erosive damage in patients with RA.

Screening Behavior and Prevalence of Hepatitis C Virus in Mexico. Cassandra Skinner-Taylor[1], Alejandro Erhard-Ramírez[1], David Vega-Morales[2], Jorge Esquivel-Valerio[1], Diana Flores-Alvarado[2], Daniel Treviño-Montes[1] and Ernesto Torres-López[3]. [1]Servicio de Reumatología, Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico, [2]Hospital Universitario UANL, Monterrey, Mexico, [3]Servicio de Inmunología del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico.

Background/Purpose: In some countries, the prevalence of Hepatitis C virus infection is high and sometimes the appropriate tests to detect it are not performed in a routine evaluation in patients with Rheumatoid arthritis (RA). Our aim was to study the hepatitis C virus infection prevalence in RA patients and to determine the clinical characteristics of the patients who were screened and to evaluate the behavior of the current screening.

Methods: Retrospective, Observational, non-comparative study. We reviewed all charts of RA patients seen between 2013 and 2014 in three settings. University Hospital (HU), Private Practice (PP), and Instituto Mexicano del Seguro Social (IMSS), all from Monterrey, Nuevo León, Mexico. We select cases that met the ACR 1987 and EULAR/ ACR 2010 criteria for RA. We look for laboratory tests including rheumatoid factor, anti CCP, the screening test for hepatitis C virus and liver function tests.

Results: Eight hundred and sixty-four patients were analyzed, 312 (36.1%) of HU, 380 (44%) of IMSS and 172 (19.9%) of PP. Females 92% (n = 792). Mean age 51.6 years (age range 17–89). Anti-TNF therapy were used in 172 patients (19.9%), and the rest used DMARDs (methotrexate, sulfasalazine, hydroxychloroquine, leflunomide and chloroquine). Rheumatoid factor was positive in 63.7%. Anti CCP was positive in 69.8%. Only 197 patients(22.8%) were screened for hepatitis C. One hundred eighty-eight (95%) from PP. The main reason because they were being treated with anti-TNF agents (golimumab, adalimumab, certolizumab pegol and infliximab). In public practice, corresponding to HU, five patients were screened and at IMSS only four. There was only one positive patient (1/197) corresponding to 0.5% for the screened patients.

Conclusion: In countries where hepatitis C virus is not endemic, as in Mexico, routine screening for HCV does not seem a regular practice for the rheumatologists, the main reason for screening in private practice was that the population was mostly being treated with anti-TNF agents, in contrast to public practice where the mainstay of treatment were DMARDs.

1426

Periodontal disease and Clinical Activity of Rheumatoid Arthritis Patients. Daniel Xibille-Friedmann[1], Jose Ivan Martinez Rivera[2], Jaqueline Rodriguez Amado[3], Carolina Bustos Rivera Bahena[4], Marisol Sandoval Rios[5] and Jose Luis Montiel Hernandez[6]. [1]Hospital General de Cuernavaca, Cuernavaca, Mexico, [2]Instituto Nacional de Salud Publica, Cuernavaca, Mexico, [3]Centro de Investigación y Desarrollo en Ciencias de la Salud, Monterrey, Mexico, [4]Science Faculty, Cuernavaca, Mexico, [5]Faculty of Pharmacy, Cuernavaca, Mexico, [6]Cytokines and Autoimmunity Laboratory, Faculty of Pharmacy, Universidad Autónoma del Estado de Morelos, Cuernavaca, México, Cuernavaca, Mexico.

Background/Purpose: Although several studies have suggested the association between periodontitis, infection by *Porphyromona gingivalis*and Rheumatoid Arthritis disease activity, its relationship with periodontal disease, oral and plasma peptidyl-arginine deiminase (PAD) activity and citrullination of soluble blood proteins still remains poorly known.

Objective: To evaluate the relationship between periodontal disease, and clinical disease activity of Rheumatoid Arthritis (RA) patients.

Methods: RA patients included fulfilled the ACR/EULAR 2010 criteria, signed an informed consent form and were followed at the rheumatology clinic for one year. Patients were divided into 2 groups according to clinical activity. Patients with secondary Sjögrens disease were excluded. Patients having a DAS28 of less than 3.4 were considered as having low activity and above that number they were grouped as having high activity. Periodontal evaluation and oral and peripheral blood samples were obtained the same day as the clinical evaluation. PAD-activity was performed using a colorimetric assay employing BAEE (Sigma) as substrate and recombinant human PAD4 (Cayman Chem) as positive control. Citrullination was evaluated by Western Blot of immunoprecipitated saliva and blood fibrinogen, employing a polyclonal anti-citrulline antibody (Millipore). Plasma pro-inflammatory cytokines and aCCP levels were evaluated by ELISA. Descriptive statistics were employed to evaluate differences between groups and the Spearman correlation test was used to associate them with clinical parameters.

Results: 48 RA patients were divided into 2 groups: 33 presented high activity and 15 low activity; their mean age was 41.2 vs. 43 years of age, respectively, BMI was 26.8 vs. 27.2, and time since onset of disease 8.5 ± 10.9 vs. 5.44 ± 3.8 years, respectively; both groups' demographic characteristics showed no statistically significant differences. High disease activity patients had a significantly lower index of periodontitis (1.57 ± 1.06; $p < 0.02$), while low disease activity patients were associated with severe periodontitis (3.0 ± 1.23). Otherwise, high disease activity patients showed a mean decrease of 1.5 DAS28 units after one year of follow-up and treatment, while low disease activity RA patients showed a lower therapeutic response (a change of <0.5 DAS28 units). No relationship was seen with PAD activity.

Conclusion: High RA disease activity is negatively associated with severe periodontitis, although the same patients showed a higher therapeutic response after one year of follow up, in comparison to low disease activity RA patients.

1427

Low Prevalence of Sarcopenic Obesity in Rheumatoid Arthritis Patients with Moderate Clinical Activity. Nina Tello-Winniczuk[1], David Vega-Morales[2], Mario Garza-Elizondo[1], Dionicio Galarza-Delgado[1], Jorge Esquivel-Valerio[1], Octavio Ilizaliturri-Guerra[3] and Jorge Rodriguez-Olivo[1]. [1]Servicio de Reumatología, Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico, [2]Hospital Universitario UANL, Monterrey, Mexico, [3]Departamento de Medicina Interna del Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Mexico.

Background/Purpose: Rheumatoid arthritis is an inflammatory systemic disease that leads to body composition alterations. Objective: The aim of our study was to identify the prevalence of sarcopenia, obesity and sarcopenic obesity in our population.

Methods: We performed an observational, analytical study with 101 rheumatoid arthritis patients. Demographic, clinical and biochemical variables were recorded. Studies of body composition by dual X-ray absorciometry were performed. We took into account different definitions to determine body composition alterations (Table 1).

Results: Ninety-seven (96%) patients were female, the rest of baseline characteristics are shown in Table 2. The mean age of our patients was 50.5 years (SD 12.3). The mean body mass index was 29.29 kg/m^2 (5.4 SD). According to the World Health Organization classification of body mass index (BMI), 24 (23.8 %) patients had normal weight, 38 (37.6%) were overweight and 39 (38.6 %) some degree of obesity. According to the BMI adjusted for rheumatoid arthritis, 13 patients (12.9 %) were normal, 34 (33.7 %) overweight and 54 (53.5 %) obese. Ten patients had sarcopenia (9.9 %). Six patients (5.9 %) had sarcopenic obesity. Patients with obesity by dual X-ray absorciometry were 83 (82.2 %). Among clinical and paraclinical variables, the only significant association with sarcopenia was a higher score in the Health Assessment Questionnaire.

Conclusion: The most prevalent body composition alteration in RA patients, were obesity. Sarcopenic obesity had a low prevalence, contrary to previous reports.

TABLE 1. Patient Baseline Characteristics

Variable	
Age, mean, SD	50.4 ± 12.3
Gender Female/Male n, (%)	97 (96)/ 4 (4)

1428

Comparison of Application of the European Society Cardiology, Adult Treatment Panel III, and ACC/AHA Guidelines for Cardiovascular Disease Prevention in a French Cohort of Rheumatoid Arthritis. Martin Soubrier[1], Zuzana Tatar[2], Maxime Chevreau[3], Bruno Pereira[4], Laure Gossec[5], P Gaudin[6] and Maxime Dougados[7]. [1]COMEDRA trial group, Paris, France, [2]Centre Jean Perrin, Clermont Ferrand, France, [3]CHU Sud Hospital, Grenoble, France, [4]Clinical research department, Clermont-Ferrand, France, [5]Sorbonne Universités, UPMC Univ Paris 06, GRC-08, Institut Pierre Louis d'Epidémiologie et de Santé Publique, paris, France, [6]CHU Hôpital Sud, Grenoble, France, [7]RAID working group for EULAR, Zurich, Switzerland.

Background/Purpose: Cardiovascular risk (CVR) is increased in RA and should be evaluated annually. EULAR recommends using the SCORE equation to calculate risk, after applying a multiplier of 1.5 in patients with RA who meet two of the following three criteria: disease duration > 10 years, rheumatoid factor or anti-CCP antibody positivity, presence of extra-articular manifestations. European guidelines (ESC) recommend statin therapy for subjects with high or very high risk i.e when CVR calculated with the SCORE equation is ≥ 10% and LDL-cholesterol is ≥ 1.8 mmol/l, or when CVR is > 5% and < 10% and LDL-cholesterol is ≥ 2.5 mmol/l (1,2). Until now the Adult Treatment Panel -III (ATP-III) guidelines recommended the use of statin therapy for primary prevention on the basis of a combined assessment of LDL cholesterol and the 10-year risk of coronary heart disease as calculated with the use of the Framingham risk calculator. American recommendations (ACC/AHA) have recently changed and a new equation to assess overall CVR has been validated. Statin therapy is recommended for subjects aged 40–75 years when CVR is ≥ 7.5.

Assess the need for statin in an established RA cohort (COMEDRA study) according to ESC, ATP-III, and ACC/AHA guidelines with application of the multiplier proposed by EULAR, in patients aged 40 years or older without diabetes, overt cardiovascular disease (CVD) and statins.

Methods: COMEDRA is a multicentre French cohort study of comorbidities in patients with RA and a self-assessment of the disease. At inclusion, general characteristics (age, sex), duration of the disease and treatments for the RA, cardiovascular risk factors (hypertension, diabetes, smoking habit, total, HDL and LDL cholesterol, obesity), RA activity assessed using the DAS28VS, DAS28CRP, SDAI, CDAI, HAQ, ESR, CRP, RA antibodies were recorded for each patient.

Results: 970 patients were included. 612 patients (82.7% women) with established RA (mean disease duration 11.3 [6.5 – 19.8] years) were analyzed (Exclusion age (n = 49); Diabetes or overt CVD (n = 65), statins (n = 168), incomplete data (n = 76)). RA was erosive in 450 (74.3 %) and 484 (79.1%) had positive RF or anti-CCP antibodies. 431 patients (70.4%) were treated with a biologic and 217 (35.6%) received glucocorticoids (mean, 5.34 ± 5.59 mg/day). 90 (14.7%) patients had a family history of early onset CVD, 147 (24.0%) were treated for hypertension, 100 (16.3%) were smokers.

Treatment recommendations based on Different Guidelines

	ESC	*ATP-III*	*ACC/AHA*
Women (n = 506)			
Treatment recommended	*7 (1.4)*	*50 (9.9)*	*155 (30.6)*
Treatment considered	*241 (47.6)*	*57 (11.2)*	*292 (57.7)*
No treatment	*257 (50.8)*	*399 (78.9)*	*59 (11.7)*
Men (n = 106)			
Treatment recommended	*9 (8.5)*	*47 (44.3)*	*76 (71.7)*
Treatment considered	*80 (75.5)*	*21 (19.8)*	*29 (27.4)*
No treatment	*17 (16)*	*38 (35.8)*	*1 (0.9)*

Conclusion: In this RA patient's aged 40 years or older, proportion of individuals eligible for statins differed substantially among the guidelines.

Systemic Inflammation in Alzheimer's Disease: Relevance to Patients with Rheumatoid Arthritis. M. Elaine Husni[1], Colin O'Rourke[2], Travis Moore[2] and Jagan Pillai[2]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Alzheimer's disease (AD) dementia is the most common form of dementia affecting > 25 million people worldwide without known cure. Research regarding involvement of inflammatory component of Alzheimer's Disease (AD) has been well documented. A recent study via whole genome and exome DNA sequencing have provided evidence that coding mutations in the TREM2 gene are associated with a ~2.5–4 fold increased risk in developing AD. Notably TREM2 is only expressed within macrophages and dendritic cells in the periphery and within microglia within the brain and is involved in innate immunity, suggesting that alterations in neuroinflammation are directly linked to the development and progression of AD. Autoimmune diseases such as rheumatoid arthritis (RA) known to be a chronic systemic inflammatory disorder may thereby be important to see if the prevalence of these diseases makes a subsequent neurodegenerative diagnosis like AD more likely.

Our objective was to investigate whether the risk of Alzheimer's disease is increased in patient with rheumatoid arthritis in a large population cohort.

Methods: Our study consists of a large retrospective hospital based cohort from a network of north east Ohio health providers through Explorys database. Population was defined by a) subjects using medications used in RA and AD, b) ICD9 codes (714.0, 294.1, 331.0, 331.11, 331.19, 331.82, 331.83, 290.0, 290.43, 294.20 and 294.21) was used to understand the specific subtypes of dementia. Descriptive analysis was performed on individual cohorts. Statistical Analysis: Relative risk of use of AD medications among subjects using RA medications will be compared with a control cohort without these medications use, to determine the risk of AD medication use in each cohort.

Results: Overall number of subjects from our database was 2,592,280 (77% females). Number of subjects with RA medication + AD medications was 430. Subjects with either RA and/or FDA approved AD medications were 52,330. Subjects with RA but no AD medications was 37,650. In this cohort, 60% of treated RA subjects had an RA diagnosis based on ICD9 codes, but only 2.2 % subjects using AD medications had an AD or AD dementia diagnosis and 1.25% had a diagnosis of mild cogntive impairment based on ICD9 codes.

Relative risk of AD medication use among subjects using RA medications was 2.02 [1.83–2.22], P<0.001. This effect was noted to be most prominent in subjects less than 65 years old.

Conclusion: Our study supports that patients with RA could be associated with an increased risk of Alzheimer's Dementia and raises the possibility of shared risk factors that may not have been appreciated previously. Further study into this association would help develop guidelines to screen for cognitive impairment and elucidate novel therapeutic options in AD.

IMPACT of Initiative to Control Cardiovascular Risk Factors in Collaboration with LOCAL Doctors in Patients with Rheumatoid Arthritis. Andrea Zacarias Crovato[1], Javier Narváez[2], Joan Miquel Nolla[3], Jesús Rodríguez-Moreno[1], Montserrat Jordana[1] and Carmen Gomez Vaquero[3]. [1]Hospital Universitari de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [3]Hospital Universitario de Bellvitge, Barcelona, Spain.

Background/Purpose: Rheumatoid arthritis (RA) is associated with cardiovascular risk (CVR) with an increased prevalence of cardiovascular events and cardiovascular mortality than the general population. Good control of both, the disease activity and cardiovascular risk factors (CVRF), reduces morbidity and mortality associated with this increase in CVR. While control of disease activity is assumed by the rheumatologist, CVRF control could correspond to both the rheumatologist and the family doctor.

Objectives:To evaluate the impact of an initiative to control CVRF in collaboration with family doctors in patients with rheumatoid arthritis.

Methods: RA patients selected consecutively when they came to visit monitoring. For each patient, we collected CVRF (body mass index, smoking, blood pressure, serum glucose, total cholesterol, LDL cholesterol and triglycerides) and calculated the SCORE and the SCORE modified. The patient was informed of the need to correct their CVRF and handed a letter to your family doctor reported in which the importance of control of cardiovascular risk factors in patients with RA and were asked for their cooperation in controlling thereof. In addition, you specify the therapeutic objective to achieve respect to LDL cholesterol: 1.7 nmol / L (70 mg / dL) in patients with high CVR (SCOREm ≥ 5%) or suffered a cardiovascular event and 2.5 nmol / L (100mg/dL) in the rest. In the next view of control, there was whether there had been any intervention, and if he had achieved the therapeutic goal.

Results: We included 211 patients (171 (81%) women) with a mean age of 60 ± 12 years and a duration of RA of 13 ± 9 years. FR was 72% and 70% + PCC +. 70% of patients were treated with glucocorticoids, 86% and 32% FAME with biological treatment. For DAS28 criteria, 71% had low activity, 27%, moderate and 2%, high activity. On a visit home, 25% of patients were overweight, 17% smoked, 51% were hypertensive, 6% were hyperglycemic, 53% had a serum total cholesterol> 5.2 mmol / L (200 mg / dL), and 23% were hipertrigliceridémico. The 5% had no cardiovascular risk factors, 20% had one, 34% two, 28% three, and 13%, more than three. The goal LDL was 1.7 in 29% of patients. There were new diagnoses of CVRF in 100 patients (47%): 1 diabetes, 18 hypertension, 82 with elevated LDL cholesterol and 27 hypertriglyceridemia. The family physician changed the treatment in 2/12 diabetes, 30/84 HTA, 74/167 with elevated LDL cholesterol and 21/51 hypertriglyceridemia in which the change was indicated. The end result of the intervention was that between the two visits, the percentage of patients with CRF who had good control over it happened: a) in diabetes, from 48% to 44%, b) in hypertension, 25% to 73% c) elevation of LDL cholesterol from 10 to 17%, and d) in hypertriglyceridemia, 25% to 38%.

Conclusion: Through the intervention has been diagnosed at least a new CVRF not known in a high percentage of patients. The response of family physicians as measured by the change in drug regimen is considered insufficient. As a result, control of cardiovascular risk factors, and mainly of dyslipidemia is suboptimal.

Influence of Radiographic Joint Damage in Mortality Risk in a Cohort of Rheumatoid Arthritis Patients: A 20 Years Survival Study. L. Rodriguez-Rodriguez[1], J. Ivorra-Cortes[2], Lydia Abasolo[1], Leticia Leon[1], Oscar Fontsere[3], B. Fernández-Gutiérrez[1] and Juan A Jover[1]. [1]Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, Spain, [2]University Hospital la Fe, Valencia, Spain, [3]Hospital Clínico San Carlos, Madrid, Spain.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with increased mortality and reduced life expectancy compared with the general population. This mortality gap has increased in the last years since mortality rates for RA have remained constant throughout time while mortality rates for the general population have decline. Excess mortality has been associated with disease activity. Radiographic joint destruction reflects the cumulative burden of inflammation and it is conceived as an objective measure of RA severity. The aim of our study was to analyze the influence of radiological joint damage in the mortality rate in a cohort of RA patients.

Methods: We included 783 RA patients in a retrospective longitudinal study, from May 1993 to November 2013, attending the rheumatology outpatient clinic of the Hospital Clínico San Carlos (Madrid, Spain). Subjects were included at the moment of their first X-ray, until October 2012, and followed until patients' death, loss of follow up or November 2013. Clinical records were examined and demographic and clinical data was collected. Radiographic joint damage of hands and wrists was assessed with the Sharp vand-der-Heijde score [total (SHS), erosion (ES) and narrowing/(sub)luxation

(NSLS) components]. Survival techniques were applied to estimate the mortality rate (MR; expressed per 1000 patients-years with a 95% of Confidence Interval [95% CI]). Cox bivariate and multivariate regression models were conducted to examine risk factors for death. Interaction terms between radiological damage and rheumatoid factor (RF) positivity, and the elapsed time from RA onset to X-ray, were introduce in the models. Proportional hazard assumption was tested using Schoenfeld residuals and the scaled Schoenfeld residuals. Results: were expressed as hazard ratio (HR) and 95% CI.

Results: Most of the patients included were women (74%), with a median age of 61 years old (interquartile range [IQR]: 47–71), 67% were RF positive, and the median (IQR) elapsed time between RA symptoms onset and the X-ray was 2 (0–7) years. The median (range) followed up time per patient was 5 [0.4–20] years. 92 patients died during a follow up time of 4758 person-years. Mortality rate (MR) was 19 per 1000 patient-year [95% CI 16–24]. We observed in the bivariate analysis that older age, male sex, higher elapsed time from RA onset to X-ray, SHS, ES, NSLS, number of hospital admissions (used as a surrogate measure of comorbidity), basal Health Assessment Questionnaire, RF positivity, earlier RA onset (in calendar time), and no treatment with biological therapy, were associated with a higher MR. 3 multivariate models were constructed, using SHS, ES or NSLS as measures for joint destruction, and adjusted by the previous variables. In none of the models radiographic damage was associated with MR. However, we observed that the interaction between ES and RF positivity was significant ($p=0.001$): ES was associated with MR only in RF negative patients.

Conclusion: Erosive joint damage seems to be a risk factor for all cause mortality only among RF negative RA patients.

Mortality Ratio of Rheumatoid Arthritis Under Biological Treatment. Umut Kalyoncu[1], Abdulsamet Erden[2], Hakan Babaoglu[2], Murat Torgutalp[2], Sadettin Kilickap[2], Omer Karadag[3], Sule Apras Bilgen[3], Ihsan Ertenli[1], Ali Akdogan[3] and Sedat Kiraz[3]. [1]Hacettepe University School of Medicine, Ankara, Turkey, [2]Hacettepe University, Faculty of Medicine, Ankara, Turkey, [3]Hacettepe University Faculty of Medicine, Ankara, Turkey.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease, which, in many patients, leads to a substantial disability and has a major effect on the quality of life. Patients with RA also have an increased mortality compared with the general population. Main causes of mortality in RA are cardivascular events and serious infections. The objective of this study was to evaluate mortaility ratio in patients with RA during biological treatment.

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological registry since 2005 that include 815 RA patients under biological treatments. Data collected includes demographic data, co-morbidities, smoking, switch ratio, baseline and follow-up disease activity parameters (such as DAS28, CRP, ESR, global VAS, swollen joint count ad tender joint count). For all individuals in the study population, follow up time began at the first known use of etanercept, infliximab, or adalimumab. The outcome of interest was death from any cause, which was identified through linkage of the study population to the Turkish Cause of Death Register through May 31, 2014. Overall and anti-TNF biologic stratified incidence rates per 1000 person-years were calculated.

Results: HUR-BIO includes 815 RA patients (77,9% female). Mean age was 51 ± 13 years and mean disease duration was 11 ± 8 years. TNFi drug duration was $2,7\pm2,6$ years and 176 (21,5%) patients were used TNFÝ drugs more than 5 years. Positive ACPA and RF were 297/465 (63,9%) and 454/740 (61,3%), respectively. First biological drugs were etanercept 321 (39,4%), adalimumab 223 (27,4%) and infliximab 115 (14,1%), rituksimab 92 (11,3%), abatecept 43 (5,3%), golimumab 20 (2,5) and tocilizumab 1 (0,1%). TNFi switch was found in 262 (32,1%) patients. Among the 815 patients in our entire study population and during a total of 2,235 person-years of follow-up (mean 2,7 years; median 1,8 years), 21 patients died. The all-cause mortality rate was 9,4 per 1000 person-years. Five of 21 patients died in our hospital (3 patients were lung infection, 1 tuberculosis and 1 acute coronary syndrome). Mortality ratio was sligthly, not significantly, higher in male patients (%38,1 vs %21,4 $p=0.071$). There were certain difference in age ($60,1\pm10,9$ vs $51,1\pm13,1$, $p=0.004$), biological drug duration ($2,7\pm2,7$ vs $0,6\pm0,9$ years, $p<0.001$), baseline erytrocyte sedimentation rate (53 ± 18 vs 40 ± 25 mm/hour, $p=0.018$), positive RF (%89,5 vs %60,6, $p=0.039$) and level of RF (median 103 (0–2500) vs 44 (0–2710), $p=0.032$).

Conclusion: Crude mortality ratio in our biological database was comparable with literature, that between 5.3 to 16.8 (1–2). Crude mortality ratio of our patients is slightly higher than general population [9,3/1000 person-year vs 4,9/1000 person-year (3)]. Biological treatments seem like relatively safe drug in our database, however, we need biological naive RA cohort for certain conclusion.

Clinical Characterization of Subclinical Rheumatoid Arthritis-Associated Interstitial Lung Disease. Masaomi Yamasraki. Shin-Yokohama Yamasaki Clinic, Yokohama, Japan.

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is a common manifestation of rheumatoid lung disease. Subclinical RA-ILD is most commonly identified on HRCT imaging. In this study, we aimed to define the clinical characteristics of subclinical RA-ILD on HRCT, and to analyze long-term prognosis of subclinical RA-ILD.

Methods: 340 patients with RA were treated at our hospital and followed them up for three years or until development of symptomatic ILD. All patients were performed chest radiological examinations at the initial presentation. The HRCT findings which include (1) ground glass opacity.(2) air-space consolidation, linear opacity including (3) septal line and (4) non-septal line, (5) honeycomb lung, (6) traction bronchiectasis, (7)pleural irregularity, and (8)pleural effusion were scored as the CT scoring system. The extent of involvement of each abnormality was assessed independently for each of the three zones of each lung. The HRCT extent score was represented the sum of the score of each lung. HRCT parameters which included the extension score, ACPA and the clinical features at the initial presentation were retrospectively analyzed.

Results: 76 (22.3%) out of 340 RA patients had abnormal chest radiological findings which consist with ILD. 5 out of 76 patients had shortness of breath and showed a rapidly progressive ILD (6.6%). The rest of 71 (48women, 23men) had subclinical RA-ILD who were either asymptomatic or have symptoms and physiologic abnormalities that are as yet unrecognized as being due to RA-ILD. There was no difference in the positive rates of anti-CCP2 between subclinical RA-ILD and clinical evident RA-ILD. However there were no difference in the HRCT findings which included nonseptal linear attenuation, ground-glass attenuation and air space consolidation between subclinical RA-ILD group and clinical RA-ILD group, subclinical RA-ILD group showed less degree in honeycombing ($p=0.0003$) and focal ILD ($p=0.0061$). There have only two cases lead to clinically evident RA-ILD within 6 months. These two cases were treated with azathioprine and with MMF showed stable ILD on HRCT.

Conclusion: HRCT finding focused on honeycombing and the extension score at the initial presentation is a sensitive technique for detection of subclinical RA-ILD. This study suggest the progression of asymptomatic radiologic changes could lead to the development of clinical RA-ILD.

The Longitudinal Association Between Inflammation and Blood Pressure in Rheumatoid Arthritis. Chih-Chin Liu[1], Daniel H. Solomon[2], Rishi Desai[2], Seoyoung C. Kim[2] and KP Liao[2]. [1]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Inflammation is hypothesized to have direct effects on arterial endothelial and vasomotor function, functions which regulate blood pressure (BP). While inflammation has been implicated in the development of elevated BP, few studies have examined BP longitudinally after diagnosis of an inflammatory disease. The objective of this study is to examine the longitudinal association between changes in levels of inflammation and changes in BP in patients with rheumatoid arthritis (RA).

Methods: We studied RA subjects classified using a validated electronic medical record (EMR) algorithm (positive predictive value 94%) linked with Medicare Claims Data (patients age>65 years) between 2006–2010. We extracted EMR data on age, gender, systolic BP (SBP), diastolic BP (DBP), erythrocyte sedimentation rates (ESR), smoking status (ever/never), and calendar year of measurements. We extracted RA treatment data from Medicare prescription data including non-steroidal anti-inflammatory drugs (NSAIDs), anti-hypertensive drugs and dates of claims. We studied all subjects with ≥2 concurrent BP and ESR measurements at separate visits at least one week apart. The baseline was defined as the 1st concurrent ESR and BP measurement 6 months after the 1st Medicare claims date. We examined the association between the change in ESR and change in SBP between baseline and follow-up using multiple linear regression models adjusted by age, gender and smoking status. We performed sensitivity analyses by including potential treatments received +/− 15 days of ESR measurements that may affect blood pressure individually into the models; the treatments included anti-TNF, NSAIDs, anti-hypertensive medications, and steroids.

Results: We identified 313 subjects with ≥2 instances with ESR and BP measured on the same date. The mean age was 69.2 years (SD 10.3), 83.7% female, and 57.6% ACPA positive. The mean SBP was 134.4(SD 18.8) mm/Hg, mean DBP was 75.7(SD 12) mm/Hg, and the mean ESR was 32 (SD 27.1) mm/hour. We observed an inverse association between change in ESR and SBP, where every 10mm/hour increase in ESR was associated with a 1.2mm/Hg lower in SBP, adjusted by age, gender and smoking status (**Table**). A similar relationship was found with DBP: each 10mm/hour increase in ESR was associated with a 0.43 mm/Hg lower DBP (95% CI −0.75, −0.01, p=0.009). The effect size of the association between change in ESR and change in BP was similar with the addition of indicator variables for anti-hypertensive treatments, anti-TNF, and NSAIDs into the model.

Conclusion: In a linked dataset containing clinical data from the EMR and detailed prescription data from Medicare, we observed that increases in ESR were associated with a modest reduction in blood pressure. These findings have potential implications for CV risk assessment in RA patients who commonly experience large fluctuations in inflammation.

Table. The association between change in ESR (per 10mm/hour) increase with change in systolic blood pressure (SBP), N=313.

Linear regression models for ΔESR and ΔSBP, adjusted by:	ΔSBP (mm/Hg) per 10mm/h Δ ESR	95% CI
Model 1: Age, gender, race, smoking	−1.22	−1.74, −0.71
Sensitivity analyses		
Model 2: Model 1 + anti-hypertensive	−1.21	−1.72, −0.70
Model 2+ anti-TNF	−1.19	−1.70, −0.70
Model 2+ NSAIDs	−1.21	−1.72, −0.70
Model 2+ Steroids	−1.21	−1.72, −0.70
Model 3: Model 1 + anti-hypertensive + anti-TNF + NSAIDs + steroids	−1.16	−1.67, −0.65

1435

Changes in the Types and Prognoses of Infections Complicated in RA Patients during the Last 15 Years, in Japan.. Yoichiro Akiyama[1], Takeo Sato[1], Takamasa Murosaki[1], Katsuya Nagatani[1] and Seiji Minota[2]. [1]Jichi Medical University, Tochigi, Japan, [2]Jichi Medical University, Tochigi-Ken, Japan.

Background/Purpose: Infliximab was introduced in 2002 as the first biological DMARD (bDMARD) in Japan. Currently, 5 TNF inhibitors, tocilizumab, and abatacept are available. Tacrolimus and leflunomide were included as immunosuppressant and synthetic DMARD (sDMARD), and methotrexate (MTX) was approved up to 16 mg/week since 2011. We investigated the type and prognosis of infections in RA patients through the course of the evolution of DMARDs during the last 15 years in Japan.

Methods: We collected, retrospectively, the hospitalized cases of RA under the diagnosis of infections from 1999 to 2013. The diagnosis of infection was based clinically, when it was not confirmed microbiologically. The years between 1999 and 2013 were divided into 5, each consisting of 3 years. The clinical characteristics of the patients, type of infections, hospitalized durations, and mortality were summed up in each period, and their changes in these 5 periods were investigated.

Results: The numbers of hospitalized cases in the 5 periods from 1999 to 2013 were 40, 60, 87, 88, and 84, respectively. When compared between the 1st period of 1999 to 2001 and 5th period of 2011 to 2013, there was no difference in age (median 66.5 vs. 67 years), sex (female to male ratio, 2.6 vs. 2.8), and RA disease duration (median 11.5 vs. 11 years). Glucocorticoid was administered in over 80% of the patients in each period. When compared between the 1st and 5th periods, MTX-use increased from 37.5% to 50.0%, and 15.5% of the patients on MTX were administered over 8 mg/week in the last period. The frequency of bDMARDs-use was 5.0% and 38.1%, in the 1st and 5th period, respectively. Immunosuppressants were used in 10.0% and 16.7%, and sDMARDs other than MTX were used in 37.5% and 14.3% of the patients, in the 1st and 5th period, respectively. The respiratory system was most frequently infected in each period. The mortality in each period was 7.5%, 6.7%, 4.6%, 9.1%, and 7.0%, from 1st to 5th, respectively (p=0.48), and there was no difference in the hospitalized duration (p=0.33). Although there was no significant difference in the prognosis, the frequency of Pneumocystis jirovecii pneumonia (PCP), and the mortality thereof increased from 7.5% to 16.7%, and 33.3% to 80.0% between 1st and 5th period. By univariate analysis of all patients, the mortality was significantly associated with PCP (crude Odds ratio 12.04, p<0.01, 95% CI 4.84 to 29.97), concurrent interstitial pneumonia (crude Odds ratio 2.56, p=0.031, 95% CI 1.09 to 6.01), and glucocorticoid-use (crude Odds ratio 1.06, p=0.001, 95% CI 1.02 to 1.10). PCP was associated with MTX- (crude Odds ratio 3.78, p<0.01, 95% CI 1.74 to 8.20) and glucocorticoid-use (crude Odds ratio 1.05, p<0.01, 95% CI, 1.02 to 1.08). There was no association between bDMARDs-use and PCP (crude Odds ratio 1.74, p=0.17), or mortality (crude Odds ratio 0.78, p=0.67).

Conclusion: With the evolution of treatment in RA during the last 15 years, infections complicated in RA have changed. Although there was no difference in hospitalized durations or mortality, the frequency of PCP and death thereof have been increasing. Compared to Western countries, PCP is more prevalent in Japan, and early diagnosis and treatment are mandatory.

Impact of Depression on Clinical and Social Outcomes in Patients with Rheumatoid Arthritis: Comparative Study in Germany and Brazil. Harriet Morf[1], Olga Malysheva[1], G da Rocha[2], Anna Beatriz Vargas[2] and Christoph G. Baerwald[1]. [1]University Hospital, Leipzig, Germany, [2]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.

Background/Purpose: Rheumatoid Arthritis (RA) can be associated with psychological disorders and especially depression. About 13 – 20 % of patients have clinical significant depression. It was shown (Dougados, 2014 COMORA Study) that depression in this group of patients has a high variability between countries (2 % Morocco – 33 % USA). However, it is still incompletely understood how RA could influence on perception of depression and its impact on quality of life in RA patients from different countries. The purpose of study was to characterise distribution of depression and its impact on pain and social status of patients with RA in different countries.

Methods: 100 RA patients from Germany (age 62,4 ± 12,3 years) and 91 RA patients from Brazil (age 56,3 ± 12,6 years), mean duration of disease in Germany was 14,3 ± 10,4 years and in Brazil 15,9 ± 10,2 years, could be included in this study. RA was diagnosed according to the ACR/EULAR Criteria 2010 and the following questionnaires were utilised: Beck depression inventory (BDI), painDETECT test (Freyn-

hagen R., et al., 2006), visual analogue scale for pain (VAS), SF - 36 and Health Assessment Questionnaire (HAQ-DI).

Results: About 20% RA patients in Brazil were diagnosed with associated depression. Furthermore 27,4 % of Brazilian patients had a subclinical depression. It is significant higher compare to RA patients in Germany (only 10%; $p = 0,039$). There is no difference between pain intensity in two groups of patients (VAS 4,7 ± 3,4 mm (Brazil) vs 3,6 ± 2.3 (Germany). However 61,5 % of Brazilian patients showed symptoms of neuropathic pain compare to 48.3 % of patients from Germany ($p = 0,001$). There are a correlation between pain and depression in both groups (Brazil: $r = 0,520$, $p < 0,001$; Germany: $r = 0,392$, $p < 0,001$). Furthermore, a significant difference was detected in psychological scales of quality of life between both groups of patients (46,6 ± 12,3 Brazil compare to 51,4 ± 11,4 Germany; $p = 0,002$). Interestingly, there was no difference between the activity of disease (DAS 28) between two groups of patients (3,4 ± 1,5, Brazil vs 3,3 ± 1,3, Germany). However Brazilian patients had more erosions (X-ray) compare to Germans group of patients ($p = 0,011$). Moreover it was significant difference between methods of therapy in both groups of patients. Only 5 % Brazilian patients had biologics compare to about 30% RA patients in Germany. There are correlation between the functional status of patients and pain (HAQ and pain: $r = 0,628$, $p < 0,001$), as well as the functional status and depression (HAQ and BDI: $r = 0,552$, $p < 0,01$). Concerning family status, more Brazilian patients were single compare to Germans patients ($p = 0,001$). In Brazil there was found an higher number of patients with children compare with Germans group (74,2 %; $p = 0,015$).

Conclusion: The study indicates that RA-related depression could contribute to diminished psychological well-being in RA patients and suggests the need for psychoeducational and management strategies that specifically target depression as part of RA management program. Future research should attempt to obtain a larger sample of male and younger RA patients to determine if there are significant gender and age differences in the impact of depression on outcomes of RA in different countries.

Cholesterol Efflux Capacity of HDL and Coronary Atherosclerosis in Rheumatoid Arthritis. Michelle J. Ormseth[1], Patricia Yancey[1], Suguru Yamamoto[1], Annette M. Oeser[1], Tebeb Gebretsadik[1], Ayumi Shintani[1], MacRae F. Linton[1], Sergio Fazio[1], Sean Davies[1], L Jackson Roberts II[1], Kasey C. Vickers[1], Paolo Raggi[2], Valentina Kon[1] and C Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Emory University, Atlanta, GA.

Background/Purpose: Cardiovascular (CV) risk is increased in patients with rheumatoid arthritis (RA), but not fully explained by traditional risk factors such as LDL and HDL cholesterol concentrations. The cholesterol efflux capacity of HDL may be a better CV risk predictor than HDL concentrations. We hypothesized that HDL's cholesterol efflux capacity is impaired and inversely associated with coronary atherosclerosis in patients with RA.

Methods: We measured the cholesterol efflux capacity of apolipoprotein B depleted serum and coronary artery calcium score in 134 patients with RA and 76 control subjects, frequency-matched for age, race and sex. The relationship between cholesterol efflux capacity and coronary artery calcium score and other clinical variables of interest was assessed in patients with RA.

Results: Cholesterol efflux capacity was similar among RA (median [IQR]: 34% removal [28, 41%]) and control subjects (35% removal [27%, 39%]) ($P=0.73$). In RA, increasing cholesterol efflux capacity was not significantly associated with decreased coronary calcium score ($OR=0.78$ (95% CI 0.51–1.19), $P=0.24$, adjusted for age, race and sex, Framingham risk score and presence of diabetes). Cholesterol efflux capacity was not significantly associated with RA disease activity score, C-reactive protein, urinary F_2-isoprostanes, or degree of insulin resistance in RA.

Conclusion: Cholesterol efflux capacity is not significantly altered in patients with relatively well-controlled RA nor is it significantly associated with coronary artery calcium score.

Background/Purpose: Increased citrullination process and anti–CCP production are not restricted to rheumatoid arthritis (RA). Other inflammatory processes could develop citrullinated proteins which may contribute to the production of such antibodies. The aim of our study was to analyze whether patients with anti-CCP positive early rheumatoid arthritis have higher frequency of previous history of chronic inflammatory conditions than anti-CCP negative patients at the time of diagnosis.

Methods: We included patients with early RA according to ACR/ EULAR classification criteria, belonging to a prospective cohort of patients with early arthritis (<2 years of disease duration). Data from the first visit were collected. We studied the relationship between anti-CCP antibodies with the previous history of chronic inflammatory conditions (ischemic heart disease, peripheral vascular disease, ischemic or hemorrhagic stroke, hypertension, dyslipidemia, asthma, chronic obstructive pulmonary disease (COPD), diabetes mellitus, hypothyroidism, tuberculosis, alcohol and smoking). The association between anti-CCP status and the presence of inflammatory processes were assessed using univariate and multivariate models.

Results: We included 557 patients with early rheumatoid arthritis. We found positive anti-CCP antibodies (≥ 25 UI/ ml) in 396 patients and negative anti-CCP antibodies in 161. There were no differences between anti-CCP negative and anti-CCP positive patients regarding to age (51 ± 14 vs 50 ± 14 years; $p= 0,76$) and female gender (83% vs 80%; $p=0,42$). When evaluating the association between anti-CCP positivity and presence of inflammatory conditions, patients with negative anti-CCP antibodies experienced significantly higher frequency of dyslipidemia (14% vs 5%; $p < 0,01$) and alcohol intake (7% vs 3%; $p= 0,03$). No association was found between anti-CCP status and ischemic heart disease, peripheral vascular disease, ischemic or hemorrhagic stroke, hypertension, chronic respiratory diseases including asthma and COPD, diabetes mellitus, hypothyroidism, tuberculosis and smoking. Multivariate logistic regression analysis with anti-CCP as dependent variable, showed that dyslipidemia [$OR=0,39$ (0,17- 0,89); $p=0,03$] and alcoholism [$OR= 0,29$ (0,15- 0,55); $p< 0,01$] were independently associated with negative anti-CCP antibodies.

Conclusion: In this cohort with early rheumatoid arthritis, we did not found higher frequency of previous chronic inflammatory conditions in patients with positive anti-CCP antibodies. Nevertheless, negative anti-CCP antibodies were significantly and independently associated with previous history of dyslipidemia and alcoholism.

1439

Miscarriage in Rheumatoid Arthritis – Association with Disease Characteristics and Medication Use. Jenny Brouwer, Joop SE Laven, Johanna MW Hazes and Radboud JEM Dolhrain. Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands.

Background/Purpose: The chance of miscarriage is increased after the diagnosis of rheumatoid arthritis (RA). The association of miscarriage with RA disease activity or anti-rheumatic medication is unclear, mainly due to lack of prospective studies. Our aim was to study the associations of miscarriage with RA serology, disease activity and periconceptional medication use in women with RA.

Methods: In a nationwide prospective cohort on pregnancy in RA (PARA study, 2002–2010) women with RA according to the 1987 American College of Rheumatology (ACR) criteria were visited preconceptionally, during pregnancy and after delivery or miscarriage. General characteristics and medication use were recorded and disease activity (DAS28) was measured. We analyzed the data retrospectively by logistic regression with purposeful selection of covariates, with inclusion at a significance level of $p<0.20$.

Results: A total of 239 preconceptional visits resulted in 181 pregnancies in 164 women. We analyzed only the first included pregnancy for each woman. Thirty (18%) of 164 pregnancies resulted in a miscarriage.

There were significant differences between women with a miscarriage and women with an ongoing pregnancy in age (33.8 (3.9) vs 32.0 (3.8) years, $p=0.022$) and presence of ACPA (83% vs 60%, $p=0.032$). The preconceptional DAS28 was higher in women who had a miscarriage (4.0 (1.0) vs 3.6 (1.2), $p=0.087$) and more women who miscarried had used MTX in the past (83% vs 68%, $p=0.121$), though these differences were not significant. There were no significant differences in RF positivity (80% vs 69%, $p=0.41$), and use of NSAIDs (20% vs 31%, $p=0.27$) or sulfasalazine (27% vs 32%, $p=0.67$).

Logistic regression with the occurrence of miscarriage as dependent variable, showed a tendency towards a higher OR for increasing age, presence of ACPA, increasing DAS28 or past MTX use, though none of these variables reached significance (table 1).

Twenty-one (70%) of the women who miscarried became pregnant again, of whom 19 within one year after miscarriage. This resulted in a live birth in 19 women (90%). Four women decided to stop trying to conceive. Five women were lost to follow up.

Conclusion: The miscarriage rate in the PARA study is comparable to that in the general population. However, this might be biased by a healthy cohort effect found earlier in this study. Despite having miscarried, the majority of patients were pregnant again within one year. RA patients who had a miscarriage tended to be older, to have higher disease activity, to be ACPA positive and to have a past of MTX use. This indicates that miscarriages are more likely to occur in a subgroup of RA patients with more severe disease. Although the PARA study is a large prospective cohort on pregnancy in RA, the associations found did not reach statistical significance due to the relative low frequency of miscarriages in the study.

Table 1. Logistic regression for the occurrence of miscarriage in women with rheumatoid arthritis in the PARA study

Variable	OR	95% Confidence interval	p-value
Age - per year	1.11	0.99–1.24	0.081
Presence of ACPA	2.71	0.94–7.78	0.065
DAS28 - per point	1.35	0.92–1.97	0.124
MTX use in past	2.78	0.95–8.09	0.061

PARA = pregnancy induced amelioration of rheumatoid arthritis; ACPA = anti-citrullinated peptide antibody; DAS28 = disease activity score with a 28-joint count; MTX = methotrexate

Asymptomatic Carotid Plaques in RA Patients Are Associated with Increased HDL Function. Silvia Rollefstad[1], Bente Halvorsen[2], Tonje Skarpengland[2], Sella Provan[1], Tore K. Kvien[3] and Anne Grete Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Oslo University Hospital Rikshospitalet, Oslo, Norway, [3]PsAID taskforce, EULAR, Zurich, Switzerland.

Background/Purpose: Reverse cholesterol transport (RCT) is a major anti atherogenic function of high density lipoprotein cholesterol (HDL) and has been shown to be related to disease activity in patients with rheumatoid arthritis (RA).Our aim was to evaluate if atherosclerosis affects HDL function differently in RA patients compared to controls.

Methods: RA patients from the ORA register and the EURIDISS cohorts without cardiovascular (CV) disease and not using statins or biologic DMARDS were included. Healthy community controls were selected by Statistics Norway. RCT was measured as plasma induced 14C-cholesterol efflux from 14C-cholesterol loaded human THP1 macrophages as previously described. Apolipoprotein (Apo) A1 and paraoxonase-1 (PON-1) activity were measured.

Results: RA patients, 10 with and 10 without carotid plaques (CP), and 10 controls were age and gender matched (Table 1). Traditional CV risk factors were comparable in RA patients with and without CP and controls; smoking: $p=0.55$, systolic blood pressure: $p=0.77$, total cholesterol: $p=0.48$, LDL-c $p=0.31$, HDL-c: $p= 0.89$, triglycerides: $p=0.85$. None had diabetes. Untraditional biomarkers of CV disease such as CRP and ESR were also comparable across the 3 groups; $p=0.53$, $p=0.86$ and $p=0.45$, respectively. RA disease factors as disease duration, rheumatoid factor, anti-CCP and DAS-28 were comparable between RA patients with and without CP ($p=0.81$, $p=0.34$, $p=0.34$ and $p=0.94$). Efflux capacity was significantly increased in RA patients with CP compared both to controls without CP ($p=0.03$) and controls with CP ($p=0.01$)(Table 2). Likewise, both ApoA1 and PON-1 activity were increased in RA patients with CP compared to controls ($p=0.02$ and $p=0.05$, respectively). Further, APOA1 and PON-1 activity were comparable between RA patients without CP and controls ($p=0.58$ and $p=0.69$, respectively).

Conclusion: The cholesterol efflux capacity was increased in RA patients with early atherosclerosis compared to controls, independent of HDL level and CRP. Our findings indicate an association between atherosclerosis and upgraded HDL function in patients with RA having low disease activity, possibly as a compensatory mechanism to the atherosclerotic process. This study is hypothesis generating and larger studies are warranted to verify these findings.

Accelerated Aging in DMARD and Treatment Naive Early Rheumatoid Arthritis Patients Measured By a Stem Cell Assay Is Associated with Increased LDL and Is Linked to Impaired Cardiopulmonary Function. Torkell Ellingsen[1], Henriette Jørgensen[2], Dino Demirovic[2], Lone Deibjerg[3], Frank Andersen[3], Agnete Hedemann-Andersen[3], Brian Bridal Løgstrup[3] and Suresh Rattan[2]. [1]Diagnostic Centre Region, Hospital Silkeborg Denmark, Odense, Denmark, [2]Laboratory of Cellular Ageing, Institute of Molecular Biology and Genetics, Århus University, Århus, Denmark, [3]Diagnostic Centre Region, Hospital Silkeborg Denmark, Silkeborg, Denmark.

Background/Purpose: The cardiovascular comorbidity seen in early treatment naive rheumatoid arthritis (RA) can be considered as an aspect of "accelerated aging".

Methods: We investigated cell migration and proliferation of human cells *in vitro* in a so-called wound healing assay, using telomerase-immortalized mesenchymal stem cells (hTERT-MSC)[1]. Confluent monolayers of hTERT-MSC were mechanically "wounded" creating a fixed size scratch and then allowed to "heal" in the presence of culture medium containing 5% serum from RA-patients (n=30) or healthy subjects (n=25) for 3 days. We examine the effect of serum from RA-patients and controls on hTERT-M and to correlate these *in vitro* measures to standardized measures of cardiopulmonary parameters assessing global longitudinal systolic strain (GLS) by speckle tracking echocardiography[2], coronary calcium score (Agaston score) by coronary computer tomography (CT COR), diffusing capacity of the lungs for carbon monoxide (DLCO), LDL, C-reactive protein (CRP), fasting Insulin (fIns) levels and whole body fat percent by whole body DXA-scan. The assay was performed on serum from 30 treatment-naive RA patients (mean age 56 yr; range 27–73) and 24 healthy controls (age 44 yr; range 24–64).RA patients and controls were free of medication at the time of serum sampling (the RA patients received methotrexate treatment at year one). Disease activity was scored by the use of the Danish national DANBIO registry using standard assessments. CCP titers, LDL and fIns were evaluated by standardized techniques before treatment was initiated.

Results: We found "accelerated aging" measured as decreased wound healing *in vitro* by mean 53% (range 20–100%) in RA patients compared to healthy controls ($p<0.0001$). One year of national guideline DMARD treatment improved the "*in vitro* decreased wound healing" to mean 60% although not significant ($p=0.068$). We found "decreased wound healing *in vitro*" to be associated with increased LDL levels ($p=0.02$; $r=0.43$) in univariate analysis (no association to GLS, Agaston calcium score, DLCO (mmol/min/kPa/L), total fat %, fIns and CRP (p-values in the range 0.31–0.79). We also found a significant difference in GLS in patients with high values of anti-CCP (titers ≥ 340) compared to patients with normal titers and anti-CCP titers CCP titers. Anti-CCP larger than 7 and below 340 $p=0.02$ (DLCO mean 88%) and if anti340 $p=0.004$ (DLCO mean 82%) in anti-CCP negative patients mean DLCO% 102%.

Conclusion: We observed a significant decreased "wound healing *in vitro*" using hTERT-MSC assay in early RA. The "decreased *in vitro* wound healing" was significantly associated with increased LDL. Further we found a significant association between increased anti-CCP titers and initial increased cardiac function and decreased pulmonary function.

The 2013 ACC/AHA Cardiovascular Risk Prediction Model and Coronary Atherosclerosis in Patients with Rheumatoid Arthritis. Vivian K. Kawai[1], Cecilia P. Chung[1], Joseph F. Solus[1], Annette Oeser[1], Paolo Raggi[2] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]University of Alberta, Edmonton, AB.

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased risk of atherosclerotic cardiovascular (CV) disease that is underestimated by the Framingham risk score (FRS). We hypothesized that the new 2013 ACC/AHA 10-year risk score could better identify patients with RA with high coronary artery calcification (CAC) scores, and consequently elevated CV risk, compared to the FRS and the Reynolds risk score (RRS).

Methods: We calculated the 10-year FRS, RRS and ACC/AHA risk score in 98 RA patients aged between 40 and 75 years who would be eligible for risk stratification using the ACC/AHA score and assigned them to either elevated or low risk categories. We identified patients categorized as having elevated CV risk based on the presence of high CAC scores using the thresholds defined by Goff et al. (≥ 300 Agatston units or ≥ 75th percentile) and compared the ability of the three risk scores to correctly categorize these patients with high CAC as having elevated cardiovascular risk. We used receiver operator characteristic (ROC) curves (or c-statistics) to compare the ability of the three risk scores to identify patients with high CAC.

Results: All three risk scores were higher in patients with high CAC than those without (all P values <0.05). The FRS (32% vs. 16%, P=0.055) and RRS (32% vs. 13%, P=0.018) both assigned more patients with high CAC than low CAC into the elevated risk category. The ACC/AHA risk score assigned more patients with high CAC into the elevated risk category (41%) and also assigned 28% of patients without high CAC into the elevated risk category so that the proportion patients with and without high CAC assigned to the elevated CV risk category was not significantly different (P=0.190). The c-statistics (95% C.I.) for the FRS, RRS and ACC/AHA risk score predicting the presence of high CAC were 0.65 (0.53–0.76), 0.66 (0.55–0.77), and 0.65 (0.53–0.76), respectively.

Table: Cardiovascular risk estimates in patients with rheumatoid arthritis with and without high coronary artery calcium

10-year cardiovascular risk scores		CAC<300 agatston units or CAC <75th percentile (n=64)	CAC≥300 Agatston units or CAC≥75th percentile (n=34)	P values
Framingham risk score	Low risk category	54 (84)	23 (68)	0.055
	Elevated risk category	10 (16)	11 (32)	
Reynolds risk score	Low risk category	56 (87)	23 (68)	0.018
	Elevated risk category	8 (13)	11 (32)	
ACC/AHA risk score	Low risk category	46 (72)	20 (59)	0.190
	Elevated risk category	18 (28)	14 (41)	

Conclusion: The new ACC/AHA 10-year risk score, despite classifying more patients with high CAC into the elevated risk category than the FRS and RRS, assigned almost 60% of patients with elevated risk as determined by a high CAC score into the low CV risk category. Modifications of standard CV risk prediction models used in the general population may not improve risk prediction in patients with RA.

Increased Occurence of Carotid and Femoral Plaques, but Not Increased Arterial Stiffness of Hypertrophy, in Classical Risk Factor-Free Patients with Rheumatoid Arthritis. Aikaterini I. Arida[1], Evaggelia Zampeli[1], George Konstantonis[1], Kalliopi Fragkiadaki[1], George D. Kitas[2], Athanasios D. Protogerou[1] and Petros P. Sfikakis[1]. [1]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, and Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Several lines of evidence indicate that classical cardiovascular disease (CVD) risk factors, such as arterial hypertension, diabetes mellitus, smoking and dyslipidemia, are significantly increased in rheumatoid arthritis (RA), which, in turn, is associated with 1.5- to 2-fold increased prevalence of CVD. The exact contribution of the RA disease *per se* in this association, in terms of systemic inflammation, drugs, disease-related genetics and/or other factors, remains under study. We aimed to test the hypothesis that RA *per se* in patients free of classical CVD risk factors is associated with accelerated subclinical arterial disease.

Methods: Consecutive patients with RA (n=267) were comprehensively studied by ultrasound for, a) subclinical atheromatosis, assessed by the presence of carotid artery and/or femoral artery plaques, b) stiffness of common carotid artery and aortic stiffness by pulse wave velocity, and, c) hypertrophy of common carotid artery assessed by intimal-medial thickness and cross sectional area (calculated adjacent to plaques, when plaques were present). Of all patients, we identified those who were CVD-free, non-smokers, without hypertension, diabetes and dyslipidemia (only 18%). Of them, 41 (aged 49+13 years, 36 women, median disease duration of 7 years, range 3–19 years) were compared to 41 healthy non-smokers, without hypertension, diabetes and dyslipidemia who were effectively matched 1:1 for age and gender and studied in parallel.

Results: Patients had more than 2-fold higher prevalence of carotid and/or femoral atheromatic plaques than healthy controls (29% vs. 12%, p=0.05). All patients with plaques had an acceptable functional status of class I or II. Moreover, body mass index, as well as family history of CVD, was similar between patients with plaques and their matched controls. Multi-arterial subclinical atheromatosis, defined as plaque presence at more than 1 of 8 arterial sites evaluated, was by far more prevalent in RA patients than controls (22% vs. 2%, p=0.007). Notably, plaque burden in the subgroup of RA patients with less than 5 years of disease duration was comparable to their matched controls. Either arterial stiffness or hypertrophy, however, was not significantly increased compared to controls, even in patients with long-standing RA.

Conclusion: These data directly show, independently of the classical CVD risk factors, an acceleration of atheromatosis in RA, but not of arterial stiffness or hypertrophy. This phenomenon is not evidenced during the first 5 years after disease onset and seems to be chronic inflammation-dependent. Also, the dissociation between atheromatosis and arterial stiffness in this selected population suggests a minimal, if any, effect of chronic inflammation in arterial remodeling and arterial stiffness. Studies testing whether early and effective RA clinical disease control prevents the development of arterial damage in the long-term are ongoing.

The Vocational Experiences of Young People with Juvenile Idiopathic Arthritis and the Role of the Multidisciplinary Team Supporting Positive Employment Outcomes. Helen Hanson[1], Ruth Hart[2], Alison Jordan[3], Rachel Tattersall[4], Ben Thompson[1] and Helen E. Foster[2]. [1]Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [4]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.

Background/Purpose: Recent decades have seen marked changes in the management of juvenile idiopathic arthritis (JIA), with improved clinical outcomes for many patients. However, unemployment rates for adults with JIA remain high compared to peers, highlighting the need to address vocational issues as an integral part of transitional care.

The aims of this study were to explore i) experiences and expectations of employment amongst young people with JIA ii) the actual and potential role of the multidisciplinary team in promoting positive employment outcomes.

Methods: We interviewed 13 young people with JIA (median age 22y, range 16–31y) and nine health professionals from three tertiary rheumatology services. A focus group for young people with JIA was held in each of the three centres. Qualitative techniques were used to analyse the transcripts.

Results: Three related themes associated with vocational experience emerged from our data analysis, i) JIA has made education and employment more challenging for all the young people in our sample, ii) young people often disclose only minimal information about their condition to educators or employers, iii) all the young people have experienced emotional challenges associated with having JIA and learning to manage these emotions would appear to contribute to vocational success. Young people from one recruiting centre have met peers with JIA at social events and many associate this with gains in both practical coping skills and emotional wellbeing.

Data relating to vocational expectations suggests two important issues. Firstly, many young people have low expectations of employers' willingness to support employees with health conditions and secondly, few are well informed about their legal rights.

Each tertiary rheumatology service includes nurses, doctors and occupational therapists, while access to other professionals varies. We identified three themes concerning perceived barriers to maintaining and improving vocational support, namely i) staff need appropriate knowledge and skills to address vocational issues (currently training or team discussions about vocation appear to be rare), ii) all staff find it challenging to provide holistic care within short appointments, with some describing a lack of attention to vocational issues, iii) dialogue with educators or employers can improve support for struggling individuals but happens less for young people compared to under 16s.

Conclusion: Young people with JIA have a significant need for vocational support from health professionals. Specifically, our work suggests that these young people would benefit from accessible information on: talking about arthritis; anti-discrimination legislation; and local support services. Many would value emotional support, which may include opportunities to meet peers.

The generic nature of vocational challenge lends itself to cross-specialty approaches to addressing training needs and facilitating dialogue with educators and employers. Further work is indicated to improve information resources, explore the needs of educators and employers and develop appropriate and cost-effective interventions.

Improving Osteoarthritis Outcomes Utilizing a Multidisciplinary Model of Care; Experience in a Diverse Multicultural Urban Teaching Hospital. Caroline Jones[1], Laurence A. Rubin[2], Angelo Papachristos[3], Elaine Harniman[3] and Jann Patrick Ong[4]. [1]St. Michael's Hospital, Aurora, ON, [2]St. Michael Hospital, Toronto, ON, [3]St Michael's Hospital, Toronto, ON, [4]University of Toronto, Toronto, ON.

Background/Purpose: In 2008, a multidisciplinary osteoarthritis (MOA) clinic was established at St. Michael's Hospital (SMH), a tertiary care academic teaching facility, serving a diverse social, economic and cultural urban population in Toronto. The team (Rheumatologist, Advanced Practice Physiotherapists) designs a comprehensive treatment plan which consists of one or more of the following:

- patient education
- weight loss strategies which may include a referral to a dietition and possible bariatric surgery
- an exercise program
- prescription for an unloader brace, orthotics or wedges
- intrarticular corticosteroid or hyaluronic acid injection
- discussion about referral for joint replacement surgery

All patients complete two questionnaires at each visit:

1) Multi-Dimensional Health Assessment Questionnaire (MDHAQ).

2) Western Ontario and McMaster Universities Arthritis Index (WOMAC).

The purpose of this continuous qualitative improvement project is to evaluate the outcomes of patients who attend the OA clinic. The research question is: How much change occurs in a patient's functional scores from the initial assessment to the three month follow up visit after a treatment intervention has occurred?

Methods: This study is a retrospective observational cohort. Patients with knee, hip, or other joint OA visiting the OA clinic from January 2009 to Dec 2011 were included in the study. Patients visiting for other reasons such as rheumatoid arthritis or bursitis were not included in analysis. A chart review of patients with baseline information and 3-month follow-up (+/− 3 weeks) were used for analysis, which includes WOMAC and MDHAQ questionnaires for both visits. Subsequent visits are on "as needed" basis, although data from those visits are still recorded and used in some of the analysis. Unfortunately, given the nature of the population and the study, no control population was available.

Results:

- Most patients attended the clinic for symptomatic knee OA.
- Approximately 1/3 of the patients were recommended for surgery consult.

There was baseline and follow-up data that was analyzed for patients with knee OA (group 1) and a subset (group 2) with moderate to severe baseline pain.

Group 1: statistically significant improvements in function (WOMAC $p = 0.0061$) and fatigue (MDHAQ $p = 0.0372$) but not pain (WOMAC $p = 0.656$ and MDHAQ $p = 0.3137$) were observed.

Group 2: the results were similar, with the exception of the change in pain, which was statistically significant as measured by the MDHAQ ($p = 0.0004$) but not the WOMAC ($p = 0.5059$).

A change in WOMAC stiffness was higher for group 2 ($p = 0.07$), but the change in duration of stiffness was similar in both groups ($p = 0.0513$ and $p = 0.0608$).

Other trends observed were:

(i) Patients with a knee effusion tended to respond better to cortisone injections,
(ii) Patients less than 40 years old respond better to treatment
(iii) Patients with neutral knee alignment did better.

Conclusion: These results reflect actual clinical situations, and validate a multidisciplinary approach to OA management. The results support a multidisciplinary approach utilizing a coordinated assessment by both rheumatologist and advanced physiotherapy practitioners in a one stop shop model to substantially improve overall OA management.

Utility of Ultrasound in the Nuffield Orthopaedic Centre Emergency Rheumatology Clinic: Survey of Clinical Effectiveness. Kuljeet Bhamra, Catherine Swales, Matthew Seymour, Catherine McClinton and Peter C. Tayrlor. University of Oxford, Oxford, United Kingdom.

Background/Purpose: The aim of the survey was to evaluate the impact of clinic-based musculoskeletal ultrasonography (MSUS) on diagnosis and management of cases seen in the Nuffield Orthopaedic Hospital emergency rheumatology clinic.

Methods: MSUS was performed on a selected population of cases, which included new patients with diagnostic uncertainty and challenging follow-up patients requiring assessment of disease activity/severity. The service was provided by a consultant rheumatologist trained and experienced in MSUS; the scans were performed during the emergency clinic appointment. Clinician evaluating patient requested MSUS for confirmation of diagnosis or in cases of diagnostic uncertainty. All scans were performed on a GE Logiq E9 using a linear transducer, recording grey-scale and power Doppler findings. Data from all patients who had undergone scans during October 2011- November 2012 was reviewed for demographics, suspected or existing diagnosis of inflammatory arthritis, clinical presentation, clinical findings and management outcome as a direct result of MSUS.

Results: There were 62 patients studied (25 men, 38 women); their mean age was 57.17 years (range 30–88). A set joint scan was performed in all patients consisting of 10 MCP and PIP joints, radiocarpal joint and ulnar styloid.

The new patient group consisted of 34 patients; all had been referred for inflammatory arthritis. Of these, at ultrasound 17 (50%) had osteophytes, 16 (47%) had grey-scale synovitis, with 15 (44%) power Doppler. In one, (3%) no abnormality was detected. This resulted in change in final diagnosis in 22 (65%) new patients and a confirmed diagnosis of active inflammatory arthritis in 12 (35%) patients. Overall, management of new patients directly influenced by ultrasound scan resulted in the discharge of 50% of patients. Of the 17/34 new patients who had a confirmed diagnosis of inflammatory arthritis, 14 (82%) started combination disease modifying anti rheumatic agents at first visit.

There were 28 patients in the follow-up group who were referred for diagnostic uncertainty. Rheumatoid arthritis, psoriatic arthritis, connective tissue disease accounted for the majority, with 17 (61%), 5 (18%), 4 (14%) and 3 (11%) patients, respectively. The impact of MSUS on the follow-up group influenced change in treatment in 13/28 (47%) of patients. Specifically, all RA patients underwent scanning for disease assessment. In 15/17 (88%) patients, treatment escalation was directly influenced by MSUS findings; co-existing pathology was detected in 3/17 (18%) which included findings of gout and osteoarthritis. Ultrasound remission was identified in 5/17 (30%) with 2/17 (12%) were started on neuromodulators for pain management.

Conclusion: This data shows the positive impact of MSUS in the rheumatology clinic, specifically highlighting multiple benefits in daily practice of reduced visits, discharge at first encounter, immediate management decisions. Our survey shows the importance of integrating MSUS service in a one-stop clinic.

Disclosure: K. Bhamra, None; **C. Swales**, None; **M. Seymour**, None; **C. McClinton**, None; **P. C. Taylor**, None.

Implementing American College of Rheumatology (ACR) Quality Indicators for Rheumatoid Arthritis (RA) in the United Arab Emirates (UAE). Hannah Beermann, Joyce Daoud and Humeira Badrsha. Dr. Humeira Badsha Medical Centre, Dubai, United Arab Emirates.

Background/Purpose: Prior to the establishment of RA standards set by the ACR, a widespread discrepancy was formed between practices, which were treating patients with RA with different levels of care. Thus, in order to regulate quality, the ACR implemented the following quality indicators worldwide: tuberculosis screening prior to biological disease modifying drugs (DMARDs), periodic assessment of disease activity, functional status assessment, assessment and classification of disease prognosis, glucocorticoid management, treatment with DMARDs, and follow up treatment with DMARDs.

The aim of our study was to audit our management of RA patients, and assess whether the before mentioned quality indicators were being implemented in our practice and whether this was reflected in better RA disease control.

Methods: Data was collected on 182 consecutive RA patients in the UAE meeting ACR criteria for RA, and measuring the care we provide with the expected standard of quality outlined.

Results: 100% of patients received a tuberculosis screening prior to being prescribed biological DMARDS (16% of the 181 total); TB tests were not applicable to patients receiving any other type of treatment for RA. 98% of patients had a periodic assessment of disease activity (DAS Score) at least once over a twelve-month span. All 100% of patients were subject to a functional status assessment by HAQ at least once during their treatment. However, no patients were provided with a disease prognosis, or prediction of how their disease may progress positively or negatively. Similarly, no patients were provided with documentation of a glucocorticoid management plan correlating with the improvement or change their disease activity (however, no patients were prescribed 10 mg of Prednisone daily for any period of time). 100% of patients were being treated with disease modifying treatments (DMARD), unless contraindicated, and 100% of patients were followed up with as treatment progressed to ensure the medication continued to be effective, and dosage adjustments made based on DAS Score. 53% of our patients were in low disease activity as defined as a DAS28 score < 3.2.

Conclusion: The majority (53%) of patients in our practice had achieved RA disease activity DAS 28 targets of <3.2, which may be a reflection that the practice is strong in upholding most of the tenets of quality with almost 100% compliance with six of the seven ACR quality indicators. There are still areas for improvement such as documenting a yearly disease prognosis and ensuring a written glucocorticoid management plan, assuming the patient is being treated with a glucocorticoid greater than 10 mg of prednisolone daily. We feel that there is correlation between achieving treatment targets and

adherence to ACR quality guidelines but this will need to be studied in larger cohorts in the region.

A Questionnaire Assessment of Knowledge about Methotrexate of Patients with Rheumatoid Arthritis. Françoise Fayet[1], Carine Savel[1], Malory Rodere[2], Bruno Pereira[3], Dihya Abdi[1], Marion Coudercr Sr. [4], Sylvain Mathieu[5], Anne Tournadre[6], Sandrine Malochet-Guinamand[6], Martin Soubrier[7] and Jean Jacques Dubost[8].[1]CHU Gabriel-Montpied, Clermont-ferrand, France, [2]CHU Gabriel-Montpied, Clermont-Ferrand, France, [3]Clinical research department, Clermont-Ferrand, France, [4]Chu G.Montpied, Clermont Ferrand, France, [5]Hopital Gabriel Montpied, Clermont Ferrand, France, [6]Rheumatology CHU Gabriel Montpied, Clermont-Ferrand, France, [7]COMEDRA trial group, Paris, France, [8]CHU G.-Montpied, Clermont-Ferrand, France.

Background/Purpose: Methotrexate is the reference treatment for rheumatoid arthritis (RA). It has potentially serious side effects which can be prevented by an improvement in patient's information.

The aim is to assess the knowledge of patients suffering from RA about their methotrexate treatment with a questionnaire.

Methods: A questionnaire containing 21 closed questions and 2 situation studies about the medication (mechanism of action, method of administration, therapeutic interactions, side effects, monitoring and implications on lifestyle) was given to all RA patients treated with methotrexate who consulted between March and September 2013 in the rheumatology department of Clermont-Ferrand Hospital.

Results: 183 patients were recruited, including 143 women (79%), with a mean age of 60 years +/−13.5 and a median RA duration of 12 years (IQR : 7–20). Methotrexate has been initiated for a mean of 8 years (IQR: 5–13). Methotrexate was identified as a DMARD by 78% of participants. The weekly administration method was well known (97%) and 67% said that the folic acid was to reduce the toxicity of treatment. Only 21% knew that trimethoprim was contraindicated. Half of the patients knew about the haematological risks and 36% about the risks of hypersensitivity pneumonia. The frequency of laboratory assessments was known (80%) but 54% thought that the only purpose of these tests was to assess the RA activity. Only 13% of men (n=38) knew that contraception was essential compared to 90% of women of child-bearing age (n=20), 75% reported that alcohol consumption should be reduced. In multivariate analysis, a low knowledge score correlated significantly, with age and low educational status. Scores were independent of sex, duration of treatment or of the RA.

Conclusion: Patients' knowledge about methotrexate, particularly about the interaction with trimethoprim, risk of hypersensitive pneumonia and need for men to use a couple contraception should be increased by the treatment education programme instruments, especially in the elderly and the lower socio-educational status population.

Combined Intra-Articular Corticosteroid and Exercise in Patients with Knee Osteoarthritis: A Randomised Trial. Marius Henriksen[1], Robin Christensen[1], Louise Klokker[1], Cecilie Bartholdy[1], Karen Ellegaard[1], Mikael Boesen[2], Robert Riis[1], Else Bartels[1] and Henning Bliddal[1]. [1]The Parker Institute, Copenhagen, Denmark, [2]Department of Radiology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiskberg, Denmark.

Background/Purpose: Combined non-pharmacological and pharmacological treatment is recommended as optimal management of knee osteoarthritis (OA). However, the two treatment approaches have mostly been investigated separately. We aimed to assess the efficacy of combined intra-articular corticosteroid injection and exercise compared to placebo injection and exercise in patients with knee OA.

Methods: This randomized, double blinded, placebo-controlled trial running over 26 weeks was designed as a superiority trial comparing the efficacy of a single intra-articular corticosteroid injection (1 mL of 40 mg/mL methylprednisolone dissolved in 4 mL 10 mg/mL Lidocaine) plus exercise, with a single placebo injection (1 mL isotonic saline mixed with 4 mL 10 mg/mL Lidocaine) plus exercise. Participants with clinical and radiographic knee OA were randomly allocated (1:1) to either corticosteroid (Steroid Group) or saline (Placebo Group) injection. Two weeks after injections, all participants started a 12 week supervised exercise program with 3 weekly sessions. Outcomes were assessed at baseline, week 2 (exercise start), week 14 (end of exercise), and week 26 (follow-up). The primary outcome was the mean change in KOOS pain subscale at week 14. Analyses were done on the intention-to-treat (ITT) population (all randomized participants). Missing data were replaced using multiple imputation. A repeated measures mixed model was used to analyze the primary outcome; week, treatment, and week x treatment were included as fixed effects, adjusting for the baseline value.

Results: A total of 263 patients were screened and 100 patients were randomized to receive either Steroid (n=50) or Placebo (n=50). Of these, 93 completed the week 14 assessment and 89 completed the 26 weeks trial. There were no group differences in the proportions completing. Mean age was 63.4 (SD 9.3) years, 61% were women. The mean exercise attendance rate was 79% (SD 15); no group difference. The mean (SD) KOOS pain score at randomization was 53.3 (11.4) and 55.2 (16.0) in the Steroid and Placebo groups, respectively. The mean (SEM) change in pain at week 14 was 13.6 (1.8) and 14.8 (1.8) in the Steroid and Placebo Groups, respectively, corresponding to a mean difference of 1.2 units (95% CI -3.8 to 6.2; P=0.64). These results were robust in sensitivity analyses using baseline observation carried-forward imputation and no imputation. There were no group differences at week 2, 14, and 26 in any of the 5 KOOS subscales and the 95% confidence intervals of the group differences did not exceed the suggested minimal clinical important difference of 8–10 KOOS points.

Conclusion: These results show comparable efficacy of intra-articular corticosteroid and placebo when combined with exercise for pain relief in knee OA.

Spironolactone As a Novel DMARD in Rheumatoid Arthritis. Inderjeet Verma[1], Pawan Krishan[2] and Ashit Syngle[3]. [1]Punjabi University Patiala, India, Chandigarh, India, [2]Punjabi University Patiala, India, Patiala, India, [3]Healing Touch City Clinic, Fortis Multispeciality Hospital, Chandigarh, India.

Background/Purpose: Synthetic disease-modifying antirheumatic drugs (DMARDs) though effective have limitations often requiring use of expensive parenteral biologic DMARDs in Rheumatoid Arthritis (RA). Hence there is a need for safe, efficacious economical therapies for management of disease and its co-morbidities. Anticytokine therapy with Biologic DMARDs is efficacious but has limitations. Given the TNF inhibiting potential of spironolactone (SPIR)[1–2], We therefore investigated the anti-inflammatory effects of SPIR in RA patients in a randomized, placebo-controlled, open label study.

Methods: We organized a 24-week study on 70 patients (36 in SPIR and 34 in placebo arm) with active RA. They were randomized to oral SPIR (2 mg/kg/day) or placebo for 24 weeks as an adjunct to existing stable DMARD regimen. Therapy results were evaluated by ESR, CRP, Disease Activity Score in 28 joints (DAS28), simple disease activity index (SDAI), ACR response criteria and pro-inflammatory cytokines (TNF-α, IL-6 and IL-1). Flow mediated dilatation (FMD) was assessed by AngioDefender™ and carotid intima media thickness (CIMT) of brachial artery. Endothelial progenitor cells (EPCs) ($CD34^+/CD133^+$) were quantified by flow cytometry. Quality of life was assessed using HAQ-DI.

Results: At 24 weeks; ESR, CRP, DAS-28 and SDAI significantly ($p<0{\cdot}05$) improved in SPIR group compared with placebo (Table 1). At 24 weeks, more patients in the 2 mg/kg/day SPIR group than in the placebo group had an ACR20 response 47.5% (n=16) versus 25% (n=8). ACR50 response rates were 23% (n=8) and 6.2 % (n=2), respectively, in the SPIR and placebo groups, and ACR70 rates were 11.7% (n=4) and 2.9% (n=1). At 24weeks, TNF-α, IL-6 and IL-1 improved significantly in SPIR compared with placebo (Table 1). With SPIR treatment the mean value of the FMD improved from 6.5 to 8.9 ($p<0{\cdot}001$) and with placebo from 7.56 to 7.7 ($p=0{\cdot}12$). SPIR significantly improved EPC population (p=0.008) compared with placebo (p=0.305) after treatment. After 24 weeks, CIMT was significantly improved in SPIR (p=0.03) compared with placebo (p=0.30) (Table 1). At 24 weeks, HAQ disability index score was significantly improved in SPIR compared to placebo group (table 1). Two patients in the SPIR and 1

patient experienced adverse events or discontinued treatment because of adverse events.

Conclusion: These results suggest that SPIR is a powerful anti-inflammatory agent that significantly reduces inflammatory biomarkers and disease severity and improves physical function in RA. It also improves endothelial dysfunction, EPC population and CIMT indicating its beneficial effects on the enhanced cardiovascular risk of RA. SPIR could therefore possibly be used as an adjunct therapy with DMARDs in patients with RA.

1451

Use of Analgesics in Patients with Knee and/or Hip Osteoarthritis: Results from the Amsterdam Osteoarthritis Cohort. Joyce van Tunen[1], Marike van der Leeden[1], Martin van der Esch[1], Leo D. Roorda[1], Willem F. Lems[2] and Joost Dekker[3]. [1]Amsterdam Rehabilitation Research Center | Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [3]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Use of analgesics is recommended by international guidelines to reduce pain complaints related to knee and/or hip osteoarthritis. Underuse of analgesics might be substantial in patients with knee and/or hip osteoarthritis due to poor implementation of guidelines. Factors associated with analgesic use are not assessed systematically, although knowledge of the use of analgesics will improve the prescription of analgesics. Therefore, the first aim of this study was to describe the use of analgesics in patients with knee and/or hip osteoarthritis, referred to an outpatient center for rehabilitation and rheumatology in the Netherlands. The second aim was to determine factors that are associated with analgesic use in this population.

Methods: Data from 497 patients with knee and/or hip osteoarthritis according to clinical ACR criteria from the Amsterdam Osteoarthritis cohort were used. Self-reported analgesic use was measured. Independent factors included predisposing (e.g. demographic and social characteristics), enabling (the ability to use care resources, e.g. referring physician) and disease-related (the most immediate cause for analgesic use) factors. Logistic regression analysis was performed to analyze the association between analgesic use and the independent factors.

Results: The mean±SD age of patients was 61,6±9,0 year and 72% were woman. Total scores on pain, stiffness and activity limitations on the Western Ontario and McMaster Universities Arthritis Index (WOMAC) were 43,5±18,1. Analgesic use was reported in 53% of the patients; 37% used acetaminophen, 21% used non-selective non-steroidal anti-inflammatory drugs (NSAIDs), 3% used coxibs and 8% used opioids. Both monotherapy or combinations of analgesics were used. Univariate logistic regression analysis showed that high scores on pain, stiffness and activity limitations on the WOMAC were associated with analgesic use. In addition, gender (women), being overweight or obese, having bilateral knee symptoms, higher levels of psychological distress and a higher amount of comorbidities were associated with analgesic use. Higher levels of psychological distress were associated with the use of acetaminophen. Preliminary results of multivariate logistic regression analysis showed that a higher score on the subscale pain of the WOMAC was associated with analgesic use.

Conclusion: Half of patients with knee and/or hip osteoarthritis referred to an outpatient center for rehabilitation and rheumatology used analgesics. More pain was associated with use of analgesics, suggesting that the analgesics used are not sufficiently effective in reducing symptoms. This may indicate that more effective strategies of pain management need to be implemented.

Timing of Decisions to Adjust Disease Modifying Anti-Rheumatic Drug (DMARD) Therapy for Rheumatoid Arthritis (RA) Patients with Active Disease in a Usual Practice Setting. Yomei Shaw[1], Chung-Chou H. Chang[2], Marc C. Levesque[2], Julie M. Donohue[1], Kaleb Michaud[3] and Mark S. Roberts[1]. [1]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA, [3]National Data Bank for Rheumatic Diseases, Wichita, KS.

Background/Purpose: Current guidelines recommend that rheumatoid arthritis (RA) patients with poor response to their current regimen of disease modifying anti-rheumatic drugs (DMARDs) have therapy adjusted until reaching low disease activity or remission. We examined factors associated with timing of decisions to adjust DMARD therapy for RA patients with active disease and how the timing of decisions impacts resolution of active disease.

Methods: Data came from the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry, which captures subjects' disease activity status (DAS28-CRP) and medications at clinic visits.

We conducted survival analyses on time to DMARD therapy adjustment and time to resolution of active disease for RACER subjects with active disease. A Cox proportional hazards model was used to assess the impact of covariates on the survival times. For both analyses, followup begins when the subject is first known to have active disease (DAS28-CRP>3.2) and ends with the event of interest (DMARD therapy adjustment or resolution of active disease). For the analysis of time to therapy adjustment, we excluded patients who adjusted therapy at t=0 and those who exited active disease before adjusting therapy, and the model included covariates for age, gender, African-American race, comorbidities, duration of RA, and current use of a biologic therapy. For the analysis of time to resolution of active disease, the model included the same covariates plus an indicator for time to therapy adjustment.

Results: We identified 562 subjects with active disease at a first timepoint and a followup DAS28-CRP measurement.

The analysis for time to therapy adjustment included 177 subjects (117 therapy augmentations observed). 364 subjects were excluded because they adjusted DMARD therapy at t=0 (n=196) or because they exited active disease status before adjusting therapy (n=162). The median time to therapy adjustment was 203 days. Age over 75 and longer duration of RA were significantly associated with longer times to therapy adjustment.

The analysis for time to resolution of active disease included 530 subjects (383 achieved DAS28-CRP ≤ 3.2). The median time to resolution of active disease was 257 days. African-American race and duration of RA >1 year were associated with longer times to resolution of active disease. (See **Table 1**)

Conclusion: Among those with persistent active disease (n=394), 60% adjusted DMARD therapy within 90 days; however 50% of subjects took longer than 257 days to achieve DAS28-CRP ≤ 3.2. We found that age ≥ 75 and longer duration of RA were associated with longer times to DMARD therapy adjustment, while African-American race and duration of RA > 1 year were associated with poorer disease outcomes. Future studies should further examine how these factors affect treatment choices as well as long term health outcomes.

Table 1 Rheumatoid arthritis patient characteristics associated with time to therapy adjustment/resolution of active disease

Parameter	Cox regression 1 Outcome: Time to DMARD therapy adjustment[+] N=177, 117 events, 60 censored[#] (33.9% censored)		Cox regression 2 Outcome: Time to resolution of active disease N=530, 383 events, 147 censored[#] (27.7% censored)	
	Hazard ratio	P-value	Hazard ratio	P-value
Age at baseline ≥ 75	0.480	0.092	1.200	0.276
Male	0.938	0.785	1.193	0.162
Charlson group 2:1*	1.200	0.408	1.024	0.837
Charlson group 3:1*	0.788	0.447	0.913	0.592
African-American	1.000	0.999	0.625	0.011
Using biologic at baseline	0.830	0.341	0.992	0.938

Gastrointestinal Risk Factors and Treatment Patterns of Rheumatoid Arthritis Versus Osteoarthritis Patients in Korea. Eun Young Lee[1], Sang Heon Lee[2], Hyo-Jin Kim[3] and Korea RA/OA OR Grroup. [1]Seoul National University College of Medicine, Seoul, South Korea, [2]Konkuk University Hospital, Seoul, South Korea, [3]Pfizer Tower, 1–11, Hoehyun-Dong 3-Ga, Jung-Gu, Seoul, South Korea.

Background/Purpose: Little is known about local data of the gastrointestinal risk faocts (GI) and treatment pattenrs in rheumatoid arthritis (RA) and osteoarthritis (OA) patients. This study aimed to investigate and compare the GI risk factors and treatment patterns of RA and OA patients in real clinical practice of Korea.

Methods: This was a nationwide, cross-sectional and observational study of patients taking non-steroidal anti-inflammatory drugs (NSAID, either non-selective or selective COX-2 inhibitor (COX2i)) from 20 hospitals between December 2012 and September 2013. Total 1,896 patients who were ≥20 years old (RA:981 OA:915) and were taking NSAID at least 1 month were enrolled. Data were collected through medical chart review and patients survey. The GI risk factors included NSAID duration (≥3 months), high-dose of NSIAD use, drinking, smoking, comorbid disease, aspirin use, anticoagulant(warfarin) use, steroid use, Helicobacter pylori infection, experience of GI event (i.e. GI bleeding or ulcer). The treatment patterns were identified as non-selective NSAID (ns-NSAID) or COX2i with/without gastroprotective agents respectively.

Results: In RA, proportion of patients taking NSAID≥3 months, smoker and steroid users were higher than in OA patients ($p<.0001$). In OA, proportion of patients who have comorbid disease and take aspirin were higher than in RA patients ($p<.0001$). The rest of the GI risk factors were present as a similar proportion in both groups. The percentage of treatment with COX2i (RA:54.3% vs OA:44.2%, $p<.001$) and gastroprotective agents (RA:83.0% vs OA:78.3%, $p=.009$) in RA patients was higher than that in OA patients. In older aged patients (age≥60) in both groups, there was tendency to get more treatment of COX2i (RA: 60.9%, OA:50.2%) compared to ns-NSAID. Interestingly, as patients get more numbers of GI risk factors, there seemed to get more proportions of ns-NSAIDs users in both RA and OA patients.

Conclusion: The proportion of GI risk factors found in OA patients was comparable to that in RA patients. There was a tendency to show preferential ns-NSAID treatment pattern rather than COX2i especially in the presence of multiple GI risk factors in arthritis patients.

Quantitative and Qualitative Tracking of Expanded CD4$^+$ T Cell Clones in Rheumatoid Arthritis Patients. Kazuyoshi Ishigaki[1], Hirofumi Shoda[1], Yuta Kochi[2], Tetsurou Yasui[1], Yuho Kadono[1], Sakae Tanaka[1], Keishi Fujio[1] and Kazuhiko Yamamoto[1]. [1]The University of Tokyo, Tokyo, Japan, [2]RIKEN, Yokohama, Japan.

Background/Purpose: The purpose of this study is to elucidate the characteristics of expanded CD4$^+$ T cell clones (ECs) in peripheral blood and synovium of rheumatoid arthritis (RA) patients by T cell receptor (TCR) repertoire and single cell transcriptome analysis.

Methods: We obtained peripheral blood from 5 RA patients and 5 control subjects. We performed TCR repertoire analysis by combination of single cell and next-generation sequencer (NGS) in CD4$^+$ T cells. We also performed single cell RNA-Seq and real time PCR analysis of ECs and non-expanded clones (NECs). Similarly, CD4$^+$ T cells from synovium were analyzed in 1 patient.

Results: We detected significantly higher frequency of ECs in peripheral blood of 4 RA patients compared with controls both in naïve and memory subset of CD4$^+$ T cells. Within memory CD4$^+$ T cells of peripheral blood, non-Th1/Th17/Tfh subset (negative for CXCR3, CCR6 and CXCR5) contained majority of expanded clones in PBMC of 3 RA patients and synovium-infiltrating clones in 1 RA patient. Gene expression analysis of the mostly expanded CD4$^+$ T cell clones in synovium of 1 RA patient and peripheral blood of 2 RA patients revealed up-regulation of GZMB, TBX21 and CD5 and down-regulation of CD28 compared with NECs. The tracking of gene expression profile of one unique EC in peripheral blood showed down-regulation of CXCR4 and CCR5 compared with that of the identical clone in synovium of the same patient.

Conclusion: ECs were more frequently observed in non-Th1/Th17/Tfh subset in peripheral blood and had gene expression profiles consistent with senescent CD4$^+$ T cells in both of peripheral blood and synovium. Given that there are no reliable markers of clonal expansion, single cell transcriptome analysis is the only method to investigate gene expression profiles of expanded clones. Combined with the robustness of NGS TCR repertoire analysis, our approach should be a rational strategy to characterize ECs and might be able to identify pathogenic clones in RA.

Ex Vivo-Expanded, but Not in Vitro-Induced, Human Regulatory T Cells Are Suitable for Cell Therapy in Rheumatological Autoimmune Diseases Thanks to Stable FOXP3 Demethylation. Maura Rossetti[1], Roberto Spreafico[1], Maryam Moshref[2], Jorg van Loosdregt[3] and Salvatore Albani[1]. [1]Singapore Health Services Pte Ltd, Duke-NUS Graduate Medical School, Translational Research Unit, Sanford-Burnham Medical Research Institute, Singapore, Singapore, [2]Translational Research Unit, Sanford-Burnham Medical Research Institute, La Jolla, CA, [3]Translational Research Unit, Sanford-Burnham Medical Research Institute, San Diego, CA.

Background/Purpose: Treg cell therapy is a promising approach for transplant rejection and severe autoimmunity. Unfortunately, sufficient Treg numbers can be obtained only upon *in vitro*culture. Functional stability of human expanded (e)Treg and induced (i)Tregs has not been thoroughly addressed for all proposed protocols, hindering clinical translation. We undertook a systematic comparison of eTreg and iTregs to recommend the most suitable protocol for clinical implementation, and then tested its effectiveness and feasibility in autoimmune rheumatological settings with cells from rheumatoid arthritis (RA) patients.

Methods: eTregs were expanded with rapamycin (rapa), while iTregs were induced from naive T cells in the presence of TGF-β with either all-trans retinoic acid (ATRA) or rapa. *FOXP3* expression and demethylation, regulatory molecular signature and suppressive function were evaluated after a first round of differentiation and a secondary restimulation deprived of differentiation factors.

Results: Regardless of the protocol, iTregs acquired suppressive functions and FOXP3 expression, but lost them upon withdrawal of differentiation factors. In contrast, rapa eTregs maintained their regulatory properties and retained *FOXP3* upon restimulation. Demethylation, but not expression, of FOXP3 predicted Treg functional stability upon secondary TCR engagement in the absence of stabilizing factors. Importantly, Treg expansion with rapa from RA patients produced functionally stable and suppressive Tregs with yields comparable to healthy donors.

Conclusion: Our data indicate *ex vivo* Treg expansion with rapa as the protocol of choice for clinical application in rheumatological settings, with assessment of *FOXP3* demethylation as a necessary quality control step.

Foxp3+ Regulatory T Cells in Peripheral Blood and Synovial Fluid of Patients with RA: A Comparative Phenotypic Analysis. Jun Saegusa[1], Fumichika Matsuki[1], Yasushi Miura[2], Goichi Kageyama[1], Seiji Kawano[1], Shunichi Kumagai[3] and Akio Morinobu[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Kobe University Graduate School of Health Sciences, Kobe, Japan, [3]Shinko Hospital, Kobe, Japan.

Background/Purpose: Human regulatory T (Treg) cells play an indispensable role for the maintenance of self tolerance and immune homeostasis. Numerous studies dealt with Treg population in peripheral blood from RA patients (RAPB) with various conclusions regarding the frequency of circulating Treg cells. Most studies reported decreased or normal proportions of Treg cells, whereas some other groups reported an increase. On the other hand, the frequency of Treg cells in synovial fluid from RA patients (RASF) has been reported to be significantly higher than that in RAPB. In addition, Treg cells in RASF have been shown to have impaired suppressive function compared to those in RAPB. However, the cause of impaired function of Treg cells in RASF is unknown. A recent study has demonstrated that human Treg cells can be separated into three functionally unique subpopulations: CD45RA+Foxp3^{low} naïve Treg cells; CD45RA-Foxp3^{high} effector Treg cells, both of which have suppressive functions, and non-suppressive cytokine-secreting CD45RA-Foxp3^{low}non-Treg cells. The purpose of this study is to determine the characteristics of Foxp3+ Treg cells in RAPB and RASF.

Methods: Synovial fluid and peripheral blood CD4+ T cells from RA patients were classified into different subsets based on the expression of CD45RA, CCR7, CD27, and CD28. The frequency of IFN-γ-, IL-17-, or TNF-α-producing cells, and of Foxp3- or RANKL-positive cells in each subset was analyzed by eight-color flow cytometry. CD4+Foxp3+ cells were further classified into three functionally distinct subsets based on the expression of CD45RA and Foxp3.

Results: The frequency of CD45RA−Foxp3^{high} effector Treg cells was significantly decreased in the peripheral blood CD4+ T cells from RA patients, compared to those from healthy controls. As a result of the decrease of effector Treg cells, more than half of the Foxp3+ Treg cells (60.5 ± 9.5%) were the CD45RA−Foxp3^{low} non-Treg cells in RAPB. Furthermore, the frequency of CD45RA−Foxp3^{high} effector Treg cells in the CD27+CD28+ central memory (T_{CM}) subset was significantly decreased in RA patients. In addition, the percentage of CD45RA+Foxp3^{low} naïve Treg cells was negatively correlated with DAS28-CRP. In RASF, the frequency of Foxp3+ cells in the CD27+CD28+ effector memory (T_{EM}) population was significantly increased in RASF, compared to that in RAPB. Most of the Foxp3+ cells in RASF were CD45RA-Foxp3^{low} non-Treg cells (81.7 ± 10.4%), and the frequency of non-Treg cells in RASF was significantly increased compared to that in RAPB. Furthermore, the non-Treg cells in CD27+CD28+ T_{EM} subset was significantly increased in RASF (RASF; 5.9 ± 4.0%, RAPB; 0.7 ± 0.5%). Collectively, increase in Foxp3+ cells in RASF was due to increased number of non-Treg cells which exist in CD27+CD28+ T_{EM} subset.

Conclusion: The decreased proportion of CD45RA−Foxp3^{high} effector Treg cells and the increased proportion of CD45RA-Foxp3^{low} non-Treg cells may have critical roles in the pathogenesis of RA.

Stem Cell Growth Factor Expression in Rheumatoid Arthritis. Youn Jung Woo[1], Young Ae Baik[1], Yong-Beom Park[1], Soo-Kon Lee[1], William H. Robinson[2] and Jason Jungsik Song[1]. [1]Yonsei University College of Medicine, Seoul, South Korea, [2]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Stem cell growth factor (SCGF) is a member of the C-type lectin superfamily, encoded by gene *CLEC11A*. SCGF is not related to stem cell factor (a ligand for the receptor-type protein-tyrosine kinase KIT) although the two proteins can be confused due to similarity in name. SCGF has been recently discovered as a growth factor of hematopoietic precursor cells in the bone marrow. However, the role of SCGF in inflammation has not been investigated. Because various growth factors such as M-CSF (macrophage colony stimulating factor) have been shown to be involved in RA pathogenesis by promoting the survival and activity of inflammatory cells, we investigated SCGF expression using samples derived from RA patients and controls.

Methods: SCGF level is measured using sandwich ELISA methods with synovial fluid and serum derived from RA patients and controls. SCGF expression in synovial tissue is evaluated by immunohistochemistry using anti-SCGF antibody. SCGF localization in synovial tissue is evaluated with confocal microscopy using anti-SCGF antibody and anti-von Willebrand Factor (vWF) antibody (a marker for endothelial cells). SCGF expression in endothelial cells is evaluated using HUVEC cell and EAhy.926 cells by quantitative PCR and immunocytostaining.

Results: SCGF levels in RA synovial fluid (n=25) were significantly elevated compared to SCGF levels in osteoarthritis synovial fluid (n=25) (RA 9.4±1.6 vs OA 4.6±0.9 ng/ml, $p<0.01$). However there was no difference in SCGF levels in serum from RA patients and healthy controls. Immunohistochemical analyses demonstrated that SCGF is highly expressed in the endothelium of synovial tissues derived from RA patients. Confocal microscopy demonstrated SCGF positive cells are colocalized with vWF positive cells. Immunocytostaining with anti-SCGF antibody detected SCGF from various types of endothelial cells, such as HUVECs and EA.hy926 cells. LPS increased *CLEC11A* mRNA in EA.hy926 cells.

Conclusion: These results suggest that SCGF expression is associated with rheumatoid arthritis. SCGF is locally produced by endothelial cells in RA synovial tissue. Inflammation promotes SCGF expression in endothelial cells. SCGF might be involved in immune cell survival and differentiation in peripheral inflammatory tissue. Studies are underway to investigate the pro-inflammatory role of SCGF in RA.

Functional Phenotype of Synovial Monocytes Modulating Inflammatory T-Cell Response in Rheumatoid Arthritis. Seong-Wook Kang[1], Seung-Cheol Shim[1], Jinhyun Kim[1], In-Seol Yoo[1], Su-Jin Yoo[1], Seung-Taek Song[1], Bo-Ruem Yoon[2] and Won-Woo Lee[2]. [1]Chungnam National University School of Medicine, Daejeon, South Korea, [2]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Monocytes function as crucial innate effectors during inflammation. Human monocytes can be divided into three distinct subsets based on CD14 and CD16 expression. Accumulating evidences suggest that three monocyte subsets have distinct functions in inflammatory responses. Here we investigated the characteristics of monocytes in synovial fluid (SF) of rheumatoid arthritis (RA) patients.

Methods: Monocytes and T cells were separated from the peripheral blood (PB) and SF obtained from patients with RA and analyzed by using flow cytometry. For global transcriptome analysis of pathogenic monocytes in RA, we performed a microarray analysis of SF and PB monocytes from the same RA patients and PB monocytes of healthy control (HC).

Results: CD16 expression on CD14^{++} monocytes in the SF was significantly increased compared with that in the PB of RA patients and HC. Microarray data showed that 3,134 genes were differentially expressed in SF monocytes compared with PB monocytes from RA and HC. Among the genes, CD80 and CD276 expression were significantly elevated on SF monocytes, while PB monocytes of RA and HC did not express both of them without stimulation. CD80 and CD276 belong to the B7 family, which plays a checkpoint role for modulating T-cell responses. To explore how SF monocytes gain unique properties, PB monocytes were stimulated with various cytokines and TLR ligands. TGF-β is a potent inducer of CD16 expression on CD14^{++} monocytes, whereas expressions of CD80 and CD276 were markedly elevated by IFN-γ and GM-CSF, respectively. *In vitro* assay, SF monocytes were found to significantly promote Th17 and Th1 responses, compared with PB monocytes of RA patients.

Conclusion: Our findings suggest the possible role for cytokine milieu of the synovial fluid in giving unique features to SF monocytes and their cardinal roles in affecting inflammatory T-cell response in RA.

IL-22 Secreted By NKp44+NK Cells Promote the Proliferation of Synovium in Patients with Rheumatoid Arthritis By Activation of STAT3. Junqing Zhu[1], Juan Li[1] and Xiaoguang Chen[2]. [1]Nanfang Hospital, College of Traditional Chinese Medicine, Southern Medical University, Guangzhou, China, [2]School of Public Health and Tropical Medicine, Southern Medical University, Guangzhou, China.

Background/Purpose: Although CD3-CD56+NKp44+ natural Killer cells (NKp44+NK cells) have been linked to autoimmune diseases including inflammatory bowel disease, ankylosing spondylitis, and primary Sjogren's syndrome, the expansion and role of those cells in rheumatoid arthritis (RA) remain less defined. Here, we investigate the proportion of NKp44+NK cells in RA patients and examine whether those cells play a role in the pathogenesis of RA.

Methods: The frequency of NKp44+NK cells using flow cytometric analysis in peripheral blood (PB) or synovial fluid (SF) and their association with disease activity were examined in RA patients and controls. The expansion of those cells in RA and OA synovial tissues was also detected by dual-labeling immunofluorescence. And then, the concentration of IL -22 secreted by NKp44+NK cells was examined by Enzyme-linked immunosorbent assay. Eventually, the proliferation of fibroblast-like synoviocytes (FLS) and detection of IL-22-dependent signal pathway were examined by methyl thiazolyl tetrazolium and western blot analysis respectively after the treatment of NKp44+NK cells culture supernatant, IL-22 antagonist, recombinant human (rh) IL-22, or a selective signalling pathways inhibitor (AG490).

Results: When compared with controls, NKp44+NK cells significantly expanded in RA PB (3.1±2.4% vs 0.5±0.8%; $p<0.001$) and SF (7.1±4.2% vs 0.9±1.2%; $p<0.001$), which were correlated positively with disease activity scroe in 28 joints and clinical disease activity index ($p<0.001$). Those cells also highly expressed in RA synovial tissues, but were not detected in

OA synovial tissues. It provided a source of IL-22 with high concentrations (5826.5±284.2pg/ml). Further, NKp44+NK cells culture supernatant promoted the proliferation of FLS which was blocked by IL-22 antagonist. Treated with rhIL-22, the proliferation and phosphorylation-STAT3 on RA-FLS increased in a dose dependent manner and time dependent manner respectively, the progress of which could be blocked by AG490.

Conclusion: The present study clarifies the expansion of NKp44+NK cells in the PB and SF of RA patients, especially in the synovial tissues of RA for the first time. STAT3 is an essential pathway in mediating the effects of IL-22 secreted by NKp44+NK cells on the proliferation of synovium in patients with RA.

Midkine, a Growth Factor, May Play a Pathophysiological Role in Patients with Rheumatoid Arthritis. Emiko Shindo, Tomoko Hasunuma, Shotaro Masuoka, Mai Kawazoe, Hiroshi Sato, Natsuki Fujio, Kotaro Shikano, Makoto Kaburaki, Sei Muraoka, Nahoko Tanaka, Kaichi Kaneko, Tatsuhiro Yamamoto, Kenji Takagi, Natsuko Kusunoki and Shinichi Karwai. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Midkine (MK) is known as a heparin-binding growth factor. Recent studies revealed that MK has various functions such as cell proliferation, differentiation, and apoptosis in various cells. Its pathological role is noted in various diseases, especially in solid tumor, such as Wilms tumor, liver cell cancer, and neuroblastoma. High level of serum MK is reported in these cancer patients who have poor prognosis. On the other hand, we reported in the last ACR meeting that high level of serum MK is correlates poor prognosis in patients with systemic vasculitis. In this study, we measured serum level of MK in patients with RA and compared with that in healthy controls. We also analyzed relationships between MK level and several clinical parameters to clarify the pathophysiological role of MK in RA. Moreover, expression of MK protein and mRNA were examined in RA synovial tissue and/or RA synovial fibroblasts (RSFs).

Methods: Serum samples were obtained from 146 RA patients (female: male = 121:25, average age ± SD: 61.0 ± 1.2 y.o.) and 85 healthy controls (female:male = 83:8, 63.2 ± 1.3 y.o.). MK concentration was measured by Human Midkine ELISA kit using a monoclonal antibody against MK (Cellmid, Merborne, Australia). Clinical parameters for RA, such as serum CRP, ESR, rheumatoid factor (RF), MMP-3, DAS28-ESR, patient and doctor VAS, HAQ, and Sharp score were also examined. Statistical analysis was conducted by StatFlex v6.0. Immunohistochemical analysis was performed using RA synovial tissue, which wasobtained at the total knee replacement surgery. Cultured RSFs separated from RA synovial tissue were stimulated with interleukin 1β (IL-1β), tumor necrosis factor-α (TNFα) or dexamethasone for 18 hours, then culture medium was collected for measuring MK protein and mRNA was extracted from RSFs. RT-PCR of MK was performed by standard methods.

Results: Serum MK level was significantly increased in RA patients compared with that of healthy controls (average value ± SD; 157.4±13.7 and 69.64±3.0 pg/mL, respectively) by Mann-Whitney U test ($P < 0.0001$). ESR, RF, MMP-3, DAS28-ESR, patient VAS, doctor VAS, and HAQ, Sharp score were correlated with MK values by univariate analysis. Multiple linear regression analysis showed that MK level was positively correlated with CRP and RF ($P = 0.00012$ and $P < 0.000001$, respectively), but not with MMP-3, DAS28-ESR, HAQ, and Sharp score. Immunohistochemical analysis showed that MK was stained in lining layer of RA synovial tissues. MK mRNA in RSFs and MK protein in the culture medium of RSFs were detectable, however, their expression levels were not changed by addition of IL-1β, TNFα or dexamethasone.

Conclusion: In this study, MK was significantly increased in serum of RA patients, and its level was correlated with several clinical markers of RA. In addition, MK protein and mRNA were detected in RA synovial lining layer and/or cultured RSFs. It might be possible that MK has a pathophysiological role in RA development.

Quantitave Analysis of Cadherin-11 and Beta-Catenin Signaling during Proliferation of Rheumatoid Arthritis-Derived Synovial Fibroblast Cells. Ryosuke Yoshioka, Yasuhiro Kita, Asako Nagahira, Atsushi Manno, Naoyuki Makita, Urara Tomita and Masao Murakrawa. Asubio Pharma Co., Ltd., Kobe, Japan.

Background/Purpose: Cadherin-11 (CDH11) is a cadherin adhesion molecule that anchors b-catenin, and is involved with various functions of synovial fibroblast cells (SFCs) during the development of rheumatoid arthritis (RA). However, the functional mechanism of CDH11 during RA-SFC proliferation is unclear. The aim of our study was to clarify the involvement of CDH11 and b-catenin signaling during human RA-SFC proliferation.

Methods: In order to investigate the involvement of CDH11 and b-catenin to proliferation, BrdU incorporation assay with each siRNA treatment was carried out. The effect of knockdown was determined by western blotting and immunohistochemistry. The values of E_{max} and EC_{50} in proliferation were caluculated by regression analysis with GraphPad Prism.

Results: Using CDH11 specific siRNAs, there were a 42% reduction in IL-1b-induced human RA-SFC proliferation and a 64% reduction in b-catenin protein levels. When b-catenin specific siRNAs were applied, there was a 63% reduction in IL-1b-induced RA-SFC proliferation. The EC_{50}values for IL-1b during RA-SFC proliferation via CDH11-mediated b-catenin-dependent, total b-catenin-dependent, and b-catenin-independent signaling were 0.0015, 0.016, and 0.18 ng/mL, respectively. Blocking homophilic CDH11 ligation with a CDH11 neutralizing antibody did not decrease IL-1b-induced RA-SFC proliferation.

Conclusion: CDH11-mediated b-catenin signaling was 42% involved in IL-1b-induced human RA-SFC proliferation and had the highest susceptibility to IL-1b. The mode of action for CDH11 during the cell proliferation was likely associated with a pool of b-catenin protein. In contrast to IL-1b, CDH11 and b-catenin were not involved in TNF-a-induced RA-SFC proliferation.

1462

Cadherin-11 mRNA Expression in the Peripheral Blood of Rheumatoid Arthritis Patients As a Marker of Active Polyarthritis. Petros P. Sfikakis[1], Panagiotis F. Christopoulos[2], Aristeidis G. Vaiopoulos[2], Kalliopi Fragkiadaki[1], Christina Katsiari[3], Violetta Kapsimali[4], George Lallas[1], Panayiotis Panayiotidis[4], Pinelopi Korkopoulou[5] and Michael Koutsilieris[2]. [1]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]Department of Physiology, Athens University Medical School, Athens, Greece, [3]School of Health Sciences, University of Thessaly, Larissa, Greece, [4]Department of Microbiology, Athens University Medical School, Athens, Greece, [5]Department of Pathology, Athens University Medical School, Athens, Greece.

Background/Purpose: Human rheumatoid arthritis synovial fibroblasts (RASF) implanted subcutaneously in immunodeficient mice trans-migrate through the vasculature and drive the progression from oligo- to poly-articular disease. On the other hand, RASFs overexpress the mesenchymal cadherin-11, an adhesion molecule involved in tumor invasion and metastasis and cadherin-11 therapeutics prevent and reduce experimental arthritis. We tested the hypothesis that aberrant expression of cadherin-11, deriving from possibly circulating RASFs with pathogenic potential, can be identified in the peripheral blood of patients with active RA.

Methods: Cadherin-11 mRNA was quantified by real-time reverse transcription-PCR in peripheral blood (3ml) from 100 consecutive RA patients (15 studied serially) and 70 healthy controls. Western blotting and flow cytometry were performed in synovial fluid and peripheral blood using an anti-cadherin-11 antibody that decorated RASFs in synovial tissue's immunohistochemistry.

Results: Cadherin-11 mRNA was detected in 69.2% of moderately or severely active disease, versus 31.8% of patients with low disease activity or clinical remission ($p=0.001$), versus 17.1 % of healthy controls ($p<0.0001$). Repeated measurements after 2–4 months confirmed these findings. Disease duration was significantly longer in cadherin-11 positive versus negative patients, whereas rheumatoid factor, ESR, CRP levels and treatment modalities were comparable. Notably, among patients with established RA (disease duration longer than one year) cadherin-11 mRNA was detectable in 88.4% of those with active polyarthritis (5 or more tender and swollen joints at the

time of sampling) versus 48.3% in those with oligo- or monoarthtitis ($p<0.0001$). Western blotting experiments were not sensitive enough to reveal cadherin-11 expression at the protein level in either synovial fluid or peripheral blood samples. However, rare cells expressing surface cadherin-11, together, or not, with the pan-hematopoietic marker CD45 were consistently present in RA-derived synovial fluid. Such rare cells were also identified in peripheral blood from 5/6 versus 1/6 patients with established or early, respectively, poly-articular RA.

Conclusion: Cadherin-11 mRNA transcripts in the peripheral blood may serve as the first biomarker of active polyarthritis in established RA. Rare circulating cells expressing surface cadherin-11 in patients with RA could possibly represent macrophages and RASFs; the latter could enter the circulation as the synovium transforms into an hyperplastic, invasive tissue with new vessel formation. Taken together, these data further identify cadherin-11 as a potential therapeutic target in RA.

Dickkopf-1 Perpetuated Synovial Fibroblast Activation and Synovial Angiogenesis in Rheumatoid Arthritis. Li Zheng, Fanlei Hu, Yingni Li, Lianjie Shi, Xiaoxu Ma, Xuewu Zhang and Zhanguo Li. Peking University People's Hospital, Beijing, China.

Background/Purpose. Dkk-1, a master regulator of joint remodeling, is elevated and leads to bone resorption in patients with RA. This study aimed to investigate the contribution of Dkk-1 to synovial inflammation and synovial fibroblasts-mediated angiogenesis in RA.

Methods: Dkk-1 concentration in synovial fluids from RA and osteoarthritis (OA) patients was evaluated by ELISA. The expression of Dkk-1 in RA synovial fibroblasts (RASF) and OASF was compared by real-time PCR and ELISA. RASF were stimulated with different pro-inflammatory factors and the expression of Dkk-1 was determined by real-time PCR and ELISA. The expression of angiogenic factors (MCP-1, SDF-1, VEGF, ADAM-10 and CD147), pro-inflammatory cytokines (TNF-α, IL-6, IL-8 and IL-1β), and MMPs (MMP-1, MMP-3 and MMP-9) in RASF was determined by real-time PCR when DKK-1 was knocked down or overexpressed. Meanwhile, the levels of MCP-1, IL-6, IL-8, and MMP-3 in the cell culture supernatants were determined by ELISA. The effects of Dkk-1 on the MAPK signaling pathway was evaluated by Western blot when it was silenced. Matrigel tube formation assay was employed to reveal the direct and indirect effect of Dkk-1 on synovial angiogenesis.

Results: Levels of Dkk-1 in synovial fluids and synovial fibroblasts were elevated in RA patients. The secretion of Dkk-1 was accelerated by various pro-inflammatory cytokines in RASF, including TNF-α,IL-6,IL-17,INF-$\gamma$and IL-1β. Dkk-1 stimulated the production of potent angiogenic factors, pro-inflammatory cytokines, and MMPs in RASF, while silencing Dkk-1 expression suppressed such factor expression. Silencing Dkk-1 in RASF dampened its mediated capillary tube organization both in direct and indirect manners, accompanied with restrained ERK, JNK, and p38 signaling pathway activation.

Conclusion: Dkk-1 exacerbated synovial fibroblasts-mediated inflammation, cartilage erosion, and angiogenesis in RA. Targeting Dkk-1 might provide novel therapeutic strategy for overcoming the persistent disease.

Numbers of Circulating CD4 Positive CD28null T Cells Are Increased in Patients with Rheumatoid Arthritis and Are Associated with Rheumatoid Factor Positivity but Not Subclinical Cardiovascular Disease. Sarah Skeoch[1], John Waterton[2], Yvonne Alexander[3] and Ian N. Bruce[4]. [1]Arthritis Research UK Centre for Epidemiology and NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]Manchester Metropolitan University, Manchester, United Kingdom, [4]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: CD4+ T cells which lack CD28 co-expression (CD28null cells) account for less than 2.5% of CD4+ T cells in healthy individuals. These cells are pro-inflammatory, resistant to apoptosis and have cytolytic properties. Increased circulating numbers are found in some RA patients and their presence is associated with extra-articular disease. In unstable angina patients, CD28null cells are independently associated with recurrent cardiac events and are thought to promote atherosclerotic plaque rupture. The aims of the current study were to quantify CD28null cells in RA patients and to investigate the association with RA disease characteristics and subclinical cardiovascular disease.

Methods: RA patients with active arthritis, who were not taking a statin, were recruited to a prospective observational study. Clinical and serological evaluation of RA disease characteristics was undertaken including extra-articular involvement, the disease activity 28 score (DAS-28) and the health assessment questionnaire (HAQ). Presence of carotid plaque was evaluated using B-mode doppler ultrasound. Plaque was defined as 2 out of 3: intimal medial thickness$>$1.5mm, luminal protrusion, increased wall echogenicity.

CD28null cells were quantified using flow cytometry. In brief, fluorescently labelled CD45, CD28 and CD4 antibodies were added to whole blood. Following red cell lysis, flow cytometry was used to measure the proportion of CD45+CD4+ lymphocytes which lacked CD28 expression. Presence of an expanded CD28null cell population was defined as $>$2.5% of CD45+CD4+ T cells lacking CD28 expression. Descriptive and non-parametric statistics were used to analyse the data.

Results: 91 RA patients were included in the study and 68 (74.2%) were female. Median (IQR) age and disease duration was 56(48, 62) and 9(4, 19) years respectively. 64 patients (70.3%) were rheumatoid factor positive and 74 patients (81.3%) were ACPA positive. 1 patient had a history of clinical cardiovascular disease.

Expanded CD28null cell populations were found in 28 patients (30.8%). Presence of CD28 null cells were associated with rheumatoid factor positivity ($p=0.02$) but not with ACPA positivity. No association was found with age, disease activity, HAQ, biologic use, extra-articular disease or with carotid plaque.

Conclusion: The current study confirms that this abnormal T cell subset is expanded in a significant proportion of RA patients. There was no association between CD28null cells and carotid plaque but these cells may contribute to plaque destabilisation and rupture rather than plaque development. Prospective evaluation of cardiovascular outcomes in this population is underway.

Follicular Helper T Cells Control Autoimmunity through IL-21/IL-21 Receptor Interaction in RA Patients. Shikha Singla[1], Minzi Chen[2], Jerry Poundsr Jr.[2], Omar Khan[2], Jerald M. Zakem[2], Kismet Collins[2], Tamika Webb-Detiege[2], William E. Davis[2], Robert Quinet[2] and Xin Zhang[2]. [1]Ochner Medical Center, New Orleans, LA, [2]Ochsner Medical Center, New Orleans, LA.

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the synovium, causing progressive joint destruction and reduction in quality of life for patients. Auto-antibodies in RA patients appear prior to the onset of clinic disease, and are responsible for disease progression. Our previous study showed that follicular helper T (Tfh) cells are increased in peripheral blood of RA patients and correlate with anti-citrullinated protein antibodies (ACPAs) production and disease activity score (DAS-28). IL-21 is the signature cytokine produced by Tfh cells. Through its receptor (IL-21R), IL-21 induces B cell differentiation into antibody producing plasma cells, and also promotes T cell differentiation in an autocrine manner. To dissect the role of IL-21 and IL-21R in RA, we examined the IL-21 and IL-21R expression on different subsets of B cells and T cells in RA patients and healthy donors, and determined their correlation with autoantibody level and disease activity.

Methods: Peripheral blood was collected from 50 subjects (25 RA patients meeting 2010 ACR/EULAR RA classification criteria and 25 age/gender matched healthy donors). Tonsils were surgically derived from non-RA donors and used as positive controls. Clinical disease activity was assessed using DAS-28 score. RA patients were divided into four groups based on DAS-28 score ranging from remisson, low, moderate and high disease activity. Serum laboratory measurements including Rheumatoid factor (RF), ACPA, Erythrocyte sedimentation rate (ESR) and C Reactive Protein (CRP) levels were obtained. IL-21 and IL-21R expression on T cell subsets (Tfh, Th1, and Th2 cells) and B cell subsets (naïve B cell, memory B cell, and pre-plasmablast) in peripheral blood and tonsils (naïve B cells, memory B cells, germinal center B cells, and plasma cells) were determined

via flow cytometry. Pearson correlation coefficient was determined in the analysis of correlation between IL-21R expression and clinic parameters.

Results: $ICOS^+CXCR5^+$ Tfh cells were identified in peripheral blood of RA patients. These circulating Tfh cells are the dominant T cell subset producing IL-21. We found that Tfh cells were significantly elevated in RA patients with moderate/high disease activity ($P<0.05$). IL-21R was expressed on naïve B cells, germinal center B cells, and plasma cells in tonsillar lymphoid follicles. As compared to healthy donors, the level of IL-21R expression on naïve B cells, pre-plasma cells, and T cells was significantly elevated in peripheral blood of RA patients and correlated with disease activity.

Conclusion: RA patients with moderate/high disease activity have elevated levels of IL-21 expression on Tfh cells and IL-21R expression on B cell subsets, similar to that seen in tonsillar lymphoid follicles. Our results indicate that IL-21/IL-21R pathway is involved in RA pathogenesis. Interruption of IL-21/IL-21R interaction may be a potential therapeutic target for RA patients.

Patients with Active Rheumatoid Arthritis Display an Expanded Population of GM-CSF Expressing Peripheral B Cells. Sofia Adamidi, Anastasia Makris, Christos Koutsianas, Christina Tsalapaki, Emilia Hadziyannis and Dimitrios Vassilopourlos. University of Athens Medical School, Athens, Greece.

Background/Purpose: GM-CSF has been implicated in rheumatoid arthritis (RA) pathogenesis and is being investigated as a novel therapeutic target. B cells secreting GM-CSF have been recently reported to participate in innate immune responses in animal models. The aim of our study was to determine the expression of GM-CSF secreting peripheral B cells in RA patients.

Methods: 23 patients with RA (fulfilling the 2010 ACR/EULAR RA Classification Criteria), 11 disease controls (psoriatic arthritis n=4, osteoarthritis n=3, ANCA-associated vasculitides n=2, Sjögren's syndrome n = 1, giant cell aortitis n=1) and 10 healthy controls were included in the study. Peripheral blood mononuclear cells (PBMC) were stimulated overnight with Phorbol Myristate Acetate (PMA) and ionomycin in the presence of Brefeldin. Cells were then stained with specific antibodies against surface CD19 and intracellular GM-CSF (BioLegend). Positive cells were quantified by flow cytometry (Partec) and compared between the different groups.

Results: 23 RA patients with moderate to high disease activity not receiving anti-rheumatic drugs (females/males=19/4, DAS28-CRP=5.53 ± 0.84, median disease duration=14 months, RF and/or anti-CCP+=52%) were studied. The % of peripheral B cells (CD19+) was similar between the RA and the 2 control groups (6.9 ± 3.9% vs. 6.3 ± 3.5% vs.8.4 ± 1.9%, p=NS). We detected an expanded population of peripheral CD19GM-CSF + cells in RA patients (4.4 ± 2.6%) compared to disease (1.1 ± 1.5%, p=0.0002) and healthy (0.2 ± 0.2%, p=0.00000002) controls while there was no difference between disease and healthy controls (p=0.512). Similarly, we did not observe any difference between seropositive (RF and/or anti-CCP+, 4 ± 2.6%) and seronegative (4.8 ± 2.5%, p=0.347) patients. GM-CSF+ B cell expression did not correlate with RA disease activity measured by DAS28 (p=0.926, Spearman correlation).

Conclusion: Our study shows for the first time an expanded population of peripheral B cells expressing GM-CSF among patients with active RA compared to patients with other inflammatory or non-inflammatory rheumatic diseases and healthy controls. The functional significance of this cell population remains to be determined.

Do G-CSF and Neutrophils Contribute to the Pathophysiology of Rheumatoid Arthritis? Gabrielle Goldberg[1], Simon Chatfield[2], Jane Murphy[1], Ee Shan Pang[1], Yunshun Chen[1], Gordon Smyth[1], Milica Ng[3], Michael Wilson[3], Clare O'Neill[2], Samantha Busfield[3], Arna Andrews[3] and Ian P. Wicks[2]. [1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]The Royal Melbourne Hospital, Melbourne, Australia, [3]CSL Limited, Melbourne, Australia.

Background/Purpose: Rheumatoid arthritis (RA) is characterised by a persistent, but poorly understood interplay between innate and adaptive immunity. Neutrophils are the predominant cell type in inflamed RA synovial fluid (SF). Granulocyte colony-stimulating factor (G-CSF) is a key regulator of neutrophil production, function and survival.

Methods: In this study peripheral blood (PB) neutrophil phenotype and function were analysed according to disease activity (DAS28 scores and other clinical parameters) in RA patients (n=50–60).

Results: We found significant correlations between disease activity and PB neutrophil percentage ($r=0.26$, $p\leq0.05$), as well as between neutrophil activation state (CD62L, CD11b) and the expression of receptors for factors regulating neutrophil production and function. For example, CD62L vs G-CSF-R ($r=0.58$, $p\leq0.0001$); CD62L vs CD35 ($r=-0.37$, $p\leq0.01$); CD62L vs CXCR2 ($r=0.42$, $p\leq0.01$); CD62L vs CXCR1 ($r=0.46$, $p\leq0.001$). To further explore the role of neutrophils and G-CSF in RA, transcriptional profiling using RNASeq was performed comparing: PB neutrophils isolated from healthy donors (HD) and RA patients (n=5); neutrophils isolated from paired PB and SF samples of RA patients (n=3); neutrophils or white blood cells from HDs stimulated with G-CSF *in vitro* (n=4). 194 genes were differentially expressed (DE) in RA neutrophils ($logFC\geq1$; adjusted $p\leq0.05$) when compared to HDs. Over 50 of those genes were also differentially expressed when neutrophils were stimulated with G-CSF *in vitro*. There were 1724 DE genes ($logFC\geq1$; adjusted $p\leq0.05$) when comparing PB and SF neutrophils from RA patients. Bioinformatic interrogation using Ingenuity Pathway Analysis software demonstrated that G-CSF was a likely regulator ($p=9.83\times10^{-21}$) of these differences.

Conclusion: These data provide evidence that neutrophils and G-CSF contribute to the pathogenesis of RA. G-CSF may therefore represent a potential therapeutic target in the treatment of RA and other inflammatory diseases where there is a pathogenic contribution from neutrophils.

Mechanism of Effectiveness of IL-6 Blockade for Reduction of SAA Production and Amyloid a Deposition in AA Amyloidosis Patients with RA. Kazuyuki Yoshizraki. Osaka University, Osaka, Japan.

Background/Purpose: AA amyloidosis is a serious complication of chronic inflammatory and infectious diseases resulting from the deposition of amyloid A protein. Serum amyloid A (SAA).a precursor molecule of AA protein produced in hepatocyte, is deposited in various organs as amyloid fibril during the development of AA amyloidosis. Proinflammatory cytokines, especially IL-6, play a key role in SAA production.

Methods:

1. The expression of SAA mRNA in hepatoma-derived cells treated by cytokines (IL-6, IL-1, TNF-a) with or without their inhibitors was examined by quantitative real-time PCR. Luciferase assay, EMSA and Chip assay were also used for analysis of SAA transcription mechanism
2. Clinical effects of IL-6 blockade on amyloidosis-related parameters including serum SAA, urinal protein and RA disease activity were evaluated in AA amyloidosis patients with RA. Scores of amyloid deposits in gastro-duodenal mucosal biopsy specimens were examined by histopathological staining and protein quantitative ELISA.

Results:

1. Our results proved that IL-6 plays a critical role in cytokine-driven SAA expression through STAT3 activation. TNF-a/IL-1 complementally contributes to the synergistic induction of the triple-cytokines-induced SAA gene through NF-kB activation. We further found that a novel STAT3 non-consensus TFBS at the immediate downstream of the NF-κB RE in the SAA1 promoter region that is required for NF-κB p65 and STAT3 to activate SAA1 transcription. In addition, the synergistic induction of SAA expression by cytokines combination was completely inhibited by tocilizumab but not by TNF-a or IL-1 inhibitor.
2. 23 AA amyloidosis with RA patients treated with tocilizumab showed significant improvements in disease activity, and reductions in serum SAA and urinal protein levels, and these effects were more pronounced in the tocilizumab group than in the TNF-a inhibitors group at 12 months after initiation of the treatment. Meanwhile, histological scores of AA deposition observed in gastroduodental biopsy specimens treated with tocilizumab showed significantly decrease in the area and concentration of amyloid deposits after the treatment.

Conclusion: Although activated NF-kB by IL-1 and TNF-a is also involved hepcidin production during inflammation, IL-6-activated STAT3 plays a key role in SAA regulation. Our clinical results with IL-6 blockage therapy suggest that the pathogenic cascade causing AA amyloidosis started from SAA induction by IL-6, so that IL-6 blockage constitute a promising molecular targeting therapy for AA amyloidosis.

Methotrexate Treatment Reduces Serum IL-6 Level By Decreasing a CD14brightCD16+ Intermediate Non-Classical Subset of Monocytes in RA Patients. Masako Tsukamoto[1], Keiko Yoshimoto[1], Noriyuki Seta[2], Katsuya Suzuki[1] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Keio university, Tokyo, Japan.

Background/Purpose: It is well known that circulating monocytes are the source of inflammatory cytokines, such as IL-6 and TNFα and newly divided into three subsets based on the expression levels of CD14 and CD16. We have previously reported that plasma IL-6 level was decreased in RA patients with clinically significant improvement after MTX treatment, but a detail mechanism is not clearly clarified. The purpose of this study is to investigate the association between three subsets of monocytes and change of serum cytokine repertoire after MTX treatment.

Methods: 33 RA patients fulfilled the 2010 ACR/EULAR RA Classification Criteria and 15 healthy donors (HD) were enrolled in this study. The patients had never been received a treatment with DMARDs or biological agents and had moderate disease activity or more (DAS28-ESR $\geq$ 3.2). Peripheral blood samples and clinical records of the patients were obtained at the time of 0 and 12 weeks after MTX treatment. Peripheral blood samples were also obtained HD. The expression levels of CD14 and CD16 on monocytes and serum levels of cytokines were measured by flow cytometric (FACS) analysis and multiplex electrochemiluminescence assays on the Meso Scale Discovery SECTOR Imager 2400 platform®, respectively. A decrease in DAS28-ESR of 1.2 or more was defined as a clinically significant improvement after MTX treatment.

Results: The mean DAS28-ESR score of the patients was 4.8 $\pm$ 0.8. There was no significant difference in clinical backgrounds between RA patients with and without improvement. Serum levels of IL-6, IL-8 and IL-10 at baseline were significantly higher in RA patients compared with HD. Only IL-6 significantly decreased in RA patients with improvement after MTX treatment. FACS analysis revealed that the proportion of CD14brightCD16+ monocytes was significantly decreased in RA patients at baseline (13.9 $\pm$ 6.9%) compared with HD (7.3 $\pm$ 2.1%) ($p<0.01$). After MTX therapy, the proportion of CD14brightCD16+ monocytes was significantly decreased (14.0 $\pm$ 6.5% vs 9.3 $\pm$ 5.0%, $p<0.01$) in RA patients with improvement, but not in those without ($p=0.3$). Moreover, the proportion of CD14brightCD16+ monocytes were significantly and positively correlated with serum IL-6 level and DAS28-ESR ($p=0.01$ and $p<0.01$) in RA patients.

Conclusion: These results indicate that CD14brightCD16+ intermediate non-classical monocytes possibly play an important role in the pathogenesis of RA by producing IL-6 and the curative effect of MTX may be demonstrated through the reduction of CD14brightCD16+ monocytes in peripheral blood.

Malondialdehyde-Acetaldehyde Adducts (MAA) and Anti-Malondialdehyde-Acetaldehyde Antibody in Rheumatoid Arthritis. Geoffrey Thiele[1], Michael J. Duryee[2], Daniel Anderson[1], Lynell W. Klassen[1], Stephen Mohring[2], Kathleen Young[2], Dathe Benissan-Messan[2], Harlan Sayles[1], Jeremy Sokolove[3], William H. Robinson[4], James O' Dell[1], Anthony Nicholas[5] and Ted R. Mikuls[1]. [1]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA, [4]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [5]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Products of oxidative stress, MAA adducts are highly immunogenic and have been associated with tolerance loss. To examine their potential role in disease-related inflammation, we investigated the presence of MAA adducts and circulating anti-MAA antibody in RA and their relationship with citrullinated proteins and anti-citrullinated protein antibody (ACPA).

Methods: Synovial tissues from RA and OA patients were examined for the presence of MAA-modified and citrullinated proteins. Anti-MAA antibody isotypes were measured in RA cases ($n = 1720$) and healthy controls ($n = 80$) by ELISA. Antigen-specific ACPA was measured in RA cases using a multiplex antigen array. Anti-MAA antibody isotype (IgG, IgM, and IgA) concentrations were compared in a subset of cases ($n = 80$) and controls ($n = 80$), matched based on age, gender, race, and smoking status. Associations of anti-MAA antibody isotypes with disease characteristics, including ACPA, were examined in all RA cases.

Results: MAA-adducted and citrullinated proteins were detected and shown to co-localize in RA synovial tissues (Fig. 1). In contrast, MAA adducts were present in negligible quantity while citrullinated proteins were absent in OA synovial tissue. All anti-MAA antibody isotypes were markedly increased in RA cases vs. controls ($p < 0.001$). Among RA cases, anti-MAA antibody isotypes were associated with anti-CCP antibody and RF positivity ($p < 0.001$) in addition to select measures of disease activity. Higher anti-MAA antibody concentrations were associated with a higher number of antigen-specific ACPA analytes positive in high titer ($p < 0.001$) and a higher ACPA score ($p < 0.001$), defined as the sum of normalized fluorescent values divided by the number of analytes examined (Fig. 2). Associations of anti-MAA antibody isotypes with ACPA score and the number of analytes positive were independent of other covariates.

Conclusion: This is the first study to show that MAA adduct formation is increased in RA and appears to result in robust antibody responses that are strongly associated with ACPA. These results support speculation that MAA adduct formation may be a co-factor that drives tolerance loss resulting in the autoimmune responses characteristic of RA.

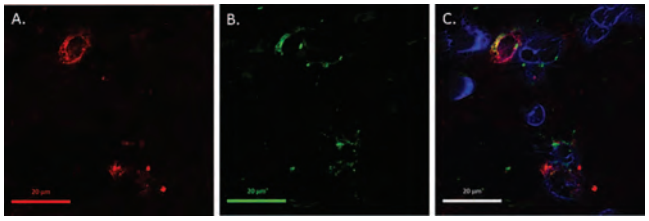

Fig. 1: Immunohistochemical staining of RA synovial tissue demonstrated the presence of: a) citrullinated proteins, b) MAA, and c) co-localization of citrullinated proteins and MAA adducts.

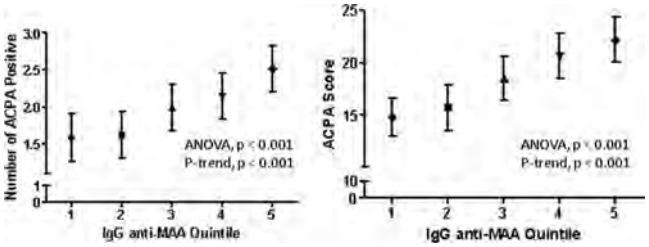

Fig. 2: Number of ACPA analytes positive (left) and total ACPA score (right) based on the quintile of circulating IgG anti-MAA antibody; similar results observed for IgA and IgM anti-MAA isotypes (data not shown).

1471

TNFα Influences the Status of B and T Cells By Acting on BCR and TCR Pathways *Via* RasGRP1 and RasGRP3 Proteins. Marie-Laure Golinski[1], Martine Hiron[2], Céline Derambure[2], Clément Guillou[1], Manuel Fréret[2], Olivier Boyer[3], Olivier Vittecoq[4] and Thierry Lequerré[5]. [1]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, Rouen, France, [3]INSERM U905, University of Rouen, Rouen, France, [4]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France, [5]Chu De Rouen, Rouen, France.

Background/Purpose: Rheumatoid arthritis (RA) is the most common inflammatory arthritis. B and T cells play a key role in the RA pathophysiology. RasGRP is a member of the CDC25 family of Ras guanyl nucleotide exchange factors. RasGRP1 is expressed in T and B cells whereas RasGRP3 is only expressed in B cells. In previous studies, we have shown that *RasGRP3 gene*expression level significantly decreased in peripheral blood mononuclear cells from RA patients responders to adalimumab and etanercept (anti-TNFa drugs), leading to the question of TNFα involvement in RasGRP1 and RasGRP3 pathways. To study TNFα effects on RasGRP1 and RasGRP3 expression levels *in vitro*.

Methods: We measured, by qRT-PCR and western-blot, RasGRP1 and RasGRP3 expression levels in B and T cells isolated from buffy coat. In each condition, cells were cultured with or without TNFα for 24 or 48 hours. C*ell proliferation was evaluated* by [^{3}H] *thymidine* incorporation. To investigate the TNFα implication on signaling pathways, MAPK and apoptosis protein arrays were used.

Results: In B cells, TNFα induced an increase of *RasGRP1* and *RasGRP3* gene expression levels without effect on B cells proliferation and BCR pathway phosphorylations, but apoptotic pathways were inhibited. In T cells, TNFα increased *RasGRP1* gene expression level but RasGRP1 protein expression level decreased, inhibiting T cell proliferation and TCR pathway phosphorylations.

Conclusion: This study suggests a link, never described previously, between RasGRP1 or RasGRP3 and the TNFa' effects on T and B cells. While the response to anti-TNFα treatments in RA patients modulates RasGRP3 gene expression, TNFα inhibits RasGRP1 protein expression leading to TCR pathway inhibition, in vitro, in pathophysiological condition. The better understanding of TNFα effects on RasGRP proteins could permit a better understanding of the mechanisms of action of TNFα blocking agents on T and B cells.

Synovial Fluid from Rheumatoid Arthritis Patients Modulates the Immunophenotype and Viability of Monocytes. Maria Sole Chimenti, Alberto Bergamini, Eleonora Baffari, Eleonora Ballanti, Alessia Musto, Paola Conigliaro and Roberto Perricrone. Department of "Medicina dei Sistemi", University of Rome "Tor Vergata", Rome, Italy.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease characterized by infiltration of the synovium by inflammatory cells that destroys the cartilage and the bone adjacent to the joint. The thickened synovium, called pannus, causes swelling of the joint with excess of synovial fluid (SF) production. A large number of proteins involved in inflammation and immune response have been identified in SF from RA patients (SF-RA). The aim of this study was to determine the effects of synovial fluids (SF) from RA patients (SF-RA) on surface phenotype, co-stimulatory activity, viability and cytokine production of monocytes, as a model for the interaction between SF and synovial tissue macrophages in RA.

Methods: Purified monocytes from healthy donors were incubated with individual specimens of SF-RA obtained from twelve RA patients with active knee arthritis and then analyzed by flow cytometry for ILT4 and CD86 expression, co-stimulation ability, rate of spontaneous apoptosis and TNFα, IL-1β and IL-10 production. Comparative analysis was carried out with serum from RA patients and medium alone.

Results: Downmodulation of ILT4 and upmodulation of CD86 expression (Figure 1), together with increased ability to co-stimulate $CD4^+$ T cells for IFNγ and TNFα production, was observed in monocytes incubated with SF-RA (SF-RA monocytes) compared with control cells, even under condition of activation by CD40L (Figure 2). A reduction of spontaneous apoptosis was observed in SF-RA monocytes compared to control cells. Adalimumab increased the rate of SF-RA monocytes apoptosis, whereas no significant influence of adalimumab was detected in control monocytes. The TNFα and IL1β response, but not that of IL-10, to LPS was greater in SF-RA monocytes compared with control cells (Figure 3).

Conclusion: Our findings suggest that soluble factors present in SF-RA could function as so-called damage-associated molecular patterns and contribute to increase the effectiveness intra-articular of the immune response and inflammation by increasing monocyte numbers and pro-inflammatory activity.

Manocept-Cy3 Localizes CD206 + Macrophages in Synovial Tissue and Fluid from Rheumatoid Arthritis Patients Differentially Compared to Controls. Nicholas A. Young[1], Larry Schlesinger[2], Thomas J. Rosol[3], Fred Cope[4] and Wael N. Jarjour[1]. [1]The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University College of Medicine, Columbus, OH, [3]The Ohio State University College of Veterinary Medicine, Columbus, OH, [4]Navidea Biopharmaceuticals, Dublin, OH.

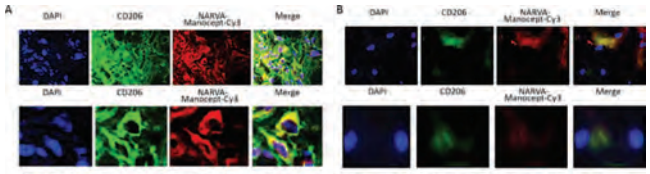
Background/Purpose: Early identification of rheumatoid arthritis (RA) would allow aggressive treatment with disease modifying rheumatic drugs and provide a system to monitor patient responses. Therefore, we developed a fluorescent agent (manocept-Cy3) that targets C-type lectin mannose receptor (CD206) to provide a diagnostic imaging tool for RA. This receptor is expressed on macrophages, which contribute to RA pathology and are strongly implicated in autoimmunity. Manocept-Cy3 follows work that was done in developing Technicium 99m Tilmanocept (Lymphoseek), which is currently used in lymph node mapping of breast cancer patients. The aim of this study was to determine if this agent could also detect these cells in synovial compartments of RA patients; thus providing the foundation to study its potential as an imaging biomarker in RA.

Methods: Rheumatoid arthritis and osteoarthritis (OA) patients, and healthy volunteers were recruited through approved institutional review board protocols. Synovial fluid was isolated and analyzed by flow cytometry. Synovial tissue was flash-frozen at the time of collection for immunohistochemical analysis and fluorescent imaging by microscopy. Tissue was incubated with DAPI nuclear stain, manocept-Cy3, and/or anti-CD206 antibody. Slides were digitally scanned for image analysis to quantitate

manocept-Cy3+ staining. To demonstrate the specificity, samples were stained with an isotype-matched control antibody for CD206 or pre-incubated with 10X unlabeled ("cold") manocept.

Results: Fluorescence microscopy showed that manocept-Cy3+/CD206+ cells were present at high levels in the synovial compartment of RA. These signals were co-localized along cellular membranes, and manocept-Cy3+ staining was statistically significant when compared to OA patients and healthy controls, as measured by digital image analysis. Flow cytometry demonstrated similar levels of CD68, CD206, and manocept-Cy3 in synovial fluid samples. No fluorescent signal was observed in RA synovial tissue incubated with CD206 isotype-matched antibody or with "cold" manocept incubation prior to manocept-Cy3 staining.

Conclusion: The identification of an imaging biomarker that is both sensitive and specific for the RA inflammatory process is critical in the diagnosis of patients with early joint symptoms and in monitoring therapeutic responses. Our results suggest that CD206-targeted manocept is a viable candidate to pursue clinically as an imaging biomarker for RA.



CD206$^+$/NAVRA-Manocept-Cy3$^+$ cells are detected in synovium of Rheumatoid arthritis patients. Synovial tissue was collected from patients with rheumatoid arthritis **(A)** or healthy controls **(B)** and flash-frozen for immunohistochemistry with anti-CD206 (green) antibody, NAVRA-Manocept-Cy3 (red), and DAPI nuclear label (blue). Enhanced image magnification is displayed in subsequent rows. Representative images are shown.

Anti-Peptidyl Arginine Deiminase 4 Antibodies in African-Americans with Rheumatoid Arthritis and Radiographic Scores. Iris Navarro-Millan[1], Andrew Westfall[1], Erika Darrah[2], Antony Rosen[3], Ted R. Mikuls[4], Richard Reynolds[1], Maria I. Danila[1], Jeffrey R. Curtis[1] and S. Louis Bridgesr Jr. [1].[1]University of Alabama at Birmingham, Birmingham, AL, [2]The Johns Hopkins University, Division of Rheumatology, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: The presence of serum autoantibodies to peptidyl arginine deiminase 4 (PAD4) have been associated with erosive rheumatoid arthritis (RA) in populations that were composed of predominantly Caucasian patients with RA but their role has not been studied in African-Americans with RA. We sought to determine the prevalence of serum anti-PAD4 antibodies in African-Americans with RA and if there was an increase in radiographic scores among those patients with anti-PAD4 antibodies (+anti-PAD4) compared to those that were negative for anti-PAD4 (-anti-PAD4).

Methods: Patients with RA included in the study were 193 participants in the Consortium for the Longitudinal Evaluation of African Americans with Early Rheumatoid Arthritis (CLEAR) Registry I and II. For this analysis we combined patients with early RA (CLEAR I) and established RA (CLEAR II). Descriptive statistics were used to determine the main characteristics of the cohort, the prevalence of anti-PAD4, the proportion of radiographic scores >0 among those that were +anti-PAD4 and those that were –anti-PAD4 and the distribution of radiographic scores. All the data for this study were analyzed cross-sectionally.

Results: The mean age was 55 years, mean disease duration was 8 years, 86% of the patients were female, 73% were positive for anti-cyclic citrullinated peptide (CCP). The prevalence of anti-PAD4 antibodies was 24% and 91% of the patients that were +anti-PAD4 were also positive for anti-CCP. There were 83% of the +anti-PAD4 patients that had radiographic scores >0 and 63% in the –anti-PAD4 had radiographic scores >0. The mean radiographic scores for the +anti-PAD4 and –anti-PAD4 patients were 52.8 (SD ± 69.7) and 31.0 (SD ± 59.8), respectively (p-value = 0.005).

Conclusion: In this cross-sectional analysis of African American RA patients, the prevalence of anti-PAD4 antibodies among African-American RA patients was similar to that reported in previous RA cohorts of predominantly Caucasian RA patients. African-American patients with +anti-PAD4 were more likely to have higher radiographic scores than those that were –anti-PAD4. Further analyses where the association of anti-PAD4 antibodies is used to determine radiographic progression among African-Americans with RA is warranted.

***Porphyromonas Gingivalis* and Bone Turnover Biomarkers in Rheumatoid Arthritis.** Manpreet Sethi[1], Anand Dusad[1], Harlan Sayles[2], Geoffrey Thiele[2], Jeffrey Payne[3], Michael J. Duryee[1], Bart Hamilton[4] and Ted R. Mikuls[5]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]University of Nebraska Medical Center, Lincoln, NE, [4]University of Nebraska Medical Centre and Omaha VA Medical Center, Omaha, NE, [5]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Periodontitis (PD) associated with *P. gingivalis* has been implicated as a risk factor for rheumatoid arthritis (RA). We have previously demonstrated that RA patients with PD have more active and more severe disease, the latter reflected by the presence of more radiographic damage in the hands and wrists (Mikuls et al. *Arthritis Rheumatol* 2014). Moreover, we have shown that antigen-specific ACPA are overexpressed in those with PD, including ACPA implicated in osteoclastogenesis and bone damage that characterizes RA. The purpose of this study was to examine whether the presence of subgingival *P. gingivalis* was associated with increased bone turnover and to further explore the associations of bone turnover markers with RA-related autoantibody and joint damage.

Methods: RA patients (n=287) underwent a standardized full-mouth periodontal examination that included the collection of subgingival plaque samples with the presence of *P. gingivalis* identified using PCR. Hand/wrist radiographs were scored using a modified Sharp score. Patients were tested for RF, anti-CCP, and anti-cit-vimentin antibody. Serum bone turnover biomarkers were measured by ELISA and included BAP (MicroVue, an indicator of bone formation); TRAP5b (MicroVue) and cathepsin-K (CTPK; Biomedica), the latter two biomarkers of bone resorption. The Kruskal-Wallis test was used to examine associations of bone biomarkers with the presence of *P. gingivalis* or PD. Spearman rank correlations were used to assess associations between these biomarkers with RA clinical measures.

Results: RA patients with subgingival *P. gingivalis* had significantly higher serum concentrations of TRAP5b (<0.001) and CTPK (p=0.003) compared to those without *P. gingivalis* (Table). CTPK, but not TRAP5b was higher in those with PD vs. those without PD. There was no difference in BAP based on PD or *P. gingivalis* status. TRAP5b demonstrated modest but statistically significant associations with modified Sharp score ($r = 0.16$, $p = 0.01$), anti-CCP ($r = -0.26$, $p < 0.001$), and anti-cit-vimentin ($r = -0.14$, $p = 0.02$) while CTPK demonstrated associations with DAS-28-CRP ($r = 0.13$, $p = 0.03$), anti-CCP ($r = 0.17$, $p = 0.005$), anti-cit-vimentin ($r = 0.13$, $p = 0.03$), and RF ($r = 0.30$, $p < 0.001$).

Conclusion: Serum biomarkers of osteoclast mediated bone resorption, TRAP5b and CTPK, are elevated in RA patients harboring *P. gingivalis* infection and are associated with disease-related autoantibody and joint damage. These results suggest that previously reported links between PD with greater RA disease severity may be related at least in part to oral infection with *P. gingivalis* with detrimental effects on bone that appear to be mediated by the increased osteoclast activity.

Table: Mean (SD) of bone turnover markers in patients with RA (n=287) based on presence/absence of subgingival *P.* gingivalis or PD; p-values generated using Kruskal-Wallis test

	Subgingival *P. gingivalis* (PCR)			Periodontitis (PD)		
Measure	**Positive**	**Negative**	**p-value**	**Positive**	**Negative**	**p-value**
BAP	22.9 (8.0)	22.5 (8.4)	0.484	23.5 (8.0)	22.4 (8.2)	0.265
Trap5b	2.6 (2.0)	1.7 (1.3)	<0.001	2.1 (1.4)	2.4 (2.0)	0.790
CTPK	13.6 (59.5)	4.5 (10.3)	0.003	11.0 (46.9)	10.2 (49.6)	0.008

A Dose Response Relationship Between Shared Epitope and ACPA Level: But Not All SE Alleles Are Created Equal. Jeremy Sokolove[1], Lauren J. Lahey[1], Catriona Wagner[2], Irene Smolik[3], David B. Robinson[3], Elizabeth D. Ferucci[4], Marianna Newkirk[5], Marvin Fritzler[6], William H. Robinson[7] and Hani El-Gabalawy[3]. [1]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA, [2]VA Palo Alto Healtlh Care System and Stanford University, Palo Alto, CA, [3]University of Manitoba, Winnipeg, MB, [4]Alaska Native Tribal Health Consortium, Anchorage, AK, [5]McGill University, Montreal, QC, [6]University of Calgary, Calgary, AB, [7]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA.

Background/Purpose: Indigenous North American populations have high prevalence of seropositive RA. The Cree/Ojibway population in Central Canada and the Alaska Native population have a high prevalence of SE alleles, specifically DRB1∗0404 and ∗1402. Presence of the SE with the non-SE allele∗0901, is associated with early RA onset and the presence of ACPA in unaffected relatives of RA patients. We examined the association of SE copy number as well as specific SE alleles with the depth and breadth and fine specificity of ACPA response.

Methods: RA patient subjects were classified as containing no copies of the SE (n=58), a single copy of the SE (SE/X, n=116), or two copies of the SE (SE/SE, n=58). We similarly stratified subjects with two copies as homozygous (n=36) or heterozygous (n=22). Using a multiplex ACPA antigen array, we evaluated the depth of the ACPA response using an ACPA score (sum of all normalized ACPA titers divided by number of epitopes) and the breadth of the ACPA response by defining the total number of ACPA positive. We used significance analysis of microarrays to compare ACPA subtypes between different SE alleles.

Results: Those with one copy of the shared epitope had more ACPA than those with no copies of the SE and those with two copies displayed more ACPA than those with one copy. Among those with two copies of the SE, the highest levels were observed among subjects heterozygous for two different SE alleles compared to those with no copies of the SE ($P<0.01$) and a trend toward higher levels in those with a single SE allele or homozogous for two copies of the same SE allele. Analysis of the predominant SE alleles within this population revealed a gradient of ACPA associations with *1402 positive patients demonstrating increased ACPA compared with all non-1402 patients and more than the *0404 population. ACPA specificities increased among the 1402 patients included several citrullinated fibrinogen epitopes and citrullinated enolase. Subjects with the *0901 allele alone (X/0901) demonstrated no increase in ACPA and no additional contribution 0901 was noted in heterozygotes expressing a single copy of the SE and *0901.

Conclusion: We observed a stepwise increase in depth and breadth of the ACPA response with increasing dose of SE, an effect primarily seen among those heterozygous for two different SE alleles. These observations support reports suggesting that a heterozygous SE allele combination is associated with RA severity. Moreover, the prominence of the *1402 SE allele as a strong risk factor for an expanded ACPA response is intriguing considering the proposed protective effect of serine residues present in positions 11 and 13 of this allele. Exploration of the peptide binding capacity of this MHC molecule will be important in understanding how it may shape the ACPA response.

Overweight and Obesity Are Associated with Reduced Risk of Rheumatoid Arthritis in Men, but Not in Women. Carl Turesson[1], Ulf Bergström[2], Mitra Pikwer[3], Jan-Åke Nilsson[2] and Lennart Jacobsson[2]. [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Lund University, Malmö, Sweden, [3]Mälar Hospital, Eskilstuna, Sweden.

Background/Purpose: There are diverging results on the relation between body mass index (BMI) and risk of rheumatoid arthritis (RA). Several studies have reported different patterns in men and women. Our purpose was to investigate the impact of overweight and obesity on the risk of RA in a prospective study.

Methods: Between 1991 and 1996, 30447 subjects (12121 men; 18326 women) were included in a population based health survey. Height and weight were measured, and life style factors were assessed using a questionnaire. From this population, we identified individuals who developed RA after inclusion by linkage to 4 different RA registers. In a structured review of the medical records, patients were classified according to the 1987 American College of Rheumatology criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the health survey database. The impact of overweight or obesity (BMI > 25 kg/m^2) compared to normal BMI (18.5–25 kg/m^2) on the risk of RA was examined in conditional logistic regression models, stratified by sex.

Results: A total of 172 patients (36 men/136 women, mean age at RA diagnosis 63 years) were diagnosed with RA after inclusion in the health survey. The median time from inclusion to RA diagnosis was 5 years (range 1–13). A total of 51 % of cases and controls combined were overweight or obese. Being overweight or obese at inclusion in the health survey was associated with a reduced risk of subsequent development of RA in men [odds ratio (OR) 0.33; 95 % confidence interval (CI) 0.14–0.76], but not in women (OR 1.01; 95 % CI 0.65–1.54). Men who fulfilled the WHO definition for obesity (BMI >30 kg/m^2) had a significantly decreased risk of RA compared to those with normal BMI (OR 0.08; 95 % CI 0.01–0.67), and there was a similar trend for those with overweight (BMI 25–30 kg/m^2) (OR 0.42; 95 % CI 0.17–1.00). Smoking was a significant predictor of RA in both sexes, and negatively associated with overweight/obesity in men. The estimated impact of overweight/obesity on the risk of RA in men was similar in analyses adjusted for smoking (OR 0.37; 95 % CI 0.16–0.87) and analyses adjusted for smoking, level of education and alcohol use (OR 0.37; 95 % CI 0.13–1.04). In women, overweight/obesity had no effect on the risk of RA in multivariate analyses.

Conclusion: Being overweight or obese was associated with a reduced risk of future RA in men. This pattern did not appear to be explained bydifferences in smoking, education or alcohol use. There was no such association in women. Factors related to adipose tissue may contribute to mechanisms that are protective from RA in men.

Pharmacokinetics, Bioavailability and Safety of a Modified-Release Once-Daily Formulation of Tofacitinib in Healthy Volunteers. M. Lamba[1], R. Wang[1], T. Fletcher[2], C. Alvey[1], A. Hazra[1], J. Kushner[1], J. Larmann[1] and T. Stock[2]. [1]Pfizer Inc, Groton, CT, [2]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). The efficacy and safety of an immediate-release (IR) formulation of tofacitinib, dosed twice daily (BID), has been assessed in patients with active moderate to severe RA. A once daily (QD) posology of tofacitinib will enhance patient convenience, ease of use, and has the potential to optimize compliance.[1] To facilitate QD dosing, a novel modified-release (MR) formulation of tofacitinib at a dose of 11 mg has

been designed to achieve comparability of systemic exposure parameters vs IR 5 mg BID. The study aimed to determine equivalence for extent of exposure between the tofacitinib MR 11 mg vs IR formulation administered as two 5 mg tablets.

Methods: This was a randomized, open-label, 2-period, 2-sequence crossover study conducted in 26 healthy volunteers (HV). Following an overnight fast, HV were randomized to receive single doses of either MR 11 mg or IR 2 × 5 mg. Treatments were separated by a 72-hour (h) washout. Pharmacokinetic (PK) parameters were calculated using non-compartmental analyses (NCA). The primary endpoint was extent of tofacitinib exposure, measured as area under the concentration-time curve from time zero extrapolated to infinite time (AUC_{inf}). A mixed-effects model was used to generate adjusted geometric mean ratios (MR/IR) and 90% confidence intervals (CIs). The steady-state profiles of tofacitinib MR and IR were predicted using single-dose data from this study.

Results: All 26 HV completed the study and were included in the analyses. The study population had mean age of 33.6 years, mean body weight of 77.5 kg, and was 81% male. For the MR and IR formulations, geometric mean AUC_{inf} (ng*h/mL) was 297.5 and 286.3, respectively, resulting in an MR/IR ratio of 103.91% (90% CI 100.49%, 107.45%). Maximum plasma concentration adjusted for formulation ($C_{max,\ adj}$; ng/mL) was 40.75 and 44.10 for MR and IR, respectively, resulting in an MR/IR ratio of 92.40% (90% CI 84.99%, 100.45%). For both parameters, 90% CI values were wholly contained within the 80–125% interval. Mean terminal half-life was 5.71 h and 3.41 h for MR and IR formulations, respectively. The most common AEs were nausea, abdominal pain, back pain, and headache. Incidence of AEs was similar between treatment groups and no serious or severe AEs were reported. Predictions following steady-state dosing indicate similar AUC, peak concentration and minimum concentration values, and similar time above JAK1/3 half-maximal inhibitory concentration signaling thresholds between MR and IR formulations.

Conclusion: This study demonstrates the single dose equivalence of AUC_{inf} and $C_{max,\ adj}$ of the MR and IR formulations of tofacitinib. Single doses of both formulations were well tolerated. This novel MR formulation of tofacitinib facilitates an opportunity to enable QD dosing, while maintaining systemic drug concentrations similar to the IR formulation (administered BID). Multiple-dose studies will be conducted to confirm the steady-state PK profile predictions and demonstrate equivalence between formulations following steady-state dosing.

Impact of Clinical Remission on Physical Function in Patients with Rheumatoid Arthritis Treated with ALX-0061: Post-Hoc Analysis of Phase I/II Data.

Katrien Van Beneden[1], Katrien Verschueren[1], Wouter Willems[1], Heidi Wouters[1], Joke D'Artois[1], Katelijne De Swert[1], Steven De Bruyn[1] and Gerhard Arold[2]. [1]Ablynx nv, Zwijnaarde, Belgium, [2]PRA International GmbH, Berlin, Germany.

Background/Purpose: ALX-0061 is a monovalent IL-6R targeting Nanobody, inhibiting signaling via soluble and membrane IL-6R. The safety, tolerability, efficacy, pharmacokinetics, and pharmacodynamics of ALX-0061 was assessed in a Phase I/II study in patients (pts) with active rheumatoid arthritis (RA) on stable methotrexate (MTX) therapy (1).

Since remission is the recommended treatment target in the management of RA, the purpose of this post-hoc analysis was to assess induction and maintenance of remission during ALX-0061 treatment. In addition, the impact of disease remission on physical function following 24-week treatment with ALX-0061 was also assessed.

Methods: Data were obtained from the multi-center, randomized, double-blind, placebo (PBO) controlled, dose escalation, Phase I/II study (1). During the first 12 weeks (wks) of the multiple ascending dose period, 37 pts received PBO (n=6) or ALX-0061 IV (n=31) at 1 or 3 mg/kg Q4W, or 6 mg/kg Q8W. Patients received stable doses of MTX ranging from 10–25 mg/week. In the second 12 wks period, pts with insufficient EULAR response had the ALX-0061 dose increased or switched from PBO to ALX-0061. 24 pts continued on their originally-assigned ALX-0061 IV dose (8 pts in 1 mg/kg arm, 8 pts in 3 mg/kg arm, and 8 pts in 6 mg/kg arm), 4 pts changed their dosing regimen, and 3 pts switched from PBO to ALX-0061. This post-hoc analysis utilized data from pts whose originally assigned ALX-0061 dose remained unmodified. Clinical remission as defined by both DAS28 < 0.5 defining normal physical function. An improvement in HAQ score 0.25 was considered to be clinically meaningful.

Results: At week 24, 62.5% (15/24) of pts treated with ALX-0061 achieved DAS28<2.6 remission, while remission using the more stringent Boolean criteria was observed in 29.2% (7/24) of the pts. Looking at maintenance of remission between 12 and 24 wks, approximately one third, i.e. 37.5% and 29.2%, of pts treated with ALX-0061 remained in DAS28 remission during the last 3 (at wks 16, 20, and 24) and 4 (at wks 12, 16, 20, and 24) consecutive time points, respectively. Maintenance of remission based on the Boolean criteria was also observed, being 20.8 and 16.7% of the pts for up to the last 3 or 4 successive time points. At week 24, clinically meaningful improvement in HAQ was observed in 66.7% (16/24) of the pts treated with ALX-0061. Compared to pts not in remission, more pts in DAS28 remission at week 24 achieved normal physical function (86.7% vs. 22.2%). Moreover, normal physical function was observed in 100% (7/7) of pts in Boolean remission at week 24.

Conclusion: In this study in pts with established RA, ALX-0061 induced and maintained remission as assessed by both DAS28 and the more stringent Boolean remission definition. Control of disease activity was also important in regaining normal physical function, supporting treat-to-target management of RA as reflected in the EULAR recommendations.

Dose Selection of GLPG0634, a Selective JAK1 Inhibitor, for Rheumatoid Arthritis Phase 2B Studies: PK/PD and Exposure-DAS28 Modeling Approach.

Florence Namour[1], Chantal Tasset[2], Béatrice Vayssière[1], Gerben van 't Klooster[2], Paul Diderichsen[3] and Eugène Cox[4]. [1]Galapagos SASU, Romainville, France, [2]Galapagos NV, Mechelen, Belgium, [3]Quantitative Solution, Breda, Netherlands, [4]Quantitative Solutions, Breda, Netherlands.

Background/Purpose: GLPG0634 is an orally-available, selective Janus kinase 1 (JAK1) inhibitor. Selective inhibition of JAK1 may combine favorable safety and clinical efficacy profiles with rapid onset of action. GLPG0634 showed encouraging pharmacodynamics, safety and efficacy in early clinical studies treating RA patients for 4 weeks. Here the contribution of exposure-response (E-R) modelling and simulation to support GLPG0634 dose selection for Phase 2B studies is presented.

Methods: Population predicted and individual responses to treatment were investigated on the basis of simulated exposures to GLPG0634 and its main metabolite. Non-linear mixed-effects E-R models were built to describe the proportion of cells showing phosphorylation of STAT1 following activation with IL-6 in healthy subjects (JAK1 activity, PD response) and DAS28 improvement from baseline in RA patients treated for 4 weeks (clinical response). Continuous covariates were evaluated in the models as a power function while binary covariates were tested as factors. The pSTAT1 response over 24-h at steady state and the contribution of the active metabolite to the biomarker response, were predicted for a male with bodyweight of 75 kg. The DAS28 E-R model was used to predict the improvement of the clinical response following 12 weeks of GLPG0634 treatment. Simulations of both biomarker and clinical responses were investigated over a 30 to 300 mg daily dose range.

Results: The PK of GLPG0634 and its active metabolite were adequately described by an integrated model with two- and one-compartmental disposition, respectively. The observed pSTAT1 response was described by a sigmoidal E_{MAX} model, with EC_{50} values of 471 ng/mL and 1770 ng/mL for GLPG0634 and its metabolite, respectively. The steady state inhibition of pSTAT1 was predicted to be between 64.3% (pre-dose) and 91.9% (at C_{max}) following treatment with 200 mg GLPG0634 QD with no relevant increase in PD response at higher doses. Biomarker response over the dosing interval correlates with the time profiles of GLPG0634 and its metabolite. While inhibition is maximal at the peak of GLPG0634, the sustained inhibition correlated with the long lasting metabolite exposure. The observed DAS28 change from baseline was adequately described by a linear direct response model using the individual predicted metabolite exposure as a predictor of response. The population DAS28 change from baseline was predicted to be -2.2 and -2.6 at week 4 and 12 following 200 mg GLPG0634 QD with no further improvement in DAS28 response at higher

doses. No covariates were included in the models of biomarker or clinical response.

Conclusion: Current modeling and simulation on the basis of early clinical data support that both GLPG0634 and its main metabolite contribute to JAK1 inhibition, as reflected in pSTAT1 biomarker response. Simulations of the pharmacodynamics (pSTAT1) and efficacy (DAS28) show a dose-related response with a maximum efficacy achieved at a daily dose of 200 mg GLPG0634. No further gain is obtained at higher doses. The overall clinical response is in the range of that observed with registered biological DMARDS. A daily dose range from 50 to 200 mg is currently being tested in the DARWIN Phase 2B program.

Phase 1 and Phase 2 Data Confirm That GLPG0634, a Selective JAK1 Inhibitor, Has a Low Potential for Drug-Drug Interactions. Namour Florence[1], Desrivot Julie[1], Annegret Van der Aa[2], Chantal Tasset[2] and Gerben van 't Klooster[2]. [1]Galapagos, Romainville, France, [2]Galapagos NV, Mechelen, Belgium.

Background/Purpose: GLPG0634 is an orally-available, selective Janus kinase 1 (JAK1) inhibitor. Selective inhibition of JAK1 may combine improved safety and clinical efficacy profiles with a rapid onset of action. GLPG0634 showed encouraging safety and efficacy results in early clinical studies treating RA patients for 4 weeks. As RA patients can be on multiple medications, an understanding of the potential for drug-drug interaction was of interest.The exploration of potential drug-drug interactions *in vitro* and in humans is presented here.

Methods: Inhibition or induction of drug-metabolizing enzymes [CYP450, uridine glucuronyltransferases (UGT)] and key drug transporters (Pgp, BCRP, BSEP, OATs, OCTs, OATP1B1 and OATP1B3) were studied using human microsomes, cell systems or recombinant enzymes with reference substrates as suitable. An open-label study in healthy subjects was conducted to confirm the in vitro conclusion on interaction potential with CYP3A4 by evaluating the effects of GLPG0634 co-administration on a sensitive CYP3A4 substrate, midazolam. The oral pharmacokinetics of midazolam was assessed following a single dose of 2 mg prior to and after once daily dosing of 200 mg GLPG0634 for 7 days. Furthermore, the potential interaction with methotrexate, a drug commonly administered to RA patients and shown in vitro to be partially eliminated in urine by OCTs transporters was investigated during a clinical study in RA patients treated with up to 300 mg daily dose GLPG0634 for 4 weeks.

Results: *In vitro* studies showed that the GLPG0634 metabolism is not CYP450 dependent and is mediated by carboxylesterases (CES)with 70% of the metabolite produced by CES2. *In vitro*, GLPG0634 and its main metabolite do not induce CYP1A2, CYP2B6 and CYP3A4 at concentrations at least two-fold of the peak concentration (C_{max}) in patients administered a 200 mg daily dose of GLPG0634. The IC_{50} for inhibition of each of the CYPs tested and UGT1A1 and UGT2B7 is at least 7-fold above the C_{max} for GLPG0634 and its main metabolite. Drug transporters are not inhibited by GLPG0634 and its metabolite, except minor effects on OCT2. The IC_{50} for OCT2 inhibition are 2.6- and 6.2-fold over the C_{max} values of GLPG0634 and its metabolite, respectively, after a daily dose of 200 mg, while. In healthy subjects, there was no difference in the plasma midazolam pharmacokinetic profile with and without GLPG0634. Adjusted geometric ratios for midazolam plus GLPG0634 were 99.3% [87.6–112.5%] and 105.4% [94.8–117.3%] for C_{max} and AUC, respectively, well within the no effect boundary guidelines (80–125%). In RA patients, neither the C_{max}, nor AUC of methotrexate in plasma was influenced by the co-administration of GLPG0634, with mean values of 156–172 ng/mL and 568–680 ng.h/mL for C_{max} and AUC, respectively. GLPG0634 was safe and well tolerated.

Conclusion: The clinical data show a lack of relevant drug interactions by GLPG0634 with CYP3A4 substrates, either through inhibition or induction of CYP3A4 activity in humans, as well as with OCTs transporters via methotrexate elimination. All together the *in vitro* data on CYP450s, UGTs and key drug transporters, support that GLPG0634 can be co-administered with drugs usually administered to RA patients without dose adjustment.

Response of Patient Reported Symptoms of Stiffness and Pain during the Day from Adding Low-Dose Delayed-Release (DR) Prednisone to Stable DMARD Therapy over 12 Weeks in Patients with Moderate Rheumatoid Arthritis (RA). Rieke Alten[1], Amy Y. Grahn[2], Patricia Rice[3], Robert Holt[4] and Frank Buttgereit[1]. [1]Charité University Medicine, Berlin, Germany, [2]Horizon Pharma, Inc., Deerfield, IL, [3]Premier Research, Naperville, IL, [4]University of Illinois-Chicago, Vernon Hill, IL.

Background/Purpose: RA patients experience stiffness which impacts their daily lives. Although this patient reported symptom was dropped from the RA classification criteria there is growing interest in understanding more about stiffness in RA. (1) Stiffness is described in temporal terms (morning, evening) and patients report difficulty distinguishing stiffness from pain and swelling. (1) The CAPRA-2 (C2) study previously demonstrated significant relative reductions in patient reported morning stiffness duration and severity with 5 mg daily DR prednisone as compared to placebo in RA patients receiving non-biologic DMARDs. (2) We report the 12 week relative change of reoccurrence of joint stiffness and pain during the day collected by patient diary to further characterize these symptoms. Previously a strong correlation between morning stiffness severity and morning pain was reported for C2. (3)

Methods: RA patients with moderate disease on non-biologic DMARDs previously randomized (2:1) to receive DR-prednisone or placebo were evaluated at baseline (BL), 2, 6, and 12 weeks for relative changes in patient reported outcomes listed in Table 1. Data on relative change from baseline to 12 weeks were analyzed for the modified-intent-to-treat population under observed-case and last observation carried forward (LOCF) conditions. Significance (least square means) and 95% confidence intervals were established based on the mean relative percent change from BL. Point biserial correlation of daily reoccurrence of joint stiffness (Y or N) and pain (100mm VAS) for all patients was performed.

Results: 350 moderate RA patients mean age 57, 58% female, mean duration of RA 8 years, 94% naïve to prednisone. 231 received 5 mg DR prednisone and 119 received placebo, all on stable DMARDs. There was a statistically significant reduction in reoccurrence of joint stiffness during the day over the 12 weeks; pain decreased for all patients with no difference in treatment groups (Table 1). Patient global assessment, SF-36 physical function and analgesic use showed significance between treatment groups. There was moderate correlation of reoccurrence of joint stiffness and pain ($r = 0.47$).

Conclusion: Adding DR prednisone to the treatment of RA patients on non-biologic DMARDs produced statistically significant reduction in reoccurrence of joint stiffness during the day, improvements in patient global assessment and SF-36 physical function and a decrease in analgesic use over 12 weeks. Correlation was shown regardless of treatment between reoccurrence of joint stiffness and pain during the day further supporting the strong patient relationship of symptoms of stiffness and pain reported previously.(3)

Efficacy and Safety of Baricitinib in Japanese Rheumatoid Arthritis Patients during a 52 Week Extension Phase. Yoshiya Tanaka[1], Kahaku Emoto[2], Zhihong Cai[2], Douglas E. Schlichting[3], Terence Rooney[3] and William Macias[3]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Eli Lilly Japan K.K., Kobe, Japan, [3]Eli Lilly and Company, Indianapolis, IN.

Background/Purpose: Baricitinib (bari), an oral JAK1/JAK2 signaling inhibitor, was evaluated in a blinded phase 2b study for 12 weeks as a treatment for rheumatoid arthritis (RA) in Japanese patients (pts) on background methotrexate therapy[1]. Clinical efficacy (ACR20 response) was significantly greater for a combined 4- and 8-mg QD baricitinib group versus placebo (PBO) and safety signals were consistent with previous experience in non-Japanese pts[2]. Baricitinib's safety and efficacy during an additional 52 weeks of treatment in Japanese RA pts completing the12 week, PBO-controlled study are reported here.

Methods: Pts were randomized (double-blind) to receive PBO or 1-, 2-, 4- or 8-mg baricitinib QD for 12 weeks (Part A; N=145). At 12 weeks, pts receiving PBO or 1- or 2-mg baricitinib were randomized 1:1 to 4- or 8-mg bari QD for an additional 52 weeks (Part B). Pts receiving 4- or 8-mg baricitinib QD during Part A received the same doses in Part B. However, those receiving 8 mg in Part B were dose-reduced to 4 mg bari QD in a blinded fashion, upon approval of a protocol amendment. Pts and investigators remained blinded to Part B treatment assignment. Efficacy and safety were evaluated by ACR response, measures of low disease activity (LDA) and remission, adverse events (AEs), and discontinuation rates.

Results: Of 145 pts randomized in Part A, 141 entered Part B and received 4 mg (n=71) or at least one dose of 8 mg (n=70) baricitinib QD (Table). Rates of ACR20 responses at 64 weeks were 66% and 73% for the 4- and 8-mg baricitinib groups, respectively. LDA rates ranged from 48% to 65% and 53% to 70%, respectively, for 4- and 8-mg baricitinib groups. Remission rates ranged from 32% to 56% and 24% to 66% for 4- and 8-mg baricitinib groups, respectively. No deaths occurred during the study. Incidences of serious AEs (SAEs) were 11% and 17% for 4- and 8-mg baricitinib, respectively. Incidences of AEs leading to discontinuation were 21% and 17% for 4- and 8-mg groups. AE incidences leading to study drug interruption occurred for 25% of 4 mg and 43% of the 8 mg baricitinib groups. Treatment-emergent AEs (TEAEs) occurred in over 95% of all pts during Part B. For those pts with TEAEs 74% and 68% were rated as mild and 9% and 12% were rated as severe for the 4- and 8-mg baricitinib groups, respectively. Treatment-emergent (TE) infections occurred in 66% of pts in each group with 3% and 6% of pts experiencing a serious infection for the 4- and 8-mg groups, respectively.

Conclusion: In a single-blind 52 week extension of a phase 2b study in Japanese RA patients, efficacy rates observed at 12 weeks[1] were well maintained at 64 weeks for patients on either 4- or 8-mg baricitinib QD. Consistent with prior phase 2 data, the benefit: risk profile seen during 64 weeks of treatment in this study continues to support further development of baricitinib for treatment of RA.

Discovery of ARN-4079 - a Potent, Orally Available Dual Target Inhibitor of Janus Kinase 3 (JAK3) and Interleukin-2 Inducible T-Cell Kinase (ITK) for Rheumatoid Arthritis. Hariprasad Vankayalapati[1], Venkatakrishnareddy Yerramreddy[1], Philip Bendele[2], Alison Bendele[3], Rueban Jacob Anicattu Issac[4], Ram Sudheer Adluri[4], Philip LoGrasso[5] and Joel M. Kremer[6]. [1]Arrien Pharmaceuticals, Salt Lake City, UT, [2]Bolder BioPATH, Inc., Boulder, CO, [3]Bolder BioPATH Inc., Boulder, CO, [4]GVK Biosciences Private Limited., Hyderabad, India, [5]The Scripps Research Institute, Jupiter, FL, [6]Albany Medical College and the Center for Rheumatology, Albany, NY.

Background/Purpose: The Non-receptor tyrosine kinases, JAK3 and ITK are key regulators of cytokine pathways and are important clinically validated targets, which offer the potential for developing targeted therapeutics in treating Rheumatoid Arthritis (RA) and other immunological, inflammatory and autoimmune diseases such as systemic lupus erythematosus, psoriasis, psoriatic arthritis, atherosclerosis, ulcerative colitis and crohns disease. Development of selective small-molecule inhibitors for both JAK3 and ITK is challenging due to the highly conserved ATP binding pocket within the Janus and TEC-kinase family members. Three variable amino acids within the ATP binding pocket of JAK3 and ITK were targeted and inhibitors were rationally designed by employing FIELDS platform. The FIELDS assisted in identifying fragments/scaffolds to a series of lead compounds, and SAR efforts lead to the discovery of the first-in-class irreversible dual JAK3 and ITK inhibitor ARN-4079 for the treatment of RA.

Methods: The JAK3 and ITK enzymatic inhibition and selectivity studies were performed at DiscoveRx. The cell-based profiling using SelectScreen was performed at Life Technologies. *In vivo*cytokine and CIA efficacy studies were conducted using BALB/c and DBA/1OlaHsd mouse models.

Results: Fragment-based discovery and lead optimization of a series of highly selective JAK3 and ITK inhibitors in tandem with control of physicochemical and ADME-Tox properties culminated in selecting clinically ready ARN-4079 from ~300 new chemical entities. ARN-4079 potently inhibited JAK3 and ITK activity with an IC_{50} = 5 nM, and 33 nM in biochemical kinase assay. The ScanKIENTIC Kds were estimated to be 2.5 and 23 nM. ARN-4079 exhibited over 100-fold cellular selectivity within the JAK family and potently inhibited IL-4 induced STAT6 phosphorylation with an IC_{50} = 70 nM. Its low mM inhibition in SelectScreen IL-6, IFN-γ, and EPO supported the JAK3 selectivity and inhibition of PLCγ1-mediated calcium release from $CD4^+$T cells (EC_{50} = 630 nM) *via* TCR engagement supports its ITK selectivity in cells. In a set of *in vivo* experiments, ARN-4079 potently inhibited IL-2, IL-4 and IFN-λ production in mice which are the key characteristics supporting its dual activity. Additionally, ARN-4079 was optimized to have many drug like characteristics in terms of solubility, cell permeation, and DMPK properties. ARN-4079 is an orally available entity (%F = 23), demonstrated efficacy 84% at 60 mg/kg which was equivalent to Tofacitinib in the mouse CIA model. PK studies indicated that, after oral dosing of ARN-4079 reached plasma levels (1080 ng/mL) that are higher or comparable to the therapeutic dose of Tofacitinib (627 ng/mL). Moreover, ARN-4079 showed no toxicity up to doses of 300 mg/kg in rats. On the basis of its strong *in vivo*efficacy and dose tolerability, ARN-4079 was selected for IND enabling studies.

Conclusion: ARN-4079 is a novel, potent, selective small molecule irreversible dual target inhibitor of JAK3 and ITK that has demonstrated dose linear pharmacokinetic, and *in vivo* efficacy in CIA models on par with Tofacitinib. Safety and IND studies are ongoing to develop ARN-4079 as a therapeutic agent for RA.

Analysis of Patient-Reported Outcomes during Treatment with Mavrilimumab, a Human Monoclonal Antibody Targeting GM-CSFRá, in the Randomized Phase 2b Earth Explorer 1 Study. Joel M. Kremer[1], Gerd Burmester[2], Michael Weinblatt[3], Angela Williams[4], Niklas Karlsson[5], Alex Godwood[4] and David Close[4]. [1]Albany Medical College and the Center for Rheumatology, Albany, NY, [2]Charité University Medicine, Berlin, Germany, [3]Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [4]MedImmune Ltd, Cambridge, United Kingdom, [5]AstraZeneca, Molndal, Sweden.

Background/Purpose: Active RA significantly impairs health-related quality of life (HRQoL) and physical function of patients. Granulocyte-macrophage colony-stimulating factor (GM-CSF) plays a key role in macrophage activation and RA pathogenesis, including inflammatory and arthritic pain development. A prior Phase 2a study (EARTH; NCT01050998) in active RA showed that mavrilimumab produced clinically meaningful improvements across a variety of patient-reported outcomes (PROs). Here we assess the benefit experienced by patients in a 24-week Phase 2b study.

Methods: This randomized, placebo (PBO)-controlled, multicenter study (NCT01706926) evaluated the efficacy/safety of 3 subcutaneous mavrilimumab doses vs PBO every 2 weeks (Q2W) over 24 weeks. Patients with adult-onset RA (18–80 years; DAS28-CRP ≥3.2; ≥4 swollen joints; inadequate response to ≥1 DMARD; receiving methotrexate) were enrolled. Co-primary endpoints were changes in DAS28-CRP score (day 1 to week 12) and ACR20 response (week 24). PRO endpoints included changes from baseline and percent responders in patient assessments of pain, HRQoL (SF-36), physical function (HAQ-DI), and fatigue (FACIT–Fatigue). Patients could enter a long-term open-label rescue study from week 12 (not reported).

Results: In total, 326 patients (mean [SD] age 51.8 [11.1] years; female 86.5%) with a mean (SD) DAS-CRP of 5.8 (0.9) and DAS28-ESR of 6.6 (0.9) were randomized to 30, 100, or 150 mg mavrilimumab, or PBO (n=81, 85, 79 and 81, respectively). Both co-primary endpoints (DAS28-CRP at week 12; ACR20 at week 24) were met at all mavrilimumab doses. At weeks 12 and 24, mavrilimumab treatment groups showed improvements in PROs vs PBO (Table), with more than half of patients receiving mavrilimumab 150 mg having a clinically meaningful response. At this dose, significant improvements (p=0.017–p<0.001) were seen vs PBO across multiple PRO endpoints at weeks 12 and 24 (Table). Statistically significant improvements in pain were seen for mavrilimumab from week 1. Of mavrilimumab 30, 100, and 150 mg patients with a pain response at week 12, 72.2% (26/36), 69.2% (27/39), and 66.7% (28/42) maintained responses at week 24. HAQ-DI responses at week 12 were maintained at week 24 in 75.0% (33/44), 84.0% (42/50), and 78.8% (41/52) patients (mavrilimumab 30, 100 and 150 mg, respectively).

Table: PRO Endpoints Data at Weeks 12 and 24

	Week 12				Week 24[c]			
		Mavrilimumab				Mavrilimumab

[a]Vs mean difference from PBO
[b]Responders were defined as: Pain=change from baseline ≤−20; HAQ-DI=change from baseline ≤−0.25; SF-36=change from baseline ≥3.8; FACIT-fatigue=change from baseline ≥3
[c]Mixed model for repeated measures used to handle missing data in analysis of mean change from baseline due to entry to open-label extension at week 12
[d]Week 24 response rates vs PBO not included due to high rates of rescue to open-label extension at week 12
FACIT, functional assessment of chronic illness therapy; HAQ-DI, health assessment questionnaire disability index; MCID, minimal clinically important difference; PBO, placebo; PRO, patient-reported outcome; SE, standard error; SF-36, short form-36

Conclusion: Targeting activated macrophages through inhibition of the GM-CSFRα pathway with mavrilimumab, especially at a dose of 150 mg Q2W, substantially and rapidly reduced RA disease activity. In turn, patients receiving mavrilimumab, vs PBO, reported significant and clinically meaningful sustained improvements in multiple PROs that reflect patients' pain, HRQoL, physical function and fatigue. The majority of mavrilimumab patients with improvement in pain and physical function at week 12 sustained these improvements to the end of the study at week 24.

Background/Purpose: Macrophages are pivotal to rheumatoid pathogenesis and their inflammatory products drive many of the signs and symptoms of disease. Mavrilimumab inhibits macrophage activation and survival via blockade of granulocyte-macrophage colony-stimulating factor receptor-α (GM-CSFRα) and has previously shown a rapid (2 week) and sustained clinical benefit in patients with RA. We present data from the EARTH EXPLORER 1 study examining speed of clinical response to mavrilimumab, and effect on the multi-biomarker disease activity (MBDA) score after week 1 (1 dose).

Methods: This was a Phase 2b, 24-week, randomized, double-blind, placebo (PBO)-controlled study (NCT01706926). Patients with adult-onset RA (18–80 years; DAS28-CRP >3.2; ≥4 swollen joints; inadequate response to ≥1 DMARD) received mavrilimumab (30, 100, or 150 mg) or PBO, administered subcutaneously every 2 weeks + methotrexate (7.5–25.0 mg/week). Efficacy assessments included DAS28-CRP, ACR responses, CRP, ESR, swollen joint count (SJC), tender joint count (TJC) and pain. MBDA score was calculated using the validated Vectra®DA algorithm, based on serum concentration of 12 biomarkers, to track the effect of mavrilimumab on disease over time. Additional assessments were conducted on MBDA biomarker components.

Results: Overall, 326 patients with mean (SD) DAS28-CRP 5.8 (0.9) were randomized to mavrilimumab (30, 100, or 150 mg) or PBO (n=81, 85, 79, and 81, respectively). At week 1 (first assessment), all mavrilimumab doses showed significant reductions from baseline in DAS28-CRP (p<0.001 vs PBO; Figure A), with treatment benefit increasing to week 12. Significant improvements for 150 mg vs PBO were seen at week 1 for CRP, ESR, SJC, TJC, and pain (Table). Effects of mavrilimumab 150 mg were near maximal vs PBO for CRP, ESR, and pain at week 1, and sustained (week 24). SJC and TJC for 150 mg improved from baseline (week 1) and continued to improve (week 12); this was sustained until week 24. Rapid onset of clinical benefit was paralleled with reduction in MBDA

score; 100 and 150 mg showed early (week 1) and sustained (week 24) significant changes in MBDA score vs PBO ($p<0.01$; Figure B), with greater decreases in DAS28-CRP responders vs non-responders (week 12). Approximately ≥50% decreases in serum IL-6, CRP, and serum amyloid-A protein levels were observed at week 1 and maintained during treatment.

A Phase 1 Dose-Ranging Repeated-Dose Trial of Parenteral Staphylococcal Protein A (PRTX-100) in Patients with Active Rheumatoid Arthritis on Methotrexate or Leflunamide Therapy. Craig Wiesenhutter[1], Rakesh Patel[2], John Lavery[3], Nighat Tahir[4], Lydie Hazan[5], Alan Kivitz[6], Elizabeth Bretton[7] and Jeffrey Kaine[8]. [1]Coeur d'Alene Arthritis Clinic, Coeur d'Alene, ID, [2]PMG Research of Salisbury, Salisbury, NC, [3]Allen Arthritis and Allergy, Allen, TX, [4]Community Rheumatology of Anderson, Anderson, IN, [5]Axis Clinical Trials, Los Angeles, CA, [6]Altoona Center for Clinical Research, Duncansville, PA, [7]Albuquerque Clinical Trials, Albuquerque, NM, [8]Sarasota Arthritis Center, Sarasota, FL.

Background/Purpose: Staphylococcal protein A (SpA) binds with high affinity to the Fc region of human immunoglobulin G and also to the Fab framework region of immunoglobulin encoded from genes of the VH3 family. At intravenous doses up to 1.5 μg/kg weekly SpA was found to have an acceptable safety profile in a Phase I rheumatoid arthritis (RA) trial. The current Phase I study evaluates the safety and effect on RA disease activity of 6 months of SpA treatment.

Methods: This study enrolled 61 RA patients (pts) at 8 US centers. In Part 1 of the study, 41 pts received 5 weekly doses of either placebo, 1.5, 3, 6 or 12 μg/kg of SpA. Partial results from Part 1 have been reported previously [1]. In Part 2, pts received placebo or a fixed SpA dose of either 240 μg or 420 μg given as 5 weekly doses followed by 'maintenance' doses at weeks 8, 12, 16 and 20 (6 months' total treatment). Adverse events (AEs), pharmacokinetics, anti-SpA antibodies and disease activity (ACR20/50/70, DAS28-CRP, and CDAI [Clinical Disease Activity Index]) are being evaluated over the course of this ongoing study.

Results: Twenty pts were randomized in Part 2: 3 pts (240 μg), 12 pts (420 μg) and 5 pts (placebo). All AEs were Grade 1 or 2 in severity with the exception of 1 pt who experienced Grade 3 influenza (unrelated to treatment) and 1 pt with Grade 3 worsening of arthritis (related to treatment). 9 pts (45%) had related AEs, the most common being transient flare of musculoskeletal symptoms usually occurring 1–3 days post-infusion. In Parts 1 and 2 of the study, there were no deaths or serious AEs considered to be related to SpA. Nine of the 12 pts in the 420 μg SpA arm met per-protocol criteria for efficacy evaluation. For comparative purposes, the control group was pooled from the 15 placebo pts enrolled in Parts 1 and 2; 13 placebo pts met per-protocol criteria for efficacy evaluation. Of the 9 pts in Part 2 that received 420 μg SpA, 56% achieved ACR20 at day 113 vs. 31% of pts in the control group (see table). A similar pattern was seen with the

ACR50: on day 113, 33% of 9 SpA-treated pts attained an ACR50 vs. 8% of pts in the control group.

ACR20 Responders: 420 μg SpA vs. Placebo

	Study Day								
	1	**8**	**15**	**22**	**29**	**43**	**57**	**85**	**113**
SpA 420 μg (9 pts)	0%	0%	38%	63%	50%	33%	50%	56%	56%
Placebo (13 pts)	0%	11%	31%	23%	31%	25%	39%	39%	31%

CDAI data also indicated some reduction in disease activity, as 44% of 420 μg pts achieved a CDAI of ≤14 on 3 or more consecutive visits vs. 23% of pts in the control group. SpA and control pts had MDHAQ mean physical function scores of 3.57 and 3.59, respectively, at baseline. By day 85, the change from baseline was –1.17 and –0.59 for SpA and control pts, respectively. At day 113, the change from baseline was –1.38 vs. –0.6, respectively.

Conclusion:

- A 6-month regimen of 5 weekly infusions of SpA followed by 4 monthly 'maintenance' infusions had an acceptable safety profile in pts with RA. The most common AEs seemed to be associated with transient worsening of musculoskeletal symptoms.
- During a 6-month study period, SpA appeared to result in some reduction in disease activity. Some patients experienced improvements.

Clinical Efficacy of Add-on Iguratimod Therapy in Patients with Active Rheumatoid Arthritis Despite of Methotrexate ~a Multicenter Registry Study~. Yasuhide Kanayama[1], Toshihisa Kojima[2], Atsushi Kaneko[3], Yuji Hirano[4], Nobunori Takahashi[2], Shinya Hirabara[4] and Naoki Ishiguro[2]. [1]Toyota Kosei Hospital, Toyota, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Nagoya Medical Center, Nagoya, Japan, [4]Toyohashi Municipal Hospital, Toyohashi, Japan.

Background/Purpose: Iguratimod (IGU) is a small-molecule antirheumatic drug that was approved in Japan in September 2012. IGU suppressed tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8, and monocyte chemoattractant protein 1 via inhibition of nuclear factorkappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. IGU also reduced immunoglobulin production by acting directly on human B lymphocytes without affecting B lymphocyte proliferation. Recently, an increased release of extracellular adenosine and a decreased production of lymphotoxins such as ammonia and superoxide have been shown to be involved in the anti-inflammatory mechanisms of methotrexate. Thus, the combination of MTX and IGU may have synergic efficacy for rheumatoid arthritis (RA) treatment. To evaluate the clinical efficacy of add-on IGU in patients with Japanese active RA who had shown inadequate responses to MTX therapy.

Methods: Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been unresponsive to MTX therapy (DAS>3.2 or CDAI>10), and who had been prescribed add-on IGU from Tsurumai Biologics Communication Registry (TBCR) between November 2012 and August 2013 were enrolled. The final study cohort of 51 patients received continuous IGU therapy more than 24 weeks. We reviewed the methods about the improvement of CRP, MMP3, DAS28-ESR and CDAI which was an index of disease activity of RA using Wilcoxon signed-rank test and the rate of remission patients at Week24.

Results: The group of patients included 8 males and 43 females. The mean age was 63.6 ± 10.3 years old; the disease duration was 8.4 ± 9.7 years and the methotrexate dose was 9.6 ± 4.2 mg/week. Clinical findings related to RA were as follows: mean tender joint count, 4.5 ± 4.9; swollen joint count, 4.2 ± 3.9; patient's global assessment of disease activity, 41.5 ± 22.8mm; Physician's global assessment of disease activity, 40.0 ± 20.8mm; CRP, 2.0 ± 2.3 mg/dL; ESR, 42.9 ± 19.2 mm/h; MMP3, 249.7 ± 284.6 ng/ml; DAS28 (ESR), 4.67 ± 0.97; and CDAI, 16.9 ± 9.4. There were no patients who had received Biologics treatment. The mean CRP improved to 1.7 ± 2.2, 1.2 ± 2.0 and 1.1± 1.9 at Week 4, 12 and 24 ($p=0.064$, $p<0.001$, $p<0.001$), mean MMP3 improved to 223.7 ± 266.1, 161.7 ± 242.1 and 148.3 ± 244.4 at Week 4, 12 and 24 ($p=0.045$, $p<0.001$, $p<0.001$), the mean DAS28 improved to 4.26 ± 1.03, 3.44 ± 1.07 and 3.32± 1.28 at Week 4, 12 and 24 ($p<0.001$, $p<0.001$, $p < 0.001$) and the mean CDAI improved to 13.1 ± 8.2, 8.3 ± 6.5 and 7.9± 7.6 at Week 4, 12 and 24 ($p<0.001$, $p<0.001$, $p < 0.001$) significantly. At Week 24 the rate of patients who achieved remission were each 33.3% and 27.5% in DAS and CDAI criteria.

Conclusion: This study suggested that the new combination therapy of add-on IGU with MTX was effective in patients with active RA with inadequate response to MTX.

1489

Influences of Disease Activity at the Initiation of Iguratimod, a Small Molecule Antirheumatic Drug, on Efficacy of Iguratimod in Patients with Rheumatoid Arthritis –a Multicenter Registry Study-. Yuji Hirano[1], Toshihisa Kojima[2], Yasuhide Kanayama[3], Shinya Hirabara[1], Nobunori Takahashi[2], Atsushi Kaneko[4] and Naoki Ishiguro[2]. [1]Toyohashi Municipal Hospital, Toyohashi, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Toyota Kosei Hospital, Toyota, Japan, [4]Nagoya Medical Center, Nagoya, Japan.

Background/Purpose: Iguratimod (IGU), known as T-614, is a small-molecule antirheumatic drug developed in Japan and used in Japanese clinical practice since June in 2012. IGU is known to inhibit nuclear factor-kappa B activation in cultured human synovial cells. Although biological agents (BIO) have good efficacy to treat rheumatoid arthritis (RA), they costs very much. IGU is not comparatively expensive and used as monotherapy or combination therapy with methotrexate (MTX). Data in clinical practice is lacking and necessary for the best use of IGU.This retrospective study investigated efficacy of IGU in RA patients with focus on disease activity at initiation of IGU using data from the Japanese multicenter registry.

Methods: 78 cases (62 female and 16 male) with RA from 9 institutes in Japan were included. These patients were divided into two groups (high disease activity group; HG and moderate and low disease activity group; MLG) using DAS28-CRP at initiation of IGU. 42 cases were included in HG and 36 cases were included in MLG. Patients' characteristics, time course of disease activity, drug retention rate at 24 weeks and change value in disease activity parameters from 0w to 24w were compared with each other.

Results: and Conclusion: Mean age was 68.3 years old in HG and 65.7 years old in MLG. Mean RA duration was 147 months in HG and 94 months in MLG. Although MTX use rate was low in HG compared with in MLG (52.4% vs. 63.9%), there was no significant difference between groups. The mean dose of MTX used was 4.7 mg/w in HG and 5.2 mg/w in MLG. The mean DAS28-CRP at 0, 4, 8, 12 and 24w was 4.99, 4.49, 4.29, 3.70 and 3.58 in HG and 3.24, 3.16, 2.76, 2.62 and 2.56 in MLG. DAS28-CRP was significantly decreased after 4w in HG and after 8w in MLG. Similar findings were observed in SDAI. Drug retention rates at 24w were 81.0% in HG and 86.1% in MLG (not significant). Delta DAS28-CRP from 0w to 24w was 1.4 in HG and 0.7 in MLG ($p=0.04$). Delta SDAI were 11.5 in HG and 4.3 in MLG ($p=0.02$). There were significant differences in delta tender joints counts, delta ESR between two groups and better improvement was seen in HG than MLG. More treatment options other than sufficient MTX and BIO are needed in RA patients with concomitant disease such as lung disease or renal dysfunction. High cost of BIO is another issue to inhibit improvement of signs and symptoms in RA patients. This study suggests that IGU is one of the options not only in RA patients with high disease activity treated with insufficient MTX.

Can Tumor Necrosis Factor Inhibitors Protect Rheumatoid Arthritis Patients from Osteoporosis? Impact of Tumor Necrosis Factor Inhibitors on Bone Mineral Density and Bone Remodeling Markers. Anaïz Nutz[1], Yohan Duny[2], Thomas Barnetche[3], Jacques Morel[4], Bernard Combe[4] and Claire Daien[1]. [1]Hopital Lapeyronie, Montpellier, France, [2]INSERM, Montpellier, France, [3]Department of rheumatology, Bordeau, France, [4]Hôpital Lapeyronie, Montpellier, France.

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by joint and bone destruction. Loss of bone in RA is not only localized in joints but is also generalized. Tumor necrosis factor (TNF) alpha is involved in the pathogenesis of joint erosion and loss of bone. TNF alpha is also known to be an inhibitor of bone formation through Wnt pathway and RANKL/osteoprotegerin balance. The use of TNF alpha inhibitors (TNFi) has effect on focal bone erosions. This has led to the hypothesis that TNFi has a positive effect on bone mineral density. The aim of this study is to summarize the published data on the effect of TNFi on bone mineral density (BMD) and bone markers in RA by a systemic review of the literature and meta-analysis.

Methods: We searched Medline via PubMed, COCHRANE and EMBASE database for articles published up to April 2014 using Mesh terms ("Bone mineral density" (MeSH) OR "bone" (MeSH) OR "bone remodeling" (MeSH) AND "rheumatoid arthritis" AND ("infliximab" OR "adalimumab" OR "etanercept" OR "certolizumab" OR "golimumab" OR "anti-TNF"). To be selected a study need to be a controlled trial with a group treated by TNFi and a control group without treatment of interest or to have values before and after treatment by TNFi or value of variation under treatment of at least one variable among BMD at hip or lumbar spine, CTX-1, Bone Alkaline bone Phosphatase (BAP), osteocalcin (OC) and type 1 collagen amino-terminal propeptide (P1NP). Statistical analysis of pre and post-data was performed using Comprehensive meta-analysis software. The percentage heterogeneity in the study results was determined by the Cochran's Q-test and the I^2 values. A significant statistical threshold of 0.05 was used.

Results: The search retrieved 49 articles. 15 articles complied with inclusion criteria. Although heterogeneity was high, BMD at hip and lumbar spine stay unchanged after TNFi (6 studies for hip BMD including 386 patients and 7 studies for lumbar spine BMD including 443 patients) with a mean difference of 0.058 (−0.220 to 0.337, IC95%) for BMD at hip and of 0.154 (−0.110 to 0.418,IC95%) for BMD at lumbar spine. In controlled trials, no difference was found for BMD at hip or at lumbar spine (6 studies; 558 patients). Concerning bone remodeling markers, CTX level was statistically decreased in 2 studies and showed a trend of decrease in 4 other studies. OC level increased statistically in 4 studies and decreased no significally in a fifth one; P1NP level was increased significally in 1 study of 3 available whereas BAP level did not significally change in studies available (2 studies). BMD change were influenced by therapeutic response to TNFi in 2 studies, with a trend in a third one whereas no association was found in 3 other studies.

Conclusion: TNFi in RA seem to decrease bone resorption and to increase bone remodeling at biologic levels but do not have an effect on BMD. However, only few data with mid-term assessment are available with an important heterogeneity in terms of patients included, disease duration, comedications and follow up. Several long term trials are required to evaluate the exact effect of TNFi on bone mineral density in rheumatoid arthritis.

Discovery and Characterization of COVA322, a Clinical Stage Bispecific TNF/IL-17A Inhibitor for the Treatment of Inflammatory Diseases. Dragan Grabulovski, Michela Silacci, Wibke Lembke, Wenjuan Zha, Richard Woods, Roger Santimaria, Julian Bertschinger and Mathias Locrher. Covagen AG, Schlieren, Switzerland.

Background/Purpose: Biologics such as TNF inhibitors have revolutionized the treatment of inflammatory diseases including rheumatoid arthritis (RA), psoriasis and psoriatic arthritis. However, recent data suggest that full and long-lasting responses to TNF inhibitors are limited because of the activation of the pro-inflammatory T_H17/IL-17 pathway in patients. Therefore, an attractive avenue to achieve superior efficacy levels in inflammatory diseases represents the combined inhibition of TNF and IL-17A. We present here COVA322, a bispecific TNF/IL-17A inhibitor that is currently being tested in a Phase Ib/IIa study in psoriasis patients.

Methods: Using phage display technology we have isolated Fynomers inhibiting human IL-17A. Fynomers are small binding proteins (7 kDa) derived from the human Fyn SH3 domain which can be engineered to bind to essentially any target of interest with high affinity and specificity. After genetic fusion of the anti-IL-17A Fynomer to a commercially validated anti-TNF antibody the resulting bispecific molecule COVA322 was characterized for its stability, dual binding characteristics, and IL-17A and TNF inhibition properties, including the inhibition of human T cell derived cytokines.

Results: The fusion of the anti-IL-17A Fynomer to the fully human anti-TNF antibody did not alter the favorable biophysical properties of the antibody: COVA322 was monomeric and its stability was comparable to the stability of the unmodified antibody. Furthermore, COVA322 could be produced and purified with very high yields (3.3 g/L obtained from our 1000 L GMP run). Importantly, COVA322 inhibited TNF and IL-17A with picomolar inhibition potencies as shown in a variety of different cell assays. Moreover, we could show that COVA322 was able to inhibit human derived cytokines from different donors.

Conclusion: COVA322 is a unique bispecific TNF/IL-17A inhibitor with excellent biophysical properties. It is currently being tested in a first in man, single dose escalation, tolerability, safety, PK and efficacy Phase Ib/IIa study in psoriasis.

Safety and Tolerability of NNC01140006, an Anti-IL-21 Monoclonal Antibody, at Multiple s.c. Dose Levels in Patients with Rheumatoid Arthritis. Frank Wagner[1], Birte Skrumsager[2] and Sergey Fitilev[3]. [1]Charité Research Org GmbH, Berlin, Germany, [2]Novo Nordisk A/S, Søborg, Denmark, [3]Department of Clinical Pharmacology, Municipal Clinic #2, Moscow, Russia.

Background/Purpose: A phase 1, randomised, double-blind, placebo-controlled, dose-escalation trial was conducted to assess the safety and tolerability of the anti-IL-21-antibody NNC0114-0006, in patients with active moderate-to-severe rheumatoid arthritis (RA) on background methotrexate (MTX) monotherapy.

Methods: Patients (N=32; 84% female) with RA (mean duration 8.9 years; 72% RF positive; 63% anti-CCP positive; mean DAS28-CRP 5.4), who were on MTX (mean duration 4.7 years; mean dose 13 mg/week) were enrolled. Patients were randomised to NNC0114-0006 or placebo (3:1) for s.c. dosing every other week for 6 weeks (a total of four doses) at 0.05, 0.25, 1 or 4 mg/kg. Dose levels of NNC0114-0006 were escalated when 6 of 8 patients in a cohort completed the third dose. The primary endpoint was incidence of adverse events (AEs) from first administration until trial completion, 26 weeks later. Secondary endpoints were changes in laboratory measurements, antibodies against NNC0114-0006, and pharmacokinetic (PK) and pharmacodynamic (PD) parameters.

Results: There were no significant differences between the treatment groups with respect to baseline data. One patient in the 1 mg/kg NNC0114-0006 group withdrew informed consent after the second dose due to intensification of joint pain considered possibly related to the use of the trial product. Overall, 42 AEs were reported in 18 of 24 (75%) NNC0114-0006 patients, while 20 AEs were reported in 6 of 8 (75%) placebo patients. Two patients receiving 4 mg/kg NNC0114-0006 experienced serious adverse events, which were considered unlikely related to the use of the trial product. No severe or life-threatening events, or fatalities were observed. Two patients at the highest dose reported AEs related to infections, compared with only one patient in each of the other treatment groups, including placebo. No treatment-related anti-drug antibodies were detected during the course of the trial. No clinically significant changes from baseline levels were observed in laboratory safety parameters. From PK measurements, systemic exposure to NNC0114-0006 increased with increasing dose levels, as expected with a mean half-life of approximately 2.5 weeks. PD assessments demonstrated an expected increase in circulating levels of total (both free and antibody-bound) IL-21 after treatment with NNC0114-0006; however, large interpatient variability was observed. No significant changes were observed in RF, CRP and ESR, IL-21R expression on selected lymphocyte subsets, B cells, or gene expression by microarray from whole blood or fractionated blood.

Conclusion: No safety or tolerability concerns were identified following multiple-dose administration of up to 4 mg/kg NNC0114-0006, and no anti-drug antibodies were detected. NNC0114-0006 has a long terminal half-life (2–3 weeks) and s.c. bioavailability similar to that of other monoclonal antibodies. An increase in circulating levels of total IL-21 after treatment with NNC0114-0006 was observed, as expected. No changes in other PD parameters were observed with increasing doses of NNC0114-0006 compared with placebo.

1493

A Phase 1 Study of FPA008, an Anti-Colony Stimulating Factor 1 Receptor (anti-CSF1R) Antibody in Healthy Volunteers and Subjects with Rheumatoid Arthritis (RA): Preliminary Results. Julie Hambleton[1], Lei Zhou[1], Seema Rogers[1], Sjoerd van Marle[2], Thijs van Iersel[2], James Zanghi[1], Emma Masteller[1], Kevin Baker[1] and Brian Wong[1]. [1]Five Prime Therapeutics, South San Francisco, CA, [2]PRA Health Sciences, Groningen, Netherlands.

Background/Purpose: Activation of CSF1R via IL34 or CSF1 results in activation, differentiation, and survival of monocytes, macrophages and osteoclasts. CSF1R activation produces inflammatory cytokines responsible for joint destruction, thus pathway inhibition may provide a therapeutic benefit to RA patients (pts). FPA008 is a humanized IgG4 anti-CSF1R antibody that blocks ligand binding and has preclinical activity in models of arthritis. This is a double-blind, randomized, placebo-controlled first-in-human trial designed in 3 parts to study safety, pharmacokinetics (PK) and pharmacodynamic (PD) biomarkers. In Parts 1 & 2, healthy volunteers received either one or two doses, respectively. Part 3 will be in RA pts, and clinical and radiographic efficacy parameters will also be explored.

Methods: In Part 1, 8 subjects were randomized (3:1) to receive a single intravenous infusion of FPA008 or placebo, per dose cohort of 0.2, 1, 3, or 10 mg/kg. In Part 2, 8 subjects were randomized (3:1) to receive 2 doses of FPA008 or placebo administered 14 days apart, at 1 or 3 mg/kg. Dose escalation decisions were based on the incidence of dose limiting toxicities (DLTs), plus attributed adverse events (AEs) beyond the DLT period. PK, bone turnover biomarkers, CSF1 and IL34 serum concentrations, and CD16+ monocytes were assessed. Part 3 consists of an open-label evaluation of 3 dose levels in RA pts whose disease is not responding to methotrexate. Three pts per dose level will receive 2 doses of FPA008 administered 14 days apart. Thereafter, 30 new pts will be randomized (2:2:1) to one of two dose levels of FPA008 or placebo, respectively.

Results: As of May 30, 2014, the first 5 cohorts in Parts 1 and 2 (up to 1 mg/kg, two doses) were completed through the DLT period. No DLTs were reported.

Frequently reported AEs were Grade 1 or 2 pruritus, headache and periorbital edema. Dosing in the 10 mg/kg cohort was associated with moderate periorbital edema, facial and finger swelling, and mild, transient blurred vision outside the DLT period. Dose-dependent elevations of CK and LDH were noted at 1 mg/kg and above; AST elevation occurred at 3 mg/kg and above; and mild ALT elevation occurred at 10 mg/kg in one subject. These elevations were not associated with clinical signs/symptoms or abnormalities in total bilirubin, CK isoenzymes or troponin, were reversible, and were expected due to FPA008-mediated inhibition of Kupffer cells responsible for removing these enzymes.

Non-linear PK was observed, with exposure increasing greater than dose proportionality from 0.2 to 3 mg/kg, suggesting target mediated clearance. Suppression of CD16+ monocytes, decreased bone turn-over biomarkers (CTx, Trap5), and dose-dependent increase in serum CSF1 and IL34 concentrations were observed.

Conclusion: FPA008 is well tolerated up to 3 mg/kg. Persistent AEs beyond the DLT period at 10 mg/kg coincide with the prolonged PK exposure. PD effects of full suppression of non-classical CD16+ monocytes and decrease of bone turnover biomarkers were noted at dose levels tested and may track with clinical benefit in RA pts. Updated data including preliminary data in RA pts will be presented.

1494

Treatment of Rheumatoid Arthritis Patients with the JAK1-Selective Inhibitor GLPG0634 Reverses an Arthritis-Specific Blood Gene Signature to Healthy State. Mate Ongenaert[1], Sonia Dupont[2], Béatrice Vayssière[2], Reginald Brys[1], Luc Van Rompaey[1], Christel Menet[1] and René Galien[2]. [1]Galapagos NV, Mechelen, Belgium, [2]Galapagos SASU, Romainville, France.

Background/Purpose: The 4 Janus kinases (JAK1, JAK2, JAK3 and TYK2) are cytoplasmic tyrosine kinases that mediate intracellular signaling of cytokines (e.g. certain interleukins and interferons) and growth factors (e.g. erythropoietin). GLPG0634 is the first JAK inhibitor that displays a high JAK1 selectivity towards the 3 other JAK family members in functional assays. It showed a favorable safety and efficacy profile in two 4-week Phase 2a studies in rheumatoid arthritis (RA) patients. In order to further characterize GLPG0634, we compared the gene expression profile of circulating leukocytes of healthy volunteers and RA patients before and after 4 weeks of daily treatment with 200 mg of GLPG0634.

Methods: RA patients participated in the Phase 2a Proof of concept, a randomized, double-blind, placebo-controlled study enrolling 36 patients with insufficient response to MTX. They were orally treated with placebo or 200 mg QD GLPG0634 for 4 weeks. Blood was sampled in PAXgene tubes at pre-dose the first and the last days of treatment. Non-matched healthy

volunteers were also sampled in PAXgene tubes. mRNA was extracted, labeled and profiled using Affymetrix U219 micro-arrays. Data analysis was performed in R/BioConductor using linear regression models (limma).

Results: The leukocyte gene signature of 12 healthy subjects was first compared to the one obtained from 24 RA patients prior to placebo or GLPG0634 treatment. As expected, genes showing differential expression compared to healthy subjects allowed for definition of a disease signature. Four weeks of treatment with GLPG0634 (200 mg QD) impacted the signal levels for 3120 probes in RA patient samples (adjusted p-value < 0.05 and absolute log2-fold change > 1 compared to the same subjects at pre-dose), while the signal levels of only 78 probes were impacted to the same extent in the placebo group. Remarkably, the highly GLPG0634-impacted genes matched with the disease-effect genes and displayed an inverse regulation (Spearman $R = -0.85$), showing that administration of GLPG0634 at 200 mg QD led to the restoration of a healthy-like gene expression profile (treatment-effect genes). Pathway analysis performed for the affected gene sets suggests an impact on immune-inflammation systems.

Conclusion: Blood transcriptome analysis of healthy volunteers and patients recruited in the proof-of-concept study of GLPG0634 in RA identified a disease signature with many genes involved in RA-linked pathways. After 4 weeks of treatment with GLPG0634, transcriptome analysis showed that the compound was able to reverse strongly the disease effect, leading to a gene signature close to that of healthy volunteers. These data are in line with the good efficacy of the 200 mg QD administration of GLPG0634 in RA patients and further support the use of GLGP0634 in RA patients.

1495

Preclinical and Clinical Phase I Profile of MK-8457, a Selective Spleen Tyrosine Kinase and Zeta-Chain-Associated Protein Kinase 70 Inhibitor, Developed for the Treatment of Rheumatoid Arthritis. Gene Marcantonio[1], Alan Bass[2], Gretchen Baltus[2], Judith Boice[1], Hongmin Chen[2], Michael Crackower[2], Jeroen Elassaiss-Schaap[3], Michael Ellis[2], Tomoko Freshwater[4], Francois Gervais[2], Jane Guo[2], Sammy Kim[2], Lily Moy[2], Alan Northrup[2], Jie Zhang-Hoover[2], Mathew Maddess[2], Richard Miller[2], Marcella Ruddy[2], Stella Vincent[2], Haoling Weng[1] and Hani Houshyar[2]. [1]Merck & Co., Whitehouse Station, NJ, [2]Merck & Co., Boston, MA, [3]Merck & Co., Oss, Netherlands, [4]Merck & Co., Rahway, NJ.

Background/Purpose: Spleen tyrosine kinase (SYK) is a potential target for treatment of several diseases including rheumatoid arthritis. SYK is a member of the Zeta-chain-associated protein kinase 70 (ZAP70) family of non-receptor protein kinases, critical in signaling downstream of Fc epsilon receptor I (FceRI) in mast cells and basophils, B-cell receptor (BCR) in B cells, and the collagen receptor in platelets. ZAP70, plays a predominant role in T-cell receptor (TCR) signaling in mature T cells. Here, we report the *in vitro*, *in vivo*, and early clinical characterization of a highly selective and potent dual SYK/ZAP70 inhibitor, MK-8457.

Methods: The *in vitro* characteristics of MK-8457 were evaluated in a series of biochemical and cellular assays. The *in vivo* characteristics of MK-8457 were evaluated in the rat adjuvant- and collagen-induced arthritis models. MK-8457 preclinical PK-PD-Efficacy relationship was established to select clinical doses required for efficacy in RA. Healthy volunteer clinical studies assessed the PK, PD, and safety of MK-8457 in single- and multiple-rising dose studies.

Results: MK-8457 is a potent, reversible ATP competitive inhibitor of SYK and ZAP70, displaying comparable cellular activity for these two kinases despite 40x enzymatic selectivity for SYK vs. ZAP70. Beyond ZAP70, out of 191 off-target kinases tested, MK-8457 inhibits only 3 kinases (TRKC, SRC, BLK) with IC_{50} values less than 100-fold above the SYK IC_{50}. *In vitro*, MK-8457 is a potent inhibitor of (1) FceRI-mediated anti-IgE induced degranulation in primary human mast cells (38 ± 20 nM) and human whole blood basophils (797 ± 365 nM), (2) BCR-mediated anti-IgM induced pBLNK activation in human RAMOS cells (35 ± 27 nM) and anti-CD79b induced CD69 upregulation in human whole blood B cells (1398 ± 505 nM), and (3) TCR-mediated anti-CD3 induced IL-2 production in Jurkat cells (84 ± 26 nM) and human whole blood phytohemagglutinin induced IL-2 production (1175 ± 362 nM). MK-8457 also inhibits collagen-induced platelet aggregation in human platelet rich plasma, with 20x reduced potency (19 ± 3 uM) as compared with the human whole blood basophil, B-cell, and T-cell assays. MK-8457 produces dose-dependent inhibition of adjuvant- and collagen-induced arthritis, as assessed by changes in paw thickness. Preclinical PK-PD-Efficacy modeling and simulations suggest that high level of SYK/ZAP70 inhibition (69%) is required to attain nearly full suppression of the CIA response. In healthy volunteers, MK-8457 is rapidly absorbed, shows increased exposure with dose, with a terminal half-life estimated to be 10–20 hours. MK-8457 was generally safe and well-tolerated in single dose up to 800 mg and multiple doses of 200 mg twice daily for up to 10 days. There was evidence of increased bleeding times at the T_{max} in single dose studies; however, there were no bleeding adverse events. The C_{max} for this effect in healthy volunteers is ~2x higher than observed at steady state for the highest dose (100 mg BID) tested in Phase II RA studies.

Conclusion: These data suggest that MK-8457 has the appropriate characteristics for assessment of the hypothesis that a selective SYK/ZAP70 inhibitor is efficacious in RA patients.

Exposure-Response Analysis for Mavrilimumab Phase2b Study in RA Patients with Informative Dropout. Chi-Yuan Wu[1], Denise Jin[1], Alex Godwood[2], David Close[2], Lorin Roskos[3] and Bing Wang[1]. [1]Medimmune, Mountain View, CA, [2]MedImmune Ltd, Cambridge, United Kingdom, [3]Medimmune, Gaithersburg, MD.

Background/Purpose: Mavrilimumab is a recombinant human monoclonal antibody which neutralizes granulocyte-macrophage colony stimulating factor (GM-CSF) activity by selectively binding to the alpha subunit of its receptor (GM-CSFRα). A Phase 2b randomized, double-blind, placebo-controlled study was conducted to evaluate the efficacy and safety of mavrilimumab in subjects with at least moderately active rheumatoid arthritis (RA). Population modeling was performed to characterize the exposure-response relationship of mavrilimumab in RA patients.

Methods: In a Phase2b study, subjects with RA received subcutaneously administered placebo or mavrilimumab (30, 100 or 150 mg) once every other week for 24 weeks. The pharmacokinetic data was pooled and analyzed using a population approach. The binary ACR20 and ACR50 responses were modeled by logistic regression. A dropout hazard function was introduced to describe the voluntary patient withdrawals during the study period. Stochastic simulations based on the final PK-ACR20(50)-Dropout model were subsequently conducted for model evaluations and exposure-response relationship assessment.

Results: A mechanistic model incorporating the subcutaneous absorption, distribution, and parallel elimination pathways of mavrilimumab by the reticuloendothelium system and GM-CSFRα mediated internalization and intracellular degradation adequately described the observed PK profiles of mavrilimumab. The placebo effect and mavrilimumab treatment effect were integrated in the logit (log odds ratio) of ACR20 or ACR50. The treatment effect was described by an Emax model for ACR20, and by a linear relationship with mavrilimumab concentration for ACR50. The dropout hazard increased with time on study, and was significantly higher in ACR20 nonresponders than in responders. The protocol-permitted rollover of patients with inadequate ACR20 responses to an open-label extension study at any time after Week 12 substantially increased the dropout risk for nonresponders in placebo and two lower dose groups. There was no change in the dropout pattern for subjects receiving the 150 mg dose.

Conclusion: The pharmacokinetics of mavrilimumab, ACR20 and ACR50 responses in patients with moderate to severe RA were well described by a model incorporating mechanistic drug disposition, logistic regression for ACR20 or ACR50, and informative patient dropout. The population model facilitated the interpretation of Phase 2b outcome and the appropriate design of late-stage clinical trials for mavrilimumab.

1497

Efficacy and Safety of Iguratimod for Rheumatoid Arthritis. Tsuneo Kondo, Akiko Shibata, Ryota Sakai, Kentaro Chino, Ayumi Okuyama, Hirofumi Takei and Koichi Amrano. Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background/Purpose: Iguratimod is a new small-molecular drug for rheumatoid arthritis (RA), which was approved on June, 2012 in Japan. The agent inhibits the production of immunoglobulins and various inflammatory cytokines (interleukin-1, -6 and -8 and TNF), and exerts anabolic effects on bone metabolism by stimulating osteoblastic differentiation and inhibiting osteoclastogenesis in mice through inhibiting the nuclear transcription factor NF-κB, but not its inhibitor, IκBα. In addition this agent is very cheap (1.5$/25 mg tablet), so 50 mg/day iguratimod therapy costs only 3$/day. In this study, We evaluate the efficacy and safety of iguratimod for RA patients. In addition, We examine NK cell counts compared with tofacitinib to evaluate the mechanism of the safety.

Methods: 62 patients who were administered iguratimod at a dosage of 25mg qd during the first month, then 50mg qd thereafter, and followed up for 24 weeks were enrolled. Efficacy and safety were evaluated utilizing clinical and laboratory findings. We also monitor the NK cell counts in peripheral blood from 20 RA patients before and 12 weeks after the commencement of Iguratimod by flow cytometery analysis.

Results: The mean age was 61.6 years and 75.8% of patients were female. MTX was used in 46.8%, the average dose was 8.6±2.9 mg/week. LOCF analysis revealed that DAS28-ESR and SDAI decreased significantly from 4.49±1.33 to 3.09±1.12 and from 18.5±10.9 to 7.44±7.11 in 24 weeks respectively ($P<0.01$). Remission and LDA rate in SDAI were 30.4% and 47.8%. HAQ-DI score also decreased from 1.2±0.8 to 0.94±0.85. The difference between the efficacy of igurarimod with and without MTX was not significant. 29.0% of the patients discontinued iguratimod within 24 weeks. The reason of cessation consisted of adverse events (21.0%) and lack of efficacy (4.8%). Adverse events were digestive symptom (n=6), liver dysfunction (n=3), nasal hemorrhage (n=2) and so on. There's no severe adverse event. Peripheral NK cell counts in 12 weeks had not been changed significantly.

Conclusion: Iguratimod was well tolerable and may have a good cost effectiveness. So iguratimod be a new useful option as small molecule DMARDs for RA patients in a manner similar to tofacitinib.

ALX-0061, an Anti-IL-6R Nanobody®for use in Rheumatoid Arthritis, Demonstrates a Different *in Vitro* Profile As Compared to Tocilizumab. Maarten Van Roy, Ariella Van De Sompel, Kristi De Smet, Jasper Jacobs, Tinneke Denayer and Hans Ulricrhts. Ablynx N.V., Zwijnaarde, Belgium.

Background/Purpose: Interleukin-6 (IL-6) is a pleiotropic cytokine inducing a wide range of biological activities via its receptor, which can either be soluble (sIL-6R) or membrane-bound (mIL-6R). In rheumatoid arthritis, blocking of IL-6R results in clinical benefit as demonstrated by the IL-6R inhibitor tocilizumab (TCZ). Signalling via the mIL-6R (classical pathway) is confined to selected cell types due to the restricted expression of mIL-6R. However, IL-6 can also activate cells through sIL-6R in a process known as trans-signalling. Unwanted pharmacology associated with IL-6 pathway inhibition has been linked to inhibition of mIL-6R. Preferential inhibition of sIL-6R could therefore provide higher therapeutic efficacy with a better safety profile compared to equivalent inhibition of both IL-6R forms (Waetzig & Rose-John, Expert Opin Ther Targets, 2012). Nanobodies are therapeutic proteins based on the smallest functional fragments of heavy chain-only antibodies, naturally occurring in the *Camelidae* family. ALX-0061 is a bispecific anti-IL-6R Nanobody engineered to have an extended half-life *in vivo* by targeting human serum albumin (HSA), in combination with strong target binding using a single anti-IL-6R building block. ALX-0061 was extensively characterised using *in vitro* systems: biological activity and affinity for both sIL-6R and mIL-6R were assessed and compared to TCZ.

Methods: Biological activity of ALX-0061 and TCZ was analysed in a cell-based assay for mIL-6R, ELISA-based neutralisation assays for sIL-6R, and cell-binding and cell-signalling (mIL-6R) experiments in whole blood from human donors using flow cytometry. The affinity of ALX-0061 for sIL-6R could not be accurately determined via surface plasmon resonance due to its very tight target binding. Consequently, the more sensitive Gyrolab™ platform was used to assess affinity for both receptors. The $K_D$for mIL-6R was determined after pre-incubation of mIL-6R-transfected cells with constant compound concentrations and subsequent quantification of free compound in the supernatant.

Results: Flow cytometry experiments demonstrated that ALX-0061 binds to mIL-6R expressed on peripheral blood leukocyte populations with expected pharmacology. ALX-0061 specifically neutralised sIL-6R with a 10-fold higher *in vitro* potency compared to TCZ, while the (apparent) affinity of ALX-0061 for sIL-6R (0.19 ± 0.08 pM) was about 2400-fold superior compared to TCZ (462 ± 138 pM). In the mIL-6R-driven cell-based assay, however, *in vitro*potencies were similar for ALX-0061 and TCZ, with the latter one showing avid binding due to its bivalency. In addition, TCZ showed a 3-fold higher affinity for mIL-6R (462 ± 138 pM) compared to sIL-6R (154 ± 16 pM), while the affinity of ALX-0061 was about 50-fold lower for mIL-6R compared to sIL-6R (9.1 ± 3.6 pM).

Conclusion: ALX-0061 demonstrates *in vitro* a preferential binding profile for sIL-6R with a lesser activity for mIL-6R, while TCZ has a higher preference for mIL-6R. Preferential inhibition of sIL-6R trans-signalling by ALX-0061 could provide improved therapeutic efficacy with a better safety profile compared to TCZ.

1499

Characterization of ABT-494, a Second Generation Jak1 Selective Inhibitor. Candace Graff[1], Annette Schwartz[1], Jeffrey Voss[2], Neil Wishart[3], Lisa Olson[1], Jonathon George[3], Deborah Hyland[3] and Heidi Camp[4]. [1]AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA, [2]AbbVie Pharmaceuticals, Worcester, MA, [3]Abbvie Pharmaceuticals, worcester, MA, [4]Abbvie, Winnetka, IL.

Background/Purpose: Jak kinase blockade can effectively manage rheumatoid arthritis (RA) and in some cases achieve remission. However, first generation Jak inhibitors have not met expectations due to dose-limiting tolerability and safety issues. ABT-494 is a second generation Jak inhibitor with high Jak1 selectivity thereby minimizing the potential for Jak2 and Jak3 related side effects. Here we describe preclinical and early clinical data that suggest ABT-494 has potential to address some of the current unmet medical needs of RA patients.

Methods: ABT-494 was engineered for increased selectivity for Jak1 using structural predictions indicating the potential for differential binding interactions outside the ATP-binding active site of Jak1 but not Jak2 or Jak3. ABT-494 efficacy and selectivity were tested in a battery of relevant cellular *and in vivo* pharmacology assays including bone marrow colony formation, adjuvant induced arthritis, erythropoietin (EPO) induced reticulocyte deployment and NK/NKT cell suppression. ABT-494 potency in a variety of complementary pharmacodynamic assays was also assessed at multiple oral dosages in healthy human subjects and patients with RA.

Results: ABT-494 is approximately 74 fold selective for Jak1 over Jak2 in cellular assays dependent on specific, relevant cytokines. The ability of ABT-494 and tofacitinib to inhibit Jak2/EPO signaling in these assays was consistent with their ability to inhibit bone marrow cell differentiation *in vitro*. Surprisingly, GMCSF (and IL3) signaling in TF1 cells were consistently more sensitive to inhibition than EPO signaling in UT7 cells indicating that Jak2 inhibition in some contexts may over-estimate inhibition of Jak2 via EPO signaling. Accordingly, in whole blood assays, ABT-494 was about 10X more potent against IL6 (Jak1) signaling than GMCSF (Jak2) driven signaling based on free drug concentrations. By contrast, tofacitinib under the same conditions was about 2X more potent. No changes in reticulocyte counts were observed in RA patients after 28 days of ABT-494 dosing.

ABT-494 and tofacitinib inhibited common gamma chain cytokine signaling (IL7, IL15 and IL21) in whole blood with similar potencies and *in vivo* were similarly potent in driving down NK cell counts in healthy rats. Consistent with its higher potency against IL6 signaling, ABT-494 had substantially greater potency in a rat arthritis model.

Conclusion: ABT-494 is a Jak1-selective inhibitor that demonstrates efficacy in rat arthritis models. Preliminary evidence suggests that compared to tofacitinib, ABT-494 may spare Jak2 and Jak3 dependent signaling. Taken together, these encouraging observations support further testing of ABT-494 in RA patients in Phase II randomized placebo controlled trials and indicate it may have increased potential to address patient needs over existing agents.

Preclinical and Clinical Characterization of MK-8457, a Selective Spleen Tyrosine Kinase and Zeta-Chain-Associated Protein Kinase 70 Inhibitor, in Normotensive and Hypertensive Cardiovascular Models. Hani Houshyar[1], Alan Bass[1], Judith Boice[2], Michael Ellis[1], Patrick Fanelli[3], Tomoko Freshwater[4], Jane Guo[1], Kimberly Hoagland[3], Janet Kerr[3], Alan Northrup[1], Mathew Maddess[1], Richard Miller[1], Marcella Ruddy[1], Stella Vincent[1], Jayanthi Wolf[3], Haoling Weng[2], Gloria Zingaro[3] and Gene Marcantonio[2]. [1]Merck & Co., Boston, MA, [2]Merck & Co., Whitehouse Station, NJ, [3]Merck & Co., West Point, PA, [4]Merck & Co., Rahway, NJ.

Background/Purpose: Spleen Tyrosine Kinase (SYK) and Zeta-chain-associated protein kinase 70 (ZAP70) are non-receptor protein kinases that bind phosophorylated receptor tyrosine-based activation motifs, critical in immune receptor signaling in multiple hematopoietic and non-hematopoietic cells, supporting potential utility of SYK/ZAP70 inhibitors in multiple indications including rheumatoid arthritis. While neither SYK nor ZAP70 are implicated in blood pressure (BP) regulation, the non-selective SYK/ZAP70 inhibitor, Fostamatinib, is associated with BP increases both preclinically and in patients. Fostamatinib's impact on BP has been attributed to off-target activity on vascular endothelial growth factor receptor 2 (VEGF-R2). Here, we report the *in vitro*, *in vivo*, and clinical profile of MK-8457 to demonstrate that a highly selective SYK/ZAP70 inhibitor does not affect BP.

Methods: The *in vitro* off-target activity of MK-8457 vs. Fostamatinib on VEGFR-2 was assessed in enzymatic as well as cellular assays. *In vivo*, the BP effects of MK-8457 were compared with Fostamatinib in conscious telemetered normotensive Wistar rats and Beagle dogs. In the clinic, MK-8457 was studied in a multi-center, randomized, double-blind, placebo controlled 2-period crossover ambulatory BP measurement (ABPM) trial in men and women with mild to moderate hypertension. This study in 29 subjects was powered to detect a 5 mmHg increase in BP, to rule out a Fostamatinib-like BP effect.

Results: In contrast to Fostamatinib, MK-8457 is devoid of off-target VEGFR2 activity in both enzymatic and cellular assays. Whereas Fostmatinib produces dose-dependent increases in BP in conscious telemetry instrumented rats, MK-8457 does not. Similarly, MK-8457 does not significantly affect BP in conscious telemetry instrumented dogs. In the ABPM study, MK-8457 was studied at a dose of 100 mg BID for 10 days, a dose projected to result in nearly complete 24 hour inhibition of SYK and ZAP70. At this dose, MK-8457 does not result in a statistically significant change in BP. The mean treatment difference (MK-8457-placebo) in 24 hr mean systolic and diastolic ABPM change from baseline was 2.02 and 1.57 mmHg, respectively.

Statistical Comparison of 24-Hour Change From Baseline in Ambulatory BP Parameters Following 10 days of Multiple dosing of MK-8457 or Matching Placebo in Hypertensive Patients

	MK-8457			Placebo			MK-8457 - Placebo	
Parameters	N	LS Mean†	95 % CI	N	LS Mean†	95 % CI	Mean Difference	90 % CI
Systolic blood pressure (mm Hg)	29	−0.47	(−2.60, 1.66)	28	−2.49	(−4.66, −0.31)	2.02	(−0.52, 4.56)
Diastolic blood pressure (mm Hg)	29	0.22	(−1.33, 1.78)	28	−1.35	(−2.93, 0.23)	1.57	(0.19, 2.96)

† Least square Mean using linear mixed effect model where the response was average 24-hour change from baseline for Day 10 and the model contained period, treatment as fixed effect and Day -1 baseline as a fixed continuous covariate and subject as a random effect.

Conclusion: These data illustrate that full SYK and ZAP70 inhibition with a selective inhibitor does not significantly impact BP preclinically or clinically in a sensitive population.

Immunogenicity Assessment of PF-06438179, a Potential Biosimilar to Infliximab, in Healthy Volunteers. Chandrasekhar Udata[1], Donghua Yin[1], Chun-hua Cai[2], Stephanie Salts[1], Steven Y. Hua[1], Muhammad I. Rehman[3] and Xu Meng[1]. [1]Pfizer Inc., San Diego, CA, [2]Pfizer Inc., Groton, CT, [3]Pfizer Inc., Cambridge, MA.

Background/Purpose: PF-06438179, a proposed biosimilar to infliximab, was evaluated for immunogenicity in a phase 1 pharmacokinetic (PK) similarity study.

Methods: In this double-blind trial (NCT01844804), 151 healthy volunteers aged 18–55 years were randomized 1:1:1 to 1 of 3 treatment groups, of which 146 received a single 10 mg/kg intravenous dose of PF-06438179 (n=49), infliximab sourced from the US (infliximab-US; n=49), or infliximab sourced from the EU (infliximab-EU; n=48). All subjects provided informed consent and were evaluated post dose for safety and immunogenicity over 12 weeks, and for PK over 8 weeks. Serum samples for detecting anti-drug antibodies (ADA) and neutralizing antibodies (NAb) were collected at 0, 336, 672, 1008, 1344, and 2016 hours post dose. ADA samples were analyzed using 2 validated electrochemiluminescent immunoassays, 1 each to detect antibodies against PF-06438179 and reference drugs (infliximab-US or -EU). A tiered approach of screening, confirmation and titer quantitation was utilized. Samples were first tested for antibodies against the dosed product and confirmed ADA positive samples were then tested for ADA cross-reactivity using the alternate assay. ADA positive samples were also analyzed for NAb using a validated semi-quantitative cell-based assay against the dosed product and for NAb cross-reactivity using the alternative NAb assay.

Results: Samples for immunogenicity assessment were collected from all 146 subjects. No subjects tested positive for ADA at baseline. Six (16.2%), 14 (32.6%) and 11 (28.2%) subjects in the PF-06438179, infliximab-EU, and infliximab-US groups, respectively, had ≥1 ADA-positive sample through Day 85. Twenty-seven of the 31 subjects (6/6 in PF-06438179, 10/14 in infliximab-EU, and 11/11 in infliximab-US) that tested positive for ADA also tested positive for cross-reactivity by the alternative assay, suggesting that anti-drug antibodies were likely developed against epitopes shared among the study drugs. Of the 31 subjects who tested positive for ADA, 26 tested positive for NAb (5/6 in PF-06438179; 12/14 in infliximab-EU; 9/11 in infliximab-US). Overall safety profiles were similar across the 3 study drugs and no infusion related reactions were reported. The 3 study drugs demonstrated PK similarity, based on the 90% confidence intervals of the test-to-reference ratios for maximum observed serum concentration (C_{max}), area under the serum concentration-time profile from time 0 to the time of last quantifiable concentration (AUC_t), and area under the serum concentration-time profile from time 0 extrapolated to infinite time (AUC_{inf}) each falling within the standard bioequivalence region of 80–125%.

Conclusion: The 3 study drugs had comparable immunogenicity profiles with a somewhat lower incidence of ADA response in the PF-06438179 group. The majority of ADA-positive subjects also developed NAb. Overall, PF-06438179 demonstrated PK similarity and comparable safety and immunogenicity profiles to infliximab in healthy subjects. Further comparative assessment of immunogenicity for PF-06438179 will be carried out in a planned phase 3 trial in patients with rheumatoid arthritis.

1502

A Phase I Trial Comparing PF-05280586 (A Potential Biosimilar) and Rituximab in Subjects with Active Rheumatoid Arthritis. Jean-Claude P. Becker[1], Donghua Yin[2], Lisa Ann Melia[2], Ruifeng Li[3], Barry Gumbiner[2], Dolca Thomas[1], George Spencer-Green[3] and Xu Meng[2]. [1]Pfizer Inc., New York, NY, [2]Pfizer Inc., San Diego, CA, [3]Pfizer Inc., Cambridge, MA.

Background/Purpose: PF-05280586, a proposed biosimilar to rituximab, has the same primary amino acid sequence as rituximab with similar physicochemical and in vitro functional properties. This pharmacokinetic (PK) similarity study in subjects with active rheumatoid arthritis on a background of methotrexate who had an inadequate response to one or more TNF antagonist therapies (NCT01526057) also evaluated the clinical response and safety of PF-05280586, and rituximab sourced from the US (rituximab-US) and EU (rituximab-EU).

Methods: 220 subjects were randomized 1:1:1 to one course of IV PF-05280586, rituximab-US or rituximab-EU 1000 mg (with stable background regimen of methotrexate) on Days 1 and 15. Clinical response was assessed via Disease Activity Score in 28 joints-C-reactive protein (DAS28-CRP) and American College of Rheumatology (ACR) assessments. After Week 17, subjects could enroll in an extension study and receive additional courses of treatment.

Results: Baseline demographics were generally similar among the treatment arms. The primary endpoint of PK similarity among the three treatment arms was achieved. Measures of disease activity were numerically higher at baseline among patients randomized to rituximab-US (Table). Although not designed to demonstrate similarity for efficacy, mean DAS28-CRP (Figure), mean number of tender/painful joint counts, mean number of swollen joint counts, and mean high-sensitivity C reactive protein values decreased over time, and improvement in ACR20, ACR50, and ACR70 scores were seen in all groups. The safety profile was similar among treatment arms. A total of 10 subjects experienced SAEs (rituximab-US: 4; PF-05280586: 5; rituximab-EU: 1).

Conclusion: In this PK similarity study, a robust improvement in clinical response occurred with PF-05280586, rituximab-US, and rituximab-EU. All 3 treatments were generally well tolerated with a low incidence of treatment-related AEs. **Role of the Study Sponsor:** Study supported by Pfizer Inc.

Table. Baseline disease characteristics

Mean (SD)	Rituximab-US n=73	Rituximab-EU n=74	PF-05280586 n=73
Swollen joint count (28)	14.1 (5.92)	13.0 (6.53)	11.7 (5.36)
Tender/painful joint count (28)	18.1 (6.45)	14.9 (6.79)	14.6 (6.70)
Swollen joint count (66)	19.3 (8.73)	17.8 (10.56)	15.6 (8.91)
Tender/painful joint count (68)	30.4 (15.33)	23.3 (13.23)	22.9 (12.46)
HAQ-DI score	1.75 (0.62)	1.59 (0.54)	1.65 (0.57)
Serum hsCRP (mg/L)	18.17 (24.80)	14.80 (17.42)	12.70 (15.28)
DAS28-CRP	6.22 (0.89)	5.79 (0.95)	5.68 (0.86)

Demonstration of Functional Similarity Comparing Adalimumab to Biosimilar Candidate ABP 501. Teresa Born[1], Jyoti Velayudhan[1], Yuh-fung Chen[2], Heather Thomas[1], Christina Pastula[1], Gwen Maher[2] and Ryan Brown[1]. [1]Amgen, Seattle, WA, [2]Amgen, Thousand Oaks, CA.

Background/Purpose: ABP 501 is being developed as a biosimilar to adalimumab, a recombinant monoclonal antibody that binds tumor necrosis factor alpha (TNF) thus inhibiting engagement of TNF receptors and initiation of consequent proinflammatory signaling. Although adalimumab and intended biosimilars share the same amino acid sequence, differences will likely exist in product quality attributes due to differences in proprietary expression systems, bioprocess and purification. Equivalence of product quality attributes, especially demonstration of comprehensive functional equivalence, is of primary importance during stepwise development of a biosimilar in order to provide confidence for similar clinical safety and efficacy in patients, including extrapolation to all indications of use.

Methods: The similarity assessment of biological activity included testing binding of ABP 501 and adalimumab to soluble TNF by surface plasmon resonance and to cell-surface expressed TNF (mbTNF) in a competitive imaging cytometry-based assay. The similarity assessment for F(ab)-mediated activity included blocking TNF-induced caspase activation, IL-8 secretion and cytotoxicity. Inhibition of TNF activity in healthy volunteer blood samples stimulated ex vivo was also compared. To assess Fc-mediated functions, binding to the neonatal Fc receptor (FcRn) was measured in a competitive cell-based assay and to FcγRIIIa (158V) by AlphaLISA™. To confirm similarity in Fc-mediated functions, antibody-dependent cell-mediated cytotoxicity (ADCC) was assessed using cells expressing mbTNF and NK92-M1 cells expressing FcγRIIIa (158V). Complement-dependent cytotoxicity (CDC) was also tested, using complement and cells expressing mbTNF. Data from up to three lots of each antibody were assessed in the described assays as part of the initial similarity assessment.

Results: Equilibrium binding affinity to TNF was similar between ABP 501 (48–52 pM) and adalimumab (48–53 pM). Binding to mbTNF was also similar between ABP 501 (100–106% relative binding) and adalimumab (100–111%). Relative potency in the caspase activation assay was similar between ABP 501 (103–107%) and adalimumab (100–110%). Dose response profiles and resulting EC50 values in the IL-8 secretion (192–294 pM for ABP 501 and 156–253 pM for adalimumab), cytotoxicity (390–457 pM for ABP 501 and 391–544 pM for adalimumab) and whole blood assays, measuring both MCP-1 and MIP-1 beta production, were also similar between ABP 501 and adalimumab.

Binding to FcRn was similar between ABP 501 (86–94%) and adalimumab (92–114%) as was binding to FcγRIIIa (158V) comparing ABP 501 (103–113%) to adalimumab (92–94%). The dose response profile for ADCC (101% relative cytotoxicity for ABP 501 and 107% for adalimumab) and CDC (97% relative cytotoxicity for ABP 501 and 93% for adalimumab) were also similar.

Conclusion: Results from an initial similarity assessment demonstrate that ABP 501 is functionally highly similar to adalimumab in multiple sensitive preclinical pharmacologic assays.

1504

Pharmacokinetic Equivalence of ABP 501 Relative to Adalimumab: Results from a Randomized, Single-Blind, Single-Dose, Parallel Group Study in Healthy Subjects. Primal P. Kaur[1], Vincent Chow[2], Nan Zhang[1], Mike Moxness[1] and Richard Markus[1]. [1]Amgen, Inc., Thousand Oaks, CA, [2]Amgen, Inc., Seattle, WA.

Background/Purpose: Adalimumab is a recombinant IgG1 monoclonal antibody that binds to TNFα blocking its interaction with p55 and p75 cell surface receptors. ABP 501 is being developed as a biosimilar candidate to adalimumab; it contains a fully human recombinant monoclonal antibody with the same amino acid sequence. Evidence from analytical comparisons indicates that ABP 501 is highly similar to adalimumab. This report describes the pharmacokinetics (PK) results of ABP 501 compared with adalimumab sourced from the United States (US).

Methods: This was a single-blind, single-dose, parallel-group study in healthy male and female subjects, 18 to 45 years of age with a body mass

index of 18 to 30 kg/m^2. Subjects were randomized to receive 40-mg subcutaneous (SC) injection of ABP 501 or adalimumab. The primary objective was demonstration of PK equivalence of ABP 501 relative to adalimumab based on area under the serum concentration-time curve from time 0 extrapolated to infinity (AUC_{inf}) and the maximum observed serum concentration (C_{max}). Pre-specified equivalence criterion for the primary PK parameters was the standard 90% confidence interval (CI) for geometric means (GM) ratio to be within 0.80 to 1.25. Secondary endpoints included the safety, tolerability, and immunogenicity.

Results: Pharmacokinetics: A total of 67 subjects received ABP 501 and 69 subjects received adalimumab. Following a single dose, the adjusted least square (LS) GM of C_{max} and AUC_{inf} for ABP 501 were 3.22 μg/mL and 2140 μg.h/mL. The adjusted LS GM of C_{max} and AUC_{inf} for adalimumab were 3.11 μg/mL and 1920 μg.h/mL. Ratios of adjusted LS GM (90% CIs) between ABP 501 and adalimumab for C_{max} and AUC_{inf} were 1.04 (0.96, 1.12) and 1.11 (1.00, 1.24). The 90% CIs of these ratios were fully contained within 0.80 to 1.25 interval, confirming PK equivalence between ABP 501 and adalimumab.

Safety: There were no deaths, treatment-related serious adverse events, or treatment-related adverse events leading to discontinuation from the study. The most frequently reported treatment-related AEs included headache, nausea, nasopharyngitis, and oropharyngeal pain.

Immunogenicity: No pre-existing anti-drug antibodies (ADA) were detected at baseline. In the ABP 501 treatment group, 36 (54%) subjects developed binding antibodies and 12 (18%) developed neutralizing antibodies. In the adalimumab treatment group, 38 (55%) subjects developed binding antibodies and 15 (22%) developed neutralizing antibodies.

Conclusion: Results of this phase 1 study demonstrated PK equivalence of ABP 501 following a single 40-mg SC injection relative to that after a 40-mg SC injection of adalimumab sourced from the US. Similar ADA rates were observed in healthy subjects.

Disclosure: P. P. Kaur, Amgen, 1, Amgen, 3; **V. Chow**, Amgen, 1, Amgen, 3; **N. Zhang**, Amgen, 3, Amgen, 3; **M. Moxness**, Amgen, 1, Amgen, 3; **R. Markus**, Amgen, 1, Amgen, 3.

1505

The Biosimilar Landscape: A Systematic Review of Its Current Status. Niti Goel and Kamali Charnce. Quintiles, Durham, NC.

Background/Purpose: In the last 5 years, the number of biosimilars in development for the treatment of immunologic diseases has increased as innovator etanercept (ETA), infliximab (IFX), adalimumab (ADA) and rituximab (RTX) near expiry of their original patents. Adequate clinical data may be achieved for a biosimilar with a single Phase (Ph) III study in a representative indication if the mode of action for the various proposed indications is similar. Disease prevalence, effect sizes for treatment response, regulatory and marketing considerations all may play a role in the indication(s) chosen for evaluation. In 2013, an IFX biosimilar, CT-P13, was the first mAb biosimilar approved in the EU on the basis of an extensive nonclinical and clinical comparative data package. Included clinical data demonstrated noninferiority to innovator IFX in just 2 indications, ankylosing spondylitis (AS) and rheumatoid arthritis (RA); approval was obtained for all pediatric and adult indications (8 in total) of innovator IFX. The US has yet to approve a biosimilar via the Public Health Service 351(k) pathway that is designated for biosimilar approval.

Methods: We performed a systematic review of ClinicalTrials.gov (CT.gov) to assess the evolution of the biosimilar trial landscape for immunologic indications. A cutoff date of 31 May 2014 was used to identify studies of biosimilars of innovator ETA, ADA, IFX and RTX, excluding oncologic studies for RTX.

Results: Overall, there were 14 unique biosimilars in development: 12 in Ph III and 2 in Ph I or I/II only; 4 each were ADA or ETA, 3 each, IFX or RTX. Thirty-one biosimilar studies were registered on CT.gov over the last 5 years, with none reported as being initiated prior to 2010. Fifteen (55%) were Ph III, double-blind, randomized controlled trials (DBRCT). Of these, 12 (80%) were or planned to be started in 2013 to 2014. Four DBRCT each evaluated ADA or IFX biosimilars (27% each); 5, ETA (33%); and 2, RTX (13%). Listed indications for the Ph III DBRCT were RA (10 studies, 67%), psoriasis (PsO; 4, 27%), and Crohn's disease (CD; 1, 7%). Only 3 biosimilars had Ph III DBRCT in $>$ 1 indication each: RA and PsO for both an ADA and ETA biosimilar, and RA and CD for CT-P13. PsO was used only for evaluation of ADA or ETA biosimilars. RA was used to also assess RTX biosimilars in Ph I, due to regulatory authorities not permitting RTX use in normal healthy volunteers. Only 7 of the Ph III DBRCT (47%) included US sites.

Conclusion: Biosimilar development has increased significantly in the last 5 years, with the majority of the Ph III studies having been or planned to be started from 2013 onward. Most biosimilars appear to be evaluating efficacy, safety and immunogenicity against the innovator in only 1 indication. The common use of RA and/or PsO as indications may reflect disease prevalence, effect sizes and actual innovator use for these indications in clinical practice. RTX biosimilar Ph I studies in RA may not translate into eventual development in RA for Ph III. Less than half of the Ph III studies involve US sites. It is unclear whether the development programs proposed will be adequate to achieve approval of a biosimilar mAb in the US for the treatment of rheumatic conditions as well as extrapolation to other indications approved for the innovator product.

Incidence of Adverse Events in Patients Treated with Intended Copies of Biologic Therapeutic Agents in Colombia and Mexico. Leonor A. Barile-Fabris[1], Fedra Irazoque-Palazuelos[2], Ramiro Hernández Vásquez[3], Sandra Carrillo Vazquez[4] and R. Gúzman[5]. [1]Hospital Especialidades CMN, Mexico City, Mexico, [2]Centro Médico Nacional '20 de Noviembre' ISSSTE, Mexico City, Mexico, [3]Hospital de Especialidades "Dr. Bernardo Sepúlveda Gutiérrez", Mexico, Mexico, [4]Hospital Angeles Lindavista, Mexico DF, Mexico, [5]IDEARG, SaludCoop, Bogotá, Colombia.

Background/Purpose: A biosimilar is a copy of an approved biologic therapeutic agent that has undergone rigorous evaluation to ensure that it is similar to the innovator in physicochemical characteristics, efficacy and safety. In many countries, there are biologic products available that have not undergone such evaluation and thus should be labeled "intended copy".[1] It is critical to examine the safety profile of these intended copies to ensure that patients receive the best medical care available. The purpose was to evaluate the incidence of adverse events reported by patients treated with intended copies of etanercept (Infinitam or Etanar) and rituximab (Kikuzubam).

Methods: These data are a compilation of observations from four hospitals in Mexico and Colombia. Patients with rheumatic diseases, e.g., rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, were treated with Infinitam/Etanar or Kikuzubam. Patients were followed from initiation of treatment till first experience of an adverse event. Based on the nature and severity of the adverse event, treatment was continued, interrupted, suspended, or discontinued as determined by the treating physician.

Results: A preliminary analysis was performed of 219 patients with various diagnoses treated with Infinitam/Etanar (14) or Kikuzubam (205) in the four hospitals. Among patients receiving treatment, 10 (4.6%) on Infinitam/Etanar and 101 (46.1%) on Kikuzubam experienced at least one treatment-related adverse event (AE). Of these, 86.7% were female, and the median age was 51.9 years (range: 22 – 93 years). The median duration of disease was 14.5 years (range: 1 – 67 years). Overall, although the majority of the AEs reported (98/118, 83.1%) were Grade 2 or less, there were several reports of Grade 3 (13/118; 11.0%) and Grade 4 (7/118; 5.9%) AEs; there were no Grade 5 AEs reported for any agent. The time to the first experience of an AE from initiation of intended copy therapy was ranged from 0 – 50 months with 38 (36.2%) patients experiencing AEs on the same day as the first treatment.

Conclusion: A significant percent (14.3%) of patients receiving Infinitam/Etanar or Kikuzubam, intended copies of etanercept and rituximab, respectively, experience Grade 3/4 AEs with a very short time to onset.

1507

Patient Perspectives on the Introduction of Subsequent Entry Biologics in Canada. Suneet Sekhon[1], Raman Rai[1], Debbie McClory[2], Carolyn Whiskin[2], Melissa Deamude[2], Cynthia Mech[2], Lauri Vanstone[2], Alpesh Shah[3], Arthur N. Lau[1] and William Bensen[1]. [1]Division of Rheumatology, McMaster University, Hamilton, ON, [2]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [3]MSc in Clinical Epidemiology, University of Western Ontario, London, ON.

Background/Purpose: Biologic medications have revolutionized the treatment of inflammatory arthritis. Subsequent entry biologics (SEBs) or biosimilars are medications that are similar but not identical to the innovator biologics. Despite a paucity of comparative trials, SEBs are poised to enter the Canadian market. They will be prescribed under the same drug name even though they are not identical. This may have implications for patients that are currently on biologic therapy. We conducted a survey of Canadian arthritis patients currently taking innovator biologics to understand their perspectives on SEBs and the possibility of being switched to them.

Methods: A survey consisting of 14 closed-ended and one open-ended question was administered sequentially to 208 patients at a biologic infusion clinic. In addition to demographic data, patients were asked about their understanding of SEBs, and after providing a definition were asked about factors that might influence them switching to an SEB. The survey results were analyzed using SAS version 9.3.

Results: Of the patients surveyed (n=208), mean age was 56 years, 67% were female, 56% of patients had an annual household income of less than $75, 000, and 63% had private drug insurance. The majority of patients had a diagnosis of rheumatoid arthritis (76%) and had been on their current biologic for 1–5 years (55%). Most preferred the subcutaneous route of administration (64%) versus intravenous. When asked about the definition of a SEB, 58% indicated they did not know, 26% chose correctly, and 16% chose incorrectly. When asked about their interest in using a SEB, 30% were neutral, 40% were somewhat or very interested, and 30% were somewhat or completely opposed to it. Potential lower cost of a SEB did not greatly influence this decision, though if an insurance company mandated use due to lower cost most opposed this (54%). The lack of testing in North American patients led to 79% of patients being somewhat or completely opposed to SEBs. Most patients were interested in continuing to use the innovator biologic if there was no further expense (70%) and felt their doctor's opinion would influence their decision (85%). Demographics, household income, diagnosis and type of current biologic therapy did not affect patient opinions.

Conclusion: Given the lack of efficacy and safety data for SEBs, there is understandable concern as these medications enter the biologic landscape. This survey identifies a lack of patient understanding of SEBs and highlights a need for further education. Patients are hesitant to use SEBs that are not tested in a North American population and would prefer to stay on innovator biologics if cost was not an issue. Patients value their doctors' opinions to help them make informed decisions about SEBs. Open dialogue is needed between patients, physicians, industry and regulatory bodies in order to safely introduce SEBs into practice.

Impact of Anti-Drug Antibody on Efficacy and Safety over Week 24 in Both CT-P10 and Innovator Rituximab Treatment Groups. Dae-Hyun Yoo[1], Won Park[2], Slawomir Jeka[3], Fidencio Cons Molina[4], Pawel Hrycaj[5], Piotr Wiland[6], Wolfgang Spieler[7], Eun Young Lee[8], Francisco G. Medina-Rodriguez[9], Pavel Shesternya[10], Sebastiao Radominski[11], Dong Hyuk Sheen[12], Mie Jin Lim[2], Jung-Yoon Choe[13], Leysan Myasoutova[14], Taek Kwon[15], Sang Joon Lee[15], Seung-Cheol Shim[16] and Chang-Hee Suh[17]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Inha University Hospital, Incheon, South Korea, [3]Clinic of Rheumatology and Connective Tissue Diseases, Bydgoszcz, Poland, [4]Centro de Investigacion en Artritis y Osteoporosis, Mexicali, Mexico, [5]Poznan University of Medical Sciences, Poznan, Poland, [6]Medical University of Wroclaw, Wroclaw, Poland, [7]ZeFOR GmbH Zentrum für Forschung, Zerbst, Germany, [8]Seoul National University College of Medicine, Seoul, South Korea, [9]Centro de Investigación Farmacológica y Biotecnológica, Mexico City, Mexico, [10]Krasnoyarsk State Medical University, Krasnoyarsk, Russia, [11]Universidade Federal do Parana, Curitiba, Brazil, [12]Eulji University Hospital, Daejeon, South Korea, [13]Catholic University of Daegu School of Medicine, Daegu, South Korea, [14]Research Medical Complex Vashe Zdorovie, Kazan, Russia, [15]CELLTRION, Inc., Incheon, South Korea, [16]Chungnam National University Hospital, Daejeon, South Korea, [17]Ajou University Hospital, Suwon, South Korea.

Background/Purpose: CT-P10 is a biosimilar candidate for rituximab. Pharmacokinetic equivalence and similarity of clinical efficacy, safety and immunogenicity had been demonstrated between CT-P10 and Innovator Rituximab (RTX) groups[1]. The immunogenicity to the biologic monoclonal antibody may affect both patient's safety and therapeutic efficacy. Until now the presence of human anti-chimeric antibodies (HACA) to rituximab was known not to change the clinical efficacy and safety of rituximab.

The purpose of this analysis was to demonstrate the impact of anti-drug antibody (ADA) on efficacy and safety of CT-P10 and RTX in patients with rheumatoid arthritis (RA) over week 24.

Methods: A total of 154 RA patients were randomized 2:1 to receive 2 infusions (1000 mg, 2 week interval) of either CT-P10 (n=103) or RTX (n=51), and efficacy, safety and immunogenicity were assessed during the study. Electrochemilumencent (ECL) assay was used to assess immunogenicity in this study since this assay is about 10 times more sensitive than the enzyme-linked immuno sorbent assay (ELISA) which was used in the historical rituximab trials.

The impact of ADA on efficacy and safety in both treatment groups was evaluated at week 24, when drug concentration was low enough not to interfere with the analysis.

Results: The proportion of patients who developed ADA at week 24 was exactly same (17.6% each) in both CT-P10 and RTX treatment groups. Similar proportion of patients achieved ACR20 and the European League Against Rheumatism (EULAR-CRP and -ESR) responses after the CT-P10 and RTX treatment in both ADA (+) and (-) subgroups (Table 1). The interference of the ADA on the clinical response was not significant in both treatment groups.

The safety profiles of CT-P10 were generally comparable to those of RTX in both ADA (+) and (-) subgroups. The proportion of patients with adverse event (AE) were 55.6% and 49.4% for CT-P10-ADA (+) and (-) subgroups and 88.9% and 67.6% for RTX-ADA (+) and (-) subgroups, respectively. Serious AE was reported in 11.1% and 15.6% in the CT-P10-ADA (+) and (-) subgroups and 22.2% and 16.2% in the RTX-ADA (+) and (-) subgroups, respectively. The proportion of patients with AE due to infections and infusion related reactions was also similar between the treatment groups in ADA (+) and (-) subgroups.

Table 1. The Impact of ADA on Efficacy in Treatment Groups (%)

	CT-P10		RTX	
Clinical Response	**ADA (+)**	**ADA (−)**	**ADA (+)**	**ADA (−)**
ACR20	61.1	67.5	62.5	75.0
EULAR response (CRP)	66.7	85.7	75.0	85.7
EULAR response (ESR)	61.1	80.5	75.0	80.0

Note: No statistical difference in all comparisons between ADA subgroups or treatment groups ($p>0.05$). EULAR (CRP/ESR): the proportion of patients with moderate or good response

Conclusion: The development of ADA did not affect clinical response or safety profiles in RA patients treated with CT-P10 or RTX, and the magnitude of impact of ADA was similar in both treatment groups. These results

confirmed the comparability of CT-P10 to those of RTX in efficacy and safety over 24 weeks regardless of the immunogenic reaction.

A Randomized, Double-Blind, Three-Arm, Parallel Group, Single-Dose Study to Compare the Pharmacokinetics, Safety, and Tolerability of Three Formulations of Infliximab (CT-P13, EU-sourced Infliximab and US-sourced Infliximab) in Healthy Volunteers. Dae-Hyun Yoo[1], Won Park[2], Seung-Cheol Shim[3], Chang-Hee Suh[4], Jihye Yun[5] and Tina Pyo[5]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Inha University Hospital, Incheon, South Korea, [3]Chungnam National University Hospital, Daejeon, South Korea, [4]Ajou University Hospital, Suwon, South Korea, [5]CELLTRION, Inc, Incheon, South Korea.

Background/Purpose: CT-P13 has been approved as the first biosimilar to innovator infliximab sourced from European Union (EU-INX) in Sep 2013. Even if it has been concluded as equivalent or comparable to EU-INX through pivotal studies and switching studies, it was questioned about the comparability between reference products with different origins[1,2,3,4].

This study was designed to demonstrate comparability among CT-P13, EU-INX and US-sourced infliximab (US-INX) in healthy volunteers and to examine whether three-biologic infliximab from the different manufacturing sources are comparable to each other primarily in pharmacokinetics (PK).

Methods: In this double blind, randomized, parallel group, single-dose study, a total of 213 healthy volunteers were randomized 1:1:1 to receive a single dose (5 mg/kg) of CT-P13, EU-INX or US-INX by intravenous infusion on Day 1 followed for 8 weeks. The primary endpoints were maximum serum concentration (C_{max}), area under the concentration-time curve from time zero to the last quantifiable concentration (AUC_{last}) and area under the concentration-time curve from time zero to infinity (AUC_{inf}) of CT-P13, EU-INX and US-INX. A total of 11 serum blood samples were obtained for the primary PK analysis, and safety and tolerability were also evaluated up to 8 weeks. Similarity of systemic exposure (C_{max}, AUC_{last} and AUC_{inf}) was considered to be demonstrated if the 90% confidence interval (CI) for the ratio of geometric means was within the acceptance interval of 0.8 to 1.25 for the following comparisons: CT-P13 vs EU-INX, CT-P13 vs US-INX, and EU-INX vs US-INX.

Results: The baseline demographics for 213 subjects among 3 study groups were highly similar. The PK parameters in the study groups were highly similar (Table 1). The 90% CI for the ratios of C_{max}, AUC_{last} and AUC_{inf} were within the acceptance interval of 0.8 to 1.25 for the comparisons of CT-P13 to EU-INX, CT-P13 to US-INX and EU-INX to US-INX.

Adverse events (AEs) were similar between 3 study groups with AEs related to the study drug reported by 39.4%, 23.9%, and 42.3% of subjects in CT-P13, EU-INX and US-INX groups, respectively. The majority of AEs related to the study drug reported in the study groups was Grade 1, and there was only 1 AE reported as Grade 3 in US-INX group based on Common Terminology Criteria for Adverse Events. No serious AE related to the study drug was reported, and no AEs led to the withdrawal of a subject from the study. All AEs related to study drug were resolved by the end of the study.

Table 1. Pharmacokinetic Exposure Estimates (Mean ± SD)

Parameters (units)	CT-P13 (N=71)	EU-INX (N=71)	US-INX (N=71)
C_{max} (ug/mL)	127.6 ± 21.6	121.3 ± 19.7	119.9 ± 19.5
AUC_{last} (h*ug/mL)	31343.2 ± 7107.3	30669.0 ± 6020.5	31629.6 ± 5886.8
AUC_{inf} (h*ug/mL)	33212.3 ± 8326.1	32986.6 ± 7806.8	34363.6 ± 8004.2

Conclusion: Equivalence of PK in terms of C_{max}, AUC_{last} and AUC_{inf} was demonstrated and comparable safety profiles were observed in the comparisons of CT-P13 to EU-INX, CT-P13 to US-INX and EU-INX to US-INX in healthy volunteers.

Blockade of TLR5 Ligation Is a Novel Strategy for RA Therapy. Seung-jae Kim[1], Zhenlong Chen[1], Abdul Essani[1], Michael Volin[2], Suncica Volkov[1], William Swedler[1], Shiva Arami[1], Nadera J. Sweiss[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Midwestern University, Downers Grove, IL.

Background/Purpose: TLR5 expression is highly elevated in RA and CIA lining and sublining macrophages and endothelial cells compared to non-arthritic controls. Additionally, expression of TLR5 in RA myeloid cells closely correlates with disease activity score, indicating that ligation of TLR5+ cells intensifies disease progression. Hence studies were conducted to determine whether dysregulation of TLR5 function can be utilized as a promising strategy for RA treatment.

Methods: CIA mice were treated with IgG or anti-TLR5 antibody on days 23, 27, 30, 34, 37, 41, 44 and 48 and mice were sacrificed on day 49 post induction. CIA joint inflammation and bone erosion were assessed by measuring ankle circumference as well as H&E and TRAP staining. Joint myeloid cell recruitment and their phenotype were evaluated by F480 and iNOS immunostaining. Proinflammatory factors secreted from CIA joint were quantified by ELISA in the IgG and anti-TLR5 antibody treated mice. Remodeling of mouse bone marrow progenitor cells into M1 macrophages was examined following flagellin treatment by real-time RT-PCR and FACS analysis.

Results: To uncover whether disruption of TLR5 ligation is a potential for RA therapy, CIA mice were treated with monoclonal anti-TLR5 antibody or IgG control. Results from these experiments demonstrate that CIA mice treated with anti-TLR5 antibody have markedly lower joint swelling starting on day 44 until day 48 post onset compared to the IgG group. Consistently, histological studies document that anti-TLR5 treatment was capable of reducing CIA synovial inflammation, joint lining thickness and bone erosion by 40% compared to the control mice. We next found that anti-TLR5 treatment impairs migration of circulating myeloid cells into the CIA joint. To better understand the mechanism by which blockade of TLR5 function relieves arthritis, joint myeloid cell phenotype was evaluated in CIA synovial tissues. Histological examination demonstrates that the frequency of iNOS+ M1 macrophages is 40% higher in the IgG treated CIA mice compared to anti-TLR5 group. Corroborating with this notion, M1 macrophage producing factors, IL-6 and CCL2, are significantly suppressed in the CIA joints following anti-TLR5 treatment compared to the control group. Confirming the findings *in vivo*, we established that flagellin ligation to TLR5 can transform naïve mouse myeloid cells into M1 macrophages. This differentiation process was assessed by transcription of TNF and IL-6 and frequency of CD80 staining which was dysregulated by blockade of TLR5. Moreover, we show that TRAP+ bone eroding osteoclasts are 30% higher in the control group compared to CIA joints treated with anti-TLR5. These findings are in agreement with our recent data, revealing that ligation of TLR5 plays a key role in osteoclast formation through a mechanism that is predominantly contingent on myeloid cells and their production of RANK and TNF-a.

Conclusion: We conclude that TLR5 ligation promotes joint myeloid cell infiltration and can further remodel the newly recruited myeloid cells into M1 macrophages or fully mature osteoclasts suggesting that blockade of TLR5 can be employed as a promising new therapeutic target in RA.

COVA322: A Clinical Stage Bispecific TNF/IL-17A Inhibitor for the Treatment of Inflammatory Diseases. Wibke Lembke, Bernd Schlereth, Julian Bertschinger, Dragan Grabulovski and Mathias Locrher. Covagen AG, Schlieren, Switzerland.

Background/Purpose: Biologic therapeutics such as TNF inhibitors have revolutionized the treatment of inflammatory diseases, including rheumatoid arthritis (RA), psoriasis and psoriatic arthritis. However, there is still a significant

unmet medical need in these indications. In RA for example, only about half of all patients achieve an ACR50 score and many become refractory to anti-TNF treatment after a few years. Several studies in preclinical mouse models of arthritis have demonstrated that simultaneous treatment with antibodies to TNF and IL-17 is significantly more efficacious than treatment with either antibody alone. We present here the non-clinical safety package of COVA322, a bispecific TNF/IL-17A inhibitor that is currently being tested in a Phase Ib/IIa study in psoriasis patients.

Methods: COVA322 was analyzed for its cross-reactivity in a GLP study with human and Cynomolgus tissues. In addition, a cytokine release study using human whole blood cells was performed. In Cynomolgus monkeys, COVA322 was tested in a single dose PK/dose range finding study and a GLP 4-week repeat-dose toxicity study at 5, 25 and 100mg/kg doses.

Results: COVA322 showed no unexpected tissue cross-reactivity and no indication for the potential to cause a cytokine release syndrome. COVA322 was well tolerated in single- and repeat-dose toxicity studies in Cynomolgus monkeys. In particular, no adverse effects on the cardiovascular-, respiratory- and central nervous system were observed. The toxicology package (no observed adverse effect level (NOAEL) = 100mg/kg) support the clinical starting dose as well as the anticipated clinical dose range.

Conclusion: COVA322 is a unique bispecific TNF/IL-17A inhibitor, which was well tolerated in non-clinical safety studies. The non-clinical data package supports the planned dose range for the currently ongoing first in man, single dose escalation, tolerability, safety, PK and efficacy Phase Ib/IIa study in psoriasis.

1512

Therapeutic Efficacy of a Novel Oral Small Molecule Macrophage Migration Inhibitory Factor [MIF] Inhibitor: A Promising Safe & Efficacious Treatment for Rheumatoid Arthritis. Anderson Gaweco[1], Samantha Palmer[1], Rambon Shamilov[1], Caroline Stremnitzer[1], Michael Fisher[1], Gregg Crichlow[1], William Windsor[1], Ellen M. Ginzler[2] and Jefferson Tilley[1]. [1]Innovimmune Biotherapeutics, Brooklyn, NY, [2]SUNY-Downstate Medical Center, Brooklyn, NY.

Background/Purpose: Macrophage migration inhibitory factor [MIF] is a cytokine secreted by activated T cells and macrophages that plays an important role in RA and autoimmune disease pathogenesis. MIF exerts its proinflammatory effects through its direct biological function and downstream signaling events following receptor engagement. The therapeutic utility in targeting MIF has been established, demonstrating preclinical efficacy in several RA and autoimmune disease models. Lead development efforts of several proprietary novel chemical scaffolds of the INV-88 portfolio of small molecule MIF inhibitors led to the identification of an INV-88 clinical compound candidate demonstrating potent *in vitro* pharmacological effects against proinflammatory effector cells and cytokines coupled with optimal druggable properties. To establish the preclinical Proof of Concept in RA prior to advancing to IND-enabling development, the *in vivo*treatment efficacy of INV-88 was assessed in the mouse CIA model.

Methods: Disease was induced in DBA1 mice according to a standard protocol. Prior mouse *in vivo*pharmacokinetic [PK] studies determined the optimal oral bioavailability and drug exposure of INV-88 enabling p.o. dosing in this study. To assess the preclinical efficacy in a mouse CIA model, INV-88 was administered orally for 7 days as a therapeutic treatment regimen following chicken collagen CII/CFA disease induction on day 0 and CII/IFA booster immunization on day 15 in DBA1 mice. Upon disease-onset, mice with a clinical arthritis score > 1 (Scale: 0–16) were randomized to receive 7-day dosing with INV-88 at 60 mg/kg (n=12) or comparator controls: Vehicle (n=11) or Dexamethasone [Dex] (n=9).

Results: Successful disease amelioration following INV-88 and Dex treatments was observed with statistically significant reduction of cumulative arthritis score of 3.72 +/− 0.36 [mean +/− SEM] ($p<0.05$) and 1.51 +/− 0.58 ($p<0.001$), respectively, in contrast to the vehicle group of 5.92 +/− 0.68. Significant rapid improvement in clinical disease scores in the INV-88 treated group was evident as early as arthritis day 2 ($p=0.041$) through end of study on arthritis day 7 ($p=0.036$). INV-88 was well tolerated and INV-88-treated mice were unremarkable with optimal body conditions.

Conclusion: The superior safety and therapeutic efficacy data following 7-day treatment of an orally bioavailable small molecule INV-88 MIF inhibitor provide the first compelling evidence ever reported of the preclinical utility of MIF inhibition and of a small molecule-based cytokine inhibitor. These profound findings support advancing INV-88 into further IND-enabling development and highlight the potential promise of INV-88 as a safe & efficacious novel RA DMARD treatment.

1513

Selection of Vagus Nerve Stimulation Parameters for a First-in-Human Study in Rheumatoid Arthritis: A Unique Translational Medicine Challenge. Frieda A. Koopman[1], Yaakov Levine[2], Mike Faltys[2], Ralph Zitnik[2] and Paul P. Tak[3]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]SetPoint Medical Corporation, Valencia, CA, [3]GlaxoSmithKline U.K. and Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Cholinergic anti-inflammatory pathway (CAP) activation by electrical vagus nerve stimulation (VNS) is being studied in rheumatoid arthritis (RA) trials (NCT01552941). CAP signaling proceeds sequentially through vagus and splenic nerves to splenic acetylcholine-secreting T cells, which in turn signal adjacent macrophages to diminish cytokine secretion after proinflammatory stilmuli(1). VNS devices depolarize nerves by application of charge, modulated by varying output current (OC), pulse width (PW), and pulse frequency (F). Stimulation duration (D), and daily stimulation interval (SI) can also be varied. Optimally activating this complex neural-immune pathway created unique translational medicine challenges. Herein we report preclinical data guiding stimulation parameter selection for RA trials.

Methods: VNS stimulation parameter effect on cytokine production and tissue inflammation was studied in 5 models: 1) TNF production in rat systemic endotoxemia with VNS delivered by cervical vagus hook electrodes (HE); 2) morphometric measurement of ulceration in rat indomethacin-induced inflammatory enteritis using cervical vagus cuff electrodes (CE); 3) reduction in *in vitro* LPS-induced whole blood TNF release using VNS delivered chronically by implanted CE in normal canines; 4) improvement in endoscopic ulceration score after dextran sulfate sodium (DSS) colitis in rats using implanted CE; and 5) improvement in ankle swelling, joint histology and systemic cytokines in rat CIA using implanted CE.

Results: Selection of PW (200–250usec) and F (10Hz) was guided by prior clinical tolerability experience with VNS in epilepsy(2). OC titration experiments in rat endotoxemia/HE showed optimal CAP activation at 0.5–1.0mA, and was confirmed in canine CE. The implanted CE used in rodent experiments surrounded the entire carotid sheath rather than only the vagus, so correlation experiments in rat endotoxemia with CE vs. HE verified 3.0 mA as optimal OC for chronic rodent models using this peri-carotid CE. D variation experiments in rat endotoxemia/HE confirmed prior findings(3) that 60 seconds sufficiently activated the CAP. SI experiments in indomethacin enteritis also confirmed prior findings(3) that a 60 second stimulus caused anti-inflammatory effects persisting for at least 24 hours. Efficacy in rodent subacute DSS colitis and CIA using peri-carotid CE was achieved using 3.0mA OC, 10Hz F, 200usec PW, 60 second D, and once daily SI. For RA trials using peri-vagus CE these same parameters were selected with exception of targeted OC of >1.0mA and 250usec PW.

Conclusion: Preclinical pharmacokinetic-pharmacodynamic-efficacy relationships are typically used to understand dose-response and guide dose selection for drug trials. CAP activation involves complex interactions between neuronal cell depolarization and immune effector cell function, complicating study of analogous stimulation parameter-response relationships. These experiments show that despite these hurdles, rational optimization of therapy delivery with "bioelectronic medicines" can be achieved. 1. Science 2011; 334:98 2. Neurology 2002; 59:S31 3. 1514

An Analysis of in-Vitro Cytokine Inhibition Profiles of Tofacitinib and Other Janus Kinase Inhibitors at Clinically-Meaningful Concentrations.
M.E. Dowty, T.S. Lin, L. Wang, J. Jussif, B. Juba, L. Li, E. Moy and J.-B. Tellriez. Pfizer Worldwide R&D, Cambridge, MA.

Background/Purpose: A number of Janus kinase (JAK) inhibitors are being actively investigated for treatment of rheumatoid arthritis (RA), including tofacitinib, baricitinib, filgotinib (GLPG0634), and decernotinib (VX-509). However, it is unclear how these drugs may differentiate from each other in the clinic based on their profiles of JAK-dependent cytokine inhibition. The aim of this work was to provide an integrated modelling approach using knowledge of both in-vitro whole cell JAK inhibition potencies and plasma pharmacokinetics to better understand profiles of cytokine inhibition for clinical JAK inhibitors in the context of clinically-meaningful doses.

Methods: IC50 values for IFNα, IFNγ, IL-6, IL-15, IL-21, IL-10, IL-27, IL-12, IL-23 and erythropoietin (EPO) signaling of tofacitinib, baricitinib, filgotinib, and decernotinib were measured in total lymphocytes, CD34+ cells (EPO) and CD3+ cells (IL-6) in human whole blood by a flow cytometry-based assay, quantifying the phosphorylation state of various STAT proteins. Human daily average plasma concentrations (C_{av}) were used as reported or predicted for tofacitinib (5 mg BID; 68 nM), baricitinib (4 mg QD; 32 nM), and filgotinib (200 mg QD; 527 nM). Confidence in the prediction of decernotinib pharmacokinetics was considered low because of high in-vitro metabolic instability and was not assessed further. Percent levels of cytokine inhibition ($IC_{xx}=100*C_{av}/(IC_{50}+C_{av})$) were determined at clinically-meaningful doses.

Results: Each JAK inhibitor showed a relatively similar profile of cytokine inhibition versus type I and II interferons (IFNα, IFNγ), the common γ-chain cytokines (IL-15, IL-21), and IL-6 and IL-27 (Figure 1). Each also showed some decrease in potency for IL-10, IL-12 and 23, and EPO. Comparing between JAK inhibitors, tofacitinib and baricitinib were overall more potent inhibitors than decernotinib and filgotinib. Clinical pharmacokinetics of tofacitinib, baricitinib, and filgotinib were available and used to further compare predicted cytokine profiles of inhibition in patients with RA. The profile of cytokine inhibition for each JAK inhibitor was in general similar at clinically-meaningful doses (Figure 1). While the pharmacokinetics were unavailable for decernotinib, the clinical dose ranges being explored are consistent with filgotinib which showed similar in-vitro inhibitory potencies.

Conclusion: These analyses illustrate the importance of studying a broad range of JAK pairing potencies and clinical concentrations when comparing JAK-inhibitor compounds. Calculated profiles of cytokine inhibition for a number of JAK inhibitors in RA are in general similar when efficacious doses are considered, suggesting limited differentiation of these JAK inhibitors based on JAK pharmacology. Ultimately, only robust clinical testing will determine whether there are clinical differences between JAK inhibitors.

Figure 1. In vitro whole blood JAK inhibitory potencies (left) and overall cytokine inhibition in the context of clinical concentrations (right) for various JAK inhibitors

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are a marker of RA and may contribute to disease progression.[1,2] ACPA analysis in patients offers the opportunity to estimate whether specific intervention during early disease may have an impact on the maturation of the ACPA response and a subsequent altering effect on the course of the disease process. Here we assessed the impact on ACPA isotypes and the number of specific epitopes recognized in patients with early RA from the AVERT study who were treated with abatacept (ABA) + methotrexate (MTX), ABA monotherapy or MTX alone.

Methods: Patients enrolled in AVERT had symptomatic synovitis in ≥2 joints for ≥8 weeks with an onset of symptoms ≤2 years, were anti-cyclic citrullinated peptide 2 positive and naïve to both MTX and biologic treatment.[3] ACPA isotype and the epitope analysis of 6 specificities were performed using custom ELISA assays and were measured in patient serum at baseline, and at Days 85 and 365.[1,2] Adjusted mean change from baseline was calculated using a longitudinal repeated measures model.

Results: Baseline means for the IgG isotype were 585.0 (ABA + MTX), 515.2 (ABA) and 575.5 (MTX) U/mL. IgM baseline means were 23,613 (ABA + MTX), 24,221 (ABA) and 28,377 (MTX) U/mL. Baseline means for the IgA isotype were 10,127 (ABA + MTX), 11,098 (ABA) and 12,335 (MTX) U/mL. Adjusted mean (+95% CI) unit changes in ACPA isotype from baseline to Days 85 and 365 are shown (Table). Of the 6 epitopes tested, the average baseline net numbers recognized were 2.6 (ABA + MTX), 2.69 (ABA) and 2.88 (MTX). Consistent with reductions in the ACPA isotypes, from baseline to Day 365, treatment with ABA + MTX reduced the average (+95% CI) net number of epitopes recognized by –0.82 (–1.03, –0.61) compared with –0.32 (–0.54, –0.10) for ABA alone or –0.42 (–0.64, –0.20) for MTX alone.

Table: Adjusted mean change from baseline (+95% CI) for ACPA isotypes (U/mL)

	Day 85			Day 365		
	IgG	IgM	IgA	IgG	IgM	IgA
ABA	−47.26 (−88.85, −5.66)	−3270 (−4898, −1642)	636.1 (−930.4, 2202)	−13.81 (−67.79, 40.17)	−356 (−3096, 2382)	3186 (843.2, 5529)
MTX	−22.94 (−63.66, 17.78)	−4604 (−6204, −3004)	−1794 (−3331, −256.6)	−30.07 (−84.51, 24.38)	−4591 (−7345, −1838)	−1914 (−4269, 440.1)
ABA + MTX	−70.58 (−110.9, −30.27)	−6392 (−7975, −4809)	−2434 (−3957, −910.8)	−135.6 (−178.4, −83.82)	−6363 (−8991, −3735)	−2230 (−4479, 19.30)
